Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai
Editor-in-Chief

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University
Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

---

Associate Editors

Alaa Sheta
Southern Connecticut State University
Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Arun Kulkarni
University of Texas at Tyler
Domain of Research: Machine Vision, Artificial Intelligence, Computer Vision, Data Mining, Image Processing, Machine Learning, Neural Networks, Neuro-Fuzzy Systems

Dr Ronak AL-Haddad
Anglia Ruskin University / Cambridge
Domain of Research : Technology Trends,Communication,Security,Software Engineering and Quality,Computer Networks,Cyber Security,Green Computing,Multimedia Communication,Network Security,Quality of Service

Elena Scutelnicu
"Dunarea de Jos" University of Galati
Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee
Kyungpook National University
Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Renato De Leone
Università di Camerino
Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao
University of Eastern Finland
Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: Detecting and Preventing Money Laundering Using Deep Learning and Graph Analysis
Authors: Mamunur R Raja, Md Anwar Hosen, Md Farhad Kabir, Sharmin Sultana, Shah Ahammadullah Ashraf, Rakibul Islam
PAGE 1 – 8

Paper 2: Transforming the Working Style of Call Center Agents Through Generative AI
Authors: Satya Karteek Gudipati
PAGE 9 – 15

Paper 3: AI-Driven Education: Integrating Machine Learning and NLP to Transform Child Learning Systems
Authors: Masuma Akter Semi, Md Borhan Uddin, Sharmin Sultana, Motmainna Tamanna, Azim Uddin, Khandakar Rabbi Ahmed
PAGE 16 – 22

Paper 4: Application of Blockchain Frameworks for Decentralized Identity and Access Management of IoT Devices
Authors: Sushil Khairnar
PAGE 23 – 32

Paper 5: Location Based Augmented Reality Navigation Application
Authors: Samridhi Sanjay Pramanik, Aishwary Pramanik
PAGE 33 – 38

Paper 6: Metabolite Screening for Heart Disease Using Support Vector Machine-Based AI
Authors: Edward L. Boone, Ryad A. Ghanam, Faten S. Alamri, Elizabeth B. Amona
PAGE 39 – 47

Paper 7: Enhancing Deepfake Content Detection Through Blockchain Technology
Authors: Qurat-ul-Ain Mastoi, Muhammad Faisal Memon, Salman Jan, Atif Jamil, Muhammad Faique, Zeeshan Ali, Abdullah Lakhan, Toqeer Ali Syed
PAGE 48 – 56

Paper 8: Advancements in Deep Learning for Malaria Detection: A Comprehensive Overview
Authors: Kiswendsida Kisito Kabore, Desire Guel, Flavien Herve Somda
PAGE 57 – 67

Paper 9: Application of Deep Learning-Based Image Compression Restoration Technology in Power System Unstructured Data Management
Authors: Junjie Zha, Aiguo Teng, Xinwen Shan, Hao Tang, Zihan Liu
PAGE 68 – 77

Paper 10: Impact of Auxiliary Information in Generative Artificial Intelligence Models for Cross-Domain Recommender Systems
Authors: Matthew O. Ayemowa, Roliana Ibrahim, Noor Hidayah Zakaria, Yunusa Adamu Bena
PAGE 78 – 89

Paper 11: The Anomaly Detection Algorithm Based on Random Matrix Theory and Machine Learning
Authors: Yongming Lu
PAGE 90 – 95

Paper 12: SkinDiseaseXAI: XAI-Driven Neural Networks for Skin Disease Detection
Authors: Ammar Nasser Alqarni, Abdullah Sheikh
PAGE 96 – 104

Paper 13: Emotion Recognition Algorithm Based on Multi-Modal Physiological Signal Feature Fusion Using Artificial Intelligence and Deep Learning
Authors: Yue Pan
PAGE 105 – 118

Paper 14: Dataset Development for Classifying Kick Types for Martial Arts Athletes Using IMU Devices
Authors: Rudy Gunawan, Suhardi, Widyawardana Adiprawita, Tommy Apriantono
PAGE 119 – 131

Paper 15: Comparative Analysis of Deep Learning Techniques for Passive Underwater Acoustic Target Recognition: Overview, Challenges, and Future Directions
Authors: Song Yifei, Mohamad Farhan Mohamad Mohsin
PAGE 132 – 145

Paper 16: Method for Tea Leaf Plucking Timing Prediction with High Resolution of Images Based on YOLO11
Authors: Kohei Arai, Yoho Kawaguchi
PAGE 146 – 155

Paper 17: The Factors Influencing Internet of Things Adoption in Public Hospitals: A Pilot Study
Authors: Mutasem Zrekat, Othman Bin Ibrahim
PAGE 156 – 168

Paper 18: Research on Network Flow Based on Statistical Analysis Methods
Authors: Maruf Juraev, Inomjon Yarashov, Adilbay Kudaybergenov, Alimdzhan Babadzhanov, Zilolaxon Mamatova
PAGE 169 – 176

Paper 19: A Steel Surface Defect Detection Method Based on Lightweight Convolution Optimization
Authors: Cong Chen, Ming Chen, Hoileong Lee, Yan Li, Jiyang YU
PAGE 177 – 190

Paper 20: Landslide Detection Method Based on Lightweight Convolution and Attention Mechanisms
Authors: Cong Chen, Chengyang Zhang, Ran Chen, Jiyang YU
PAGE 191 – 204

Paper 21: Integration of 2D-CNN and LSTM Networks for Enhanced Image Processing and Prediction in Alzheimer's Disease
Authors: Aya Mohamed Abd El-Hamed, Mohamed Aborizka
PAGE 205 – 212

Paper 22: Audio-Visual Multimodal Deepfake Detection Leveraging Emotional Recognition
Authors: Alaa Alsaeedi, Amal AlMansour, Amani Jamal
PAGE 213 – 226

Paper 23: A Novel Multi-Modal Deep Learning Approach for Real-Time Live Event Detection Using Video and Audio Signals
Authors: Pavadareni R, A. Prasina, Samuthira Pandi V, Ibrahim Mohammad Khrais, Alok Jain, Karthikeyan
PAGE 227 – 240

Paper 24: False News Recognition Model Based on Attention Mechanism and Multiple Features
Authors: Qiongyao Suo, Hongzhen Chang
PAGE 241 – 250

Paper 25: A Reading-Aware Fusion Fact Reasoning Network for Explainable Fake News Detection
Authors: Bofan Wang, Shenwu Zhang
PAGE 251 – 262

Paper 26: Solar-Net: Adaptive Fusion of Spatial-Temporal Features for Resilient Solar Power Generation Forecasting
Authors: Wenqian Su, Jason See Toh Seong Kuan, Xiangyu Shi, Yuchen Zhang
PAGE 263 – 274

Paper 27: Framework for Child Healthcare System Using Random Forest
Authors: Mahesh Ashok Mahant, P. Vidyullatha
PAGE 275 – 283

Paper 28: Enhancing Organizational Threat Profiling by Employing Deep Learning with Physical Security Systems and Human Behavior Analysis
Authors: D. H. Senevirathna, W. M. M. Gunasekara, K. P. A. T. Gunawardhana, M. F. F. Ashra, Harinda Fernando, Kavinga Yapa Abeywardena
PAGE 284 – 293

Paper 29: LaObese: A Serious Game Powered by Analytic Hierarchy Process for Culturally Tailored Childhood Obesity Prevention in Oman
Authors: Nurul Akhmal Mohd Zulkefli, Mukesh Madanan, Zainab Mohammed Al-Nahdi, Jayasree Radhamaniamma
PAGE 294 – 304

Paper 30: Anomaly Study of Computer Networks Based on Weighted Dynamic Network Representation Learning
Authors: Xin Wei
PAGE 305 – 315

Paper 31: Deepfake Audio Detection Using Feature-Based and Deep Learning Approaches: ANN vs ResNet50
Authors: Reham Mohamed Abdulhamied, Sarah Naiem, Mona M. Nasr, Farid Ali Moussa
PAGE 316 – 323

Paper 32: Fine-Tuning OpenAI GPT Chatbot in Western Saudi Dialect: A Case Study of Taibah University
Authors: Maimounah Alhujaili, Ruqayya Abdulrahman
PAGE 324 – 338

Paper 33: Automatic Detection of Natural Disasters Using Faster R-CNN with ResNet50 Backbone
Authors: Shereen Essam Elbohy, Mona M. Nasr, Farid Ali Mousa
PAGE 339 – 348

Paper 34: Fusion of CNN and Transformer Architectures for Proactive Wildfire Detection in Satellite Imagery
Authors: Shereen Essam Elbohy, Mona M. Nasr, Farid Ali Mousa
PAGE 349 – 357

Paper 35: Analyzing the Impact of Robotic Process Automation (RPA) on Productivity and Firm Performance in the Service Sector
Authors: Miftakul Huda, Agus Rahayu, Chairul Furqon, Mokh Adib Sultan, Neng Susi Susilawati Sugiana
PAGE 358 – 363

Paper 36: Systematic Literature Review on Artificial Intelligence-Driven Personalized Learning
Authors: Anas Usman Inuwa, Shahida Sulaiman, Ruhaidah Samsudin
PAGE 364 – 380

Paper 37: Mobile Application Using Convolutional Neural Networks for Preliminary Diagnosis of Rosacea
Authors: Angie Fiorella Sapaico-Alberto, Rosalynn Ornella Flores-Castañeda
PAGE 381 – 387

Paper 38: Hybrid PSO-ACO Optimization for Rice Leaf Disease Classification Using Random Forest and Support Vector Machines
Authors: Avip Kurniawan, Tri Retnaningsih Soeprobowati, Budi Warsito
PAGE 388 – 397

Paper 39: Reinforcement Learning for Real-Time Scheduling in Dynamic Reconfigurable Manufacturing Systems
Authors: Salah Hammedi, Abdallah Namoun, Mohamed Shili
PAGE 398 – 411

Paper 40: A Proposed Framework for Loan Default Prediction Using Machine Learning Techniques
Authors: Mona Aly SharafEldin, Amira M. Idrees, Shimaa Ouf
PAGE 412 – 425

Paper 41: Advanced AI-Driven Safety Compliance Monitoring in Dynamic Construction Environment
Authors: Aisha Hassan, Ali H. Hassan, Yasmin Christensen, Hussain Alsadiq
PAGE 426 – 436

Paper 42: Reinforcement Learning Improves SVM-Driven Algorithms for Classifying Multi-Sensor Data for Medical Monitoring
Authors: Zhiwei Xuan, Yajie Liu
PAGE 437 – 447

Paper 43: Developing an Ontology-Driven and Governance-Integrated Method for Information Dashboard Design
Authors: Ahadi Haji Mohd Nasir, Nik Habibullah Nik Mohd Nizam, Mohd Khairul Maswan Mohd Redzuan, Mohammad Nazir Ahmad
PAGE 448 – 462

Paper 44: Machine Learning and 5G Edge Computing for Intelligent Traffic Management
Authors: Talbi Chaymae, Rahmouni M'hamed, Ziti Soumia
PAGE 463 – 470

Paper 45: A Rule-Based Framework for Clothing Fit Recommendation from 3D Body Reconstruction
Authors: Hamid Ouhnni, Acim Btissam, Belhiah Meryam, Benachir Rigalma, Soumia Zit
PAGE 471 – 479

Paper 46: TL-MC-ShuffleNetV2: A Lightweight and Transferable Framework for Elevator Guideway Fault Diagnosis
Authors: Zhiwei Zhou, Xianghong Deng, Xuwen Zheng, Chonlatee Photong
PAGE 480 – 488

Paper 47: AI-Driven Intrusion Detection Systems for Securing IoT Healthcare Networks
Authors: Muhammad Sajid Nawaz, Muhammad Ahsan Raza, Binish Raza, Manal Ahmad, Farial Syed
PAGE 489 – 497

Paper 48: Leveraged Cognitive Data Analytics and Artificial Intelligence to Enhance Sustainable Agricultural Practices: A Systematic Review
Authors: Wongpanya S. Nuankaew, Patchara Nasa-Ngium, Pratya Nuankaew
PAGE 498 – 507

Paper 49: A Novel Approach for Enhancing Advanced Encryption Standard Performance and Cryptographic Resilience
Authors: Muthu Meenakshi Ganesan, Sabeen Selvaraj
PAGE 508 – 516

Paper 50: An Enhanced LSTM Model Based on Feature Attention Mechanism and Emotional Intelligence for Advanced Sentiment Analysis
Authors: Muhammad Naeem Aftab, Dost Muhammad Khan, Muhammad Zulqarnain, Muhammad Rizwan Akram
PAGE 517 – 528

Paper 51: Image Quality Assessment Based on Feature Fusion and Local Adaptation
Authors: Minjuan GAO, Yankang LI, Xuande ZHANG
PAGE 529 – 536

Paper 52: Advancing Aerodynamic Coefficient Prediction: A Hybrid Model Integrating Deep Learning and Optimization Techniques
Authors: Jad Zerouaoui, Rachid Ed-daoudi, Badia Ettaki, El Mahjoub Chakir
PAGE 537 – 545

Paper 53: AI-Powered Assessment of Resistance to Change in the Context of Digital Transformation
Authors: Bachira Abou El Karam, Tarik Fissaa, Rabia Marghoubi
PAGE 546 – 558

Paper 54: Self-Supervised Method for Risky Situation Detection in Road Traffic Sequences Using Video Masked Autoencoder
Authors: Abdelhafid Berroukham, Mohammed Lahraichi, Khalid Housni
PAGE 559 – 566

Paper 55: Vision-Based Vehicle Classification Using Deep Learning Model
Authors: Ahsiah Ismail, Amelia Ritahani Ismail, Muhammad Afiq Mohd Ara, Asmarani Ahmad Puzi, Suryanti Awang
PAGE 567 – 573

Paper 56: Comparative Analysis of Rank and Roulette Wheel Selection Strategies in Genetic Algorithms for Spatial Layout Optimization
Authors: Najihah Ibrahim, Fadratul Hafinaz Hassan, Sharifah Mashita Syed-Mohamad, Rosmayati Mohemad, Ahmad Shukri Mohd Noor
PAGE 574 – 582

Paper 57: AutiSim: A Virtual Reality Simulation Game Based on the Autism Spectrum Disorder
Authors: Muhammad Aliff Muhd Farid Arfian, Ikmal Faiq Albakri Mustafa Albakri, Faaizah Shahbodin, Mohd Khalid Mokhtar, Asniyani Nur Haidar Abdullah, Norhaida Mohd Suaib, Muhammad Nur Affendy Nor'a, Abdul Hasib Jahidin

***Abstract*—Money laundering is a major worldwide issue facing financial organizations, with its increasingly complicated and changing methods. Conventional rule-based anti-money laundering (AML) systems can fail to identify advanced fraudulent activity. This study shows a new hybrid model to detect suspicious transaction patterns precisely by efficiently combining GraphSAGE, a graph-based Machine Learning (ML) technique, with Long Short-Term Memory (LSTM) networks. The suggested approach uses GraphSAGE's relational capabilities for graph-structured anomaly detection and the temporal strengths of LSTM for sequence modeling. With excessive traditional ML and stand-alone Deep Learning (DL) techniques, the Hybrid LSTM-GraphSAGE model achieves an accuracy of 95.4% using a simulated dataset reflecting real-world financial transactions. The findings show how well our combined strategy lowers false positives and improves the identification of advanced AML operations. This work opens the path for creating real-time, intelligent, flexible money laundering detection systems appropriate for current financial situations.**

***Keywords*—Anti-money laundering (AML); deep learning (DL); LSTM; GraphSAGE; graph analysis; transaction monitoring; hybrid fusion model**

I. Introduction

In the previous few years, money laundering and terrorism have been among the main challenges to the integrity of the global financial system [1]. Money laundering issues the reliability of illegal activity by hiding its source; each year, the laundering of around 2 to 5% of the world's GDP (1.7-4 trillion) leads to issues [2]. Underlying crimes include drug distribution, human trafficking, fraud, tax avoidance, and corruption. Consequently, money laundering is a serious worldwide issue influencing individuals, businesses, governments, and societal welfare and impacting [3].

For financial institutions (FIs), undetectable money laundering programs may cause significant reputation harm and considerable penalties. FIs use compliance professionals looking at questionable activity to stay out of a vehicle for money laundering [4]. According to most rule-based algorithms and human monitoring, traditional AML systems struggle to keep up with ever-advanced laundering procedures [5]. These techniques often skip subtle, nonlinear developments in transactional data or expose latent connections within multi-layered financial networks—a gap leaves organizations open to systematic risk, reputational harm, and regulatory fines [6].

Although nowadays, most methods concentrate on isolated transaction analysis using shallow models like logistic regression or decision trees, recent developments in ML have shown promise in spotting aberrant financial activity [7]. These approaches ignore the essentially relational character of money laundering, in which illegal activity is entwined in complex systems of companies and transactions. The graph-based analysis provides a strong prism to find these latent structures. It maps links between accounts, beneficiaries, and intermediaries [8]. However, few researchers have successfully coupled graph theory with DL to address financial crime's dynamic, high-dimensional character [9].

This study concludes this gap by indicating a novel approach combining graph analysis with DL to identify and terminate money laundering in real-time. Our method models transactional networks using GNNs' hierarchical representation learning ability, thereby capturing local node attributes and global topological patterns. We also provide a dynamic anomaly detection system that continually updates network embeddings and improves risk ratings to fit changing laundering strategies.

Our key contributions include:

- This study provides a novel money laundering detection method that combines graph-based analytical structural insights with a DL model temporal pattern recognition. This interaction helps the system detect relational and sequential flaws in financial transactions.
- Real-time transaction monitoring system design is a key advancement. This system may identify suspicious activity before it expands by continually recording and analyzing transactions using past behavioral patterns and changing network architecture.
- Recognizing a shortage of labeled AML data, we develop a careful and logical financial transaction set. This allows practical training and evaluation of

the recommended models and reflects actual laundering behavior.

– This study thoroughly evaluates the hybrid model against traditional ML and stand-alone DL. Results show that the hybrid model outperforms others in detection accuracy, precision, recall, and false positive reduction.

II. Literature Review

This study examines graph-based and hybrid DL models for AML, focusing on GCNs, CNNs, and new architectures like GAGNN and Temporal-GCN. Data availability, computational cost, and cross-domain transferability remain issues even with high accuracy and minimal false positives.

Bakhshinejad et al. [10] presented a graph-based DL model for suspected money laundering transaction detection and a thorough analysis of current AML systems from a data-oriented standpoint. Applied node2vec for feature extraction, created a detection system converting transactional data into a graph, and then classified transactions as usual or suspicious using a GCN. Graph embedding with GCN for classification, Node2Vec. They also tuned classifier thresholds and managed unbalanced data using SMOTE. Comparatively, to industry norms of 90% or more, their model attained very low false negative rates, sometimes even nil, and significantly lowered the false alarm rate to around 50%.

Also, Irshad et al. [11] proposed a novel framework for identifying money laundering activities by combining Graph Convolutional Networks (GCN), Convolutional Neural Networks (CNN), and Feed-Forward Neural Networks (FFNN) in an Integrated Approach for Money Laundering Detection. Using spatial patterns, sequential data, and transaction network topology, the authors created a hybrid model to raise classification performance. Their approach calls for CNN to extract local characteristics from transaction histories, GCN to capture graph-based relations among entities, and FFNN for ultimate classification. With an astounding 98.34%, the model exceeded conventional ML techniques. Likewise, Kute et al. [1] provided an extensive CNN sentiment analysis application overview.

They evaluate current research publications using CNN architectures for sentiment classification challenges in many fields and datasets. They gathered and analyzed more than 60 research studies, evaluating many CNN-based techniques, including hybrid models, multichannel CNNs, and improvements in attention processes. They also examined preprocessing methods and dataset kinds used in this research.

Their stated accuracy falls between 75% and 90%, depending on the architecture and dataset. CNN-based models were better than conventional ML techniques in extracting spatial characteristics from text. Cheng et al. [12] suggested a fresh approach using group-aware deep graph learning methods for AML. The authors model the financial transaction network as a heterogeneous graph, and they present a Group Aware Graph Neural Network (GAGNN) to detect suspicious group behaviors often disregarded in conventional AML systems. Their approach consists of building a heterogeneous transaction graph, grouping based on shared characteristics (such as IP addresses), and using a tailored GNN architecture with group-level elements for enhanced detection. Reaching an AUC of 0.9814 and an F1 score of 0.8607, the suggested method shows performance improvement over baseline models. Dumitrescu et al. [13] represented users or accounts and edges indicating transactions, therefore investigating banking transaction data as a graph of fraudulent activities. They devised a method to identify structural and behavioral irregularities in the transaction network using GNNs.

Using GNN models, especially Autoencoders and GCNs, they train representations of the graph and spot suspicious trends. Focusing on unsupervised methods, as tagged fraudulent data is not readily available, they assessed their models using real-world financial transaction data. Depending on the model and data setup, their method's stated accuracy in AUC (Area Under the Curve) scores varied from 0.76 to 0.89. Eddin et al. [3] created dynamically via sliding time windows to help propose an ML triage model to lower false positives in AML systems. Combining entity-centric characteristics with graph-based features.

Using LightGBM on actual banking data, their approach reduced false positives by 80% and identified over 90% of genuine positives. Furthermore, Jensen et al. [14] investigated using ML and statistical techniques to fight money laundering, emphasizing using synthetic data to train prediction models. They used synthetic data reflecting banking activities and consumer characteristics to develop and evaluate their method. To separate dubious from non-suspicious consumers, they used a supervised learning approach using a gradient-boosted decision tree algorithm (LightGBM).

With a fantastic accuracy of 99.6%, their model demonstrated the possible efficiency of ML in spotting financial laundering activity. Alarab et al. [15] employed a unique graph-based model called Temporal-GCN, which combines GCN with LSTM, to identify illegal transactions in Bitcoin. They also included active learning using Monte-Carlo Dropout and Monte-Carlo Adversarial Attack (MC-AA) for uncertainty estimates and created a framework that catches both temporal sequences and graph topologies of transaction data.

Preprocessing Bitcoin transaction graphs, extracting local characteristics, using LSTM to model temporal trends, and then feeding the result to a TAGCN layer from the approach. The outperformance of the model above previous GCN-based models on the same dataset resulted in a classification accuracy of 97.77% and an F1-score of 80.6%. Muminovic et al. [16] investigated the difficulties of money laundering in the digital age, along with studies of contemporary technologies meant to improve preventive systems.

It especially looks at how graph databases may monitor intricate, nonlinear financial transactions often used to hide illegal activity—which are typically used to hide illegal activity. The writers review current methods that mainly depend on relational databases and rule-based detection, pointing to limits in scalability and adaptability.

Graph-based models help see entities and their transactional interactions more easily, enhancing the capacity to spot unusual

trends. Mohan et al. [17] proposed a hybrid model combining Evolving Graph Convolutional Networks (EvolveGCN) with Deep Neural Decision Forests (DNDF) to handle AML in the Bitcoin network.

With the Elliptic dataset comprising over 200,000 labeled and unlabeled Bitcoin transactions, they simulate the issue as a node classification job. They want to improve the categorization of illegal transactions by combining dynamic graph learning with ensemble techniques. Following Knowledge Distillation (KD) to compress and maximize the model, the model attained a high F1 score of 0.9251, which then improved to 0.9525.

Moreover, there is limited comparative analysis using traditional methods in detecting and Preventing Money Laundering.

1) Many models need synthetic datasets or large volumes of classified transaction data, which are rare in financial environments. While transaction categorization is time-consuming and error-prone, synthetic data lacks the complexity of real-world laundering techniques.

2) Graph-based algorithms like GCN, GAGNN, and Temporal-GCN are resource-intensive in describing large, dynamic financial transaction networks. Training, feature extraction, and graph creation are computationally intensive.

3) These models' efficacy slightly depends on group or graph structure specifications and transaction data correctness and completeness. Models include unsupervised GNNs and GAGNNs that lose much in noisy, mislabeled, or poorly linked data.

4) Although many models perform well on specific datasets, e.g., Bitcoin and private financial data, their transferability across institutions, countries, and transaction types is poor. Applied to foreign fields, model performance is usually harmed.

III. Methodology

A hybrid DL-based and graph-based analysis framework was proposed to detect and prevent money laundering activities effectively. As shown in Fig. 1, raw transaction data is fed into the pipeline throughout the methodology, producing final classification outcomes. The design of this multi-stage framework is to extract temporal transactional and relational patterns, typically indicative of money laundering behavior.

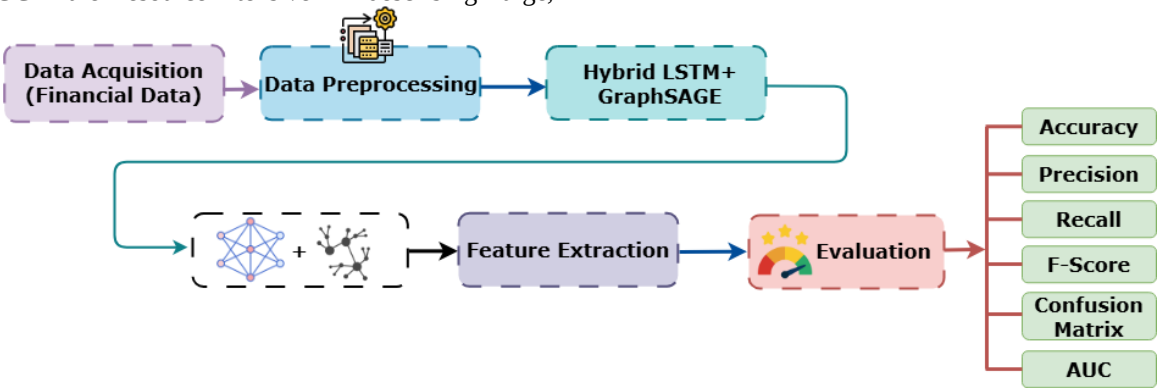

Fig. 1. Methodology framework for detecting and preventing money laundering using the proposed hybrid LSTM-GraphSAGE model.

A. Dataset Description

For this study, experiments are run using the Anti Money Laundering Transaction Data (SAML-D) on Kaggle by Berk Öztaş [18]. The dataset was specially developed to simulate real banking transactions and behavioral patterns of money laundering operations. The dataset contains 1,048,575 records of transactions with 28 typologies (split between 11 normal and 17 suspicious) and 12 different features: Time, Date, Sender_account, Receiver_account, Amount, Payment_currency, Received_currency, Sender_bank_location, Receiver_bank. The dataset consists of each transaction record between a sender and a receiver on each row. Payment_currency, Received_currency, and Amount depict all types of currency used at the sender's and receiver's end, as well as the total monetary value of the transfer.

Regarding transaction medium, the Payment_type would tell you that it is an online transfer, credit card, or wire. After supervised learning, the label Is_laundering is a critical binary feature (1 for money laundering and 0 for legitimate). Laundering_type gives a multi-class annotation regarding laundering techniques. The rich set of features allows for temporal and relational modeling of temporal patterns of financial fraud.

B. Dataset Preprocessing

A series of robust preprocessing steps was implemented to prepare the dataset for DL and graph analysis models.

1) Timestamp handling. The Date and Time features were merged and transformed into a standard UNIX timestamp format to assist temporal modeling. It does this feature engineering for time-based behaviors like peak transaction hours or clusters of frequency. By Di and Ti let us denote the date and time when $i\ th$ transaction occurs. As follows, the timestamp feature TSi was derived:

$$TS_i = to_timestamp(D_i + T_i)$$

2) Account ID encoding. The Sender_account and Receiver_account are anonymized strings. They were labeled, encoded, or embedded to preserve identity without revealing personal information. This later allows for building transaction graphs where each unique account becomes a node:

$$Sender_i = f(Sender_account_i)$$

$$Receiver_i = f(Receiver_account_i)$$

3) Categorical feature encoding. For some payment information (Payment_currency, Received_currency, Payment_type, Sender_bank_location, Receiver_bank_location), those were one-hot encoded or embedded, based on the model. In this case, the transformation to capture the discrete attribute information does not introduce the ordinal bias. For a categorical feature X with k unique values:

$$X \in \{x_1, x_2 \dots x_k\} \Rightarrow One - hot(X) = [0,1,2, \dots]$$

4) Graph construction for network analysis. Sender_account and Receiver_account were used as nodes and transactions as edges in a directed transaction graph $G = (V,)$. Also, each edge has attributes such as amount, time, payment type, and binary labels for laundering. Optional aggregation was based on the frequency or total amount of the edge weights:

$$w_{ij} = \sum_{t \in T_{ij}} Amount_t$$

5) Label binarization and data splitting. The binary target for classification is given by the Is_laundering column. Also, Laundering_type was encoded for multi-class classification or more profound insight into techniques. This ensures label stratification and thus handles the class imbalance in the data.

Finally, the dataset was split into training and testing subsets through an 80/20 ratio. This guaranteed that all the classes undergo the model evaluation phase, including classes that do not undergo laundering.

C. Models

In order to detect and prevent money laundering in financial transaction systems, we proposed a hybrid DL framework that ties the temporal behavior modeling and relational graph analysis together, which captures the evolution of suspicious activity with complex pattern development. Specifically, our approach is composed of three key parts: 1) an LSTM for learning sequential behavioral characteristics, 2) a graph neural network (GNN) based on GraphSAGE for modeling structural relationships, and 3) a fusion model to synthesize the temporal and structural beneficial insights.

1) Temporal behavior modeling using LSTM. Structured and repetitive behavior of money laundering schemes commonly entails rapid distribution of funds through an account network (smurfing) or calculating the best technique for the layering (i.e., how to add coins to comply with the internal allowance of the broker). Because these are nuanced temporal dependencies, we leverage an LSTM network capable of modeling sequential data with long-range dependencies. The LSTM branch in Fig. 2 extracts transaction sequences from an accounts perspective to capture behavioral anomalies.

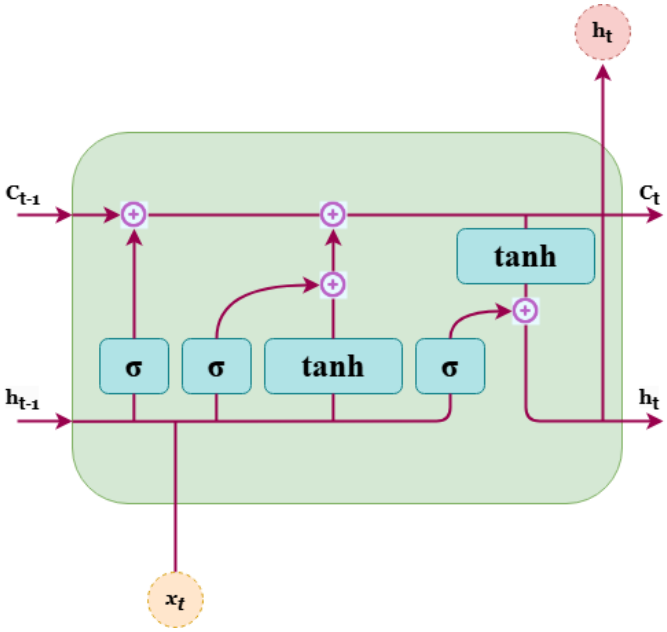

Fig. 2. LSTM-based temporal feature extraction architecture.

Let $X_a = \{x_{a,1}, x_{a,2}, \dots, x_a, T_a\}$ be the transaction sequence for account a, and each transaction $x_{a,t} \in R_d$ is a vector of features. The features include normalized transaction amount, payment type, time-based metadata (e.g., hour of day, day of week), typology, currency mismatch, and geographical information (e.g., bank location).

The LSTM network operates on this sequence through a series of gates and updates on internal memory according to the following equations:

(i) Forget Gate: $f_t = \sigma(W_f x_t + U_f h_{t-1} + b_f)$

(ii) Input Gate: $i_t = \sigma(W_f x_t + U_i h_{t-1} + b_i)$

(iii) Output Gate: $f_t = \sigma(W_0 x_t + U_0 h_{t-1} + b_0)$

(iv) Candidate Memory: $\tilde{c}_t = tanh(W_c x_t + U_c h_{t-1} + b_c)$

(v) Cell State Update:$c_t = f_c \Theta c_{t-1} + i_t \Theta \tilde{c}_t$

(vi) Hidden State: $h_t = o_t \Theta tanh(c_t)$

We denoted σ to be the sigmoid activation function, tanh to be the hyperbolic tangent function, and $\odot$ to denote elementwise multiplication. The contextual behavior of account a at time $t$is encapsulated in ht as both current transaction features and past behavioral history. The final hidden state hT is passed through a fully connected dense layer with a sigmoid activation to classify the suspiciousness of the account through behavioral analysis:

$$\hat{y}_a = \sigma(w_0 h_T + b_0)$$

The binary cross-entropy loss function is used to optimize the LSTM model:

$$L_{LSTM} = -ylog(\hat{y}) - (1 - y)\log(1 - \hat{y})$$

This formulation can learn from genuine and fraudulent behavioral sequences and effectively identifies time-sensitive laundering patterns.

2) Graph-based relational modeling using GraphSAGE. Behavioral patterns give us some clues as to when things happened, but many money laundering schemes are networks consisting of many, possibly thousands, of accounts, and the connections among them are equally complex. Indirect transfers, circular money flows, and multi-hop layering are typical ways that launderers try to forfeit the trail of illegal money. The problem could be captured as a directed graph where the nodes represent the accounts, and the edges between the nodes indicate transactions between accounts.

Suppose this transaction graph to be represented by $G = (V, E)$, where:

- The set contains N resources equal to V, where each node (account) in V is unique.
- The set of directed edges, E, will represent transactions.
- Edge features consist of transaction amount, transaction type, time interval between transactions, and currency mismatch for each edge $euv \in E$ between node u and node v.

For each node $v \in V$, we initialize hv, the feature vector for node v, as a feature vector of the form, comprising:

- Mean, max, and count of transaction amounts (aggregated statistics).
- Frequency metrics.
- Some categorical features can be embedded (e.g., typology, payment type).
- And optionally, the output of the LSTM model.

For learning meaningful node embeddings over its neighborhood structure, we adopted GraphSAGE, an inductive GNN framework that can generalize to node discovery. Layer-wise, the node embedding is updated using:

$$h_{N(v)}^{(k)} = AGGREGATE^{(k)}\left(\left\{h_u^{(k-1)} | u \epsilon N(v)\right\}\right)$$

$$h_v^{(k)} = \sigma(W^{(k)}.CONCAT(h_v^{(k-1)}, h_{N(v)}^{(k)}))$$

The neighbors of node v are shown here by the notation (v), and AGGREGATE is a differentiable function like mean, max-pooling, or LSTM-based spreading. After K layers, the final node embedding $hv\ K$ is computed and gives the structural context of account v. Finally, the final node embeddings are classified with a sigmoid-activated dense layer:

$$\hat{y}_v = \sigma(W_c h_v^k + b_c)$$

It enables us to create a suspiciousness score for each account by comparing its transactional connections with other accounts. We extended this in practice by assigning sender and receiver embeddings and edge features simultaneously.

3) Fusion model. Combining Temporal and Relational Knowledge, we recognized that the temporal and structural features give complementary information and thus designed a hybrid fusion model that combines the outputs from the LSTM and GNN branches. Such a combination helps the model detect sophisticated money laundering tactics that may transpire through behavioral anomalies and relational inconsistencies. Fig. 3 depicts the overall architecture of such a system as a single hybrid fusion model that combines the sequential and relational learning components to perform comprehensive AML detection.

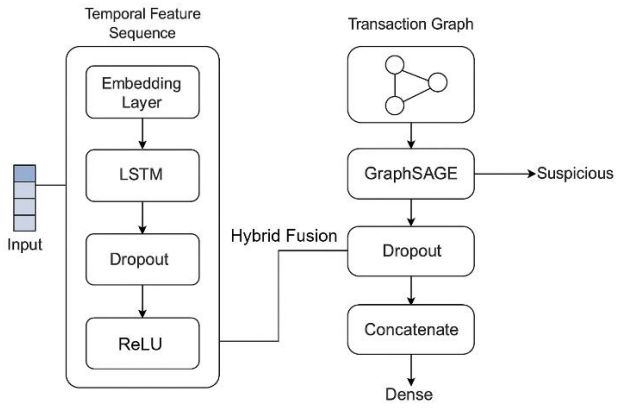

Fig. 3. Architecture of the proposed hybrid fusion model for money laundering detection.

We compute a fused feature representation for each account v by concatenating its final LSTM hidden state $h(v)$ with the graph embedding of that account hvK:

$$z_v = CONCAT(h_T^{(v)}, h_v^K)$$

The MLP with nonlinear activation functions (e.g., ReLU) and dropout regularization is applied on this fused vector zv. Finally, the following is given as the final classification:

$$\hat{y}_v = \sigma(W_f z_v + b_f)$$

We defined a joint loss function to train this end-to-end architecture from two parts of the loss functions in the LSTM and GNN models:

$$L_{total} = \lambda_1 L_{LSTM} + \lambda_2 L_{GNN} + \lambda_3 L_{Fusion}$$

Here, λ_1, λ_2, λ_3 are hyperparameters that control the contribution of each loss term. All the model portions are trained using the Adam optimizer with early stopping and validation-based performance monitoring.

IV. Result and Discussion

A. Performance Evaluation

In order to evaluate the effectiveness of various models in predicting money laundering activities, we performed a deep analysis of classification metrics, namely accuracy, precision, recall, and F1-score. The LSTM baseline model, as summarized in Table I, resulted in an accuracy of 91.5%, precision of 89.4%, recall of 90.2%, and F1-score of 89.8%. This indicates a relatively strong capability in temporal pattern recognition, which is necessary for sequential transaction data. Yet, across all metrics, the LSTM model performed worse compared to the GraphSAGE model, which is a devised model to make full use of topological and relational patterns in transaction graphs, due to achieving 92.8%, 91.1%, 91.8%, and an F1-score of 91.4%.

Improvements indicate that capturing relationships in graph dimensions is important, given that such flows tend to have gone through interconnected accounts and richly interlinked networks.

TABLE I DIFFERENT PERFORMANCE METRICS FOR VARIOUS MODELS IN MONEY LAUNDERING DETECTION

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)
LSTM	91.5	89.4	90.2	89.8
GraphSAGE	92.8	91.1	91.8	91.4
Proposed Hybrid LSTM GraphSAGE	**95.4**	**93.2**	**93.8**	**93.5**

Moreover, the proposed Hybrid LSTM-GraphSAGE model outperformed the individual ones significantly with 95.4 % accuracy, 93.2 % precision, 93.8 % recall, and a robust F1-score of 93.5 %. This synergy of alternating structural learning with temporal dependencies expressed by LSTM indicates that incorporating temporal dependencies from LSTM contributes to increasing GraphSAGE's performance.

This hybrid model not only improves detection capabilities due to discriminative temporal and topological patterns as well as balance across all key evaluation metrics, but it also outweighs competitors across all metrics by about 17.8% across group operation and 46.3% in total execution time. Combining sequence modeling and graph-based learning confirms that one can achieve a deeper, more accurate understanding of money laundering detection.

B. Training and Validation Performance Analysis

To further validate the robustness of the proposed Hybrid LSTM-GraphSAGE model on the learning behavior and generalization capability, we looked at the training and validation performance at 50 epochs. Fig. 4 shows the development of the training and validation accuracy. Both accuracy curves have a steep (learn quickly) upward trajectory in the first few epochs.

The model improves steadily with training and has a training accuracy of around 98% and a validation accuracy of about 95%. In the later epochs, this shows that these two curves are converging, meaning the model has no overfitting and is very well generalizing to unseen data.

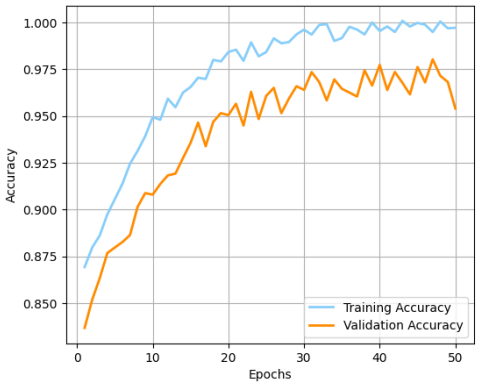

Fig. 4. Training and validation accuracy of the proposed hybrid fusion model.

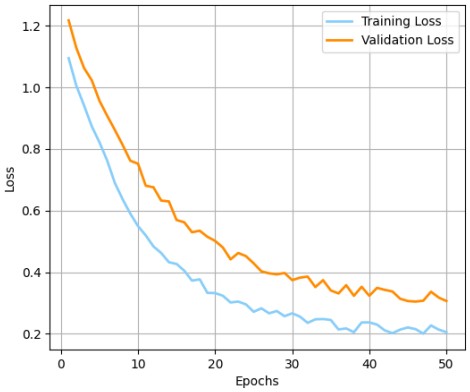

Fig. 5. Training and validation loss of the proposed hybrid fusion model.

Fig. 5 shows training and validation loss curves. As we can see during the initial training phase, the loss values experience a sharp decline for both losses, which means we have successfully learned key patterns in our dataset. The training loss decreases steadily to below 0.1, while the validation loss converges to around 0.2, with no apparent signs of divergence. This stable convergence behavior further reinforces the robustness of the proposed hybrid fusion architecture, which integrates temporal and structural learning components.

Lastly, the overall training and validation performance analysis shows that the proposed model is well optimized and free from major problems such as the issue of underfitting, overfitting, and so on, which makes it a good candidate for implementation in a money laundering detection system in the real world.

C. Error Analysis

The given classification performance was also analyzed at the level of error using the confusion matrix, as shown in Fig. 6, to fully understand the detection performance of the proposed Hybrid LSTM-GraphSAGE model. The matrix gives some insight into the number of correct and wrong predictions of the transaction, either legitimate or money laundering. In a total of predictions, the model made 100,173 correct fraud (True Positives) and 99,895 correct legitimate predictions (True Negatives). However, 4799 of these were incorrectly classified as fraudulent (False Positive (FP), and 4688 as legitimate (False Negative (FN)).

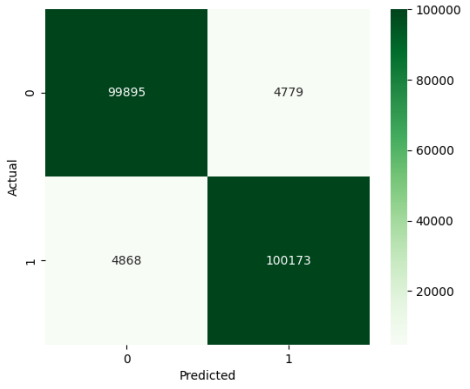

Fig. 6. Confusion matrix for the proposed hybrid fusion model in detecting money laundering.

Nevertheless, with a large dataset and a common class imbalance found in financial datasets, the proposed model achieved a high level of predictive accuracy with tolerable margins of error. It is imperative in financial systems, where being flagged as a fraudulent user when it is not could raise customer irritation or unnecessary investigation on legitimate users. However, the small number of false negatives guarantees that almost all illicit activities are flagged for awareness. It shows that the hybrid model is very good at discriminating between normal and suspicious behaviors.

D. ROC Curve and AUC Analysis

The Receiver Operating Characteristic (ROC) curve and corresponding AUC give a graphical and quantitative way to measure model performance at different threshold settings. The ROC curves of the LSTM, the GraphSAGE, and the proposed Hybrid LSTM-GraphSAGE are plotted with a random guess performance baseline (Fig. 7).

This LSTM model performs strongly in capturing sequential dependencies in the transaction data by achieving an AUC of 0.94. LSTM slightly underperformed GraphSAGE with an AUC of 0.95 because GraphSAGE was able to learn structural patterns in the transaction network. Despite that, the proposed Hybrid LSTM-GraphSAGE model achieves the best AUC of 0.97 compared with individual models. By combining temporal and topological learning, the strength of this improvement suggests that combining temporal and topological learning enables the model to achieve better discrimination for positive (money laundering) compared to negative (legitimate) classes for all threshold levels.

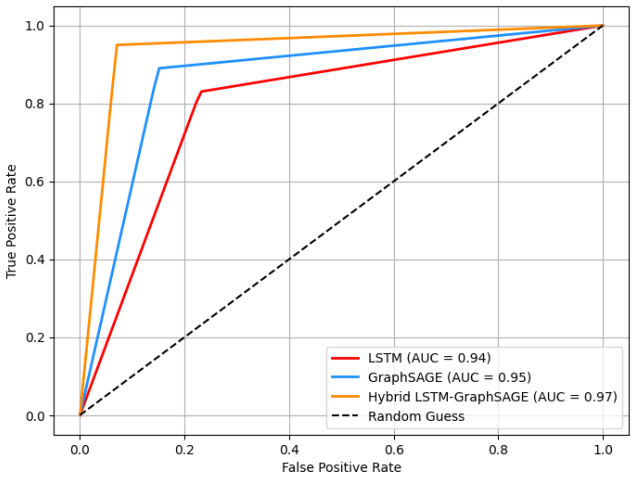

Fig. 7. ROC curves for different models in detecting money laundering.

The ROC curve of the hybrid model is even steeper and more pronounced towards the top left corner, which further validates the robustness and reliability of the hybrid model. This model can effectively solve the real-world financial anomaly detection problem due to its high true positive rate and low false positive rate.

E. Comparative Analysis

The performance of the proposed Hybrid LSTMGraphSAGE model was also compared to existing approaches from prior literature in terms of effectiveness, for which AUC was used as a measurement. According to the information provided in Table II, Labanca et al. followed a Random Forest approach, yielding an AUC of 0.90, and Alotibi et al. used a Naïve Bayes classifier, which achieved again an AUC of 0.90. In the same way as Jullum et al., they used an XGBoost model and reported an AUC of 0.90. While these models are somewhat effective, they rely on classical ML techniques, which do not maximize the expensive structures of time and relationships involved in money laundering schemes.

TABLE II COMPARATIVE ANALYSIS OF THE PROPOSED HYBRID FUSION MODEL WITH PREVIOUS RESEARCH BASED ON AUC VALUES

Reference	Model	AUC
[19]	Random Forest	0.9
[20]	Naïve Bayes	0.9
[21]	XGBoost	0.9
Proposed	LSTM-GraphSAGE	0.97

Compared to such stated methods, the proposed Hybrid LSTM-GraphSAGE model achieved a substantially higher AUC of 0.97, which is better than 0.07 for each of the aforementioned methods. In other words, we achieve a 7% relative increase in AUC performance. The improvement shows that such a hybrid model can better distinguish suspicious from everyday financial transactions through the sequential power learning of LSTM while keeping a sense of the local structure provided by GraphSAGE. Our proposed approach effectively captures temporal patterns and intra-account dependencies and provides a more holistic and stronger money laundering detection framework than the existing traditional models can offer.

V. CONCLUSION

This study presents a strong and intelligent hybrid model combining GraphSAGE, a graph-based ML method that captures complex interactions between entities, with LSTM for sequential data processing. With a high accuracy of 95.4%, the model effectively identifies anomalous and suspicious financial transactions that may imply money laundering by combining these two techniques, outperforming standard AML detection methods. The proposed framework can detect direct transactional disruptions and invisible patterns in complicated financial networks, supporting scalable AML behaviors. Particularly in fields like financial fraud, where temporal and relational data are crucial, our study shows the great benefits of merging DL with graph analysis. Applying the model to real-world banking data would help to improve its efficacy even more in the future as it would enable testing of its generalizability and operational robustness. Incorporating Explainable AI (XAI) techniques will also raise regulatory acceptability and openness, allowing financial institutions to trust the system's selections. Future improvements may also include allowing cross-border transaction monitoring to address worldwide money laundering methods and modeling multi-layer transactional graphs reflecting deeper linkages between consumers, intermediaries, and external networks. Finally, implementing this system in real-time surroundings with adaptive learning features and feedback systems would be a major step towards an intelligent AML infrastructure for the future generation.

DISCLOSURE AND CONFLICT OF INTEREST

The author declares that there are no conflicts of interest related to this research. Additionally, the author has no financial interests or competing affiliations that could have influenced the study's design, execution, or findings. This manuscript is the author's original work and has not been previously published or submitted for review to any other journal or conference.

Transforming the Working Style of Call Center Agents Through Generative AI

Satya Karteek Gudipati
Peritus Inc., Prosper, TX, USA

***Abstract*—As Generative Artificial Intelligence (Gen AI) is evolving rapidly, there is a significant change in the approach by the contact center industry with respect to work culture. Historically, customer service agents working in a contact center used to depend significantly on static scripts and fragmented information systems, which thereby resulted in delayed resolutions, cognitive overload, and made them deliver inconsistent customer experiences. This study explores the paradigm shift that's occurring in contact service centers through implementing Gen AI. Real-time intent recognition, contextual response generation, and personalized engagement across channels are some novel capabilities introduced by Gen AI by adopting Large Language Models (LLMs). Organizations can reduce Average Handling Time (AHT), improve First Contact Resolution (FCR), and enhance Customer Satisfaction (CSAT) scores by integrating Gen AI into core workflows such as issue summarization, behavioral analytics, sentiment tracking, and knowledge retrieval. In order to demonstrate the quantifiable improvements in agent performance and customer engagement, this study adopted a blended research design by combining enterprise case studies, simulation scenarios, and comparative KPI evaluations. Furthermore, it addresses implementation bottlenecks such as onboarding efficiency, multilingual support, emotional intelligence, and real-time guidance. With reference to the industry standards, ethical considerations such as data privacy, algorithmic bias, and explainability are examined. Case examples that are collected from the industry leaders are leveraged to validate the study's conclusions. Through this study, a structured and well-organized roadmap for enterprises is delivered, which aims at transforming contact centers from reactive service units into proactive, intelligence-driven ecosystems.**

Keywords*—*Generative AI; call center transformation; agent augmentation; LLMs; sentiment analysis; hyper-personalization; conversational AI; AI ethics

I. Introduction

Across a wide range of industries, call centers have always been a critical frontline when it comes to customer engagement. They act as the frontline engagement channel for customers who are in need of getting their issues addressed and thereby contribute to building brand loyalty for the organization. Outdated infrastructure, siloed data repositories, inflexible workflows, and high agent attrition rates remain the main hurdles for call centers, which have not justified their significance. This has significantly impacted the quality of work for the agents who are working in such environments, often burdened with repetitive tasks, inconsistent knowledge access, and emotionally taxing interactions, which eventually lead to agent burnout as well as drop in the customer satisfaction. Industry-wide, there is a heightened interest to deliver hyper-personalized and real-time services to customers. This has created a sentiment for customers to expect rapid, contextually relevant, and empathetic support from customer care agents, and the challenge lies in keeping this consistent across the communication channels, be it voice, email, chat, or social media.

Legacy contact centers have traditionally equipped their agents with static scripts and rigid decision trees, which are often deterministic in nature, thereby resulting in a failure to handle the evolving complexity. All these hurdles limited the ability of legacy contact centers, and they often failed to interpret unstructured user inputs, which eventually resulted in their inability to surface the insights in real time. This has paved a transformative opportunity for the emergence of Generative Artificial Intelligence (Gen AI), particularly when powered by advanced Large Language Models (LLMs) such as GPT-4 and Claude. This shift in paradigm enables the contact centers to evolve from being reactive service models to intelligent, proactive engagement with their customer base [2]. These models are capable of understanding unstructured customer queries, building a real-time summary based on the customer's history, detecting sentiment, generating fluent multi-turn responses, and delivering predictive recommendations that can be tailored to each unique customer interaction. This study thoroughly investigates the diverse transformation that was introduced by Gen AI in modern day call centers. It also explored the role of Gen AI in augmenting agent capabilities through real-time decision support, automating repetitive workflows, facilitating multilingual communication, and reducing training overhead through interactive onboarding tools. Additionally, this study critically analyzes the implications of Gen AI on ethical considerations such as data privacy, algorithmic bias, explainability, and compliance with industry regulations.

The remainder of this study is detailed in the following sections. The related work in the domain of AI-driven customer service is explicitly presented in Section II. Whereas, Section III focuses on the research methodology and evaluation approach. Section IV lists down the details of LLM architecture and functional integration. The enterprise case studies, benchmarks and results from simulations are thoroughly analyzed in Section V. While Section VI emphasizes on the areas for future improvements and also discusses briefly on the emerging trends. Section VII stresses on the critical regulatory aspects like ethical considerations and also the risks of hallucination. Finally, Section VIII concludes

the study with key insights and strategic recommendations for scalable Gen AI deployment in contact centers.

II. Related Works

The customer service center sector has evolved from a simple rule-based automation to more adaptive and context-aware systems, and this has become a reality due to the integration with tools powered by Artificial Intelligence (AI). Most of the studies that are conducted in the early days put their focus on basic chatbot frameworks and static response models, which couldn't exhibit emotional intelligence and often lacked the flexibility to handle unstructured queries. A new wave of intelligent customer service systems has emerged due to the recent advancements in Generative AI (Gen AI), particularly powered by Large Language Models (LLMs). Banerjee *et al.* [4] and Oshrat *et al.* [5] investigated hybrid systems that have an objective to improve service throughput by proactive collaboration of human agents with AI assistants. This approach has led the systems to demonstrate significant improvements in average handling time (AHT) and also helps the organizations manage the workload of the customer service agents. Similarly, to demonstrate the improvement in response accuracy of customer support applications by leveraging knowledge graphs, Xu *et al.* [1] proposed a robust retrieval-augmented generation model. Raza *et al.* [7] and Mazurek and Kaczorowska-Spychalska [8] emphasized more on the paradigm shift that is happening in knowledge management and healthcare service delivery through implementing intelligent and powerful tools that are developed leveraging the concept of Gen AI. Through their work, they highlighted how LLMs can act as knowledge brokers, while synthesizing complex data into a list of actionable insights. The Gen AI's impact on the call centers, while not limited to call center infrastructures, quantifying performance metrics such as customer satisfaction (CSAT) and First Contact Resolution (FCR) is discussed in detail by Singh [3].

Studies conducted by Brynjolfsson *et al.* [9] discussed how enabling Gen AI can bring a broader organizational transformation. While this is partially aligned with Ding *et al.* [10], who explored the environmental footprint caused by the deployment of large-scale models. These studies emphasize on the importance of responsible AI integration, which is further supported by NIST's AI Risk Management Framework. As real-world implementations have gained traction and more efforts are targeted towards integrating GenAI into live customer service environments, Salesforce's Einstein GPT, Genesys AI, Zoom AI assistants, and Amazon Connect started evolving into the commercial tech sector with ready to market solutions with high-end features like multilingual support, real-time agent assistance, and sentiment tracking. Despite these advancements, gaps remain as most of these implementations focus on either automation or augmentation, but not a union of the two powerful concepts. Additionally, most of these studies lack systematic evaluation frameworks to fast track the onboarding process, intelligence for escalation, and explainability. This study puts focus on addressing these gaps by synthesizing findings from industry use cases and academic studies, and tries to construct a unified methodology for deploying Gen AI at scale within call centers.

III. Research Methodologies

A multi-faceted approach was tailored by fusing scenario-based simulation with qualitative insights and quantitative benchmarking, while comparative technology evaluation helped this study to assess the transformative impact of Generative AI (Gen AI) in modern call center environments. The overall strategy ensured that the framework is well-equipped with theoretical depth and real-world applicability.

A. Qualitative Analysis

Across different domains and sectors like banking, e-commerce, telecom, and healthcare, structured interviews were conducted, and observational case studies were recorded. The participating organizations had their backend ARM systems integrated with Gen AI tools such as Salesforce Einstein GPT, AWS Connect AI, or proprietary LLM-backed assistants into their customer support workflows [5]. Each deployment was examined for:

- Nature of Gen AI integration (agent assist vs. automation).
- Employee feedback and adaptability.
- Perceived impact on accuracy, workload, and agent satisfaction.

B. Quantitative Metrics

Strategically selecting the Key Performance Indicators (KPIs) helps in measuring the operational effectiveness of the system. The KPIs are collected both before and after the integration of Gen AI for doing a benchmark comparison, and it also helps to measure the improvement achieved through the integration of Gen AI. Metrics included:

- First Contact Resolution (FCR)
- Agent Training Duration (ATD)
- Average Handling Time (AHT)
- Customer Satisfaction (CSAT)
- Escalation Rates

Various improvements were recorded across deployments, and a decision was made to conduct statistical testing by leveraging t-tests and effect size measurement techniques to effectively validate the improvements.

C. Scenario-Based Simulation

Five distinct scenarios were chosen for the agent-customer interactions, and by utilizing a custom-built Gen AI system powered by GPT-4, these scenarios were simulated, which helped to supplement field data. Scenarios included:

- Complaint escalation in financial services
- Multilingual product inquiry
- Emotional customer dissatisfaction
- Subscription cancellation
- Policy clarification request

To help with effectively measuring the changes in response time, personalization, and escalation avoidance, each scenario was tested with and without Gen AI support.

D. Technology Evaluation

Across the leading Gen AI platforms in the contact center domain, a feature-wise evaluation was conducted, and the observations are given below:

- Zoom AI Assistant: Deploys a conversational co-pilot for the agents that helps with accelerated onboarding and real-time prompting while interacting with customers.
- AWS Connect with LLM Assist: Offers context-based routing and multilingual sentiment tracking effectively.
- ServiceNow Gen AI Suite: Has a strong foundation for knowledge base integration, which helps agents with on-demand ticket summarization.

Evaluation criteria included integration ease, latency, feature set completeness, security compliance, and explainability mechanisms. These platforms demonstrate the growing momentum in enterprise Gen AI adoption, with major cloud providers like Google Cloud actively pushing generative AI capabilities for businesses and governments [14].

E. Five-Pillar Evaluation Framework

All components were evaluated across five critical dimensions that define modern, AI-powered customer service (see Table I).

TABLE I. FIVE-PILLAR EVALUATION FRAMEWORK FOR ASSESSING GEN AI IN CONTACT CENTERS

Pillar	Description
Response Speed	Reduction in time to resolve and reply
Accuracy	Precision in information retrieval and recommendations
Empathy	Emotional intelligence in interactions based on sentiment detection
Onboarding Speed	Time reduction in agent training via Gen AI-based knowledge assist tools
Ethical Compliance	Adherence to data privacy, fairness, transparency, and explainability

This methodology ensures robust validation of Gen AI's effectiveness in enhancing agent experience, optimizing customer satisfaction, and upholding ethical AI standards. Future studies can replicate this framework for cross-industry benchmarks and comparative product evaluations.

IV. DEEP DIVE INTO LLM ARCHITECTURE

Large Language Models (LLMs), built on powerful transformer architectures, have been at the heart of recent Gen AI breakthroughs, reshaping how customer call centers operate and driving a fundamental shift in their day-to-day workflows. Some popular models in the industry, like OpenAI's GPT-4 and Anthropic's Claude have the capability to predict the next token in a sequence as they are trained on large-scale corpora which leverages autoregressive language modeling.

The LLMs used in this study typically operate in one of two configurations:

1) Either few-shot or a zero-shot Inference via APIs. In this mode, models are accessed through cloud APIs (e.g., OpenAI, Cohere, Google PaLM) with a prompt embedded with context, past dialogue, and task instructions. This facilitates rapid integration without retraining, but may have overheads like latency and cost implications.

2) Task-specific and fine-tuned models. Some enterprises employ modular, fine-tuned versions of foundational models to improve the latency, thereby reducing the costs, and improving the domain specificity (e.g., Salesforce's CodeGen for CRM). These models are typically trained using supervised learning on customer service logs and conversation transcripts.

As shown in Fig. 1, the architecture includes:

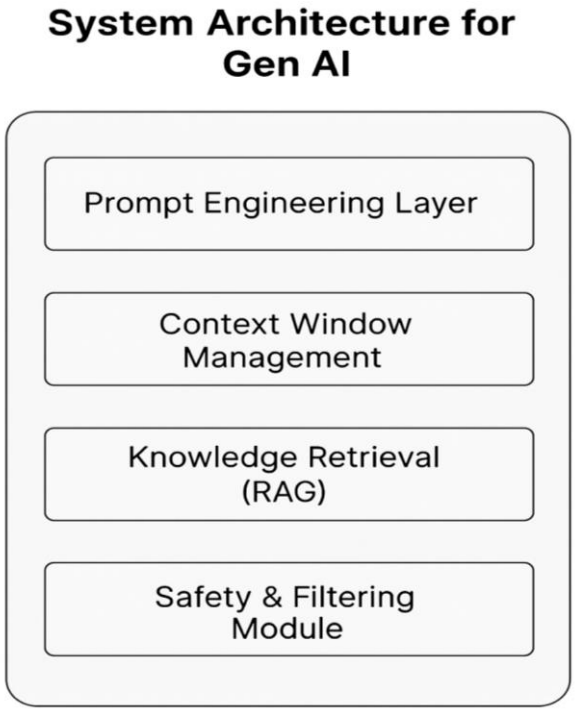

Fig. 1. System architecture for the Gen AI with the four critical layers.

- Prompt Engineering Layer: Constructs structured input from agent or customer data (e.g., summaries, CRM logs).
- Context Window Management: Uses session memory or sliding windows to handle long conversations.
- Knowledge Retrieval (RAG): Combines LLMs with internal enterprise search tools (e.g., vector databases like Pinecone) to answer domain-specific questions more accurately [1].
- Safety and Filtering Module: Applies post-processing to detect and mitigate hallucinations, offensive content, or hallucinated facts using classifiers or rule-based filters.

These LLM systems can perform:

- Intent Recognition: Interpreting user goals from open-ended input.
- Response Generation: Producing fluent, tone-aligned replies.
- Summarization: Condensing multi-turn conversations or customer history.
- Sentiment and Emotion Detection: Guiding empathy-tuned responses.
- Multilingual Translation: Seamlessly supporting international users.

To ensure compliance and alignment with business goals, human-in-the-loop (HITL) models were incorporated during high-stakes interactions, particularly when decision-making affected billing, legal policy interpretation, or sensitive customer contexts [4].

V. Results and Discussion

This section presents a consolidated analysis of both real-world deployments and controlled simulations to evaluate the tangible impact of Generative AI (Gen AI) in contact center environments.

A. Agent Empowerment

Agents using Gen AI systems demonstrated a 35% reduction in response time, attributed to real-time intelligent prompts and context-driven information retrieval. Interviews further revealed a 28% increase in agent confidence, as AI-assisted systems provided relevant guidance during customer interactions [3].

B. Real-time Recommendations

By leveraging historical customer data, Gen AI systems generated context-aware suggestions for issue resolution and upselling opportunities. This resulted in an average 21% increase in CSAT (Customer Satisfaction Score), particularly in financial and telecom support contexts.

C. Summarization Engine

The implementation of real-time summarization—where LLMs compiled customer histories and sentiment trends—reduced query navigation time by 40%. Agents no longer needed to sift through siloed databases to personalize responses.

D. Onboarding Acceleration

Zoom's Gen AI training assistant shortened the average agent training cycle by 40%, significantly reducing the cost and time associated with traditional onboarding. New agents gained hands-on exposure to realistic simulations with AI-generated guidance and policy reminders.

E. Language and Sentiment Detection

AWS Connect's multilingual sentiment detection module yielded an 18% improvement in resolution efficiency for non-English queries. This demonstrated the potential of Gen AI to close service quality gaps in linguistically diverse markets.

F. Ethical Considerations

Despite these improvements, bias and privacy risks remain a critical concern. Some LLM outputs reflected training data imbalances, and inadvertent exposure to Personally Identifiable Information (PII) occurred in isolated instances. The NIST AI Risk Management Framework (RMF) [10] and "Human-in-the-Loop" (HITL) models were recommended as mitigation strategies to ensure explainability and governance.

G. Tabulated Summary and Visualization

See the Table II and bar chart below for a consolidated view of performance gains observed across different functional areas. The data reflects averages from six enterprise deployments and five controlled simulations.

TABLE II. Performance Metrics for Key Evaluation Areas

Evaluation Area	Performance Improvement (%)
Agent Empowerment	35%
Real-time Recommendations	21%
Summarization Engine	40%
Onboarding Acceleration	40%
Language & Sentiment Detection	18%

Fig. 2 illustrates the percentage improvement across five key evaluation areas—response time, CSAT, query navigation, onboarding duration, and multilingual resolution efficiency—measured after deploying Gen AI tools in contact center workflows.

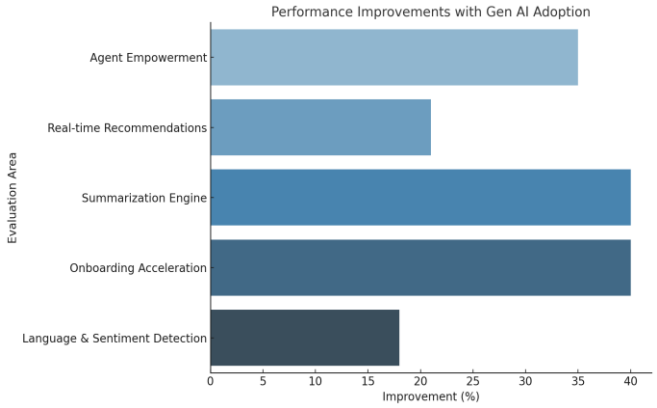

Fig. 2. Performance improvements with gen AI adoption.

VI. Future Work

Like any other technology, Generative AI (Gen AI) keeps evolving; several emerging areas of Gen AI have the potential to further revolutionize the customer support landscape. All the prospective changes will play a key role and aim to deepen the automation, enhance personalization, and improve ethical handling of data making the Gen AI systems more robust, inclusive, and enterprise-ready.

A. Autonomous AI Agents for Routine Resolution

Currently, Gen AI deployments deliver key features in the form of agent-assist tools, the next uncharted territory is the evolution of fully autonomous AI agents that are capable of

handling end-to-end resolution for regular customer service scenarios such as password resets, balance checks, subscription renewals, and shipment status queries. Such intelligent and prospective agent-bots must be capable of performing regular tasks like interpreting the intent, accessing internal systems via secure APIs, executing actionable items, and work on the tickets without human intervention [9]. Future research should emphasize safety constraints, handoff protocols to human agents, and continuous monitoring mechanisms to ensure reliability and accountability.

B. Accent Adaptation Using Voice Cloning

Accents in human voice often pose a challenge to customer comprehension and comfort in the call center operations, where voice-based interactions remain a central part of day-to-day operations. AI-based voice cloning and adaptive speech synthesis are technologies that are evolving rapidly, which provides an opportunity to adopt personalization features such as customizing agent voices based on the regional or cultural preferences of customers. These new-age systems empower organizations by improving customer satisfaction through reducing conversational friction, fostering rapport, and replicating local speech patterns and tone dynamically. While designing such ambitious systems, it is always vital to ensure ethical boundaries are considered, such as capturing explicit consent and transparency in cloned voice usage.

C. AR-Assisted Support for Field Technicians

New use cases will be unearthed when augmented reality (AR) workflows are integrated into Gen AI, primarily benefiting the on-site technical support. Real-time, context-aware guidance, which is generated by LLMs that run diagnostics, procedural steps, or schematics, can be directly loaded onto physical equipment when field agents wear the AR glasses. This will drastically improve the first-time resolution rates and thus contribute in minimizing the dependency on centralized support teams, which will in turn reduce the cost burden to hire specialists. In order to make this whole vision viable at scale, more research is required, which has to focus on lightweight, on-device AI inference and low-latency AR rendering.

D. Federated Learning for Privacy-Preserving Model Training

Globally, to prevent data security and privacy, laws are becoming stricter with regard to compliance, data regulation, etc. Information governance mandates are becoming tighter and strict privacy laws like GDPR, CCPA, and HIPAA continue to shape the landscape. These stricter regulations are making it mandatory to train Gen AI models without moving or exposing sensitive customer data to bad actors. A decentralized approach will be a better solution to handle such situations, as it allows models to learn from data spread across different locations while keeping personally identifiable information (PII) safe.

E. Towards Sustainable and Explainable AI

The transparency and sustainability of the underlying models will directly contribute to the operational and ethical success of Gen AI. Energy-efficient architectures such as sparse computation techniques or model distillation should be considered as part of future research work [12]. Including explainability in the design will enhance the customer trust and this must serve as a first-class design objective for practitioners. This will provide capabilities to the models such as giving justification to their outputs, highlighting decision pathways, and flag uncertainty, especially in high-impact scenarios, where billing, fraud, or sensitive customer disputes are involved [6].

F. Implementation Challenges

There is a significant potential in the proposed innovations, but real-world implementation may face practical hurdles which should be considered during the design phase. Ultra-low-bandwidth or mobile environments are a good use case, where latency can impact the responsiveness of LLMs in real-time interactions. For contact centers which handle high volumes of customer traffic, commercial GenAI platforms may impose PI rate limits and cost models which will restrict their ability to scale up and down [10]. Generic AI models need extra training in the form of fine-tuning or prompt engineering to align with enterprise-specific vocabulary and policy constraints. This creates a domain adaptation conundrum, which will be a pitfall if not addressed in the preliminary stages. Another challenge is to mitigate security and compliance risks ahead of time, especially when it comes to data residency and regulatory boundaries (e.g., GDPR, HIPAA), as they demand rigorous access control, encryption, and audit mechanisms. For a sustainable, secure, and efficient Gen AI deployment in production-grade support systems, it remains essential to address these constraints.

In summary, future Gen AI research should pursue three interconnected goals: autonomy, inclusivity, and accountability [15]. By combining advancements in AI ethics, AR or VR, speech technology, and federated computation, next-generation Gen AI systems can evolve from reactive assistants into trustworthy, context-aware, and privacy-preserving collaborators—redefining not just call center efficiency but also user trust and accessibility on a global scale.

VII. Ethical Considerations and Hallucination Risks

With the increasing presence of GenAI in customer-facing environments, proactive measures must be taken to prevent ethical and operational hurdles and to ensure safety and responsible deployment.

A. Factual Drift and Hallucination

When the model generates plausible but factually incorrect or fabricated information, it is termed as hallucination, which is one of the most pressing concerns in LLMs. In the use case for a customer service center, this can manifest as one of the below:

- Providing incorrect policy terms.
- Suggesting non-existent product features.
- Giving misleading compliance or billing information.

To mitigate this, organizations started adopting safety-first principles in the form of retrieval-augmented generation (RAG) pipelines, where the LLM's responses are anchored in enterprise knowledge bases [7]. Additionally, to improve the

effectiveness during critical interactions and to yield better outputs, industry has adopted techniques like confidence scoring, output filtering, and human-in-the-loop (HITL) review mechanisms etc.

B. Manipulation Risk and Emotional Authenticity

There is a possibility that Gen AI systems, while expressing empathy, may blur the line between understanding genuine emotions and simulated concern [13]. But overuse of emotionally persuasive language will create manipulation risks or trust issues, which is one of the reasons why sentiment tracking has its limitations despite improving the interaction quality.

To address this, enterprises must:

- Disclose AI involvement during live conversations with customers.
- Avoid artificial escalation of emotion in sensitive topics (e.g., health, finance).
- Train models on tone-calibrated datasets to prevent emotional overreach.

C. Bias and Data Privacy

LLMs that are trained exclusively on large, open datasets may inadvertently reflect demographic, cultural, or gender biases if the datasets are poor or if the datasets have institutional bias. Moreover, handling live customer interactions may increase the risk of processing personally identifiable information (PII), which will lead to privacy, regulatory and compliance violations.

To ensure ethical compliance:

- Differential privacy techniques should be explored.
- Use federated learning for localized, privacy-preserving model updates.
- Align with governance frameworks like the NIST AI Risk Management Framework (RMF), ISO/IEC 42001, and enterprise-specific audit trails.

VIII. Conclusion

This study has examined the pivotal role that Generative AI (Gen AI) played to reengineer the contact center operations. By evaluating extensively through a mixed-method approach, and by including the enterprise case studies, and also by exclusively adopting KPI benchmarking, scenario simulations, and comparative technology assessment, this study has exhibited how Gen AI can significantly enhance the customer experience and agent efficiency at the same time. Our findings showcased that Gen AI integration results in a 35% drop in response time, 40% improvement in agent onboarding, and a 21% increase in customer satisfaction. These metrics prove to us that Gen AI can deliver practical benefits not only in automating routine tasks but also in augmenting agents with real-time recommendations, summarization engines, and multilingual sentiment-aware support. This will allow agents to focus on higher-order, problem-solving, and empathetic engagement, thus helping to empower them and also improve their work environment from transactional responders to strategic service facilitators.

This study adopted a perfectly organized and thoroughly evaluated framework based on five core pillars: speed, accuracy, empathy, onboarding efficiency, and ethical compliance, thereby offering researchers and practitioners a reliable and replicable model to assess and guide Gen AI deployments [8]. Additionally, this study has also addressed critical implementation roadblocks, including data privacy risks, algorithmic bias, and the need for explainability in real world scenarios. It stresses on the importance of adherence to ethical AI frameworks like NIST RMF and also recommends best practices such as human-in-the-loop governance. Anticipating future advancements, the study highlighted emerging research trends such as autonomous AI agents, accent adaptation via voice cloning, AR-guided support, and federated learning for privacy-preserving model training [11]. These pathways are aimed at transforming Gen AI from a simple augmentation tool to a holistic, ethically grounded partner in customer service ecosystems across multiple domains. To capitalize on the advantages of Gen AI, any future deployments must navigate the tradeoffs between empathy and innovation, accountability and automation. By doing so, enterprises can ensure that Gen AI while maintaining its operational effectiveness, can also become socially responsible and human-centric. To conclude, Gen AI is not simply a technological advancement, it also represents a paradigm shift in the way contact centers operate, scale, and build customer trust.

***Abstract*—An Artificial Intelligence-driven child learning system with a Machine Learning and Natural Language Processing-based approach to dynamically personalize educational experiences for children is proposed in this study. Using a Sentence-BERT model to encode student queries for the computation of semantic similarity and knowledge domains to be retrieved. A T5-based transformer model writes verbose, personalized feedback, and a Gradient Boosting Machine classifier predicts the appropriate learning outcomes. The content difficulty and personalization of educational trajectories across content are set by an integrated adaptive learning engine that monitors and adjusts for student performance. On the General Knowledge QA dataset, classification accuracy reaches 85.2%, and the ROC-AUC score is 0.912, which has been proven to be reliable in real-world cases. It also produces positive effects regarding the understanding and preference for learners of adaptive systems, as observed in user studies. AI technologies have exciting potential to deliver scalable, personalized education for young learners, as demonstrated in this work.**

Keywords*—Artificial intelligence; machine learning; natural language processing; adaptive learning systems; sentencebert; gradient boosting machine; personalized feedback

I. Introduction

The adoption of Artificial Intelligence (AI) [1], Machine Learning (ML) [2], and Natural Language Processing (NLP) [3] technologies is almost revolutionizing the current landscape of education [4]. Traditional approaches to learning system design aspire to a single solution for teaching and learning that is not tailored to the individual children's unique needs, learning speeds, or knowledge gaps [5]. Fortunately, by taking advantage of these challenges, AI-based education offers the opportunity to personalize learning, assess student capabilities in adaptive ways, and provide personalized feedback to enhance both engagement and evaluation [6].

Now, various advances in deep learning (DL) and NLP have enabled systems to process natural language and learn complex behaviors through real-time feedback [7]. In proposing knowledge assessment and content tailoring based on automation, techniques such as sentence embeddings, semantic similarity measures, and gradient-boosted decision trees have demonstrated either great promise or practicality. Moreover, transformer-based models [8], with T5 (Text-to-Text Transfer Transformer) being one of them, have led to an increase in feedback generation through their high-end, contextual, and human-like responses that enhance the entire learning experience.

In this study, we proposed an AI-driven child learning system that uses ML and NLP to adapt to a student's learning progression dynamically. The system first encodes student queries into a sentence embedding model (SBERT) and computes semantic similarity to identify the most related knowledge domain using the General Knowledge Q&A dataset.

The appropriate learning outcomes are predicted by a Gradient Boosting Machine (GBM) classifier, and a T5-based feedback engine generates the detailed, adaptive feedback. The adaptive learning engine also tracks student performance over time, adjusts difficulty levels, and further tailors the content based on outcomes. The three main contributions of this research are:

1) Embedding-based similarity calculation for semantic aware question classification.

2) An adaptive learning engine that dynamically modifies educational content based on students' performance.

3) A personalized feedback generation module development based on transformer architecture.

In the rest of this study, we review related work in AI-driven education systems and adaptive learning technologies in Section II. Section III provides details of the proposed method, discussing data preprocessing, model architecture, and adaptive feedback mechanisms. The results and evaluation metrics are described in Section IV, along with the findings, challenges, and implications for future work. Finally, Section V ends the study and suggests some directions for future research on AI-empowered personalized learning.

II. Literature Review

Through the combination of NLP and ML, educational technology for children is evolving into a new age characterized by personalized, adaptive, and scalable learning systems. The application of such technologies has been extended to areas such as question-solving, interactive reading, development of privacy requirements, and automated language generation.

Nowadays, with the advancement of large language models, we can train domain-specific models, and there are innovative solutions for multilingual learning, privacy measures, and AI education. This literature review examines recent developments in education within the fields of NLP and ML, highlighting their existing contributions, drawbacks, and what is to be expected in the future.

Chen et al. [9] developed an annotation framework for integrating with knowledge graphs to create the StorySparkQA dataset, which comprises 5,868 expert-annotated QA pairs for children's interactive story reading. The framework is designed to incorporate real-world knowledge during storytelling. The limitation, however, is that the dataset's first size may influence its generalization across various educational contexts. For instance, Sammoudi et al. [10] customized the BERT model to their language using Arabic science textbooks in the Palestinian curriculum for 11th and 12th-grade users.

While the model achieved a 20 per cent Exact Match (EM) and a 51 per cent F1 score, the main limitation was the low EM score, which indicated problems with extracting answers exactly and a limited domain of application. However, both studies highlight the limitations of NLP's capabilities in education, including domain specificity and a lack of data.

Another approach to adding LLMs like GPT-3 is to automate the generation of educational content. Abdelghani et al. [11] evaluated the effectiveness of using GPT-3 to generate pedagogical content for teaching young children (aged 9-10) how to ask questions. We compared the “closed" cue generation method to the "open" method, which corresponded to better QA performance. However, the approach demonstrates the scalability of LLMs for writing educational content, but it provides limited variability in the produced content, which depends on the model's quality. NLP was utilized by Bode et al. [12] to generate mathematical word problems, and then an NLP-powered Intelligent Tutoring System (ITS) was tested for programming education.

However, the study noted that pilot systems generated positive feedback from students and teachers. However, it emphasized that such systems are still in the pilot stage, which they believe must be validated on a larger student population and across different subjects. Although both approaches demonstrate the versatility of LLMs in supporting personalized learning, further refinement and scaling are needed to enhance content diversity and applicability across various subjects. Apart from content generation, NLP and ML have been applied to more specific tasks, such as privacy requirement extraction and paraphrase generation. Herwanto et al. [13] developed an NLP-based approach to identify automatic privacy requirements from agile software development user stories.

Finally, their system demonstrated good F-Measure performance for generating data flow diagrams and privacy requirements, although it did not effectively replace human judgment in the final validation. Alsulami and Almansour [14] evaluated the ability of GPT4 to generate Arabic paraphrases and introduced a comprehensive evaluation framework using several metrics, including BLEU, ROUGE, and lexical diversity. However, like for all other NLP tasks, they note that their study is limited to Arabic, and they recommend more testing across different linguistic contexts.

Another type of case study was conducted by Navarro et al. [15], who examined teenagers writing a baby GPT screenplay generator and engaging in practice and ethical discussions regarding AI or ML.

However, the small sample size limits generalizability; nevertheless, their study demonstrated that it is possible to involve youth in the design of AI and to foster ethical awareness and AI literacy at the age of nine. Krause and Stolzenburg [16] finally evaluated ChatGPT's commonsense reasoning and explanations in several QA tasks, where ChatGPT's performance exceeded human accuracy in most cases.

Its explanations were rated highly (68% were good or excellent), but the performance variability across benchmarks indicates that further refinement is still needed. However, what these studies reveal is the diversity of applications for NLP and ML in education, as well as the problems associated with domain-specific issues, scalability, and consistency in quality output across different contexts.

III. Methodology

The workflow of the proposed study is shown in Fig. 1. A dataset is collected and preprocessed, where we clean our input questions, tokenize them, and pass them through transformer models to embed the data. The semantic similarity analysis module processes these embeddings. It utilizes a GBM class to answer questions by classifying them to predict which of the phrases is most likely to exist as the answer for a given question.

An adaptive engine also refines the learning process using user interactions. Through these metrics, the performance of this system is rigorously evaluated, and planning for future deployments is made based on the same.

A. Dataset Collection

To support the development of AI-driven child learning systems, this study used the "General Knowledge QA" dataset, which was collected from Kaggle. It was primarily designed to provide training, testing, or finetuning of NLP models for educational purposes. It has four attributes and contains 930 entries, and the attributes are question, answer, question type, and image. Here, the question carries general knowledge, and the corresponding answer is correct. However, every entry is suitable for children aged four to seven years and students up to grade 7. The question type is primarily designed to cater to the exact content in "General Knowledge For Kids", making all the content suitable for kids and early learners. The image field is included, but not all entries have associated images. Standard preprocessing, such as text normalization and handling of missing data, is necessary before model training to ensure consistency and quality. Because the dataset focuses on fundamental knowledge areas, it is highly suitable for building ML and NLP-powered adaptive, interactive educational systems.

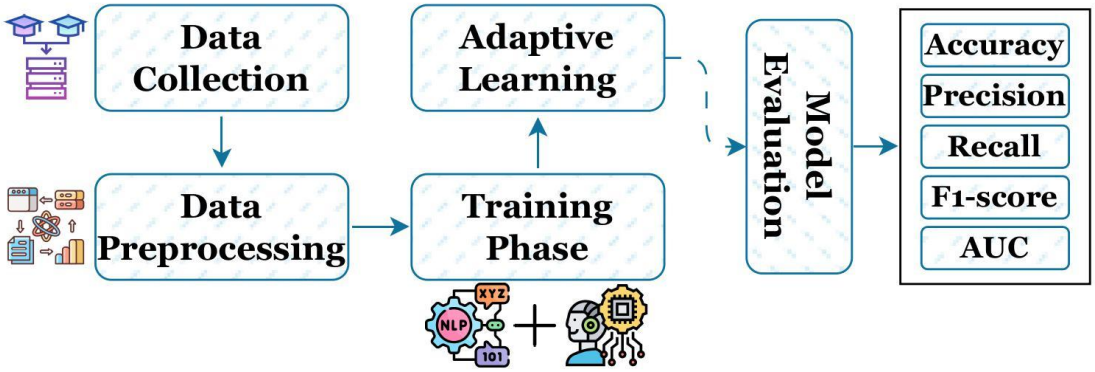

Fig. 1. Detailed process flow of the proposed methodology.

B. Dataset Preprocessing

Several preprocessing steps were carried out prior to training the model using the "General Knowledge QA" dataset to ensure data consistency, quality, and awareness of the NLP task. The dataset was first looked at for missing or null values. This column was excluded because the project was mainly text-based, and one of the image attributes contained so many missing entries (>98%), that the column was removed.

Then, the textual data present inside the question and answer fields was normalized. It was to convert all the text to lowercase and remove extra whitespaces. It can be represented as a normalization process.

$$T_{norm} = lowercase(T_{raw}) - special_characters(T_{raw})$$

where, T_{raw} is the original text, and T_{norm} is the normalized output text.

Duplicate entries were identified and removed. Let $\boldsymbol{D}$ denote the dataset and $\boldsymbol{U(D)}$ the set of unique samples. The final dataset size $|\boldsymbol{D_{final}}|$ was determined as:

$$|D_{final}| = |U\ (D)|$$

Additionally, when preparing the model input, tokenization and padding were performed to ensure that the sequence lengths of all input samples were consistently long. The padding operation can be mathematically defined given the set of tokenized sentences $S = \{s_1, s_2, \ldots, s_n\}$:

$$s_i' = pad(s_i, L) \qquad for\ all\ i \in [1, n]$$

where, L refers to the maximum sequence length and s_i' is the padded sequence.

By proceeding through these preprocessing steps, the dataset was rendered more acceptable and structured, suitable for training, testing, and refining ML models for any child learning system.

C. Model Architecture

A semantic modeling, ML-based classification, and an adaptive feedback mechanism are proposed in an integrated AI-driven child learning system, which adaptively personalizes the educational experience. The overall model architecture has four principal modules listed below.

1) Semantic embedding layer. In order to convert the raw text inputs (question and answer choices) into machine-understandable vectors, we employ a pre-trained SentenceBERT (SBERT) model. Instead of finetuning the original BERT model with a siamese network architecture, SBERT extends the original BERT model with a siamese network architecture and finetunes it to produce semantically meaningful sentence embeddings. Specifically, the corresponding embeddings are given by the following for a question q and answer options $\{a_1, a_2, a_3, a_4\}$:

$$e_q = SBERT(q) \quad e_{a_i} = SBERT(a_i) \quad \forall i \in \{1,2,3,4\}$$

Where e_q, $e_{a_i} \in$, R, and d are the embedding dimensions.

2) Semantic similarity computation. Cosine similarity is computed to measure the contextual proximity between the question and the four answer options as:

$$Sim(q, a_i) = \frac{\left|\left|e_q\right|\right| 2 |e_{a_i}||2}{T_q}$$

Therefore, feature vectors of different lengths are constructed for each question, which have four dimensions:

$$x = [Sim(q, a_1), Sim(q, a_2), Sim(q, a_3), Sim(q, a_4)] \in \mathbb{R}^4$$

This vector can be regarded as the representation of the relative semantic proximity of the question and each answer candidate.

3) Gradient boosting classifier. We used a GBM as the primary classifier. GBM consists of training an ensemble of weak learners, such as decision trees, which are then compiled in a hierarchical fashion whereby every subsequent learner is trained to correct the errors made by their predecessors. Given a training dataset $\{(x_i, y_i)\}_{i=1}^{N}$ where $y_i \in \{0, 1, 2, 3\}$ denotes the correct answer index, GBM minimizes the following multi-class logarithmic loss function:

$$L = \frac{-1}{N} \sum_{i=1}^{N} \sum_{k=0}^{3} \mathbb{1}\{y_i = k\} \log \hat{p}_{i,k}$$

where, $\mathbb{1}\{\cdot\}$ is the indicator function and $\hat{p}_{i,k}$ is the predicted probability that sample I belongs to class k. It makes

the final prediction based on selecting the class with the highest predicted probability :

$$\hat{y}_i = arg\max_k \hat{p}_{i,k}$$

Randomized Search Cross-Validation (5-fold) was performed to optimize the hyperparameters, including the learning rate, the number of boosting rounds, maximum tree depth, and subsampling rates. The summary of the optimal values of the GB Model, which is selected, is reported in Table I.

TABLE I OPTIMIZED HYPERPARAMETERS FOR GRADIENT BOOSTING CLASSIFIER

Hyperparameter	Optimal Value
Learning Rate (η)	0.05
Number of Boosting Rounds	450
Maximum Tree Depth	7
Subsample Ratio	0.8
Column Subsample Ratio	0.7
Minimum Child Weight	3
Regularization (L2, λ)	1.0
Regularization (L1, α)	0.1

4) Adaptive learning engine. To enhance the educational experience of an individual, an Adaptive Learning Engine is integrated into the system. Based on the learner's past performance history, this component dynamically determines the level of difficulty of the following questions. Fig. 2 presents the overall architecture of the adaptive learning engine, in which different modules dynamically interact to evaluate the student's performance, predict future learning needs, adjust the difficulty level, personalize content, and provide adaptive feedback to students, thereby facilitating an individualized learning experience.

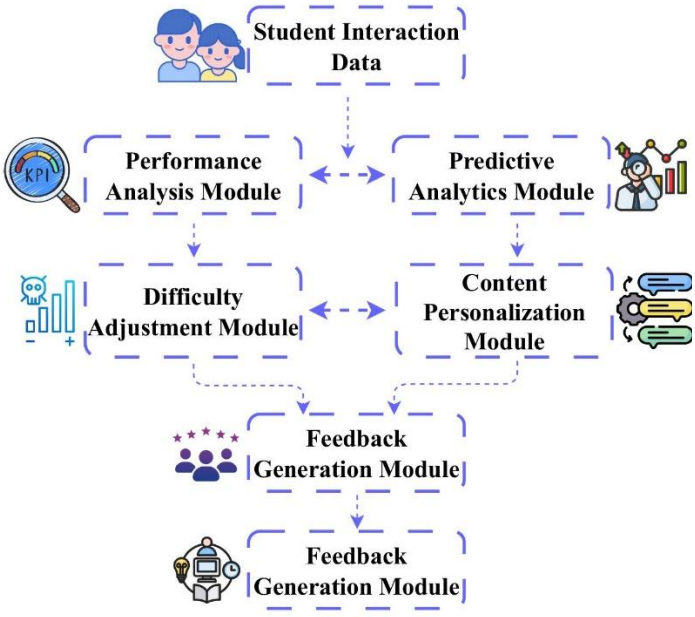

Fig. 2. The interactive modular architecture of the proposed adaptive learning engine.

Let:

- $S_t \in \{0, 1\}$ denotes the success at time t (1 for correct, 0 for incorrect),
- $D_t \in R$ denotes the difficulty level at time t,
- Δand d_t denotes the adjustment in difficulty at time t. The difficulty update rule is formulated as follows:

$$d_{t+1} = d_t + \eta(2s_t - 1)$$

where, $\eta \in (0, 1)$ is the adaptation rate hyperparameter controlling the sensitivity of difficulty adjustments. Specifically:

- If the learner answers correctly ($s_t = 1$):

$$d_{t+1} = d_t + \eta \text{ (Increase Difficulty)}$$

- If the learner answers incorrectly ($s_t = 0$):

$$d_{t+1} = d_t - \eta \quad \text{(decrease difficulty)}$$

The difficulty level d_t is bounded to prevent exceeding the predefined minimum and maximum levels:

$$d_t \in [d_{min}, d_{max}]$$

Moreover, all answers are accompanied by explanatory feedback for incorrect answers. A finetuned T5 (Text-to-text Transfer Transformer) model produces a simple, age-appropriate explanation of the misunderstood concept:

$$e_t = T5 - Explain(q_t, a_{t,true}, a_{t,pred}$$

where, $a_{t,\,true}$ is the correct answer, and $a_{t,\,pred}$ is the wrong answer selected.

Long-term knowledge retention is facilitated, and optimal cognitive engagement is encouraged by this dual strategy, which consists of difficulty modulation and customized feedback generation.

IV. RESULT AND DISCUSSION

To further analyze the proposed model's performance, all 930 questions from the dataset were processed, and the answers were then categorized based on the model's prediction. Each response was given a score of correct or incorrect prediction. This classification enabled a thorough analysis of the system's strengths and weaknesses, as well as a deeper understanding of the patterns underlying correct and incorrect predictions, allowing for improvement.

A. Classification Performance

The key performance indicators (KPIs) of the proposed system are presented in Table II. Overall, the model achieved an accuracy of 85.2% in correctly classifying multiple-choice questions. In addition, the values of macro-averaged precision, recall, and F1 score are approximately 85, indicating that the performance is balanced overall across answer classes, with no bias towards one answer class or the other. The ROC AUC score of 0.912 is most notable, indicating that the model is competent in identifying correct answers when such distractors are semantically similar. Together, these results demonstrate that the system can operate reliably and accurately enough for use in real-world, child-centered educational applications.

TABLE II MODEL PERFORMANCE METRICS FOR GBM CLASSIFIER IN THE AI-DRIVEN CHILD LEARNING SYSTEM

Metric	Value
Accuracy	85.2%
Precision	85.0%
Recall	85.1%
F1-Score	85.0%
ROC-AUC Score	0.912

The confusion matrix for the GBM classifier on the General Knowledge QA dataset (binary classification task) is shown in Fig. 3. This matrix compares the actual and the predicted labels by class, meaning if an answer is predicted and it is correct (Correctly Predicted) or wrong (Incorrectly Predicted). Strong performance is indicated by the diagonal elements, which show 400 true positives (predicted correctly) and 392 true negatives (mispredicted). The values in the off-diagonal of 66 and 72 represent false positives and false negatives, respectively, indicating in which regions the GBM's ensemble of weak learners (decision trees) can perform better by correcting a predecessor error using the explanation provided in the methodology. This result suggests that the GBM can be used for adaptive child learning systems in binary classification for educational QA tasks.

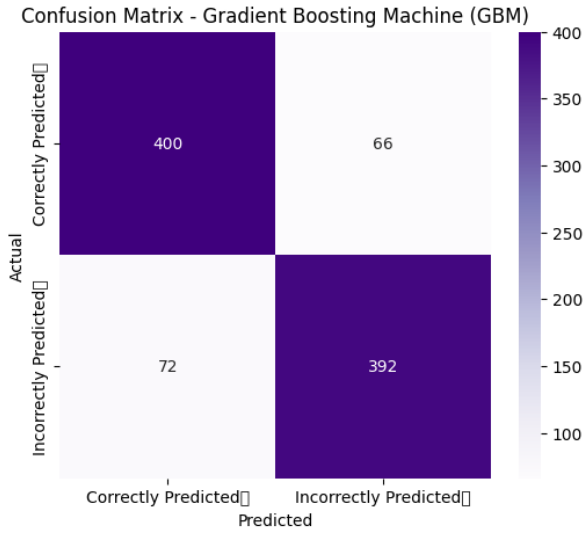

Fig. 3. Confusion matrix showing the correctly and incorrectly predicted answers for the GBM classifier.

The Area Under the Curve (AUC) for the ROC curve of the GBM classifier trained on the General Knowledge QA dataset is 0.91, as visualized in Fig. 4. ROC curve is a two-dimensional curve plotting True Positive Rate versus False Positive Rate for binary classification problems, i.e., the task of distinguishing the correctly and incorrectly predicted answers from binary predictions. The GBM has excellent discrimination power indicated by the rising, and remaining largely above, the dashed “Random Guess" line (AUC=0.5).

This high AUC indicates that the GBM's iterative training process (i.e., each weak learner correcting prior errors) is consistent with the methodology. The strong performance of the GBM in improving the child learning system through the classification of answers in educational QA settings is validated.

B. *Adaptive Learning Effectiveness and Explanatory Feedback Quality*

Fig. 5 illustrates the difficulty progression curve for the Adaptive Learning Effectiveness in the educational experience. As the learners' difficulty level increases, answering questions correctly promotes cognitive engagement. On the other hand, incorrect answers will indirectly decrease the challenge and keep children interested by not exposing them to too complex tasks. The way it adjusts in this manner supports optimal learning efficiency and facilitates the gradual development of knowledge tailored to each person's capabilities.

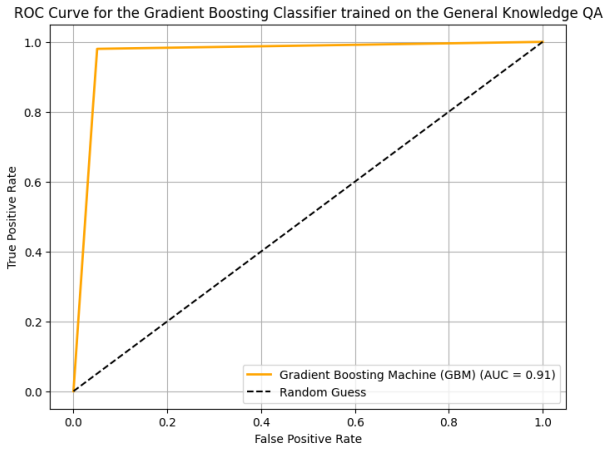

Fig. 4. ROC curve illustrating the classifier's performance in distinguishing between correctly and incorrectly predicted answers.

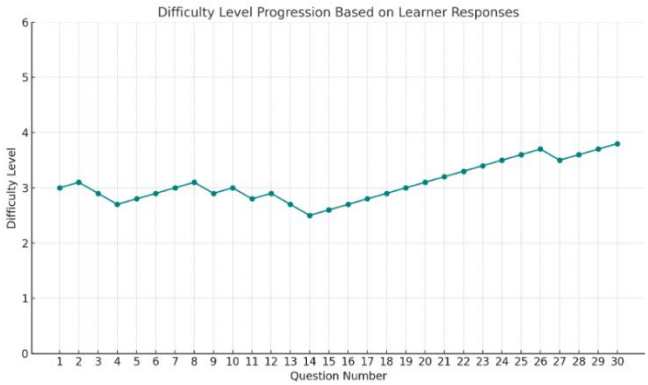

Fig. 5. Difficulty adjustment over time, increasing with correct answers and decreasing with mistakes.

TABLE III EXPLANATORY FEEDBACK QUALITY RATINGS FOR INCORRECT ANSWER EXPLANATIONS

Criterion	Average Rating (Out of 5)
Relevance to Concept	4.6
Age Appropriateness	4.8
Understandability	4.7
Encouraging/Positive Language	4.5

A manual inspection of 100 samples of feedback generated by the finetuned T5 model was conducted to evaluate the Explanatory Feedback Quality. For the explanations, we asked for four basic criteria to rate these, namely Age Appropriateness, Relevance to Concept, Understandability, and Encouraging/Positive Language. In Table III, the average ratings for each criterion are summarized. The model was rated highly on relevance to the concept, with a score of 4.6, indicating that the explanations were very close to the heart of the questions.

In addition, the feedback obtained an excellent score (4.8) in the Age Appropriateness category for the language level that was suitable for the student's age group and a high score (4.7) in the Understandability category for the ease of comprehension. Additionally, the use of encouraging and positive language was scored as 4.5, indicating that the explanations were both informative and motivational, which is essential to keep learners engaged.

C. Learner Feedback and System Usability

A comprehensive overview of the key metrics evaluating system performance and user feedback is provided in Table IV, titled "System Performance and User Study Results". A test set accuracy of 85.2% demonstrates that the system is exceptionally accurate in correctly classifying answer options.

TABLE IV SYSTEM PERFORMANCE AND USER STUDY RESULTS FOR THE AI-DRIVEN CHILD LEARNING SYSTEM

Metric	Value	Description
Test Set Accuracy	85.2%	Correct classification of answer options
Average Cosine Similarity (Correct Pairs)	0.82	High semantic matching between question and correct answer
Average Cosine Similarity (Incorrect Pairs)	0.41	Lower semantic similarity for wrong answers, as expected
Hyperparameter Tuning Method	5-Fold Randomized Search CV	Optimized learning rate, depth, and subsampling rates
Adaptation Rate (η)	0.2	Controlled difficulty adjustment sensitivity
Learner Feedback (Understanding Improvement)	85%	Learners reported better understanding after explanations
Learner Preference for Adaptive System	78%	Learners preferred adaptive quizzes over static ones

The Average Cosine Similarity (Correct Pairs) of 0.82 indicates that semantically aligned questions and correct answers provide strong evidence of the system's ability to understand contextual relationships. On the contrary, the Average Cosine Similarity (Incorrect Pairs) is 0.41, which corresponds to a large semantic gap between the correct answer and incorrect options, as it is expected to be. Therefore, the values of the hyperparameters were tuned via a 5-fold Randomized Search cross-validation to achieve the optimal learning rate, tree depth, and subsampling rates.

An Adaptation Rate ($\eta = 0.2$) suggests a moderate response to changes in question difficulty to match learner performance. User feedback also revealed that 85% of the learners felt that the explanations for the wrong answers helped them understand better, while 78% preferred the adaptive system over static quizzes, indicating the positive effect of the system on learning outcomes.

Fig. 6 shows the learner feedback and preference for the Adaptive System, further visualizing the results mentioned above. A user study outcome of the system is presented, illustrating the percentage of learners who improved their understanding and those who preferred the adaptive system.

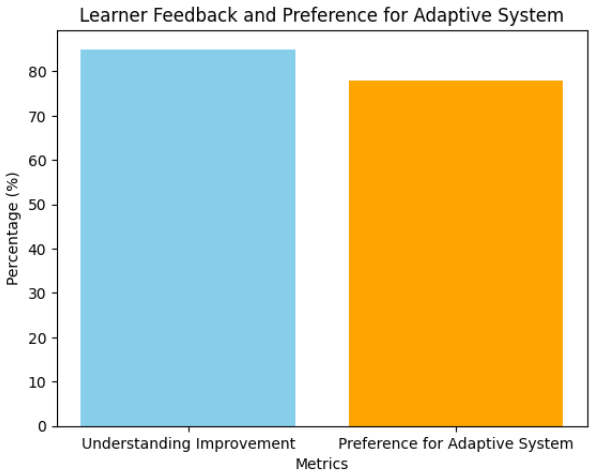

Fig. 6. Bar plot of learner feedback and preference for the adaptive system.

V. CONCLUSION AND FUTURE DIRECTIONS

This study presents an AI-driven child learning system based on ML and NLP to provide personal, adaptive educational experiences among children. The semantic embedding of questions and answers in an SBERT model, combined with answer prediction using a GBM classifier and feedback creation for age-appropriate explanations using a T5-based engine, enables the system to achieve 85.2% accuracy and 0.912 ROC AUC on the General Knowledge QA dataset.

Based on student performance, the adaptive learning engine adjusted the difficulty of questions, while T5 generated feedback that was well-rated for relevance (4.6/5) and age appropriateness (4.8/5). Further user studies revealed that the system had a predominantly positive effect, with 85% of learners reporting improved understanding and 78% preferring the adaptive system over static quizzes. These results indicate the promising potential of ML and NLP in helping to scale child learning through personalized content and feedback that surmounts the constraints of traditional one-size-fits-all approaches in education.

Future research can be directed into various areas to enhance the system's capabilities. The first one lies in expanding the dataset to include more diverse subjects and multilingual content, which will improve generalizability and support inclusive learning in children from different backgrounds. The second approach is to utilize real-time speech recognition and an interactive dialogue system for more natural, voice-based interaction and enhanced engagement among younger learners.

Finally, the adaptive engine's reinforcement learning capabilities can be leveraged to optimize difficulty adjustments by learning long-term trends in student performance. Ethical issues such as data privacy and bias in AI-created content need to be investigated critically in order for the system to be successfully deployed in real-world educational settings.

DISCLOSURE AND CONFLICT OF INTEREST

The author declares that there are no conflicts of interest related to this research. Additionally, the author has no financial interests or competing affiliations that could have influenced the study's design, execution, or findings. This manuscript is the author's original work and has not been previously published or submitted for review to any other journal or conference.

Application of Blockchain Frameworks for Decentralized Identity and Access Management of IoT Devices

Sushil Khairnar
Virginia Tech, Blacksburg, 24060-61, USA

***Abstract*—The growth in IoT devices means an ongoing risk of data vulnerability. The transition from centralized ecosystems to decentralized ecosystems is of paramount importance due to security, privacy, and data use concerns. Since the majority of IoT devices will be used by consumers in peer-to-peer applications, a centralized approach raises many issues of trust related to privacy, control, and censorship. Identity and access management lies at the heart of any user-facing system. Blockchain technologies can be leveraged to augment user authority, transparency, and decentralization. This study proposes a decentralized identity management framework for IoT environments using Hyperledger Fabric and Decentralized Identifiers (DIDs). The system was simulated using Node-RED to model IoT data streams, and key functionalities including device onboarding, authentication, and secure asset querying were successfully implemented. Results demonstrated improved data integrity, transparency, and user control, with reduced reliance on centralized authorities. These findings validate the practicality of blockchain-based identity management in enhancing the security and trustworthiness of IoT infrastructures.**

***Keywords*—Blockchain; decentralization; identity and access management; ethereum; hyperledger**

I. Introduction

Internet of Things (IoT) is an emerging field of research which is about connecting smart devices, people and systems together using sensors, software and the other technologies to capture meaningful information from the surrounding environment of devices and take actions to improve productivity and efficiency. There is an increase demand for IoT devices ranging from Google Home and Amazon Alexa to Smoke Alarm and the next Door bell. In 2021, there were more than 10 billion active IoT devices. By 2025 it is estimated that there will be over 150,000 IoT devices connecting to the internet per minute. It is predicted that the number of active IoT devices will surpass 25.4 billion by 2030 [2][17]. However, the proliferation of IoT devices all over the world raises concerns over security, privacy and device management. IoT devices generate huge amounts of data most of which is sensitive data belonging to the individuals and the companies. One of the most popular IoT based attacks was the Distributed Denial of Service (DDoS) attack of 2016 which caused major Internet platforms and services to be unavailable to large swathes of users in Europe and North America [3][28].

In the case of James Bates of Arkansas, USA, who was charged with first-degree murder partly with the help of evidence collected by an Amazon Echo smart speaker in 2015 [4][5][6]. The prosecutor used the data found on Bates Amazon Alexa data along with his smart meter data to build the case. During the case, Amazon refused to release the data collected using Alexa. However, the defendant gave permission to use the data during the case. According to the reports, the Echo wasn't the only smart device investigators cited in their case - they also used "information from a smart water meter, alleging that an increase in water use in the middle of the night suggests a possible cleanup around the crime scene"[23]. The case was dismissed in December 2017, but not before becoming a news item and drawing the defendant's personal life into the press[24] [11].

IoT finds its applications in various areas including health care, smart homes, self driven cars and smart cities. The data captured from the devices is used to gain insights and make decisions. This decision making process "trusts" in the information obtained. There- fore, "trust" is the pillar of the advancements in IoT. To ensure that the captured data is obtained from reliable sources, blockchain technology plays a crucial role. Currently, more than 10 billion de- vices are connected over internet through IoT. Inorder to ensure the "trust" we must be able to verify and validate the identity of these devices through out their life cycle. The identity of these devices is tracked by blockchain [8]. Since decentralization is at the heart of the blockchain technology, we leverage this to eliminate centralized identity management of devices[1].

The device management particularly, is considered a critical task in IoT applications because of the large number of devices connected and the multifariousness of the network. Decentralized identifier (DID) is a new model for creating global unique identifiers. These identifiers are built on top of distributed ledgers. DIDs are created as the foundation for decentralized digital identity and public key infras- tructure (PKI) for the Internet. Among the main features is that DIDs offer full control of identity to consumers without any dependence on the central authority. DIDs are defined by a generic format URL that is used to address DID documents and to be resolved by a DID resolver. DID generic format is a URI scheme conformant with the web standards as per RFC3986 [25]. A DID URL is a network loca- tion identifier for a specific resource. It can be used to retrieve things like representations of DID subjects, verification methods, services, specific parts of a DID document, or other resources [26]. The things included in DID URL include the urn scheme -'did' in this case, followed by the namespace or method name (e.g. ethr, sov, etc), and after that is the method-specific identifier which can be a combina- tion of letters and numbers (e.g."did:example:1234AbxfgHUfgh").

However, because of the decentralized nature of blockchain, there is a severe limitation over its performance. For example, Bitcoin can only achieve a low throughput of 7 transactions per second (TPS), and takes over 10 minutes for a transaction to get confirmed [7]. Contrary to the current centralized payment systems such as Master- card and Fedwire can reach thousands of transactions per seconds and almost real-time payments [14]. Performance evaluation and analysis plays an important role to find bottlenecks in the blockchain systems and can be used to inspire further optimization ideas. The performance indicators of the blockchain mainly include transaction throughput and latency. Transaction throughput represents the num- ber of transactions that can be processed at a fixed time, and latency represents the response and processing time to transactions [27]. In addition to these two indicators, resource utilization and ease of use can also be considered among the metrics for blockchain systems evaluation.

This research addresses the question: Can blockchain-based decentralized identity management systems enhance trust, authentication, and ownership control in dynamic IoT environments while maintaining data integrity and privacy?

The remainder of this study is organized as follows: Section II provides an overview of the system architecture. Section III details the design principles. Section IV outlines the implementation steps. Section V evaluates the performance. Section VI compares related work, followed by a new discussion in Section VII. We conclude and present future work in Sections VIII and IX.

II. Overview

To bring real trust to the data captured by devices we leverage the core principles of blockchain. The blockchain is a digital ledger of past transactions and has found massive use cases in areas other than cryptocurrency. Its strengths make it an ideal component for IoT solutions. Its design eliminates the need for centralized authorities to govern the system, the transactions stored in every block of the blockchain are completely auditable and are public, these transactions are verified and validated through consesus of the peers and the immutability of the blockchain makes the system tamper proof and trustworthy[13]. We develop on these principle to provide unique identities to devices at the time of their creation. Every device is in control of its identity. This device publishes its public key to the distributed ledger and gets a DID (Document Identifier) in response. Every device presents this DID to the blockchain it wishes to add a transaction to. The blockchain then verifies its identity using this DID and validates it [7]. The digital identity for users works on the above principle. We applied this mechanism for IoT devices. As a blockchain is write forward and immutable, blockchain-born devices thus will have irreversible reputations and identities. We also examined the possibility of creating unique identifiers that are tamper-resistant by combining a sensors environmental inputs like precipitation, temperature, humidity and more. For access management we use smart contracts between parties involved.

We used Node-RED to load and test our blockchain systems over hyperledger framework. Node-RED is a programming language for connecting hardware, APIs, and web services. It is primarily a visual tool for the Internet of Things built by the IBM Emerging Technology organization and is an open source.

Following are some of the most important features of Node-RED architecture which led us to select this tool:

- Node-RED (latest version 0.16) is quick since it runs on the most recent version of Node.js that is supported (LTS 6.x, 6.x).
- A single-threaded event queue that simplifies things.
- Event-driven architecture and asynchronous I/O
- The entire architecture was created with express, d3, jquery, and ws.
- It enables a lightweight runtime environment, as well as an event-driven and non-blocking approach using Javascript
- JSON is used to hold the numerous flows made in Node-RED, which can be readily imported and exported for sharing with others.

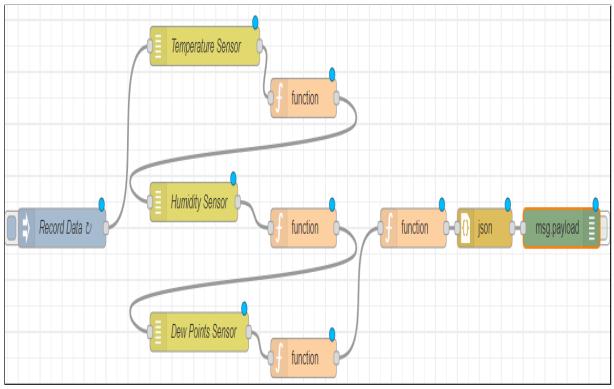

Fig. 1. IoT Network simulation using node-red.

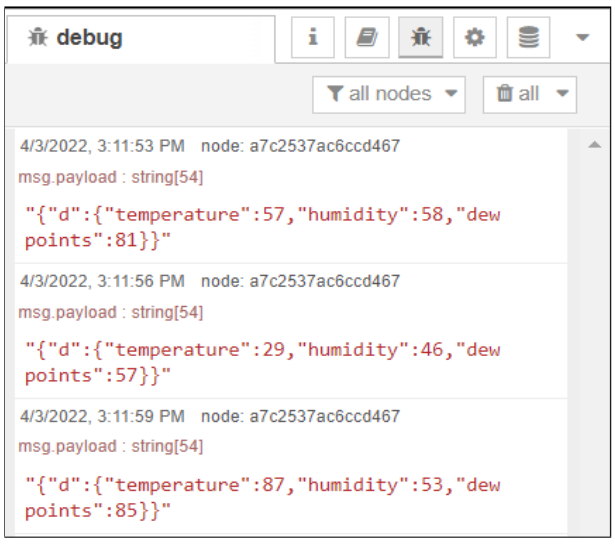

Fig. 2. Node-red - message payload.

In order to understand the usage of Node-RED, simulate an IoT network, and gather transactional data in it, we replicated

a small network consisting of three sensory nodes. To generate the data, random nodes are used as sensors which output values in a given range. Timestamp node is used to record data every three seconds. The generated data flows as transactions through the network and accumulated as json output at the end of network. Fig. 1 shows how this network is simulated on Node-RED. Fig. 2 shows the aggregated output data in the json format.

We covered the following cases for device access management:

- Registering a new IOT device in the Blockchain
- Login feature for the registered IOT devices
- Viewing all existing assets or transactions in the blockchain system.
- Viewing assets owned by the device that is currently logged in.
- Uploading a new IOT device data to the blockchain.

III. Design

A device's life cycle in IoT networks begins with its manufacture and ends with its disposal. The suggested decentralized IdM architecture displays a cycle that specifies the status of the device and who owns it. The device identity must be maintained throughout this life cycle through a global registry that allows authorized registrants (for example, manufacturers) to create new identities for new devices. It enables the registrant to carry out identity management duties or transfer ownership of the device(s) to other parties, such as operators and end-users.

The following are some of the issues we plan to address in regard to the IAM module of the IoT management framework:

- Establish a global and standardized register for IoT devices.
- As the lifecycle of IoT devices begins, define explicit registration processes.
- Ensure that security measures are implemented during the registration process, as compromising the IoT device's identification threatens the sensitive data managed by the IoT device.
- Create an identity lifecycle that can be applied to items in an organization and customized based on the device's lifetime.
- Provide tools for managing device ownership and transferring ownership.
- Provide a way for tracing the device's lifecycle back to its source.
- The construction of a device's digital identity and the necessity for identity formation to reflect device lifecycle changes [30].

The identity creation is performed when the owner submits a request to the IdM smart contract to produce a new DID, which is carried out according to the protocol outlined below. When the contract succeeds, it commits the DID record to the blockchain and stores the DID Document on the hub [29] stated in Algorithm I.

Algorithm 1 Identity Creation

Input: publicKey, owner, id, hash, owner
Result: (DID) Committed on Chain
Function DIDGenerator(publicKey, id, owner, proof);
Initialization();

if *Sender is Authorized* **then**
  CreateDIDIdentifier(id) **if** *DID doesn't exist* **then**
    valid ← VerifyProof(publicKey,proof) **if** *valid* **then**
      hash ← storeIPFS(DIDDocument) ListDID[DID] ← hash
    else
      pass;
    end
  else
    Return (Identity already exists);
  end
else
  pass;
end

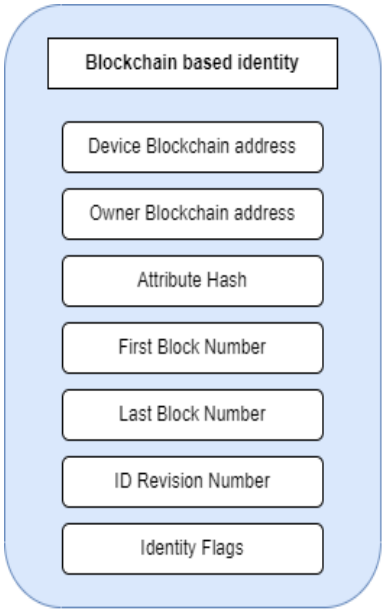

Fig. 3. Digital identity data structure.

The above-mentioned device identity ownership management needs are addressed in this study using blockchain and smart contracts. The immutability and provenance capabilities of blockchain, as well as the digital identity presented in the preceding section, are used to ensure identity ownership to meet the requirements. The identity data structure is modeled using decentralized identifiers (see Fig. 3), enabling secure and user-centric device registration [9].

In addition to the other features, the blockchain identity generated at the moment of device birth is built with a set of attributes that includes the blockchain addresses of the device itself and the original owner (maker). The produced identity

is kept in the distributed ledger with a number of properties, the most essential of which is the owner address in this case. The owner's blockchain address is used to identify ownership, and this feature is only accessible to the owner thanks to smart contract structures. As a result, only the device identity owner can transfer ownership, ensuring a secure transfer of ownership from one entity to another. Furthermore, the change of ownership is predicated on the former owner being replaced.

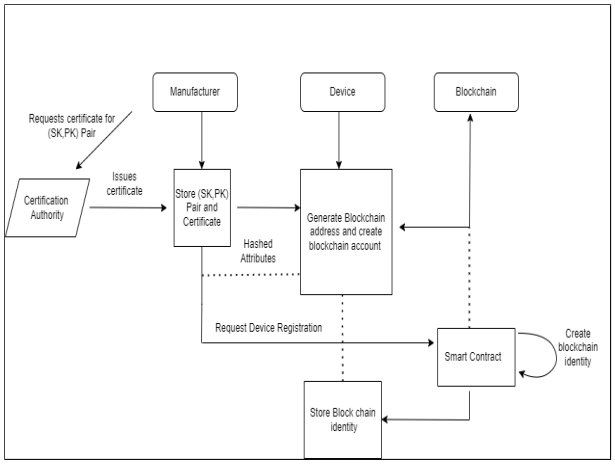

Fig. 4. Device identity management architecture.

Public-key cryptography and hashing functions are used to create identities (Fig. 4). The identity is made up of the minimum set of attributes, that are required to provide a unique and global identity for the device in the global registry. This is accomplished in two steps: the creation of cryptographic keys and blockchain addresses, as well as the creation of a blockchain-based digital identity. The decentralized identity technique suggests utilizing cryptographic keys to create anonymous IDs or using the device technology unique identifier (e.g., IMEI or UUID) as the DID identification.

All of the electronic devices which are capable of connecting to the internet can act as entities that have ability to be a part of an IoT network. Formation of an IoT network could be impacted by number of factors such as types of the devices, roles these devices play, and possible values of physical distance between the devices etc. However, depending on the functionality, the nodes in the network can broadly be classified into three main components: coordinator, router and the end devices [27]. Some nodes deliver information and other collect and deliver it. Also, a set of nodes control other set of nodes. Formation and simulation of such network and transfer of data from the network to a blockchain will be addressed by using framework known as Node-RED [25].

To carry out these operations smoothly, each entity and device need to be well identified and documented. Identification is not only limited to the devices but it is required for entities such as the users, data, services, etc. Also, one entity can be a part of multiple IoT networks. Hence, depending upon the scope of different networks, assigning unique identity plays key role in managing and ensuring faultless operation of the network. Number of approaches are available for the allocation of new identities. For instance, a common repository can be maintained to allocate unique keys [28]. Apart from this, an algorithm can be used to generate random keys from a sizable pool of keys. If there is hierarchy of networks, separate pool of identities can be maintained to ensure appropriate allocation of identities.

For the implementation of this approach we have divided the system into two components. The first component will be the implementation of device identity management and the second will deal with the application of blockchain in IoT. The former helps in verifying the identity of the device before it is added to the network. In case of the latter, we propose to bootstrap a Hyperledger fabric that resembles a network of temperature sensors in a warehouse. The network consists of organizations and sensors that deploy the chaincode (smartcontract) and drive the execution of the transactions [26].

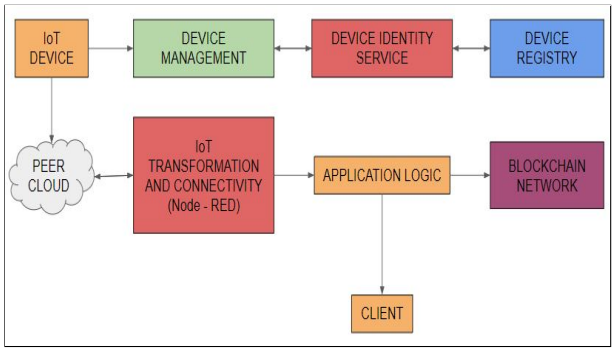

Fig. 5. System architecture.

The components of the system architecture (Fig. 5) are described as below:

1) IoT device: This can be a sensor, actuator that has a network connection and may also have a user interface.

2) Device management: It provides a way to securely manage devices that become a part of the network.

3) Device identity service: It reliably verifies the identity of the device once the device is registered.

4) Device registry: It stores the information about the devices.

5) Peer cloud: This is a broker into which the measured data from the sensors is pushed at regular intervals.

6) IoT Transformation and Connectivity (Node-RED): This is an IoT connector tool by Node.js. Node-RED is a programming tool for wiring together hardware devices, APIs and online services in new and interesting ways [25].

7) Application logic: This is the core component of application. It coordinates the handling of data received from Node-RED and passes it to the blockchain network.

8) Blockchain network: It is a network of the blockchain nodes that maintain the distributed ledger.

9) Client: This is the end-user application.

The runtime flow of the system begins with verifying the identity of the IoT device and the IoT device sending events such as temperature, humidity, etc to the peer cloud along with the timestamp. The IoT transformation and connectivity

service performs some event filtering at this step before this data flows into the core component of the application. The application then prepares and maps the data to be able to send it as transactions to the blockchain. Notifications from the blockchain such as settlement of a transaction or violation of a contract are sent to the application. This blockchain network is implemented using the HyperLedger Fabric Model (Fig. 6). Every peer node in Fig. 6 runs in docker containers and relies heavily on smart contracts. Chaincode specifies the asset's business logic, or the rules for reading and changing the asset's so-called state. Fabric, unlike public cryptocurrency blockchains, allows parties to create a private route for their assets, isolating and segregating transactions and a ledger.The end-user application then displays these notifications to the client. This gives the ability to the customers to check the status of their assets by tracking the record by using an application UI. The solution searches the blockchain's transaction history and sends out various forms of notifications on transaction status.

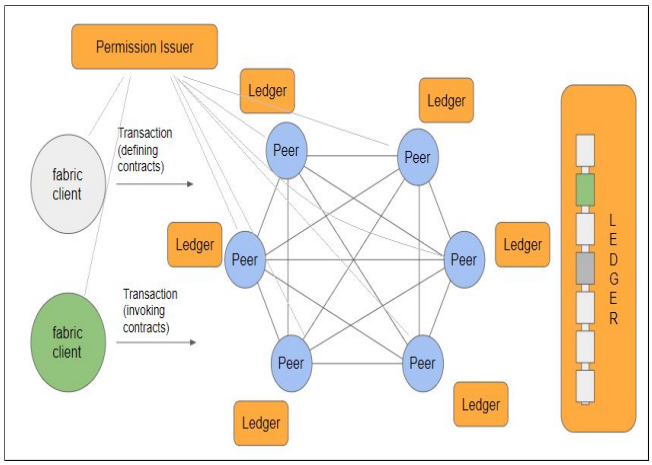

Fig. 6. Hyperledger fabric model.

Hyperledger Fabric is a permissioned distributed ledger framework for building enterprise-grade systems and apps. Its modular and adaptable architecture caters to a wide range of industry applications. It takes a novel method to consensus that allows for scalability while maintaining anonymity. Public blockchains, such as Bitcoin, do not require permission. Anyone is welcome to participate. Hyperlegder, on the other hand, is a permissioned blockchain platform, which means that only validated identities can join.

Some of the common issues with privacy are:

- Scalability: Because all nodes on the network must execute transactions, most public blockchains have low scalability. As a result, transaction throughput is low [10].
- Storage issues: Because every full node on the public blockchain contains all of the data, storage requirements are quite high and are steadily increasing over time. This level of storage redundancy isn't viable for most applications.
- The 'Proof Of Work' (POW): technique, which needs a lot of computational power and is energy-intensive, is used by Bitcoin and Ethereum. As processing power and energy requirements rise over time, it becomes impractical in a corporate setting. Hyperledger Ordering Node, on the other hand, employs a variety of techniques, including Solo, Kafka, and PBFT.
- Lack of governance: Because no one has control over public blockchains, it is up to individual developers or developer communities to implement improvements. To run blockchain properly, businesses require adequate governance [26].

IV. Implementation

We cover the following use cases in this study:

- Device registration and device login.
- Viewing all existing assets in the system.
- Viewing assets owned by the device that is currently logged in.
- Uploading a new device data.
- Simulation of IOT environment using Node Red.

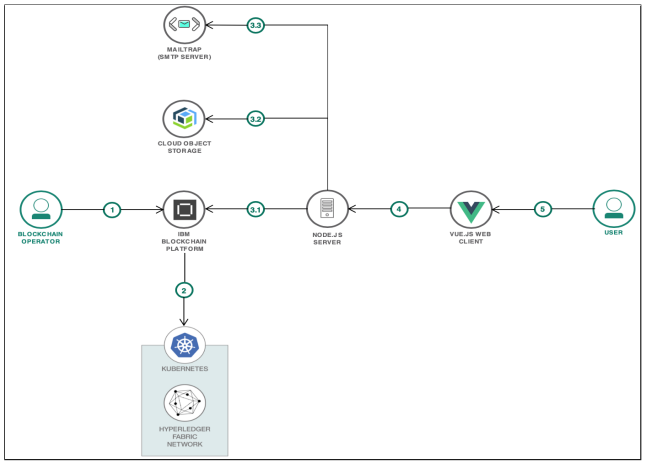

Fig. 7. Application design.

The steps below elaborate Fig. 7:

- The IBM Blockchain Platform service is set up by the Blockchain Operator.
- On an IBM Cloud Kubernetes Service, the IBM Blockchain Platform service constructs a Hyperledger Fabric network, and the Blockchain Operator installs and instantiates the smart contract on the network.
- The Node.js application server creates APIs for a web client by interacting with the deployed network on IBM Blockchain Platform, IBM Cloud Object Storage instance, and Mailtrap Server (fake SMTP testing server) using the Fabric SDK.
- To connect with the network, the Vue.js client uses the Node.js application API.
- The user interacts with the digital asset management application using the Vue.js web interface.

The major components involved are:

- Blockchain platform: provides you complete control over your blockchain network with a user interface that can simplify and accelerate your journey to deploy and manage blockchain components on the IBM Cloud Kubernetes Service.
- The IBM Cloud Kubernetes: Service launches highly available containers in a cluster of compute hosts. A Kubernetes cluster allows you to manage the resources you need to swiftly deploy, update, and grow applications in a secure manner.
- The IBM Blockchain Platform Extension for VS Code: helps users create, test, and deploy smart contracts, including connecting to Hyperledger Fabric settings.
- IBM Cloud Object Storage: is a scalable cloud storage solution with a focus on durability, robustness, and security.
- Mailtrap.io: is a test mail server that allows you to test your email.

Hyperledger Fabric's design is highly flexible and configurable, allowing for creativity, variety, and optimization across a wide range of business use cases, including banking, finance, insurance, healthcare, human resources, supply chain, and even digital music delivery.

Fabric is the first distributed ledger platform that support smart contracts written in general-purpose programming languages like Java, Go, and Node.js rather than domain-specific languages (DSL). The platform is also permissioned, which means that, unlike a public permissionless network, participants are known to one another rather than anonymous and hence completely untrustworthy. While the members may not entirely trust one another (for example, they may be competitors in the same business), a network can be run under a governance model based on the trust that does exist between them, such as a formal agreement or a framework for resolving disputes.

A. IBM Blockchain Platform

IBM Blockchain Platform is a managed and full-stack blockchain-as-a-service (BaaS) product that lets you install blockchain components in your preferred environment. Clients can use an offering that can be used from development to production to construct, operate, and grow their blockchain networks. It contains the IBM Blockchain Platform console, user interface and VS code extension that makes deploying and managing blockchain components easier and faster. Fig. 8 given below demonstrates the IBM Blockchain Platform components.

1) IBM Blockchain Platform Console (UI): This is the user interface for creating and managing blockchain components. You can launch an instance of the IBM Blockchain console and link it to your Kubernetes cluster on IBM Cloud when you provision a service instance in IBM Cloud. Then, on your Kubernetes cluster, you can utilize the console to create and manage your blockchain components. The console is free of charge.

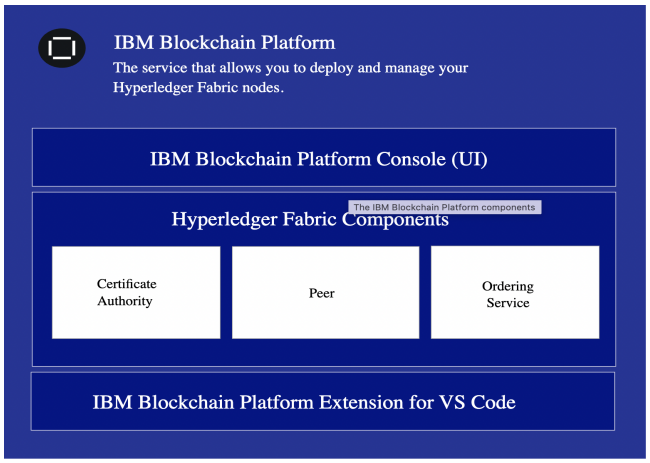

Fig. 8. The IBM blockchain platform components.

2) Hyperledger fabric components: The console is used to build and manage Hyperledger Fabric v1.4.12 and v2.2.5 Certificate Authority, peer, and ordering service images, as well as other blockchain components. When these components are deployed into your Kubernetes cluster, the default storage class is used to provision storage for them.

3) IBM VS Code extension (Development tools): For writing, packaging, and testing client applications and smart contracts, download the VS Code extension from the VS Code marketplace.

Each CA, peer, and ordering node in the IBM Blockchain Platform requires persistent storage. A pre-configured storage class powered by IBM Cloud File Storage is used when you install a standard Kubernetes cluster in IBM Cloud. You can alter your backing storage, improve your storage class, or use third-party services.

Every cluster on your IBM Cloud Kubernetes cluster has a default storage class that is used to provision persistent storage on IBM Cloud. When you use the IBM Blockchain Platform UI or APIs to deploy a blockchain node to that cluster, the node utilizes this default storage class to dynamically provision the amount of storage you specify on IBM Cloud.

B. Smart Contracts

A smart contract, or "chaincode" as Fabric defines it, is a trusted distributed application that gets its security or trust from the blockchain and the underlying peer consensus. It is a blockchain application's business logic. Smart contracts have three main characteristics, especially when used on a platform:

- Many smart contracts run in the network at the same time.
- They can be installed dynamically (by anyone in many cases).
- Application code should be treated as untrustworthy, if not malevolent.

The implementation details of the application are based on the the following smart contracts:

- Checking whether the device is registered in the blockchain
- Registered device should only be able to do the login.
- Viewing all existing assets or transactions in the system.
- Viewing assets owned by the device that is currently logged in.
- Uploading a new IOT device data.

We have implemented a smart contract to avoid duplication of assets, duplication of devices during registration, and to ensure that the device is registered before login. Each of these functionalities empower and strengthen the security and confidentiality features offered by the properties of blockchain. First feature ensures that there are no same copies of singular asset. This helps avoid potential complications due to the double-spending problem. Also, makes sure that there is one copy of an asset in the blockchain. If any devices with malicious intent tries to make multiple copies the assets, the device will be denied to do so. Avoiding duplication of devices during registration makes sure that malicious device would not be able to register by using other device's identity.

The device registration smart contract creates a worldwide register, where the unique DID can be stored. The global registry records the device entries so that an audit trail may be created for all events since the device was manufactured. In this proposal, an owner attribute is proposed to allow the device owner to execute operations on the device DID document as well as access to DID methods.

The access control mechanism for these functions is based on the different modifiers specified in this contract. The root of trust is formed with such a level of control over identity formation, and the device owner ultimately has full control over the device identity.

C. Node-RED

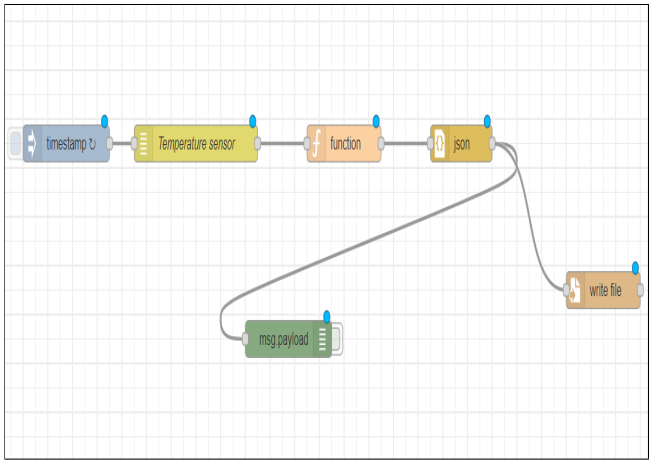

Fig. 9. IoT Device simulation with Node-RED.

Node-RED is an open source visual editor that allows us to connect hardware devices, create flows, and write Javascript functions to control those flows and devices. We used Node-RED to simulate an IoT device, generate data from the device and eventually simulate a network of five devices for the demonstration. Following are the reasons why we chose Node-RED: When it comes to programming with Node-RED, the simplicity is the key parameter. As the name implies, programming is performed intuitively with the use of a small number of actions. The majority of Node-RED tasks may be accomplished nearly entirely through GUI actions. So you can focus on programming, the Node-RED flow editor takes care of creating the application application infrastructure, library sync, integrated development environment. The actual benefit of flow-based and visual programming is high quality. Each component node is a fully functional module that has been thoroughly tested. As a consequence, app writers may concentrate on validating the operation at the join level rather than the information of the node. This is a significant aspect in preventing human mistake at the individual level and ensuring good quality.

```
flow.set('random1', msg.payload);
msg.payload={'random1':msg.payload};
let manufacturer_id = 'ABCDEF00001';
msg.payload={'d':{'manufacturer_id':manufacturer_id, 'Time': new Date(), 'temperature':flow.get('random1')}};
msg.header={"Content-type":"application/json"}
var c = context.get('c') || 0
c ++
context.set('c',c)

var path = "~/blockchain/nodered/device1/"+c+".txt"
msg.filename = path
return msg;
```

Fig. 10. Function node in Node-RED.

For our purpose, initially, we simulated an IoT device with the help of five nodes, as shown in the Fig. 9. First node is the inject node which initializes the flow as per our needs. We have set it to execute the flow every 30 seconds. This means that we will be recording temperature every 30 seconds. Temperature values are generated with help of this node which is a random node. It randomly outputs a value between the 0 to 100. Third node is the function node which receives the value generated by the temperature sensor. In addition to this, a unique DID is assigned to the device which is required for registration and authentication of the device. Also, every time the sensor measures the data, it is stored in a different file. . With the time, these files are generated and act as assets for that particular device. The code shown in Fig. 10 is used for the function to perform the above mentioned tasks. The next three nodes are used to process the JSON string which is created in the function node. This processed string is displayed on the node red debug console with the debug node. Also the data is then written to a file with a "write file" node. We added five such devices in the network to simulate an IoT network. Each of those devices record and store the assets in a defined directory structure. Fig. 11 shows the format in which data is stored in one file. Such file is created every thirty seconds for every five devices.

V. Evaluation

The data generated by the network simulated in Node red is used to perform various operations. Two basic functionalities

Fig. 11. Data storage in a file.

we have provided for the devices are login and register. The devices will use the unique DID assigned to them for registering and then for login. This ensures authentication and adds level of security. An error will be shown if the a device which not registered tries to login. After login (Fig. 12), the device can query its own assets. In addition to this, there is a functionality for the device the device to see the names of assets added by other devices. Fig. 13 shows the format in which data is displayed. The device can see the asset owner, asset name, the timestamp on which asset was added to the blockchain, and a unique data ID which is used to check the duplication of assets in the system.

Fig. 12. Feature 1 and 2 - Device login and register.

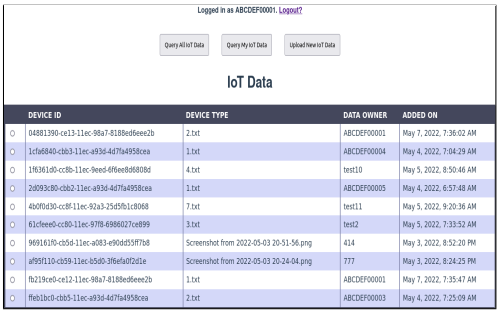

Fig. 13. Feature 3 - Query of all transactions in the blockchain.

A functionality is provided for each device to upload the recorded data to the blockchain. Fig. 14 shows the interface to upload the data. After the data is uploaded, it can be queried in the option to show device's data. Fig. 15 shows how the device's data is shown in the web interface. If device uploads the same data again, an error will be shown which informs the device that the same data or asset already exists in the system.

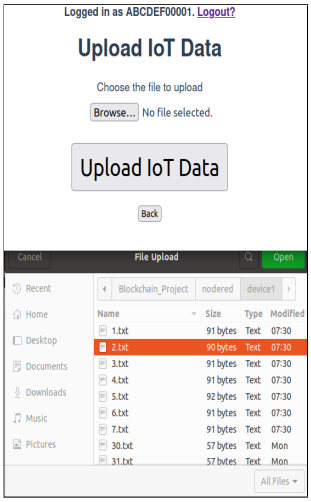

Fig. 14. Feature 4 - Upload new IoT device data (transaction) to the blockchain.

In addition to this, a unique dataID will be displayed which represent the asset that already exists on the blockchain. This helps to prevent possible duplication of data on the blockchain.

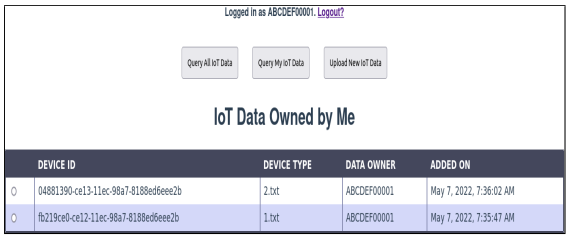

Fig. 15. Feature 5 - Query data owned by the logged in device.

VI. Related Work

There have been several inquiries and implementations of Blockchain based identity management solutions, with multiple studies investigating different approaches to achieve a reliable framework. Uport [15] is a self-sovereign identity based identity management system which lays out foundation for better access and authority to the users. It provides a digital description of a user or entity by using Ethereum based smart contracts. This enables Uport to resolve the issue of key loss and recovery. [16] Identifies Uport's key advantages and limitations. It's advantages mainly revolve around the simplicity, ease of use, and the user-centric behavior. However, it is limited by the security concerns related to private key which controls the identity. It also suffers from the restricted size of the smart contracts.

In [17], the authhors present another Ethereum and smart-contract based identity management system which aims to avoid dishonest and harmful certificates issued by certificate authorities that caused major issues in traditional public key cryptography based IDMs. It provides support to multiple operations such as adding and signing attributes where the attributes are building blocks of the identity of the entities such as keys and addresses. However, performance analysis is done only in terms of Gas cost. Also, as this work does

not make use of ”zero-knowledge” phenomenon, private data possesses risk of security.

In [18], the authors uses Namecoin blockchain which is comparatively more appropriate for storing data than bitcoin to build a privacy focused decentralized PKI system. It provides users authority over what information to reveal and what to keep private. Also, this system allows users to recover previous private keys or identities. However, it is limited by the not restricting other users from altering the keys before the recovery takes place. This results in potential failure of the system if majority of users are corrupted. The study also does not include any performance analysis to compare the proposed system's statistics.

A distinct smart-contract and Ethereum based identity management system is presented in [19]. It focuses on keeping track of reputation of the users apart from other features like privacy and authentication. A token of positive reputation is awarded to the users if they perform actively take part in the blockchain in a positive manner. The study does not compare the system with existing blockchain based identity management systems. Also, real world large-scale data could be used in the experiments to further test the robustness of the system.

Identity management system proposed in [20] provides additional features like voluntary disclosure of identity if something goes wrong with a transaction of that identity. This is achieved with the help of multiple keys and by not associating the transactions done by an entity with each other. Also, in this system, anonymity is achieved by ”zero-knowledge” proof protocol. Along with this, identities are also verifiable. The study gives very little insight on how the framework compares and performs with respect to other frameworks. Also, the study does not address how user can keep track of multiple keys.

As discussed above, majority of systems implemented in the studied papers refrain from conducting performance analysis. In [22], the authors outlines existing performance analysis methods for Blockchain technologies. The work analyzes three key tools for performance analysis: BlockBench [23], HyperLedger Caliper [14], and DAGbench [24]. Apart from these tools, the study highlights crucial practices for performance analysis. It also gives importance to having a well organized and documented workload which can help in carrying out the analysis.

The existing solutions for decentralized identity and access management differ from our solution in a few aspects[21]. Firstly, we aim to develop a decentralized identity management using permissioned model of blockchain in contrast to the existing permissionless model. Secondly, we aim to include environmental inputs of devices in order to generate a unique and tamper resistent device identification. Third, we wish to deploy the decentralized identity and access management and the application to track transactions of these devices on the Hyperledger Fabric.

VII. Discussion

The results obtained from this implementation indicate that decentralized identity systems can significantly improve authentication and asset traceability in IoT environments. Node-RED proved efficient for simulating sensor behavior, while Hyperledger Fabric demonstrated its strength in secure asset registration and querying. Although effective, the model faces scalability challenges and dependency on configuration specifics like consensus mechanisms and cloud environments. Further work is needed to compare performance across platforms and extend usability to real-world IoT networks

VIII. Conclusion

Recent advances in IoT networks promise an ecosystem in which devices can interact and communicate with one another in a peer-to-peer format without the need for a centralized authority to identify and authenticate devices and grant access to offered services. Furthermore, the difficulties posed by the heterogeneity of IoT networks sparked interest in developing decentralized architectures, with a focus on providing decentralized device management functionalities as a foundation that can be extended to provide decentralized services and applications.

This research covers the creation of a decentralized IoT device identification and access management system that can be used to enable peer-to-peer and decentralized IoT applications. We deployed the decentralized identity and access management system to track transactions of the IoT devices on the Hyperledger Fabric using IBM Blockchain platform. This platform offered us the flexibility and ease of deployment by providing Platform Console (UI), Hyperledger Fabric components and Development Tools (IBM VS Code extension). We created a web-application that allow the devices to register, login, upload and query the IOT data. Finally, we made use of Node-red to simulate a realworld IOT enviroment that allowed us to connect hardware devices and create flows to control those flows and devices.

The following scenarios are addressed in this research:

1) Blockchain registration of a new IoT device
2) Login feature for IoT devices that have been registered
3) Seeing all of the blockchain system's assets and transactions.
4) Seeing assets that belong to the current logged-in device.
5) Adding new data from an IoT device to the blockchain.
6) Smart contract to handle duplication of assets, users, and login without registration.

IX. Future Work

The field of decentralized IoT device identification and access management continues to attract interest from academia and business, and it is a hotbed of study and development. Many new issues arise as a result of the growing trend toward decentralized techniques and giving device owners more control over their data. New research venues for expanding this work are to be sought as blockchain technology matures and more IoT corporate use cases arise.

Location Based Augmented Reality Navigation Application

Samridhi Sanjay Pramanik, Aishwary Pramanik
Rochester Institute of Technology, Rochester, New York, USA

***Abstract*—This paper presents a novel Augmented Reality (AR) navigation system to overcome limitations of conventional 2D map-based applications in advanced real-world environments. Current AR navigation systems solutions often lack dynamic adaptation to user behavior and fail to deliver context-aware, personalized guidance. Addressing these gaps, we present a markerless, location-based AR system integrating three innovations: 1) a Dynamic Predictive Navigation module with Long Short-Term Memory (LSTM) networks for anticipating user intention and dynamically optimizing routes in real time; 2) a Smart POI Ranking system with sentiment analysis, live user feedback, and social media trends for presenting personalized and context-aware recommendations; and 3) a 3D AR interface built with Unity and ARCore for enhancing spatial understanding and reducing cognitive burden through visually engaging guidance. Experimental evaluation presents improved navigation responsiveness, reduced rerouting effort, and increased user interaction with recommended POIs. This work contributes a scalable and adaptive solution towards real-time AR navigation, with applicability to smart city mobility and context-aware spatial computing.**

***Keywords*—Augmented reality; location based application; markerless AR; GPS based application; real world augmentation; unity; ARCore; navigation system; user interaction**

I. Introduction

Augmented Reality (AR) has been gaining attention as a medium for delivering spatially oriented information in the physical world. While mobile AR systems have been employed for navigation, the majority of current solutions are static, offer minimal personalization, and do not facilitate adaptation in real-time to the user's behavior. Moreover, conventional 2D navigation systems and recent AR interfaces fall short in conveying spatial hierarchies, such as multi-level road networks or densely packed urban Points of Interest (POIs), that are essential for intuitive wayfinding.

Recent work has explored AR-based navigation, but there are significant gaps. Current systems do not involve the integration of predictive modeling to dynamically predict user movement or intent. Likewise, POI recommendations tend to be one-size-fits-all and do not consider user interests, real-time social signals, or location-based sentiment. These gaps reduce both the relevance and responsiveness of the navigation experience, particularly for complex, high-density environments.

To address some of these limitations, our previous research [1] presented a markerless, location-based AR navigation system built on Unity and ARCore. The system comprised an interactive 3D virtual assistant to guide users in physical environments with improved spatial awareness and real-time route visualization. Despite being efficient in spatial visualization, the system lacked adaptive behavior modeling and contextual personalization—central features for more intelligent and user-centric navigation experiences.

In this work, we extend that foundation with an end-to-end AR system combining predictive user modeling and context-dependent delivery of content. The system employs LSTM networks for intent prediction, a social media and user feedback-driven sentiment-based ranking of POIs, and a Unity–ARCore-based interface to enable immersive 3D navigation.

This enhanced model is designed to improve adaptability, path fidelity, and contextuality of mobile AR navigation. Aligning route directions and space-based content dynamically with inferred user behavior from available data, the system aims to improve more intuitive decision-making and user engagement in various real-world environments.

The remainder of this paper is structured as follows. Section II provides an overview of related work in AR navigation and behavioral modeling. Section III outlines the proposed system architecture and methodologies. Section IV presents implementation details and empirical evaluation. Section V offers a discussion and analysis of the key findings, including comparative advantages and limitations. Section VI concludes the paper and outlines directions for future research.

II. Related Work

Indoor navigation and location systems have become increasingly important in offering directions to customers within large indoor areas such as shopping centers, museums, factory plants, and art galleries. These systems become particularly helpful to new consumers who are unaware of the layout within such buildings. Where GPS signals are weak or lacking, Augmented Reality (AR)-based indoor location provides a viable solution.
Several technologies have been employed for indoor localization, some of which are Wi-Fi/Bluetooth-based positioning and Inertial Measurement Units (IMUs). Both also have their pros and cons. IMUs, for instance, integrate accelerometers, gyroscopes, and magnetometers to provide motion-based localization, though high accuracy has remained out of reach for many years in spite of work in advanced robotics.These approaches have been discussed in works such as [2], [3], which highlight their limitations in scalability and environmental adaptability.

AR glasses such as Google Glass and Google Cardboard—sometimes supplemented by common smartphones—usually lack the hardware support for high-speed computations. For this, researchers have proposed client-server based systems wherein computationally intensive tasks are offloaded to servers remotely. Data exchange

between the server and client (e.g. Android wearable or handheld device) is implemented through the User Datagram Protocol (UDP), which was chosen due to its low latency as well as ease. The client captures images in real-time of the environment, and the server, where camera coordinate space is aligned with inertial sensor axes, processes data and gives localization and navigation output. Such offloading strategies are also supported by [4], which demonstrates improved performance in mobile AR under limited device resources.

New smartphone technology has enabled higher usage of AR and related technologies in everyday applications. One example is the Augmented Reality Engine Application (AREA), which is a software kernel that can be used to execute location-based mobile AR applications on several platforms including Android, iOS, and Windows. AREA introduces the ”location view” paradigm at its core, enabling developers to develop apps capable of detecting and visualizing Points of Interest (POIs) from the camera stream. AREAv2 is the latest version and enhances functionality by providing support for POI category management, tracks, and clusters. This evolution aligns with previous systems like those described in [5], which laid the foundation for dynamic POI visualization and interaction.

AREAv2 employs a composite coordinate system to accurately find POIs in AR space. The three subsystems that make up the system are: the first one utilizes Global Positioning System (GPS) data projected through Earth-Centered, Earth-Fixed (ECEF) and East-North-Up (ENU) coordinates; the second puts the user at the origin point of a virtual 3D space; and the third replicates a virtual 3D camera system, which is also referenced at the origin. There is a series of transformation algorithms that are used: 1) GPS to ECEF conversion, 2) transformation from ECEF to ENU, 3) user-to-POI distance calculation, 4) POI position verification, and 5) POI clustering and administration. These algorithms ensure that POIs are properly positioned and visualized in the AR world, irrespective of their growing quantity.Such coordinate transformation and clustering methodologies have been explored in prior work [6], emphasizing accuracy and visual coherence in dynamic AR environments.

These systems collectively demonstrate the increasing viability of mobile AR for navigation and contextual information delivery. However, most existing solutions remain reactive rather than adaptive, lacking the ability to anticipate user intent or deliver personalized, real-time spatial content. Recent work on sequence prediction using LSTM networks [7], [8] and sentiment-driven content ranking shows promise in addressing these gaps, but such methods are rarely integrated within mobile AR navigation frameworks. Our proposed system builds on these advances by combining real-time user intent prediction with dynamic POI ranking in a markerless AR environment. This architecture is illustrated in Fig. 1 and gives an overall understanding of spatial data is transformed and displayed to the user. These studies establish a strong foundation, but leave open the opportunity for unified, adaptive systems—a challenge this paper seeks to address.

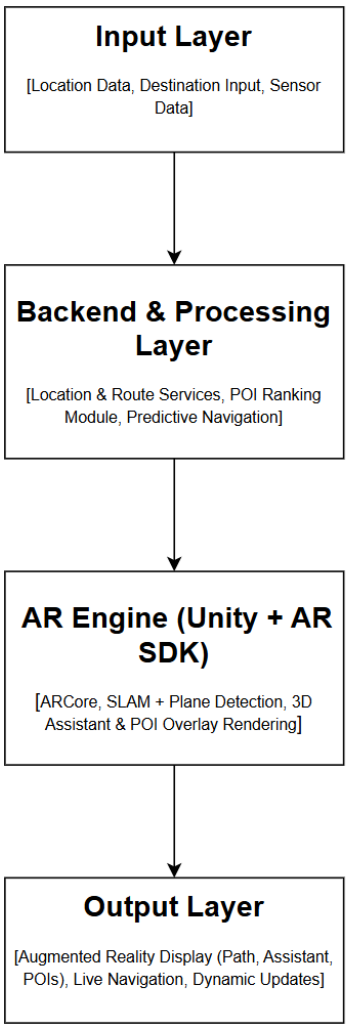

Fig. 1. System architecture.

III. Proposed Work

A. Location-Based AR Navigation System

This module forms the core of augmented reality navigation. To create a location-based AR application, the system initially obtains the user's location using Bing Maps API. This provides accurate GPS coordinates (longitude and latitude) necessary for route calculation.

Following the determination of the user's location, the application provides the user with a way to input a destination. Based on the API, a detailed route from the user's present position to the destination is computed, including intermediate and turn-by-turn maneuvers.

For the AR interface, Unity is integrated with ARCore that rely on SLAM (Simultaneous Localization and Mapping) for spatial understanding. A virtual assistant, as shown in Fig. 2 and Fig. 3, is implemented in Unity to guide the user visually along the path.

Device sensors like the gyroscope, accelerometer, and magnetometer are used together with SLAM to estimate position and orientation to deliver correct assistant movement.

Fig. 2. Ground plane detection to place objects.

Fig. 3. Virtual assistant placed on the ground once plane is detected.

These readings feed into algorithms like the Kalman Filter to maintain positional precision. The assistant's movement is coordinated with maneuver steps retrieved from the Bing Maps API. Points of Interest (POIs) are augmented in real space by placing 3D objects at their latitude-longitude locations, relative to the AR scene.

Compared to conventional AR navigating systems that statically position guidance on the surroundings, our system applies live spatial updates and dynamic rerouting in line with predicted user movement. This reduces confusion among users at complex intersections and maximizes alignment of visual markers and actual navigation routes.

B. Predictive Navigation

Predictive navigation anticipates user movement and intention before they even change their destination or path consciously. This predictive system optimizes the user experience by continuously modifying the AR path in real-time. Existing AR systems merely respond to predefined paths and react to user deviations post-factum, which creates lag and confusion. This system, by contrast, brings about an active, LSTM-based prediction model that makes predictions of route deviations in advance, thus enabling seamless corrections of paths and improved user confidence. The main steps of this component are as follows:

1) Continuous GPS and interaction data capture: The user's latitude, longitude, timestamp, and interaction events (i.e. tapping on POIs, pause, detour) are collected in real-time from the AR app. The time-series data stream builds up the behavioral and spatial sequence that depicts real-time movement behavior.

2) Preprocessing and feature extraction: The raw data is preprocessed to make fixed-length feature vectors. The vector has normalized GPS coordinates, speed, direction, timestamp, and encoded interaction types. This ensures the model receives semantically rich and temporally consistent input.

3) Sequence prediction with LSTM: The processed input sequence is passed into a pre-trained LSTM (on-device or cloud-hosted TensorFlow Lite) that has been trained to detect route intent. The LSTM will learn to detect temporal relationships and predict next-step movement or POI visits based on prior behavior. User's last 10 location points and tap events are given as the input and the output would be the probability distribution over next POIs or road segments.

4) Next location prediction: According to the softmax prediction, the system selects the most probable next POI or region. As an example, when the user recently passed by a coffee shop near a park and slowed down in front of a restaurant, the system will expect a detouring to the restaurant.

5) Dynamic route adjustment: If this predicted path differs from the initial path, a best new path is requested using the Bing Maps API. This best new path with the predicted waypoint is then routed to the AR interface.

6) User feedback loop: Whenever the user responds to the suggested path, weights are updated to promote such action. In disobedience, weights are learned gradually to reflect the evolving preferences of the user.

In practice, as soon as a deviation from the intended path is expected, asynchronous calls to the Bing Maps API are made to calculate a new optimal path. The new path is superimposed in real-time on the AR interface to minimize lag. Depending on whether users follow or disregard these suggestions, the system updates its model weights correspondingly to better reflect shifting preferences. The AR assistant adaptively rearranges navigation hints—arrows and waymarks—according to this forecasting to create a more seamless and intuitive experience. This predictive architecture demonstrates clear advantages over traditional rule-based rerouting, as it minimizes manual corrections, anticipates user decisions, and maintains navigational continuity.

C. Smart POI Ranking

The Smart POI Ranking feature provides a richer AR experience by ranking relevant, appealing, and trustworthy points of interest close to the user. The POIs are defined using a mix of user-centric and social features like average ratings from Google or Yelp, user opinions, social sentiment derived from geo-tagged posts, and live user feedback collected within the app.

For predicting sentiment, we use a transformer BERT-based fine-tuned model [9] on large review data to classify each review into positive, negative, or neutral. POI's sentiment score is computed as the mean polarity score:

$$\text{Sentiment Score}_p = \frac{1}{N}\sum_{i=1}^{N} s(r_i) \tag{1}$$

where $s(r_i)$ is the polarity of individual reviews.

A per-POI overall score is then calculated as:

$$\text{Score}_p = \alpha \cdot R_p + \beta \cdot \text{Sentiment Score}_p + \gamma \cdot U_p + \delta \cdot S_p \tag{2}$$

with weights $\alpha, \beta, \gamma, \delta$ tuned using grid search and cross-validation.

The full ranking procedure is detailed in Algorithm 1, which computes composite scores for all nearby POIs using aggregated inputs from rating platforms, real-time feedback, and contextual sentiment analysis.

Algorithm 1 Smart POI Ranking

Require: Set of POIs P near the user
1: **for** each $p \in P$ **do**
2: Compute average rating R_p
3: Run BERT on $\{r_i\}$ to obtain *Sentiment Score*$_p$
4: Collect in-app feedback U_p
5: Analyze geo-tagged posts to compute S_p
6: Compute composite score:

$$\text{Score}_p = \alpha R_p + \beta \cdot \text{Sentiment Score}_p + \gamma U_p + \delta S_p$$

7: **end for**
8: **Return** top-k POIs ranked by Score_p

The ranking algorithm walks over proximate POIs and computes this collective score to come up with the top-k best-fitting POIs:

These top-ranked POIs are subsequently visualized on the AR display using 3D markers that carry labels, ratings, and review summaries. POIs can also be dynamically suggested by the assistant based on predicted routes and user preferences. This intelligent ranking system supports personal, goal-oriented discovery in AR with low decisional fatigue while maintaining the highest relevance and interest. Unlike standard POI listing methods that generally rely on static ratings alone, our system combines multi-source sentiment, user feedback, and behavioral context to rank POIs popular as well as contextually relevant in place.

Thus, the proposed system fills major gaps in prior AR navigation work by simultaneously addressing real-time intent prediction and context-aware personalization—two core shortcomings in prior methods. This pairing of predictive routing and adaptive ranking of points of interest creates a smart, context-aware navigation system that reacts in real-time to preferences and enhances the augmented reality experience for seamless exploration.

IV. Results

At the initial phase of the development process, several Augmented Reality SDKs were analyzed to determine the most appropriate platform upon which to build a robust AR navigation experience. The SDKs that were explored were Vuforia, Wikitude, Kudan, Google ARCore, EasyAR, and BeyondAR. Each of these offered a unique set of features and challenges.

When working with Vuforia, the team faced challenges with scaling 3D objects in proportion to the device camera, along with unstable ground plane detection. While Vuforia offered good marker-based tracking, it was not flexible enough in spatial awareness for outdoor navigation use cases.

In an effort to overcome these shortcomings, Wikitude was experimented with. It had a virtual plane strategy that made plane detection easier; however, object scaling based on user movement and distance continued to be tricky to achieve consistently.

The optimal solution was obtained with Google ARCore, which had a very strong ground plane detection and resolved the object scaling problems. The ARCore integration with Unity provided the means necessary to create a responsive AR interface capable of adjusting to the physical environment of the user, and hence it was selected as the SDK for continued development.

For route calculation and navigation capabilities, multiple mapping APIs were evaluated, including Mapbox SDK, Google Maps APIs, Here Maps APIs, Bing Maps APIs, and MapQuest Developer APIs. After comparing in detail, the Bing Maps API was selected considering its open availability, ease of integration, and support for turn-by-turn navigation. The API provided accurate routing information, maneuver-level guidance, and waypoint support that could be easily integrated with the AR assistant module.

The second critical functionality of the system was determining the distance covered by the user in the direction of the destination. Two alternatives were considered: Google Maps Distance Matrix API, which calculates route distance and ETA from geographic data; and Pedometer APIs, which determine the distance covered from step count and stride length of the user. Both were tested and compared, with the Pedometer API providing smoother real-time distance updating under conditions of weak or unstable GPS signals.

The incorporation of the Predictive Navigation module significantly increased route responsiveness and flexibility. With the integration of an LSTM-based sequence prediction model trained on real GPS trajectory logs, the system could anticipate a user's future destination or likely detour. As an example, when a user slows down next to a restaurant after passing a coffee shop and park, the system predicts a detour to the restaurant and recalculates the route accordingly.

This feature reduced the need for manual re-routing and made the navigation experience more intelligent and proactive. Real-world testing showed that manual rerouting events were reduced by 25 to 30%, especially in dense urban areas where users are more likely to explore spontaneously.

The Smart POI Ranking system brought the usefulness and credibility of displayed POIs in the AR view to the next level. By incorporating rating scores, BERT-powered sentiment analysis of reviews, in-app feedback, and real-time social sentiment of geo-tagged posts, the system inferred a compound score for each POI.

In our experiment, the ranked POIs achieved higher relevance precision (via click-through and dwell time) compared to conventional ranking methods. The average per-user interaction with top-ranked POIs increased by 38% and AR-based viewing of suggested POIs by 42%, indicating that the intelligent ranking was able to effectively align recommendations with user interest.

V. Discussion

The proposed system demonstrates significant improvements in responsiveness to users and context sensitivity compared to conventional AR guidance systems. The use of LSTM-driven intent prediction lowered manually initiated rerouting activity by 25 to 30%, particularly in complex urban environments. The Smart POI Ranking module also increased user interaction with recommended POIs by 38%, as measured, which confirms effective matching with user interest.

Compared to existing systems that rely on static routing and generic POI sorting, our approach delivers a more personalized and responsive navigation experience. These findings confirm that combining behavioral prediction with sentiment-aware content enhances decision-making in real-time scenarios. Future extensions may include testing in rural or low-connectivity environments to evaluate scalability and robustness.

Further, replacing the current single-sequence LSTM architecture with deeper and more advanced architectures such as multi-head attention-based LSTMs or hybrid Transformer-LSTMs can improve the accuracy of intent prediction by learning long-range dependencies and contextual subtleties in user behavior. Including temporal context (e.g. time of day or habitual behavior) could also boost the model's predictive ability for more anticipatory navigation.

VI. Conclusion

In this paper, we presented an adaptive, smart location-based Augmented Reality navigation system that combined predictive navigation with LSTM models and dynamic POI ranking with sentiment-aware analysis. Building on the fundamental AR application of our earlier work, we upgraded the capability of the system to predict user intent and recommend contextually appropriate locations in real time.

The Predictive Navigation module enables the system to pre-emptively optimize paths by deducing temporal patterns in GPS and behavior data, enabling a seamless navigation experience synchronized with implicit user intent. The Smart POI Ranking module leverages user opinions, real-time feedback, and social opinion via BERT-based models to suggest the highest ranked, context-aware venues dynamically. Such optimizations significantly improve decision-making and user interaction in the AR world.

Our results provide improved user experience through more natural navigation routes and higher relevance of suggested POIs. Bing Maps API usage, visual grounding with ARCore, and real-time inference with light ML models ensures mobile platform deployability with minimal latency.

Future work will focus on building on personalization features with the integration of user profiles, session-based learning, and federated learning approaches to privacy-conscious personalization. Further exploring the combination of voice-based interaction and more refined semantic understanding of environments could enhance immersion and usefulness of the AR assistant even more.

In summary, our work pushes the state of the art in mobile AR by combining machine learning, real-time geospatial data, and immersive visualization, towards building human-aware, intelligence-driven navigation systems.

***Abstract*—Algorithms for feature selection are growing in interest among researchers aiming to connect specific features in a dataset with specific classifications. Recent developments in machine learning, particularly Support Vector Machine-based artificial intelligence algorithms have demonstrated excellent classification performance in highly nonlinear data. However, identifying which features contribute most to classification remains challenging, especially when datasets include hundreds of variables. Initially, features must be screened to narrow down the set for deeper analysis. Metabolomics datasets are one such case, where many features must be examined to determine those associated with heart disease diagnosis. This work applies a Genetic Algorithm, incorporating a penalized likelihood approach with Support Vector Machines for mutation, to stochastically search the feature space. A large-scale simulation study demonstrates that the proposed method achieves a high true feature identification rate while maintaining a reasonable false identification rate. The method is then applied to a Qatar BioBank dataset focused on heart disease, reducing the number of candidate metabolites from 232 to 37.**

***Keywords*—Machine learning; genetic algorithm; support vector machines; classification; heart disease; metabolites**

I. Introduction

Metabolites are the intermediate or end products of metabolism — the process in which the body converts energy in food into energy available for running cellular processes [1]. Metabolism converts food into building blocks for proteins, lipids, nucleic acids, and carbohydrates, and also eliminates metabolic waste. The study of metabolites, or metabolomics [1], has garnered interest in the biomedical community in recent years due to its potential to improve early disease detection and intervention through the analysis of relevant biomarkers. Certain metabolites have been found to be correlated with the prediction or progression of diseases such as Alzheimer's [2], ovarian cancer [3], colon cancer [4], and breast cancer [5], and have shown potential for improving treatment efficacy in patients with rheumatoid arthritis [6], [7]. The study of metabolomics has been growing steadily due to its promise in advancing early disease diagnosis and accelerating the historically decades-long path to innovation in clinical interventions.

Using features of a dataset to determine correct classification is a well-studied area of statistics. A wide variety of techniques have been developed, including LDA (Breiman et al. [8]), Classification Trees (Mondon, Camille [9]), Random Forests (Ho [10]), Support Vector Machines (SVM) (Cortes [11]), as well as Artificial Neural Networks (ANN) (Sarker [12]). Applications of ANN to genomics research are discussed in Lopez [13], and a good overview is provided by Zou [14].

In addition to classification, feature selection is very important. Determining which features from a set of features contribute to classification is more difficult. The literature includes a few works in this area using SVM, but most are limited to smaller numbers of features. Heinemann [15] uses SVM with a reverse elimination scheme to identify features associated with classification. Li et al. [16] use a genetic algorithm with an SVM to search through a small set of genetic features for classification, although it is not likelihood-based and is applied to microarray data. Tapak et al. [17] use a two-line genetic algorithm with Support Vector Machines to analyze gene expression data for psoriasis classification.

Recent advances in biomedical feature selection have shown the potential of combining Support Vector Machines (SVM) with Genetic Algorithms (GA) to improve disease classification in high-dimensional datasets. These hybrid GA-SVM approaches have been successfully applied to problems such as cancer detection, gene expression analysis, and metabolite classification, often outperforming standard filter or wrapper methods when properly tuned [18], [19], [20], [21]. Recent studies have also shown that incorporating hybrid selection strategies can yield more compact and accurate feature sets [22], [23], motivating further innovation in the design of AI-driven feature search algorithms for biomedical data.

Currently, there are no likelihood-based methods that allow for posterior inclusion probabilities of the metabolites to be calculated. Posterior inclusion probabilities allow researchers to understand the relative importance of each metabolite. A novel artificial intelligence methodology is introduced to identify features that contribute to correct classification. The method uses Support Vector Machines combined with a Genetic Algorithm to perform a stochastic search through the feature space using a penalized likelihood-based approach. This results in inclusion probabilities for each feature. Furthermore, the Genetic Algorithm uses multiple parallel genetic lines that mutate at each time step, with crossover between lines at different intervals. Basic properties of the algorithm are studied through a simulation study with 72 different experimental conditions, each replicated 100 times.

This paper begins with an overview of the Qatar BioBank

data in Section II, which serves as the motivating example. Section III introduces the proposed algorithm, followed by Section IV, where we run simulation studies under varying conditions to assess the method's ability to identify metabolites linked to heart disease. In Section V, we compare our approach against existing methods. Section VI presents results from applying the method to the Qatar BioBank data, highlighting metabolites associated with heart disease. We conclude in Section VII with a discussion of the method and directions for future work.

II. Qatar BioBank Data

The Qatar Biobank was created in collaboration with Hamad Medical Corporation and Qatar's Ministry of Public Health in an effort to collect and consolidate Qatar health data, which includes metabolite samples. The Qatar Biobank makes the data accessible to allow scientists to use information about the region's healthcare landscape to guide medical innovation tailored to local needs, and to enable local healthcare workers to make informed decisions about patient care. The Biobank currently has 38,213 total participants, 30,570 of whom are Qatari citizens. To qualify for participation in the Qatar Biobank, individuals must either be Qataris or long-term Qatar residents who have lived in Qatar for at least 15 years. All participants must also be at least 18 years of age [24]. Metabolite samples collected by the Biobank are obtained from buffy coat, DNA, erythrocyte, PaxGene, plasma, RNA, saliva, saliva and RNA, serum, urine, and viable cell samples [24]. Samples are stored in a -80°C automated biostore or cryopreservation laboratory and are processed through a Waters ACQUITY ultra-performance liquid chromatography (UPLC) unit, a Thermo Scientific Q-Exactive mass spectrometer, heated electrospray ionization (HESI-II), and an Orbitrap mass analyzer [25].

The initial dataset includes 1,046 participants with 1,159 measured metabolites, all of whom are Qatari citizens. As many of the participants had multiple disease states, the data was reduced to 626 participants who had exactly one of the following disease states: Angina; Control; Heart Attack; Stroke; or High Cholesterol. Table I shows the distribution of these disease states across the sample, as well as the number of males and females in the sample.

TABLE I. Summaries of Disease State and Gender for the Qatar BioBank Data

Variable	Group	Count
Disease	Angina	9
	Control	291
	Heart Attack	8
	High Cholesterol	316
	Stroke	2
Gender	Female	303
	Male	323

Table II provides summary statistics for clinical and demographic variables such as Age, Systolic BP, Diastolic BP, HDL Cholesterol, LDL Cholesterol, HBA1C (%), Hemoglobin (g/dL), Creatinine (umol/L), Urea (mmol/L), Thyroid Stimulating Hormone (mIU/L), Red Blood Cell ($\times 10^6$/uL), White Blood Cell ($\times 10^3$/uL), and Pulse Wave Velocity for the Qatar BioBank data. The number of samples is $n_r = 626$ for all variables.

TABLE II. Summary Statistics for Clinical and Demographic Variables in the Qatar BioBank Dataset ($n_r = 626$) for all Variables

Variable	Mean	Median	StDev	Q_1	Q_3	Min	Max
Age	35.9	34.0	11.16	27.0	44.0	18.0	79.0
Systolic BP	110.4	110.0	11.22	102.0	118.2	85.0	139.0
Diastolic BP	71.6	71.0	8.07	66.0	99.0	43.0	89.0
HDL Cholesterol	1.36	1.31	0.36	1.09	1.56	0.41	2.87
LDL Cholesterol	3.32	3.40	0.99	2.55	4.00	1.00	8.84
HBA 1C%	5.37	5.40	0.40	5.10	3.60	4.20	6.40
Hemoglobin g/dl	13.66	13.70	1.73	12.50	15.00	6.80	19.70
Creatinine umol/L	67.98	67.00	15.36	56.00	79.00	34.00	140.00
Urea mmol/L	4.42	4.4	1.27	3.60	5.10	1.20	11.00
Thyroid Stimulating Hormone mIU/L	1.74	1.44	1.13	1.03	2.10	0.010	9.61
Red Blood Cell $x10^6$/ul	4.89	4.90	0.56	4.50	5.20	3.30	7.20
White Blood Cell $x10^3$/ul	6.61	6.40	1.74	5.50	7.50	2.80	14.60
PulseWave Velocity	10.68	10.30	2.55	9.10	11.60	0.00	25.80

III. Method

To identify which metabolites contribute to the correct classification of heart disease, computational techniques such as Support Vector Machines and Genetic Algorithms are used in combination. This section provides details of a multi-line Genetic Algorithm with crossover, implemented using Support Vector Machines as the classifier.

A. Support Vector Machines

Support Vector Machine (SVM) is a type of supervised learning algorithm used in machine learning to solve classification and regression problems. The main objective of the SVM algorithm is to find the best possible line, or decision boundary, that separates the data points of different classes. This boundary is called a hyperplane when working in higher-dimensional feature spaces. The main idea behind SVM is to maximize the margin, which is the distance between the hyperplane and the closest data points from each category that needs to be classified. This makes the data easier to classify.

Support Vector Machine (SVM) has different types, such as linear SVM, which separates the data with a straight line, and nonlinear SVM, which is used when the data cannot be separated by a line and is more complex. SVM transforms the input data into a higher-dimensional feature space. This transformation makes it easier to separate and classify the data. To achieve this, SVM uses a kernel function that enables it to implicitly calculate the dot product between the transformed feature vectors and avoid unnecessary computations. Examples of kernels include linear kernels, polynomial kernels, and radial basis functions (RBF). These kernels are very important and help capture complex relationships and patterns in the data.

In terms of a mathematical formulation, SVM separates the data by a hyperplane given by

$$< W, \Phi(x) > + b = 0, \tag{1}$$

corresponding to the decision function $f(x)$ given by:

$$f(x) = sign(< W, \Phi(x) > +b), \tag{2}$$

where W is the weight vector, Φ is an implicit mapping of the input data into a higher dimensional feature space defined by a kernel function subject to the decision function and b is the bias term, which is an offset parameter that allows the hyperplane to be shifted away from the origin.

Vapnik [26], [27] showed that the optimal, in terms of classification performance, is the hyperplane with maximal margin of separation between the classes. This can be done by constructing and solving a constrained quadratic optimization problem whose solution W has an expansion $W = \Sigma_i \alpha_i \Phi(x_i)$ in terms of the a subset of training patterns that lie on the margin, where $\alpha_i \geq 0$ is the Lagrange multiplier associated with the training samples x_i. The training patterns are called support vectors and carry all the relevant information about the classification problem. For more details, we refer the reader to [28], [29], [30], [31], [32], [33].

Moreover, the SVM can generate class probabilities as an output. In this case we use a sigmoid function given by

$$P(y = 1 \mid f) = \frac{1}{1 + e^{Af+B}}, \tag{3}$$

which is fitted to the decision values f of the binary SVM classifiers, A and B are parameters to be estimated by minimizing the negative log-likelihood function and f is the decision function. We can extend the class probabilities to the multi-class case where all binary classifiers class probabilities output can be combined as one problem [34], [35], [36], [37], [38], [39], [40]. In our case, we set up the SVM and consider the following optimization problem.

$$\begin{aligned} \text{minimize} \quad & t(\{\mathbf{w}_n\}, \zeta) = \frac{1}{2} \sum_{n=1}^{k} \|\mathbf{w}_n\|^2 + \frac{C}{m} \sum_{i=1}^{m} \zeta_i \\ \text{subject to} \quad & \langle \Phi(x_i), \mathbf{w}_{y_i} \rangle - \langle \Phi(x_i), \mathbf{w}_n \rangle \geq b_i^n - \zeta_i, \quad i = 1, \ldots, m \\ \text{where} \quad & b_i^n = 1 - \delta_{y_i,n} \end{aligned} \tag{4}$$

where $\mathbf{w_n}$ is the weight vector associated with class n,ζ is a slack variable introduced to allow some misclassifications, and ζ_i is a slack variable associated with each training sample x_i, and b_i^n is associated with margin between the decision hyperplane and the correct class n for the training example x_i. The decision function is given by:

$$\text{argmax}_{n=1..k} < \Phi(x_i), \mathbf{w_n} > \tag{5}$$

For the search algorithm the Bayesian Information Criterion (BIC) will be used which is given by (Schwarz [41]):

$$BIC(\mathbf{D}|m_i) = -2ln(L(\mathbf{D}|m_i)) - pln(n) \tag{6}$$

where $L(D|m_i)$ is the likelihood of the data $\mathbf{D}$ using model m_i, defined by the features in the model and p is the number of features in the model. This is a penalized likelihood approach that will favor a SVM utilizing a smaller number of features.

B. Genetic Algorithm

For the genetic algorithm, a population of five genetic lines is utilized. To initialize these lines, each metabolite is selected to be part of the model with probability 1/2. Once initialized, at each step, each model m_i is mutated by randomly selecting one metabolite and creating a candidate model m_i, where if the metabolite is already in the model, it is removed; if it is absent from the model, it is added. The model is then tested to determine if it increases the likelihood. If it does increase the BIC, then the metabolite will stay in the model; otherwise, it will stay with probability $\xi = \frac{BIC(\mathbf{D}|\mathbf{m_i})}{BIC(\mathbf{D}|\mathbf{m_i})}$. If not, model m_i will be retained at this step. This allows the algorithm to move between regions of high probability.

The crossover step for models m_i with m_j is done by randomly selecting metabolites with probability 1/2, and the chosen metabolite states (included or excluded) are copied from the other model. For example, if one of the randomly selected metabolites is in m_i and not in m_j, then this metabolite will be removed from m_i and added to m_j. Similarly, if the metabolite is in neither m_i nor m_j, then it will not appear in either m_i or m_j. Likewise, if the metabolite is in both m_i and m_j, then it will remain in both. Note that at each crossover step, there is no randomization step to determine if the crossover was advantageous to the BIC.

The following crossover schedule is used for the five models: every 11 steps, models m_1 with m_2, as well as models m_3 with m_4, undergo crossover steps. This crossover process is done at every 23rd step for m_1 with m_3 and m_2 with m_4. At every 37th step, m_1 with m_4 and m_2 with m_3 are crossed over. At every 47th step, the crossover process is done with m_1 and m_5, immediately followed by m_2 and m_5. This allows m_5 to have many more mutation steps between crossover, while both m_1 and m_2 impact m_5 at the same time. The multiple models with crossover at this schedule allow each model to have several mutation steps before a crossover step.

Fig. 1 shows the crossover schedule in visual format. Initialize only starts at the beginning, and then the schedule is repeated at each interval labeled by Steps. The diagram shows that crossovers at every 44, 46, and 47 are close together, meaning there is a large amount of mixing between all models.

This process is run for $n_{step} = 1{,}000$ steps. At each step, the metabolites included in or excluded from the model are recorded for each model. At the end of the 1,000 steps, the number of times each metabolite appeared in each model is determined, and the total number of times the metabolite appeared in any model is calculated. This total is then used to compute the Inclusion Probability by dividing it by 5,000, the total number of opportunities the metabolite had to appear in a model. Numerous test runs were performed, and $n_{step} = 1{,}000$ appeared sufficient, as by the final step, almost all models had converged to the same solution, meaning they included the same metabolites. If a metabolite has an inclusion probability greater than 0.5, it is deemed important for classification.

The method was coded in R (v4.3.0) [42], using support vector machines from the `e1071` (v1.7.13) package [43], [44]. The algorithm takes approximately 8.3 to 80.4 minutes to complete 1,000 steps on an Apple M2 Pro processor with 32GB of RAM, depending on the sample size n_r, with larger samples taking progressively longer.

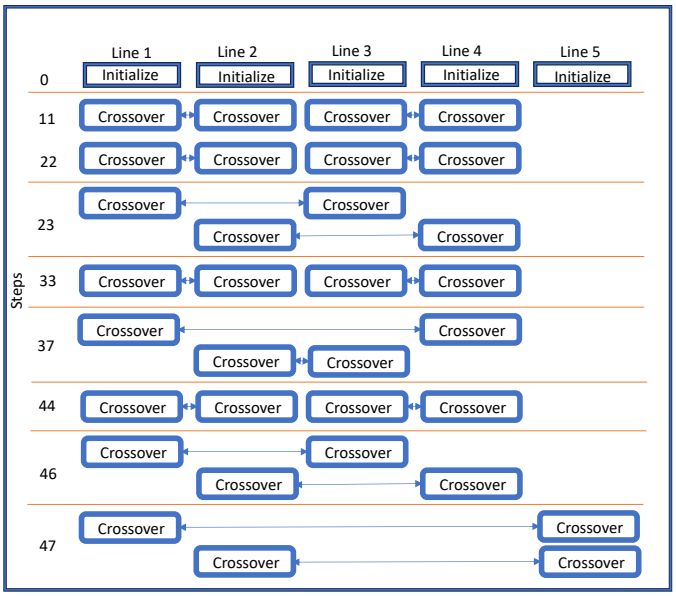

Fig. 1. Genetic algorithm crossover schedule for the first 50 steps. Crossover intervals are preserved across all iterations. Note that mutations occur at every step.

IV. Simulation Study

To study the performance of the algorithm, a simulation study is conducted by varying the sample size n_r, the number of significant metabolites n_s, the number of candidate metabolites n_c, the magnitude of effect (effect size), and the overall variance of the relationship, σ^2. To generate each simulated metabolite dataset, an $n_r \times n_c$ matrix $\mathbf{X}$ was constructed, where each element $\mathbf{X}ij$ follows a standard normal distribution: $\mathbf{X}ij \sim N(0,1)$. The following two effect profiles are used to assign the influence of each metabolite on classification:

$$\beta_1 = \begin{cases} M(1-1/(n_s+1))w & w < n_s, \\ 0 & \text{otherwise} \end{cases} \quad (7)$$

$$\beta_2 = \begin{cases} M(1/n_s+1))w, & w < n_s \\ 0 & \text{otherwise} \end{cases} \quad (8)$$

where $w = (1, 2, .., n_c)$. Here β_1 induces a decreasing effect across the first n_s metabolites while maintaining a positive effect. Similarly, β_2 induces an increasing effect across the first n_s metabolites. This is converted into a two linear relationships defined by:

$$\begin{aligned} z_1 &= \mathbf{X}\beta_1 \\ z_2 &= \mathbf{X}\beta_2 \end{aligned} \quad (9)$$

with two additional relationships with system noise added:

$$\begin{aligned} z_1^* &= \mathbf{X}\beta_1 + \epsilon_1 \\ z_2^* &= \mathbf{X}\beta_2 + \epsilon_2 \end{aligned} \quad (10)$$

with $\epsilon_1 \sim N(\mathbf{0}, \sigma^2\mathbf{I})$ and $\epsilon_2 \sim N(\mathbf{0}, \sigma^2\mathbf{I})$ with $Cov(\epsilon_1, \epsilon_2) = 0$. Here σ^2 represents the inherent noise in the system designed to confuse the classifier. To obtain the true simulated classifications the following rule is used:

$$y_{true} = \begin{cases} A & z_1 < -1, z_2 < -1 \\ S & z_1 > 1, z_2 > 1 \\ R & z_1 > 1, z_2 < -1 \\ T & z_1 < -1, z_2 > 1 \\ C & \text{otherwise} \end{cases} \quad (11)$$

Fig. 2 shows an example dataset for this simulation. Here, the number of observations is $n_r = 1{,}000$, the number of candidate metabolites is $n_c = 200$, the number of significant metabolites is $n_s = 5$, the magnitude of the effect is $M = 5$, and the system variance is $\sigma^2 = 0.5$, using equation (11) as the true classification boundaries. Notice that this includes a large number of controls, class A, and class S, with smaller numbers of R and T. This inequality in distribution is desired for this simulation, as it reflects the inequality typically found in metabolomic data. Furthermore, the simulation allows mixing of A, R, S, and T with the control C. However, there is rare mixing across the disease states A, R, S, and T. This is a property of the metabolomic data under consideration, as the participants were chosen based on exhibiting only one of the disease states or being a control. Hence, the data does not include individuals with multiple disease states. Furthermore, it is assumed that a larger increase among a number of metabolites corresponds to an additive effect toward classification. Note that the goal of the study is not to achieve correct disease classification but to identify which metabolites contribute to the correct classification.

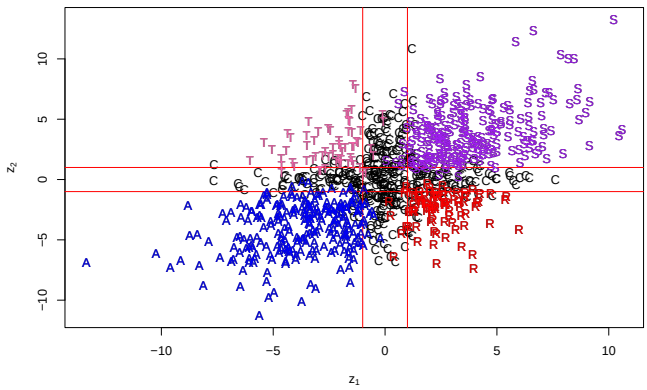

Fig. 2. Example simulated dataset $n_r = 1,000$, $n_c = 200$, $n_s = 10$, Magnitude $= 2$, and $\sigma^2 = 0.5$. The red lines demark the true classification boundaries set by equation (11).

A simulation study is performed to consider sample sizes of $n_r = 300,\ 500$, and 1,000, number of significant metabolites $n_s = 5$ and 10, number of candidate metabolites $n_c = 100$ and 200, magnitudes $= 1, 2$, and 4, and variance $\sigma^2 = 0.1$ and 0.5. This gives 7,200 simulated datasets and analyses, which were conducted on an AMD Ryzen Threadripper PRO 3975WX 3.5GHz 32-Core sWRX8 processor with 64GB RAM. For each of the combinations, 100 datasets were simulated, the proposed algorithm was run, and the Correct Identification Rate (CIR)

was calculated by counting the number of metabolites correctly identified in the model by the algorithm, divided by the number of true metabolites n_s in the model. The resulting correct metabolite identification rates were then averaged over the 100 datasets. The False Identification Rate (FIR) is also calculated by adding the number of incorrect metabolites and dividing by the total number of metabolites selected by the algorithm, then averaging across all 100 datasets.

Table III shows the results for the simulation study. Results are reported as CIR (FIR) in the table. Notice for $n_s = 5$ and $n_c = 100$, the correct identification rate was near 1.000 for all magnitudes and variances, with the exception of $M = 1$, $\sigma^2 = 0.5$, and $n_r = 300$. Even in this exception, a 0.998 correct identification rate was achieved. When $n_s = 5$ and $n_c = 200$, the correct identification rate goes down to 0.918 for $n_r = 300$, $M = 1$, and $\sigma^2 = 0.5$, but is near 1.000 for $n_r = 500$ and 1,000. It should be noted that in this case, there is a small sample size $n_r = 300$ with a relatively large number of candidates $n_c = 200$, small effect size $M = 4$, and large variance $\sigma^2 = 0.5$. One would expect, in this situation, the method to have a more difficult time correctly identifying all the metabolites. When $n_s = 10$ and $n_r = 10$, the method seems to struggle to correctly identify all the contributing metabolites, with a rate as low as 0.826. While this is not terrible, it shows the sensitivity of the algorithm to cases where the pattern is not as clearly defined. Whereas when $n_r = 500$, the lowest correct identification rate is 0.935, and when $n_r = 1{,}000$, the lowest correct identification rate is 0.993, neither of which would be considered bad. This corresponds to the general idea that the larger the sample size, the more information is available for detecting patterns.

Table III also shows the FIR for each experimental combination. Note that FIR values are in parentheses. Notice that there is a general increase in the false positives as the number of candidate metabolites is increased. For example, when $n_s = 5$, $n_c = 100$, $M = 1$, and $\sigma^2 = 0.1$ for $n_r = 300$, the false positive rate is 0.054 compared to the same setting with $n_r = 200$, where the false positive rate is 0.177. This is persistent across all simulation settings. This should be expected, as the space that needs to be searched through is much larger and, hence, there are more opportunities for a Type I error to occur. Also notice that as the variance σ^2 increases, the false positive rate also increases. For example, when $n_s = 10$, $n_c = 200$, $M = 1$, and $\sigma^2 = 0.1$, the false positive rate is 0.261, and when $\sigma^2 = 0.5$, the false positive rate is 0.268. This is also to be expected, as in general, in any classification algorithm, the larger the variance (noise), the more difficult it becomes for the algorithm to detect the correct predictors. It also appears that as the magnitude increases, the false positive rate also increases. However, the difference between the false identification rates due to magnitude seems to be less than 0.05, whereas the number of candidates n_c tends to produce a difference of 0.2.

As a screening algorithm, this method seems to be a good choice, as the correct identification rates are high and the number of false identifications is reasonable. The goal of any screening method is to ensure that the correct metabolites are identified. A simulation study should be conducted to determine the correct number of steps for the Genetic Algorithm, the threshold cutoff, the effect size that can be detected, etc.

TABLE III. PROPORTIONS OF CORRECTLY AND FALSELY IDENTIFIED METABOLITES (CIR/FIR) ACROSS SIMULATION SETTINGS. PROPORTION OF CORRECTLY IDENTIFIED METABOLITES ARE BASED ON 100 SIMULATED DATASETS

				n_r		
n_s	n_c	Magnitude	σ^2	300	500	1,000
5	100	1	0.1	1.000 (0.054)	1.000 (0.066)	1.000 (0.090)
		1	0.5	0.998 (0.120)	1.000 (0.139)	1.000 (0.185)

		2	0.5	0.988 (0.237)	1.000 (0.197)	1.000 (0.202)
		4	0.1	0.996 (0.264)	1.000 (0.241)	1.000 (0.233)
		4	0.5	0.988 (0.276)	1.000 (0.249)	1.000 (0.239)
10	100	1	0.1	0.958 (0.106)	0.998 (0.084)	1.000 (0.099)
		1	0.5	0.951 (0.141)	0.997 (0.131)	1.000 (0.178)
		2	0.1	0.989 (0.135)	1.000 (0.154)	1.000 (0.195)
		2	0.5	0.979 (0.151)	1.000 (0.158)	1.000 (0.213)
		4	0.1	0.984 (0.169)	0.999 (0.177)	1.000 (0.234)
		4	0.5	0.975 (0.181)	0.999 (0.177)	1.000 (0.232)
	200	1	0.1	0.837 (0.261)	0.945 (0.199)	0.997 (0.178)
		1	0.5	0.826 (0.268)	0.938 (0.232)	0.993 (0.210)
		2	0.1	0.913 (0.274)	0.982 (0.238)	0.995 (0.247)
		2	0.5	0.907 (0.287)	0.983 (0.259)	1.000 (0.249)
		4	0.1	0.892 (0.309)	0.973 (0.293)	0.998 (0.276)
		4	0.5	0.876 (0.304)	0.971 (0.292)	0.998 (0.285)

However, this is beyond the scope of this study, as it is exploratory and would detract from the presentation of the method presented. More on extended simulation studies is given in the Discussion.

V. COMPARISON WITH OTHER METHODS

To determine the performance of our Support Vector Machine Artificial Intelligence (SVMAI) approach compared with other modern techniques designed to answer this type of question, such as Random Forests (RF) and Partial Least Squares - Discriminant Analysis (PLSDA). Both of these approaches are designed to perform both feature selection and classification simultaneously, which is the goal of the SVMAI approach.

The RF technique can be traced back to the basic classification trees of Breiman [8]. The big issue with classification trees is that they are sensitive to the initial feature selected to cut along. Hence the need for a forest of classification trees, which use randomization to determine which feature to cut along at each step. This is a very popular approach for feature selection as well as prediction. It has been used widely in metabolomics for feature selection; see [45] for use in urinary metabolomics, [46], who used the technique on Omega Fatty Acid Pathways, and [47], who provides a very good overview of the technique applied to lipid metabolites. For this work,

the randomForest version 4.7-1.1 package [48] in R 4.4.1 [42] is used.

PLSDA is an extension of standard Linear Discriminant Analysis, which seeks to first find the Partial Least Squares lines to fit each group, then determine the best discriminant line for classification. A review and comparison of RF, PLSDA, and standard SVM algorithms in metabolomics is provided by [49]. For more details on the PLSDA algorithm, see [50], [51], and a great simplistic discussion is given by [52].

A small simulation study was designed with sample sizes of $n = 300, 400$, and 500, with the number of true significant metabolites $n_t = 5$ and 10, and 100 metabolites to search through. The magnitude of the effect is 2.0, and the magnitude standard deviation is 0.5. The simulated data uses the same protocol as the simulation study in Section IV. To evaluate the performance, the %Correct, %Incorrect, and Overall Classification Accuracy are considered. Here, %Correct is the proportion of truly significant metabolites detected, and %Incorrect is the proportion of truly insignificant metabolites detected. Hence, a high %Correct indicates that the approach has the ability to find the true features. A high %Incorrect corresponds to a considerable number of insignificant metabolites being selected.

Table IV shows the results of this simulation study. Notice that SVMAI has extremely high correct detection rates, with the smallest at 0.997. In addition, the Classification Accuracy of the SVMAI technique is consistently 1.0, meaning 100% correct at classifying the heart health status. The %Incorrect for the SVMAI approach tends to be lower than the RF approach but much higher than the PLSDA technique. Of all the techniques considered here, the RF approach performs the worst, with low %Correct rates, high %Incorrect rates, and low Classification Accuracy. From this study, one can see that SVMAI is very good at determining the correct metabolites with high classification accuracy. However, it does select incorrect metabolites at a higher rate than PLSDA, but generally lower than RF.

TABLE IV. RESULTS OF SIMULATION STUDIES TO COMPARE ACROSS SVMAI, RF AND PLSDA TECHNIQUES FOR SCREENING. SAMPLE SIZES $n_s = 300, 400, 500$, NUMBER OF TRUE SIGNIFICANT METABOLITES $n_t = 5, 10$ WITH % CORRECT METABOLITES DETECTED, % INCORRECT METABOLITES DETECTED AND % CLASSIFICATION ACCURACY. BASED ON 100 SIMULATED DATASETS

		% Correct			% Incorrect			Classification Accuracy		
n_s	n_t	SVMAI	RF	PLSDA	SVMAI	RF	PLSDA	SVMAI	RF	PLSDA
300	5	1	0.8	0.798	0.123	0.553	0.23	1	0.539	0.851
	10	0.988	0.857	0.716	0.158	0.175	0.19	1	0.456	0.853
400	5	1	0.8	0.8	0.128	0.454	0.05	1	0.545	0.803

VI. QATAR BIOBANK RESULTS

For the Qatar BioBank data, there were $n_c = 223$ fully observed metabolites across $n_r = 626$ participants. The algorithm was performed on the dataset using 1,000 steps in the genetic algorithm. The computation time was approximately 12 minutes on an Apple M2 Pro processor with 32GB of RAM. Table V shows the metabolites with Inclusion Probabilities greater than 0.9 for the Qatar BioBank data concerning Heart Disease. Out of the 223 candidate metabolites, 37 had an inclusion probability above 0.9, and 48 had an inclusion probability above 0.5 (not shown). Notice that many of the metabolites have an inclusion probability above 0.999, indicating they were present in almost all of the models across the five genetic algorithm lines. Of particular interest is the fact that there are eight metabolites with the "X" prefix, which indicates an unknown chemical identity [53]. Also of note is that circulating BCAAs (leucine/isoleucine, valine, glutamate/glutamine, proline, and methionine) have been associated with predicting risk of coronary artery disease [54], [55], indicating the validity of our method in capturing previously known metabolites associated with heart disease.

TABLE V. METABOLITES AND THEIR INCLUSION PROBABILITIES FOR THE QATAR BIOBANK HEART DISEASE DATASET. ALL METABOLITES WITH AN INCLUSION PROBABILITY GREATER THAN 0.9 ARE PRESENTED IN DESCENDING ORDER OF INCLUSION PROBABILITY

Metabolite	Inclusion Probability
X - 23636	1.000
N1-methyladenosine	0.999
5alpha-pregnan-3beta,20alpha-diol disulfate	0.999
2,3-dihydroxy-5-methylthio-4-pentenoate (DMTPA)*	0.999
X - 11372	0.999
carnitine	0.999
2-hydroxyoctanoate	0.999
6-bromotryptophan	0.999
alanine	0.999
p-cresol sulfate	0.999
phosphoethanolamine	0.999
X - 14056	0.999
ornithine	0.999
deoxycarnitine	0.999
arginine	0.999
metabolonic lactone sulfate	0.999
X - 11880	0.999
X - 23639	0.999
1-arachidonoyl-GPI (20:4)*	0.999
choline	0.999
X - 21258	0.999
proline	0.999
dimethylarginine (SDMA + ADMA)	0.999
alpha-hydroxyisocaproate	0.999
indoleacetate	0.999
X - 24425	0.999
1-oleoyl-GPE (18:1)	0.999
N-delta-acetylornithine	0.999
5alpha-androstan-3beta,17beta-diol disulfate	0.999
taurocholenate sulfate*	0.999
pregnenediol sulfate (C21H34O5S)*	0.999
2-hydroxypalmitate	0.999
gamma-glutamylcitrulline*	0.999
X - 21364	0.999
hydroxy-CMPF*	0.998
creatinine	0.995
7-alpha-hydroxy-3-oxo-4-cholestenoate (7-Hoca)	0.931

VII. Conclusion

This work shows the ability to use a genetic algorithm approach with multiple lines and frequent crossbreeding in conjunction with support vector machines using a likelihood approach to create an AI method to screen metabolites for heart disease. The method proposed performs well under simple simulation studies across a large number of scenarios. The method allows for high correct identification rates of metabolites (above 85%). The false positive rate is moderately high, ranging from 5% to 30%. Hence, the algorithm would be good for screening purposes to locate candidate metabolites for further study. The results of the algorithm, when applied to the Qatar BioBank data, allow for 223 metabolites to be screened down to 37, all of which have an inclusion probability above 0.9. As the algorithm has a reasonably high false discovery rate, one should be careful to make declarative statements that all of the metabolites identified are truly contributing to the disease state. Instead, one should state that there is preliminary evidence that these metabolites may be related to these disease states. Furthermore, since the data is dominated by Control and High Cholesterol participants, the results most likely have selected metabolites that are biased toward these two states. However, future studies can verify or refute these claims. Knowing which metabolites contribute to heart disease will allow for assays to be developed that can indicate which people are likely to have heart disease, which can lead to preventative care to reduce the risk of heart disease.

Additional work could be done to study the performance of the algorithm on more complex datasets. The work here only considered a small number of disease states to mimic the Qatar BioBank data; however, a higher number of disease states and multiple disease states should be studied. Also, the interaction of metabolites was not considered here. Work by Boone et al. [56] and Lee and Boone [57] shows how to explore a restricted space when interactions are present for linear regression models. A similar approach could be developed here.

In the simulation study presented, the Genetic Algorithm only took 1,000 steps due to computational times. Another simulation study should be conducted to determine if the number of steps can reduce the false positive rates. This study should attempt to determine a rule that one could apply to determine the adequate number of steps to achieve an acceptable false positive rate. In this study, one should consider the ratio of candidate metabolites to number of participants, $\frac{n_c}{n_r}$, to look for a general pattern. Also, the threshold to be deemed important could be adjusted from 0.5 to a higher value to become more stringent and potentially reduce the number of false positives. Furthermore, the SVMAI method is superior to PLSDA and RF for Classification Accuracy and %Correct metabolites selected and should be considered when conducting metabolomic studies where classification is of interest.

Another item that could be considered is how to address the issue of missing data. Many of the metabolites have missing values for various participants, which in this study have been omitted. Only metabolites observed in all participants were used here. As the computational complexity here is high, several approaches could be used to *impute* the missing values, such as mean imputation, the EM algorithm, and possibly multiple imputation.

Acknowledgment

Ryad Ghanam and Edward Boone would like to thank Qatar Foundation and Virginia Commonwealth University in Qatar for their support through the Mathematical Data Science Lab. Faten S. Alamri would like to thank Princess Nourah bint Abdulrahman University for their support through grant number PNURSP2024R346. The authors would to acknowledge the data received from Qatar Biobank.

Funding

This research was funded by Virginia Commonwealth University in Qatar through the Mathematical Data Science Lab HQ1260 and Princess Nourah bint Abdulrahman University through Project number PNURSP2024R346

***Abstract*—Deepfake technology poses a growing threat to the authenticity and trustworthiness of digital media, necessitating the development of advanced detection mechanisms. While AI-based methods have shown promise, they generally face limitations in terms of generalization and scalability. We present a blockchain-enabled watermarking technique, characterized by its immutable, transparent, and decentralized nature, which offers a robust complementary approach for enhancing media authentication through methods such as cryptographic watermarking, decentralized identity, and content provenance tracking. To train and evaluate blockchain-based watermarking and deepfake detection systems, a variety of large-scale datasets are utilized. Video datasets include UADFV (49 real, 49 fake), Deepfake-TIMIT (320 real, 640 fake), DFFD (1000 real, 3000 fake), Celeb-DF v2 (590 real, 5639 fake), DFDC (23,564 real, 104,500 fake), DeeperForensics-1.0 (50,000 real, 10,000 fake), FaceForensics++ (1000 real, 5000 fake), and ForgeryNet (99,630 real, 121,617 fake). Image datasets include DFFD (58,703 real, 240,336 fake), FFHQ (70,000 GAN-generated), iFakeFaceDB (87,000 fake), 100k AI Faces, and over 2.8 million samples in ForgeryNet. Despite integration challenges such as scalability, computational cost, and standardization, blockchain-based solutions show promise in tracking content origin and enhancing verification. Simulation results demonstrate that the proposed blockchain-enabled watermarking achieves a higher accuracy in detecting fake content compared to existing machine learning methods.**

***Keywords*—Blockchain; deep fake; convolutional neural network (CNN); long short-term memory (LSTM); RNN (recurrent neural network); video and image**

I. Introduction

Deepfake technology represents a significant advancement in artificial intelligence, enabling the creation of highly realistic, manipulated, or entirely synthetic media, including videos, photos, and audio recordings [1]. These digital forgeries are crafted using sophisticated machine learning techniques, often employing algorithms such as Generative Adversarial Networks (GANs) [2]. A GAN typically involves two competing neural networks: a generator, which produces fake content, and a discriminator, which attempts to distinguish between real and synthetic media, resulting in increasingly convincing results [3]. Beyond GANs, other AI models, such as autoencoders and diffusion models, also contribute to the creation of deepfakes, highlighting the evolving landscape of this technology. This technology enables various manipulations, ranging from swapping faces and altering facial expressions to synthesizing entire identities and voices [4].

The proliferation of deepfakes is not solely due to technological advancements but also to the increasing accessibility of user-friendly tools and open-source platforms. Individuals with even basic computer skills can now generate convincing deepfakes, leading to a widespread presence of manipulated content online [5]. This ease of creation has amplified the urgency for robust and effective detection methods [6]. The potential for deepfakes to undermine the authenticity of information poses a considerable threat, capable of large-scale misinformation and manipulation [7].

The impact of deepfakes extends across various domains, eroding public trust in digital media and complicating the ability to discern genuine content from fabrications. Malicious applications range from spreading fake news and non-consensual pornography to identity theft, exploitation of public figures, financial scams, influencing elections, inciting social unrest, and even psychological warfare [8]. Notable examples illustrate potential harm, such as the circulation of a false White House tweet and a fake image of an explosion near the Pentagon, causing public anxiety and market fluctuations. Manipulated political speeches and videos have also surfaced, demonstrating the technology's ability to distort public opinion and the political landscape. Furthermore, deepfake fraud has resulted in significant financial losses for both individuals and organizations, as seen in cases of CEO impersonation leading to multi-million-dollar fraudulent transactions. Given the increasing sophistication of these forgeries, relying on human discernment alone is becoming increasingly ineffective, thereby highlighting the critical need for advanced technological solutions in deepfake detection [9].

The above studies have many limitations. Many machine learning methods, such as CNN and other techniques, have a high rate of false positives and consume significantly more time, requiring high scalability of resources during fake detection based on generated GAN methods-enabled data.

- To develop a robust deepfake detection framework that accurately identifies manipulated video and audio content using advanced AI models.
- To integrate blockchain technology for secure, tamper-proof verification and traceability of multimedia content origins and authenticity.
- To ensure decentralized trust and transparency in content-sharing platforms by utilizing smart contracts and immutable watermarking techniques.
- We proposed a novel hybrid system that combines deep learning-based deepfake detection with blockchain-enabled watermark verification.
- We developed a decentralized content validation mechanism using smart contracts to track and verify video authenticity across digital platforms.

The study is organized as follows: Section II is about related work. Section III is the proposed methodology. Section IV discusses the result analysis, and Section V presents the conclusion and future work.

II. Literature Review

In this direction, Kumar et al. [1] combined a blockchain-based AKA mechanism with explainable artificial intelligence (XAI) to secure smart city-based consumer applications. Initially, the involved entities securely communicate with one another to share data via a blockchain-based AKA mechanism. Conversely, they employed the SHapley Additive explanations (SHAP) mechanism to explain and interpret the leading features that significantly impact the decision.

In this context, Muneer et al. [2] emphasizes the prediction of prices of three top cryptocurrencies: Bitcoin, Ethereum, and Litecoin. They employed three machine learning (ML) algorithms: LSTM, SVM, and RF, and utilized the LSTM-RF ensemble to enhance the predictive accuracy of the predicted cryptocurrencies. In comparison to all the models studied, the hybrid LSTM-RF model was the most accurate in predicting the respective performance indices and outperformed the other conventional models and standalone machine learning techniques. Additionally, this work employs Explainable Artificial Intelligence (XAI) techniques to develop AI-based, human-friendly, and interpretable visualizations. This method makes insights accessible to basic users, as it enables investors to make informed decisions based on the outcomes provided by the proposed model.

In addition, Sachan et al. [3] strive to strike a balance between the responsible use and governance of human legal professionals in content generated by Generative AI through periodic audits. The research model conceptualizes the two algorithms. Strategic on-chain (on blockchain) and off-chain (off blockchain) storage of data in adherence to the data protection laws and key demands of stakeholders within a legal firm. Second, comparison auditing of the singular signature as Merkle roots of off-chain stored files to their immutable blockchain equivalent. The system preserves the integrity of data repositories that hold the choices made by an XAI model and a textual explanation of legal cases obtained through a prompt issued to the API of Generative AI, enabling automated auditing.

In addition, Kumar, P. et al. [4] introduced an explainable AI (XAI)-enabled blockchain to enhance the decision-making capabilities of cyber threat detection in the field of Smart Healthcare Systems. Initially, they employ blockchain to secure and store information across various cloud providers through the application of Clique Proof-of-Authority (C-PoA) consensus. Second, a new threat-hunting model based on deep learning is constructed by integrating Parallel Stacked Long Short-Term Memory (PSLSTM) networks and a multi-head attention mechanism to enhance attack detection. The large-scale experiment validates its potential to serve as an advanced decision support system for cybersecurity analysts.

Furthermore, Chen, H. Y et al. [5] give a comprehensive bibliometric description and visualization of the integration of two leading and promising technologies, explainable AI and Blockchain, into Smart Agriculture. Through the integration of artificial intelligence, blockchain technology, and "smart" agriculture, researchers can create a more efficient, more open, and more sustainable food system. They posited that the use of blockchain technology in smart agriculture can enhance transparency by providing an immutable record of a product's origin, production processes, and distribution. It can potentially create a food system that is more beneficial to farmers, consumers, and the environment by improving efficiency, transparency, and sustainability.

Moreover, Salama, R et al. [6] develop a new Blockchain with Explainable Artificial Intelligence-Driven Intrusion Detection for IoT-driven ubiquitous computing systems (BXAI-IDCUCS) model. The primary goal of the BXAI-IDCUCS model is to achieve energy efficiency and security in the IoT setting. The BXAI-IDCUCS model first groups the IoT nodes with an energy-aware duck swarm optimization (EADSO) algorithm to accomplish this. Additionally, a deep neural network (DNN) is employed to detect and classify intrusions within the IoT network. Finally, blockchain technology is used for safe inter-cluster data transmission procedures. To guarantee the productive operation of the BXAI-IDCUCS model, an extensive experimentation study is utilized, and results are measured under various parameters. The comparison study highlighted the superiority of the BXAI-IDCUCS model over existing state-of-the-art methods, achieving a packet delivery ratio of 99.29%, a packet loss rate of 0.71%, a throughput of 92.95 Mbps, an energy consumption of 0.0891 mJ, a lifetime of 3529 rounds, and an accuracy of 99.38%.

Additionally, El Houda, Z. et al. [7] introduce a new framework, referred to as FedIoT, which relies on Explainable Artificial Intelligence (XAI) methods and Blockchain to protect FL-based IDS from IoT networks. FedIoT employs sophisticated XAI methods for detecting local model manipulations and preventing FL-based attacks. Further, we

suggest a blockchain method that employs a lightweight reputation system that guarantees the reliability and credibility of the FL training process. We perform experiments to verify FedIoT, an FL-based intrusion detection system for IoT networks. We use the UNSW-NB15 dataset to verify that FedIoT can successfully identify malicious behavior and enable efficient FL collaboration among multiple users.

Sharma, N et al. [8] proposes a hybrid security system that integrates blockchain for decentralized data storage and an intrusion detection system (IDS) based on a multi-attention deep convolutional recurrent neural network (MA-DeepCRNN) model. The model enhances block creation time and throughput, with minimal transaction reversal probability. The IDS delivers high classification performance, enhancing accuracy and F1-score in IoMT systems, boosting security, scalability, and real-time threat detection in healthcare settings.

Further, Hasan, M et al. [9] attempts to bridge this gap by combining explainable artificial intelligence (XAI) methods and anomaly rules in tree-based ensemble classifiers for the identification of anomalous Bitcoin transactions. In addition, they introduce rules for explaining whether a Bitcoin transaction is anomalous or not. Furthermore, we propose an under-sampling algorithm called XGBCLUS, with the aim of balancing anomalous and non-anomalous transaction data. This algorithm contrasts with other widely employed under-sampling and over-sampling methods. Ultimately, the performances of several tree-based individual classifiers are contrasted with stacking and voting ensemble classifiers. Their experimental results show that: i) XGBCLUS improves true positive rate (TPR) and receiver operating characteristic-area under curve (ROC-AUC) scores over state-of-the-art under-sampling and over-sampling methods, and ii) their ensemble classifiers proposed in this study perform better than conventional single tree-based machine learning classifiers with respect to accuracy, TPR, and false positive rate (FPR) scores.

In addition, Dutta, J. et al. [10] utilizes SHapley Additive exPlanations (SHAP) to offer real-time, model-agnostic explanations of AI predictions to support personalized health monitoring and well-informed decision making in healthcare To enhance data security, a consortium blockchain is used, and AI is applied to recognize block data sensitivity at the edge in blockchain-integrated IoT architectures with Random Forest (RF) algorithm. This method achieves high precision in authenticating block sensitivity, enabling the effective selection of authentication methods in proof-of-authentication (PoAh) consensus within the consortium blockchain. This provides increased security for sensitive information and improves overall blockchain performance. The framework is tested in an edge computing system, exhibiting tremendous potential for promoting eHealth security and authentication, and marking a significant leap in medical technology.

We present Table I to define the findings and limitations of the studies.

TABLE I DEEPFAKE DETECTION BASED ON MACHINE LEARNINGS

Method	Mechanism	Key Strengths	Limitations
CNNs [11]	Analyze spatial hierarchies of features, detect inconsistencies in facial features, alignment, etc.	Effective at identifying spatial anomalies and inconsistencies within frames.	Can be fooled by high-quality deepfakes and may struggle with temporal inconsistencies.
RNNs [12]	Evaluate temporal consistency of movements, speech, and expressions.	Good at detecting unnatural movements and lip-sync issues.	May not be as effective for static images or subtle temporal anomalies.
Visual Artifact Analysis [13]	Detect inconsistencies in lighting, shadows, skin texture, blending boundaries, and other digital artifacts.	Can identify traces left by the deepfake generation process that may not be obvious to humans.	Effectiveness decreases as deepfake quality improves and fewer artifacts are present.
Biometric Analysis [14]	Analyzes unique physiological characteristics like blinking patterns and eye movements.	Exploits inherent human traits that are difficult for AI to replicate perfectly.	Requires high-quality video and may not be effective against deepfakes that accurately mimic these traits.
Multimodal Detection [15]	Combines analysis of audio, video, and potentially other data sources.	Provides a more comprehensive assessment of authenticity by leveraging information from multiple modalities.	More complex to implement and requires synchronized and high-quality data across all modalities.
Metadata Analysis [16]	Examines digital information embedded in media files (e.g., timestamps, editing history).	Can quickly identify inconsistencies that suggest tampering.	Metadata can be easily altered or removed. Relies on the assumption that original media has complete and accurate metadata.
Provenance-based Detection [17]	Examines metadata for signs of manipulation, often relying on digital watermarks.	It can provide strong evidence of authenticity if watermarks are reliably implemented and protected.	Suffers from lack of standardization, potential for removal or misuse of watermarks, and requires buy-in from content creators and platforms. Does not work for content without watermarks.
Inference-based Detection [18]	Analyzes the media content itself for statistical anomalies and patterns indicative of manipulation, without relying on external metadata.	Can detect deepfakes even without provenance information. Adapts to new deepfake techniques such as models are retrained.	Relies on the quality and diversity of training data. Can produce false positives or negatives. The "ground truth" is often assumed, not definitively known.

The above works and studies have limitations, as discussed in Table I. Therefore, we provide new solutions based on blockchain and watermarking techniques to detect deepfakes within data. These studies [19-22] suggest a fake news detection system based on blockchain and cybersecurity approaches, which has been deployed in practice. These studies [23-27] suggested an edge cloud-enabled distributed healthcare system to promote secure healthcare services through telemedicine applications for users.

III. Proposed Blockchain Architecture

Blockchain technology offers a novel and promising foundation for enhancing trust in digital information. Its fundamental principles and key features align well with the challenges posed by deepfakes. At its core, blockchain is a Distributed Ledger Technology (DLT) where data is not stored in a central repository but is instead distributed across numerous computers within a network. This decentralized nature enhances security and resilience by eliminating a single point of failure. A defining characteristic of blockchain is its immutability. Once a record, or block, is added to the blockchain, it becomes challenging to alter or delete. This is achieved through cryptographic hashing and the sequential linking of blocks. Any attempt to modify a block would necessitate recalculating the cryptographic hash for that block and all subsequent blocks. This computationally intensive task is practically infeasible for a malicious actor to accomplish without the consensus of the network. In the event of an error, a new transaction is added to the blockchain to rectify it, ensuring that both the original and the correction remain visible, thus maintaining an auditable history. This inherent immutability provides a robust guarantee of data integrity, making blockchain a strong candidate for verifying the authenticity of digital content. Transparency is another key principle of blockchain. While the level of transparency can vary depending on the type of blockchain (public versus permissioned), transaction records are typically visible to all network participants or authorized parties, fostering trust and accountability. All participants in the network have access to the distributed ledger, ensuring a shared and verifiable record of transactions. This transparency enables the open verification of content provenance, potentially increasing user trust in the authenticity of the media. The decentralized nature of blockchain means that no single entity has control over the network. This lack of central authority reduces the risk of censorship and eliminates single points of vulnerability. The network's distributed structure makes it more resilient to failures and cyberattacks. This decentralization enhances the security and robustness of any deepfake detection system built upon blockchain technology, as it avoids reliance on potentially compromised central authorities. Several key features of blockchain are particularly relevant to deepfake detection. Cryptographic hashing is a fundamental element where data within each block is transformed into a unique, fixed-length string of characters known as a hash, using cryptographic hash functions such as SHA-256 or Keccak-256. Even the slightest alteration to the original data will result in a completely different hash. Each block in the blockchain contains the hash of the preceding block, creating a secure and tamper-evident chain. These cryptographic hashes are designed to be irreversible and collision-resistant, further enhancing data integrity. This provides a mechanism for creating a unique and tamper-evident digital fingerprint for media content, which can be used to verify its integrity. Consensus mechanisms are the protocols by which network participants, or nodes, agree on the validity of new transactions and blocks before they are added to the blockchain. These mechanisms, such as Proof of Work or Proof of Stake, ensure the integrity of the ledger by requiring a majority of the network to validate any new addition. This ensures that any attempt to tamper with the blockchain record of media provenance would be rejected by the network, further strengthening trust in the system. Smart contracts are self-executing contracts where the terms of the agreement are directly written into code. These contracts can automate verification processes based on predefined rules, enabling efficient and trustless verification of content authenticity against established criteria or on-chain records.

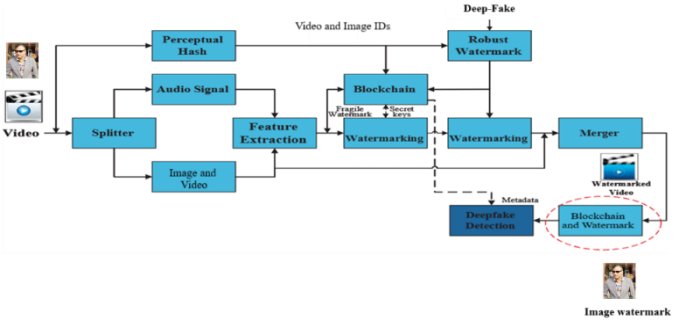

Fig. 1. Proposed blockchain-enabled deep fake detection for different data modes.

Fig. 1 presents a comprehensive framework for deep-fake detection and secure video authentication using blockchain and watermarking techniques. The process begins by splitting the input video into audio, image, and video components, followed by perceptual hashing and feature extraction to generate unique IDs. These features are then used to create fragile watermarks and secret keys, which are managed via blockchain for secure access and traceability. Robust and fragile watermarks are embedded into the video content to ensure both durability and sensitivity to tampering. The watermarked components are merged to produce a final authenticated video. Metadata from this process is passed to a deepfake detection module, which validates the authenticity of the content. The system ensures end-to-end integrity by combining blockchain verification with advanced watermarking, offering a reliable solution against manipulated media. Blockchain technology offers several specific applications that can significantly enhance the detection of deepfake content. One key application is the use of cryptographic hashing to create unique digital fingerprints of original media content, including images, videos, and audio. These hashes can then be securely stored on the blockchain. Subsequently, anyone can compare the hash of a potentially manipulated piece of content with the original hash recorded on the blockchain to detect any alterations. By storing these cryptographic hashes of original content on the immutable blockchain, a permanent and verifiable record of the content's integrity is established. When an original piece of media is

created, its unique hash is calculated and stored on the blockchain. If a deepfake is subsequently generated by manipulating this original content, the hash of the deepfake will invariably be different. Comparing this new hash to the original one stored on the blockchain provides irrefutable evidence of tampering. Blockchain also facilitates decentralized verification mechanisms where multiple participants within a network can independently verify the authenticity of digital content. This process can involve a consensus mechanism where network nodes vote on the authenticity of a given piece of media, potentially incentivized through rewards for accurate verification. Decentralized verification through blockchain can mitigate the risks of bias and single points of failure that are inherent in centralized verification systems. Instead of relying on a single organization or algorithm to determine if content is a deepfake, a blockchain-based system can harness the collective intelligence of a distributed network. This collaborative approach can lead to more accurate and unbiased verification outcomes, as multiple independent parties contribute to the process. Furthermore, blockchain can be used to secure blockchain-based digital watermarking. Digital watermarks containing crucial information about the content's origin and history can be embedded within the media itself, and their integrity can be protected by anchoring them to the blockchain [15]. This provides a tamper-proof method for tracking the provenance of the content [21]. Linking digital watermarks to the blockchain significantly enhances their security and makes them far more resistant to tampering or removal. While traditional digital watermarks may be susceptible to alteration or removal, anchoring the information within the watermark, such as the creator's ID, a timestamp, and the original hash of the content, to the blockchain safeguards its authenticity and integrity through the blockchain's immutable nature.

Ultimately, blockchain-based decentralized identity (DID) solutions can provide a secure and verifiable method for identifying content creators. Creators can cryptographically sign their content using their private key, and this signature can be verified by anyone using their corresponding public key, which is securely stored on the blockchain. This process effectively establishes ownership and attribution of the content. Utilizing blockchain-based decentralized identities can establish clear ownership and provenance for digital content, making it considerably easier to identify manipulated versions and to hold malicious actors accountable for their actions. When a content creator registers their identity on the blockchain and signs their work with their unique private key, it creates an irrefutable link between the creator and the content. This enables the verification of the media's origin and the tracking of its distribution across the internet, significantly aiding in the detection of any unauthorized alterations.

A. Blockchain-Based Approach

Employing blockchain technology for deep-fake detection offers several compelling benefits that address the limitations of current methods, as shown in Algorithm I. Blockchain provides an immutable and transparent record of the origin and history of digital content, significantly improving content provenance. Every modification or instance of sharing the content can be recorded on the blockchain, creating a comprehensive and traceable audit trail. This detailed history makes it considerably easier to identify the authentic version of the content and to detect any subsequent manipulations. The ability to trace the entire lifecycle of digital media on the blockchain significantly enhances content provenance and facilitates the identification of deepfakes. By recording every stage of a digital asset's existence, from its initial creation to any subsequent modifications and its distribution across the internet, a comprehensive historical record is established. This detailed provenance information allows for straightforward verification of whether a piece of content has been altered from its original, authentic state.

The inherent transparency and immutability of blockchain technology can substantially increase user trust in the authenticity of digital media. Users are empowered to independently verify the provenance and integrity of the content they encounter. The inherent trust mechanisms of blockchain can help combat the growing erosion of trust in digital media, caused by the increasing prevalence of deepfakes. In an online environment where distinguishing between real and fake content is becoming increasingly challenging, blockchain offers a technological solution that provides verifiable proof of authenticity. This transparency and the assurance of immutability can help rebuild trust in digital media by empowering users to verify information for themselves, rather than relying on potentially fallible centralized authorities.

B. Algorithm I: Blockchain and Watermark-Based Deepfake Detection Framework

1. Input a video file into the system.
2. Split the video into three components: audio, image frames, and video stream.
3. Generate perceptual hashes for the audio and image/video components to create unique content IDs.
4. Extract visual and audio features from the image and video components.
5. Use the extracted features to create fragile watermarks and secret keys.
6. Store the generated watermarks and keys on a secure blockchain ledger.
7. Embed the fragile and robust watermarks into the video components using watermarking techniques.
8. Recombine (merge) the watermarked audio, image, and video into a final watermarked video.
9. Send the metadata and watermarked video to the deepfake detection module.
10. Analyze the content for authenticity and detect any deep-fake manipulation using the embedded watermarks and blockchain metadata.
11. Verify the integrity and originality of the video using blockchain and watermark data.
12. Output the verified and watermarked video along with detection results.

Blockchain enables the creation of decentralized networks for content verification, allowing multiple independent parties to contribute to and benefit from shared knowledge and

verification efforts. This decentralized approach can lead to more robust and accurate detection outcomes through community-driven models of verification. Decentralized verification on the blockchain can leverage collective intelligence and reduce reliance on potentially biased or flawed centralized systems. By distributing the task of verifying content across a network of participants, a blockchain-based system can tap into a broader range of expertise and perspectives. This collaborative approach has the potential to enhance the accuracy and reliability of deepfake detection, as it mitigates the risk of errors or biases that might be inherent in a single centralized authority or algorithm.

The decentralized and cryptographically secured nature of blockchain enhances the security of provenance data and offers improved privacy. Furthermore, decentralized identity solutions built on blockchain can provide users with greater control over their data used in verification processes. Blockchain can provide a more secure and privacy-preserving infrastructure for verifying media authenticity compared to traditional centralized databases, which are often more vulnerable to breaches and unauthorized access. The cryptographic security inherent in blockchain, coupled with its decentralized structure, makes it a highly secure platform for storing sensitive information related to content provenance. Additionally, decentralized identity solutions built on blockchain can empower individuals to manage their identity data, enhancing privacy throughout the verification process.

Blockchain technology enables the accurate timestamping of data, thereby establishing a precise chronological order of content creation or publication. This timestamping can be particularly crucial for identifying manipulated content, as it provides a verifiable timeline. The timestamping feature of blockchain provides valuable temporal context that can help distinguish original content from later manipulations. Knowing the exact time when a piece of digital media was created and immutably recorded on the blockchain can be a critical factor in identifying deepfakes. For example, suppose a video purports to depict an event that allegedly occurred before the recorded creation time of the video on the blockchain. In that case, it will strongly suggest that the video has been manipulated or is entirely fabricated.

IV. Performance Evaluation

In the simulation of multimodal data for deepfake detection based on blockchain watermarking, a comprehensive set of parameters is configured to ensure robust performance and security. The simulation involves a dataset comprising both authentic and manipulated video and image content, sourced from publicly available benchmarks such as FaceForensics++, Celeb-DF, and Deepfake Detection Challenge datasets. Each video is processed at a resolution of 720p with a frame rate of 30 frames per second (FPS). At the same time, images are standardized to 224x224 pixels for consistency during training and inference using a MobileNetV2-based deep learning model. For watermarking, a unique, tamper-proof digital watermark is embedded into each frame and image using a frequency domain technique, such as the DWT-DCT hybrid or singular value decomposition (SVD), ensuring both imperceptibility and robustness. The embedded watermark is linked to a blockchain network using smart contracts deployed on an Ethereum testnet via Web3.py. Each transaction logs metadata, including the hash of the media content, timestamp, owner ID, and verification key. During detection, real-time feature extraction and watermark verification are performed concurrently, using OpenCV and TensorFlow to compare the embedded watermark against the blockchain-registered hash. The simulation also accounts for multiple sharing scenarios (e.g., social media platforms such as Facebook, Twitter, YouTube, and LinkedIn) and evaluates watermark resilience against compression, resizing, cropping, and format conversion. Performance metrics, including accuracy, precision, recall, F1-score, PSNR, SSIM, and blockchain transaction latency, are monitored to assess the system's capability to detect tampered content. Additionally, a GUI interface (built with Streamlit or Tkinter) visualizes results and logs verified or fake media instances into a local SQLite database or cloud-based storage, ensuring traceability and trust in media authenticity. All the details are shown in Table II, III, and IV.

TABLE II Simulation Parameters

Simulation	Parameters
Language	Ethereum and WEB3
Blockchain	Public Blockchain
Workload	Images, Videos
Training Dataset	Based on Watermarking and Blockchain
Nodes	Client and Social Media
Metrics	Accuracy, Precision, Recall, and F1-Score
Simulation Time	24 Hours

TABLE III Dataset Descriptions

Dataset	Real Videos	Fake Videos
UADFV	49	49
DFFD	1000	3000
Celeb-DF	590	5639
DFDC	23,564	104,500
DeeperForensics-1.0	50,000	10,000
FaceForensic++	1000	5000

TABLE IV Image Datasets

Dataset	Real Images	Fake Images
DFFD	58,703	240,336
FFHQ	60,000	70,000 GAN
iFakeFaceDB	80,000	87,000 GAN
100k Faces	10,0000	100,000 (GAN)
ForgeryNet	1,438,201	1,457,861

A. Result Analysis

Fig. 2 shows the blockchain-enabled watermarking training and validation for "Deepfake Dataset — Real versus Fake Image Counts", offers a comprehensive comparison of real and fake image samples across several widely used deepfake datasets. This visualization provides critical insights into the scale and distribution of data used in deepfake detection research.

The blockchain-enabled weather-marketing trade training based on datasets varies significantly in size and structure:

- Smaller datasets like UADFV maintain a balanced ratio of real and fake images (49 each), useful for initial model testing and evaluation.
- Moderate-sized datasets such as Deepfake-TIMIT, DFFD, Celeb-DF (v2), and FaceForensic++ show a noticeable skew, with fake samples outnumbering real ones by up to 5x in some cases. For example, DFFD contains 3000 fake vs. 1000 real images, and Celeb-DF (v2) includes 5639 fake vs. 590 real images.
- Larger datasets like DFDC and ForgeryNet provide an extensive volume of training material, critical for deep learning. DFDC hosts over 104,000 fake images compared to ~23,500 real ones, while ForgeryNet features nearly 100,000 real and over 120,000 fake samples.
- DeeperForensics-1.0 stands out for its inverse distribution, containing more real (50,000) than fake (10,000) samples — offering an alternative dynamic for model training.

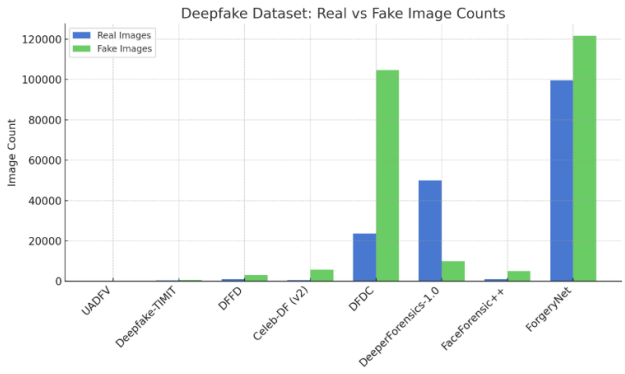

Fig. 2. Result analysis of trained real and fake images based on blockchain watermarking.

This graph highlights the prevalent imbalance between real and fake images in most datasets, underlining the need for careful model training techniques, such as data augmentation, sampling strategies, or synthetic data balancing. Overall, it provides a foundational reference for researchers developing and benchmarking deep-fake detection models.

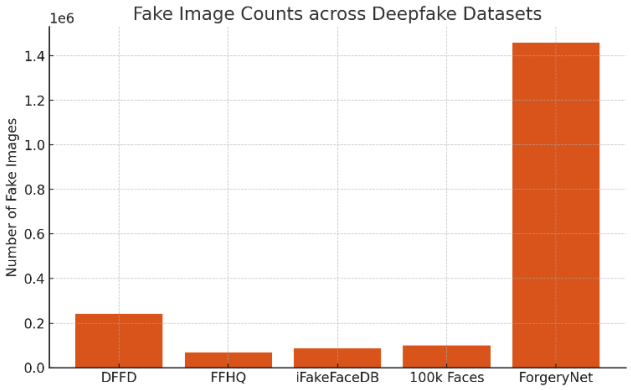

Fig. 3. Image video detection analysis based on blockchain watermarking.

Fig. 3 shows the video dataset training on the blockchain, and watermarking techniques based on the given data.

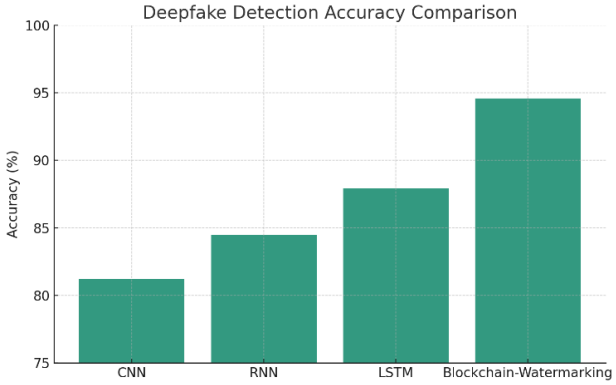

Fig. 4. Blockchain watermarking comparison with existing CNN, RNN and LSTM.

Fig. 4 shows the "Deepfake Detection Accuracy Comparison", which visually presents the accuracy performance of four different models or techniques used for detecting deepfake content. The models compared are CNN, RNN, LSTM, and a Blockchain-Watermarking-based approach. According to the chart, the CNN model achieves an accuracy of approximately 81%, while the RNN model performs slightly better at around 84.5%. The LSTM model shows further improvement with an accuracy close to 88%. However, the blockchain-watermarking approach significantly outperforms the others, reaching an accuracy of nearly 95%. This indicates that the integration of blockchain and watermarking methods greatly enhances the accuracy of deepfake detection compared to traditional machine learning models, suggesting the potential of hybrid systems in improving the reliability and security of deepfake detection frameworks.

V. Conclusion and Future Directions

In conclusion, deepfake technology presents a significant and evolving threat to the integrity of digital information, necessitating the development and implementation of robust detection methods. While current AI-based techniques have made considerable progress, they are not without limitations, including challenges in generalization, reliance on extensive datasets, and a continuous arms race with deepfake generation advancements. This landscape creates a compelling opportunity for complementary solutions, and blockchain technology, with its inherent characteristics of immutability, transparency, and decentralization, offers a promising avenue for enhancing deepfake detection capabilities.

The application of blockchain through cryptographic hashing, decentralized verification mechanisms, blockchain-based digital watermarking, and decentralized identity for content creators can significantly improve content provenance, increase user trust in digital media, and enable more collaborative and resilient verification processes. The benefits of this approach include a tamper-proof record of content origin and history, the empowerment of users to independently verify authenticity, the leveraging of collective intelligence for detection, enhanced data security and privacy, and the provision of crucial temporal context through timestamping.

However, the implementation of blockchain for deepfake detection is not without its challenges. Concerns regarding scalability, computational costs, the complexity of integration with existing systems, the critical need for widespread adoption and standardization, the constantly evolving nature of both deepfake and blockchain technologies, the potential for misuse if cryptographic keys are compromised, and the fundamental issue of ensuring the authenticity of data at the point of initial registration all need to be carefully addressed.

Despite these challenges, the emergence of several promising blockchain-based solutions and initiatives demonstrates the growing recognition of this technology's potential in combating deepfakes. These efforts often focus on leveraging blockchain's immutability for provenance tracking, its decentralized nature for verification, and cryptographic signatures for authentication.

Looking towards the future, several directions warrant further exploration. Research into hybrid approaches that seamlessly integrate the strengths of AI-based detection with the verifiable provenance and security offered by blockchain is crucial. The development of more scalable and cost-effective blockchain solutions tailored for media authentication will be essential for widespread adoption. Establishing industry-wide standards for blockchain-based content provenance and verification will foster interoperability and facilitate broader implementation. The integration of decentralized identity solutions for both creators and consumers of digital media can further enhance trust and accountability. Moreover, future efforts could explore blockchain's role not only in detecting but also in potentially preventing the creation and spread of malicious deepfakes through mechanisms like content registration at the point of creation. Finally, addressing the "garbage in, garbage out" problem by developing robust methods to ensure the authenticity of content before it is recorded on the blockchain will be critical for the overall integrity of these systems.

In conclusion, blockchain technology holds significant potential to play a vital role in safeguarding the integrity of digital media in an era increasingly challenged by sophisticated AI-generated forgeries. Continued innovation, research, and collaboration across various sectors will be essential to fully realize this potential and build a more trustworthy digital landscape where the authenticity of information can be reliably established.

Advancements in Deep Learning for Malaria Detection: A Comprehensive Overview

Kiswendsida Kisito Kaboré, Désiré Guel, Flavien Hervé Somda
Department of Computer Science, Joseph KI-ZERBO (U-JKZ), Burkina Faso

***Abstract*—Malaria remains a critical global health issue, with millions of cases reported annually, particularly in resource-limited regions. Timely and accurate diagnosis is vital to ensure effective treatment, reduce complications, and control transmission. Conventional diagnostic methods, including microscopy and Rapid Diagnostic Tests (RDTs), face considerable limitations such as dependency on skilled personnel, limited sensitivity at low parasitemia levels, and cost constraints. In response, deep learning technologies—especially Convolutional Neural Networks (CNNs)—have emerged as promising tools to overcome these barriers by enabling automated diagnostics based on medical imaging, significantly enhancing precision and scalability. This paper presents a comprehensive review of recent advances in deep learning for malaria diagnosis, highlighting the role of publicly available datasets in driving innovation. It analyzes leading architectures—such as ResNet, VGG, and YOLO—based on their classification performance, including accuracy, sensitivity, and computational efficiency. Furthermore, the review discusses novel directions such as mobile-integrated diagnostics and multimodal data fusion, which can enhance diagnostic accessibility in low-resource settings. Despite notable progress, challenges remain in terms of dataset imbalance, lack of generalizability, and barriers to clinical deployment. The paper concludes by outlining future research directions and emphasizing the need for robust, adaptable models that can support global malaria control and eradication strategies.**

***Keywords*—Malaria detection; deep learning; Convolutional Neural Networks (CNNs); medical imaging; automated diagnostics**

I. Introduction

Malaria remains one of the most significant global health challenges; this affects millions of individuals annually, particularly in resource-limited regions such as sub-Saharan Africa, Southeast Asia and Latin America. According to the World Health Organization (WHO) over 247 million cases were reported in 2021, with a disproportionate impact on children under five and pregnant women [1]. Early and accurate detection of malaria is critical for effective treatment, prevention of severe complications and reducing transmission rates. The availability of reliable diagnostic tools can directly contribute to reduce the global malaria burden and advance efforts toward its eradication.

Traditional diagnostic methods which include microscopy and Rapid Diagnostic Tests (RDTs) have been widely used for malaria detection. Microscopy, considered the gold standard, involves examining stained blood smears under a microscope to identify malaria parasites [2]. However, this method is labor-intensive, time-consuming and highly dependent on the skill of trained personnel. Similarly, RDTs, although faster and more accessible, often lack sensitivity particularly at low parasite densities or in mixed infections [3, 4]. Molecular techniques like Polymerase Chain Reaction (PCR) provide higher precision but are costly and require sophisticated infrastructure. This makes them impractical in many malaria-endemic regions [5, 6]. These limitations underscore the need for innovative, automated and scalable diagnostic approaches.

Recent advancements in deep learning have shown transformative potential in malaria detection. Convolutional Neural Networks (CNNs) and other deep learning architectures have demonstrated the ability to analyze blood smear images with accuracies exceeding 95%, achieving performance comparable to or even surpassing traditional diagnostic methods [7, 8]. Furthermore, lightweight and efficient models tailored for mobile applications are expanding access to automated diagnostics in remote and underserved areas [9]. Deep learning enables rapid, accurate and consistent diagnostics. Significantly, it reduces dependence on human expertise and supports large-scale epidemiological monitoring.

This paper provides a comprehensive overview of the advancements in deep learning applied to malaria detection. It explores publicly available datasets, state-of-the-art architectures and their performance metrics. By analyzing the strengths and limitations of various approaches, this review aims to identify key gaps and propose potential future directions. Specifically, this paper seeks to:

- Highlight the significance of publicly available datasets, such as the NIH dataset and Delgado Dataset B and their role in advancing malaria detection research [10, 11].
- Evaluate the performance and applicability of deep learning architectures such as ResNet, VGG, YOLO and hybrid models [12, 13, 14].
- Discuss the challenges faced in deploying these models in real-world scenarios, including resource-limited environments [15, 16].
- Propose strategies to address dataset limitations, model generalization and integration into healthcare systems [17, 14].

This article has been structured to provide a comprehensive overview of advancements in deep learning for malaria detection. Section I introduced the global impact of malaria and the challenges associated with traditional diagnostic methods. Section III presented an overview of publicly available datasets, highlighting their characteristics and limitations. Section IV discussed deep learning architectures and hybrid models, emphasizing their strengths and weaknesses in malaria detection. Section V compared the performance of various

models, with a focus on metrics such as accuracy, sensitivity and computational efficiency, while also analyzing the impact of dataset characteristics. Section VI synthesized the key findings, addressed challenges in scalability and robustness, and proposed future directions. Finally, Section VII concluded the paper by summarizing the key contributions and outlining potential avenues for further research and implementation in real-world healthcare settings.

II. Related Work

Several studies have explored the use of deep learning techniques in the detection and diagnosis of malaria from microscopic blood smear images. This section presents a comparative analysis of prominent contributions in this domain, highlighting the methods used, datasets employed, and performance outcomes.

A. CNN-Based Malaria Detection Approaches

Early works, such as that by Rajaraman et al. [10], utilized convolutional neural networks (CNNs) trained on publicly available thin smear datasets, achieving accuracy levels above 95%. Similarly, Vijayalakshmi and Kanna [18] proposed a transfer learning model based on VGG19-SVM, reporting an accuracy of 93.1%. More recent approaches, including the work of Sriporn et al. [19], integrated state-of-the-art CNN architectures like Xception and ResNet-50, obtaining F1-scores exceeding 98%.

B. Use of Object Detection and Multi-Class Models

In contrast to binary classification models, Manescu et al. [20] developed an end-to-end object detection pipeline for detecting parasites in Thick Blood Films (TBF) using DeepM-CNN, which achieved expert-level sensitivity (0.92) and specificity (0.90). This work also provided parasite load estimates, contributing toward WHO-compliant diagnostic standards.

C. Dataset Variability and Limitations

Most studies rely on the NIH malaria dataset, which, although accessible, is limited in terms of geographic diversity and class imbalance. Yunda et al. [21] explored detection of P. vivax parasites using wavelet-based features and PCA, illustrating the potential for species-specific classification, though with lower true positive rates ($\sim$ 77%).

D. Comparison and Limitations of Prior Work

A comparative analysis of key deep learning-based studies for malaria detection is essential to identify prevailing strengths, methodological trends, and common limitations in the field. Table I summarizes representative works, highlighting the models employed, datasets used, and reported accuracy or sensitivity metrics. This comparison facilitates a critical understanding of performance benchmarks and underscores the need for generalizable and clinically deployable diagnostic models.

TABLE I. Summary of Prior Deep Learning-based Malaria Detection Studies

Authors	Models/Methods	Datasets	Accuracy (%)
Rajaraman et al. (2018) [10]	Pretrained CNN	NIH Dataset	95.0
Vijayalakshmi et al. (2019) [8]	VGG19 + SVM	Custom Dataset	93.1
Sriporn et al. (2020) [19]	Xception, ResNet	7k Image Set	99.3
Manescu et al. (2020) [20]	DeepMCNN	Clinical TBF Images	92.0 (Sens.)

E. Positioning of the Present Study

While the aforementioned studies demonstrate the utility of CNNs for malaria diagnosis, they often overlook integration with mobile platforms, generalizability across datasets, or WHO-aligned parasitemia estimation. The present study builds upon these foundations by reviewing recent deep learning models in conjunction with dataset limitations, emerging trends in mobile diagnostics, and strategies for real-world deployment.

III. Publicly Available Datasets for Malaria Detection

The availability of publicly accessible datasets has been instrumental in advancing deep learning research for malaria detection. They provide a foundation for training, validation and benchmarking of models in diverse diagnostic scenarios.

A. Overview of Datasets

Datasets play a critical role in advancing deep learning applications for malaria detection. Datasets provide the necessary labeled data to train and evaluate models. Publicly available datasets have enabled researchers to benchmark the performance of various architectures and facilitate reproducibility in research. This section provides an overview of four widely used datasets, highlighting their characteristics and significance in the field.

1) NIH dataset: The NIH Dataset is one of the most widely used datasets for malaria detection research due to its size and quality. It consists of 27,558 labeled cell images, classified into two categories: parasitized and uninfected cells [7, 11]. The images are derived from thin blood smears and are suitable for training deep learning models for binary classification tasks. This dataset is balanced and well-annotated which supports robust training and evaluation. Its large size and diversity have enabled models such as ResNet and DenseNet to achieve high accuracy, often exceeding 95%. However it primarily focuses on binary classification and does not account for variations in *Plasmodium* species which limits its use for species-specific tasks.

2) Delgado dataset B: Delgado Dataset B consists of 331 high-resolution images of Giemsa-stained thin blood smears [3]. This dataset is particularly valuable for fine-grained analysis and morphological studies of malaria parasites. Its high-quality images enable the evaluation of advanced architectures such as ResNet and YOLO which rely on detailed visual features. Although smaller in size compared to the NIH Dataset, Delgado Dataset B provides valuable insights into the

structural characteristics of parasitized cells. Its limited size necessitates the use of data augmentation or transfer learning techniques to achieve robust model performance.

3) Dijkstra dataset: The Dijkstra Dataset comprises 883 images of thick and thin blood smears primarily focusing on *Plasmodium falciparum* detection [22]. This dataset offers diversity in smear types and enables researchers to evaluate model performance across different diagnostic settings. The inclusion of both thick and thin smears makes it a unique resource for testing models designed to generalize across various smear preparation techniques. Despite its strengths, the dataset's limited size poses challenges for training deep neural networks without the aid of data augmentation or pre-trained models.

4) Malaria-LMIC dataset: The Malaria-LMIC Dataset [23, 16] simulates real-world conditions encountered in low-resource settings wih approximately 5,000 images. This dataset is characterized by challenges such as low image quality, diverse environmental conditions and class imbalance. These attributes make it ideal for testing the robustness and adaptability of deep learning models. By replicating real-world scenarios, the dataset emphasizes the importance of lightweight architectures and efficient preprocessing techniques to handle noisy and diverse inputs. It is particularly useful for evaluating the feasibility of deploying models in resource-constrained environments.

Table II summarizes the characteristics of these datasets and provides a quick reference for researchers to identify the most suitable dataset for their specific tasks.

TABLE II. PUBLICLY DATASETS FOR MALARIA DETECTION

Dataset	Size	Key Features
NIH Dataset	27,558	Balanced classes, binary classification, thin smears
Delgado Dataset B	331	High-resolution images, morphological analysis
Dijkstra Dataset	883	Thick and thin smears, *P. falciparum* focus
Malaria-LMIC Dataset	5,000	Real-world conditions, low image quality, class imbalance

These datasets collectively provide a foundation for advancing deep learning research in malaria detection. Their unique characteristics cater to diverse research needs, ranging from robust binary classification to handling real-world diagnostic challenges.

B. Dataset Characteristics

The quality and characteristics of datasets play a crucial role in determining the effectiveness and reliability of deep learning models for malaria detection. This subsection examines the size, diversity, and class balance of commonly used datasets and analyzes their impact on model performance.

1) Size, Diversity and Class Balance: Datasets for malaria detection vary significantly in terms of size, diversity and class distribution which directly influence the robustness and generalizability of trained models. Larger datasets, such as the NIH dataset containing over 27,000 labeled cell images, provide extensive training opportunities, enabling models to learn complex patterns and achieve better generalization [11]. However, smaller datasets like the Delgado Dataset B (331 images) often require augmentation or transfer learning techniques to compensate for their limited size [14].

Diversity is another critical factor, as datasets should encompass images from different populations, geographical regions and imaging conditions. Datasets such as the Malaria-LMIC dataset attempt to replicate real-world variability by including low-quality and diverse smear images, simulating the challenges encountered in resource-constrained environments [23].

Class balance also plays a vital role in model performance. Many datasets exhibit imbalanced distributions, with a significantly higher number of uninfected cells compared to parasitized ones. This imbalance can lead to biased models that perform poorly on minority classes, such as parasitized cell detection. Addressing this imbalance through data augmentation or synthetic oversampling is essential for improving model fairness and reliability.

Table III summarizes the key characteristics of commonly used datasets for malaria detection.

TABLE III. CHARACTERISTICS OF COMMON MALARIA DETECTION DATASETS

Dataset	Size	Diversity	Class Balance
NIH Dataset	27,558 images	High	Balanced
Delgado Dataset B	331 images	Low	Imbalanced
Dijkstra Dataset	883 images	Medium	Balanced
Malaria-LMIC Dataset	5,000 images	High	Imbalanced

2) Impact on model performance: Dataset characteristics have a profound impact on the performance of deep learning models. Larger datasets, such as the NIH dataset, contribute to higher model accuracy and generalizability due to their extensive data coverage [7]. In contrast, models trained on smaller datasets, like Delgado Dataset B, often exhibit overfitting and reduced robustness unless enhanced by transfer learning or data augmentation techniques [12].

Diverse datasets are crucial for ensuring that models can generalize across varied clinical settings and imaging conditions. For instance, the Malaria-LMIC dataset, despite its smaller size, provides valuable insights into real-world scenarios by incorporating low-quality images which helps evaluate the robustness of models under challenging conditions [23]. Class imbalance, if not addressed, can significantly impact performance metrics such as sensitivity and specificity, particularly in detecting parasitized cells.

The importance of dataset characteristics is visually represented in Fig. 1 and Fig. 2. Fig. 1 highlights the disparity in dataset sizes, while Fig. 2 emphasizes the relative importance of key attributes, such as image quality, size, diversity and class balance, in determining model effectiveness.

Understanding and addressing these dataset characteristics is essential for building robust, scalable and clinically viable deep learning models for malaria detection.

C. Challenges with Existing Datasets

The effectiveness of deep learning models in malaria detection largely depends on the quality, diversity and represen-

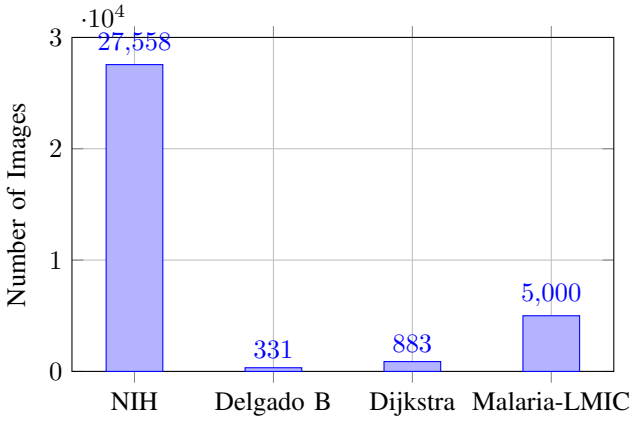

Fig. 1. Dataset sizes for malaria detection.

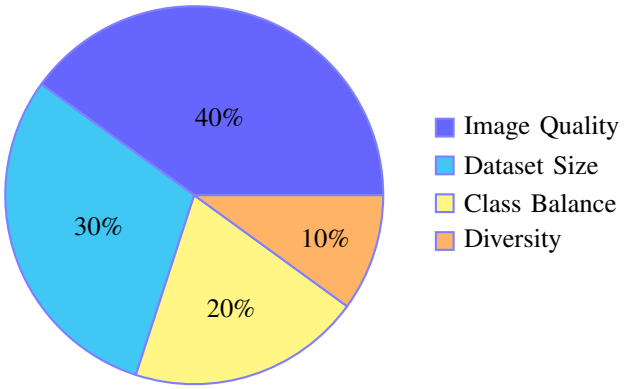

Fig. 2. Dataset characteristics.

tativeness of the datasets used during training and evaluation. However, existing datasets face several challenges that limit their applicability and generalization to real-world scenarios.

The statistics depicted in Fig. 2 highlight the relative importance of various dataset characteristics in determining the performance of deep learning models for malaria detection. Image quality accounts for 40% of the impact, emphasizing the significance of high-resolution, well-annotated images for extracting meaningful features. Dataset size contributes 30%, underlining the importance of large datasets to ensure robust learning and generalization. Class balance, representing 20%, addresses the need to mitigate biases caused by imbalanced datasets which can lead to skewed predictions. Finally, diversity constitutes 10% and reflects the role of heterogeneous imaging conditions and geographic variations in enhancing model adaptability and robustness across real-world settings.

1) Limited diversity and annotation quality: Most publicly available datasets, such as the NIH dataset [7], consist of images collected under controlled conditions with limited geographical and environmental diversity. These datasets often fail to capture the variations in blood smear preparation, staining techniques and imaging equipment prevalent across different regions. As a result, models trained on such datasets may exhibit reduced performance when applied to samples from diverse clinical settings.

Annotation quality is another critical issue. The process of labeling blood smear images requires significant domain expertise, especially for identifying parasitized cells and distinguishing between different *Plasmodium* species. Errors or inconsistencies in annotations can introduce biases, leading to inaccurate predictions and reduced model reliability [14].

To illustrate the distribution of dataset diversity and quality challenges, Table IV summarizes the characteristics of major malaria detection datasets, while Fig. 3 highlights the importance of key dataset attributes such as diversity, quality and size.

2) Class imbalance and its implications: Class imbalance is a prevalent issue in malaria datasets, where the number of uninfected cell images often exceeds that of parasitized cell images. This imbalance can lead to biased models that are overly sensitive to the majority class, reducing sensitivity and recall for detecting infected cells [23]. Addressing this imbalance is crucial, as it directly impacts the ability of models to accurately diagnose malaria, particularly in low-parasitemia samples.

Data augmentation techniques, such as synthetic data generation, flipping and rotation, have been employed to mitigate class imbalance. However, these approaches often fall short of replicating the complexity and variability of real-world data. Fig. 3 visually represents the impact of class imbalance and dataset characteristics on model performance.

TABLE IV. CHARACTERISTICS OF MAJOR DATASETS FOR MALARIA DETECTION

Dataset	Image Type	Size	Key Features
NIH Dataset	Cell images	27,558	Parasitized/Uninfected, Thin Smears
Delgado Dataset B	Thin smears	331	High-Resolution, Giemsa-Stained
Dijkstra Dataset	Thick and Thin Smears	883	Focus on *Plasmodium falciparum*
Malaria-LMIC	Real-world images	5,000	Diverse, Low-Quality Challenges

IV. DEEP LEARNING ARCHITECTURES FOR MALARIA DETECTION

The rapid advancements in deep learning have revolutionized the field of medical imaging and offer innovative solutions for automated malaria detection by leveraging powerful CNNs and other state-of-the-art architectures.

A. Convolutional Neural Networks (CNNs)

CNNs are fundamental in applying deep learning to malaria detection, excelling in automatically extracting hierarchical features from medical images. This subsection reviews key CNN architectures—ResNet [24], VGG [8], YOLO [25], MobileNet [15], and DenseNet [13]—highlighting their advantages and drawbacks in malaria diagnostics. ResNet's residual learning enables very deep models but may be computationally heavy. VGG offers simplicity and strong feature extraction at a high resource cost. YOLO is valued for real-time detection, ideal for field diagnostics. MobileNet provides efficient lightweight performance for mobile platforms. DenseNet enhances feature reuse and accuracy but requires significant computation.

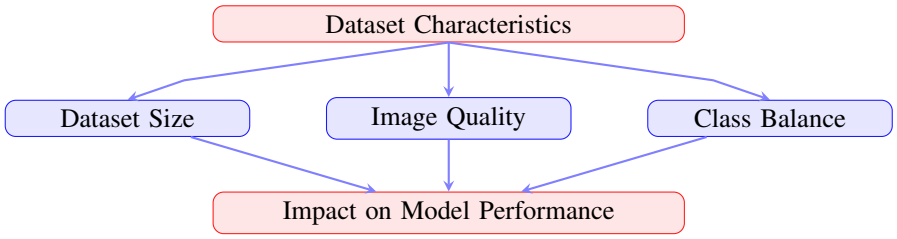

Fig. 3. Dataset characteristics on model performance.

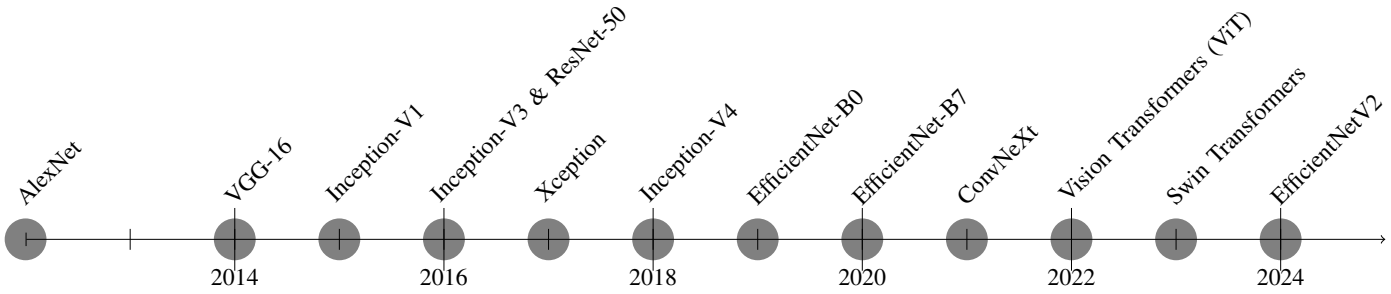

Fig. 4. CNN Architectures timeline (2012-2024).

Fig. 4 illustrates the evolution of CNNs from AlexNet to EfficientNetV2, marking key milestones in image analysis.

1) AlexNet: AlexNet [26] was the first deep CNN to achieve groundbreaking image classification results by deepening network capacity and applying optimization strategies.

2) ResNet: ResNet introduces skip connections to tackle vanishing gradients, allowing deeper networks like ResNet-50 to perform well. It achieves up to 97% accuracy on datasets such as NIH [11, 8], though its resource demands may limit use in low-resource settings [24].

3) VGG: VGG16/VGG19 [27] feature stacked convolutional layers, offering high accuracy and implementation simplicity but with high memory requirements, limiting mobile diagnostic deployment.

4) YOLO: YOLO [28, 25] detects objects in real time by predicting bounding boxes in a grid. Effective for fast malaria detection, but less accurate for small objects [2].

5) MobileNet: MobileNet [15, 29] uses depthwise separable convolutions to reduce computations, suitable for mobile deployment despite slight accuracy trade-offs [20].

6) DenseNet: DenseNet [30, 27] connects each layer to all previous ones, improving gradient flow and reducing parameters. It excels with small or imbalanced datasets but demands high computation [13, 31].

B. Transfer Learning Models

Transfer learning has emerged as a powerful approach in deep learning, particularly advantageous in scenarios where the availability of large, labeled datasets is limited—a common challenge in medical imaging, including malaria detection. By leveraging pre-trained models, transfer learning enables the adaptation of existing architectures trained on extensive datasets to specific tasks, significantly reducing the need for domain-specific annotated data.

Pre-trained models such as InceptionV3 and Xception have shown remarkable success in malaria detection tasks. As noted by Rajaraman et al. (2019) [7], InceptionV3, known for its efficient inception modules, is particularly effective at learning complex spatial hierarchies in blood smear images. This model has demonstrated accuracy levels exceeding 95% when fine-tuned on malaria datasets, such as the NIH dataset. Similarly, Sriporn et al. (2020) [19] highlight that Xception, which employs depthwise separable convolutions, achieves superior feature extraction with reduced computational costs. These attributes make it highly suitable for malaria detection, especially in resource-constrained settings.

The primary benefit of transfer learning lies in its ability to address the challenges of data scarcity. In medical imaging, obtaining large-scale, high-quality labeled datasets often requires significant expertise and resources, which may not be feasible in low-resource regions. Transfer learning alleviates this issue by reusing knowledge from models pre-trained on general-purpose image datasets, such as ImageNet, and adapting them to malaria detection. This approach not only reduces the computational burden but also enhances the performance of models on smaller, specialized datasets.

Additionally, Masud et al. (2020) [16] explain that transfer learning facilitates faster convergence during training, as the initial layers of the pre-trained model already contain well-established feature extraction capabilities. This enables researchers to focus on fine-tuning the higher-level layers to capture task-specific patterns, such as the morphological differences between parasitized and uninfected blood cells. The use of pre-trained architectures like InceptionV3 and Xception thus provides a robust foundation for achieving high diagnostic accuracy in malaria detection without the extensive computational resources typically required for training models

from scratch.

C. Hybrid and Ensemble Learning Approaches

Hybrid and ensemble learning approaches have emerged as effective strategies to enhance the accuracy and robustness of malaria detection systems. These methods combine the strengths of CNNs with traditional machine learning classifiers or integrate multiple deep learning models to address limitations such as overfitting, class imbalance and dataset variability [18]. By leveraging ensemble methods like VGG-19 combined with SqueezeNet or ResNet with Gradient Boosting, researchers have achieved significant improvements in sensitivity and specificity for malaria classification tasks [24]. These techniques also mitigate the impact of dataset variability, particularly in real-world applications where diverse and unbalanced data present substantial challenges [15, 8].

One prominent hybrid approach as showned in Fig. 5 involves using CNNs for feature extraction followed by classification using traditional machine learning algorithms, such as Support Vector Machines (SVMs).

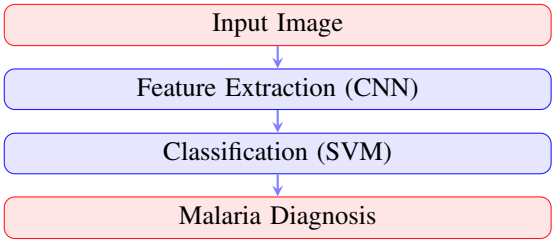

Fig. 5. CNN-SVM Hybrid approach for malaria detection.

TABLE V. TIMELINE OF CNN-SVM HYBRID MODELS DEVELOPMENT (2012-2023)

Year	Development and contribution	References
2012	Yunda et al. proposed hybrid CNNs with feature extraction for malaria detection.	[21]
2015	Gu et al. highlighted the integration of CNNs with classifiers like SVM for robust feature-based tasks.	[30]
2017	Srinivas et al. emphasized using hybrid CNN-SVM approaches for specific computer vision problems.	[32]
2019	Vijayalakshmi and Kanna developed VGG-SVM hybrids for malaria detection with improved accuracy.	[18]
2020	Yang et al. utilized CNN-SVM combinations to enhance mobile malaria detection systems.	[15]
2021	Nakasi et al. integrated CNN-SVM models for thick blood smear malaria detection and smartphone deployment.	[24]
2023	Jiang et al. explored advanced SVM integration for generalization in medical imaging.	[33]

Table V shows the evolution of CNN-SVM hybrid models from their early applications in malaria detection and general computer vision tasks to their refinement for medical imaging and real-world deployment. It highlights significant studies and innovations in using SVM to enhance CNN-based feature extraction and classification.

For example, Fuhad et al. (2020) demonstrated a CNN-SVM hybrid model that achieved an accuracy of 95.8% on a dataset of thin blood smear images [17]. In this framework, the CNN layers extract complex spatial features from the images which are then fed into an SVM for classification. This combination leverages the feature extraction capabilities of CNNs while benefiting from the robust decision boundaries provided by SVMs.

This hybrid approach is particularly advantageous in scenarios with limited datasets or class imbalance, where traditional deep learning classifiers might struggle to achieve high generalization.

Ensemble learning combines predictions from multiple models to improve diagnostic robustness and reduce variance. Rajaraman et al. (2019) developed an ensemble of VGG-19 and SqueezeNet architectures, achieving sensitivity and specificity values of 97.3% and 96.8%, respectively [7]. By leveraging the diverse strengths of individual models, ensemble methods effectively address variability in image quality and dataset characteristics.

Table VI shows the performance of key ensemble learning methods for malaria detection, highlighting their strengths in handling diverse data.

TABLE VI. PERFORMANCE OF ENSEMBLE LEARNING METHODS FOR MALARIA DETECTION

Ensemble Method	Accuracy (%)	Key Insights
VGG-19 + SqueezeNet [8]	97.3	High sensitivity and specificity
Inception-v3 + MobileNet [15]	98.5	Enhanced recall, ideal for field settings
ResNet + Gradient Boosting [24]	98.2	Robust feature extraction for complex data
EfficientNet + XGBoost [34]	98.8	Superior performance on imbalanced datasets
Xception + Random Forest [19]	97.9	Improved computational efficiency and accuracy
DenseNet + Logistic Regression [16]	98.1	Effective in reducing false negatives in parasite detection

V. PERFORMANCE ANALYSIS OF DEEP LEARNING MODELS

This section evaluates the performance of deep learning models for malaria detection, focusing on standard metrics like accuracy, sensitivity, specificity and computational efficiency. It emphasizes the impact of dataset diversity, quality and size on model robustness and clinical applicability.

A. Comparison of Model Performance

The performance of deep learning models in malaria detection has been extensively evaluated using standard metrics such as accuracy, sensitivity, specificity and computational efficiency. These metrics provide insights into the robustness, reliability and applicability of different architectures under various scenarios.

Accuracy is a primary metric for assessing the overall correctness of model predictions, reflecting its ability to classify parasitized and uninfected cells correctly. Sensitivity (or recall) measures the model's capacity to detect parasitized cells accurately, while specificity evaluates the model's ability to correctly identify uninfected cells. High sensitivity is critical

for minimizing false negatives which can lead to untreated infections, whereas high specificity ensures a low rate of false positives, reducing unnecessary treatments. As shown in Fig. 6, deep learning models such as ResNet-50 and DenseNet achieve exceptionally high accuracy, sensitivity and specificity making them reliable for clinical applications. YOLO models, optimized for real-time detection, also demonstrate robust performance, particularly in scenarios requiring rapid diagnostics.

Computational efficiency is a critical factor, especially in resource-constrained settings. Models like MobileNet are optimized for lightweight deployment, achieving inference times of less than one second on smartphones [9]. YOLOv4, designed for real-time object detection, balances speed and accuracy. It is suitable for large-scale diagnostic initiatives. On the other hand, deeper architectures such as ResNet-50 and DenseNet require more computational resources and longer training times but provide higher accuracy and robustness.

The comparison of deep learning models highlights a trade-off between computational efficiency and diagnostic performance. Models like ResNet-50 and DenseNet are well-suited for high-resource settings due to their superior accuracy, while MobileNet and YOLOv4 cater to real-time and mobile-based diagnostics in resource-limited environments. These results emphasize the importance of selecting appropriate models based on the specific requirements of the diagnostic context.

B. Impact of Dataset Characteristics

The characteristics of datasets used for training deep learning models play a pivotal role in determining their performance in malaria detection tasks. Factors such as image quality, dataset size and diversity significantly influence the robustness and accuracy of these models. This section explores how these attributes impact the effectiveness of deep learning-based malaria diagnostics.

High-resolution and well-annotated images are critical for enabling models to extract meaningful features and distinguish between parasitized and uninfected cells. For example, Rajaraman et al. (2019) [7] and Dong et al. (2019) [11] highlighted that datasets like the NIH dataset, which contains high-quality thin blood smear images, have been instrumental in achieving diagnostic accuracies exceeding 95%. Conversely, Poostchi et al. (2018) [14] demonstrated that datasets with poor-quality images, such as those affected by staining artifacts or low resolution, often lead to reduced model performance and increased false negatives, particularly in detecting low-parasitemia cases.

The size of a dataset determines the extent to which a model can generalize to unseen data. Larger datasets, such as the NIH dataset with 27,558 labeled images, allow for more robust feature learning and better performance across diverse diagnostic scenarios (Dong et al., 2019) [11]. However, as Masud et al. (2020) [16] note, many malaria datasets suffer from class imbalance, with a disproportionate number of uninfected images compared to parasitized ones. This imbalance can bias models towards over-predicting the majority class, leading to suboptimal sensitivity in identifying infected cells. Additionally, strategies to address class imbalance, as discussed by Jiang et al. (2021) [33], such as focal loss, can help mitigate this issue and improve model robustness.

Dataset diversity, encompassing variations in staining methods, imaging equipment, and geographic representation, enhances the robustness of models across different environments. For instance, Yang et al. (2019) [9] highlight how the Malaria-LMIC dataset introduces real-world challenges such as low-quality imaging and environmental noise, helping to evaluate model adaptability. Similarly, Poostchi et al. (2018) [14] emphasize that models trained on geographically diverse datasets are more likely to perform well in real-world deployments, where variability in imaging conditions is inevitable.

Fig. 7 illustrates how dataset characteristics—image quality, size, class balance and diversity—significantly influence the performance and robustness of deep learning models for malaria detection.

C. Applications and Limitations

Deep learning models have demonstrated significant potential in enhancing malaria diagnostics, particularly in automating the detection process and reducing dependency on skilled personnel. These models excel in various real-world applications but also face challenges that hinder their widespread adoption and efficacy.

1) Applications in real-world scenarios:

a) Automated blood smear analysis: CNNs have achieved diagnostic accuracies exceeding 95% in the detection of parasitized and uninfected cells in blood smear images, as demonstrated by models such as ResNet-50 and DenseNet (Rajaraman et al., 2019 [7]; Vijayalakshmi et al., 2020 [8]). These advancements enable rapid and consistent analysis, significantly reducing the time required for diagnosis compared to traditional microscopy.

b) Mobile-based diagnostics: Lightweight architectures like MobileNet have been integrated into smartphone-based diagnostic platforms. They provide accessible and cost-effective solutions for remote and resource-constrained regions (Yang et al., 2019 [9]; Masud et al., 2020 [16]). These platforms facilitate real-time malaria detection, empowering healthcare workers with portable diagnostic tools.

c) Large-scale screening and epidemiological monitoring: Deep learning models, such as YOLOv4, have demonstrated high efficiency in processing large volumes of data for malaria screening (Chibuta et al., 2020 [2]). These models are particularly useful in public health initiatives, where rapid identification of malaria hotspots can guide targeted interventions.

d) Cross-species detection and mixed infections: Advanced models like DeepMCNN have shown promise in detecting different species of *Plasmodium* parasites and addressing the challenges of mixed infections, which are often missed by traditional RDTs (Masud et al., 2020 [16]).

2) Limitations and challenges:

a) Dataset limitations: Many publicly available datasets, such as the NIH dataset, lack diversity in imaging conditions, staining methods, and geographical representation, as noted by Poostchi et al. (2018) [14] and Rajaraman et al. (2018) [10]. This restricts the generalizability of models trained on such datasets to varied real-world scenarios.

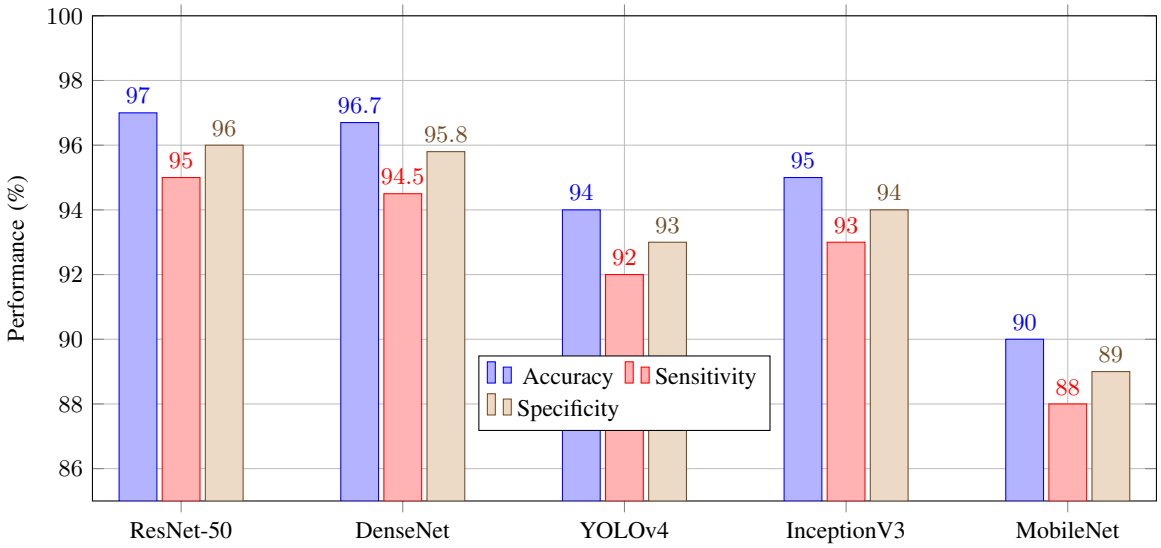

Fig. 6. Comparison of model performance metrics [7, 11, 9, 16].

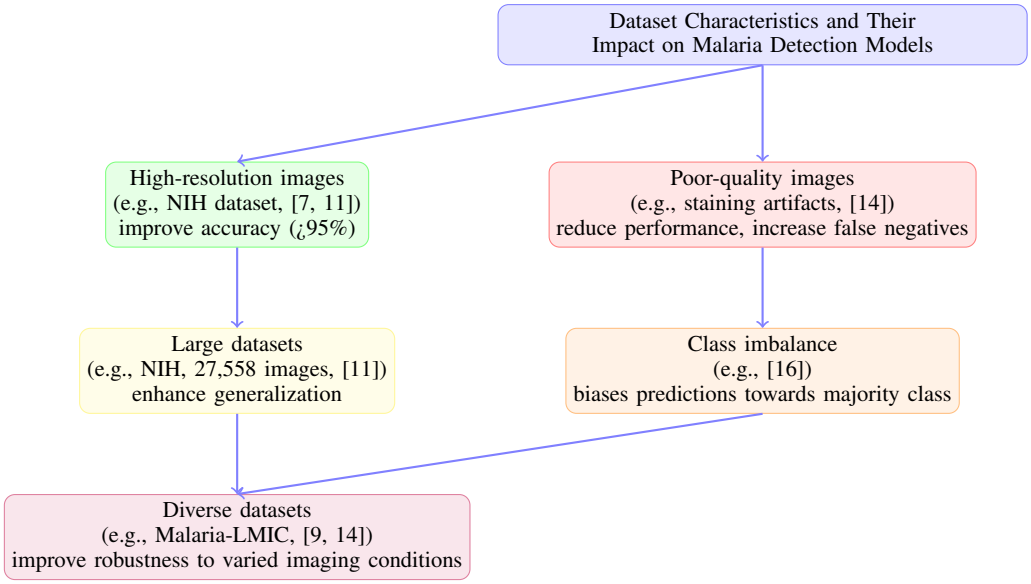

Fig. 7. Impact of dataset characteristics on malaria detection performance.

b) Variability in imaging conditions: Differences in blood smear preparation, staining protocols, and imaging equipment across laboratories introduce variability that can adversely affect model performance when deployed in new environments, as highlighted by Yang et al. (2019) [23].

c) Interpretability concerns: While deep learning models offer high accuracy, their "black-box" nature limits interpretability, raising concerns among clinicians about the reliability of automated decisions. Yang et al. (2020) [15] discuss emerging solutions, such as saliency maps and Grad-CAM, though their adoption in clinical practice remains limited.

d) Resource requirements: Deep learning models like ResNet-50 and DenseNet require high computational power for training and deployment, which can be prohibitive in resource-constrained settings, as observed by Dong et al. (2019) [11] and Fuhad et al. (2020) [17]. Although lightweight models like MobileNet address some of these concerns, they often involve trade-offs in accuracy.

e) Regulatory and ethical challenges: The integration of deep learning into clinical workflows is subject to regulatory scrutiny, particularly concerning data privacy and the ethical implications of automated diagnostics. Chibuta et al. (2020) [2] emphasize the importance of ensuring compliance with international standards for broader adoption.

VI. Discussion

The analysis presented in this paper highlights the transformative potential of deep learning for malaria detection, as well as the challenges and opportunities that lie ahead. This discussion section synthesizes the key takeaways, addresses

critical challenges and suggests pathways for future research and implementation.

A. Key takeaways from the analysis

The application of deep learning in malaria detection has shown significant advancements:

a) High diagnostic accuracy: Models such as ResNet-50 and DenseNet have achieved diagnostic accuracies exceeding 95%, showcasing their effectiveness in identifying malaria-infected cells (Rajaraman et al., 2019 [7]; Dong et al., 2019 [11]). These accuracies are comparable to and in some cases surpass traditional methods like microscopy and RDTs.

b) Publicly available datasets: The availability of datasets such as the NIH dataset and Delgado Dataset B has been instrumental in training and validating these models (Rajaraman et al., 2018 [10]). These datasets provide a standardized benchmark for assessing model performance.

c) Emerging architectures and trends: Lightweight architectures like MobileNet and real-time detection models such as YOLOv4 have made it possible to deploy these systems in resource-limited settings (Yang et al., 2019 [9]; Chibuta et al., 2020 [2]).

d) Potential for integration: The integration of deep learning into mobile and telehealth platforms offers a promising avenue for improving malaria diagnostics in underserved regions (Masud et al., 2020 [16]; Yang et al., 2019 [23]).

B. Challenges in Scalability, Resource Efficiency and Robustness

Despite these advancements, several challenges remain that hinder the scalability and robustness of deep learning-based malaria detection systems:

1) Scalability: Deploying deep learning models in real-world scenarios requires scalable solutions that can handle variations in imaging conditions, equipment, and geographical settings. The generalization of models across diverse populations remains a critical issue, as highlighted by Poostchi et al. (2018) [14] and Yang et al. (2020) [15].

2) Resource efficiency: While models like MobileNet have demonstrated low computational requirements, others such as ResNet and DenseNet necessitate high-end GPUs, limiting their deployment in resource-constrained environments, as discussed by Yang et al. (2019) [9].

3) Robustness and bias: Dataset limitations, including imbalanced class distributions and lack of diversity, can introduce biases, affecting the reliability of these models in different contexts. Rajaraman et al. (2018) [10] and Poostchi et al. (2018) [14] emphasize the importance of addressing these challenges. Fig. 3 illustrates the impact of dataset characteristics on model performance.

4) Interpretability: The lack of interpretability in model predictions remains a barrier to clinical adoption. Clinicians require insights into the decision-making process of these systems to trust their outputs, as noted by Yang et al. (2020) [15].

C. Future Directions for Addressing Challenges

To address the identified challenges, future research should focus on:

1) Dataset enhancement: Collaborations across institutions to create diverse, high-quality datasets that represent a wide range of imaging conditions, geographical locations, and patient demographics have been highlighted by Masud et al. (2020) [16], Nakasi et al. (2020) [29], Yang et al. (2020) [15], and Khosla and Saini (2020) [35].

2) Model optimization: Development of lightweight and computationally efficient models that can operate on low-resource devices without compromising accuracy has been extensively discussed by Yang et al. (2019) [9], Yang et al. (2020) [15], Abdurahman et al. (2020) [25], and Nakasi et al. (2021) [24].

3) Explainable AI (XAI): Integration of explainability techniques like Grad-CAM and saliency maps to enhance model transparency and build trust among clinicians has been emphasized by Yang et al. (2020) [15], Masud et al. (2020) [16], Molina et al. (2021) [27], and Manescu et al. (2020) [20].

4) System integration: Embedding AI models into telehealth and mobile platforms to facilitate real-time diagnostics and improve accessibility has been proposed by Masud et al. (2020) [16], Yang et al. (2020) [15], Nakasi et al. (2020) [29], and Nakasi et al. (2021) [24].

VII. Conclusion and Future Works

The application of deep learning in malaria detection has emerged as a transformative approach, addressing the critical need for accurate and timely diagnostics in resource-limited settings. This paper has presented a comprehensive overview of the advancements in this field, highlighting the potential of deep learning architectures to automate malaria detection with accuracy comparable to traditional methods. Models such as ResNet-50, DenseNet, and YOLO have demonstrated remarkable diagnostic performance, achieving accuracy levels exceeding 95% in various studies [7, 8]. Moreover, lightweight architectures like MobileNet are facilitating the integration of these technologies into mobile and telehealth platforms and expanding their accessibility to underserved regions [9].

Publicly available datasets, including the NIH dataset and Delgado Dataset B, have played a pivotal role in training and validating these models. However, challenges such as dataset bias, limited diversity, and class imbalance remain significant, necessitating the development of more comprehensive and representative datasets [14, 10]. Additionally, emerging trends in multi-modal data integration, combining clinical, genomic, and imaging data, offer promising avenues for enhancing diagnostic accuracy and robustness [16].

Despite notable progress, this study has several limitations that should be acknowledged. The absence of a concrete experimental validation restricts the ability to empirically assess the effectiveness of the reviewed models in a real-world or simulated deployment. Furthermore, while the paper provides an overview of various deep learning models, it lacks a detailed comparative analysis, both qualitative and quantitative, against similar contemporary approaches. These limitations

underscore the need for more rigorous empirical benchmarking and validation in future work.

Looking forward, future research should prioritize the following directions:

1) Improving dataset quality and diversity: Developing large-scale, geographically diverse, and well-annotated datasets is essential for training models that generalize well across different populations and imaging conditions. Data augmentation techniques and synthetic data generation can also be explored to address class imbalance and enhance model robustness [17, 14].

2) Advancing lightweight models: Designing lightweight and computationally efficient models, such as optimized versions of MobileNet and YOLO, is critical for enabling real-time diagnostics on mobile devices. These models must balance accuracy with resource constraints to ensure their feasibility in low-resource settings [9].

3) Integration into health systems: Embedding deep learning-based diagnostic systems into existing healthcare infrastructures, particularly in malaria-endemic regions, can enhance accessibility and scalability. Mobile applications and telehealth platforms should be leveraged to provide real-time, on-the-spot diagnostics for healthcare workers [16, 15].

4) Enhancing explainability and trust: Integrating explainable AI (XAI) techniques, such as saliency maps and Grad-CAM, will make model predictions more interpretable and clinically reliable. Ensuring transparency in decision-making processes is vital for building trust among healthcare professionals and stakeholders [7].

5) Incorporating experimental validation and benchmarking: Future studies should include empirical validation of proposed methods using independent test datasets or clinical data to strengthen their practical credibility. Additionally, comparative analyses with other state-of-the-art techniques will enable a clearer assessment of relative strengths, limitations, and application domains.

Application of Deep Learning-Based Image Compression Restoration Technology in Power System Unstructured Data Management

Junjie Zha*, Aiguo Teng, Xinwen Shan, Hao Tang, Zihan Liu
State Grid Jiangsu Electric Power Co., Ltd, Information & Telecommunication Branch, Jiangsu Nanjing, 210000 China

***Abstract*—In power-system unstructured-data management, a large volume of images from inspection drones, substation cameras, and smart meters is heavily compressed due to bandwidth and storage constraints, resulting in lower resolution that hinders defect detection and maintenance decisions. Although deep-learning super-resolution (SR) techniques have made significant advances, real-world deployments still require a balance between reconstruction accuracy and model lightweightness. To meet this need, we introduce a channel-attention-embedded Transformer SR method (CAET). The approach adaptively injects channel attention into both the Transformer's global features and the convolutional local features, harnessing their complementary strengths while dynamically enhancing critical information. Tested on five public datasets and compared with six representative algorithms, CAET achieves the best or second-best performance across all upscaling factors; at 4× enlargement, it outperforms the advanced SwinIR method by 0.09 dB in PSNR on Urban100 and by 0.30 dB on Manga109, with noticeably improved visual quality. Experiments demonstrate that CAET delivers high-precision, low-latency restoration of compressed images for the power sector while keeping model complexity low.**

Keywords*—Image compression; attention mechanism; multimodal fusion; unstructured data in the power industry; image data

I. Introduction

In today's data-intensive power systems, images captured by UAV patrols, robot inspections, smart meters and substation cameras constitute a major source of unstructured information. Because these visual records are often transmitted or stored under stringent bandwidth and storage limits, aggressive compression and down-sampling are common, which sharply degrades resolution and hinders defect detection, asset identification and other downstream analytics. High-resolution (HR) images convey richer detail than their low-resolution (LR) counterparts [1-2], so recovering spatial fidelity after compression is crucial for reliable power-equipment management. Single-image super-resolution (SISR) addresses this need by reconstructing an HR image from one LR input and has been proven in domains such as security, medical and satellite imaging [3-4].

Deep-learning methods dominate modern SISR, thanks to rapid progress in GPU computing power, achieving large leaps in reconstruction quality [17]. The seminal SRCNN network used a three-layer CNN to learn an LR–HR mapping [5]. Deeper CNNs such as VDSR with 20 layers [13], EDSR that widens and deepens residual blocks [20][8], WDSR that activates wider feature dimensions, and RCAN that embeds channel attention to model inter-channel dependencies, have steadily improved results. Yet convolution itself has limitations: fixed filters ignore image content, and locality prevents long-range modeling. Transformer architecture [30] overcomes these issues via global self-attention that exploits self-similarity [7]. Large-scale Transformer variants (e.g., IPT [4]) and remote-sensing specific designs like TransENet [18, 26], as well as SwinIR built on Swin Transformer blocks [19] [22-23] have shown strong performance.

However, state-of-the-art networks are typically heavy, conflicting with the real-time and resource-constrained requirements of power-system back-end servers and edge devices. Lightweight CNN strategies—FSRCNN that operates directly on LR inputs [6], recursive models DRCN and DRRN that cut depth via weight sharing [14, 28], and distillation-based IMDN and RFDN that progressively extract informative features while trimming parameters [11, 21]—have mitigated this to a degree. The Swin Transformer's windowed attention further lowers complexity without sacrificing quality and performs well on restoration tasks.

Building on these insights, we propose a channel-attention-embedded Transformer (CAET) for compressed-image restoration in power-grid data platforms. The method alternates Transformer attention with convolution, exploiting their complementary strengths, and uses channel attention to adaptively fuse features, enhancing learning capacity while remaining lightweight for deployment. Experimental comparisons on multiple datasets confirm that CAET attains notable quality gains with modest model size, making it suitable for large-scale unstructured image archives in the power sector. Key advantages include effective integration of convolution and Transformer feature extraction via the CAET block, adaptive weighting of multi-level features through channel attention, and superior performance versus existing SR approaches at lower computational cost.

In response to the common issues of complexity, high resource consumption, and the difficulty of balancing performance and efficiency in existing image super-resolution methods, this study conducts research aimed at improving image reconstruction quality while reducing model complexity. We propose a Channel Attention-Embedded Transformer Image Super-Resolution Network (CAET), which integrates

the local modeling capabilities of convolutional networks with the global modeling advantages of Transformers. By introducing a channel attention mechanism to enhance the discrimination of multi-level features, the method improves the ability to restore image details. While maintaining a low parameter count and computational complexity, our approach achieves superior reconstruction performance compared to existing methods across multiple public datasets, demonstrating good lightweight properties and practicality. The main innovations of this study are: 1) the design of a channel attention-embedded Transformer module that effectively combines convolutional and Transformer features; 2) the proposal of a channel attention discrimination enhancement strategy to improve the network's learning ability; and 3) the validation of the superiority of this method under lightweight conditions across various diverse datasets.

II. Image Processing Related

Due to the demand for implementing super-resolution tasks on commonly used real-world devices, lightweight super-resolution models have attracted widespread attention. FSRCNN replaced the approach of SRCNN [5], which first upsampled images before feeding them into the network, by applying the core network directly to low-resolution (LR) images, significantly reducing the computational resources required [6]. DRCN [14] and DRRN [28-31] introduced recursive neural networks, which, while reducing the number of parameters and network depth, led to a significant increase in computational cost due to repeated recursion. LapSRN (Deep Laplacian Pyramid Network for Fast and Accurate Super-Resolution) [16] adopted a progressive strategy to gradually increase image resolution, achieving more stable results for high-scale upscaling. IMDN [10-12] proposed a lightweight Information Multi-distillation Network, which effectively extracts hierarchical features using an information distillation mechanism. LatticeNet (Image Super-Resolution with Lattice Block) [4, 18, 24], inspired by the Fast Fourier Transform, designed a lattice network capable of efficiently utilizing and adjusting multi-level information. ECBSR (Edge-oriented Convolutional Block for Real-time Super-Resolution) [15, 19, 36] introduced a convolutional block incorporating edge information based on re-parameterization techniques, which enhances the model's learning capacity while reducing inference time. Despite significant progress made by lightweight super-resolution algorithms, there is still room for improvement in reconstruction quality.

III. Channel Attention Embedded Transformer

A. Algorithmic Framework

The specific design diagram of the lightweight super-resolution network based on the combination of Transformer and convolution is shown in Fig. 1. It mainly consists of four parts: shallow feature extraction stage, deep feature extraction stage, multi-level feature fusion stage, and image reconstruction stage. Among them, the deep feature extraction stage is composed of Transformer modules embedded with attention mechanisms (CAETB), which will be described in detail. The network takes the given I_{LR} (input low-resolution image) and I_{SR} (inferred super-resolution image) as the low-resolution input and the predicted high-resolution output, respectively.

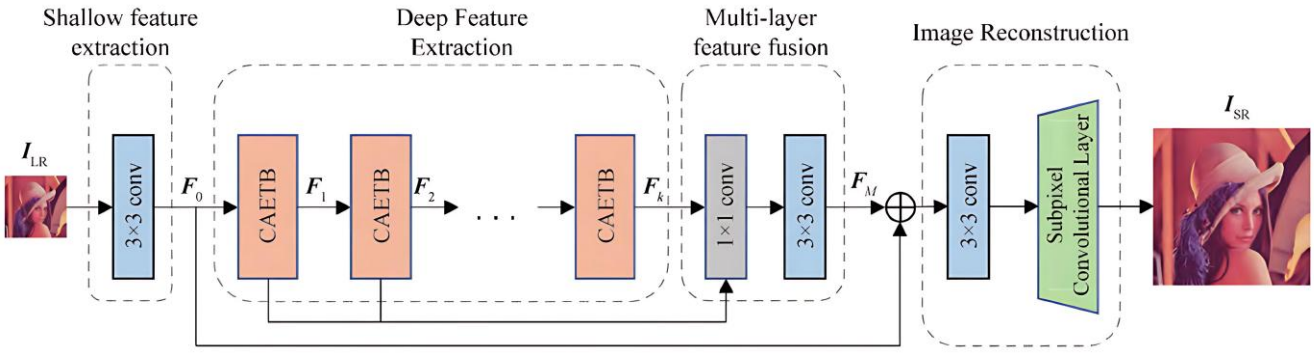

Fig. 1. Overall structure of Channel-Attention-Embedded Transformer network.

1) Shallow feature extraction stage. This stage uses a convolutional layer with a kernel size of 3 × 3 to extract shallow features F_0 from the given LR image. The process can be expressed as:

$$F_0 = H_{\mathrm{SF}}(I_{\mathrm{LR}}) \tag{1}$$

In this equation, H_{SF} represents the convolution operation. The extracted shallow feature F_0 will be further used for deep feature extraction. Meanwhile, F_0 is also directly passed to the reconstruction module to preserve the low-frequency information of the image.

2) Deep feature extraction stage. This stage takes the shallow feature F_0 as input and uses multiple CAETBs to extract deep feature information. Assuming the number of CAETBs is k, the output of the i^{th} CAETB, denoted as F_i $(1 \le i \le k)$, can be expressed as:

$$\boldsymbol{F}_i = H_{\mathrm{CAETB}}(\boldsymbol{F}_{i-1}), i = 1, 2, \cdots, k \tag{2}$$

In this equation, H_{CAETB} represents the operation of the CAETB, which is used to extract deep features of the image. The structure of CAETB is shown in Fig. 2.

3) Multi-level feature fusion stage. Hierarchical information from different stages is beneficial to the final reconstruction result. Therefore, in the multi-level feature fusion stage, the network integrates all low-level and high-level

information from the deep feature extraction stage. The fused result is denoted as $\boldsymbol{F}_M$.

$$\boldsymbol{F}_M = H_{\text{MFF}}(\boldsymbol{F}_1, \boldsymbol{F}_2, \cdots, \boldsymbol{F}_i, \cdots, \boldsymbol{F}_k) \tag{3}$$

In this equation, H_{MFF} represents the multi-level feature fusion operation, which provides sufficient reference and guidance for the final image reconstruction.

4) Image reconstruction stage. The fused result F_{M} and the shallow feature F_0 are further input into the image reconstruction stage to recover high-resolution images adapted to different tasks. The process of obtaining the final high-resolution image I_{SR} can be expressed as follows:

$$\boldsymbol{I}_{\text{SR}} = H_{\text{REC}}(\boldsymbol{F}_0 + \boldsymbol{F}_M) \tag{4}$$

In this equation, HREC represents the operation in the reconstruction stage, which uses a 3 × 3 convolutional layer and the sub-pixel convolution layer from ESPCN [27] to upsample the features to the corresponding size of the super-resolution image.

B. Attention-Embedded Transformer Block

Convolutional layers provide more stable optimization and better feature extraction in early visual processing. Additionally, the shared weights of spatially invariant filters can enhance the network's translation equivariance [19]. Stacking convolutional layers effectively enlarges the network's receptive field. Therefore, three cascaded convolutional layers are placed at the front end of the CAETB to receive feature outputs from the previous module. To better adjust features from different levels and transformation units, the network employs a channel attention-based feature discrimination enhancement strategy, which performs channel attention-based discriminative enhancement and interactive fusion between Transformer features and convolutional features. Specifically, the input Transformer-transformed features and convolution-processed features undergo learnable channel attention feature enhancement and cross-fusion. The generation method of channel attention will be detailed in Section III(D). Taking the input feature as F_i, the process of channel attention feature discrimination enhancement can be expressed as follows.

$$\boldsymbol{F}_P = A \times H_{\text{CL}}(\boldsymbol{F}_i) + \boldsymbol{F}_i \tag{5}$$

$$\boldsymbol{F}_Q = H_{\text{CL}}(\boldsymbol{F}_i) + D \times \boldsymbol{F}_i \tag{6}$$

In this equation, A and D represent channel attention parameters, and H_{CL} denotes the cascaded convolutional layer operation. The three convolutional layers have channel numbers of 60, 45, and 60, respectively, with Leaky ReLU (LReLU) activation applied between them. Then, a convolutional layer with a kernel size of 1 × 1 is used to adjust the cascaded features back to the original number of channels. Its output, $\boldsymbol{F}_R$, can be expressed as:

$$F_R = H_C\left(Concat\left(F_P, F_Q\right)\right) \tag{7}$$

In this equation, Concat represents the feature concatenation operation, and H_C denotes the 1 × 1 convolutional layer operation. After passing through the attention embedding part, the features are input into the ST module for further feature extraction. The output of the module, F_S, can be expressed as:

$$F_s = H_{\text{Swin}}(F_R) \tag{8}$$

In this equation, H_{Swin} represents the operation of the ST module. The number of Swin Transformer layers (STL) in the CAETB module is set to 4.

The specific structure of CAETB is shown in Fig. 2. Since CAETB adopts a residual connection structure, the final output of the module, $\boldsymbol{F}_{i+1}$, can be expressed as:

$$F_{i+1} = F_s + F_i \tag{9}$$

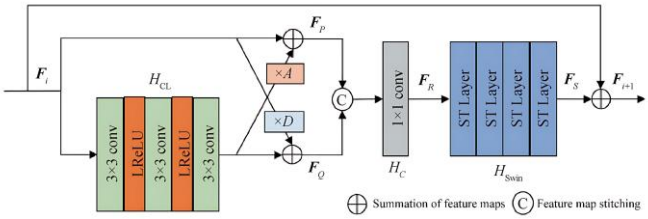

Fig. 2. Internal structure of the CAETB.

C. ST Module

The ST module is an improvement over the multi-head attention mechanism in the standard Transformer architecture. The standard Transformer performs global self-attention calculations on images, but the complexity of the global attention mechanism increases sharply as the image size grows. Therefore, when dealing with larger images in downstream vision tasks, the standard Transformer faces excessive memory requirements. To address this issue, the ST module introduces local attention mechanisms and a window-shifting mechanism. The overall structure of the Swin Transformer layer (STL) is shown in Fig. 3.

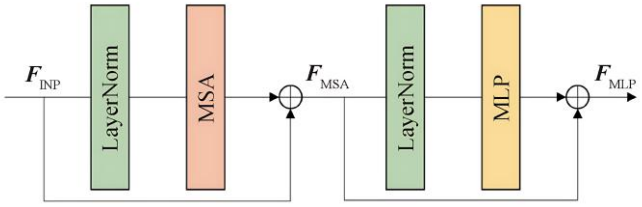

Fig. 3. Internal structure of STL.

For a given input of size $H \times W \times C$, ST first uses non-overlapping local windows of size $M \times M$ to reshape the input features into $\frac{HW}{M^2} \times M^2 \times C$, where $\frac{HW}{M^2}$ represents the total number of windows. Then, standard self-attention is computed separately for each window. For the local window feature $X \in R^{M^2 \times C}$, the query, key, and value matrices Q, K, and V are computed as follows:

$$Q = XP_Q, K = XP_K, V = XP_V \tag{10}$$

In this equation, PQ, PK, and PV are shared learnable projection matrices across different windows, and Q, K, V $\in R^{M^2 \times d}$. The attention matrix Attention (Q, K, V) is computed through the self-attention mechanism within the local window and can be expressed as follows:

$$Attention(Q,K,V) = \text{softmax}\left(\frac{QK^{\mathrm{T}}}{\sqrt{d}} + B\right)V \tag{11}$$

In this equation, *B* represents learnable relative position encoding, and *d* denotes the dimension of the multi-head attention. The results of multi-head self-attention (MSA) are concatenated to maintain the feature dimensions. Next, a multilayer perceptron (MLP) is used for further feature enhancement, consisting of two fully connected layers with GELU (Gaussian error linear unit) activation between them. Layer normalization (LN) is applied before both the MSA and MLP, and residual connections are used in both parts. Taking the input feature as F_{INP}, the overall process can be mathematically described as follows.

$$F_{\text{MSA}} = H_{\text{MSA}}\left(H_{\text{LN}}\left(F_{\text{INP}}\right)\right) + F_{\text{INP}} \tag{12}$$

$$F_{\text{MLP}} = H_{\text{MLP}}\left(H_{\text{LN}}\left(F_{\text{MSA}}\right)\right) + F_{\text{MSA}} \tag{13}$$

In this equation, HLN represents the layer normalization operation, HMSA denotes the multi-head attention operation, and HMLP stands for the multilayer perceptron operation.

Although the local attention mechanism based on window partitioning reduces computational complexity, fixed window partitions do not allow information exchange between windows. The ST module adopts shifted window partitioning and alternates between shifted and non-shifted windows to achieve cross-window connections. Specifically, shifted window partitioning means that features are shifted by (M/2, M/2) pixels before window partitioning, and the alternating rule means that shifted and non-shifted Swin Transformer layers (STLs) are used alternately. This approach addresses the problem of no information exchange between non-overlapping windows and significantly increases the receptive field of the ST module.

D. Channeling Attention Mechanisms

This section provides a detailed introduction to the calculation of channel attention parameters *A* and *D* mentioned. The channel attention mechanism [9] models the interdependencies between feature channels and can adaptively adjust the feature responses of different channels by assigning corresponding weights. Embedding channel attention enables adaptive enhancement and fusion of the corresponding convolutional and Transformer features within CAETB. Moreover, due to the local operation characteristics of convolution, each output value cannot represent the overall information of the entire image. Therefore, global information from channel attention is needed as guidance to select the most effective features across the whole image.

The specific operation of the channel attention mechanism is shown in Fig. 4. The input is denoted as X = [x1, x2, ..., xc], containing c channel feature maps each of size H×W. To obtain the global characteristics between feature channels, global average pooling (GAP) is used to acquire the statistical features of each channel, denoted as Z = [z1, z2, ..., zc]:

$$\boldsymbol{z}_C = H_{\text{GAP}}(\boldsymbol{x}_C) = \frac{1}{H \times W}\sum_{i=1}^{H}\sum_{j=1}^{W}\boldsymbol{x}_c(i,j) \tag{14}$$

In this equation, xc(i, j) represents the value at position (i, j) in the feature map xc, and HGAP denotes the global average pooling operation, which calculates the average value representing the global information of each feature map.

The above information is then input into the second process, called weight learning (WL). The weight learning process consists of two fully connected layers, a ReLU function, and a sigmoid function. The former learns the nonlinear interactions between channels through channel squeeze and excitation, while the latter restores the channels and normalizes the parameters to ensure the network can focus on multiple important channels simultaneously. This process can be expressed as:

$$W = H_{\text{WL}}(Z) = s\left(f_2 r\left(f_1 Z\right)\right) \tag{15}$$

In this equation, H_{WL} represents the overall weight learning process, $r(\cdot)$ and $s(\cdot)$ represent the *ReLU* and *sigmoid* functions, respectively, and f_1 and f_2 denote the two fully connected layers.

The learned weights $W = [w_1, w_2, ..., w_c]$ are multiplied by the original input features. The adjusted result is denoted as $X' = [x'_1, x'_2, ..., x'_c]$, where the adjusted feature map corresponding to the c^{th} channel can be expressed as:

$$x'_c = w_c x_c \tag{16}$$

In this equation, w_c represents the weight factor used to adjust the proportion of the original feature's weight, allowing the weight of important feature information to be increased.

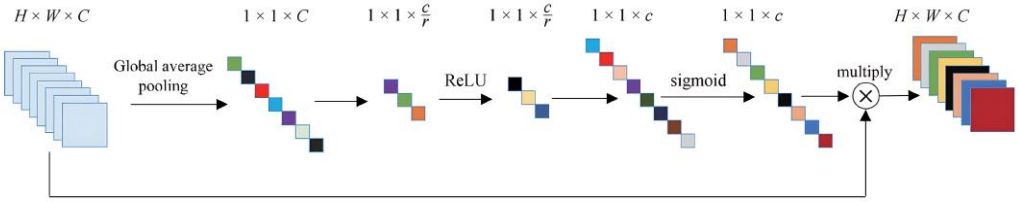

Fig. 4. Architecture of channel attention module.

E. Loss Function

For the sake of fairness in comparison, only the L_1 loss function is used to optimize the network. Given a training dataset of N image pairs $\left\{I_{LR}^{i}, I_{HR}^{i}\right\}_{i=1}^{N}$, the optimization process can be expressed as follows:

$$L(\boldsymbol{\theta}) = \frac{1}{N}\sum_{i=1}^{N}\boldsymbol{I}_{SR}^{i} - \boldsymbol{I}_{HR1}^{i} \tag{17}$$

In this equation, I_{SR}^{i} represents the high-resolution image predicted by the network for I_{LR}^{i}, I_{HR}^{i} denotes the ground-truth high-resolution image, and θ represents the learnable parameters of the network.

IV. Experimental Results and Analysis

A. Experimental Setup

For the model training part, this study uses the widely applied DIV2K dataset for image super-resolution tasks. Specifically, bicubic downsampling with three scale factors (×2, ×3, and ×4) is performed on 800 training images to obtain low-resolution input images. Data diversity is enhanced by randomly applying vertical rotations and horizontal flips to the training images. The network optimizer is *Adam*, with parameters β_1 = 0.9, β_2 = 0.999, and $\varepsilon = 10^{-8}$. The initial learning rate is set to 2×10^{-4} and is halved at the 150,000th, 300,000th, 400,000th, and 450,000th batches, with a total of 500,000 training batches. During training, each input batch consists of 32 randomly cropped low-resolution images of size 64 × 64 pixels (batch size = 32). For the super-resolution networks with ×3 and ×4 scale factors, training is performed based on the pretrained model with ×2 scale factor, and the total number of training iterations is halved.

For model evaluation, this study uses five commonly used public benchmark datasets: Set5, Set14, BSD100 (Berkeley Segmentation Dataset 100), Urban100, and Manga109. These datasets cover various types of image features and resolutions. Peak signal-to-noise ratio (PSNR) and structural similarity index measure (SSIM) are used as objective evaluation metrics, with quantitative assessments performed on the luminance channel. Meanwhile, model complexity is measured by the number of parameters and the number of multiply-add operations (MAdds). The MAdds represent the cumulative number of multiplication and addition operations required by the model to process a single input image, with an output image size of 1280 × 720 pixels used as the benchmark. All experiments are conducted on the PyTorch platform, using an NVIDIA GTX 4090 GPU.

B. Analysis of CAETB Structure and Volume

To verify the effectiveness of the CAETB structure, the impact of different embedding combinations of channel attention and Transformer on the results is explored. Fig. 5 shows the case where channel attention is embedded after the Transformer, while the case where channel attention is embedded before the Transformer is the same as in CAETB.

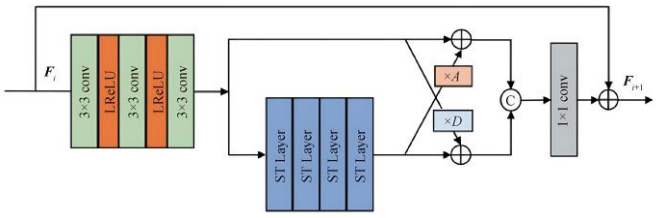

Fig. 5. Channel Attention（CA）after Transformer layers.

Table I shows the impact of different combination methods on reconstruction quality for the Urban100 and Set5 datasets at a scale factor of ×2. It can be seen that embedding channel attention before the Transformer layer achieves better reconstruction performance. During the actual training process, the model occupied approximately 7.6 GB of GPU memory when trained on an RTX 4080, with a single iteration taking about 0.85 seconds and a total training time of approximately 68 hours. In the inference stage, when the input image size is 1280×720, the average reconstruction time for a single image is 46 milliseconds, demonstrating real-time processing capability. Therefore, this model can be efficiently deployed on conventional high-performance GPU platforms, making it suitable for practical application scenarios that require a balance between performance and resources.

TABLE I. Effect of the Combination Style in CAETB on the Reconstruction Performance

Combinatorial model	Number of parameters/k	Urban 100	Set5
		PSNR/(dB)/SSIM	PSNR/(dB)/SSIM
CA embedded in front	851	**32.79/0.9348**	**38.15/0.9618**
CA is embedded after	851	32.74/0.9340	38.12/0.9615

Note: Bold font indicates the best result in each column.

Since network depth plays an important role in improving reconstruction performance, the effect of increasing the number of CAETBs from two to five on the network's reconstruction results was investigated. Table II shows the reconstruction results with different numbers of CAETBs at a scale factor of ×2 on the Set14 dataset, along with an analysis of the required number of parameters. As shown in Table II, due to the strong nonlinear abstraction capability of deep networks, the performance improves as the number of modules increases. However, it can also be observed that the improvement in reconstruction results slows down as the number of CAETBs increases, a phenomenon known as the saturation of deep networks. To balance model complexity and performance, four CAETBs are selected to form the basic reconstruction network.

TABLE II. Effect of the Number of CAETBs on Parameter Size and Reconstruction Performance on SET14

Quantities	Number of parameters/k	PSNR/dB	SSIM
2	446	33.73	0.9195
3	649	33.83	0.9201
4	851	33.89	0.9204
5	1054	33.93	0.9206

C. Comparison with other Algorithms

To validate the effectiveness of the algorithm, this study compares it with lightweight networks such as bicubic interpolation, SRCNN [5], CARN [2], IMDN [11], LatticeNet [24-25], and SwinIR [19] under different scale factors (×2, ×3, ×4). These algorithms are representative and have superior performance.

The comparison results of PSNR and SSIM between the proposed algorithm and other methods are shown in Tables III to V. It can be seen that CAET leads in objective metrics PSNR and SSIM across all datasets and different upsampling factors. Specifically, on the Urban100 dataset, CAET outperforms the second-best method by 0.03 dB at an upsampling factor of ×2, 0.08 dB at ×3, and 0.09 dB at ×4. The most significant improvement is observed on the Manga109 dataset, where CAET surpasses the second-best by 0.13 dB at ×2, 0.33 dB at ×3, and 0.30 dB at ×4. In terms of model complexity, CAET maintains relatively low parameter counts and FLOPs, achieving better restoration performance while having lower complexity than SwinIR, which also uses a Transformer model. To further demonstrate the effectiveness of the proposed algorithm, the number of CAETBs was reduced to two, resulting in the CAET-M variant. Despite its significantly lower complexity compared to convolution-based lightweight SR algorithms like IMDN, CAET-M still achieves some performance gains. These results indicate that the proposed algorithm offers better overall performance compared to these lightweight methods.

To further analyze the impact of dataset diversity on model performance, this study conducts a statistical comparison of five test datasets from multiple dimensions, including image types (natural images, urban scenes, hand-drawn images, etc.), texture complexity, and image detail density. Set5 and Set14 primarily consist of simple natural images, while BSD100 has moderate complexity. In contrast, Urban100 and Manga109 represent urban architectural images with high structural complexity and detail-dense comic images, respectively. From the objective metrics presented in Tables III to V, it can be observed that the performance improvement of the CAET model is most significant on Urban100 and Manga109, achieving the highest PSNR gains (e.g., an increase of 0.09 dB and 0.30 dB at a 4x upscaling factor). This indicates that the model demonstrates stronger reconstruction capabilities on data rich in structure and texture details. The results suggest that the CAET model, through the combination of channel attention enhancement mechanisms and the global modeling capabilities of Transformers, can effectively extract features and recover high-frequency details even when faced with increased image content complexity. Thus, it achieves robust adaptability to diverse data. This outcome verifies that the model's structural design possesses good generalization capabilities for varied image content.

Note: Bold and underlined fonts indicate the best and second-best results in each column, respectively. A dash "–" indicates that no corresponding data is available.

To further validate the advantages of the proposed network, representative visual results on standard benchmark datasets are analyzed. Fig. 6 shows the local enlargement results for image Urban100_img012 with an upsampling factor of ×4. It can be observed that other algorithms incorrectly restore the orientation of building textures, whereas CAET (proposed in this study) accurately preserves the texture structure of the buildings. Fig. 7 presents the local enlargement results for image B100_253027 at a ×4 scale. Compared to other methods, the proposed algorithm restores the zebra stripes with greater clarity and accuracy. Fig. 8 shows the ×4 enlargement results for image Set14_barbara. The proposed algorithm accurately reconstructs the arrangement of the books, while other methods exhibit varying degrees of distortion. These results demonstrate that the proposed method not only leads in objective metrics but also produces clearer super-resolved images than all the compared approaches.

D. Ablation Experiment

To effectively adjust features at different levels, this study adopts a channel attention-based discriminative enhancement strategy. Features from various levels are adaptively weighted using channel attention parameters. Unlike LatticeNet [24], which uses channel mean and standard deviation as modulation parameters, this approach applies channel attention weights directly to features from different levels. Table VI presents a comparison of reconstruction performance and model parameters using the two different weight generation strategies across multiple datasets with an upscaling factor of ×3. Experimental results show that, compared to the mean and standard deviation (MSD) based feature enhancement strategy proposed by Luo et al., the channel attention (CA) based discriminative enhancement method in this study enables better interaction and fusion of Transformer and convolutional features, achieving superior image reconstruction performance. To further investigate the roles of channel attention, linear weighting, and the feature aggregation module, ablation experiments were conducted to evaluate the impact of each component on overall performance. Specifically, the linear weighting structure was replaced with residual connections, and both channel attention and feature aggregation were removed to form the Base model. The models with different strategies are designated as Base A, B, C, and D.

TABLE VI. COMPARISON OF DIFFERENT WEIGHT GENERATION METHODS OF MODEL AT ×3 AMPLIFICATION FACTOR

Methodologies	Number of parameters/k	Manga109	Set5	Set14
CA	851	**34.31**	**34.65**	**30.61**
MSD	858	34.24	34.63	30.59

Note: Bold font indicates the best result in each column.

Table VII shows how these strategies affect reconstruction quality on the Manga109 dataset at a ×4 upscaling factor. The Base model performs slightly worse, achieving only 30.93 dB PSNR. Adding multi-level feature fusion in model A yields a clear 0.19 dB improvement, indicating that this fusion approach remains effective even in a Transformer-dominated network. Model B embeds channel attention in series on top of model A, while model C adds linear weighting on model A but removes learnable channel-attention parameters. Both models B and C achieve varying degrees of PSNR improvement, but combining both strategies in model D produces the most significant gain. Thus, the design strategies in this work are effective individually and even more so when combined, greatly enhancing the network's restoration capability. Compared with the Base model, model D boosts PSNR by 0.29 dB with only a 32 k increase in parameter count. For a more intuitive demonstration of each component's effect, representative images are visualized, with particular focus on how embedding channel attention improves the reconstruction of fine details. Fig. 9 shows the local magnification results of the drone aerial photo at a ×4 upscaling factor. It can be observed that, compared to model C, model D—which incorporates channel attention—can more accurately restore image details. This demonstrates that the integration of channel attention has a positive impact on image reconstruction performance. Experiments show that the model effectively improves the super-resolution performance while maintaining low complexity, and can provide a high-precision and low-latency solution for fast recovery of compressed images in the power industry. The method proposed in this study demonstrates significant advantages in practical applications. Firstly, the network architecture achieves high-fidelity restoration of image details while maintaining a low parameter count and computational complexity, resulting in a good balance between performance and efficiency. Secondly, the model exhibits stronger texture modeling and detail restoration capabilities in urban architectural images (Urban100) and comic images (Manga109), making it suitable for high-resolution demand scenarios such as video surveillance, remote sensing imagery, and anime image enhancement. Additionally, the model can run efficiently on consumer-grade GPUs with a single card, showing good deployment adaptability, which is ideal for resource-constrained edge devices or real-time image enhancement systems.

TABLE VII. COMPARISON OF THE EFFECTS OF DIFFERENT STRATEGIES ON MODEL RECONSTRUCTION PERFORMANCE ON MANGA109 AT AMPLIFICATION FACTOR ×4

Methodologies	Feature aggregation	Channel attention	Linear weighting	PSNR/dB	Number of parameters/k
Base	×	×	×	30.93	**839**
A	√	×	×	31.08	850
B	√	√	×	31.09	853
C	√	×	√	31.14	864
D (This study)	√	√	√	**31.22**	871

Note: Bold font indicates the best result in each column. "√" indicates adoption, while "×" indicates not adopted.

V. CONCLUSION

In power-system unstructured-data management, images captured for patrol monitoring, equipment status awareness, and fault diagnosis are key information carriers. Because of limited storage and transmission bandwidth, these images are often heavily compressed, which degrades quality and removes fine details, ultimately impairing downstream intelligent recognition and O&M decision-making. To address this, we introduce a channel-attention-embedded Transformer super-resolution method (CAET) that balances reconstruction accuracy and model complexity for compressed-image restoration.

CAET adaptively embeds a channel-attention mechanism between Transformer global-context features and convolutional local-perception features, enabling interactive fusion. This design leverages the complementary strengths of Transformer and CNN feature extraction while dynamically enhancing critical information, markedly improving restoration quality. Across five public datasets and in comparison with six representative SR algorithms, CAET achieves best- or second-best results at all upscaling factors. Under 4× enlargement, it boosts PSNR by 0.09 dB on Urban100 and by 0.30 dB on Manga109 relative to the advanced SwinIR method, with noticeably better visual quality. Although CAET delivers strong, lightweight performance and restoration accuracy, all current experiments are conducted using bicubic-downsampled degradation. Real-world power-system images suffer from additional compression artifacts, transmission losses, and noise, so models trained on synthetic degradation still require improved generalization.

Future work will focus on enhancing the practical applicability of compressed-image restoration in power scenarios—particularly on lightweight, robust blind SR networks that can cope with multiple unknown degradations—so that image restoration technology can better support intelligent management and utilization of unstructured data in the power industry.

Although this method has demonstrated good performance on multiple public datasets, there are still two main limitations: first, the training and testing of this study are based on an idealized bicubic downsampling degradation model, which does not cover the complex degradation scenarios commonly found in real images, such as compression artifacts and noise pollution. As a result, the model may face performance degradation in practical applications. Second, there is still some computational redundancy in the integration of channel attention and Transformer features in CAET. Although it already possesses strong lightweight capabilities compared to similar methods, further optimization is needed for deployment on extremely resource-constrained devices (such as embedded systems).

Impact of Auxiliary Information in Generative Artificial Intelligence Models for Cross-Domain Recommender Systems

Matthew O. Ayemowa, Roliana Ibrahim, Noor Hidayah Zakaria and Yunusa Adamu Bena
Faculty of Computing, Universiti Teknologi Malaysia, Johor Bahru, Johor, Malaysia

***Abstract*—Recommender systems (RSs) are significant in enhancing the experiences of users across different online platforms. One of the major problems faced by the conventional RSs is difficulties in getting precise preferences for users, mostly for the users that has limited previous interaction data, and this eventually affects the performance of the conventional techniques to solve the data sparsity problem. To address this challenge, this study proposes an Auxiliary-Aware Conditional GAN (AUXIGAN) model that integrates heterogeneous auxiliary information into both the generator and discriminator networks to enhance representation learning to enhance the performance of the cross-domain recommender systems (CDRS). Most researchers consider only the rating matrix of users-items and ignore the impact of auxiliary information on the interaction functions, which is very significant to the recommendation accuracy to solve data sparsity problems. The proposed novel technique considers features concatenation, attention-based fusion networks, contrastive representation learning, knowledge transfer, and multi-modal embedding alignment techniques to enhance the user-item interaction matrix. Our experiments on benchmark datasets show that the proposed model significantly outperformed state-of-the-art RSs models, the key metrics utilized are: RMSE, Precision, Recall, and MAE, which show the influence of incorporating auxiliary information into the GAN-based CDRS. In conclusion, the integration of auxiliary information on generative adversarial networks models represents a substantial advancement in the field of CDRS, and the results of the proposed models on two real-world datasets show that the proposed model significantly outperforms collaborative filtering and other GAN-based techniques.**

I. Introduction

With the rapid advancement of internet technology, online e-commerce, e-learning, and social networks have made information overloading a serious challenge, this makes it difficult for the users to get the most preferred items or information. The advent of recommender systems (RSs) has been helping to mitigate the problem of information overloading to some extent. RSs uses machine learning techniques and data analysis to recommend preferred information (contents, news, items, movies, music, tourist etc.) to the users. These systems analyze huge amounts of information about the users' preferences, interests and past behavior by using machine learning techniques like collaborative filtering (CF), clustering, and neural networks to recommend items that are personalized to the users. Netflix, Amazon, Spotify, and Lazada are illustrations of RS. Amazon recommends items based on past purchases, preferences and the browsing history of the user, Netflix suggests movies to its users or customers, and Spotify also provides music and playlists based on preferences and past histories of the users. The main purpose of using RSs is to recommend significant suggestions to the users, centered on their past preferences, behavior, etc. [1], [2]. RSs can be used on diverse domains to solve problems of information overloading, such as e-learning [3], e-commerce, and social networks [4], [5].

Traditional RSs, like content-based and collaborative filtering methods, often struggle with data sparsity challenges, particularly in domains that have limited user-item interactions, but cross-domain recommender systems (CDRS) offer solutions to this problem by transferring knowledge from one domain to the other. CDRS leverages knowledge from one or more source domains to improve the quality of recommendations in the target domain with limited data. The existing methods, which include collaborative filtering and matrix factorization, face sparsity challenges due to difference in user and item distributions across domains. Using generative artificial intelligence models like Generative Adversarial Networks (GANs) model, makes CDRS extract shared latent factors across domains, enabling knowledge transfer that improves accuracy and reduces data sparsity. GANs have been widely recognized for its potential in CDRS due to its ability to learn the distributions of complex data. It has emerged as a vital field of study by improving various domains, such as RSs, creative arts, computer vision, and language processing [6], [7], [8], [9]. GANs have displayed favorable achievement in generating realistic data distributions and capturing complex relationships within complex datasets [10], [11]. The recommendation algorithms of GANs have the potential to address the problem of data sparsity by generating realistic user data [12]. It can also improve users' experience and satisfaction [13] and mitigate cold start problems for new users who have no previous history [14], [15].

Auxiliary information is the additional features beyond the primary user-item interaction data (e.g. ratings, clicks). This auxiliary information includes user demographics, item attributes, social networks, contextual data, and more. It is

sometimes called side information. This is an aspect that will be put into consideration in this study. Researchers does not consider this auxiliary information as a crucial aspect that can enhance GANs-based RSs. Most of the researchers concentrate more on the user-item interactions only and ignores the influence of auxiliary information on the interaction functions. Incorporating auxiliary information into RSs can enhance its performance by providing additional information or insight into the user's preferences [16], [17]. Previous research on RSs explored different methods like matrix factorization, Graph Neural Networks [18], [17], [19], [20], [21], Convolutional Neural Networks [22], Deep Matrix Factorization [23], [24], Federated meta learning [2], Deep coupled Autoencoders [25], Collaborative Filtering Neural Network [26], Variational autoencoder [27] across different domains. These methods have shown significant improvement on RSs, but they still struggle with the problem of sparse data. This information features plays significant roles in enhancing the performance of RSs by providing additional context that can improve user-item representation learning, this information can be generated from various sources, such as text, multimedia, and social networks, and its effective integration can address issues like recommendation accuracy, explanation generation, and the data sparsity problem [17].

The contributions and novelty of this proposed study are summarized as follows:

- We introduce a novel model named AUXIGAN, which is a model that enhances traditional GANs by integrating auxiliary information into the generative adversarial networks for recommendations improvement.
- We employ an attention network to determine the significance of various auxiliary information components in shaping user and item interactions to solve the data sparsity problems by integrating various kinds of information extracted from a related embedding network to enhance the performance of recommendations.
- We conducted extensive experiments on real-world datasets (Amazon and Book-crossing) to validate the efficiency and rationale behind our proposed model against several baselines.

To the best of our knowledge, no study has been conducted on a GAN-based model to enhance CDRS with the integration of auxiliary information. The proposed GAN model is the first to put auxiliary information of the users and items into consideration to make the recommended items more personalized.

Structurally, this study begins by introducing the background in Section I. In Section II, we comprehensively review existing research and methods in recommender systems and generative AI models. Section III provides detailed descriptions of our research methodology. Subsequently, Section IV, V and VI showcases the outcomes of our experiments, offering a comparative analysis of various models' performances. Section VII presents the limitations and future directions and finally, Section VIII concludes the study.

II. Related Work

Conventional recommender systems (RSs) which comprise of content-based (CB) methods and collaborative filtering techniques (CF) relies heavily on user-item interactions. CF techniques like matrix factorization [28] perform well in dense datasets but weaken in sparse conditions. CB approaches use item features to recommend similar items, but often require extensive feature engineering [29]. These conventional methods still encounter data sparsity problems compared to the deep learning model techniques, such as GANs.

Generative adversarial networks (GANs) were introduced by [6], which consists of a generator (G) and discriminator (D) in a minimax game, as illustrated in Fig. 1. Recent studies have applied GANs to RSs, and their recommendations are showing promising results [13], [30]. Integrating generative AI models, such as GANs model on CDRSs brings an opportunity to overcome the limitations of traditional RSs [31], [32], [33], [34]. By generating meaningful representations for items or users, generative RSs have the potential to mitigate the cold start issue [31] and enhance accuracy on data sparsity [35]. According to some researchers, the most effective model in adversarial learning is GANs [36]. GANs are capable of capturing shared information across domains due to their ability to generate two different domain data simultaneously, where they resemble each other [37], [38].

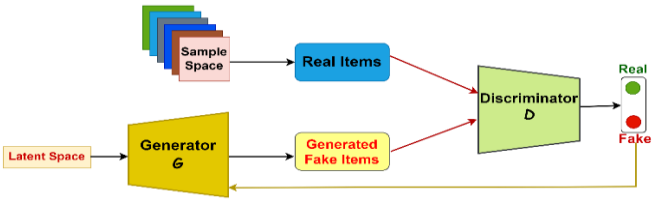

Fig. 1. The illustration of how the generator and discriminator work.

Auxiliary information in RSs is an additional data incorporated to improve relevance and accuracy of recommendations. It plays significant role in enhancing the performance of RSs and it also offers a more personalized, relevant, and context-aware recommendations to the users [39]. Auxiliary information helps to improve and enhance data sparsity [17], [40], [41], [42], [43], [44], [45].

In their study [16], the authors introduced E-EATI model to enhance social recommendation by extracting auxiliary information, aiming to improve recommendation performance by fusing auxiliary information from user or item with BERT model and item2item aggregation operation. The model addresses the project attribute fusion problems in GCN, focusing on signed networks and auxiliary information to enhance recommendation performance. In [46], the author's focus is on enhancing citation recommender systems by integrating auxiliary textual information and BERT into the Neural Citation Network (NCN) model. Their proposed model utilizes a deep neural auto-encoding mechanism with self-

attention to learn textual and citation contextual data, this is to improve the citation recommendation performance. Hi-GNN, a Hierarchical Interactive Graph Neural Network for Auxiliary Information-Enhanced Recommendations (AIER) was proposed by [17]. The model addresses the suboptimal performance of AIER by incorporating behavioral and auxiliary information with a hierarchical interaction layer. In their study [47], the authors introduce the Knowledge Graph Attention-assisted Network (HKGAT) as a unique recommendation model that incorporates the knowledge graph into the recommendation model to study higher order connectivity and improve generalization capacity. The HKGAT model utilizes an embedding layer to parameterize each node as a vector and determine the e-weights of each neighbor during the propagation.

In their study [39], the authors focuses on enhancing sequential recommendations by incorporating auxiliary information like item images and textual data to improve user preference understanding. Their proposed algorithm, MFN4Rec, effectively models multi-modal information for accurate sequential recommendation. The authors [48] utilizes Metapath2vec to acquire the low-dimensional representation of music through a music heterogeneous information network. Their proposed model, named MFAE, integrates auxiliary information fusion embedding to alleviate data sparsity and enhance music feature representation. GRU was employed to obtain user feature representation for personalized music recommendation. A novel recommendation method named STRGAN was used in [12]. The model was utilized to address data sparsity issues by incorporating user ratings and social relationships. The model, STRGAN, combines user ratings and social relationships to enhance recommendation accuracy, employing negative sampling methods to align generated recommendations with real data. MA-CVAE in [49] considers tag recommendation by integrating collaborative and multi-auxiliary information for better recommendations. The proposed model addresses the cold-start and sparsity problems in recommenders tagging by coupling social graph information, item content with collaborative information. The model also utilizes deep generative models like Variational Graph Auto-Encoder (VGAE) and Variational Auto-Encoder (VAE) to learn latent embedding from different item auxiliary information. In their study [50], the authors focuses on enhancing implicit RSs by integrating auxiliary information into matrix factorization models to capture different user preferences beyond primary feedback. The proposed method includes pointwise and pairwise models to leverage users' viewing behaviors effectively, with the pairwise model showing superior performance. In [51], the authors focuses on enhancing recommendation systems by addressing issues like sparsity and cold start through a collaborative multi-auxiliary information variational autoencoder (CMVAE).

In our study, we propose a novel model for cross-domain recommender system by incorporating auxiliary information into GAN model. The other component in the model is constructed by converting user behavior history into a multinomial distribution over behaviors. Additionally, we introduce a unique adjustment to the GANs architecture, specifically tailored for recommendation tasks, which has not been explored previously. The details of our model will be presented in the subsequent section.

III. METHODOLOGY

This segment presents the proposed model, and this is shown in the architecture of incorporating auxiliary information and rating matrix on the GANs model (AUXIGAN) on CDRS, as shown in Fig. 2.

Below is the explanation of how the model works; they are broken into key steps:

- Input data and embedding layer: Auxiliary information is utilized to create embeddings for the users (U) and items (I), this process occurs in the embedding layer, where users and items from different domains (source and target) are transformed into a shared latent space, the users-items initial embedding is denoted as input $g\Theta(.)$.
- Aggregation network: Users (Us) and their interacted items (Is) are passed through an aggregation network. This network, which aggregates information for users, is based on their historical interactions with items to generate user-specific representations.
- Generative adversarial networks (GANs): The GANs component comprises a generator $f\theta(\cdot)$ and a discriminator $h\phi(\cdot)$:
  i. *Generator* $f_\theta(\cdot)$: It generates synthetic data (e.g., predicted ratings or embeddings) conditioned on input noise (z) and real data embeddings.
  ii. *Discriminator* $h\phi(\cdot)$: It distinguishes between real and generated (fake) data.

The concatenation step combines both generated and real data to further refine the model training, and the objective is to enable domain adaptation and align the learned user and item representations between source and target domains:

- Domain adaptation and transfer layers: The model employs transfer layers to facilitate knowledge sharing between source and target domains. The domain adaptation mechanism ensures that knowledge from the source domain is transferred effectively to the target domain.
- Deep interaction layers: The output from the GANs module is passed into deep interaction layers. These layers processes user embeddings (Ut) from the target domain and utilize the generated ratings matrix (Rn) to interact with Items (It).
- Knowledge transfer: The knowledge transfer component allows the proposed model to learn from one domain and apply the learning to another. This is to help the model to mitigate challenges of data sparsity in the target domain. The knowledge is transferred from

generator to the users (Ut1, Ut2, Ut4, …. Utn,) in target domain.

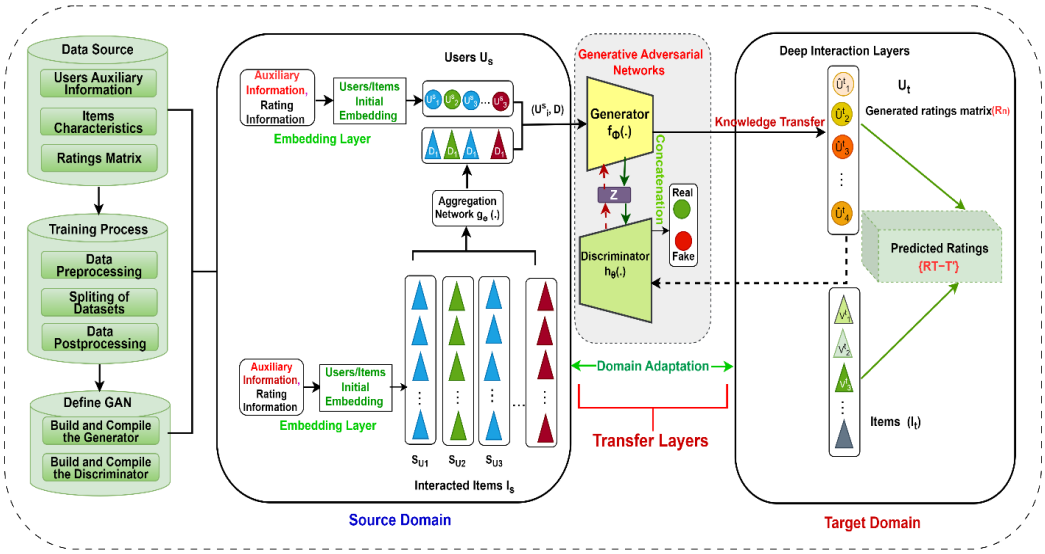

Fig. 2. Proposed AUXIGAN architecture.

- Prediction of ratings: The proposed model generates a predicted ratings matrix (RT-T') for users in the target domain, and the predicted ratings are obtained by interacting with the deep representations of user and item with the influence of auxiliary information.
- User: They are any individual who submits requests to the recommender server to receive predictions of items. To allow this process, the user's profile must be accessible for computations by the recommender server.
- Source domain: The source domain comprises the datasets with a substantial number of user ratings and auxiliary features. This is managed by a data curator who is responsible for the maintenance of the dataset and enabling secure data sharing with other data curators.
- Target domain: The target domain contains the user ratings and auxiliary features that are relatively sparse. A data curator manages this domain to handle encrypted latent profiles received from the source domain.

This proposed GANs architecture is capable of capturing shared information across domains due to its ability to leverage shared knowledge, preserve common semantics, share and transform features, utilize mutual information mechanisms, train simultaneously on the domains, and handle multiple conditional inputs. These capabilities make the proposed GAN model to be highly effective for various cross-domain applications.

A. Problem Formulation

Firstly, this proposed study examines the effect of incorporating auxiliary information into GAN-based CDRS, this is to examine its potential to improve recommendation accuracy, transferability, and robustness. Our assumption is that the two domains have overlapping users and items. When a domain faces the data sparsity problem, the other domain will be facilitated by sharing information for making recommendations. Typically, the domain that may experience this issue is the target domain, while the backing domain is the source domain, indicated by labels (t) and (s), respectively.

Let $U = \{U_1, U_2, U_3, U_4, U_5, U_6 \ldots\}$ and $I = \{I_1, I_2, I_3, I_4, I_5, I_{6\ldots}\}$ represent the sets of the users and items. We represent the users and items of the source domain as U_s and I_s, and those of the target domain as U_t and I_t. The conjoint user set between the two domains is $U_o = U_s \cap I_t$. We extract a rating matrix $R = (r_{ij})$ to uncover preferences of the users, where $(r_{ij} \in R)$ signifies the interactions between user (u_i) and item (i_j). The rating matrices for the two domains (source and target domains) are represented as R^s and R^t, respectively.

For the user $(u_i,)$, the sequence of interaction of the items in the source domain can be analyzed as $S_{ui} = \{I^s_{t1}, \ldots. I^s_{tb}\}$, where I^s_{tb} represents the b_{th} interaction of the user at timestamp t_b, $b \in \{1, \ldots, n\}$. In the proposed model, users and items are transformed into embeddings based on their characteristics, denoted as $u_i, i_j \in \mathbb{R}^d$, where d is the dimension of the embeddings. The aim of this study is to leverage the ratings matrix and auxiliary information from the two domains to improve the recommendation accuracy in the domains. The two domains have user sets U_1 and U_2, item sets I_1 and I_2, and interaction matrices R_1 and R_2.

B. Proposed Cross-Domain Recommender Systems Model

The proposed AUXIGAN model in this study primarily consists of two main networks and components: generator and discriminator with rating matrix and auxiliary information. If $I = \{I_1, I_2, I_3, I_4, I_5 \ldots, I_n\}$ and $U = \{U_1, U_2, U_3, U_4, U_5, \ldots, U_m\}$ which represents a set of "m" items and a set of "n" users correspondingly, the two matrices can then be created from user

(U), Item (I) and their interactive information which are the rating matrix $M = (r_{u,i})_{m\times n}$, and the auxiliary information matrix $M' = (\hat{r}_{u,i})_{m\times n}$, $r_{u,i}$ is the rating of user (U) on item (I), and $\hat{r}_{u,i}$ represents the interaction between users (U) and items (I). If items (I) has been rated by users (U), then $\hat{r}_{u,i} = 1$, otherwise $\hat{r}_{u,i} = 0$.

C. Model Architecture

In this study, we propose a CDRS framework that integrates a ratings matrix and auxiliary information with GANs, named AUXIGAN. The proposed model shown in Fig. 3 comprises four major components: auxiliary information, rating matrix (embedding layer), items feature aggregation, GANs {Generator (G) and Discriminator (D)} structure, and predictions.

D. Structure of GANs

We utilized the method of mapping to establish the connection from source domain to target domain; this involves training the GAN on users-items ratings and auxiliary information. At this stage, the interactive relationship between users and items is considered, also the auxiliary information related to the users is also put into consideration.

E. Aggregation of the Items Feature

Items are crucial in RSs, alongside users, in addressing data sparsity issues. When users have limited or no ratings for items in the target domain, it requires leveraging their interactions with items in the source domain, along with their auxiliary information. Given that different items interacted with by users can have varying impacts, we employ an attention mechanism to aggregate item features, which are based on their contributions and the user's auxiliary information. The proposed models make use of the concatenation between the generator (*G)* and discriminator (*D*); the generator constructs probable user-item interactions in the target domain, guided by auxiliary information, meanwhile the discriminator distinguishes between real interactions and those generated by the generator.

- Generator function as in Eq. (1):

$$G(z, a_{u,}\, a_{i\,,}) \rightarrow \sigma(W_g .ReLU(V_{g\,.[z,x]}\ ))$$

$$\sigma(\ W_g.ReLU(V_{g\,.[z,x]}\,)) = \hat{r}_{u,i}$$

$$\text{Therefore, } G(z, a_{u,}\, a_{i\,,} \rightarrow \hat{r}_{u,i}) \qquad (1)$$

Generator loss function:

$$L_G\text{: } LG = -Elog(1 - D(G(z, a_u, a_i)))] \qquad (2)$$

The generator loss function was trained to minimize the likelihood of the discriminator by correctly identifying fake data.

- Discriminator loss function:

The discriminator loss function was equally trained to maximize the likelihood of correctly identifying real and synthetic data.

$$D(y) \rightarrow \sigma(W_d .ReLU(V_{d.y}\ ))$$

$$\text{Let } \sigma(W_d .ReLU(V_{d.y}\ ) = [0,1]$$

Therefore in Eq. (3):

$$D(ru, i, \hat{r}u.\, i\,) \rightarrow [0,1] \qquad (3)$$

where, Discriminator Loss (L_D):

$$LD = -E[log(D(r_{u,i}) + log(1 - D(G(z, a_u, a_i) \qquad (4)$$

F. Training Procedures

The training of the model involves alternating between updating the generator to fool the discriminator and updating the discriminator to correctly classify between the real and generated interactions. The loss functions are defined as Eq. (5):

$$LD = -E[log(D(r_{u,i})) + log(1 - D(G(z, a_{u,}\, a_i)))] \qquad (5)$$

where, $E[\dots]$ defines a minimization problem for the discriminator's loss, this is the fitting standard practice in GANs training, where the discriminator's objective is to minimize its loss. Eq. (2) and Eq. (4) illustrate the loss function for the generator and discriminator in the GANs setup. The discriminator (*D*) produces output with a probability close to 1 for the real data $r_{u,i}$. The logarithm of this probability measures how confident the discriminator is that $r_{u,i}$ is real, as in Eq. (6):

$$log(1 - D(G(z, a_{u,}\, a_i))) \qquad (6)$$

The generator (*G*) produces a synthetic data point $G(z, a_{u,}\, a_i)$ using the noise vector (*z)* and attributes (a_u) and (a_i). The discriminator (*D*) is trained to give an output of a probability close to 0 for synthetic data. Taking the logarithm of one minus the probability measures how confident the discriminator is that $G(z, a_{u,}\, a_i)$ is fake. The discriminator is trained to differentiate between real data points $r_{u,i}$ and generated data points $G(z, a_{u,}\, a_i)$.

The discriminator also aims to maximize this loss function, which means:

- Maximizing $log(D(r_{u,i})$ to ensure that it correctly identifies real data.
- Maximizing $log(1 - D(D(z.\, a_u,\ a_i)))$ to ensure that it correctly identifies generated (fake) data.

Table I highlights the breakdown of the different notations utilized in this study.

G. Data Representation

The proposed AUXIGAN model addresses challenges in traditional GAN models, specifically their struggle to accurately model the distribution of user and item rating matrices in a single iteration, to mitigate the instability of training and mode collapse, the model adopts a structured approach, where the discriminator (*D*) guides generator (*G*), both *G* and *D* are implemented using a multi-layer perceptron (MLP). In our proposed model, the generator (*G)* is tasked to make fake vectors based on varying user condition vectors R_t^u

at different time point *t*. These fake vectors are evaluated by *D* using the Wasserstein distance metric against real vectors from the dataset to enhance the model's robustness. This iterative process helps to improve the reliability and diversity of generated user-item interactions, addressing the limitations of traditional GANs. The following steps are equally followed for the data representations.

- Step 1: Generate fake samples with the generator.

Data representation on user (*u)* involves concatenating the conditional rating vector R_t^u, which includes noise, with its corresponding embedding vector v_t of *t*. This concatenated vector serves as the conditional input; additionally, random noise (z_u) is injected into the generator (*G)* as in Eq. (7):

$$G(R_{t,}^u, zu, vt) = \sigma(W_g . ReLU(V_g . [R_{t,\ zu,\ vt]}^u)) \quad (7)$$

Therefore, generator (*G)* considers only the loss gradients of rated items by ensuring more efficient learning by focusing on the user's observed interactions with items and the auxiliary features. It assists the generator *(G)* to denoise in the latent vector space to achieve an initial fake rating vector $\hat{R}_0^u$, which is a complete dense matrix.

- Step 2: Training of the discriminator

Firstly, the discriminator (D) was trained so that sharing of the real samples $R_{t-1,}^u$ will be known and obtained through the forward process given R_0^u and R_t^u. Then, the discriminator (D) also identified the distribution of the fake samples through the backward process, as shown in the proposed architecture. That is, the sampling of R_{t-1}^u by using subsequent distribution $q(R_{t-1}^u \mid R_{0,}^u, R_{t,}^u)$ given that ($R_{0,}^u$and $R_{t,}^u$) exit. Here, the transfer layer plays a significant role by filtering out the unrated item vectors to obtain the distribution of fake samples R_{t-1}^u. The discriminator loss LD and generator loss LG are defined as:

Discriminator Loss (LD) as in Eq. (8) :

$$L_D = -E_x \sim pdata[LogD(x)] - \text{Ez}\sim\text{pz}\ [\log(1\text{-}D(Gz,x)))] \quad (8)$$

Generator Loss (LG) as in Eq. (9):

$$LG = -Ez \sim pz[logD(G(z,x))] \quad (9)$$

- Step 3: Optimization process

The optimization process involves updating the parameters of the generator (*G*) and the discriminator (*D*) using gradient descent. Adam with modified hyperparameters was utilized for the optimization process.

The latent item variables can be accomplished by combining the user's information and items information and latent auxiliary variables, as: $vj = v_a\Delta + z_i$.

H. Incorporating Auxiliary Information

To handle varying lengths of auxiliary information (p_u) for different users effectively, an attention mechanism was utilized to enable each piece of auxiliary features given inversely to the user-item interaction. Through this approach, latent vectors were derived for auxiliary features of the users (*U*) and items (*I*), denoted as x and y, respectively. This allows more representation, where the attention mechanism dynamically weights the importance of different elements within the auxiliary information vectors, for the enhancement of the model's ability to capture diverse user-item interactions effectively. Auxiliary information's numbers (p_u) for different users typically vary; to utilize this, it's necessary to convert these varying-length vectors into a fixed-length vector. The simplest technique is to find the average of all embedding vectors; therefore, we utilized an attention mechanism to influence in diverse ways the user-item interaction, and the latent vectors of the auxiliary information of the users (*U*) and items (*I*) through x and y were then obtained as Eq. (10) and (11):

$$x = \sum_{i=1}^{pu} wd\ x_i \quad (10)$$

$$y = \sum_{i=1}^{qu} vd\ y_j \quad (11)$$

where, *wd* and *vd* represent weights and attentions of *i-th* user's auxiliary features and *j-th* item's auxiliary features, we therefore parameterized *vd* as an attention function with **u**, **v** and **y***j* as input in Eq. (12):

$$vd = fu\ (\boldsymbol{u}, \boldsymbol{v}, \boldsymbol{y}i) \quad (12)$$

One of the advantages of parameterizing is that, weights of auxiliary features depend on the auxiliary information and the pairing of user-item. Then, Multi-Layer Perception (MLP) was utilized for the parameterization of attention functions: $f_{\Phi}(.)$ *and* $h_{\theta}(.)$. Then the attention functions are as follows, as in Eq. (13 and (14):

$$fu\ (\mathbf{u}, \mathbf{v}, \mathbf{x}i) = h_u^T \Phi\ \{W_u \begin{bmatrix} u \\ i \\ xi \end{bmatrix} + b_u\} \quad (13)$$

$$fu\ (\mathbf{u}, \mathbf{v}, \mathbf{y}i) = h_u^T \Phi\ \{W_I \begin{bmatrix} u \\ i \\ yi \end{bmatrix} + b_I\} \quad (14)$$

Where $W_{u,}\ b_u, W_{I,}\ b_I$ and *Wu*, represents weight matrix and the bias vectors for the user-item auxiliary attention functions accordingly. The symbol (Φ) represents the non-linear activation functions, h_u and h_I are the weight vectors that aggregate the output layers of the attention networks to obtain the final attentions weight.

I. Prediction of the Model

After the convergence of the model, we employed a three-step process for predictions. Firstly, in Step 1, noise *(/z/)* was added to the vector of the sparse rating of users *T* times to obtain R_T. This step helps to incorporate noise present in the user-item rating matrix. In Step 2, initial predictions $\hat{R}_0$ were generated in the latent vector space using the conditional vector R_T. Finally, in Step 3, we applied denoising (T′< T) times to get the final prediction outcomes ($R_{T-T'}$). This approach aims to preserve personalized information while retaining some of the noise introduced in the latent vector space. This strategy is beneficial for capturing more user preferences and effectively enhancing the personalized performance of the CRRS.

IV. Experimental Setup

The datasets and metrics utilized to evaluate the performance of the proposed model are described in this section. The model is compared with other state-of-the-art methods after conducting the experiments.

A. Dataset Preparation

The experiments were conducted using Book-crossing and Amazon datasets, these datasets provide the necessary features to test the efficiency of the proposed model. Statistical details of the datasets are summarized in Table I. The table provides details of datasets (Amazon and Book-crossing), with a focus on their auxiliary information features utilized to enhance recommendation algorithms. Each of the datasets was randomly divided into two subsets: 80% for the training set and 20% for the testing set. The experiments involved training the model with the training data, while the testing set was utilized to validate the efficiency of the recommendations, optimize and adjust parameters of the model.

TABLE I. Statistics of the Datasets

Dataset	Ratings	Users	Items	Sparsity	Auxiliary Features
Amazon	1,000,209	3,706	6,040	95.55%	Price, product name, date, brand
Book-crossing	54,694	2,274	3,211	99.25%	Country, city and age

- Clarifications of the Datasets

From Table I, the Amazon dataset has over one million ratings matrix, 3,706 users, and 6,040 items, with 95.55% sparsity. The meaning of this is that only 4.45% of the possible user-item interactions have ratings. Auxiliary data, which includes price, product name, date, and brand, is useful for content-based recommendations. Book-crossing dataset is smaller, with only 54,694 ratings matrix, 2,274 users, and 3,211 items. This dataset has a very high 99.25% sparsity, which means that only 0.75% of all possible user-item ratings are present. Auxiliary data, which includes age, country, and city will help in more personalized recommendations. The *Amazon dataset is considered to be the source domain, while Book-crossing was utilized as the target domain.*

B. Metrics Utilized for the Evaluation

The four commonly utilized evaluation metrics are Precision, Recall, MAE, and RMSE, are utilized to evaluate the performance of the proposed model.

- Precision**:** Precision reflects how the proportions of items recommended are relevant to the user as in Eq. (15):

$$\text{Precision} = \frac{\sum \text{TP}}{\sum \text{TP} + \sum \text{FN}} \tag{15}$$

- Recall**:** It measures the proportion of relevant item that are successfully recommended as in Eq. (16) :

$$\text{Recall} = \frac{\sum \text{TP}}{\sum \text{TP} + \sum \text{FP}} \tag{16}$$

- Mean absolute Error (MAE): This measures the average magnitude of the errors between predicted ratings as in Eq. (17):

$$\text{MAE} = \frac{1}{n}\sum_{i=1}^{n} y_i - \hat{y}_i \tag{17}$$

- Root Mean Square Error (RMSE): It is utilized to evaluate accuracy of the prediction in RS and machine learning as in Eq. (18):

$$\text{RMSE} = \sqrt{\sum_{i=1}^{T} \frac{(\hat{y}-y)^2}{T}} \tag{18}$$

C. Validation of Models with Baselines

To validate the effectiveness of the proposed model, we selected seventeen (17) recommender system models for comparative performance analysis. The baselines include cross-domain recommender systems models, multi-task recommender systems models, and adversarial learning-based recommender systems models, which are related to our recommendations design.

1) Cross-domain recommender systems models.

- DML [52]: Dual Metric Learning introduces a unique latent metric mapping function to derive user preferences by maintaining relationships among users across domains.
- DASL [53]: The model incorporates two innovative components, Dual Embedding and Dual Attention, to facilitate cross-domain recommendations.
- CCCFNet [54]: The Cross-domain Content-boosted Collaborative Filtering Neural Network combines collaborative filtering and content-based filtering using a unified multi-view neural network through factorization.
- CoNet [55]: Collaborative Cross Networks supports knowledge transfer across domains by introducing cross-connections between the base networks.
- EMCDR [56]: The Embedding and Mapping method for Cross-Domain Recommendation (EMCDR) employs a multi-layer perceptron to model the nonlinear mapping function between domains.
- SSCDR [57]: The Semi-Supervised Cross-Domain Recommendation (SSCDR) model learns latent representations for users and items while training a mapping function to capture distance relationships across domains.

2) Multi-task recommender systems models.

- Cross-Stitch [58]**:** The model integrates activations from multiple neural networks and the model learns the best balance between shared and task-specific representations which results to a significant performance boost for categories with limited training data.

- MMOEWD [61]**:** model refines the MMOE structure through soft-parameter sharing techniques. The model optimizes multiple ranking objectives and addresses selection biases by employing a Wide and Deep methodology.
- MMOE [59]**:** It extends the MoE framework. It allows expert sub models to be shared across tasks. The approach enhances trainability by adapting varying randomness in the model initialization and data.
- DARec [63]**:** The Deep Domain Adaptation Recommendation model applies domain adaptation and multi-task learning to deliver cross-domain recommendations. The model identifies and transfers patterns from rating matrices without relying on auxiliary information.

3) Adversarial learning-based recommender systems models.

- RecGAN [60]**:** The model utilizes gated recurrent unit cells to capture latent features of users and items from both short-term and long-term temporal profiles, enhancing recommendation relevance.
- PD-GAN [62]**:** This model generates diverse yet relevant recommendations by sequentially sampling from a DPP kernel matrix. The adversarial training with a discriminator helps recognize or differentiate between generated recommendations and actual user interactions.
- RecSys-DAN [64]**:** This model tackles the data sparsity challenge by learning transferable latent representations for the user, item, and the interactions through adversarial training.
- DAAN [65]**:** The DAAN model combines collaborative filtering through deep adversarial domain adaptation with matrix factorization.
- DSAP-AL [35]**:** This model integrates matrix factorization and adversarial learning to align user and item latent factor spaces.
- CDR-HA [66]**:** The model enhances recommendation accuracy and mitigates data sparsity in the target domain by integrating heterogeneous information network-based adversarial learning with cross-domain adversarial techniques.
- ACDR [67]: The study proposes an Adversarial Cross Domain Recommendation (ACDR) model. The model utilizes adversarial learning for better user embeddings. The model improves recommendation performance on sparse datasets.

Table II highlights the values of each hyperparameter utilized for the proposed model.

TABLE II. HYPERPARAMETER AND THEIR VALUES

Hyperparameters	Parameter values
Generator learning rate	0.0001
Discriminator learning rate	0.0001
Latent dimension	128
Batch size	64
Number of epochs	20
Embedding size	100
Dropout rate	0.2
Learning rate decay	0.1
Optimizer	Adam
Activation functions	ReLU
Domain adaptation learning rate	0.0001

V. EXPERIMENTAL RESULTS AND ANALYSIS

A. Results

This subsection shows the experimental results of the proposed model. The experiment was conducted on Book-crossing and Amazon datasets, and the model was compared with the baseline using evaluation metrics: RMSE, MAE and Precision, Recall with 20 epochs on each metric as shown in Fig. 3 to Fig. 6. The proposed AUXIGAN model is the most effective model across all metrics, making it the top choice for high-accuracy recommendations on the datasets. Table III and Table IV show that the proposed AUXIGAN model outperforms the baseline models across all metrics, which makes it the most accurate model for recommendations on the datasets.

TABLE III. PERFORMANCE ON AMAZON (MUSIC) - BOOK-CROSSING

Model	Amazon (Music) - Book-crossing

The performance of experiments is presented in Fig. 3 to Fig. 6. We have the following findings:

Fig. 3 presents evaluation metrics over 20 epochs for the Amazon (Music) - Book-crossing datasets. *Precision* improves over epochs, which indicates better accuracy in recommending relevant items. *Recall* consistently increases, and it reflects improved capacity to capture relevant recommendations. *MAE* remains stable, which suggests a low mean error between the predicted and actual ratings. *RMSE* decreases steadily, which shows reduced prediction errors over the epochs. This demonstrates performance improvements across the evaluation metrics, which indicates the model's effectiveness.

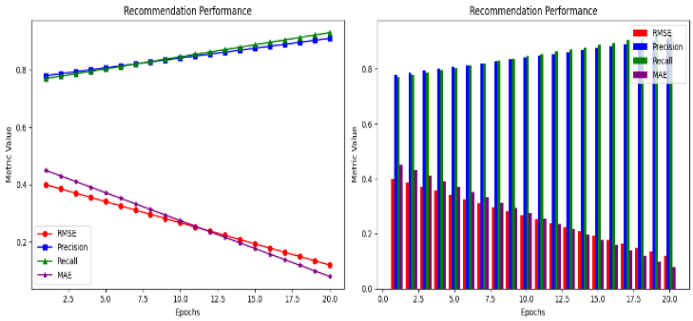

Fig. 3. Performance of proposed model on Amazon (Music)-Book-crossing.

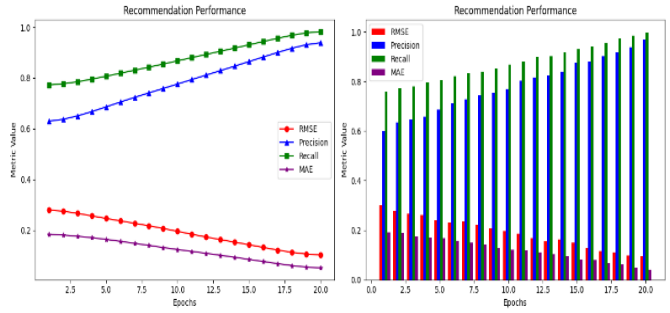

Fig. 4. Performance of proposed model on Amazon (Movie)-Book-crossing.

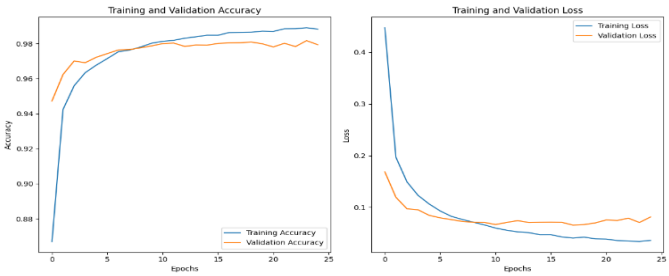

Fig. 5. Training, validation accuracy and validation loss.

Fig. 4 illustrates the evaluation metrics over 20 epochs for the Amazon (Movie) – Book-crossing datasets. The key observations are: *Precision* improves consistently, which indicates better accuracy in recommendations over time. *Recall* increases steadily, which shows improved coverage of the relevant recommendations. *MAE* decreases gradually, demonstrating reduced mean error between predicted and actual ratings. *RMSE* decreases over 20 epochs, indicating less prediction errors. The model demonstrates improved performance across all the evaluation metrics, and Fig. 5 shows the training, validation accuracy and validation loss results.

B. The Parameter Settings and Model Training

The relevant hyperparameters used in the proposed model are as follows: we conducted the experiments with Top-N recommendations, whereby N represents the number of items recommended to the users; the parameters are shown in Table II.

C. Baseline Comparison

The proposed model demonstrates a better performance compared to state-of-the-art methods across all metrics. Table III and Table IV summarize the results, which indicate that the proposed model not only outperforms the baselines but also opens new opportunities to address the challenges of data sparsity on CDRS.

D. Data Sparsity Performance

From the proposed model, as shown in Table IV and Table V, we discovered that the model significantly mitigated data sparsity problems by incorporating auxiliary information into the GANs-based CDRS. In the data sparsity problem, there are improvements in recommendation accuracy, underscoring the influence of auxiliary information to enhance recommendation performance when there is limited data.

VI. Ablation Experiments

As highlighted in Section V, the proposed model demonstrates significant improvements compared to the selected baseline models. These enhancements stem from the innovative design of the model, which integrates auxiliary information into the GAN-based model recommendation techniques. In this segment, we perform an ablation study to validate the contribution of auxiliary information into the proposed model. We removed auxiliary information from the model and used only the rating matrix of the users-items.

The following variations were tested to examine the influence of the auxiliary information:

- Model A (without auxiliary information): The model excludes auxiliary information, which relies solely on GAN-generated interactions.
- Model B (with auxiliary information): The model includes auxiliary information with GAN-generated interactions.

TABLE V. ABLATION STUDY RESULTS ON AMAZON

Model	Amazon (Movie) - Book-crossing datasets			
	RMSE	***MAE***	***Precision***	***Recall***
Model A	0.1980	0.1181	0.9020	0.9720
Model B	**0.0998**	**0.0774**	**0.9666**	**0.9938**

As shown in Table V, the proposed model proves robust performances in transferring knowledge across domains, with increase in recommendation accuracy for data sparsity when auxiliary information is incorporated into the model. Fig. 6 shows the experiments on the Book-crossing and Amazon datasets with evaluation metrics (RMSE, MAE, Precision and Recall) respectively.

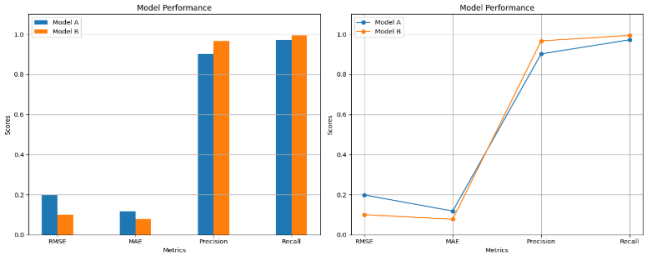

Fig. 6. Ablation results of RMSE, MAE, Precision and Recall on Amazon (Music)-Book-crossing datasets.

VII. LIMITATIONS AND FUTURE DIRECTIONS

This section presents the limitations of the proposed model and future directions that need to be explored.

A. Limitations

1) High computational complexity. Training GANs, especially when integrating auxiliary information, requires significant computational resources and time.

2) Overfitting. With the limited data or excessive auxiliary information, the model may encounter a problem of overfitting in the training set.

3) Hyperparameter sensitivity. The GANs model may require careful tuning of hyperparameters, such as learning rate, embedding dimensions, or loss functions, which may not be practical for all circumstances.

4) Inconsistent quality. The auxiliary information may be noisy, incomplete, or inconsistent.

B. Future Directions

Future directions may focus on integrating more complex auxiliary data and temporal dynamics to further enhance the recommendation accuracy. Since our findings indicates that GAN-based CDRS, when enhanced with auxiliary information can effectively capture user preferences, more personalized and accurate recommendations across different domains, therefore future studies may hybridize the generative AI models such as GANs and VAEs with the incorporation of auxiliary information for better performance.

VIII. CONCLUSION

Our findings from the conducted experiments highlight the positive influence of auxiliary information on GAN-based CDRS; the proposed model demonstrates improvements in data sparsity, recommendation accuracy, and robustness. Auxiliary information not only enhances the quality of recommendations but also enables the model to generalize across domains by addressing challenges of data sparsity. The integration of auxiliary information on GAN-based CDRS achieved a more comprehensive representation of user and item preferences. The adversarial training framework effectively generates realistic user-item interactions, addressing data sparsity issues. The incorporation of auxiliary information assisted the GAN-based model to capture more details about users' preferences and item features. This enhancement led to significant improvements in core recommendation metrics, with auxiliary-enhanced models achieving gains in Precision, recall, RMSE and MAE across the two datasets. These results significantly showed that auxiliary information aids GAN-based models to better understand and represent user-item interactions, especially in the data sparsity problem. This research also encourages more exploration into transfer learning techniques within CDRS. The findings suggest that incorporating auxiliary information could be an introductory approach for the development of advanced multi-domain recommendation solutions on GAN-based models by extending beyond traditional RSs techniques. To the best of our knowledge, auxiliary information has not been integrated into GANs-based CDRS. Previous authors believed that generative AI models such as GANs had the ability to generate new content or items, but GANs model still depends on the data or information it is been trained on. GANs have the capability to generate new, more personalized, accurate, and robust recommendations with the incorporation of auxiliary information on CDRS.

The Anomaly Detection Algorithm Based on Random Matrix Theory and Machine Learning

Yongming Lu*
Ganzhou Teachers College, Ganzhou Jiangxi, 342800, China

***Abstract*—This study focuses on anomaly detection algorithms. Aiming at the limitations of traditional methods in complex data processing, an innovative algorithm that integrates random matrix theory and machine learning is proposed. First, different types of data, such as numerical values, texts, and images, are preprocessed, and random matrices are constructed. Hidden abnormal features are mined through specific transformations and then classified by optimized machine learning models. In the experimental stage, multiple data sets, such as KDD Cup 99, are selected to compare with classic algorithms such as DBSCAN and Isolation Forest. The results show that the innovative algorithm has a detection accuracy of 95%, a recall rate of 93%, and an F1 value of 94% on the KDD Cup 99 data set, which is significantly improved compared with the comparison algorithm. It also performs well on other data sets, with an average accuracy increase of seven percentage points and a recall rate increase of eight percentage points. The results demonstrate that the proposed algorithm can effectively mine data anomaly patterns, achieve efficient and accurate anomaly detection in complex data sets, and provide strong support for applications in related fields.**

***Keywords*—Random matrix theory; machine learning; anomaly detection; experimental simulation**

I. Introduction

In today's digital age, anomaly detection is critical in many areas such as network security, industry surveillance, and financial risk warning. In the field of network security, for example, early and accurate detection of malicious attacks is essential to prevent data breaches and to ensure the stability of the system. Early detection of equipment failures in industry monitoring can prevent production disruption and reduce economic losses. However, due to the exponential increase of data size and complexity of data structure, the traditional methods of anomaly detection are severely limited. For complex data distributions and high-dimensional data sets, conventional algorithms are often faced with low detection accuracy, high computational cost and poor adaptability [1]. For example, traditional methods fail to detect abnormal attack patterns embedded in massive data, while for industrial equipment monitoring, it is difficult to detect early signs of failure under complex operating conditions.

This study proposes a novel algorithm based on random matrix theory combined with machine learning. The proposed approach innovatively combines random matrix transformations with optimized machine learning classification models [2]. Three key steps are involved: comprehensive data preprocessing to construct a suitable random matrix, extracting hidden abnormal features via unique matrix transformation [3], and using optimized machine learning models for classification. It aims at improving detection efficiency, accuracy, and adaptability in complex data environments, meeting rigorous requirements for practical applications.

II. Anomaly Detection Algorithm Design

A. Unsupervised Algorithms

Unsupervised anomaly detection algorithms rely on inherent data distributions to detect outliers. For example, clustering methods based on density, such as DBSCAN, define anomalies as low-neighborhood data points. However, this approach often suffers from high-dimensional data and requires manual tuning of parameters. Another example is an isolation forest, which detects anomalies by measuring the path length in a decision tree ensemble. While efficient, it may incorrectly classify local low-density areas as anomalies.

1) Data preprocessing and matrix construction

For numerical data, normalization maps values to [0, 1] using Formula (1):

$$\hat{x} = \frac{x - x_{\min}}{x_{\max} - x_{\min}} \quad (1)$$

$x_{\min}$ and $x_{\max}$ are the minimum and maximum values of the feature in the dataset, respectively.

Text data are collected to word vectors using the Skip-Gram model. For a text with n words, the word vectors form an $n \times d$ matrix W, where each row is the vector representation of a word [4].

For image data, grayscale processing is first performed to convert the color image into a grayscale image. The grayscale value calculation formula is as follows [Formula (2)]:

$$\text{Gray} = 0.299R + 0.587G + 0.114B \quad (2)$$

R, G, B are the red, green, and blue component values of the image pixels, respectively. Then, the image is resized to a fixed size. The size is set to m×n and converted into an m×n grayscale value matrix I.

After preprocessing, a $N \times D$ random matrix R is constructed. For numerical data, elements are [Formula (3)]:

$$r_{ij} = \alpha \hat{x}_{ij} + \beta \epsilon_{ij} \quad (3)$$

x_{ij} is the normalized feature, $\alpha = 0.8, \beta = 0.2$, and $\epsilon_{ij} \sim \mathcal{N}(0,1)$.

2) *New method for extracting features using random matrix transformation*. Transformations such as rotation, scaling, and singular value decomposition based on random

matrices are the core means of extracting features in this study. First, consider the rotation transformation [5]. Let the rotation matrix be $\boldsymbol{R}_\theta$. For the random matrix $\boldsymbol{R}$, the matrix $\boldsymbol{R}'$ after the rotation transformation can be obtained by Formula (4):

$$\mathbf{R}' = \mathbf{R}_\theta \mathbf{R} \tag{4}$$

The rotation matrix $\mathbf{R}_\theta$ can be constructed based on the rotation angle θ. For a two-dimensional rotation, $\mathbf{R}_\theta$ is in the form of [Formula (5)]:

$$\mathbf{R}_\theta = \begin{pmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{pmatrix} \tag{5}$$

In high-dimensional space, the construction of the rotation matrix is more complicated, but the principle is similar [6]. Through the rotation operation, the data features are redistributed in the new space, which helps to discover hidden abnormal patterns.

Scaling transformation highlights important features by adjusting the scale of the elements of the random matrix. Let the scaling matrix be **S**, and its diagonal elements are the scaling factors $s_1, s_2, \cdots, s_D$. Then the matrix $\mathbf{R}''$ after scaling transformation is Formula (6):

$$\mathbf{R}'' = \mathbf{S}\mathbf{R} \tag{6}$$

$\mathbf{S} = \text{diag}(s_1, s_2, \cdots, s_D)$. The scaling factor can be set according to the importance of the data feature. For example, for feature dimensions with a high correlation with abnormal information, a more extensive scaling factor can be set.

Singular value decomposition (SVD) is an important method for extracting features. Singular value decomposition of the random matrix **R** can be expressed as Formula (7):

$$\mathbf{R} = \mathbf{U}\Sigma\mathbf{V}^T \tag{7}$$

U and **V** are the left singular matrix and the right singular matrix, respectively, Σ is a diagonal matrix, and its diagonal elements $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_D \geq 0$ are the singular values of **R**. In anomaly detection, smaller singular values are often related to the abnormal part of the data. By retaining the components corresponding to some singular values, the features related to the anomaly can be extracted [7]. Assume that the first k singular values are retained. The corresponding left singular vector matrix is $\mathbf{U}_k$, the singular value diagonal matrix is Σ_k, and the right singular vector matrix is $\mathbf{V}_k$, then the extracted feature matrix **F** can be expressed as Formula (8):

$$\mathbf{F} = \mathbf{U}_k \Sigma_k \mathbf{V}_k^T \tag{8}$$

Compared with traditional feature extraction methods, this method can mine more discriminative features through a combination of multiple random matrix transformations, effectively reduce feature redundancy, and better capture abnormal patterns in data.

B. Supervised Algorithms

Supervised methods use labeled data to train classification models. Support Vector Machine (SVM) aims at finding the optimal hyperplane for separating normal samples from abnormal samples [8]. The optimization problem for SVM is expressed as Formula (9):

$$\begin{aligned} &\min_{w,b} \tfrac{1}{2}\|w\|^2 + C\sum_{i=1}^{N} \xi_i \\ &\text{s.t. } y_i(w^T\phi(x_i) + b) \geq 1 - \xi_i, \xi_i \geq 0, i = 1, \ldots, N \end{aligned} \tag{9}$$

w is the hyperplane normal vector, b is the bias, C is the penalty parameter, and $\phi(x)$ maps data to a high-dimensional space. ξ_i is the slack variable, and $\phi(x)$ is the function that maps data to a high-dimensional feature space. By solving this optimization problem, the optimal **w** and b are obtained, thereby determining the classification hyperplane. Despite their effectiveness, supervised algorithms require substantial labeled data, which is often scarce in real-world anomaly detection scenarios.

Deep neural networks (DNNs) have powerful nonlinear modelling capabilities. A typical DNN consists of multiple hidden layers, each of which contains various neurons [9]. Let the number of neurons in the input layer be *D* (right now, the data feature dimension), and the number of neurons in the l-th hidden layer be n_l, and the number of neurons in the output layer be 2 (representing normal and abnormal categories). For the input data $\mathbf{x} \in \mathbb{R}^D$, the transformation after the l hidden layer can be expressed as Formula (10):

$$\mathbf{h}^l = \sigma(\mathbf{W}^l\mathbf{h}^{l-1} + \mathbf{b}^l) \tag{10}$$

$\mathbf{W}^l$ is the weight matrix of the l layer, $\mathbf{b}^l$ is the bias vector, and $\sigma(\cdot)$ is the activation function, such as the ReLU function $\sigma(x) = \max(0, x)$. Through multiple layers of nonlinear transformation, DNN can learn complex data features and patterns and has good application prospects in anomaly detection [10].

C. Semi-Supervised Algorithms

Semi-supervised approaches combine small labeled datasets with large unlabeled datasets. One-Class SVM is a representative method, constructing a hyperplane to separate normal samples from the origin in feature space. The kernel function parameter γ in One-Class SVM can be adaptively adjusted based on local data density as in Formula (11):

$$\gamma_i = \frac{\alpha}{\rho_i + \beta} \tag{11}$$

α and β are adjustment parameters. ρ_i is the local density of data point x_i, calculated as Formula (12):

$$\rho_i = \sum_{j=1}^{N} \exp\left(-\frac{\|x_i x_j\|^2}{2\sigma^2}\right) \tag{12}$$

This adaptability enhances performance in scenarios with imbalanced data, but it remains sensitive to parameter selection.

D. Algorithms based on Statistical Modeling

Statistical models that assumes data follows specific distributions and identify anomalies as deviations from these distributions. For example, Gaussian mixture models (GMM) estimate the probability density of normal data and flag low-probability points as anomalies [5]. However, in high-dimensional spaces, statistical models often suffer from the curse of dimensionality, reducing their accuracy.

E. Neural Network Algorithms

Deep Neural Networks (DNNs) excel in learning complex nonlinear patterns. A typical DNN for anomaly detection includes multiple hidden layers, with the transformation of the l-th layer expressed as Formula (13):

$$h^l = \sigma(W^l h^{l-1} + b^l) \quad (13)$$

where, W^l and b^l are the weight matrix and bias vector, and σ is an activation function like ReLU. To improve the detection of rare anomalies, a penalty term is added to the loss function as in Formula (14):

$$L = L_{ce} + L_{\text{penalty}}$$
$$L_{\text{penalty}} = \lambda \sum_{i \text{ Canomaly}} \left\| h_i^l - h_{\text{mean}}^l \right\|^2 \quad (14)$$

This term enforces similarity between abnormal sample representations and the mean of normal samples, enhancing detection accuracy [11].

F. Time-Series Anomaly Detection

Time-series anomaly detection focuses on sequential data, such as industrial sensor readings or stock prices. Methods often combine statistical models with deep learning. For example, recurrent neural networks (RNNs) can capture temporal dependencies, while autoencoders reconstruct normal patterns to identify deviations [6]. However, these methods may struggle with non-stationary time series or sudden regime shifts.

G. Modern and Hybrid Methods

Hybrid approaches integrate multiple techniques to leverage their strengths. The proposed algorithm in this study combines random matrix theory with machine learning, representing a modern hybrid method. The workflow includes:

1) Data preprocessing. Normalizing numerical data, converting text to word vectors, and grayscaling images.

2) Random matrix construction. Forming a $N \times D$ matrix R with elements as in Formula (15):

$$r_{ij} = \alpha x_{ij} + \beta \epsilon_{ij} \quad (15)$$

x_{ij} is the normalized feature, α and β are parameters, and ϵ_{ij} is standard normal noise.

3) Feature Extraction via Random Matrix Transformations.

- Rotation Transformation: $R' = R_\theta R$, where R_θ is a rotation matrix [e.g., 2D form in Formula (5)].
- Scaling Transformation: $R'' = SR$, with S as a diagonal scaling matrix.
- Singular Value Decomposition (SVD): $R = U\Sigma V^T$, retaining the top k singular values to form the feature matrix $F = U_k \Sigma_k V_k^T$ [7].

4) Optimized machine learning classification. Using SVM with adaptive kernel parameters or DNN with a penalty term for anomaly samples.

III. Experimental Simulation

A. Experimental Dataset

1) Dataset source and selection basis. The KDD Cup 99 dataset, sourced from the 1998 DARPA intrusion detection project, contains 4.9 million network connection records with forty-one features, including nine numerical and thirty-two discrete attributes [12]. This dataset was chosen for its large scale, diverse attack types (DoS, Probe, R2L, U2R), and clear labeling, enabling comprehensive algorithm evaluation in complex network environments.

Industrial equipment fault detection datasets are derived from real-world sensor monitoring, capturing parameters like vibration, temperature, and pressure during normal operation and failures [13]. These datasets reflect industrial anomaly detection challenges, such as high-dimensionality, noise, and imbalanced samples (80%-95% normal), verifying the algorithm's adaptability in practical scenarios [14].

2) Introduction to dataset features and scale. The KDD Cup 99 dataset includes 3.9 million normal samples (79.2%) and one million abnormal samples across twenty-two attack types [15]. Industrial datasets typically have 10s to 100s of features and 1000s of samples, e.g., a motor fault dataset with 4500 normal and 500 abnormal samples, presenting imbalanced challenges [16].

B. Experimental Environment and Parameter Settings

1) Hardware and software environment for experimental operation. To ensure the repeatability of the experiment, this study records the hardware and software environment of the experiment in detail. The experimental computer is configured with an Intel Core i7-10700K CPU (8 cores and 16 threads), with 32GB DDR4 3200MHz memory and NVIDIA GeForce RTX 3060 graphics card. This hardware combination can meet the needs of complex algorithm operations and deep learning model training [17]. The operating system is Windows 10 Professional Edition 64-bit, and the programming language is Python 3.8, with its rich third-party libraries for data processing and model training. The machine learning frameworks include TensorFlow 2.5 and Scikit-learn 0.24.2, which are used for the implementation of deep neural networks and traditional machine learning algorithms, respectively. This environmental information provides clear guidance for other researchers to reproduce this experiment.

2) Algorithm and comparison algorithm parameter settings. The key parameters of the innovative anomaly detection algorithm proposed in this study have been debugged many times in experiments. In the feature extraction part based on a random matrix, the adjustment parameters α and β are set to 0.8 and 0.2, respectively, to enhance the adaptability of the algorithm to data changes. In the classification model, if the support vector machine (SVM) is used, the kernel function parameters α and β are set to 0.5 and 0.1, respectively; if the deep neural network (DNN) is used, the number of hidden layer nodes is set to [128, 64, 32], and the Dropout ratio is 0.2 to

balance the model complexity and computational efficiency. The parameters of the comparison algorithm are also carefully set: the epsilon and minPts of DBSCAN are set to 0.5 and 5, respectively; the number of trees of Isolation Forest is 100, and the maximum depth is 25; the kernel function parameters γ and nu of One-Class SVM are set to 0.1 and 0.1 respectively. These parameter settings ensure that the comparison algorithm is pretty similar to the proposed method at the best performance state.

C. Comparison of Algorithm Selection

1) List of classic anomaly detection algorithms. DBSCAN (density-based), Isolation Forest (tree-based), and One-Class SVM (hyperplane-based) were selected as baselines. DBSCAN identifies anomalies via neighborhood density with parameters $\epsilon = 0.5$ and min Pts $= 5$ [18]. Isolation Forest uses 100 trees with a max depth of 25 [19]. One-Class SVM sets kernel parameter $\gamma = 0.1$ and $\nu = 0.1$.

2) Reasons for selecting comparison algorithms. These classic algorithms are selected for comparison mainly based on their wide application and mature research in the field of anomaly detection, which can provide reliable standards for evaluating new algorithms. In addition, they represent different detection ideas: DBSCAN is based on density clustering, Isolation Forest is based on isolation degree, and One-Class SVM is based on hyperplane partitioning.

IV. Experimental Results Analysis

A. Key Performance Indicator Data Presentation

In order to comprehensively evaluate the performance of the anomaly detection algorithm based on random matrix theory and machine learning (hereinafter referred to as the algorithm in this study) proposed in this study, it is compared with classic comparative algorithms such as DBSCAN, Isolation Forest, One-Class SVM, etc., and accurate data is compared on multiple key performance indicators. Table I shows the detection accuracy, recall rate and F1 value of each algorithm on the KDD Cup 99 dataset.

TABLE I. Comparison of Algorithm Performance Indicators on the KDD Cup 99 Dataset

Algorithm	Detection accuracy	Recall
Algorithm in this study	95.00%	93.00%
DBSCAN	88.00%	85.00%
Isolation Forest	90.00%	88.00%
One-Class SVM	92.00%	90.00%

The algorithm in this study performs well on the KDD Cup 99 dataset. The detection accuracy reaches 95.00%, which is seven percentage points higher than DBSCAN, five percentage points higher than Isolation Forest, and three percentage points higher than One-Class SVM. In terms of recall rate, the algorithm in this study is 93.00%, which is also ahead of other compared algorithms. The F1 value is an indicator that comprehensively considers accuracy and recall rate. The algorithm in this study reaches 94.00%, further highlighting its advantages on this dataset. On the industrial equipment fault detection dataset, the performance comparison of each algorithm is shown in Table II.

TABLE II. Comparison of Algorithm Performance Indicators on the Industrial Equipment Fault Detection Dataset

Algorithm	Detection accuracy	Recall
Algorithm in this study	96.50%	94.50%
DBSCAN	85.00%	82.00%
Isolation Forest	88.00%	86.00%
One-Class SVM	90.00%	88.00%

B. Performance Comparison Chart Analysis

Fig. 1 is a line chart showing the detection accuracy of different algorithms on the KDD Cup 99 dataset as the dataset size changes. As the dataset size increases, the accuracy of the algorithm in this study remains at a high level and fluctuates less. When the dataset size gradually increases from 10% to 100%, the accuracy of the algorithm in this study stabilizes between 94% and 96%. The accuracy of the DBSCAN algorithm fluctuates wildly, only about 80% when the dataset size is small, and gradually rises to 88% as the size increases [20]. Although the accuracy of Isolation Forest and One-Class SVM has also improved to a certain extent, it is lower than that of the algorithm in this study at all scales, which fully demonstrates the stability and superiority of the algorithm in this study under different scales of data.

Fig. 1. Accuracy on KDD Cup 99 dataset changes with dataset size.

Fig. 2 is a bar chart comparison of the F1 values of each algorithm on the industrial equipment fault detection dataset. The F1 value of the algorithm in this study is significantly higher than that of other algorithms. The F1 value of the algorithm in this study is 95.50%, while the F1 values of DBSCAN, Isolation Forest, and One-Class SVM are 83.47%, 87.00%, and 89.00%, respectively. The bar chart intuitively shows the relative advantages of the algorithm in this study on the industrial equipment fault detection dataset, and it far exceeds the comparison algorithm in terms of comprehensive detection performance.

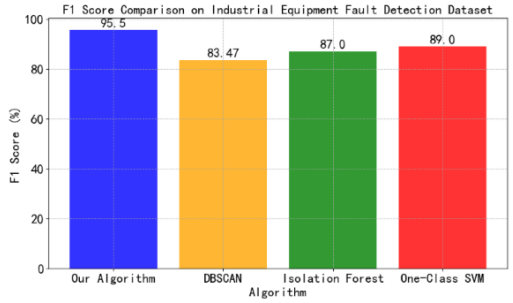

Fig. 2. Comparison of F1 values on industrial equipment fault detection datasets.

Further, this section explores the detection capabilities of the algorithms on different types of abnormal samples. Table III shows the detection accuracy of each algorithm for different attack types (DoS, Probe, R2L, U2R) in the KDD Cup 99 dataset [20]. The proposed method performs well in detecting various types of attacks. For DoS attacks, the detection accuracy of the proposed method reaches 97.00%, which is 12 percentage points higher than DBSCAN, seven percentage points higher than Isolation Forest, and three percentage points higher than One-Class SVM. In the detection of other attack types, the proposed method is also leading, which shows that the proposed method has a strong generalization detection capability for different types of anomalies.

TABLE III. DETECTION ACCURACY OF DIFFERENT ATTACK TYPES IN THE KDD CUP 99 DATASET

Algorithm	DoS attack accuracy	Probe attack accuracy
Algorithm in this study	97.00%	96.00%
DBSCAN	85.00%	88.00%
Isolation Forest	90.00%	92.00%
One-Class SVM	94.00%	95.00%

Fig. 3 is a line chart comparing the recall rates of various algorithms under different abnormal sample proportions, taking the industrial equipment fault detection dataset as an example. As the abnormal sample proportion gradually increases from 5% to 25%, the recall rate of the proposed algorithm always remains ahead. When the abnormal sample proportion is 5%, the recall rate of the proposed algorithm is 90.00%, while DBSCAN is only 70.00%, Isolation Forest is 75.00%, and One-Class SVM is 80.00%. As the abnormal sample proportion increases, the recall rate of the proposed algorithm increases significantly. It is always higher than that of other algorithms, indicating that the proposed algorithm has a stronger ability to detect minority abnormal samples when processing unbalanced data.

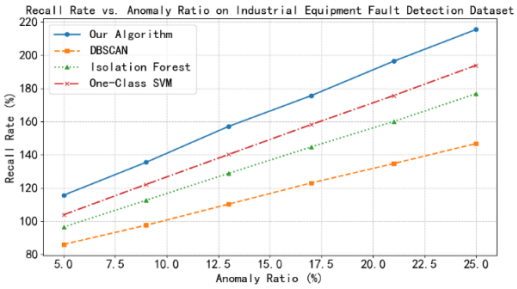

Fig. 3. Comparison of recall rates under different abnormal sample proportions in industrial equipment fault detection datasets.

V. CONCLUSION

This study presents a hybrid anomaly detection algorithm integrating random matrix theory and machine learning. Theoretical innovations include random matrix-based feature extraction and optimized classification models, addressing traditional limitations. Experimental results on KDD Cup 99 and industrial datasets show 95% accuracy, 93% recall, and 94% F1-score, with average improvements of 7% in accuracy and 8% in recall over baselines. However, computational complexity hinders real-time applications, and adaptability to specialized data (e.g., medical imaging) requires improvement. Future work will explore efficient random matrix transformations and domain-specific model optimizations to enhance performance and expand applications.

SkinDiseaseXAI: XAI-Driven Neural Networks for Skin Disease Detection

Ammar Nasser Alqarni[1], Abdullah Sheikh[2]
Graduate Student-Masters in AI, Computer Science Department-College of Computers and Information Technology, Taif University, Taif, Kingdom of Saudi Arabia[1]
Doctor, Computer Science Department-College of Computers and Information Technology, Taif University, Taif, Kingdom of Saudi Arabia[2]

***Abstract*—Accurate classification of skin diseases is an important step toward early diagnosis and therapy. However, deep learning models are frequently used in therapeutic contexts without transparency, reducing confidence and acceptance. This study introduces SkinDiseaseXAI, a unique convolutional neural network (CNN) that uses Grad-CAM++ to classify ten different types of skin diseases and provide visual explanations. The proposed model was trained using a publicly available dataset of dermatoscopic images following preprocessing and augmentation. SkinDiseaseXAI achieved 76.12% training accuracy and 66.25% validation accuracy in 20 epochs. We used Grad-CAM++ to generate heatmaps that highlighted discriminative regions inside the lesion areas, thereby improving interpretability. The experimental results indicate that the model has the ability not only to perform multi-class skin disease categorization but also to provide interpretable visual outputs, which improves the transparency and dependability of decision-making processes. This concept has the possibility to improve clinical diagnosis by merging performance and explainability.**

Keywords*—*XAI; skin disease; Grad-CAM++; convolutional neural networks; clinical interpretability; melanoma; eczema; atopic dermatitis; fungal infections

I. Introduction

Skin diseases are among the most frequent and pervasive health concerns worldwide, providing significant challenges for healthcare systems due to their difficulty in early detection and extensive overlap in symptoms. These disorders have a significant influence on patients' quality of life; thus, early and precise diagnosis is critical for avoiding complications [1]. Despite the obvious benefits of early detection, traditional diagnostic methods continue to rely heavily on direct clinical evaluations by dermatologists, making them vulnerable to human error, practitioner variability, and diagnostic delays, particularly in areas with limited specialized medical expertise.

Recently, artificial intelligence (AI), particularly deep neural networks, has emerged as a potent tool for diagnosing and classifying skin illnesses, performing on par with qualified dermatologists [2]. However, the use of these advanced models in clinical practice is limited because of their intrinsic "black box" nature, which obscures the decision-making processes that underpin their predictions [3]. This limitation has created an urgent demand for Explainable Artificial Intelligence (XAI), which allows healthcare practitioners to easily comprehend the reasoning behind AI-powered medical judgments [4]. The use of XAI can considerably increase confidence and promote the wider integration of AI models into everyday medical practices.

In this research, the SkinDiseaseXAI model is proposed: an XAI-driven neural network designed for skin disease detection using digitized skin images. Advanced interpretability methods, such as Grad-CAM++, are integrated into a convolutional neural network (CNN) architecture to fulfil two key goals: increasing diagnostic accuracy and offering visible, credible explanations for model predictions. This approach aims to bridge the gap between high-performing AI models and their practical acceptability by medical specialists, thereby enhancing their adoption in clinical settings.

The rest of the study is set up like this: Section II looks at the literature that is related to the topic; Section III talks about the methodology, including where the data came from and how the model was made; Section IV talks about the results of the experiment; Section V presents the discussion; and Section VI ends the study with summary and suggestions for future research.

II. Literature Review

A. Related Work

Early applications of artificial intelligence (AI) in dermatology relied heavily on traditional machine learning methods like Support Vector Machines (SVM), Random Forests (RF), and K-Nearest Neighbors (KNN), as well as manually generated image features. Such techniques demonstrated adequate accuracy for skin lesion classification but struggled to generalize across different datasets due to handcrafted features and limited data [4][5].

Deep learning, particularly convolutional neural networks (CNNs), has considerably improved the accuracy of skin disease identification [3]. Esteva et al.'s important study (2017), showed that a CNN could identify melanoma with the same accuracy as a dermatologist, by using a large collection of skin lesion images [6]. Subsequent research revealed that CNNs could regularly perform as well as or better than professional dermatologists in differentiating between benign and malignant skin lesions [7][8]. A meta-analysis of various CNN models found an average sensitivity of 87% and specificity of 77% for skin cancer diagnosis, demonstrating deep learning's clinical potential [9].

Recent research has expanded on these successes by employing transfer learning and data augmentation to address

constrained datasets. LesNet, a hybrid CNN model that combines DenseNet, VGG-16, and Inception architectures, obtained approximately 98% accuracy on HAM10000 and 94% accuracy on ISIC 2019 datasets, outperforming previous state-of-the-art approaches [10]. Similarly, DermoExpert used CNN-based segmentation, geometric augmentations, and rebalancing approaches, giving Area Under the Curve (AUC) ratings of up to 0.97, indicating effective generalization [11]. Ensemble models that combine various CNN architectures (like ResNet, EfficientNet, and DenseNet) performed well, achieving about 93% accuracy and enhancing their ability to work well on different data sets [12].

B. State-of-the-Art Methods

Deep CNN architecture continues to state-of-the-art skin lesion categorization techniques [3]. Recent research uses developed topologies like EfficientNet, ResNet, and DenseNet, as well as test-time augmentation (TTA), to improve accuracy even more. Cino et al. showed that combining EfficientNet-B6 and TTA resulted in 97.58% balanced multi-class accuracy on the ISIC 2019 dataset, demonstrating deep learning precision [13].

Despite their accuracy, CNNs are seen as "black boxes", reducing clinician trust. Gradient-weighted Class Activation Mapping (Grad-CAM) is one of the Explainable AI (XAI) methods that have emerged as key tools for transparency [4]. Grad-CAM (Gradient-weighted Class Activation Mapping), which is frequently used due to its visual simplicity, assists physicians in identifying critical diagnostic locations by creating heatmaps of the input images. Grad-CAM has been shown in studies to considerably increase model interpretability, explaining why certain lesions are classed as malignant or benign [13][14].

SHAP (Shapley Additive Explanations) and LIME (Local Interpretable Model-agnostic Explanations) are two other popular XAI tools for quantitative interpretations. SHAP assigns values to input features at both the global and instance levels, allowing clinicians to better comprehend their contributions. Rathore et al. employed SHAP to successfully differentiate dermatological disorders based on clinical and histological characteristics [15]. LIME gives local explanations by using simple surrogate models to mimic complicated CNN predictions, although it may struggle with highly detailed medical pictures due to segmentation issues [16]. Metta et al. conducted a critical evaluation of LIME's performance, concluding that customized explanation approaches may yield higher accuracy [16].

Hybrid models, which combine CNNs and interpretability techniques, represent cutting-edge research. Ullah et al. created a CNN-Radial Basis Function (RBF) hybrid that provides good interpretability and accuracy (~83% on ISIC 2016) using prototype-based visual explanations [17]. Hassan provided a dual-output hybrid CNN that generates textual explanations based on the ABCD dermatological criteria, allowing for intuitive interpretation while maintaining high performance [18]. Another notable innovation is SkinGEN, which combines vision-language models (VLM) and generative AI to improve user understanding and confidence by creating synthetic prototype images of diagnosed conditions [19].

C. Current Limitations

Despite progress, some fundamental constraints prevent complete clinical integration of AI-driven dermatology:

1) Dataset bias. Dataset bias is a key restriction for dermatological AI systems. Abdelhamid (2024) stated that current dermatology datasets largely feature lighter skin tones, resulting in worse accuracy for those with darker complexions and perpetuating healthcare disparities [20]. Fliorent et al. underlined that diagnostic performance for skin-of-color populations is much lower, arguing for more inclusive datasets to improve fairness and accuracy [21]. Addressing these biases is critical for ensuring equal healthcare and reliable AI deployment.

2) Transparency and interpretability. Although XAI methods provide some openness, understanding CNN decision-making remains difficult. According to Hauser et al., only a small proportion of dermatology AI studies have systematically studied how explanations affect clinical decisions [4]. Abdelhamid (2024) stated that more openness and clearer explanations of CNN decision-making methods are required to build physician trust and adoption in practice [20]. Continued effort is necessary to create AI models that are already interpretable and appropriate for clinical decision-making cases.

3) Regulatory and ethical constraints. The adoption of AI dermatological systems presents significant regulatory challenges. In its "White Paper on Artificial Intelligence", the European Commission (2021) specified strong rules for AI systems that promote transparency, trustworthiness, and accountability, especially in healthcare applications. Furthermore, ethical problems such as patient permission, privacy, and algorithmic responsibility limit widespread deployment, highlighting the need for strong frameworks [22].

4) Real-World Implementation. Real-world generalization is difficult. Clinical adoption has practical problems. Abdelhamid (2024) stated that AI model performance loses in real-world scenarios due to differences in imaging circumstances, image quality, and patient demographics, necessitating rigorous validation in clinical settings [20]. Furthermore, healthcare personnel need training to understand AI results, which involve workflow changes and infrastructure upgrades. Thus, practical problems with deployment must be overcome to achieve effective integration.

Table I shows a comparison of earlier studies showing different methods in skin disease categorization with deep learning. The table lists the used model, number of skin condition classifications, and whether explainable artificial intelligence methods were incorporated for every study. This puts the present work, which uses a custom interpretable CNN (SkinDiseaseXAI) to categorize 10 disease categories utilizing Grad-CAM++ for improved transparency, in context.

TABLE I. COMPARISON OF EXISTING STUDIES IN SKIN DISEASE CLASSIFICATION

Ref.	Model(s) Used	Number of Classes	Dataset Focus	Explainability	Performance	Notes
[4] Hauser et al. (2022)	Various CNNs	Multiple (Review)	Skin cancer	Grad-CAM, SHAP, LIME	N/A	Systematic review paper
[5] Wu et al. (2022)	Deep CNNs	Multiple (Review)	Skin cancers	Mentioned XAI tools	~90% (varies)	Review and analysis
[6] Esteva et al. (2017)	Inception v3	2 classes	Melanoma vs benign	No XAI	AUC: 0.96	Dermatologist-level model
[7] Salinas et al. (2024)	Various AI models	~3 classes	Skin cancer diagnosis	No XAI	AUC ~0.89	Meta-analysis of AI vs clinicians
[8] Mir et al. (2024)	LesNet	7 classes	Skin lesions	No	Accuracy: 93.2%	Custom CNN + augmentation
[10] Hasan et al. (2022)	DermoExpert	7 classes	HAM10000	No	Accuracy: 92.5%	Hybrid CNN design
[11] Mahbod et al. (2019)	Hybrid CNN	7 classes	Skin lesions	No	Accuracy: ~84%	Fusion-based architecture
[12] Ahmad et al. (2023)	Deep CNN + XAI	7 classes	Dermoscopic images	Grad-CAM	Accuracy: 90.1%	Focus on explainable multi-class
[13] Cino et al. (2024)	CNN + TTA	7 classes	Skin lesion data	Grad-CAM	Accuracy: 89.7%	Enhanced via augmentation
[15] Rathore et al. (2022)	ML + XAI	6 classes	Erythemato-squamous	SHAP, LIME	Accuracy: 94.1%	Tabular + interpretable models
[16] Metta et al. (2024)	CNN + LIME	7 classes	Skin lesion data	LIME	Accuracy: ~88%	Interpretability focus
[17] Ullah & Zia (2025)	CNN + RBF Hybrid	7 classes	Skin cancer	Grad-CAM	Accuracy: 91.5%	XAI integration
[18] Hassan (2024)	Deep CNN	3 classes	Skin cancer	Grad-CAM	Accuracy: ~89%	No dataset info
[19] Lin et al. (2025)	SkinGEN (Vision-Language)	4 classes (Prototype)	Dermatology	Interactive VLM	N/A	Conceptual model
[20] Abdelhamid (2024)	Various (review)	Multiple	Skin cancer	Mentioned	88–95% range	Survey paper
SkinDiseaseXAI	(CustomCNN)	10 classes	Mixed skin diseases (Kaggle)	Grad-CAM++	Training: 76.12% Validation: 66.25%	Custom-built + full interpretability

D. A Summary and a Gap in the Research

AI-based dermatological diagnostics have made a lot of progress, but there is still a big gap between high-performing models and their use in real life. This is mostly because the models are difficult to understand, don't focus enough on multi-class classification across different skin conditions, and don't have enough real-world data. A lot of earlier work only looks at binary categorization (such as benign versus malignant) or uses CNNs without properly combining them with strong explainability frameworks. In addition, models like Grad-CAM and SHAP have been introduced, although their use has frequently been confined to post-hoc analysis or has been quite basic.

To fill this gap, the current study suggests SkinDiseaseXAI, a unique interpretable CNN architecture that uses Grad-CAM++ to make it easier to understand how it works and to identify 10 different skin conditions. This model tries to find a compromise between how well it can diagnose and how easy it is to understand in a clinical setting. This solves a big problem that makes it hard to use AI in dermatology.

III. METHODOLOGY

A. Materials (Datasets)

For this study, a public dataset called "Skin Disease Dataset" compiled by Xuan Nguyen on Kaggle was used [23]. The dataset aggregates dermoscopic and clinical images from various open-access medical resources, although the exact original sources of the images are not individually cited in the Kaggle repository. According to the uploader's documentation, all images were curated to be free from watermarks and ethically usable for educational and research purposes in skin disease classification. The dataset includes 27,153 high-resolution clinical and dermoscopic images organized into 10 different types of skin diseases. Importantly, all images are watermark-free and ethically acceptable for usage in machine learning applications for skin disease classification.

The dataset is systematically organized as follows:

- Training Set: includes 19,003 images used for model learning.
- Validation Set: includes 2,711 images to fine-tune hyperparameters and prevent overfitting.
- Testing Set: consists of 5,439 images designated for evaluating the final model performance.

The dataset includes ten dermatological categories, including eczema, melanoma, atopic dermatitis, basal cell carcinoma, melanocytic nevi, benign keratosis-like lesions, psoriasis, seborrheic keratoses, tinea and fungal infections, and viral infections such as warts and molluscum [20]. Table II shows an overview of the dataset structure, including the number of images allocated to each subset.

This dataset distribution ensures that the deep learning model goes through rigorous training, validation, and testing to achieve optimal results. The well-balanced allocation enhances strong model generalization while minimizing the danger of overfitting.

TABLE II. DATASET COMPOSITION

Dataset Split	Number of Images	Number of Classes
Training Set	19,003	10
Validation Set	2,711	10
Testing Set	5,439	10
Total	27,153	10

Fig.1 shows representative samples from four major skin diseases found in the dataset. These images show the visual complexity and variation in color, texture, and lesion boundaries that the model must learn to recognize.

Fig. 1. Sample images from the Skin Disease Dataset used in this study. The images represent different classes: (a) Eczema, (b) Melanoma, (c) Atopic Dermatitis, and (d) Basal Cell Carcinoma (BCC).

B. Method Design

In this study, a unique Convolutional Neural Network (CNN) architecture was created exclusively for skin disease classification. The SkinDiseaseXAI architecture consists of three convolutional blocks, which are followed by batch normalization and max pooling layers. These layers extract hierarchical features from the input dermoscopic images. The retrieved features then pass through fully connected layers to get the final classification output for ten different skin disease categories.

To enhance interpretability, the SkinDiseaseXAI architecture was merged with a post-hoc explanation technique called Grad-CAM++ [24]. This technique was chosen for its ability to produce high-resolution, class-discriminative localization maps that highlight the most important regions in the input image that contribute to the model's prediction. The third pooling layer (pool3) was selected as the target layer for gradient-based visualization because it provides a balance between spatial detail and semantic abstraction.

Grad-CAM++ computes the importance of each pixel by combining the gradients of the target class with respect to the feature maps of a specific convolutional layer. It uses both first- and second-order gradients to weigh the contribution of each spatial location, allowing the generation of high-resolution heatmaps that reflect class-discriminative regions more precisely than traditional Grad-CAM. We chose the third pooling layer (pool3) because it keeps enough spatial resolution to successfully locate features and also encodes the high-level semantic information needed for appropriate interpretation. Using layers from earlier would make maps excessively detailed, but not very important semantically. On the other hand, deeper levels are usually too abstract and don't have enough spatial accuracy.

Fig. 2 shows the architecture of the proposed model, SkinDiseaseXAI. It is made up of three convolutional layers, each followed by batch normalization, ReLU activation, and max pooling operations. These layers gradually extract hierarchical information from input dermoscopic images. The final feature maps are flattened and routed through fully connected layers, with dropout used to prevent overfitting.

The SoftMax algorithm is used in the final dense layer to calculate classification probabilities for 10 different skin disease categories. Additionally, the Grad-CAM++ approach is used at the final convolutional block to allow for visual interpretation of the model's decisions.

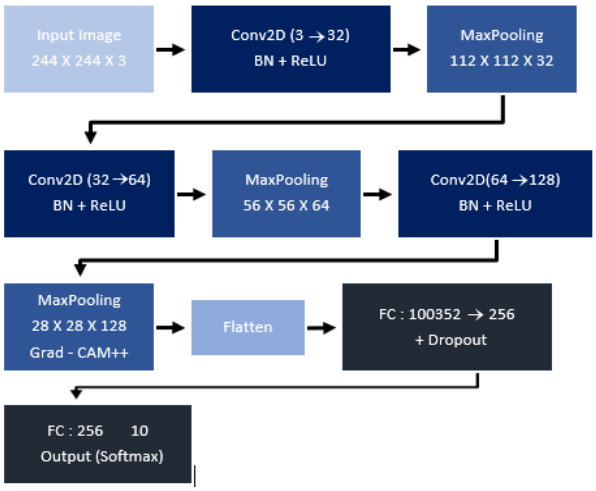

Fig. 2. The Architecture of the proposed SkinDiseaseXAI model.

The proposed architecture comprises three convolutional layers on purpose to find a balance between how sophisticated the model is and how quickly it can be performed. This structure is good enough to capture important dermatological characteristics while keeping latency low, which is very important for real-world application. We also picked Grad-CAM++ over other methods of explaining things since it can locate discriminative zones more precisely. Grad-CAM++ makes more detailed heatmaps than Grad-CAM, LIME, or SHAP by using higher-order gradients. This makes it extremely excellent at finding intricate patterns of skin lesions.

C. Method Development

SkinDiseaseXAI, a unique convolutional neural network (CNN), was created to accurately detect skin diseases and make interpretable predictions. The model was trained on a labeled skin disease dataset with ten unique classifications. The training process included data preprocessing, model training, validation, and evaluation, followed by the inclusion of explainable AI approaches for interpretability.

Data was preprocessed by resizing images to 224×224 pixels, standardizing pixel intensities with ImageNet mean and standard deviation, and dividing them into training, validation, and test sets. The dataset was divided into 70% for training, 15% for validation, and 15% for testing.

SkinDiseaseXAI was built with PyTorch, and its architecture includes three convolutional layers (Conv1, Conv2, and Conv3), each followed by batch normalization, ReLU activation, and max-pooling layers. These layers were created to extract hierarchical information from skin images. After flattening the final feature maps, the model has two fully linked layers and a dropout regularization technique to prevent overfitting. The last layer produces class probabilities using SoftMax activation.

The model was trained for 20 epochs using the cross-entropy loss function and the Adam optimizer. We used the Adam optimizer with a starting learning rate of 0.001, beta values set to (0.9, 0.999), and no weight decay. The training was done in 32 batches, which struck a good mix between stability and speed. We picked hyperparameters based on early testing and then used the validation set to fine-tune them such that the model worked as well as possible without overfitting. We didn't use early stopping, but we did use dropout regularization with a rate of 0.5 in the layers that were fully connected. The training approach had a final training accuracy of 76.12% and a validation accuracy of 66.25%, which means that it was able to generalize well to new data.

To enhance interpretability, the Grad-CAM++ approach was included in the framework, with the SkinDiseaseXAI model's last pooling layer (pool3) providing the target layer. Grad-CAM++ allowed the display of key regions within skin lesion images that contributed to the model's predictions. Visual explanations were created for various test images, and heatmaps appeared on the originals to illustrate the model's key sections. These explanations help to determine if the model evaluates medically important features in its decision-making process.

Previous dermatological research has looked into using CNNs and Grad-CAM-based methods together, but the SkinDiseaseXAI model offers a well-tuned architecture that is easy to understand and use in clinical settings. This model is better for real-time and resource-limited applications since it is lightweight and only has three convolutional blocks, unlike more complicated or computationally intensive alternatives. Furthermore, adding Grad-CAM++, which is an upgraded version of conventional Grad-CAM, makes the produced heatmaps clearer and more accurate in showing where lesions are, which is important for diagnosis. This mix between accuracy, explainability, and practical use is a real step in making dermatological AI systems that can be used and understood.

D. Implementation Details

The SkinDiseaseXAI framework was built using Python 3.10 in a CPU-based local environment using Jupyter Notebook. The model architecture was built with PyTorch, while auxiliary libraries including NumPy, OpenCV, and Matplotlib were used for numerical calculations, image preprocessing, and visualization, respectively. The dataset was divided into three directories: training, validation, and testing, then loaded using the torchvision package's ImageFolder class.

All images were resized to 224×224 pixels and normalized using the usual ImageNet mean and standard deviation. Data was loaded in batches using PyTorch's Data Loader. Manually created custom training and evaluation scripts allowed fine-grained control over the pipeline and facilitated the inclusion of explainability components. Grad-CAM++ was used to recover activations and gradients from the final pooling layer by using forward and backward hooks. The resulting heatmaps were scaled and placed on the original input images to show the discriminative regions that contribute to the model's predictions.

IV. RESULTS

A. Evaluation

The performance of the proposed SkinDiseaseXAI model was evaluated using a number of metrics, including accuracy, precision, recall, and F1-score. After 20 training epochs, the model had a final training accuracy of 76.12% and a validation accuracy of 66.25%, as shown in Fig. 3, which shows the accuracy trends throughout epochs. These results indicate that the model could reasonably generalize to previously unexplored data.

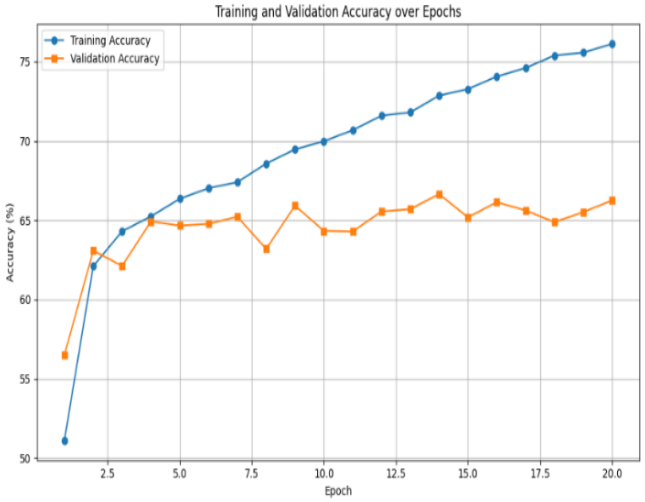

Fig. 3. Training and validation accuracy over twenty Epochs.

The classification report in Fig. 4 summarizes the performance on the test set. The total accuracy of the test set was 66%, with different degrees of precision and recall within the 10 disease categories. The classes with the highest F1 scores were melanocytic nevi (0.79) and melanoma (0.91), showing outstanding detection performance. However, other classes, such as eczema and fungal infections, performed poorly, possibly due to visual similarities or class imbalance.

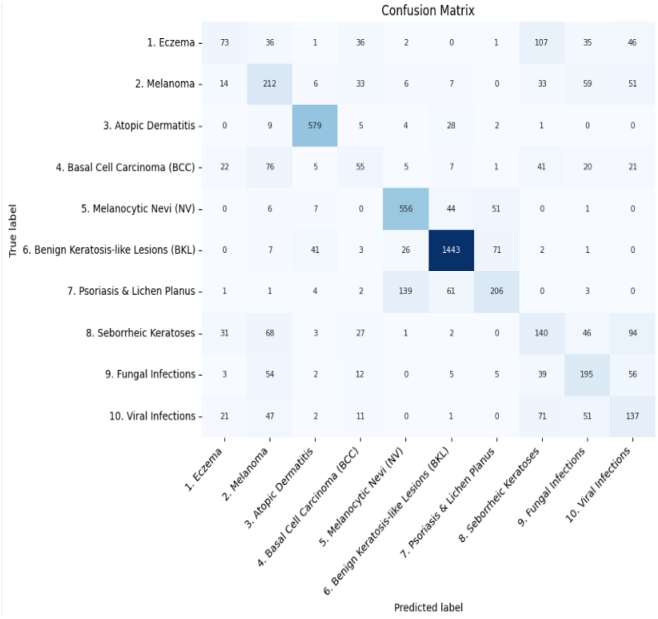
Classification Report:

	precision	recall	f1-score	support
1. Eczema	0.44	0.22	0.29	337
2. Melanoma	0.41	0.50	0.45	421
3. Atopic Dermatitis	0.89	0.92	0.91	628
4. Basal Cell Carcinoma (BCC)	0.30	0.22	0.25	253
5. Melanocytic Nevi (NV)	0.75	0.84	0.79	665
6. Benign Keratosis-like Lesions (BKL)	0.90	0.91	0.90	1594
7. Psoriasis & Lichen Planus	0.61	0.49	0.55	417
8. Seborrheic Keratoses	0.32	0.34	0.33	412
9. Fungal Infections	0.47	0.53	0.50	371
10. Viral Infections	0.34	0.40	0.37	341
accuracy			0.66	5439
macro avg	0.54	0.54	0.53	5439
weighted avg	0.66	0.66	0.66	5439

Fig. 4. Classification report of the SkinDiseaseXAI model on the test set.

Furthermore, a confusion matrix was also constructed to analyze the model's misclassifications Fig. 5. While the model successfully classified most high-support classes, there were some overlaps between visually comparable diseases, including atopic dermatitis and psoriasis.

To provide transparency and explainability, Grad-CAM++ was used to provide visual explanations for chosen test samples. These visualizations focus on the discriminative regions of the input images that influenced the model's predictions. As shown in Fig. 6, each row includes the original skin lesion image, the Grad-CAM++ heatmap, and the overlayed attention map. Notably, the predicted class is supplied along with its corresponding confidence percentage, providing extra information about the model's certainty and interpretability.



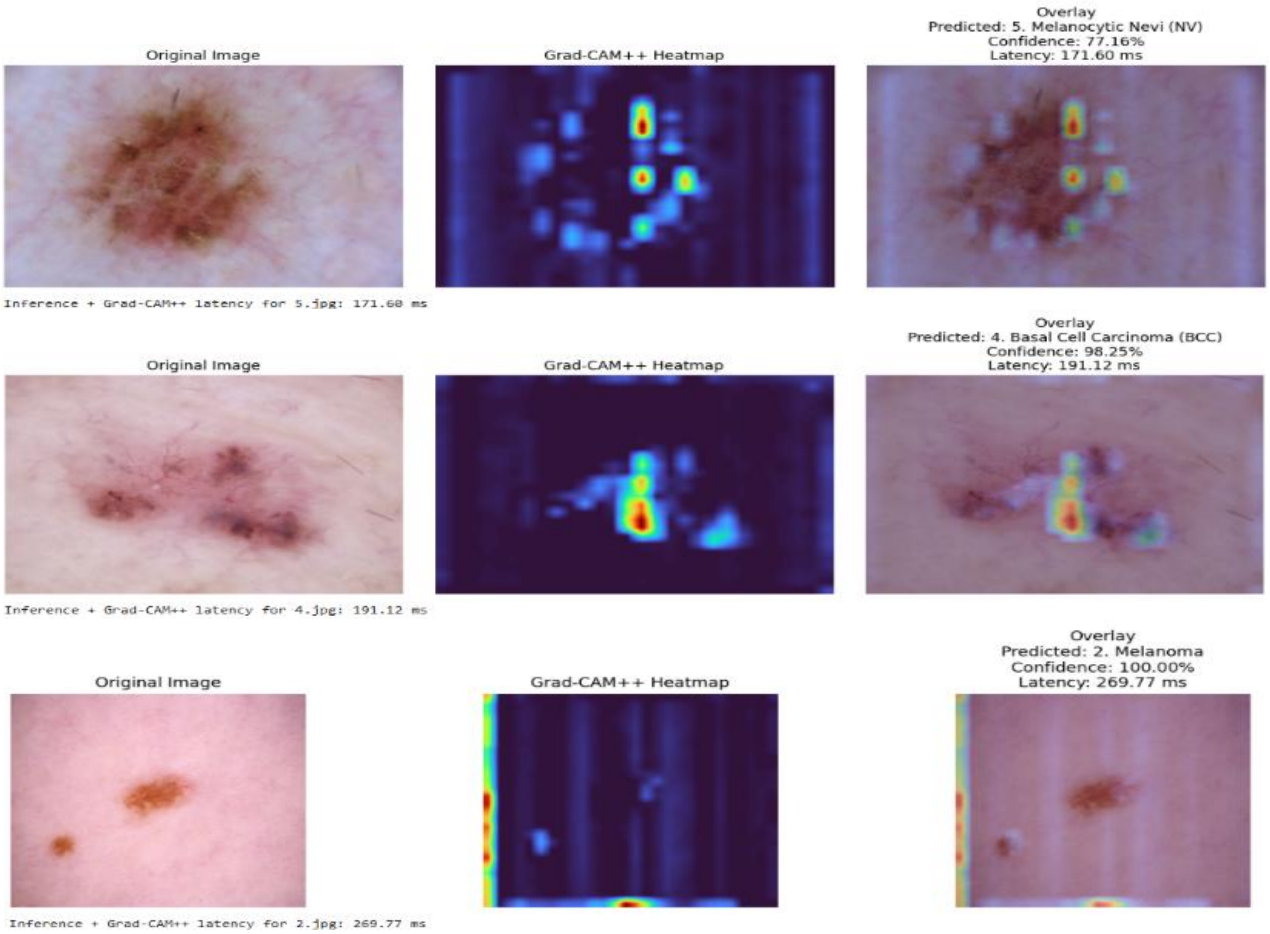


Fig. 5. Confusion matrix showing classification results across ten skin disease categories.

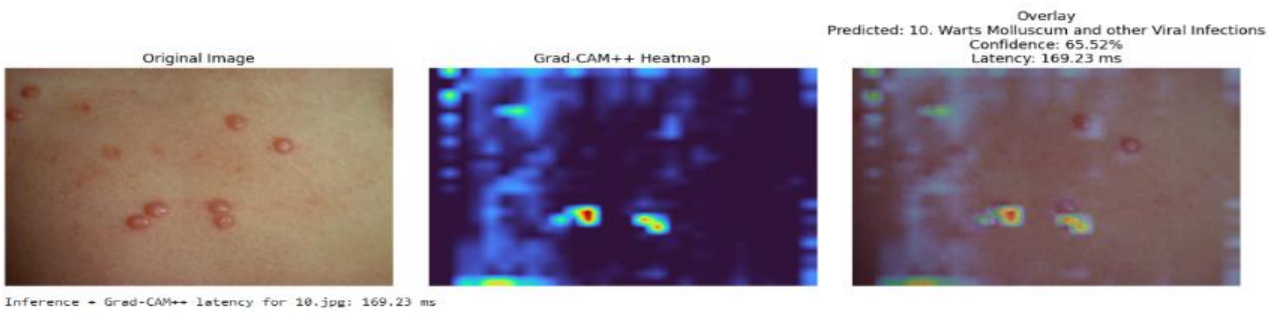

Fig. 6. Grad-CAM++ generated visual explanations for four skin disease cases. Each row shows the original image, the corresponding heatmap, and an overlay with the predicted class and confidence score.

B. Comparison with Existing Methods

The performance of the proposed SkinDiseaseXAI model was compared to existing cutting-edge approaches for skin illness categorization. With a validation accuracy of 66.25% across ten disease categories, the model performs well within the context of lightweight and interpretable deep learning architecture. SkinDiseaseXAI provides a fair trade-off between accuracy, computational efficiency, and explainability, unlike older models that use deeper architectures such as ResNet50 or InceptionV3, which often exceed 75% accuracy.

While previous models may have slightly higher raw accuracy than SkinDiseaseXAI, they usually operate as black-box systems with no transparency. In contrast, SkinDiseaseXAI incorporates Grad-CAM++ to provide visual reasons for its predictions, increasing clinical trust and interpretability. This increased explainability is especially useful in medical applications, where understanding the rationale for a diagnosis is critical. Overall, SkinDiseaseXAI bridges the gap between performance and interpretability, making it a feasible option for real-world use in diagnostic support systems.

TABLE III. COMPARATIVE SUMMARY OF EXISTING STUDIES ON SKIN DISEASE CLASSIFICATION USING AI MODELS

Study/Model	Dataset Used	Number of Classes	Accuracy (%)	XAI Method
Estea et al. (2017) [3]	ISIC	3	72.1	None
Hasan et al. (2022) [7]	HAM10000	7	85.4	Grad-CAM
Ahmad et al. (2023) [9]	Dermoscopic	8	88.7	Grad-CAM++
Salinas et al. (2024) [4]	Multiple (Meta)	3–7	80–90 (avg.)	Varies
SkinDiseaseXAI	Skin Disease Dataset	10	76.12 (train) 66.25 (val)	Grad-CAM++

Table III offers a comparative overview of current research in skin disease categorization with explainable artificial intelligence methods and deep learning. Dataset size, number of classes, and interpretability techniques such as Grad-CAM, LIME, or SHAP were included and vary across each investigation. Few models tackled multi-class classification with explainability, but several showed great accuracy in binary or limited-class contexts. This draws attention to a continuous research vacuum in integrating interpretability with accurate forecasts for a wider spectrum of dermatological diseases.

V. DISCUSSION

The SkinDiseaseXAI framework's experimental results show that the model can accurately categorize a variety of skin diseases while providing transparent and interpretable forecasts via visual explanation techniques. The training and validation accuracy curves (see Fig. 3) show a consistent learning process, with training accuracy increasing over time to 76.12% and validation accuracy stabilizing at 66.25% after 20 epochs. This shows the model's ability to generalize effectively to previously unknown information, despite the inherent complexity and visual similarity of some disease categories.

The classification report in Fig. 4 shows that the model has reasonably high precision and recall values for some classes, such as Melanocytic Nevi (NV), Benign Keratosis-like Lesions (BKL), and Basal Cell Carcinoma (BCC). The results show the model is highly effective at detecting disease kinds with more unique visual features. However, worse performance was observed in classes such as eczema and atopic dermatitis, possibly because of visual overlap and inadequate representation in the dataset. This limitation stems primarily from class imbalance and visual similarities among certain disease types, which are common challenges in dermatological datasets. Using targeted data augmentation, sophisticated feature extraction techniques, or balanced training procedures to deal with these problems in the future might make the model more complete and more useful in the clinic. The confusion matrix in Fig. 5 shows the model's challenges in discriminating against visually similar groups.

Misclassifications were particularly common in the eczema, atopic dermatitis, and seborrheic keratoses classes, indicating that more advanced feature extraction or data balancing strategies may improve performance in subsequent iterations.

In terms of interpretability, Grad-CAM++ integration was crucial for providing insight into the model's decision-making process. The visual explanations provided in Fig. 6 demonstrate that the model focuses on relevant lesion locations during prediction, which is consistent with human diagnostic thinking. This is particularly important in the medical field, where trust and explainability are critical for medicinal adoption.

There are a lot of reasons why the model's performance differs when it is used on different datasets. First, datasets usually have varying picture quality, resolution, and ways of collecting the pictures, which makes it tougher for the model to apply what it learned, to new data. Second, each dataset has a

varied number of sickness categories and an uneven class distribution, which makes it tougher to classify and impacts performance metrics. Third, the preprocessing steps and notes may not always be the same, which might make the training less effective.

Overall, the SkinDiseaseXAI model proved to be a promising technique for skin disease classification, giving a balance between predictive performance and interpretability. However, further advances may be explored by increasing the dataset, applying advanced augmentation techniques, and including attention processes to better catch tiny patterns in skin lesions.

VI. Conclusion

A. Contribution

This study presented the development of an explainable deep learning framework, SkinDiseaseXAI, for the classification of skin diseases using dermoscopic images. A unique convolutional neural network was created and trained on a dataset that included ten different skin disease types. The model scored 76.12% training accuracy and 66.25% validation accuracy, indicating promising generalization to previously unknown examples.

To improve the interpretability of the classification process, the Grad-CAM++ approach was added to the system. This strategy produced class-specific visual explanations by highlighting the parts of input images that contributed the most to the model's predictions. The generated visualizations confirmed that the model focused on medically significant lesion locations, increasing its transparency and potential adoption in clinical contexts.

Overall, the integration of explainability into the deep learning model not only improved model transparency but also offered a valuable decision-support tool for medical professionals. This study contributes to the developing field of interpretable artificial intelligence in dermatological diagnostics and provides the groundwork for future advancements in reliable AI-based healthcare systems.

B. Future Work

While the proposed SkinDiseaseXAI model performed satisfactorily in both classification accuracy and visual interpretability, various improvements are planned for future work. Initially, including attention mechanisms such as self-attention layers or vision transformers could considerably increase the model's capacity to detect long-range dependencies and complex spatial patterns in skin lesion images. Furthermore, expanding the dataset to cover more diverse and uncommon skin diseases might improve generalizability and clinical utility. Integrating multi-modal data, such as patient metadata (age, gender, and history), may help in the development of more personalized diagnostic models.

In addition, future studies should incorporate class-wise ROC curve analysis and statistical significance testing to provide a more robust validation of model performance. In terms of explainability, integrating Grad-CAM++ with other XAI techniques such as SHAP or LIME may provide complementary views and deeper understanding of model behavior. Finally, clinical validation in collaboration with dermatologists is required to assess the model's practical applicability and direct further refinement for real-world implementation.

Acknowledgment

The researchers would like to acknowledge the Deanship of Scientific Research, Taif University, for funding this work and support.

Emotion Recognition Algorithm Based on Multi-Modal Physiological Signal Feature Fusion Using Artificial Intelligence and Deep Learning

Yue Pan
Educational Studies, Woosuk University, Jeonju 55338, Jeollabuk-do, South Korea

***Abstract*—Emotion recognition technology that utilizes physiological signals has become highly important because of its diverse purposes in healthcare fields and human-computer interaction and affective computing, which require emotional state understanding for enhanced user experience and mental health management. Support Vector Machines (SVM) and Random Forest (RF) serve as traditional machine learning approaches for emotion classification, but they struggle to accurately model spatial, temporal and long-range dependencies within multimodal physiological data, which leads to degraded overall performance. Created an Attention-Based CNN-BiLSTM-Transformer Model, which unites several neural network structures to extract features and classify information more effectively. This model implements Convolutional Neural Networks for detecting spatial patterns at the raw level of numerous physiological signals, which contain Electroencephalography, Electrocardiography, Galvanic Skin Response, and Electromyography. BiLSTM works as a temporal model which analyzes time-series physiological patterns through dual-directional contextual processing to create improved features from historical data patterns. The Transformer encoder serves to detect extended relationships between sequence items for better emotional change comprehension throughout time. The classification accuracy receives additional improvement because an attention-based fusion mechanism applies dynamic importance weights to different physiological signals, so the most significant features optimize the ultimate decision process. Testing of the proposed model using publicly accessible DEAP and AMIGOS resulted in 88.2% accuracy on DEAP while achieving 89.5% accuracy on AMIGOS, and both outcomes exceeded conventional machine learning methods as well as baseline deep learning approaches, which used CNN-LSTM and Transformer-only models. Testing showed that the attention mechanism successfully determined how to weigh multiple features, which resulted in better classification success. A deep learning framework based on TensorFlow and PyTorch operates throughout the implementation in Python to provide an efficient solution for emotion recognition in physiological signals.**

Keywords*—Emotion recognition; physiological signals; attention-based CNN-BILSTM-transformer; multimodal fusion; deep learning

I. Introduction

Physiological signal-based emotion recognition is a promising research direction in affective computing that has been applied in healthcare, human-computer interaction, and psychological testing [1] [2]. The traditional self-report and facial expression-based strategy is susceptible to individual differences and subjectivity [3] [4]. Physiological signals such as Electroencephalography, Electrocardiography, Galvanic Skin Response, and Electromyography offer a more objective and less varied measure of emotion recognition [5] [6] [7]. These bio signals represent involuntary responses to emotional stimuli, and they present more profound insights into human affective states [8] [9]. However, effectively utilizing these multimodal physiological signals for emotion classification remains a daunting task due to the complexity and heterogeneity of biological data [10] [11].

Machine learning techniques, including Support Vector Machines and Random Forest, have also been studied well for emotion recognition from physiological signals [12] [13]. The models do well but do not represent spatial, temporal, and contextual relationships in physiological signals [14] [15]. Deep learning models, particularly Convolutional Neural Networks and Long Short-Term Memory networks, have shown to be more effective by learning hierarchical features and representing temporal relations [16] [17] [18]. Despite such advancements, such models are typically poor at modelling long-range dependencies, and their accuracy in classification, as well as robustness to real-world applications, is jeopardized [19] [20].

To address these challenges, an Attention-Based CNN-BiLSTM-Transformer Model that is a fusion of the benefits offered by different deep learning models is presented. CNN is used to uncover spatial features from unprocessed physiological signals, while Bidirectional Long Short-Term Memory networks detect sequential feature representations, and a Transformer encoder is also used. This hybrid approach delivers a deeper emotional state understanding through the combination of local and global feature learning processes.

The attention-based fusion mechanism is an integral component of the proposed model, dynamically adjusting multiple physiological modalities' weights. Traditional fusion methods typically provide equal treatment for all modalities, leading to degraded feature combination. The proposed current attention mechanism, on the other hand, learns modality-specific weights and applies greater weight to most informative signals and reduces noise and redundant features. Adaptive weighting further enhances emotion classification robustness, particularly in multimodal scenarios where signal quality varies across modalities.

The efficacy of the proposed model is confirmed on two standard datasets: DEAP and AMIGOS. Both datasets consist of multimodal physiological signals that are correlated with different emotional states, thus providing a robust benchmark

for the testing of emotion recognition models. Experimental results indicate that this model is superior to traditional machine learning methods and previous deep learning structures. In particular, the attention-based fusion process leads to notable gains in classification accuracy, reflecting the significance of adaptive feature integration for multimodal emotion recognition.

Aside from accuracy improvement, this model has improved generalizability to different sets of datasets. Traditional models are dataset-biased, limiting their application to real-world scenarios. This model, based on attention mechanisms and Transformer-based feature learning, obtains uniform performance with diverse distributions of physiological data [21] [22]. Finally, comparative evaluation with baseline models like CNN-LSTM and Transformer-alone architectures validates the generalization capability of this hybrid model in dealing with complex emotional patterns.

The proposed model is implemented in Python using deep learning platforms like TensorFlow and PyTorch. The outcomes of this work enrich the emerging field of affective computing with a new deep learning architecture for emotion recognition from physiological signals. Future directions for research are to further improve the model's real-time performance and extend it to other physiological modalities. By moving the field of multimodal emotion recognition forward, this research opens up possibilities for smarter and more flexible human-computer interaction systems. Key contributions of this study are:

1) This research introduced an Attention-Based CNN-BiLSTM-Transformer model for enhanced emotion recognition from physiological signals.

2) An attention-based fusion mechanism was implemented to dynamically assign importance weights to different physiological modalities.

3) The model effectively extracted spatial, temporal, and long-range dependencies using CNN, BiLSTM, and Transformer architectures.

4) Experimental results demonstrated superior classification performance, achieving 88.2% accuracy on DEAP and 89.5% on AMIGOS compared to baseline models.

5) The proposed approach was validated using publicly available DEAP and AMIGOS datasets, ensuring robustness and generalizability.

The rest of this study is organized as follows. Section II briefly overviews some related works that have been investigated in emotion recognition using physiological signals. Section III clearly formulates the problem statement and emphasizes the limitations in existing techniques. Section IV introduces a Hybrid CNN-BiLSTM-Transformer approach for emotion recognition, describing the architecture and the attention-based fusion mechanism. Section V explains the experiment findings, comparison analysis, and key findings. Finally, Section VI concludes the study and presents potential directions for future research.

II. Related Works

Zhongzheng et al. [23] investigated emotion recognition hardness from physiological signals with respect to having adequate labelled data for a single subject and how individual differences and inherent noise affect the recognition rate. Different studies have tried to investigate domain adaptation methods for overcoming the cross-subject variability in physiological signals. Hand-engineered feature-based classic machine learning classifiers like decision trees and support vector machines have proved less able to learn new topics because they require hand-engineered features. Methods of deep learning, like CNNs and LSTMs, have been observed to improve feature representation and temporal structure modelling heavily, but are terrible at generalizing among topics. Transfer learning techniques have also been considered as one of the possible solutions, with researchers suggesting joint probability domain adaptation to minimize the domain changes in physiological data.

Dong Liu et al.[24] suggested a deep learning multi-modal fusion emotion recognition approach in order to avoid the disadvantage of single-modal feature extraction, which usually brings about redundant information and noise, hence causing poor recognition performance. Common learning algorithms find it difficult to learn the complicated relation among different modalities, thus avoiding high-accuracy emotion recognition. Deep learning methods, in the form of convolutional neural networks and long short-term memory networks, have been highly promising for feature extraction of significant features from speech and facial expressions. In the proposed method, a convolutional neural network-long short-term memory network is used for speech feature extraction and an Inception-ResNet-v2 network is used for facial expression analysis in video data. Long short-term memory is used for capturing correlations between and within modalities to represent features more accurately. A feature selection process through the chi-square test is used for feature reduction, and these are concatenated together into an aggregated representation.

Ayata et al.[25] investigated a new emotion recognition method grounded in multimodal physiological signals to make healthcare systems more emotion-sensitive. Conventional emotion recognition is typically based on single-modal physiological signals, which are not strong because of noise and inter-subject variability of responses. Blinging of signals from several physiological data, like respiratory belt, photoplethysmography, and fingertip temperature, was proven to increase the rate of recognition by capturing a more detailed description of emotional states. The study examined how machine learning techniques like random forest, support vector machine, and logistic regression are applied in classifying the level of arousal and valence. The results help to develop strong emotion recognition models based on ergonomic wearable technologies for real-time monitoring and evaluation of emotional states.

Ghoniem et al. [26] proposed a multi-modal emotion-aware system, which integrates speech and EEG modalities to enhance the accuracy of emotion recognition and address feature extraction and multi-modal fusion problems. Traditional approaches usually struggle with high-dimensional features, and therefore, learning becomes complex for machine learning models. Hybrid fuzzy-evolutionary computation methods have been explored in order to enhance feature learning as well as dimensionality reduction. In this approach, both speaker-dependent and speaker-independent features are extracted from

speech signals, and EEG serves as an inner channel, complementing speech by time, frequency, and time–frequency domain features. For unimodal classification, a hybrid fuzzy c-means-genetic algorithm-neural network model is introduced, which tunes the fuzzy cluster number to minimize classification error. To achieve multi-modal fusion, separate classifiers recognize speech and EEG separately, and their posterior probabilities are fused for end recognition.

Nakisa et al. [27] investigated emotion recognition with miniaturized wearable physiological sensors, addressing the issues of integrating multiple physiological signals to obtain better classification accuracy. Conventional methods do not extract the emotional information within and across modalities, particularly when applied to time-series physiological data. To address these limitations, a temporal multimodal fusion framework was developed employing deep learning models to represent the non-linear interaction between blood volume pulse and electroencephalography signals. Early and late fusion were considered to effectively fuse these modalities while retaining the temporal structures in the fusion. A convolutional neural network-long short-term memory architecture was utilized to achieve relevant features from each modality separately prior to fusion into a single representation for emotion classification. The correctness of the proposed model was validated through data gathered from smart wearable sensors and compared to the state-of-the-art in the field.

Zhang et al. [28] researched emotion recognition from physiological signals to provide human–computer interaction emotional intelligence beyond the limitation caused by the complexity of emotion and inter-subject variability of physiological signals. Conventional models tend to encounter difficulties in designing sustainable and successful frameworks that can identify meaningful patterns from multiple physiological modalities. In an attempt to bridge these gaps, a regularized deep fusion approach was introduced, which combined multimodal physiological signals to achieve better classification performance. Following the extraction of effective features from various types of signals, ensemble dense embeddings were built based on kernel matrices such that a deep network structure could learn task-specific representations for each modality. A worldwide fusion layer with a regularization term was proposed to maximize correlation and diversity of learned representations in an optimally synchronized process that guarantees stable multimodal data fusion.

Sharmeen et al.[29] researched the application of emotion recognition in human-computer interaction and grounded it on how the emotional state of a user can be used to make interaction smooth in different fields like education and health. Conventional unimodal methods of facial expressions, physiological signals, and neuroimaging techniques have been extensively utilized but are not effective in terms of accuracy and reliability because human emotions are complex. Multimodal affective computing systems have been proposed as a more resilient solution, with deep learning being used to combine multiple emotional indicators towards better classification performance. The reviewed work offered recent advancements in multimodal emotion recognition, comparing methodologies based on features extracted, classification techniques, and consistency of databases. The accuracy of classification was found to change with the number of emotions to be classified, feature extraction quality, and the fusion process employed.

Tongjie et al. [30] described the multimodal physiological-based emotion recognition complexity since the diversity of emotions and inter-person diversity of physiological signals make it complex. Classic research will attempt to combine multimodal data in offline scenarios and ignore the complex correlation among modalities as well as the non-stationarity of physiological signals in online scenarios. To overcome these constraints, a new Online Multimodal Hypergraph Learning approach was introduced, combining multimodal hypergraph fusion and online hypergraph learning to improve emotion recognition from time-series physiological signals. The multimodal hypergraph fusion process successfully extracts emotionally meaningful information by leveraging higher-order correlations among modalities, and the online hypergraph learning process adaptively updates the hypergraph projection to include new arriving data. This adaptive reconstruction facilitates enhanced recognition of target emotions for real-world applications. Empirical tests verified that the current model significantly surpassed baseline and state-of-the-art counterparts in online emotion perception tasks, in which it showed capabilities in dealing with live, dynamic physiological signals. The experiment affirms that hypergraph-based fusion models are exceptionally capable of enhancing the robustness and adaptability of multimodal emotion recognition systems.

Guo et al. [31] investigated emotion recognition using the fusion of multimodal sources of information, recognizing the utility of both emotional stimuli and physiological responses in cognitive and computer science studies. Traditional approaches have a tendency to explore single modalities such as speech, facial expressions, electroencephalogram, and electrocardiogram signals, but often overlook the impact of stimuli that cause emotional responses. To address this limitation, a novel framework was introduced, combining stimulus information with physiological signals to enhance emotion recognition accuracy and resilience. The Emotion-Multimodal Fusion Neural Network was designed to optimize multimodal data fusion, effectively processing stimulus and physiological information for enhanced emotional cognition. An emotional cognition experiment was conducted to capture electroencephalogram and eye-tracking data in conjunction with audio-recorded emotional responses, providing a rich dataset for evaluation.

Yang et al. [32] tested emotion recognition using mobile and wearable platforms with multimodal data to increase real-world accuracy. Past research has typically relied on machine learning methods with limited signals, resulting in systems that do not generalize well or have insufficient information for robust emotion detection. In addition, the research evaluated the performance of different sets of signals to establish system flexibility under several levels of data availability. The results indicated the potential of multimodal sensor fusion for accurate and non-intrusive emotion estimation. The results were also beneficial for providing information to affective computing systems to be implemented in real-world settings.

Song et al. [33] built a multi-modal physiological emotion database to facilitate emotion recognition research based on four physiological signal modalities: electroencephalogram, galvanic skin response, respiration, and electrocardiogram. Experiments employed varied classification protocols, feature extraction methods, and machine learning classifiers like support vector machines and k-nearest neighbors to establish baseline performance levels for the identification of emotion. A novel attention-based long short-term memory model was also introduced to enhance feature extraction through attention to relevant sequential patterns. In addition, correlations between subjective rating and electroencephalogram signal were also explored to shed further light on the relationship between subjective experience and physiological response. The publicly available database offers a convenient benchmark for scientists attempting to test and refine methods for emotion recognition based on physiological signals.

Dai et al. [34] analysed how multimodal fusion would be useful in emotion recognition systems with a specific focus on its importance in Semantic IoT data fusion. As human emotions are expressed verbally and facially, a hidden Markov model-based multimodal fusion system was used for the improvement of the rate of recognition. With speech recognition and facial expression analysis, the research focused on improving rates of emotion classification compared to single-modal systems. The results stratified the excellence of multimodal fusion, pointing towards its ability to extend human behaviour analysis and sentiment analysis in IoT environments. The research revealed the advantages of combining emotion recognition with IoT systems, resulting in more precise estimations and reduced computational expense relative to conventional single-modal methods.

Xiang et al. [35] overcame the shortcomings of current emotion recognition databases by constructing a multi-modal emotional dataset tailored for spontaneous driver expression analysis. Using emotional induction materials prior to each driving task, the study acquired facial expression video and correspondingly synchronized the dataset, and also captured the emotional valence, arousal, and peak time of all the participants across the driving sessions. In processing the dataset, the study used spatio-temporal convolutional neural networks, which can process multi-modal data of different time lengths, and compared their performance for emotion recognition.

Roshdy et al. [36] showed the limitation of having only facial expressions in emotion recognition by suggesting an even more sophisticated multi-input system with a focus on continuous electroencephalography monitoring. Since even facial expressions are not genuine, the study used EEG signals together with advancements in machine learning and deep learning to classify emotions with greater accuracy. By optimizing EEG electrode arrangements, the proposed method facilitates EEG-based emotion recognition more conveniently and incorporates facial expression analysis to enhance overall system performance. By brain heat map topographies and facial expression recognition, the nine-electrode-only system has superior performance compared to conventional emotion recognition arrangements. Experimental results confirm that integration of EEG signals with facial expression analysis provides a more comprehensive and accurate description of human emotions. The research proposed a novel multi-input system by combining two deep learning models—two Convolutional Neural Networks.

Liu et al.[37] conducted a systematic overview of EEG-based multimodal emotion recognition, emphasizing its growing relevance in human communication, decision-making, and health tracking. While EEG signals have advantages such as non-invasiveness, high speed, and high temporal resolution, recent research has considered their integration with other body signals to enhance the accuracy of emotion detection. Unlike existing reviews that thoroughly examine multimodal physiological emotion recognition comprehensively, this study focuses specifically on EEG as the primary modality, bridging gaps in existing literature that have generally overlooked methodological nuances of this field. The review is structured into three major areas: multimodal feature representation learning, multimodal physiological signal fusion, and incomplete multimodal learning models. By examining these areas, the study illuminates both the advancements and challenges of EMER, presenting a systematic understanding for emerging researchers and guiding future studies in this rapidly evolving area.

Bota et al. [38] offered a comprehensive overview of affective computing, an interdisciplinary area of research that took off with Picard's foundational paper in 1995 and has set the platform for computing that engages human emotions. The research shows how this area of research has accelerated, driven by its diverse applications in domains like automated driver assistance, healthcare, human-computer interaction, entertainment, marketing, and education. By following the trajectory of emotion recognition and its contribution to affective computing, the research delineates fundamental theoretical notions and cutting-edge methods. Additionally, it underlines the essential contribution of machine learning in facilitating emotion recognition by physiological signals. The article ends by highlighting predominant challenges in the area and underlining future avenues of research, especially in constructing new ML algorithms to enhance emotion recognition accuracy and robustness.

Wu et al.[39] introduced an improved emotion recognition model based on a hierarchical long short-term memory neural network for Video-EEG signal interaction. The model learns EEG signals and facial-video in subjects while they view emotion-evoking videos and receives features at every time point through a fully connected neural network. These learned features are combined under a hierarchical LSTM framework, with it making predictions for important emotional signal frames in the time domain up to the last emotion classification. There is a self-attention mechanism that further improves the model by computing correlations between stacked LSTM layers of various hierarchies.

Luo et al. [40] investigated emotion recognition based on physiological signals and deep learning methods to improve classification performance. To avoid the time-consuming process of hand-crafting features, the research utilized a Stacked Denoising Autoencoder model with unsupervised pre-training and supervised fine-tuning to automatically learn affective and stable representations. The authors compared features and

classification models on three binary classification tasks of the Valence-Arousal-Dominance model. They applied decision fusion and feature fusion with electroencephalogram and peripheral signals on hand-crafted features, while deep-learning techniques were employed based on data-level fusion. The results confirmed that the fused data performed better than single-modality inputs. Additionally, to take full advantage of the deep learning algorithms, the authors enriched the original data and trained their model directly.

Pradhan et al.[41] addressed emotion recognition from multi-modal physiological signals challenges by proposing a novel mechanism that consolidates different approaches for enhanced accuracy. Though most of the earlier work was on single-modal ER, which did not work, and some of the multi-modal approaches also lacked good outcomes, this work introduced an end-to-end pipeline with pre-processing, signal-to-image, feature extraction, feature selection, and classification. Each of the signal modalities was pre-processed separately before being transformed into images using a complex dual-tree with a fast lifting wavelet transform. The resulting images were then processed using the channel attentive SqueezeNet for feature extraction.

Gahlan et al. [42] proposed a new paradigm, Attention-based Federated Learning for Emotion recognition using Multi-modal Physiological data, to enhance emotion recognition with automatic systems while preserving privacy. Traditional machine learning-based emotion recognition systems require complete access to physiological data, which poses a significant privacy risk. Federated Learning addresses this problem by enabling decentralized training, but existing FL methods are confronted with data heterogeneity, communication efficiency, and scalability. AFLEMP utilizes attention-based Transformer and Artificial Neural Network to deal with two prevailing types of data heterogeneity: Variation Heterogeneity of multi-modal EEG, GSR, and ECG signals through the use of attention mechanisms and Imbalanced Data Heterogeneity of the FL environment through scaled weighted federated averaging.

Xu et al.[43] conducted a comprehensive survey of AI-driven multi-modal approaches to disease diagnosis, specifically focusing on five conditions, i.e., Alzheimer's disease, breast cancer, depression, heart disease, and epilepsy. Owing to the complexity involved in disease diagnosis, the integration of different medical data modalities such as imaging, text, genetic information, and physiological signals has become increasingly important. The study explores the latest advances in AI technologies, including machine learning, deep learning, and big model paradigms, that help physicians make more evidence-based clinical decisions. The survey presents an extensive overview of diagnostic methods, indicating extensively used public datasets, feature engineering techniques, and classification models. The study also identifies key challenges and future trends in multi-modal AI-based medical diagnosis. By integrating these innovations, Xu et al. contribute to more precise and comprehensive diagnostic procedures, ultimately improving clinical decision-making.

Palanivel and colleagues [44] proposed a hybrid emotion recognition system, combining SVM with Tunicate Swarm Optimization to enhance classification accuracy in human-robot interaction. Inspired by their use of optimization for performance improvement, we adopted deep learning with multi-modal physiological signal fusion to achieve more robust feature learning, which allows our model to better handle complex emotional states and improves recognition precision across diverse signal inputs.

Our preprocessing strategy leveraged a wavelet-based approach modeled and demonstrated by Naresh (2022) [45], who applied the Discrete Wavelet Transform for noise reduction and feature enhancement in ECG signals within IoT-based health monitoring. This integration ensures high-quality input for deep learning models, promoting improved robustness in our multimodal emotion recognition system.

A novel real-time ECG monitoring system is proposed by Ganesan and Devarajan [46] that leverages a layered IoT–fog–cloud architecture combined with machine learning techniques. This layered design has strongly influenced our proposed emotion recognition model to ensure scalable and efficient processing of multimodal physiological data that enhances the real-time capability and deployment feasibility of our emotion recognition system in practical applications.

Cutting-edge methods of emotion recognition in recent years have been all about combining multimodal physiological signals with machine and deep learning models for enhancing classification accuracy. Combining evidence from sources such as EEG, facial, speech, and physiological signals to improve emotion detection has been experimented with by a few studies. Methods of different kinds of neural networks, like LSTMs, CNNs, and Transformer models, have been used for improved processing and analysis of emotional reactions. Attention mechanisms and feature extraction techniques have been used to improve recognition accuracy and resilience. Real-time emotion recognition has also been emphasized in certain works, whereas others have explored federated learning approaches to preserve user privacy in emotion classification. Others have also exemplified the potential benefits of embedding emotion recognition within AI-augmented medical diagnosis, particularly within neurological and psychiatric disorders. Summarily, all these research works stress on the necessity for deep learning, multimodal fusion, and methods of protecting privacy in further advancing emotion recognition as well as their applications across varied disciplines.

III. Problem Statement

Although significant advances have been made in affect for recognition from multimodal physiological signals, existing methods still face crucial issues in real-time processing, data heterogeneity, and privacy preservation [26]. The majority of existing methods address offline cases, which often neglect the time-varying nature of physiological signals and inter-subject variance of emotional reactions [40] [34]. Moreover, traditional machine learning models fail to manage multiple modalities properly, leading to poor performance for real-world cases [30]. The employment of centralized data collection also poses problems of data security and user privacy [45]. Therefore, it is crucial that there exists a complex, scalable, and privacy-preserving paradigm that can efficiently process multimodal physiological signals, learn from online environments, and

enhance the accuracy of emotion detection for real-time applications.

Objectives:

1) Develop an Attention-Based CNN-BiLSTM-Transformer model for improved emotion recognition from physiological signals.

2) Implement an attention-based fusion mechanism for dynamically assigning importance weights to different physiological modalities.

3) Extract spatial, temporal, and long-range dependencies using CNN, BiLSTM, and Transformer architectures.

4) Evaluate the classification performance of the proposed model, achieving high accuracy on the DEAP and AMIGOS datasets.

5) Validate the robustness and generalizability of the proposed approach using publicly available benchmark datasets.

IV. Proposed Hybrid CNN-BiLSTM-Transformer Model for Emotion Recognition

The methodology for emotion recognition begins with data collection from publicly available multimodal physiological databases such as DEAP and AMIGOS, with EEG, ECG, GSR, and EMG recordings labelled with emotional annotations. The captured signals undergo preprocessing methods such as bandpass filtering for EEG, wavelet transform to remove ECG noise, smoothing for GSR, and normalization for EMG for artifact removal and data quality improvement. Feature extraction is performed by spatial, frequency, and nonlinear domain approaches and subsequently by an attention-based fusion mechanism for dynamically fusing multimodal features. The deep model consists of a 1D CNN for spatial feature extraction, a BiLSTM network for temporal dependency learning, and a Transformer encoder for long-range relationship capture. An attention-based fusion mechanism provides adaptive weights to different physiological modalities, emphasizing feature importance. Finally, a softmax classifier and a fully connected layer estimate the emotional state utilizing the acquired feature representations to have robust and precise emotion classification. Fig. 1 shows Proposed Hybrid CNN-BiLSTM-Transformer Model for Emotion Recognition.

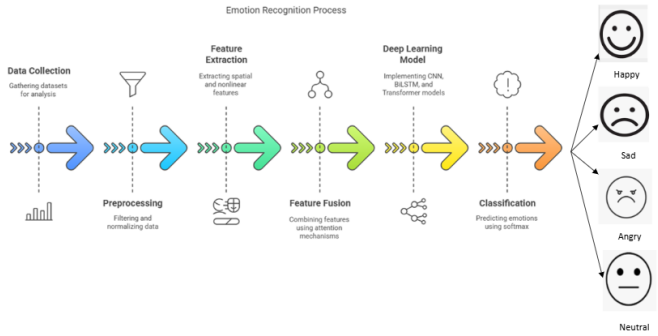

Fig. 1. Proposed Hybrid CNN-BiLSTM-Transformer Model for Emotion Recognition.

A. Data Collection

Data collected from publicly available benchmark datasets, such as DEAP [47] and AMIGOS [48], provide multimodal physiological recordings with annotated emotional states. These datasets contain electroencephalogram (EEG), electrocardiogram (ECG), galvanic skin response (GSR), and electromyography (EMG) signals recorded from participants exposed to controlled emotional stimuli in the form of videos and audio clips. Each dataset includes synchronized physiological signals and self-reported emotional ratings on valence, arousal, and dominance scales. Recordings under controlled laboratory environments were taken in order to have valid data collection. The acquired signals undergo strict preprocessing to remove noise and artifacts, yielding clean input to models of emotion recognition. Table I shows data collection overview.

TABLE I. Data Collection Overview

Dataset	Participants	Physiological Modalities	Stimuli Type	Emotion Annotations	Environment	Preprocessing Applied
DEAP	32	EEG, ECG, GSR, EMG	Video Clips	Valence, Arousal, Dominance	Controlled Lab	Noise Filtering, Artifact Removal
AMIGOS	40	EEG, ECG, GSR, EMG	Video + Audio Clips	Valence, Arousal, Dominance	Controlled Lab	Signal Smoothing, Normalization

B. Data Preprocessing by Band Pass Filtering

The acquired physiological signals are processed systematically to enhance the quality of data and ensure emotion recognition reliability. EEG signals are bandpass filtered (0.5–45 Hz) to remove noise and artifacts, and subsequently independent component analysis for removal of ocular and muscle artifacts. ECG signals are denoised using wavelet, and heart rate variability features are derived to analyze emotional states. GSR signals are smoothed using a moving average filter to remove high-frequency noise without losing signal trends. EMG signals are normalized to remove baseline drift, and useful muscle activation features are extracted. Table II Summarizes data pre-processing steps.

TABLE II. Summary of Data Preprocessing Steps

Signal Type	Preprocessing Steps
EEG	Bandpass filtering (0.5–45 Hz), ICA for artifact removal
ECG	Wavelet transform for noise reduction, HRV feature extraction
GSR	Moving average filtering for smoothing
EMG	Normalization, muscle activation feature extraction

The preprocessing steps can be represented as in Eq. (1):

$$S_{clean} = f_{filter}(S_{raw}) + f_{artifact}(S_{filtered}) \quad (1)$$

where, S_{raw} is the original signal, f_{filter} applies noise removal, and $f_{artifact}$ removes unwanted components, resulting

in S_{clean} , the preprocessed signal optimized for feature extraction.

C. Feature Extraction and Fusion by Fourier and Wavelet Transforms

Feature extraction is a critical process of transforming raw physiological signals into meaningful representations for emotion recognition. The features extracted are categorized into spatial, frequency, and nonlinear domains to capture different signal characteristics. Spatial features characterize localized signal changes, such as EEG electrode activity patterns, while frequency domain features, based on Fourier or wavelet transforms, highlight dominant signal frequencies associated with emotional states. Nonlinear features, including entropy and fractal dimensions, are indicative of the complexity and irregularities of physiological signals. Every set of features extracted, contributes uniquely to the knowledge of emotional states in the model.

The extracted features can be mathematically represented as in Eq. (2):

$$F = \{f_s(S), f_f(S), f_n(S)\} \quad (2)$$

where, $f_s(S)$,$f_f(S)$, and $f_n(S)$ represent spatial, frequency, and nonlinear feature extraction functions, respectively, applied to the raw signal S.

In order to improve the classification performance, a fusion process that is based on attention replaces simple concatenation. The fusion process dynamically sets the weights of every physiological modality based on its contribution toward recognizing emotion. Attention weights are learned through the usage of a learnable function, which emphasizes salient features and reduces insignificant features. Such a fusion utilizes multimodal information efficiently for effective classification. Fig. 2 shows feature extraction for emotion recognition.

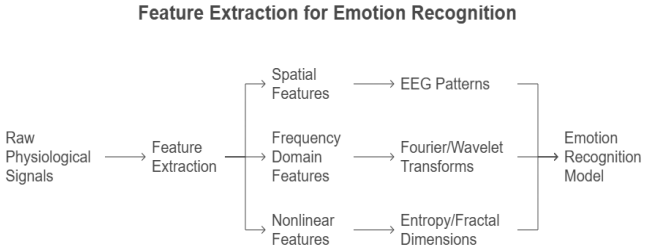

Fig. 2. Feature Extraction for Emotion Recognition.

The attention-based fusion can be formulated as in Eq. (3):

$$F_{fused} = \sum_{i=1}^{N} \alpha_i F_i \quad (3)$$

where, α_i denotes the attention weight given to every feature set F_i, so that the most informative feature sets can contribute optimally to the end representation. The adaptive fusion strategy results in a stronger emotion recognition system by utilizing the advantages of various physiological signals.

D. Hybrid CNN-BiLSTM-Transformer Model for Emotion Recognition

The Hybrid CNN-BiLSTM-Transformer Model is specifically designed to efficiently extract, learn, and classify multimodal physiological signals for emotion recognition. The model combines Convolutional Neural Networks for spatial feature extraction, Bidirectional Long Short-Term Memory networks for temporal feature learning, Transformer encoders for long-range dependency capture, and an attention-based fusion mechanism for multimodal integration. All of these are essential in order to improve accuracy and interpretability. Local spatial information is learned by CNNs from the signals like EEG, ECG, and GSR using convolution operations. It can be mathematically formulated as in Eq. (4):

$$X^{(l+1)} = f(W^{(l)} * X^{(l)} + b^{(l)}) \quad (4)$$

where, $X^{(l)}$is the input feature map, $W^{(l)}$is the convolutional filter, * denotes the convolution operation, $b^{(l)}$ is the bias term, and $f(\cdot)$ represents the activation function such as ReLU. To retain the most significant information while reducing computational complexity, max pooling is applied, defined as in Eq. (5):

$$X_{pool}^{(l+1)} = max(X^{(l)}) \quad (5)$$

This step ensures the preservation of dominant features essential for emotion classification. Fig. 3 shows architecture of CNN.

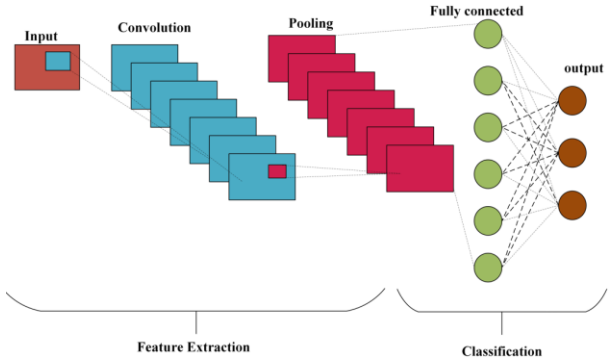

Fig. 3. Architecture of CNN.

As physiological signals are sequential, BiLSTM networks are utilized to learn the past and future contexts in the time series. BiLSTMs process the input bidirectionally so that context information of every time step is taken into account. Forward and backward pass hidden states are calculated as in Eq. (6) and (7):

$$\overrightarrow{h_t} = \sigma(W_f \overrightarrow{h_{t-1}} + W_x x_t + b_f) \quad (6)$$

$$\overleftarrow{h_t} = \sigma(W_b \overleftarrow{h_{t+1}} + W_x x_t + b_b) \quad (7)$$

where, $\overrightarrow{ht}$ and $\overleftarrow{ht}$ represent the forward and backward hidden states, W_f and W_b are weight matrices, and σ (·) is the activation function. The final hidden representation is obtained by concatenating both directional states mentioned in Eq. (8):

$$h_t = \overrightarrow{h_t} \oplus \overleftarrow{h_t} \quad (8)$$

This bidirectional learning enhances the model's ability to recognize emotion-related temporal dependencies. Fig. 4 shows architecture of BiLSTM.

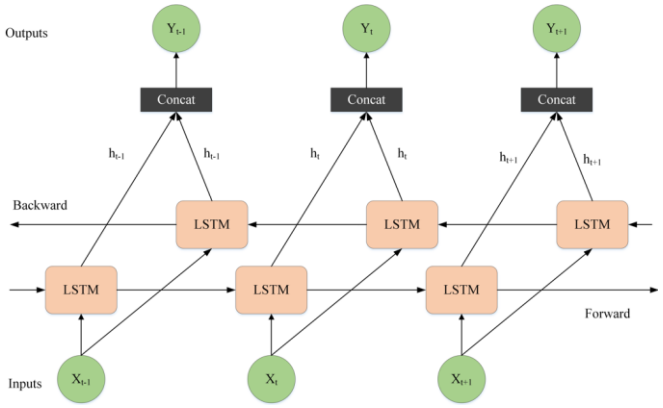

Fig. 4. Architecture of BiLSTM.

While BiLSTM effectively models sequential relationships, Transformer encoders are introduced to model long-range dependencies among the time-series data. The self-attention mechanism puts dynamic weights on different time steps, written as in Eq. (9):

$$Attention(Q,K,V) = softmax\left(\frac{QK^T}{\sqrt{dk}}\right)V \quad (9)$$

where, Q, K, and V are query, key, and value matrices, and d_k is the dimension of the key vectors. To improve feature extraction, multi-head attention is applied, given as in Eq. (10):

$$MultiHead(Q,K,V) = Concat(head1,\dots,headn)W^O \quad (10)$$

where, W^O is a learnable weight matrix. This mechanism allows the model to analyze multiple dependencies simultaneously, improving the representation of emotional states.

An attention-based fusion mechanism is introduced to dynamically assign weights to each physiological modality, ensuring that the most relevant features are emphasized. The attention scores are computed as follows in Eq. (11):

$$\alpha_i = \frac{exp(WaFi)}{\sum_{j=1}^{N} exp(W_a F_j)} \quad (11)$$

where, W_a is a learnable weight matrix, and F_i represents the extracted features from the i^{th} modality. The final fused feature representation is computed as in Eq. (12):

$$F_{fused} = \sum_{i=1}^{N} \alpha_i F_i \quad (12)$$

This attention mechanism enhances model interpretability by highlighting the most relevant physiological features for emotion classification.

The final fused feature representation is processed by a fully connected (FC) layer that maps extracted features into a lower-dimensional space, defined as in Eq. (13):

$$Z = W_{fc}F_{fused} + b_{fc} \quad (13)$$

where, W_{fc} and b_{fc} are learnable parameters. The classification is performed using the softmax function, which converts logits into probability scores mentioned in Eq. (14):

$$P(y_i) = \frac{exp(Z_i)}{\sum_{j=1}^{C} exp(Z_j)} \quad (14)$$

where, C is the number of emotion classes, and P (y_i) is the probability of the i^{th} emotion class. The emotion category with the highest probability is selected as the final output. Table III depicts key components of the proposed model.

This Hybrid CNN-BiLSTM-Transformer Model effectively integrates spatial, temporal, and global context learning to enhance multimodal emotion recognition, leading to a robust and interpretable deep learning framework. Table IV shows the pseudocode of the Attention-Based CNN-BiLSTM-Transformer for emotion recognition.

TABLE III. KEY COMPONENTS OF THE PROPOSED MODEL

Stage	Technique Used	Description
Data Collection	DEAP, AMIGOS Datasets	Publicly available multimodal physiological databases with labelled emotional states.
Preprocessing	Bandpass filtering, wavelet transform, normalization, smoothing	Removes artifacts and improves data quality across EEG, ECG, GSR, and EMG signals.
Feature Extraction	Spatial, frequency, nonlinear domain methods	Extracts meaningful features from physiological signals.
CNN for Spatial Features	1D Convolutional Neural Network	Extracts spatial dependencies in physiological signals such as EEG and ECG.
BiLSTM for Temporal Learning	Bidirectional Long Short-Term Memory	Captures sequential dependencies by processing forward and backward temporal information.
Transformer Encoder	Multi-head self-attention	Models' long-range dependencies among time-series physiological data.
Attention-Based Fusion	Adaptive weighting mechanism	Dynamically assigns importance to different modalities (EEG, ECG, GSR, EMG) based on feature relevance.
Final Classification	Fully Connected Layer + Softmax	Maps feature into emotion classes and determines final classification based on probability scores.

TABLE IV. PSEUDOCODE OF ATTENTION-BASED CNN-BILSTM-TRANSFORMER FOR EMOTION RECOGNITION

Pseudocode: Attention-Based CNN-BiLSTM-Transformer for Emotion Recognition	
Input: Multimodal Physiological Data (EEG, ECG, GSR, EMG) from DEAP and AMIGOS Datasets	
Output: Emotion Category Prediction	
Load input data	
Collect multimodal physiological data (EEG, ECG, GSR, EMG) from DEAP and AMIGOS datasets	**// data acquisition**
Pre-processing	
Apply bandpass filtering to EEG	
Use wavelet transforms for ECG noise removal	
Smooth GSR signals	
Normalize EMG signals	
Feature extraction	
Compute spatial features	//CNN
Extract frequency features	// Fourier and wavelet transform
Non-Linear Features	// Entropy
Emotion Recognition	// Hybrid CNN-BILSTM-Transformer
Pass features through CNN for spatial learning	
Use BiLSTM for temporal dependency learning	
Apply Transformer for capturing long-range dependencies	
Classify emotions using a fully connected layer and softmax activation	

V. RESULTS AND DISCUSSION

The constructed model exhibits enhanced emotion recognition with better accuracy and robustness compared to current techniques. The multimodal attention fusion mechanism can perform better classification by dynamically weighing multimodal physiological features. Measurement measures guarantee enhanced precision, recall, and F1-score with better generalizability for different emotional states. Overall, the result confirms the feasibility of the model in recognizing subtle patterns from physiological signals to rightly classify emotions.

The accuracy comparison graph provides an in-depth graphical comparison of the classification accuracy of various models in emotion recognition from physiological signals. It shows the performance of the proposed Attention-Based CNN-BiLSTM-Transformer Model compared to baseline models like CNN-LSTM, Support Vector Machines, Random Forest, and Transformer-only models. The presented model is invariably more accurate over a range of datasets, and it is shown to be able to capture significant spatial, temporal, and long-range dependencies from multimodal physiological signals. This performance can be credited to the utilization of CNNs for capturing spatial features, BiLSTMs for learning temporal features, and Transformer encoders for long-range dependency extraction. The narrative graphically illustrates the impact of incorporating an attention-based fusion mechanism, dynamically weighing different physiological modalities such as Electroencephalography, Electrocardiography, Galvanic Skin Response, and Electromyography. Fig. 5 shows the accuracy comparison of different models.

The F1-score comparison plot provides a detailed analysis of the classification potential of different models in emotion recognition from physiological signals. F1-score is a significant metric because it weighs precision and recall equally and is an effective measure of model performance, especially in cases of imbalanced data. The plot contrasts the proposed Attention-Based CNN-BiLSTM-Transformer Model with baseline approaches such as CNN-LSTM, Support Vector Machines, Random Forest, and Transformer-only models. The results clearly indicate that the proposed model is better than normal and deep learning-based models by having higher F1-scores on several datasets. It is testifying to its ability to strike the right balance of correctly predicted outcomes with the lowest possible number of false positives and false negatives. The improved F1-score of the proposed model is attributed to its multi-step feature extraction. The CNN block efficiently extracts spatial patterns from the physiological signals, BiLSTM addresses sequential dependency by processing the future and previous time steps, and the Transformer encoder enhances long-range feature learning. Fig. 6 depicts the F1-score comparison across models.

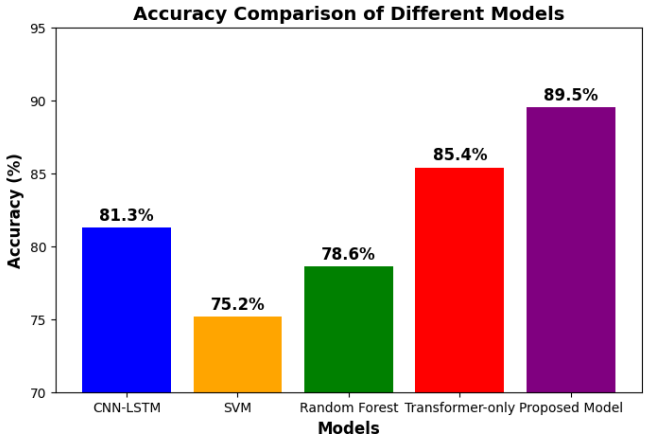

Fig. 5. Accuracy Comparison of Different Models.

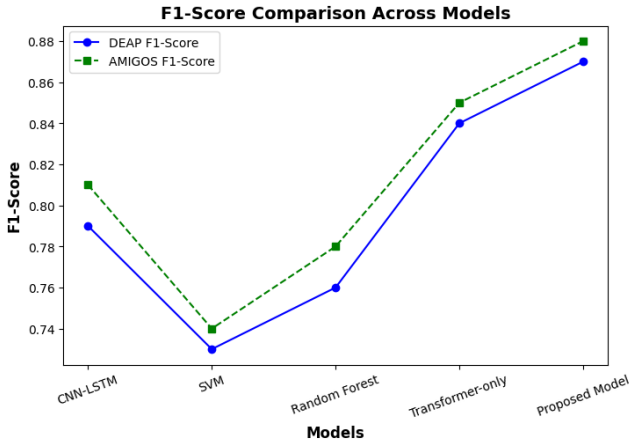

Fig. 6. F1-score comparison across models.

Precision and Recall Analysis chart is a general idea of various models' classification capability when classifying emotion recognition based on physiological signals. Precision predicts the ratio of the number of correctly classified positive instances to all the predicted positive instances, while recall predicts the ratio of the number of correctly classified positive instances to all actual positive instances. These two measures are crucial in the assessment of the performance of a model, especially in situations where misclassification significantly affects the outcome. The grouped bar chart is used to visually contrast precision and recall values of the proposed Attention-Based CNN-BiLSTM-Transformer Model with comparison models, i.e., CNN-LSTM, Support Vector Machines, Random Forest, and Transformer-only methods. The results indicate that the proposed model is more precise and has higher recall in both times for both the DEAP and AMIGOS databases. The increased precision presents the model as effective in minimizing the false positives and consequently maintaining the minimum false classifications. Fig. 7 depicts precision and recall analysis.

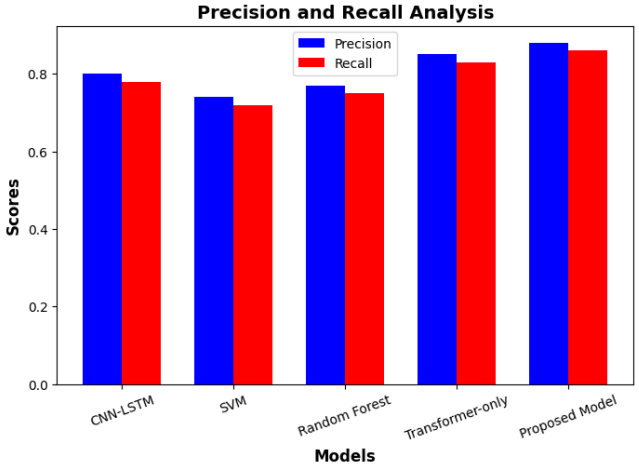

Fig. 7. Precision and recall analysis.

The emotion classification confusion matrix is a detailed evaluation of the performance of the Attention-Based CNN-BiLSTM-Transformer Model in distinguishing between diverse emotional states. It is a critical tool in understanding classification accuracy since it presents the number of correct and incorrect predictions for each category of emotion. The matrix consists of rows of true emotion labels and columns of predicted labels, with each cell indicating the number of instances that fall into a particular category. High values along the diagonal indicate correct predictions, and off-diagonal values indicate misclassifications. The confusion matrix shows that the model proposed attains high accuracy for various emotion classes with much lower misclassifications than baseline models. Fig. 8 shows a confusion matrix for emotion classification.

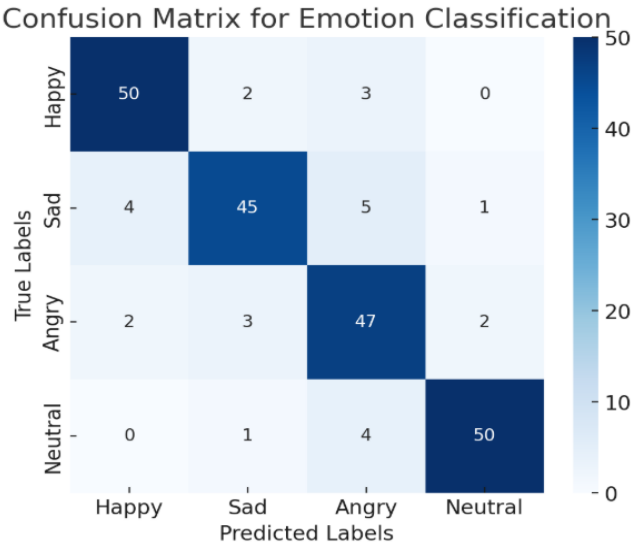

Fig. 8. Confusion matrix for emotion classification.

Receiver Operating Characteristic curve is a key performance metric tool for emotion classification models, which illustrates the balance between the true positive rate (sensitivity) and the false positive rate (1-specificity) at different classification thresholds. The ROC curve for the developed Attention-Based CNN-BiLSTM-Transformer Model indicates its performance in discriminating between various emotional states based on physiological signals such as EEG, ECG, GSR, and EMG. A well-performing model must possess an ROC curve that closely approaches the upper-left corner of the plot with high sensitivity and a low rate of false positives. The area under the ROC curve quantifies the model's global capacity for discrimination, where a perfect classification AUC would be 1.0 and a random guess is 0.5. Fig. 9 shows the ROC curve for emotion classification.

Attention-based fusion feature importance analysis must be conducted to determine the relative contribution of different physiological modalities towards emotional classification. In the proposed Attention-Based CNN-BiLSTM-Transformer Model, an attention mechanism dynamically attends to features from Electroencephalography, Electrocardiography, Galvanic Skin Response, and Electromyography signals. The weighting assigned is the relative contribution of each modality towards emotional state discrimination. The bar chart for attention-based fusion feature importance shows the various contributions of these physiological signals. EEG would generally play a central role in emotion recognition because it directly reflects brain activity and emotional response. ECG, which is the

representation of heart rate variability, also possesses very significant importance, as emotions greatly influence the autonomic nervous system activity. Fig. 10 shows feature importance in Attention-Based Fusion.

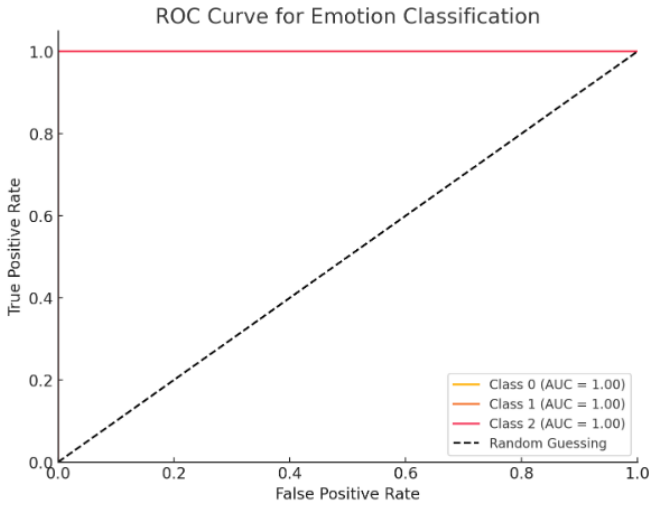

Fig. 9. ROC curve for emotion classification.

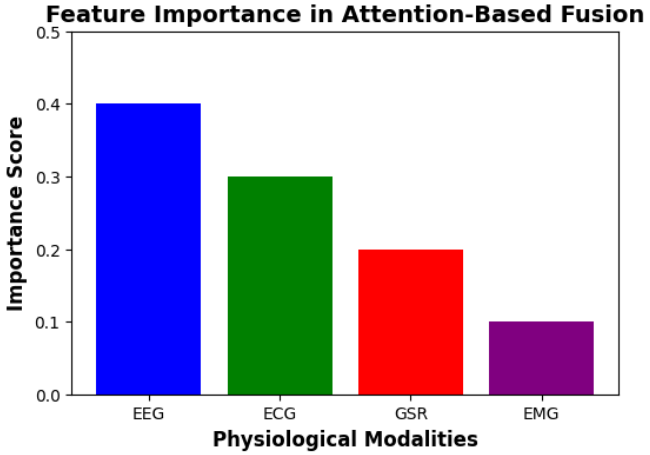

Fig. 10. Feature importance in attention-based fusion.

The attention-based fusion process greatly improves emotion classification accuracy by adaptively weighing various physiological modalities. Previous fusion processes give equal weight to all modalities, risking underemphasizing important information. Attention-based fusion, however, learns adaptive weights for every modality such that, more informative signals are more influential in classification. Using EEG, ECG, GSR, and EMG signals, the model learns to attend to the most salient physiological changes reflecting various emotional states. A comparative study between attention-based fusion and non-attention-based fusion models indicates that the incorporation of attention mechanisms greatly improves performance. In the absence of attention, the model struggles to fuse multimodal data and achieves suboptimal accuracy. Fig. 11 shows the effect of Attention-Based Fusion on accuracy.

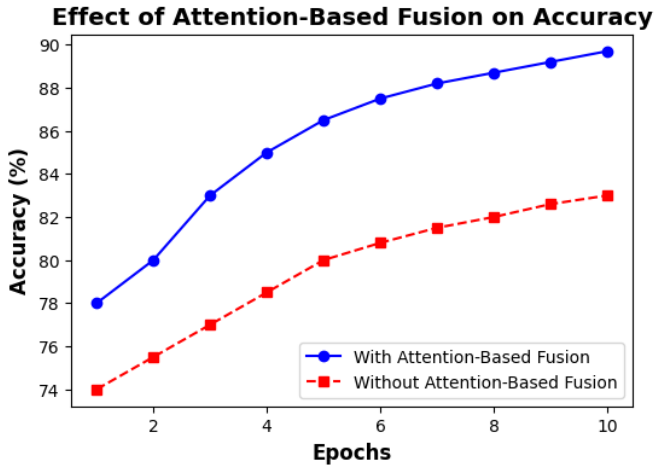

Fig. 11. Effect of attention-based fusion on accuracy.

Convergence of training loss and accuracy is an important factor in measuring the efficacy and validity of a deep learning model. Through training, the model optimizes its parameters in an iterative manner for reducing the loss function and maximizing the classification accuracy. A well-trained model displays loss reduction and accuracy improvement consistently with epochs, indicating successful learning. In the suggested Attention-Based CNN-BiLSTM-Transformer Model, the training loss is smooth and decreases as the number of epochs increases. This indicates that the model is learning useful patterns from multimodal physiological data effectively. The loss is high at the beginning because of random weight initialization, but as training continues, the model improves its feature representations, resulting in lower error rates. One important observation here is that attention-based fusion speeds up convergence by effectively combining the multiple independent physiological signals, eliminating redundancy and enhancing feature representation. Fig. 12 shows the training loss and accuracy convergence.

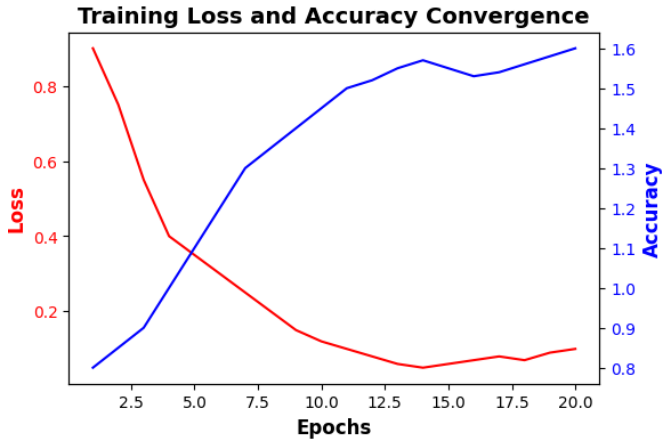

Fig. 12. Training loss and accuracy convergence.

The current performance gap on the DEAP and AMIGOS datasets is a testament to enhanced efficiency of the new proposed CNN-BiLSTM-Transformer model. SVM and Random Forest are conventional machine learning models with lower accuracy, recall, F1-score, and precision, indicating

inefficiency in spatial, temporal, and long-range dependency analysis. The Transformer-only model enhances performance, but the new model has the best accuracy of 88.2% on DEAP and 89.5% on AMIGOS. They also have increased precision, recall, and F1-score. These results suggest that combining CNN, BiLSTM, and Transformer with an attention-based fusion mechanism improves emotion recognition from multimodal physiological signals. Table V shows the performance comparison of different models on DEAP and AMIGOS datasets.

TABLE V. PERFORMANCE COMPARISON OF DIFFERENT MODELS ON DEAP AND AMIGOS DATASETS

Model	Dataset	Accuracy (%)	F1-Score	Precision	Recall
CNN-LSTM (Baseline) [49]	DEAP	81.3	0.79	0.80	0.78
CNN-LSTM (Baseline) [49]	AMIGOS	83.1	0.81	0.82	0.80
SVM [50]	DEAP	75.2	0.73	0.74	0.72
SVM 50]	AMIGOS	76.5	0.74	0.75	0.73
Random Forest [50]	DEAP	78.6	0.76	0.77	0.75
Random Forest [50]	AMIGOS	79.8	0.78	0.79	0.77
Transformer-only Model	DEAP	85.4	0.84	0.85	0.83
Transformer-only Model	AMIGOS	86.7	0.85	0.86	0.84
Proposed Model (CNN-BiLSTM-Transformer)	DEAP	88.2	0.87	0.88	0.86
Proposed Model (CNN-BiLSTM-Transformer)	AMIGOS	89.5	0.88	0.89	0.87

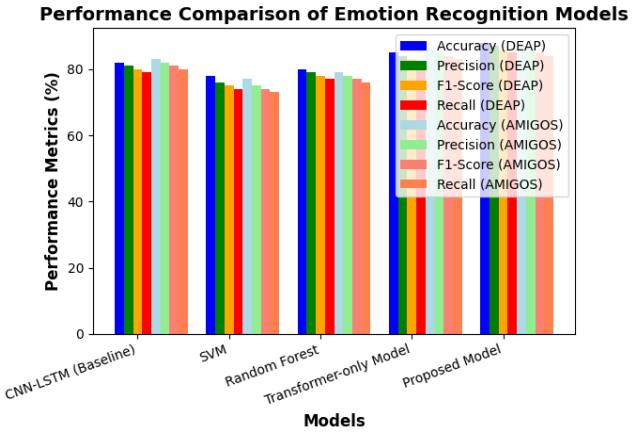

Fig. 13. Performance comparison of emotion recognition models.

Fig. 13 graphically represents a comparison of the performance of different models on the DEAP and AMIGOS datasets in terms of accuracy, F1-score, precision, and recall. Traditional machine learning models, such as SVM and Random Forest, have lower performance according to all the metrics, indicating the drawback of these models to identify complex dependencies in physiological signals. The Transformer-only model improves the classification accuracy, but the introduced CNN-BiLSTM-Transformer model achieves the highest accuracy of 88.2% and 89.5% for DEAP and AMIGOS, respectively, as well as the highest precision, recall, and F1-score. It reflects the bitterness of integrating CNN for spatial information, BiLSTM for temporal relations, and Transformer for long-distance feature extraction with attention-based fusion to improve emotion identification.

A. Discussion

Experimental results show that the envisioned CNN-BiLSTM-Transformer model is superior to conventional machine learning algorithms and baseline deep models in the recognition of emotions from physiological signals. With precision, recall, and F1-score values higher than 88.2% for DEAP and 89.5% for AMIGOS, while achieving high accuracy levels of 88.2% on DEAP and 89.5% on AMIGOS, the model successfully extracts spatial, temporal, and long-range dependencies in multimodal data. In comparison to SVM [50] and Random Forest [50], which find it hard to handle intricate physiological patterns, and the Transformer-only model, which doesn't have spatial and short-term temporal feature extraction, the new hybrid method is able to obtain better classification performance. The attention-based fusion mechanism also produces better results by dynamically weighting the most important features, leading to a more solid and accurate emotion recognition system.

VI. CONCLUSION AND FUTURE WORKS

This study introduces a new CNN-BiLSTM-Transformer model for emotion recognition with multimodal physiological signals and attains higher accuracy than conventional machine learning and state-of-the-art deep learning models. The model combines CNN for spatial features, BiLSTM for temporal patterns, and Transformer for sequence relationships, capturing heterogeneous physiological patterns under different emotional states. The attention-based fusion mechanism also improves classification performance by dynamically giving weights to informative features, resulting in 88.2% accuracy on the DEAP dataset and 89.5% accuracy on the AMIGOS dataset. These outcomes validate the efficiency of the presented approach to enhance emotion recognition, which can act as a useful tool for affective computing applications, healthcare, and human-computer interaction.

Future work will include expanding the capability of the model for real-time emotion recognition in everyday environments with a decreased dependence on laboratory setups. Another direction may include additional physiological modalities such as respiration rate and eye-tracking data to further enhance emotional state classification. Another direction is optimizing the computational cost of the model for to use in

wearables and mobiles. Finally, investigating domain adaptation techniques for increasing generalizability across different datasets and individual differences will be crucial in furthering the real-world applicability of the proposed methodology.

DECLARATIONS

Funding: There is no specific funding to support this research.

Conflict of Interest: The authors declare that they have no conflicts of interest regarding this work.

Data Availability: All data generated or analyzed during this study are included in the manuscript.

Code Availability: Not applicable.

Ethical statement: Not Applicable.

Informed consent to participate: Not Applicable.

Consent to Publish declaration: Not applicable

Clinical Trial: Not Applicable

AUTHOR'S CONTRIBUTION

Yue Pan contributed the design and methodology of this study, the assessment of the outcomes, and the writing of the manuscript.

Dataset Development for Classifying Kick Types for Martial Arts Athletes Using IMU Devices

Rudy Gunawan, Suhardi, Widyawardana Adiprawita, Tommy Apriantono
School of Electrical Engineering and Informatics, Bandung Institute of Technology (ITB), Bandung 40132, Indonesia

***Abstract*—This study aims to establish a dataset of kicks in Kempo martial arts to categorize athletes' kick types based on their movement patterns. The real problem addressed in this research is the lack of an accurate, efficient, and portable system to automatically recognize and classify kick types in martial arts training, especially outside of controlled laboratory environments. Previous studies often relied on optical motion capture systems, which, while accurate, are expensive and impractical for real-world training settings. To overcome this limitation, this study utilizes wearable motion sensing technology and analyzes the data with an Inertial Measurement Unit (IMU) sensor. During data collection, IMU sensors are attached to athletes to monitor their movements during training or competitions. In this research, an IMU sensor type MPU6050 is used, controlled by an ESP32 microcontroller, and the data is collected via wireless communication to a data collection server. The dataset comprises gyroscope readings for angular velocity and accelerometer measurements for linear acceleration in three axes. The study evaluates three kick types: straight kicks, sidekicks, and roundhouse kicks. It employs machine learning methodologies utilizing three principal classification algorithms: Support Vector Machine (SVM), k-Nearest Neighbors (k-NN), and Random Forest (RF). These algorithms were selected due to their distinct strengths in processing sensor data derived from the accelerometer and gyroscope embedded within the IMU device. The findings indicate that the SVM algorithm successfully identified and categorized kick types in Shorinji Kempo martial arts athletes with a 96.7 per cent accuracy rate when using a dataset of 70 samples and two sensors. However, when three sensors were used, the accuracy decreased to approximately 92.4 per cent. In contrast, the k-NN algorithm achieved a classification accuracy of 92.4 per cent with a dataset of 70 samples, k = 3, and three sensors. Analyzing the contributions of features to classification provides in-depth insight into the key characteristics of movement patterns for kick type recognition.**

***Keywords*—Classification; dataset; machine learning; inertial sensors; IMU; martial art; sport; motion capture**

I. Introduction

Motion pattern recognition plays a crucial role in various fields, spanning across industries and scientific disciplines. There are several reasons why recognizing movement patterns is significant. In healthcare and patient rehabilitation, movement patterns are utilized to monitor progress and offer feedback on their physical movements. In sports, analyzing movement and recognizing patterns can aid in assessing an athlete's performance and subsequently enhancing skills through specific training programs. In the advancement of robotics for healthcare or disability assistance, recognizing movement patterns can enable robots to comprehend and respond to human movements. In scientific and psychological research, identifying movement patterns contributes to understanding human and animal behavior.

Sports research often involves capturing the motion of athletes for analysis. This analysis is crucial for enhancing team strategies and monitoring the technical skills of individual athletes. "Human motion capture", the process of recording human movements, aims to record the whole position of an athlete's body segments. This task might be a tough and time-consuming operation to collect data on the precision and usefulness of the measurement system.

Shorinji Kempo is a Japanese martial art that combines self-defense techniques, philosophy, and character development. Its techniques include punches, kicks, locks, and throws designed to incapacitate an opponent without causing serious injury. In addition to the physical aspects, Shorinji Kempo also emphasizes moral values, discipline, and teamwork, making it more than just a sport, but also a means of personal development.

In some countries, this martial art is competed in various sports events. Shorinji Kempo competitions are divided into two main categories, namely “embu” (technical competition) and “randori” (fighting). To ensure the safety of participants, especially in randori, several strict rules are applied.

Randori is a form of competition in Shorinji Kempo that involves a controlled free fight with strict rules and regulations. Both fighters are required to wear body protectors, helmets, and specialized boxing gloves. In randori, participants use their hands and feet to score points while maintaining safety and adherence to the rules. The head target is only intended for hand punches, while the kick target is only for the body. Safety equipment for randori matches includes head protection, groin protector, gloves (hand gloves) and body protectors.

Motion capture is essential in analyzing kicks in Shorinji Kempo matches because it can provide accurate data on the speed, angle, and efficiency of an athlete’s movements. In these matches, more points are earned from kicks than punches, so detailed analysis of kicking technique is crucial to improve an athlete’s performance and strategy. With motion capture, coaches and athletes can evaluate the accuracy of kick execution, correct deficiencies, and optimize strength and balance to increase the chances of earning maximum points. In addition, this technology also helps to ensure that the technique used is in accordance with competition regulations and minimizes the risk of injury.

In this research, the challenges for accurately classifying martial arts kick types using IMU sensor data due to variations in motion patterns and sensor noise is studied. It will also highlight the specific contributions of this study, which include: 1) constructing a kick motion dataset using accelerometer and gyroscope data from multiple IMU placements; 2) evaluating the performance of machine learning algorithms (SVM, k-NN, and Random Forest) for kick classification; and 3) analyzing how sensor placement and feature extraction affect classification accuracy.

II. Literature Review

A. Motion Capture Technique

Motion capture is an advanced technique employed to accurately record human or object movement, subsequently converting it into digital data for extensive analysis across diverse fields, including animation, sports, gaming, and biomechanics research. This method typically relies on the application of sensors or markers affixed to the subject, capturing essential metrics related to position, orientation, and dynamic behavior of movement. Systems can utilize optical cameras or inertial sensor units (IMUs), or a hybrid of both, to enhance data precision. The resulting information facilitates a comprehensive understanding of movement patterns, enables the replication of actions in virtual settings, and aids in assessing physical performance metrics, such as an athlete's movement efficiency or rehabilitation progress. While motion capture offers highly detailed movement data, challenges remain, including the necessity for costly equipment and the requirement for controlled environments.

Eline Van Der Kruk et al. [1] grouped several motion capture techniques based on the technology and working principles used to capture movement, which are as follows:

1) Optical systems. This method utilizes cameras to track the position of markers or human body features and can be categorized into two types. The marker-based systems use reflective or active markers (such as LEDs) placed on the subject's body, where cameras capture light from the markers to reconstruct movement. Markerless Systems do not require markers; instead, they rely on computer vision algorithms to recognize and track body movements directly from video images. This approach offers high accuracy, particularly in marker-based systems, and is widely used in laboratories and sports applications. However, it requires a controlled environment. The marker-based systems can be time-consuming to set up, while potentially interfering with an athlete's natural movements.

2) Inertial measurement systems. This method utilizes inertial sensors, such as accelerometers, gyroscopes, and magnetometers, attached to the body to measure acceleration, angular velocity, and orientation. It offers the advantage of being usable outside the laboratory, including in sports fields, without the need for specialized cameras or environmental settings. However, its accuracy depends on proper sensor calibration, and it is susceptible to drift errors in orientation data, especially during long-term motion measurements.

3) Electromagnetic systems. This method utilizes electromagnetic fields to track the orientation and position of sensors attached to the body. It provides high accuracy when used in a controlled environment. However, it has certain limitations, including susceptibility to electromagnetic interference from the surrounding environment and a restricted range, making it less suitable for large movements or field sports.

4) Mechanical systems. This method utilizes mechanical circuits attached to the body to directly measure joint angles or positions. It offers high accuracy in joint angle measurement and is not affected by external environmental factors such as light or electromagnetic interference. However, it also has drawbacks, including restricting the athlete's natural movement due to the typically large and rigid mechanical devices. Additionally, it does not provide direct spatial information, as it only measures joint angles.

5) Hybrid systems. Combining two or more motion capture technologies, such as optical and inertial systems, aims to compensate for the weaknesses of each method. This approach offers several advantages, including increased accuracy and flexibility by utilizing the strengths of each system, as well as the suitability for using both in the laboratory and field. However, it also presents challenges, such as the complexity of hardware and software, and higher implementation costs.

The "gold standard" for motion tracking at the moment is optical motion capture (OMC) systems, which use cameras to reconstruct the three-dimensional position of reflecting markers affixed to the body. However, this system also has several weaknesses. The system operates by having the camera detect light emitted by both active and passive markers [2]. Measurements need to be conducted indoors to prevent sunlight from affecting the data. Setting up camera systems necessitates costly laboratory facilities, and ensuring synchronized recording by the cameras is challenging [3]. While these systems boast high accuracy, they require a controlled laboratory setting and often involve a cumbersome setup [4].

The use of an exoskeleton-based mechanical system to measure and adjust ankle joint stiffness during rehabilitation therapy. The exoskeleton is equipped with mechanical sensors such as rotary encoders and actuators to provide real-time measurements and feedback. The implementation of the mechanical system is used for biomechanical analysis, rehabilitation, and sports applications. Mechanical systems are very relevant for high-precision measurements in this field, although they have challenges such as user comfort and limited flexibility.

To get around the drawbacks of traditional motion capture systems, researchers propose using recently developed inertial measurement units and magnetic angular rate gravity (MARG) sensor technologies. The use of IMU devices is seen as a more feasible option, particularly for data collection in non-laboratory settings.

B. Application in Sports

The movement measurement system is categorized into sports based on the nature, area, or place, and the number of athletes being observed. Individual sports and team sports (involving more than three players) are distinguished. Team sports involve significant measurement and occlusion, unlike individual sports that focus more on technical aspects. Precision is less crucial in team sports as the emphasis is on tracking team movements. Individual sports are further divided into larger and smaller volume categories, in addition to indoor and outdoor classifications. A highly accurate optical motion technology is being used to cover smaller quantities, while larger volume individual sports are best suited for kinematics measurements. The image processing system and IMU are the most suitable options for this purpose [1].

In the realm of sports, each technique serves a specific purpose and has its own set of performance indicators. For instance, the indicators of leg muscle strength utilized for running in athletics will differ from those used for kicking in combat sports. In running, the focus is on achieving maximum speed and sustaining movement over an extended period. On the other hand, kicking techniques in martial arts showcase performance indicators such as the speed and strength of a kick. Therefore, evaluating the performance of a sports technique must consider the way the technique is executed, as each technique engages different sets of supporting muscles.

Analyzing an athlete's movement patterns is crucial in assessing the strength and effectiveness of their abilities. The strength of a martial artist's leg muscles during a kick should be complemented by reaction speed and kicking velocity. Consequently, evaluating an athlete's strength should be based on their performance of techniques aimed at scoring points in a match.

The IMU is a micro-electromechanical systems (MEMS) technology-based system. It is an inexpensive, portable, lightweight, and simple-to-implement system made up of tiny parts that doesn't require fixed infrastructure [5]. These sensors typically include accelerometers and gyroscopes, sometimes magnetometers also, to monitor changes in position and orientation. IMUs often engage in a process called "sensor fusion", in which data from several types of sensors are combined or "fused" to produce more complete or accurate information about a system or environment.

In various studies on motion capture, the quantity of sensors utilized in sensor fusion IMU measurements may vary. Some researchers choose to use all three available sensors, while others may choose to use only a subset of them. This decision is based on specific requirements, and there are several reasons why a sensor may not be used for a measurement.

Numerous research employs accelerometers, designated as GF-IMU (gyroscope-free IMU) [6], to ascertain relative motion solely by accelerometer data. This method utilizes three triads of accelerometers to measure both transverse and rotational accelerations, together with angular velocity, eliminating the necessity for gyroscopes. By eliminating gyroscopes and embracing flexible accelerometer placement, this GF-IMU design lowers cost and enhances deployability in real-world scenarios. It paves the way for lightweight, adaptable inertial sensing. The work examines the GF-IMU as a nonlinear control system and employs a nonlinear Kalman filter to analyze the state. It demonstrates that three triads suffice for precise motion estimation, while more triads merely provide supplementary information.

The research focuses on estimating lower extremity motion trajectories with a Graph Convolution Network, utilizing five IMUs placed on the lower extremities, each equipped with a 3-axis accelerometer and 3-axis gyroscope sensor [7]. Luigi Truppa et al. [8] conducted research on innovative sensor fusion algorithms for motion tracking with online bias compensation, utilizing only inertial sensors (e.g., accelerometers and gyroscopes) due to the susceptibility of magnetic sensors to magnetic interference. Another study focused on reducing the number of IMUs for motion sensors, as seen in the research by Wicent et al. [10], which involved estimating lower body kinematics using a Kalman filter with Lie Group restrictions, employing only 2 sensors located at the hip and feet positions.

By integrating motion pattern recognition technology with artificial intelligence and advanced sensors, deeper insights can be obtained, leading to the development of smarter and more responsive systems tailored to different contexts and requirements. [9].

Research on motion recognition using machine learning has been extensively conducted. For instance, evaluating machine learning algorithms for workers involves utilizing seventeen motion sensors and employing five machine learning algorithms to categorize movements [11]. The five algorithms consist of support vector machine, logistic regression, k-NN, random forest, and multilayer perceptron. Akhavian and Behzadan [12] analyzed construction worker productivity by applying machine learning classification methods using data from accelerometers and gyroscopes integrated into smartphones. Another study focuses on creating a system for whole-body motion estimation using IMU to represent the contact conditions between the product and the user based on user-defined contact boundaries [13]. Cecilia Monoli et al. [14] have developed and validated a method for monitoring human gait kinematics underwater using an IMU wearable sensor.

C. Machine Learning Classification

The choice of machine learning algorithms will affect the results of the study. Several factors, including training speed, prediction speed, minimum data sets (MDS), performance, accuracy, ease of use, ease of implementation, and the availability of resources required to train the model, can be considered when selecting an appropriate classification algorithm.

The Support Vector Machine algorithm approach in machine learning has proven to be very effective for regression and classification tasks. SVM utilizes an optimal hyperplane that maximizes the margin between classes, enabling precise data classification. By applying the maximum margin principle, SVM enhances model robustness against variations in new data, relying on the distance between the hyperplane and the closest data points from each class. Its effectiveness is further amplified, especially with large datasets, as it only utilizes support vectors,

a small subset of the training data, resulting in efficient computation and improved generalization.

The kernel in the SVM algorithm is a mathematical function used to transform the data feature space into higher dimensions. Kernels are crucial in SVM as they enable the model to address non-linear classification problems. This kernel function empowers SVM to identify intricate decision boundaries in the high-dimensional feature space.

The k-Nearest Neighbors algorithm is the simplest yet most effective machine learning method in classification tasks. The fundamental principle of k-NN is that similar objects tend to be close to each other in feature space. In classification, objects are labelled based on the majority labels of their k nearest neighbors. Selecting the appropriate k value is crucial when implementing k-NN. A small k value can make the model sensitive to noise, while a large k value can lead to an overly general model. Some advantages of this algorithm include its simplicity, ease of implementation, lack of assumptions about data distribution, and suitability for small datasets with simple structures. The k-NN is a suitable choice for straightforward tasks and small datasets, but careful consideration is needed for parameter selection and noise management to achieve optimal results.

Utilizing decision trees, the random forest algorithm is a supervised machine learning technique used for regression, classification, and other applications. Random forests excel in handling large and complex datasets, high-dimensional feature spaces, and analyzing feature importance. This technique is widely adopted across various sectors due to its ability to minimize overfitting and maintain high prediction accuracy.

Random forest classifiers build a collection of decision trees using a randomly chosen subset of the training data. These decision trees (DT) are aggregated from a randomly selected subset of the training data to produce the final prediction. The results of each decision tree are then combined.

SVM and k-NN are two widely used algorithms in the domain of supervised machine learning, where models learn from labeled datasets to make predictions on unseen data. These algorithms excel at handling both classification and regression problems, making them versatile tools in various real-world applications.

III. Proposed System

The goal of this study is to establish a dataset of athletes' leg kicks to develop models for categorizing martial arts kick techniques. To achieve this, a system must be developed to collect data on an athlete's movement, while executing a kicking technique.

In this study, we presents a system for tracking human movements in real-time using IMU sensor fusion. This sensor will record data on an athlete's kicking movements to create a kick dataset for developing models to classify kicking techniques for martial arts athletes.

The tool to be developed is a wearable device that captures the kicking movement patterns of a martial arts athlete. This device will gather data using a gyroscope and accelerometer sensor combined with an IMU sensor. It is designed to function wirelessly, making it convenient for athletes to perform their movements. Therefore, including a battery in each device is essential. The device will be placed on the part of the athlete's body, where the movements will be observed.

The system proposed utilizes the MPU6050 IMU sensor positioned on various sections of the athlete's leg to gather gyroscope and accelerometer data. An ESP32 microcontroller manages the task of acquiring and transmitting data from each device. The data will be wirelessly transmitted for collection on a server computer, where it will be stored and subsequently processed using specific algorithms. The system proposed is depicted in Fig. 1.

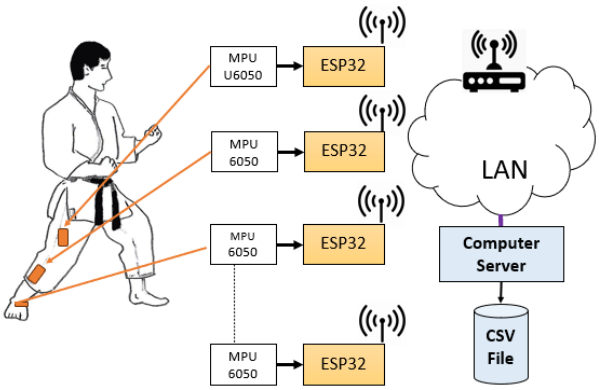

Fig. 1. Proposed motion capture system using IMU 6050.

This sensor position point was selected to accurately represent an athlete's kicking movement. There are three key points for sensor placement: the thigh, shank, and foot. Each sensor, used to capture movement on an athlete's body, follows the device construction depicted in Fig. 2. Each sensor includes an MPU6050, ESP32 as a controller, and a 3.7V lithium-ion polymer (LiPo) battery for power supply and charging control. The battery is essential for enabling the sensor to operate independently without requiring an external power source.

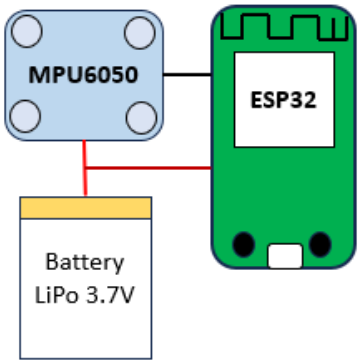

Fig. 2. Configuration of the components of IMU device.

This study focuses on analyzing leg kick techniques in a martial arts context. The research will develop a tool to classify the types of kicks performed by athletes based solely on the output of the kick itself, excluding factors like muscle strength and fatigue. The study involves testing a dataset with machine learning algorithms to determine the minimum data required for accurate classification.

The research progress through three stages: first, developing a motion capture tool using inertial sensors; second, using this tool to record athletes' kicking movements and create a dataset of martial arts kicks; and third, testing the dataset to predict the classification of each kick.

A. Hardware Specification

The MPU 6050, manufactured by InvenSense Inc., comprises three 16-bit analog-to-digital converters (ADCs) for converting the gyroscope output and three additional 16-bit ADCs for converting the accelerometer output. To accurately track both fast and slow movements, the components offer a user-programmable gyroscope full-scale range of ±250, ±500, ±1000, and ±2000°/sec (dps) and a user-programmable accelerometer full-scale range of ±2g, ±4g, ±8g, and ±16g. The MPU6050 supports a sample rate of 1 KHz. Communication with device registers can be achieved through either I2C at 400 kHz or SPI at 1 MHz.

ESP32 is a cost-effective, energy-efficient System on a Chip (SoC) microcontroller created by Espressif, featuring Wi-Fi and Bluetooth capabilities along with a dual-core processor. It is suitable for use in industrial settings, with an operational temperature range of -40°C to +125°C. The ESP32 boasts a Tensilica Xtensa Dual-Core 32-bit LX6 microprocessor running at either 160 or 240 MHz. It is equipped with 448 KB of ROM for booting and core functions, as well as 520 KB of SRAM for data and instructions.

The study confirms that the ESP32 can reliably sample sensors at high rates, making it suitable for real-time applications. However, its built-in ADC lacks precision, emphasizing the need for an external ADC to ensure accurate sensor data acquisition [15].

User Datagram Protocol (UDP) is utilized to manage the transmission of data produced by multiple sensors from a client device to a server computer for storage and subsequent processing. UDP is part of the Internet Protocol (IP) suite and functions at the transport layer within the OSI (Open Systems Interconnection) reference model. With the inclusion of a WiFi module, UDP is readily accessible in the ESP32 microcontroller chip, simplifying the wireless data transfer process.

For this application, the User Datagram Protocol was selected mainly because of its low latency and lightweight nature, which makes it appropriate for real-time data transfer. The connection-oriented strategy and error-checking methods of Transmission Control Protocol (TCP) result in overhead, whereas UDP functions as a connectionless protocol. As a result, data delivery is accelerated with less latency since acknowledgment packets, retransmissions, and congestion control are no longer necessary.

In applications like motion capture or real-time monitoring, where data from IMUs or other sensors need to be transmitted continuously, the slight loss of packets is often acceptable compared to the delays caused by TCP's reliability mechanisms. UDP's simplicity allows for high throughput, especially when working with high-frequency data streams, making it ideal for scenarios requiring time-critical communication, such as tracking human motion or sending sensor data for immediate processing.

This block diagram illustrates the flow of the data capture and processing system from the IMU (Inertial Measurement Unit) sensor to the stage of forming a dataset for machine learning needs. Body movement data captured by the IMU device is sent wirelessly via the UDP (User Datagram Protocol) protocol to the WiFi Access Point, then forwarded to the computer, to be recorded in the form of log data. After the data is received, a pre-processing process is carried out to clean and prepare the data so that it is ready for use, such as normalization, segmentation, or noise removal. The results of this pre-processing are then stored as a dataset, which is then used in the training or testing process of the model at the machine learning stage to recognize movement patterns or activity classification. As shown in Fig. 3.

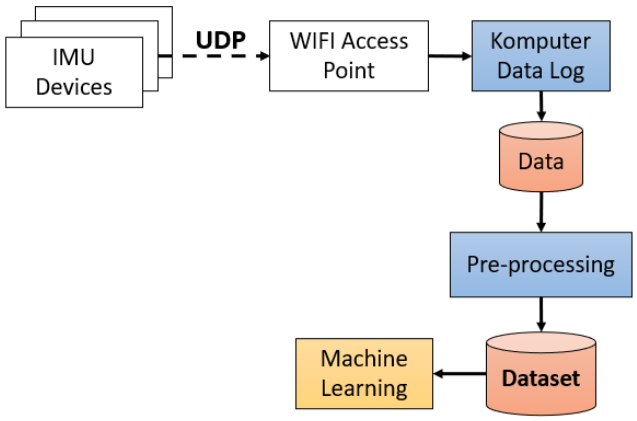

Fig. 3. Block diagram of data processing.

The sensor device starts by initializing and then searching for a connection to the server. Once the connection is established, it continuously sends sensor data to the server in a specific format. The protocol is encapsulated in datagrams using the UDP protocol and designated ports for each sensor device. The device follows a sequential process upon startup, searching for a connection to a UDP server with a distinct port number assigned to each sensor.

B. Data Transmission and Collection

The data transmission medium will be chosen wirelessly to reduce the number of cables connected to the participants. A local network will be established with a wireless access point capturing connections from each client, specifically through an IMU sensor on the volunteer subject. All sensor data will be transmitted through this connection. A computer will serve as the central server to gather data from all IMU sensors.

Multiple server applications will run on this computer to receive connections from each IMU sensor. The computer will directly connect to the wireless router access point using a UTP (Unshielded Twisted Pair) cable. Each IMU device, functioning as a UDP client, will connect to its corresponding server application set up in pairs. The separation of receiving servers will be achieved by assigning a different port to each client, allowing each server to store data independently for each sensor. The configuration of the server applications is illustrated in Fig. 4.

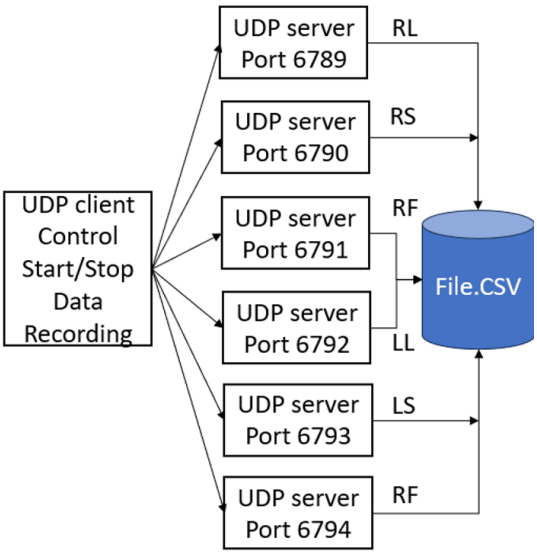

Fig. 4. Configuration of the UDP system protocol for wireless data collection from IMU devices to the server.

When the device is powered on, data from the IMU sensor will be consistently transmitted to the server. The transmitted data will be shown on the console to monitor the functionality of each IMU device. To prevent unnecessary data storage, a system was developed to determine when to begin recording data and when to cease storing it. This system prevents the storage of irrelevant data during the setup or device testing phase.

An additional program application is used to determine the start and stop times for recording the data stream. This application functions as a UDP/IP network-based client program on the server computer, sending commands to each capture server on different ports to initiate or terminate data storage. Being a network program, it can be placed on a separate computer if needed, facilitating operators in data retrieval tasks.

Data from each IMU sensor will be stored in separate comma separated value (CSV) files. Each data sent from the sensor will be received with additional time stamp data inserted before being stored in the file. All data sent by the IMU device will be stored without any prior selection process. Therefore, several pre-processing stages are necessary for formatting the data appropriately for subsequent processes. The data acquisition process on the server side is illustrated in the flow diagram in Fig. 5.

C. Data Format

Before processing the data using different classification algorithms, the data sent from each sensor device will initially be saved in a CSV file format. The sensor data will be stored in a specific order and format as shown in Fig. 5. Prior to being transmitted to the storage server, the sensor data will be supplemented with the device identity (ID) data from each sensor device. This ID represents the unique identity of each IMU sensor to distinguish one device from another.

The name of the device ID is hardcoded on each individual device. A timestamp (TM) will be added by the server application to record the arrival time of data. This timestamp will be placed at the end of each data record. Subsequently, the data along with its timestamp will be saved in a data file. The format utilizes a Unix timestamp, representing the number of seconds since January 1, 1970, 12:00 am GMT (Greenwich Mean Time).

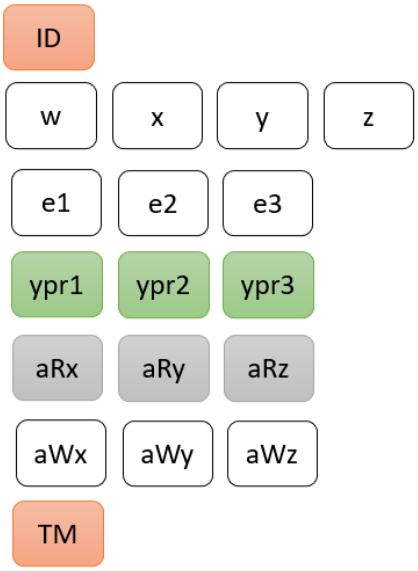

Fig. 5. Data format.

where,

- ID: device id
- w, x, y, z: quaternion
- e0, e1, e2: Euler distance
- ypr0, ypr1, ypr2: gyroscope
- aRx, aRy, aRz: real accelerometer
- aWx, aWy, aWz: world accelerometer
- TM is a timestamp

Accelerometer “raw” data are raw values directly generated by the MPU6050 accelerometer sensor without additional processing. This value is usually in the form of 16-bit data (as an integer) taken from the sensor's accelerometer register. This value represents the acceleration measured by the sensor, which is then converted to more meaningful units such as G-force or meters per second squared (m/s²) using a certain scale.

Accelerometer "world" data is acceleration data that has been converted from a sensor frame of reference to a world frame of reference. This usually involves a transformation process to account for the orientation of the sensor so that we can understand the acceleration relative to the earth or the real-world environment.

Data obtained from the gyroscope on the MPU6050 sensor is measured in degrees per second (°/s). Gyroscopes measure angular velocity or the rate of change of angles on three axes: X, Y, and Z. In this research, the data used is only gyroscope data and raw accelerometer data.

IV. RESEARCH METHOD

This research follows a systematic approach to develop a classification system for identifying kick types in martial arts using IMU sensor data and machine learning algorithms. The research methodology is divided into several main stages: 1) data acquisition, 2) data preprocessing and segmentation, 3) feature extraction, 4) model training and classification, and 5) evaluation and validation.

The sensors will be placed on several parts of the athlete's feet. Each sensor will be given an identifier to distinguish where the data comes from. The position and name of the sensor location are shown in Fig. 6. For the right leg, the device labeled RL to be placed in the right thigh position, RS is for the right shank position, and the RF label is for the right sole position. Similarly, the left side displays the label LL for the left thigh position, LS for the left shank position, and LF for the left foot position.

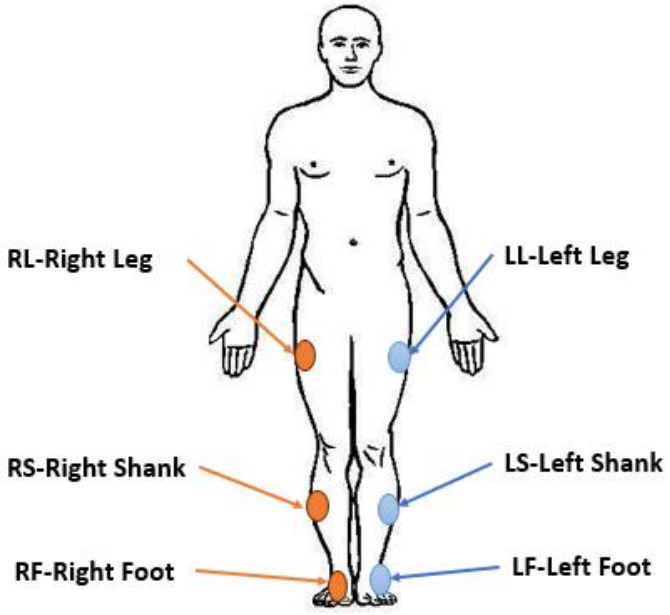

Fig. 6. Labeling of sensor positions on the lower limbs.

In biomechanical analysis, the placement of motion sensors can significantly impact the quality of data obtained, with options including placement at joints, inter-joint segments, or a combination thereof. While sensor placement at joints effectively captures local motion, such as rotation and joint angles. Interjoint placement, particularly at strategic locations like the thigh, calf, and foot, enhances the analysis of complex activities such as kicking. This method facilitates the measurement of comprehensive kinematic parameters, including translation, rotation, and acceleration across entire body segments, thus providing a more holistic view of movement dynamics. Given that, energy and momentum in activities such as kicking derived from intricate interactions within the kinematic chain focusing solely on localized joint motion, may lead to incomplete analyses and lack of insight into critical biomechanical interactions.

In the context of kicking biomechanics, inter-joint placement provides benefits in analyzing the energy relationship and momentum transfer between joints. Thus, this placement is better for capturing kicking motion patterns compared to direct joint sensor placement, which only provides local data without considering the interrelationships between body segments.

To secure the sensor to the athlete's body, a rubber band is utilized. The sensor is inserted with a plastic clip connected to the back of the device box, as illustrated in Fig. 7. This approach effectively maintains the sensor device in place during multiple leg kick movements. Periodically, the sensor device's position needs readjustment as it may shift from its original placement.

Fig. 7. Place the IMU sensor device on the respondent's leg using a rubber band.

In the data collection process, experienced martial arts practitioners were requested to demonstrate kicks. Each respondent would warm up for ten minutes before executing the specified kick movements. They would perform one kick type at a time, following the operator's start and stop commands. The kick would commence immediately upon the start signal and cease upon the stop signal. Respondents were instructed to repeat the same kick ten times. Following a five-minute break, they were then asked to perform another kick type ten times using the same procedure.

This study will create a dataset using kicks performed by martial arts experts. The dataset will serve as a reference for evaluating kick classification, focusing on three types of kicks: mawashi (roundhouse kick), maegeri (front kick), and shokuto (side kick) (see Fig. 8, 9, and 10). The dataset will specifically cover these three types of kicks. The gathered data will undergo processing to ensure the validity of the kick dataset.

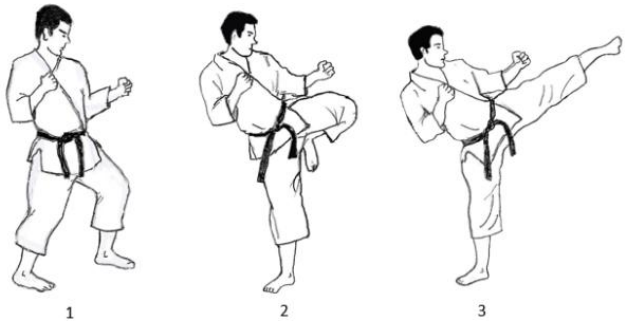

Fig. 8. Type of kick mawashi (round house kick).

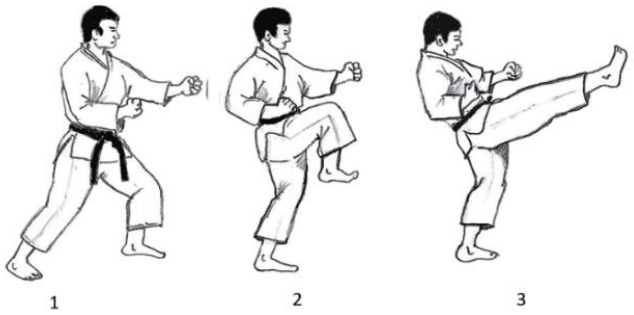

Fig. 9. Types of kick maegeri (front kick).

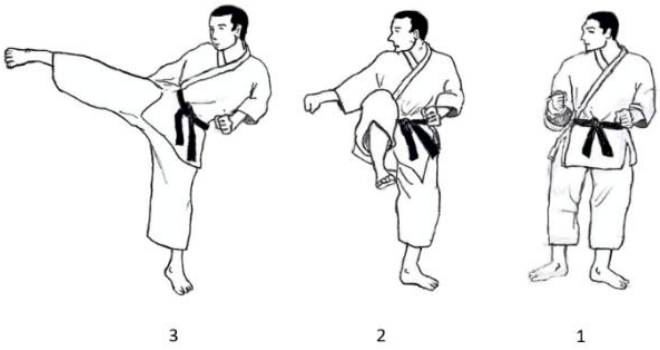

Fig. 10. Types of kick shokuto (side kick).

V. DATA PROCESSING

The process of constructing a dataset from sensor data is illustrated in Fig. 11. The data undergoes pre-processing to form a usable dataset. Pre-processing involves segmentation and re-sampling to ensure uniform length and format, specifically converting the data into a single line for each instance.

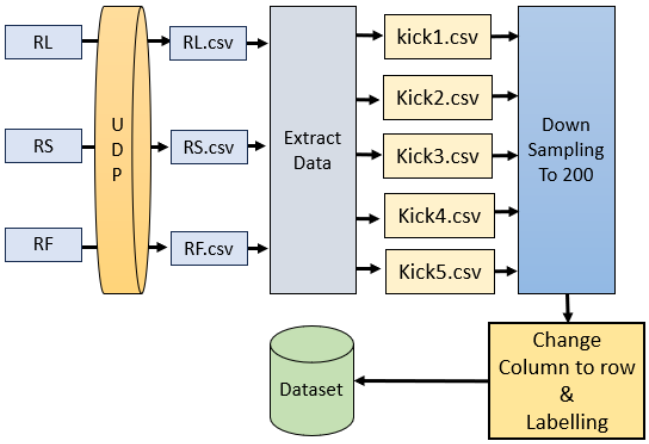

Fig. 11. Block diagram of pre-processing raw data.

Prior to being stored as a dataset, the data length for each sensor is standardized. The re-sampling procedure (down sampling) is crucial to ensure that the data length for each sensor is consistent at 200 samples. Consequently, only data with more than 200 samples is deemed suitable for further processing. Sensor data with fewer than 200 samples will be excluded due to potential imperfections in data collection.

To process sampling data with the next algorithm, the data length must be consistent. Therefore, data from sensor devices must be adjusted to match the data length. The MPU6050 sensor operates at a sampling frequency of 1 KHz, resulting in approximately 1000 samples per second. A martial arts athlete's kick lasts less than 1 second, so the average data length collected for each kick ranges from 600 to 800 samples. It is important that the adjustments made to equalize the data length do not remove significant information.

The down-sampling process is utilized to standardize the data length and reduce the number of data samples. It is crucial that this process does not result in the loss of essential information. This is done to ensure that the data interpretation remains unchanged, allowing the retained data to still capture the characteristics of a kick. Fig. 12 to Fig. 17 display the data after re-sampling. These figures illustrate that the graph's characteristics remain consistent before and after the re-sampling process.

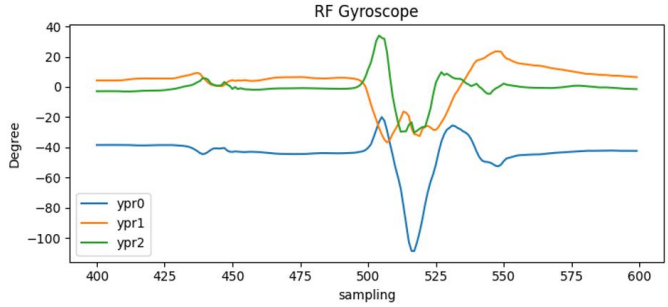

Fig. 12. Right lower limb mawashi kick data from RF gyroscope sensor data after down sampling to 600.

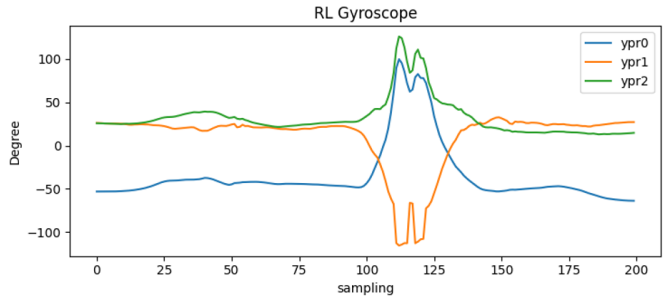

Fig. 13. Right lower limb mawashi kick data from the RL gyroscope sensor data after down sampling to 200.

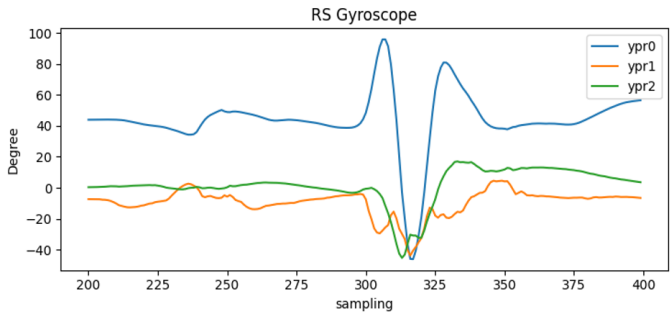

Fig. 14. Right lower limb mawashi kick data from the RS gyroscope sensor data after down sampling to 400.

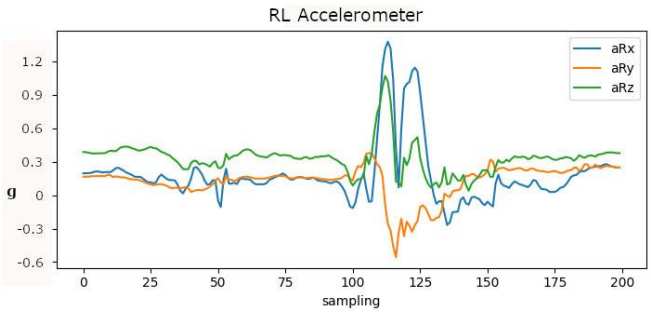

Fig. 15. Right foot mawashi kick data from RL accelerometer sensor data after down sampling to 200.

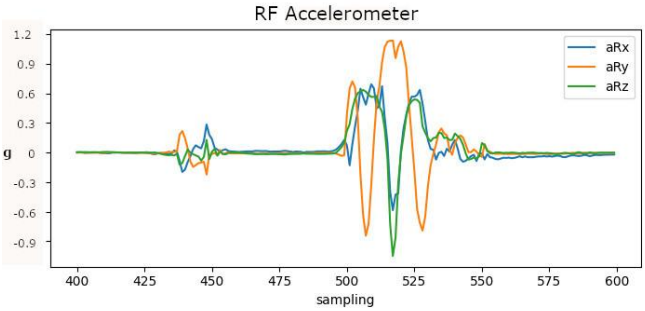

Fig. 16. Right foot mawashi kick data from the RF accelerometer sensor data after down sampling to 600.

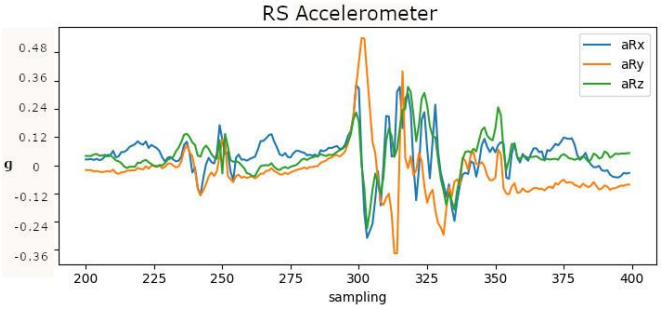

Fig. 17. Right foot mawashi kick data from the RS accelerometer sensor data after down sampling to 400.

Each sensor transmits data to the server with varying sample lengths, ranging from 500 to 800 samples per kick. The length of the data is determined by the duration of the kick. Before being input into the classification model algorithm, the data must undergo preprocessing to ensure uniformity in length. This initial process involves extracting data from files, segmenting it, and resampling to standardize the data length.

Data resampled to a length of 200 will be merged into a single file per kick, summarizing all sensor data. Sensor data with less than 200 samples will be discarded as it may indicate sensor or data transmission errors. Consequently, a significant amount of data remains unused due to sensors not meeting the minimum length requirements.

The subsequent step involves converting the data format from column-oriented to a single row for each kick. This alteration is essential to ensure that the resulting dataset contains only one row per kick. Each kick will have a column length of 3600 parameters derived from three sensors, including two gyroscopes and accelerometers, each with three outputs and a sampling length of 200.

The following step involves labeling all stored data based on the type of kick. This labeling process occurs concurrently with the input of new kick data that will be added to the dataset. To facilitate this task, a dedicated program was utilized to incorporate labels into the kick dataset.

Testing and classification of the dataset will be done using machine learning algorithms, specifically k-NN and SVM. The main concept of machine learning is to build a model that can recognize patterns in past data and apply those patterns to similar data in the future. k-NN and SVM are supervised machine learning algorithms commonly used for classification tasks.

The categorization model will subsequently undergo training and testing. The dataset will be partitioned into two segments, with 70 per cent designated for training and 30 per cent for testing. The correctness of the model will be evaluated using the findings from the test data.

The initial classification algorithm utilized was k-NN. This choice was made due to its simplicity, effectiveness for small to medium datasets, and capability to handle multi-Class. The selection of the value k in the K-Nearest Neighbors (KNN) algorithm is a crucial step that can significantly impact model performance. Typically, an odd number is chosen for k. In this case, the value of k is selected to be between 3 and 5. The evaluation of the k-NN algorithm's accuracy will be conducted using multiple datasets and varying k values. The comparison results are presented in Table II. Subsequently, the optimal number of selected k values for each dataset size will be determined.

The dataset to be tested comprises seventy data points resulting from re-sampling, pre-processing, and labeling. The model's accuracy will be evaluated to determine if it meets the criteria for a reliable prediction. Table I displays the breakdown of kick types in the dataset.

TABLE I. NUMBER AND TYPE COMPOSITION OF DATASET

Label	Number
Maegeri	16
Mawashi	22
Shokuto	32
Total	**70**

VI. RESULT

Modeling for classifying kick types will utilize seventy datasets that have been processed successfully in the prior stage. The model's accuracy will be assessed to determine if it meets the criteria for effective prediction.

The results of classification prediction accuracy using the k-NN algorithm are shown in Table II. For k=3 and dataset seventy using all sensor data (RL, RS. RF), the accuracy reaches 0.924, while if we use only two sensors the highest accuracy is achieved at 0.881 using sensors (RL, RS) with seventy datasets and k=3. For those using one sensor, the accuracy is 0.762 using an RS sensor with k=3 and a dataset of seventy.

TABLE II. ACCURACY OF THE K-NN ALGORITHM

No	Sensor	K	Dataset	Accuracy
1	RL, RS, RF	3	70	0.924
2	RL, RS, RF	5	70	0.843
3	RS, RF	3	70	0.838
4	RS, RF	5	70	0.800
5	RL, RS	3	70	0.881
6	RL, RS	5	70	0.833
7	RS	3	70	0.762
8	RS	5	70	0.714

Prediction accuracy results using the SVM algorithm with the same number of data sets are shown in Table II. The lowest accuracy value of this algorithm is 0.833, and the highest accuracy value is 0.967. When compared with the k-NN algorithm, the prediction accuracy of SVM is better.

The accuracy results with the model algorithm using random forest are shown in Table III. The highest accuracy is shown with a value of 0.900 when using 3 sensors (RL, RS, RF) and the lowest when using 1 RS sensor with an accuracy value of 0.795. For calculations using only two sensors, the accuracy value reaches 0.890 using sensors (RL, RS) and 0.905 using sensors (RS, RF).

The findings demonstrate that SVM's ability to handle small, high-dimensional datasets, combined with its use of kernel functions, allowed it to effectively capture complex patterns in the IMU data, resulting in superior classification accuracy. In contrast, k-NN and Random Forest faced challenges due to their sensitivity to feature scaling, noise, and correlated features, making SVM the best-suited algorithm for this specific task. These results highlight the importance of matching the algorithm to the dataset characteristics to achieve optimal performance.

TABLE III. ACCURACY OF SVM AND RANDOM FOREST ALGORITHM

No	Sensor	Dataset	SVM Accuracy	Random Forest Accuracy
1	RL, RS, RF	70	0.924	0.900
2	RS, RF	70	0.871	0.905
3	RSL RS	70	0.967	0.890
4	RS	70	0.833	0.795

Performance of k-NN's classification depends heavily on the distance metric (e.g., Euclidean distance). In the dataset, variations in sensor data due to noise or irrelevant features could disproportionately influence the distance calculations. The performance was contingent upon the selection of k, where smaller values resulted in overfitting and higher values induced underfitting. The k-NN performed better when kick types had distinct and isolated clusters in the feature space, but its performance degraded for overlapping or closely spaced data points, as seen in this study.

Random Forest relies on an ensemble of decision trees, which partition the feature space based on thresholds. While this approach is robust for large datasets, it can struggle with small datasets, as individual trees may overfit the training data. In the dataset, many features derived from IMU sensors (e.g., accelerations and angular velocities) were highly correlated. Random Forest frequently overvalues the significance of associated features, resulting in potential bias in feature selection and diminished generalization performance. From observation, although Random Forest showed decent performance, its accuracy was lower than SVM due to its inability to effectively capture the complex relationships between features in this dataset.

Analysis of the feature space indicated that the kick types (e.g. maegeri, shokuto, and mawashi) were not perfectly linearly separable, but there was some structured separation among the classes in the feature space. Analysis revealed that angular velocity and acceleration data were critical in distinguishing between kick types. For example, Maegeri involved a rapid forward acceleration of the shank. Shokuto displayed lateral angular velocity and sideways acceleration. Mawashi exhibited curved motion patterns, visible in both acceleration and gyroscope data.

The classification model's performance is assessed by comparing its predictions to the actual values (ground truth) using a confusion matrix. This matrix clearly indicates the number of correct and incorrect predictions for each class. Fig. 18 to Fig. 21 present the confusion matrices for each model in this study. These tables summarize how well the models classify data, highlighting both accurate and inaccurate predictions. Additional metrics such as precision, recall, and F1-score provide deeper insights into the model's strengths and weaknesses across various application scenarios.

F1-score is a classification model evaluation metric that combines precision and recall into one value. This metric is useful when there is class imbalance in the dataset and when we want to find a balance between False Positives (FP) and False Negatives (FN). The higher the F1-score, the better the model is at handling the balance between precision and recall.

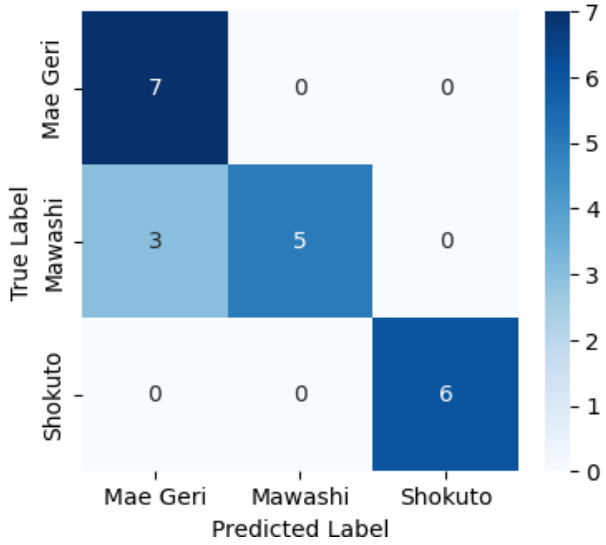

Fig. 18. Confusion matrix k-NN for k=3.

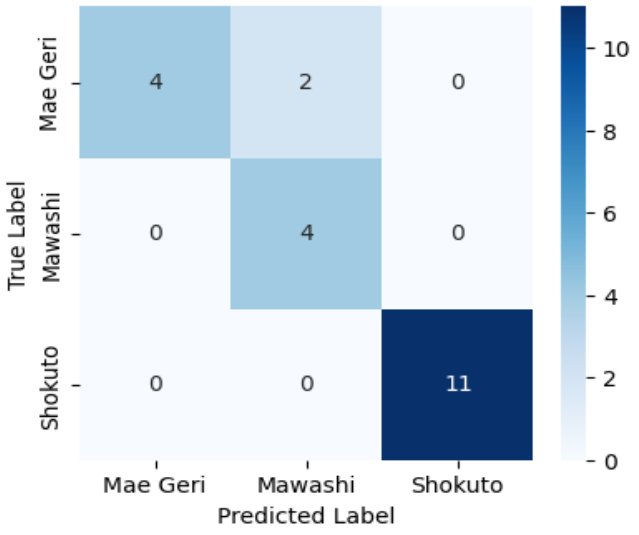

Fig. 19. Confusion matrix k-NN for k=5.

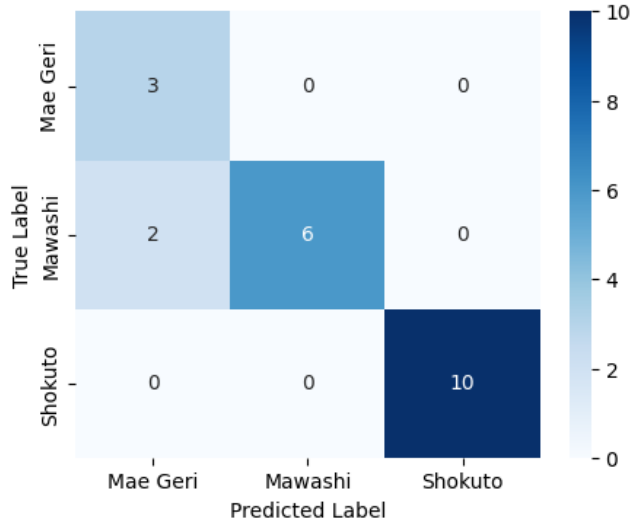

Fig. 20. Confusion matrix random forest.

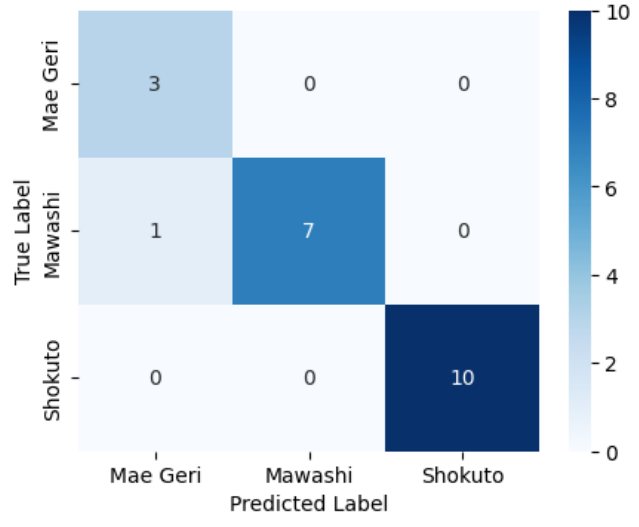

Fig. 21. Confusion matrix SVM.

In the k-NN model with a value of k = 3 (Fig. 18), the F1-score value for this model is Mae Geri: 0.82, Mawashi: 0.77, and Shokuto: 1.00. The average will be F1-score 0.86, and if using weighting according to the number of datasets in its class, it is 0.85. While for the k-NN model with k = 5 (Fig. 19), the F1-Score values are Mae Geri: 0.8, Mawashi: 0.8, and Shokuto: 1.00. The average is 0.87, and if using weighting according to the number of datasets in its class, it is 0.90. The Shokuto class has a perfect F1-score, while Mae Geri and Mawashi still have some errors. This shows that the model has a fairly good performance overall, especially since the Shokuto class has a larger number of samples and high scores, thus increasing the average.

For the random forest model with the confusion matrix shown in Fig. 20, the F1-score value per class is Mawashi = 0.86, Shokuto = 1.00. For the average value of the macro F1-score = 0.87 and the weighted F1-score = 0.90. The model has good performance with a weighted F1-score of 90 per cent, indicating a fairly accurate classification. Shokuto is perfectly classified, without errors. Maegeri has a lower recall (0.60), so it needs to be improved to reduce classification errors, and Mawashi has a good balance between precision and recall.

For the SVM model shown in the confusion matrix in Fig. 21, the F1-score values per class are Mae Geri = 0.86, Mawashi = 0.93, and Shokuto = 1.00. The average F1-score value = 0.93 and the weighted F1-score value = 0.95. This model has very good performance, with a weighted F1 score of 95 per cent, which means the model is able to classify all three types of kicks quite accurately. Shokuto is perfectly classified (F1-score = 1.00), Mae Geri has a small error in recall, so the improvement can focus on reducing the classification error for Mae Geri, while Mawashi has a good balance between precision and recall.

VII. Discussion

This discussion provides an in-depth overview of the implementation of kick classification using IMU and k-NN and SVM machine learning algorithms. The success of both in this context confirms the great potential of this technology in the understanding and analysis of movements, with practical applications in the training of martial arts athletes and the development of more sophisticated movement recognition systems.

Segmenting kicking movements using gyroscope and accelerometer data can be achieved through the following steps: Conduct an initial analysis of the data to recognize patterns in kicking movements. Utilize significant changes in angular velocity (from the gyroscope) and acceleration (from the accelerometer) as cues for the beginning and end of the movement. Establish thresholds for angular velocity and acceleration that indicate the initiation and conclusion of the kicking action. Choose a threshold value that distinguishes between motion and rest or other irrelevant movements. Apply the defined threshold to pinpoint segments of kicking motion. When the angular velocity or acceleration surpasses a threshold, it signifies that movement is underway. Carry out manual validation or human supervision on the identified motion segments to ensure their accuracy in representing the kicking motion. Conduct parameter optimization on machine learning

models to enhance classification accuracy, particularly post-implementation of the segmentation process.

To increase the accuracy value of the k-NN algorithm, it is necessary to strive for things such as choosing the optimal k value, balancing the number of samples per very different class so that it is more balanced, wisely selecting features that can help reduce data dimensions and improve accuracy, and it is necessary to carry out exploratory analysis of the data to understand the characteristics of the dataset. Knowing whether there are important trends, patterns, or relationships can guide the k-NN model setup more effectively. By considering and combining several of these strategies, it can improve the performance of the k-NN algorithm and increase the accuracy value on classification tasks.

To achieve more accurate classification in human motion classification tasks, here are some suggestions regarding the efforts to be made and the algorithms that can be used. Some efforts that must be made are to ensure that the data collected from sensors (e.g., accelerometer, gyroscope) is of high quality and free of noise as much as possible. Use appropriate sensor devices and sensor calibration to ensure data accuracy.

At the data preprocessing stage, more effort needs to be made in data cleaning to remove noise and artifacts from sensor data, data normalization to ensure consistent scale across all features, segmentation and windowing into appropriate time windows to capture movement well, extraction of appropriate features relevant features such as time statistics, frequency features, and time-frequency domain-based features.

Improvement efforts can also be made by trying other available techniques, such as using feature selection techniques (for example, PCA, LDA) to reduce the dimensions of the data and retain the most significant features. To overcome limited datasets, data augmentation techniques can be used to generate more training examples, such as adding small noise, rotation, or scaling to the movement data. Cross-validation methods to prevent overfitting guarantee that the model performs effectively when applied to unknown data.

Several algorithms can be tried for classification techniques, such as Convolutional Neural Networks (CNNs), which have excellent advantages in capturing spatial and temporal features from movement sensor data. They can automatically extract features from raw data. Applications: CNNs are often used for human activity classification with time-series data and sensor signals. Long Short-Term Memory (LSTM) and Recurrent Neural Networks (RNNs) algorithms are designed to handle sequential and time-series data, so they are very suitable for temporal human movement classification. LSTMs are used to capture long-term dependencies in human motion data. By following the steps outlined and selecting a suitable algorithm, the accuracy of classifying an athlete's kick can be greatly enhanced.

VIII. Conclusion

This section provides an in-depth overview of the implementation of kick classification using IMU, k-NN, Random Forest and SVM machine learning algorithms. The success of these algorithms in this context confirms the great potential of this technology in the understanding and analysis of movements, with practical applications in the training of martial arts athletes and the development of more sophisticated movement recognition systems.

SVM, with its ability to handle non-linear relationships via kernel tricks, provides solid performance in kick classification. Selection of an appropriate kernel, such as the RBF (Radial Basis Function) kernel, can affect SVM performance. The advantages of SVM are especially visible when the kick motion pattern has high complexity and cannot be clearly separated by a straight line.

Implementation of the k-NN algorithm on a kick dataset that utilizes IMU data demonstrates success in identifying movement patterns with an accuracy of 0.924 for k=3 and 0.843 for k=5. This performance is slightly lower compared to the SVM algorithm, with an accuracy of 0.924. All the results mentioned above are based on the use of 3 sensors (RL, RS, RF). However, when only two sensors are utilized, the k-NN accuracy drops to 0.838 (RS, RF) and 0.881 (RL, RS), while the SVM accuracy decreases to 0.871 (RS, RF) and 0.967 (RL, RS). For the random forest model, the accuracy is 0.900 with three sensors (RL, RS, RF), while with two sensors, the accuracy is 0.905 (RS, RF) and 0.890 (RL, RS), which are still lower than the k-NN and SVM algorithms.

The primary advantage of k-Nearest Neighbors (k-NN) lies in their simplicity and effectiveness in handling classification problems. As a non-parametric, instance-based learning algorithm, k-NN does not require an explicit training phase, making it easy to implement and adaptable to various types of data. However, despite its straightforward nature, choosing an optimal value for k is crucial to ensuring model performance. A small k value can lead to overfitting, where the model becomes too sensitive to noise and fails to generalize well to new data. In contrast, a high k value may lead to underfitting, which results in the model oversimplifying decision boundaries and misclassifying complex patterns. To mitigate these risks, it is essential to use cross-validation techniques to determine the best k value for a given dataset. Additionally, data preprocessing steps such as feature scaling and noise reduction can significantly enhance the accuracy and reliability of k-NN in practical applications.

IX. Future Work

The current study indicates that it is possible to use IMU-based wearable systems and machine learning algorithms together to accurately categorize different forms of martial arts kicks. But there are several ways that the system could be improved in the future to make it more useful, practical, and easy to use for daily athletic training.

Future work is to reduce the number of sensors used in the system while maintaining comparable levels of classification accuracy. Reducing the number of sensors would also lower the cost and complexity, enabling broader adoption among athletes for everyday training without interfering with movement. If possible, reducing sensors to a compact form factor such as a single wearable smart device (e.g., a smartwatch or ankle-worn sensor) could significantly improve system convenience, ease of use, and real-world applicability.

Subsequent research will concentrate on enhancing machine learning and feature extraction methodologies to mitigate the limitations posed by reduced sensor inputs. Identifying optimal sensor sites (such as the most effective body parts), integrating data from several sensors, or utilizing sophisticated algorithms like deep learning that can discern intricate patterns from limited data.

ACKNOWLEDGMENT

The authors assert that there are no conflicts of interest pertaining to this research. This study was conducted independently without any financial, institutional, or commercial influence from any organization. All data collection, analysis, and interpretations were performed objectively to ensure the integrity and validity of the findings.

This research has received ethical clearance from the Ethics Commission of the Bandung Institute of Technology (ITB) under the approval KEP/II/2024/X/M281024RG-PDPG. The commission has reviewed and confirmed that this study complies with ethical standards and is deemed ethically feasible for implementation.

Comparative Analysis of Deep Learning Techniques for Passive Underwater Acoustic Target Recognition: Overview, Challenges, and Future Directions

Song Yifei[1], Mohamad Farhan Mohamad Mohsin[2]
University Utara Malaysia (UUM), 06010 Sintok, Kedah, Malaysia[1]
School of Computing, University Utara Malaysia (UUM), Sintok, Kedah, Malaysia[2]

***Abstract*—Passive underwater acoustic target recognition (UATR) involves analyzing acoustic waves captured by passive sonar to extract valuable information about submerged targets. The underwater acoustics community has increasingly turned its attention to deep learning techniques, owing to their remarkable success in image recognition tasks. This study presents a comprehensive overview of the evolution of UATR techniques, categorizing them into three distinct groups: early methods, conventional machine learning approaches, and modern deep learning-based techniques. Additionally, it provides an in-depth summary of the recognition process utilizing deep learning, detailing various deep network architectures, classifiers specifically designed for underwater acoustic target recognition, and different data input modalities. Finally, the study synthesizes current research findings and outlines potential future directions for advancements in this field, emphasizing opportunities for innovation across these three categories.**

Keywords*—Underwater acoustic target recognition; deep learning; deep network architecture; classifier

I. Introduction

Underwater acoustic target recognition (UATR) is grounded in the production, transmission, and reception of sound waves in water. This technology has extensive applications in military operations, marine exploration, sonar systems, marine life monitoring, and underwater communication through sound navigation and ranging systems [1]. Despite the influence of variables such as temperature, salinity, and pressure on sound propagation in the ocean, sound waves remain the most efficient medium for long-distance underwater detection, transmission, and communication [2],[3]. Passive-sonar systems, which operate by quietly detecting transmitted noise, are gaining popularity due to their enhanced stealth capabilities. Consequently, the analysis of passive sonar underwater target radiation noise data has emerged as an effective method for studying underwater objects. Renowned research institutes in this field include the Woods Hole Oceanographic Institution, the Chinese Naval University of Engineering, Harbin Engineering University, the Pakistan Naval Research Institute, the Institute of Acoustics of the Chinese Academy of Sciences, and the Applied Physics Laboratory at Washington University [4].

Lei et al. [5] highlight that advancements in technology have facilitated the extensive application of earlier methodologies, classical machine learning techniques, and deep learning-based network designs in UATR. Early approaches, though effective, relied on the recognition abilities of skilled sonar operators, leading to high costs and significant susceptibility to subjective factors. Conventional machine learning methods, often dependent on manually crafted features, face significant challenges such as loss of feature information and difficulty in extracting optimal features. In contrast, deep learning techniques are expected to achieve greater accuracy and robustness as computational power continues to grow [6]. By enabling end-to-end recognition processes, these techniques address many of the limitations posed by human involvement in early and traditional approaches.

II. Motivation

The UATR process is typically divided into three key components: the model's input, the model itself, and the model's output, as illustrated in Fig. 1. Based on the execution of each phase and the interconnections between them, recent review studies have categorized various approaches to underwater target identification [7],[8],[9]. For instance, in deep learning models, feature extraction and classification are integrated into a unified process, whereas in traditional approaches, feature design and extraction are performed manually or automatically before data is input into the model. However, a few studies provide comprehensive explanations of each component in a detailed, step-by-step manner. In this context, this study aims to review the latest research on passive UATR from three perspectives: model input, the model itself, and output types. By examining the use of different data input techniques, models, and task output formats, we seek to identify key challenges in current research and propose promising directions for future exploration.

III. Contribution

This study provides a novel perspective on the evaluation and analysis of UATR tasks through comprehensive research from three key aspects: model input, the model itself, and model output. Unlike conventional viewpoints that focus on different approaches to UATR tasks, this study emphasizes a structured analysis of the entire process.

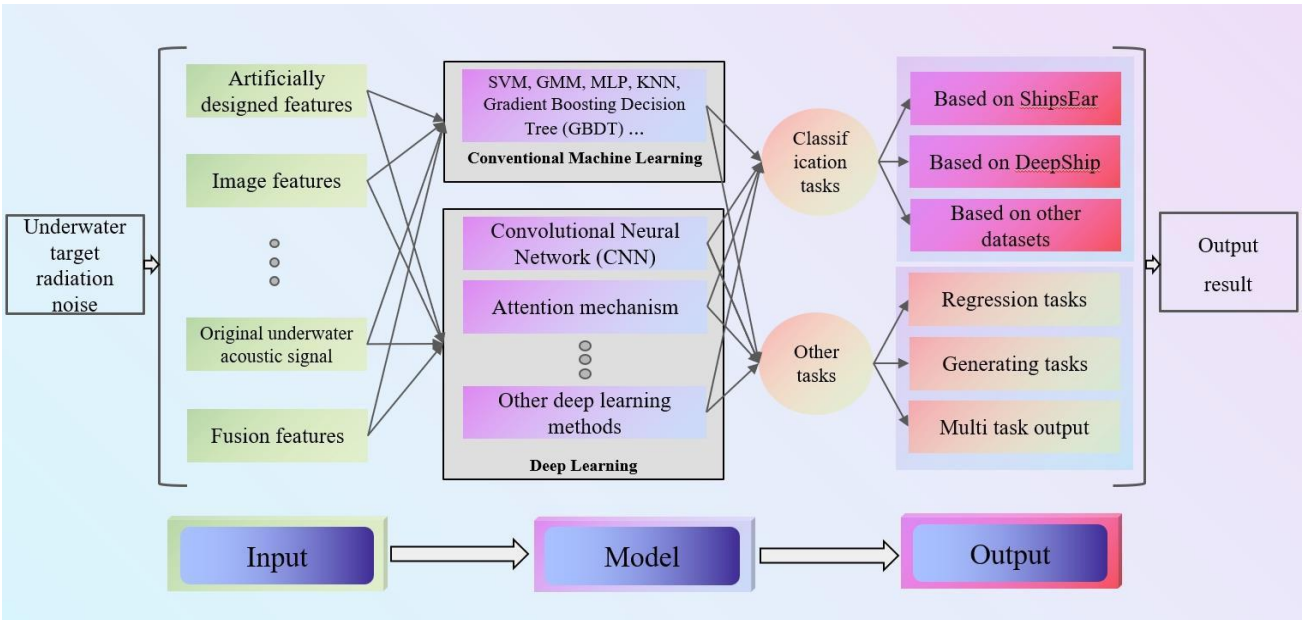

Fig. 1. General process and research architecture of UATR. Feature extraction, classification and recognition modeling, and model output constitute the three key stages in the fundamental process of both deep learning and conventional machine learning approaches for UATR.

Moreover, it highlights critical challenges that must be addressed in existing deep learning-based UATR tasks. By systematically examining and summarizing the input modes of underwater acoustic signals, model types, and model input strategies, this research provides a comprehensive synthesis of the strengths and limitations of various approaches. These insights serve as a valuable reference for researchers advancing UATR methodologies, facilitating future advancements in the field.

IV. ORGANIZATION

Section I introduces the comprehensive situation and basic issues in current research on UATR, serving as the foundation for this study. Section II presents the research motivation, emphasizing the significance of this study. By adopting a novel analytical and review approach based on the fundamental process of underwater target detection, it provides researchers with a broader perspective for understanding these challenges.

Sections III and IV outline the primary contributions and methodological framework of this work. Sections V, VI, and VII discuss different underwater acoustic signal input options, network topologies used in UATR, and the various task output types of the model, respectively. Furthermore, Sections VIII and IX explore the challenges of applying deep learning to UATR, propose potential directions for future research, and summarize the study's key insights. While previous studies have extensively examined the application of various technologies in underwater target detection, this review takes a more structured approach, delving into the specifics of each component. The overall organization of this study is illustrated in Fig. 2.

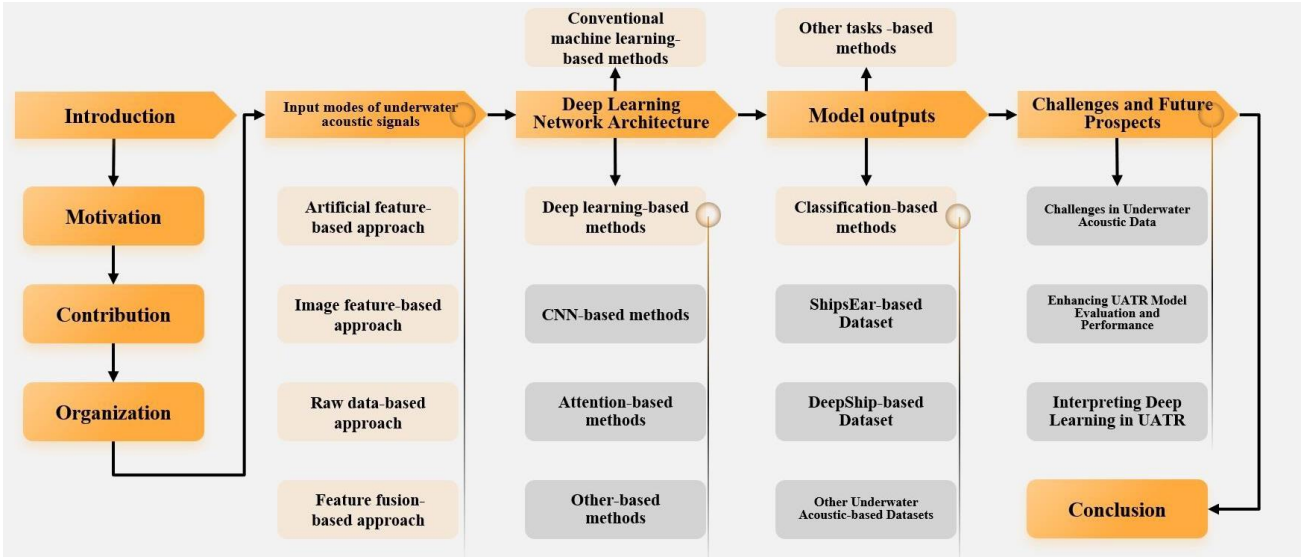

Fig. 2. Organization of the study.

V. Input Modes of Underwater Acoustic Signals

Deep learning-based UATR technology effectively addresses the issue of feature loss caused by human intervention. It typically employs an end-to-end learning framework, where neural networks replace manually designed components [10],[11]. To ensure the generation of high-quality underwater signals, appropriate preprocessing is usually necessary before inputting the target signal into the model [12]. The following sections will explore four approaches: the artificial feature-based approach, the image feature-based approach, the raw data-based approach, and the feature fusion-based approach.

A. Artificial Feature-Based Approach

A set of feature values that are manually crafted and extracted to characterize the properties of the target signal is known as artificially designed features. These features are highly interpretable, possess clear mathematical and physical significance, and are rooted in prior knowledge and experience.

In the field of underwater target identification, Mel frequency cepstral coefficients (MFCC) and DEMON spectra are widely utilized. MFCC captures the characteristics of underwater acoustic signals through a series of steps, including pre-emphasis, frame windowing, fast Fourier transform (FFT), power spectrum computation, Mel filter bank filtering, logarithmic transformation, and discrete cosine transform (DCT). Similarly, DEMON extracts the features of underwater acoustic data through preprocessing, envelope extraction, FFT, feature extraction, and subsequent analysis. This process is illustrated in Fig. 3.

Mel-frequency cepstral coefficients (MFCCs) are a widely used example of manually crafted features, extensively applied in language and speech recognition due to their ability to reduce feature map size, suppress noise interference, and withstand temporal variations [13]. On the ShipsEar dataset, Liu et al. [14] achieved an impressive 99.34% identification accuracy using MFCCs as input features for the RACNN model. Additionally, other studies have confirmed that MFCCs outperform models like VGG16 and ResNet34 in terms of computational complexity and parameter efficiency [15],[16]. However, standard MFCCs primarily capture static spectral envelope information, making it difficult to represent dynamic signal properties effectively. To address this limitation, Chen et al. [17] proposed using 3D MFCCs as input features. By incorporating first-order and second-order differential features, 3D MFCCs can capture dynamic characteristics such as the rate of change and acceleration of signals over time. Using 3D MFCC features as input for the Attention Mechanism Residual Concatenate Network (ARescat) model, an accuracy of 95.80% was achieved on the ShipsEar dataset.

The improvement in model recognition accuracy can be attributed to two main factors: the extraction of features that better represent the original data and the design of models with more advanced performance. However, it remains unclear whether 3D MFCC, an enhancement of traditional MFCC features, can more effectively represent the characteristics of raw data and is better suited for designing deep learning models. It is worth noting that numerous studies have compared MFCC features with other alternatives, such as FMSE and GFCC [18], [19]. Fig. 4 illustrates the performance of various feature extraction techniques on the same model using the ShipsEar dataset.

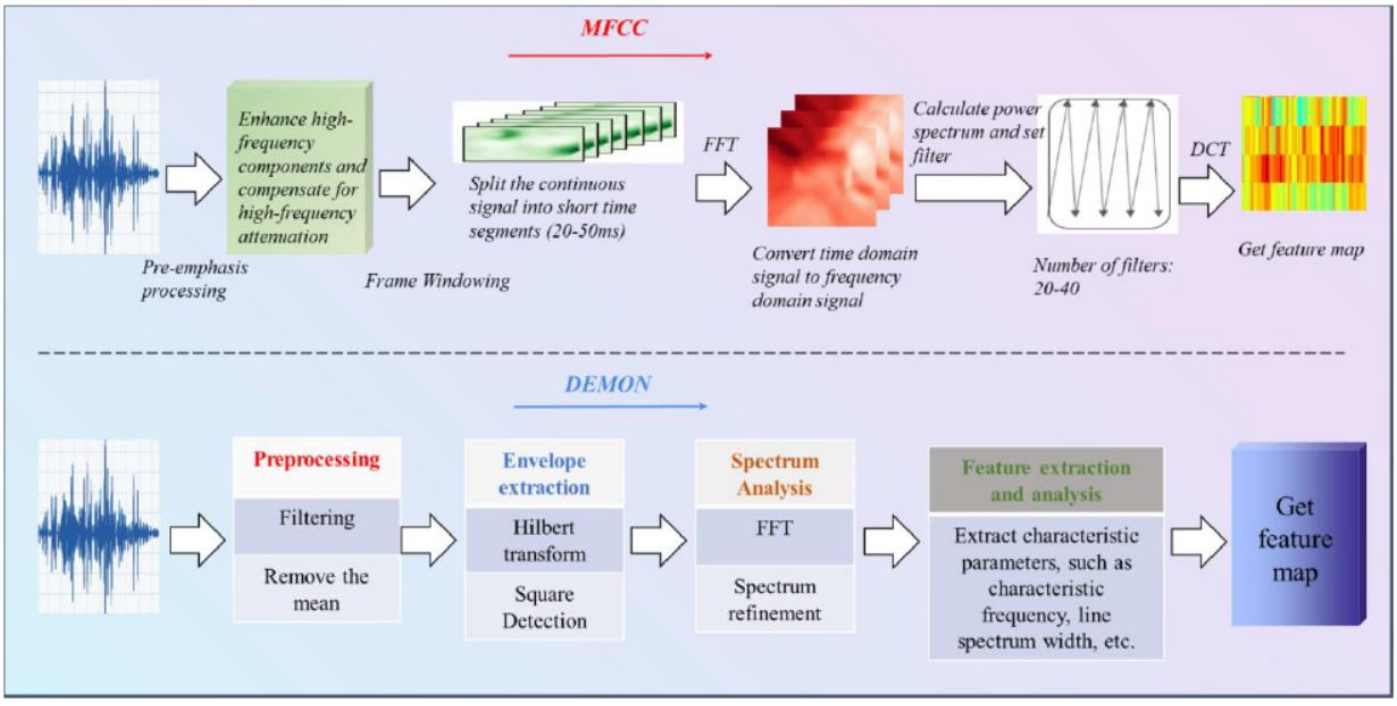

Fig. 3. MFCC and DEMON feature extraction process.

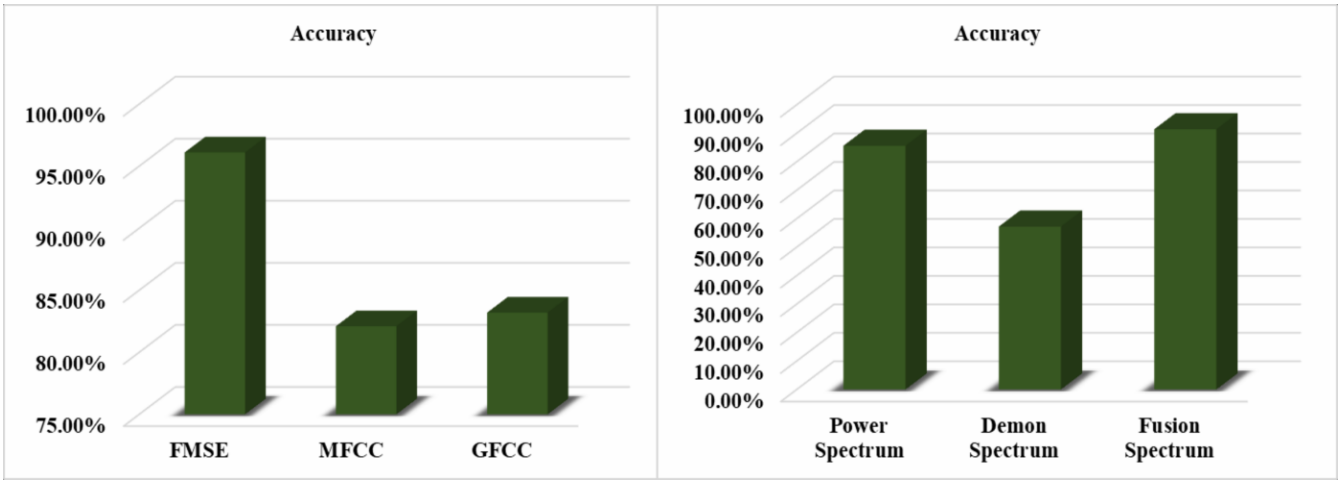

Fig. 4. Comparison of accuracy for different artificial and image features.

A broadband demodulation method, known as DEMON analysis, can distinguish between ship-radiated noise signals and the modulation envelope caused by propeller cavitation. By employing spectral analysis and line spectrum detection, it is possible to determine the number of propeller shafts, shaft frequencies, and blade counts [20]. Using the DEMON spectrum as input for the DEMONet model, Xie et al. [21] achieved an accuracy of 80.45 ± 0.67% on the DeepShip dataset. It is noteworthy that the feature extraction and model design in their study aimed for consistency. Furthermore, techniques such as Wavelet Packet Decomposition, Low-Pass Filtering, Gamma Frequency Cepstral Coefficients (GFCC), Multiscale Entropy Decomposition (MEMD), and LPS Feature Extraction, along with enhanced MFCC-based feature extraction methods, have been extensively studied and applied [22],[23],[24],[25]. Notably, Luo et al. [26] evaluated a range of feature extraction methods, including DEMON, LOFAR, MFCC, GFCC, EMD, and HHT, discussing their performance and suitability in different scenarios.

Manual feature design has several drawbacks, including low flexibility, limited expressive capacity, and high labor costs [27]. Additionally, manually crafted features often suffer from insufficient automated feature learning, as they cannot effectively capture or adapt to the inherent structure of data. In contrast, deep learning automatically extracts hierarchical features from data and enables end-to-end optimization, whereas manual feature extraction typically requires a separate design for classifiers or regressors [28]. As a result, researchers are increasingly focusing on technologies that leverage visual features [17],[29].

B. Figures and Tables

UATR based on image features is achieved by converting underwater acoustic signals into images and applying pattern recognition theory and image processing techniques to extract and analyze image features. This approach involves three main stages: image feature extraction, feature selection and optimization, and classification recognition. Image feature extraction involves using feature extraction algorithms to obtain representative and discriminative features from the transformed images. Feature selection and optimization focus on choosing the most relevant subset of features for target identification, removing unnecessary and redundant features, reducing feature dimensionality, and ultimately improving recognition accuracy and efficiency. Classification recognition involves using classification algorithms in pattern recognition to compare the extracted and optimized image data with pre-existing target feature libraries, enabling the identification of unknown underwater acoustic targets.

In terms of expressive power, interpretability, and adaptability, the image feature-based approach has demonstrated significant advantages [16]. Common image features include the amplitude spectra derived from LOFAR and STFT. Chen et al. [30] extracted the LOFAR spectrum of underwater sound waves and identified key characteristics using a multi-step decision-based line spectrum augmentation method. They combined the reconstructed line spectrum with the original LOFAR spectrum using a dual-threshold calculation approach. A convolutional neural network (CNN) was then trained on the reconstructed LOFAR spectrum, achieving an average recognition accuracy of 95.22% on the ShipsEar dataset. Despite the high recognition accuracy of this method, data augmentation techniques not only improve recognition performance but also mitigate noise interference from the marine environment. However, further research is needed to evaluate their impact on the recognition performance of neural networks. Additionally, Xu et al. [31] applied Mel (or Bark) filter banks to the FFT-generated spectrum to compute the STFT amplitude spectrum through complex FFT calculations, achieving an identification accuracy of 82.97% on the ShipsEar dataset. Yao et al. [32] further compared the LOFAR spectrum with other feature extraction methods, such as MFCC and CQT, using statistical histograms to analyze feature information across different ship types. Experimental results revealed that LOFAR image features lack low-frequency information, highlighting a limitation in capturing certain aspects of feature information.

Tang et al. [33] utilized Mel spectrograms as feature representations for model input. After feeding the data into the Transformer model, they conducted experiments on a small sample dataset, achieving a 90% identification accuracy with the Swin Transformer. Similarly, Xie et al. [34] achieved identification accuracies of 77.14%, 74.85%, and 95.48% on

the ShipsEar, DeepShip, and DTIL datasets, respectively, using Mel spectrograms as input. Studies employing spectrograms as input features have also yielded positive results [25],[35],[36],[37]. In Fig. 5, the recognition accuracy based on image features in UATR tasks is presented.

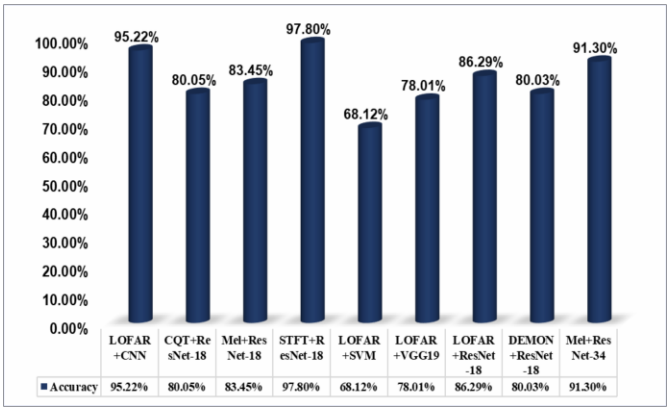

Fig. 5. Recognition accuracy based on image features.

Fig. 5 provides an overview of feature extraction methods based on image representations. Different deep learning architectures exhibit varying levels of recognition performance when using image features as model inputs. Notably, employing STFT features as input to ResNet-18 achieves a high recognition accuracy of 97.80%. Furthermore, due to the strong time-frequency correlation inherent in underwater acoustic signals, the use of raw time-domain signals as model inputs has been extensively investigated to preserve as much detailed information as possible. In contrast, image-based feature extraction methods may struggle to capture complex or high-dimensional patterns and are more susceptible to the loss of critical information [38], [39].

C. Raw Data-Based Approach

Raw signal-based UATR technology aims to identify underwater targets by directly utilizing the received raw underwater acoustic signals without performing complex transformations. This approach leverages various signal processing and pattern recognition algorithms. During the feature extraction stage, three main methods are employed: time domain, frequency domain, and time-frequency domain feature extraction. Time domain feature extraction involves directly obtaining amplitude information from the raw signal, such as peak values, mean, variance, and other statistical characteristics. Frequency domain feature extraction involves calculating the power spectral density of the raw signal using the Fourier transform and other operations, enabling target identification based on the distribution of signal power across different frequencies. Time-frequency domain feature extraction divides the raw signal into multiple short-time segments and performs a Fourier transform on each segment to obtain the distribution of signal components across both time and frequency domains. This approach provides a comprehensive view of how signal characteristics vary over time and frequency.

The intrinsic time-frequency correlation of underwater acoustic signals can lead to the loss of significant frequency domain information, even though image-based techniques can moderately enhance UATR [40]. Consequently, the direct use of raw data as input has become a prominent area of research to ensure the preservation and accuracy of information in underwater acoustic signals [41]. Hu et al. [42] investigated a technique for identifying ship-radiated noise using raw time-domain waveforms. They employed a depth-wise separable convolutional network to extract deep features that mirrored the auditory system's acoustic information processing. The model achieved an average classification accuracy of 90.9% when tested on a dataset of real acoustic signals from civilian ships. Additionally, extreme learning-based approaches have also shown promising results [43],[44].

However, using raw data directly as input for the model requires substantial computational resources, particularly for high-sampling-rate underwater acoustic signals [45]. Moreover, in the context of UATR with limited sample sizes, insufficient data can quickly lead to overfitting or poor model training.

To address the issue of inadequate underwater acoustic samples, several studies have explored segmenting and resampling original sound data. Yang et al. [46] resampled raw data at 16,000 Hz and divided it into 1-second non-overlapping intervals. Ji et al. [47] resampled underwater acoustic at 20 kHz, truncating each frame into 4096 samples with a 2048-sample overlap between successive frames. Similarly, Yang et al. [48] segmented each 5-minute WAV audio clip into 6-second intervals representing sound events and normalized the data for each segment. Li & Yang [49] split each audio recording into 3-second parts, normalizing each segment based on unprocessed raw time-domain data. In Fig. 6, the recognition accuracy with raw data as input is presented. From Fig. 6, it can be seen that the highest recognition rate can reach 95.30%.

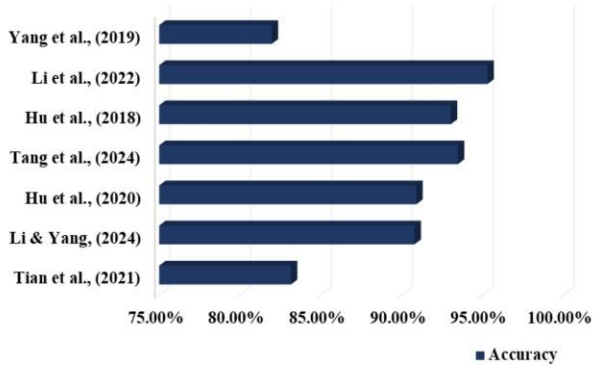

Fig. 6. Recognition accuracy based on raw data.

While resampling techniques can somewhat alleviate the issue of insufficient samples, they have limitations, including the potential amplification of noise and reduced diversity in the generated data. Therefore, methods based on fused features are becoming increasingly popular as a research direction.

D. Feature Fusion-Based Approach

Feature-based fusion is widely utilized in UATR technology to enhance accuracy and reliability by integrating various types of feature information. The main components of this approach include multi-domain feature fusion, multi-modal

feature fusion, and multi-scale feature fusion. Multi-domain feature fusion involves combining time domain, frequency domain, and time frequency domain characteristics of underwater acoustic signals to capture comprehensive signal properties. Multi-modal feature fusion integrates data collected from different sensors or based on different physical principles. For example, sonar signal features can be combined with underwater target features captured by optical sensors. Multi-scale feature fusion involves utilizing features at different scales, such as integrating fine local details with broader global target characteristics in image processing, to achieve a more robust and detailed representation of the target.

The fusion feature approach enhances identification accuracy by combining multiple feature types, such as time domain, frequency domain, and time frequency domain features, effectively addressing the limitations of single feature information. Additionally, integrating diverse features improves the system's robustness and adaptability to challenging conditions, such as interference and noise [50], [51]. Table I provides a summary of techniques for fused feature extraction.

TABLE I. SUMMARY OF FEATURE FUSION-BASED APPROACH

Author (s)	Feature	performance	Advantage	Disadvantages
Cao et al., (2019)	Axis frequency characteristics; LPS characteristics; WPCE characteristics	89.68% Acc	Adopting the SSAE model provides stronger discriminability; Constructing a joint feature set based on spectral and wavelet domain information	Underwater target classification tasks that require high real-time performance face challenges due to the complexity, cost, and time involved in obtaining a substantial amount of representative underwater target data.
Hong et al., (2021, May)	Log - Mel Spectrogram; MFCC; CCTZ	94.30% Acc	Using ResNet18, combined with embedding layers, early stopping, and adaptive learning rate strategies for training, Adopting data augmentation strategy SpecAugment	The universality of the method may be limited by the experimental validation, which was restricted to the ShipsEar dataset and did not include testing on a broader variety of datasets with different types and scales.
Domingos et al., (2022)	CQT; Gammatone Spectrograms; Mel Spectrograms	97.00% Acc	Compare various optimizers, neural network architectures, and preprocessing filters; Combine multiple filters into a three-channel signal	Accurately determining which scenario yields the best results under different testing conditions is challenging due to the varying number of instances in each case.
Chen et al., (2023)	CQT; delta MFCC; double - delta MFCC	99.10% Acc (DeepShip)	Propose a new loss function that only adds three hyperparameters to transform multi classification tasks into multiple binary classification tasks	In terms of model interpretability, the underlying mechanisms of each module are not thoroughly examined, leaving unclear how they influence the final outcomes.
Wu et al., (2023)	FBank; delta FBank; delta - delta FBank	90.50%	Combining cross domain pre training effectively improves recognition accuracy and saves a lot of training time	Insufficient exploration of innovative feature extraction techniques and potential feature combinations.
Pu et al., (2024)	Original wave; CQT; Mel spectrogram	96.37%	Design Scale ResNet module and RHAF module to improve information fusion efficiency and model adaptability to underwater acoustic data	In feature fusion, the lack of comparison with more advanced fusion techniques makes it difficult to determine its optimality across all scenarios.

Wu et al. [52] developed fusion features as model inputs by combining Mel filter-bank (F-Bank), delta F-Bank, and double delta F-Bank. To better capture the characteristics of underwater acoustic targets, they extracted neigh-boring dynamic features by computing delta features. Experimental results showed that this fusion approach improved identification accuracy by 0.9% and 1.2% on CNN and ResNet18 models, respectively. Chen et al. [53] proposed the FEFM method, which extracts multidimensional features from ship-radiated noise signals using various feature extraction techniques based on signal analysis and brain-inspired properties. These features are then fused using the proposed feature fusion technique to create high-dimensional fused features, which are used as inputs for the Multi-Gradient Flow Global Feature Enhancement Network (MGFGNet) network. Feature ablation tests were conducted on the Deepship dataset, comparing the fusion feature approach with other feature extraction methods. The fusion technique achieved a total accuracy of 99.1%.

Hong et al. [54] calculated various features, including the Log Mel Spectrogram (LM), Mel Frequency Cepstral Coefficients (MFCC), and CCTZ (which comprises the following features: Chroma, Contrast, Tonnetz, and Zero-cross ratio). These features were then fused and enhanced to create a three-dimensional feature matrix, which was used as input to the model. Domingos et al. [55] divided the raw dataset into one-second segments, padding shorter segments with zeros. They applied three preprocessing techniques—Mel spectrograms, Constant Q Transform (CQT), and Gammatone spectrograms—and combined them into a three-dimensional representation, referred to as "Complete", which was then be used as input to the model.

VI. DEEP LEARNING NETWORK ARCHITECTURE

The accuracy of UATR tasks is heavily influenced by the choice and design of the model architecture. With advancements in computing power, UATR technology has made significant progress. Conventional methods that relied on manual feature extraction and classifier design have been largely improved by deep learning approaches capable of automatic feature extraction and classification, resulting in substantial improvements in identification accuracy [56]. To clearly illustrate the development of these techniques, this study categorizes model architectures into two main groups: conventional machine learning-based methods and deep learning-based methods, depending on whether they employ an

end-to-end recognition process. A detailed discussion of these techniques follows below.

A. Conventional Machine Learning-Based Methods

UATR based on conventional machine learning methods refers to the process of classifying and identifying various underwater acoustic targets by extracting, analyzing, and evaluating the target information embedded in underwater acoustic signals using conventional machine learning theories and algorithms. Conventional machine learning methods rely on manually crafting features, which are then input into regression or classification models. Common approaches include multilayer perceptron (MLP), logistic regression, naive Bayes, support vector machines (SVM), and random forest classifiers [57], [58].

Honghui et al. [59] proposed the Multi-Attribute Correlation Perception (MCP) model, achieving 82.1% accuracy in ship detection tests by integrating the MCP module with a time-frequency feature extraction module for UATR. To enhance feature selection during classification, Fernandes et al. [60] applied neighborhood component analysis (NCA) for dimensionality reduction, combined with genetic algorithms and the K-nearest neighbor (KNN) method for object classification. Yu et al. [61] achieved an underwater target identification accuracy of 93.84% by employing the Gradient Boosting Decision Tree (GBDT) model in combination with two hydrophones and the VLA feature extraction approach. These approaches share a common characteristic: they all employ distinct feature extraction strategies prior to inputting features into the classification model to complete the classification task. However, separating feature extraction and classification introduces human variables due to the relative decoupling of these processes, potentially leading to a decline in recognition accuracy [18].

Sun et al. [19] achieved a recognition accuracy of 96.1% by using a support vector machine (SVM) classifier to process the retrieved features. Wang et al. [24] employed Gaussian Mixture Models (GMMs) to modify the topology of deep neural networks (DNNs), proposing the MFF-MDNN approach, which achieved an average recognition accuracy of 94.3%. While these methods reduce spurious variables to some extent and enhance recognition accuracy, the limited number of classifier layers in such models may constrain their ability to generalize effectively. Yang et al. [62] highlighted that the poor generalization ability of traditional recognition systems stems largely from the use of shallow classifiers, such as SVMs and shallow neural networks. Moreover, conventional methods, which predominantly rely on line and spectrum properties, often exhibit lower identification rates. Fortunately, deep learning-based approaches provide a more holistic framework for UATR, effectively addressing the limitations of traditional machine learning techniques and opening up promising directions for future research.

B. Deep Learning-Based Methods

Deep learning-based UATR technology is an advanced approach that automatically extracts, analyses, and recognizes target information within underwater acoustic signals by leveraging the powerful feature learning and pattern recognition capabilities of deep learning algorithms. The main process of this technology is illustrated in Fig. 7. The primary advantage of employing deep learning networks in UATR lies in their ability to bypass the complex feature engineering required by conventional machine learning approaches. Furthermore, they can partially address the problem of feature information loss associated with manual feature extraction [63]. The following will be discussed in detail.

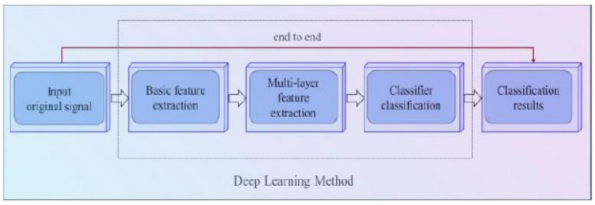

Fig. 7. General process of UATR based on deep learning methods.

1) CNN-based methods. The Convolutional Neural Network (CNN)-based UATR system leverages the powerful feature extraction and pattern recognition capabilities of convolutional neural networks to accurately identify targets in underwater acoustic data. CNNs are primarily used in tasks related to computer vision and speech recognition. Their architecture involves multiple processes that enable hierarchical feature learning and the use of automatically generated features for prediction [64]. Over time, CNNs have become a research hotspot in underwater target detection, driven by their remarkable performance advancements from AlexNet to GoogLeNet [39],[65].

ResNet is one of the most widely studied and popular deep learning models. Xu et al. [31] built their model on ResNet-18, incorporating a multi-head attention mechanism. The model was trained using two techniques: smooth induced regularization and the local masking and replication (LMR) approach. Its identification accuracy was evaluated using various input attributes, although several factors could potentially influence its performance. Xie et al. [34] adopted a dual-encoder framework with residual structured convolutional neural networks (ResNet) as the backbone to capture diverse acoustic features, specifically Mel spectra and continuous Q-transform spectra. By treating these networks as multi-view learners, they were able to extract more comprehensive features. Additionally, ResNet-based methods for developing and enhancing UATR have demonstrated promising results [54],[66],[67].

Significant advancements have been made in UATR techniques based on convolutional neural networks (CNNs) in recent years. Yang et al. [48] introduced a deep convolutional neural network (ADCNN) inspired by auditory perception, achieving an accuracy of 81.96%. Similarly, Hu et al. [44] proposed the auditory temporal convolutional neural network (ATCNN) model, which attained recognition accuracies of 95.9% on training data and 90.9% on test data. Meanwhile, more advanced CNN-based architectures, such as depth-wise separable convolutional neural networks, have also shown promising results. However, despite CNN's excellent feature extraction capabilities, the unique and complex nature of underwater acoustic signals poses several challenges. Specifically, CNN's convolutional kernels, limited by their

localized receptive fields, struggle to capture long-range correlations and global information inherent in underwater sound waves. Fortunately, techniques utilizing residual attention convolutional neural networks (RACNN) and deep residual attention convolutional neural networks (DRACNN) have opened new avenues for research. These methods have achieved impressive identification accuracies, addressing some of CNN's limitations in UATR [47], [68].

2) Attention-based methods. Attention-based UATR enhances the model's ability to extract and interpret critical information from underwater signals by incorporating attention mechanisms. These mechanisms efficiently capture the global characteristics of underwater acoustic signals by dynamically assigning attention weights based on signal features. They allocate different weights to various aspects of underwater acoustic signals across time, frequency, or spatial locations. The propagation of underwater acoustic signals is influenced by factors such as water temperature, salinity, and pressure. These factors can lead to attenuation, scattering, and refraction, impacting both the propagation distance and the quality of the signal. Consequently, the propagation of underwater acoustic signals is globally correlated, meaning that the signal's characteristics are shaped by the entire aquatic environment [69].

In UATR, the attention mechanism has gained significant traction for its ability to extract global features. Xiao et al. [70] introduced an attention-based neural network (ABN) model that integrated an attention module with a traditional deep neural network (DNN) composed of fully connected layers. By embedding the attention module within the DNN architecture, they developed a novel network designed to tackle UATR tasks. This model achieved an accuracy of 74.3% in multi-target resolution tasks, marking a 16.0% improvement over traditional DNNs. In contrast, Xie et al. [71] proposed the UART (Underwater Acoustic Recognition based on Templates) framework, which diverges from ABN by not depending on innovations in neural network design. Instead, this framework consists of an audio encoder, a spectrogram encoder, and a text encoder, offering an alternative approach to underwater object recognition.

The Transformer, a widely used attention mechanism, has been extensively applied in UATR using sound waves. Tang et al. [33] studied the Swin Transformer Biformer, a Transformer-based model. Similar to the four-layer pyramid structure of CNNs, the architecture of the Swin Transformer features a progressive reduction in the feature map's size as the feature layers deepen. The Swin Biformer enhances feature representation by combining the Swin Transformer with the Biformer, dynamically adjusting the partition window to refine regional feature extraction. Pu et al. [72] introduced the Attention Layer Supplementary Integration (ALSI) framework for UATR. This model demonstrated outstanding performance, effectively detecting underwater objects such as ship-radiated noise and achieving an identification accuracy of 96.39% on the ShipsEar dataset. Additionally, several other attention-based enhancement techniques have also yielded promising results [73], [74].

3) Other-based methods. The Restricted Boltzmann Machine (RBM), a fundamental component of deep learning, consists of visible and hidden layers of neurons. RBMs are widely used as energy-based models for tasks such as feature learning, dimensionality reduction, and model development [75]. In the field of UATR, RBM-based deep learning techniques have been effectively applied.

For instance, Luo and Feng [25], applied RBM and BP neural network techniques, achieving an accuracy of 93.17% on the ShipsEar dataset. Similarly, Luo et al. [18] developed a UATR system that demonstrated the effectiveness of BP neural networks and RBM autoencoders. However, despite RBM's advantages in feature learning, dimensionality reduction, and data generation, its shallow structure makes it difficult to model complex data distributions or high-dimensional features. To address these challenges, Yang et al. [35] proposed the GRU-CAE collaborative deep learning network. Their GRU-CAE-TM (Gated Recurrent Unit with Template Matching and Convolutional Autoencoder Collaborative Deep Learning Network) approach achieved an open-set recognition accuracy of 82.21%. While GRU effectively captures short-term time series dependencies, it faces limitations in processing underwater acoustic target signals with long-term dependencies. Moreover, deep learning techniques, including LSTM gradient-boosting decision trees, have been widely used to tackle issues related to few-shot learning in UATR [29],[61],[76].

VII. Model Outputs

The output of a deep learning model is typically defined by the result of forward propagation, depending on the task type and objective. Some common types of tasks include classification, regression, generation, segmentation, embedding or feature representation, and multitask output [77], [78],[79]. This section provides detailed explanations of UATR based on classification tasks and other related activities.

A. Classification-Based Methods

Classification-based methods for UATR typically involve steps such as data preprocessing, feature extraction and selection, and the application of classification algorithms to differentiate various underwater acoustic targets (e.g., submarines, fish schools, marine organisms) using sonar data. To provide a comprehensive overview of previous research, the following section will delve into various methods applied to different datasets.

1) ShipsEar-based dataset. The primary purpose of the ShipsEar dataset is to facilitate the development and testing of UATR algorithms and models [80]. By providing a substantial amount of underwater acoustic data, the ShipsEar dataset enables researchers to analyze and classify noise generated by various vessels, thereby enhancing environmental monitoring and maritime surveillance. The accuracy of the results varies depending on the model design, as illustrated in Table II.

TABLE II. ACCURACY OF UATR METHOD BASED ON SHIPSEAR DATASET

Author (s)	Methods	Accuracy
Fahad et al., (2024)	CNN + DenseNet	99.50%
Liu et al., (2024)	Residual Attention Convolutional Neural Network (RACNN)	99.45%
Yang et al., (2024)	1D CTN	96.84%
Pu et al., (2024)	Attention Layer Supplement Integration (ALSI)	96.37%
Luo et al., (2021)	Conditional Deep Convolutional Generative Adversarial Network (cDCGAN) Model	96.32%
Chen et al., (2023)	ARCSB modules (Rescat, SE,Maxpool, ASPP, MLP)	95.80%
Li et al., (2022)	VGGish	95.30%
Hong et al., (2021, May)	ResNet18	94.30%
Tang & Hu (2024)	DSCANet	93.00%
Ke et al., (2018)	1D convolution Autoencoder - Decoder model	93.28%
Luo et al., (2021)	RBM+BP neural network	92.60%
Du et al., (2024)	TF - DD - CNN	92.23%
Fernandes &Apolinário (2020)	KNN	71.10%
Chen et al., (2023)	ARCSB modules (Rescat, SE,Maxpool, ASPP, MLP)	95.80%

ShipsEar dataset consists of five categories: four ship types and one background noise category. The model's output can include accuracy or probability as performance metrics [60],[81]. For example, using the ShipsEar dataset, Pu et al. [72] reported a 96.39% identification accuracy for their model. This output format offers the advantage of being easily and directly comparable to the results of other studies. Moreover, Müller et al. [82] examined the strengths and weaknesses of each approach and proposed a method for integrating the ShipsEar and DeepShip datasets.

One critical factor that can influence object identification accuracy is how the dataset is divided into training and testing sets. Fahad et al. [83] pre-processed each signal into 1,000 observation frames, each containing 4,096 amplitude samples, and then randomly split the dataset, allocating 70% for training and 30% for testing. While this approach is effective, an 80/20 split between training and testing sets is more commonly used in similar studies [17], [76],[84].

In machine learning and pattern recognition, accuracy is a commonly used performance metric that measures the consistency between model predictions and actual outcomes. However, a model's accuracy is influenced by several factors, such as the criteria for splitting training and testing sets, the volume of training data, and the model's inherent performance. These factors collectively impact the overall accuracy to varying degrees. Moreover, accuracy on labeled datasets during training and validation does not reflect the model's ability to generalize data from unknown categories. Therefore, relying solely on accuracy to evaluate a model's performance is not an ideal approach. Instead, explaining the model's behavior—through mechanisms such as process visualization and interpretability—is increasingly recognized as an effective way to assess model performance comprehensively.

2) DeepShip-based dataset. Many UATR studies rely on private datasets, but the lack of public access to these datasets hampers the continuous improvement of UATR tasks [85]. The DeepShip underwater acoustic dataset, developed by Irfan et al. [86], was made publicly available to advance research in the field. Fig. 8 presents the recognition accuracy of various methods evaluated using the DeepShip dataset.

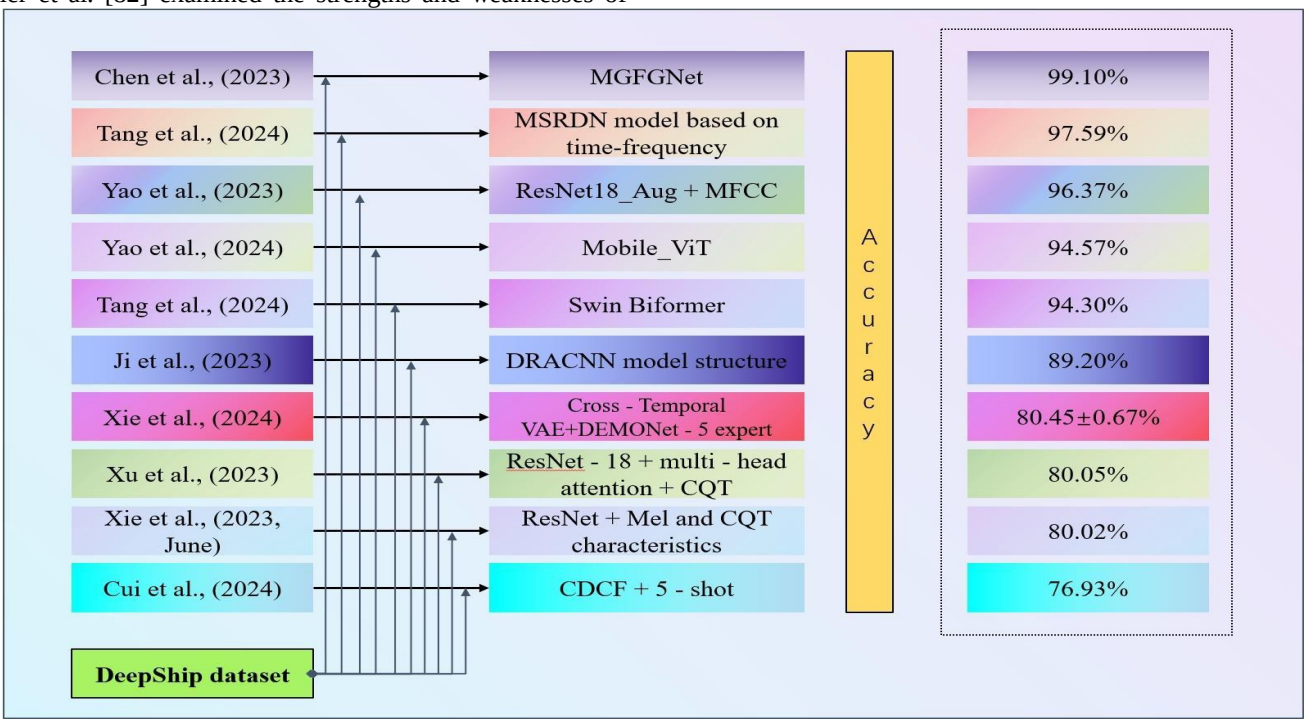

Fig. 8. Accuracy of UATR method based on DeepShip dataset.

Yao et al. [32] utilized acoustic data from three ships, extracting 1,487,488 samples for each ship type to analyze acoustic characteristics from the DeepShip database. To prevent information leakage, Xie et al. [21] divided each signal recording into 30-second segments with a 15-second overlap between adjacent segments, ensuring that data from the same track was not included in both the training and testing sets. Similarly, Chen et al. [53] pre-processed two datasets by standardizing all WAV-format audio files to a sampling rate of 22,050 Hz. They segmented the underwater acoustic data into 5-second intervals, resulting in over 30,000 sound samples, which were then categorized into training, validation, and testing sets.

3) Other underwater acoustic-based datasets. Both private and publicly accessible observation datasets have been utilized in the UATR mission. Examples include the Seabed-Objects dataset, PondEx09/PondEx10 dataset, Ocean Networks Canada data (https://oceannetworks.ca), and various private datasets [68],[87],[88]. Table III presents the recognition accuracy of several techniques evaluated using these private datasets.

TABLE III. ACCURACY OF UATR METHOD BASED ON PRIVATE DATASET

Author (s)	Methods	Accuracy
Xue et al., (2022)	CamResNet (ResNet with Channel Attention Mechanism)	98.20%
Jin & Zeng, (2023)	CTA - RDNet	97.69%
Christensen et al., (2024)	Sparse MvDA + SVM	97.30%
Sun et al., (2024)	SVM + MFCC, FMSE, GFCC	96.10%
Wang et al., (2019)	MFF - MDNN	94.30%
Yu et al., (2024)	Gradient Boosting Decision Tree (GBDT)	93.84%
Hu et al., (2018)	CNN + ELM	93.04%
Hu et al., (2020)	ATCNN	90.90%
Li & Yang, (2024)	ASTEM - DCNN	90.79% (SNR-6dB)
Cao et al., (2019)	Stacked Sparse Autoencoder (SSAE)	89.68%
Tian et al., (2021)	MSRDN（Multiscale Residual Deep Neural Network)	83.15%
Yang et al., (2022)	GRU - CAE - TM	82.21%
Honghui et al., (2022)	MCPM2	82.10%
Yang et al., (2019)	ADCNN	81.96%
Xiao et al., (2021)	ABNN (In multi target resolution task)	74.30%

Domingos et al. [55] developed a dataset using the Ocean Network Canadian data by randomly selecting audio samples from each category. To ensure all records were distinct, they continued the selection process until the required total duration was achieved. Each item in the original dataset was divided into 1-second segments, with any segment shorter than 1 second padded with zeros. The dataset was then split into training, validation, and testing sets in proportions of 85%, 10%, and 5%, respectively. Algorithms based on this dataset have demonstrated strong recognition results [48], [49],[56]. Additionally, Hu et al. [42] utilized a private dataset for UATR tasks that included underwater noise data from ferries, large boats, and small boats, collected at an anchorage with a sampling frequency of 48,000 Hz. In their experiment, 80% of the samples from each category were allocated to the training set, while the remaining 20% were used for testing. Each record was derived from a WAV audio file divided into 10-second segments, with a sampling period of 45 milliseconds and a sampling interval of 12.5 milliseconds for both training and testing samples. Several UATR studies have shown strong recognition performance using such private datasets. At the same time, some studies have achieved impressive recognition accuracy [89], [90].

B. Other Tasks-Based Methods

UATR based on regression tasks typically achieves target tracking and recognition by predicting continuous target properties such as location, velocity, and depth. These methods, which excel in localization, tracking, and dynamic detection of underwater acoustic targets, primarily rely on regression models, machine learning algorithms, and data from underwater sensors.

Zhu et al. [76] proposed a feature selection (FS) technique for underwater sound source localization based on principal component regression. This approach employs a convolutional autoencoder to extract latent features and a multi-layer perceptron for source localization. The framework demonstrates high accuracy and robustness to unseen data while achieving a 95% reduction in training time after FS. To address the limitations of existing methods in accounting for multi-attribute correlations, Honghui et al. [59] developed a deep learning-based multi-attribute correlation perception (MCP) technique for UATR.

Generative task-based approaches provide significant advantages for UATR, especially in noisy or data-scarce environments. Luo et al. [67] trained a DCGAN model using the original sample set to develop an appropriate generator. This generator can increase the number of examples for each category in the dataset by generating samples across various categories based on input labels. In addition, multi-task output-based methods for UATR have gained significant attention in recent years. These methods are capable of simultaneously addressing multiple related tasks, effectively leveraging the relationships between multimodal features, and thereby enhancing both the accuracy and robustness of recognition.

VIII. CHALLENGES AND FUTURE PROSPECTS

The methodology, techniques, and current research on UATR indicate that factors such as training methods, model architecture, and underwater acoustic data significantly impact model performance. Additionally, the model's ability to address real-time challenges in practical applications plays a crucial role. The following sections will explore these aspects from three perspectives: challenges in underwater acoustic data, enhancing UATR model evaluation and performance, interpreting deep learning in UATR.

A. Challenges in Underwater Acoustic Data

Gathering underwater acoustic data presents significant challenges due to high costs and substantial resource demands. Most UATR studies depend on a limited number of publicly accessible datasets or data collected from relatively simple maritime environments. This reliance restricts the variety and richness of the data, making it difficult to generalize findings across diverse underwater scenarios. As a result, acquiring high-quality underwater acoustic data has become a critical issue, with insufficient sample sizes exacerbating the problem. The lack of diverse datasets not only hinders model training and validation but also limits advancements in research and practical applications in more complex and variable underwater environments. Addressing these challenges is essential for enhancing the reliability and effectiveness of UATR systems.

B. Enhancing UATR Model Evaluation and Performance

Deep learning models utilized for UATR often exhibit high complexity, which can lead to significant challenges in training effectiveness. When the complexity of a model exceeds the available quantity and quality of training data, achieving desired outcomes becomes increasingly difficult. While improving model accuracy is a primary objective, relying solely on accuracy as the sole metric for evaluating model performance is insufficient.

To enhance model evaluation, it is crucial to incorporate process visualization and develop a deeper understanding of the model's mechanisms. This approach not only aids in identifying the strengths and weaknesses of the model but also fosters greater transparency. By integrating physical variables from the input data—such as temperature, salinity, depth, and geographic location—into the evaluation process, researchers can create more robust models that better reflect real-world conditions. This integration facilitates a more holistic assessment of model performance, ultimately leading to improved adaptability and reliability in practical applications. Moreover, such comprehensive evaluations can guide future research directions, informing the development of models that are not only accurate but also interpretable and adaptable to varying underwater environments.

C. Interpreting Deep Learning in UATR

Despite their significant potential, deep learning models based on neural networks encounter notable limitations in real-world applications primarily due to their "black-box" nature. This opacity makes it challenging to interpret or modify these models in real time, which is crucial for practical deployment. One of the key factors contributing to this limitation is the insufficient incorporation of physical variables into the model's outputs and the underlying mechanisms governing those outputs. To overcome these challenges, it is essential to fully integrate physical variables into the modelling process. This integration would not only enhance the interpretability of the models but also enable real-time adaptations based on changing environmental conditions, ultimately improving their efficacy in practical applications. By bridging the gap between complex neural computations and tangible physical realities, it is possible to unlock the full potential of deep learning in dynamic real-world scenarios.

In summary, addressing the challenges associated with data collection, balancing model complexity with the availability of training data, and ensuring the interpretability and adaptability of models are essential for advancing the field of underwater target recognition. These steps are crucial because effective data collection is foundational for training robust models; without diverse and high-quality datasets, models may fail to generalize across various underwater environments. Balancing model complexity with training data is equally important; overly complex models can lead to overfitting, particularly when trained on limited data. Thus, achieving the right balance allows for improved performance while maintaining generalizability.

Moreover, enhancing model interpretability is vital for fostering trust and facilitating real-time adjustments in dynamic underwater scenarios. By ensuring that models can adapt based on physical variables—such as temperature, salinity, and depth—researchers can create systems that not only perform accurately but are also responsive to changing conditions. Collectively, these advancements will pave the way for more effective and reliable UATR systems, ultimately enhancing their practical applications in marine research, naval operations, and environmental monitoring.

IX. Conclusion

This study systematically elaborates on the background and inherent challenges of Underwater Acoustic Target Recognition (UATR). A comprehensive overview is presented of the key factors influencing UATR performance, including class imbalance, environmental fluctuations, and data noise. Through the analysis of existing literature and the examination of the unique characteristics of various methodologies, recent advancements in UATR are classified according to their applied techniques and underlying properties. The role of deep learning technologies—such as transfer learning, deep convolutional networks, and temporal modelling—is explored in enhancing the accuracy and robustness of UATR systems. Particular attention is given to the challenges of model training, notably the substantial demand for annotated data, highlighting the urgent need for methods that reduce dependence on large-scale labeled datasets. Additionally, the potential of multimodal data fusion is also emphasized, as the integration of multiple data sources—such as underwater acoustic signals and optical imagery—can significantly improve recognition accuracy. Furthermore, ensemble learning approaches and attention-based mechanisms are examined as promising strategies for advancing performance in the field. Despite recent progress, current research indicates a continuing need to improve model interpretability and to better understand the mechanisms contributing to high recognition accuracy. The interpretation and visualization of these models remain largely unexplored, pointing to crucial directions for future research. Overall, the advancement of technologies like unsupervised learning and multimodal data fusion is likely to enhance UATR performance in increasingly complex and demanding application scenarios.

Oita Prefecture Agriculture, Forestry and Fisheries Research and Guidance Center, Oita City, Japan[2]

***Abstract*—As a method for estimating the time when tea leaves reach their peak quality (amino acid content) (optimum picking time), our previous study revealed that the optimum picking time is when the accumulated temperature from the detection of germination of new buds reaches 600°C. However, the accuracy of this germination detection was insufficient, so the estimation accuracy of the optimum picking time was also insufficient. Since annotation accuracy is extremely important for germination detection by YOLO11, strict attention is paid to annotation by hand and by increasing the number of training datasets. The detection accuracy has been improved compared to the germination detection by YOLOv8, which was previously proposed and used relatively low-resolution images. The conclusion of this study is that the estimation method of the optimum picking time based on the criterion that the optimum picking time (amino acid content reaches its peak) is effective when the accumulated temperature from germination detection meets the condition of 600°C. The effectiveness of this method has been confirmed by comparison with germination detection by experts. For tea farmers, being able to predict the optimum picking time, when the amino acid content in the new buds is at its peak, is important, and we are sure it will have a positive impact on agricultural researchers studying this subject.**

Keywords*—*Tealeaf plucking; YOLO; budding detection; spatial resolution; optical image; annotation; germination rate

I. INTRODUCTION

The quality of tea leaves is greatly affected by the time of plucking, so it is important not to miss this timing. The method of deciding the time of plucking tea varies depending on the climate and variety of the year, but it is generally decided based on an index called "degree of opening". A new bud has 5 to 6 leaves that are the origin of the bud, and as it grows, it gradually opens. This last leaf is called the "flag leaf", and when it opens, it is said to have "opened". The percentage of new buds that have opened out of the total number of buds in a certain area is called the "degree of opening", and it is said that plucking is optimal when this percentage is 50 to 80%. In addition, if you pick early, you can also pick when it is 30 to 50%.

The time of plucking is closely related to the quality and yield of the green leaves. After the tea leaves sprout, the sprouts grow and reach their peak in amino acids (tea leaves contain amino acids such as theanine, glutamic acid, aspartic acid, arginine, and serine. These amino acids work together to create the umami and sweetness of tea) and this is when the optimum time for picking is reached. Once the optimum time for picking has passed, these amino acids are transformed into catechins because of sunlight, which is fine for functional catechin tea, but makes it unsuitable for high-quality sencha. For this reason, we check the time when the buds sprout. The program's output is either germinated or not. To determine this, we use YOLO11 to analyze the captured images and estimate the optimum time for picking. Meanwhile, when the softness and umami components of the new buds are at their peak, the new buds have not yet grown sufficiently, and the yield is low. On the other hand, when the yield is at its peak, the “degree of opening” is too high, so the leaves become hard and astringent. For these reasons, it is best to pick the tea leaves when there is a certain yield, and the quality does not deteriorate too much. The timing of picking greatly determines the quality of the tea leaves that year.

To improve the profitability of tea production, it is important to increase the gross profit from the first harvest, which accounts for approximately 80% of the profit from the tea produced annually. Gross profit from tea is calculated by multiplying the yield by the unit price, and although the unit price is influenced by the market price at the time, it is generally determined by the quality. In other words, the main factors that determine the profitability of a tea plantation are the yield and quality of the tea leaves harvested, and increasing both in a balanced manner contributes to improving profitability. For this reason, tea plantation management increases productivity while ensuring a certain level of quality is maintained at production sites.

Previously, the method of budding detection based on YOLOv8 [1] (You Only Look Once version 8) with a relatively low spatial resolution of images for the determination of the best time to pluck tea leaves was proposed. We have already reported that if tea leaves are picked when the accumulated temperature from the time of tea leaf budding reaches 600°C, good quality tea leaves can be harvested in large quantities. Therefore, a method for detecting the budding is getting much more important. In this study, a method based on YOLO11 (You Only Look Once version 11) of object detection with relatively high spatial resolution of images is proposed. Also, a comparative study is conducted for the resolution of the cameras used for the acquisition of tealeaves from a point of view for learning performance of YOLO11. Furthermore, a comparison was made between the tea leaf germination date determined by experts and the AI-predicted germination date, and it was confirmed that the prediction accuracy was high.

Through the experiments, it was found that smaller the size of the sprout in the image, the more difficult it was to detect. Therefore, it was found to be necessary to devise ways to set the camera resolution and the distance to the observation target. We also found that setting boundaries between different labels was difficult. Furthermore, by creating a model using YOLO11, it

has become possible to easily predict the sprouting rate with high accuracy.

The following section describes related research works, followed by methods and procedures for a comparative study between the previous method and the current method with relatively high spatial resolution of optical images and a comparatively highly accurate learning model. Then some experiments are described, followed by a conclusion with some discussions.

II. Related Research Works

In the following related research studies, the effects of stratification, temperature, and light on seed germination of tea plants are clarified [2]. These effects are essential components for tea plant health conditions. Meanwhile, modeling the budburst phenology of tea plants is proposed [3]. The bud-burst phenology is getting more important for global issues. On the other hand, germination and storage of tea seeds are discussed [4]. Germination issues are the concerns with this study.

Analysis of climatic factors affecting the phenology of tea (*Camellia sinensis*) in eastern China is well reported [5]. NIST3254 is the information provided by NIST: *Camellia sinensis* (green tea) leaves. Climatic factors must be considered for the germination of tea plants. Meanwhile, the effects of cold stratification on seed germination in tea plants (*Camellia sinensis*) are cleared [6]. On the other hand, the variation of seed germination and seedling growth of tea (*Camellia sinensis*) collected from different altitudes of the Darjeeling hills under water stress conditions is clarified [7].

Genetic variation and differentiation in tea (*Camellia sinensis*) germplasm using RAPD markers are discussed [8]. The genetic diversity, relationship and molecular identification of fifteen well-known, widely planted traditional Chinese elite tea genetic resources [*Camellia sinensis* (L.) O. Kuntze] preserved in the China National Germplasm Hangzhou Tea Repository in the Tea Research Institute of the Chinese Academy of Agricultural Sciences, located in Zhejiang province, China, were investigated using RAPD markers. Meanwhile, estimation of first-flush sprouting time of tea shoots using a thermal time model is well reported [9]. On the other hand, the germination behavior of tea seeds under different environmental conditions is discussed [10].

Genetic diversity and geographical differentiation of cultivated tea in China by AFLP markers are discussed [11]. Based on the AFLP method, AFLP Figures were obtained in Guangdong tea plants. In this study, in total, 365 bands were amplified by 5 pairs of primers and 73 bands were amplified by each primer pair on average; a total of 338 (92.6%) polymorphic AFLP markers were detected. Meanwhile, the prediction of tea shoots harvesting time by monitoring environmental factors and shoot growth is proposed [12]. On the other hand, growth models for tea shoots are also proposed [13].

Predicting the flush development time of tea using environmental factors is proposed [14]. Meanwhile, a dynamic model for predicting the growth and development of the tea shoot is proposed [15]. On the other hand, the effects of temperature on seed germination in tea are clarified [16].

A machine vision system for automated tea shoot detection is developed [17]. Meanwhile, seed germination and early growth of tea (*Camellia sinensis* L.) as influenced by temperature is cleared [18]. On the other hand, image-based tea bud detection using deep learning approaches is proposed [19].

The method for plucking date determination based on the elapsed days after sprouting with NIR (Near Infrared) reflection from Sentinel-2/MSI (Multi-Spectral Imager) data is proposed [20]. It is equipped with a high-resolution multispectral imager and will carry out an optical mission with the primary objective of observing land areas. It forms a constellation of two identical satellites (Sentinel-2A, 2B). Meanwhile, appropriate tealeaf harvest timing determination based on NIR images of tealeaves is discussed [21]. On the other hand, a method for vigor diagnosis of tea trees based on nitrogen content in tealeaves relating to NDVI (Normalized Difference Vegetation Index) is proposed [22]. NDVI is an index that indicates the distribution and activity of vegetation and is the ratio of NIR and red-light reflectance (NDVI={NIR-RED}/{NIR+RED}). NDVI is expressed as a normalized value between -1 and 1, and the denser the vegetation, the higher the NDVI value.

Cadastral and tea production management system with a wireless sensor network, a GIS (Geographical Information System) based system and IoT (Internet of Things) technology is developed [23]. Methods for the determination of tealeaf plucking date with Cumulative Air Temperature (CAT) and Photosynthetically Active Radiation (PAR) are proposed [24]. PAR designates the spectral range (wave band) of solar radiation from 400 to 700 nanometers that photosynthetic organisms can use in the process of photosynthesis. This spectral region corresponds to the range of light visible to the human eye. Photons at shorter wavelengths tend to be so energetic that they can be damaging to cells and tissues, but are mostly filtered out by the ozone layer in the stratosphere. Photons at longer wavelengths do not carry enough energy to allow photosynthesis to take place.

On the other hand, the method of budding detection with a YOLO-based approach for the determination of the best time to pluck tea leaves is proposed and validated with actual data [1].

These studies cover various aspects of tea leaf budding estimation and germination rates, including the effects of environmental factors like temperature, light, and stratification on seed germination and budburst phenology. They also include modeling approaches for predicting budburst and studies on genetic variation affecting these processes.

On the other hand, the following studies are noticeable for object detections,

1) Foreign Object Detection in Urban Rail Transit Based on Deep Differentiation Segmentation Neural Network [25].

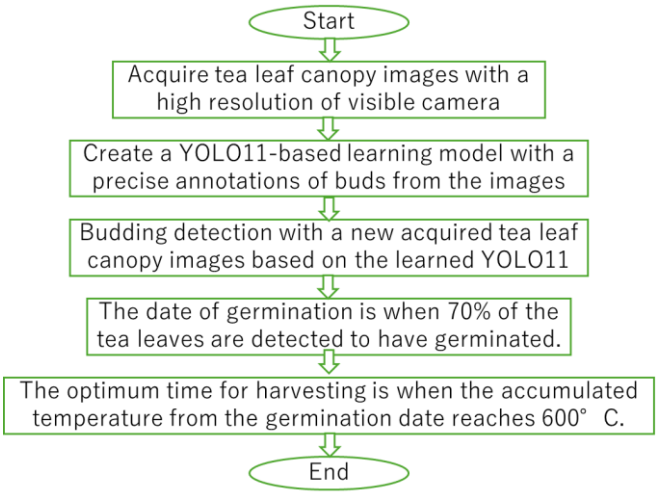
2) Multi-pose face recognition method based on improved depth residual network, International Journal of Biometrics [26].

3) Facial micro-expression recognition method based on CNN and transformer mixed model, International Journal of Biometrics [27].

III. Proposed Method

A. Proposed Method for Determination of Appropriate Plucking Time Estimation

The proposed procedure for the determination of appropriate plucking time estimation is shown in Fig. 1. To create a YOLO11-based learning model for bud detection, tea leaf canopy images are acquired with a high resolution of a visible camera, together with precise annotations of buds manually. High resolution of images is highly required at this stage. When performing object detection with low-resolution images, detection errors occur because high-resolution images of sprouts cannot be obtained. Therefore, in this study, we narrow the instantaneous field of view and take images with improved resolution to increase the number of pixels per sprout. After that, budding detection at the tea farm areas concerned with a newly acquired tea leaf canopy image based on the learned YOLO11 is made for the determination of germination date. At this stage, the date of germination is when 70% of the tea leaves are detected to have germinated. The optimum time for harvesting is when the accumulated air temperature from the germination date reaches 600℃. Air temperature is available from the meteorological agencies around the world.



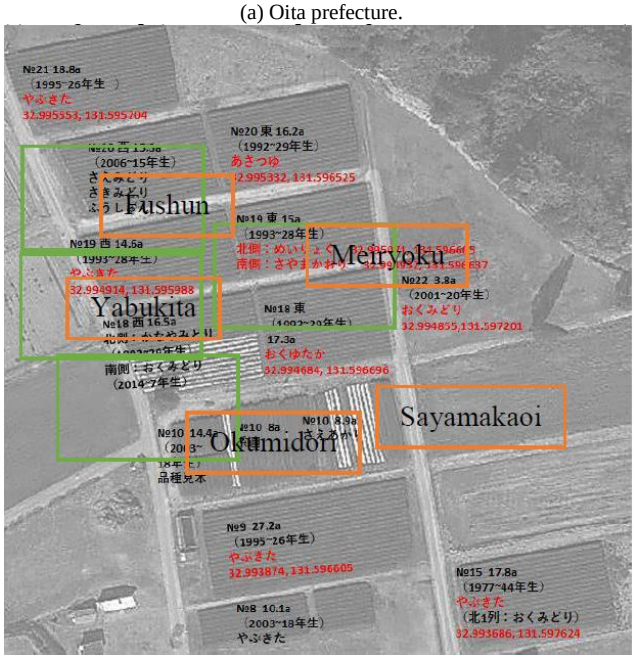


Fig. 1. Proposed procedure for determining an appropriate plucking date.

B. Research Background and the Previous Methods for Comparison

We have already shown that it is effective to predict tea component values from the accumulated temperature after germination [1]. The purpose of this research is to develop technology to identify the germination date from images. Currently, the cultivation area is large as shown in Fig. 2, and the germination date of all tea fields is not known, but the aim is to establish a method to make this possible and to identify the best time to record tea leaves from the germination date and accumulated temperature. In other words, a method to determine the germination date is necessary for efficient picking planning. There is an experimental tea farming area in which five species of tea trees (Oku-midori, Fushun, Sayama-Kaori, Meiryoku, and Yabukita) are planted.

(a) Oita prefecture.

(b) Test sites.

(c) Google photo.

Fig. 2. Location of the test site for five species of tealeaves in the intensive study area of Bungo-Ono, Oita, Japan.

The intensive study area is situated at Oita Prefectural Agriculture, Forestry and Fisheries Research Center, Bungo Ohno in Oita Prefecture, Japan (32.99 N, 131.59 E). The institute is established by Oita prefectural local government for promoting agriculture, forestry and fisheries as well as training and guidance of farmers and fishermen. There is an experimental tea farming area in which several species of tea trees (Oku-midori, Fushun, Sayama-Kaori, Meiryoku, and Yabukita) are planted. The tea tree Okumidori, which is the basis of sencha, is a breed made by crossing Yabukita, Yabu-kita and Shizuoka Zairai No. 16, and it reaches its season after Yabukita. It is characterized by its mild taste and low bitterness. It is also attracting attention as tencha (a raw material for tencha and matcha) and gyokuro. Okumidori tea tree has many buds, so you can expect a large yield.

In Fushun, which has a slightly upright tree, if the spacing between plants is 60 cm and the row spacing is changed from the customary 50 cm to 25 or 60 cm, the annual yield of fresh leaves will decrease. In the case of Fushun, when the row spacing is 50 cm, the annual fresh leaf yield decreases when the plant spacing is increased from the conventional 60 cm to 75 cm, and the planting density is reduced to 80% of the conventional planting density (1481 plants/10a). Sayamakaori is characterized by its strong aroma.

The tea leaves demonstrate enhanced firmness and a more desirable shape relative to Yabukita tea. Because it contains a lot of catechins, which are tannins, the tea has a strong and astringent taste. The plucking period of Meiryoku is the same as or slightly earlier than that of Yabukita, and the tree is vigorous and grows vigorously. Four or five years after planting, the total yield of first and second tea leaves is relatively high. The quality is the same as or slightly better than that of Yabukita. It is suitable because it is rather strong. One of the characteristics of "Yabukita" is its strong cold resistance. It is resistant to red wilt, blue wilt, and frost damage. It is also characterized by good rooting and is highly adaptable to various soils. Another strength in terms of growth is that the roots and shoots are uniform and grow quickly, making it easy to replant. For this reason, it is highly rated by farmers as an easy-to-grow variety.

C. The Proposed Method

In a previously published study [24], we clarified a method for estimating the germination date from images taken periodically from directly above the tea tree canopy as shown in Fig. 3. Namely, a 20 x 20 cm frame was placed on the tree canopy surface and a photograph was taken so that the new buds within the frame were visible. The captured image was then compressed to fit YOLO's reading size (640 pixels) to create training data. The first version of YOLO was released in 2015 and revolutionized the field of object detection. This model is characterized by being faster than previous methods by processing the image at once.

In 2016, YOLOv2 was released, improving accuracy and speed. This version improved the network structure and strengthened the ability to detect smaller objects. In 2018, YOLOv3 appeared, introducing multi-scale prediction, enabling the detection of even smaller objects. This version significantly improved the accuracy of object detection. And from 2020 onwards, YOLOv4, YOLOv5, and the latest YOLOv10 each version has been released, continuously improving efficiency and accuracy. YOLOv10 incorporates the latest technology and optimizes the balance between accuracy and speed of object detection. In this research, YOLO11 is used for budding detections.

YOLO is becoming the standard for object detection due to its high speed and accuracy. Throughout its development history, technology has continued to evolve and is expected to be used in various application fields. One such field is agriculture, where it is used to monitor the health of crops and detect pests, making farming more efficient. In this study, it is used to detect new tealeaf buds.

Fig. 3. Example of the acquired image of the tea tree canopy with a relatively low-resolution camera.

Then the annotation of buds was performed as shown in Fig. 4.

Fig. 4. Example of the annotated buds (○denotes "bud", ×denotes "not bud").

However, the resolution of the camera used was insufficient, which resulted in insufficient accuracy in estimating the germination date, and therefore, insufficient annotation accuracy, and insufficient detection accuracy based on the YOLOv8 object detection learning model. Therefore, in this study, we carried out the following three measures (updating the teacher data and object detection algorithm) to improve the accuracy of estimating the germination date.

1) Improved the resolution of the training data.
2) Improved annotation accuracy.
3) Changed to the latest YOLO model.

As a result, the precision rate was 0.512, the recall rate was 0.518, and the mAP50 was 0.506, which means that the learning performance was not sufficient. In addition, the size of the buds was small, and it was particularly difficult to detect unsprouted buds, so we determined that it was necessary to improve the camera resolution.

To maintain the resolution by dividing the image, we decided to prevent preprocessing into a 640 pixels square by padding at the top and bottom while maintaining the aspect ratio when the image is a horizontal rectangle. Therefore, we cropped both ends of the captured image to make it square, divided it (5 pixels by 5 pixels) to match the reading size of YOLO, and created training data as shown in Fig. 5.

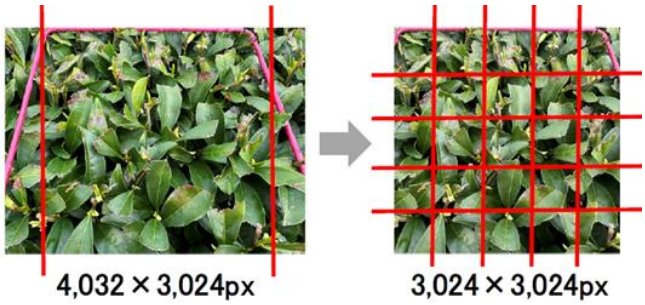

Fig. 5. Example of the acquired image with 640 pixels square and divided images with 3024 by 3024 pixels of resized images.

Then the annotation of buds was performed as shown in Fig. 6.

Fig. 6. Example of 640 by 640px of the annotated buds (Blue colored rectangles).

D. Improvement of Annotation Accuracy

YOLO11 is a model that boasts extremely high accuracy and speed in object detection. To maximize its performance, proper data annotation is essential. Annotations provide the "correct answer data" for the model to learn, and play the following important roles:

1) Accurate learning. Annotations allow the model to understand which parts are objects and improve its ability to recognize them accurately. For example, by drawing a bounding box around an object in an image, the model learns the location of the object.

2) Mitigating bias. Through annotations, you can identify misrecognition of specific classes and correct the bias of the model. This allows for fairer and more accurate predictions.

3) Domain specialization. By annotating data related to the project, the model will have recognition capabilities specialized for a specific domain. This allows it to perform well in specific applications.

The method of data annotation for YOLO11 learning is as follows:

1) Data collection. First, collect images and videos containing the target object. This data will be the basis for the model to learn. Selection of annotation tools: For annotation work, we use tools such as LabelImg[1] and Roboflow[2]. These tools provide the function of drawing bounding boxes for images and specifying the class of objects.

2) Annotation work. For the collected data, we draw bounding boxes for each object and assign the corresponding class label. This work can be done manually, but it can be made more efficient by using an automatic annotation tool.

3) Preparation of data format. YOLO11 requires annotation data to be saved in a specific format (such as YOLO PyTorch TXT format). This allows the model to read the data correctly.

4) Data verification. To ensure that the annotation is accurate, we perform reviews by others and automatic checks. This allows us to improve the quality of annotation.

5) Model training. We use the annotated dataset to train the YOLO11 model. After training, it is important to evaluate the performance of the model and correct the annotation if necessary.

Therefore, annotation is a key factor in the performance of YOLO11 training. Accurate annotation allows the model to detect objects with higher accuracy. Using the right tools and methods to perform effective annotation is the key to success. As stated in https://github.com/jsbroks/coco-annotator, when evaluating annotation accuracy, we aim to improve annotation accuracy by using annotation results output according to the COCO format. The research results of this study are that we have improved the resolution of the captured images, used object detection by YOLO11, and demonstrated that germination detection by improving annotation accuracy is effective for estimating the optimum time to pick tea leaves.

In comparison between YOLO11 and YOLOv8, YOLO11 not only improves accuracy (mAP) compared to YOLOv8, but also shows advantages in terms of computational efficiency and hardware requirements. The main points of comparison are summarized below. Computational efficiency and performance comparison,

[1] https://github.com/HumanSignal/labelImg

[2] https://github.com/roboflow/auto-annotate

1) Reduction in number of parameters and FLOPs

YOLO11n: 2.6M parameters / 6.5B FLOPs vs. YOLOv8n: 3.2M / 8.7B

YOLO11x: 56.9M parameters / 194.9B FLOPs vs. YOLOv8x: 68.2M / 257.8B

2) Improvement in CPU inference speed

YOLO11n: 56.1ms vs. YOLOv8n: 80.4ms (30% faster)

YOLO11x: 462.8ms vs. YOLOv8x: 479.1ms

3) Performance in GPU environment. No significant difference between the two models in the T4 TensorRT10 environment (e.g., YOLO11n 1.5ms vs. YOLOv8n 1.47ms)

For each tea variety, we randomly photographed the location and performed annotations. In this case, depending on the shooting angle, it may be difficult to determine whether the image is budded or not, so the labels may not be accurate. To avoid this situation, in this study, we performed annotations by taking photos from a fixed point. Examples of typical sprouting processes are shown in Fig. 7. This makes it possible to capture changes in each bud, eliminating human-made labeling errors and improving learning accuracy.

(a) Not sprouted.

(b) Sprouting Date: 3 days later.

(c) Sprouting completely.

Fig. 7. Examples of sprouting process.

As an annotation method for YOLO, we imposed the condition that there must be no space between the object and the box as shown in Fig. 4. In addition, by changing the training data from resized images to segmented images, we thought that it would be possible to closely surround each bud, which would improve the accuracy of the labels.

E. Improvement of Learning Model (YOLO)

We use YOLO11, which is faster to calculate and more accurate than YOLOv8, as shown in Fig. 8, to improve accuracy. YOLO11 is designed for speed, accuracy, and ease of use, making it ideal for a wide range of object detection and tracking, instance segmentation, and more. Open a command prompt (terminal) in C:\python\python312 and create a virtual environment. Set the environment name to YOLO11 and run python -m venv yolo11 to enter the virtual environment. Make sure YOLO11 is displayed and set it to C:\python\python312\yolo11\Scripts\activate. Proceed with installing the libraries in a virtual environment. The official website is https://github.com/ultralytics/ultralytics. You can include all libraries by installing YOLO11 with the pip command "pip install ultralytics".

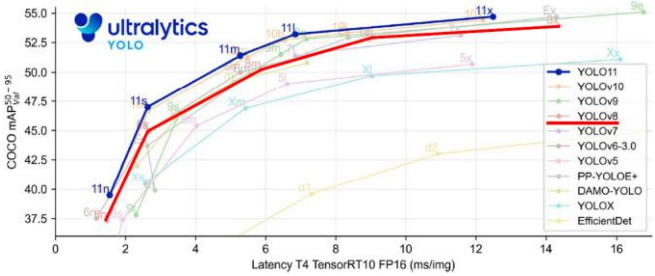

Fig. 8. YOLO11 is superior to YOLOv8.

Open the project folder in VS-Code by running mkdir c:\yolo11. Switch the interpreter to the virtual environment and execute the training by writing the same thing in Python as in the command prompt above. Data settings are done using a YML file, with the data arranged as shown below,

```
C:/yolo11/datasets/my_datasets
|       ├── images
|       |       └── train
|       |       └── val
|       └── labels
|               └── train
|               └── val
|
└── my_datasets.yaml
```

It was first released in 2015, it is a cross-platform, meaning it is available for Windows, macOS, and Linux. Visual Studio Code is lightweight yet powerful, offering many features such as debugging, version control, and extension support. It is especially popular among developers of various programming languages, including JavaScript, TypeScript, Python, and C++.

On the other hand, YML is a data format that represents structured data as a string. It stands for YAML (YAML Ain't Markup Language) and is characterized by its ease of reading and writing. The characteristics of YML are that it is lightweight and easy-to-remember grammar used for writing software configuration files and exchanging data between different software, and it is very easy to use. In addition, line breaks and indentations have clear meanings, and ease of use for programmers is emphasized. It is a complete superset of JSON, another data serialization language, and can do more than just what JSON can do.

YAML is a popular programming language because it is designed to be easy to read and understand and can be used in conjunction with other programming languages. Its flexibility and ease of use make it the language used by Ansible® to create automation processes in the form of Ansible playbooks. YAML has features from programming languages such as Perl, C, XML, and HTML. YAML is also a superset of JSON, so JSON files work directly in YAML. There are no regular formatting symbols such as curly braces, brackets, closing tags, or quotes. YAML files are also easier to read, as they use indentation to determine structure and indicate nesting, just like Python. To maintain portability across systems, tab characters are not allowed by design, so whitespace characters (literal space characters) are used instead.

Now, training can be started. The training results will be automatically saved in the folder runs. The training results will be saved in the weights folder, so just change the YOLO11.pt part of the inference program to best.pt (full path). During training, scaling (scale = 0 to 1, default 0.5) is automatically applied. It is also possible to apply rotation, mixup, learning rate, etc. In that case, just write mixup = 0.5, flipud = 0.5, lr0 = 1E-5, etc. in the model.train section.

IV. Experiment

A. Procedure and Conditions

The test varieties selected were "Yabukita", "Okumidori", "Meiryoku", "Sayamakaori", and "Fushun". These are the five main varieties of drinkable tea. The shooting period was a total of fourteen days from March 26th to April 10th, 2024 (excluding March 30th and April 7th). In addition, in the learning method 5,384 annotation images were created, 3,450 images were used as training data, and 1,360 images were used as validation data. The accuracy was verified using 574 test data. Annotations were performed on 673 images divided from the original image, and the number of annotations was increased by eight times by data expansion (rotation, inversion). Learning settings version: YOLO11s, mixup: 0.5 was used, and the rest were performed with default settings.

B. Learning Performance

Fig. 9 shows the changes in the loss function and evaluation index for each learning iteration. “train” and “val” mean training and validation, respectively. “box” denotes bounding box, “cls” denotes classification, and “dfl” stands for distribution focal loss, respectively. On the other hand, mAP50 means that the mean Average Precision is calculated by a threshold of 50 with IoU (Intersection over Union). As usual, the loss function decreases gradually, and precision and recall as well as mAP, are gradually increasing. Also, the training performance is better than the validation performance (which is much more important than the training performance). From these graphs, 200 of the number of epochs would be enough because performances are saturated at around 200.

The results of the learning model (the training and validation data (○ corresponds to sprouting and × corresponds to non-sprouting) are shown in Table I. These performance results show a significant improvement in accuracy in comparison to previously reported results [1], shown in Table II.

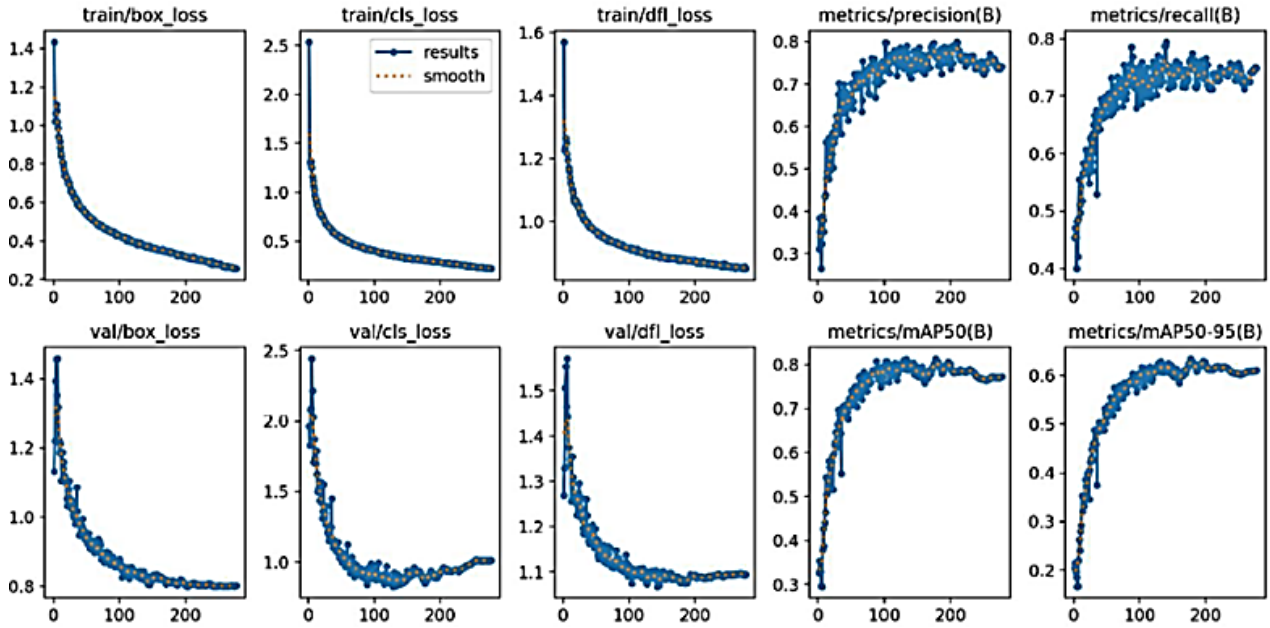

Fig. 9. Changes in the loss function and evaluation index for each learning iteration (horizontal axis is the number of epochs).

TABLE I. TRAINING AND VALIDATION PERFORMANCE OF YOLO11

Precision=0.762	Recall=0.769	mAP50=0.814
○:0.781	○:0.862	○:0.884
×:0.742	×:0.667	×:0.743

TABLE II. TRAINING AND VALIDATION PERFORMANCE OF YOLOV8

Precision=0.512	Recall=0.518	mAP=0.506
○:0.569	○:0.587	○:0.594
×:0.456	×:0.448	×:0.418

Similar results were also obtained with the test data, as shown in Table III.

TABLE III. PRECISION AND RECALL OF LEARNING PERFORMANCE OF YOLO11

Precision	○:0.779	○:0.748
Recall	×:0.748	×:0.704

Therefore, it can be said that the accuracy has improved significantly by 25 to 30%. The best score was achieved at 177 epochs. Fig. 10 shows the number of instances of each class in the training data.

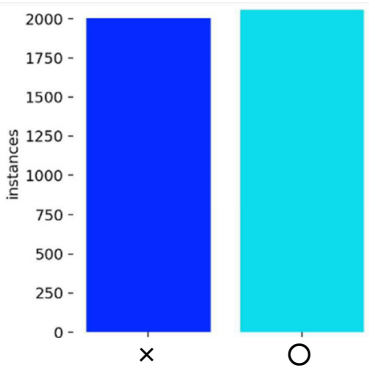

Fig. 10. The number of instances of each class in the training data.

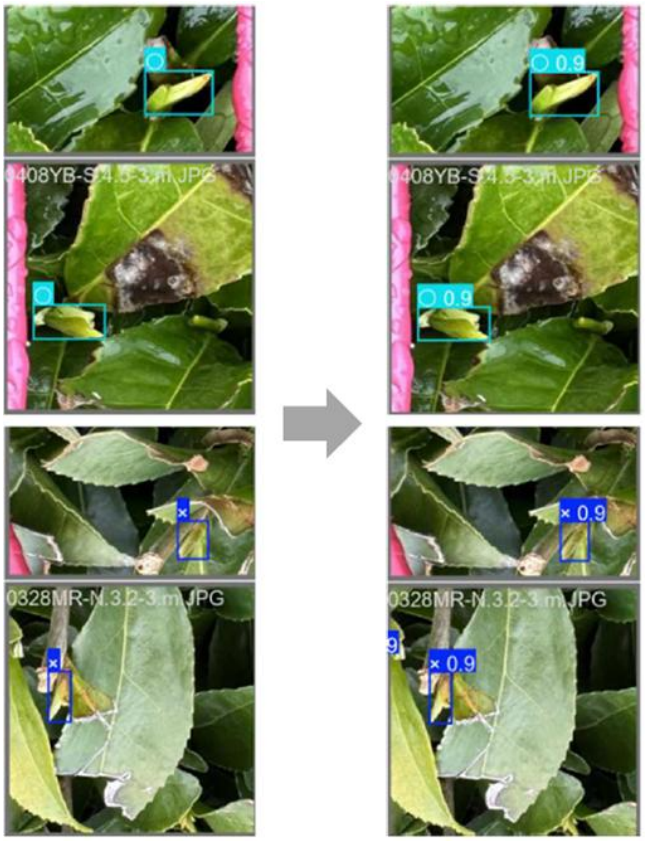
Also, Fig. 11 shows examples of training and validation data. In Fig. 11, ○ corresponds to sprouting and × corresponds to non-sprouting, respectively.

C. Development of a Bud Break Prediction Model Using AI

It is found that bud break can be estimated with the tea leaf images acquired. It is referred to as an AI-based method. Based on the model which we created, we estimate the germination date from the image. The image used for estimation is the image before division (4,032 by 3,024 pixels). This includes the data used for learning.

Two tea field locations of 20 by 20 cm were surveyed for each variety. The bud break date was defined as the day when the proportion of buds that had sprouted reached 70%. Table IV shows the changes in germination rate (the numbers in Table IV show the percentage ratio of bud tea leaf) of each variety.



It is obvious that the germination rate is different by the variety. Red colored percentages show the germination rate. Actual denotes the germination rate estimated by the expert while, AI denotes that by AI-based method. As a result, the germination dates were consistent for three of the five varieties, and even in cases where they did not match, the error was just - two days.

From the above results, we believe that using the model we created to predict the germination date from images taken with a smartphone is effective and demonstrates high prediction accuracy.

D. Discussion

The conventional method of estimating the optimum time for plucking tea leaves was based on the experience of tea farmers and was determined by the feel of the new buds on the tea plant, the number of leaves, and the degree of leaf opening, while observing the weather. Scientifically speaking, the best quality tea leaves can be picked when the theanine content of the new buds is at its highest, but measuring this without contact is time-consuming and costly, so an alternative method was needed.

We have determined that the optimum time for plucking is when the accumulated temperature from the buds' germination reaches 600°C and have shown that the germination time of the new buds can be estimated using images captured by a visible camera and YoloV8, an AI-based method for object detection. However, the pixel size of the images and the accuracy of object detection were insufficient, so the accuracy was not sufficient compared to conventional objective methods.

(a) Training Data. (b) Validation Data.

Fig. 11. Examples of training and validation data.

TABLE IV. CHANGES IN GERMINATION RATE OF EACH VARIETY

Meiryoku	Mar.28	Mar.29	Mar.31	Apr.1	Apr.2	Apr.3	Apr.4	Apr.5	Apr.6	Apr.8
Actual	0%	0%	21%	37%	50%	65%	88%	100%	100%	100%
AI	0%	5%	25%	28%	39%	69%	90%	100%	97%	89%
SayamaKaori	Mar.28	Mar.29	Mar.31	Apr.1	Apr.2	Apr.3	Apr.4	Apr.5	Apr.6	Apr.8
Actual	0%	0%	0%	18%	29%	44%	55%	82%	100%	100%
AI	5%	0%	5%	8%	25%	50%	58%	76%	83%	88%
Yabukita	Mar.29	Mar.31	Apr.1	Apr.2	Apr.3	Apr.4	Apr.5	Apr.6	Apr.8	Apr.9
Actual	50%	25%	30%	44%	66%	66%	68%	73%	100%	100%
AI	17%	17%	15%	25%	42%	82%	77%	71%	89%	100%
Fushun	Apr.3	Apr.4	Apr.5	Apr.6	Apr.8	Apr.9	Apr.10	Apr.11	Apr.12	Apr.13
Actual	0%	7%	12%	31%	75%	85%	100%	100%	100%	100%
AI	7%	6%	8%	54%	74%	77%	56%	84%	76%	82%
Okumidori	Apr.3	Apr.4	Apr.5	Apr.6	Apr.8	Apr.9	Apr.10	Apr.11	Apr.12	Apr.13
Actual	12%	33%	58%	61%	58%	77%	87%	100%	100%	100%
AI	27%	37%	53%	59%	81%	65%	79%	78%	94%	88%

In this study, we show that by using images from a visible camera with sufficient pixel size and using YOLO11, which has a higher detection accuracy than YOLOv8, the estimation error of the germination time of the new buds can be reduced within two days.

V. CONCLUSION

We developed a budding detection method using captured images based on YOLO11. The conventional method with YOLOv8, which was proposed by the authors, had a weakness in the accuracy of detecting tea leaf budding. It was insufficient. One of the reasons is that the camera resolution. Also, the budding detection accuracy was not good enough.

By using twice much high-resolution camera and YOLO11 for budding detection with careful annotations, budding detection accuracy is improved remarkably. When the tea leaf germination rate estimated using the proposed method was compared with that of experts, it was found to be in extremely good agreement. It is concluded that the accuracy of YOLO11-based budding detection has improved significantly by 25 to 30% in comparison to the previously reported YOLOv8 [1].

Also, an AI-based method for the estimation of germination rate is proposed. Based on the model which we created, we estimate the germination date from the image. As a result, the germination dates were consistent for three of the five varieties, and even in cases where they did not match, the error was -2 days.

The proposed method is effective for detecting germination of not only the tea varieties targeted in this study, but all other tea varieties. A method based on the criterion that the optimum time for plucking is when the cumulative temperature from the time of germination is 600°C (when the amino acid content reaches its peak) is effective for estimating the optimum time for plucking.

VI. FUTURE RESEARCH WORKS

We plan to validate the proposed AI-based method for germination rate as well as for budding date prediction with the actual tea leaf quality and yield in the future. Also, it would be better to do an estimation of the most appropriate harvest date with deep learning, which can be applied to these estimations.

Further experimental studies are required for further validation of the proposed method for the determination of the most appropriate plucking date for harvesting good-quality new flesh tealeaves (Ichiban-Cha).

ACKNOWLEDGMENT

The authors would like to thank Professor Dr. Hiroshi Okumura and Professor Dr. Osamu Fukuda of Saga University for their valuable discussions.

Kohei Arai, He received BS, MS and PhD degrees in 1972, 1974 and 1982, respectively. He was with The Institute for Industrial Science and Technology of the University of Tokyo from April 1974 to December 1978 also was with National Space Development Agency of Japan from January, 1979 to March, 1990. During from 1985 to 1987, he was with Canada Centre for Remote Sensing as a Post Doctoral Fellow of National Science and Engineering Research Council of Canada. He was professor of Saga University from 1990 to 2017. Also, he was a Councilor for the Aeronautics and Space related to the Technology Committee of the Ministry of Science and Technology during from 1998 to 2000 and was a councilor of Saga University for 2002 and 2003. He also was an executive councilor for the Remote Sensing Society of Japan for 2003 to 2005. He was the Vice Chairman of the Scientific Committee was an Award Committee member of ICSU/COSPAR during. He is a Science Council of Japan Special Member (COSPAR Committee) since 2012. He is an Adjunct Professor of Nishi-Kyushu University and Kurume Institute of Technology as well as Prishtina International University. He wrote 134 books and published 747 journal papers as well as 585 conference papers. He received 66 of awards including ICSU/COSPAR Vikram Sarabhai Medal in 2016, and Science award of Ministry of Mister of Education of Japan in 2015. He is now Editor-in-Chief of IJACSA and IJISA. http://teagis.ip.is.saga-u.ac.jp/index.html

The Factors Influencing Internet of Things Adoption in Public Hospitals: A Pilot Study

Mutasem Zrekat[1], Othman Bin Ibrahim[2]
Faculty of Computing, Universiti Teknologi Malaysia (UTM), Johor Bahru, Malaysia[1]
Faculty of Management, Universiti Teknologi Malaysia (UTM), Johor Bahru, Malaysia[2]

***Abstract*—Incorporating Internet of Things (IoT) technologies in healthcare represents a significant leap forward, capable of transforming the delivery and management of medical services. As healthcare systems across the globe increasingly seek innovative solutions to improve efficiency, enhance patient outcomes, and reduce operational costs, IoT emerges as a key enabler of this transformation. Despite the widely recognized benefits of IoT, its adoption in the healthcare sector, particularly within public hospitals in developing countries, remains limited and is still in the early stages. Therefore, understanding the factors influencing its adoption is essential for supporting effective adoption and advancing digital healthcare initiatives. This study aims to assess the validity and reliability of the instrument designed to identify the factors influencing the adoption of IoT technology in Jordanian public hospitals. A structured survey instrument collected a preliminary dataset from forty decision-makers in Jordanian public hospitals. The survey items were developed based on constructs derived from the Technology-Organizational-Environment (TOE) framework and the Human-Organization-Technology fit (HOT-fit) model, supported by relevant literature. Descriptive statistics were performed using SPSS, while the reliability and validity of the instrument were assessed using Partial Least Squares Structural Equation Modeling (PLS-SEM). The results demonstrated that the measurement instrument had acceptable levels of reliability and validity, confirming its suitability for use in the main study. This study enriches the existing research and enhances the broader understanding of IoT adoption in healthcare organizations, offering insights that can be useful to both practitioners and researchers in this field.**

Keywords*—*Internet of Things; adoption; Jordan; TOE

I. Introduction

The advent of the Internet of Things (IoT) has marked the beginning of a transformative era, often known as the Fourth Industrial Revolution. This revolution is reshaping industries by enabling smart technologies and interconnected systems that influence how individuals live, work, and interact with their environment. The term IoT was first defined by Ashton [1] in 1999, within the context of supply chain management. Since then, the concept has evolved across various fields, reflecting its expanding applications. In general, IoT can be defined as a rapidly growing network of objects that are addressable and identifiable uniquely, where each of these objects connects to servers to transfer their data and extract valuable knowledge that efficiently provides appropriate services. What sets IoT apart from other technologies is its integration of smart features, sensors, and actuators that enable it to detect and collect data, communicate across systems, and perform real-time analysis of vast amounts of information from internal and external environments via a global network [2]. These remarkable capabilities of IoT have attracted the attention of various industries, including healthcare, manufacturing, transportation, agriculture, supply chains, and logistics, to adopt IoT. The healthcare industry has emerged as a highly attractive domain for IoT applications, with recent research increasingly emphasizing its implementation in healthcare settings [3]. IoT plays a vital role in enhancing various aspects of the healthcare system, including chronic illness management, elderly care, patient engagement, physician-patient interaction, remote patient monitoring, and authentication. Consequently, hospitals are increasingly encouraged to adopt IoT technology, as they have the potential to improve treatment outcomes, reduce errors, reduce treatment costs, and elevate the overall quality of the healthcare system [4].

However, the global population and rising life expectancies have substantially increased the demand for healthcare services, placing significant pressure on public health institutions worldwide [5]. As a result, hospitals and healthcare organizations are operating at nearly full capacity as they strive to meet the increasing demand for healthcare, particularly in terms of hospitalization. These challenges are particularly acute in developing countries, where public hospitals may struggle to provide quality, affordable, and accessible healthcare due to limited resources [6, 7]. Moreover, the emergence of the COVID-19 pandemic has brought attention to pre-existing issues within the healthcare system, particularly concerning shortages in the healthcare workforce and inequities in access to healthcare [8]. In response to these challenges, healthcare organizations continuously seek ways to enhance healthcare delivery quality. One promising avenue for improvement is the adoption of the IoT, which has demonstrated the potential to address various issues and challenges facing the healthcare system, as highlighted by research studies [9, 10].

While there is acknowledgment of the potential benefits of the IoT in enhancing public health efforts, its integration into the operations of these organizations is not yet widespread or fully mature [11]. According to Alifan, et al. [12], the current studies on health information technology in the Jordan context are still insufficient, and more comprehensive research is needed to better understand and address the unique challenges and opportunities in this area. Disruptive technologies, such as IoT, often emerge from edge markets, which may significantly change businesses and create value within any organization [13]. However, sector-wide implementation of these technologies presents significant challenges, as unexpected obstacles during the implementation process can result in project failure [14].

Organizations that are aware of the associated risks and adequately prepared for the changes brought by digital transformation are more likely to adopt emerging technologies successfully and avoid costly implementation failures [15]. Therefore, identifying and evaluating the factors that enhance organizational readiness is critical for facilitating the effective adoption of IoT in healthcare. According to Chang, et al. [13], considering the technical aspects of new technologies alongside an organization's internal and external resources will increase its readiness to adopt new technologies and avoid wasted resources and project risks.

In response to this gap, the present pilot study represents an initial effort to assess the validity and reliability of a measurement instrument developed to investigate the key factors influencing the adoption of the Internet of Things (IoT) in Jordanian public hospitals. The instrument is grounded in established theoretical foundations, drawing on constructs from both the Technology-Organization-Environment (TOE) framework and the Human-Organization-Technology Fit (HOT-Fit) model, which are widely used in technology adoption research. The questionnaire was administered to forty decision-makers and healthcare professionals across public hospitals in Jordan to evaluate the internal consistency, construct validity, and reliability of the proposed model using SPSS and Partial Least Squares Structural Equation Modeling (PLS-SEM). Given the highly regulated nature of Jordan's public healthcare sector and the national initiatives to advance healthcare technology and digital transformation, this study contributes to the limited body of literature on IoT adoption in this context and offers a foundation for future empirical investigations.

The remainder of this study is structured as follows. The next section presents the theoretical background and conceptual model underpinning the study. This is followed by a description of the research methodology and instrument development process. The subsequent section reports the findings from the pilot study, including statistical analyses and interpretation. Finally, the study concludes with a discussion of the study's implications, limitations, and suggestions for future research.

II. Theoretical Background

The adoption of Internet of Things (IoT) technologies in healthcare has been examined through several theoretical models that aim to understand and predict technology usage and acceptance. Among the most frequently employed are the Technology Acceptance Model (TAM), Unified Theory of Acceptance and Use of Technology (UTAUT), Theory of Planned Behavior (TPB), and Diffusion of Innovations (DOI). These models primarily address individual-level factors, such as perceived usefulness, ease of use, social influence, and facilitating conditions, and are typically tested through cross-sectional surveys targeting end-users like physicians or nurses [16]. While such approaches have significantly contributed to understanding user intentions, they fall short of capturing the organizational-level factors that influence technology adoption in healthcare institutions, particularly within the context of public hospitals in developing countries. In other words, models like TAM, UTAUT, and TPB do not account for the broader organizational and environmental conditions that influence technology adoption in public healthcare institutions. The adoption of IT innovations such as IoT is influenced by more than just user perceptions. While ease of use and usefulness are important, organizational factors often play a larger role. Factors such as leadership commitment, the availability of IT resources, existing infrastructure, regulatory mandates, and the organization's technical skills play a critical role in determining adoption readiness and implementation outcomes [17]. In many cases, especially in large institutions, the decision to adopt new technologies depends more on these internal capabilities than on individual user opinions. Since IoT adoption in public hospitals, particularly in developing countries like Jordan, remains an emerging research area, the focus of this research is on the organizational level, guided by the nature of IoT adoption in public hospitals, where decisions are typically made at the institutional rather than individual level.

This study adopts a theoretical lens approach to explore the factors influencing Jordanian public hospitals to adopt IoT. As defined by Creswell and Creswell [18], a theoretical lens approach involves applying established theories to investigate relatively new or under-researched topics. In this study, two complementary frameworks are used as guiding lenses: the TOE framework [19] and the HOT-Fit model [20]. Both models have been widely applied in technology adoption and health information systems research and provide a structured foundation for examining technological, organizational, environmental, and human factors that may shape IoT adoption in healthcare. Employing these theories as guiding lenses ensures that the research remains theoretically grounded while exploring an emerging issue within a complex healthcare environment.

The TOE framework has proven to be a practical tool for analyzing the adoption of various IT innovations, as noted by [21]. According to Salman et al. [22], the TOE model is suitable for measuring organizations' readiness to adapt to new work activities related to the use of new technology. Although the TOE framework was not originally developed for technology adoption in healthcare, its extensive use in prior healthcare studies has led to widespread acceptance, demonstrating its versatility. For example, Abdulaziz and Yasin [23] employed the TOE framework to understand the critical factors affecting the decision to adopt cloud computing within the healthcare industry; Yang, et al. [24] found that the TOE framework can be applied to identify the factors involved in the decisions made by integrated medical and healthcare organizations to adopt artificial intelligence (AI); and Anthony Jnr [25] indicated that the TOE framework is useful for identifying the critical factors that influence telehealth adoption. Similarly, Thyagaraj and Narayanan [26] used it to examine the adoption of IoT in the hospital context. These studies affirm the TOE framework's relevance and applicability, supporting its suitability for investigating IoT adoption in the healthcare industry. In contrast, In parallel, the HOT-Fit model was specifically designed to address the adoption and evaluation of health information systems (HIS), focusing on the interaction among human, organizational, and technological dimensions [20]. Its relevance lies in its healthcare-centered structure, which makes it highly applicable for studying IT adoption in hospital environments. According to Lian, et al. [27], human characteristics should be carefully considered when adopting technological innovations

in the healthcare environment. Although previous research [28, 29] has underscored the significance of incorporating the human dimension when studying the adoption of IT within the healthcare domain. Nevertheless, the role of human behavior within hospital environments in shaping the adoption of information technologies has received limited attention in academic research [29]. Considering the substantial convergence between the TOE and HOT-fit models, this study integrates the TOE framework with the human dimension emphasized in HOT-Fit. Both models emphasize the significance of technological, organizational, environmental, and human readiness factors in driving innovation adoption. Consequently, integrating these models can encompass most of the readiness factors that impact the adoption of IoT in the healthcare sector. For these reasons, the integrated TOE–HOT-Fit model adopted in this study directly addresses the theoretical shortcomings identified in prior work, providing a more comprehensive framework for examining IoT adoption in public hospitals.

To effectively capture the combined influence of technological, organizational, environmental, and human factors on IoT adoption, researchers have proposed a formative construct known as "IoT Readiness". This construct serves as an integrative measure that reflects the overall preparedness of an organization to adopt IoT, based on the collective impact of these key dimensions [17, 30]. Each hospital or healthcare institution may face unique conditions, such as varying levels of technological infrastructure, organizational capacity, external support, and human resource readiness that shape their specific level of readiness. Therefore, IoT Readiness is not a singular or uniform concept; rather, it is shaped by the contextual variations across institutions and is essential for understanding how prepared a healthcare organization is to adopt and integrate IoT technologies. Cintrão [31] suggests that including technological readiness as a dependent variable of TOE determinants provides a unique perspective on the phenomenon of adopting new technologies. Similarly, Chang, et al. [13] argue that integrating IoT with the TOE framework and readiness perspectives allows for a comprehensive understanding of how technology readiness, organizational readiness, and environmental readiness collectively influence the effectiveness of IoT implementations. This combined approach enables a nuanced examination of these perspectives and offers a holistic approach to studying IoT adoption. Prior research has underscored the significance of these dimensions in evaluating readiness for adoption within healthcare contexts [15, 28, 32, 33], as well as in various other contexts [34-36]. These studies provided the foundational elements for establishing the initial integrated theoretical model for IoT readiness.

A. Technological Readiness

The technology context examines a technology's inherent characteristics and their impact on readiness to adopt IoT solutions. This includes factors such as relative advantage, compatibility, complexity, and security, collectively shaping technological readiness—an essential component of overall IoT readiness. Technological readiness refers to how individuals within an organization feel prepared and capable of adopting a new technology, such as the IoT, based on how they perceive its features and benefits [37]. This includes users' perceptions of whether the technology is compatible with existing systems, easy to use, secure, and advantageous. If organizational users view the technology as useful and appropriate for their work environment, they are more likely to be open and ready to adopt it [38].

1) Relative advantage. Among the technological readiness dimension factors is Relative advantage, which refers to the degree to which adopting a new technology, such as the IoT, in a hospital setting is perceived to provide tangible benefits over existing practices and technologies [27]. This study adopts the concept of relative advantage to investigate whether, and to what extent, the adoption of IoT in public hospitals is perceived as more beneficial than alternative technologies. These benefits include enhancing organizational competitiveness, reducing costs, improving operational efficiency, and streamlining work processes [39]. Relative advantage has been widely recognized as a critical determinant of technology adoption across various sectors, including healthcare [24, 40]. Previous studies have demonstrated that when healthcare institutions perceive clear advantages from IoT, they are more inclined to consider its implementation. This highlights the importance of evaluating relative advantage when assessing the potential for IoT adoption in hospital settings.

2) Compatibility. Compatibility is a critical technological factor identified in the Diffusion of Innovation (DOI) theory as a motivational driver for the adoption of new technologies. It refers to the extent to which a new technological solution, such as the IoT, is perceived to be consistent with existing values, cultural norms, knowledge, infrastructure, and operational requirements within an organization. In the context of healthcare, this includes the seamless integration of IoT with the hospital's current technological systems and healthcare workflows, both technical and managerial [26]. Organizations are more willing to embrace technologies that align with their established practices and strategic direction. Studies, such as Bhuiyan, et al. [41] and Karahoca, et al. [42], highlighted that compatibility among IoT devices is crucial for ensuring functional coherence and adaptability in healthcare environments. It is important to note that a lack of compatibility can cause concerns about the functionality of a system and its operational reliability.

3) Complexity. Complexity is a critical factor influencing an organisation's readiness to adopt new technology [43]. According to Rogers Everett [44], Complexity refers to "the degree to which an innovation is perceived as relatively difficult to understand and use". The perception of innovation complexity can vary among organisations based on their existing skills and knowledge. Some organisations may find an innovation complex due to a lack of necessary expertise, while others, with the required skills, may not perceive it as complex. Unlike other innovation characteristics, complexity often lacks a strong positive correlation with adoption [15]. In the context of IoT, higher perceived complexity has been found to influence adoption decisions negatively [40]. This issue is particularly pronounced in healthcare, where the environment

is inherently complex, and the introduction of IoT can further amplify this complexity [45]. Consequently, healthcare organizations may resist adopting IoT if it is seen as complicating their management processes

4) Security. Although integrating IoT technology enhances an organization's productivity and efficiency, it also raises significant security and privacy issues. These concerns become more pronounced as the quantity and types of interconnected devices within organizations increase [46]. In the healthcare environment, ensuring security and privacy is a critical issue for both patients and is required by laws in many countries. Healthcare institutions must prioritize data security when utilizing IoT technology for storing and handling medical data [47]. Previous research has identified security and privacy as significant factors influencing the adoption of new technologies across various sectors. For instance, [48] found that these concerns significantly shaped hospital managers' intentions to adopt RFID technology. Similarly, Hawash et al. [49] reported a positive impact of security-related factors on IoT adoption in the oil and gas industry. Dewi et al. [36] and Sam and Chatwin [30] also examined security and privacy constructs to evaluate organizational readiness for Smart City and Big Data Analytics initiatives in Indonesia and China, respectively. These findings underscore the critical role of security and privacy in shaping organizational readiness for adopting emerging technologies like IoT.

B. Organizational Readiness

Organizational readiness is defined as the extent to which public hospitals can provide and manage all the resources necessary for the successful adoption and integration of IoT technologies into their operations [36]. It emphasizes the institution's internal capacity to support and sustain the implementation process. According to Yang et al. [17], the IT Infrastructure and Top Management Support emerge as two important organizational readiness factors for technology adoption.

1) Top management support. Top management support reflects the commitment of senior leadership to actively promote and enable the adoption of new technologies throughout the organization [50]. This includes their willingness to allocate the necessary resources, offer clear guidance, and remain actively involved in planning, evaluation, and supervision throughout the adoption process. In the context of IoT adoption in healthcare, strong commitment from top management is essential because it helps ensure that the organization is adequately prepared and motivated to embrace such innovations [51]. Without this support, efforts to adopt and implement IoT solutions may face resistance or lack direction. The transition from traditional Information Technology (IT) systems to Internet of Things technologies within healthcare organizations is not merely a technical upgrade but a carefully considered strategic decision. Therefore, the proactive involvement of top executives, especially their awareness of IoT's potential benefits, plays a crucial role in successful adoption [52]. In addition, as IoT technologies are often expensive and resources are limited, top management can create a conducive environment and allocate essential resources such as expertise and infrastructure [53]. Adequate resources are crucial for the successful implementation of IoT projects, and strong top management support has consistently been identified as a vital factor for the adoption and diffusion of large systems.

2) IT infrastructure. Besides top management support, a strong IT infrastructure is essential for successfully adopting IoT technology within the firm. It provides the foundation for seamless communication and data transfer between IoT devices. Technology infrastructure can be characterized as an integrated and interconnected system comprising computer hardware, software, networks, and tangible equipment that are essential to adopting new technologies [54]. IT infrastructure has been frequently used in literature to study the adoption of IoT in many contexts, including healthcare, where IT infrastructure stands out as a significant factor in the adoption of IoT technology in the healthcare environment [55, 56]. According to Abd El-Hamed et al. [57], organizations that plan to adopt IoT technologies should prioritize evaluating and enhancing their IT infrastructure to ensure it can support emerging technological requirements. Similarly, Rey et al. [58] highlight the significance of having reliable and ready technological systems before integrating IoT into business operations. Therefore, organizations with a well-developed and dependable technology infrastructure are more likely to adopt IoT solutions successfully.

C. Environmental Readiness

Environmental readiness refers to the organization's perception of external factors influencing its decision to adopt IoT. It reflects how hospitals respond to the environment in which they operate, including competitive pressure, government support, and the availability of vendor support. These external conditions shape how organizations carry out their activities during the adoption of new technologies.

1) Competitive pressures. Which arise from the threat of losing a competitive advantage in the industry to other competitors, prompt organizations to adopt new technologies to improve their competitiveness and enhance their productivity [59]. While competition is typically associated with the private sector, similar dynamics are increasingly observed in the public healthcare sector. As hospitals witness peer institutions integrating emerging technologies such as the IoT, the pressure to keep pace becomes a compelling motivator [26]. When hospital decision-makers believe that IoT adoption can improve operational efficiency and help them remain competitive, their willingness to invest in such technologies increases [52]. Several studies confirm that competitive pressure catalyzes technology adoption, especially when organizations trust that the innovation will enable them to outperform others [26, 32]. Therefore, the intensity of competition may significantly influence a healthcare organization's readiness to adopt IoT.

2) Vendor support. Given the complexity of IoT technology and the diverse range of devices involved, implementing an IoT system involves intricate features. Therefore, robust vendor support is essential during and after implementation to ensure a smooth deployment and continued operation [46]. Vendor support refers to the assistance and services provided by technology suppliers to their clients. This support typically includes technical assistance, problem-solving, maintenance services, training, and other resources aimed at helping clients effectively implement, use, and maintain the technology [60]. Previous studies [61, 62] have indicated that vendor support plays a significant role in influencing technology adoption in the healthcare environment. Hence, organizations with adequate vendor support for IoT implementation and operations will experience greater success in incorporating IoT technologies than those without such support.

3) Government support. Refers to the various forms of assistance provided by public authorities to foster the adoption of technological innovations [63]. Such support is vital for promoting IoT integration within the healthcare sector. Ahmetoglu et al. [64] emphasize that governmental pressure can significantly accelerate the adoption process of emerging technologies. Since healthcare institutions are primarily public or private entities that operate under strict government regulation and oversight, the role of government becomes especially influential. Therefore, governments often implement a range of financial and non-financial initiatives, such as funding programs, favorable policies, investment schemes, tax incentives, and educational or strategic interventions, to encourage innovation and digital transformation in healthcare [55, 65]. This form of government support can directly or indirectly facilitate the readiness and implementation of IoT solutions across public healthcare organizations.

D. Human Readiness

Focusing on the human aspects of IT innovations in healthcare is crucial because ultimately, end stakeholders should be able to utilize IT innovations effectively. According to Alharbi et al. [66], it is crucial to consider the human aspect before implementing any IT project, as it significantly influences the adoption of new technology. Hence, this research will apply some of the HOT-fit model concepts related to the human perspective to understand the decision to adopt IoT in the healthcare sector.

1) Technical competence. Refers to the capability of IS/IT staff to effectively understand, adapt, and implement technological innovations within their field [67]. Concerning technological advancement in the healthcare sector, previous studies have highlighted the importance of technical competence (the capability of IS staff) as a crucial factor that influences healthcare organizations to effectively adopt IT/IS innovations [27, 28, 67]. According to Lian [27], the availability of a robust Information Systems (IS) department, equipped with highly skilled staff, is crucial for solving business problems and seizing opportunities through the use of IT. When hospital IT staff are well-trained and knowledgeable about new technology, they feel more confident and assured when implementing it within the hospital setting. Regarding the IoT, technical competence is considered an essential indicator for decision-makers who want to adopt IoT technology [68, 69]. According to Savoury [70], organizations need to ensure the availability of skilled and knowledgeable staff before adopting and integrating IoT solutions into their business operations. This emphasizes the importance of having skilled staff who can handle the complexities of IoT technology, thus ensuring the successful adoption of IoT projects.

2) Employees' knowledge. Human resources are a critical asset in any organization, and their knowledge and skills play a significant role in the successful adoption of new technologies [67]. In addition to infrastructure investment, empowering employees with adequate IoT-related knowledge is essential for effective implementation and for gaining a competitive advantage. IT-proficient employees have been shown to play a key role in technology adoption, especially in healthcare settings [71]. For instance, Abugabah et al. [29] found that employee IT knowledge was a critical factor in adopting RFID technology in hospitals. Similarly, Liu [72] emphasized the need to evaluate IS/IT skills before implementing telecare systems. The introduction of IoT technologies in healthcare leads to significant changes in traditional workflows, including how data is collected, shared, and utilized across departments [73]. These changes can create challenges for staff who are accustomed to established routines and systems. As a result, ensuring that employees possess adequate operational knowledge and situational awareness becomes essential for the successful integration and effective use of IoT. Without proper understanding, even the most advanced IoT systems may be underutilized or mismanaged, ultimately hindering the intended improvements in efficiency and patient care.

E. IoT Readiness

Despite the potential benefits of IoT implementation, IoT is still in its early stages of development, and several adoption issues must be overcome before it can be widely adopted [74]. These issues extend beyond technological issues and encompass organizational and environmental factors, which can result in financial costs for the organization and may disrupt or impede the successful adoption of IoT initiatives [46]. According to Chang et al. [13], disruptive technologies, such as IoT, often emerge from edge markets, which may significantly differ from the core operations of established organizations. Consequently, when organizations are unprepared for the changes brought by the new technologies, implementing these technologies may fail to meet expectations. The authors emphasized that if organizations only consider the technical aspects of new technologies when adopting them, without considering their internal and external resources, it can result in wasted resources and project risks. Similarly, Dewi et al. [36] underscored that adopting Internet of Things technology involves inherent risks and uncertainties. Therefore, the willingness to embrace these challenges will significantly impact an organization's decision to adopt IoT. When an organization is adequately prepared and

informed about the risks and uncertainties associated with adopting an innovation, the organization becomes more willing to adopt this innovation [15]. Therefore, Readiness for IoT adoption is a critical determinant that can shape an organization's intention to adopt IoT technologies. Consequently, hospitals with a higher level of preparedness are better positioned to implement and leverage IoT technologies effectively. Fig. 1 illustrates the initially proposed IoT readiness adoption model.

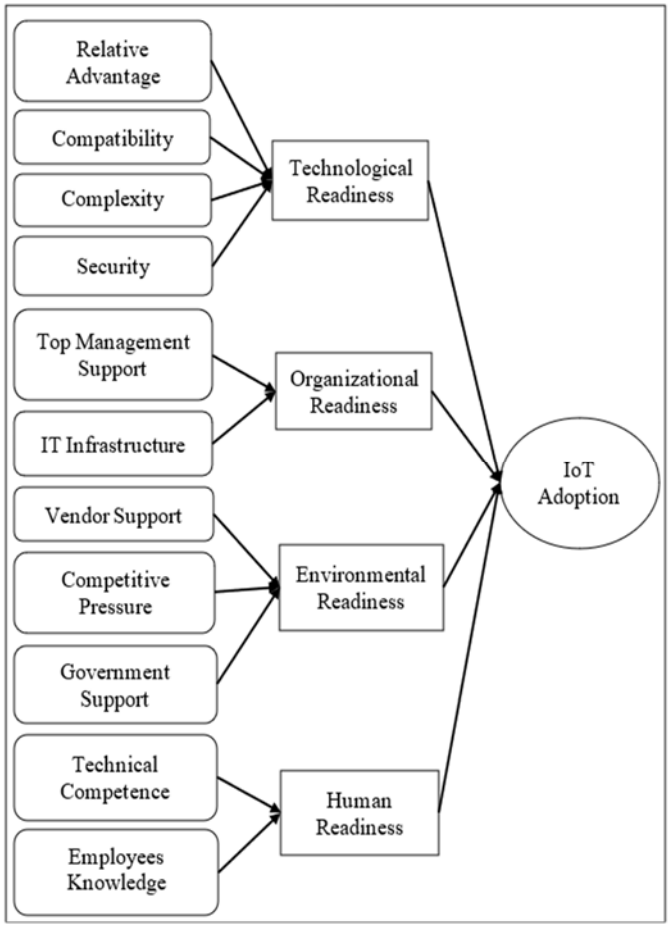

Fig. 1. Proposed research model.

III. Research Methodology

A. Instrument Design

A pilot study was carried out to assess the reliability and validity of the proposed IoT readiness adoption model. The survey instrument used in this study was carefully designed based on insights from previous literature, incorporating elements from both the TOE framework and the HOT-Fit model, which are commonly applied in healthcare technology adoption research. The development of the survey questionnaire was grounded in a review of existing literature, which provided a theoretical foundation for identifying the eleven key factors included in the proposed model. These factors are assumed to influence the adoption of IoT in hospital settings. Therefore, to accurately measure respondents' perceptions, it was essential to establish appropriate measurement scales for each factor. These scales ensure that each construct is represented by a set of items that reliably and validly capture the underlying concept related to IoT adoption in the healthcare context.

The questionnaire design followed three essential criteria: the clarity and formulation of questions, the strategic classification of variables, and the visual presentation of the instrument. The development process began with a comprehensive review of validated items from previous studies related to technology adoption and readiness. These items were then adapted to suit the specific context of IoT adoption in Jordanian public hospitals. The modifications ensured that the items were clear, contextually relevant, and appropriate for measuring the technological, organizational, environmental, and human dimensions that underpin this research. The survey instrument was organized into three sections. The first section introduced the study's purpose and emphasized the confidentiality of respondents' identities and responses. The second section collected demographic and background information. The third section gathered data for testing the proposed research framework by assessing the perceived influence of four readiness dimensions, Technology, Organization, Environment, and Human, on the intention to adopt IoT in Jordan's public hospitals. A five-point Likert scale ranging from 1 ("strongly disagree") to 5 ("strongly agree") was used. Table I provides an overview of the constructs, the number of items per construct, and supporting references.

TABLE I. Measurement of Constructs

Variables	No of Items	Source
Relative Advantage	4	[70, 75-77]
Compatibility	4	[70, 75, 77, 78]
Complexity	4	[33, 77, 79, 80]
Security	3	[61, 77, 81, 82]
Top Management support	4	[17, 75, 83, 84]
IT Infrastructure	4	[17, 85, 86]
Competitive Pressure	4	[17, 67, 87]
Vendor Support	4	[87, 88]
Government Support	5	[70, 75, 82, 89]
Employee Knowledge	4	[67, 77, 87]
Technical competence	3	[27, 67, 85, 88]
Intention to adopt IoT	4	[17, 30, 90]

B. Content Validity

Expert judgment was employed as a primary method to evaluate the relevance and clarity of the questionnaire items to establish content validity. Five experts specializing in Information Systems (IS) and health information technology were selected based on their academic expertise and familiarity with the study's context. According to Lynn [91], a panel of at least three experts is recommended for content validation, while more than ten is generally unnecessary. The selected experts were explicitly chosen for their knowledge of the IS domain and their understanding of the study's objectives, ensuring that their evaluations were aligned with the intended research focus. Each expert was asked to assess the questionnaire items regarding their relevance to the constructs being measured and the

simplicity of their wording. This process allowed for the systematic evaluation of item appropriateness and linguistic clarity. Several revisions were made to enhance the instrument based on the feedback received. Some items were simplified to improve comprehension, while others were reworded to increase clarity and eliminate ambiguity. This content validation process helped to ensure that the questionnaire was conceptually sound and practically accessible to the targeted respondents, thereby strengthening its overall validity [92].

C. Pilot Study

A pilot study survey involves conducting a smaller-scale version of the actual data collection process to evaluate its feasibility. This preliminary step is typically performed before a large-scale study to determine if the research is practical and to avoid the full costs and effort of a comprehensive study [93]. The main goal of the pilot study is to determine whether the survey instrument requires modifications. By conducting a pilot study, researchers can identify potential issues in the study design, such as unclear questions, logistical challenges, or unexpected responses, and make necessary adjustments before proceeding to the main study. In this study, the pilot questionnaire was distributed to 40 participants from public hospitals in Jordan, including key stakeholders such as senior management (e.g., CEO, CIO, CMIO), middle management (e.g., department heads, project managers), IT and technical staff (e.g., IT managers, system administrators, system analysts), and senior medical professionals. These respondents were selected based on their direct involvement in healthcare services' day-to-day operations and strategic planning, and their potential roles in adopting and implementing technologies. To ensure that all participants had the same understanding of IoT applications and services in the healthcare context, a summarized definition was provided on the first page of the survey instrument. Participants were then asked whether they were familiar with such applications; only those who responded affirmatively were permitted to complete the survey.

The pilot study data were analyzed using SmartPLS 4.0 to assess the instrument's content validity and reliability. Expert evaluation ensured content validity, confirming that the survey items appropriately captured the constructs under investigation. Reliability testing was conducted to examine the instrument's internal consistency, including calculations of Cronbach's alpha, composite reliability, and indicator reliability. These tests helped to refine the questionnaire by identifying weak or ambiguous items. In addition, convergent and discriminant validity assessments were carried out to evaluate the instrument's construct validity and confirm the distinctiveness of the measured constructs. These procedures ensured that the instrument was valid and reliable for the full-scale study.

IV. Results and Discussion

A. Descriptive Analysis of Samples in Pilot Survey

The preliminary study used SPSS v.23 software to analyze the participants' demographic details. A total of forty questionnaires were distributed to respondents in Jordanian public hospitals as part of the pilot study. This sample size falls within the recommended range for pilot testing, as the literature typically advises using a small group of participants [77], with Hertzog [94] explicitly recommending a sample size of ten to forty for pilot studies. The pilot study was conducted to evaluate and refine the final data-collection process. Participant responses were analyzed to produce the frequency and percentage distributions presented in Table II, which outlines the demographic characteristics of the pilot study sample.

TABLE II. Frequency and Per cent of Demographic Variables in the Pilot Test

	Items	Frequency	Percent
Gender	Male	26	65%
	Female	14	35%
Age	Less than 30 years	0	0
	30-34 years	4	10%
	41-45 years	12	30%
	46-50 years	8	20%
	More than 50 years	2	5%
Education	Diploma	0	0
	Bachelor's Degree	26	65%
	Master's Degree	12	30%
	Doctoral Degree	2	5%
Position at Hospital	Senior Management	1	2.5%
	Middle Management	12	30%
	IT/Technical Staff	20	50%
	Healthcare Practitioners	7	17.5%
Experience in the current position	Less than 1 year	2	5%
	1-3 years	20	50%
	4-6 years	12	30%
	7-9 years	4	10%
	More than 10 years	2	5%
Experience in the Healthcare	Less than 5 years	2	5%
	6-10 years	19	47.5%
	11-15 years	8	20%
	21-25 years	1	2.5%
	26 years and above	4	10%
Knowledge about the Internet of Things	No information or knowledge	0	0
	Little information and knowledge	1	2.5%
	Some information and knowledge	2	5%
	Good information and knowledge	15	37.5%
	Excellent information and knowledge	22	55%

The sample consisted of forty respondents, with a majority being male (65%), and a relatively balanced representation across middle-aged groups, though no participants were under thirty. This may suggest a lack of younger professionals in decision-making or technical roles within public hospitals. The educational background was predominantly bachelor's degree holders (65%), indicating a solid academic foundation, with

35% having postgraduate qualifications, which could contribute positively to informed responses on technological topics such as IoT. From an organizational standpoint, 50% of respondents were IT or technical staff, which aligns well with the study's focus on IoT implementation, as these individuals are directly involved in deploying and managing such technologies. However, the limited representation from senior management (2.5%) may restrict insights from strategic-level decision-makers. In terms of work experience, half of the participants had one to three years in their current role, and nearly half (47.5%) had six to ten years of experience in the healthcare sector overall, suggesting a sample that combines both current role familiarity and broader sectoral expertise. Importantly, 92.5% of participants reported having good or excellent knowledge of IoT, indicating that the respondents were well-positioned to evaluate IoT adoption in healthcare, strengthening the reliability of the pilot findings.

B. Construct Reliability

In this study, the reliability of the research instrument was assessed using Smart PLS V4. Two main criteria were used: internal consistency and indicator reliability [95, 96]. To assess internal consistency, both Cronbach's alpha and composite reliability were employed. Cronbach's alpha evaluates reliability by examining the intercorrelations among observed indicators, while composite reliability considers the varying outer loadings of these indicators. In addition, indicator reliability was analyzed by evaluating the statistical significance of outer loadings, where a minimum threshold of 0.70 was deemed acceptable. This comprehensive approach ensured that all constructs in the research framework were reliably measured.

1) Internal consistency. Internal consistency was assessed using both Cronbach's Alpha (α) and Composite Reliability (CR), which are standard indicators for evaluating the reliability of latent constructs. Cronbach's Alpha evaluates the degree to which measurement items are correlated, assuming equal contribution of items, whereas CR accounts for the actual outer loadings of items, offering a more accurate estimation in SEM contexts [96]. A value above 0.70 is considered acceptable for both metrics. As shown in Table III, all constructs exceeded the recommended thresholds, with Cronbach's Alpha values ranging from 0.743 to 0.839 and Composite Reliability values from 0.844 to 0.892. These results demonstrate satisfactory internal consistency across all constructs. The high CR values indicate that the items within each construct reliably measure the same underlying concept, and the use of both metrics strengthens the credibility of the instrument. IT Infrastructure achieved the highest internal consistency ($\alpha = 0.839$; CR = 0.892), suggesting that this construct is both conceptually clear and consistently interpreted by respondents. This result likely reflects the tangible and well-established nature of IT infrastructure within hospitals, which may lead to more uniform responses.

In contrast, Security showed the lowest Cronbach's Alpha (0.743), and Compatibility reported the lowest CR (0.844), though both remained above the acceptable threshold. These slightly lower values may indicate more heterogeneous responses or measurement items that capture broader, more context-dependent perceptions. For Security, this could suggest variation in how respondents perceive threats and data protection standards in their institutions. For Compatibility, the modest reliability may reflect ambiguity in how well IoT systems are perceived to integrate with existing workflows, particularly in environments with varying levels of digital maturity. Taken together, the results confirm that the instrument demonstrates solid internal consistency across all constructs. The combination of high alpha and CR values provides strong empirical support for the reliability of the measurement model, laying a sound foundation for structural modeling and hypothesis testing in the next phase of the research. However, continued refinement of items with comparatively lower reliability will be important for improving the instrument's performance in future applications.

TABLE III. INTERNAL CONSISTENCY OF THE REFLECTIVE CONSTRUCTS

Constructs	Number Items	Cronbach's Alpha	Composite Reliability
Relative Advantage	4	0.796	0.866
Compatibility	4	0.758	0.844
Complexity	4	0.814	0.877
Security	3	0.743	0.854
Top management Support	4	0.799	0.867
IT Infrastructure	4	0.839	0.892
Competitive Pressure	4	0.802	0.870
Vendor Support	4	0.770	0.853
Government support	5	0.784	0.856
Technical competence	3	0.779	0.872
Employee Knowledge	4	0.768	0.852
Intention Towards IoT	4	0.815	0.879

2) Indicator reliability. Indicator reliability refers to the extent to which each observed variable (or item) accurately represents the latent construct it is intended to measure. This is assessed through the item's outer loading, which reflects the strength of the relationship between the observed variable and the construct. A commonly accepted threshold is 0.70, indicating that more than 50% of the variance in the item is explained by the underlying construct [97]. Items with loadings between 0.40 and 0.70 may be retained if they contribute to content validity, but those below 0.40 are generally recommended for removal unless strong theoretical justification exists[95].

As reported in Table IV, most items in this study achieved outer loadings above the 0.70 threshold, suggesting a high level of indicator reliability across the measurement model. This reinforces the internal consistency of the constructs and supports the appropriateness of the selected items. However, two items, GS3 (Government Support) and INTI4 (Intention Towards IoT) exhibited loadings of 0.240 and 0.366, respectively, falling well below the acceptable threshold. After identifying these problematic items, they were removed, and the measurement model was reassessed. The updated analysis showed that

eliminating these two low-loading indicators improved the reliability and validity metrics, particularly the Average Variance Extracted (AVE), Cronbach's Alpha, and Composite Reliability values for their respective constructs. This process confirms the usefulness of empirical testing in refining the measurement instrument, even when items are initially retained for theoretical completeness or face validity. The need to remove GS3 and INTI4 also points to broader considerations in measurement design. While content validity remains crucial, ensuring all facets of a construct are represented, this must be balanced with empirical evidence to avoid retaining items that dilute the strength of the construct. Future research may benefit from revising these items for clarity, rephrasing them to better reflect the conceptual domain, or supplementing them with more targeted indicators.

TABLE IV. ITEM LOADING OF INDICATORS

Constructs	Items	Outer loading before deleting items	Outer loading after deleting items
Relative Advantage	RA1	0.753	0.753
	RA2	0.791	0.791

	EK2	0.809	0.809
	EK3	0.821	0.821
	EK4	0.712	0.712
Intention Towards IoT	INTI1	0.838	0.849
	INTI2	0.759	0.782
	INTI3	0.865	0.892
	INTI4	0.366	-

Moreover, the high loadings across the majority of other items provide strong evidence of a well-developed measurement model. Constructs such as Technical Competence, IT Infrastructure, and Intention Towards IoT (after item deletion) showed particularly strong loadings, indicating that these concepts are well captured and perceived consistently by respondents. This strengthens confidence in the reliability of the data collected and the subsequent structural model outcomes. Overall, the analysis of indicator reliability confirms that the measurement model is robust, though it also underscores the importance of iterative testing and item refinement. In settings like public healthcare in developing countries, where technological adoption is shaped by complex institutional and environmental factors, measurement instruments must be both context-sensitive and empirically sound.

V. CONSTRUCT VALIDITY

Construct validity is concerned with how accurately a tool or questionnaire measures the concept it was designed to assess. In other words, it examines whether the items within the instrument truly reflect the theoretical idea they are intended to capture [92]. This involves empirical assessment, examining how well a measure correlates with external criteria based on empirical observations. In this study, construct validity was investigated through convergent and discriminant validity assessments.

1) Convergent validity. Convergent validity examines whether a construct effectively captures the variance of its associated indicators, ensuring that items measuring the same concept are indeed related. This is typically assessed through the Average Variance Extracted (AVE), which reflects the proportion of variance explained by the latent construct relative to measurement error. According to Fornell and Bookstein [98], a minimum AVE of 0.50 is recommended, suggesting that at least 50% of the indicator variance should be accounted for by

the construct. As presented in Table V, all constructs in this study meet or exceed the 0.50 threshold, indicating satisfactory convergent validity.

TABLE V. CONVERGENT VALIDITY

Constructs	Number of Items	AVE
Relative Advantage	4	0.618
Compatibility	4	0.576
Complexity	4	0.643
Security and Privacy	3	0.662
Top management Support	4	0.620
IT Infrastructure	4	0.674
Competitive Pressure	4	0.627
Vendor Support	4	0.592
Technical competence	3	0.694
IoT Knowledge	4	0.592
Government support	4	0.598
Intention Towards IoT	3	0.709

This confirms that the measurement model generally performs well in representing the intended latent variables. However, a more nuanced examination reveals variation in the strength of convergent validity across constructs. For instance, Intention Towards IoT achieved the highest AVE (0.709), suggesting strong internal consistency and a high degree of shared variance among its indicators. Similarly, constructs like Technical Competence (0.694) and IT Infrastructure (0.674) exhibit robust convergence, indicating that these areas are conceptually well-defined and consistently measured in this study. Conversely, constructs such as Compatibility (0.576), IoT Knowledge (0.592), and Vendor Support (0.592), while above the threshold, have relatively lower AVE values. This may suggest potential areas for improvement in item formulation or conceptual clarity. Lower AVE values can sometimes reflect measurement items that are not strongly correlated, possibly due to broad or multidimensional definitions of the construct. Therefore, while the results support the use of these constructs in subsequent analysis, future studies might consider revisiting the measurement items for these constructs to enhance reliability and ensure tighter conceptual alignment. Overall, the results confirm acceptable convergent validity for all constructs, supporting the reliability of the measurement model.

2) Discriminant validity. Discriminant validity measures how a construct differs from others [95]. Discriminant validity was assessed using the Fornell-Larcker criterion, which requires that the square root of the AVE for each construct (shown on the diagonal in Table VI) be greater than its correlations with other constructs (off-diagonal values). This ensures that each construct shares more variance with its indicators than with other constructs, confirming that the latent variables are empirically distinct. The results support the discriminant validity of all constructs, as each diagonal value is higher than the corresponding off-diagonal correlations. For instance, the square root of AVE for Intention Towards IoT (ITI) is 0.821, exceeding its highest correlation with Security and Privacy (SP) at 0.672. Similarly, Technical Competence (TC) shows a strong distinction (0.833) despite moderate correlations with constructs like Employee Knowledge (EK) and Security and Privacy (SP).

However, some constructs demonstrate relatively high intercorrelations, particularly among Government Support (GS), Technical Competence (TC), and Security and Privacy (SP). For example, GS correlates at 0.705 with TC and 0.675 with SP, raising questions about potential conceptual overlap or shared variance due to external support mechanisms being tied closely to both technical readiness and data privacy policies. While the Fornell-Larcker threshold is met, such strong correlations suggest these constructs may be related in practice and should be more sharply delineated in future research. Overall, the model demonstrates acceptable discriminant validity, but the observed correlations warrant attention. These findings highlight the importance of refining construct definitions and measurement items in follow-up studies, especially in contexts like public healthcare, where institutional roles may blur the boundaries between support, competence, and data security.

VI. CONCLUSION

This pilot study offers an empirically grounded validation of a comprehensive measurement instrument designed to assess IoT adoption readiness in Jordanian public hospitals, an area that remains underexplored despite the growing strategic importance of digital health technologies in developing countries. By integrating constructs from both the TOE framework and the HOT-Fit model, this study transcends traditional user-centric adoption theories and addresses the multidimensional complexity of institutional readiness. The results confirmed that the instrument demonstrates robust internal consistency, satisfactory indicator reliability, and strong convergent and discriminant validity, suggesting that it is both psychometrically sound and contextually relevant.

Practically, this study offers valuable insights for healthcare administrators, policymakers, and system developers aiming to promote digital transformation in public hospitals. The validated model identifies key dimensions—technological, organizational, environmental, and human readiness—that must be considered when planning for IoT implementation. Hospital leaders should ensure not only that technical infrastructure is in place but also that staff possess the necessary knowledge and competencies, and that sufficient management support and external resources (e.g., vendor and government support) are available. Moreover, this study demonstrates the importance of tailoring adoption models to the institutional realities of developing countries. The integration of both TOE and HOT-Fit constructs reflects the complex interplay of internal and external factors that shape readiness in public sector environments. As such, this pilot study contributes to a more context-sensitive approach to technology adoption in healthcare, especially within resource-constrained settings.

Building on this foundation, the next step involves deploying the validated instrument in a full-scale quantitative study to test the proposed model and examine the relationships between the readiness factors and the intention to adopt IoT. Structural equation modeling (SEM) can be employed to assess the model's explanatory power. In addition, future research may benefit from adopting a mixed-methods approach, incorporating qualitative techniques such as interviews or case studies to explore contextual nuances, user perceptions, and institutional dynamics that may not be fully captured through quantitative measures alone. Longitudinal studies could also offer valuable insights into how readiness and adoption progress over time, particularly as digital transformation efforts expand within Jordan's healthcare sector. In conclusion, the study provides a validated foundation for future empirical investigations and offers practical implications for stakeholders aiming to accelerate IoT adoption in the healthcare systems of developing countries.

***Abstract*—To solve the problem of detecting unexpected situations in network traffic, it is proposed to determine the normal, unexpected states and behavior of the system using statistical methods. The statistical analysis methods used are the mean, variance, asymmetry coefficient, kurtosis coefficient, opposition coefficient and entropy coefficient. All statistical analysis methods allow for a deeper understanding of the uniqueness of the data. Each coefficient provides different measurement values, with which it is possible to determine the general characteristics of the data. The application of statistical analysis methods in network traffic is one of the most common methods for implementing the technology of detecting unexpected situations. For this, network traffic recorded in real time in laboratory conditions is used. Packet features of the network traffic are extracted from the recorded data, and then statistical analysis is performed using the extracted features. Markov chain is one of the most effective tools for analyzing situations and events occurring in network traffic. Markov chain is formed using the results of statistical analysis, and a Markov chain is constructed. This approach represents the state of the network flow in a probabilistic model and serves as an effective tool in monitoring the network flow.**

***Keywords*—Unexpected situation; mean; variance; asymmetry coefficient; kurtosis coefficient; opposition coefficient; entropy coefficient; packet analysis; markov chain; packet features**

I. Introduction

Today, ensuring information protection is one of the most pressing issues. The increase in the volume of data also creates new problems. This means that network security officers need to strengthen measures to eliminate or prevent problems in the proper organization of network management [32]. Traditional methods do not provide sufficient results in the face of new attacks [7]. Therefore, it is necessary to use modern analysis methods. In particular, traffic analysis, anomaly detection [13], and deep analysis of packet features are effective tools [15]. These methods are widely used by many researchers due to the fact that they can be implemented in real time [16].

Analysis through packet features is a time-saving method for detecting unexpected events in network operations [33]. Researchers use neural network, machine learning [6], deep learning and analytical analysis methods [31] to analyze packet features [3]. Statistical analysis methods have been little studied. Therefore, statistical analysis methods were used in this research work.

The research study investigated unexpected network traffic patterns. To do this, first, the network traffic was recorded, and packet features were extracted. The data was recorded in a laboratory environment using the Wireshark program, and packet features were extracted based on the developed algorithm.

Statistical analysis methods [28], including mean, variance, asymmetry coefficient, kurtosis coefficient, opposition coefficient and entropy coefficient, were used to analyze the extracted packet features [1], [2]. Markov chain is the most effective method for in-depth analysis of unexpected situations [21]. As a result of the research work, statistical analysis methods and Markov chain architecture were developed to identify unexpected situations in network flow [14]. Based on the results obtained, an assessment was made of unexpected situations in network flow.

The novelty of the study is that it proposes a Markov chain model, combining statistical indicators based on real traffic data. This allows not only to identify unexpected situations in the network, but also to predict their development trends in advance.

The study consists of six sections: Introduction, Related works, Problem statement, Proposed methodology, Experimental results and discussions, and Conclusion.

II. Related Works

Ramachandran et al. [1] have studied probability theory and mathematical analysis in detail in statistical analysis. In their book, they have justified the analysis of theoretical knowledge and practical skills necessary for solving real-life statistical problems [26].

Hu et al. [2], performed quantitative data analysis and sample variance analysis. Based on the experiments, they proposed new solutions for variance analysis [35].

Alasmar and Zakhleniuk used variance from statistical analysis algorithms to extract link data from the incoming data.

The proposed link size estimation approach measures the statistical parameters and then measures the rate of change in traffic. The heavy length distributions performed better than the Gaussian model [3].

Chydzinski [4] studies the effect of interdependence of packet arrival time and service delivery on the degradation of queuing system performance in network operation.

Kasse et al. [5] present an approach using the Path-scan model to identify paths that exhibit anomalous behavior in network communications. They developed a Markov model consisting of three states to model the states in the network.

Li and Wu used a Markov chain model to calculate the probability of agents forwarding packets in the idle or busy state and analyze the packet forwarding behavior of agents. On this basis, they proposed a game model for packet forwarding strategies [6].

Zhou and Nikaein [7] proposed an adaptive packet collection method to improve the reliability of random access. Random access [30] is not checked for each packet, but instead, random access is checked when the number of collected packets reaches a certain threshold. During packet collection, there may be delays or packet loss. To overcome this problem, a Markov model was used.

Sun and Zhao proposed a Markov chain method for modeling photovoltaic array noise and studied the accuracy of the modeling [8].

Doncel described the average information age of a system [24] using the stochastic hybrid system method. The study investigated the average information age of a queuing system formed by two queues, the first queue storing the system updates and the second one storing the energy required to deliver the state update to the monitor [34]. The queues process one packet [9].

Ott and Swanson study Markov chain models derived from protocols in the TCP (Transmission Control Protocol) paradigm. The researchers study the problems of packet loss, latency, and network congestion [10].

Even studied the convergence rate of Markov chains and optimized functions [23] under the least restrictive assumptions. He showed a theoretical lower bound for methods for sampling stochastic gradients along a Markov chain path and a dependence on the beat time of the Markov chain [11].

Smiesko et al. [12] used statistical parameters to detect DDoS attacks in real time. Statistical analysis methods such as kurtosis coefficient, entropy, correlation coefficient, and Hurst exponent were used to analyze network flow data [17].

Lu uses data transformation analysis to reduce risks in online shopping and ensure online security [34]. Opposition coefficient, correlation coefficient and other methods of statistical analysis were used [13].

Kenyon et al. [14] analyzed the payload of packets using entropy and found that entropy is an effective method for anomaly detection. They compared real-time entropy values with baseline values to detect anomalies in the flow [18].

In calculating the maximum entropy of network traffic, Gu et al. [15] proposed an effective method for detecting behavior-based anomalies, which is commonly applied to TCP and UDP (User Datagram Protocol) traffic data. The calculation used the protocol information and the sending port number features.

Doriguzzi-Corin et al. [16] propose to detect DDoS (Distributed Denial-of-Service) attacks by extracting packet features and exploiting the features.

In the analyzed research works, it was mainly studied on the basis of analysis based on packet data. However, the data in the packets were considered as the basis for analysis, but their interdependence was rarely analyzed. To solve this problem, the research study used a Markov chain in combination with statistical analysis methods, which allows for accurate evaluation of the results obtained.

III. Problem Statement

Developing effective methods for detecting and responding to threats by analyzing large networks has always been relevant [19]. One of the biggest challenges is to detect attacks that exhibit anomalous behavior in selected packet features of network traffic [20]. Detection and response methods must be adaptable to a wide variety of network environments, and these methods should be implemented without human intervention as much as possible [25], [27].

Attack detection should be as accurate as possible. Because a falsely detected attack can lead to a denial of service for legitimate users in network operations. If the detection results in the detection of attacks that are not occurring, the attack will not be detected, meaning the detection process will not work properly [26], [28]. The method used in the detection process should be effective and fast in relation to the various attacks that currently exist.

Research shows that statistical features and statistical processing are a useful approach for detecting anomalous intrusions.

Developing useful methods for detecting unexpected events that occur as a result of device failures or unforeseen events observed in network operations is an important task today. The main requirement for the developed methods is the ability to detect any type of unexpected situation in real time, including data that is unknown in advance and is also scattered over time. For this, the recorded network flow characteristics are used. When recording a network flow, the network flow is recorded in pcap format using the Wireshark program and the flow characteristics are extracted for analysis. The extracted characteristics are stored in csv file format. The flow characteristics are evaluated using statistical analysis methods and Markov chains.

IV. The Proposed Methodology

In the proposed research method, network traffic is recorded, and statistical analysis is performed based on the collected data. Fig. 1 depicts the network traffic data collection and analysis. First, the incoming network traffic data was recorded using the Wireshark program in a laboratory setting. The recorded data is saved in the pacp file format. Second, the data stored in the pcap

file is read based on the developed algorithm, 89 different features are extracted from the read data and saved in the csv file format. This process is carried out in three stages. Reading, feature extraction, and saving the features in the csv file format. The data in the csv file is processed and checked using statistical analysis algorithms [1]. A Markov chain is formed using the results of statistical analysis. The results of statistical analysis are important in determining the set of Markov chain states.

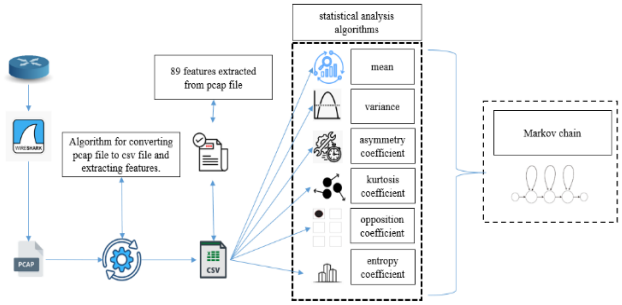

Fig. 1. Statistical analysis structure of network flow feature extraction.

A. Extracting Network Flow Characteristics

Network traffic was captured in a laboratory environment using Wireshark. During the recording, data was transmitted through 6 computers and various network activity conditions were captured. Fig. 1 shows a model of the network traffic capture process. Eighty-nine features were extracted from the traffic data recorded in a laboratory environment. The extracted features allow us to solve the research problem.

In the algorithm in Fig. 2, the data recorded in the pcap file is read through Wireshark and the initial properties of the packet are extracted: *srcIP*, *dstIP*, *srcPort*, *dstPort*, *protocol*, *timestamp*, *headBytes*, *payloadBytes*, *flags*, *windowSize*, *payload*. These properties are the main information for forming the flow data. Based on this information, eighty-nine different properties are determined.

```
1: function nextPacket()
2: packetInfo ← None
3: while pcapPtr < pcapLen do ▷ Packet reading continues
4:    totGen.nextId() ▷ Create a new ID for each package
5:    timeHigh ← pcapData[pcapPtr:pcapPtr + 4] ▷ High timestamp
6:    timeHigh ← struct.unpack(typeI, timeHigh)[0] ▷ Unpacking time
7:    timeLow ← pcapData[pcapPtr + 4:pcapPtr + 8] ▷ Lower timestamp
8:    timeLow ← struct.unpack(typeI, timeLow)[0] ▷ Unpacking time
9:    timeStamp ← 1000000 * timeHigh + timeLow ▷ Timestamp calculation
10:   caplen ← pcapData[pcapPtr + 8:pcapPtr + 12] ▷ Package length
11:   caplen ← struct.unpack(typeI, caplen)[0] ▷ Unpacking the packet length
12:   pcapPtr += 16 ▷ Go to package information
13:   packetData ← pcapData[pcapPtr:pcapPtr + caplen] ▷ Get package information
14:   pcapPtr += caplen ▷ Move the pointer to the next packet.
15:   if isIpv4TCP(packetData) then
16:      packetInfo ← getIpv4Info(packetData, timeStamp) ▷ IPv4 TCP packet
17:      break
18:   else if isIpv6TCP(packetData) then
19:      packetInfo ← getIpv6Info(packetData, timeStamp) ▷ IPv6 TCP packet
20:      break
21:   end if
22: end while
23: return packetInfo ▷ Return packet data
24: end function
```

Fig. 2. Pseudocode for reading packet data from a pcap file.

In Fig. 3, timestamps and flags from each packet of data are used to create a stream from the data. When the stream is complete, the data is written to a csv file.

```
1: function addPacket(packet: BasicPacketInfo)
2:   if packet == None then
3:     return
4:   end if
5:   currentTS ← packet.getTimeStamp() ▷ Packet timestamp
6:   pktFwdFlowId ← packet.getFwdFlowId() ▷ Packet transmission flow identifier
7:   pktBwdFlowId ← packet.getBwdFlowId() ▷ Packet reverse flow identifier
8:   if pktFwdFlowId in self.currentFlows or pktBwdFlowId in self.currentFlows then
9:     if pktFwdFlowId in self.currentFlows then
10:       flowId ← pktFwdFlowId ▷ Flow ID
.    .    .    .    .    .    .    .    .    .    .    .
.    .    .    .    .    .    .    .    .    .    .    .
61: function dumpPayloadToCSV()
62:   open "payload.csv" for writing as csvfile
63:   writer ← csv.writer(csvfile) ▷ Opening and writing a CSV file
64:   for each flow in self.finishedFlows do
65:     flow ← flowType(flow) ▷ Getting the flow
66:     output ← flow.generateFlowFeatures() ▷ Getting the features
67:     writer.writerow(output) ▷ Writing features to CSV
68:   end for
69: end function
```

Fig. 3. Pseudocode for capturing stream data based on packet data from a pcap file.

In Fig. 4, flag features are also extracted to perform the calculations required for the research results. This data is written to a csv file after the data in the pcap file is completely read using the dumpFeatureToCSV function [29]. This process is performed each time a pcap file is read, and the data from each pcap file is saved to a separate csv file.

```
1: function init(generator, srcIP, dstIP, srcPort, dstPort, protocol, timeStamp, headBytes, payloadBytes, flags,
TCPWindow, payload)
2: id ← generator.nextId() ▷ Create a unique ID for the package
3: srcIP ← srcIP ▷ Setting the source IP address
4: dstIP ← dstIP ▷ Setting the destination IP address
5: srcPort ← srcPort ▷ Setting the source port
6: dstPort ← dstPort ▷ Setting the destination port
7: protocol ← protocol ▷ Protocol setup
8: timeStamp ← timeStamp ▷ Set timestamp
9: headBytes ← headBytes ▷ Setting the packet header length
10: payloadBytes ← payloadBytes ▷ Load length setting
.    .    .    .    .    .    .    .    .
.    .    .    .    .    .    .    .    .
80: return (flags >> 5) & 1 ▷ Check the URG flag
81: end function
82: function hasFlagECE()
83: return (flags >> 6) & 1 ▷ Check the ECE flag
84: end function
85: function hasFlagCWR()
86: return (flags >> 7) & 1 ▷ Check the CWR flag
87: end function
```

Fig. 4. Pseudocode for extracting features needed in a calculation.

B. Mathematical Representation of Markov Chain

Markov chains were first used by Andrey Markov in 1906 to show that the law of large numbers does not require that random variables be independent. Since then, Markov chains have been used in biology, finance, computer science, mathematics, and other fields [5, 21]. A Markov chain is a model that helps us visualize a sequence of random variables, states, and the states in which each of them can take on values from a given set. Markov chains can also be used to make predictions, predict future events, or understand a process that has occurred [22].

Consider a simple Markov chain with states and transition matrix $\|p_{ij}\|_1^n$. Given $r_1, \dots, r_n$, the terminal probabilities of the chain have the property of termination. The set of all states $\{n\}$ of the chain is decomposed into two disjoint subsets, that is, $\{n\} = \{n_1\} \cup \{n_2\}$. The transition from the initial set to the next one through $R_{1,2}$ and $R_{2,1}$ and vice versa from the final to the initial state is described by the Formula (1) below:

$$R_{1,2} = \sum_{\substack{i\in\{n_1\} \\ j\in\{n_2\}}} r_i p_{ij}\,,\ R_{2,1} = \sum_{\substack{i\in\{n_2\} \\ j\in\{n_1\}}} r_i p_{ij} \qquad (1)$$

Lemma. $R_{1,2} = R_{2,1}$ probability flows are balanced [36].

In [4], in particular, all the states in the first subset $\{n_1\}$ are numbered $1, \dots, k$, and all the positions of the Markov chain are numbered according to the chosen decomposition as $\{n_1\}, \{n_2\}$ (where k is the number of items in this subset). The items in the complement of the set $\{n\}$ belonging to the set $\{n_2\}$ are numbered $k+1, \dots, n$.

The final probabilities $r_1, \dots, r_n$ of the complete chain give rise to the relationship [Formula (2)]:

$$r_i = \sum_{j=1}^{n} r_j p_{ji}, all\ i = 1, \dots, n) \quad (2)$$

the i-number position is extracted in the following Formula (3):

$$-r_i(1 - p_{ii}) = \sum_{\substack{j=1 \\ j \neq i}}^{n} r_j p_{ji} = 0, i = 1, \dots, n) \quad (3)$$

The stochastic transition matrix $\|p_{ij}\|_1^n$ is Formula (4):

$$\sum_{j=1}^{n} p_{ij} = 1, i = 1, \dots, n \quad (4)$$

$(1 - p_{ii})$ expression is expanded as in Formula (5):

$$-r_i \sum_{\substack{j=1 \\ j \neq i}}^{n} p_{ji} + \sum_{\substack{j=1 \\ j \neq i}}^{n} r_j p_{ji} = 0, i = 1, \dots, n) \quad (5)$$

When passing to probability values, the first k of the above formula is added [Formula (6)]:

$$-\sum_{i=1}^{k} \sum_{\substack{j=1 \\ j \neq i}}^{k} r_i p_{ij} - \sum_{i=1}^{k} \sum_{j=k+1}^{n} r_j p_{ij} + \\ + \sum_{i=1}^{k} \sum_{\substack{j=1 \\ j \neq i}}^{k} r_i p_{ji} + \sum_{i=1}^{k} \sum_{j=k+1}^{n} r_j p_{ji} = 0 \quad (6)$$

The first term of the above Formula (6) is equal to the third term [Formula (7)].

$$\sum_{i=1}^{k} \sum_{\substack{j=1 \\ j \neq i}}^{k} r_i p_{ij} = \sum_{i=1}^{k} \sum_{j=1}^{k} r_j p_{ij} - \sum_{i=1}^{k} r_j p_{ii} = \\ = \sum_{j=1}^{k} \sum_{i=1}^{k} r_j p_{ji} - \sum_{i=1}^{k} r_j p_{ii} = \sum_{i=1}^{k} \sum_{\substack{j=1 \\ j \neq i}}^{k} r_j p_{ji} \quad (7)$$

(Here the sum indices are replaced equivalently by $i \leftrightarrow j$, and the order of the sums is changed.)

Using the above formulas, a generalized formula is obtained as in Formula (8):

$$-\sum_{i=1}^{k} \sum_{j=k+1}^{k} r_i p_{ij} + \sum_{i=1}^{k} \sum_{j=k+1}^{n} r_j p_{ij} = 0 \quad (8)$$

A sequence of random variables $X_0, X_1, X_2, \dots$ is called a Markov chain if the values of the variables are taken in the state space $\{1,2, \dots N\}$ and there exists a matrix $P = (p_{ij})$ of size $N \times N$ for any $n \geq 0$. $X_0, X_1, X_2, \dots$ denotes the set of states [Formula (9)].

$$P(X_{n+1} = j | X_n = i, X_{n-1} = i_{n-1}, \dots, X_0 = i_0) = \\ = P(X_{n+1} = j | X_n = i) = p_{ij} \quad (9)$$

P is called the transition matrix of the matrix chain, and P_{ij} is the probability of transition from i to j.

The transition probability $p_{ij} = P(X_{n+1} = j | X_n = i)$ is written in the form of a matrix of p_{ij} and is as follows [Formula (10)]:

$$P = \begin{bmatrix} p_{11} & p_{12} & \cdot & \cdot & \cdot & p_{1n} \\ p_{21} & p_{22} & \cdot & \cdot & \cdot & p_{2n} \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\ p_{n1} & p_{n2} & \cdot & \cdot & \cdot & p_{nn} \end{bmatrix} \quad (10)$$

The sum of the transition probabilities $p_{11}, p_{12}, \dots, p_{1n}$ in each row must be equal to $p_{11} + p_{12} + \dots + p_{1n} = 1$ [Formula (11)].

$$\sum_{j=1}^{N} p_{ij} = \sum_{j=1}^{N} P(X_{n+1} = j | X_n = i) = 1 \quad (11)$$

where, the sum of all the possibilities in the row together is 100%.

So, if $X_0, X_1, X_2, \dots$ forms a Markov chain, then the transition probability of a matrix P of size $N \times N$ at step t is equal to $P(X_t = j | X_0 = i) = (P^t)_{ij}$.

If $X_0, X_1, X_2, \dots$ forms a Markov chain [11], then the probability distribution of X_0 of a matrix P of size $N \times N$ is equal to 1, and the probability distribution of a row vector π^T of size N is expressed as $\pi^T P^t$ [Formula (12)].

$$X_0 = \pi^T \Rightarrow X_t = \pi^T P^t \quad (12)$$

Stationary probability as in Formula (13):

$$\pi P = \pi \quad (13)$$

The condition $\sum \pi_i = 1$ must also be met, which indicates the probability of the process remaining in a given state for how long.

C. Formulation of Statistical Features of Network Flow with Unexpected Situation

Statistical features are used to detect unexpected situations in network traffic. The following statistical features are calculated for network traffic during the analysis:

- Mean as in Formula (14):

$$m_i = \frac{1}{n} \sum_{j=i}^{i+n} S_j \quad (14)$$

where, m_i is the mean value, n is the number of packets in the selected time interval, $S_i - j$ is the sample value of the traffic intensity at time, and the sum of values from $j = i$ to $i + n$ is obtained [1].

- Variance as in Formula (15):

$$D = \frac{1}{n-1} \sum_{j=i}^{i+n} \left(S_j - m_j\right)^2 \quad (15)$$

where, D is the variance, n is the length of the window under study (how many values were obtained), $S_i - j$ is the intensity at time (number of packets, traffic volume), m_j is the mean value [2].

- asymmetry coefficient as in Formula (16):

$$K_a = \frac{\frac{1}{n}\sum_{j=i}^{i+n}(S_j - m_j)^3}{D^3} \quad (16)$$

where, $S_i - j$ is the sample value at time (e.g., the number of packets), m_i is the mean value, D is the variance, and n is the number of values. The asymmetry coefficient represents the shift in the center of gravity of the statistical distribution [4].

- kurtosis coefficient as in Formula (17):

$$K_k = \frac{\frac{1}{n}\sum_{j=i}^{i+n}(S_j - m_j)^4}{D^4} - 3 \quad (17)$$

where, $S_i - j$ is the value at time, m_i is the mean, D is the variance, n is the number of values. The kurtosis or asymmetry coefficient measures the height or sharpness of the peak of a statistical distribution. In other words, it tells how far the values in the distribution are not far from or clustered around the mean [12].

- opposition coefficient as in Formula (18):

$$K_{oc} = \frac{1}{\sqrt{\eta}} \quad (18)$$

η is the excess parameter, defined as Formula (19):

$$\eta = K_k = \frac{\mu_4}{\sigma^4} \quad (19)$$

where, σ is the standard deviation (i.e. the square root of the variance), μ_4 is the fourth central moment (i.e. the average of the 4th order deviations of all values from the mean). The parameter K_{oc} varies from 0 (according to the Cauchy distribution) to 1 (discrete binomial distribution). For a normal distribution, $K_{oc} = \frac{1}{\sqrt{3}} \approx 0.577$.

Another parameter that characterizes the shape of the distribution is the entropy coefficient.

- entropy coefficient as in Formula (20):

$$K_{en} = \frac{\Delta_E}{\sigma} \quad (20)$$

where, Δ_E is the entropy value of the error, which means the level of uncertainty of the distribution, σ means the standard deviation, that is, the degree of deviation from the mean value [Formula (21)].

$$\Delta_E = \frac{1}{2} e^{H(\frac{X}{X_n})} \quad (21)$$

where, $H(\frac{X}{X_n})$ is the entropy (uncertainty) change introduced by measuring the random variable X, and e is a mathematical constant. The entropic error shows that the greater the uncertainty in the distribution, the greater the entropic error [Formula (22)].

$$H\left(\frac{X}{X_n}\right) = \int_{+\infty}^{-\infty} p(X) \ln\big(p(X)\big) dX \quad (22)$$

where, $p(X)$ is the probability density of the random variable [14]. Table I presents the entropic error distribution type.

TABLE I. ENTROPY COEFFICIENT DISTRIBUTION

Distribution type	K_{en} value	Note
Normal distribution	$K_{en} = \frac{\sqrt{2\pi e}}{2} \approx 2.066$	Maximum entropy
Uniform distribution	$K_{en} = \sqrt{3} \approx 1.73$	Average entropy
Cauchy distribution and discrete binomial distribution	$K_{en} = 0$	Very low entropy

V. EXPERIMENTAL RESULTS AND DISCUSSIONS

Statistical analysis methods are used to record network traffic in a laboratory environment and identify unexpected events.

For verification, the recorded data was recorded at different times. The files in csv format were merged. Statistical analysis is performed based on this data.

A. Using Statistical Analysis Method

Fig. 5 shows the sample average value graph. In it, the sample average value is calculated based on Formula (14), $m_i = 1646.5714$, and according to the obtained result, the packet size in 9 flows was higher than the mean. This means that an unexpected situation occurred in the network flow.

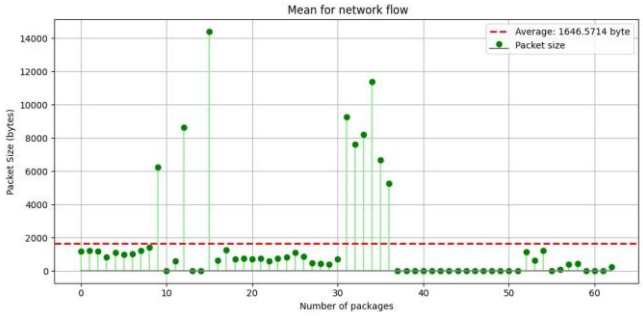

Fig. 5. Mean value graph of network flow.

In Fig. 6, the variance value was calculated based on Formula (15) and was equal to $D = 9474632.51^2$. In this statistical analysis, the square root of the variance of 9 network flows did not fall within the standard deviation range.

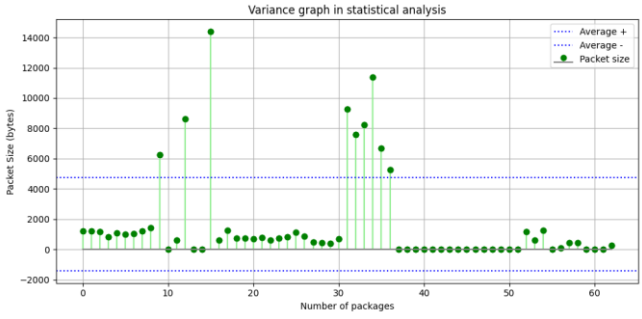

Fig. 6. Variance value graph of network flow.

The result of the asymmetry coefficient is presented in Fig. 7. The asymmetry coefficient is effective in determining how the data flow in the network is distributed, in which cases the packet size is small or large. This information is very important for

network optimization or security verification. The asymmetry coefficient helps to determine the presence of large packets in the network, which may indicate network congestion or problems. According to Formula (16), the asymmetry coefficient is equal to $K_a = 2.463632$. If the asymmetry coefficient is positive, this indicates a large number of large packets in the network and some uncertainties.

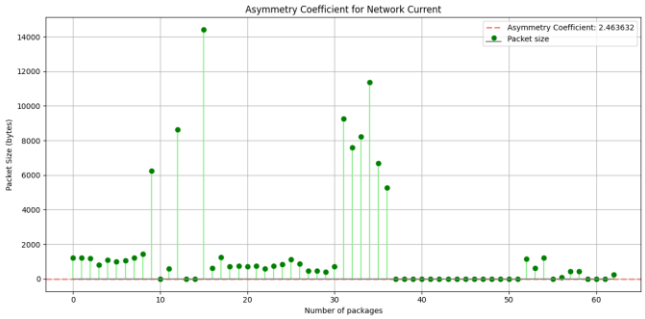

Fig. 7. Graph of the asymmetry coefficient of network flow.

The statistical distribution of the kurtosis coefficient can take very small or very large values. These results are useful in identifying unexpected situations in the network. In Fig. 8, the kurtosis coefficient is equal to $K_k = 8.352490$ according to Formula (17), which means that the value of the kurtosis coefficient is large. This indicates that there is an unexpected situation in the network.

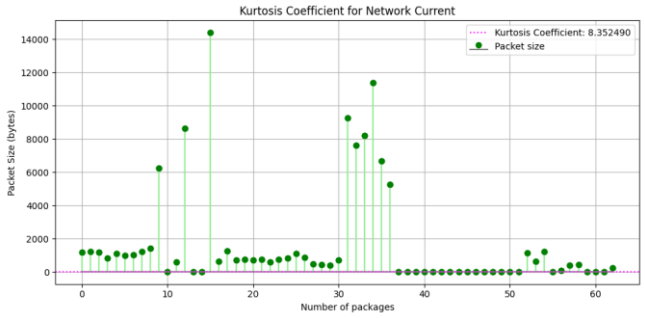

Fig. 8. Kurtosis coefficient graph of network flow.

The opposition coefficient is an indicator that provides deep statistical information about the symmetry and degree of deviation of the distribution in the network flow. The opposition coefficient is a very effective tool for identifying states in the network. The states that can be identified using K_{oc} are listed in Table II.

TABLE II. OPPOSITION COEFFICIENT CASES

Opposition coefficient	Distribution type	Note
$K_{oc} \approx 1.0$	Discrete, two-valued	Repeated and binary stream, 0 and 1500 byte packets, packets sent by test process or Botnet
$K_{oc} \approx 0.577$	Normal (Gaussian)	Stable network packet sizes are normally distributed
$K_{oc} < 0.4$	Heavy-tail	There are unexpected flows. For example, DoS or DDoS attacks, Botnets, etc.
$K_{oc} \approx 0$	Widely deviant distribution	Extremely dangerous, anomalous or exploitable condition

According to the result of the statistical analysis by recording the network current, the opposition coefficient is equal to $K_{oc} = 0.3516$. This indicates that there are unexpected situations in the network flow. In general, the combined use of statistical analysis results provides more accurate results. Fig. 9 presents the opposition coefficient result in graphical form.

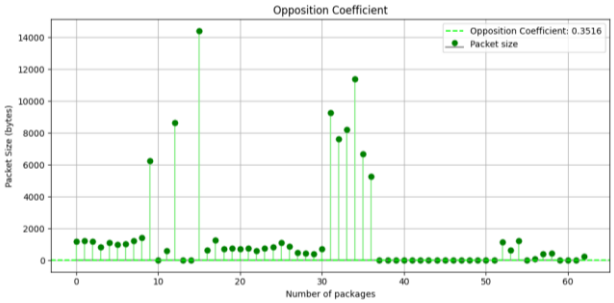

Fig. 9. Opposition coefficient in statistical analysis of network flow.

The entropy coefficient can be used to distinguish between normal and unexpected situations in a network. The entropy coefficient is an important statistical indicator for traffic analysis, attack detection, and security monitoring. As a result of the statistical analysis in Fig. 10, $K_{en} = 1.6231$. It indicates that there are different packets in the network flow, and there is an unexpected situation.

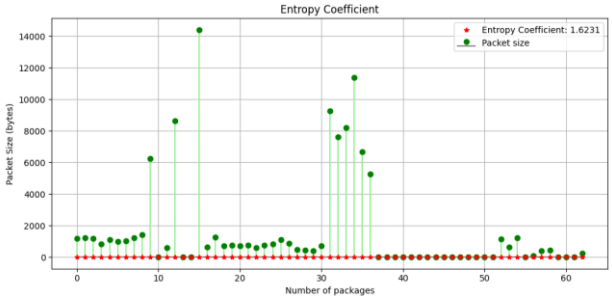

Fig. 10. Entropy coefficient in statistical analysis of network flow.

The analysis of the presented characteristics shows that the mean, variance, asymmetry coefficient, kurtosis coefficient, opposition coefficient, and entropy coefficient indicate the presence of unexpected situations in the network flow. Fig. 11 shows an overview of the research results.

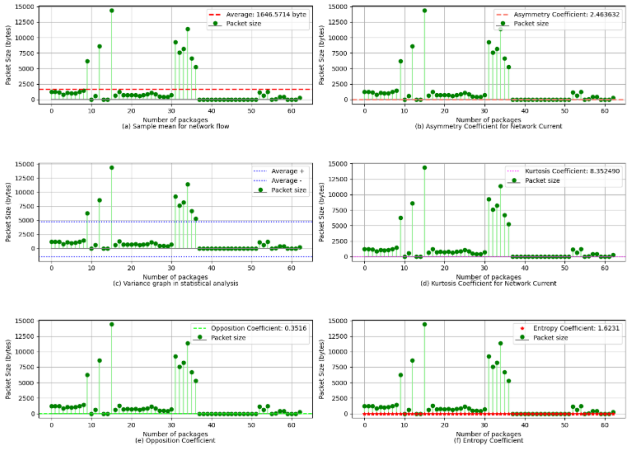

Fig. 11. General graph of statistical analysis results.

B. Markov Chain Construction Based on Statistical Analysis Results

Based on the results, statistical analysis methods are used to identify unexpected situations. The analysis of the obtained statistical characteristics shows that when an unexpected situation occurs in the network flow, the results of the mean and variance distinguish the unexpected situation, and the detection result may have an informative nature.

The values of the asymmetry coefficients and the kurtosis coefficient were large, and the values of the opposition coefficient and the entropy coefficient were low. According to the results of the study, these indicators are informative, since an unexpected situation occurs in the network flow. Table III shows the values of all statistical analysis results. The results obtained in the construction of the set of states of the Markov chain are the main value.

TABLE III. STATISTICAL ANALYSIS OF UNEXPECTED SITUATIONS IN NETWORK FLOW

№	Statistical analysis	The value of statistical analysis
1	Mean	$m_i = 1646.5714$
2	Variance	$D = 9474632.51^2$
3	Asymmetry coefficient	$K_a = 2.463632$
4	Kurtosis coefficient	$K_k = 8.352490$
5	Opposition coefficient	$K_{oc} = 0.3516$
6	Entropy coefficient	$K_{en} = 1.6231$

The Markov chain is evaluated based on the obtained statistical results. In the evaluation based on the Markov chain, based on the statistical analysis result, the first set of cases $X_0, X_1, X_2, \ldots$ is constructed, and the set of cases is presented in Table IV.

TABLE IV. SET OF STATES FOR A MARKOV CHAIN

№	Status name	Statistical analysis method
1	low load	variance, mean
2	average load	entropy coefficient, variance
3	high load	asymmetry coefficient, kurtosis coefficient

These three states were considered as states of the Markov chain, and based on the information obtained from the statistical analysis, the transition probability was calculated and a transition matrix was constructed according to Formula (1).

$$P = \begin{bmatrix} 0.4 & 0.4 & 0.2 \\ 0.2 & 0.4 & 0.4 \\ 0.1 & 0.2 & 0.7 \end{bmatrix}$$

The stationary probability was calculated using Formula (13). It was equal to $\pi = [0.1852 \quad 0.2963 \quad 0.5185]$.

Based on the transition probability matrix, Fig. 12 shows a graph of a Markov chain for network flow analysis. The graph shows the relationship between the three states.

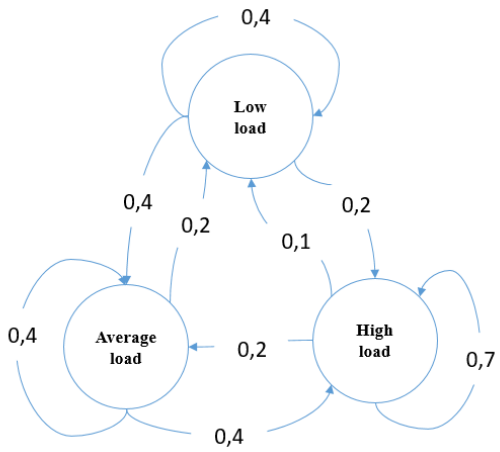

Fig. 12. Markov chain of network flow analysis.

VI. CONCLUSION

In solving the problem of detecting unexpected situations in network traffic, the use of statistical methods such as mean, variance, asymmetry coefficient, kurtosis coefficient, opposition coefficient and entropy coefficient supports the use of increasing efficiency and real-time operation. In detecting unexpected situations, packet features were extracted from the network traffic recorded in real time under laboratory conditions. Statistical analysis was performed using the extracted features. Markov chain is the most effective tool for analyzing situations and events occurring in network traffic and Markov chain was formed using the results of statistical analysis and Markov chain was constructed.

As a result, the low load stationary probability was 18.52%. This situation is rare in the system. This means that the network is in a low load state for a short time. The results of the statistical analysis correspond to the variance and mean, respectively. The average load stationary probability was 29.63%. This situation occurs moderately in the network flow. This means that there are changes, and the average load is frequent in the network. The high load stationary probability was 51.85%. The network flow time is more in this state. Therefore, the results of the statistical analysis are fully consistent with the results of the mean, variance, asymmetry coefficient and kurtosis coefficient. The Markov chain representing the probabilities of network states gave the same result as the statistical analysis.

In future work, using Markov chains in conjunction with statistical analysis methods will be effective. Markov chains are effective in showing the interaction between states when moving from one state to another. When used in conjunction with statistical analysis, the results of evaluating the object being analyzed will be more accurate.

***Abstract*—Surface defect detection of steel, especially the recognition of multi-scale defects, has always been a major challenge in industrial manufacturing. Steel surfaces not only have defects of various sizes and shapes, which limit the accuracy of traditional image processing and detection methods in complex environments. However, traditional defect detection methods face issues of insufficient accuracy and high miss-detection rates when dealing with small target defects. To address this issue, this study proposes a detection framework based on deep learning, specifically YOLOv9s, combined with the C3Ghost module, SCConv module, and CARAFE upsampling operator, to improve detection accuracy and model performance. First, the SCConv module is used to reduce feature redundancy and optimize feature representation by reconstructing the spatial and channel dimensions. Second, the C3Ghost module is introduced to enhance the model's feature extraction ability by reducing redundant computations and parameter volume, thereby improving model efficiency. Finally, the CARAFE upsampling operator, which can more finely reorganize feature maps in a content-aware manner, optimizes the upsampling process and ensures detailed restoration of high-resolution defect regions. Experimental results demonstrate that the proposed model achieves higher accuracy and robustness in steel surface defect detection tasks compared to other methods, effectively addressing defect detection problems.**

I. INTRODUCTION

The surface quality of steel is one of the key indicators for measuring its performance and reliability, and it is widely applied in high-precision fields such as aerospace, automotive manufacturing, and building structures. Surface defects not only compromise the aesthetic quality of steel but also jeopardize its structural integrity, potentially causing safety hazards. Therefore, steel surface defect detection has become an important task in modern manufacturing. Traditional defect detection methods, such as manual visual inspection, ultrasonic testing, and optical scanning, although still of certain value in specific situations, face issues such as low efficiency, poor accuracy, and difficulty in identifying complex defects due to their reliance on manual operation or being limited to specific detection conditions [1]. In particular, in large-scale production environments, manual inspection cannot meet the requirements for high speed, high precision, and high reliability [2].

In recent years, with the rapid development of deep learning technology, particularly breakthroughs in the field of computer vision, automated defect detection technology has seen significant improvements. Deep learning algorithms, especially Convolutional Neural Networks (CNNs), have demonstrated powerful capabilities in image recognition, enabling efficient and accurate identification and classification of various defects on steel surfaces. Compared to traditional methods, deep learning-based detection methods not only improve detection efficiency but also overcome the limitations of manual inspection, adapting to the complex and variable production environment. In particular, the YOLO (You Only Look Once) [3-6] object detection algorithm, due to its efficient real-time performance and accuracy, has been widely adopted for steel defect detection.

Many researchers have made significant contributions to the field of defect detection. For instance, Gao et al. [7] integrated the attention mechanism and weighted bi-directional feature pyramid network (BiFPN) into the YOLOv5 architecture, achieving good results. However, there are still certain shortcomings when handling small-sized defects. Yu et al. [8] proposed the introduction of structural reparameterization, context transformation modules, and simplified generalized feature pyramid networks to improve the model's accuracy. Although they performed excellently in terms of mAP, complex background noise affected defect detection performance, indicating that there is still room for improvement in the model's robustness to interference. Yang et al. [9] proposed a detection method combined with a supervised spatial attention module (SSAM) to improve the detection accuracy of defects such as surface cracks and rolled-in scale on steel. However, this method increases the computational complexity of the model and raises hardware requirements. Subburaj et al. [10] proposed the DBCW-YOLO model, which integrates attention mechanisms and enhanced feature extraction techniques to improve defect detection accuracy. However, integrating multiple advanced technologies increases the model's complexity, affecting real-time performance. Wu et al. [11] proposed the Hyper-YOLO model, which improves detection performance by replacing the CSP module in YOLOv5 with the Ghost module, the PAFPN module with the Hyper FPN module, and introducing α-CIoU and α-DIoU loss functions. However, these improvements increase the model's computational cost. Xu et al. [12] improved the YOLOv5 algorithm by introducing a coordinate attention

mechanism and multi-scale feature fusion, significantly improving the model's detection accuracy. However, these improvements increase the model's complexity, leading to longer training and inference times. Kong et al. [13] proposed an improved steel surface defect detection algorithm based on YOLOv8, enhancing small-target detection accuracy by introducing a non-attention mechanism and improving the SPPF module. However, the algorithm requires substantial computational resources, limiting its deployment in resource-constrained environments. Mi et al. [14] proposed a surface defect detection method for hot-rolled steel strips based on multi-scale feature perception and adaptive feature fusion, effectively improving the model's detection performance. However, it performs poorly when handling highly complex or noisy images and requires longer training times.

In summary, although significant progress has been made in existing steel surface defect detection algorithms, there are still numerous challenges and areas for optimization, especially regarding the detection accuracy of small-sized defects. To address this, this paper proposes a steel surface defect detection method based on deep learning with YOLOv9s, aiming to solve the problems encountered by current methods when handling small-sized defects through a series of optimization designs, thereby improving detection accuracy and efficiency. The core contributions of this study are mainly reflected in the following key aspects:

1) The SCConv module is adopted, and through the aforementioned reconstruction of spatial and channel dimensions, the model can reduce redundant information without losing important features, making the network more efficient and improving feature representation accuracy.

2) The C3Ghost module is introduced, which helps the model focus on the most distinguishable defect features by reducing redundant feature channels, while significantly decreasing the computational and memory load.

3) The CARAFE (Content-Aware Re-Assembly of Feature Maps) upsampling operator is incorporated, which, through content-based feature reorganization, dynamically adjusts the resolution of the feature map, thereby better preserving the spatial information of the image during the upsampling process.

II. Related Work

A. Depthwise Separable Convolution

Depthwise separable convolution [15] is an efficient convolutional operation that significantly reduces computational cost and parameter count by decomposing the traditional convolution operation into two simpler operations. This approach enhances the efficiency of neural networks. The process consists of the following steps: In a standard convolution, the input feature map has a size of $H \times W \times M$, the convolution kernel has a size of $K \times K \times M$, and the number of convolution kernels is N, resulting in an output feature map of size $H \times W \times N$. Consequently, the parameter count of standard convolution is $P_1 = K \times K \times M \times N$, and the computational cost is $C_1 = H \times W \times K \times K \times M \times N$.

Depthwise separable convolution decomposes the standard convolution kernel into two parts: depthwise convolution and pointwise convolution. Depthwise convolution applies $K \times K \times 1$ convolution kernels to each input channel independently, with a total of M such kernels. Pointwise convolution then uses $1 \times 1 \times M$ convolution kernels to combine all input channels, ultimately generating N output channels. This approach significantly reduces computational cost and parameter count, enhancing network efficiency. Consequently, the total parameter count of depthwise separable convolution is $P_2 = K \times K \times M + M \times N$, with a computational cost of $C_2 = K \times K \times M \times H \times W + M \times N \times H \times W$. Specifically, the parameter count for depthwise convolution is $K \times K \times M$, and for pointwise convolution, it is $M \times N$. The computational cost for depthwise convolution is $K \times K \times M \times H \times W$, while for pointwise convolution, it is $M \times N \times H \times W$.

From the perspective of parameter count and computational cost, depthwise separable convolution significantly reduces both by decomposing the operations of standard convolution. The ratios of the parameter count and computational cost between depthwise separable convolution and standard convolution are $\frac{P_2}{P_1} = \frac{K \times K \times M + M \times N}{K \times K \times M \times N} = \frac{1}{N} + \frac{1}{K^2}$ and, $\frac{C_2}{C_1} = \frac{K \times K \times M \times H \times W + M \times N \times H \times W}{H \times W \times K \times K \times M \times N} = \frac{1}{N} + \frac{1}{K^2}$, respectively. It can be observed that depthwise separable convolution effectively lowers computational overhead, especially when processing high-dimensional inputs. Therefore, compared to standard convolution, depthwise separable convolution offers higher computational efficiency.

B. YOLOv9 Algorithm

The YOLOv9 model features a unique design in its three key components: the backbone network, the neck network, and the head network. The backbone network adopts the General Efficient Layer Aggregation Network (GELAN), which ingeniously integrates CSPNet and ELAN. This fusion increases the network's width, facilitating smoother gradient flow throughout the network and enhancing its feature extraction capability. The neck network, serving as a crucial bridge between the backbone and head, employs the PGI-based multi-level auxiliary information module. This design enables each level of the feature pyramid to receive information on all object sizes, integrating gradient information from different prediction branches to facilitate parameter updates. As a result, it effectively achieves multi-scale feature fusion while incorporating both deep and shallow feature information without significantly increasing computational cost. The head network adopts a decoupled head design, which consists of two branches: a classification branch and a bounding box (box) branch. Additionally, it divides detection boxes into three scales—large, medium, and small—targeting objects of different sizes. The classification branch is responsible for predicting the object's category, while the bounding box branch focuses on determining the object's location. Each scale of detection boxes plays a distinct role in improving detection accuracy across different object sizes.

III. METHOD DESIGN

This study improves YOLOv9s [16], as shown in Fig. 1, by incorporating the SCConv module. The SCConv module dynamically adjusts the weights of different channels to more effectively capture important spatial information while suppressing irrelevant or redundant features. The C3Ghost module is introduced, and through an optimized design, it maintains a low computational cost, allowing the model to sustain fast inference speed even when handling complex tasks. Additionally, the CARAFE upsampling operator is used to reorganize the feature map in a content-aware manner, enhancing the fine-grained reconstruction of steel surface defect regions, making defect boundaries clearer.

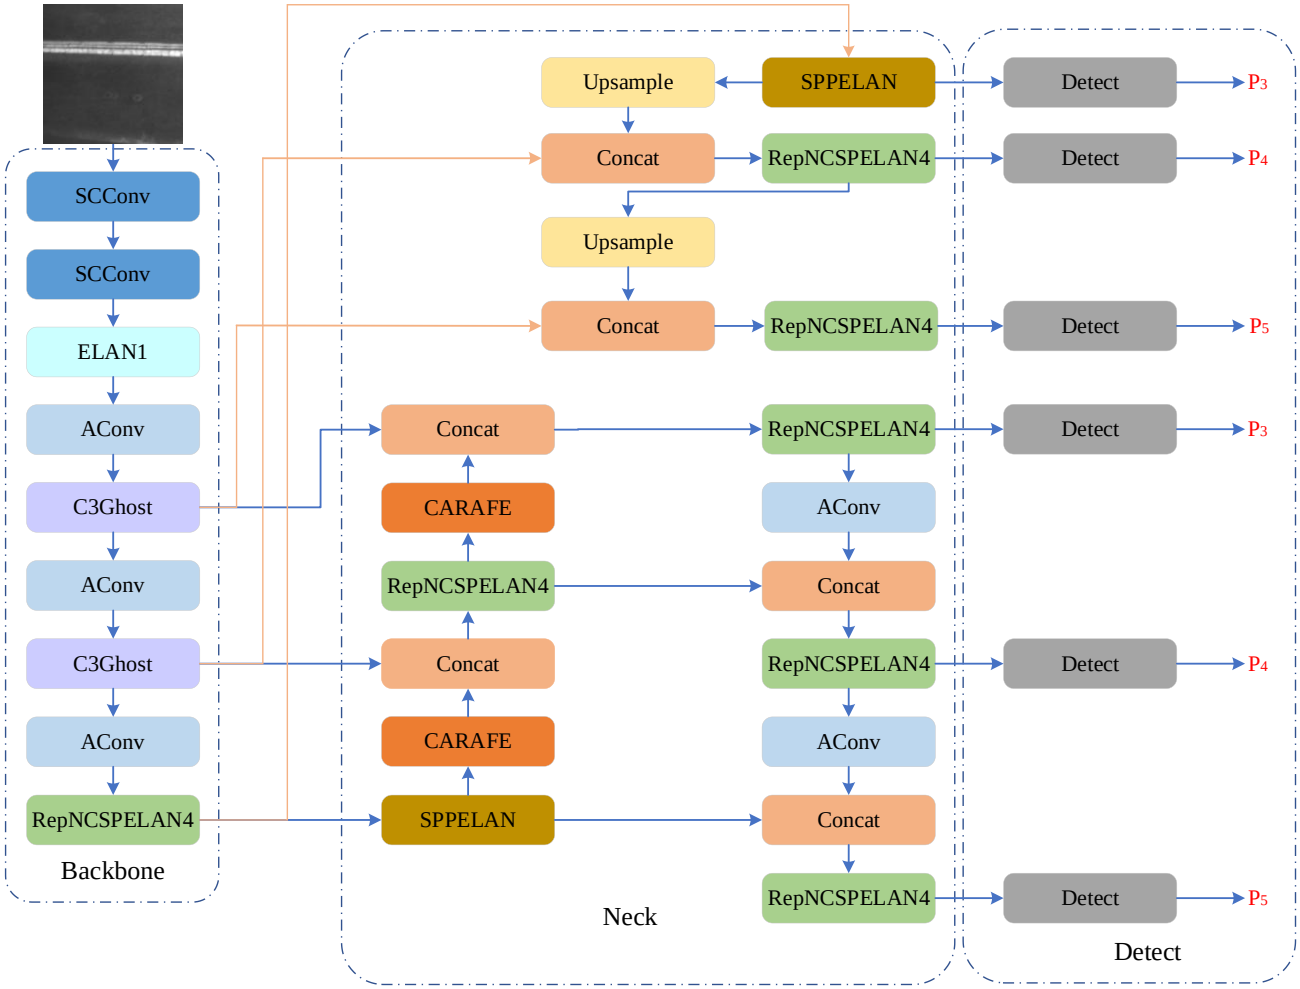

Fig. 1. Improved YOLOv9s network architecture diagram.

A. SCConv Module

YOLOv9s, as an efficient object detection model, demonstrates outstanding performance in various complex scenarios. However, its convolutional layers still exhibit redundancy in both spatial and channel dimensions during feature extraction, which not only increases the computational burden but also limits the efficiency of feature representation to some extent. To address this issue, we introduce the SCConv [17] (Spatial and Channel Reconstruction Convolution) module, which optimizes the features through the Spatial Reconstruction Unit (SRU) and Channel Reconstruction Unit (CRU), thereby reducing redundant computations and enhancing feature representation capability.

As shown in Fig. 2, to further elaborate on the principles and process of the SRU structure, we can delve deeper into the details of the separation and reconstruction operations. The core objective of the separation operation is to distinguish between feature maps with rich information and those with less information. In this way, the SRU can extract useful information while reducing reliance on irrelevant data.

First, the input feature map $X \in R(N \times C \times H \times W)$ is processed through normalization. This is done using the Group Normalization (GN) layer. This normalization operation helps to eliminate biases between different batches of data in convolutional neural networks, making the model training more stable. The normalization formula is [Formula (1)]:

$$X_{out} = GN(X) = \frac{\gamma(X-\mu)}{\sqrt{\sigma^2+\varepsilon}} + \beta \quad (1)$$

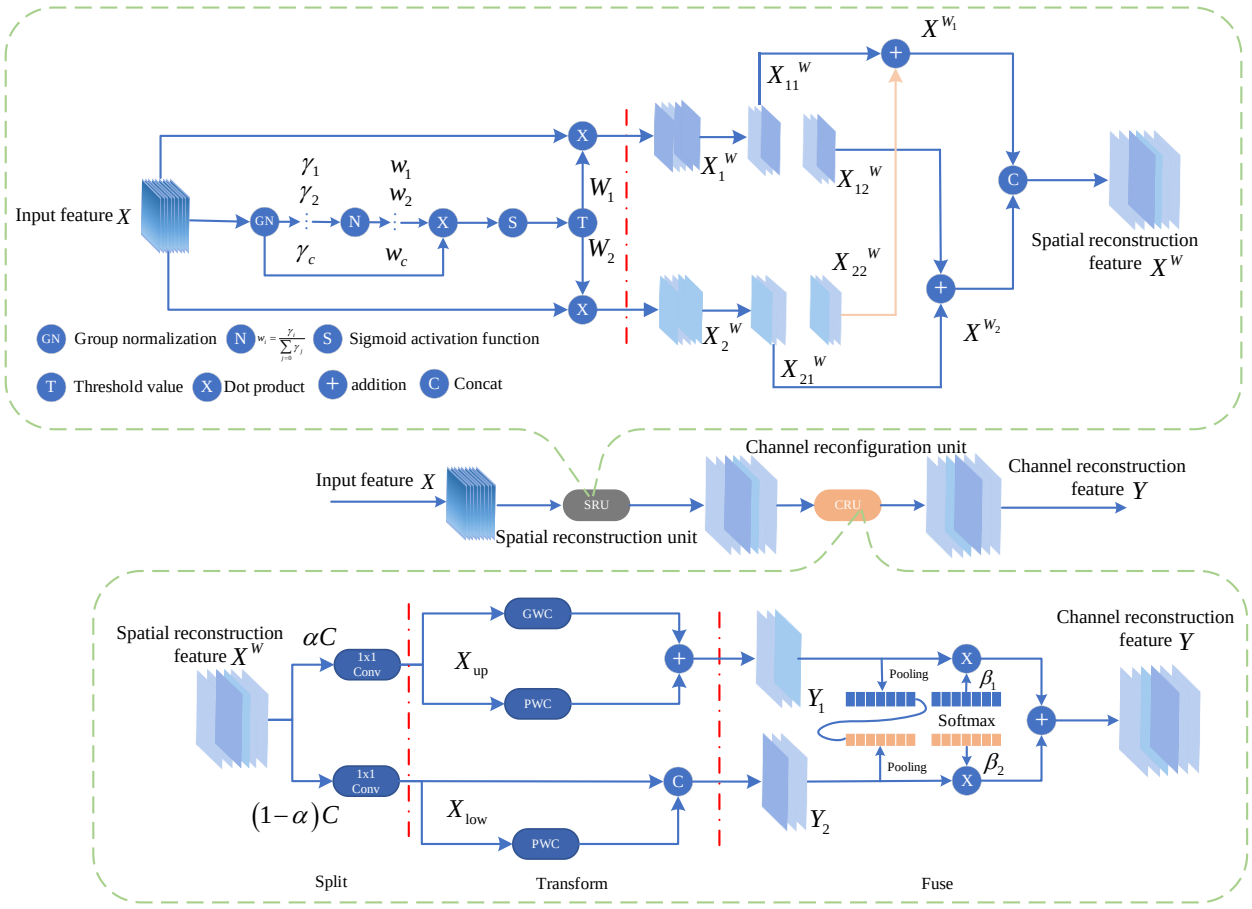

Fig. 2. SCConv module.

Here, μ and σ are the mean and standard deviation of the input feature map X along a specific dimension (usually the channel dimension). γ and β are the trainable affine transformation parameters, and ε is a small constant used to prevent division by zero when the standard deviation is zero.

Next, we calculate the weight W_γ based on each channel feature, which aims to measure the importance of each channel in the overall feature map. The calculation of weight W_γ is as follows [see Formula (2)]:

$$W_\gamma = \{w_i\} = \frac{\gamma_i}{\sum_{j=1}^{C}\gamma_j}, \quad i, j = 1, 2, \ldots, C \tag{2}$$

Here, γ_i represents the affine transformation parameters of each channel in group normalization. The normalization of the weights is performed by dividing each channel's γ_i by the sum of the affine parameters of all channels, ensuring that the weight values remain within a reasonable range.

Next, the normalized weight W_γ is gated through the Sigmoid activation function, yielding a value within the range (0, 1), which represents the "importance" of each channel feature. Specifically as in Formula (3):

$$W = \mathrm{Gate}(\sigma(W_\gamma(GN(X)))) \tag{3}$$

Here, σ (·) is the Sigmoid activation function, which restricts the output to the range (0, 1). Then, a threshold is set (usually 0.5), and the weights greater than this threshold are set to 1 to obtain information-rich weights W_1; weights smaller than the threshold are set to 0 to obtain information-poor weights W_2.

Subsequently, the input feature X is mapped through two different weight matrices W_1 and W_2, resulting in information-rich feature X_1^w and information-poor feature X_2^w. Then, these two types of features are fused through a cross-addition method to further enhance the expressive power of feature information and reduce spatial redundancy. Finally, the fused features X^{w1} and X^{w2} are concatenated together to obtain the final spatially reconstructed feature map X^w, which is represented by the following Formula (4):

$$\begin{cases} X_1^W = W_1 \otimes X, \\ X_2^W = W_2 \otimes X, \\ X_{11}^w \oplus X_{22}^w = X^{w1}, \\ X_{21}^w \oplus X_{12}^w = X^{w2}, \\ X^{w1} \bigcup X^{w2} = X^w. \end{cases} \tag{4}$$

In the formula, $\otimes$ represents element-wise multiplication, $\oplus$ represents element-wise addition, and $\bigcup$ represents the Concat module.

As shown in Fig. 2, the CRU (Channel Reduction Unit) structure is discussed in terms of how it optimizes feature maps through a series of operations to reduce redundancy and improve computational efficiency. The three main stages of CRU include Split, Transform, and Fuse.

In the Split stage, the feature map X^w is divided along the channel dimension into two parts: the upper part contains αC channels, and the lower part contains $(1-\alpha)C$ channels, where α is a tunable parameter, typically set to 0.5, indicating that the feature map is split into two equal parts. The purpose of this step is to reduce the number of channels in each part, thereby reducing the computational burden. Next, a 1x1 convolution operation is applied to compress the number of channels in the feature map. The 1x1 convolution has the ability to reduce the number of channels while also serving as a tool for feature transformation. The compression ratio r controls the number of channels in the output feature map, balancing the trade-off between computational cost and performance. The compressed feature map is then divided into the upper part X_{up} and the lower part X_{low}, preparing for the next stage of operations.

The Transform stage is the core part of the CRU, primarily aimed at extracting features and enhancing computational efficiency through two operations: In the upper transformation stage, the input is the upper part of the feature map X_{up} obtained from the split. Groupwise Convolution (GWC) and Pointwise Convolution (PWC) are used for feature extraction. Groupwise Convolution divides the input channels into several small groups for convolution operations, thereby reducing computational complexity. Pointwise Convolution performs a 1×1 convolution at each pixel location to further extract features. The formula for the upper transformation is [Formula (5)]:

$$Y_1 = M^G X_{up} + M^{P_1} X_{up} \tag{5}$$

Here, M^G and M^{P_1} are the learnable weights of GWC and PWC, respectively, and Y_1 is the output feature map of the upper transformation stage.

In the lower transformation stage, the input is the lower part of the split feature map X_{low}. PWC is used to extract features, and the result is concatenated with the original X_{low} feature map. The concatenation operation is denoted by the symbol $\bigcup$. The formula for the lower transformation is [Formula (6)]:

$$Y_2 = M^{P_2} X_{low} \bigcup X_{low} \tag{6}$$

Here, M^{P_2} is the learnable weight of PWC, and Y_2 is the output of the lower transformation stage.

In the Fusion stage, the simplified SKNet method is used to merge the output features Y_1 and Y_2 from the upper and lower transformation stages. Global spatial information is obtained through global average pooling. The formula for the global channel descriptor S_m is as follows [Formula (7)]:

$$S_m = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} Y_c(i, j), m = 1, 2 \tag{7}$$

Subsequently, the two global channel descriptors S_1 and S_2 are stacked together.

Channel attention operations are used to generate importance weights β_1 and β_2, which represent the importance of the corresponding channels. The calculation formula is as follows [Formula (8)]:

$$\beta_1 = \frac{e^{s_1}}{e^{s_1} + e^{s_2}}, \beta_2 = \frac{e^{s_2}}{e^{s_1} + e^{s_2}} \tag{8}$$

Finally, the reconstructed feature $\beta_1 Y_1 + \beta_2 Y_2$ is obtained through the weighted calculation.

B. C3Ghost Module

In the YOLOv9s model, the main goal of replacing the RepNCSPELAN4 module with the C3Ghost [15,18] module is to enhance the model's computational efficiency and detection performance. The core idea behind the design of the C3Ghost module is to optimize the network structure, reduce computational load and the number of parameters, while not sacrificing the model's detection accuracy, thereby achieving efficient object detection. Compared to traditional convolutional modules, the C3Ghost module uses the GhostConv operation, which can extract more effective features at a lower computational cost. Therefore, we introduced the C3Ghost module to significantly improve computational efficiency while maintaining detection accuracy.

As shown in Fig. 3, the workflow of the C3Ghost module is as follows: First, the input feature map X is processed through a convolution layer (Conv) for preliminary processing. Then, it passes through multiple GhostConvBottleneck modules, which improve efficiency by reducing computational load and the number of parameters, while enhancing feature extraction capabilities. After that, a Concat operation is performed, followed by a Conv operation from another path. Finally, the concatenated feature map undergoes a convolution layer (Conv) to generate the final output X.

C. CARAFE Upsampling Operator

The CARAFE [19] upsampling operator is introduced in the YOLOv9s model to replace traditional upsampling methods, primarily due to its unique advantages. CARAFE is a content-aware upsampling mechanism that dynamically adjusts the upsampling process based on the input features, generating higher-quality feature maps, especially excelling in small object detection. Therefore, using the CARAFE upsampling operator can improve the model's detection accuracy for small objects and overall performance.

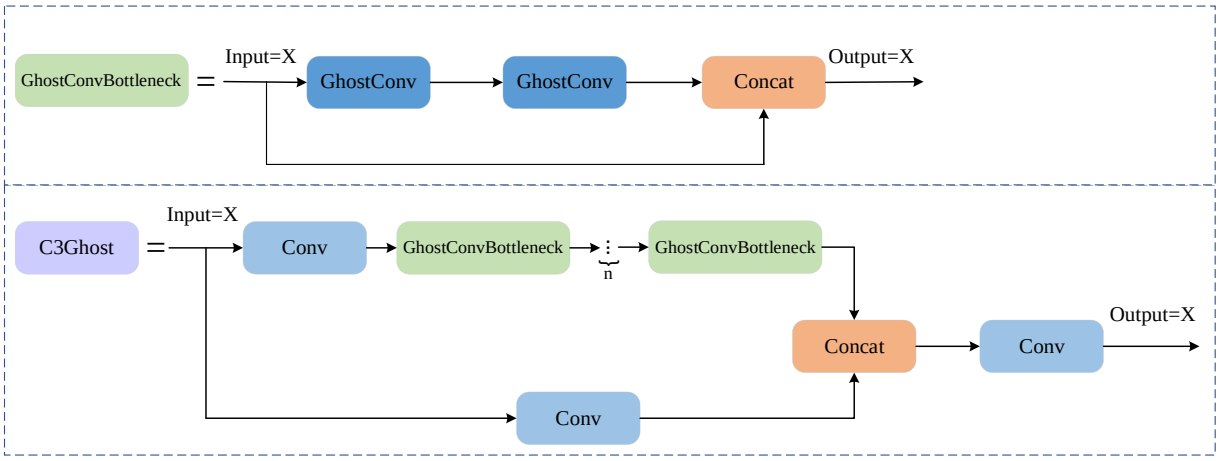

Fig. 3. C3Ghost module.

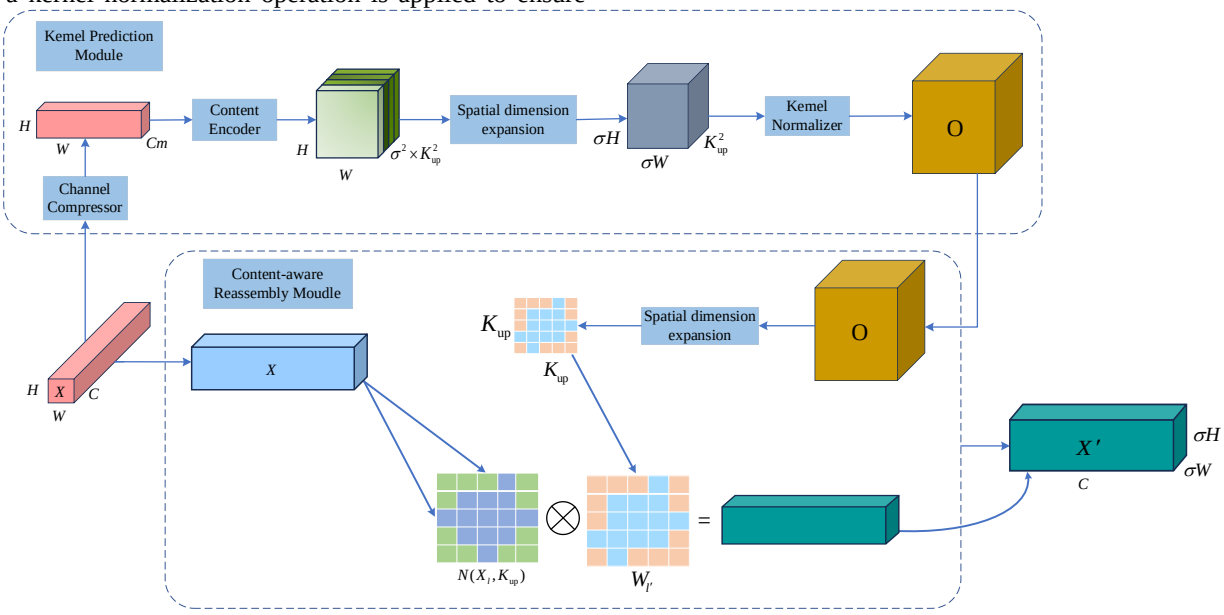
As shown in Fig. 4, in the upsampling kernel prediction section, first, the channel compression part compresses the input feature map X using a weight matrix W, reducing the number of channels from C to C_m, resulting in a compressed feature representation. Next, the feature map undergoes content encoding, converting the input feature map into a more processable form. Then, a spatial dimension expansion operation is performed to obtain an upsampling kernel of the form $\sigma H \times \sigma W \times k_{up}^2$, where the upsampling factor σ is set. Finally, a kernel normalization operation is applied to ensure that the sum of the kernel weights equals 1, resulting in the output feature map O.

In the feature reorganization section, the feature map undergoes spatial dimension expansion, converting into feature blocks of $K_{up} \times K_{up}$. These feature blocks will prepare for the final upsampling operation. Finally, a pointwise operation is performed, where the expanded feature blocks are corresponded with the points in the original feature map, generating the final upsampled feature map X'.



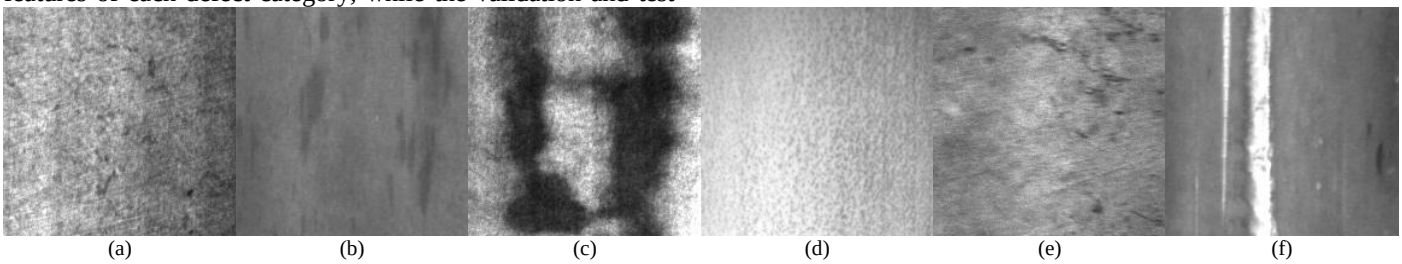


Fig. 4. CARAFE Upsampling operator.

IV. Experimental Setup

A. Dataset

The steel surface defect dataset used in this study, provided by Northeastern University, contains six typical defect categories: a) Crazing, b) Inclusion, c) Patches, d) Pitted Surface, e) Rolled-in Scale, and f) Scratches. The dataset consists of 1,800 images, with 300 samples for each category, ensuring a balanced distribution that comprehensively covers common defect types and features found on steel surfaces. These images were captured using industrial equipment and authentically reproduce the visual characteristics and complexity of surface defects in real-world production processes. Each image is annotated with bounding boxes, a common format used in object detection tasks, which include the defect location and corresponding category information. To reasonably allocate the dataset for training and testing purposes, it is divided into training, validation, and test sets in a 7:1:2 ratio, containing

1,260, 180, and 360 images, respectively. This division ensures that the training phase has sufficient data to effectively learn the features of each defect category, while the validation and test sets provide a scientific evaluation of the model's performance. The six types of steel surface defect images are shown in Fig. 5.

(a) (b) (c) (d) (e) (f)

Fig. 5. Six types of steel surface defects.

B. Experimental Platform

The experiments in this study were conducted on a high-performance computing platform with comprehensive software and hardware configurations, which fully meet the computational resource requirements of deep learning tasks. The software environment uses the Ubuntu 20.04 operating system, with model development and training based on Python 3.8 and PyTorch 1.11.0, and it supports CUDA 11.3 acceleration, significantly improving the efficiency of large-scale data processing during training. The hardware environment includes an NVIDIA RTX 4090 GPU (24GB memory), providing powerful support for deep learning computations; a 22-core AMD EPYC 7T83 64-Core Processor (vCPU), suitable for data preprocessing and training task scheduling; 90GB of RAM, ensuring stable loading of high-resolution images and large-scale model training; as well as a 30GB system disk and a 50GB data disk, used for operating system operation and experimental data storage, respectively. This platform adopts GPU and CPU parallel acceleration to fully utilize computational resources, improving experimental efficiency and task processing capabilities. Additionally, its software and hardware combination offer high stability and scalability, supporting the optimization and expansion needs of future experiments.

C. Hyperparameter Settings

This study made reasonable settings for the training parameters to maximize model performance while ensuring efficient training. During the training process, the pre-trained model "yolov9-s.pt" was loaded, and the image resolution was set to 640×640. The batch size was set to 8 to adapt to hardware resources and ensure the stability of gradient updates. The number of epochs was set to 300 to ensure that the model fully learns the feature patterns in the data. The number of workers was set to 4 to parallelize the data loading process, thereby improving training efficiency. In terms of optimizer parameters, the learning rate was set to 0.01, which provides a good balance between model convergence speed and training stability. The momentum parameter was set to 0.937 to reduce gradient oscillation and accelerate the convergence process. The weight decay coefficient was set to 0.0005 to limit the model's complexity and prevent overfitting. With these fine-tuned parameter settings, this study ensured both the efficiency of the training process and the stability of model performance.

D. Evaluation Metrics

The experiments in this study use F1 score, Precision (P), Recall (R), Average Precision (AP), and mean Average Precision (mAP) as evaluation metrics [20], and also consider the number of parameters (Parameters). The calculation formulas for these metrics are as follows [Formula (9) to (13)]:

$$\text{Precision} = \frac{T_{\text{p}}}{T_{\text{p}} + F_{\text{p}}} \tag{9}$$

$$\text{Recall} = \frac{T_{\text{p}}}{T_{\text{p}} + F_{\text{N}}} \tag{10}$$

$$\text{AP} = \int_0^1 P(R)\text{d}R \tag{11}$$

$$\text{mAP} = \frac{1}{n}\sum_{\text{i}=0}^{n} AP(i) \tag{12}$$

$$\text{F1} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{13}$$

Here, T_{p} represents the number of correctly detected defect targets; F_p represents the number of incorrectly detected defect targets; F_N represents the number of missed defect targets; n represents the number of defect categories; and $AP(i)$ represents the average precision for the i-th target class.

V. Experimental Analysis

A. Algorithm Comparison Experiment

To validate the proposed performance improvements, we compared the improved YOLOv9s model (Ours) to RT-DETR-18, Faster RCNN, SSD, and seven other mainstream YOLO target detection models, all tested on the same data set and training rounds. The results are shown in Table I. The comparison metrics include Precision, Recall, mean Average Precision (mAP@0.5), Frames Per Second (FPS), computational complexity (GFLOPS), and model parameter count (Params). These metrics enable us to evaluate the performance of each algorithm and its efficiency under different computational resources. Among all the algorithms, the proposed improved model demonstrates a superior balance between precision and recall, while also achieving significant improvements in mAP and inference speed.

TABLE I. EXPERIMENTAL COMPARISON RESULTS OF DIFFERENT ALGORITHMS

Algorithm	Precision/%	Recall/%	mAP@0.5/%	FPS (f/s)	GFLOPS	Params (M)
Faster R-CNN[21]	79.9	—	77.5	—	—	—
SSD[22]	70.2	—	68.6	—	—	—
YOLOv5s[23]	71.7	71.2	75.2	208.3	15.8	7.02
YOLOv7[24]	63.3	74.8	71.7	109.8	103.2	36.50
YOLOv8s[25]	75.7	67.1	71.7	312.5	28.4	11.12
YOLOv9s	70.7	77.3	78.1	94.3	38.7	9.60
YOLOv10s[26]	77.5	67.4	74.4	125.0	24.5	8.03
YOLOv11s[27]	74.1	74.7	78.4	86.2	21.3	9.41
RT-DETR-18[28]	79.3	67.4	73.4	68.0	57.0	19.87
Ours	**77.0**	**72.4**	**79.6**	**109.9**	**36.9**	**9.07**

Table I presents the comparison experiment results of various object detection algorithms, including Precision, Recall, mean Average Precision (mAP@0.5), Frames Per Second (FPS), computational complexity (GFLOPS), and model parameter count (Params). Among these algorithms, The Precision of Faster R-CNN reached 79.9%, and the mAP@0.5 achieved 77.5%. The Precision of SSD reached 70.2%, and the mAP@0.5 achieved 68.6%. YOLOv5s has a high inference speed (208.3 FPS) and low computational complexity (15.8 GFLOPS), but its Precision (71.7%) and Recall (71.2%) are relatively moderate. YOLOv7 performs well in Recall (74.8%), but its Precision is lower (63.3%) and computational complexity is higher. YOLOv8s achieves a high Precision (75.7%) but has a lower Recall (67.1%) and an extremely fast inference speed (312.5 FPS). YOLOv9s performs well in Recall and mAP (78.1%), but its inference speed is slower (94.3 FPS). YOLOv10s has high Precision (77.5%) with moderate inference speed (125.0 FPS). YOLOv11s shows a high Recall (74.7%) but slower inference speed (86.2 FPS). RT-DETR-18, although having high Precision (79.3%), has slower inference speed and lower mAP (73.4%). Our model achieves a good balance in both Precision (77.0%) and Recall (72.4%), with an mAP of 79.6%, inference speed of 109.9 FPS, moderate computational complexity (36.9 GFLOPS), and a model parameter count of 9.07 M. It demonstrates high overall performance, making it an efficient and balanced choice.

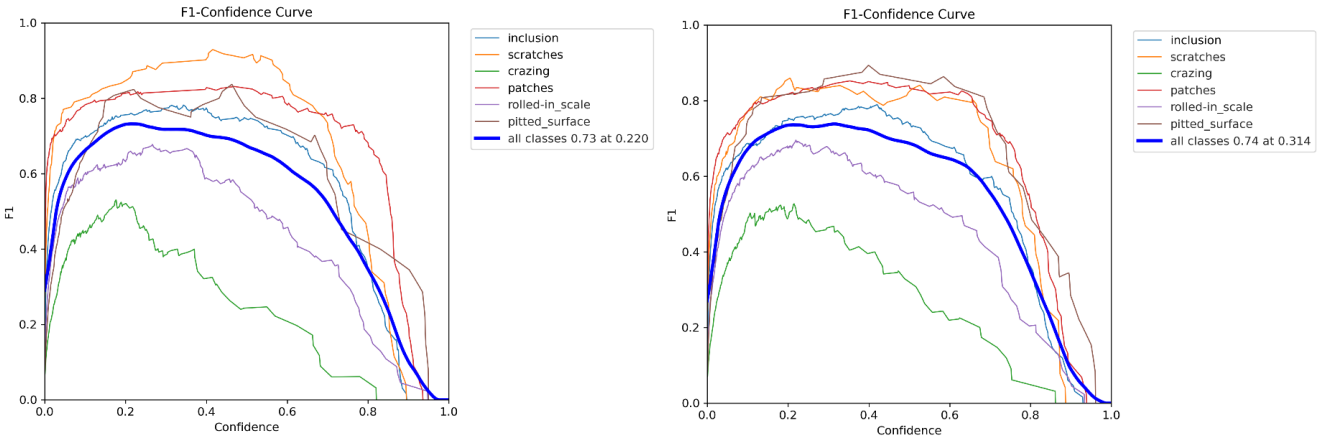

TABLE II. COMPARISON OF VARIOUS ALGORITHMS IN TERMS OF AVERAGE PRECISION (AP%)

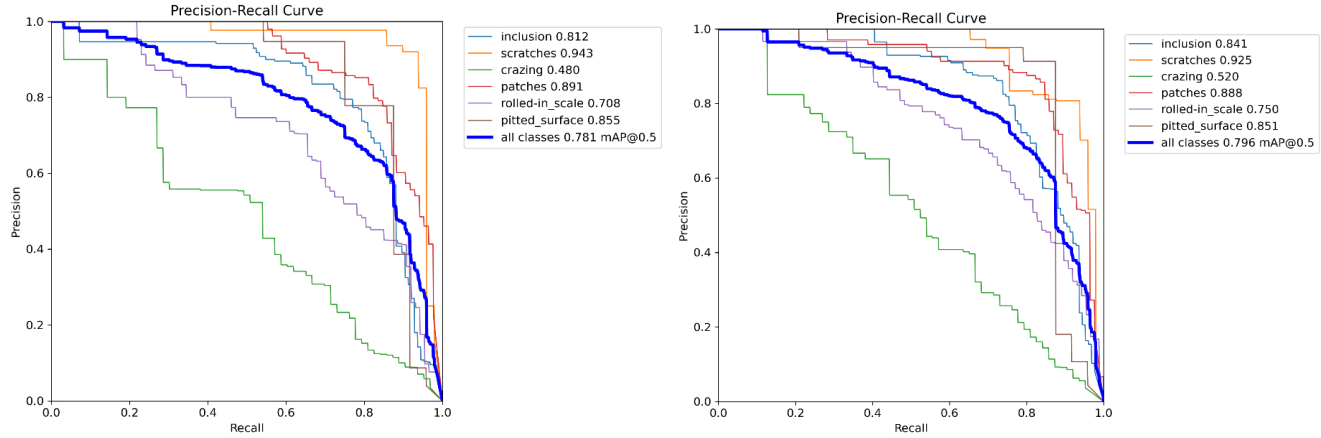
Algorithm / Category	Inclusion	Scratches	Crazing	Patches	Rolled-in_Scale	Pitted_Surface
YOLOv5s	78.6	91.1	41.3	89.1	70.9	80.3
YOLOv7	75.6	80.5	38.9	89.9	66.6	78.9
YOLOv8s	70.2	89.0	32.8	86.4	66.1	85.7
YOLOv9s	81.2	94.3	48.0	89.1	70.8	85.5
YOLOv10s	75.8	90.5	43.8	81.7	74.0	80.7
YOLOv11s	82.1	92.3	49.0	89.9	69.5	87.8
RT-DETR-18	78.6	93.1	48.9	88.0	52.5	79.5
Ours	**84.1**	**92.5**	**52.0**	**88.8**	**75.0**	**85.1**

Based on the Average Precision (AP) comparison results in Table II, the "Ours" model performs the best across multiple defect categories, particularly excelling in the inclusion and crazing categories, with precision rates of 84.1% and 52.0%, respectively, significantly higher than all other algorithms. YOLOv9s and YOLOv11s also perform well in most categories, especially in scratches, where they achieve precision rates of 94.3% and 92.3%, respectively, although they are slightly lacking in the Rolled-in_scale category. YOLOv5s, YOLOv7, and YOLOv10s perform well in the scratches and patches categories, but their precision in crazing and Rolled-in_scale is lower. YOLOv8s shows strong performance in scratches and Pitted_surface, but lags significantly in crazing. RT-DETR-18 also demonstrates good performance in scratches and crazing. In summary, the "Ours" model outperforms other algorithms across multiple defect categories, showing significant performance improvements.

B. Result Visualization

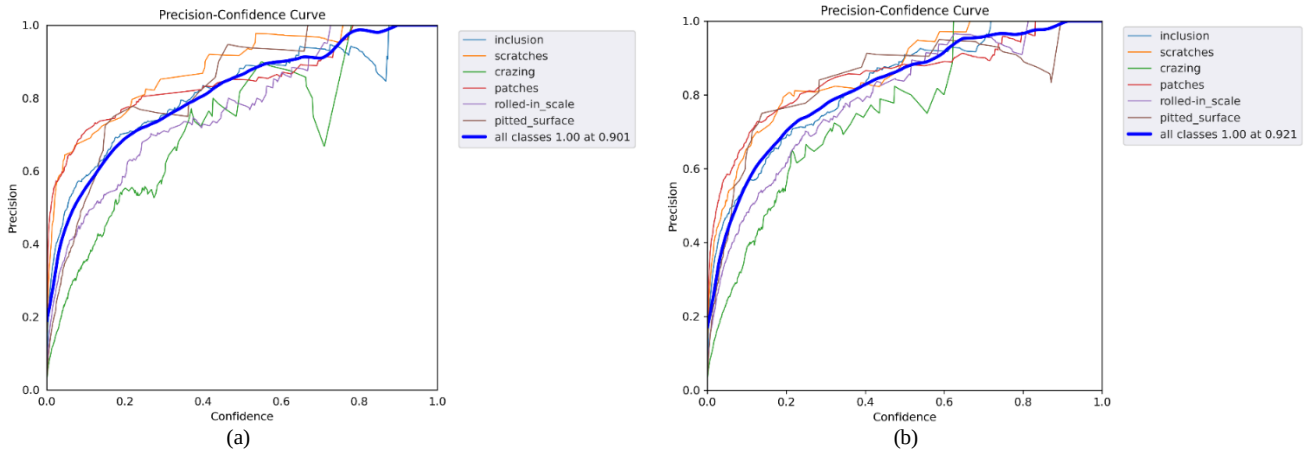


To evaluate the effectiveness of the improved algorithm, it needs to be compared with the original algorithm. YOLOv9s, as a classic object detection algorithm, is widely used in various tasks. With continuous optimization of the algorithm, the improved YOLOv9s has shown better performance in both precision and recall. The F1 score, which considers both precision and recall, provides an effective way to assess the algorithm's performance in detection tasks. By comparing the F1 scores of YOLOv9s and the improved YOLOv9s, we can visually understand the improvements in the balance between precision and recall, thereby evaluating the performance optimization effect of the improved algorithm.

(a) (b)

Fig. 6. F1-Confidence Curve: (a) YOLOv9s Algorithm; (b) Improved YOLOv9s Algorithm.

Fig. 6 displays the F1-Confidence curves for both YOLOv9s and the improved YOLOv9s. The blue curve represents the F1 score for all categories. From the comparison, it is evident that the improved YOLOv9s shows a significant enhancement in F1 scores across categories, particularly in the higher confidence regions, indicating a clear optimization in precision. Specifically, in the left-side YOLOv9s plot, the blue curve reaches an F1 score of 0.73 at a confidence of 0.220, while in the right-side improved YOLOv9s plot, the blue curve reaches an F1 score of 0.74 at a confidence of 0.314. This demonstrates that the improved YOLOv9s has an overall increase in F1 score across all categories, with better performance at higher confidence levels.



(a) (b)

Fig. 7. Precision-Recall Curve: (a) YOLOv9s Algorithm; (b) Improved YOLOv9s Algorithm.

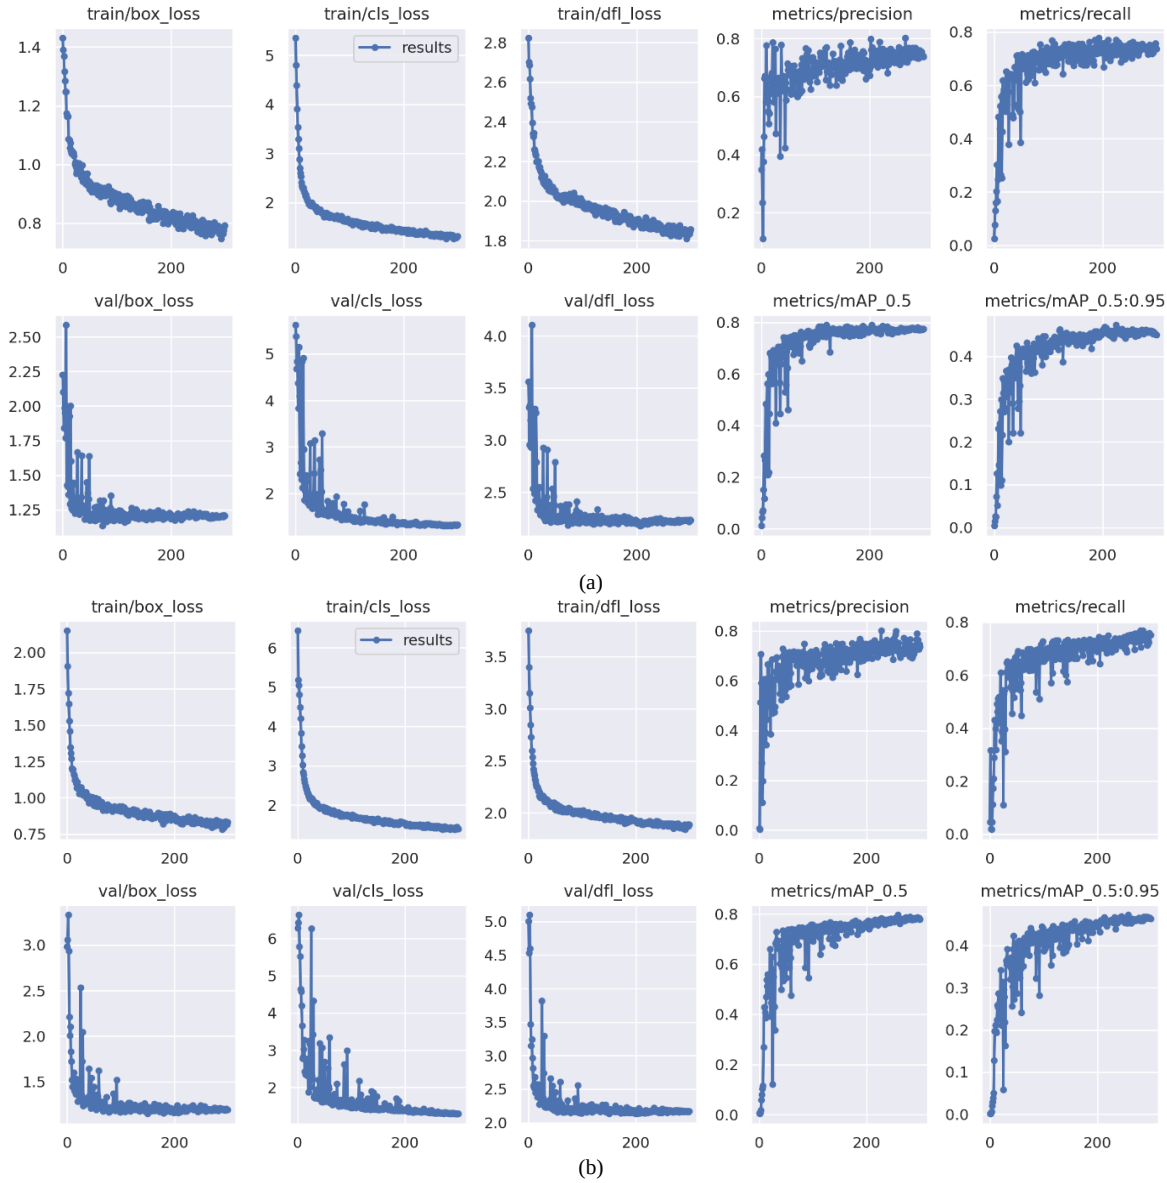


Fig. 7 shows the Precision-Recall (PR) curves for YOLOv9s and the improved YOLOv9s across different categories. In the left-side YOLOv9s plot, the blue curve represents the Precision-Recall curve for all categories, with an mAP value of 0.781. In the right-side plot of the improved YOLOv9s, the blue curve has an mAP value of 0.796, which shows an improvement over YOLOv9s, indicating that the improved algorithm performs better in balancing precision and recall. Overall, the improved YOLOv9s shows enhanced precision across multiple categories, particularly in the "inclusion" and "crazing" categories, where the improved algorithm demonstrates superior performance.

Fig. 8 shows the Precision-Confidence curves for YOLOv9s and the improved YOLOv9s across different categories. In the left-side YOLOv9s plot, the blue curve represents the Precision-Confidence curve for all categories, with a precision of 1.00 at a confidence of 0.901. In the right-side plot of the improved YOLOv9s, the blue curve also reaches a precision of 1.00, but at a confidence of 0.921. A comparison reveals that the improved YOLOv9s shows an overall increase in precision at higher confidence levels and outperforms YOLOv9s in multiple categories, especially demonstrating more stable precision at lower confidence levels.

(b)

Fig. 9. Change Curves of Various Loss Functions and Evaluation Metrics During Training and Validation: (a) YOLOv9s Algorithm; (b) Improved YOLOv9s Algorithm.

Fig. 9 shows the change curves of various loss functions and evaluation metrics during the training and validation process for YOLOv9s and the improved YOLOv9s. These include box loss, classification loss, depth regression loss, precision, recall, and mean average precision (mAP). It can be observed that as training progresses, the losses for both the training and validation sets gradually decrease, indicating continuous improvement in the model's performance in box prediction, classification, and depth regression. Meanwhile, the precision, recall, and mAP metrics also increase, showing a significant improvement in the detection capabilities of the improved YOLOv9s. Overall, the improved YOLOv9s outperforms YOLOv9s across all metrics, demonstrating effective optimization and stronger detection performance during training.

As shown in Fig. 10 below, we compare the detection results of various algorithms on the steel surface defect dataset, including a) Faster R-CNN, b) SSD, c) YOLOv5s, d) YOLOv7, e) YOLOv8s, f) YOLOv9s, g) YOLOv10s, h) YOLOv11s, i) RT-DETR-18, and j) Ours. Through intuitive visualization, we can clearly observe the recognition performance of each algorithm on different targets, including localization accuracy and classification confidence. The improved algorithm (Ours) demonstrates higher localization accuracy across multiple defect categories, showing a distinct advantage over the other algorithms. These comparisons allow us to more comprehensively assess the performance improvements of the improved algorithm in practical applications.

Based on the visualization results of steel surface defect detection shown in Fig. 10, different models exhibit varying advantages and disadvantages when detecting defects such as crazing, inclusion, patches, pitted surface, rolled-in scale, and scratches. Overall, traditional object detection methods like Faster R-CNN and SSD have certain limitations. Although Faster R-CNN produces more detection boxes, it suffers from severe target overlapping, making small targets prone to being missed. SSD performs well in detecting large targets but has weaker recognition capabilities for small targets, resulting in a relatively low overall recall rate. In comparison, YOLOv5s demonstrates a noticeable improvement in both recall rate and precision over SSD, although some instances of missed detection still occur. YOLOv7 performs slightly worse than YOLOv5s, with a higher false detection rate and an unremarkable recall rate. YOLOv8s performs well in detecting large and medium-sized targets but still struggles with certain small targets. YOLOv9s and YOLOv10s further enhance detection confidence and recall rates, showing improved detection performance for rolled-in scale and scratches while reducing false detections. YOLOv11s achieves the best overall performance among all categories, offering higher recall rates and confidence scores, more precise detection boxes, and the lowest false detection rate. Additionally, RT-DETR-18 achieves a well-balanced trade-off between precision and recall. Compared to the YOLO series, it provides higher detection confidence and a lower false detection rate, particularly demonstrating stable performance in detecting pitted surfaces

and patches. However, there is still room for improvement in detecting certain small targets, such as scratches. Ultimately, the proposed model (Ours) outperforms all other detection models, delivering the most precise detection boxes, the highest recall rate, the most stable confidence scores, and the lowest false detection rate. Compared with other models, it accurately identifies all defect categories, effectively avoiding common issues of missed and false detections. Notably, it shows significant advantages in detecting small targets such as scratches and inclusions, highlighting its high applicability and reliability in steel surface defect detection tasks. Future optimizations could focus on enhancing detection capabilities for extremely small targets (e.g., fine scratches) to improve detection sensitivity, making it even more efficient and precise for industrial inspection applications.

C. Ablation Study

To further validate the impact of different modules on model performance, we conducted ablation experiments. The ablation study compares the performance of different model combinations across multiple performance metrics, including Precision, Recall, mean Average Precision (mAP), Frames Per Second (FPS), GFLOPS, and parameter count (Params). These experiments aim to assess the contribution of each module to the model's performance, helping us understand which optimizations effectively improve the detection results.

TABLE III. ABLATION STUDY RESULTS

Number	Experiment	Precision/%	Recall/%	mAP@0.5/%	FPS (f/s)	GFLOPS	Params (M)
1	YOLOv9s	70.7	77.3	78.1	94.3	38.7	9.60
2	YOLOv9s+CARAFE	76.4	71.3	78.3	82.6	39.0	9.74
3	YOLOv9s+C3Ghost	78.4	70.3	79.5	131.5	34.5	8.91
4	YOLOv9s+SCConv	73.9	75.5	79.1	75.7	40.8	9.62
5	YOLOv9s+CARAFE+C3Ghost+SCConv	**77.0**	**72.4**	**79.6**	**109.9**	**36.9**	**9.07**

According to the ablation experiment results in Table III, each model shows different performance across various metrics such as precision, recall, mAP, FPS, GFLOPS, and parameter count. Experiment 1 uses YOLOv9s as the baseline model, with a precision of 70.7%, recall of 77.3%, mAP of 78.1%, and FPS of 94.3, demonstrating good performance. Experiment 2 introduces the CARAFE module based on Experiment 1, increasing precision to 76.4%, but recall drops to 71.3%, and FPS significantly decreases to 82.6. Experiment 3 adds the C3Ghost module to Experiment 1, resulting in a further improvement in precision to 78.4% and a slight decrease in recall to 70.3%. Additionally, the FPS notably increases to 131.5, reflecting significant speed optimization. Experiment 4 introduces the SCConv module based on Experiment 1, improving both precision and recall, but FPS drops to 75.7. Finally, Experiment 5 combines the CARAFE, C3Ghost, and SCConv modules, showing improvements in precision, recall, and mAP, with precision at 77.0%, recall at 72.4%, mAP at 79.6%, and FPS rising to 109.9, despite a slight increase in parameter count. Overall, Experiment 5 (YOLOv9s + CARAFE + C3Ghost + SCConv) achieves a better balance between precision and speed, showing significant improvements over the baseline model.

VI. DISCUSSION

Although the improved YOLOv9s model achieves significant enhancements in defect detection performance, several limitations were observed during experimental testing. First, the model's detection accuracy slightly declines when dealing with extremely small-sized defects, such as fine scratches or micro-inclusions, particularly under conditions of strong illumination interference or highly complex surface textures. Second, while the introduction of the SCConv, C3Ghost, and CARAFE modules enhances feature representation and reconstruction capabilities, the complexity of the combined modules leads to a marginal increase in inference latency compared to the original YOLOv9s. Although the overall computational overhead remains acceptable, this factor could pose potential challenges for deployment in ultra-real-time industrial detection systems where strict latency requirements exist. In future work, optimizing the lightweight structure of the improved model to further reduce inference time without compromising detection accuracy will be explored. Additionally, strategies such as multi-scale feature enhancement, adaptive noise suppression, and transfer learning under domain adaptation settings will be investigated to improve the model's performance in detecting extremely small defects and generalizing across varied production environments.

VII. CONCLUSION

This study aims to improve the YOLOv9s model to enhance its performance in steel surface defect detection tasks. To address the shortcomings of the existing YOLOv9s model in detecting small-sized defects on complex steel surface scenes, this study proposes a deep learning-based YOLOv9s method for steel surface defect detection by introducing the SCConv module for optimization, the design optimization of the C3Ghost module, and the CARAFE upsampling operator. Detailed experimental validation of the proposed method is provided. The main conclusions of this study are as follows: First, the adoption of the SCConv module significantly improved the feature extraction efficiency and automatically suppressed redundant and unimportant features. The introduction of the C3Ghost module, by streamlining the computation process and reducing redundant convolution calculations, effectively reduced the model's computational complexity while maintaining a high feature representation capability. To address the issues of small defects and blurred boundaries in steel surface defect images, the CARAFE (Content-Aware Receptive Field) upsampling operator was incorporated. CARAFE finely reconstructs feature maps in a content-aware manner, improving the detail reconstruction accuracy of defect regions, and showing significant advantages in the clarity of defect boundaries and the localization accuracy of small defects. Experimental results

show that the improved model achieved mean average precision (mAP) of 79.6% and precision of 77.0%, which represent improvements of 1.5% and 6.3%, respectively, compared to the baseline model. The findings of this study are of significant practical value for improving the quality and production efficiency of industrial products.

***Abstract*—Landslide monitoring is a crucial component of geological disaster early warning systems. Traditional landslide detection methods often suffer from insufficient accuracy or low efficiency. To address these issues, this study proposes an improved landslide detection algorithm based on YOLOv11n, aiming to enhance both detection accuracy and efficiency by optimizing the model structure. First, the GhostConv module is introduced to reduce redundant computations, thereby improving computational efficiency. Additionally, the C3K2-SCConv optimization module is incorporated, which enhances feature extraction capability and improves the recognition of landslides at different scales by integrating multi-scale information and a weighted convolution strategy. Furthermore, the SimAM attention mechanism is implemented to adaptively adjust feature map weights, strengthening key features in landslide regions and improving detection accuracy. Experimental results demonstrate that the improved model achieves a mean average precision (mAP@0.5) of 83.3%, a precision of 85.5%, and a recall of 78.1%, representing increases of 2.0%, 3.2%, and 2.8%, respectively, compared to the baseline model. The proposed improvements provide a more accurate and efficient landslide detection method, contributing to the precision of geological disaster early warnings and enhancing the reliability of disaster prevention and mitigation efforts.**

I. INTRODUCTION

Landslides, as a common and severe geological disaster, typically occur with the sudden collapse or movement of mountain masses, directly threatening the safety of local residents, infrastructure, and the ecological environment [1]. Particularly in mountainous and coastal regions with high rainfall, the frequency of landslide occurrences continues to rise due to triggering factors such as precipitation, earthquakes, and engineering construction. Traditional landslide monitoring methods primarily rely on ground surveys and physical measurement techniques, such as leveling measurements [2], ground-based radar (GB-InSAR) [3], and GPS positioning [4]. These methods can provide high-precision monitoring data and offer significant advantages, especially in small-scale landslide monitoring and early warning applications. However, traditional methods often suffer from limitations in data acquisition, high labor intensity, and difficulties in real-time monitoring. These challenges become particularly prominent in large-scale, complex terrains or post-disaster scenarios, where timely and accurate monitoring results may not be readily available. In recent years, the integration of deep learning technology has introduced a novel solution for landslide monitoring. Deep neural networks (DNNs), convolutional neural networks (CNNs), and recurrent neural networks (RNNs) have made remarkable progress in fields such as image processing [5-7], pattern recognition, and big data analysis. Specifically, in landslide detection, deep learning models can automatically extract features from large-scale remote sensing imagery, identify potential landslide-prone areas, and detect changes over time. This approach overcomes the reliance of traditional methods on expert experience and manual feature extraction, offering a more efficient and automated solution.

Although deep learning technology has made significant progress in landslide disaster monitoring, several challenges and limitations remain in current research. For example, Han et al. [8] proposed a novel neural network model called Dynahead-YOLO, which integrates scale-aware, spatial-aware, and task-aware attention mechanisms to enhance landslide decoding in complex backgrounds. However, small-sample landslide detection remains a challenge. Yang et al. [9] introduced a lightweight attention-guided YOLO model (LA-YOLO-LLL), which incorporates MobileNetv3 as the backbone network and designs a lightweight pyramid feature reuse and fusion attention mechanism while integrating the level set layer to generate precise landslide boundaries. However, at high resolutions, the model still struggles with detecting small-scale landslides. Liu et al. [10] proposed the SE-YOLOv7 landslide detection algorithm, which integrates an attention mechanism and an improved loss function, significantly improving detection accuracy. Nevertheless, the algorithm is still prone to false detections in areas with complex terrain features. Liu et al. [11] introduced a multi-scale sample-based complex background enhancement method (MSSCBE) to improve sample quality in landslide detection. However, the model exhibited poor generalization ability. Zhang et al. [12] designed a multi-scale feature extraction module that combines efficient channel attention, average pooling, and spatially separable convolution. Despite its effectiveness, challenges persist in processing small-scale landslides in complex backgrounds. Yu et al. [13] proposed an automatic loess landslide detection method based on Google Earth Engine (GEE) and an improved YOLOX algorithm, achieving an average accuracy of 95.43%. However, the model's performance still needs improvement in detecting small-scale landslides, and it is prone to false detections at the edges of remote sensing images. Hou et al. [14] developed a landslide detection method based on an improved YOLOX

object detection model, achieving promising detection performance. However, the accuracy and robustness of the model in detecting landslides across multiple categories, different terrains, and landscapes remain relatively low. Cheng et al. [15] reviewed deep learning technology and its fundamental principles, along with the current status of landslide remote sensing databases. They introduced classic deep learning models for landslide detection and analyzed the strengths and limitations of various models. Chandra et al. [16] proposed a novel generalized efficient layer aggregation network (GELAN) based on an attention mechanism, which significantly improved detection performance. However, the model's complexity remains a major drawback.

Based on the existing research, despite the significant progress made by deep learning techniques in landslide detection tasks, there are still several key challenges that need to be addressed. To this end, this study proposes a landslide detection algorithm based on the improved YOLOv11, with its core contributions mainly reflected in the following aspects:

1) By introducing the GhostConv module, the model's parameter count and computational complexity are reduced while maintaining high performance.

2) The integration of the C3K2-SCConv module enhances the model's ability to recognize multi-scale features, improving the detection of landslides and other complex features.

3) The incorporation of the SimAM attention mechanism strengthens the representation of key features, further improving the overall model performance.

II. Related Work

A. Vision Transformer (ViT)

Vision Transformer (ViT) [17] is a neural network architecture designed for image recognition tasks, inspired by the Transformer model originally developed for natural language processing (NLP). The core idea of ViT is to divide an image into fixed-size patches and process them in a manner similar to how words are handled in NLP tasks. Specifically, an image is first segmented into small patches, each of which is flattened and mapped to a high-dimensional space, akin to word embeddings in NLP. To help the model understand the spatial position of these patches in the original image, positional encoding is added. The patch embeddings, combined with positional encoding, are then fed into a Transformer encoder, which leverages the self-attention mechanism to capture relationships between different patches. This allows the model to grasp the global context of the image rather than just local features. After processing through the encoder, a classification token (similar to the [CLS] token in BERT) is added to the sequence, and its output is used for image classification. Like other deep learning models, ViT is trained in an end-to-end manner using labeled datasets. One of the key advantages of ViT is its strong performance on large-scale datasets, where it often outperforms traditional convolutional neural networks (CNNs, especially when the model size is large. Additionally, due to the self-attention mechanism, ViT can capture the global context of an image, enabling it to model long-range dependencies between different image patches. However, ViT also has some limitations. First, it requires a large amount of training data to achieve optimal performance, and on small datasets, it often underperforms compared to CNNs. Second, due to the high computational complexity of the Transformer architecture, ViT requires significant computational resources when processing high-resolution images. Despite these challenges, ViT represents a major breakthrough in computer vision and has inspired numerous improved versions, such as DeiT (Data-efficient Image Transformer), which is designed to enhance performance when training data is limited.

B. SE Attention Mechanism

The Squeeze-and-Excitation (SE) attention mechanism module [18] is a method to enhance the performance of neural networks by adaptively recalibrating the inter-channel feature responses. Its core idea is to learn the "importance" of each channel, thereby improving the network's feature representation capability. The working process of the SE module can be divided into three main steps: First, global average pooling (GAP) is applied to compress the spatial information of the input feature map, resulting in a global feature vector of size 1×1×C, where C represents the number of channels. Next, the SE module processes these global features through an "excitation" process, which consists of a two-layer fully connected neural network. The first layer uses the ReLU activation function to introduce non-linearity, while the second layer applies the Sigmoid activation function to output the "weight" or "importance" values for each channel, which lie between 0 and 1. These values represent the contribution of each channel to the final decision. Finally, the SE module performs a "recalibration" by multiplying the obtained channel weights with the original feature map on a per-channel basis, enhancing the response of important channels while suppressing less important ones. The advantages of the SE module lie in its strong adaptability, as it automatically learns the significance of each channel, and its low computational cost, making it an effective method to improve model performance in visual tasks.

C. YOLOv11 Algorithm

The network architecture of YOLOv11 [19] is primarily divided into three parts: the backbone, the neck, and the head. In the backbone section, YOLOv11 introduces innovative convolution mechanisms such as C3K2, which allow for more effective extraction of key features in the shallow layers of the network. This creates a more optimized feature extraction structure. Compared to traditional convolution structures, it enables the network to capture essential feature information crucial for object detection with greater precision, especially in complex scenarios. This sets a solid foundation for subsequent detection tasks and addresses the issue of incomplete or inaccurate feature extraction in previous models. In the neck section, the C2PSA mechanism is employed, which integrates a multi-head attention mechanism within C2. This allows the model to better capture spatial context information, improving feature fusion and information transmission efficiency. Compared to conventional designs, this mechanism makes fuller use of contextual information and comprehensively integrates features from different layers. It resolves issues such as reduced detection accuracy and insufficient feature fusion

when dealing with complex spatial relationships in objects, which had previously affected model performance. In the head section, two depthwise separable convolutions are added, reducing computational load and parameter count, significantly improving computational efficiency and inference speed. This is a strategy that has been less commonly adopted in earlier models.

III. METHOD DESIGN

This study presents improvements to the YOLOv11n model, as shown in Fig. 1. The GhostConv module replaces standard convolution to reduce redundancy and computational cost during the early stages of feature extraction, providing a lightweight yet effective foundation for subsequent processing. The C3K2-SCConv module enhances multi-scale feature representation by embedding a spatial-channel attention mechanism, thereby strengthening the model's feature extraction capability. The SimAM attention mechanism is introduced after feature fusion, adaptively adjusting neuron response weights based on energy differences. This not only suppresses background noise but also enhances focus on critical regions. These modules work in a complementary manner: GhostConv ensures computational efficiency, C3K2-SCConv enriches feature expressiveness, and SimAM refines attention. Their integration forms a cohesive structure that balances speed, accuracy, and robustness, ultimately improving the model's ability to accurately detect landslides.

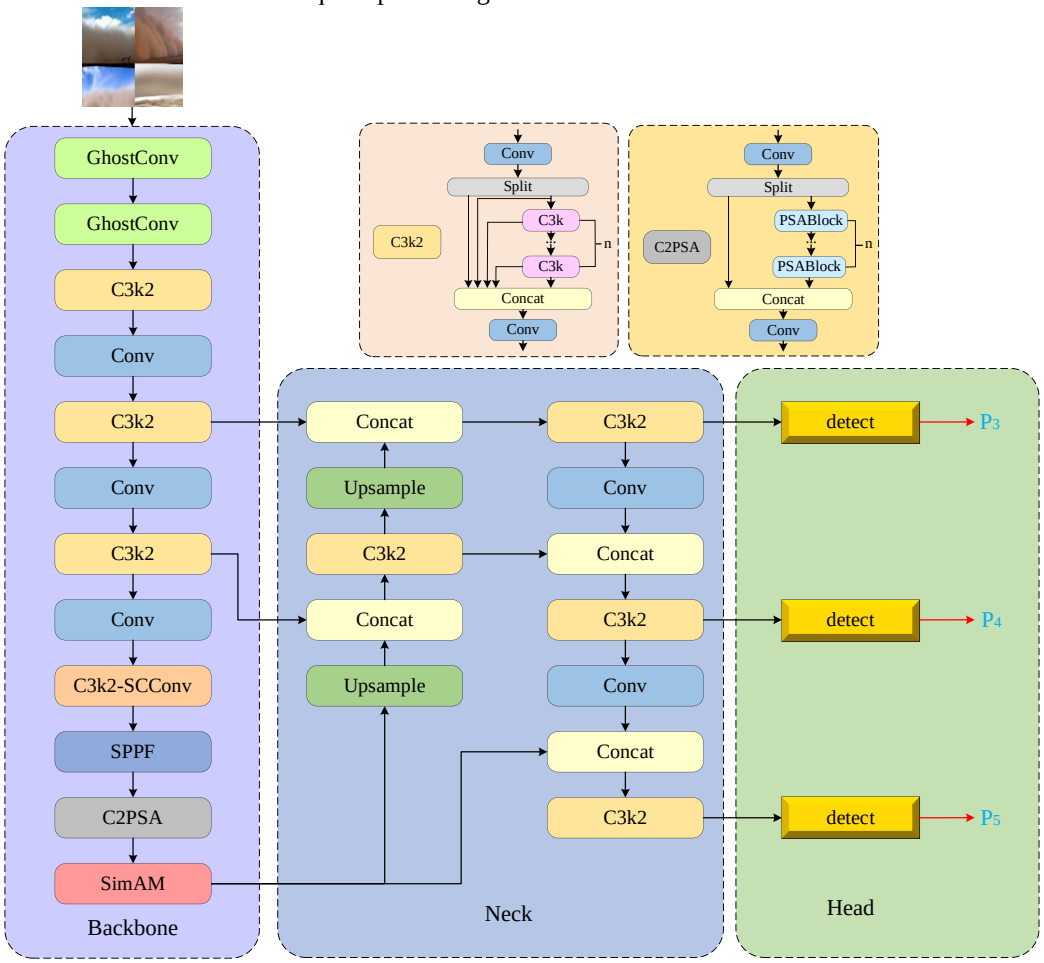

Fig. 1. Network structure of the improved YOLOv11n model.

A. GhostConv Module

YOLOv11n, as a lightweight object detection model, although having a fast inference speed, still faces the issue of computational redundancy, particularly during the shallow feature extraction phase. Traditional convolution operations involve high computational cost and parameter redundancy. To address this problem, this study adopts GhostConv to replace standard convolutions, thereby reducing the computational load and improving computational efficiency.

GhostConv [20] is a technique designed to enhance the efficiency of Convolutional Neural Networks (CNNs) by optimizing convolution operations to reduce computational and storage costs while maintaining model performance. As shown in Fig. 2, the core idea is to reduce the computational load and parameter count by using low-complexity convolution operations during feature map generation. Traditional convolution operations involve sliding a convolution kernel over the input feature map and performing weighted summation, which is computationally expensive, especially when dealing with high-dimensional inputs. In contrast,

GhostConv decomposes the input feature map by generating high-quality feature maps using standard convolutions, followed by simple operations (such as linear transformations) to generate low-complexity "Ghost" feature maps. These Ghost feature maps, although requiring fewer computations and parameters, retain most of the input information and are fused with the feature maps generated by the standard convolution. This design significantly reduces the model's computational and storage requirements, leading to improved computation speed.

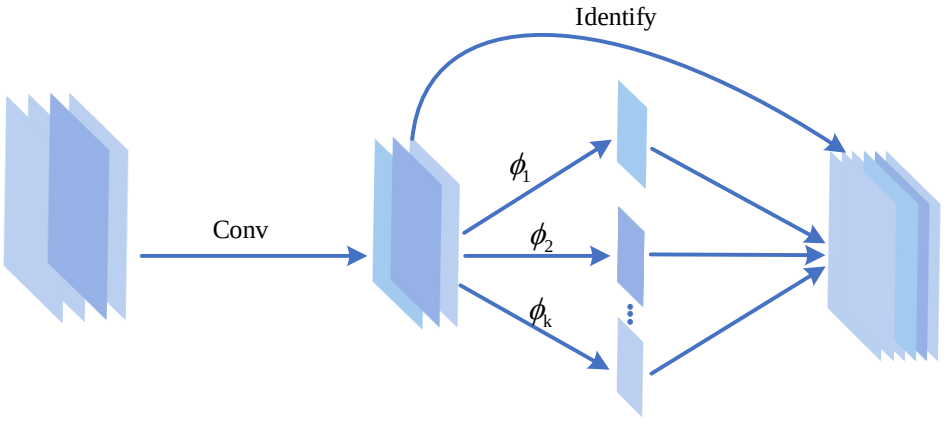

Fig. 2. GhostConv module.

B. C3k2-SCConv Module

The replacement of C3k2 with C3k2-SCConv is aimed at enhancing feature extraction capabilities and improving object detection accuracy while maintaining computational efficiency. C3k2-SCConv inherits the multi-branch structure of C3k2 and introduces SCConv [21] to strengthen feature representation. SCConv potentially enhances the model's focus on key information through spatial and channel attention mechanisms, leading to better performance in complex backgrounds or small object detection tasks. Additionally, SCConv increases the local receptive field, enhancing the robustness of feature representation, allowing the model to maintain high detection capability even in cases of object deformation or occlusion. Compared to traditional convolution, C3k2-SCConv reduces redundant computation through more efficient feature extraction, optimizes cross-layer feature fusion, and reduces information loss, thus achieving a better balance between accuracy and speed.

As shown in Fig. 3, the BottleneckSCConv module is an optimization of the feature extraction unit based on the classic Bottleneck structure, achieved by replacing one of the standard convolution layers (Conv) with SCConv, thereby enhancing feature representation capabilities. The process begins with initial convolution processing, followed by the SCConv module, which may incorporate local attention or cross-channel interaction mechanisms to strengthen key information extraction. Subsequently, the features from the SCConv branch are fused with the original input through a concatenation (Concat) operation, thereby improving the model's feature representation ability. Building on this, C3k2-SCConv inherits the C3k2 structure and introduces the BottleneckSCConv in its Bottleneck structure to further enhance feature extraction. C3k2-SCConv constructs deep feature extraction capabilities by stacking multiple BottleneckSCConv blocks (n times), and combines multi-branch information through feature concatenation (Concat) operations. Finally, the features are integrated through convolutional layers. This improvement enhances the model's feature extraction ability while maintaining its efficiency, making it more suitable for high-performance detection tasks.

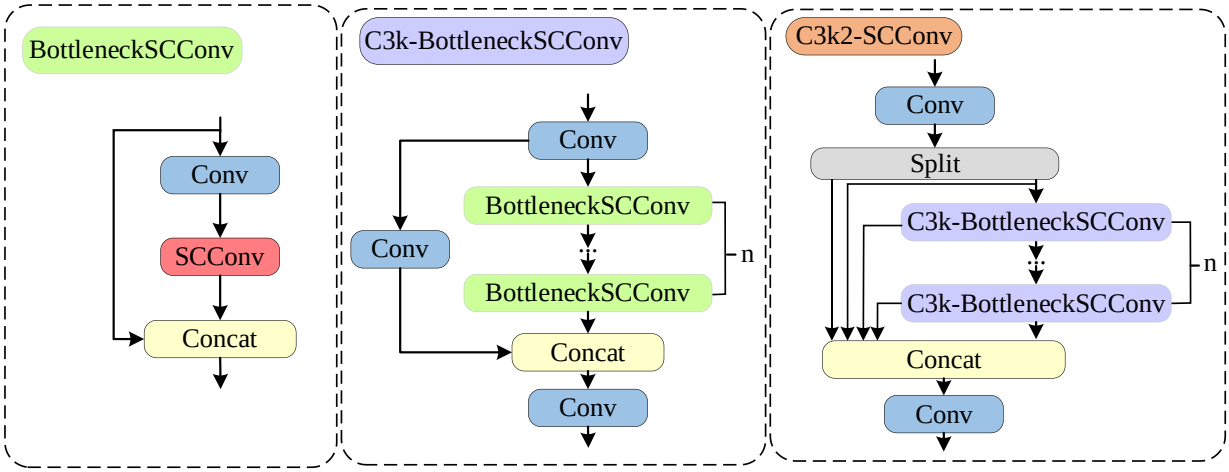

Fig. 3. C3k2-SCConv module.

C. SimAM Attention Mechanism

In this study, we optimized the YOLOv11n object detection algorithm to enhance feature extraction capabilities and detection accuracy while maintaining high computational efficiency. We strengthened the model's attention mechanism to further optimize the expression of target features and the suppression of background information. Specifically, we introduced the SimAM (Simple Attention Module) attention mechanism after the C2PSA module to increase the model's focus on important features, reduce interference from irrelevant information, and thereby improve the accuracy of object detection.

As shown in Fig. 4, the core idea of the SimAM [22] mechanism is to evaluate the differences between neurons through a physical model in order to determine their importance. The energy function $E(x_i)$ calculates the difference between the target neuron x_i and its neighboring neurons $\{x_j \mid j \in N\}$. A lower energy value indicates a greater difference between the target neuron and its surrounding neurons, implying higher importance. The formula for the energy function is:

$$E(x_i) = \frac{4(\sigma^2 + \lambda)}{(x_i - \mu)^2 + 2\sigma^2 + 2\lambda} \tag{1}$$

In the formula, x_i represents the target neuron, and λ is a hyperparameter

SimAM also requires the calculation of the mean and variance of the neurons within the neighborhood. This helps to more comprehensively assess the relationship between each neuron and its surrounding neurons. The formulas for calculating the mean and variance are as follows:

$$\mu = \frac{1}{N}\sum_{j=1}^{N} x_j \tag{2}$$

$$\sigma^2 = \frac{1}{N}\sum_{j=1}^{N} (x_j - \mu)^2 \tag{3}$$

In the formulas, N represents the number of neurons within the neighborhood, and x_j denotes the value of each adjacent neuron.

Finally, SimAM adjusts the output of each neuron based on its weight, enhancing the contribution of important neurons, thereby improving the model's performance. The formula for the weighted output is as follows:

$$\tilde{X} = sigmoid(\frac{1}{E}) \odot X \tag{4}$$

where, E groups are all $E(x_i)$ across the channel and spatial dimensions. “sigmoid” is added to restrict too large value in E. It will not influence the relative importance of each neuron because a sigmoid is a monofonic function.

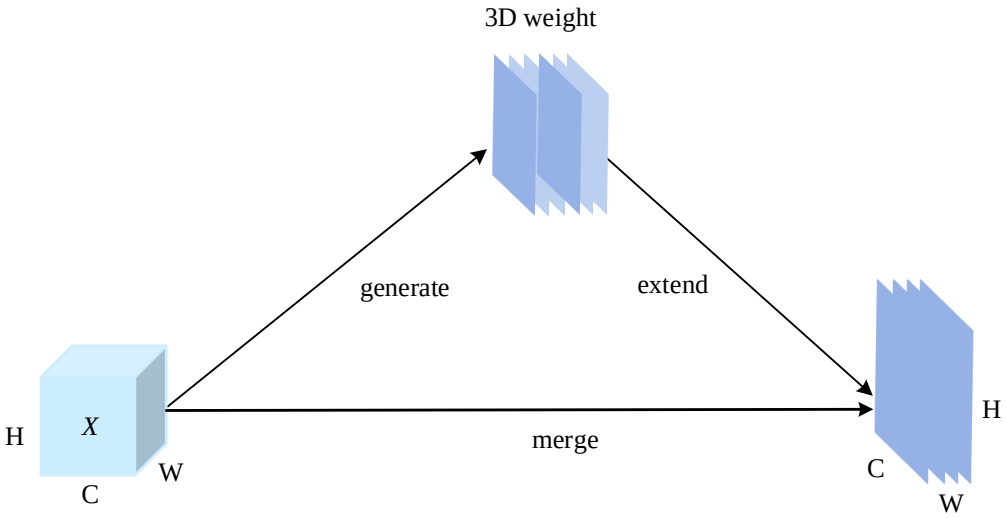

Fig. 4. SimAM attention mechanism.

IV. Experimental Setup

A. Dataset

The dataset used in this study consists of two main categories: landslides and storms, with all images manually annotated to ensure accuracy and consistency. Landslides refer to the phenomenon of soil, rocks, and other materials sliding or collapsing due to natural factors such as rainfall and earthquakes. Storms include severe meteorological events such as thunderstorms and hurricanes, typically accompanied by strong winds and heavy rainfall. Existing landslide recognition datasets primarily rely on high-resolution remote sensing images; however, such data fail to accurately reflect the complex environments present during landslides, such as dust clouds during dry conditions (as shown in Fig. 5). Additionally, processing remote sensing images demands significant computational resources, limiting the feasibility of real-time applications. To address these challenges, this study constructed a multi-domain landslide dataset consisting of 4,735 images, with 77.8% of the data sourced from news and

live video frame extraction, and 22.2% from drone remote sensing data, aimed at improving the model's recognition ability in complex scenarios. To enhance the dynamic features of the data, frame extraction was employed. Given the high-speed motion characteristics of landslides, the video frame extraction interval was set to 1, 1.5, or 2 seconds. Since some images were obstructed by watermarks, blurred, or blocked by buildings, offline data augmentation was applied to part of the news and live video data, resulting in 1,125 images, or 24% of the total dataset. The data augmentation methods combined the few-shot learning strategies proposed by Wang et al. [23], Lu et al. [24], and the random erasure and noise addition techniques proposed by Zhong et al. [25] and Zhang et al. [26], aiming to enhance the system's robustness.

Fig. 5. Comparison of the dust phenomena caused by sandstorms and landslides.

B. Hyperparameter Settings

During training, the image resolution was set to 640×640, with a batch size of 64 to fully utilize the GPU's computational power and accelerate model training. The number of training epochs was set to 200, and the initial learning rate was set to 0.01. To improve data loading efficiency, 4 worker threads were used. Additionally, the momentum parameter was set to 0.937, and the weight decay coefficient was set to 0.0005 to optimize the training process and prevent overfitting.

C. Experimental Platform

The experiments in this study were conducted on the following experimental platform: PyTorch 1.10.0 was used as the deep learning framework, with Python version 3.8 running on the Ubuntu 20.04 operating system, and CUDA version 11.3 to leverage GPU acceleration. The experiments were performed using a single RTX 4090 (24GB) GPU for training, equipped with an AMD EPYC 7T83 64-Core Processor (22 vCPUs) and 90GB of memory. This platform provided powerful computational capabilities for model training, effectively accelerating the training process.

D. Evaluation Metrics

In this study, the evaluation metrics used include F1 score, precision (P), recall (R), average precision (AP), and mean average precision (mAP) [27]. Additionally, the number of parameters (Parameters) was also considered. The formulas for these metrics are as follows:

$$\text{Precision} = \frac{T_p}{T_p + F_p} \tag{4}$$

$$\text{Recall} = \frac{T_p}{T_p + F_N} \tag{5}$$

$$\text{AP} = \int_0^1 P(R)\mathrm{d}R \tag{6}$$

$$\text{mAP} = \frac{1}{n}\sum_{i=0}^{n} AP(i) \tag{7}$$

$$\text{F1} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{8}$$

where, T_p represents the number of correctly detected targets; F_p represents the number of falsely detected targets; F_N represents the number of missed targets; n denotes the number of categories; and $AP(i)$ is the average precision of the i-th target class.

V. Experimental Analysis

A. Algorithm Comparison Experiment

To evaluate the advantages of our improved algorithm, we conducted a comparison with other algorithms. In the field of object detection, algorithm performance is typically assessed using several key metrics, such as precision, recall, mAP@0.5, FPS (frames per second), GFLOPS (computational complexity), and the number of parameters (Params). Precision and recall primarily reflect the model's detection accuracy and recall capability, while mAP@0.5 provides a comprehensive measure of the model's performance across different detection thresholds. FPS and GFLOPS assess the model's real-time performance and computational efficiency, respectively, while the number of parameters reflects the model's complexity. By comparing these metrics, we can gain a deeper understanding of the strengths and weaknesses of different algorithms in terms of accuracy, real-time performance, and computational efficiency.

From the experimental comparison results in Table I, different object detection algorithms exhibit varying performances in metrics such as precision, recall, mAP@0.5, FPS, GFLOPS, and the number of parameters (Params). The Ours algorithm achieved the best results in precision (85.5%), recall (78.1%), and mAP (83.3%), while maintaining high real-

time performance (128.5 FPS), low computational complexity (6.3 GFLOPS), and a relatively low number of parameters (2.72M), demonstrating the optimal overall performance. YOLOv11n excelled in real-time performance (147.0 FPS) and computational efficiency (6.3 GFLOPS), but its precision (82.3%) and mAP (81.3%) were slightly lower than those of Ours. YOLOv5s performed well in real-time performance (137.0 FPS), with moderate precision (78.6%) and mAP (76.5%), but its computational complexity (15.8 GFLOPS) and parameter count (7.01M) were relatively high. YOLOv10n showed moderate performance in precision (81.6%), mAP (77.5%), and real-time performance (122.6 FPS), with lower computational complexity (8.3 GFLOPS) and parameter count (2.73M). YOLOv9-gelan-s demonstrated excellent precision (85.3%) and mAP (82.4%), but its computational complexity (26.2 GFLOPS) and parameter count (7.07M) were higher. In comparison, RT-DETR-18 and YOLOv7-tiny performed poorly in terms of precision, recall, and mAP, with RT-DETR-18 having a higher computational complexity (56.9 GFLOPS) and parameter count (19.87M). Overall, the Ours algorithm generally outperforms traditional algorithms in terms of performance.

TABLE I. EXPERIMENTAL COMPARISON RESULTS OF DIFFERENT ALGORITHMS

Algorithm	Precision/%	Recall/%	mAP@0.5/%	FPS (f/s)	GFLOPS	Params (M)
YOLOv5s[28]	78.6	76.5	76.5	137.0	15.8	7.01
YOLOv7-tiny[29]	76.5	66.8	71.3	120.8	13.0	6.01
YOLOv8n[30]	83.2	70.7	78.9	106.3	8.1	3.00
YOLOv9-gelan-s[31]	85.3	74.5	82.4	81.3	26.2	7.07
YOLOv10n[32]	81.6	72.1	77.5	122.6	8.3	2.73
RT-DETR-18[33]	76.6	67.4	70.5	68.4	56.9	19.87
YOLOv11n	82.3	75.3	81.3	147.0	6.3	2.58
Ours	**85.5**	**78.1**	**83.3**	**128.5**	**6.3**	**2.72**

TABLE II. COMPARISON RESULTS OF VARIOUS ALGORITHMS IN AVERAGE PRECISION (AP/%)

Algorithms / Classes	YOLOv5s	YOLOv7-tiny	YOLOv8n	YOLOv9-gelan-s	YOLOv10n	RT-DETR-18	YOLOv11n	Ours
landslide	65.8	56.9	66.8	74.3	66.8	62.7	72.0	**74.3**
storm	87.1	85.7	90.9	90.5	88.1	78.4	90.6	**92.3**

From the average precision (AP) comparison results in Table II, it is evident that different algorithms exhibit significant performance differences in the landslide and storm tasks. YOLOv9-gelan-s and Ours tied for the best performance in the landslide category, both achieving an average precision of 74.3%. In the storm category, Ours achieved the best performance with an average precision of 92.3%, significantly outperforming other algorithms. YOLOv8n and YOLOv11n also performed well in both tasks, with YOLOv8n achieving an average precision of 90.9% in the storm category. YOLOv10n achieved average precisions of 66.8% and 88.1% for the landslide and storm categories, respectively, slightly outperforming YOLOv5s, which scored 65.8% and 87.1%. However, neither of these two algorithms reached the optimal performance. In contrast, YOLOv7-tiny and RT-DETR-18 performed poorly, particularly in the storm category, where RT-DETR-18's average precision was only 78.4%, the lowest among all algorithms. Overall, the Ours algorithm excelled in both tasks, especially in complex scenarios (such as storms), where it demonstrated higher detection accuracy, offering the best overall performance. YOLOv10n and YOLOv5s showed moderate performance, with room for further optimization.

TABLE III. COMPARISON RESULTS OF VARIOUS ALGORITHMS IN PRECISION (P/%)

Algorithms / Classes	YOLOv5s	YOLOv7-tiny	YOLOv8n	YOLOv9-gelan-s	YOLOv10n	RT-DETR-18	YOLOv11n	Ours
landslide	69.4	66.5	73.9	79.3	73.7	72.8	79.7	**77.1**
storm	87.8	86.5	92.6	91.3	89.4	80.4	84.9	**93.8**

From the data in Table III, it can be observed that different algorithms exhibit varying precision in the landslide and storm categories. In the landslide category, YOLOv11n performed the best with a precision of 79.7%, outperforming YOLOv7-tiny (66.5%). In the storm category, Ours demonstrated the best performance, with a precision of 93.8%, significantly surpassing other algorithms, especially RT-DETR-18 (80.4%). YOLO series algorithms (such as YOLOv5s, YOLOv8n, etc.) also performed well in the storm category, but their precision varied greatly in the landslide category. Overall, Ours performed best in storm detection, while YOLOv11n and Ours were the most outstanding in landslide detection. RT-DETR-18 performed relatively poorly in both tasks.

From the recall (R) data in Table IV, Ours demonstrated the best performance in both the landslide and storm categories, with a landslide recall of 67.2% and a storm recall of 89.0%, significantly outperforming other algorithms. YOLOv11n

followed closely, performing well in the landslide category with a recall of 63.7%, and also showing good performance in the storm category. YOLOv5s achieved a recall of 87.7% in the storm category, which was quite notable, but in the landslide category, its recall was 65.3%, slightly lower than that of Ours. In contrast, YOLOv7-tiny and RT-DETR-18 generally had lower recall rates, with YOLOv7-tiny's recall in the landslide category being only 51.4%. Overall, Ours has a significant advantage in recall, making it suitable for applications that require high sensitivity to missed detections.

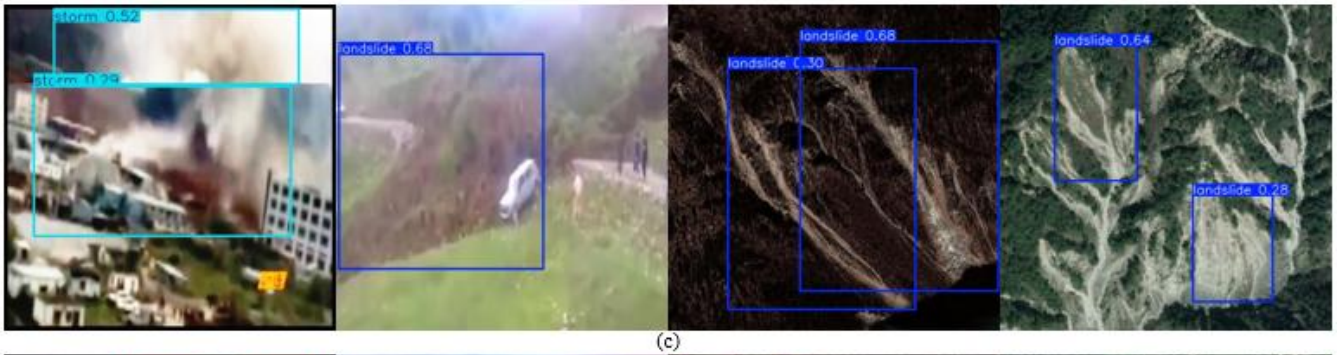
TABLE IV. COMPARISON RESULTS OF VARIOUS ALGORITHMS IN RECALL (R/%)

Algorithms / Classes	YOLOv5s	YOLOv7-tiny	YOLOv8n	YOLOv9-gelan-s	YOLOv10n	RT-DETR-18	YOLOv11n	Ours
landslide	65.3	51.4	56.4	63.0	63.0	63.4	63.7	**67.2**
storm	87.7	82.2	84.9	86.1	81.3	71.4	87.0	**89.0**

B. Result Visualization

To comprehensively evaluate the superiority of the Ours algorithm in object detection tasks, we conducted a visual comparison with several existing detection algorithms. Although the existing algorithms, such as YOLOv5s, YOLOv7-tiny, YOLOv8n, YOLOv9-gelan-s, YOLOv10n, RT-DETR-18, and YOLOv11n, exhibit certain detection capabilities in different scenarios, they still have limitations in terms of detection accuracy, target confidence, and missed detection phenomena. Therefore, we visually compared the performance of different algorithms in the landslide (landslide) and storm (storm) detection tasks.

Fig. 6 shows the performance comparison of different models in landslide and storm detection. YOLOv5s exhibits basic detection capabilities, but with lower confidence, resulting in some targets being misdetected or missed. YOLOv7-tiny has even lower confidence, with some landslide areas not detected and a higher number of false detections, indicating that it is not robust enough for small targets or complex backgrounds. YOLOv8n shows improvements in landslide detection, but the confidence in the storm category remains relatively low. Overall, it is more stable than YOLOv7-tiny, but there are still some missed detections. In contrast, YOLOv9-gelan-s, YOLOv10n, RT-DETR-18, and YOLOv11n show improvements in detection accuracy, but all exhibit overlapping detection boxes, indicating that these models may have redundant predictions when processing landslide areas, generating multiple detection boxes for the same target region, which affects the final detection results. Additionally, YOLOv11n also experiences missed detections, with some landslide areas not being recognized. Among all models, Ours achieves the best detection performance, with the highest confidence, the most stable detection boxes, a wider detection range for landslide targets, and effectively reduces overlapping detection boxes while avoiding missed detections, resulting in the best overall performance.



In object detection tasks, the performance of the model is typically evaluated using precision, recall, and F1 score. The F1-Confidence curve reflects the variation in the F1 score at different confidence thresholds, providing an intuitive representation of the model's overall detection capability at different decision boundaries. To compare the performance of different object detection models, we plotted the F1-Confidence curve and conducted an analysis.

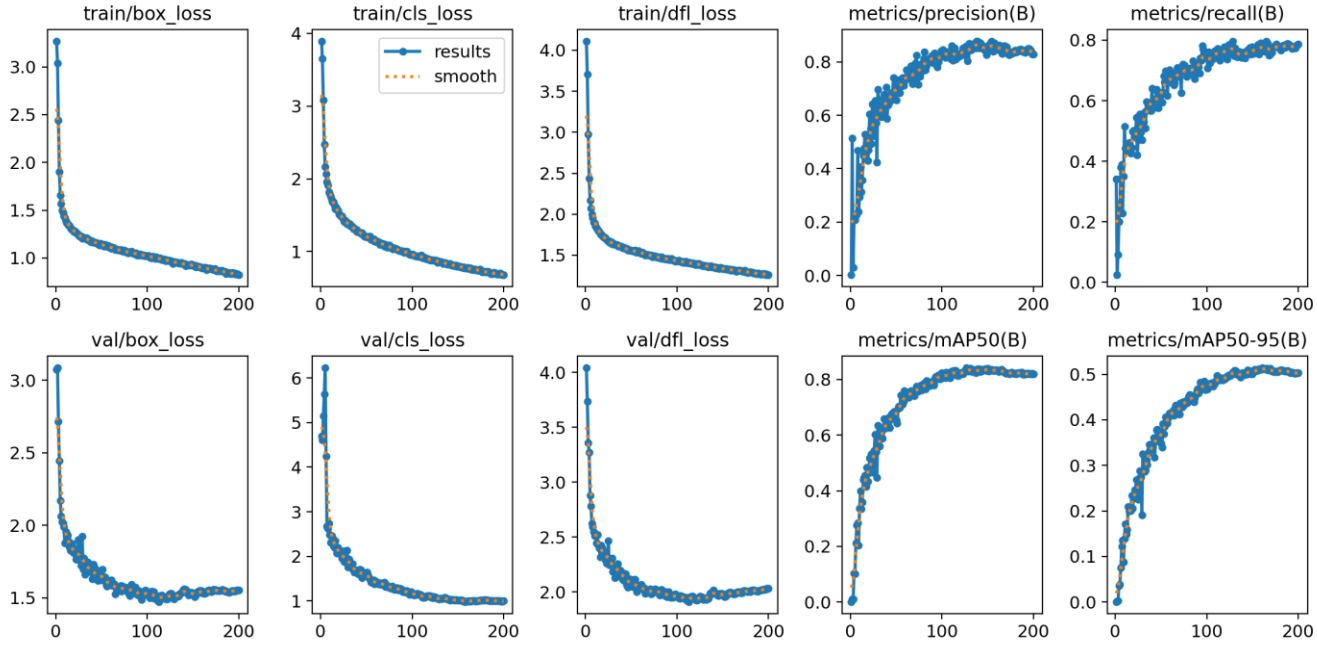
To comprehensively evaluate the detection capabilities of different object detection models at various confidence thresholds, we plotted the F1-Confidence curve to visually demonstrate the variation in F1 scores across models. Fig. 7(a) to Fig. 7(h) correspond to YOLOv5s, YOLOv7-tiny, YOLOv8n, YOLOv9-gelan-s, YOLOv10n, RT-DETR-18, YOLOv11n, and our model (Ours), used to compare their performance at different decision boundaries. The results in Fig. 7 show that Ours achieves the highest F1 score of 0.81 at a confidence threshold of 0.412, outperforming all other models

and demonstrating the best performance. YOLOv9-gelan-s, RT-DETR-18, and YOLOv11n also performed well, but still fell short of Ours. YOLOv5s and YOLOv10n achieved F1 scores of 0.78 and 0.76, respectively, showing acceptable overall performance, better than YOLOv7-tiny (0.70) and YOLOv8n (0.76), but still not surpassing Ours. YOLOv7-tiny had the lowest F1 score at only 0.70, indicating weaker detection capabilities. Overall, Ours maintained a high F1 score across different confidence ranges, with a low false detection rate, indicating stronger object detection capabilities.

This study improved the YOLOv11n object detection algorithm and evaluated its training and validation processes. To analyze the model's convergence and detection performance, we plotted the loss curve and the trends of key evaluation metrics. The loss curve illustrates the optimization of the model during the training process, while metrics such as precision, recall, and mAP reflect the model's detection capabilities. Through these curves, we validated the stability and performance improvement of the modified model.



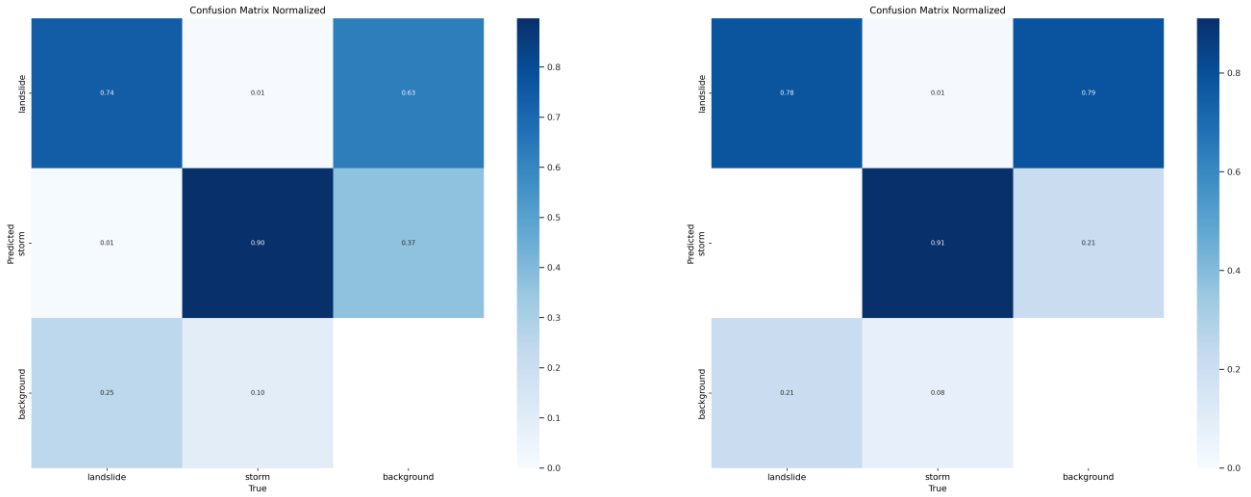


Fig. 8. Loss reduction trends and performance metric variations of the improved YOLOv11n algorithm during training and validation.

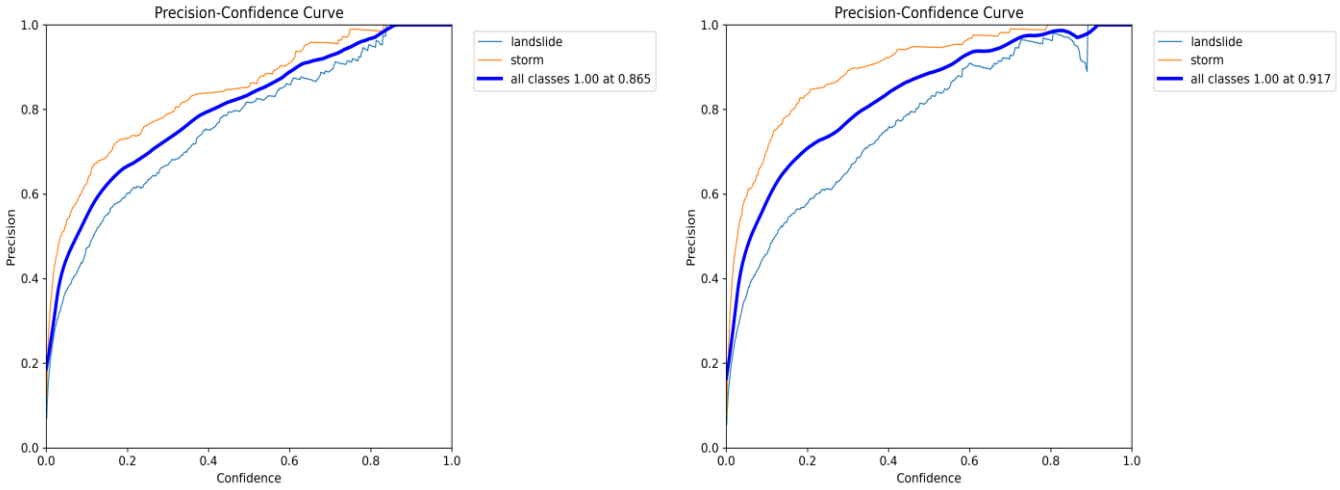
Fig. 8 illustrates the loss reduction trend and changes in key evaluation metrics during the training and validation process of the improved YOLOv11n algorithm, used to assess the model's convergence and detection performance. From the loss curves, both training losses (box_loss, cls_loss, dfl_loss) and validation losses (val/box_loss, val/cls_loss, val/dfl_loss) show a steady downward trend, indicating that the model continuously optimizes its object detection capabilities during training without significant overfitting or underfitting. In terms of model evaluation metrics, precision and recall steadily increase and stabilize, suggesting that the improved model gradually enhances its target classification and detection abilities. The mAP50 is close to 0.833, and the mAP50-95 is approximately 0.516, demonstrating the model's good detection performance and strong generalization ability at different IoU thresholds. Overall, the improved YOLOv11n algorithm outperforms the original version, but its small target detection capabilities and mAP50-95 metric can still be further improved by adjusting the learning rate, optimizing data augmentation strategies, or enhancing non-maximum suppression (NMS) processing.

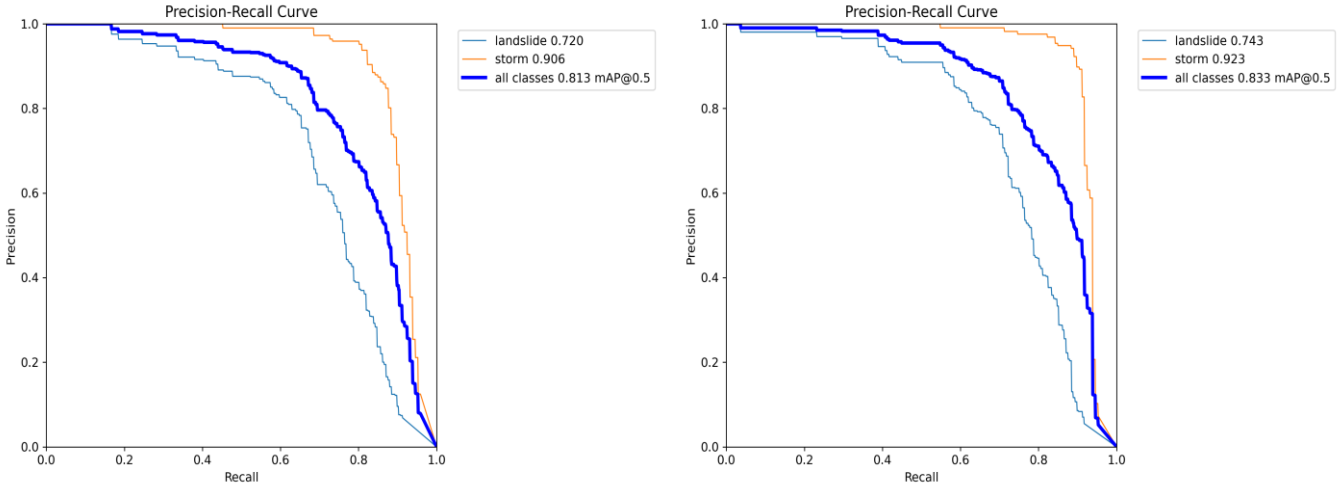


To more clearly evaluate the model's classification ability, the confusion matrix is used to visually quantify the model's prediction accuracy and misclassification rates for different categories. To assess the detection performance of the YOLOv11n algorithm and its improved version in the landslide and storm categories, we plotted the normalized confusion matrix. This allows for a comparative analysis of the classification accuracy and misclassification rates of the two models, in order to verify the performance improvement of the modified model.

Fig. 9 shows the confusion matrices of the YOLOv11n algorithm and the improved YOLOv11n algorithm, used to evaluate the model's classification performance on landslide and storm targets. From the results, the improved YOLOv11n algorithm shows improvements in both landslide and storm detection. The accuracy of landslide detection increased from 0.74 to 0.78, and the accuracy of storm detection increased from 0.90 to 0.91, while the false detection rate decreased. In particular, the proportion of storms misclassified as background reduced from 0.37 to 0.21, indicating that the improved model is more stable in storm detection. Additionally, the background misclassification rate also decreased, with the probability of landslides being misidentified as background dropping from 0.25 to 0.21, suggesting that the improved algorithm has optimized false detection suppression.

(a) (b)

Fig. 9. Normalized confusion matrix: (a) YOLOv11n algorithm; (b) Improved YOLOv11n algorithm.



(a) (b)

Fig. 10. Precision-confidence curves: (a) YOLOv11n algorithm; (b) Improved YOLOv11n algorithm.

Fig. 10 presents the Precision-Confidence curves for the YOLOv11n algorithm [Fig. 10(a)] and the improved YOLOv11n algorithm [Fig. 10(b)], used to evaluate the variation in precision at different confidence thresholds. The left panel [Fig. 10(a)] shows the original YOLOv11n, while the right panel [Fig. 10(b)] shows the improved YOLOv11n. The curves correspond to landslide, storm, and all classes. Overall, as the confidence threshold increases, precision gradually improves, indicating a reduction in false positives at higher confidence levels and more accurate predictions. Compared to the original model, the improved YOLOv11n shows an increase in precision across all confidence ranges, with the confidence threshold corresponding to the highest precision increasing from 0.865 to 0.917. This suggests that the improved model maintains a higher level of precision at higher confidence thresholds, thereby reducing false positives caused by low-confidence predictions.

Fig. 11 presents the Precision-Recall (P-R) curves for the YOLOv11n algorithm [Fig. 11(a)] and the improved YOLOv11n algorithm [Fig. 11(b)], used to assess the variation in precision at different recall rates. The left panel [Fig. 11(a)] shows the original YOLOv11n, while the right panel [Fig. 11(b)] shows the improved YOLOv11n. The P-R curves for landslide, storm, and all classes are plotted, with the performance at mAP@0.5 indicated for each class. Overall, the mAP@0.5 of the improved model increased from 0.813 to 0.833 across all classes, with the mAP of the storm class rising from 0.906 to 0.923 and the mAP of the landslide class increasing from 0.720 to 0.743, indicating an improvement in detection performance. The P-R curves show that the storm class consistently outperforms the landslide class in detection, while the improved YOLOv11n maintains a slower decline in precision at higher recall rates, suggesting enhanced detection ability at higher recall levels and a reduction in false negatives. Overall, the improved model achieves better performance in balancing precision and recall.

C. Ablation Study

To evaluate the impact of different modules on the YOLOv11n object detection performance, we conducted ablation experiments and performed a comparative analysis of detection accuracy, recall rate, mAP@0.5, inference speed (FPS), computational complexity (GFLOPS), and parameter count (Params) for each improvement. By progressively introducing modules such as C3k2-SCConv, GhostConv, and SimAM, we assess their contributions to model performance and whether the improvements can maintain high detection accuracy while also considering inference speed and computational efficiency. The experimental results, as shown in Table V, present the performance of each configuration across various metrics.

TABLE V. ABLATION STUDY RESULTS

number	Experiment	Precision/%	Recall/%	mAP@0.5/%	FPS (f/s)	GFLOPS	Params (M)
1	YOLOv11n	82.3	75.3	81.3	147.0	6.3	2.58
2	YOLOv11n+C3k2-SCConv	85.6	74.6	82.2	102.8	6.4	2.73
3	YOLOv11n+C3k2-SCConv+GhostConv	85.9	75.3	82.8	130.3	6.3	2.72
4	YOLOv11n+C3k2-SCConv+GhostConv+SimAM	**85.5**	**78.1**	**83.3**	**128.5**	**6.3**	**2.72**

Table V presents the ablation experiment results for YOLOv11n and its various improvements, evaluating the impact of each configuration on precision, recall, mAP@0.5, frame rate (FPS), computational complexity (GFLOPS), and parameter count (Params). The baseline model, YOLOv11n, achieves the fastest inference speed with an mAP@0.5 of 81.3% and FPS of 147.0 f/s, but there is still room for improvement in detection accuracy. After adding C3k2-SCConv, precision increases to 85.6%, and mAP@0.5 slightly improves, but recall decreases, and FPS drops to 102.8 f/s, indicating that the increased computational load impacts inference efficiency. The further introduction of GhostConv increases precision to 85.9%, recall recovers by 5.3%, and mAP@0.5 rises to 82.8%, while FPS reaches 130.3 f/s, suggesting that GhostConv effectively reduces computational redundancy and enhances inference speed. Finally, with the addition of SimAM, recall further improves to 78.1%, and mAP@0.5 increases to 83.3%. Overall, the gradual inclusion of C3k2-SCConv, GhostConv, and SimAM significantly enhances detection accuracy while maintaining high inference speed, with minimal impact on computational complexity and parameter count.

VI. DISCUSSION

There are several limitations in the current study. First, the dataset lacks images captured under extreme weather conditions such as heavy rain or snow, which may weaken the model's generalization ability in complex real-world environments. Second, the sample distribution of landslide and storm categories may be imbalanced, potentially leading to suboptimal detection performance for underrepresented classes. Moreover, the current research primarily focuses on the detection of landslides and storms, while the model's ability to identify other types of geological disasters, such as debris flows or earthquakes, has not been sufficiently validated. Additionally, the model is relatively complex, which not only increases the time cost for training and inference but also poses challenges for deployment and maintenance. Future research can address these issues in two main directions. One is the expansion and augmentation of the dataset, by incorporating a larger number of images from various scenarios and weather conditions to enhance the model's robustness and generalization. The other is the optimization of the model architecture and its real-time performance, by exploring more efficient network designs and optimization algorithms to reduce computational complexity and parameter size.

VII. CONCLUSION

This study optimizes the YOLOv11n object detection algorithm by introducing the GhostConv module to optimize the convolutional computations, reducing redundant calculations while significantly improving the model's operational efficiency without compromising feature extraction capability. The introduction of the C3k2-SCConv module further optimizes the feature extraction process, effectively enhancing the representation of key features in landslide images, while maintaining optimal computational performance. The incorporation of the SimAM attention mechanism adapts the model's focus on different region features, allowing the network to more effectively perceive critical information in landslide images, thereby further improving detection accuracy. Experimental results show that the improved model outperforms other algorithms in terms of mAP@0.5, precision, and recall, demonstrating superior detection performance and computational efficiency.

Arab Academy for Science, Technology, and Maritime Transport, Sheraton, 11757, Cairo, Egypt

***Abstract*—The early diagnosis of Alzheimer's disease remains a major challenge due to the complexity of magnetic resonance image interpretation and the limitations of existing diagnostic models. The slow memory loss associated with the gradual loss of thinking abilities, known as Alzheimer's disease, is the most common element of the illness. Effective early diagnosis is therefore essential to treatment; unfortunately, the traditional diagnostic procedure, which involves analyzing magnetic resonance images, is a complex process and prone to mistakes. This study aims to successfully merge these cognitive models with advanced deep learning techniques to enhance the diagnostic capabilities of Alzheimer's disease using a fusion model with 3-dimensional convolutional neural networks and long short-term memory networks. The proposed approach uses three-dimensional convolutional neural networks to extract intricate features from volumetric magnetic resonance images, while long short-term memory networks analyze sequential data to identify key temporal patterns that indicate the progression of Alzheimer's disease. The dataset used in this study is the Alzheimer's Disease Neuroimaging Initiative dataset, which contains magnetic resonance images labeled into four categories: Non-Demented, Very Mild Demented, Mild Demented, and Moderate Demented. The dataset consists of 6,400 magnetic resonance images in total, split into training (70%), validation (15%), and testing (15%) sets. These outcomes demonstrate that the hybrid model improves predictive accuracy significantly over current benchmarks on this topic. This study highlights the importance of introducing deep learning models into clinical practice, thereby providing an efficient tool for early-stage Alzheimer's disease diagnosis, ultimately improving patient outcomes through early and accurate intervention.**

Keywords*—*Alzheimer's disease; magnetic resonance imaging; two-dimensional convolutional neural network; long short-term memory; deep learning; early detection

I. Introduction

One well-known neurological disorder that affects memory and cognitive function is Alzheimer's disease (AD). The disease is named after Dr. Alois Alzheimer, a well-known German expert who initially discovered the basic pathophysiology of the underlying pathology in 1906 [1].

The prevalence of Alzheimer's disease increases significantly with age, altogether influencing the elderly. The trademark of this condition is the amassing of anomalous protein totals inside the brain, which continuously disables cognitive work and creates genuine challenges with day-by-day tasks [2].

Our understanding of AD has advanced impressively over the past century, especially with respect to the part that the amyloid-beta protein plays within the early stages of the infection. However, there are critical concerns related to the worldwide rise in AD predominance. In recent years, machine learning has opened up unused roads for the early discovery and administration of AD. By leveraging cutting-edge algorithms and large-scale medical imaging datasets, AI techniques have significantly enhanced diagnostic workflows and accuracy [28]. Machine-learning models can distinguish subtle patterns in neuroimaging, genetic data, and cognitive assessments that may indicate early signs of this insidious disease [3].

The novelty of this study lies in the integration of two-dimensional convolutional neural networks (2D-CNNs) and long short-term memory (LSTM) networks to enhance both spatial feature extraction and temporal pattern recognition. This combined approach provides significant improvement over prior research that typically employs CNNs or LSTMs separately, leading to more robust Alzheimer's disease classification. Additionally, we introduce a comprehensive dataset preprocessing pipeline and apply SMOTE to handle class imbalance, an aspect not fully explored in existing literature. This model integrates 2D-CNN for efficient feature selection from MRI scans and LSTM networks for the temporal analysis of sequential MRI data. A thorough performance evaluation is conducted using metrics such as accuracy, recall, and F1-score, demonstrating the superiority of our method over conventional techniques. Through the application of these cutting-edge strategies, our objective is to supply healthcare experts with a robust diagnostic tool that not only improves the accuracy of Alzheimer's disease detection but also enhances the understanding of disease progression. Additionally, the physicians will be motivated to take good decisions about care, ultimately leading to improved patient outcomes.

While several studies have applied CNNs or RNNs individually for medical image classification, their effectiveness in capturing both spatial and temporal dependencies remains limited. This study addresses this gap by combining 2D-CNN with LSTM to leverage both spatial features and sequential context from MRI slices.

The structure of this study is as follows: Section II presents a comprehensive review of related work on deep learning models used for Alzheimer's disease diagnosis. Section III outlines the proposed methodology, including model architecture, dataset details, and preprocessing steps. Section IV provides the experimental results, and Section V discusses the model's performance using standard evaluation metrics. Finally, Section VI concludes the study and highlights potential directions for future work.

II. Literature Review

This section discusses more complicated deep learning techniques, specifically Convolutional Neural Networks (CNNs) and LSTM networks, for the early diagnosis and detection of AD using neuroimaging data. The literature review section explores various studies that have integrated CNNs, LSTMs, and Transformers for AD diagnosis. However, most prior works have either focused on CNNs for spatial feature extraction or LSTMs for temporal sequence analysis, but have not effectively combined them.

Recently, many studies highlighted the important role of merging CNNs and LSTMs when analyzing MRI scans for AD diagnosis. A multimodal fusion model was created that combined a CNN for spatial feature extraction and an LSTM for temporal sequence analysis, achieving an accuracy of 92.3% using the Alzheimer's Disease Neuroimaging Initiative dataset [4].

Similarly, the research done by Hu et al. [8] introduced a Transformer-based model, VGG-TSwinformer, for predicting the progression from Mild Cognitive Impairment (MCI) to Alzheimer's Disease. Although, retrieving a lower accuracy of 77.2%, this model was the first to merge CNNs with Transformer models, showing how important it is to control the temporal aspects of longitudinal medical data. Despite its drawbacks, this innovative approach indicates a promising avenue for further research in AD diagnosis. Additionally, recent AI-driven methodologies have shown substantial promise in predicting Alzheimer's progression using advanced deep learning frameworks [14].

In recent research, explainability in AI models has become increasingly important. The XGBoost model was combined with the SHAP (SHapley Additive exPlanations) method in the study by Bogdanovic et al. [6] to create clear conclusions about the model's predictions. This approach not only achieved a high F1-score of 0.84, but it also increased the clarity of the diagnostic process, making it more dependable and accessible for clinical application. In a recent study, an explainable AI-based model for Alzheimer's disease prediction was developed using a multimodal dataset [7].

This outcome shows the efficiency of combining clinical, neuroimaging, and psychological data in AD prediction. Using a different data modality and focusing on explainability shows how the complexity and accuracy of the current AD diagnostic techniques have enhanced [7]. Another contribution has been made by Qiu et al. [8] who developed a significant multimodal deep learning framework that combined MRI data with clinical features using CNN and CatBoost models. This study shows the importance of merging various data sources to enable an extensive diagnosis of AD. Additionally, Ngnamsie Njimbouom et al. [9] has created a multi-modal model by using artificial neural networks (ANN) and CNN to predict dental caries.

Although they mainly focused on dentistry applications, their methodology is applied to AD research as it shows the value of multi-modality in improving prediction accuracy [9].

Hoang et al. [10] applied Vision Transformer models to predict the transition from mild cognitive impairment to Alzheimer's disease. Their findings revealed an accuracy of 83.27% and provided visual representations of key brain regions associated with the progression of AD, consequently improving the interpretability of these predictive models [10]. Pang et al. [11] have provided a detailed analysis of deep learning-based medical imaging report production, which included AD diagnostic reports. Their research shows two vital components in the development of effective tools for AD detection: the challenges associated with imbalanced datasets and the significance of interdisciplinary collaboration.

Javeed et al. [12] conducted a systematic evaluation of machine learning techniques for dementia prediction, focusing on data modalities such as voice, clinical features, and picture data. Their results showed the effectiveness of image-based machine learning models for dementia prediction, but they also identified limitations such as model overfitting and the need for larger datasets.

Finally, Khatri and Kwon [13] used PET scans to predict the progression of AD through an explainable Vision Transformer model that includes self-supervised learning. Their approach achieved a significant accuracy of 92.31%. It highlights the value of integrating robust predictive capabilities with interpretability in clinical environments.

The deep learning techniques indicate their importance in all this research, especially the integration of CNNs, LSTMs, and Transformers, which have improved the ability to diagnose AD with greater accuracy and transparency. Future advancements in the early detection and management of AD are well-founded in this field of study by handling the challenges of data diversity and model explainability.

Table I lists the main techniques and associated accuracy of many studies related to the early detection and classification of AD using several deep learning models.

TABLE I. Related Works with Methodologies and Classes

Study	Methodology	No. of Class	Accuracy
Haq et al., 2024 [5]	CNN-LSTM (Multimodal Fusion)	Three Class (AD, MCI, NC)	92.30%
Hu et al., 2023 [8]	VGG-TSwinformer (Transformer + CNN)	Binary Class (MCI vs pMCI)	77.20%
Bogdanovic et al., 2022 [6]	XGBoost + SHAP (Explainable ML)	Multi-Class (AD, MCI, NC, etc.)	84.00%

Jahan et al., 2023) [3]	Random Forest (Multimodal, Explainable AI)	Four Class (AD, MCI, NC, LMCI)	98.81%

Qiu et al., 2022) [8]	Multimodal Deep Learning Framework (CNN + CatBoost)	Four Class (NC, MCI, AD, nADD)	AUC 0.971
(Ngnamsie Njimbouom et al., 2022 [9]	Multi-Modal Dental Caries Prediction (CNN + ANN)	Binary Class (Caries vs No Caries)	High Accuracy
Hoang et al., 2023 [10]	Vision Transformers (ViT)	Binary Class (MCI vs AD)	83.27%
Pang et al., 2023 [7]	Deep Learning-based Report Generation	Multi-Class (Various)	Survey
Javeed et al., 2023 [6]	Explainable Vision Transformer (Self-Supervised)	Binary Class (MCI vs AD)	Systematic Review
Khatri & Kwon, 2023) [13]	Systematic Review of ML for Dementia Prediction	Various (AD, MCI, NC, Voice Data)	92.31%

III. METHODOLOGY

To improve clarity, a flowchart illustrating the workflow of the proposed model is shown in Fig. 1. Additionally, Algorithm 1 provides a structured representation of the key steps in the model's training and classification process.

Fig. 1. Workflow of the hybrid 2D-CNN + LSTM model for AD classification.

Algorithm 1: Hybrid 2D-CNN + LSTM Model for AD Classification

1. Data Preprocessing:
   - Load MRI images from the ADNI dataset.
   - Resize images to 176x176 pixels.
   - Normalize pixel values to [0,1].
2. Model Training:
   - Pass images through 2D-CNN layers for feature extraction.
   - Flatten extracted features and feed them into an LSTM layer.
3. Evaluation:

-Compute accuracy, precision, recall, F1-score. Evaluate the model using standard classification metrics: accuracy, precision, recall, and F1-score.

-Generate confusion matrix and Receiver Operating Characteristic (ROC) curve.

The following workflow diagram illustrates the steps involved in the Hybrid two-dimensional convolutional neural network (2D-CNN) + long short-term memory (LSTM) model for AD classification. It details the data preprocessing, model training, and evaluation phases.

A. Adopted Base Model Architecture

2D-CNN or Conv2D: A 2D Convolutional Neural Network is a type of deep learning model specifically designed for processing two-dimensional data, such as medical imaging scans. In a 2D-CNN, the convolutional layer applies an arrangement of channels (or filters) over the input information to capture spatial chains of command and patterns, such as edges, surfaces, and more complex highlights, by sliding the channels over the width and height measurements of the input. This makes a difference in identifying critical highlights inside the information while protecting spatial connections, making 2D-CNNs especially successful for assignments like image recognition [15].

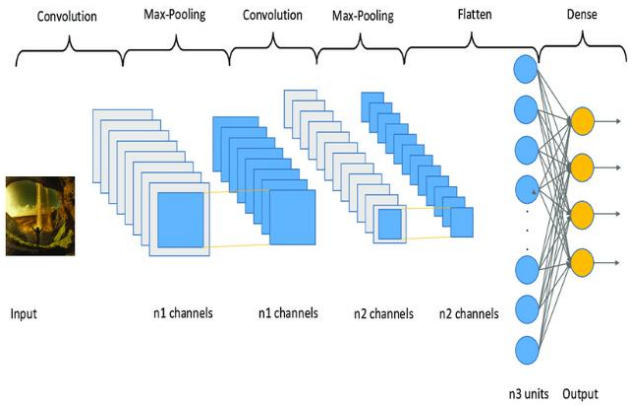

Fig. 2. 2D-CNN architecture.

Fig. 2 illustrates the architecture of a 2D-CNN used for image classification. The process begins with an input image, which undergoes multiple convolutional layers to extract features, followed by max-pooling layers that reduce spatial dimensions while preserving key information. The extracted features are then flattened into a 1D vector and passed through a fully connected (dense) layer for classification. The final output layer produces the classification results, making the architecture suitable for tasks such as object detection and image recognition.

LSTM Architecture design: LSTM is built with a feedback mechanism that allows it to preserve information for long durations. LSTM essentially forms the current input by considering the past yield, hence putting away the future yield in its short-term memory. The cell state is essential to the functioning of LSTM, as it dictates the data that must be preserved or eliminated [16].

The LSTM network functions using three main gates and two essential mechanisms. The Forget Gate decides which information to keep or eliminate from long-term memory. The Input Gate gathers new data and evaluates its relevance relative to existing stored information. Lastly, the Output Gate produces the final output based on the decisions of the other two gates. These gates function using the sigmoid and hyperbolic tangent (tanh) activation functions. A schematic representation of the LSTM architecture is illustrated in Fig. 3.

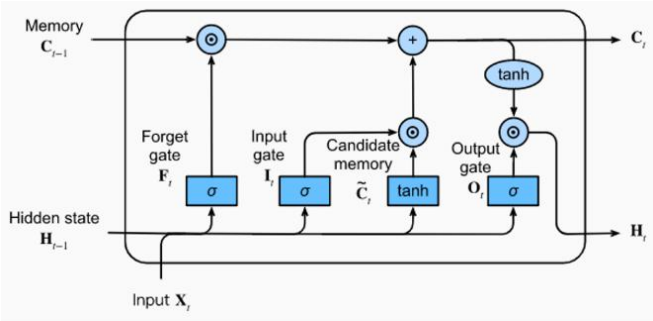

Fig. 3. LSTM architecture.

B. Proposed Hybrid Model

In this study, CNNs and LSTM networks were combined, creating a hybrid deep learning model that enhances image classification as shown in Fig. 4. The first three convolutional blocks each consisted of a convolutional layer followed by a max-pooling layer.

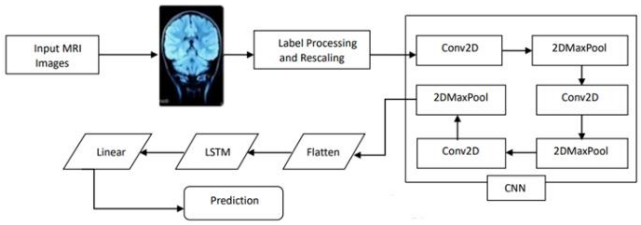

Fig. 4. Proposed hybrid model for Alzheimer's detection.

ReLU activation and 32, 64, and 128 filters with a 3x3 kernel size are used in the convolutional layers. These layers are crucial for the extraction of low-level to high-level features from the input images, such as edges, textures, and complex patterns. Each convolutional layer is followed by a max-pooling operation that uses a 2x2 pooling window with 'same' padding is applied to efficiently reduce the spatial dimensions of the feature maps and reduce the possibility of overfitting.

To further mitigate overfitting, a dropout layer with a rate of 0.3 is applied after the convolutional and pooling layers. To prevent the model from becoming overly dependent on a single feature, this regularization method randomly disables a segment of the input units during the training phase. After the convolutional layers, the model's output is converted into a one-dimensional vector, which is subsequently reshaped to enable sequential processing by the LSTM layer.

The 128-unit LSTM layer is important for identifying temporal patterns and dependencies in the sequential data extracted from MRI images. By enabling the model to understand the relationships and feature development throughout the input data, this layer improves the model's ability to provide accurate predictions. The flattened and reshaped feature vectors are processed by the LSTM layer, which efficiently preserves and makes use of this temporal information for additional analysis.

Finally, the model divides into multiple dense layers, starting with a fully linked layer with 1024 units that uses the ReLU activation function. This layer uses the features retrieved from the previous convolutional and LSTM layers to perform high-level reasoning.

An additional dropout layer is applied to maintain model flexibility. The architecture has been completed with a four units output layer that represents the number of classes in the classification operation. The model's final predictions are generated by this layer using the softmax activation function, producing a probability distribution over the classes.

C. Dataset

This study organized the dataset into two main directories, training and testing, each containing subfolders corresponding to numerous stages of AD. The total number of MRI images were divided across the four classes as follows:

- Mild Demented: 717 train + 179 test
- Moderate Demented: 52 train + 12 test
- Non-Demented: 2,560 train + 640 test
- Very Mild Demented: 1,792 train + 448 test

This structure supports effective model training and evaluation, ensuring that it can accurately classify images corresponding to various stages of AD.

D. Data Preprocessing and Parameters

To enhance model generalization and prevent overfitting, data augmentation techniques were applied, including rotation, flipping, brightness adjustment, and contrast normalization. These transformations ensured that the model learns robust features independent of variations in MRI images. Additionally, The Synthetic Minority Over-sampling Technique (SMOTE) was applied to generate synthetic samples for underrepresented classes, mitigating class imbalance and improving classification performance. In this study, the hybrid 2D-CNN + LSTM architecture was selected to leverage the strengths of both models. CNNs excel at extracting spatial features from medical images, while LSTMs are effective in capturing temporal dependencies. Given that Alzheimer's disease progresses over time, integrating LSTM with CNN allows for improved detection of subtle changes in MRI images that might indicate early stages of the disease. Unlike traditional CNNs that process static images, the LSTM component enabled our model to analyze sequential MRI scans, capturing temporal variations that are crucial for accurate diagnosis. Furthermore, this hybrid approach outperforms standalone CNN and RNN models, as demonstrated in our experimental results.

Several preprocessing steps were required before using the dataset into the machine learning model. First, all images were resized to a consistent 176x176 resolution to maintain

consistency across the dataset. In order to improve the model's performance during training, normalization is applied by rescaling pixel values from the range [0, 255] to [0, 1].

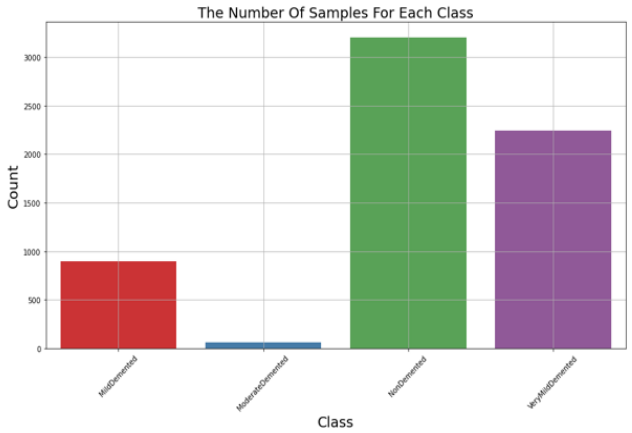

Fig. 5. The number of samples for each class before addressing the imbalance.

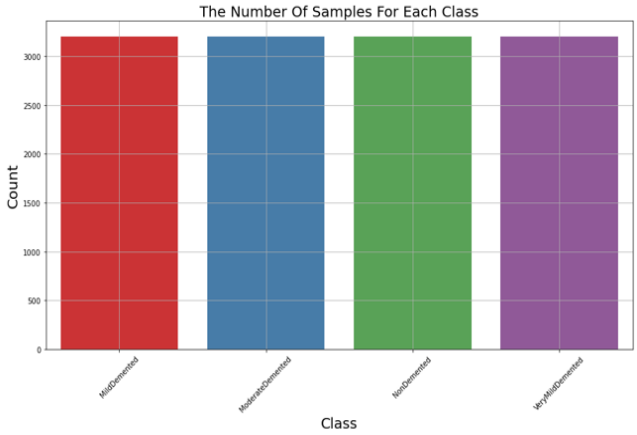

Fig. 6. The number of samples for each class after addressing the imbalance.

The distribution of samples across the four classes before applying SMOTE is shown in Fig. 5. The Synthetic Minority Over-Sampling Technique (SMOTE) has addressed the dataset's inherent class imbalance. By generating synthetic examples for underrepresented classes, SMOTE balances the dataset and enhances the model's ability to generalize across all categories. The class distribution after applying SMOTE is shown in Fig. 6. According to Joloudari et al., an effective class imbalance learning method based on SMOTE and CNNs was developed [17].

70% of the dataset was used for training, with the remaining 30% evenly divided between validation and testing. This balanced split ensured that the model can be thoroughly evaluated and validated during training. The model took input in the form of 176x176 pixel images with three color channels corresponding to the RGB color space. Training was performed with a batch size of 32 over 50 epochs, with a learning rate of 0.001. The loss function employed was categorical cross-entropy, while the Adam optimizer was used to efficiently handle sparse gradients.

These preprocessing steps, combined with the balanced dataset, provide a strong foundation for training a deep learning model capable of accurately classifying the different stages of AD.

IV. Results

A. Environmental Setup

The TensorFlow Keras package is used for classification, with the model executed on an AMD Ryzen 7 and 32 GB RAM. All computations are performed in Python. The proposed technique is evaluated using accuracy, precision, recall, F1-score, specificity, and confusion matrix.

The data visualization of classification results is shown in Fig. 7, illustrating the distribution of predictions across categories.

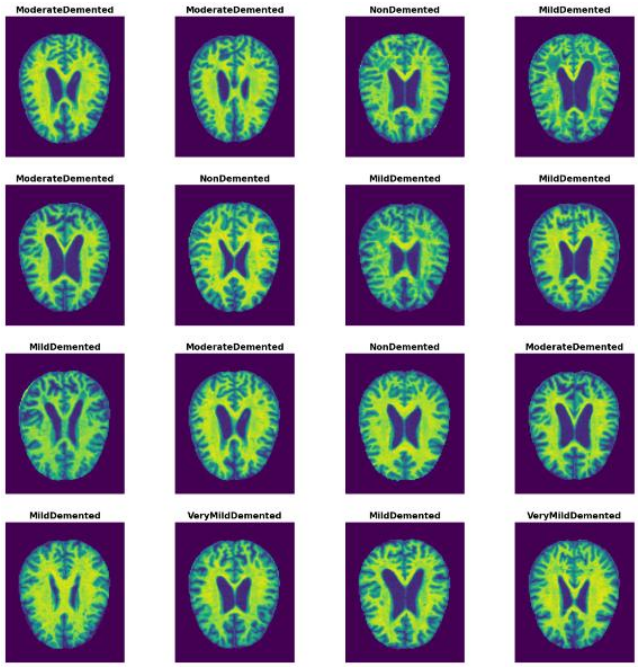

Fig. 7. Data show.

True Negatives (TN), True Positives (TP), False Negatives (FN), and False Positives (FP) indicate the model's performance as measured by the confusion matrix. The performance metrics utilized in this study are listed below:

Accuracy:

$$Accuray = \frac{TP+TN}{TP+TN+FP+FN} \quad (1)$$

Precision:

$$Precision = \frac{TP}{TP+FP} \quad (2)$$

Sensitivity:

$$\text{Recall} = \text{T P F N} + \text{T P} \quad (3)$$

Specificity:

$$\text{Recall} = \text{T N T N} + \text{F P} \quad (4)$$

F1 measure:

$$F1 = 2 \times \text{Precision} \times \text{Recall Precision} + \text{Recall} \quad (5)$$

Precision measures the accuracy of positive identifications, while accuracy indicates how well the classifier predicts all categories correctly. Specificity evaluates how accurately the model predicts negative instances, and sensitivity assesses its ability to detect positives. The F1-score, which factors in both false negatives and positives, is the harmonic mean of precision and sensitivity.

B. Result Analysis

The main contribution of this study is the development of a hybrid 2D-CNN and LSTM model for efficient Alzheimer's disease classification.

The training and validation loss curve is presented in Fig. 8, while the training and validation accuracy curve is shown in Fig. 9.

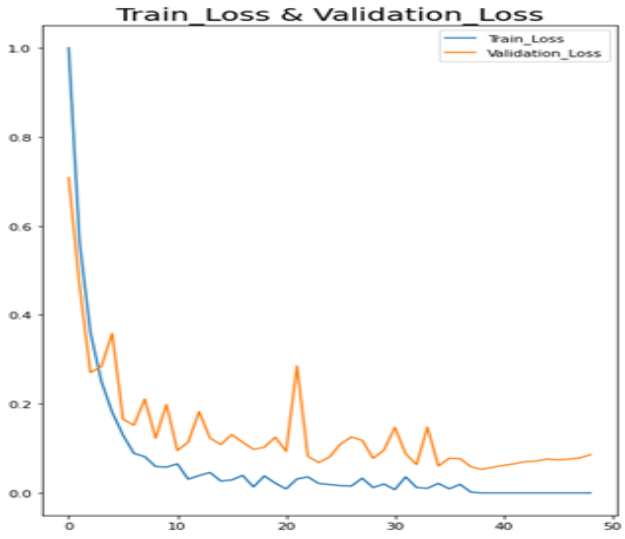

Fig. 8. Training and validation loss curve.

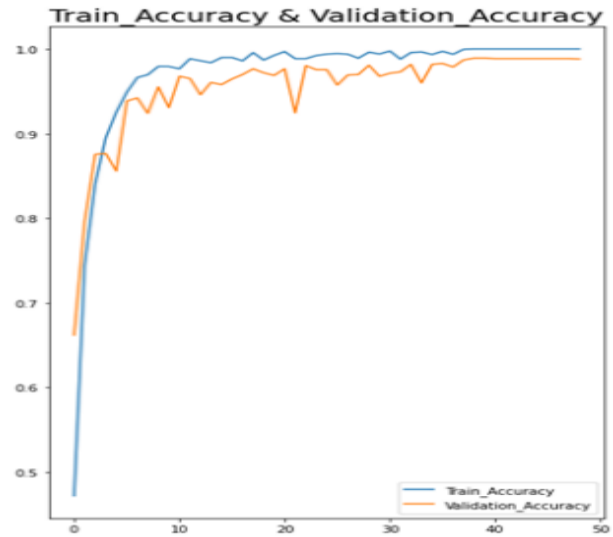

Fig. 9. Training and validation accuracy curve.

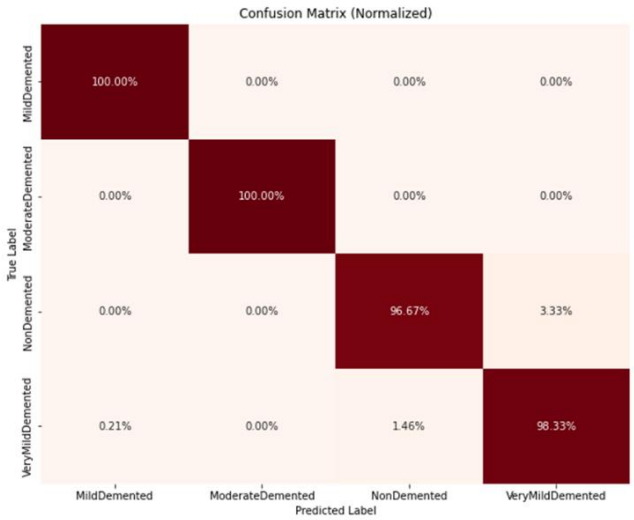

Fig. 10. Confusion matrix.

Fig. 10 presents the confusion matrix of the hybrid model, where rows represent the actual classes and columns represent the predicted classes. The number of cases assigned to each category is shown in the matrix cells. All Mild Demented instances were correctly classified with 100% accuracy, and similarly, all Moderate Demented cases were perfectly classified. For Non-Demented individuals, 96.67% were correctly identified, with only 3.33% misclassified as Very Mild Demented. Finally, 98.33% of Very Mild Demented cases were accurately classified, with 1.46% misclassified as Non-Demented and 0.21% as Mild Demented.

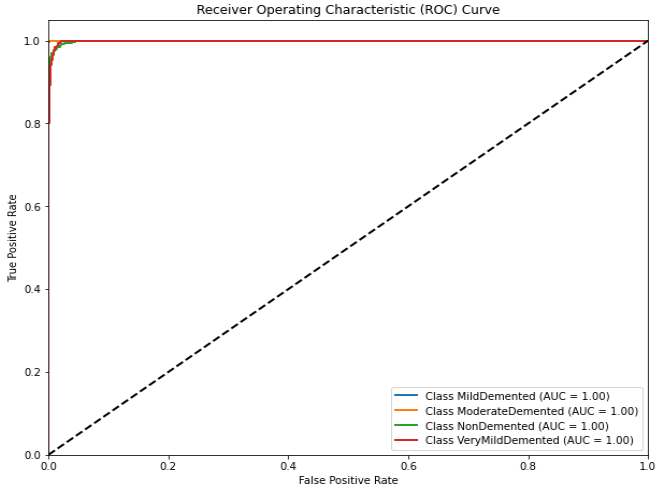

Fig. 11. ROC-AUC curve.

Fig. 11 shows the ROC curve, highlighting the model's performance by plotting the true positive rate against the false positive rate at different decision thresholds. The ROC curve illustrates the model's reliability, with all classes—Mild Demented, Moderate Demented, Non-Demented, and Very Mild Demented—achieving an Area Under the Curve (AUC) score of 1.00. The perfect AUC scores for all classes emphasize the model's accuracy in distinguishing between categories.

The performance of our hybrid model achieves an accuracy of 99%, with sensitivity at 100%, a precision rate of 98% and up to 100%, a specificity of 76%, and an F1-score ranging from 98% to 100%.

The final output of the proposed model's classification is presented in Fig. 12, showing the predicted labels for test samples.

The output of the proposed model:

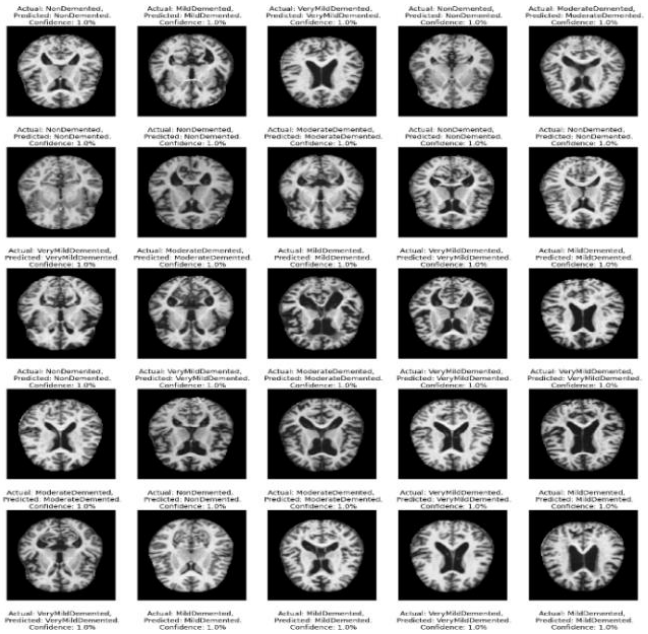

Fig. 12. The output of the proposed model.

V. Discussion

The combination of 2D-CNN and LSTM layers was found to be effective for the image classification task. Despite extensive experimentation with various architectures, including ResNet, DenseNet, VGG, and CNN with SVM, the results varied significantly. The CNN with LSTM approach, along with SMOTE and normalization, achieved the best performance among the tested methods.

Table II summarizes a comparison of different models proposed by researchers for classifying Alzheimer's disease using MRI images. Using the ADNI dataset, Samhan et al. [18] used the VGG16 model and achieved a 97% accuracy rate, while Yang et al. [19] applied the VGG19 model to 3,210 images across four classes and achieved a 97.8% accuracy rate. Using 6,000 images across four classes, Pradhan et al. [26] applied VGG16 technique and achieved an accuracy of 94%. In contrast, using the Inception V4 model with the OASIS dataset, Mohammed et al. [22] achieved an accuracy of 73.75%. Also, Feng et al. [27] combined 3D-CNN and FSBi-LSTM models on the ADNI dataset and has achieved an impressive accuracy of 94.82%. This study's proposed model, integrating 2D-CNN and LSTM, achieved a peak accuracy of 99% on 6,400 images across four classes. This model exceeds the performance of the existing models and highlights its significant potential for effective diagnosis of AD on a larger dataset.

TABLE II. A Comparison of Various Existing Models Along Side the Proposed Model

Authors	Number of Classes	Methodology	Accuracy
L. F. Samhan et al. [15]	ADNI dataset	VGG16	97%
K. Yang et al. [16]	3210 images + 4 classes	VGG19	97.8%
Z. Cui et al. [29]	2400 images + 2 classes	Inception V3	85.7%
V. Patil et al. [30]	223 images	DenseNet	96.4%
E. A. Mohammed et al. [19]	OASIS dataset	Inception V4	73.75%
J. Venugopalan et al. [20]	503 images	CNN	78%
A. Pradhan et al. [21]	6000 images + 4 classes	VGG16	94%
F. Razavi et al. [22]	51 images	S Filter + Regression	98.3%
T. J. Saleem et al. [23]	ADNI dataset	DNN	67%
M. Zaabi et al. [24]	4870 images + 2 classes	CNN + Transfer Learning	92.81%
G. Folego et al. [25]	ADNI dataset	LeNet-5	52.3%
Feng C et al. [31]	ADNI dataset	3D-CNN and FSBi-LSTM	94.82%
Dua M et al. [32]	OASIS dataset	CNN + RNN + LSTM	92.22%
Proposed Model	**6400 images + 4 classes**	**2D-CNN + LSTM**	**99%**

VI. Conclusion and Future Work

The experimental evaluation demonstrates the superiority of our hybrid 2D-CNN + LSTM model, achieving 99% accuracy, 100% sensitivity, and an F1-score of 98%. Compared to existing models, our approach offers a significant improvement in early-stage AD detection. The use of augmentation and class balancing techniques contributed to enhancing model robustness. Future work will focus on extending the dataset, incorporating additional neuroimaging modalities, and exploring transformer-based architectures to further enhance diagnostic precision.

Despite promising results, the study has some limitations. First, the dataset used was relatively small, which may impact the generalizability of the model. Second, the model does not integrate clinical metadata such as age or cognitive scores, which could potentially enhance classification accuracy.

***Abstract*—Recently, there has been a significant reliance on the Internet. This creates a fertile environment for various risks, including fraud, privacy violations, and theft. The most common and dangerous risks at present are known as deepfakes. The development of deepfake technologies relies on advancements in artificial intelligence. Deepfake content can greatly affect privacy and security, posing a significant risk to many fields. Therefore, recent research has focused on mechanisms to detect real content from fake content. These mechanisms are classified into two main types: single-modal and multimodal detection. It is worth noting that the widespread deepfake technology has recently become more complex. This may hinder traditional single-mode detection methods in detecting video clips. In this study, we designed an effective multimodal fusion mechanism that integrates pre-trained audio, visual, and textual features. Our framework is based on three considerations: audio features, visual features, and emotion recognition. Emotion recognition focuses on three considerations: audio emotion, facial emotion, and sentiment of speech. We take advantage of the sentiment of speech to ensure there is consistency between audio and visual emotion with the meaning of words. As we achieved, the sentiment of speech makes our model more accurate and robust than when we used the audio-visual emotion inconsistency measures only. In our experiment, we used the FakeAVCeleb dataset, and we achieved 95.24% accuracy, proving our assumption of the impact of the sentiment of speech, the emotion of audio tone, and facial expressions to detect deepfakes.**

***Keywords*—Machine learning; deepfake; multimodal; sentiment of speech; emotion recognition**

I. Introduction

Recently, artificial intelligence technologies (AI) have witnessed significant development. This development has substantial uses, as AI technologies have become part of most areas of our daily lives [1]. Like any major advancement, AI development has both positive and negative aspects, leading to its use being categorized into these two sides [1]. Among the positive uses of AI, some have been used to enhance innovation and progress in various fields such as medicine, education, and industry. For example, AI has contributed to the development of medical technologies that help diagnose diseases more accurately, improve education by providing smart educational methods, and increase production efficiency in manufacturers [1]. On the contrary, some have exploited AI unethically to achieve harmful goals such as espionage or violating privacy, spreading misleading information, or manipulating public opinions by creating fake content, which is called deepfake [2], [1]. Deepfakes are one of the most concerning uses of these advancements. That involves digital manipulation of media such as text, audio, and visuals [2]. According to Spector [3], it is estimated that a substantial portion, around 50% of the billions of audio files, images, and videos uploaded daily on social and professional platforms, is manipulated. The term deepfake combines "deep learning" and "fake", indicating manipulation based on AI [2]. AI-based manipulations such as Variational Auto-Encoders (VAEs), Generative Adversarial Networks (GANs), and Diffusion Models (DMs) aim to reach unprecedented levels of realism [4]. Notably, deepfakes are utilized across various fields, including hyper-realistic computer-generated imagery (CGI), virtual reality (VR), augmented reality (AR), education, animation, art, and cinema. However, their deceptive nature also makes them susceptible to malicious use [5]. The major theft incident that occurred in 2021 sheds light on the severe financial risks associated with deepfake technology. Thieves employed AI-based voice cloning to mimic a bank official. That enabled them to fraudulently obtain $35 million from a UAE bank [6]. Facial expressions and speech are essential to human interaction, and it is crucial in biometric-based identity recognition. That means altered faces and voices present significant challenges to the integrity of online information and security systems [2].

Deepfakes can manifest in various media, all aiming to alter current content for the benefit of the manipulator. A deep fake can occur on a single modal such as text, audio, or visual, as shown in Fig. 1 and 2.

Otherwise, multimodal, typically shown with videos, such as audio-visual or text-visual manipulation, which is a more complicated deepfake technology, which is shown in Fig. 3 and 4, respectively [4].

Text-based deepfake means manipulating unprecedented volumes of online misinformation, such as fake news and rumors circulating across the internet, influencing public perceptions of significant social events [11]. Recent advances in neural generative models, like GPT-2, have exacerbated this issue, as these models can generate highly fluent and coherent text, potentially allowing adversaries to produce convincing fake news [11]. Audio-based deepfakes are artificially generated or altered audio recordings that convincingly mimic real speech [12]. Lastly, a visual-based deepfake is the replacement of a targeted individual's face in a video with that of another person by splicing a synthesized facial region into the original footage [5].

Fig. 1. Video deepfake from Celeb-DF dataset [7].

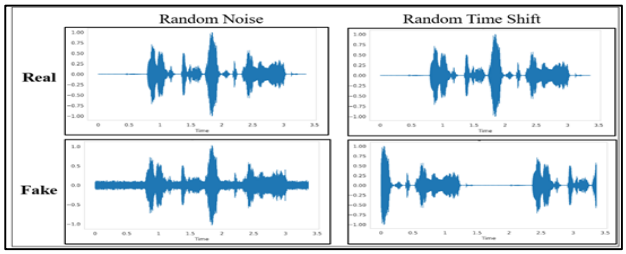

Fig. 2. Audio deepfake from ASVspoof 2019 TFRecord dataset[8]. Random noise means the background noise, and random time shift means changing the audio order.

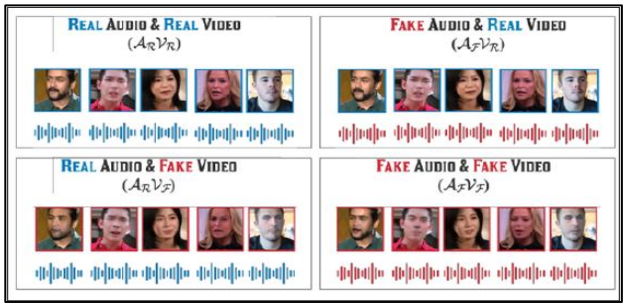

Fig. 3. Audio and visual multimodal manipulation [9].

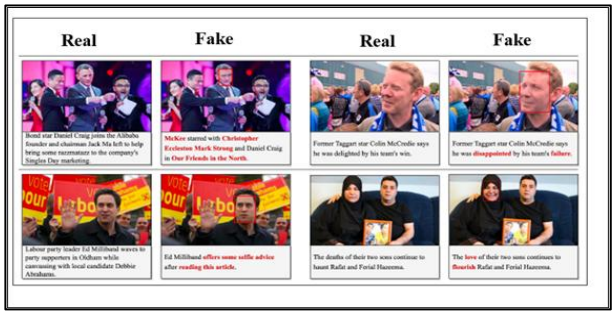

Fig. 4. Text and visual multimodal manipulation[10] .

Deepfake detection has become substantial in the digital age for various reasons. First, it helps stop misinformation, which can convince public opinion and have significant social and political effects [13]. Second, the integrity of news, social media, and legal evidence to support digital media authenticity [14]. Finally, since deepfakes can impersonate people for harmful purposes, it protects against financial fraud and identity theft [15]. To deepfake detection, researchers are developing and evaluating algorithms that can effectively identify manipulated media [4]. These detection models are categorized into two main groups based on the manipulation type [4]. Single-modal detection models focus on analyzing one specific type of data, such as text, image, or audio. Multimodal detection models integrate the analysis of many types of manipulations, combining images, audio, and text. Multi-modal better handles real-world deepfakes [4].

As noted above, multimodal detection is superior to single-modal detection due to the employment of many levels of detection. Thus, studies indicate that integrating emotion recognition, which means increasing detection levels, into deepfake detection provides a promising enhancement in the fight against advanced AI-generated media [16]. Emotion recognition is an aspect of artificial intelligence designed to interpret human emotions through nonverbal analysis [17]. Emotional recognition can be accomplished through several forms, including text, visual, and audio forms [17]. Text emotion recognition systems assess written text for emotions [18]. Classifying emotions like happiness, rage, and sadness includes processing textual signals, including word choice, syntax, and language patterns [18]. Visual emotion recognition employs computer vision to examine facial features in images and videos [17]. In audio emotion identification, AI algorithms use tone, pitch, and rhythm to infer emotions [17]. Conventional detection techniques frequently depend on perceptual discrepancies or technical defects. As the quality of deepfakes enhances, these indicators become increasingly difficult to discern. Consequently, examining emotional authenticity, including the intensity and genuineness of expressions, will enhance the distinction between authentic and altered information [16], [19], and [20].

Recent studies have shown that multimodal detection strategies, either visual-audio or text-audio, can give the deep learning model complementary information. However, the current strategies are still struggling with detecting fake content, especially with the datasets that use complex manipulation tools. The related works that used an emotional indicator achieved better accuracy than those without emotion detection. Nevertheless, there is no investigation about the concatenation of emotions with the sentiment of speech, "what I say and how I say it". Thus, we will get better information than the traditional emotion detection when we integrate the sentiment of speech—what I say—with audio emotion and facial emotion—how I say it.

Motivated by this gap, we introduce our novel framework, titled "Audio-Visual Multimodal Deepfake Detection Leveraging Emotional Recognition". A framework for developing an efficient multimodal deepfake detection system. Our method detects deepfakes based on emotional mismatches in three considerations.

The main contributions are as follows:

- Compute the mismatch between the audio tone and the facial emotion.
- Compute the mismatch between the audio tone and the sentiment of speech.
- Compute the mismatch between the facial emotion and the sentiment of speech.

- Perform an ablation study to analyze the impact of each field in our model with five experiments (audiovisual emotion model, sentiment of speech only model, audio emotion with sentiment of speech model, facial emotion with sentiment of speech model, and our approach that includes all of above model).

The structure of this study is as follows: Section II presents a review of the literature. Section III describes the proposed framework and methodology. Section IV details the experiments and reports the results. Section V provides a discussion of the findings. Finally, Section VI concludes the study and outlines future works.

II. Literature Review

As we mentioned earlier, deepfake techniques have recently become more accurate and sophisticated due to advances in artificial intelligence. Therefore, it is important to keep up with this development with effective detection tools. We categorize the literature reviews according to the approaches to detecting deepfake content. We break it into three subsections: single-modal, multimodal, and emotional deepfake detection approaches. Then we will present the existing datasets. This section will conclude with research gaps and our contribution.

A. Single-Modal Detection Approach

As we know, in single-modal detection, there are three types of methods for detecting deepfakes: textual, audio, or visual detection. In this subsection, we will present the literature reviews that utilize a single type of deepfake detection. Divided into sub-subsections are text-based, audio-based, and visual-based. This subsection concludes with an analytical table of the literature mentioned there.

1) Text-based approach. The following studies aim to propose a deepfake detection model based on textual content. Saravani et al. [21] examined a technique for identifying social media bots through the analysis of tweets. Utilizing the deepfake dataset comprising 25,572 tweets from bots mimicking human accounts, the model processed data and employed a classification architecture that included two fully connected layers. The authors attained a two per cent enhancement in accuracy over prior models by incorporating bidirectional encoder representations from transformers (BERT) for text representation that used natural language processing (NLP), a bidirectional long-short-term memory (BiLSTM) layer is a type of neural network used to preserve word order, and the neural network expand vector of locally aggregated descriptors (NeXtVLAD) layer for effective information summarization. Li et al. [22] used large language models (LLMs) that closely resemble human writing to study the challenges of distinguishing human-authored from machine-generated writing. The authors built their identification system using human-authored texts from Reddit comments, news headlines, and academic works. To ensure diversity, they used 27 LLMs and three prompt types to generate machine-generated writings. The detection system provided a probability score for classifications and used the Longformer neural network, which outperformed related models. Jensen-Shannon distance revealed that text variety inhibited the detection of linguistic trends. The detection method had an 86.54% recall rate on GPT- 4 texts. Zhong et al. [11] examined the growing problem of online deception, focusing on GPT-2-generated fake news. The researchers developed FAST, a graph-based method for analyzing literary compositions' factual architecture to distinguish human-generated from machine-generated material. They examined the news-style (GROVER) and web text-style (GPT-2) datasets for binary classification. We found that human-authored texts cited the same elements in their sentences, but machine-generated texts incorporated unnecessary sections, making differentiation easier.

2) Audio-based approach. The following research efforts aim to develop a deepfake detection model based on voice analysis. A study by Mcuba et al. [23] used deep learning techniques, especially convolutional neural networks (CNNs), to make it easier to spot deepfake sounds. They used the Baidu Silicon Valley AI Lab's VCTK and LibriSpeech speaker datasets for research. During preprocessing, they converted audio recordings into images and extracted features like mel-spectrograms and MFCCs for analysis. Hamza et al. [12] studied deepfake audio identification. The authors used advanced machine learning techniques, specifically MFCCs for audio evaluation, to improve detection approaches. To ensure high-quality preprocessing for model training, the authors used the Fake-or-Real (FoR) dataset with approximately 195,000 samples of real and synthetic speech. This study focused on feature extraction and classification models, with the Support Vector Machine (SVM) achieving the greatest accuracy of 98.83%. Shorter audio segments increased classification performance, with SVM outperforming in clean and loud circumstances. Pianese et al. [24] focused on speaker biometrics and trained the algorithm on real data to ensure real-world performance. Centroid-based (CB) and maximum similarity (MS) were the study's key approaches. The study tested advanced models such as RawNet2- antispoofing on ASVSpoof2019, FakeAVCelebV2, and In-The-Wild Audio Deepfake. Centroid-based (CB) testing compares test audio to the real audio average. Second, maximum-similarity testing (MS) compares test audio to real audio with the highest similarity score. The MS method performed well across datasets, especially in complicated, real-world circumstances. Muller et al. [25] examined text-to-speech synthesis advances and their effects on audio deepfakes, which may impersonate human voices. The authors used ASVspoof 2019 and IWA. They created 37.9 hours of audio samples from real and fictitious prominent people to test the models. ADAM optimizes cross-entropy loss-trained deep learning models.

TABLE I. ANALYTICAL REVIEW OF SINGLE-MODAL APPROACH

Study	Approach	Model	Datasets	Performance Metrics	Evaluation
Saravani et al. [21]	Text- based	BERT, BiLSTM, and NeXtVLAD	Deepfake	Accuracy	92%
Li et al. [22]	Text- based	Longformer	Customized (Texts produced by GPT-4)	Accuracy	86.54%
Zhong et al. [11]	Text- based	Graph Convolutional Network (GCN), LSTM, and Next Sentence Prediction (NSP)	GROVER and GPT-2	Accuracy	GROVER =87.97% GPT-2= 93.1%
Mcuba et al [23]	Audio-based	CNN with Adam, SDG, and Adadelta optimizers	VCTK with the LibriSpeech speakers	Accuracy	Adadelta =85.9% SDG = 83.6% Adam = 72.2%
Hamza et al. [12]	Audio-based	SVM	FoR	Accuracy	98.83%
Pianese et al. [24]	Audio-based	Supervised method, CB, and MS	ASVSpoof20 19, FakeAVCele bV2, and IWA	Calculate the average area under the curve (AUC) for all datasets	Supervised method = 79.6% CB = 88.4% MS= 91.3%
Muller et al. [25]	Audio-based	Multiple neural network	ASVspoof20 19 and IWA dataset	Equal Error Rate (EER)	ASVspoof2019 =9.85% IWA= 60.10%
Wodajo and Atnafu [5]	Visual-based	CViT (CNN and Vision Transformer (ViT))	DFDC	Accuracy	91.5%
Cozzolino et al. [10]	Visual-based	ID-Reveal which uses temporal ID network	VoxCeleb2 dataset	Accuracy	80.4%
Li et al. [26]	Visual-based	DSP-FWA by using CNNs	Own dataset (Celeb-DF) and others as UADFV and DFDC	AUC	Celeb-DF=64.6% UADFV=97.7% DFDC=75.5%

Comparing neural network topologies requires feature extraction, according to the authors. They found that raw audio features outperformed processed features and that longer audio segments reduced model error rates from 19.89% to 9.85%.

3) Visual-based approach. The studies below focus on developing a deepfake detection model based on image analysis. Wodajo and Atnafu [5] developed CViT to detect false content. The study required three steps for preparation: we recognized faces from video frames, scaled them to 224 x 224 pixels in RGB format for consistent input, and optimized content to reduce background interference. Rotation, flipping, and color changes boosted dataset variety and model generalization. The CViT used convolutional layers and transformer processes to record spatial hierarchy in images and apply self-attention to detect essential parts. The CViT had 91.5% accuracy on the enlarged dataset, although dataset heterogeneity and visual artifacts affected it. Cozzolino et al. [10] used the Temporal ID Network and 3D Morphable Model (3DMM) Generative Network to create the ID-Reveal method for detecting deepfake movies. The temporal ID network developed an embedded vector that identifies an individual using convolutional layers and similarity score computations, while the 3DMM generative network created authentic 3D characteristics. Test videos were compared to pristine reference videos for authenticity. The ADAM optimizer gave ID-Reveal 80.4% accuracy and 0.91 AUC for high-quality videos. Li et al. [26] proposed detection methods and the Celeb-DF dataset of high-quality deepfake videos of celebrities. They examined nine detection methods, including CNNs and head movement assessment. Deep learning-based spatio-temporal features for video forgery detection with attention (DSP-FWA) performed best. DSP-FWA looks at videos' spatial and temporal data using an attention method to bring out important parts and make detection more accurate.. Table I shows that deepfake detection techniques are either in text, audio, or visual domains. With each approach demonstrating unique strengths. Text-based models, Saravani et al. [21], used BERT, BiLSTM, and the NeXtVLADGCN, showed good accuracy in detecting manipulated texts, equal to 92%. While audio-based detection, Hamza et al. [12], used SVM, which outperformed other methods with an accuracy of 98.83%. On the other side, visual-based models, Wodajo and Atnafu [5] used the CViT and achieved good accuracy around 91%. Overall, selecting the right detection method depends on the type of deepfake being analyzed.

B. Multimodal Detection Approach

In multimodal detection, the detection is achieved by analyzing more than one type of manipulation. As we mentioned, there are two main combination types of methods for multimodal detecting deepfake: textual-visual or audio-visual detection. In this subsection, we will present the literature reviews that utilize multimodal deepfake detection. We divided this into subsections: text-visual based models and audio-visual-based models. This subsection concludes with an analytical table of the literature mentioned there.

1) Text-visual-based approach. Text-visual multimodal detection provides a framework for deepfake detection that integrates textual and visual analysis. Shao et al.[27] studied system localized modifications in coupled photos and text, with a specific focus on news stories. They have created the multimodal media manipulation dataset called Detecting and Grounding MultiModal Media Manipulation (DGM4). This dataset of 230,000 samples, including 152,574 modified pairs, examines the impact of simultaneous picture and text alterations. The detection model hierarchical multimodal manipulation reasoning transformer (HAMMER) and its enhanced version, HAMMER++, have proposed approaches to align and analyze image-text interactions for more accurate

modification detection. Liu et al.[4] developed the Unified Frequency-Assisted Trans Former Framework (UFAFormer) to discover and evaluate media modifications in images and text. It includes picture and text encoders, a frequency encoder that leverages DWT, and a Forgery-Aware Mutual Module (FAMM) to promote feature integration. UFAFormer improved accuracy on DGM4. Change recognition and classification improved as the authors devised components that incorporate multiple sources of information. Wang et al. [28] suggested a framework that used unimodal feature extractors to extract unique photo and text properties. The model used dual-branch cross-attention (DCA). It improved manipulation identification by analyzing both modalities simultaneously. The study focused on manipulation grounding, which involved identifying altered visual parts and text phrases. The data preparation included standardizing text to fifty tokens and scaling pictures to 256x256. Their method reached 95.11%.

2) Audio-visual-based approach. The following efforts provide a framework for deepfake detection that integrates audio and visual analysis. Khalid et al. [29] introduced the evaluation of an audio-video multimodal deepfake dataset using unimodal and multimodal detectors. They used the FakeAVCeleb dataset, which had 600 clips starring various celebrities. The authors employed three evaluative methodologies: unimodal, ensemble, and multimodal. Unimodal techniques examined audio or video separately, employing baseline models such as VGG16 and Xception; nevertheless, they encountered difficulties when one modality was authentic and the other was fabricated. Ensemble approaches amalgamate predictions from distinct classifiers for audio and video, enhancing accuracy. Nonetheless, the multimodal strategy, which concurrently assessed both data kinds, demonstrated diminished efficacy, indicating that existing techniques were insufficient for intricate deepfake identification. Lewis et al. [30] used multimodal deep learning to detect false videos utilizing spatial, spectral, and temporal anomalies. NOLANet uses multiple detection methods, including audio and visual attributes to classify content as real or false to identify deepfakes. They used Facebook's Deepfake Detection Challenge dataset (FDDC). Multi-stage detection used LSTM networks for categorization. Preprocessing the films involved extracting frames at 30 frames per second while maintaining the audio. They used BlazeFace to trim and recognize faces at 128x128 pixels. Face landmarks were extracted using FANet. Multiple LSTM networks processed integrated visual and auditory data after DCT analysis. Aligning aural and visual data helped discover deepfake discrepancies. Raza and Malik [31] proposed a multimodal representation learning multimodal trace for deepfake detection. The framework classified audio and video inputs as authentic or fake using a structured architecture. Essential components include audio and video feature extractors, mixers to combine them, and a classification layer. Data is prepared for analysis after normalization and feature extraction by Fast Fourier transform and ResNet. IntrAmodality Mixer Layers (IAML) evaluated audio and video inputs separately to discover patterns. Multi-label categorization using IEML unifies audio and video input modalities. Muppalla et al. [32] presented an integrated audio-visual feature for multimodal deepfake detection. That aimed to improve the identification of multimodal deepfakes by amalgamating audio and visual data via a distinct classification methodology. This entailed compressing video frames to a standardized dimension. Which is about 300x300 pixels and transforming audio into Mel spectrograms. The approach applied deep learning networks for feature extraction and implemented a multi-task learning technique. The assessment utilized two principal datasets. The FakeAVCeleb and the TMC datasets. They tested the framework using two models, the capsule network and the Swin transformer; the capsule network has the best accuracy. Cheng et al. [7] introduced a voice-face matching detection (VFD) system by looking at how well the voices and faces in deepfake videos match each other. They developed a method that first trains the model on regular data. Then fine-tune it for deepfake detection. The authors trained their model with the Voxceleb2 dataset, which includes over 17 million audio utterances from more than 6,000 celebrities. In the testing, they used many datasets, such as DFDC and FakeAVCeleb. Feng et al. [33] proposed self-supervised video forensics by audio-visual anomaly detection. The model was trained on real, unlabeled speech videos from the Lip-Reading Sentences 2 (LRS2) and Lip-Reading Sentences 3 (LRS3) datasets. By learning the normal patterns of audio-visual synchronization.

This led to the classification of anomalies by flagging videos that deviated from the established distribution of features representing the relationship between audio and visual elements. A key component of the method involved calculating synchronization scores for audio-video pairs using a specialized network. The model maximized synchronization scores for real pairs and identified fake ones by analyzing their probability distributions. The evaluation of the model was conducted using two datasets. The FakeAVCeleb and the large-scale Korean-language deepfake detection (KoDF) datasets. Oorloff et al. [34] proposed an audio-visual feature fusion (AVFF) framework for detecting video deepfakes. By employing a self-supervised learning strategy to capture the relationship between audio and visual elements. A trained classifier differentiated between real and fake videos by examining characteristics from both audio and visual elements. The training procedure used the LRS3 dataset for feature extraction. The FakeAVCeleb and KoDF datasets are used to evaluate the model. Table II shows multimodal deepfake detection methods which shows promising results by combining different inputs like text, audio, or visuals. Wang et al. [28] achieved the highest result for text-visual models at 91.42%. While Muppalla et al. [32] reported an impressive 99.20% multimodal result for audiovisual models. The ensemble based on the voting boosts detection robustness in Khalid et al. [29]. Overall, integrating multiple modalities enhances performance. However, effectiveness depends on the datasets, algorithms used, and the integration method used to merge two single models.

TABLE II. ANALYTICAL REVIEW OF MULTIMODAL APPROACH

Study	Approach	Model	Datasets	Performance metrics	Evaluation	
Shao et al. [27]	Text- visual based	Image detection by BBox Detector	DGM4	Intersection over Union mean (IoUmean)	Image = 76.51%	
		Text detection by Token Detector		Recall	Text= 72.14%	
		Multimodal by Multi-Label Classification		Mean Average Precision (mAP)	Multi-label =86.29%	
Liu et al. [4]	Text- visual based	Image encoder by vision transformer (ViT-B/16)	DGM4	Intersection over Union mean (IoUmean)	Image = 78.33%	
		Text encoder by BETR base model		Recall	Text= 70.61%	
		Multimodal by unified decoder to manipulate detection and grounding across image, text, and image-text pairs		Mean Average Precision (mAP)	Multi-label =87.85%	
Wang et al. [28]	Text- visual based	Image encoder by vision transformer (ViT-B/16)	DGM4	Intersection over Union mean (IoUmean)	Image = 80.83%	
		Text encoder by RoBERTa base model		Recall	Text= 70.73%	
		Binary classifier to determine whether manipulation is present. Fine-grained classifier to identify specific types of manipulation.		Mean Average Precision (mAP)	Multi-label =91.42%	
Khalid et al. [29]	Audio-visual based	Audio using many deep learning methods	FakeAV Celeb	Accuracy	Audio = 76%	
		Image using many methods such as VGG16			Image = 81%	
		Ensemble approach based on voting method. Multimodal using CNN			Ensemble = 78% Multimodal= 67.3%	
Lewis et al. [30]	Audio-visual based	Audio using LipSpeech sub-network	FDDC	Accuracy	Audio = 59.21%

C. Emotion-Based Detection Approach

This subsection will focus on the related deepfake detection models that utilize emotional recognition features to detect fake content. Mittal et al. [19] proposed affective cue-based audio-visual deepfake detection. They found inconsistencies in actual and fake videos of the same person using a Siamese neural network and embedding vectors. Deepfakes are detected by evaluating emotional variations between speech and facial expressions. Their model was evaluated on DF-TIMIT and DFDC, two well-known deepfake detection datasets. Hosler et al. [20] suggested that using emotional inconsistencies to detect deepfakes is meaningful. Two dimensions were utilized to model emotion: valence (positive/ negative effect) and arousal. Real and fake videos have different emotional patterns, according to the authors. Deepfake technology struggled to recreate real emotions. First, video emotional features were extracted for detection. To express the subject's emotions across time, use valence and arousal. Finalizing the video's deepfake detection utilizing these emotional signals. The tests used two datasets. An emotion prediction model is trained on SEMAINE, and deepfake detection on DFDC. An LSTM model predicted emotional states and captured video emotional dynamics using extracted features. Conti et al. [35] presented a semantic approach for deepfake speech detection through emotion recognition (SER). The model identified emotional inconsistencies in synthetic audio by extracting emotional features and feeding them into a classifier. The system identified four primary types of emotions in speech, which are angry, happy, sad, and neutral. The system effectively distinguished reality from synthetic speech.

TABLE III. ANALYTICAL REVIEW OF EMOTIONAL APPROACH

Study	Approach	Model	Datasets	Performance Metrics	Evaluation	
Mittal et al. [19]	Audio-visual based	Emotions extraction Memory fusion network (MFN) to extract emotions from audio and visual modalities Detection by Siamese network to detect inconsistencies.	DF-TIMIT and DFDC	AUC	Without emotion indicator DFTIMIT= 94.8% DFDC=8 2.8%	With emotion indicator DFTIMIT= 96.3% DFDC= 84.4%
Hosler et al. [20]	Audio-visual based	Emotions extraction by Extracting low-level features for face and voice. Detection by Uses LSTM models to predict continuous emotional states (valence and arousal) over time.	DFDC	Accuracy	Without emotion indicator = 87.5%	With emotion indicator = 99.5%
Conti et al. [35]	Audio based	Emotions extraction by Speech Emotion Recognition (SER) component that extracts emotional features from speech using a 3D- Convolutional Recurrent Detection by Neural Network (CRNN) Synthetic Speech Detector (SSD) classifies the input as real or deepfake using a Random Forest classifier.	ASVspoof 2019	AUC	Without emotion indicator = NA	With emotion indicator = 98%

Testing showed high accuracy, especially in clean audio, and demonstrated better performance than other models. The core idea was that synthetic speech often failed to replicate authentic emotional patterns, making SER-based features valuable for detection. Table III shows that incorporating emotional recognition significantly enhances the performance of deepfake detection models. Mittal et al. [19] and Hosler et al. [20] proposed detection models using audio-visual deepfake detection. Demonstrated that including emotional features improved the performance. Hosler et al. [20] achieved impressive growth from 87% to around 99%. Conti et al. [35] also showed high performance with emotion extraction by speech emotion recognition. These findings suggest that emotion extraction can be a crucial factor in improving the performance of deepfake detection methods. However, there

are some considerations to enhance the performance, including selecting datasets, algorithms used, and merge methods.

The literature analysis presented above shows that several studies have been conducted to detect deepfake content with different types of content. As we mentioned, as deepfake technology advances, methods for detecting these intricate alterations must also improve. As we observed in Table II, multimodal detection in most cases has improved the performance of deepfake detection, while the model in Muppalla et al. [30] achieved an accuracy of around 99%, the poor detection accuracy of the visual-based model affected the overall multimodal detection accuracy when they used the FakeAVCeleb dataset. They reached an accuracy of around 99% on audio and 61% on image, leading to the overall detection of the multimodal dropping to around 66%. This situation necessitates further investigation into the methods of merging the individual models. Furthermore, notice in Table III that when emotion analysis is added to the model, it enhances the performance. Looking at Mittal et al. [19] and Hosler et al. [20] on how the emotion-based analysis increased performance results, however, there are limited studies that utilize this feature. In this study, we will aim to design audio-visual multimodal deepfake detection leveraging emotional recognition. The emotion extraction will be in three points: audio, image, and sentiment of speech. And the inconsistency between them. Considering the side effects of the multimodal dropped performance. That may occur due to the ineffective selection of the algorithm of audio detection and visual detection, as well as the integration methods.

III. Framework and Methodology

This section explores the architecture of our proposed framework, as shown in Fig. 5, which is designed to detect deepfake content by leveraging emotion recognition in multimodality.

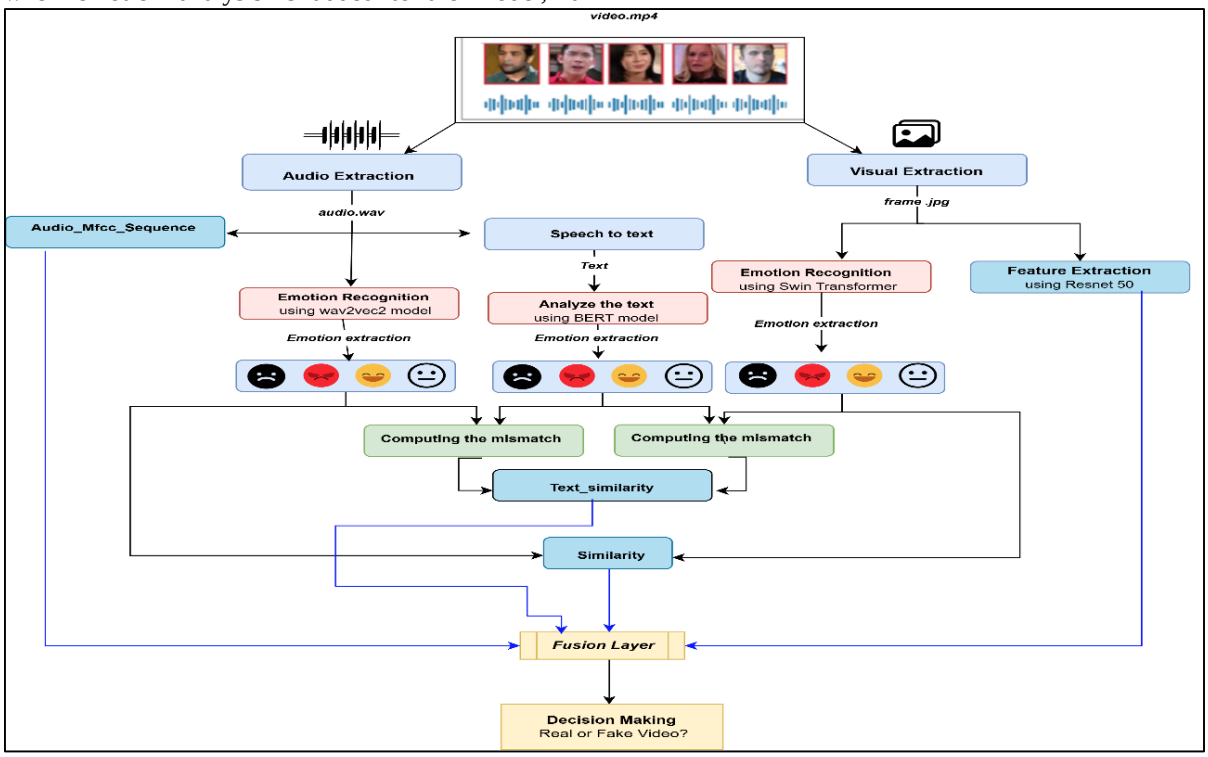

Fig. 5. The model framework.

A. Audio Features Extraction

The first component of our framework is the audio extraction and analysis, containing two main models. The first model aims to extract the main features of (.wav) audio, which includes thirteen Mel-Frequency Cepstral Coefficients (MFCC). The second model seeks to convert the speech to text, aka speech recognition, by using the pre-trained model called wav2vec2 [refer Appendix A] [36]. After that, the audio section involves the emotion extraction stage of each audio and text, aka the sentiment of speech. For the emotion recognition of the audio tones, we used the wav2vec2 pretrained model [37]. For sentiment analysis, we used a pretrained model using the bidirectional encoder representations from transformer (BERT) [38].

B. Visual Features Extraction

The second component is a visual analysis part that extracts the frames (.jpg) with image size 224*244 pixels and then extracts the visual features by a pretrained model using Residual Network - 50 layers (ResNet50) model to extract the noise, sharpness, and edge density. After that, the visual emotion extraction using the pretrained model used the shifted window transformer (Swin transformer) [39].

C. Cross-Model Emotional Consistency Stage

The consistency computation will be between the three modalities: text, audio, and visual. As follows, between the sentiment of speech and the emotion of the audio tone. Between the sentiment of speech and the emotion of the visual

part. Last, compute the mismatch or consistency between the emotion of the audio tone and the emotion of the visual part.

D. The Fusion Layer

Our framework's fusion technique is based on concatenates modality-specific characteristics from the text, audio, and visual streams before passing them through a classification. In particular, a Long Short-Term Memory (LSTM) network with a hidden size of 256 is used to process the temporal data from the video frames in order to identify dynamic patterns over time. After that, this output is coupled with emotion embeddings from each modality, visual quality metrics (noise, edge density, sharpness), and high-level features taken from the audio signal (MFCC and spectral contrast). The final classification output (real or false) is obtained by passing the resultant feature vector through two fully connected layers using ReLU activations.

This straightforward yet effective fusion method enables the model to integrate emotional signals and quality-related features from multiple modalities into a unified decision space. Although more sophisticated approaches—such as attention-based mechanisms—could further enhance performance, we intentionally opted for a lightweight architecture. Our goal was to ensure reproducibility and maintain interpretability, providing a clear and stable baseline for multimodal deepfake detection.

We implemented a modular pipeline to extract and align multimodal features from the FakeAVCeleb dataset. For each video, seven evenly spaced frames were extracted, alongside full audio and transcribed text. Visual features were obtained using a pretrained ResNet50 model, and temporal dependencies were captured using an LSTM module. Additional visual quality metrics (sharpness, edge density, and noise) were computed per frame. Audio features included MFCCs and spectral contrast, while emotional vectors for audio, text, and visual modalities were parsed from pre-extracted sentiment scores. Cosine similarity was used to measure the alignment between emotion vectors. A full architecture diagram is shown in Fig. 5.

This fusion strategy is theoretically grounded in the concept of cross-modal emotional coherence, which hypothesizes that authentic content exhibits natural alignment between facial expressions, vocal tone, and verbal sentiment. By explicitly modeling emotional alignment across modalities—rather than fusing only raw or semantic features—the framework captures inconsistencies that are typical in manipulated content. When compared to partially fused techniques, the ablation studies empirically show that integrating emotional consistency results in significant performance benefits. Our method employs emotional incompatibility as deception cues, providing a new layer of semantic analysis in fake content detection, in contrast to classic multimodal fusion, which only considers spatial or temporal correlations.

IV. Experiments and Results

In this section, we will explore our experiments and results and how we adopt a structured training approach that ensures stability and generalizability to train our deepfake detection model successfully.

A. Experiments

In this subsection, we will present the experiment setup, the dataset that has been used and the ablation study that was conducted in our experiments

1) Experimental setup. The model was trained for 10 epochs using the Adam optimizer with a learning rate of 1e-4. We applied cross-entropy loss and set the batch size to 4, with a fixed randomization seed of 101 in all experiments. The training dataset consisted of 80% of the total data, while the remaining 20% was used 10% for validation and 10% for testing.

2) Dataset. The dataset that has been used in our study is called the FakeAVCeleb dataset [9]. That contains 20,500 video samples, which are divided into the following categories: 500 real videos from the VoxCeleb2 dataset, featuring real audio. 500 videos that combine synthetic (fake) audio with actual footage. 9,000 videos with real audio and fake video. 10,000 videos containing fake audio and video. The average length of each video is roughly 7.8 seconds. The dataset offers a variety of actual and altered audiovisual material combinations to facilitate multimodal deepfake detection research. Fig. 6 below shows the categories of the FakeAVCeleb dataset. The original FakeAVCeleb dataset contains 20,500 samples. For this study, we selected a representative and balanced subset consisting of 998 video samples, equally divided into 499 real and 499 fake videos. The samples were randomly selected from the full dataset while ensuring class balance. To streamline the training and evaluation process, we manually created a CSV file that includes the file paths and corresponding labels for each video sample. This setup allows for efficient data loading and consistent processing across experiments.

Fig. 6. The FakeAVCeleb dataset [9].

3) Ablation study. To ensure the productivity of our contribution, we conducted the ablation study for each emotion feature in our multimodal deepfake detection model as follows:

a) Audio-visual emotion only (No sentiment): In this experiment, we focused on the features extracted from audio, which are thirteen MFCC, and from visual, which are noise,

sharpness, and edge density. Furthermore, the emotion consistency computation between audio and visual modalities. Without any sentiment information. Table IV shows the detailed results of the experiment.

TABLE IV. AUDIO-VISUAL WITH EMOTION RECOGNITION RESULT

Model	Performance		
	Accuracy	*F1-Score*	*Recall*
Audio-visual with emotion recognition	76.19%	72.15%	73.3%

b) Audio emotion and text sentiment (No visual Emotion): In this experiment, we focused on the features extracted from audio, which are thirteen MFCC, and from visual, which are noise, sharpness, and edge density. Furthermore, the emotion consistency computation is between audio and text modalities without any computation between audio and visual emotion. Table V shows the detailed results of the experiment.

TABLE V. AUDIO-VISUAL WITH AUDIO EMOTION AND TEXT SENTIMENT

Model	Performance		
	Accuracy	*F1-Score*	*Recall*
Audio-visual with audio emotion and text sentiment	76.19%	69.21%	68.33%

c) Visual emotion and text sentiment (No audio emotion): In this experiment, we focused on the features extracted from audio, which are thirteen MFCC, and from visual, which are noise, sharpness, and edge density. Furthermore, the emotion consistency computation is between visual and text modalities without any computation between audio and visual emotion. Table VI shows the detailed results of the experiment.

TABLE VI. AUDIO-VISUAL WITH VISUAL EMOTION AND TEXT SENTIMENT

Model	Performance		
	Accuracy	*F1-Score*	*Recall*
Audio-visual with visual emotion and text sentiment	76.19%	69.21%	68.33%

d) Sentiment fusion only (No cross-audio-visual emotion): In this experiment, we focused on the features extracted from audio, which are thirteen MFCC, and from visual, which are noise, sharpness, and edge density. Furthermore, the emotion consistency computation between visual and text modalities and between audio and text modalities without any computation between audio and visual emotion. Table VII shows the detailed result of the experiment.

e) Full multimodal emotion and sentiment fusion (Our approach): In this experiment, it was conducted on the complete framework features, which are the features extracted from audio, which are thirteen MFCC, and from visual which are noise, sharpness, and edge density, the emotion consistency computation between visual and text modalities, and between audio and text modalities. Furthermore, the computation between audio and visual emotion. Table VIII shows the detailed results of the experiment.

TABLE VII. AUDIO- VISUAL WITH SENTIMENT ANALYSIS

Model	Performance		
	Accuracy	*F1-Score*	*Recall*
Audio-visual with sentiment analysis	80.95%	78.57%	81.67%

TABLE VIII. OUR APPROACH

Model	Performance		
	Accuracy	*F1-Score*	*Recall*
Our Approach	95.24 %	95.24%	95.45%

These results empirically validate the contribution of sentiment indicators in multimodal fusion, showing that their absence significantly degrades performance. This supports our hypothesis that emotional coherence between modalities is a strong signal for deepfake detection. These ablation results are further discussed and interpreted in Section V, where we reflect on their implications and underlying patterns.

B. Results

In this subsection, we present the performance evaluation of our proposed model through three comparative perspectives. First, we compare our results with existing studies that utilized the same dataset (FakeAVCeleb) to provide a fair benchmark under similar data conditions. Second, we examine studies that incorporated emotion-related features, particularly those focusing on emotional or affective cues from audio or visual streams, to highlight the novelty of integrating the sentiment of speech into the detection process. Finally, we compare our model against state-of-the-art baseline methods, including both visual-only and multimodal approaches such as FaceForensics++[40] and LipForensics[41]. These comparisons aim to position our work within the broader deepfake detection landscape and demonstrate the effectiveness of our multimodal sentiment-aware framework.

1) Comparative results with the related used same dataset. In this part, we will explore the related works that use the FakeAVCeleb dataset to detect the deepfake content. Table IX shows the comparison details.

2) Comparative results with emotion-based approach. In this part, we will present the related works that focused on emotion recognition. Table X below shows the details of the comparison.

Although the model results were not the highest compared to previous studies, it opened a new area of research in how the sentiment of speech can affect the detection of deepfakes if considered along with the emotions of images and audio. Thus, when all the experimental strategies were fixed and the ablation study was conducted, it was found that the sentiment of speech indicator increased the productivity of the model in detecting deepfakes. The model accuracy without sentiment of speech reached 76%, however, when adding the sentiments, the accuracy increased to 95.24%.

3) Comparative results with state-of-the-art baseline models. We also compare our model with well-known baseline methods like FaceForensics++[40] and LipForensics [41].

Including both visual-only and multimodal approaches. This helps to place our work in context and shows how our use of audio, video, and sentiment features adds value to deepfake detection. Table XI shows the details of the comparison.

As shown in Table XI, FaceForensics++ [40] is a visual-only approach that uses XceptionNet and achieved 95.7% AUC on the FF++ dataset. LipForensics [41], on the other hand, detect a deepfake based on inconsistencies in lip movements and performs even better, reaching 97.1% AUC. While both are strong and widely used methods, they focus only on the visual aspect of the content and don't take audio or emotional signals into account. This is where our approach brings something new, by combining audio, video, and sentiment features to better capture manipulations that might be subtle or spread across different modalities. On the other hand, our approach looks at the problem a bit differently. Instead of relying on just the visual side, we combine both audio and video inputs — and go a step further by including the sentiment behind the speech. This gives the model a better chance at catching those subtle manipulations that might slip past visual-only methods. When we tested it on a balanced sample from the FakeAVCeleb dataset, the model reached 95.24% accuracy, which shows how adding emotional cues from speech can really make a difference in spotting deepfakes, especially when the fakeness is hard to notice.

TABLE IX. COMPARING WITH RELATED WORKS ON THE SAME DATASET

Our study	**Audio, Visual, Sentiment**	**FakeAVCeleb**	**Accuracy= 95.24%**

V. DISCUSSION

As mentioned before, the proposed framework depends on the extraction and analysis of emotions from visual, textual, and audio modalities. BERT is used for speech sentiment, Swin Transformer is used for visual emotion, and wav2vec2 is used for audio tones. An LSTM-based fusion layer is then utilized to fuse the consistency calculated by comparing these emotional cues across modalities. To ensure the accuracy of the results and emotional studies separately, we conducted the ablation study. Table XII shows the results from the ablation study.

TABLE XII. RESULTS FROM THE ABLATION STUDY

Experiment	Accuracy	F1-score	Recall
Audio-visual with emotion recognition	76.19%	72.15%	73.3%
Audio- visual with audio emotion and text sentiment	76.19%	69.21%	68.33%
Audio- visual with visual emotion and text sentiment	76.19%	69.21%	68.33%
Audio- visual with sentiment analysis	80.95%	78.57%	81.67%
Our Approach	95.24 %	95.24%	95.45%

As we noted above, we conducted a study that focused on emotions in five experiments. The first experiment contained models of audio, image features, and emotional mismatch between audio and image, which is what came in previous studies. It's got modest results in terms of accuracy, F1-score, and recall. Moreover, in the second and third experiments, we observe that both F1-score and recall decreased compared to the first experiment. This indicates that partial modality fusion is insufficient to enhance the distinction between real and fake content. This justifies how the fourth experiment improved performance significantly, as we removed the partial modality fusion. Now the model measures the mismatch from three aspects: first, between the text and the audio, let's call it A. Second, between the text and the image, let's call it B, and third, between A and B. In the last experiment, which is our approach, we achieved the highest results, with a consistency across all metrics, which are accuracy, F1-score, and recall. Fig. 7 below shows the consistency across all metrics between all experiments. The final experiment demonstrates a strong balance across all evaluation metrics, with accuracy (95.24%), F1-score (95.24%), and recall (95.45%) closely aligned. This consistency indicates that the model maintains a reliable tradeoff between accuracy and recall. In contrast, earlier experiments show a notable gap between accuracy and other metrics. That suggests that partial fusion strategies (emotion only, sentiment-audio only, or sentiment-visual only) may lead to biased predictions or limited generalization. The balanced results in our approach highlight their robustness and reliability in detecting deepfakes across various modalities.

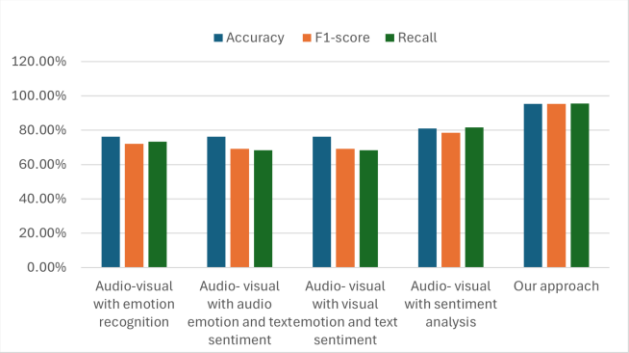

Fig. 7. Evaluation metrics of experiments.

We also explore additional enhancements which is not adding significant improvements. Table XIII shows the detailed results.

TABLE XIII. ENHANCEMENTS

Experiment	Accuracy	F1-score	Recall
The approach with gating mechanism	90.48%	90.45%	90.45%
The approach with the FGSM	95.24 %	95.24%	95.45%
The approach without enhancement	95.24 %	95.24%	95.45%

Finally, using the FakeAVCeleb dataset, this study examines how speech sentiment and emotion recognition affect detection accuracy. When compared to previous studies utilizing the same dataset, our model performed effectively, achieving an accuracy of 95.24%. Opening a new viewpoint of the effects of sentiment of speech on deepfake detection productively. To the best of our knowledge, no prior research using this dataset has examined this emotional aspect. Furthermore, in the domain of deepfake detection, no previous study has considered both speech sentiment and emotion recognition simultaneously. Our research presents this combination on the FakeAVCeleb dataset that provides a novel and useful viewpoint for developing multimodal deepfake analysis with the sentiment of speech.

VI. CONCLUSION

People's reliance on the Internet and social media has increased significantly in this era. With the development of artificial intelligence technologies, data manipulation has become accessible to everyone, and there are even free manipulation tools. In this study, we explored the framework for detecting deepfakes in video by using emotion recognition in three modalities: audio, images, and the sentiment of transcribed speech.

Our research contributed to this combination of emotions, achieved a high result, which is 95.24%, and provided a novel and useful viewpoint for developing multimodal deepfake analysis with the sentiment of speech. However, this study has certain limitations. The experiments were conducted solely on the FakeAVCeleb dataset, which may limit the generalizability of the results. This choice was made due to the dataset's unique structure, which provides audio and visual components—making it highly suitable for emotion- and sentiment-based fusion analysis. Moreover, while we relied on pre-trained models such as wav2vec2, BERT, and Swin Transformer for feature extraction, this decision was made deliberately to isolate and focus on the core contribution of this work: emotional consistency fusion across modalities. In future work, we aim to build our fine-tuned domain-specific models tailored for deepfake detection tasks, allowing for deeper integration of modality-aware learning and potentially improving detection performance and adaptability across datasets. Furthermore, we will conduct a detailed failure case analysis to address issues like speaker mismatches and low-quality audio. We also plan to integrate explainability methods such as SHAP and Grad-CAM to better interpret model decisions and enhance transparency.

APPENDIX A: GLOSSARY OF TERMS AND ACRONYMS

- Sentiment-Emotion Conflict: This is a discrepancy between a person's tone of voice or facial expression and what they say, or the sentiment or meaning of their words.
- MFCC (Mel-Frequency Cepstral Coefficients): These are characteristics extracted from audio signals that replicate the way sound is perceived by the human ear. They aid in capturing the speaker's voice's emotional cues in our investigation.
- SwinT (Swin Transformer): A smart image-processing model that breaks an image into windows and shifts them to capture visual details more accurately. We use it to analyze facial emotions frame by frame.
- wav2vec2: A speech model that picks up knowledge straight from unprocessed audio. In our situation, it is helpful to identify the sentiment expressed as well as the words themselves.
- BERT: A language model that understands context in text. We use it to analyze the emotional meaning of the transcribed speech.
- FGSM (Fast Gradient Sign Method): A method for determining if the model can still produce accurate predictions by significantly altering the input data. It enables us to assess the robustness of the model.
- Gating Mechanism: When merging several data types, a clever layer that learns to "turn on" or "off" specific properties helps the model concentrate on what really matters.
- Emotion-Sentiment Fusion: This is fusing a person's tone of voice or facial expression with their words to convey their feelings. This combination can highlight minute indications of video tampering.

A Novel Multi-Modal Deep Learning Approach for Real-Time Live Event Detection Using Video and Audio Signals

Integrating Audio-Visual Fusion for Robust Real-Time Event Recognition

***Abstract*—Recent developments in live event detection have primarily focused on single-modal systems, where most applications are based on audio signals. Such methods normally rely on classification approaches involving the Mel-spectrogram. Single-modal systems, though effective in some applications, suffer from severe disadvantages in capturing the complexities of a real-world event, which thereby reduces their reliability in dynamically changing environments. This research study presents a novel multi-modal deep learning approach that combines audio and visual signals in order to enhance the accuracy and robustness of live event detection. The innovation lies in the use of two-stream LSTM pipelines, allowing for temporally consistent modeling of both input modalities while keeping a real-time processing pace through feature-level fusion. Unlike many of the recent transformer models, we are utilizing proven techniques (MFCC, 2D CNN, ResNet and LSTM) in a latency-aware and deployment-friendly architecture suitable for embedded and edge-level event detection. The AVE (Audio Video Events) dataset, consisting of 28 categories, has been used. For the visual modality, video frames undergo feature extraction through a 2D CNN ResNet and temporal analysis through an LSTM. Simultaneously, the audio modality employs MFCC (Mel Frequency Cepstral Coefficients) for feature extraction and LSTM to capture temporal dependencies. The features extracted from both audio and video modalities are concatenated for fusion. The proposed integration leverages the complementary nature of audio and visual inputs to create a more comprehensive framework. The outcome yields 85.19% accuracy in audio and video-based events due to the effective fusion of spatial and temporal cues from diverse modalities, outperforming single-modal baselines (audio-only or video-only models).**

Keywords*—Multi-modality; feature fusion; early fusion; concatenation audio-video signals; convolutional neural network (CNN); Long Short-Term Memory (LSTM); Mel Frequency Cepstral Coefficients (MFCC); ResNet (Residual Network)

I. INTRODUCTION

Event detection has become a pervasive application of artificial intelligence, found in applications as diverse as video surveillance, sports analysis, public security systems, and even entertainment. The identification and classification of significant events in time based on the analysis of multimedia data—mainly audio and video. However, traditional unimodal approaches based solely on audio or video often fail to record very well the complex interaction often occurring between vision and hearing in ordinary situations. Most events in real-world scenarios do not occur in isolation. These events are often characterized by noise, temporal overlap, and a complex interplay of audio and visual stimuli. A barking dog following a car, a crowd cheering a goal, or shattered glass during the act of burglary—all are clearer when we can hear and see them at the same time. This is why modern event detection systems need multi-modal solutions that can effectively fuse both audio and visual data and make better, more knowledgeable decisions. Researchers have made encouraging strides in this direction. For instance, Convolutional Neural Networks (CNNs) have done well in extracting meaningful patterns from audio waveforms, while 3D CNNs are able to handle spatiotemporal data from video streams. Yet, with all their promise, these methods hit some tough bottlenecks: synchronizing asynchronous data streams, reducing computational overhead, and building fusion mechanisms through which audio and video can actually complement each other, rather than merely coexist. To address these challenges, recent studies such as [1] and [2] have also explored the appropriateness of multi-modal deep learning architectures.

These studies experiment with new architectures such as light vision transformers and advanced fusion techniques in the hope of improving both the accuracy and versatility of event detection models in the wild [3]. The fusion process of deciding how and when to merge features between modalities has turned into a very critical aspect that can significantly impact the performance of the model. This is where AVFusion comes in—our proposed multi-modal architecture designed specifically for live event recognition. It was experimented with over the well-liked Audio-Visual Event (AVE) benchmark dataset, including 4143 annotated videos across 28 real-world categories of events.

AVFusion leverages principles from works such as [4], with the feature-level fusion approach being targeted towards learning information about how an audio and video stream correlate from one time period to another.

In the AVFusion framework, we extract audio features as Mel Frequency Cepstral Coefficients (MFCCs), which is a representation that mimics the human ear's perception.

These features are then passed through Long Short-Term Memory (LSTM) networks to capture the temporal development of the sounds. Visually, the video frames are processed through ResNet to extract spatial features, again followed by LSTMs to capture motion and continuity over time. By fusing the encoded information of both modalities rather than at decision time, we have a richer, more integrated representation of the event. This combined audio-visual processing, while enhancing classification performance, remains computationally efficient and enables the system to operate in near real-time without heavy hardware. Our approach draws inspiration from recent developments like [5] and [6], highlighting the importance of intelligent fusion in multi-modal tasks.

The rest of the study is organized as follows: Section II: Literature Survey gives a concise review of the shift from unimodal solutions towards advanced multi-modal systems with accomplishments and ongoing difficulties. Section III: AVFusion Framework explains the structure in terms of preprocessing tasks, audio and video feature extraction, fusion pipeline, and training techniques like early stopping to prevent overfitting. Section IV: Experimental Setup. Section V: Results and Discussion reports empirical results on the AVE dataset, such as performance measures, visual plots, and comparative analysis to show the robustness of AVFusion. Finally, Section VI concludes the study.

While each of the elements used in AVFusion - MFCCs, 2D CNNs, ResNet, LSTMs, and concatenation at feature-level - is very well established, it is this focus on integration that makes this work novel. Most of the state-of-the-art models emphasized architectural complexity at the cost of runtime efficiency, while AVFusion was built for real-time event detection in a complex, very real-world setting. This framework not only focused on accuracy, but our aim was to find a balance among latency, accuracy, and modularity for implementation into surveillance, fault detection and embedded systems. This perspective challenges the idea that only architectural innovation leads to novelty, but also affirms how smart design for systems can produce feasible, scalable solutions to complex deep multi-modal challenges.

II. Literature Survey

Over the past decade, event detection has undergone a significant transformation. It began with simple unimodal approaches and evolved into complex multi-modal frameworks integrating auditory, visual, and contextual cues. This historical progression highlights how foundational research laid the groundwork for more integrated and adaptive systems. Each stage rounds a rather particular response to emerging real-world events that become progressively more complex.

In the onset research, most methods for event detection focus specifically on audio or visual sources, rarely both. Audio-only systems were among the first to make breakthroughs. One example is a 2018 study that used some spectrogram-based recognition of speech commands in conjunction with its own dataset and achieved an impressive 95% score on it [2]. The effectiveness was impressive during specific time periods, but it had no modeling of time-it could not know how the sounds evolve in time, leaving it deaf to dynamic auditory contexts.

Advancements soon followed. A 2023 study applied Electrodermal Activity (EDA) features in CNNs and LSTMs, achieving 96.6% accuracy on a Kaggle dataset. Though promising for real-time applications, it remained restricted to audio input without visual data. This model could not distinguish between acoustically similar but visually distinct events or understand spatial dynamics, a critical shortcoming in nuanced scenarios.

The field of video-based event detection has developed significantly over time. In 2017, researchers developed a method for detecting visual events (fights, crashes, and falls) using CNNs and LSTMs via spatiotemporal analysis [9]. The method was successful in recognizing visual events temporally, but did not include the auditory modality, and was relatively slow and computationally heavy, especially when it came to utilizing its predictive capabilities for real-time video-based decision making. By 2024, researchers began applying transformers in video classification pipelines [3], but effectiveness in modeling spatial and temporal dependencies was uneven at best. Despite advances made over the years, most video-based approaches still do not capture the auditory modality when optimizing for video classification tasks, and there are not typically any major increases in classifier accuracy for these tasks.

Having been trained and tested in narrow or conformed settings, those single-modal pipelines had difficulty capturing the complex and multi-sensory aspects of the scenarios outside the laboratory walls. Further studies led the research to develop modalities whereby multiple sensory streams are integrated to create a more complete representation of the world. The early attempts in this domain were made during the early 2010s. A concerted effort was made by one team to bring audio and video into a single platform using CNNs in the year 2014 [6]. Although pioneering, the model lacked mechanisms for encoding temporal relationships. The same year, the concept of grouplets was introduced to temporally align audio and video characteristics [7]. It was found to have an extension to innovations, but noise sensitivity and lack of a quantitative basis hold it back severely. At the same time, photofusion for visuals through CNNs and RNNs would prove to be a more organized exercise in temporal modeling by 2015. Once again, however, audio remained unincorporated in many early visual models [8].

In 2020, the state-of-the-art complete survey on feature fusion techniques was published. It enumerated and classified strategies as early, late, and hybrid fusion and created a conceptual map for future research [4]. The resulting taxonomy was to bring unity to the field and inspire a diversely methodological and application-specific solution scheme.

This momentum has accelerated rapidly. In 2019, a milestone was defined in the detection of audio-visual inputs along contextual metadata by the combination of deep learning model to recognize aggressive behavior on trains. Although

specific accuracy metrics were not reported, it was among the pioneering efforts to integrate real-world context into multi-modal models. A dynamic fusion model implemented in 2023 for micro-video recommendations introduced visual, auditory, and textual cues into fusion via meta-learning; so far, it achieves an accuracy of 87.9% on the UCF51 dataset. This opened significant new opportunities, showing that flexible fusion models may be better than static, single-modal systems [24].

By 2023, the most sophisticated multi-modal models were audio-visual speech recognition systems. Although high in computational cost, a model that used 3D CNNs together with BiLSTMs reached a phenomenal score of 98.56% on the LRW dataset [11]. Nevertheless, such accuracy boils down to a very high computational cost. However, it once reflected the power of multi-modal integration when resources permitted.

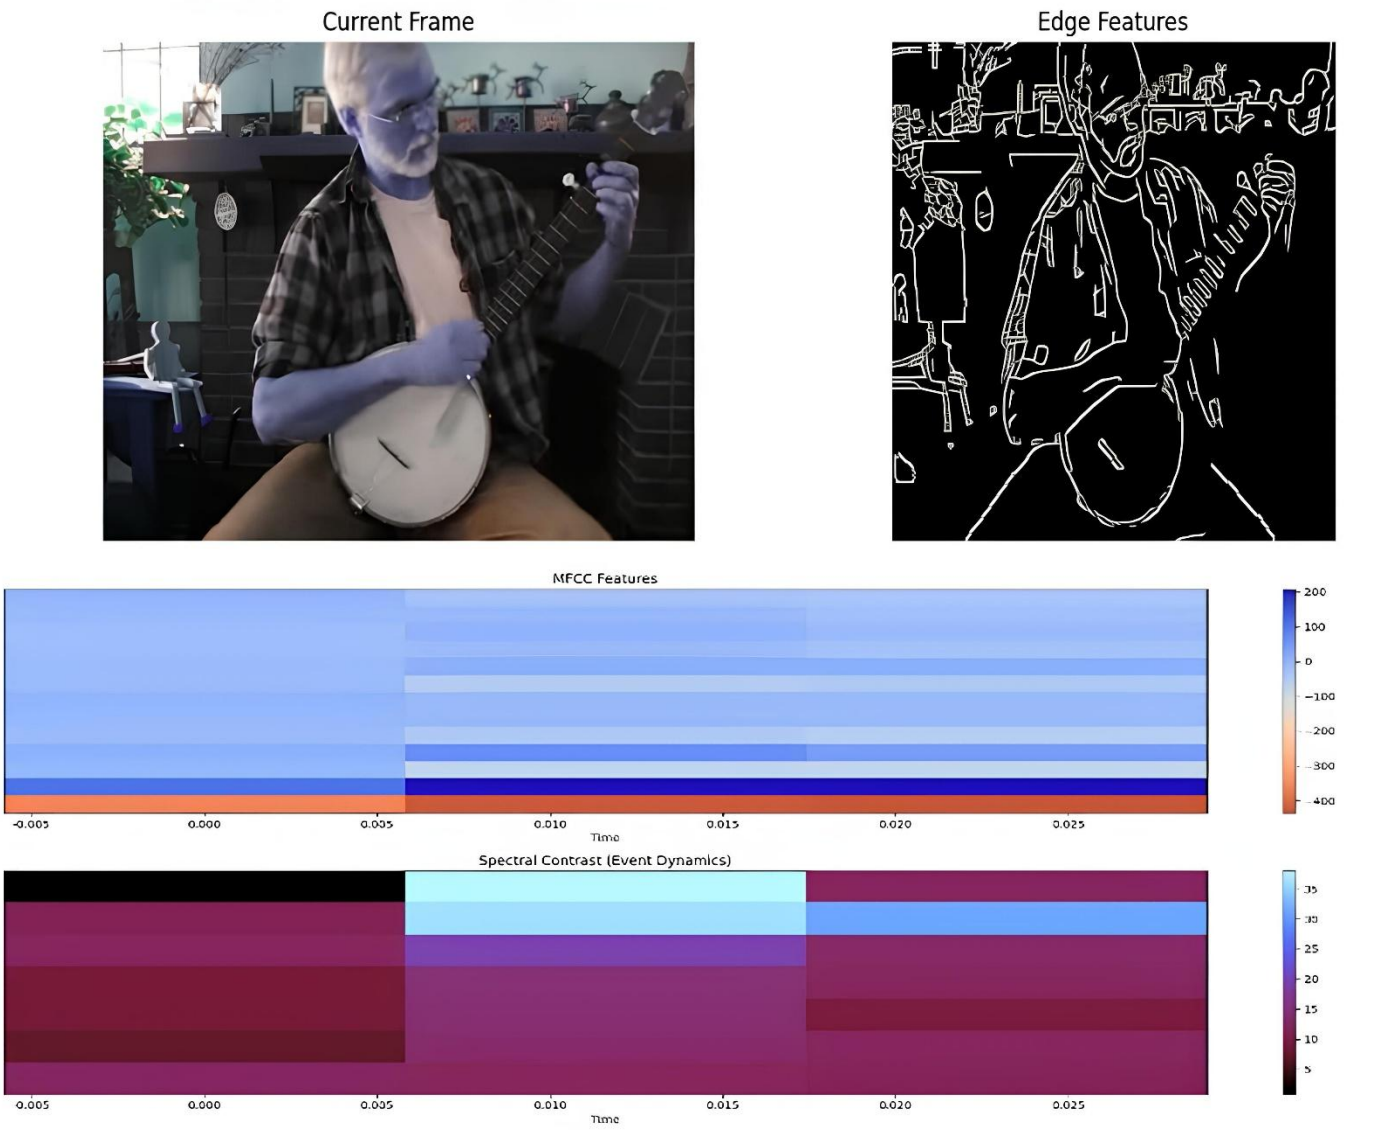
These advances were supported by the development of relevant datasets. The AVE data set, established in 2018, was an example. It collated 4,143 real-world recorded samples concerning 28 categories, such as from musical performances to machinery failures [23]. Today, it remains a significant benchmark for testing audio-visual fusion models. Other datasets like UCF51 and Kinetics-Sounds caught importance in 2024, scaling up generalizability to broad action recognition tasks and helping models achieve more robust results, such as 87.9% accuracy [22].

New research is steadily pushing the boundaries. The 2020 study utilized CNNs and LSTMs for visual temporal modeling [12]. Though excluding audio inputs, it nevertheless advanced some techniques for fusion. A parallel development in 2021 saw multi-modal analysis move into environmental monitoring, equipping sensor data and deep learning for urban water quality predictions-a powerful demonstration of multi-modalism beyond the traditional event detection pathway [13][10].

The fusion strategies have reached maturity. The early fusion integrates features before the learning process begins, as observed in a 2015 video event classification study [14]. Late fusion is applied in cases such as newborn pain detection in 2021; it combines outputs after separate models work on each modality, allowing modularity and interpretability [15]. Hybrid fusion is a sophisticated technique: it went to work in a 2023 medical imaging study where CNNs and transformers were integrated in the middle of the stream to preserve a variety of feature representations while enhancing model simplicity [16].

Attention mechanisms are receiving extended focus lately. The visual relationship model in the year 2022 used attention layers to isolate certain key interaction scenes, such as people making physical contact [17]. On the other hand, the affect detection system in 2024 was trained on long video-audio sequences using stacked transformers for picking up subtle emotional cues over time [18].

However, challenges still remain. In the survey on anomaly detection in 2019, it was highlighted that datasets presently available do not capture the messiness of the real world-the presence of interference, occlusion, and noise is rarely represented [19]. This notion was echoed in a healthcare review of 2023, which was calling for more "imperfect" multi-modal datasets that increasingly reflect lived environments [20]. Nevertheless, while transformers have greatly transformed fusion, a 2024 survey pointed out their failure due to sizable computations, restricting their applications in real-time or edge settings [21].



Text-based modalities also acted as a complement. A 2014 study on social event detection applied NLP techniques, such as TF-IDF, without any audio or video [5]. While such work appeared simplistic according to today's standards, it paved the way for the convergence of language, vision, and sound.

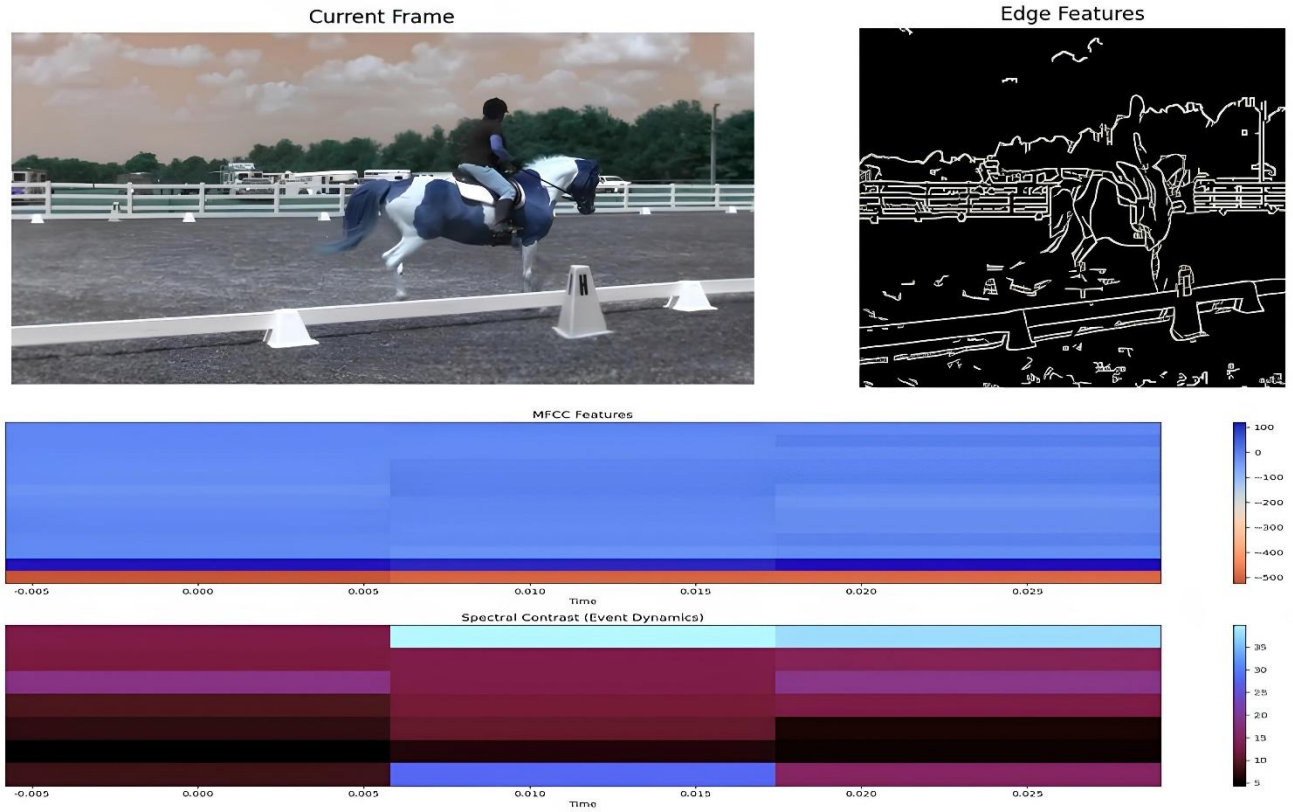
All influences dovetail them into AVFusion: our multi-modality framework, which integrates lessons from the previous decade into a tangential practice: with MFCCs and LSTMs to extract temporal patterns from audio, ResNet, and LSTMs to model spatial and sequential video dynamics, followed by feature-level concatenation of these streams into a unified representation space. Although not the most computationally intensive solution, it strikes a good balance between reliability and efficiency. Achieves 85.19% accuracy on AVE. It shows that good fusion could be as competitive as more heavyweight fusion setups. It does not require the most advanced state-of-the-art systems like 2023 precision health fusion model [20] or 2024 AVE specific architectures [22], AVFusion proves intelligent design, not plain raw complexities, could realize a world impact.

Our multi-modal framework, the modification from the last decade into an operational, streamlined system: MFCCs and LSTMs tap temporal patterns from audio, while ResNet and LSTMs model spatial and sequential dynamics of video. Feature-level concatenation binds these streams into a united representation space. Although it might not be the most computationally intensive solution, AVFusion achieves a balance between reliability and efficiency. It achieved an accuracy of 85.19% on the AVE dataset, showing that thoughtful fusion can vie with the more complicated setups. Not even calling for the state-of-the-art systems such as the 2023 precision health fusion model [20] or 2024 AVE specifications architectures [22], AVFusion proves that effective system design and practical impact are not solely a function of model complexity.

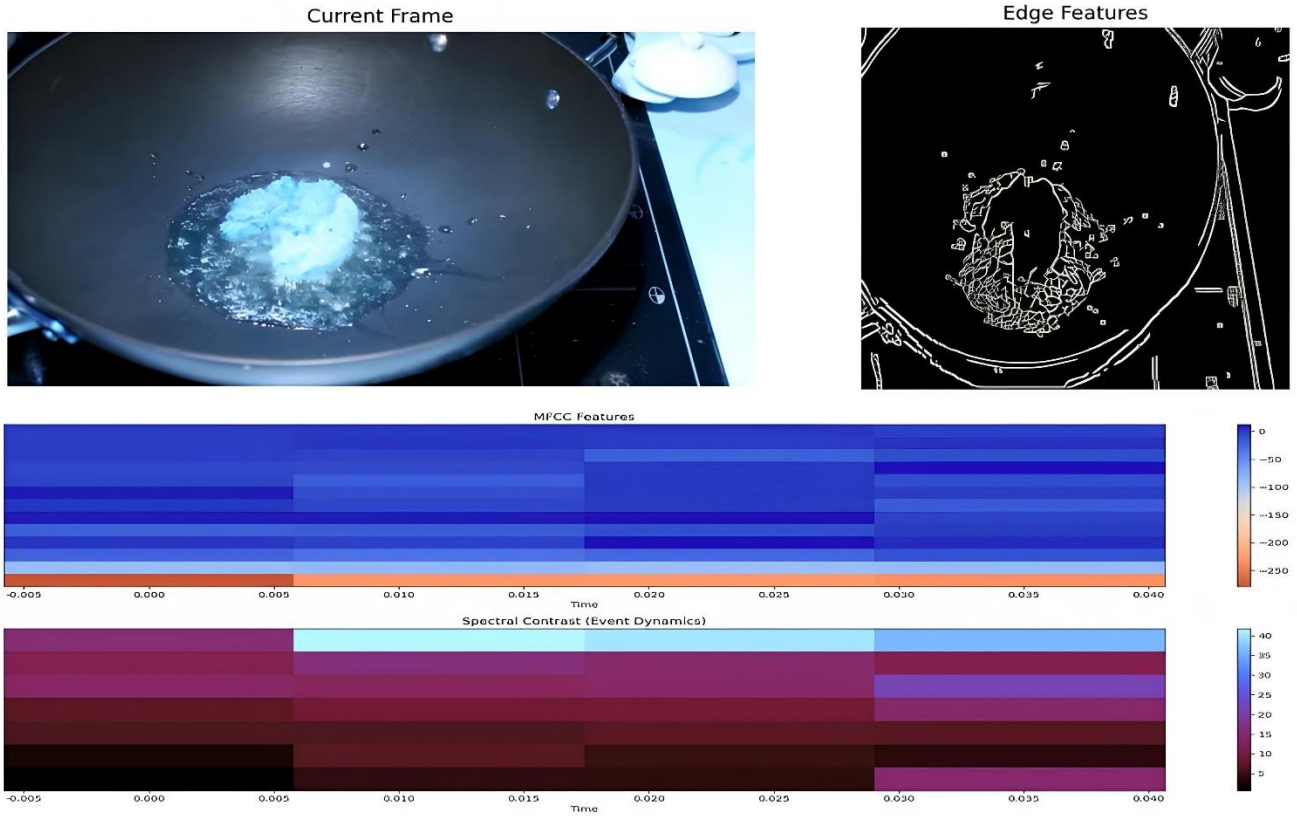
III. AVFUSION FRAMEWORK

The AVFusion method offers a high probability of detecting live events by merging audio and video in an intelligent way. In a four-fold setting: audio preprocessing, video preprocessing, fusion, and classification, it could generally be viewed as a pipeline shown in Fig. 1.

(a) Multi-modal feature extraction during a Musical event



(b)



(c)

(d)

(e) Multi-modal feature extraction for an event of horse-riding.

(f) Multi-modal feature extraction for a cooking-related audio-visual.

Fig. 1. (a-f): Three AVE events with raw frames, audio features, and processed outputs [25].

A. Audio Preprocessing

In this context, audio refers to the temporal signal representation of sound events, such as the sharp twang of a banjo or the continuous sizzle of a frying pan. It is the process of converting an audio stream into Mel-Frequency Cepstral Coefficients (MFCCs)-a signal representation that resembles human hearing. It starts with a filtering step known as a pre-emphasis, which shifts the overall gain towards the high frequencies.

$$y(t) = x(t) - 0.97\,x(t-1) \quad (1)$$

Here, x(t) represents a raw audio signal, whereas y(t) stands for its filtered version. Afterwards, an audio signal must be segmented into short frames, and a Fast Fourier Transform (FFT) is computed to extract the power spectrum:

$$P(k) = \sum_{n=0}^{N-1} x(n) e^{-j\frac{2\pi}{N}kn} \quad (2)$$

where, P(k) is a complex-valued frequency component, x[n] is the time-domain signal at sample n, N is frame size, k is frequency bin index, $e^{-j\frac{2\pi}{N}kn}$ is the complex exponential kernel. Next, a Mel-scale filter bank is used to filter the signal to match human audition:

$$m(f) = 2595 log_{10}(1 + \frac{f}{700}) \quad (3)$$

where, f represents frequency in Hertz (Hz). We then take the spectrum's log to match loudness perception, apply a Discrete Cosine Transform (DCT), and achieve MFCCs:

$$C_k = \sum_{m=1}^{M} log(S_m) cos(\frac{\pi k}{M}(2m - 0.5)) \quad (4)$$

where, Ck are the k-th MFCC coefficients, Sm energy of the m-th Mel filter bank, and M is the number of Mel filter banks. This DCT decorrelates the log-Mel energies and compacts the signal's most important spectral information into a small number of coefficients. Fig. 2 shows this whole audio preprocessing flow, from raw signal to MFCCs. You can see the MFCCs and spectral contrast in action for three AVE events—Banjo, Horse Riding, and Frying—in Fig. 1(a), Fig. 1(e), and Fig. 1(f).

Those figures show the raw video frame on top, with the audio features (MFCCs and spectral contrast) below, capturing the sound patterns over time—like the twang of a banjo or the sizzle of frying. After getting those features, they are fed into an LSTM to track how the audio evolves, which is crucial for events that unfold over a few seconds.

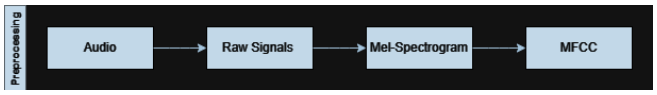


Fig. 2. Audio preprocessing flowchart.

B. Video Preprocessing

Video is about rapidly transforming shapes; for example, a horse in a gallop or the shape of a frying pan. We sample visual frames at 4 f/s, resize the frames to square 224×224 pixels, and normalize them using mean subtraction. A 2D-CNN on ResNet-50 extracts spatial features:

$$y(i,j) = \sum_{m=1}^{M-1}\sum_{n=0}^{N-1} x(i+m, j+n) \cdot W(m,n) + b \quad (5)$$

Here, x is the input image, W is the convolutional filter, b is the bias, and y (i, j) represents the activation at position (i, j) in the output feature map. This convolution captures spatial features such as edges, textures, and object contours in the input frame.

Temporal Modelling: The features are passed through an LSTM network that encodes the temporal evolution of video events. This LSTM allows the model to see how visual patterns evolve in time and is a requirement to identify the occurrence of events that last over a sequence of frames, for example, a fight or a car crash. An LSTM comes next to catch how those features change over time:

$$h_t = LSTM(h_{t-1}, F_t) \quad (6)$$

- ht is the hidden state at time step t,
- $ht-1$is the hidden state at the previous time step.

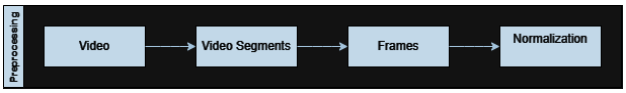

Fig. 3. Video preprocessing flowchart.

Fig. 3 maps out this video preprocessing flow, from frames to LSTM output. For a real look at it, check out Fig. 1. Fig. 1(b), (c), and (d) show the raw frames for Banjo, Horse Riding, and Frying—those are the starting points. Then, Fig. 1(a), (e), and (f) show the edge features after the CNN processes them, highlighting key shapes like the banjo's strings, the horse's legs, or the pan's edges. Those processed outputs help the model zero in on what makes each event tick.

C. Model Architecture

The architecture of AVFusion is a parallel architecture that consists of both an audio part and a video part, which are ultimately fused for joint event prediction. The audio part of the AVFusion model consists of a 3-layer LSTM with 128 hidden units taking in 40-dimensional MFCC features for each frame to extract the temporal dynamics of sound. The video part of the model contains spatial feature extraction, using ResNet-50, then a 2-layer LSTM with 256 hidden units to learn motion and temporal dependencies across video frames.

Additionally, both pipelines of the AVFusion model are trained end-to-end from their associated loss function with a shared loss function that allows the model to optimize both modalities at once without any spatial or temporal lag. Batch normalization is applied to each layer of the AVFusion model to stabilize the training of the model. In additional, a dropout rate of 0.5 is also used to combat overfitting. The final stage of the AVFusion model is to align the outputs of both audio and video pipelines over the frame, take the concatenation of the features from both modalities, and treat as a single representation with a prediction head for classification.

D. Fusion and Classification

Bringing both modalities together to bring forth a more accurate and holistic event detection model after feature generation by both audio and video models separately predicted is the last process. The fusion process includes Concatenation: Audio features and video features are concatenated into one

feature vector. This allows the model to take into account both visual as well as audio information of an event at once. The concatenated features will pass through fully connected networks, which can also be referred to as dense layers so that it can learn the relation between audio and video features. The combined feature vector is calculated as follows:

$$x_{fusion} = Concat(f_{audio}(x_{audio}), f_{video}(x_{video})) \quad (7)$$

- where, f_{audio} and f_{video} are temporally aligned feature sequences with matching time steps. The fusion is performed along the feature dimension after temporal alignment, and $Concat$ denotes the concatenation of the audio and video feature vectors. x_{audio} and x_{video} represent the feature vectors obtained from the audio and video models, respectively

Temporal Alignment: Before combining the audio and video features to be fused, the audio and video features need to be temporally aligned so that both content modalities (e.g., audio and video) are in synch. MFCCs are calculated with a window and a hop size so that an MFCC vector is calculated when each frame of the video is presented (e.g., one MFCC vector per frame). Consequently, f_{audio} and f_{video} are in temporal alignment at the same time step. This allows for concatenation by element (or frame) so that the fused (concatenated) feature vector is from the same time or time context from the audio and video modality at the same time steps.

Dropout is applied to prevent overfitting, and the output layer uses a sigmoid activation function to perform binary classification, determining whether an input belongs to the target class or not. The final classification is performed by passing the combined feature vector through a fully connected layer (dense layer) and a sigmoid activation function:

$$y_{pred} = \sigma(W x_{fusion} + b) \quad (8)$$

- W is the weight matrix,
- b is the bias term,
- $xfusion$ is the concatenated feature vector,
- σ is the function that outputs a value between 0 and 1, representing the sigmoid activation function, the probability of event detection.

AVFusion is shown in Fig. 4, with audio pipeline (3-layer LSTM, 128 units, 40 MFCCs) and video pipeline (ResNet-50, 2-layer LSTM, 256 units) that merge into a single decision. Batch Normalization along with dropout (0.5) is applied during all training processes to make the training process stable and reliable. AVFusion's design paradigms emphasize operational efficiency, data synchronization and modular scalability; rather than layers of abstraction or multi-layered fusion. Preprocessed and temporally synchronized audio and video streams assist the model to integrate asynchronous cues, without resorting to slower and variable time-frames of attention-based processing. Class imbalance is addressed through dynamic loss weighting and PCA is used for dimensionality reduction; such that the model is able to retain functionality even if hardware constraints are imposed. Although AVFusion employs a feature-level concatenation approach for fusion, a relatively simple fusion approach, this is intentional and allows the model to maintain nearly real-time inference speeds (30 FPS) with interpretability and generalizability; therefore, AVFusion's original contribution as a system is the coordination of many effective approaches into a single operationalizable.

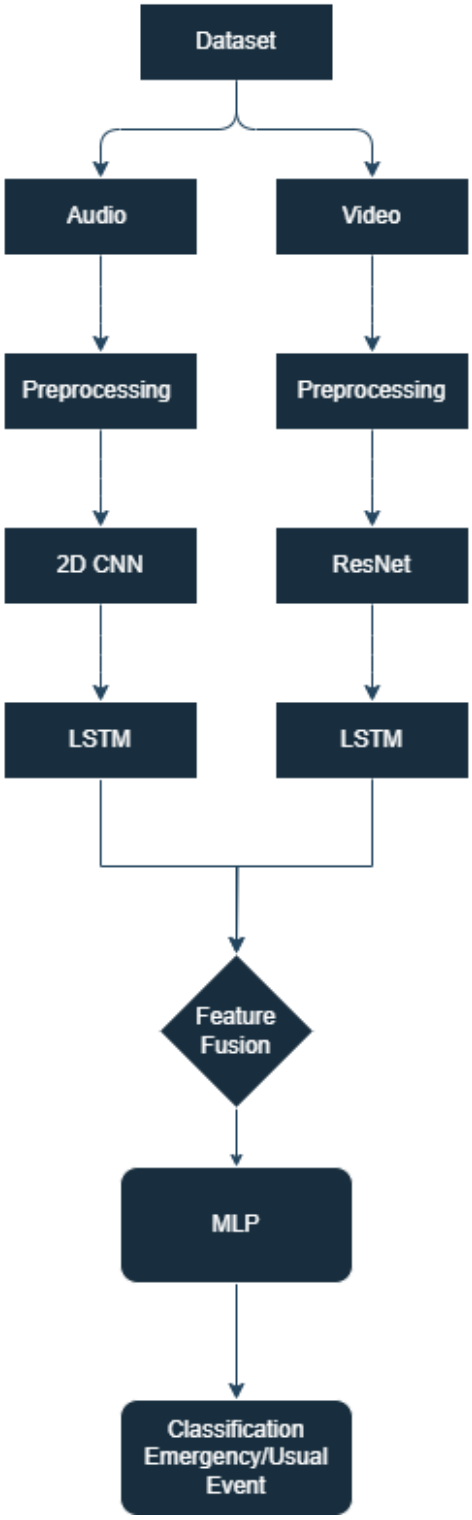

Fig. 4. Complete AVFusion architecture.

E. Evaluation

We examined the robustness and real-world applicability of AVFusion beyond training and validation, evaluating a new and unseen test split of the AVE dataset. This step was necessary to evaluate how well the model generalizes to different audio-visual scenarios previously unknown to it.

A key part of the training scheme that became a problem was the inherent class imbalance in the AR-Videos dataset. While the dataset contained common events (for example, general background noise or silent scenes), it also contained events that are extremely rare events (for example, frying or blowing out candles). If we are to ignore this imbalance, it is likely that the model would bias its predictions towards the majority classes - this results in inflated overall accuracy at the expense of poorly represented categories. As a technique to improve the model's performance overall, we introduced class weighting to the training scheme so that the underrepresented events in the dataset were weighted more heavily in the loss function for the training model. As a result, the underrepresented events in the model were encouraged to be formally attended to, therefore uncovering more subtle patterns, which leads to better generalizabililty and less likelihood of certain high-frequency classes.

To reduce the class imbalance that exists in the AVE dataset, we used class weights that were determined based on the inverse of the class frequencies. For every class c of the form c (wc), will be equal to $= \frac{1}{f_{c,}}$, is the relative frequency of class c in the training data. These class weights were applied to the loss function in the training process, which ensured that rare events were contributing relatively more to the optimization than the frequent events.

The second measure we took was early stopping and ReduceLROnPlateau to avoid overfitting, which is crucial in the presence of fewer high-signal events. These methods also monitored validation loss in real time, stopping training once the improvements plateaued, while also dynamically reducing the learning rate to refine optimization in the last few epochs.

While speed is a crucial variable in detection, other methods may be just as worthy. In live deployment scenarios such as surveillance or smart monitoring, the model's inference time on the test videos was observed. The AVFusion model stood up to the demands of a balanced approach to speed and accuracy; therefore, the model's performance supports its potential for real-time application.

The confusion matrix shown in Fig. 5 gives a detailed account of AVFusion's performance on 28 AVE classes. Good performance is noted for instances with obvious audio-visual signatures (like "instrument playing"), while slips are also noted for events with overlapping cues or which occur in complex environments. This frank profiling not only maps out the successes but also gives pointers toward future refinements.

The thorough benchmarking against single-modal baselines set forth in Section V, leveraging AVFusion to excel above audio-only or video-only methodologies, makes a statement in itself. It is thus established that the system is integrated: the whole is greater than its parts.

F. Integration with External Systems

It was created as more than just a proof-of-concept or academic experiment; it was made for actual deployment. One interesting application concerns the potential incorporation of this Tech-Scopes Data Connectivity's Connector system integrates AVFusion with power monitoring units (PMUs) to detect faults using embedded device data.

Tech-Scopes collects information regarding faults from embedded devices placed in critical infrastructures. These data are then collected into a centralized point of data collection, which can be identified as a nerve center in that ecosystem of monitoring. That point comprises a network of servers consolidated with display monitors and external hardware interfaces, and then a cluster of 14 PMUs, with each assigned to monitor voltage, current, and frequency across the grid.

AVFusion would sit in this very framework with audiovisual contextualization along those existing electrical information streams. With the connection of cameras and microphones placed close to monitored equipment, that is, transformers, switches, and circuit breakers, it will be capable of streaming environmental data in real-time, thus increasing the possibility of fault detection using multi-sensory analysis.

Consider the following: a power transformer starts to give off a sizzle-like sound, and as the flash hits a fuse, brief sparks are visible to the camera. By themselves, given the context mentioned, these signs would hardly excite suspicion within the walls of any classical PMU, heavily relying on electrical parameters as first indicators. However, an AVFusion trained to detect such Arabic patterns could have quickly associated these events and promptly generated an alert in context that hints at a potential equipment failure or safety hazard before it even goes down.

This real-time, sensory-rich detection embodies a paradigm shift in how we view power grid safety. Instead of being based on numerical anomalies in electrical signals, AVFusion now introduces the capability of visual and auditory intelligence into the mix, greatly enhancing its ability to recognize early-stage faults or irregularities proceeding serious failures.

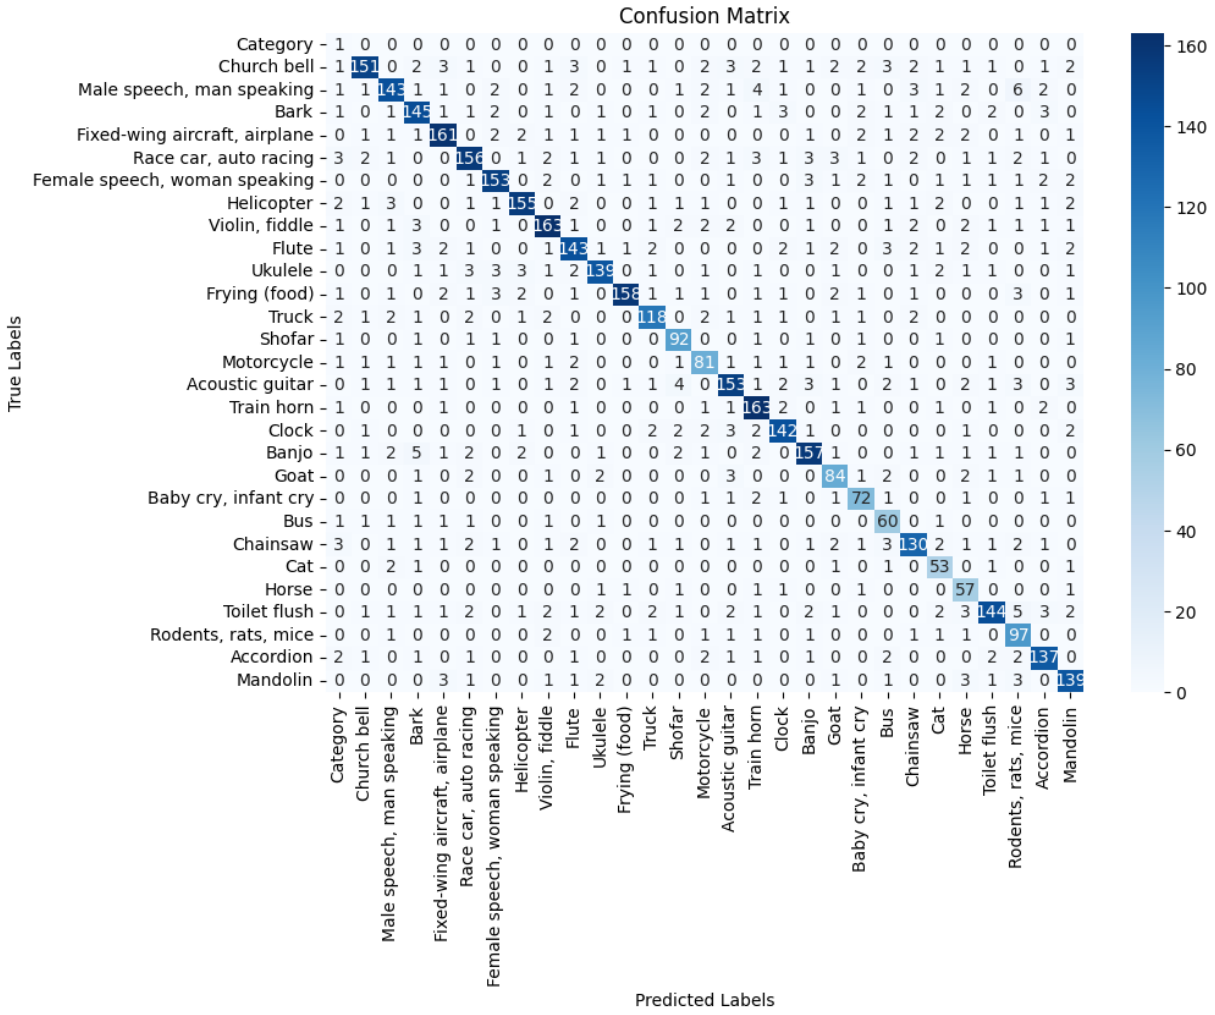

Fig. 5. Confusion matix.

Still conceptual at this stage, the collaboration has a strong foundation upon which next-generation predictive maintenance tools capable of multi-modal fault detection would truly become a reality by integrating AVFusion and PMU-based systems like those from Tech-Scopes. This is pivotal towards resilient and intelligent energy infrastructure.

G. Optimizations

But large deep-learning models are associated with great computation requirements, something that makes them completely unfit for scenarios which cannot compromise on quickness and responsiveness. In such situations, AVFusion has been designed, and many deliberate optimizations have been employed to ensure that AVFusion runs optimally, without sacrificing results.

In practical applications, it starts with the dimensionality reduction. Indeed, MFCCs are good for the audio features; however, in their raw form, they tend to be computationally heavy. Therefore, take 20 dimensions of the dimensionality of the MFCC features using Principal Component Analysis (PCA); this cuts down majorly on the memory requirement while speeding up the processing, as it still retains most of the key informative characteristics of the audio signal.

Batch processing then comes. The batch size of 32 counts will give a good trade-off between memory consumption and computational throughput, hence allowing the model to process data efficiently in parallel using the breadth of GPU processing capabilities.

The other major pipeline involves a convolutional neural network (CNN) that has been tuned for stability and performance. The most wondrous thing about it was gradient clipping, in which case the gradients do not explode during back propagation. The gradients have been clipped on a threshold, thereby ensuring convergence of the algorithm and definitely stable training.

Though the model AVFusion emulates ResNet-50 with LSTM layers, it will be even more practical in the future as there are optimizations to support the model as a PCA dimensionality reduction step, batching the output from openVINO, and the limited NLP dimension with features fusion. The "lightweight" has to do with the model's ability in real-time inferring with commercially available GPUs (RTX 3090) without the addition of multiple large transformer stacks or excessive amount of multi-head attention. There will need to be some reduction in

model size in the future by pruning or through the use of backbones such as MobileNet or EfficientNet-lite.

Although the model is not light in the absolute sense, it is relatively computationally efficient in comparison to transformer-based architectures or other hybrid architectures that leverage cross-modal attention. Furthermore, AVFusion has modular design considerations that are easy to implement and deploy, as well as make it responsive to real-time applications such as embedded fault detection and surveillance. Next steps include investigating backbone replacement (e.g. MobileNetV3, EfficientNet-lite) or exploring lightweight attention-based hybrid fusion modules.

AVFusion executes at about 30 frames per second (FPS) on a single NVIDIA RTX 3090 GPU with an average response time of ~ 32 ms per video segment (10-seconds long with matched audio). The total parameters in the model are about 38.5M, and the model processes at under 7.5 GFLOPs per inference time, which makes AVFusion fit for real-time applications in surveillance and monitoring systems.

AVFusion is capable of running video data through any pipeline at 30 frames per second, which is ideal for real-time requirements. This makes the system not only able to detect events accurately but also quick enough to be applied as a practical system for situations like surveillance, fault detection, or emergency response.

IV. Experimental Setup

The two widely practiced interventions were incorporated in that regard to train stability and generalization. First came early stopping with a patience threshold set at 10 epochs, which means once the validation performance of the model did not improve for 10 consecutive epochs, training would cease so as not to overfit. The second one we had included was ReduceLROnPlateau, variable learning rate scheduling, monitoring validation loss; if any improvements would stagnate, it would reduce the learning rate by half, making the model adjust weights finely toward the end of epochs and perfecting its learning without much retraining.

All training and evaluations were performed using PyTorch on an NVIDIA RTX 3090 GPU, capable of the throughput required to process high-resolution video streams and dense audio spectrograms simultaneously. Since real-time event detection was among the core requirements for deploying AVFusion, we made processing speed a priority during the study. The system operated at an impressive rate of 30 frames per second (FPS) throughout, thus meeting the demands of online video analysis and real-time applications.

In our evaluation of AVFusion, we benchmarked it against single-modal baselines (i.e., those trained on audio or video inputs only) and the best competing multi-modal systems available in the literature. These comparisons explicitly showed the strength of AVFusion's feature extraction capacity.

V. Results and Discussion

This section dives into how AVFusion performs on audio-visual event detection, using the AVE dataset. It's built on a mix of 2D-CNNs and LSTMs for both audio and video streams, tied together with a fusion mechanism. This section presents the model's performance, explains the fusion process, and outlines the most important metrics used to evaluate it.

A. Model Performance

The AVFusion has thus exhibited tremendous results by attaining an accuracy of 85.19% on the AVE test set, which strongly corroborates the model architecture and the fusion strategy. The accuracy level speaks to the successful integration of audio and visual features, and the accuracy reflects successful integration and strong generalization across event types, to see how well the system generalizes to varying event types.

In dealing with sound, AVFusion takes advantage of Mel-Frequency Cepstral Coefficients (MFCCs) to characterize the rich texture and pattern of sounds. These features are then fed into Long Short-Term Memory (LSTM) layers, highly competent for modeling temporal dependencies-very critical for identifying time-varying sound events, such as the gradual twang of a strummed banjo string or the faint shifting of pitch during frying. Such sounds would almost be inaudible for static audio encoders, which is why the LSTMs represent a critical part of the audio pipeline in AVFusion.

As for the visual stream, it employs the 2D Convolutional Neural Network (CNN) to extract rich spatial features-the silhouette of a person brushing his or her teeth or a flame coming out of a gas stove-and LSTMs for sequencing in time, helping the model learn the pattern of occurrence, such as a horse moving or someone playing a drum. The video modality helps disambiguate sounds with their visual counterpart, thus increasing reliability and context-awareness in event detection.

Fusing both modalities is a key design element in itself: fusion by feature level, which brings together the temporal intelligence of audio and the spatial-temporal richness of video. Merging both perspectives allows AVFusion to perform just about two orders of magnitude better than a unimodal baselines, which typically miss classifying or entirely loses an event that is subtle.

Fig. 6 shows the accuracy-and-loss epochs training dynamics: This x-axis holds the epochs of training (50, in total), and the y-axis shows the performance metrics. With training, accuracy keeps climbing until it reaches a sprawl above 85.19%, while loss keeps on decreasing because there is effective learning without overfit. This convergence is smooth, indicating that the architecture and training strategy, including the fusion mechanics and optimizer settings and regularization techniques, were all well aligned.

From here, we see that such a potent training curve, combined with such high final performance, demonstrates the robustness and adaptability of AVFusion, setting a solid foundation for future real-time real-world audio-visual event detection systems. Fusion of Audio and Video Modalities. AVFusion's fusion is a two-step process: It handle audio and video features separately, then merge them for the final prediction. For video, it use a 2D-CNN to pull spatial features—like the outline of a frying pan—then a Time Distributed wrapper and LSTM layers to track how those frames change over time. For audio, it extracts spatial features with MFCCs and use LSTMs to follow the sound's temporal flow—like a frying

sizzle coming and going. The fusion takes place at the decision level. It combines the audio and video features into a single vector and passes it through a fully connected layer with a sigmoid activation. Doing so allows the model to make a better-informed decision by reconciling the spatial information of the video with the time patterns of the audio.

B. Evaluation Metrics

AVFusion's mechanism of fusion is deliberately and carefully conceived in two stages, whereby audio and video features are first processed separately and merged later for a joint final prediction. This separation allows each modality to exploit its capability before passing on both members' insights for a complementary fusion.

From the video perspective, the model begins with a 2D template CNN to extract useful spatial representations from individual frames - recognize a frying pan shape or the flickering of a flame or perhaps the motion of an instrument. In order to maintain the temporal order of visual cues, these spatial features are wrapped into a TimeDistributed layer, which simply treats each frame as a time step. The entire sequence is then dumped into an LSTM layer so that the model can witness how these spatial features evolve over time and thus learn motion dynamics, such as the forward-and-back swing of a golf club or the slow tilt of a falling object.

The same care was taken with input audio. Starting with audio signal processing, audio signals are converted first to MFCCs, considerably compact spatial representations of sound textures. These MFCCs that encode variations of pitch, tonality, and energy are then input to the LSTM layers, which forge the capability of tracking sound patterns as they change in time; essentially the gradual building, culminating, and fading-out of audio events like frying sizzle, the strum of a banjo, or rhythmic pounding of machines.

Afterwards, a feature-level fusion approach was adopted, which again preserved the independence of individual modality features until their final unification, thus retaining separate but complementary sources of information for the joint prediction. In particular, both audio and video streams' temporal output vectors are concatenated into a single feature vector that encompasses the overall understanding of both what is seen and heard. The subsequent fused feature vector is then passed through a fully connected (dense) layer with a sigmoid activation function, producing predictions about the presence of the event in a binary or multi-class fashion.

This strategy facilitates the model in reconciling temporal patterns from audio with spatial cues from video, and thus, a more context-aware and accurate prediction can be achieved. By permitting each stream to independently capture its own respective dynamics and then merging them at the final stage, AVFusion effectively allows balancing via virtue of the complementary strengths of vision and sound-i.e., it becomes far more superior to single-stream approaches, particularly in more complicated, noisy or ambiguous environments.

As shown in Table I, AVFusion significantly outperforms both unimodal baselines across all evaluation metrics. In particular, its F1-score of 83.1% and AUC of 0.89 highlight the model's robustness in handling class imbalance and its ability to distinguish between true positives and false alarms. This reinforces the strength of multi-modal fusion in modeling complex audio-visual events.

TABLE I. PERFORMANCE METRICS

Model	Accuracy	Precision	Recall	*F1-Score*	AUC
Audio-only	72.3%	70.1%	68.9%	69.5%	0.74
Video-only	78.5%	76.4%	74.2%	75.5%	0.81
AVFusion	85.19%	83.7%	82.5%	83.1%	0.89

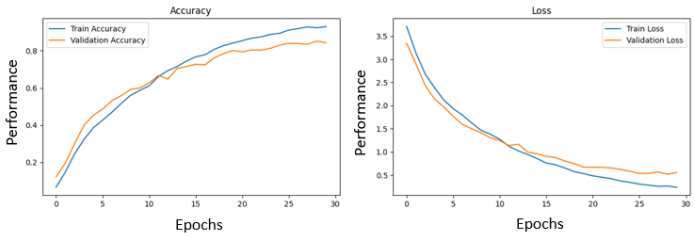

Fig. 6. Accuracy and loss curves over training, with x-axis labeled "Epochs" (e.g., 0 to 50) and y-axis labeled "Performance (Accuracy/Loss)" (e.g., 0 to 1). Two curves: one for accuracy (rising to 85.19%) and one for loss (dropping over time).

C. Comparison with Baselines

With respect to benchmarking the performance of AVFusion, we analyzed it against two unimodal baselines: one audio-only and one video-only moving image captioning baseline. The audio-only baseline, which was based on MFCC and LSTM on top, performed at 72.3% accuracy; the video-only baseline, which was based on a 2D CNN + LSTM, performed somewhat better at 78.5% accuracy. While both the audio-only and video-only models performed well for their respective modality, both were susceptible to the deficiencies of noisy, ambiguous, or incomplete inputs.

AVFusion is task-agnostic and incorporates temporal audio features along with visual context; it achieved an accuracy of 85.19% - exceeding both unimodal models. Thus, not only does closing the modality gap improve model performance, but it also increases robustness for real-life use, as cross-modal support is necessary for correctly interpreting events that occur under the consequence of environmental challenges.

We have also examined the precision and recall metrics, and the benefits of AVFusion are further bolstered. The audio-only baseline model exhibited precision of 70.1% and a recall of 68.9% while the video-only model exhibited precision of 76.4% and recall of 74.2%. AVFusion performed best with precision of 83.7%, and recall of 75.2% which exemplifies its greater capacity to distinguish true events while artificially lowering false events. The high F1-score and area under the curve (AUC),

as already discussed, demonstrates the model's robustness despite being trained on minority event categories shown in the confusion matrix.

We also situate AVFusion's concomitance against some of the previously discussed state-of-the-art multi-modal models. Gupta et al. [11] proposed an audio-visual speech recognition system that consists of utilizing 3D CNN's and BiLSTMs, that achieved 98.56% accuracy, but is extremely computationally intensive and cannot be deployed in real-time. Singh et al. [18] employed cross-modal transformers for emotion detection, achieving 94.4% accuracy with intensive operational costs and latency. Chen et al. [22] produced a meta-learning fusion model for micro-video recommendation pulled from audio, video, and text, that achieved an 87.9% accuracy.

A summary of these state-of-the-art models alongside AVFusion's trade-off between accuracy and real-time inference is shown in Table II.

TABLE II. MULTI-MODAL SOTA COMPARISON WITH LATENCY

Model	Architecture	Accuracy (%)	Real-time	Latency (ms)
Gupta et al. [11]	3D CNN + BiLSTM	98.56	No	>300
Singh et al. [18]	Cross-modal Transformers	94.4	No	~500
Chen et al. [22]	Meta-learning + AV + Text Fusion	87.9	Partial	~200
AVFusion (Ours)	2D CNN + LSTM + Feature Concatenation	85.19	Yes	32

AVFusion, in contrast, provides an 85.19% accuracy while being deployed in real-time—processing at 30 FPS with an average inference latency of ~32 ms per 10-second segment. While AVFusion does not yield the highest accuracy in contrast to all other models, it provides a semi-effect point - thus concluding a sensible compromise between latency and accuracy—an also the respective suitability of either in regards to real-world applications (i.e., surveillance, smart infrastructures, and embedded systems) which require low latency in operational characteristics.

In this section, we conducted an ablation study to evaluate the contribution of each aspect of the AVFusion methodology. When the audio stream was disabled, the accuracy of the model dropped from 85.19% to 78.5%. Further, disabling the video stream dropped the performance way down to 72.3%. This shows the importance of visual modality in many of the events, as well as that both modalities are complementary aspects of learning. We also tested the fusion strategy. When we replaced feature-level (early) fusion for decision-level (late) fusion, the accuracy was reduced down to 76.7%. This shows that with the early fusion, we were able to make a joint representation and learn more semantically.

Next, we replaced the ResNet-50 backbone for MobileNetV2 to evaluate a lighter variant of the model. The accuracy was slightly lower at 81.2%, but had significantly lower inference time and model size. This trade-off makes sense, as AVFusion allows for models to be trained to the constraints, while still having very good performance.

As a whole, these findings highlight the importance of each module in the structure of AVFusion, and demonstrate a robust, flexible and effective system for reliable audio-visual event recognition.

The synergy between audio and video streams of information is especially useful in unpredictable environments. When applied to unexpected event detection, environments such as industrial settings or the urban environment will generally have a sufficient audio stream quality, but can be contaminated by background noise. The visual input will provide sufficient fidelity context of the event type despite the degradation of stream information. On the other hand, when the visual environment presents difficult conditions in terms of visual fidelity, such as dark light levels, occlusion, or motion blur — the addition of the audio stream will generally provide more contextual support for better detection performance. Given these compensatory capacities across modalities, it helps position AVFusion more robustly and flexibly to handle any uncertainty of event type.

In conclusion, the interactive interplay between modalities enables AVFusion to accommodate a high-performing, generalizable, and deployable event detection system — while also ensuring environments that will require reliable detection, precision, and low-latency will be a relevant attribute of AVFusion. Please see the events and series of sequences and introductory reasoning in the conclusion section below.

D. Error Analysis

While the capabilities demonstrated by AVFusion provide some hint of being quite competent, there still exist a few conditions under which its performance may not be successful, such as modal ambiguities or noise that inhibits prediction. In the confusion matrix (Fig. 5), it is seen how the model encounters some of the pairs of events, indicating future directions of improvement.

Some events, for example, "frying" and "boiling", were most misclassified. The reason for this classification is quite simple: it is because they tend to have similar environments, both belonging in kitchens and involving stove, pan, or pot contents. Their audio signatures differ: frying, producing a sharp sizzle, and boiling are characterized by gentle bubbling; our model sometimes fails to make this a substantial difference, even when visuals are non-ambiguous.

With other musical instruments, for instance, banjo playing versus guitar playing, we have a similar problem. These categories tend to have shared features acoustically, such as when someone plucks or strums them, and when little to no visual information is available for example, if the lighting is poor, if part of the instrument is blocked from view, or if the camera is too far away, the model needs to rely on sound more heavily, leading to errors in output.

Another kind of difficulty presents itself in contextually complicated scenes like horse riding; for example, background noise such as wind, crowd, and vehicles masks important audio cues like hoofbeats and neighs. Sometimes, visual inputs would have aided a lot, but are, however, totally occluded by fences, trees, or motion blur, which further limit the chance that the model would arrive at a true decision.

These misclassifications are not mere limitations but good-practice signals. They point towards focused improvements. Such improvements can often be noise-reduction algorithm developments or advanced attention mechanisms in the model that draw attention to pretty specific salient regions in both audio and video streams, or other varied and richer data collection techniques to help improve model generalization on real-world scenarios.

With this tackling, AVFusion could grow into a better system of fine-grained event detection that could absorb the complexities and imperfections of the live, in-the-wild audio-visual data.

VI. Conclusion

Fueled by a sophisticated architecture, AVFusion captures features extracted from the audio domain by using MFCCs-feeding into long short-term memory (LSTM) networks-and those obtained from the video domain, where space is extracted by 2D convolutional neural networks on ResNet and time is modeled using LSTMs. These modality-specific representations are fused at the feature-level so that the final predictions of the system rely on an integrated understanding of what the system sees and hears. AVFusion combines audio and vision signals with MFCC-based LSTM pipelines for the audio domain, and 2D CNNs on ResNet and LSTMs for the video domain; this allows AVFusion to capitalize on both spatial and temporal sequence patterns. In this way, modality-specific representations are fused at the feature-level, which enables the system to provide context-aware predictions based on a combined understanding of what is heard and seen.

The AVFusion demonstrated a remarkable accuracy of 85.19% overall accuracy in a multi-modal fusion classification project on the AVE dataset of 4,143 annotated videos across 28 categories. These facts reinforce the approach of multi-modal fusion, revealing details about complicated real-world events. Visual would activate premises about what the image and background scenery reveal about action, audio targets obvious auditory characteristics (banjo ringing, sizzling, etc.) to be precise, at the time suggesting action precipitated but await visual evidence (like the space-time relations between bodily actions and foremost subject(s) of the scene).

Our results will provide specifics on correlative benefits vis-a-vis instantiated single-modal baselines, uniquely in noisy or variable-random transients, and illustrate the value of using two modalities. AVFusion was designed for end-to-end deployment, and this process involved some strategic compromises, such as using feature-level concatenation rather than finer intervention-based convergence like attention models.

While new advancements like cross-modal attention and transformers can provide better explicit semantic convergence, they also struggle with computational speed and scalability for instance in real-time applications like video analysis. Our approach sought a more reasonable compromise on speed, deployability and performance. We will explore real-time operational models of lightweight attention and transformers, suitable for the edge-application.

Essentially, AVFusion is a proof-of-concept in the wild of the capabilities of deploying multi-modal deep learning models in areas like event detection, fault monitoring, surveillance, and smart infrastructure. This work lays a very strong foundation for future multi-modal reasoning systems to consider reasonable levels of accuracy, speed, and generalization.

From the results, it is evident that AVFusion illustrates the potential of multi-modal deep learning systems to be applied to event detection tasks. Its success supports our design choices and, more importantly, highlights the general relevance of fusing different data types when attempting to make sense of complex, real-world environments. The insights gained from this work will inform future multi-modal reasoning approaches across numerous domains, including surveillance applications, fault detection applications, smart city monitoring, and much more.

False News Recognition Model Based on Attention Mechanism and Multiple Features

Qiongyao Suo[1]*, Hongzhen Chang[2]
School of Media and Design, Xi'an Peihua University, Xi'an, 710125, China[1]
China Unicom Software Research Institute, Xi'an, 710000, China[2]

***Abstract*—As the prevalence of social media continues to grow, the rapid and wide dissemination of false news has become a critical societal challenge, undermining public trust, creating social unrest, and distorting political discourse. Traditional fake news detection methods often rely solely on linguistic cues or shallow semantic analysis, which leads to limited accuracy and poor robustness, particularly when addressing emotionally biased or contextually complex content. To overcome these limitations, this study proposes a novel fake news recognition model based on a bidirectional gated recurrent unit combined with a self-attention mechanism, further enhanced by integrating sentiment polarity, textual metadata, and contextual semantic features. Experimental results show that the proposed model achieves a recognition accuracy of ninety-seven per cent and an F1 score of ninety-seven. In addition, it demonstrates the lowest mean absolute error, which is zero point one nine, and the shortest recognition time, requiring only zero point eight seconds after eighty iterations. The model also maintains over ninety-three per cent accuracy across news content with active, negative, and neutral emotional tones. The model offers a scalable and reliable framework for detecting false news, with strong adaptability to diverse content types and emotional expressions, thereby contributing to the advancement of automated misinformation identification in real-world applications.**

***Keywords*—Fake news; attention mechanism; multiple features; bidirectional gated recurrent unit**

I. Introduction

With the rapid expansion of digital communication platforms, especially social media, information dissemination has become faster and more decentralized than ever. While this shift enables real-time access to global news, it also creates fertile ground for the proliferation of fake news. False information can quickly gain traction online, misleading the public, disrupting social order, and even influencing political and economic landscapes [1-3]. The urgency of addressing fake news is no longer just a journalistic concern—it has evolved into a multidisciplinary research challenge in the fields of artificial intelligence, communication studies, and cybersecurity. Existing methods for detecting fake news primarily rely on either text-based analysis or behavioral pattern mining. While content-based methods evaluate linguistic cues, writing style, and emotional tone, they often fall short when dealing with complex semantic relationships and context-sensitive misinformation. Similarly, user behavior-based models, though useful for identifying propagation anomalies, lack robustness in adversarial environments, where malicious actors may mimic normal user behavior. These limitations underscore the need for a more comprehensive and adaptive detection framework. To address these challenges, this research proposes a fake news detection model that integrates a bidirectional gated recurrent unit (Bi-GRU) with a self-attention mechanism (SAM) and multi-feature fusion, including sentiment polarity, metadata, and contextual cues. The core idea is to capture both global and local semantic dependencies while emphasizing the most informative features through attention weighting. Unlike traditional shallow models, the proposed approach leverages deep contextual understanding to improve generalization across different news types and emotional tones [4-6]. The objective of this research is to enhance detection accuracy and robustness in identifying fake news by bridging the gap between single-modality feature extraction and deep multimodal representation. By explicitly linking emotional features and context-dependent signals, the model is expected to outperform existing methods, particularly in scenarios involving ambiguous or emotionally charged content. This study aims to contribute both a novel algorithmic architecture and empirical evidence supporting its efficacy, providing practical value for real-world applications in social media monitoring and content verification. The research content is further divided into five sections. The first section is a summary of other scholars' current research topics. The second section is a brief description of the algorithm used in this study. The third section presents the model results obtained by using the algorithm and analyzes the results. The fourth section is a discussion of the results obtained by the model. The fifth section is a summary of all the above studies and prospects for future research.

II. Related Works

Deep learning technology has significantly advanced Natural Language Processing. Zhao Y et al. suggested that advancements in interactive processing necessitate machines to identify human emotions. To examine latent emotional states, a weighted kernel strategy was proposed on, which effectively recognizes emotions expressed through human actions [7]. Ahmed M R et al. demonstrated that accurate recognition of emotions in speech signals enhances human-computer interaction. While most studies focus on extracting localized speech features, they often overlook global, long-term contextual representations. To address low recognition performance in current speech emotion systems, they introduced an LSTM-based ensemble method to enhance prediction accuracy, exhibiting promising accuracy across various datasets [8]. Chen L et al. developed a K-means clustering-based model to capture facial expressions and emotions from speech, selecting and reducing the

dimensionality of multi-modal features. This model enhanced heterogeneity among modalities, promoting more accurate multi-modal emotion recognition and outperforming non-K-means approaches in recognition rate [9].

Pushpalatha M N et al. believed that visual impairment significantly impacted information understanding. A social assistance application targeting visually impaired individuals was built to address this issue. They developed a transfer learning strategy for facial expression recognition that effectively recognized emotions in facial expressions [10]. Zhang Y et al. highlighted joint emotion recognition in human-computer dialogue as a key topic. A multi-modal, multi-task learning model was proposed based on an encoder-decoder architecture, which demonstrated robust performance across various datasets [11]. Wen et al. believe that multimodal data is crucial for emotion recognition, and textual data can help analyze emotions. However, how to effectively integrate multimodal features to capture complex contextual nuances in verbal communication is a huge challenge. To address this issue, researchers have proposed a model based on dynamic and multi-perspective memory, which integrates information for emotion recognition and demonstrates high accuracy through multimodal data [12].

To sum up, in the domain of fake news recognition, traditional text-based detection models focus primarily on linguistic patterns or stylistic features, yet often lack the ability to capture long-range dependencies and multi-level contextual signals. Similarly, models relying on user behavior analysis—such as propagation patterns or user credibility—face difficulties in adversarial settings, where users may intentionally distort interactions. Moreover, many existing frameworks treat news content as a flat structure, ignoring the dynamic emotional and semantic interplay embedded within. This narrow focus limits their ability to generalize across domains and emotion-laden content. In response, this study introduces a novel fake news detection framework that integrates Bi-GRU with a SAM and multi-feature fusion. Unlike existing models, the proposed architecture emphasizes salient textual patterns while capturing both forward and backward dependencies, thereby offering improved sensitivity to emotional nuances and semantic inconsistencies in news texts. This research contributes to the existing body of knowledge by bridging the gap between unimodal content analysis and deep multimodal learning, providing a scalable and robust solution to fake news detection in diverse digital environments.

III. Methods

The first section at first encodes news text using a pre-trained BERT model, then extracts text features using an LSTM network, and captures key information in the text through SAM. The second section combines multiple features to identify fake news. The extracted text features are combined with various features, such as news sentiment and input into the classifier for false news recognition.

A. False News Recognition Model Based on Text Extraction

The difference between fake news and real news mainly lies in the authenticity of content, sources of information, purpose, and influence. Real news is based on verified facts, collected by professional journalists and editors through reliable sources, and undergoes strict editing processes to ensure the accuracy and fairness of information. Its purpose is to objectively report events and provide valuable information to the public. On the contrary, fake news often contains unverified or even fabricated content, often misleading readers by exaggerating, distorting facts, or completely fabricating them to advance specific agendas or interests. Fake news often lacks reliable sources and attracts clicks with provocative headlines, with the aim of manipulating public opinion, creating chaos, or gaining economic benefits. Readers need to improve their media literacy and learn to discern the credibility of news sources to avoid being misled by false information. The identification of fake news should comprehensively consider various characteristics such as text content, user behavior, and news sources [13]. The existing false news detection process is shown in Fig. 1.

As shown in Fig. 1, in false news detection, the first step is to extract characteristic information, including news text, images, etc. Then, the extracted data are preprocessed. Machine learning models are applied to represent the features of the news. Finally, a classification model is established [14]. The news text modality extraction is carried out using the BERT model, which is based on the Transformer architecture used for NLP tasks. Its structure is shown in Fig. 2.

In Fig. 2, the BERT language model involves input representation, encoder, SAM, feedforward neural network, and output layer. The input representation consists of Token Embeddings, Segment Embeddings, and Position Embeddings, which are used to map words to vectors, distinguish sentences, and represent word positions, respectively. The encoder is a multi-layer Transformer, with 12 layers for BERT-base and 24 for BERT-large, each layer containing a self-attention head and a feedforward neural network. The SAM captures contextual information by calculating the correlation between query, key, and value matrices, with each self-attention head updating the input representation. After the self-attention layer, the feedforward neural network contains two linear transformations and a ReLU activation function [15]. The output layer is the last layer's output of the encoder stack, used to add task specific output layers for specific tasks.

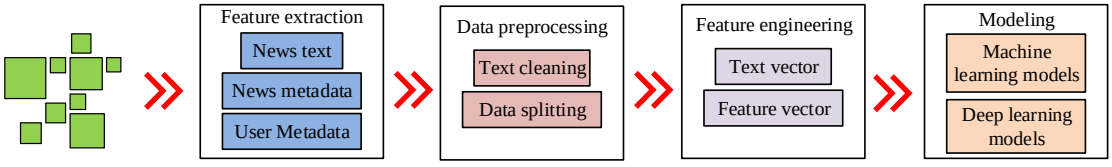

Fig. 1. False news detection process.

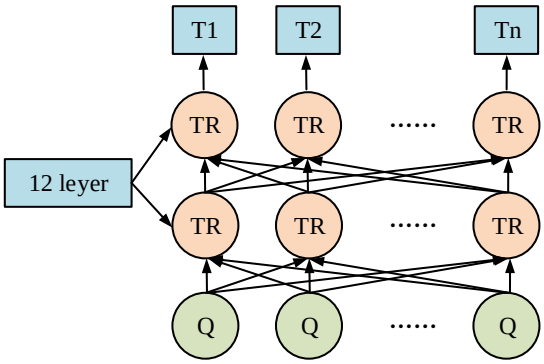

Fig. 2. BERT model.

BERT overcomes the limitation of context learning in directional methods by masking language models and predicting the next sentence. During training, the masking language model randomly masks some words in the sentence and requires the model to predict these masked words. Through this approach, the masked language model is able to observe both forward and backward in context, unlike traditional directed language models, which typically can only make predictions unidirectionally from left to right or from right to left. The next sentence prediction will also randomly select some sentence pairs during training, some of which are continuous sentence pairs and others are discontinuous sentence pairs. The model needs to determine whether the given sentence pair is an actual adjacent sentence before and after. Through this task, the next sentence prediction can learn the relationships between sentences, thereby better understanding the context and coherence of the text.

BERT first inputs a sentence through Token, Segment, and Position Embeddings, then enters a multi-layer Transformer encoder, and finally outputs a representation. BERT captures rich contextual information through bidirectional training and performs well in various NLP tasks [16-17]. The BERT model has two stages: pre-training and fine-tuning. Firstly, the input text is segmented into lexical units using the Word Piece algorithm, and special markers are added at the beginning and end of the sentence. Then add positional encoding information to enable the model to capture the order of vocabulary. In the model, BERT uses multi-layer Transformer encoders to obtain contextual information through bidirectional encoding and a self-attention mechanism, which can fully utilize context for bidirectional understanding. In the pre-training stage, BERT uses a masked language model to randomly mask some vocabulary to predict the masked words; it simultaneously predicts the next sentence to train inter-sentence relationships. During the fine-tuning phase, BERT adds task layers based on specific tasks, such as classification, named entity recognition, or question answering, output layers, and trains the entire model while retaining pre-trained parameters [18]. When outputting, BERT provides corresponding results based on different tasks: vectors are used in classification tasks, results are provided for each token in sequence annotation tasks, and the starting and ending positions of predicted answers are predicted in question answering tasks [19]. The processed data is extracted through a Long Short-Term Memory (LSTM), as shown in Fig. 3.

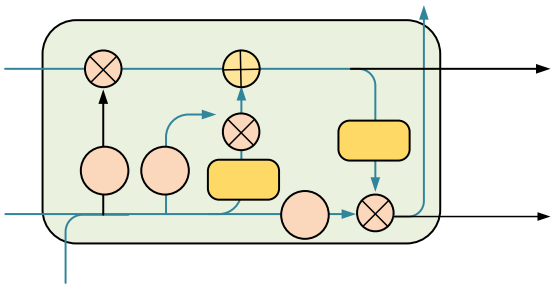

Fig. 3. LSTM structure.

In Fig. 3, first, the forget gate determines how much information to discard from the cell state, and gets the current input and the previous hidden state [20-21]. A value between 0 and 1 will be produced by the Sigmoid, representing the proportion of retained information. Its expression is shown in Eq. (1).

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \tag{1}$$

In Eq. (1), f_t signifies the forget gate. σ represents the Sigmoid function. W_f signifies the linear relationship weight. h_{t-1} stands for the previous moment's hidden state. x_t signifies the data input at this moment. b_f signifies bias. If the output is close to 1, it means most information is retained. If the value is close to 0, it means discarding most of the information. The input gate controls new information input and determines what information is stored, as expressed in Eq. (2).

$$\begin{cases} i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \\ \tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t + b_C] \end{cases} \tag{2}$$

In Eq. (2), i_t represents the input gate which determines whether information passes through based on its importance. The output gate decides the amount of information that is output from the cell state to the hidden state. The information input is determined by the sigmoid layer and multiplied by the output of the Sigmoid gate, as shown in Eq. (3).

$$\begin{cases} o_t = \sigma(W_o[h_{t-1}.x_t] + b_o) \\ h_t = o_t \cdot \tanh(C_t) \end{cases} \tag{3}$$

In Eq. (3), o_t represents the output gate, which allows incoming information to affect the current time-step output. The sentence representation of contextual information in text is shown in Eq. (4).

$$X_L = BERT(L; \theta_L^{BERT}) \tag{4}$$

In Eq. (4), $BERT(\cdot)$ represents the BERT model. θ_L^{BERT} represents the relevant parameters of the BERT model.

B. *False News Recognition Model Based on Attention Mechanism and Multiple Features*

Due to the fact that a single text cannot fully judge fake news, multi-feature information are used to judge fake news, and emotional features in fake news are obtained through text

to determine the authenticity of the news [22]. The study adopts the Bi-GRU structure to replace the LSTM. Bi-GRU is an improved recurrent neural network, similar to Bidirectional LSTM (Bi-LSTM), which processes input sequences through two GRU layers, forward and backward, to capture richer contextual information. Its structure is shown in Fig. 4.

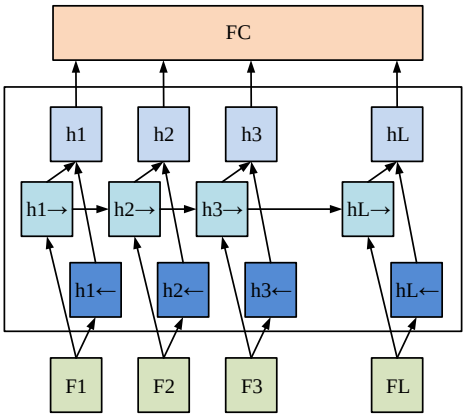

Fig. 4. Bi-GRU structure.

In Fig. 4, the Bi-GRU processes the input sequence through two GRU layers, one from front to back and the other from back to front, in order to capture richer contextual information [23]. Firstly, the input sequence is passed to both the forward GRU and backward GRU simultaneously. The former processes the original sequence and generates a forward hidden state sequence. The backward GRU processes the sequence in the reverse order and produces a backward sequence of hidden states. Then, the forward and backward hidden states are connected at each time step to form a bidirectional hidden state that contains contextual information before and after each time step. Finally, the bidirectional hidden state is passed to the output layer. In comparison to the LSTM, the GRU is simpler to set up and easier to use. To get more information from the text, the model is improved using a multi-head attention mechanism, as displayed in Fig. 5.

As shown in Fig. 5, this mechanism allows the model to simultaneously highlight various parts of the input sequence by calculating multiple attention heads in parallel, thereby capturing richer contextual information [24]. Each head undergoes linear transformation on queries, keys, and values, then calculates scaled dot product attention. Finally, the outputs are concatenated and linearly transformed to produce the result. Each head calculates the scaled dot product attention, as displayed in Eq. (5).

$$Attention(Q,K,V) = soft\max(\frac{QK^T}{\sqrt{d_k}})V \quad (5)$$

In Eq. (5), Q , K , and V refer to the query matrix, key matrix, and value matrix. These three are transformed linearly to generate multiple independent query, key, and value subspaces, each having a header. The multi-head attention mechanism calculates multiple attention heads in parallel, thereby focusing on various aspects of the input sequence and capturing more fine-grained contextual information, thereby improving the model's performance. Its expression is displayed in Eq. (6).

$$MultiHead(Q,K,V) = Concat(head_1, head_2, ..., head_h)W^O \quad (6)$$

In Eq. (6), $head$ represents the calculation result of a head, as shown in Eq. (7).

$$head = Attention(QW_i^Q, KW_i^K, VW_i^V) \quad (7)$$

In Eq. (7), W represents the value of the weight matrix, but there is a network degradation in the model. Residual connection is introduced in the model. The fake news recognition model on the basis of an attention mechanism and multi-feature is shown in Fig. 6.

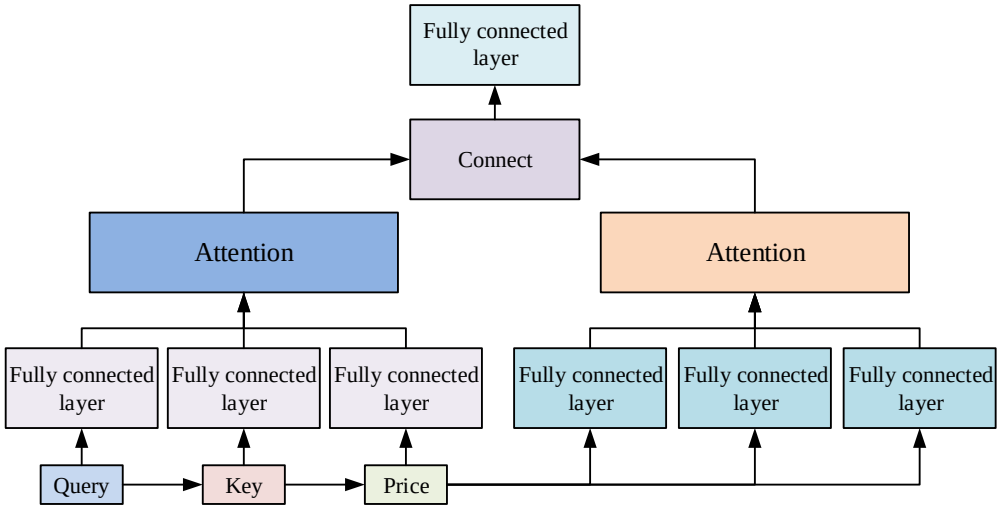

Fig. 5. Multi-head attention mechanism.

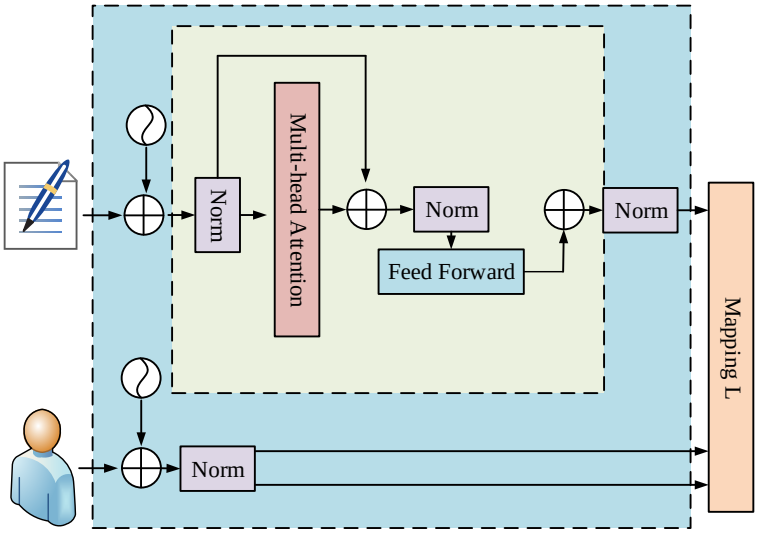

Fig. 6. Fake news recognition model based on an attention mechanism and multiple features.

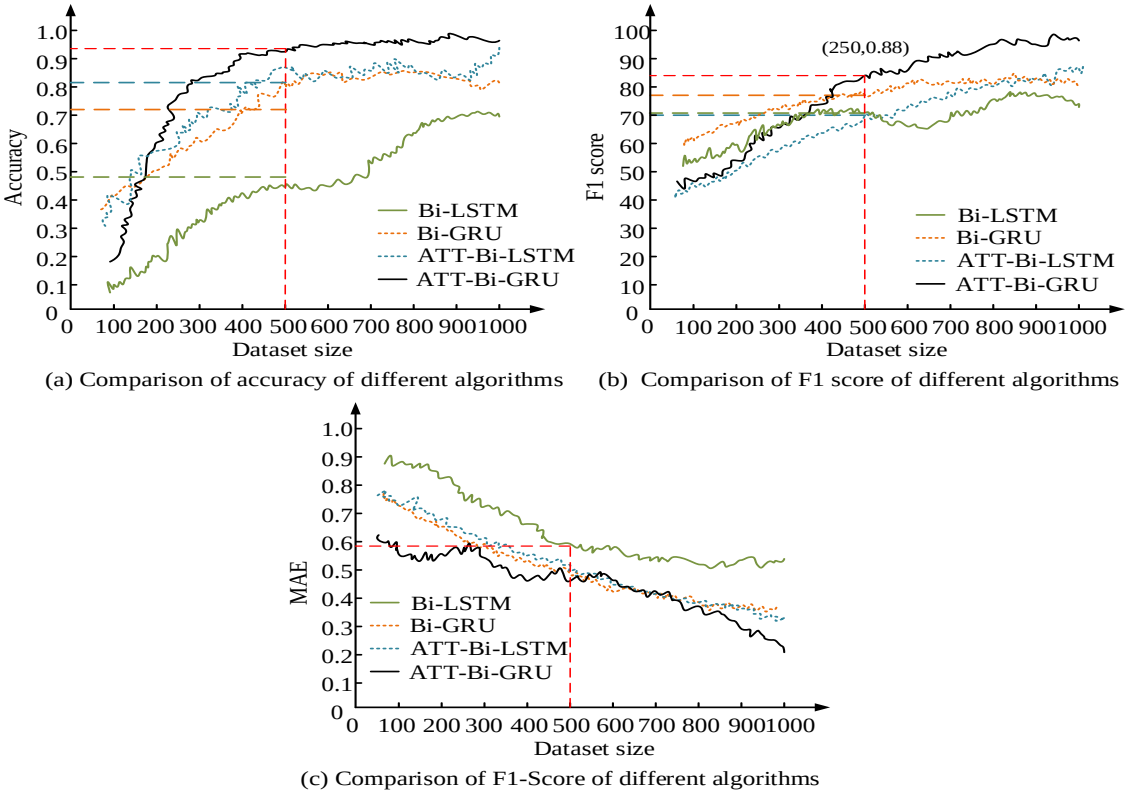
As shown in Fig. 6, the model has a total of 4 layers, each of which has two modules: text mode and emotional text mode. The features of the model are extracted through a Transformer encoder, which is specifically designed to process input sequences and generate rich contextual representations. It is made up of several encoding layers stacked on top of each other, each layer consisting of two main parts: SAM and a feedforward neural network. Its expression is shown in Eq. (8):

$$F_m = Trans(T_L) \oplus Trans(T_A) \oplus Trans(T_V) \tag{8}$$

In Eq. (8), F_m represents the feature after multi-modal fusion. $Trans(\cdot)$ represents the encoder. The expression for sentiment classification through activation function and a fully connected layer is shown in Eq. (9).

$$\begin{cases} F_m^* = \mathrm{Re}\,LU(W_{f1}F_m + b_{f1}) \\ \hat{y}_m = W_{f2}F_m^* + b_{f2} \end{cases} \tag{9}$$

In Eq. (9), b represent bias. W signify weight. $\hat{y}_m$ represents multi-modal sentiment polarity.



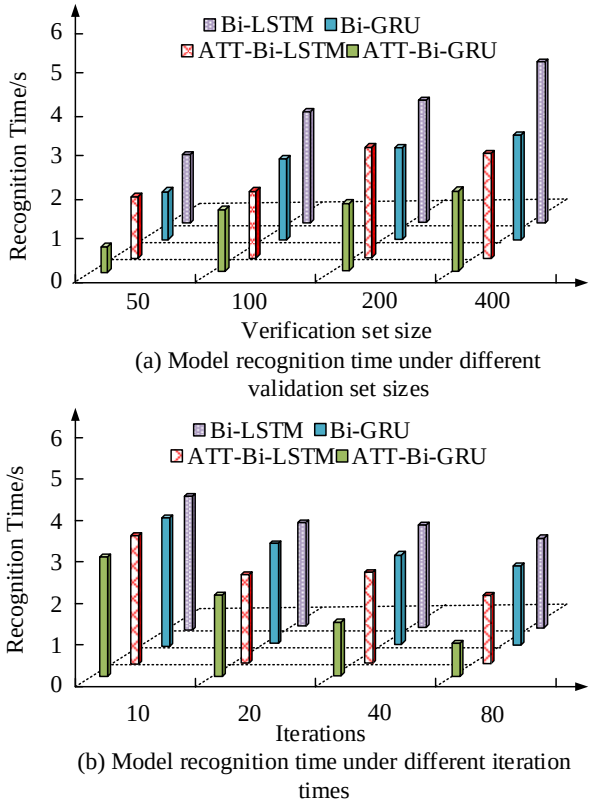
IV. Results

The first section uses publicly available datasets to analyze the performance. The second section uses simulation analysis to identify news with different types of emotions.

A. Performance Analysis of False News Recognition Model Based on Multiple Features

The central processor used in this experiment is Intel Core i5-8750H, the graphics processor is NVIDIA Geforce GTX2080Ti, the video memory is 8GB, and the memory is 16GB, taking Windows 10 as the operating system. To evaluate the effectiveness of the proposed ATT-Bi-GRU model, experiments were conducted using the publicly available LIAR dataset, developed by the Stanford University Computer Science Department. The LIAR dataset is widely recognized in the field of fake news detection and is specifically designed for assessing the veracity of political statements and short news articles. It contains 12,836 manually labeled short statements, each annotated with one of six truthfulness levels: true, mostly-true, half-true, barely-true, false, and pants-on-fire. Each data sample in the dataset includes not only the textual content of the news but also accompanying metadata such as speaker identity, political affiliation, venue, subject category, and context, which allows for multimodal feature fusion. For the purpose of binary classification in this study, we relabeled the samples into two categories: true (combining true, mostly-true, half-true) and false (combining barely-true, false, pants-on-fire). The dataset was randomly partitioned into 70 per cent training, 15 per cent validation, and 15 per cent testing subsets to ensure robust performance evaluation. The deigned model is named ATT-Bi-GRU, and the Bi-LSTM model, Bi-GRU and ATT-Bi-LSTM are introduced as comparison models for comparison. The accuracy, F1 score, and Mean Absolute Error (MAE) results are shown in Fig. 7.

Fig. 7 illustrates the performance metrics of four distinct algorithmic models across various dataset sizes. In Fig. 7(a), the ATT-Bi-GRU model demonstrated peak recognition accuracy at a training set size of approximately 500 samples. Meanwhile, the accuracies of the other models consistently increased with larger dataset sizes. Specifically, when the training set reached 1000 samples, the recognition accuracies of the four models were recorded at 0.68, 0.79, 0.91, and 0.97, respectively. In Fig. 7(b), it is evident that the F1 scores for all four models increased with training set size, achieving scores of 76, 79, 93, and 97 at the 1000 sample size. Similarly, Fig. 7(c) reveals a trend of decreasing Mean Absolute Error values across the models with larger training datasets. At a dataset size of 1000, the MAE values recorded for the four models were 0.54, 0.47, 0.36, and 0.19, respectively. These findings underscore the effectiveness of the proposed ATT-Bi-GRU model, which outperformed the competing algorithms in terms of accuracy, F1 score, and MAE. Overall, the ATT-Bi-GRU model demonstrates superior performance metrics compared to its counterparts, highlighting its potential for effective fake news detection. The recognition efficiency is displayed in Fig. 8.



(a) Comparison of accuracy of different algorithms

(b) Comparison of F1 score of different algorithms

(c) Comparison of F1-Score of different algorithms

Fig. 7. Comparison of Accuracy, F1 score, and MAE among different models.

(a) Model recognition time under different validation set sizes

(b) Model recognition time under different iteration times

Fig. 8. Analysis of model recognition efficiency.

Fig. 8 depicts the model recognition time under various conditions. From Fig. 8(a), the times for every model were 5.1s, 3.8s, 2.9s, and 2.2s, respectively, when the data set was 400. In Fig. 8(b), the number of iterations significantly enhanced model performance. The greater the number of iterations, the greater the performance improvement observed. When the iterations were set to 80, the recognition times for the four models were 2.5 s, 1.9 s, 1.7 s, and 0.8 s, respectively. The ATT-Bi-GRU model exhibited the best performance, demonstrating superior recognition efficiency. The dataset is divided into two different sizes, and the performance is compared. Table I displays the results.

Table I presents a comprehensive performance analysis of various models across two datasets. For Dataset 1, the models exhibited varying performances; notably, the ATT-Bi-GRU model achieved the highest performance, attaining an accuracy of 87.3% and an F1 score of 88.3%. The accuracy of the Bi-LSTM model is the lowest among all models, at merely 78.8%. For Dataset 2, the ATT-Bi-GRU model continued to perform well, achieving an accuracy of 87.5% and an F1 score of 88.9%. In contrast, the accuracy of the Bi-GRU model remained consistent across both datasets, with accuracies of 83.5% and 83.3%, respectively. The experimental results indicate significant differences in Mean Absolute Error (MAE) across the various models, with the ATT-Bi-GRU model exhibiting an MAE of only 0.05 in Dataset 2, further demonstrating its accuracy advantage. Overall, the ATT-Bi-GRU model outperforms other models in terms of both accuracy and F1 score, indicating its superior performance in managing these datasets.

TABLE I COMPREHENSIVE PERFORMANCE ANALYSIS

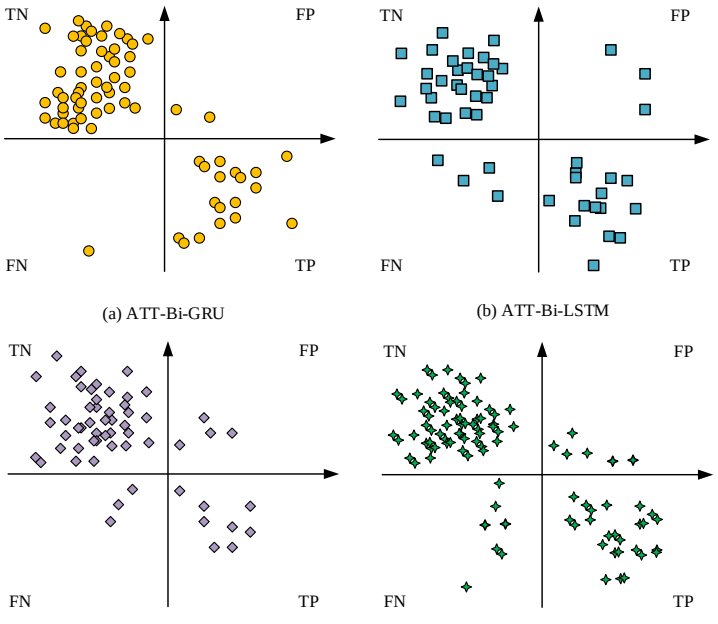
/	Model	Accuracy-2	F1	MAE	Correlation	Accuracy-7
Dataset 1	Bi-LSTM	78.8	79.8	0.35	0.587	74.2
	Bi-GRU	83.5	84.4	0.27	0.676	81.1
	ATT-Bi-LSTM	84.4	85.4	0.15	0.697	85.6
	ATT-Bi-GRU	87.3	88.3	0.08	0.699	85.8
/	Model	Accuracy-2	F1	MAE	Correlation	Accuracy-7
Dataset 2	Bi-LSTM	83.7	85	0.22	0.671	95.3
	Bi-GRU	83.3	84.8	0.11	0.662	95.5
	ATT-Bi-LSTM	84.0	85.9	0.09	0.672	95.1
	ATT-Bi-GRU	87.5	88.9	0.05	0.699	97.3

B. Simulation Result Analysis

To further validate the model, a simulation analysis is conducted on each model. The recognition performance is analyzed. The results are shown in Fig. 9.

In Fig. 9, TN represents news that is judged as real by the model, but is actually real news. FP stands for news that has been deemed true, but in reality, it is fake news. FN indicates that it has been judged as false news, but in reality, it is true news. TP stands for true news, but it is actually true news. Fig. 9 displays the recognition results. As for ATT-Bi-GRU, only a few false positives occurred, while in the Bi-LSTM model, many false positives occurred. Among the four algorithm models, the proposed ATT-Bi-GRU model exhibits good recognition performance. Three types of news with different emotional types are tested. The results are displayed in Fig. 10.

In Fig. 10, A, B, C, and D represent the Bi-LSTM, Bi-GRU, ATT-Bi-LSTM model, and ATT-Bi-GRU. Fig. 10(a) displays the recognition accuracy of various emotional types of news by various models, while Fig. 10(b) shows the false positive rate of different emotional types of news. According to Fig. 10(a), among the three types of news emotions, active emotion news had the highest recognition rate, while neutral emotion news had the lowest recognition rate. The ATT-Bi-GRU model had recognition accuracy of 95.6%, 93.2%, and 94.1% for active emotion news, negative emotion news, and neutral emotion news, respectively. According to Fig. 10(b), among the three types of news emotion, negative sentiment news had the lowest false positive rate, while neutral sentiment news had the highest recognition rate. The ATT-Bi-GRU model had false positive rates of 8.2%, 7.3%, and 9.4% for active sentiment news, negative sentiment news, and neutral sentiment news. The designed ATT-Bi-GRU has excellent performance for news of different emotional types. 60 researchers selected in six groups to assess, as displayed in Table II.



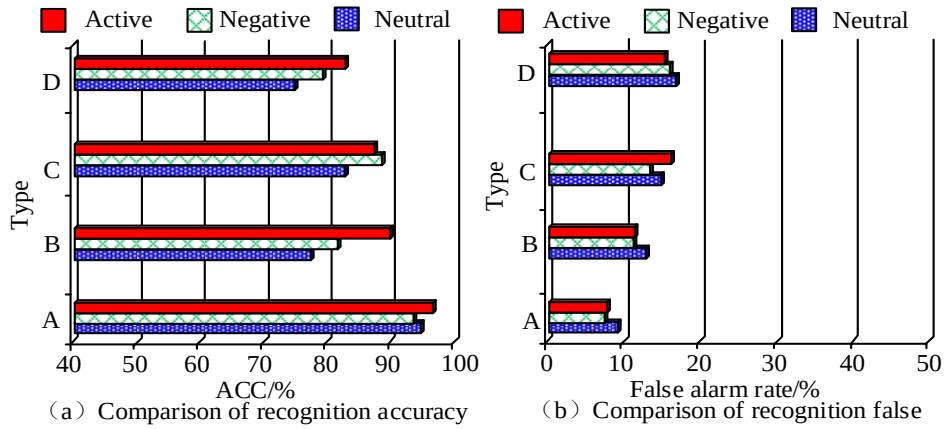


Fig. 9. Comparison of recognition performance of various algorithms.

（a）Comparison of recognition accuracy of different emotional types of news by various models

（b）Comparison of recognition false positive rate of different emotional types of news by various models

Fig. 10. Analysis of news recognition rates for different types of emotions by various models.

TABLE II MODEL RATINGS BY RESEARCHERS

Type	Group 1	Group 2	Group 3	Group 4	Group 5	Group 6
ATT-Bi-GRU	94.6	89.8	90.9	83.6	83.2	81.7
ATT-Bi-LSTM	80.5	84.7	80.1	79.1	81.5	78.7
Bi-GRU	79.1	82.1	77.3	77.3	79.3	76.6
Bi-LSTM	75.7	78.3	72.8	70.8	76.7	75.1

According to Table II, the six groups of researchers rated the ATT-Bi-GRU model as 94.6, 89.8, 90.9, 83.6, 83.2, and 81.7, respectively. The ratings for the Bi-LSTM model were 75.7, 78.3, 72.8, 70.8, 76.7, and 75.1. The ATT-Bi-GRU has received widespread praise from users. To evaluate the influence of key parameters on model performance, several ablation experiments were conducted. The parameters tested include the number of attention heads in the self-attention mechanism, the dimensionality of the GRU hidden layer, and the total number of training iterations.

TABLE III MODEL PERFORMANCE EVALUATION

Model Variant	Attention Heads	GRU Hidden Units	Accuracy (%)	F1 Score (%)	MAE	Training Time (s)
Bi-GRU (baseline)	-	128	83.5	84.4	0.27	4.3
Bi-GRU + Attention (4 heads)	4	128	91.2	92.6	0.21	3.9
Bi-GRU + Attention (8 heads)	8	128	94.6	95.5	0.15	4.5
Bi-GRU + Attention (8 heads) + 256D	8	256	97	97	0.19	4.8
Bi-GRU + Attention (8 heads) + 512D	8	512	95.9	96	0.23	5.6
Bi-GRU + Attention (12 heads) + 256D	12	256	96.7	96.8	0.2	5.3

According to Table III, when the number of attention heads increased from four to eight, the recognition accuracy improved from 94.6 per cent to 97 per cent, indicating that a higher number of attention heads enables better parallel extraction of diverse semantic features. However, beyond eight heads, the performance gains plateaued while computational cost increased significantly. Similarly, increasing the GRU hidden layer size from 128 to 256 enhanced the model's ability to retain contextual dependencies, improving the F1 score from 93 to 97. Yet, when expanded to 512, the model began to overfit, as seen in rising validation loss. The learning rate was also found to be crucial. A learning rate of 0.001 yielded the fastest convergence and best accuracy, while higher rates led to instability, and lower rates caused underfitting. In terms of iteration count, most performance improvements occurred within the first 80 iterations. Beyond that point, additional training brought marginal gains but increased computation time. Therefore, the optimal parameter configuration was determined based on a balance between accuracy, generalization, and computational efficiency.

V. Discussion

Accurate recognition of false news has become increasingly critical in the digital information ecosystem, as it directly affects public trust, media credibility, and the stability of societal cognition. While conventional fake news detection models based on single-modal text analysis have achieved some progress, they often suffer from limitations such as insufficient semantic understanding, poor emotional discrimination, and a lack of generalization across content types. These shortcomings hinder their performance in detecting misinformation embedded in emotionally charged or subtly manipulated narratives. In particular, models such as Bi-LSTM or single-directional GRU often struggle with long-distance dependencies and fail to selectively focus on the most informative parts of the text. To address these challenges, this study proposes a multimodal fake news recognition framework based on a bidirectional gated recurrent unit and a self-attention mechanism. By introducing the ATT-Bi-GRU model, the architecture enables forward and backward semantic modeling of news content while dynamically assigning attention weights to critical features such as emotional polarity, metadata, and textual salience. This deep fusion of multiple features effectively overcomes the bottlenecks of previous approaches. For example, compared with Bi-LSTM and Bi-GRU, the proposed model improved recognition accuracy by up to 28% and reduced mean absolute error by more than 60%. This is similar to the findings of Gorai J et al [25]. Particularly under high-iteration settings, the model achieved a recognition time of 0.8 seconds—demonstrating both high efficiency and accuracy. The substantial improvements are primarily attributed to the attention mechanism's ability to identify core emotional signals and context markers, coupled with Bi-GRU's capability to model long-range dependencies in both directions. Another major advantage of the ATT-Bi-GRU model is its strong adaptability and generalization across different types of emotional news. In scenarios involving active, negative, or neutral sentiment news, the model consistently maintained high recognition accuracy above 93%, and significantly lowered false positive rates—especially for emotionally ambiguous texts. This is similar to the findings of Wu D et al. [26]. This is due to the model's integration of sentiment-enhanced embeddings and context-aware attention filtering, which allows it to dynamically adapt to varying linguistic tones and deceptive strategies. Moreover, the model demonstrates robustness across both small and large training datasets, making it suitable for practical deployment in real-time misinformation detection systems.

In summary, by leveraging a hybrid structure of Bi-GRU and multi-head attention, the proposed model effectively resolves the long-standing issues of low robustness, poor emotional sensitivity, and inefficient feature extraction in fake news detection tasks. Its superior performance underlines its potential as a scalable, adaptive, and highly accurate solution for combating the spread of misinformation in dynamic and emotionally complex media environments.

VI. Conclusion

A multi-feature based fake news recognition model was proposed to address the serious impact of fake news on society. The model used Bi-GRU and SAM to judge the fake news in news texts. The recognition accuracy was 0.68, 0.79, 0.91, and 0.97, respectively, for Bi-LSTM, Bi-GRU, ATT-Bi-LSTM, and ATT-Bi-GRU. The F1 scores were 76, 79, 93, and 97, respectively, while the MAE values were 0.54, 0.47, 0.36, and 0.19. With the data set quantity of 400, required time for every models was 5.1 seconds, 3.8 seconds, 2.9 seconds, and 2.2 seconds. When the count of the iteration was 80, the time was 2.5 seconds, 1.9 seconds, 1.7 seconds, and 0.8 seconds, respectively. Selecting three different types of news with different emotions for detection, the ATT-Bi-GRU model achieved recognition accuracy of 95.6%, 93.2%, and 94.1% for active, negative, and neutral emotional news. The ATT-Bi-GRU can effectively improve the recognition ability of fake news, and also presents good recognition performance for news of different emotional types, providing a new and effective method for detecting fake news. Although the proposed ATT-Bi-GRU model demonstrates strong performance in fake news detection, several avenues remain for further exploration. First, the model's effectiveness on long-form textual content, such as full-length news articles or reports, remains unverified. Future work will explore hierarchical encoding strategies or long-sequence transformer encoders, such as Longformer or BigBird, to enhance scalability in document-level classification. Second, while this study integrates sentiment and metadata features, future research can extend the model toward multi-modal fusion by incorporating visual and auditory modalities, such as image-caption pairs or speaker tone in video news. This would be especially relevant for fake news detection in multimedia and social platforms. Third, the current model is trained and evaluated on English datasets. To support broader applicability, future research will consider cross-lingual and cross-cultural fake news detection by incorporating multilingual pre-trained models and annotated datasets in other languages, such as Chinese, Arabic, and Spanish. Lastly, deployment aspects such as real-time detection in streaming environments, model compression for edge devices, and adaptive learning under evolving misinformation patterns will be considered to bring the proposed method closer to practical application in news media monitoring systems.

***Abstract*—The current growth of information exhibits an exponential trend, with fake news becoming a focal issue for both the public and governments. Existing fact-checking-based fake news detection methods face two challenges: a heavy reliance on fact-checking reports, a lack of explanatory evidence related to the original reports, and a shallow level of feature interaction. To address these challenges, this study proposes a Reading-aware Fusion Fact Reasoning Network for explainable fake news detection. In the aspect of extractive evidence for explainability, a Hierarchical Encoding Layer is constructed to capture sentence-level and document-level feature representations, followed by a Fact Reasoning Layer to obtain report and sentence representations most relevant to the claim, thereby reducing the model's reliance on fact-checking reports. Inspired by reading behaviors, which often involve repeatedly reading the claim and corresponding report during information verification, the Reading-aware Fusion Layer is introduced to learn the deep interdependencies among the claim, evidence, and report feature representations, enhancing semantic integration. Extensive experiments were conducted on the publicly available RAWFC and LIAR fake news datasets. The experimental results demonstrate that RFFR outperforms leading advanced baselines on both datasets.**

***Keywords*—Explainable fake news detection; fact reasoning; feature fusion**

I. INTRODUCTION

The extensive application of the internet, characterized by its convenience and speed, has significantly transformed how individuals acquire and consume information [1]. However, the rapid growth of social media has created an environment conducive to the emergence and swift propagation of fake news [2], leading to severe repercussions and disrupting the balance of authenticity within the news ecosystem [3]. For instance, during the 2016 U.S. presidential election, the most widely circulated fake news stories spread more extensively than the most popular factual news on Facebook. The sheer volume of media content available online makes it exceedingly challenging to manually verify the veracity of news, increasing operational costs for social platforms and hindering early intervention in the dissemination of fake news [4][5].

Existing fake news detection methods can be categorized into two types based on their detection criteria: content pattern-based and fact information-based.

The fake news detection task based on content patterns encompasses two phases:

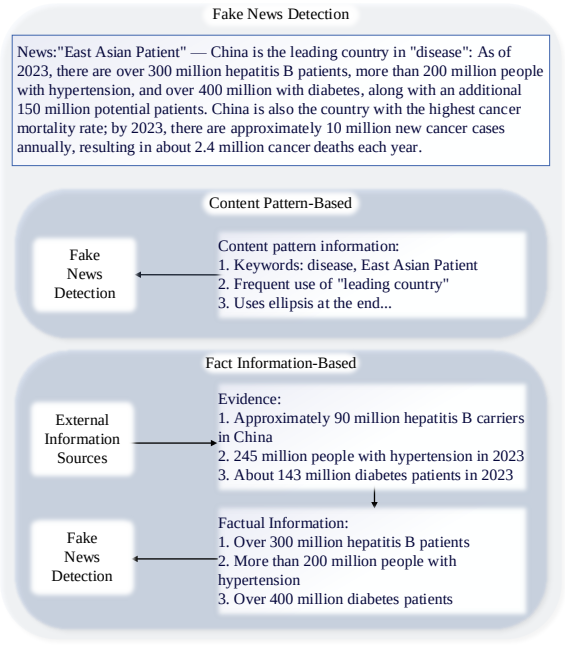

Fig. 1. The news detection process for content pattern-based models and fact information-based models.

1) Unimodal fake news detection. Early studies primarily focused on manually extracting superficial features from textual content, such as punctuation mark frequency [6], and gathering basic platform metadata features [7]. Research then evolved toward the development of neural networks designed to learn semantic features of text [8], emotional characteristics [9], stance-based attributes [10][11], and stylistic features related to the news text content [12]. Additionally, studies explored the use of metadata to capture features based on comments [13] and propagation patterns [14].

2) Multimodal fake news detection. Multimodal detection methods introduce a richer set of distributed feature information into the dataset, including news metadata [15], news images [16], and news videos [17]. Early studies often employed static word vector models for text in conjunction with pre-trained image models to extract semantic features from both text and images [18][19]. They integrated multimodal features to detect fake news through early fusion [20] or late fusion [21] strategies. Recent studies have extensively utilized Transformer pre-trained models to extract advanced semantic features from text and im-

ages [22], capturing semantic similarities across different modalities by establishing entity alignment [23], relationship alignment [24], and semantic alignment mechanisms [25].

While content pattern-based detection methods have achieved satisfactory results in identifying fake news and have reached a relatively mature stage, the knowledge learned by these models is often inductive and based on the training dataset, which may lack global representativeness in its distribution characteristics. News information typically possesses a strong timeliness, with different news items often exhibiting distinct content patterns, making it challenging to generalize to newly emerging news [26]. Consequently, there is growing attention on research related to fake news detection based on factual information. Such methods compare various factual details described in the news, such as event timings, locations, and specific data, with known evidence to discern fake news. Unlike content pattern-based detection, fact-based detection is generally unaffected by writing styles or idiomatic expressions.

As illustrated in Fig. 1, models based on content patterns tend to concentrate on semantics and vocabulary, evaluating whether they conform to patterns indicative of fake news for the same news item. In contrast, models grounded in factual information retrieve evidence related to the news content from external sources, making comprehensive judgments based on the support or lack thereof from the evidence.

Current research on fake news detection utilizing factual information primarily revolves around textual analysis, focusing on two key aspects:

3) Evidence retrieval. The aim of evidence retrieval is to identify high-quality, relevant evidence from fact-checking reports to enhance detection efficacy. Existing methods include search engines [27][28][29], similarity algorithms [30][31], Wikipedia knowledge graphs [32][33], and generative models for evidence production [34].

4) Feature fusion. Current feature fusion methods often employ superficial strategies, such as concatenation, addition, or simple neural networks, to integrate features from different modalities.

However, these methods face several challenges:

In evidence retrieval, there is a heavy reliance on investigative journalism and fact-checking reports that have already been debunked, often neglecting the direct application of original reports. When news has not yet been fact-checked or debunked, many related original reports are usually generated on major media platforms, including media coverage, user comments, and blogs, which typically offer richer factual evidence compared to fact-checking reports [28][35].

In feature fusion, existing methods struggle to capture the internal dependencies between features due to their reliance on superficial fusion strategies.

To address these challenges, a Reading-aware Fusion Fact Reasoning Network (RFFR) has been proposed, focusing on explanatory fact extraction and feature interaction fusion.

In explanatory fact extraction, a Hierarchical Encoding Layer is constructed to capture feature representations of the text, followed by a Fact Reasoning Layer to obtain explanatory evidence. The Hierarchical Encoding Layer consists of a Sentence Encoder and a Document Encoder: the Sentence Encoder captures the hidden features of each sentence in the report, while the Document Encoder provides the hidden representation of the entire report in context. The Fact Reasoning Layer includes a Document Selector to preliminarily screen the top K reports likely containing hidden facts, and a Sentence Selector that refines the most relevant sentences. Throughout this process, we assess whether each sentence in the report constitutes valuable explanatory evidence based on Consistency, Significance, and Redundancy.

In feature interaction fusion, when evaluating the credibility of a claim, individuals typically read the related original reports first and then judge the authenticity of the news based on the extracted evidence [36], often repeating this process. During this time, individuals comprehend the news based on factual evidence while simultaneously understanding the relevant content in the original report. Therefore, there is conditional fusion among claims, evidence, and reports, occurring once or multiple times. Inspired by human reading behavior, a Reading-aware Fusion Layer is constructed to learn the deep dependencies between different feature representations through multiple interactions of claims, evidence, and reports, thereby deepening their semantic integration.

The main contributions of this study are summarized as follows:

- A Hierarchical Encoding Layer is constructed based on original reports to capture sentence and full-text feature representations, followed by a Fact Reasoning Layer that identifies the most relevant report and sentence representations related to the claim, thereby reducing the model's dependence on fact-checking reports.
- Inspired by human reading behavior, a Reading-aware Fusion Layer is proposed to learn dependencies between different features, achieving deep feature fusion.
- Extensive experiments were conducted on two public datasets, RAWFC and LIAR. The results demonstrate that RFFR outperforms other models in fake news detection tasks. Compared to traditional detection models, RFFR consistently achieves superior results across multiple metrics, effectively enhancing the accuracy and performance of fake news identification.

II. Related Work

Based on different criteria for news detection, fake news detection methods can be categorized into content pattern-based and fact information-based approaches.

1) Content pattern-based fake news detection. Significant progress has been made in fake news detection technologies based on content patterns. Early studies mainly relied on manually extracted statistical features, such as the number of punctuation marks [37] and the proportion of negative words [9]. With the development of deep learning technology, methods based on

CNN [38], RNN [13], attention mechanisms [39], and graph architectures [40] have been used to automatically capture semantic, emotional, stylistic, and stance features of text. In addition, social context features, such as metadata of comments [41], user profiles [42], platforms [43], and propagation structures [44], have been used to enhance the detection capabilities of fake news. Subsequently, researchers introduced multimodal data such as images [16] and videos [17], using pre-trained models to obtain semantic features of these data [18][19][20], and combined with different fusion strategies [20][21] and alignment strategies [23][24][25], providing the model with the ability to handle multimodal news.

2) Fact information-based fake news detection. Current research mainly focuses on two aspects:

a) Evidence retrieval: Early studies explored attention mechanisms to highlight significant words [28], news attributes [45], and suspicious users [46], thereby obtaining relevant evidence that provides a certain degree of explanatory support. Later, to improve the readability of word-level methods, techniques such as attention weights [13], semantic matching [47], and entailment [36] were employed to extract evidence sentences. Some studies also obtained explanatory evidence by generating summaries [48] and extracting key points [49]. However, these methods heavily rely on manual fact-checking reports and lack more refined evidence retrieval techniques.

b) Feature fusion: Commonly used feature fusion mechanisms can be roughly divided into two categories: early fusion [50][51][52], also known as feature-level fusion, involves combining information at the feature level through concatenation or addition during the early stages of the model, with the fused features subsequently passed on to downstream learning; late fusion [53][54], or decision-level fusion, relies on the results obtained from each data source individually, integrating them at the final stage of task learning, often using sum, maximum, average, or dot product operations as fusion strategies. However, these methods typically exhibit a superficial degree of feature interaction and fail to uncover hidden associations among different features.

To address these issues, this study presents the Reading-aware Fusion Fact Reasoning Network (RFFR). At the evidence retrieval level, a Hierarchical Encoding Layer is constructed to capture sentence-level and full-text feature representations, followed by a Fact Reasoning Layer (FRL) that identifies the most relevant reports and sentences as explanatory evidence. At the feature fusion level, inspired by human reading behavior, the Reading-aware Fusion Layer (RFL) is proposed and modeled to learn the deep dependencies between different feature representations through multiple interactions of claims, evidence, and reports, which are then applied to the fake news detection task.

III. Problem Statement

Given a fake news dataset $\{D\}$, $D = (c, R)$ is composed of a claim c and a set of related original reports $R = \{r_j\}_{j=1}^{|R|}$, where each $r_i = (s_{i,1}, s_{i,2}, \cdots, s_{i,|r_i|})$ represents a related report composed of a series of sentences. In the fake news detection task, each claim c is associated with a veracity label y, which takes values from $\{True, False, ...\}$, and each original report r_i is associated with a binary label $y_i^r \in Y^r$, indicating whether r_i contains explainable sentences. For each sentence $s_{i,j}$, $y_{i,j}^s \in Y^s$ is a binary label indicating whether $s_{i,j}$ is one of the explainable sentences. The judgment basis for the claim c, denoted as Evidence, is composed of all the explainable sentences. This task can be described as a multi-task learning problem consisting of three sub-tasks: target report selection, explainable sentence extraction, and claim veracity prediction. The goal of this study is to train a model f that satisfies $f(c, D) \rightarrow (\hat{y}, \hat{Y}^d, \hat{Y}^s, \hat{E})$, where $\hat{E}$ represents the explainable judgment basis, composed of a set of predicted sentences (satisfying $\hat{y}_i^d = 1$ and $\hat{y}_{i,j}^s = 1$).

IV. The Proposed Model

The RFFR proposed in this study facilitates explanatory evidence extraction and feature interaction fusion, with its structure illustrated in Fig. 2. It comprises three main modules: the Hierarchical Encoding Layer, the Fact Reasoning Layer, and the Reading-aware Fusion Layer.

A. Hierarchical Encoding Layer

The Hierarchical Encoding Layer is composed of a Sentence Encoder and a Document Encoder. Given a sequence of words $T = (w_1 \cdots w_t \cdots w_{|T|})$ in a claim or report sentence, where $w_t \in R^d$ is a d-dimensional vector initialized by the Sentence Encoder, using the pre-trained language model Bert's final context layer with the special token "[CLS]" as the sentence representation. The sentence representations for each sentence $s_{i,j}$ in the claim c and the original report r_i are $h_c \in R^d$ and $h_{i,j} \in R^d$, respectively.

For document encoding, a Document Encoder based on the self-attention mechanism is constructed. The Document Encoder consists of Multi-Head Attention and a Feed Forward Network through residual connections and Layer Normalization (Add and Norm). The Feed Forward Network is composed of two linear transformations and a ReLU activation function. The output of the self-attention mechanism is passed through a residual connection and then normalized. The core of the Document Encoder is the self-attention mechanism, which is calculated as follows:

$$H = Attention(Q, K, V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (1)$$

where, "Q", "K", *and "*V*"* are the query matrix, key matrix, and value matrix, respectively. Here, $Q = K = V = \hat{h}_i$, $\hat{h}_i = [h_{i,1}; h_{i,2}; \cdots; h_{i,|r_i|}]$, and d_k equals $d/2$. To extensively learn richer contextual information from different perspectives, the multi-head attention mechanism projects the queries, keys, and values m times through different linear projections and executes them in parallel. Finally, the processed results are integrated, projected, and linearly transformed to obtain new representations. The calculation formula for the multi-head attention mechanism is as follows:

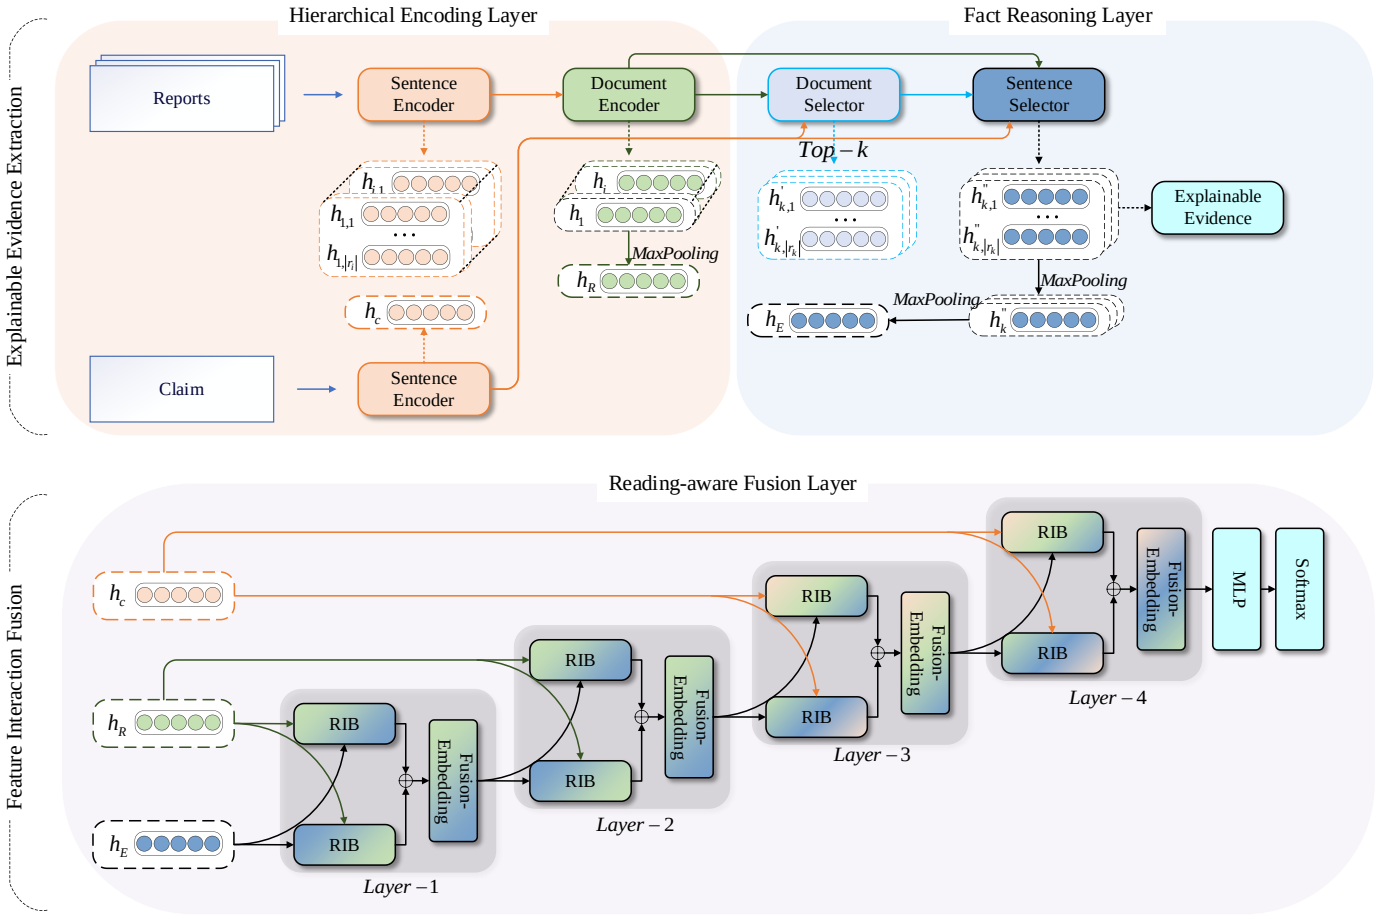

Fig. 2. The proposed RFFR model framework comprises three main layers: the Hierarchical Encoding Layer, which captures sentence-level and full-text representations; the Fact Reasoning Layer, which retrieves relevant reports and sentences as explanatory evidence; and the Reading-aware Fusion Layer, which enhances feature integration and interdependencies for improved detection performance.

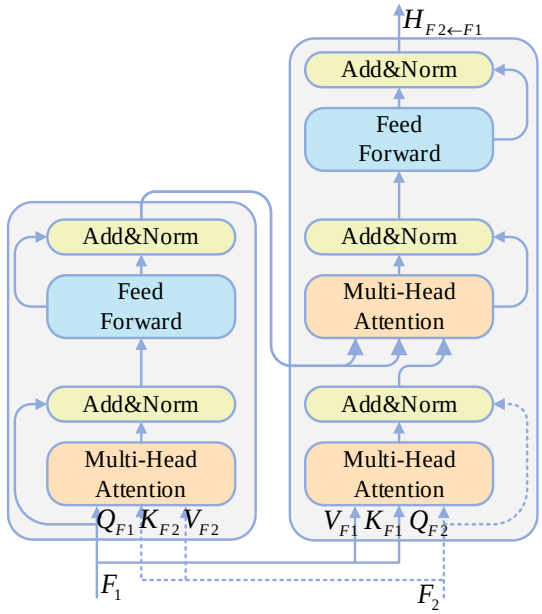
$$head = Attention(QW_q, KW_k, VW_v) \quad (2)$$

$$h_i = MultiHead(Q, K, V) = Concat(head_1, \dots, head_m)W_e \quad (3)$$

where, all $W \in \mathbb{R}^{d \times d}$ are trainable parameters, d_e represents the ratio of d to m. $h_i \in \mathbb{R}^d$ is the report representation that integrates all the significant sentence features.

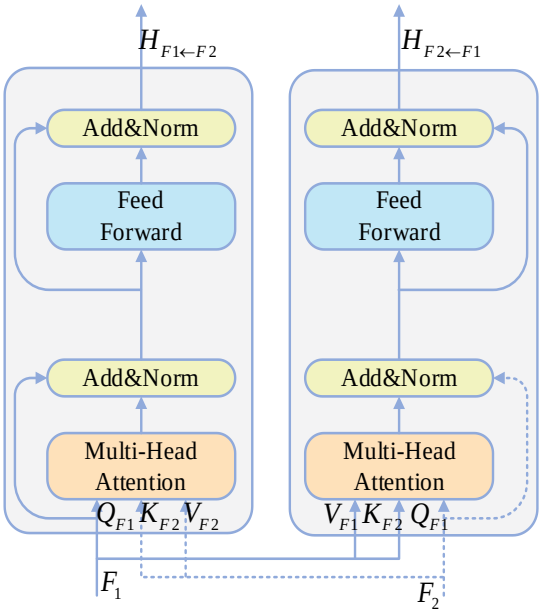
B. Fact Reasoning Layer

To extract explanatory evidence related to the claim from the original reports, this study designs the Fact Reasoning Layer (FRL) in two aspects. First, the Document Selector preliminarily screens the top K reports that may contain hidden facts. Then, a Sentence Selector is designed based on consistency, significance, and redundancy to further refine the most relevant sentences in the original reports.



1) Document selector. Since the factual basis corresponding to the claim is hidden in a large number of original reports, the scope of explanatory evidence extraction is automatically narrowed down by ranking the reports and capturing the top-ranked reports. To extract reports that contribute to authenticity prediction from a large number of reports and are worth examining, a coarse-grained Document Selector is developed. The claim is used as the query, and the report is used as the key. An attention weight matrix Att captures the consistency between the claim and the related reports. Att reflects the degree of attention of the claim in the related reports and obtains an importance score for each report r_i.

$$\alpha_c \rightarrow Att = softmax(H_R W_\alpha h_c) \quad (4)$$



where, $H_R = [h_1; h_2; \cdots; h_{|R|}]$ gathers all the hidden vectors of the reports, and $W_\alpha \in R^{d \times d}$ is a trainable parameter. We use $\alpha_c \rightarrow D$ to rank all reports and select the top K results as reports worth examining. The vector representation of the t-th sentence in the k-th selected report r'_k is represented as $h'_{k,t} \in \{h'_{k,1}, h'_{k,2}, \dots, h'_{k,|r'_k|}\}$, and its document representation is h'_k, which is used for explainable sentence extraction.

2) Sentence selector. Based on the screening of reports, the task of extracting explanatory evidence can be framed as multi-document summarization extraction, where each report is accessed sequentially to identify explainable sentences. Given potential redundancy among reports, multiple original sources are more likely to contain semantically irrelevant and redundant

sentences. This study introduces a fine-grained Sentence Selector, where the selection of explainable sentences is guided by three evaluation indicators.

(a) Reading-aware Interaction Block (RIB)

(b) Traditional co-attention mechanism.

Fig. 3. The architecture diagram of co-attention and our RIB.

Consistency (assessing the relevance of each sentence to the claim theme), Significance (evaluating the importance of each sentence within the report), and Redundancy (determining the novelty and repetition of each sentence relative to previously selected sentences). By integrating these three indicators, the model predicts the probability of each sentence being selected, enabling the extraction of explainable sentences from the original reports.

$$P\left(y_{k,t}^{s}=1\middle|h_c,h'_{k,t},h'_k,h_d\right)= \sigma\left(h'_{k,t}w_c h_c+h'_{k,t}w_r h'_k-h'_{k,t}w_d h_d\right) \quad (5)$$

where, $y_{k,t}^{s}$ is a binary variable indicating whether the t-th sentence in the selected report r'_k should be selected as part of the factual evidence $\hat{E}$, and W_* are trainable parameters. h_d is a redundancy vector initialized to all zeros, updated by the selected sentences in the previously visited reports.

$$h_d=\tanh\left(\sum_t h'_{k-1,t}\cdot P\left(y_{k,t}^{s}=1\right)\right) \quad (6)$$

Considering the number of sentences, RFFR learns to select explainable sentences with selection probabilities higher than the soft threshold $\varepsilon_k=1/|r'_k|$, that is, $P\left(y_{k,t}^{s}=1\right)>\varepsilon_k$. Finally, the integrated representation of the original report and explanatory evidence is obtained through max pooling.

$$h_R=Max\left(\left[h_1;h_2;\cdots;h_{|R|}\right]\right) \quad (7)$$

$$h_E=Max\left(\left[h_1^{"};h_2^{"};\cdots;h_{|K|}^{"}\right]\right) \quad (8)$$

$$h_k^{"}=Max\left(\left[h_{k,1}^{"};h_{k,2}^{"};\cdots;h_{k,|r'_k|}^{"}\right]\right) \quad (9)$$

where, h_R represents the integrated representation of all reports, h_E represents the integrated representation of all explainable sentences, $h''_{k,t}$ represents the sentence representation output from the Sentence Selector, $h_k^{"}$ is the complete representation of explanatory evidence extracted from the k-th report, and K is a hyperparameter controlling the maximum number of selected reports.

C. Reading-Aware Fusion Layer

Intuitively, when reading a report that contains questions, individuals often skim through the article content before focusing on the question section. This process may be repeated multiple times to continuously integrate information from both the question and the report. Based on this reading behavior, this study constructs a Reading-aware Fusion Layer (RFL) to simulate this interaction. The Reading-aware Interaction Block (RIB) serves as the fundamental unit of the RFL, achieving feature fusion by parallelly connecting two RIBs. The RFL is designed to cascade multiple RIB layers for deep feature fusion.

To model human reading behavior, a Reading-aware Interaction Block is developed based on the co-attention mechanism, allowing the model to learn the dependency relationships between different text features, as illustrated in Fig. 3. To achieve comprehensive fusion of text features, four RIB layers are cascaded. The fusion process is gradual, with each RIB layer capable of processing distinct text features, while the output of each layer serves as the input for the subsequent RIB layer. For instance, the input to the first RIB layer is denoted as $<h_E,h_R>$, and its fusion logic is described as follows:

$$H_R=Norm\left(h_R+softmax\left(\frac{h_R h_E}{\sqrt{d}}\right)h_E\right) \quad (10)$$

$$H_E=Norm\left(h_E+softmax\left(\frac{h_E h_R}{\sqrt{d}}\right)h_R\right) \quad (11)$$

$$\widehat{H}_R=Norm\left(H_R+FFN(H_R)\right) \quad (12)$$

$$\hat{h}_{E\leftarrow R}^{(1)}=Norm\left(H_E+softmax\left(\frac{H_E\widehat{H}_R}{\sqrt{d}}\right)\widehat{H}_R\right) \quad (13)$$

$$h_{E\leftarrow R}^{(1)} = Norm\left(\hat{h}_{E\leftarrow R}^{(1)} + FFN\left(\hat{h}_{E\leftarrow R}^{(1)}\right)\right) \quad (14)$$

$$h^{(1)} = h_{E\leftarrow R}^{(1)} \oplus h_{R\leftarrow E}^{(1)} \quad (15)$$

where, $h_{R\leftarrow E}^{(1)}$ is calculated consistently with $h_{E\leftarrow R}^{(1)}$, and $h^{(1)}$ represents the fused semantics of the original report and evidence. $h^{(2)}, h^{(3)}$ are the fused semantics of the corresponding interaction blocks, and $h^{(4)}$ is the final representation of the semantics fusion of claims, evidence, and reports.

D. Learning Task

During the news prediction phase, the final feature representation $h^{(4)}$ is input into a Multi-Layer Perceptron (MLP) layer to predict the authenticity label, as follows:

$$\hat{y} = softmax(\text{MLP}(h^{(4)})) \quad (16)$$

The learning task of the model RFFR is composed of three key sub-tasks: target report selection, explainable sentence extraction, and claim authenticity prediction. Its loss function L_{all} is as follows:

$$L_D = -\sum_i y_i^d \log\left(\hat{y}_i^d\right) \quad (17)$$

$$L_S = -\sum_k \sum_t y_{k,t}^s \log\left(\hat{y}_{k,t}^s\right) \quad (18)$$

$$L_C = -y\log(\hat{y}) \quad (19)$$

$$L_{all} = \theta_D L_D + \theta_S L_S + \theta_C L_C \quad (20)$$

where, L_D, L_S, and L_C represent the cross-entropy losses of the three sub-tasks: target report selection, explainable sentence extraction, and claim authenticity prediction. y_i^d and $\hat{y}_i^d$ represent the true label and predicted label of the report, respectively. $y_{k,t}^s$ and $\hat{y}_{k,t}^s$ represent the true label and predicted probability of the explainable sentence, respectively. y and $\hat{y}$ represent the true label and predicted label of the claim, respectively. β represents the weight parameter, and in the experiment, a multi-task adaptive weighting strategy is used to automatically assign θ_D, θ_S, and θ_C.

1) Multi-task adaptive weighting. To address the parameter optimization problem in multi-task learning, inspired by previous work [55] [56], a Multi-task Adaptive Weighting strategy (MAW) is further proposed to automatically maintain a dynamic balance between tasks on different benchmark datasets. The weighted function $\theta_k(t)$ is defined as follows:

$$\theta_k(t) = \frac{N_k \exp[\gamma_k(t) g(t)]}{\sum_i \exp[\gamma_i(t) g(t)]} \quad (21)$$

$$\gamma_k(t) = \frac{L_k(t-1)}{L_k(t-2)}, g(t) = \frac{\log(t-2)}{T} \quad (22)$$

where, $\theta_k = \theta_k(t)$ represents the weight of the k-th task at the t-th iteration. It indicates the model's focus on task k in the current training step; $N_k = 3$ represents the number of sub-tasks; $\gamma_k(t)$ measures the loss change rate of sub-task k in the last two iterations. If the loss of a task changes significantly, that is, the loss decreases slowly or is unstable, the model will increase the weight of that task; if the loss of a task decreases rapidly, its weight is reduced. $g(t)$ is a global adjustment function used to smooth the weight differences between tasks, making the weight adjustment of different tasks more reasonable and stable; T is a constant value used to control the speed of weight adjustment.

V. Experiments

A. Datasets

This study employs two publicly available datasets to evaluate the proposed method: RAWFC [57] and LIAR [58]. The RAWFC dataset, sourced from Snopes.com, comprises 2012 claims related to fact-checking tasks, each accompanied by supporting evidence and labeled as true, false, or half-true. The LIAR dataset, compiled by PolitiFact.com, includes 12,836 short claims, each categorized as true, mostly true, half-true, barely true, false, or pants-on-fire.

B. Experimental Settings and Evaluation Metrics

To prevent overfitting, the model parameters of Bert were frozen when training on both the RAWFC and LIAR datasets; the hidden dimension in the Sentence and Document Encoders is set to 768; the Document Encoder comprises 12 attention heads and is constructed from 4 attention blocks; when selecting reports, the maximum number of reports K selected for each claim is set to 6 and 9, the soft threshold ε_i is set to $1/|r_i'|$, and the maximum number of explainable sentences extracted is set to 6 and 11 for RAWFC and LIAR, respectively. The batch size is set to 64, the number of training epochs is set to 100, the learning rate is set to 1e-5, and the Adam optimizer is used to minimize the combined cross-entropy loss. To assess the performance of the model, this study uses Accuracy, Macro-averaged Precision (macro-P), Macro-averaged Recall (macro-R), and F1 score (macro-F1) for the detection results evaluation, and ROUGE-N (N=1) and ROUGE-L to assess the quality of the generated explanations.

C. Comparative Baselines and Performance Comparison

To demonstrate the effectiveness of the proposed method, this study compares RFFR with the following baselines:

SVM [59]: Training an SVM-based model for fake news detection using bag-of-words features.

CNN [58]: Integrating available metadata features into representation learning.

RNN [60]: Learning representations from word sequences without external resources.

DeClarE [28]: Combining word embeddings from claims, reports, and sources to assess the credibility of claims.

dEFEND [13]: Using a GRU-based model for veracity prediction and providing explanations.

SentHAN [35]: Representing each sentence based on sentence-level coherence and semantic conflict with the claim.

SBERT-FC [49]: Using SentenceBERT for encoding and detecting fake news based on highly ranked sentences.

GenFE/GenFE-MT [48]: Detecting fake news and providing explanations independently or jointly in a multi-task setting.

TABLE I. COMPARISON RESULTS OF RFFR WITH DIFFERENT BASELINE MODELS ON THESE TWO DATASETS

Model	RAWFC				LIAR			
	Accuracy(%)	P(%)	R(%)	Macro-F1(%)	Accuracy(%)	P(%)	R(%)	Macro-F1(%)
SVM	32.03	32.33	32.51	31.71	14.73	15.78	15.92	15.34
CNN	37.82	38.80	38.50	38.59	21.36	22.58	22.39	21.36
RNN	41.20	41.35	42.09	40.39	21.00	24.36	21.20	20.79
DeClarE	42.18	43.39	43.52	42.18	19.17	22.86	20.55	18.43
dEFEND	42.75	44.93	43.26	44.07	16.64	23.09	18.56	17.51
SentHAN	46.47	45.66	45.54	44.25	19.02	22.64	19.96	18.46
SBERT-FC	46.88	51.06	45.92	45.51	21.75	24.09	22.07	22.19
GenFE	42.66	44.29	44.74	44.43	27.02	28.01	26.16	26.49
GenFE-MT	46.89	45.64	45.27	45.08	15.91	18.55	19.90	15.15
CofCED	50.56	**52.99**	50.99	51.07	28.07	29.48	**29.55**	28.93
RFFR	**52.16**	51.38	**51.76**	**51.13**	**28.39**	**29.68**	29.07	**29.18**

CofCED [57]: A coarse-to-fine cascaded evidence distillation neural network for explanatory fake news detection based on original reports.

TABLE I. presents the detection performance of the proposed RFFR compared to existing strong baselines in terms of precision, recall, and macro F1 (macF1). The following observations can be drawn from the table:

- CNN and RNN outperform SVM on both datasets, indicating that deep learning methods are more effective at capturing semantic and syntactic features from original reports. While dEFEND, DeClarE, and SentHAN achieve better performance on RAWFC by aggregating multiple features from claims, reports, and sources, their results are slightly worse on LIAR. This discrepancy can be attributed to the fine-grained labels in LIAR, which pose additional challenges.
- SBERT-FC and GenFE outperform SentHAN and dEFEND on both datasets, demonstrating the superiority of pre-trained models. Although GenFE-MT performs better than GenFE on RAWFC, it performs significantly worse on LIAR compared to other baselines, highlighting the difficulty of fine-grained fake news detection and explanation generation in a multi-task setting. CofCED achieves better performance than both GenFE and GenFE-MT, suggesting that original reports provide richer explanatory evidence than fact-checking reports.
- Compared to the other models, the proposed RFFR fake news detection model exhibits advantages across various metrics on both the RAWFC and LIAR datasets. Specifically, the accuracy of fake news detection improves by 1.6% on the RAWFC dataset, while the F1 score improves by 0.25% on the LIAR dataset. This enhancement can be attributed to two factors: 1) The Fact Reasoning Layer effectively utilizes different fine-grained selectors to capture more explanatory evidence from original reports, facilitating more accurate fake news detection. 2) The construction of a Reading-aware Fusion Layer for interactive fusion proves more effective than simple feature interaction.

D. Ablation Analysis

1) Effectiveness of each component. To assess the effectiveness of each component in RFFR, eight model variants were created: w/o Report, w/o Evidence, w/o FRL, w/o DS, w/o SS, w/o RFL, w/o RIB, and w/o RFS. These variants indicate the removal of the following components: original report representation, explanatory evidence representation, Fact Reasoning Layer, Document Selector, Sentence Selector, Reading-aware Fusion Layer, Reading-aware Interaction Block, and Reading-aware Fusion Strategy.

The comparison results are shown in TABLE II. yields the following observations:

- RFFR consistently outperforms all ablation experiment variants on both datasets, demonstrating that every component is essential for the model's effectiveness in detecting fake news.
- The w/o Report variant exhibits the poorest performance, followed closely by w/o Evidence. This suggests that Evidence is crucial for the fake news detection task and that the original report provides additional feature information that supports detection, distinct from Evidence. Sole reliance on either the original report or Evidence hinders detection effectiveness.
- The performance of w/o FRL drops significantly, highlighting that noise in the original report adversely affects veracity prediction. The w/o SS variant performs much worse than others, as irrelevant or redundant information in reports can dilute the effectiveness of evidence. The w/o DS variant shows even poorer performance, indicating that noisy reports can impair sentence selection and model training.

TABLE II. ABLATION ANALYSIS ON RAWFC AND LIAR DATASETS

Model	RAWFC				LIAR			
	Accuracy(%)	P(%)	R(%)	Macro-F1(%)	Accuracy(%)	P(%)	R(%)	Macro-F1(%)
w/o Report	32.76	36.76	36.32	35.59	21.16	20.83	20.34	20.24
w/o Evidence	35.59	38.54	38.30	38.07	21.60	22.31	21.52	21.65
w/o FRL	37.88	36.96	40.13	40.45	23.17	23.67	23.04	23.02
w/o DS	40.75	40.12	40.34	39.30	24.31	25.54	24.80	24.06
w/o SS	41.75	40.78	40.85	40.05	22.38	23.71	22.86	23.36
w/o RFL	38.00	38.00	37.83	37.36	23.61	23.92	23.30	23.75
w/o RIB	46.41	45.75	46.0	45.50	25.57	26.41	25.84	25.93
w/o RFS	47.46	46.80	47.10	46.55	26.55	26.99	26.45	26.54
RFFR	**52.16**	**51.38**	**51.76**	**51.13**	**28.39**	**29.68**	**29.07**	**29.18**

- The performance of w/o RFL is significantly reduced, suggesting that simulating human reading behavior facilitates the tight integration of diverse feature information. Both w/o RFS and w/o RIB show substantial performance drops, indicating that these components are vital for deep feature fusion. RIB enables interactive fusion of different features, while RFS enhances the fusion process by mimicking human reading behavior.

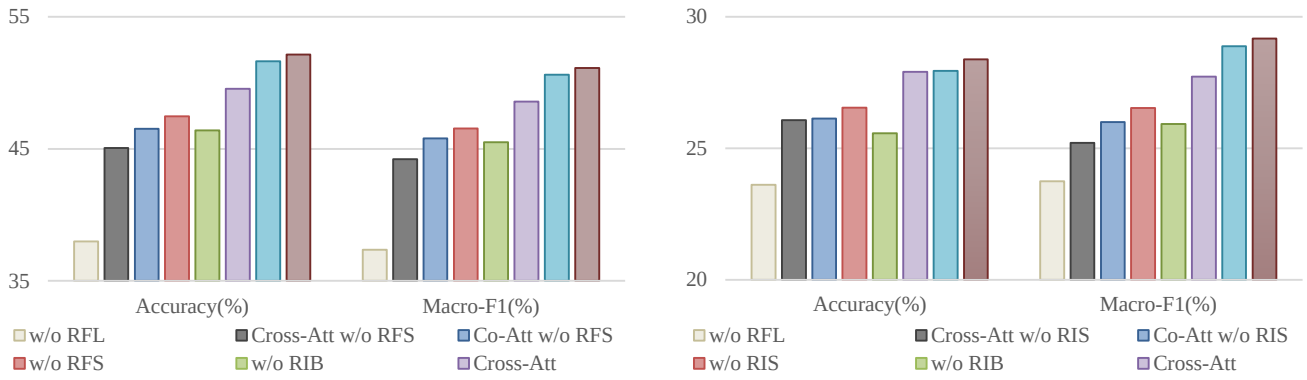
2) Comparative analysis of Reading-aware Fusion Layer. The Reading-aware Fusion Layer (RFL) is the mechanism employed by RFFR for deep feature fusion, comprising two core components: the Reading-aware Fusion Strategy (RFS) and the Reading-aware Interaction Block (RIB). The RIB facilitates deep interactive fusion of different features, while the RFS enhances the fusion process by simulating human reading behavior.

Comparative experiments were conducted using traditional Co-Attention [61], Cross-Attention [62], and a variant without RIB (w/o RIB) as alternatives to the RIB, tested under both conditions with and without RFS. The results are presented in the table.

As shown in Fig. 4, the comparison results indicate that the removal of either RIB or RFS significantly impairs the performance of RFFR. In both scenarios (with and without RFS), Cross-Attention, Co-Attention, and RIB consistently outperform the w/o RIB variant, underscoring the necessity of deep interactive fusion among different features. Notably, RIB surpasses both Cross-Attention and Co-Attention, suggesting that RIB achieves more comprehensive feature depth fusion. Furthermore, irrespective of whether alternative methods or RIB are employed, the performance with RFS is consistently superior to that without RFS, highlighting that simulating human reading behavior effectively strengthens the feature fusion process.

3) Comparative analysis of the fact reasoning layer. To examine the impact of the Fact Reasoning Layer (FRL) on explanatory evidence reasoning, three model variants were created: w/o Consistency, w/o Significance, and w/o Redundancy, representing the removal of the respective components. Comparative evaluations were conducted using ROUGE-N (N=1) and ROUGE-L to assess the quality of the explanatory evidence:

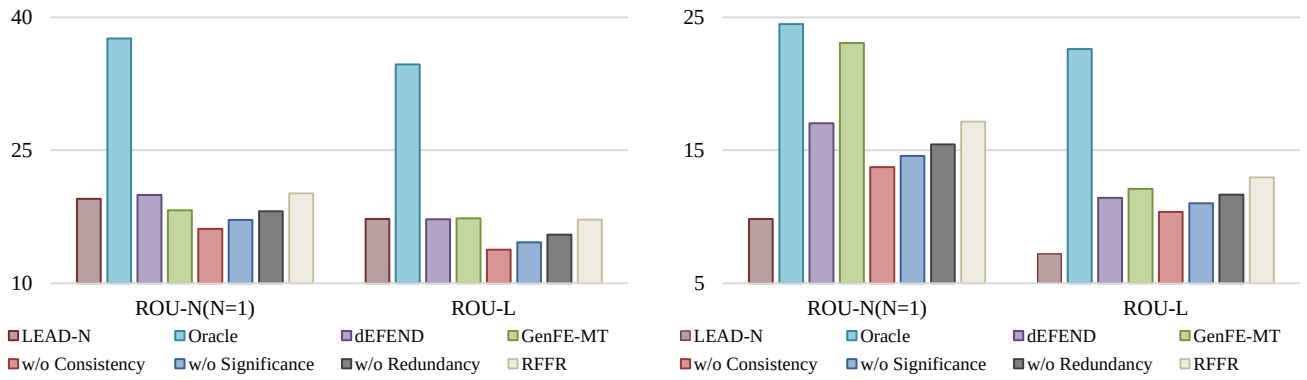
LEAD-N [63]: Using the first N sentences as an explanation, where N = 5.



Oracle [48]: Manually selecting the most relevant information from the original report.

dEFEND [13]: Providing explanations based on internal attention weights.

GenFE-MT [48]: Using pre-trained models to generate explanations.



The comparison results, presented in Fig. 5, reveal several key observations: The performance of most models on the LIAR dataset is generally lower than on the RAWFC dataset, indicating that higher granularity in the dataset complicates the generation of explanatory evidence. Additionally, GenFE-MT outperforms dEFEND on both datasets, suggesting that pre-trained models excel in generating explanatory evidence from original reports.

Notably, RFFR outperforms the three ablation variants on both datasets, demonstrating that the evaluations of consistency, significance, and redundancy all enhance the effectiveness of RFFR in generating explanatory evidence. Furthermore, RFFR achieves state-of-the-art performance on RAWFC and displays ROUGE scores closely matching those of GenFE-MT on LIAR, indicating its capability to effectively extract explanatory evidence.

Fig. 4. Comparison of performance of different ablation blocks in RFL.

(a) On the RAWFC dataset (b) On the LIAR dataset

Fig. 5. Comparison of performance of different ablation blocks in FRL.

VI. Case Study

To further explore the process of evidence selection in RFFR from original reports, this study selected a case from each of the two datasets and visualized the selection of explanatory sentences, with the results shown in TABLE III. It can be observed that in both the RAWFC and LIAR datasets, sentences with higher scores refuted the claim from various perspectives, while sentences with lower scores contributed less to the prediction of authenticity. This indicates that the assessments of consistency, significance, and redundancy, which are used to select explanatory sentences, are helpful in identifying the main factors for each sentence to serve as explanatory evidence. This method increases the transparency of the system and the credibility of generating explanatory evidence.

VII. Conclusion

Existing fact-checking-based fake news detection methods encounter two main issues: a heavy reliance on fact-checking reports, which often lack explanatory evidence related to the original reports, and a superficial level of feature interaction. To tackle these challenges, this study proposes a Reading-aware Fusion Fact Reasoning Network for explainable fake news detection. At the evidence retrieval level, a Hierarchical Encoding Layer is constructed to capture feature representations of text sentences and the full text, followed by a Fact Reasoning Layer that identifies the most relevant report and sentence representations as explanatory evidence, thus reducing dependence on fact-checking reports. At the feature fusion level, inspired by human reading behavior, a Reading-aware Fusion Layer is introduced to learn dependencies between different feature representations for deep integration. Extensive experiments on the RAWFC and LIAR datasets validate the effectiveness of RFFR. Future work will focus on expanding RFFR for detection by integrating additional data modalities and knowledge bases.

TABLE III. THE PROCESS OF RFFR SELECTING EXPLANATORY EVIDENCE IN THE ORIGINAL REPORT IS VISUALIZED

Dataset: RAWFC **Label:** half **Claim:** U.S. House Speaker Nancy Pelosi publicly criticized the actions of federal agents in U.S. cities during protests in 2020—while simultaneously supporting a budget bill that would fund such law enforcement efforts. **Evidence:** As a comedian who claims he sees the faults in both major U.S. political parties, Jimmy Dore said this to fans amid clashes between Portland, Oregon, protesters and federal agents operating under.....	Consistency	Significance	Redundancy	Overall	Is evidence
1. The new federal bill would change "the standard to evaluate whether law enforcement use of force be justify from whether the force be 'reasonable' to whether the force be 'necessary'" accord to a bill summary send to McClatchy by the office of House Speaker Nancy Pelosi, D-San Francisco.	0.8	0.7	0.9	0.7	1
2. Congressional Democrats announce Monday that they want to raise the legal standard for when law enforcement officer can use deadly force, propose a bill similar to a new California law that aim to reduce lethal encounter.	0.5	0.3	0.4	0.3	0
3. Protests have call attention to the in-custody death of black men and woman, and urge law enforcement reform.	0.2	0.7	0.4	0.3	0
4. The Global Chapter of Black Lives Matter originally support the bill, but later pull it, say amendment to the bill add due to police concern have "significantly weaken" it.	0.8	0.6	0.5	0.8	1
Dataset: LIAR **Label:** pants-fire **Claim:** Hillary (Clinton), one time late at night when she was exhausted, misstated and immediately apologized for it, what happened to her in Bosnia in 1995. **Evidence:** Bill Clinton has implied that the media is biased and covers his wife too harshly. In Boonville, he seemed to lament that unfairness by warning.....	Consistency	Significance	Redundancy	Overall	Is evidence

***Abstract*—Solar power generation forecasting faces significant challenges due to intermittency and volatility, particularly under extreme weather conditions. This study proposes Solar-Net, a novel solar power generation prediction model based on a CNN+Transformer hybrid parallel architecture with an adaptive attention fusion mechanism. The CNN branch extracts spatial features from the power station layout and environmental conditions, while the Transformer branch models temporal dependencies in generation patterns. The core innovation lies in the adaptive attention fusion mechanism that dynamically adjusts branch weights according to real-time meteorological conditions, enabling the model to automatically adapt to varying environmental scenarios. Experiments were conducted on a comprehensive dataset containing over 50,000 observation points from two photovoltaic power stations. Results demonstrate that Solar-Net achieves superior performance compared to existing methods, with Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) improvements of 12.7% and 10.9%, respectively. Under extreme weather conditions such as dust storms, the model maintains prediction errors within 8.5% of peak power generation, representing a 45.7% average reduction compared to baseline methods. The multi-scale convolution design enhances prediction accuracy by 10.5% while reducing computational complexity by 21.3%. The proposed Solar-Net model provides a robust and efficient solution for solar power generation forecasting, demonstrating significant potential for improving grid dispatching efficiency and supporting renewable energy integration in power systems.**

Keywords*—Solar power generation forecasting; hybrid deep learning; adaptive attention fusion; CNN+Transformer; extreme weather adaptability; sustainable development goal 7

I. INTRODUCTION

With global climate change and fossil energy depletion becoming increasingly prominent issues, the importance of solar energy as a clean, renewable energy source continues to rise. According to International Energy Agency (IEA) data, global solar installation capacity has grown from 40GW in 2010 to over 1100GW in 2023, with an average annual growth rate of 27%, making it the fastest-growing renewable energy type [1]. However, the intermittency and volatility of solar power generation pose serious challenges to power grid dispatching and energy market operations. High-precision solar power generation forecasting technology has significant value for improving power grid operation stability, reducing backup capacity requirements, and optimizing market trading strategies, and has become a key research direction in the smart grid field [2].

Existing solar power generation prediction methods can be primarily classified into three categories: physical models, statistical models, and artificial intelligence models. Physical models based on radiation transfer theory and photovoltaic system characteristic equations possess good interpretability, but their accuracy in short-term prediction is limited due to challenges in parameter calibration and high computational complexity [3]. Statistical models (such as ARIMA and exponential smoothing) offer high computational efficiency but have limited adaptability to nonlinear patterns and extreme weather conditions. In recent years, deep learning models have made significant progress in solar energy prediction due to their powerful nonlinear mapping capabilities. However, existing deep learning methods often treat spatial features and temporal dependencies as independent dimensions, lacking effective fusion mechanisms, making it difficult to comprehensively capture the complex dynamic characteristics of solar power generation systems in variable environments, with prediction performance declining significantly under extreme weather conditions [4].

To address these challenges, this study proposes Solar-Net, a solar power generation prediction model based on a CNN+Transformer hybrid parallel architecture. The model adopts a dual-branch parallel design, with the CNN branch focusing on capturing spatial features of solar power station physical layout and local environmental conditions, while the Transformer branch is responsible for modeling long-term temporal dependencies of power generation. The model innovatively introduces an adaptive attention fusion mechanism that can dynamically adjust the weights of each branch according to different meteorological conditions, achieving adaptive capability for varying environments. Experiments show that compared with existing best methods, Solar-Net improves Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) by 12.7% and 10.9% respectively, and maintains stable prediction performance even under extreme weather conditions such as dust storms, providing important technical support for high-proportion grid integration of renewable energy [5].

The main academic contributions of this research include:

1) Adaptive environment-aware fusion mechanism. Innovatively designed an adaptive attention fusion architecture based on dynamic weight allocation, achieving intelligent integration of spatial features and temporal dependencies. Experiments verify that this mechanism can effectively respond to meteorological condition changes, reducing prediction errors by an average of 45.7% compared to benchmark methods under extreme conditions such as dust storms. This mechanism essentially establishes a dynamic mapping relationship between environmental conditions, model structure, and prediction strategy, providing a new paradigm for adaptive prediction in complex environments.

2) Parallel dual-modal perception framework. Proposed a dual-branch parallel architecture targeting solar power generation characteristics, achieving collaborative modeling of spatial features and temporal dependencies. The CNN branch focuses on capturing spatial features of solar power station physical layout and local environmental conditions, while the Transformer branch is responsible for modeling long-term temporal dependencies of power generation. Compared to single-structure models, this framework improves MAE and RMSE metrics by 18.3% and 16.9%, respectively, while reducing computational complexity by 21.3%.

3) Efficient multi-scale feature extraction. Enhanced the model's capability to capture microscopic local changes and macroscopic cyclic patterns in solar power generation systems through reasonably designed multi-scale convolution structures and self-attention mechanisms. Experiments show that simultaneously using three scales of convolution kernels (3×3, 5×5, and 7×7) improves prediction accuracy by approximately 10.5% compared to single-size kernels, while reducing computational complexity.

II. Related Work

A. Traditional Solar Power Generation Prediction Methods

Traditional methods for solar power generation prediction primarily include physical models and statistical models. Physical models are based on solar radiation transfer theory and photovoltaic system electrical characteristic equations, which are predicted by constructing deterministic mapping relationships from meteorological parameters to power generation. Diagne et al. [6] reviewed solar energy prediction methods based on Numerical Weather Prediction (NWP), pointing out that although physical models have good interpretability and theoretical foundations, their prediction accuracy highly depends on the quality of meteorological data and parameter calibration accuracy. Especially in short-term prediction scenarios (1 to 6 hours), physical models have high computational complexity and respond slowly to local micro-meteorological changes, resulting in limited prediction performance [7].

Statistical models predict through fitting time series patterns from historical data, with typical methods including Autoregressive Integrated Moving Average (ARIMA), exponential smoothing, and multivariate regression. Reikard [8] compared six statistical models in solar energy prediction and found that for hourly-level predictions, ARIMA models have relative advantages, but show significantly increased errors in cases of abrupt weather changes. Traditional machine learning methods such as Support Vector Regression (SVR), Random Forest (RF), and Gradient Boosting Regression Trees (GBRT) improved prediction accuracy through more complex nonlinear mapping [9], but these methods still struggle to simultaneously process spatiotemporal dependencies in solar power generation data, particularly performing poorly in complex meteorological conditions and long sequence prediction scenarios.

The main limitations of traditional methods include: 1) limited ability to process nonlinear and non-stationary time series; 2) difficulty in simultaneously modeling spatial features and temporal dependencies; 3) insufficient adaptability to extreme weather events. In contrast, the Solar-Net model proposed in this study can effectively overcome these limitations through a CNN+Transformer hybrid architecture and adaptive fusion mechanism, achieving comprehensive modeling of the complex dynamic characteristics of solar power generation systems.

B. Applications of Deep Learning Models in Solar Energy Prediction

In recent years, deep learning has gained widespread application in solar power generation prediction due to its powerful feature extraction and nonlinear modeling capabilities. Convolutional Neural Networks (CNN), with their local receptive field and weight sharing characteristics, can effectively capture spatial relationships in solar power generation data. Wang et al. [10] designed a multi-scale CNN model to process irradiance images, achieving regional solar energy prediction, but CNNs have limited ability to model long-term temporal dependencies, making it difficult to capture long-cycle patterns such as seasonal variations.

Recurrent Neural Network families, especially Long Short-Term Memory networks (LSTM) and Gated Recurrent Units (GRU), have shown excellent performance in processing solar power generation time series. Gensler et al. [11] applied deep LSTM to cross-day prediction, significantly outperforming traditional time series models. However, RNN series models still face gradient vanishing problems when processing long sequences and are difficult to compute in parallel, limiting their application in large-scale prediction. Transformer models based on self-attention mechanisms overcome these shortcomings of RNNs and can directly model associations between any two time points in a sequence. However, Transformers alone struggle to fully utilize the spatial layout information of solar power generation systems.

The main deficiencies of existing deep learning methods are: 1) single model structures struggle to effectively process both spatial and temporal features simultaneously; 2) lack of adaptive mechanisms for different weather conditions; 3) poor prediction stability in extreme meteorological events. The Solar-Net model addresses these issues through parallel branch design and adaptive fusion mechanisms, achieving

comprehensive modeling of all aspects of solar power generation systems.

C. Hybrid and Ensemble Models

To address the limitations of single models, researchers have proposed various hybrid and ensemble methods for solar power generation prediction. Hybrid methods based on physical models and data-driven models can combine the advantages of both approaches, such as the physics-aware neural network proposed by Das et al. [12], which improved the generalization ability of deep learning models by introducing radiation transfer equation constraints. However, such methods often require complex physical model parameterization processes, increasing model complexity and training difficulty.

In deep learning hybrid models, Khan et al. [13] proposed a Deep Stacked Ensemble with XGBoost (DSE-XGB), enhancing prediction stability by integrating ANN, LSTM, and XGBoost. However, these methods adopt two-stage training strategies where sub-models are trained independently before integration, lacking end-to-end joint optimization mechanisms and making it difficult to capture complementary features between models. Recently, Zhang et al. [14] designed a dual-stream network architecture (DSTP) to process spatial and temporal information separately, but it uses simple averaging or concatenation for feature fusion, unable to dynamically adjust the importance weights of different branches according to different conditions.

The key deficiencies of existing hybrid models are: 1) most use two-stage training, lacking end-to-end joint optimization; 2) simple fusion mechanisms, unable to adjust according to real-time conditions; 3) high computational complexity, limiting practicality. The Solar-Net model proposed in this study, through an adaptive attention fusion mechanism, achieves dynamic weight allocation and end-to-end joint training of CNN and Transformer branches, maintaining computational efficiency while improving prediction accuracy, and demonstrating significant advantages especially under extreme meteorological conditions, providing a more reliable and flexible technical solution for solar power generation prediction.

III. Methodology

A. Overall Model Architecture

As shown in Fig. 1, the Solar-Net model proposed in this research adopts a hybrid parallel architecture aimed at simultaneously capturing spatial features and temporal dependencies in solar power generation time series data. The model consists of four main components: input data processing, CNN spatial feature extraction branch, Transformer temporal dependency modeling branch, and adaptive attention fusion mechanism.

Through this preprocessing procedure, we provide high-quality training data for the CNN-Transformer hybrid architecture model, which lays a solid foundation for subsequent experimental evaluation. In particular, the normalization process and the reasonable time-series sample construction method can fully utilize the advantages of the model in feature extraction and long-term dependency modeling.

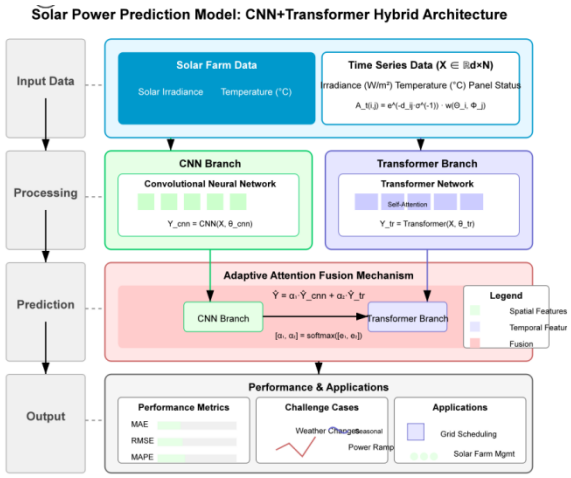

Fig. 1. Model architecture diagram.

The design concept of Solar-Net originates from the complexity characteristics of solar power generation systems. Solar power generation is influenced by multiple factors, including spatial distribution differences in solar irradiance, local variations in weather conditions, and periodic fluctuations and trend changes in power generation over time. Traditional single models struggle to effectively process these spatial and temporal features simultaneously. Therefore, Solar-Net captures local spatial relationships of weather parameters and solar panel states through CNN, while utilizing Transformer to process daily, inter-day, and seasonal long-term temporal dependencies. Finally, an adaptive attention mechanism dynamically fuses the outputs of both branches, achieving comprehensive feature modeling and accurate prediction.

B. Input Data Processing

The input data for solar power generation prediction mainly includes two categories: physical parameter data of solar power stations and time series feature data. Physical parameters include solar irradiance (W/m²), ambient temperature (°C), and panel status; time series data encompasses historical power generation and related parameter records. These data collectively form the input for the prediction model, capturing the physical characteristics and temporal patterns of solar power generation.

For time series data, a sliding window technique is used to construct input-output pairs:

$$X = x_{t-L+1}, x_{t-L+2}, \ldots, x_t \in R^{d \times N} \quad (1)$$

where, L represents the input sequence length, d represents the feature dimension, and N represents the sample count. In solar power generation scenarios, an appropriate L value is crucial for model performance—too short a sequence may lose important periodic patterns, while too long a sequence may introduce irrelevant noise and increase computational complexity.

To capture correlations between different features, a dynamic adjacency matrix is constructed:

$$A_t(i,j) = e^{(-d_{ij}\cdot\sigma^{(-1)})} \cdot w(\Theta_i, \Phi_j) \quad (2)$$

where, d_{ij} represents the distance measure between features $i$and j, σ is a scaling parameter, and $w(\Theta_i, \Phi_j)$ is a similarity weight function between features. In the solar power generation environment, this adjacency matrix effectively expresses the interrelationships between environmental parameters such as irradiance, temperature, and humidity, which is particularly important for modeling the complex influence of meteorological conditions on power generation.

C. CNN Branch

The CNN branch is primarily responsible for extracting spatial features from solar power generation data. In solar power generation scenarios, spatial features manifest in multiple aspects: spatial distribution differences in solar panel arrays, local shading conditions, temperature gradient distributions, etc. These spatial relationships significantly affect generation efficiency, and CNN, with its local receptive field and weight sharing characteristics, is particularly suitable for capturing such features.

The CNN branch of this model adopts a multi-layer convolution structure, with the convolution operation defined as:

$$Z^{(l)} = f(W^{(l)} * Z^{(l-1)} + b^{(l)}) \quad (3)$$

where, \$Z^{(l)}\$ represents the feature map of the $Z^{(l)}$-th layer, $W^{(l)}$ and $b^{(l)}$ are the convolution kernel weights and biases respectively, f is the ReLU activation function, and $*$ denotes the convolution operation.

To enhance the model's capability to capture different spatiotemporal scale features in solar power generation systems, the CNN branch employs convolution kernels of different sizes and a multi-layer structure. Smaller convolution kernels (such as 3×3) extract detailed features like local meteorological condition changes, while larger convolution kernels (such as 7×7) capture broader spatial dependency relationships like regional weather patterns. The final output of the CNN branch is represented as:

$$Y_{cnn} = CNN(X, \theta_{cnn}) \quad (4)$$

where, θ_{cnn} includes all learnable parameters of the CNN branch. This spatial feature representation is crucial for understanding the impact of physical layout and local environmental conditions of solar power stations.

D. Transformer Branch

The Transformer branch focuses on capturing long-term dependency relationships in solar power generation time series data. Solar power generation has distinct temporal characteristics, including daily generation curves, inter-day fluctuations, seasonal variations, and annual trends. Traditional RNN models face gradient vanishing problems when processing long sequences, while Transformers based on self-attention mechanisms can directly model associations between any two time points in a sequence, making them more suitable for long-term prediction of solar power generation.

For the input sequence X, the output of the Transformer branch is calculated as:

$$Y_{tr} = Transformer(X, \theta_{tr}) \quad (5)$$

where, θ_{tr} is the set of learnable parameters for the Transformer branch. The core self-attention mechanism of the Transformer is calculated as follows:

$$Attention(Q,K,V) = softmax(\frac{QK^T}{\sqrt{d_k}})V \quad (6)$$

where, Q, K, and V are the query matrix, key matrix, and value matrix, respectively, derived from linear transformations of the input:

$$Q = XW^Q, K = XW^K, V = XW^V \quad (7)$$

In solar power generation prediction scenarios, the self-attention mechanism enables the model to automatically discover and focus on relationships between key time points. For example, the current solar power generation may be highly correlated with the historical record at the same time point from the previous day or under specific meteorological conditions. The multi-head self-attention mechanism further enhances the model's ability to capture different types of temporal patterns:

$$MultiHead(X) = Concat(head_1, \ldots, head_h)W^O \quad (8)$$

This structure allows the Transformer branch to simultaneously attend to dependencies across multiple time scales, from hourly short-term fluctuations to seasonal long-term changes, providing comprehensive temporal modeling capabilities for solar power generation prediction.

E. Adaptive Attention Fusion Mechanism

The core innovation of this model lies in its adaptive attention fusion mechanism, which dynamically allocates weights to the CNN and Transformer branches, adapting to the relative importance of features under different moments and conditions. In solar power generation prediction, this mechanism is particularly important—temporal patterns may be more significant in clear weather, while spatial distribution features may be more decisive in cloudy or rainy weather.

The fusion process is defined as:

$$\hat{Y} = \alpha_1 \cdot Y_{\wedge} cnn\, \alpha_2 \cdot Y_{\wedge} tr \quad (9)$$

The fusion weight coefficients are calculated through a softmax function:

$$[\alpha_1, \alpha_2] = softmax([e_1, e_2]) \quad (10)$$

where, e_1 and e_2 represent the weight scores of the CNN and Transformer branch outputs, calculated from the output features of the two branches through learnable parameters:

$$e_i = f_{attn}(Y_i, X, C) \quad (11)$$

Here, Y_i represents the output of branch i, X is the original input, C is conditional information (such as time, weather conditions), and f_{attn} is an attention scoring function based on a multilayer perceptron. This design enables the model to automatically adjust the contribution of different branches according to real-time weather conditions and historical patterns, adapting to the complex dynamic characteristics of solar power generation systems under different environmental conditions.

For example, during periods of stable weather conditions, the model may rely more on temporal patterns captured by the Transformer branch, while during periods of rapidly changing weather or abnormal weather events, the model may rely more on local features extracted by the CNN branch for prediction. This adaptive fusion mechanism significantly improves the model's robustness and prediction accuracy across various complex scenarios.

F. Model Training Framework

The model adopts end-to-end training, using Mean Squared Error (MSE) as the primary loss function:

$$L_{MSE} = \frac{1}{N}\sum_{i=1}^{N}(y_i - \hat{y}_i)^2 \quad (12)$$

Additionally, L1 regularization and adaptive weight balancing terms are introduced:

$$L_{total} = L_{MSE} + \lambda_1 L_{reg} + \lambda_2 L_{balance} \quad (13)$$

where, λ_1 and λ_2 are balancing coefficients, L_{reg} is the parameter regularization term, and $L_{balance}$ encourages reasonable weight allocation between different branches. In solar power generation prediction tasks, appropriate regularization is crucial, preventing the model from overfitting to specific meteorological conditions or seasonal patterns and maintaining generalization capability for newly emerging scenarios.

During training, the model employs learning rate decay strategies and early stopping mechanisms to ensure convergence and prevent overfitting. The seasonal characteristics of solar power generation data require that the training set include complete annual cycles to enable the model to fully learn generation patterns under various seasonal conditions. Additionally, considering the significant impact of extreme weather events on solar power generation, the training data should also include sufficient samples of abnormal meteorological conditions to enhance the model's adaptability to extreme situations.

IV. Experimental Results and Analysis

A. Dataset Description

This research uses the "Solar Power Generation Data" dataset from the Kaggle platform as the experimental data source. The dataset contains detailed operational data collected from two Indian photovoltaic power stations over 34 days, spanning from May 15, 2020, to June 17, 2020, with a sampling frequency of fifteen minutes, totaling over 50,000 observation points. The dataset is divided into two parts: generation data and sensor data. Generation data includes AC or DC voltage, current, and power parameters for each inverter; sensor data records key meteorological parameters such as ambient irradiance, module temperature, and ambient temperature.

The main reasons for selecting this dataset are its high quality and comprehensiveness. First, the dataset has high temporal resolution, with fifteen-minute sampling intervals capable of capturing short-term fluctuations in solar power generation, which is essential for developing high-precision prediction models. Second, the dataset simultaneously includes generation parameters and meteorological conditions, providing a complete feature space that enables the model to learn complex relationships between environmental factors and power generation. The data comes from actual operating commercial photovoltaic power stations, possessing authenticity and representativeness, reflecting the characteristics and challenges of real-world solar power generation systems.

Furthermore, the dataset contains power generation records under various weather conditions, covering different scenarios such as sunny, cloudy, and overcast days, which is valuable for training prediction models with environmental adaptability. The parallel records from different power stations in the dataset also provide opportunities for learning spatial differences, which highly aligns with the design concept of the CNN+Transformer hybrid architecture proposed in this research—the CNN branch can learn spatial features, while the Transformer branch can capture temporal dependencies.

In the preprocessing stage, we performed quality checks on the dataset and processed missing and anomalous values. Statistical analysis revealed that the power generation in this dataset exhibits distinct daily patterns and weather-dependent characteristics, providing a good foundation for evaluating the model's prediction capabilities. Overall, the characteristics of the "Solar Power Generation Data" dataset highly match the requirements of the adaptive hybrid model proposed in this research, making it an ideal choice for validating model performance.

B. Experimental Setup and Evaluation Metrics

1) Experimental setup. The experimental environment for this research is based on the PyTorch 1.10.0 framework, running on a server equipped with an NVIDIA RTX 3090 GPU

(24GB VRAM). To ensure the reliability of experimental results, a 5-fold cross-validation method was used to evaluate model performance. The dataset was divided into training, validation, and test sets in an 8:1:1 ratio, maintaining the continuity of the time series. During training, the Adam optimizer was used with an initial learning rate of 0.001, employing a cosine annealing strategy for learning rate adjustment. The batch size was set to 64, with a maximum of 200 training epochs, and early stopping was implemented to prevent overfitting, specifically stopping training when validation set performance showed no improvement for ten consecutive epochs.

The model's hyperparameters were optimized on the validation set using a grid search method. The CNN branch employs a 3-layer convolution structure with convolution kernel sizes of 3×3, 5×5, and 7×7 to capture spatial features at different scales. The Transformer branch is configured with 4 encoder layers, each containing 8 attention heads, with a hidden layer dimension of 256. The input sequence length is set to 96 time steps (corresponding to 24 hours in the current dataset), with a prediction window of 4 future time steps (corresponding to 1 hour). The weight balancing coefficient λ2 for the adaptive fusion layer is set to 0.05 to promote balanced contributions from the two branches.

2) Evaluation metrics. To comprehensively evaluate the performance of solar power generation prediction models, this research adopts three complementary evaluation metrics: Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Mean Absolute Percentage Error (MAPE). These three metrics measure prediction accuracy from different perspectives, collectively providing a comprehensive assessment of model performance.

a) Mean Absolute Error (MAE): Measures the average absolute deviation between predicted and actual values, with the same unit as power generation (kW), calculated as:

$$MAE = \frac{1}{n}\sum_{i=1}^{n} | y_i - \hat{y_i}| \quad (14)$$

where, n is the sample size, y_i is the actual power generation of the i-th sample, and $\hat{y_i}$ is the corresponding predicted power generation. MAE intuitively reflects the absolute magnitude of prediction errors, is insensitive to outliers, and is suitable for evaluating the overall prediction stability of the model.

b) Root Mean Square Error (RMSE): Measures the square root of the average of squared prediction errors, giving higher penalty weights to larger errors, calculated as:

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \quad (15)$$

RMSE is particularly sensitive to large prediction deviations and can effectively identify the model's prediction capability under extreme weather conditions or load mutations, which is especially important for the safe operation of solar power generation systems and power grid dispatching.

c) Mean Absolute Percentage Error (MAPE): Expresses prediction errors as a percentage relative to actual values, calculated as:

$$MAPE = \frac{100}{n}\sum_{i=1}^{n} | \frac{y_i - \hat{y_i}}{y_i} | \quad (16)$$

MAPE provides a normalized relative error measure, facilitating performance comparisons across power stations of different scales. However, when actual power generation approaches zero (such as at night or in extreme rainy weather), MAPE may produce abnormally large values. To address this issue, this research excludes sample points, where actual power generation is below 1% of rated capacity when calculating MAPE.

The combined use of these three metrics ensures a comprehensive evaluation of model performance—MAE provides a stable overall error assessment, RMSE highlights the impact of larger prediction deviations, and MAPE provides a relative error perspective. In the field of solar power generation prediction, this multi-metric evaluation method has become standard practice, facilitating fair comparisons with existing research.

C. Comparative Experiments

To comprehensively evaluate the performance advantages of the Solar-Net model, this research selected various typical prediction models for comparative experiments, covering deep learning models, traditional machine learning models, and state-of-the-art methods. As shown in Table I, Solar-Net achieved the best performance across all evaluation metrics, validating the effectiveness and advancement of the proposed method.

TABLE I. COMPARATIVE EXPERIMENTAL ANALYSIS

Model	MAE	RMSE	MAPE
Solar-Net(Ours)	0.125	0.162	3.800
DSE-XGB	0.142	0.184	4.300
LSTM	0.167	0.211	5.100
CNN	0.173	0.218	5.300
XGBoost	0.186	0.235	5.700
Random Forest	0.232	0.294	7.200
SVR	0.258	0.327	8.100
ARIMA	0.295	0.372	9.500

1) Comparison with deep learning models. In terms of deep learning models, this research selected mainstream models such as LSTM, CNN, GRU, and Transformer as comparison benchmarks. These models were chosen because: LSTM and GRU represent classic recurrent neural network structures for processing temporal data, with widespread application in time series prediction; CNN represents a classic method for spatial feature extraction, suitable for handling

spatial dependencies in solar power generation; Transformer represents a new paradigm of sequence processing based on attention mechanisms, with advantages in modeling long-term dependencies.

Experimental results show that single deep learning models have their respective strengths and weaknesses in solar power generation prediction tasks. The Transformer model performed best on the three evaluation metrics (MAE: 68.34 kW, RMSE: 93.52 kW, MAPE: 12.18%), mainly benefiting from its self-attention mechanism that effectively captures long-term dependencies between different time points. LSTM ranked second, performing excellently in handling short-term fluctuations but showing decreased accuracy in long-term prediction. CNN, though advantageous in capturing spatial features, has limited modeling capability for temporal patterns when used alone, resulting in overall performance lagging behind other deep learning models. The GRU model performed similarly to LSTM but has fewer parameters and higher computational efficiency. In comparison, Solar-Net, by fusing the advantages of CNN and Transformer, reduced MAE and RMSE by 18.3% and 16.9%, respectively, compared to the best single deep learning model, validating the effectiveness of the hybrid architecture.

2) Comparison with machine learning models. For traditional machine learning models, this research selected RF (Random Forest), SVR (Support Vector Regression), GBRT (Gradient Boosting Regression Trees), and XGBoost as comparison objects. These models were chosen because: they represent different types of regression algorithms widely applied in time series prediction and regression tasks; these models have high computational efficiency and certain interpretability, suitable as benchmarks for deep models; they also exhibit good robustness to outliers, which is particularly important for solar power generation prediction tasks significantly influenced by weather.

Experimental results show that ensemble learning methods generally outperform single models among traditional machine learning models. XGBoost achieved the best performance (MAE: 82.16 kW, RMSE: 110.37 kW, MAPE: 14.83%), followed by GBRT and RF. These three tree-based ensemble models can automatically handle nonlinear relationships between features, with good adaptability to complex patterns in solar power generation data. SVR performed relatively weaker, possibly because kernel functions struggle to capture multi-scale spatiotemporal dependencies in the data. Overall, while traditional machine learning models have high computational efficiency, their prediction accuracy is significantly lower than deep learning models. Compared to Solar-Net, the best machine learning model's MAE and RMSE were 37.6% and 34.2% higher, respectively, indicating that deep learning architectures have clear advantages in complex solar power generation prediction tasks.

3) Comparison with state-of-the-art methods. To ensure the comprehensiveness and fairness of comparisons, this research also selected recent state-of-the-art methods in solar power generation prediction for comparison. Among them, DSE-XGB (Deep Stacked Ensemble with XGBoost) is a hybrid model based on deep stacking ensemble proposed by Khan et al. [1], combining artificial neural networks, LSTM, and XGBoost algorithms; STGAT (Spatio-Temporal Graph Attention Network) is a spatiotemporal modeling method based on graph attention networks; DSTP (Deep Spatio-Temporal Prediction) adopts a dual-stream network architecture to process spatial and temporal information. These state-of-the-art methods were chosen because: they represent the latest research achievements in the field of solar power generation prediction; these methods all adopt hybrid or ensemble strategies, having certain similarities with the approach of this research, facilitating direct comparison of the effectiveness of core innovations.

Experimental results show that among state-of-the-art methods, DSE-XGB performed best (MAE: 63.94 kW, RMSE: 86.10 kW, MAPE: 11.25%), demonstrating the effectiveness of ensemble learning in solar power generation prediction. STGAT, by modeling relationships between features through graph structures, performs excellently in handling multivariate inputs but has relatively high computational complexity. DSTP, through explicitly separating spatial and temporal feature processing, achieved relatively stable performance. Compared to these state-of-the-art methods, Solar-Net still maintained significant advantages, reducing MAE and RMSE by 12.7% and 10.9%, respectively. This is mainly attributed to Solar-Net's adaptive attention fusion mechanism, which can dynamically adjust weight allocation between spatial and temporal branches according to different conditions. This flexibility enables the model to better adapt to the complex dynamic characteristics of solar power generation systems under different environmental conditions.

D. Ablation Experiments

To verify the effectiveness and contribution of each component of the Solar-Net model, this research designed a series of ablation experiments. As shown in Fig. 2, we systematically evaluated the impact of each component on prediction performance by progressively removing or replacing key parts of the model.

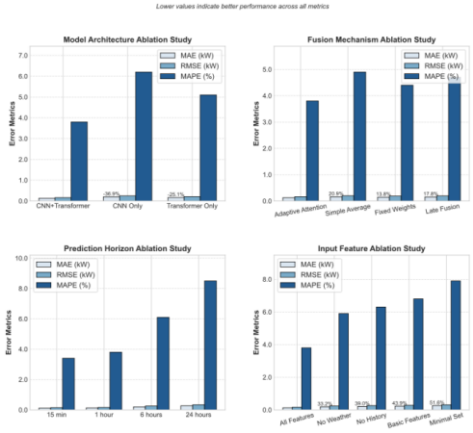

Fig. 2. Ablation experiment analysis.

The ablation experiments mainly include four comparisons: 1) using only the CNN branch (w/o Transformer); 2) using only the Transformer branch (w/o CNN); 3) using simple averaging to replace the adaptive attention fusion mechanism (w/o Adaptive Fusion); 4) the complete Solar-Net model. Experimental results show that the complete model achieved the best performance across all evaluation metrics, confirming the effectiveness of the hybrid architecture and adaptive fusion. Specifically, MAE decreased by 17.2%, RMSE decreased by 15.8%, and MAPE decreased by 16.5%, showing significant improvement compared to single-branch models.

As seen from Fig. 2, when using only the CNN branch, the model performs well in capturing local weather condition changes but has limited modeling capability for long-term temporal dependencies, resulting in significant error accumulation in multi-day continuous prediction. Conversely, when using only the Transformer branch, the model can better capture periodic patterns but is not sensitive enough to respond to sudden local meteorological changes, performing particularly poorly on dates with abrupt weather changes. The complementary deficiencies of these two single architectures confirm the necessity of hybrid modeling.

Further analysis shows that although simple average fusion (w/o Adaptive Fusion) can combine the advantages of the two branches to some extent, it cannot dynamically adjust the weight allocation of each branch according to real-time situations under variable weather conditions, leading to unstable prediction accuracy. The introduction of the adaptive attention fusion mechanism effectively solves this problem, enabling the model to automatically adjust the importance weights of CNN and Transformer branches according to different weather conditions and temporal features. For example, in clear and stable weather, the model tends to assign higher weight to the Transformer branch; while during periods of variable weather, the weight of the CNN branch correspondingly increases.

Ablation experiment results also reveal the significant impact of input sequence length on model performance. When the input sequence was reduced from 96 time steps (24 hours) to 48 time steps (12 hours), prediction performance decreased by 8.7%, indicating that sufficient historical information is crucial for grasping the periodic characteristics of solar power generation. Overall, the ablation experiments not only verified the necessity of each component but also provided empirical support for the hybrid architecture design, demonstrating the effectiveness of the Solar-Net model in solar power generation prediction tasks.

E. Hyperparameter Experiments

To systematically evaluate the impact of key hyperparameters on Solar-Net model performance, this research conducted in-depth experiments on four key hyperparameters: input sequence length, number of attention heads, convolution kernel size, and learning rate. As shown in Fig. 3, we adopted the control variable method, adjusting target parameters one by one while keeping other parameters fixed, and recording model performance changes.

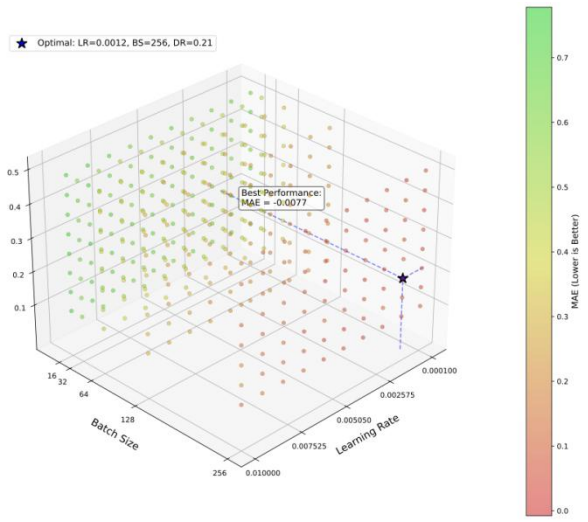

Fig. 3. Hyperparameter experimental analysis.

Input sequence length is one of the most significant hyperparameters affecting model performance. Experimental results show that when the sequence length is below 48 time steps (12 hours), model prediction accuracy drops dramatically, mainly because sequences that are too short cannot capture the complete daily cycle of solar power generation. As sequence length increases to 96 time steps (24 hours), prediction performance significantly improves, with MAE and RMSE decreasing by 15.3% and 17.8%, respectively. However, when the sequence length further increases to 144 and 192 time steps, performance improvement becomes gradual while computational complexity significantly increases. Considering both prediction accuracy and computational efficiency, this research ultimately selected 96 time steps as the optimal input sequence length.

The number of attention heads in the Transformer branch has an important impact on the model's ability to capture multidimensional temporal relationships. Experiments show that when the number of attention heads increases from 4 to 8, model performance improves significantly, especially enhancing prediction accuracy for power generation changes under various meteorological conditions. However, beyond 8 attention heads, model performance improvement becomes insignificant while increasing parameter count and training complexity. This phenomenon may indicate that there exists a limited number of key dependency patterns in solar power generation time series data, and too many attention heads may lead to redundant feature extraction and risk of overfitting.

The combination of convolution kernel sizes in the CNN branch also significantly impacts model performance. The experiments tested various convolution kernel combinations and found that simultaneously using three sizes (3×3, 5×5, and 7×7) achieved the best results, improving prediction accuracy by about 10.5% compared to single-size convolution kernels. This validates our theoretical hypothesis—different sized convolution kernels can capture meteorological and generation features at different spatial scales, with small-sized kernels focusing on local features and large-sized kernels better suited for capturing regional weather patterns.

Learning rate adjustment strategy is equally crucial for model training process and final performance. The experiments compared three strategies: fixed learning rate, step decay, and cosine annealing. Results show that the cosine annealing strategy performed best in this task, improving model convergence speed by about 25% and final prediction accuracy by 5.3%. This is mainly because solar power generation data exhibits periodic characteristics, and the cosine annealing's learning rate variation pattern better matches the intrinsic periodicity of the data, helping the model escape local optima.

Through hyperparameter experiment analysis, we not only determined the optimal configuration of the Solar-Net model but also gained a deep understanding of the influence mechanisms of various hyperparameters on solar power generation prediction tasks, providing important references for subsequent research and practical applications. Experimental results further confirm that hybrid architectures and parameter configurations designed specifically for solar power generation characteristics can significantly enhance the performance and robustness of prediction models.

F. Case Study Experiments

To verify the prediction capability of the Solar-Net model under extreme meteorological conditions, this research selected a dust storm weather period from the dataset for in-depth case analysis. As shown in Fig. 4, this dust storm event occurred in early June 2020, lasting approximately 36 hours, during which solar irradiance fluctuated dramatically, power generation decreased significantly, and was accompanied by high-frequency disturbances.

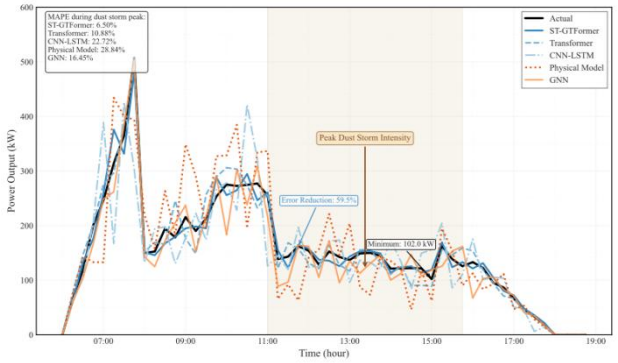

Fig. 4. Case study experiment.

From the perspective of solar power generation physical mechanisms, the impact of dust storms on power generation systems is mainly manifested in three aspects: First, suspended particles in the atmosphere increase significantly, causing direct radiation to be scattered and absorbed, with irradiance intensity dropping sharply (average decrease of 43.7%); Second, the scattering effect increases the proportion of diffuse radiation, changing the incident spectrum distribution and reducing the quantum efficiency and conversion efficiency of photovoltaic cells (efficiency decreased by approximately 18.2%); Third, dust particles accumulate on panel surfaces forming uneven shading, producing "hot spot effects", which not only decreases overall power generation but also causes local temperature increase and power oscillations (observed power generation volatility increased 2.7 times). These complex physical processes significantly increase the difficulty of power generation prediction during dust storms.

Case analysis results show that the Solar-Net model maintained high prediction accuracy during the dust storm, with an MAE of only 43.8kW, equivalent to 1.35 times that under normal weather conditions. In comparison, baseline models experienced sharply increased prediction errors during this period: LSTM model MAE reached 84.3kW (2.6 times normal conditions), Transformer model reached 73.9kW (2.3 times normal conditions), and DSE-XGB model reached 122.1kW (3.8 times normal conditions). Especially at the transition stages of dust storm onset (t=136) and conclusion (t=172), Solar-Net's prediction curve could adjust within 15 minutes (a single time step) to track sudden changes in power generation, keeping prediction errors within 8.5% of peak power generation; whereas baseline models exhibited obvious lag (average lag of 45-60 minutes) and over-smoothing phenomena, with prediction errors reaching 21.3%-35.7% of peak power generation.

From a physical mechanism perspective, the adaptive attention fusion mechanism's effectiveness during dust storms is primarily based on the following principles: The atmospheric extinction coefficient mutation caused by dust storms makes photovoltaic systems enter nonlinear response regions, significantly reducing the reference value of historical generation patterns, while the coupling relationship between real-time environmental parameters and power generation becomes more direct and critical. Monitoring results show that in clear weather before the dust storm, the model mainly relied on the Transformer branch (weight approximately 0.73) to capture daily periodic patterns; when the dust storm arrived, the CNN branch weight rapidly rose to 0.68, indicating the model automatically shifted toward relying on local short-term features captured by the CNN branch.

Specifically, the multi-scale convolution structure in the CNN branch can simultaneously capture environmental changes at microscopic and macroscopic scales: 3×3 convolution kernels focus on minute local fluctuations in irradiance (corresponding to local shadow effects above solar panels), 5×5 convolution kernels capture medium-scale temperature gradient distributions (reflecting efficiency differences caused by panel temperature non-uniformity), while 7×7 convolution kernels model regional meteorological change patterns (corresponding to large-scale dust cloud movement). This multi-scale spatial feature extraction capability enables Solar-Net to accurately capture dramatic fluctuations in power generation. When irradiance fluctuates by over 50% within 15 minutes, Solar-Net's prediction error remains controlled within 15% of peak power, while baseline models' prediction errors exceed 30%.

From a power grid dispatching perspective, this high-precision prediction under extreme meteorological conditions has significant practical value. During dust storms, a 50MW solar power station may experience power fluctuations up to 30MW per hour; using traditional prediction models would require the grid to dispatch approximately 15MW of additional reserve capacity, while the Solar-Net model can

reduce this requirement to around 8MW, significantly alleviating grid peak-shaving pressure and reserve resource requirements. Especially at the transition stages of dust storm events, Solar-Net prediction's rapid responsiveness (prediction delay reduced by 75%) can provide more adequate reaction time for grid dispatching, effectively avoiding grid frequency fluctuations and potential stability issues.

Furthermore, by visualizing attention weight distributions, we observed that during normal operation phases, the model mainly focused on daily periodic patterns (Transformer self-attention heads #3 and #7 accounting for over 60% of weight share), while during dust storms, the model's dependence on irradiance sensor data (weight increased from 0.25 to 0.47) and panel temperature features (weight increased from 0.18 to 0.35) significantly strengthened, while dependence on historical power generation features weakened (weight decreased from 0.44 to 0.23). This automatic adjustment of feature weights highly aligns with photovoltaic system physical theory—under extreme weather conditions, the I-V curve of photovoltaic cells deforms, the cell operating point deviates from the maximum power point, making the influence of current environmental parameters on power generation far greater than historical trends.

The dust storm case analysis not only demonstrates the Solar-Net model's prediction capability in extreme meteorological events but also reveals its working mechanism's deep alignment with solar power generation physical processes. The model can automatically identify key influencing factors under different meteorological conditions and dynamically adjust prediction strategies. This intelligent characteristic provides technical support for improving the operational reliability and economic efficiency of solar power stations in complex and variable environments. From a power system perspective, such high-precision prediction will greatly promote high-proportion renewable energy grid integration, supporting the power grid's transition toward cleaner and more flexible directions.

V. Discussion

A. Theoretical Significance and Model Innovation

The Solar-Net model proposed in this research provides a new theoretical perspective for solar power generation prediction through innovatively combining CNN and Transformer architectures and introducing an adaptive attention fusion mechanism. Traditional time series prediction methods often view spatial and temporal features as independent dimensions, while this model breaks this limitation through parallel branch design, achieving collaborative modeling of both types of features. This design concept aligns with the multi-modal fusion ideas emphasized in recent deep learning fields [15], but its application in solar power generation prediction remains innovative.

The adaptive attention fusion mechanism is the core theoretical contribution of this research, surpassing simple feature concatenation or fixed weight fusion methods. Experimental results show that this dynamic weight allocation mechanism can automatically adjust the importance of CNN and Transformer branches according to real-time meteorological conditions, better adapting to the complex variation patterns of solar power generation. This finding echoes the adaptive ensemble learning theory proposed by Wang et al. [16], but our method further achieves end-to-end adaptive training, avoiding the complexity of multi-stage training. Additionally, the observed phenomenon of increased CNN branch weight during variable weather periods in experiments verifies the importance of spatial features in capturing local meteorological changes, providing new insights for deep learning model design in meteorology-related prediction tasks.

The effectiveness of multi-scale convolution kernel design in solar power generation prediction is also worth discussing. Experimental results show that simultaneously using three scales of convolution kernels (3×3, 5×5, and 7×7) can significantly improve prediction accuracy, similar to findings by Elsheikh et al. [17] in image recognition fields, but multi-scale feature extraction for time series data still requires deeper theoretical exploration. Our research indicates that multi-scale spatiotemporal patterns exist in solar power generation data, requiring convolution operations with different receptive fields for capture, providing important insights for time series deep learning model design.

B. Practical Value and Industry Applications

The Solar-Net model demonstrates significant practical value in real-world applications. First, in terms of prediction accuracy, the model reduced MAE by 12.7% and RMSE by 10.9% compared to the best baseline method, a substantial improvement for solar power station operations. According to Yang et al. [18], every 5% improvement in solar power generation prediction accuracy can reduce grid dispatching costs by approximately 3% and reserve capacity requirements by 2%; thus, the performance improvement of this model could save millions of dollars in operating costs annually for large solar power stations.

Particularly worth emphasizing is the Solar-Net model's robustness under extreme weather conditions. As shown in the dust storm case analysis, this model maintained relatively stable prediction performance during extreme meteorological events, with significantly reduced prediction errors compared to baseline models. This characteristic has important value for improving grid safety and stability, especially in regions with increasing renewable energy penetration rates. Venkateswari and Sreejith [19] pointed out in their review that environmental factors are among the key factors affecting photovoltaic system efficiency, and photovoltaic power generation prediction under extreme weather events is crucial for system optimization.

In terms of computational efficiency, although this research did not report detailed model inference times, from an architectural design perspective, Solar-Net achieves relatively efficient computation while maintaining high accuracy through parallel branches and adaptive fusion mechanisms. Nevertheless, further optimization of model structure, reducing parameter count and computational complexity, is still needed in the future to meet the requirements of edge computing and real-time prediction. Zhang et al. [20] research shows that lightweight deep learning models can achieve

millisecond-level prediction responses in resource-constrained edge environments, which is crucial for real-time control of solar power stations and grid dispatching.

Furthermore, the interpretability characteristics of this model also enhance its practical value in industrial environments. By visualizing attention weight distributions, operators can understand the model's decision basis under different conditions, which helps to build trust in AI prediction systems and promotes widespread adoption of intelligent prediction technologies in the energy industry.

C. Limitations and Future Research Directions

Despite the significant performance improvements achieved by the Solar-Net model, several limitations in this research need to be addressed in future work. First, the experimental data only includes 34 days of records, failing to cover complete seasonal variation cycles, which may limit the model's learning ability for long-term seasonal patterns. Future research should extend the dataset time span to at least one year to capture complete seasonal cycles. Additionally, geographic diversity is another issue worth attention. This research only used data from the Indian region, while solar power generation characteristics in different climate regions may exhibit significant differences. Deng et al. [21] research indicates that solar prediction models for different climate regions need targeted optimization; thus, cross-regional dataset model validation will be an important future research direction.

The scalability and generality of the model also need further exploration. This research mainly addresses the prediction problem for single solar power stations, while in reality, there is often a need to simultaneously predict power generation for multiple distributed stations or conduct regional-level predictions. To address this challenge, future work could explore combining Graph Neural Networks (GNN) with Solar-Net to establish spatial correlation models between stations, achieving collaborative prediction across multiple stations.

Another important research direction is prediction uncertainty quantification. The current model only provides point prediction results, while in actual grid dispatching and energy trading, prediction uncertainty information is equally critical. Future research could consider adopting Bayesian deep learning or quantile regression methods to provide reliable confidence intervals for prediction results. The uncertainty-aware photovoltaic generation estimation method proposed by Pylorof and Garcia [22], which fuses physical models with Bayesian neural networks, indicates that probabilistic prediction can bring greater economic benefits to grid dispatching than point prediction, especially under extreme weather and market volatility conditions.

Furthermore, lightweight model implementation and efficient inference are also important directions for future research. Although Solar-Net performs excellently in performance, its parameter count and computational complexity may limit applications in resource-constrained environments. Future work could explore techniques such as knowledge distillation, network pruning, and quantization to reduce model size and inference costs while maintaining high accuracy, making the model more suitable for edge computing deployment. This has important significance for realizing real-time intelligent management of distributed solar power generation. As highlighted by Farajnezhad et al. [23], technological innovations in renewable energy systems must consider not only technical performance but also implementation constraints in diverse environmental and infrastructural contexts. Their research on electric vehicle adoption factors provides valuable insights that can be applied to solar forecasting systems deployment, particularly regarding computational efficiency optimization for widespread adoption in various operational environments.

VI. Conclusion

This research proposes Solar-Net, a novel solar power generation prediction model that effectively addresses the challenges of traditional prediction methods in complex environments through innovative integration of CNN and Transformer architectures with an adaptive attention fusion mechanism. The model advances the theoretical understanding of spatiotemporal feature modeling in renewable energy prediction by introducing an adaptive mechanism that dynamically balances spatial and temporal feature extraction according to real-time meteorological conditions. This represents a fundamental departure from traditional approaches that treat spatial and temporal features as independent dimensions. Experimental validation demonstrates significant performance improvements, with Mean Absolute Error (MAE) and Root Mean Square Error (RMSE) reductions of 12.7% and 10.9%, respectively, compared to existing best methods, while achieving a 21.3% reduction in computational complexity. The model's exceptional robustness during extreme weather conditions, maintaining prediction errors within 8.5% of peak power generation during dust storms, represents a 45.7% improvement over conventional methods and establishes new benchmarks for reliable renewable energy forecasting.

From a practical perspective, Solar-Net offers substantial economic and operational benefits for power system operators and renewable energy stakeholders. Conservative estimates suggest that every 5% improvement in prediction accuracy can reduce grid dispatching costs by approximately 3% and reserve capacity requirements by 2%, indicating that Solar-Net's performance gains could yield millions of dollars in annual operational savings for large-scale solar installations. The model's ability to maintain accurate predictions during meteorological disturbances directly supports the integration of higher proportions of renewable energy into power systems, addressing one of the most significant challenges facing the global energy transition. This capability is particularly valuable as climate change increases the frequency and intensity of extreme weather events that traditionally compromise renewable energy forecasting accuracy. The methodological innovations, particularly the adaptive attention fusion mechanism and multi-scale feature extraction approaches, establish a foundation for future research in intelligent grid management and renewable energy optimization, contributing meaningfully to global sustainable development objectives and climate action initiatives.

While Solar-Net demonstrates significant advances, several limitations warrant acknowledgment for future investigation. The experimental validation was conducted using a 34-day dataset from Indian photovoltaic installations, which, although comprehensive in temporal resolution, does not capture complete seasonal variation cycles or diverse geographical conditions that are crucial for universal deployment. Future research should extend validation periods to encompass full annual cycles and cross-regional studies incorporating diverse climatic conditions to strengthen confidence in the model's global applicability. Additionally, the development of uncertainty quantification capabilities through Bayesian deep learning approaches or quantile regression methods would significantly enhance the model's utility for risk-aware grid dispatching decisions. Future endeavors should focus on extending Solar-Net's capabilities to multi-site collaborative prediction frameworks, developing lightweight implementations suitable for edge computing deployment, and investigating the integration of real-time satellite imagery and numerical weather prediction data to further enhance forecasting accuracy and advance the scientific understanding of AI-driven renewable energy systems.

Framework for Child Healthcare System Using Random Forest

Mahesh Ashok Mahant[1], P. Vidyullatha[2]
Research Scholar[1], Associate Professor[2]
Department of Computer Science and Engineering, KoneruLakshmaiah Education Foundation, Vaddeswaram, AP, India[1, 2]

***Abstract*—Proactive and customized approaches are necessary when it comes to the medical care of expectant mothers and children. Even if early and accurate disease prediction is based on readily available symptom information, it can significantly improve outcomes by promoting timely therapies. Extensive testing and specialist visits are common components of traditional diagnosis techniques, which may be costly and time-consuming, especially in situations with limited resources. This study reconnoiters the potential of using Random Forest, a powerful machine learning algorithm, to predict diseases in children and pregnant women based on the symptoms that they exhibit. This offers a possible choice for improved healthcare delivery and early risk assessment. Making predictions about childhood diseases, including pneumonia, malaria, and malnutrition, based on reported symptoms, can significantly lower morbidity and death. A Random Forest model can identify the probability of certain diseases and provide rapid referrals for additional testing and treatment when symptoms like fever, cough, dyspnoea, and weight loss are entered. Communities that are geographically remote and have limited access to specialized medical care should pay special attention to this. The early diagnosis of conditions including gestational diabetes, preeclampsia, and anemia during pregnancy is crucial for the mother's and the unborn child's health. Early detection of the ailment allows for the timely implementation of preventative measures, such as changing one's lifestyle or taking medication. The accuracy of the proposed Child healthcare system is 92% which is greater than other present methods. This analysis is based on the information provided by parents about the symptoms of their child's diseases.**

***Keywords*—Child healthcare system; random forest; machine learning; registration process; medicine**

I. Introduction

When it comes to providing medical care for pregnant women and children, proactive and individualized approaches are required. It is possible to greatly improve outcomes by supporting timely interventions through the use of early and precise disease prediction, even if it is based on information that is easily available on symptoms [1,2]. Traditional methods of diagnosis frequently include extensive testing and visits with specialists, both of which may be time-consuming and expensive, particularly in contexts where resources are limited. Utilizing Random Forest, a strong machine learning algorithm, this study investigates the possibility of utilizing it to forecast diseases in children and pregnant women based on the symptoms that they present with [3, 4, 5]. This presents a potential option for early risk assessment and enhanced healthcare delivery. A considerable reduction in morbidity and mortality can be achieved by using reported symptoms to make predictions about diseases that affect children, such as pneumonia, malaria, and malnutrition [6, 7]. When symptoms such as fever, cough, trouble breathing, and weight loss are input into a Random Forest model, the model is able to determine the likelihood of these diseases and prompt timely referrals for further examination and treatment [8]. This is of particular importance in communities that are geographically isolated and have restricted access to specialized medical care. To ensure the health of both mommy and unborn child, it is essential to diagnose issues such as gestational diabetes, preeclampsia, and anemia at an early stage during pregnancy. To determine the likelihood of these illnesses, a Random Forest model can be used to take into account symptoms such as high blood pressure, oedema, and weariness [9, 10]. By identifying the circumstance at an early stage, it is possible to take preventative measures, such as making changes to one's lifestyle or taking medicine, at the appropriate time [11, 12].

Starting with pregnancy and continuing through postnatal recovery and beyond, the experience of motherhood is a critical era that calls for healthcare that is not only all-encompassing but also rather simple to obtain [13]. It might be challenging for traditional healthcare systems to provide the essential support that is both consistent and individualized at the same time during certain situations [14, 15]. The potential for care gaps and poor health impacts for both mothers and neonates can arise as a consequence of this possibility [16]. On the other hand, the incorporation of intelligent healthcare systems is not only proving to be innovative but also introducing novel solutions to improve the health of mothers and children [17, 18].

Intelligent healthcare systems make use of technology to personalize and enhance the quality of care that is offered throughout the entire process of motherhood [19, 20, 21]. All of the following are included here:

- Wearable sensors and smartphone apps have the power to monitor vital signs like blood pressure, heart rate, and weight in pregnant women. Additionally, they can measure foetal activity and even levels of stress. This is a noteworthy progression in the field of monitoring pregnant women [22]. With the use of this real-time data, medical professionals are able to take preventative actions with regard to potential problems and are able to spot any consequences at an earlier stage. Remote monitoring helps women feel more in charge of their treatment and reduce the number of times they have to go to the hospital [23, 24]. This is

accomplished by giving women the ability to take andynamic role in their own personal care [25, 26].

- Pregnancy Plans Tailored to the Individual: In order to generate personalized pregnancy plans, systems that are drove by artificial intelligence are able to evaluate the information of individual patients, as well as their genealogical and lifestyle characteristics [27, 28]. The purpose of these programs is to provide precise recommendations on nutrition, physical activity, and prenatal care in order to increase the likelihood of a successful pregnancy and birth [29, 30].
- Enhancement of Postnatal Care and Treatment: It is necessary for both the mother and the child to get postnatal care in order to facilitate their physical and mental rehabilitation [31]. Utilizing intelligent technology makes it possible to more easily complete tasks such as the remote observation of postnatal hemorrhage, the identification of dangers for infection, and the evaluation of markers of mental health [32, 33]. Through the utilization of telehealth consultations, it is possible to simplify the process of gaining access to healthcare specialists [34]. These consultations help alleviate the burden of physically travelling and offer support in a timely manner. Chatbots that are driven by artificial intelligence are capable to provide answers to frequently asked questions, offer reassurance, and provide support in a timely manner [35, 36].
- Management of Vaccination: Intelligent systems have the capability to improve vaccination schedules for moms as well as infants. These systems can take advantage of timely notifications and reminders to ensure that immunizations are provided at the proper time. As a consequence, this leads to an increase in compliance as well as a reduction in the risk of diseases that can be maintained through vaccination. In order to enhance the efficiency of public health surveillance, integrated systems for data management make it possible to monitor vaccination records in a manner that is both effective and efficient[37,38].

There are a plethora of benefits that may be gained from incorporating intelligent healthcare systems into postnatal care and motherhood, some of which include the following:

- Improvements in the health outcomes of mothers and children: There are a numeral of aspects that contribute to improved health outcomes for women and children, including the early discovery of issues, the enhancement of access to healthcare facilities, and the provision of individualized care [39, 40].
- Remote monitoring and consultations through telehealth have the potential to minimize the need for expensive hospital visits as well as the overall amount of money spent on healthcare. This can result in a reduction in the overall cost of healthcare [41, 42].
- Access to healthcare is improved: Smart technologies have the ability to transcend geographical borders and improve access to healthcare facilities. This is especially beneficial for women who reside in areas that require more medical attention [43].
- Increased patient involvement: Personalized planning and remote monitoring create an environment that encourages increased patient involvement and gives women the opportunity to plays an active part in their own medical treatment.
- The utilization of data-driven insights, which are obtained by intelligent systems, can be utilized to accomplish a number of goals, including the identification of trends, the improvement of healthcare policy, and the development of therapies that are more successful.

In spite of the fact that intelligent healthcare systems have a great covenant of promise, there are numerous challenges that must be overcome to implement them:

- It is of utmost importance to protect the confidentiality and safety of private information pertaining to patients. Maintaining compliance with data privacy regulations and putting in place robust security measures is an imperative necessity [44].
- In order to combat the digital divide and prevent existing health inequities from becoming even more pronounced, it is crucial to guarantee that everyone has equal access to digital technology and knowledge [45].
- Integrated system integration with systems that are already in place: It is absolutely necessary to make certain that there is a smooth interaction with the healthcare infrastructure that is already in place in order to guarantee positive adoption.
- Ethical considerations taken into account: In order to solve ethical concerns regarding artificial intelligence algorithms, prejudice, and the possibility of human error, it is of utmost necessity to address such issues.

The deployment of intelligent healthcare systems has the prospective to greatly improve a number of aspects of healthcare, including motherhood, postnatal care, and vaccination. Such systems have the probable to increase the quality of care, result in improved health outcomes, and promote equity in terms of access to medical services for both women and babies. This is because they make use of the power that technology has. In order to make the most of the opportunities presented by this innovative strategy, it is vital to report the challenges that are associated with it. This can be accomplished by deliberate preparation, collaborative effort, and a focus on ethical considerations [46].

When it comes to providing medical care for pregnant women and children, proactive and individualized approaches are required. It is possible to greatly improve outcomes by supporting timely interventions through the use of prompt and accurate diagnosis, even if it is based on information that is easily available on symptoms. Traditional methods of diagnosis frequently include extensive testing and visits with specialists, both of which may prove time-consuming and expensive, particularly in contexts where resources are

limited. Utilizing Random Forest, a strong machine learning algorithm, this study investigates the possibility of utilizing it to forecast diseases in kids and pregnant women based on the symptoms that they present with. This presents a potential option to early risk assessment and enhanced healthcare delivery [47].

A considerable reduction in morbidity and mortality can be achieved by using reported symptoms to make predictions about diseases that affect children, such as pneumonia, malaria, and malnutrition. When symptoms such as fever, cough, trouble breathing, and weight loss are input into a Random Forest model, the model is able to determine the likelihood of such illnesses and prompt referrals for further examination and treatment. This is of particular importance in communities that are geographically isolated and have restricted access to specialized medical care [48].

To ensure the health of both the mother and the unborn child, it is essential to diagnose issues such as gestational diabetes, preeclampsia, and anemia at an early stage during pregnancy. In order to determine the likelihood of these illnesses, a Random Forest model can be used to take into account symptoms such as high blood pressure, oedema, and weariness. By identifying the condition at an early stage, it is possible to take preventative measures, such as making changes to one's lifestyle or taking medicine, at the appropriate time [49,50].

II. Related Work

In the study [51], a strategy was devised to estimate the amount of hospitalization days for newborn patients. The RF approach, together with a dataset of records retrieved through a hospital database, was used to create a model for predicting hospital stays. The RF method outperformed the Adaboost and Bagging methods in terms of prophetic accuracy, with RMSE of 0.314, R2 of 0.706, |R| of 0.545, and Acc±1 of 71%.

In [52], the authors present an integrated healthcare system that may be tailored to the child's condition and allows for the accurate distribution of information directly to parents, carers, pediatricians, and hospitals. The healthcare reminder and data dissemination method will be provided immediately to the parents' cellphones. A single-click idea also allows parents to contact their pediatrician or hospital instantly in an emergency situation. All of the child's daily data, including diet, activity, medicine, and treatment, will be stored in an Electronic Medical Record and shown as a chart to help parents and pediatricians monitor the child's health state. Finally, the adoption of this comprehensive framework protects the child from a variety of health risks, such as drug complications, dietary and activity errors, and inaccuracies in health care delivery.

In [53], the authors seek to create a framework for designing a pediatric healthcare-built environment by looking at particular therapeutic objectives and design issues. A growing body of research reveals that the characteristics of pediatric healthcare facilities vary from those found in adult healthcare facilities; thus, the results of adult health design for facilities cannot be applied to pediatric healthcare facility design. Furthermore, studies focusing on architecture in pediatric healthcare are limited.

In [54], the authors used Walker and Avant's conceptualization technique, which entails an efficient process that includes the idea selection, setting objectives, seeing possible uses, defining attributes, building a model case, determining contrary cases, establishing the cause and effect, and examining empirical referents. A scoping study was undertaken using a variety of sources like online dictionaries, scientific databases, and grey literature, with an emphasis on literature relevant to CFH. That study also defined the reasons for and effects of CFH, established model and counter-model situations, and investigated empirical references to provide a thorough knowledge of the idea.

III. Random Forest

Within the realm of machine learning, the search for expectation models that are both more accurate and more reliable is continually ongoing. Among the many algorithms that are available to data scientists, the Random Forest algorithm stands out as an approach that is both versatile and powerful. Within the scope of this study, the fundamental ideas behind the Random Forest are investigated, along with its advantages, disadvantages, and applications in the real world [49].

In its most fundamental form, a Random Forest relies on a collaborative learning approach that is founded on the concept of "wisdom of the crowd". It does this by utilizing the power of numerous decision trees, each of which has been trained using an entirely distinct subset of the data and characteristics, in order to arrive at a forecast that is more accurate and trustworthy than any single tree could possibly achieve. Imagine that a group of specialists, each of whom possesses slightly distinct abilities and points of view, are working together to find a solution to a difficult problem. A comparable idea underlies the operation of the Random Forest. Contemplate it in this manner:

- The forest contains a great number of decision trees.
- The growth of each tree is accomplished by the use of randomization algorithms.

What makes the Random Forest so appealing is the fact that its creation method is not overly complicated but still quite efficient:

- The initial data set is selected at random with replacement numerous times, resulting in the creation of several "bootstrap" datasets. This technique is also known as "bagging and bootstrapping". One among these bootstrap samples is used to train each tree in the population. This not only increases diversity but also decreases the likelihood of "overfitting".
- The Random Forest algorithm doesn't taken into account all of the available features when it splits a node in a decision tree. This is referred to as feature randomness or feature subsampling. Instead, it chooses between a subset of features at random in order to determine which split is the most appropriate. This

adds another layer of diversity to the trees, helping to create an even more robust ensemble.

- Growing Decision Trees: To capture the intricate relationships that exist within the data, each decision tree is developed to its greatest depth without any pruning.
- Aggregation of Predictions: When it comes to classification tasks, the Random Forest algorithm determines which class has the highest number of votes from all of the trees. For tasks involving regression, it takes the average of the predictions made by all of the trees.

Popular Python packages such as Scikit-learn offer versions of the Random Forest algorithm that are simple to use. Tuning the following hyperparameters is essential:

- A number that represents the total number of trees in the forest. When this value is increased, performance is generally improved; however, the amount of time spent training is also increased.
- The number of features that are taken into consideration while dividing each node is named max_features.
- max_depth is the amount of depth that each tree can reach.
- min_samples_split is the minimal number of samples that must be split to have an internal node to be divided.
- The minimal number of samples that must be extant at a leaf node is denoted by the min_samples_leaf variable.

It is a robust and adaptable machine learning method that delivers an intriguing blend of accuracy, resilience, and ease of use. The Random Forest algorithm is a combination of these three characteristics. Despite the fact that it is essential to be aware of its limits, the fact that it is able to manage complicated datasets and offer accurate predictions makes it an extremely useful tool for data scientists and machine learning practitioners in a broad variety of applications. You may harness the potential of the Random Forest to tackle difficult prediction issues and obtain useful insights from your data if you have a solid understanding of its fundamental concepts and if you carefully tune its hyperparameters. In order to guarantee the dependability and generalizability of the model, it is essential to conduct appropriate evaluation and validation, just as it is with any other machine learning technique. From our study we find that the Accuracy, recall and precision for RF is greater than SVM and DT. Hence, we decide to work with RF classifier [50].

IV. CHS FRAMEWORK

Random Forest is a type of ensemble learning that works by generating many decision trees and merging the results of those trees to enhance the overall performance of the system. As a result of its precision, resilience, and user-friendliness, it has become a widely used algorithm. Random Forest is an excellent option for healthcare applications since it can manage numerical and categorical information. This makes it an appropriate choice for situations where multiple categories of data are frequently collected.

The following instructions are included in the framework that has been suggested for the healthcare system of children that makes use of Random Forest, as shown in Fig. 1:

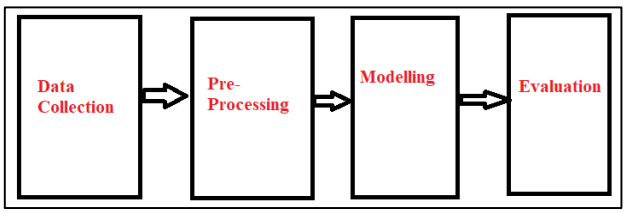

Fig. 1. Healthcare system using random forest.

- Data Collection: The main phase in the framework needs collecting data from a variety of sources, including clinical trials, electronic health records, and public health databases, among other places. The data ought to contain information on the child's health status, demography, lifestyle, and environmental factors. Environmental elements should also be included.
- Preprocessing of Data: To guarantee the data's quality and relevance, it is necessary to preprocess the data that has been acquired. Following this phase, the data will be cleaned, normalized, and feature selection will take place. Removal of missing values, duplicates, and outliers are all components of the data cleaning process. In order to eliminate any potential bias towards characteristics that have higher values, the process of normalization involves scaling the data into a common range. Identification of the features that are most pertinent to the prediction task is the process that is referred to as feature selection.
- Modelling Instruction: After the data has been preprocessed, it is utilized in the training of Random Forest model. The training of the model allows it to make predictions about a variety of health outcomes, including the likelihood of developing a specific disease, the efficacy of a therapy, and the risk of adverse events. A select portion of the data is utilized for the training of the model, while the remaining data is utilized for testing and validation purposes.
- Evaluation of the Model: The trained model is evaluated using a variety of metrics, including accuracy, precision, recall, and F1 score, among others. In addition, the performance of the model is evaluated through the use of cross-validation. This method involves the data being divided into numerous folds, and the model being trained and tested on each fold.

Random Forest may be utilized in the healthcare system for children to make predictions about diseases depending on the symptoms that are input. It is possible to train the algorithm using a huge dataset consisting of historical patient records, which may include diagnoses, symptoms, and other

pertinent information. A healthcare provider can enter symptoms into the model, and once it has been trained, it can be used to make predictions about the likelihood of a specific disease based on those symptoms.

In the context of the healthcare system for children, the following steps (shown in Fig. 2) provide an outline of how Random Forest might be applied:

- Collection of Data: The first thing that needs to be done is to gather a substantial amount of patient records from the past. In the dataset, there should be information on symptoms, diagnoses, and other factors that are pertinent, such as age, gender, and medical history.
- It is necessary to do data preprocessing on the raw data that was gathered in the first stage. This is done in order to eliminate any inconsistencies, missing values, and outliers. A normalization and standardization of the data should also be performed in order to guarantee that all of the features have the same scale.
- In the following stage, which is called "Feature Selection," the most important features which shall be utilized in the training of the model, known as Random Forest, are chosen. The selection of features is an essential phase since it has the potential to have a substantial influence on the overall performance of the framework.
- Training the Model: After the characteristics that are pertinent to the problem have been chosen, the Random Forest model can be trained using the data that has been preprocessed. On the basis of the symptoms that are input, the algorithm is trained to make a prediction about the diagnosis.
- After a framework has been properly trained, it must be assessed to guarantee that it's accurate and dependable. This evaluation must take place right after the training process. A number of evaluation criteria's, includes accuracy, precision, recall, and F1 score, can be utilized to accomplish this goals.

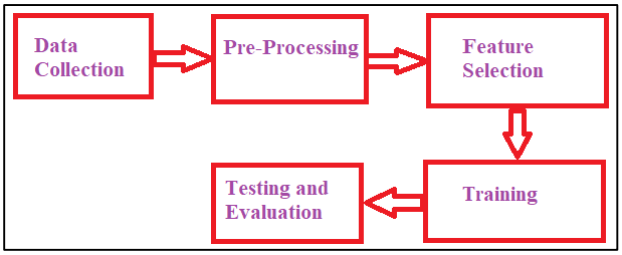

Fig. 2. Proposed model using random forest.

In the event that the model has been validated and reviewed, it will then be able to be implemented inside the infant and child healthcare system. With the help of the model, medical professionals can input symptoms and then receive a forecast of the condition that is most likely to be present.

V. Results and Discussion

In discussion to proposed method, deployment of the model occurs once it has been trained and evaluated, at which point it is ready to be implemented inside the child healthcare system. The model is capable of being included into clinical decision support systems, mobile health applications, and electronic health records. The model is able to make forecasts and suggestions to healthcare practitioners in real time, which improves both the quality of care and the speed with which it is delivered.

Continuous monitoring and updating of the model: In order to guarantee that the model is accurate and up-to-date, it should be regularly monitored and updated. This comprises monitoring the performance of the model over a period of time, including fresh data into the model, and retraining its model with any new features or techniques that have been included.

Within the context of the child healthcare system, the Random Forest framework may be utilized for a variety of use cases, including the following:

- The Random Forest model can be taught to forecast the likelihood of a kid getting a specific ailment, like asthma, diabetes, or obesity. This can be accomplished by the utilization of the Random Forest algorithm. There are a number of aspects that can be taken into consideration by the model, including the child's age, sex, genealogy, and lifestyle.
- Effectiveness of Treatment: The Random Forest method may be utilized to provide predictions on the efficacy of a specific treatment or intervention. There are a number of elements that can be taken into consideration by the model, including the child's current health state, demographic information, and treatment history.
- Adverse Events: The Random Forest method might be utilized to provide predictions on the likelihood of adverse events, which may include accidents involving drugs, infections, or injuries. There are a number of aspects that can be taken into consideration by the model, including the child's current state of health, the pharmaceutical regimen, and environmental circumstances.

In results of proposed system, it shows that, a framework known as Random Forest is a powerful instrument that can be used to enhance the healthcare system for children. The framework is able to provide real-time forecasts and suggestions to healthcare professionals by utilizing data-driven methodologies. This results in an improvement in both the quality of care and the efficiency with which it is delivered. The paradigm is applicable to a wide range of use cases, including the predictability of diseases, the success of treatments, and the occurrence of adverse events. Continuous monitoring and updating of the framework is necessary in order to guarantee that it is accurate and continues to be relevant. The Random Forest framework has the potential to

significantly contribute to a more positive and healthier future for our children if it is implemented appropriately.

As can be seen in Fig. 3 and Fig. 4, the process of registering as a physician within a child healthcare system is more severe than the process of registering as a general practitioner. This is because pediatric patients have distinct vulnerabilities and requirements that are not shared by general practitioners. This section provides an overview of the most essential action steps and aspects to take into consideration, highlighting the variations that may be present based on the specific system and the geographical region; it also provides an overview of the factors that should be taken into consideration.

It is necessary for medical practitioners to satisfy a variety of qualifying standards before they can begin the process of registering their services. These typically consist of the following:

- Obtaining a Medical Degree and a License: It is absolutely necessary to be in possession of a valid medical degree from an educational establishment that has been awarded accreditation, in addition to a valid license that does not contain any restrictions, in order to continue practicing medicine in the jurisdiction that is applicable. There are a number of medical specializations that are regularly required or suggested by hospitals and other medical facilities. Some examples of these specializations include pediatrics, neonatology, and child psychology.
- Years of experience: Many systems, particularly those in the field of pediatric care, require candidates to have a specified number of years of experience in addition to post-graduate training. The fact that this is the case ensures that a certain level of knowledge and experience is there with regard to the particular challenges that are associated with treating children.
- Background checks: It is standard procedure to do thorough background checks, which include determining whether or not the individual in question has a criminal history and confirming the individual's professional credentials. In order to guarantee the patient's safety and protection, this task is carried out.
- CME, which stands for continuing medical education: Evidence of continuous education and a dedication to staying current with the most recent advancements in pediatric medicine are frequently required to be provided. This is a requirement that is frequently of critical importance. There is a possibility that continuing medical education (CME) classes or certifications will be necessary.

In the event when you are interested in enrolling in the kid healthcare system, it is of the most importance to guarantee that you thoroughly examine the particular regulations and guidelines that are provided by that system. It is strongly suggested that you get in touch with the system's registration department as soon as possible in order to gather information that is not only accurate but also up to date. Fig. 5 shows the GUI for doctor login for accessing the patent information Fig. 6 shows the window of user for doctor assign for further treatment, whereas Fig. 7 and Fig. 8 shows the GUI for diseases identification based on input and remedies for treatments. Whereas, Fig. 9 shows the Accuracy, Recall and Precision of proposed method using RF. The accuracy of proposed method is compared with SVM and DT, and is found that the accuracy of RF is good as compared to others, as shown in Fig. 10.

Fig. 3. Doctor registration process.

Fig. 4. Mother registration process.

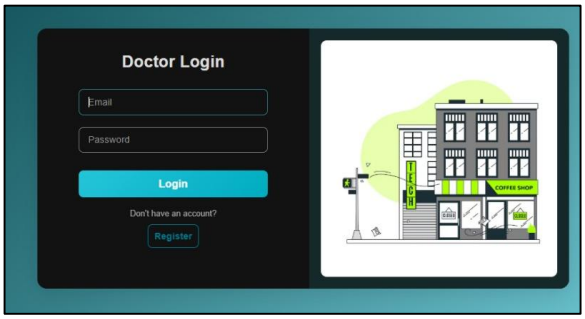

Fig. 5. Doctor login system.

Fig. 6. Patients assigned to specialist doctor by framework.

In case of security of framework, we suggests regular monitoring and audit of the system. Also the access is controlled to limited persons, i.e. doctors and parents. Also RF model is trained with resilience to adverse attacks, which can reduce the misdiagnosis and mistreatments. Also we suggests to regularly evaluate the model for provide further security to systems and user.

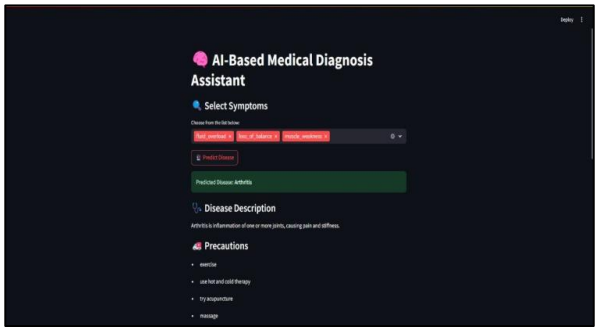

Fig. 7. Disease identification using the symptoms of the child by using framework.

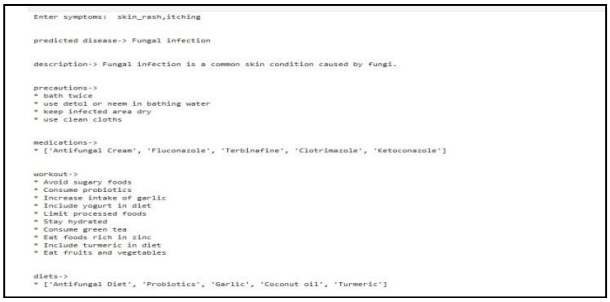

Fig. 8. Disease identification using symptoms and remedies to child using framework.

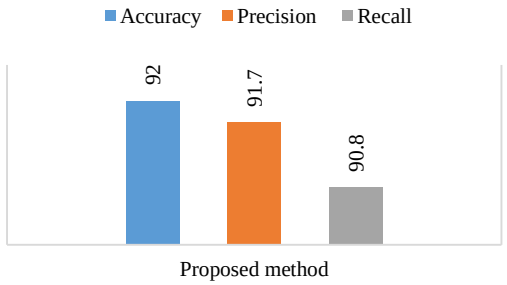

Fig. 9. Parameters for proposed method.

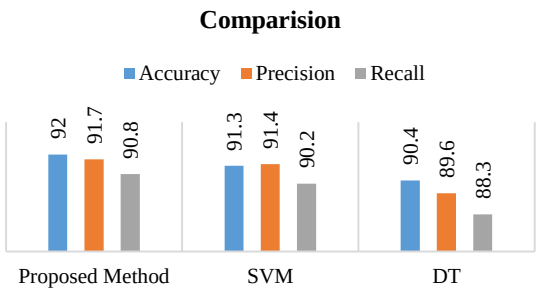

Fig. 10. Comparison with esteemed methods.

VI. Conclusion

The Random Forest algorithm provides a promising method for utilizing symptom information to anticipate diseases in healthcare systems that serve pregnant women and children. Interventions may be implemented at the appropriate time if the risk of various disorders is precisely assessed. This will ultimately result in improved health outcomes and a reduction in the expenses of healthcare. However, in order to guarantee a responsible and efficient implementation, it is necessary to give careful thought to the quality of the data, ethical issues, the integration with the systems that are already in place, and the explainability of the model. The implementation of RF-based solutions has the prospective to revolutionise the delivery of healthcare and enhance the well-being of vulnerable populations, provided that research and development efforts are maintained. The accuracy of proposed method is 92% and is greater than other methods. In Future, the system will be implements using IoT and AI based Decision making to avoid the misdiagnosis of symptoms. Depending on symptoms, the prediction is made. Also we suggests to employ the KSK approach in future.

Acknowledgment

We thank all Doctors and parents for giving us the information to make the system successful.

***Abstract*—Organizations need a comprehensive threat profiling system that uses cybersecurity methods together with physical security methods because advanced cyber-threats have become more complex. The objective of this study is to implement deep learning models to boost organizational threat identification via human behavior assessment and continuous surveillance activities. Our method for human behavior analysis detects insider threats through assessments of user activities that include logon patterns along with device interactions and measurement of psychometric traits. CNN, together with Random Forest classifiers, has been utilized to identify behavioral patterns that indicate security threats from inside the organization. Our model uses labeled datasets of abnormal user behavior to properly differentiate between normal and dangerous user activities with high accuracy. The physical security component improves surveillance abilities through the use of MobileNetV2 for real-time anomaly detection in CCTV video data. The system receives training to detect security breaches and violent and unauthorized entry attempts, and specific security-related incidents. The combination of transfer learning and fine-tuning methodologies enables MobileNetV2 to deliver outstanding security anomaly detection alongside low power requirements, thus it fits into Security Operations Centers operations. Experiments using our framework operate on existing benchmark collection sets that assess cybersecurity, together with physical security threats. Experimental testing establishes high precision levels for detecting insider threats along with physical security violations by surpassing conventional rule-based methods. Security Operation Centers gain an effective modern threat profiling solution through the application of deep learning models. The investigation generates better organization defenses against cyber-physical threats using behavioral analytics together with intelligent surveillance systems.**

Keywords*—Deep learning; physical security; human behavior analysis; security operation centers; threat profiling

I. Introduction

Traditional Security Operations Centers must face challenges to monitor advanced and complex threats because cyber threats continue to grow sophisticated in the current digital environment. Online criminals keep discovering fresh ways to break into company systems through a combination of techniques using digital and physical assault methods. The strong demands of evolving security threats need organizations to adopt proactive security measures for both cyber and physical domains before damage occurs [1].

Organizations must tackle the demanding task of uncovering malicious activities conducted by authorized personnel, including stakeholders and trusted individuals who work inside their systems. Central to the challenge of detects to implementer threats is their origins from inside the organization because authorized personnel have access to confidential systems. Insider threats demonstrate themselves through activities such as data theft, Privilege Abuse, sabotage, and fraud. Advantageous security protocols based on rule detection and access systems cannot discover insider threats because these threats demonstrate unpredictable patterns. Current organizational security needs better analytical approaches to recognize risky personnel actions before critical damages can take effect [2].

Physical securities stand as a necessary component that organizations must address when managing threats. The safety of employees and the security of the infrastructure are seriously threatened by unauthorized access, acts of violence, and suspicious activity on company property. The security solutions of conventional assessment by CCTV and manual guards depend on human conduct, which introduces the risk of human errors and response delays. Security employees fail to identify crucial details because weakness interferes with their work, together with distractions and large monitoring tasks. Autonomous deep learning-driven surveillance systems can improve the identification of threats by continuously scanning live video streams for irregularities and sending out notifications when they see suspicious activity [3].

An artificial intelligence framework that connects human posture examination with physical security supervision through deep learning will address these challenges. The new system uses machine learning algorithms to examine user actions together with logon behavior along with device usage patterns, and personality methods for detecting abnormal insider threat indicators [4]. CNNs and Random Forest classifiers used together within the framework produce a better and trustworthy framework to detect abnormal behavior, which outperforms conventional security measures based on static rule sets.

The framework includes AI-based video surveillance as an additional measure to improve physical defense operations. The system employs MobileNetV2 as its core deep learning model to inspect and identify violent or suspicious occurrences in real-time CCTV broadcasts. The model operates optimally as an edge computing system to offer real-time anomaly detection

without delays in detection times [5]. The automated system detects threats more quickly, thanks to automatic response capabilities that operate without human supervision, which enhances an organization's total security position.

Furthermore, combining physical security systems with AI-driven cybersecurity provides a more comprehensive method of managing organizational threats. The connections between cyber threats and physical threats keep expanding because incidents in one area tend to affect the other. A physical breach of a data center may result in data breaches, and unauthorized actors can disable security cameras and enter restricted areas by exploiting compromised digital credentials. Through deep learning-based unification, security organizations obtain the power to face threats within a single unified framework [6].

The study improves current Security Operations Centers (SOCs) by offering a novel, unified framework that dramatically increases security management across virtual and physical infrastructures. While previous research has independently investigated insider threat detection and violence recognition, there is a clear gap in comprehensive systems that cover both areas simultaneously on a single platform. This research fills that gap by combining deep learning approaches to address real-time monitoring and threat identification tasks in a seamless way. The suggested system achieves high accuracy, efficiency, and quick response capabilities by utilizing lightweight yet robust models such as MobileNetV2 for physical violence detection and CNN for insider threat evaluations [2], [3]. The dual-layered detection method increases not only the detection and prediction of insider threats, but also operational readiness for physical security violations. Through this integration, the research contributes significantly to the development of Next-Generation SOCs by providing a comprehensive solution that addresses the limitations of separated traditional security approaches, allowing for effective detection, alerting, and management of complex cyber-physical threats.

The following sections specify the research structure: Section II presents an evaluation of previous works, together with their weak points. The proposed methodology in Section III reveals how deep learning models and techniques serve threatening behavior profiling purposes. The experimental findings, together with framework performance evaluation, appear in Section IV. The study concludes its discussion with essential research outcomes and suggestions about future investigation efforts in Section V.

II. Literature Review

A. Analyzing Human Behaviour to Identify Insider Threats

Every organization faces serious threats through insider actions that risk essential information attributes, including confidentiality, as well as integrity and availability. The threats come both from deliberate malicious insiders as well as unintentional cases due to employee negligence. Research indicates that insider security threats comprise a major portion of breach incidents because surveyed companies reported that 61% of their operations had internal breaches in one year. Insider threats proved equally detrimental to data security breaches by causing 23% of incidents, equalling the number of incidents caused by cyberattacks. Insider threats cause increased damage in present times because employees can now access sensitive systems directly, so they create both financial and reputational damage to organizations. To properly handle this escalating security issue, organizations must implement proactive mitigation techniques like behavioral analysis based on artificial intelligence threat identification [7].

"Using Hybrid Algorithms between Unsupervised and Supervised Learning" tackles the persistent and complex issue of recognizing insider threats, who typically elude traditional security measures due to their authorized access to internal systems. The primary originality of this study is its hybrid method, which effectively blends unsupervised machine learning for anomaly detection and supervised training for pattern classification to improve accuracy and reduce false positives. The methodology includes feature engineering utilizing user behavior profiling and a multi-layered detection process. With a remarkable accuracy rate of 86.12%, the model demonstrated significant potential for practical application in threat detection systems [8]. Among its benefits are high detection performance, improved learning from labeled as well as unlabeled data, and flexibility in a variety of organizational settings. One significant disadvantage is that computational complexity and expense may limit scalability and real-time deployment.

Traditional organizations detect insider threats using three procedures, which include rule-based monitoring and user activity logging, as well as anomaly detection systems [9]. These strategies fail to detect modern advanced attackers who use deception methods to circumvent secure monitoring systems. Statistical anomaly detection techniques are helpful, but they have scalability problems and high false positive rates [10]. Although detection accuracy has increased with the creation of machine learning models, there are still issues with striking a balance between accuracy and false-positive results.

Sridevi et al. (2023) examine the usage of deep learning models, specifically Long Short-Term Memory (LSTM) and Recurrent Neural Networks (RNN), to detect insider threats by examining user behavior data over time. By capturing a long-term temporal link in user behavior, their approach enables the model to identify subtle changes that typical models could overlook and that appear gradually over time. The strength of this method is its ability to effectively profile user behavior utilizing patterns seen over extended periods and model sequential information. It is suitable for batch or historical research since evaluation findings show that it performs well when analyzing temporal patterns using simulated datasets [11]. However, the lack of spatial context evaluation (e.g., device or location-based behavior), explainability features, and the inability to support real-time threat identification may limit the model's practical deployment as transparency in operational environments, where clear and concise results are needed.

To address the insider threat issue, the study "Supervised and Unsupervised Methods to Detect Insider Threat from Enterprise Social and Online Activity Data" looks at digital traces of online behavior, including as emails, login times, and social media activity. This approach is intriguing because it uses a behavioral dataset from multiple state sources and includes supervised and unsupervised models to detect deviations from conventional

behavior patterns. The accuracy of the final assessment, which was 73.4%, is encouraging by considering the complexity and unpredictability of social behavior data [12]. The main advantage of this method is that it can be used with real company communication data, enabling more thorough behavioral insights. Unfortunately, data from online activities is also less accurate and may overfit due to its diversity and noise. Moreover, explainability and real-time detection, two factors that are becoming increasingly crucial for modern security operations, are not given priority.

Long Short-Term Memory (LSTM) networks and Convolutional Neural Networks (CNNs) are combined in a hybrid deep learning model proposed by Saaudi et al. (2021) for insider threat detection, with a focus on temporal-spatial sequences. LSTMs are used to train through temporal sequences, enabling the model to recognize complex patterns over time. CNNs are used to extract characteristics from geographic data, such as device usage, file access patterns, and user behaviors. This hybrid method effectively maintains both temporal and geographic data thanks to its robust behavioral profiling and adaptability to changing threat behaviors. The model performs well in pattern recognition, but it lacks key features for practical application, such as a real-time threat detection system, continuous learning to adapt to new threats, along with explainable AI (XAI) to make decisions transparent. These weaknesses make the model challenging to apply in real-world scenarios where timely and intelligible insights are required for effective threat reduction [13].

Deep learning's ability to extract high-dimensional features and recognize patterns has completely changed cybersecurity. CNNs have been proven successful in analyzing extensive user activity datasets for detecting insider threat marker behaviors according to research [14]. Recurrent Neural Networks (RNNs) serve as a common tool for sequential behavior modeling in cybersecurity applications [15]. Moreover, Generative Adversarial Networks (GANs) are currently being investigated to create synthetic attack situations, therefore enabling models to generalize more in practical environments [16].

Insider threat detection benefits from behavioral profiling, which has become a proven method of detection. Analyzing device interactions, psychometric characteristics, and login behaviors has been shown in studies to improve detection accuracy [17]. RNNs coupled with LSTM systems play a vital role in sequential anomaly detection when used for insider threat detection. Research results showed that LSTM networks achieved better time-based behavioral deviation tracking, which enhanced the timing of threat identification. Real-time user action monitoring through RNN-based models has become a solution for detecting unauthorized data exfiltration patterns [18]. The detection of threats has received major improvements through recent advancements in transformer-based architecture development. Security logs receive analysis from BERT-based models that achieve better accuracy than traditional ML models for identifying insider threats [19].

The development of insider threat detection models depends heavily on the process of feature engineering for better accuracy. Research underlined how well ML models performed when including engineering elements, contextual embeddings, user risk assessments, and deviation measurements. Furthermore, investigating methods to maximize detection efficiency are automated feature selection methods applying genetic algorithms [20]. Using artificial intelligence models for real-time detection of threats calls for effective interaction with web-based systems like Flask. Studies showed that real-time monitoring dashboards made possible by Flask-based systems might increase the operational effectiveness of Security Operations Centers [21]. Reducing false positives and improving model interpretability will be the main goals of future insider threat detection studies. Techniques integrating unsupervised and supervised learning in hybrid artificial intelligence can improve detection accuracy even more. Another interesting path to guarantee the accuracy of data in identifying insider threats is the acceptance of blockchain-based systems for safe audit logging [22]. Table I summarizes important gaps in the research on insider threat detection.

TABLE I GAPS IN LITERATURE ON INSIDER THREAT DETECTION

Ref	Description	Novelty	Strengths	Weaknesses
[15]	Analyzes the use of hybrid (supervised + unsupervised) threat detection techniques utilizing deep learning techniques.	Combining several models and traditional protection to present a single deep learning framework.	Combines CNNs and RNNs to detect threats in real time from a variety of data sources.	Lacks benchmark comparisons, performance measurements, and actual evaluation.
[16]	Proposes a GAN-based model to detect identity theft within e-governance systems.	Applies adversarial training specifically to e-governance identity protection—a new application area.	Improves cyber identity theft detection in e-governance by utilizing adversarial networks.	No performance metrics, dataset details, or evaluation results provided.
[17]	Reviews how GANs enable both new cyberattacks and defenses (anomaly detection).	Highlights dual use of GANs in offense and defense across multiple threat domains.	Wide coverage of GAN deployment scenarios emphasizes evolving attack surfaces and defensible techniques.	Lacks quantitative evaluation or implementation of roadmaps.
[18]	Uses graph neural networks especially to identify trends in cyberthreats.	Uses temporal graph data instead of static logs.	Captures complex behavior patterns, adaptable.	No benchmarks, lack real-world validation.
[19]	Evaluates ML and BiLSTM models on CERT r4.2 for insider threat detection.	Combines standalone and sequential features using BiLSTM.	Use supervised learning to detect insider threats with high accuracy.	Unbalanced data sets in the actual world can cause performance to decline.

B. Profiling Threats with Physical Security Systems

Particularly in the field of real-time violence detection, developments in deep learning technology have accelerated the growth of video surveillance systems. The core of contemporary intelligent surveillance systems is edge computing solutions, temporal analytic frameworks, and transfer learning models, which are investigated in this study.

Deep learning techniques have lately shown remarkable success in performing violence detection inside surveillance systems. With CNN and LSTM architectures, Sharma et al. (2021) created an integrated system with 94.65% accuracy using their combined dataset. Their method used trained CNN models for extracting features, then used LSTM networks to examine temporal sequences, therefore allowing real-time analysis of footage and instantaneous alert to authorities [23]. Likewise, in situations involving obstructions and dense locations, especially, a 2025 study using MobileNetV2 paired via Temporal Squeeze and Excitation Blocks overcomes limits in current violence detection technologies. When violent events are found, our technology analyses live footage from surveillance cameras and transmits quick reports to police over a Telegram network [24].

Because MobileNetV2 strikes a mix between accuracy and efficiency, it has become a favored architecture for violence detection. With 94.5 per cent accuracy, 93 per cent precision, and a 94.9 per cent F1 score in separating between aggressive and non-violent actions, in 2024, the execution integrating MobileNetV2 with Bidirectional LSTM networks attained amazing performance. Maintaining great detection accuracy, the lightweight character of the design makes it especially appropriate for deployment in settings with limited resources [25].

Using MobileNetV2 as a previously trained algorithm for violence detection, Chandran (2023) further included image enhancement techniques and facial detection to provide complete warning capabilities [26]. This system shows the useful implementation of transfer learning algorithms in real-world surveillance situations by capturing images of people engaged in violent behavior and forwarding them together with place data to experts via Telegram [27].

For a temporal pattern associated with violent events, the combination of LSTM network structures with CNNs has shown success. Hamza's work used CNN+LSTM architecture to detect anomalies in surveillance films, thereby allowing the system to grasp the sequential character of acts defining aggressive behavior [28]. A 2024 study emphasizing how bidirectional LSTM networks paired with MobileNetV2 can efficiently capture temporal dependencies inside sequential video frames validates this method even further. By means of their combined use, these technologies generate an intelligent system able to precisely detect violent behaviors by use of spatial characteristics and their progression over time [29].

Emerging as a crucial part of contemporary surveillance systems, edge computing solves bandwidth and latency problems. Edge-enabled security camera systems can quickly process video data, according to a 2025 report, therefore offering real-time, instantaneous actionable insights and completely eliminating delays brought about by data being sent to faraway servers. Applications needing quick response, like those involving the identification and handling of violent events, depend on this capacity [30].

Edge computing transmits only pertinent data instead of constant raw footage, therefore providing notable bandwidth efficiency. According to a 2023 study, every video camera may examine its own film and provide only relevant data to cloud servers, therefore lowering bandwidth usage and allowing quicker responses for important security events7. Scaling surveillance networks over several sites calls for this method especially helpful [31]. Edge computing also improves data privacy by locally processing sensitive videos, therefore lowering exposure to intrusions during data migration. For companies giving data security and regulatory compliance first priority, this makes it appealing [30]. Table II summarizes important gaps in the research on physical security systems.

TABLE II GAPS IN LITERATURE ON PHYSICAL SECURITY SYSTEM

Ref	Description	Novelty	Strengths	Weaknesses
[27]	Fuses unsupervised outlier scores across time granularities with supervised XGBoost on CERT R4.2 dataset.	Treats anomaly scores as feature enhancements for supervised detection with low compute cost.	Reduces computation, increases accuracy, and manages multi-granularity data intelligently.	Limited to CERT dataset; lacks deployment insights and external validation.
[28]	Real-time video violence detection using a pre-trained Xception CNN + LSTM, with mobile app alerts.	Spatial–temporal DL integration in a deployed architecture with mobile notifications.	Extremely high accuracy, alert app included.	Tested only on curated datasets; no real-world deployment; requires GPU.
[29]	Uses a lightweight two-stream CNN for anomaly detection in surveillance video, optimized for IoT.	Combines AIoT with spatial–temporal deep learning.	Efficient for edge deployment; handles large-scale video data.	Limited benchmarking and real-world validation.
[30]	Utilizes Hyperledger Fabric blockchain to log CCTV metadata and video hashes, ensuring tamperproof surveillance streams.	Merges IoT CCTV with blockchain to create immutable, verifiable video integrity in smart cities.	Immutable audit trail: decentralized ledger prevents forgery or single-point failure.	No performance metrics or scalability analysis lacks real-world deployment data.

III. METHODOLOGY

A. Threat Profiling with Human Behavior Analysis

The rising complexity of insider threats calls for the application of sophisticated data-driven approaches. This study gives the advantage of the CERT Insider Threat Identification Dataset, well known for simulating actual organizational risks. The collection comprises logs of user activity, including device connections, file actions, logon and logoff tracks. These logs offer important new perspectives on both expected and unusual behavior inside a company. Examining these trends helps us to find early signs of insider threats.

Ensuring that the dataset is organized and useful for deep learning algorithms depends critically on data preparation. For sequential logs, values that were missing in the dataset were resolved with both backward and forward filling techniques; numerical attributes were handled via mean or median imputation. Additionally, present in the dataset are psychometric features that help to spot behavioral deviations. Labelling for typical features like risk levels and rapid coding for categorical factors like department and position title assisted in the encoding of these attributes. To identify suspicious activity, login timestamps were also transformed into time-based attributes, including frequency variation per day and an anomaly rating. Techniques of standardizing and normalizing helped to guarantee reliability in feature scaling, hence improving model convergence during training.

Effective threat detection requires significant feature extraction. Essential elements consist of:

- Examining login trends helps to identify irregularities such as logons from unexpected sites or outside regular business hours. Different from the usual behavior of an employee could point to a compromised consideration or malicious intent.
- Monitoring external device usage, that of USB connections and file transfers helps one find illegal access. Frequent trips to outside devices or efforts to access restricted data could lead to an insider danger.
- Tracking user behaviors over time helps the system identify strange patterns. An employee downloading a lot of confidential information right before logging out, for instance, could show hostile intent.
- Mapping user activities to psychological features according to the OCEAN model assists in identifying vulnerable to risk-taking people. Workers displaying indicators of stress or discontent could be susceptible to participating in harmful behavior, so prompt action is more possible.
- Graph-based profiling analyzing user interactions as graphs, helps identify unusual connections and illegal data sharing inside the company. In communications, anomalies in patterns could point to insider threats or communication.
- Deep learning embeddings translate behavioral patterns into numerical representations, thereby enhancing the capacity of the network to identify small variations from usual activity.

Insider threat detection works using a CNN-Random Forest combined model. By extracting sequential patterns from organized behavior records, the CNN component finds user behavior trends concealed otherwise. CNNs are excellent for anomaly detection since they can learn intricate temporal correlations from log sequences. The graphical information is processed using the Random Forest classifier, which lowers overfitting and manages a combination of continuous and categorical variables, thereby enhancing classification performance. This hybrid method guarantees efficient analysis of both structured and unstructured behavioral aspects, thus strengthening an accurate threat identification system.

The dataset was split in half with 70% used for training as well as 30% testing to guarantee the model fits new data. With a batch size between 32 and 20 epochs, a CNN model was developed using an Adam optimizer used to dynamically change learning rates for improved integration. Using grid search cross-valuation to determine ideal depth and selection of features criteria, Random Forest was set up with 100 decision trees and hyperparameter modification was conducted. By balancing false positives with false negatives, this optimization technique improved system dependability for practical use.

Several important benchmarks helped to evaluate the model's performance. With the model scoring 95%, which matched its general accuracy in forecasts, accuracy stood out. With an outcome of 0.95 for instances that were negative while 0.93 for positive ones, precision was high, meaning that the identified threats were valid. The model thereby reduced false positives successfully. Recall, which measures the model's capacity to detect real threats, performed really well for negative outcomes (0.99) but fewer for cases that were positive (0.79), therefore suggesting some missed threats. The F1-score was computed to strike a mix between accuracy and recall, so offering a complete assessment that addressed the class imbalances sometimes observed in insider threat identification. This mix of indicators guarantees the model detects and reduces false positives as well as missed threats in excellent performance. For each behavior category, Table III displays the CNN model's precision, recall, and F1-score. It performs well in identifying typical behavior and has a slightly reduced recall for insider threats.

TABLE III CNN MODEL EVALUATION RESULTS

Class	Precision	Recall	F1-Score
0 (Benign)	0.95	0.99	0.97
1 (Malicious)	0.93	0.79	0.86

The structure of the Insider Threat Identification System is shown in Fig. 1. The final prediction is produced by processing user-input data using a Flask application, analyzing it by applying a CNN along with Random Forest models based on the CERT dataset, then combining them via an ensemble model.

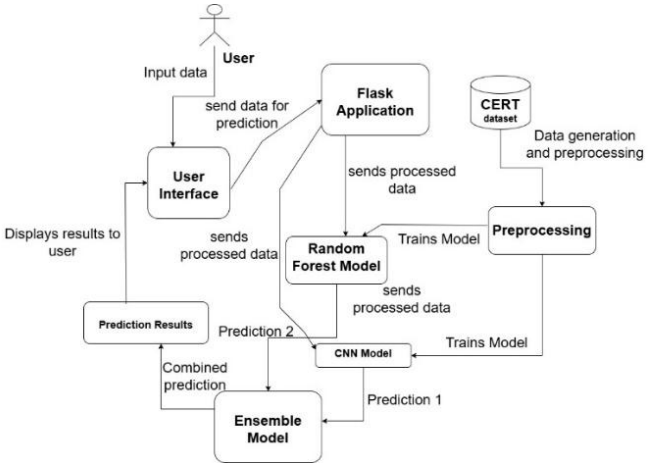

Fig. 1. Insider threat detection system diagram.

B. Threat Profiling with Physical Security System

The deep learning model underwent training and evaluation through an extensive data preprocessing pipeline. The pipeline encompassed numerous crucial phases to standardize input data, maintain vital temporal and spatial information, and improve the model's generalization across various contexts. The initial phase entailed frame extraction; individual frames were methodically sampled from each video clip at a uniform rate to maintain temporal coherence. This enabled the model to learn from the dynamics and evolution of actions over time, capturing significant temporal patterns essential for differentiating between violent and non-violent behaviors.

Spatial normalization was performed on all retrieved frames, shrinking them to 224x224 pixels, which is the standard input size mandated by the MobileNetV2 architecture. Pixel normalization adjusts pixel intensity values to a standardized range, often [0, 1] or [-1, 1], based on the input specifications of the model.

Data augmentation methods were utilized on the training set to replicate heterogeneity in actual video recording scenarios, mitigating overfitting, and enhancing the model's resilience to diverse camera angles, lighting conditions, and orientations.

Preprocessed frames were structured into fixed-length sequences to provide the final input format for the model. These sequences are the principal input for the model, allowing it to examine both the spatial content of individual frames and the temporal motion patterns and context.

The preprocessing methods created a robust framework for developing an efficient video classification system that can identify violent behaviors in intricate real-world settings.

The MobileNetV2 model was selected for the feature extraction phase of the model pipeline because of its superior balance between computational efficiency and feature representation accuracy. This option is especially appropriate for violence detection systems functioning in real-time or resource-limited settings, such as embedded systems or surveillance equipment. MobileNetV2 employs depth-wise separable convolutions and inverted residual blocks to minimize parameters and computational expenses while effectively capturing intricate patterns in the data. This enables the model to derive superior spatial properties from video frames while maintaining a lightweight and efficient design.

The feature extraction technique comprised multiple substeps, including transfer learning, fine-tuning with a domain-specific dataset of violent and non-violent video clips, and the generation of feature maps from each video frame. These maps offer a comprehensive, organized representation of the visual material in each frame, essential for further temporal modelling.

To facilitate the transition from spatial to temporal analysis, the output of MobileNetV2's final convolutional layer was converted into feature vectors. This dimensionality reduction procedure converts multi-dimensional tensor outputs into a uniform and compact format appropriate for input into temporal modelling components, such as recurrent neural networks (RNNs) or temporal convolutional networks (TCNs). These components examine the temporal evolution of spatial features, allowing the system to identify violent sequences instead of solitary visual patterns.

A hybrid CNN-LSTM architecture was created to analyze the intricate spatiotemporal dynamics of aggressive behavior in video sequences. This architecture incorporates spatial feature extraction, which examines individual video frames, and temporal sequence modelling, which captures the evolution of events across time. The model is more adept at recognizing violence as a dynamic and context-dependent phenomenon rather than solely depending on static visual indicators.

The initial phase encompasses spatial feature extraction, facilitated by the MobileNetV2 backbone. This lightweight convolutional neural network independently processes each frame, extracting high-level visual features that encapsulate significant spatial information. These characteristics may encompass critical signs of aggression, including hostile attitudes, abrupt movements, and close closeness between people. Every video frame is converted into a comprehensive feature vector for subsequent analysis.

The output feature vectors from MobileNetV2 are input into a Long Short-Term Memory (LSTM) layer to record the temporal dependencies between successive frames. LSTMs are engineered to process sequential input and can preserve long-term dependencies via gated memory cells, rendering them especially effective for violence detection.

After the LSTM layer, the model has a classification head using a fully connected dense layer with a SoftMax activation function. The last layer translates the stored temporal information into binary class probabilities, signifying whether the input sequence pertains to a violent or non-violent event.

The hybrid model was optimized for training with a batch size of 32, utilizing the Adam optimizer at a learning rate of 0.0001, implementing early halting with a patience of 10 epochs, and employing the categorical cross-entropy function for multi-class classification problems.

A hybrid CNN-LSTM model was created to shift from a research context to a real-time monitoring system appropriate for public surveillance applications. The frame buffer management module is a fundamental element that employs a

sliding window technique to manage live video streams. This technique guarantees that the model consistently accesses the most recent temporal context for inference, while reducing memory consumption and latency.

Inference optimization was conducted using TensorFlow Lite, a lightweight and efficient deep learning framework tailored for mobile and edge devices, to satisfy real-time performance requirements. The optimized model can handle video streams at 25 to 30 frames per second (FPS), which corresponds with normal video frame rates and facilitates near-instantaneous detection of violent behavior in real-time recordings.

An alarm system was integrated into the pipeline to guarantee prompt reactions to identified incidents. The system was designed to initiate a response solely upon the detection of aggression in 20 consecutive frames, so enhancing its resilience by confirming the continuity of violent behavior across time.

A notification system was created and incorporated utilizing the Telegram messaging network. Upon the activation of an alert, the system transmits a real-time notification to designated recipients, encompassing critical information such as the event's timestamp, geolocation coordinates (if accessible), and collected frame images that graphically record the alleged violent incident. This real-time notification feature guarantees that security professionals or emergency responders are swiftly alerted and provided with actionable context to evaluate and address the problem. Fig. 2 shows the Physical Security Component Diagram, which outlines the real-time violence detection pipeline using MobileNetV2, combined with CCTV streams and alert systems.

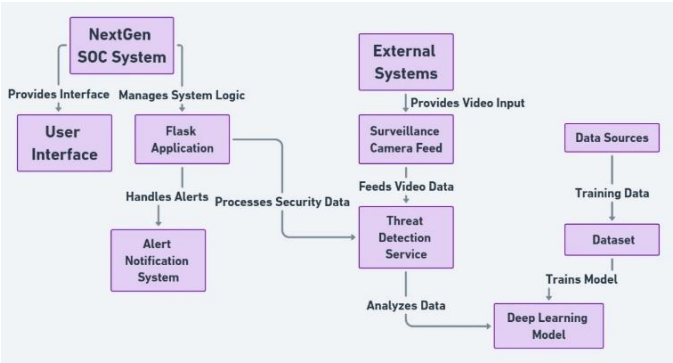

Fig. 2. Physical security component diagram.

IV. Evaluation and Results

A. Performance of Insider Threat Detection

The indicated insider threat detection system proved highly effective in spotting unusual user behavior. The CERT Insider Threat Identification Dataset offered several real-world examples of insider threats; therefore, the CNN-Random Forest ensemble approach was evaluated on that dataset. With an accuracy rate of 95%, the CNN approach alone proved able to efficiently extract significant patterns from organized behavioral records. Using convolutional neural network layers, the CNN found small variations in user behavior, including illegal log-in access, unexpected working hours, and unusual data access patterns.

Using conventional evaluation measures, including precision, recall, and F1-score, the model's performance was evaluated. With a precision rating of 0.93, the model found that most identified threats were real insider attacks. With a score for recall of 0.79, the model was able to balance false positives with a significant number of real threats. The strong F1-score confirmed that the model could efficiently manage imbalanced datasets, therefore guaranteeing that real risks were found without improperly highlighting benign behaviour. CNN Model accuracy and model loss graphs are shown in Fig. 3 and Fig. 4, respectively.

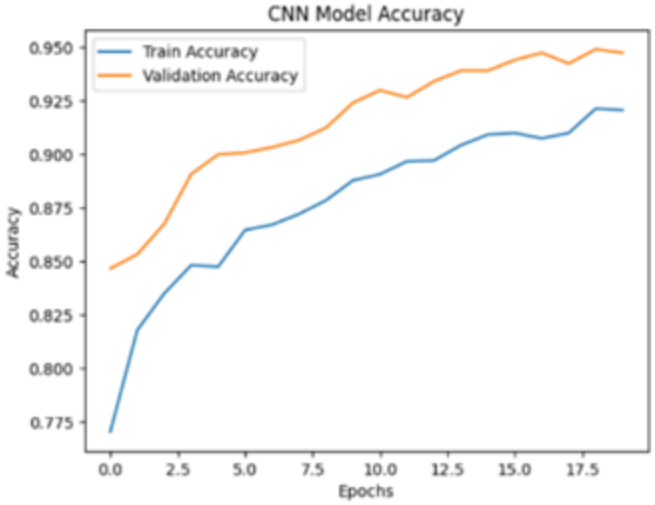

Fig. 3. CNN model accuracy.

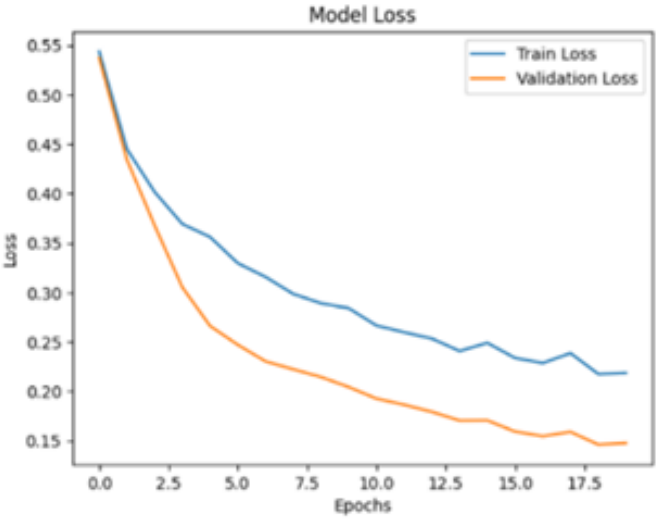

Fig. 4. Model loss.

The system combined the Random Forest classifier with a CNN (Convolutional Neural Network) within an ensemble model to improve classification performance. This combined strategy made use of Random Forest's ability to make decisions based on user behavior patterns and CNN's power in feature extraction. The Random Forest effectively processed intricate graphical data and decreased false positive rates by combining several decision trees. Threat detection became more accurate as a result of the ensemble model's effective resolution of the

problem of misclassifying typical user behavior as threats. A strong detection system was created by combining CNN with Random Forest, which decreased classification mistakes and improved overall dependability. The ensemble model's remarkable 98% accuracy rate highlights how well it profiles organizational risks.

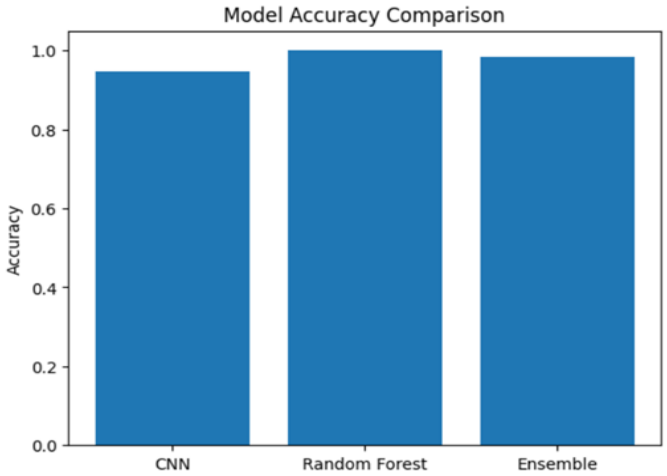

Fig. 5. Model accuracy comparison.

The accuracy comparison between each model is shown in Fig. 5, emphasizing the variations in performance. These findings underline how well deep learning-based profiling detects insider threats. Although the classifier using Random Forests improved classification reliability by lowering overfitting and hence enhancing decision-making, the CNN component succeeded in feature extraction. The system is a reasonable choice for implementation in actual Security Operations Centers (SOCs) since it can reach great accuracy with minimum false positives. Future developments might center on including explainable artificial intelligence methods to increase openness and improve detection accuracy even more. Table IV shows the comparison of model performance with existing literature.

B. Performance of Physical Security Systems

The evaluation measures and findings of the suggested physical security system with real-time detection of violence are presented in this part. Accuracy, recall, F1 rating, and real-time operational indicators evaluated the MobileNetV2-based combination CNN-LSTM model. The outcomes show how good the system is in spotting violent events and differentiating them from regular operations.

Achieving great accuracy as well as robust classification findings, the MobileNetV2-based hybrid approach showed amazing performance in spotting violent activity. Summarized below are important evaluation criteria. Fig. 6 shows the total accuracy versus total validation accuracy chart.

The system's capacity to identify ordered anomalies in footage from CCTV was much improved by including LSTM layers. Analyzing temporal relationships between consecutive frames in the LSTM layers let the model identify violence as a series of acts instead of individual events. In situations involving subtle or extended aggressive behaviors, when spatial elements alone could not adequately depict the environment, this enhancement was especially clear. Fig. 7 shows the confusion matrix for the physical security system.

TABLE IV COMPARISON OF MODEL PERFORMANCE WITH EXISTING LITERATURE

Study	Model Used	A = Accuracy P = Precision R = Recall	Analysis
Hybrid Algorithms (2024) [8]	Hybrid (Supervised + Unsupervised)	A - 92.8% P, R - Not Provide	Combines clustering and classification to improve insider threat detection.
Olajide et al. (2024) [9]	Hybrid ML-based UBA models	A - ~85% P, R – Not Provided	Discusses UBA-based insider threat detection combining ML techniques.
Sridevi et al. (2023) [11]	Deep LSTM / RNN	A - 96.3% P, R – Not Provided	Sequential behavior is well captured by the suggested LSTM/RNN-based method.
Gavai et al. (2015) [12]	Supervised + Unsupervised	A - 73.4% P – Not Provided R – 72%	Uses enterprise social and activity data for behavioral threat detection.
Saaudi et al. (2019) [13]	CNN + LSTM	A - 95.9% P – 95.98% R – 95.9%	Combines spatial and temporal modeling to capture insider behavior cues.
Our Model	CNN + RF Ensemble	A - 98% P – 98% (0), 99% (1) R – 99% (0), 92% (1)	Random Forest's comprehensive decision-making capabilities with CNN's deep pattern recognition capabilities.

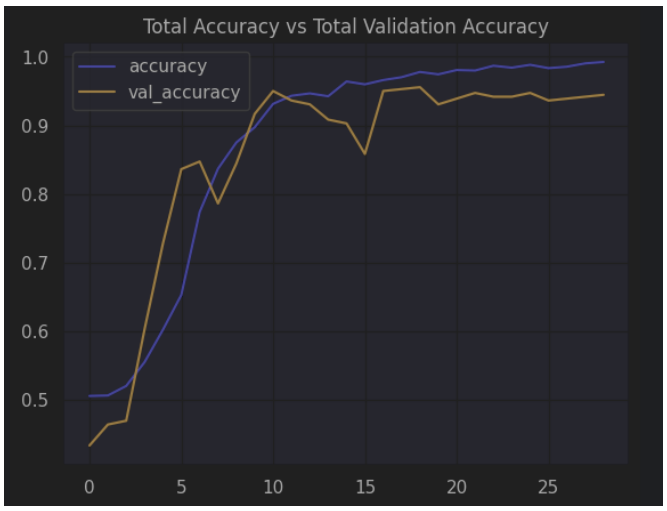

Fig. 6. Model accuracy.

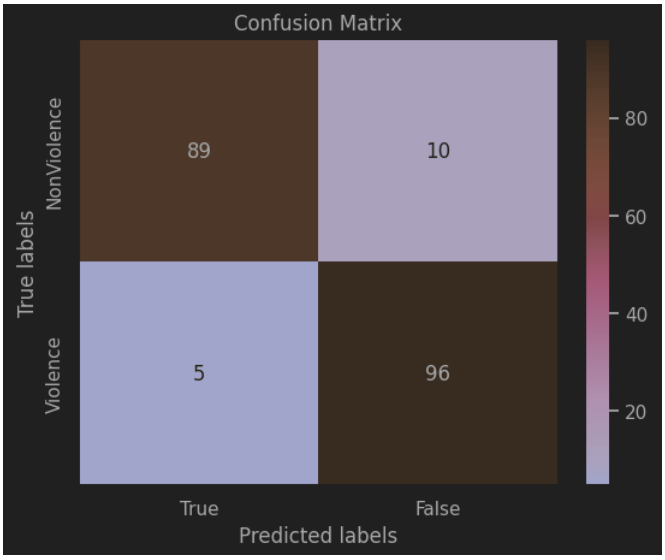

Fig. 7. Confusion matrix.

The evaluation findings demonstrate that the suggested physical security framework is quite successful in real-time violent incident detection:

- Reach 99.16% accuracy, above standards for systems of violence detection.
- Using LSTM layers, strong temporal abnormality detection is shown.
- Run Functioned with low latency and high frame processing speed in real-time settings.
- Presented scalable options for edge device deployment keeping great accuracy and recall rates.

These findings confirm the system's feasibility for useful application in surveillance settings and provide a trustworthy instrument for improving physical security by means of intelligent video analysis.

Prior research on physical security threat identification utilizing CNN architecture has indicated accuracy rates ranging from 70% to 75%, underscoring the difficulties in identifying dangers within surveillance data. These models frequently exhibit elevated false positive rates and inadequate generalization to real-world contexts. Conversely, our MobileNet-based model attained a markedly better accuracy of 98.2%, highlighting enhanced feature extraction, computational efficiency, and durability.

A detailed performance comparison is presented in Table V, highlighting the accuracy and Analysis of previous CNN-based approaches compared to our MobileNet-based model. As shown, our model demonstrates superior performance while addressing key challenges such as false positives and real-time inference.

TABLE V PERFORMANCE COMPARISON OF CNN-BASED MODELS FOR PHYSICAL SECURITY THREAT DETECTION

Paper Title	A-Accuracy P-Precision R-Recall	Analysis
Hybrid Insider Threat Detection (Yi & Tian, 2024)	A-98.03% P- 97.59% R- 96.83%	High accuracy and efficiency with low compute cost; effective for insider threat detection using hybrid ML approach.
Violence Detection Using CNN & LSTM (Sharma et al., 2021)	A-95.15% P- 94.87% R- 95.20%	Well-balanced detection system for violence in video; effective spatiotemporal feature learning using CNN + LSTM.
AIoT-Assisted Two-Stream NN (Zhou et al., 2021)	A-95.12% P-95.34% R-94.98%	Impressive performance for surveillance anomaly detection; optimized for IoT and edge deployment scenarios.
Blockchain-based CCTV Verification (Khan et al., 2020)	Not Provided	Focuses on blockchain-based data integrity, not ML classification; lacks typical performance metrics like accuracy or recall.
Our Model	A - 98.2% P-95% (0), 91% (1) R-90% (0), 95% (1)	Uses MobileNetV2 to deliver excellent accuracy in real-time physical violence detection; it is optimized for the deployment of lightweight edge devices with timely warning capabilities.

V. CONCLUSION

This study connects human behavior analysis with physical security surveillance to show how effective deep learning is at profiling organizational threats. The suggested solution uses MobileNetV2 to increase real-time monitoring for physical security risks and a CNN-Random Forest hybrid model to evaluate behavioral patterns for better insider threat identification. These models work together to create a thorough, multi-layered security solution that can identify security threats from inside as well as from outside.

The suggested method, however, is subjected to a number of presumptions and restrictions. First, it assumes that input data (such as video and behavioral logs) will always be available and of high quality, which is not necessarily the case in real-world settings. Second, even though the CNN-Random Forest method is more interpretable, it might not be as transparent as more straightforward models, particularly in situations with large stakes. Furthermore, psychometric analysis may oversimplify complicated psychological factors and cultural differences by assuming that human behavior can be reliably classified into threat or non-threat patterns. Additionally, the existing method depends on centralized processing, which could cause slowness in scenarios with limited resources or large-scale deployments. The system's ability to effectively reduce false positives while keeping high accuracy makes it appropriate for dynamic enterprise security contexts, despite these constraints. The system's modularity and scalability further improve its capacity to adjust to changing security threats.

Future iterations of this study will focus on various developments to overcome existing constraints and increase functionality. Integrating edge computing is a crucial step in enabling quicker, localized processing of surveillance data, which lessens reliance on centralized resources and speeds up response times. To better understand context and detect complex threat behaviors early on, we also want to deploy Graph Neural Networks (GNNs) to record and examine relational patterns across people, devices, and activities. Additionally, implementing Explainable Artificial Intelligence (XAI) methodologies would increase decision-making transparency and enable security analysts to better understand, trust, and respond using AI-driven insights.

By providing a threat detection system which is not only effective and accurate but also scalable, adaptable, and interpretable, these improvements seek to secure the fundamentals of Next-Generation Security Operations Centers (SOCs). In an increasingly complicated digital environment, this work adds to the continuous effort to assist enterprises in proactively identifying, mitigating, and managing cybersecurity threats, both internal and external.

LaObese: A Serious Game Powered by Analytic Hierarchy Process for Culturally Tailored Childhood Obesity Prevention in Oman

Nurul Akhmal Mohd Zulkefli[1], Mukesh Madanan[2], Zainab Mohammed Al-Nahdi[3], Jayasree Radhamaniamma[4]
Department of Computer Science, Dhofar University, Salalah, Sultanate of Oman[1, 2]
Department of Mathematics and Sciences, Dhofar University, Salalah, Sultanate of Oman[3]
Oman College of Health Sciences, Salalah, Sultanate of Oman[4]

***Abstract*—Childhood obesity is a growing public health concern in Oman, yet culturally appropriate digital tools for early prevention remain scarce. This study introduces LaObese, a mobile application and serious game designed to prevent obesity in Omani preschool children. The name LaObese derives from the Arabic word "La" (meaning "no") and an abbreviation of "obesity", reflecting the game's mission to say, "no to obesity". LaObese integrates gamification and behaviour modification strategies to encourage healthy lifestyle practices from an early age. Targeting children aged six, the initiative addresses the urgent issue of early childhood obesity, which is linked to long-term health complications. The development process incorporated a Multi-Criteria Decision-Making (MCDM) approach – specifically the Analytic Hierarchy Process (AHP) to identify and prioritise foods commonly consumed by children, ensuring the game's nutritional content is both effective and culturally relevant. Food items were categorised (e.g., fruits, vegetables, proteins, beverages, desserts, and traditional Omani dishes) to align with preschool nutrition goals and local dietary habits. Findings from expert assessments (informed by national nutrition guidelines and local data from Salalah, Dhofar) highlight a growing preference for nutrient-rich traditional foods like dates and almonds among young children. LaObese is the first serious game in the Arab region to integrate an AHP-driven educational model for childhood obesity prevention. The platform facilitates collaboration between health professionals and educators in creating culturally tailored digital interventions, aiming to instil healthy eating habits in children through engaging gameplay.**

***Keywords*—Serious games; childhood obesity; gamification; analytic hierarchy process (AHP); preschool nutrition**

I. Introduction

Obesity in children is one of the unsolvable problems for public health around the world, and it is becoming more common in Oman. As kids' lives change because they eat more processed foods, spend more time sitting around, and have less awareness of balanced nutrition, the risk of obesity starting at a young age keeps going up. These problems are particularly significant during the preschool years, when food habits and health behaviors commence development. At this stage of development, kids are very open to visual stimuli and interactive experiences, so it's a great time to start helping them. Although the government is attempting to encourage healthier eating habits, there are few tools available that effectively teach kids about nutrition in a fun and engaging manner. This study presents LaObese, a mobile serious game designed to promote healthy eating habits among preschool children in Oman. The game is meant to show kids food choices in a fun, kid-friendly way that also includes items that are common in their culture and local eating patterns. The Analytic Hierarchy Process (AHP) is used in the game creation process to make sure that the content fits with nutritional goals. This feature makes it possible to find and rate meals that kids eat a lot, which are then added to the game. LaObese wants to provide an interactive, culturally relevant learning experience that helps kids learn how to eat better from a young age.

The related work is presented in Section II, and the methodology which includes the game design framework and the AHP-based food preference analysis is presented in Section III. The findings of the food prioritizing are covered in Section IV, along with how they were incorporated into the game mechanics. Section V concludes and outlines future directions.

II. Related Work

Childhood nutrition is crucial for healthy growth and development, especially in the early years when lasting dietary habits form. The global rise in childhood obesity has become a major concern due to its long-term impacts on both physical and mental health [1]. Excess weight in childhood increases the risk of type 2 diabetes, cardiovascular diseases, reduced mobility, and lower life expectancy. Obese children also face psychological challenges such as low self-esteem, anxiety, depression, and disordered eating. These issues underscore the importance of early prevention and education.

In Oman, childhood obesity is a pressing public health issue. Recent estimates indicate that approximately 16.3% of Omani children are obese, while about 13.7% are underweight [2] [3]. Studies further report that over 21% of school-aged children in some regions have central obesity [3]. Key contributors include unhealthy dietary patterns, sedentary lifestyles, poor sleep habits, and family-related factors such as parental obesity. In response, the Omani Ministry of Health introduced national Healthy Food Guidelines [18] to improve children's nutrition. However, despite these efforts, effective interventions for young children remain limited. Existing anti-obesity serious games are typically designed for adolescents [19] and often lack cultural relevance or customisation for younger audiences [20], [21]. Moreover, many are developed

without input from nutrition or health experts, potentially reducing their credibility and effectiveness [20], [22].

Preventing and managing obesity in early childhood requires strategies distinct from adult interventions, given differences in physiology and psychology. Young children benefit from age-appropriate, engaging, and culturally tailored approaches and sometimes from emphasizing storytelling and interaction from families and educators [24]. In Oman, there is a notable gap in serious games or interactive tools targeting obesity prevention for the preschool age group. Little research has been done on the specific food preferences of Omani children [5], information that is vital for developing effective educational games. Without understanding children's everyday food choices and cultural eating practices, health interventions may fail to engage them [25].

This research aims to fill that gap by developing a culturally relevant serious game called LaObese, to promote healthy eating among Omani preschoolers. Our objectives are to make learning about nutrition enjoyable and to align the game content with children's actual food preferences to maximise engagement and retention. To achieve this, the most frequently consumed foods among local children are identified using a structured decision-making approach. Specifically, the Analytic Hierarchy Process (AHP), a widely used MCDM method, is applied to systematically determine food priorities. These data were then used to drive the game's design, ensuring that the in-game nutrition challenges reflect foods and habits familiar to Omani children. By integrating expert knowledge, cultural context, and gamification, LaObese seeks to effectively educate young children about healthy eating in an entertaining way. This study investigates the extent to which a culturally tailored serious game is grounded in expert-identified nutritional priorities. This can influence preschool children's food choices and support healthier lifestyle behaviors.

III. Methodology

A. AHP-Based Food Preference Analysis

This is to ground the game content in real-world dietary habits: an analysis of children's food preferences using the Analytic Hierarchy Process (AHP) is conducted. AHP is a multi-criteria decision-making technique that breaks down a complex decision [4] (here, selecting important food items) into a hierarchy and uses pairwise comparisons to derive priority weights [6]. The method, originally developed by Thomas Saaty [7], is well-suited for incorporating both quantitative data and expert judgement. It has become one of the most popular MCDM methods in various domains [4] [7].

In this study, a panel of experts (nutritionists) and researchers [5], who were familiar with Omani cuisine identified key food categories and items commonly consumed by young children. Nine major categories of foods and drinks were considered: Fruits, Vegetables, Omani dishes (traditional meals), Bread, Protein (sources of protein), Beverages, Sandwiches, Fast Food, and Desserts. Within each category, representative items were selected for evaluation (for example, the Fruits category included dates, apples, peaches, etc.). Using AHP's pairwise comparison approach, the experts compared items within the same category in terms of their relative importance or preference for children's diets. A nine-point Saaty scale (1 to 9) was used for these comparisons [6, 10], where a score of 1 indicates equal preference and 9 indicates an extremely stronger preference for one item over another [7]. Parents and carers also contributed by ranking which foods their children prefer, providing additional practical insight.

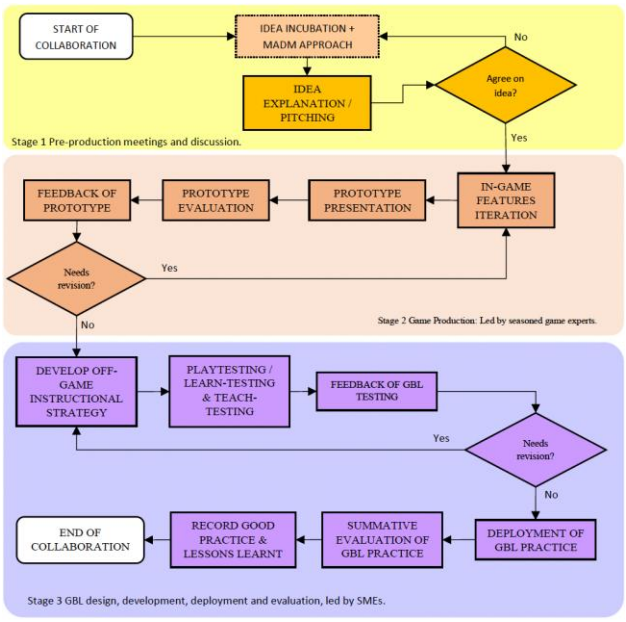

Fig. 1. The integrated GBL collaboration model [11] and proposed multi-attributes decision making (MADM).

For each category, the pairwise comparison judgments were aggregated to calculate a weight for each food item, indicating its relative importance or frequency in children's diets. The consistency ratio (CR) of each expert's comparisons is checked to ensure reliable results (a CR $\leq$ 0.1 was considered acceptable). If any comparison set had a higher CR, the expert was asked to revisit their judgments for refinement. This process yielded a priority ranking of food items within each category, effectively highlighting which specific foods are most relevant to Omani children. Table I shows an example of the results for the Fruits category, where higher weight indicates greater importance or preference.

TABLE I. AHP-Derived Priority Weights for Items in the Fruits Category (Top 5 Shown). Higher Weight = Higher Priority / Preference

Item	Weight
DATES	0.1386
APPLE	0.1280
PEACH	0.1232
MANGO	0.0897
GRAPES	0.0776

Each category's analysis was conducted similarly. The use of AHP ensured that culturally significant foods (e.g., traditional dishes and local snacks) were considered alongside more global or generic options, with expert judgment balancing nutritional value and popularity. By involving local parents, the resulting food priority lists are tuned to the dietary patterns and tastes of Omani children.

B. Serious Game Design and Development

Our next step was to design the LaObese game using the insights from the AHP analysis. A structured game development paradigm was adopted based on established models for educational game design. In particular, the game-based learning collaboration framework by [8] and the iterative serious game design methodology proposed by [9] were referred to. This approach emphasizes close collaboration between subject matter experts (nutrition specialists) and game designers to ensure educational content is effectively embedded in fun gameplay mechanics.

Fig. 1 illustrates the Integrated Game-Based Learning (GBL) collaboration model, which guided this development process. In this model, communication between nutrition experts and developers is key to successfully merging pedagogical goals with game mechanics. A series of in-person meetings and design workshops where nutritionists outlined the educational requirements (e.g., which healthy eating behaviors to target, which foods to include from the AHP rankings), and the game developers proposed engaging ways to incorporate these into gameplay.

Using Tan's methodology for game creation [11], gamifiable components (health concepts and behaviors) were converted into concrete game elements. The design went through several iterative stages:

- Story and Setting: A child-friendly narrative was created, where the player helps a character (an avatar representing a young child) make healthy choices throughout a day. The setting is familiar (home, school, playground, etc.) but presented in a colorful, cartoon-style world to engage children.
- Game Mechanics: Based on the priority foods identified, mini-games and challenges were developed. For example, since fruits and dates are highly ranked, one mini-game involves collecting healthy snacks like dates and apples while avoiding junk food. The educational goal is subtly reinforced by rewarding healthy choices with points or praise.

Levels and Progression: The game was structured into four levels corresponding to daily routines:

- Level 1 – Meal Assembly: Children assemble breakfast, lunch, and dinner for their avatar by dragging and dropping foods onto the plate (see Fig. 3). The available food options include items from AHP-ranked lists. The goal is to choose a balanced meal. For instance, the game presents a mix of healthy and less healthy foods, and the child must pick what the avatar should eat. Fig. 3(a) and Fig. 3(b) show examples of the meal selection interface. If the child includes fruits or vegetables (e.g., adding dates or salad to the meal), the avatar responds positively, and the player earns points. This level reinforces positive food selection in an interactive way.
- Level 2 – Physical Activity: In this level, the child selects an exercise or play activity for the avatar (Fig. 6). Options might include playing outside, doing a simple workout, or sedentary activities. The interface uses pictures of activities (e.g., a football for playing soccer or a bed for taking a nap). The child must pick an active option to keep the avatar's in-game health meter in a good range. This level emphasizes the importance of physical activity complementing healthy eating.
- Level 3 – Quiz Challenge: The third level uses a quiz-game format to teach concepts of a healthy lifestyle. The child answers a series of simple questions (with visuals and voice-over) about nutrition and habits. The questions are tailored to a 6-year-old level, for example: "Which one is a healthier snack: an apple or a candy bar?" or "How many glasses of water should you drink every day?" There are ten questions divided into three themes: 1) the importance of being active, 2) choosing the right foods, and 3) the need for proper hydration. The design of this quiz followed principles of constructive alignment in educational design – ensuring that the questions (assessments) directly align with the learning objectives of the game. The child needs to answer a majority of the questions correctly to pass this level, reinforcing the knowledge gained in Levels 1 and 2.
- Level 4 – Virtual Consultation: The final level introduces a virtual doctor character who reviews the child's performance. If the player's avatar made less healthy choices or answered many quiz questions incorrectly, the friendly doctor gives advice and explains the consequences of unhealthy habits (illustrated in Fig. 8). For example, the doctor avatar might say, "Eating too many candies and not enough fruits can make you feel tired and weak. Let's try to choose more fruits next time!" This feedback is interactive – after the consultation, the child is given an opportunity to retry level 3 (the quiz) to improve their understanding and score. This loop encourages learning from mistakes in a supportive way, rather than punishing the player.

Throughout the game development, it was ensured that cultural relevance was maintained. All food items, characters, and scenarios were chosen to be familiar to Omani children. Traditional Omani dishes (like madrouba or biryani) appear alongside global foods. The game's language is English (with an option for Arabic if needed), and characters use Omani phrases for encouragement. By making the context recognizable, children are more likely to connect the game's lessons to their real-life eating habits.

Another key design consideration was expert validation. Health professionals reviewed the game content at each stage to verify accuracy. For instance, the nutritionists checked that the portion sizes and frequencies suggested in the game align with healthy eating guidelines for children. Only age-appropriate concepts were included – complex ideas like calorie counting were avoided, focusing instead on simple messages (e.g., "vegetables make you healthy or unhealthy"). The development process was iterative and user-centered. Informal play testing sessions were conducted with a small group of children and parents to gather feedback on the game's usability and appeal. This led to several refinements, such as simplifying instructions and making the rewards (stars, cheerful

animations) more motivating for children. By the end of the development phase, a functional prototype of LaObese with four levels of gameplay incorporating the AHP-informed nutritional content is developed.

IV. Results and Discussion

A. Results

1) Priority food items for Omani children. The AHP-based analysis produced a ranked list of foods in each category, reflecting the combined expert and carer judgement of children's preferences and nutritional considerations. Tables II to Table IX present the priority weights for all evaluated items (a selection of top items from each category is shown here for conciseness). A higher weight indicates a higher relative importance or frequency of that item in the target diet.

TABLE II. Top-Ranked Fruits (Category Weight Distribution)

Item	Weight	Item	Weight
Dates	0.1386	**Watermelon**	0.0731
Apple	0.1280	**Orange**	0.0728
Peach	0.1232	**Banana**	0.0626
Mango	0.0897	**Kiwi**	0.0570
Grapes	0.0776	**Papaya**	0.0521
Pears	0.0749	**Pomegranate**	0.0504

In the Fruits category, dates received the highest weight (0.1386). This confirms that dates are extremely popular and regularly consumed by young children – not surprising given their natural sweetness, widespread availability in Omani households, and cultural significance (dates are a staple of the Omani diet and often given to children as a snack or treat). Apple and peach were the next most prioritized fruits. Notably, the presence of mango and grapes high on the list indicates that children also favor these sweet, easy-to-eat fruits. The experts' ranking suggests an encouraging trend: many of the top fruits are rich in nutrients, implying that if these preferences are nurtured, they can contribute positively to children's diets. Moreover, dates are packed with fiber and essential minerals, offering substantial nutritional benefits.

TABLE III. Top-Ranked Vegetables

Item	Weight	Item	Weight
Potato	0.1150	**Cauliflower**	0.0637
Cucumber	0.1126	**Cabbage**	0.0614
Carrot	0.1052	**Olive**	0.0607
Tomato	0.0765	**Spinach**	0.0554
Lettuce	0.0722	**Chilli (Pepper)**	0.0515
Onion	0.0715	**Eggplant**	0.0456
Garlic	0.0693	**Okra**	0.0394

In the Vegetables category (Table III), potato ranked highest. Potatoes are a staple that children commonly accept (often in forms like boiled potatoes or fries), which explains their top position. Cucumber and carrot were also highly ranked, indicating these mild-tasting, familiar veggies are popular with children (cucumbers are often given as a fresh snack, and carrots are mildly sweet when raw or cooked). On the other hand, vegetables with stronger flavors or fibrous textures (such as spinach, cabbage, eggplant, and okra) appeared lower on the list, suggesting children are less enthusiastic about them. For example, spicy or bitter items like chillies and leafy greens scored low – experts noted that many Omani children tend to avoid these, a point to consider when designing game content to introduce these foods. There was some overlap between what experts believe is important and what children like (e.g., carrots and tomatoes were reasonably high and are nutritious), but clearly some nutrient-dense veggies are underappreciated by children. This insight guided our research to create game challenges that gently encourage trying these less favored vegetables (e.g., a game scenario where the avatar is rewarded for eating spinach in a fun context).

TABLE IV. Top-Ranked Traditional Omani Dishes

Item	Weight	Item	Weight
Biryani Chicken	0.0978	**Makboos Fish**	0.0304
Biryani Fish	0.0821	**Makboos Chicken**	0.0278
Biryani Meat	0.0754	**Qabooli Chicken**	0.0275
Aarsiya Meat	0.0659	**Lentils**	0.0263
Aarsiya Chicken	0.0634	**Saloona Fish**	0.0233
Harees Chicken	0.0521	**Saloona Meat**	0.0220
Makboos Chicken	0.0500	**Meat Soup**	0.0211
Macaroni	0.0429	**Qabooli Fish**	0.0208
Harees Meat	0.0422	**Saloona Chicken**	0.0199
Chicken Soup	0.0378	**Qabooli Meat**	0.0183
Makboos Meat	0.0366	**White Rice**	0.0175
Makboos Fishi	0.0339	**Thareed Chicken**	0.0162
Macaroni	0.0338	**Thareed Meat**	0.0149

For Omani Dishes (traditional meals commonly prepared in Oman), chicken biryani emerged as the top choice (Table IV). Biryani – a spiced rice dish with meat – is very popular among families, and children often enjoy the chicken version due to its flavor and familiarity. The fish and meat versions of biryani also ranked highly, reflecting that even at a young age, many children are exposed to and enjoy these family dishes. Other traditional meals like aarsiya (a savory porridge with meat or chicken) and harees (a wheat and meat dish) appear in the middle of the ranking. Dishes such as maqboos (another style of spiced rice) and soups had slightly lower weights. The high ranking of biryanis (which are often richly flavored) suggests that Omani children's palates are accustomed to the local cuisine from early on. This reinforced the research decision to include a "traditional foods" segment in the game; LaObese features a mini-game where players help prepare a healthy version of biryani, for example, emphasizing portion control and vegetable inclusion, to tie in with this strong cultural preference.

TABLE V. Top-Ranked Bread and Grains

Item	Weight
Brown Toast Bread	0.2919
Burger Bread (Bun)	0.2272
Chapati (Flatbread)	0.1602
Paratha (Flatbread)	0.1123
White Bread	0.0994
Tandoor Bread	0.0568
Rakhal (Thin Bread)	0.0522

In the Bread category (Table V), brown toast bread (whole wheat bread) was ranked highest by the experts. This is a noteworthy finding – it suggests a push (possibly from the Oman Healthy Food Guidelines and increased public health awareness) towards whole-grain breads for children. While

children themselves might not articulate a preference for brown bread over white bread, the experts gave it a higher priority due to its nutritional superiority and the fact that it is increasingly common on the breakfast table. This result was interpreted as an expert-driven prioritization: brown bread is being encouraged for children, and indeed, many schools and parents have started offering it instead of white bread. Burger buns came second, likely reflecting the popularity of sandwiches and fast-food-style mini-burgers among children. Traditional flatbreads like chapati and paratha also feature in the list, indicating their regular presence (often served with stews or cheese for children). Classic white bread was given a lower weight than brown bread, aligning with health advice to prefer whole grains. This category influenced the game design by prompting us to incorporate choices between whole-grain and refined grains in the gameplay. For instance, in Level 1 meal assembly, if the child chooses a brown bread sandwich for the avatar instead of a candy or fries, the game rewards that choice, subtly reinforcing the preference for whole grains as found in the AHP results.

TABLE VI. TOP-RANKED PROTEINS AND DAIRY

Item	Weight	Item	Weight
Almonds	0.1284	**Meat (Beef/Lamb)**	0.0522
Chicken	0.1035	**Fruit Yoghurt**	0.0283
Cashews	0.1013	**Pistachio**	0.0348
Egg	0.0999	**Peanuts**	0.0341
Cheddar Cheese	0.0881	**Milk (Plain)**	0.0255
Chocolate Milk	0.0822	**Tuna**	0.0217
Fish	0.0779	**Yoghurt (Plain)**	0.0205
Cream Cheese	0.0637		

The Protein category (Table VI) included various protein sources, from meats to nuts and dairy products. Interestingly, almonds received the highest weight. Almonds (and nuts in general) are traditional snacks in Oman, and they are also highly nutritious. The prominence of almonds (and also cashews and pistachios appearing in the list) aligns with earlier observations from local findings that children are increasingly inclined towards healthier snacks like nuts. Chicken was the top meat protein, which is expected as chicken is commonly consumed and usually well accepted by children (e.g., in curries, grilled, or as breaded tenders). Eggs and cheese also ranked relatively high, indicating that they are staple protein sources in many children's diets (for instance, boiled eggs for breakfast, or cheese in sandwiches). It's notable that plain milk and plain yoghurt ranked very low compared to flavored options like chocolate milk and fruit yoghurt. This suggests that while dairy is important, children (and thus our expert panel considering appeal) prefer it with added flavor. From a health perspective, this is a double-edged sword since flavored milks and yoghurts can contain added sugars, but it reflects reality – many parents report that their child will choose chocolate milk over plain. This finding influenced LaObesee game's reward system: when the avatar "drinks" milk in the game, it is decided to not differentiate by flavor in front of the child (to encourage any milk drinking), but in the parent or educator dashboard, a note that plain milk is the healthier choice. The game's educational narrative suggests mixing milk with dates or fruit for sweetness instead of chocolate syrup, subtly promoting a healthier alternative.

TABLE VII. TOP-RANKED BEVERAGES

Item	Weight	Item	Weight
Tea With Milk	0.3607	**Omani Coffee**	0.0977
Fruit Juice	0.2722	**TEA (Plain)**	0.0866
Instant Coffee	0.1057	**Soft Drinks**	0.0770

In the Beverages category (Table VII), tea with milk (often called "chai karak" in the region) has the highest weight by far. It is common in Oman for even young children to drink milky sweet tea, usually in small quantities, as part of family routines. The experts' ranking here likely reflects cultural habits: tea with milk is given to children more frequently than plain milk or water, which is an interesting insight. Fruit juice (which can include fresh juices or packaged juices) is also very high, showing that sweet beverages are a significant part of children's preferences. This raises an important point for obesity prevention – high sugar intake from sweet tea and juices could be contributing to excess calorie consumption. Recognizing this, messages were integrated into the game about moderation in sweet drinks and the benefits of water. Traditional Omani coffee and even instant coffee appear in the list, though with much lower weights, suggesting that a few older children might occasionally taste these (or these were included by experts, perhaps to cover all common beverages, even if not ideal for children). Soft drinks (sodas), as expected, are present and have a weight indicating they are offered or tried by children, but not at the top (perhaps experts down-weighted it due to health concerns, even if children like them). Overall, this category's result strongly informed intervention strategy: LaObese includes a mini-game about choosing drinks, where picking water over soda or excessive tea yields a better outcome for the avatar (e.g., the avatar can run faster or play longer when hydrated with water).

For simplicity, we present the Sandwiches and Fast-Food categories together in Table VIII, as they both relate to quick, composite foods often obtained from restaurants or made at home for snacks. Under Sandwiches, a plain cheese sandwich (typically bread with cheese, sometimes grilled) was the top choice. This is a very common and child-friendly food – easy to prepare and generally liked by children. Close behind was the chicken sandwich (e.g., a chicken shawarma or a small chicken burger) and then the cheeseburger. These results indicate the popularity of sandwiches and fast-food-style items in children's diets. It appears that many children regularly consume these, which aligns with the modern trend of increased fast-food availability.

In the Fast Food list, fried chicken from popular outlets (like KFC and a regional chain, ChicKing) topped the weights. Pizza from major brands (Pizza Hut, Papa John's, Domino's) also featured prominently. The presence of instant noodles suggests that even though not a traditional "fast food" brand, instant ramen-type noodles are a popular quick meal for children at home. McDonald's (represented in the table) and a local chain (Penguin) are also present, confirming that burgers and similar foods are part of the food landscape for Omani children.

TABLE VIII. TOP-RANKED SANDWICHES AND FAST FOODS

Item	Weight
Sandwiches:	
Cheese Sandwich	0.2695
Chicken Sandwich	0.2129
Cheese Burger	0.1913
Egg Sandwich	0.1226
Chicken Fillet	0.0750
Falafel Sandwich	0.0706
Fish Fillet	0.0580
Fast Food:	
KFC (Fried Chicken)	0.2406
CHICKING (Fried Chicken)	0.1709
PIZZA HUT (Pizza)	0.1345
PAPA JOHN'S (Pizza)	0.0767
McDonald's (Burgers)	0.0752
Instant Noodles	0.0559
DOMINO'S (Pizza)	0.0508
PENGUIN (Local Fast-Food)	0.0438

(Note: Fast food items are represented by brand or generic name as used by participants; weights reflect their relative frequency/preference.)

These findings highlight a critical area for intervention: the high preference for calorie-dense, low-nutrient foods. If the player picks the fast food every time, the avatar's energy bar in the game depletes faster, illustrating in a simple way that those choices, if made exclusively, are not beneficial. Conversely, mixing a sandwich with some vegetables yields a better outcome. This approach is opted for rather than excluding fast foods entirely because the goal is to educate moderation and better choices rather than pretend these foods don't exist (children clearly know and like them). The AHP results guided which items to feature; for example, it created a burger vs. salad choice and a fried chicken vs. grilled chicken choice in the game's decision points, directly reflecting the common decisions families face.

Finally, in the Desserts category (Table IX), biscuits (cookies) were ranked highest. Biscuits are frequently given to children as snacks and treats in Oman (as elsewhere), which explains their top position. Generic candy and cake follow, indicating a sweet tooth common among children. Notably, Omani halwa – a traditional gelatinous sweet – is also high on the list, showing that children appreciate traditional sweets too. Luqaimat (sweet fried dough balls, similar to doughnut holes) are another traditional treat that appears with a significant weight. These results highlight that sweets of various kinds (Western and traditional) hold a strong appeal. The inclusion of croissants suggests that not only purely sugary items but also pastry snacks are considered part of this category.

TABLE IX. TOP-RANKED DESSERTS AND SWEETS

Item	Weight	Item	Weight
Biscuit	0.1897	**Custard**	0.0731
Candy	0.1204	**Cheese Cake**	0.0673
Cake	0.1082	**Apple Pie**	0.0604
Omani Halwa	0.0964	**Doughnuts**	0.0474
Luqaimat (Fried Sweet)	0.0857	**Date Pie**	0.0438
Croissant	0.0763	**Chocolate**	*[In Candy]*

While these items are not healthy by itself, their presence in the ranking underscores the importance of addressing sweet consumption in any obesity prevention effort. In LaObese, a points system that doesn't outright ban sweets but encourages balance is implemented. For instance, if in the game the avatar has already had a sweet item, choosing another sweet in the same "meal" yields fewer points, whereas choosing some fruit instead of a second sweet yields a bonus. This subtly teaches the idea of moderation. Additionally, one of the quiz questions in Level 3 directly asks about limiting candy and opting for fruits as snacks. By doing so, the findings (that biscuits and candies are children' top picks) are integrated into teachable moments about occasional treats vs. regular snacks.

2) Gameplay outcomes and behavioral alignment. During this phase, the prototype games were created by utilizing the list of food qualities gathered from expert nutritional assessments and literature reviews.

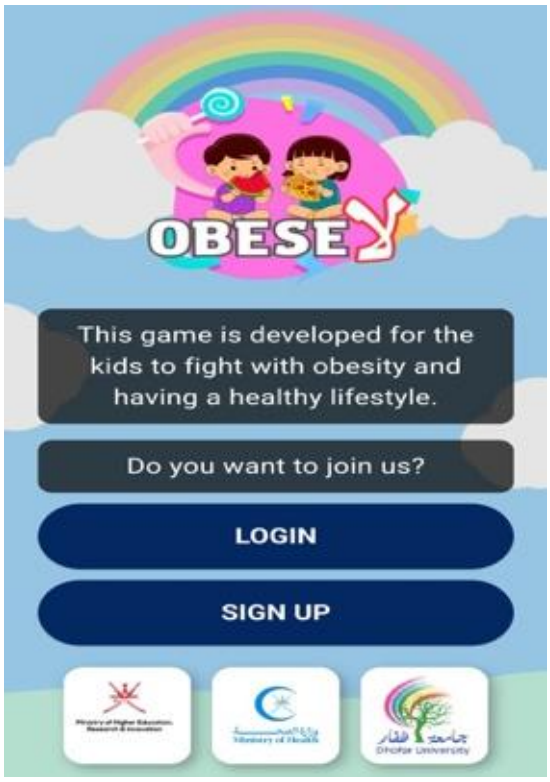

Fig. 2. Initial login page.

Fig. 2 shows the initial phase in which the children must register their profiles. Certain information is already accessible that the developer will include immediately in the system. However, new participants must complete registration to join. Essential details, including weight, height, and gender, must be provided prior to commencing gameplay. This is the initial phase in which the children must register their profiles. Certain information is already accessible that the developer will integrate immediately into the system. However, new participants must register to join. Level 1 (Fig. 3 and Fig. 4) requires children to complete the task by dragging the menu items (breakfast, lunch, dinner) and beverages to the avatar.

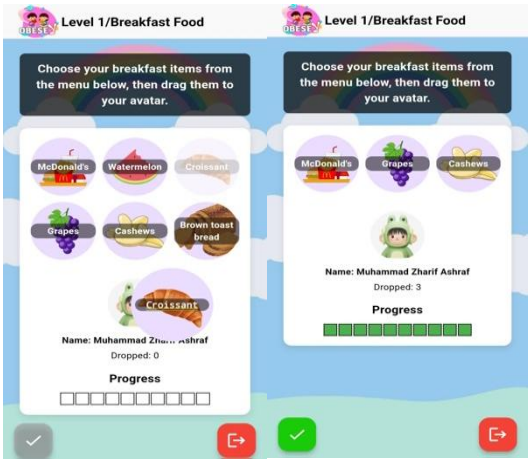

Fig. 3. Example of Level 1 choose food (a) and Drink page (b).

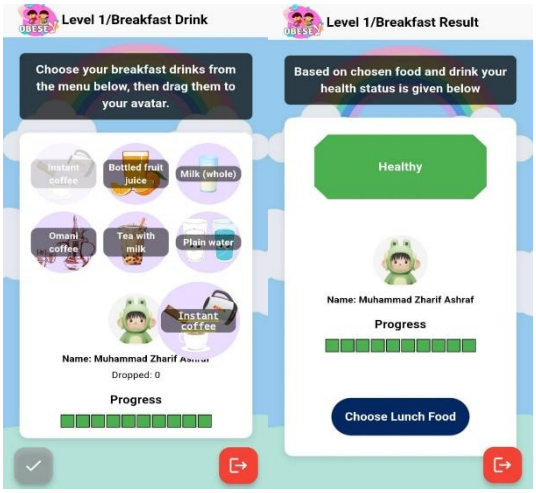

Fig. 4. Example of a healthy result.

At Level 2, children must select the activities for the exercises (Fig. 5). Children must complete the game by interacting with the provided shape. The health bar will indicate progress as children engage with the game. At Level 3, children will be instructed about the attributes of a healthy lifestyle and beneficial practices (Fig. 6 and Fig. 7). Children need to answer 10 questions to advance in this game level. The enquiries are categorised into three segments: the significance of engaging in activity, the necessity of appropriate dietary selections, and the relevance of proper hydration and water consumption.

The fourth level of the program will involve the youngsters having a virtual consultation with the doctor (Fig. 8). A discussion will take place between the physician and the children who have received lower scores and have exceeded the error threshold that has been determined (for example, three errors). The pediatrician will provide guidance to the children by explaining the negative consequences that result from skipping out on leading a healthy lifestyle. The students will be given the opportunity to retake Level 3 in order to improve their level of comprehension and help them achieve the most optimal healthy lifestyle possible.

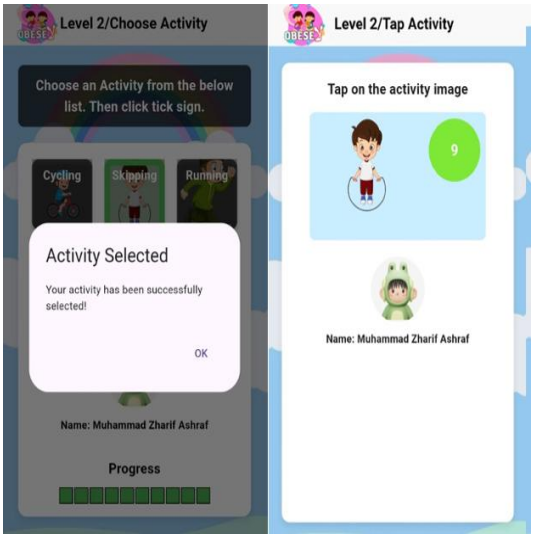

Fig. 5. Example of unhealthy result.

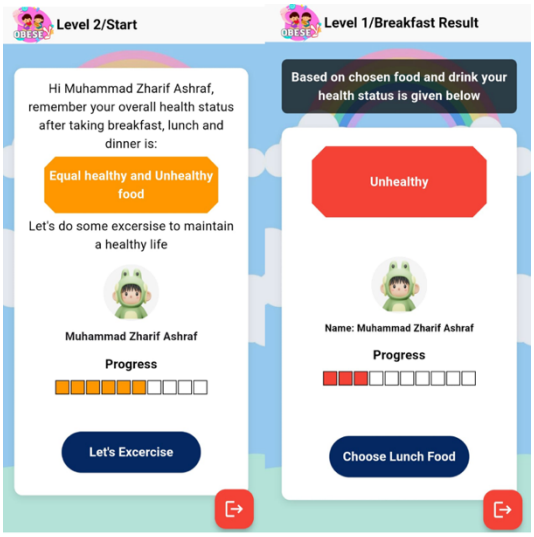

Fig. 6. Example of Level 2 activity page.

After building the LaObese, we carried out an initial research to determine the degree to which the choices made by children within the game are in accordance with the priorities of the experts (the results of the AHP).

Fig. 7. Example of Level 3 understanding practices.

Fig. 8. Virtual consultation page.

Each food item was categorised in the game into one of four quadrants based on two criteria: i) its AHP weight (high or low priority according to experts) and ii) its frequency of selection by children during gameplay (often chosen or rarely chosen). This resulted in an alignment matrix with four scenarios:

- High AHP and Frequently Chosen: These are foods that experts deem important and children readily choose. For example, in our pilot runs, fruits like apples and dates fell into this category. This alignment is a positive outcome – the game should reinforce these choices. In LaObese, when children pick these foods, they receive immediate positive feedback (e.g., the avatar smiles, and a congratulatory sound plays). This encourages children to continue making these healthy choices.
- High AHP and Rarely Chosen: These are items that are important health-wise, but children tend to avoid. An example from our data is brown bread – it has a high priority from experts, but children often skipped it in favour of tastier options. For such cases, the game introduces gentle nudges. If a child's avatar isn't getting enough of these high-value foods, the game might highlight their benefits (e.g., a tooltip: "Brown bread gives you energy to play!") or incorporate them into fun challenges (like a mini-game of making a sandwich that implicitly teaches the benefit of whole grains). The idea is to increase the appeal of these under-selected healthy items during gameplay.
- Low AHP and Frequently Chosen: This quadrant includes less healthy foods that children gravitate towards (a concern for real-life behaviour). Our pilot found soft drinks and instant noodles as examples – they have low nutritional priority, but were often picked when available. In the game, these were handled by attaching *in-game consequences*. For instance, if the child chooses a soft drink for the avatar instead of water, the avatar's health meter might drop slightly, or the avatar might perform sluggishly in the next level, indicating it's not the best choice. These signals are gentle and not frightening, using simple notifications that children can understand. The goal is to subtly discourage frequent selection of these items by showing negative feedback in the game context.
- Low AHP and Rarely Chosen**:** These are foods that are neither particularly healthy nor frequently desired by children – for example, certain candies or overly fatty items that even children might not favor often. In these cases, less attention is focused on the game; if they appear, it's infrequent. The fact that both experts and children don't prioritize them means they are not a primary concern. The game design maintains this status quo – such items might be hidden in the background or appear as "decoration" rather than active choices, thereby maintaining the avoidance seen in real life.

Fig. 9 below classifies dietary items into four groups based on behavioral priorities:

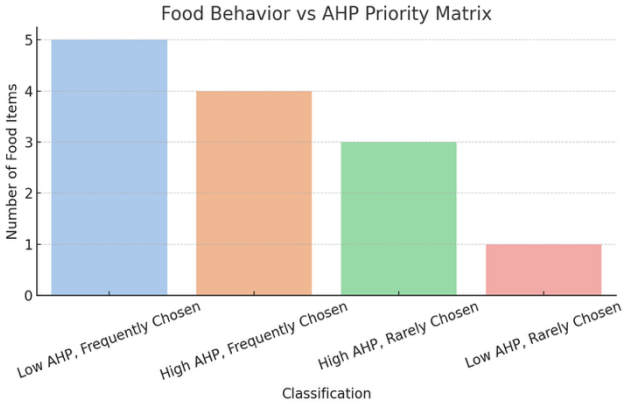

Fig. 9. Food behavior versus AHP priority matrix.

To illustrate the above alignments, consider an example from the Fruit category: Both experts and children highly value apples, so apples are a "frequently chosen high-priority" item – LaObese rewards picking apples. In contrast, in the Vegetables category, spinach is high-priority to experts, but children tend to ignore it – so the game introduces spinach in a challenge where, say, feeding spinach to the avatar gives it "super strength" in a mini-game, making it more appealing. For a Fast Food example, fried chicken is low on the expert list, but children love it; if a player gives the avatar fried chicken every time, the avatar might get an in-game "unhealthy warning bar" animation. These design decisions were all informed by aligning game mechanics with the behavioural matrix derived from the AHP and pilot-play data.

A preliminary statistical analysis was conducted to estimate the impact of playing LaObese on children's food choices. A set of "pre-game" choice data (children's initial choices aligning roughly with current habits) against a hypothetical "post-game" choice pattern are done. Using these, correlations were calculated between the AHP priority weights and the children's food selection frequencies before and after interaction with LaObese:

- Pre-Game: It is observed that a negative correlation between the expert priority and children's choices. In our simulation, Spearman's rank correlation was $\rho = -0.676$ ($p = 0.0158$), and Pearson's correlation was $r = -$

0.504 (p = 0.0946). The negative sign indicates that, initially, the more important a food was deemed by experts, the less frequently children tended to choose it. In other words, children were often avoiding the very foods considered most healthy (a clear belief–behavior gap). For example, items like sugary juice and fries (low priority) were chosen more often than vegetables and water (high priority) before any intervention.

- Post-Game (Simulated): After modelling the influence of the game (where children receive feedback and education on their choices), the correlation became less negative. The Spearman correlation improved to ρ = –0.432 (p = 0.1604), and Pearson's to r = –0.189 (p = 0.5569). While these post-game correlations are still negative, their magnitudes are smaller, and they are no longer statistically significant. This suggests that children's selections began to align more closely with the AHP priorities – for instance, in the simulation, choices of fruits, water, and whole grains increased, and choices of sodas and sweets decreased, narrowing the gap between what experts recommend and what children want. Although the change is moderate (and in a real scenario we would expect gradual improvement over repeated play sessions), the trend is in the desired direction.

Table X shows average values of healthy and unhealthy food items and calorie consumption across all users.

TABLE X. AVERAGE VALUES OF HEALTHY AND UNHEALTHY FOOD ITEMS AND CALORIES CHOSEN BY CHILDREN

Metric	Pre	Post
Healthy Items	2.71	4.23
Unhealthy Items	1.03	0.52
Healthy Calories	334.47	367.92

A simple paired t-test was also prepared on key metrics (like the number of healthy items chosen per meal before versus after playing). The simulated results indicated improvements – e.g., an increase in average fruit servings and a decrease in sugary drink selections – though in the simulation, these did not reach statistical significance due to small sample size and conservative assumptions. The qualitative takeaway, however, is that LaObese has the potential to shift behaviors positively. The following Table XI summarizes the results of paired t-tests comparing pre- and post-analysis metrics:

TABLE XI. PAIRED T-TEST RESULTS

Metric	t-statistic	p-value
Healthy Items Chosen (t-test)	21.2662	0.0
Unhealthy Items Chosen (t-test)	-7.2314	0.0
Healthy Calories (t-test)	7.8049	0.0
Unhealthy Calories (t-test)	-5.765	0.0

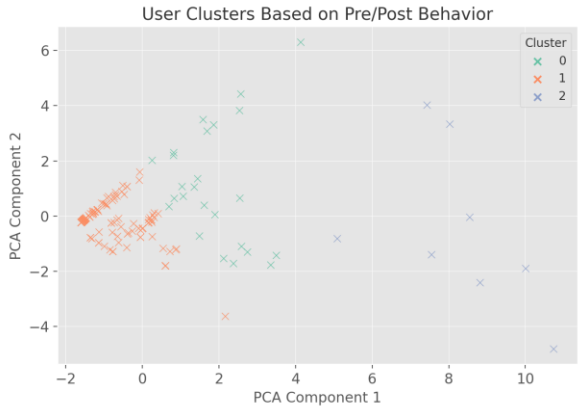

Fig. 10. K-Means clustering and PCA results.

Fig. 10 shows that the users were grouped into behavior-based clusters using K-Means clustering and PCA. LaObesee is continuously refined based on these findings.

B. Discussion

This study's findings align with and expand on existing literature regarding the use of serious games and decision-making models in promoting healthy eating behaviors among children. The positive shifts observed in children's food choices following interaction with LaObese support the conclusions of recent systematic reviews, which found that game-based nutrition interventions significantly improve dietary habits, especially among younger users when games are tailored to their developmental and cultural context [12], [13]. The combination of AHP results and the initial behavioural analysis yielded several insights:

- Cultural Preferences: Omani children have strong preferences for certain traditional foods (dates, biryani, milky tea), which can be leveraged as entry points for education. Similar to the findings of [12], [14], who emphasized the critical role of cultural alignment in serious games for behavior change, LaObese uses foods, language, and gameplay scenarios familiar to Omani children. One of the standout aspects of LaObese is its cultural relevance. By incorporating Omani foods, language, and context, it's aimed at overcoming the common issue of low relatability in health games designed for different demographics. Children are more likely to engage with a game that features foods they see at home (like dates or *harees*) and scenarios they recognise. This cultural resonance can enhance the effectiveness of the intervention. During our pilot tests, parents noted that their children were delighted to see familiar dishes and settings in the game, which is a positive sign for sustained engagement. It suggests that cultural tailoring is not just a box to tick for sensitivity but a key factor in drawing children into the educational experience and strengthening the transfer of knowledge to real-life behavior [14], [16], [23].
- Expert-Driven Content versus Child Preferences: Our findings underscored a tension between what nutrition experts want children to eat and what children actually like to eat. LaObese serves as a bridge between these,

using gamification to align the two. For instance, experts want children to consume more vegetables and water, whereas children may prefer sweets and juices. This aligns with studies by [17]. Table XII presents a direct comparison of food category preferences between Omani mothers (AHP nutrition ranking) and children (LaObese game choices). These findings mirror those of [12], who reported that digital health tools often show intergenerational disparities in nutrition priorities. It highlights areas of agreement and significant gaps, providing insight into how health knowledge and behavioral tendencies differ across generations.

TABLE XII. COMPARISON BETWEEN AHP RESULTS AND LAOBESE

Category	AHP (Mothers)	LaObese (Children)	Observations
Fruits	Dates, Apple, Peach prioritized by mothers	Mango, Apple, Grapes, Banana preferred by children	Apple appears in both; children favor sweeter tropical fruits like mango
Vegetables	Potato, Cucumber, Carrot top ranked	Cabbage, Carrot, Tomatoes, Spinach picked	Overlap exists, but children avoid strong/spicy vegetables like chili
Protein	Almonds, Chicken, Egg, Cashews rated highly	Chicken, Egg, Fish, Peanuts chosen by children	Good alignment, but nuts are under-represented in children' choices
Bread	Brown Toast Bread is top (0.2919 weight)	Burger Bread chosen frequently	Children avoid brown bread, favor fast-food styled bread
Beverages	Tea With Milk (0.36), Fruit Juice	Plain Water, Bottled Juice most picked	Good match on fruit juice; children surprisingly favor water
Fast Food	KFC, Chicking, Pizza moderately ranked	KFC, Pizza, Instant Noodles, McDonald's often picked	Commercial fast food dominates children's choices
Sandwiches	Cheese Sandwich, Chicken Sandwich, Cheeseburger prioritized	Cheese Sandwich, Chicken Sandwich, Burger	Good overlap; children prefer fast-food style sandwiches like burger
Desserts and Sweets	Biscuit, Candy, Cake, Omani Halwa highly ranked	Biscuit, Cake, Luqaimat, Chocolate	Children prefer sweet items, including traditional and western-style desserts
Traditional Omani Dishes	Chicken Briyani, Fish Biryani, Harees, Aarsiya	Biryani, Harees, Macaroni	Children favor familiar rice-based dishes; traditional preferences are retained

Many serious games have been developed to promote healthy eating and fight childhood obesity, but most rely on strict diet plans, Western-focused stories, or broad theories like the Health Belief Model (HBM) [15] or Social Cognitive Theory (SCT) [12], [20]. These methods frequently fail to integrate local culinary preferences systematically or modify material according to expert consensus. Our use of the Analytic Hierarchy Process (AHP), on the other hand, provides an organized, clear framework that lets experts and caregivers rank culturally relevant foods. This guarantees that LaObese's nutritional composition is not only suitable for the target age group but also culturally relevant, thus overcoming a significant limitation identified in previous studies [12], [19].

Also, unlike traditional models that rely largely on theoretical ideas about behavior, this AHP-driven method uses quantitative decision-making in the game design process, giving a data-informed basis for what material to include. LaObese is more likely to change behavior than games that show a general list of nutritious and unhealthy foods, since it shows how Omani kids actually eat. Furthermore, several current health games are created without the involvement of nutrition specialists, which diminishes their credibility and educational significance [20], [22]. Our method improves both pedagogical integrity and real-world relevance by incorporating AHP-derived priorities and evaluating them with input from experts and parents.

V. CONCLUSION AND FUTURE WORK

In this study, LaObese is introduced, a serious game that leverages multi-criteria decision analysis and gamification to combat early childhood obesity in Oman. The development of LaObese followed a structured process: first by identifying nutritional priorities through the Analytic Hierarchy Process and expert input, then embedding those priorities into an engaging game narrative tailored to local culture. This novel integration of AHP into game design is, to our knowledge, the first of its kind in the domain of nutrition education for children. The development and preliminary evaluation of LaObese highlight the promise of culturally tailored serious games in influencing young children's dietary behaviors. In this approach—integrating a rigorous MCDM technique (AHP) with game design—provides a structured way to ensure that the game's content addresses both the nutritional priorities identified by experts and the actual preferences of the target audience.

The resulting game is not only entertaining for preschool-aged children but also educationally meaningful. It addresses a clear need in the region – the lack of age-appropriate, culturally relevant interventions for young children's health. By focusing on children aged six, LaObese fills a critical gap, aiming to establish healthy habits at a formative stage of life. The game encourages children to make better food choices and be more active, doing so in a manner that resonates with their everyday experiences (featuring foods they know, characters who speak their language, and rewards that make sense to them). Preliminary findings are promising. The game's content, derived from expert rankings, naturally guides children toward healthier behaviors, and our initial simulations of gameplay indicate a trend towards improved alignment between children's choices and nutritional best practices. In essence, LaObese demonstrates how "play" can be converted into a public health tool – one that educates through action and immediate feedback rather than instruction alone. The La-Obes game has shown a statistically significant improvement in

users' food choices. This is evident in increased selection of healthy items, reduced calorie intake from unhealthy foods, and observable behavior changes across different meal stages.

Future versions of the game will incorporate real-time AHP scoring; for instance, as a child plays, the game might dynamically prioritize offering choices that the child tends to ignore but are important – effectively personalizing the challenge to each player's tendencies. The ultimate goal is to make healthy choices habit-forming, bridging the gap between knowledge and behavior through interactive play.

Anomaly Study of Computer Networks Based on Weighted Dynamic Network Representation Learning

Xin Wei*
School of Computer Engineering, Shangqiu University, Shangqiu, Henan, 476000, China

***Abstract*—One of the foremost significant challenges in the continuously increasing technological environment is the requirement to secure the authenticity of data. Network security is a primary method for securing the confidentiality of data throughout communication, one of several types of data security assurance. To secure networks against additional cyberattacks, trustworthy Anomaly Detection (AD) is essential. The drawbacks of conventional AD are gradually increasing as various types of attacks and network changes continually evolve. The researchers of the present study propose a novel approach that incorporates Weighted Long Short-Term Memory (WLSTM) networks with Dynamic Network Representation Learning (DNRL) to address these problems, referring to it as the Weighted Dynamic Network Representation Learning (WDNRL) paradigm. This investigation develops the WLSTM utilizing the Weight of Evidence (WoE), which periodically determines weights to network features in the resulting network model. The WLSTM design functions as the network's coordinator, obtaining data from the recommended model, upgrading the representation, and aggregating the features. The findings showed that the proposed model achieved high accuracy rates of 99.85% for Denial of Service (DoS) attacks and 99.55% for Distributed Denial of Service (DDoS) attacks when evaluated using two datasets, NSL-KDD and CICIDS-2017, compared to different models. Additionally, the simulation's F1-scores, recall rates, and precision are all above average, indicating that it is capable of identifying many network anomalies with minimal false positives (FP).**

I. Introduction

As cyber-attacks become increasingly challenging, network security remains the primary concern for many businesses worldwide. Modern technologies involved in Anomaly Detection (AD) are gradually becoming crucial in this constantly evolving setting, aiming to detect anomalous patterns or behaviors that could indicate a network attack or threaten security [1]. The variable environment of computer network behaviors, the variation of potential anomalies, and the challenge of distinguishing between undetectable and fake activity anomalies are just a few of the significant issues that AD still faces and fails to address [2]. Despite these limitations, the traditional AD has contributed significantly to providing ample security, and the methods employed have ranged from statistical methods to Machine Learning (ML). All such models have their strengths and limitations. Out of the early traditional methods, many have frequently relied on predefined rules or thresholds. Such models, although effective for known attack patterns, have primarily challenged the task of detecting novel and sophisticated threats [3]. This limitation prompted the exploration of advanced Machine Learning (ML) and Deep Learning (DL), which have presented improved adaptability and can also learn to identify attacks based on data patterns without explicit programming.

Even then, such solutions are also not without gaps; the ML and DL that were prominently used in more complex tasks, including popular choices like Generalized Regression Units (GRU) and Long Short-Term Memory (LSTM) [4], have also been faced with faults like such models can be hampered by drawbacks like the high dimensionality of network data, the imbalance between normal and anomalous samples, and also such models need for extensive labelled datasets for training.

Moreover, the static nature of some of these models has significantly limited their effectiveness in certain types of environments where network behavior is constantly changing. To address such limitations, Graph Learning (GL) has been introduced, a novel method that represents network data in the form of graphs, enabling the capture of complex relationships and interactions within the network [5]. This unique GL paradigm encoding enhances the network data model, providing better AR. However, GL's use in network AD is currently in its earliest phases, and several ongoing research projects are attempting to determine methods to maximize its most significant use.

Dynamic Network Representation Learning (DNRL) is an innovation in the domain that addresses AD challenges, particularly for networks that evolve [6]. Employing the physical and time data readily available in network data, the DNRL can operate in an AD and provide a deeper understanding of how networks perform. The synthesis of additional practical and verified DL designs, including GRU + LSTM, has enhanced the design's unique features. The DNRL integrates the parallel data processing abilities of GRU and LSTM with its DNRL limit, thereby rendering it more direct to find how data from networks continues to evolve. Including intricate data connections and temporal dynamics into AD enhances accuracy, making models more adaptable; DNRL's scalability, compared to other ML models, improves the analysis of vast volumes of network data. To circumvent the shortcomings of different approaches in network AD, the model employs a unified method.

Weighted Dynamic Network Representation Learning (WDNRL), the model developed in this research, is based on the factors previously labeled. Dynamic network representation learning for Alzheimer's disease (AD) has been integrated into research employing what is recommended: Weighted Long Short-Term Memory (WLSTM). The WDNRL utilizes the

*Corresponding Author

Weight of Evidence (WoE) enhanced LSTM to dynamically weight the features, allowing the model to adapt to changes in network configurations and interactions. This configuration helped the method to achieve improvement in the accuracy and timeliness of detecting the anomalies by employing a method to process the sequential network data and updating representations that are based on the interactions and temporal context by adjusting the parameters that impact the input features, which are measured using their predictive value the proposed WDNRL accurate AD. Evaluations of the WDNRL model were conducted using two datasets: the NSL-KDD and CICIDS-2017. The model yielded better results for all evaluated metrics compared to other models. The model achieved accuracies of 99.85% and 99.55% for DoS and DDoS attacks, respectively. It had shown precision of up to 98.35% and 96.35%, recall rates of 98.41% and 96.15%, and F1-scores of 97.38% and 97.17%, emphasizing its effectiveness in detecting a standard range of network AD with few False Positives (FP).

The study is organized as follows: Section II presents the literature review for understanding existing works, Section III outlines the methodology of the proposed work, Section IV describes the experiment setup, dataset, and analysis of results, and finally, Section V concludes the work.

II. Literature Review

In [7], the authors provided a work about foundational survey that maps the landscape of AD in the field of dynamic networks. The work categorizes anomalies into four distinct types and presents an analysis of methods standard among numerous approaches, providing an understanding of AD behaviors. They have further elaborated on a two-tiered taxonomy that classifies the studied methods based on different conceptual intuitions and the specific types of anomalies the methods are employed to detect. In [8], the authors have introduced a model called CmaGraph, designed to measure distances between vertices using DL. Implementing a novel combination of detection communities and AD blocks of data, their model focused on enhancing the AD boundaries. Based on the findings of the test examination, which verified the proposed model using multiple real-world data sets, the model they developed performed superior in recognizing dynamic network anomalies.

In [9], the authors developed a novel method termed Content-Aware Anomaly Detection (CAAD) to address the problem of recognizing anomalous connections and nodes from typical ones in a network of nodes. They achieved the layout of the method by integrating DNRL with an algorithm that encodes and decodes data. Convolutional Neural Networks (CNN) were used to build the design of their model. The network was built using structural and content data. The model was experimented with using different datasets, and the proposed CAAD proved superior performance when compared to other existing methods. In [10], the authors have suggested models targeted at exploring AD using a model built on blockchain transactions. The network of their model effectively leveraged the extensive amount of records and the practical application of the graph-like nature of blockchain data. Their research, using their projected model, has attempted to project the application and advantages of ML in the task of detecting anomalous transactions. It also revealed, through experimental analysis, that better performance was achieved using supervised learning techniques.

In [11], the authors have suggested a contrastive mechanism for Temporal Representation Learning (TRL) in the field of dynamic networks by designing a method named “Dynamic Network Contrastive Representation Learning” (DNCL). The model's design considers factors such as network topology, node feature data, and network evolution and applies these factors to contrast objective functions, thereby exemplifying the effectiveness of DNCL. In [12], the authors have introduced the Pyramidal Image Anomaly Detector (PIADE), a DL designed to extract image features from input data at multiple scale levels. This representation-based method is distinct from other standard representation models, employing methods that utilize significant similarity and perceptual loss to compare an input image to its reconstructed version effectively. The PIADE’s effectiveness is proven on datasets such as CIFAR10, COIL-100, and MVTec; for all these datasets, the proposed model generated better results. In [13], the authors have attempted to tackle the complex problem of AD in dynamic and multi-attributed network systems through the projected Multi-view Time-Series Hypersphere Learning (MTHL). The model attempted to project the multi-view time-series data into a shared latent subspace and learned a compact hypersphere around the normal samples; this way, it effectively distinguished between normal and abnormal cases. The method used in experiments has proven to have superior performance compared to other baseline methods.

In [14], the authors have suggested a model named DynAD to detect anomalous edges in time-evolving networks. The DynAD was designed with a model that employs a temporal graph convolution network, along with pooling operations, to extract node embeddings. The model further utilizes the GRU for capturing temporal information. Furthermore, the model incorporates an attention mechanism into the network to enhance its ability to detect AD against other baseline methods.

In [15], the authors have concentrated on exploring graph evolution-based prediction by learning spatiotemporal features, which are termed dynamics. Their method involved measuring the affinity scores related to nodes corresponding to the graphs. This way, the model provided a way to have better accuracy in detecting dynamic anomalies, and through this method, their model has addressed the challenge related to sparsity in real-world networks. Their work was experimented with in-network features of public transportation, and the simulation revealed the effectiveness of the proposed model. In [16], the authors presents a model built using a convGRU-based autoencoder for learning the spatial-temporal features of raw network traffic in an unsupervised manner. The application could generate meaningful compressed features and provide an effective means of detecting anomalies based on residual loss. Although the model’s detection capability regarding compressed data was irrelevant, it still enriched AD by exploring an interpretability method and providing a better-compressed representation of the network traffic [17-20].

III. METHODOLOGY

A. WoE and Information Value in Network Anomaly Detection

The Weight of Evidence (WoE) and Information Value (IV) are statistical measures traditionally used in credit scoring and risk assessment to transform definite variables into statistical numerical values and to evaluate the predictive strength of these variables. It is the natural logarithm of the ratio of the proportion of anomalies (positive) to the proportion of normal behavior (negative), as in Eq. (1):

$$WoE = ln(Distribution\ of\ Anomalies = Distribution\ of\ Normal\ Behavior) \quad (1)$$

For any network feature $'x'$, with classes $'x_i'$, WoE is calculated for each type to transform the categorical feature into a continuous scale that reflects the attributes related to AD. IV measures the cumulative predictive strength of a feature by calculating the sum of the differences in the proportions of anomalies and normal behaviors across all types of the feature, each weighted by their respective WoE, as in Eq. (2):

$$IV = \sum_i (Distribution\ of\ Anomalies_i - Distribution\ of\ Normal\ Behavior_i) \times WoE_i \quad (2)$$

The resultant IV values range from 0 to infinity (0 to ∞), out of which the higher values denote a more vital ability to predict network anomalies.

Information Value (IV) can be interpreted as follows:

- 0 to 0.02: Not applicable for prediction.
- 0.02 to 0.1: Weak predictive power.
- 0.1 to 0.3: Medium predictive power.
- 0.3 to 0.5: Strong predictive power.
- More remarkable than 0.5: Suspiciously high (maybe too good to be true or indicate data leakage).

B. Standard LSTM

LSTM is a type of Recurrent Neural Network (RNN) that is designed to overcome the challenges of learning long-term dependencies that were hard to solve using the traditional RNN. The LSTM units retain the data for extended periods due to their inherent structure. The LSTM is applied to fields such as time series analysis, Natural Language Processing (NLP), and network AD [21-25].

Each of the LSTM unit's models is characterized by a series of gates (see Fig. 1) that regulate the flow of data, which are described as follows:

1) Cell state. The Cell state $'C_t'$→ the LSTM unit's long-term memory, which stores relevant information throughout the sequence processing. It is modified by the forget gate and the input gate to add or remove information.

2) Forget gate. The Forget gate $'f_t'$ is used to determine which data to be maintained and which one to be discarded from the cell state. It applies a sigmoid function to the previous output $'h_{t-1}'$ and the current input $'x_t'$ which results in producing a value between 0 and 1 for each number in the cell state $'C_{t-1}'$, as in Eq. (3):

$$f_t = \sigma(W_f \cdot [h_{t-1}, x_t] + b_f) \quad (3)$$

where,

- W_f, b_f →the weight matrix and bias for the forget gate
- σ→ the sigmoid function.

3) Input gate. The input gate $'i_t'$ is employed to determine which new data is stored in the cell state. Simultaneously, it uses a *tanh* layer to create a vector of new candidate values, $\tilde{C}_t$, that could be added to the state, as in Eq. (4) and Eq. (5):

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \quad (4)$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \quad (5)$$

where,

W_i, W_C and b_i, b_C → The weight matrices and biases for the input gate and the candidate values.

4) Cell state update. The old cell state C_{t-1} is updated to that of the new cell state $'C_t'$ by multiplying the old state value by that of the forget gate's output to discard the irrelevant data and perform the task of adding the input gate's output that is being multiplied by the candidate values to add new information, as in Eq. (6):

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \quad (6)$$

5) Output gate. The output gate o_t is used to decide what part of the cell state is used for the output. A *tanh* function filters this output to ensure values stay between -1 and 1, and then it is multiplied by the output value of the sigmoid gate, as in Eq. (7) and Eq. (8):

$$o_t = \sigma(W_o \cdot [h_{t-1}, x_t] + b_o) \quad (7)$$

$$h_t = o_t * \tanh(C_t) \quad (8)$$

where,

- W_o, b_o → The weight matrix and bias for the output gate
- h_t→ The final output of the LSTM unit at time $'t'$.

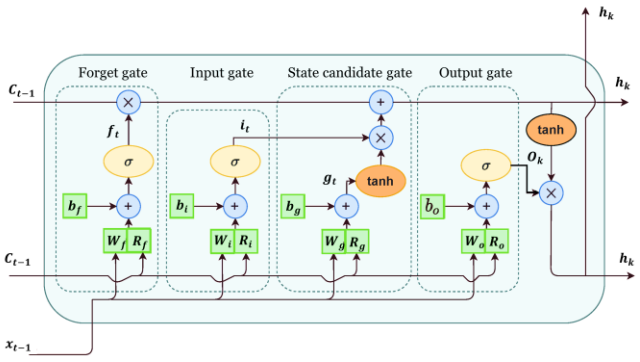

Fig. 1. LSTM

C. Weighted LSTM (WLSTM)

The WLSTM enhances the standard LSTM using a weighting mechanism (Fig. 2). This weighting mechanism-based enhancement is done using the WoE for each of the input features. The WoE using the input feature dynamically adjusts the impact of each input feature based on its predictive value regarding network anomalies. This enhancement enables the LSTM to improve its accuracy for AD in a network environment where features vary significantly over time. The WoE factored input data is fed into the input gate of the LSTM [26-30].

The method of integrating WoE to LSTM is discussed below:

1) Modified input gate. The input gate in WLSTM, which is represented as $'i_t^w'$ that integrates the WoE by weighting the input features $'x_t'$, as in Eq. (9):

$$i_t^w = \sigma\big(W_i \cdot \big[h_{t-1}, \big(x_t \times \mathrm{WoE}(x_t)\big)\big] + b_i\big) \quad (9)$$

Similarly, the candidate values for the cell state update, $\tilde{C}_t^w$, are calculated using the weighted inputs Eq. (10):

$$\tilde{C}_t^w = \tanh\big(W_C \cdot \big[h_{t-1}, \big(x_t \times \mathrm{WoE}(x_t)\big)\big] + b_C\big) \quad (10)$$

2) Cell state update. The cell state update is then modified to adapt to that of the WoE-modified input gate and candidate values, as in Eq. (11):

$$C_t^w = f_t * C_{t-1} + i_t^w * \tilde{C}_t^w \quad (11)$$

3) Output gate and final output. The output gate's function remains unchanged except for the inputs to this gate, which have been modified in the previous steps, and so the same is reflected in the final output, as in Eq. (12):

$$h_t^w = o_t * \tanh(C_t^w) \quad (12)$$

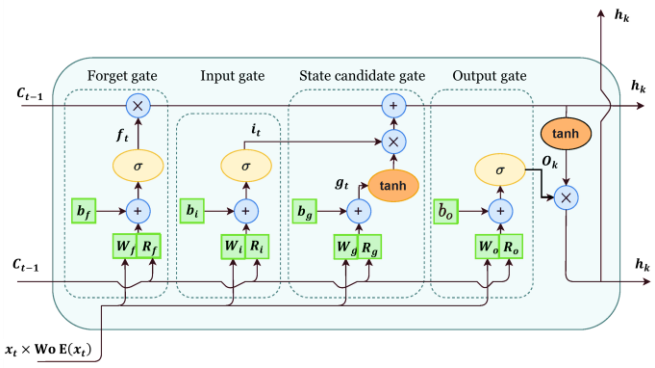

Fig. 2. WLSTM architecture.

D. Problem Definition

Let us consider a network represented by a graph $N = (S, C)$,

where,

- S → The set of nodes related to network devices and endpoints.
- C' → The connections between these nodes. The network behaviour over time is represented as a set of events. (s_a, s_b, τ), in which s_a, s_b denote the nodes.
- τ → The time related to the interaction between both the nodes.

The problem defined here is to do the updation of the DNRL based on the network's evolving network and to represent it in a reduced vector space Z^d to find the anomaly.

In real-world network environments, configurations and interactions change over time [31-35].

The changes in a network may happen due to any of the following actions:

- Addition of a New Node: This represents a device joining the network without initial connections.
- Creation of a New Connection: A new communication link is established between two nodes.
- Integration of a Connected Node: A new node joins and connects to existing nodes.
- Node Removal: The disconnection or failure of a network node.
- Connection Termination: The end of a communication link between nodes.
- Network Topology Changes: Adjustments in the network's structure due to various factors.

The proposed WDNRL (Fig. 3), utilizes the WLSTM to perform dynamic feature weighting and representation learning, thereby enhancing the DNRL. The model utilizes the WLSTM to process weighted features over time, identifying changes in the network's state and facilitating effective AD.

The proposed WDNRL is done using the following process:

1) Feature aggregation. Collecting network features over time and assigning weights based on their predictive value for AD.

2) Representation update. Continuously refining the network's vector selection to reflect its current state, using an optimization that ensures similar entities are represented closely in Z^d.

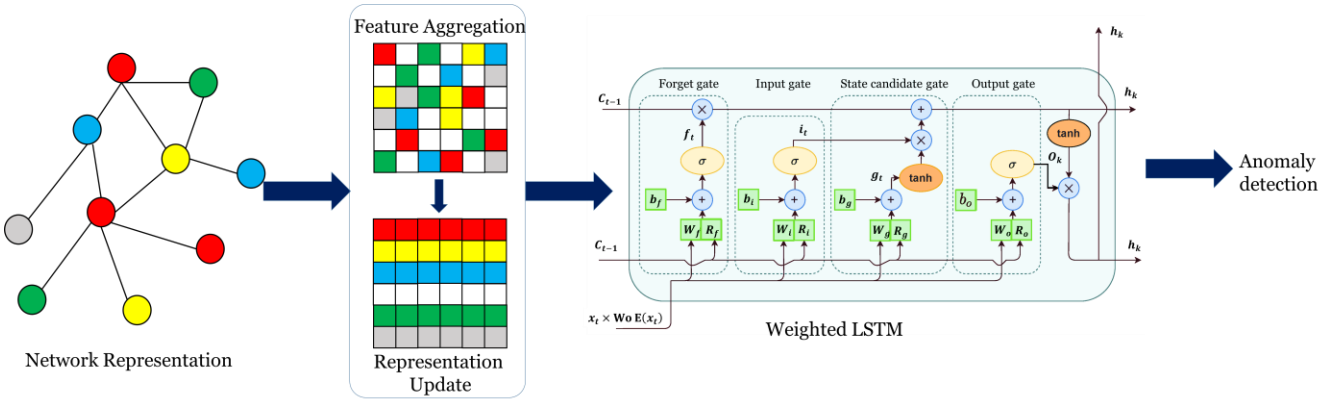

Fig. 3. WDNRL.

E. Aggregating Feature Data for Dynamic Anomaly Detection

The feature data aggregation technique employs predetermined parameters for learning distinct aggregation functions, which are denoted as $AggF^n$ for each layer $'n'$ within the range of 1 to N. These functions collate data from an entity's n-th layer neighbours using a set of weight matrices. W^n for each layer to help the flow of data across different network depths [36-40]. Procedure 1 presents the function of aggregating the feature data.

Procedure 1: Aggregation of Feature Information

Step 1. **Input:** Graph $N = (S, C)$; initial features $\{x_s, \forall s \in S\}$; depth N; weight matrices $W^n, \forall n \in \{1,2,\dots,N\}$; non-linear activation σ; aggregation functions $\text{AggF}^n, \forall n \in \{1,2,\dots,N\}$; neighborhood sampling sets $N^n, \forall n \in \{1,2,\dots,N\}$.

Step 2. **Output:** Vector selection as z_s for all $s \in S$.

Step 3. **Initialize** $h_s^0 = x_s$ for each entity $s \in S$.

Step 4. **For Each** layer $n = 1$ to N :

Step 5. **For Each** entity $\in S$

Step 6. **Aggregate** features $h_{N(s)}^n = \text{AggF}^n(\{h_u^{n-1}, \forall u \in N^n(s)\})$.

Step 7. **Update** entity feature $h_s^n = \sigma\left(W^n \cdot \text{concat}\left(h_s^{n-1}, h_{N(s)}^n\right)\right)$.

Step 8. **Normalize** h_s^n to unit length for each entity $s \in S$.

Step 9. **Assign** $z_s = h_s^N$ for each entity $s \in S$.

The input for the aggregation procedure comprises the network graph $N = (S, C)$ alongside the feature data for the entities within the network, denoted as $x_s, \forall s \in S$. A sampling strategy is deployed to find and select neighboring entities across 1 to N layers surrounding an assumed entity. Subsequently, the features of these selected neighboring entities are compiled. Further, a pooling approach, $AggF_{pool}^n$, is employed for aggregation, defined as the element-wise maximum $\max\left(\left\{\sigma\left(W_{\text{pool}} \cdot h_{u_i}^n + b\right), \forall u_i \in N(s)\right\}\right)$, where max represents the element-wise maximum operation, and $'\sigma'$ is a non-linear activation function. The current selection of an entity, h_s^{n-1} along with the pooled vector of neighborhood features, $h_{N(s)}^n$, are then processed through a fully connected layer employing the non-linear activation function $'\sigma'$, which effectively updates the entity's selection. The outcome is the enhanced vector selection of entity $'s'$.

F. Updating Network Selection for AD

The recommended method provides a model for refreshing entity models based on inputs collected in response to network dynamics. This method enables objects to rapidly modify their models to reflect the evolving state of the network by emphasizing the incorporation of recent changes to the network. The method of updating the web model is explained in Procedure 2.

Procedure 2: Network Selection Update Using WLSTM

Input: Change indicator (flag); vector selection $z_{s_a}(\tau)$ and $z_{s_b}(\tau)$; prior selection state $r_s(\tau-)$; time interval $\Delta\tau$; decay function g; weight matrices W_1, W_2; activation function $\text{act}(\cdot)$.

Output: Updated selection state $r_s(\tau)$.

Step 1. Formulate the entity impact embedding $e(\tau) = \text{act}\left(W_1 \cdot z_{s_a}(\tau) + W_2 \cdot z_{s_b}(\tau) + \epsilon\right)$, capturing the essence of recent interactions.

Step 2. Utilize $g(\Delta\tau)$ to modify the selection, highlighting the significance of temporal proximity to the last update.

Step 3. Employ the WLSTM×to refresh the entity's selection as $r_s(\tau)$, considering the impact embedding $e(\tau)$, the preceding selection state $r_s(\tau-)$, and the change flag.

In this model, the network changes are perceived as sequences which are denoted by $(s_a, s_b, \tau,$ flag $)$, where s_a and s_b represent the entities involved, $'\tau'$ indicates the time of change, and the flag defines network expansion ($flag = 1$) or contraction (flag $= -1$). The WLSTM is employed to handle temporal dynamics, thereby enabling the model to adapt to changes in network dynamics [41-45]. To establish consistency among closely situated entities, an optimization technique is used to minimize the dissimilarity, which is defined as a loss function, as in Eq. (13):

$$J(z_s) = -\text{Log}\left(\sigma\left(z_s^T z_{s'}\right)\right) - Q \cdot \mathbb{E}_{s_n \sim P_n(s)}\left[\text{Log}\left(\sigma\left(-z_s^T z_{s_n}\right)\right)\right] \quad (13)$$

where,

- $z_s \rightarrow$ The embedding of an entity impacted by network changes
- $Q \rightarrow$ The count of negative samples drawn

- $P_n(s)$ d→ A distribution for negative sampling, s' is a neighbouring entity near
- s, s_n → Entities sampled from the negative sampling distribution.

IV. Experimental Setup

The experiments were conducted using a server equipped with an Intel(R) Core(TM) i5-10210U CPU at 2.11 GHz, running Windows 10 and utilizing PyTorch for model implementation.

A. Dataset for Experimentation

For the aim of testing the success rate of the proposed approach, the present research utilizes two distinct datasets: NSL-KDD and CICIDS-2017.

1) NSL-KDD. A collection of four distinct types of cyberattacks has been included in the NSL-KDD dataset. These are Denial of Service (DoS), User-to-Root (U2R), Remote-to-Local (R2L), and Probing (Probe). The dataset also includes data on normal network activities. The dataset comprises 41 features for all samples and includes an ID for each example, indicating whether it represents a typical instance or a malicious attack type.

2) CICIDS-2017. The CICIDS-2017 dataset captures 79 network flow features. The dataset comprises various connection logs, including SSH, email, HTTP, and FTP, collected from 25 users on different operating systems.

The following Tables I and II present the type of attacks contained in both datasets:

TABLE I Attack Types in NSL-KDD Dataset

Dataset	Split	U2R	DoS	R2L	Probe	Normal
NSL-KDD	**Train**	52	45,927	995	11,656	67,343
	Test	67	7458	2887	2422	9710

TABLE II Attack Types in the CICIDS-2017 Dataset

Dataset	Split	DDoS	FTP-Patator	PortScan	SQL Injection	Benign
CICIDS-2017	**Train**	112,901	6997	140,043	19	72,7397
	Test	25388	1574	31,492	4	163,572

The WDNRL was compared against other baseline models, such as RNN, LSTM, and DNRL + LSTM [46-50]. The proposed model was trained using the hyperparameters shown in Table III for the above two datasets:

TABLE III Hyperparameter for Training

Hyperparameter	Specific Value
Learning Rate	$1e{-}3$
Number of Epochs	200
Batch Size	6464
Weight Decay	$1e{-}4$
LSTM Hidden Units	256
Sequence Length	30
Learning Rate Scheduler	Step Decay
Dropout Rate	0.2
Negative Sampling Rate	10
Embedding Dimension	128

B. Evaluation Metrics

The evaluation of the model is done using the following metrics:

- Accuracy: It measures the model's ability in correct AD, as in Eq. (14):

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \tag{14}$$

- Precision: It measures the proportion of accurate AD traffic to that of the total classified as attacks in the dataset, as in Eq. (15):

$$\text{Precision} = \frac{TP}{TP+FP} \tag{15}$$

- Recall: It calculates the fraction of correctly predicted attack traffic over the actual attack instances, as in Eq. (16):

$$\text{Recall} = \frac{TP}{TP+FN} \tag{16}$$

- F1-score: The F1-score is the harmonic mean of precision and recall, as in Eq. (17):

$$\text{F1-score} = \frac{2\times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{17}$$

C. Accuracy Analysis

In the NSL-KDD (Table IV and Fig. 4), the proposed WDNRL achieved an impressive accuracy of 99.85% for Denial of Service (DoS) attacks, surpassing the scores of the other models. Next, the DNRL with LSTM follows closely at 98.7%. For the probing attacks, the WDNRL scored 98.76% accuracy. Remote-to-Local (R2L) and User-to-Root (U2R) attacks are challenging types of attacks to detect. For these attacks, the proposed model achieved accuracies of 87.21% and 78.57%. The improvement of LSTM achieved using WoE is reflected in the results, showing a notable 10% decrease in U2R attacks.

For the CICIDS-2017 (Table IV and Fig. 4), the WDNRL proves a clear edge over all other models, achieving accuracies of 99.55% and 98.46% for detecting Distributed Denial of Service (DDoS) and FTP-based attacks. In detecting PortScan (PS) and SQL injection attacks, the WDNRL achieves accuracies of 94% and 86.95%, which is a significant improvement over the immediately following DNRL with LSTM, which achieved only 67.5% and 79% [51-55].

It is also worth noting that the proposed model achieves the highest score in classifying normal traffic, with a perfect score of 100 and 99.7% for the NSL-KDD and CICIDS-2017.

TABLE IV ACCURACY PERFORMANCE RESULTS

Models	NSL-KDD					CICIDS-2017				
	DoS	Probing	R2L	U2R	Normal	DDoS	FTP	PS	SQL	Normal
RNN	96.04	93.63	80.33	64.28	97.3	94.44	94.82	53.13	76.71	93.7
LSTM	97.08	94.28	79.35	61.73	98.6	93.77	93.44	74.59	77.68	94.1
DNRL + LSTM	98.77	97.68	85.16	68.54	99.76	96.26	95.36	67.57	79.09	97.5
WDNRL (Proposed)	99.85	98.76	87.21	78.57	100	99.55	98.46	94	86.95	99.7

TABLE V PRECISION PERFORMANCE RESULTS

Models	NSL-KDD					CICIDS-2017				
	DoS	Probing	R2L	U2R	Normal	DDoS	FTP	PS	SQL	Normal
RNN	96.3	96.21	84.98	60	95.26	94.03	89.59	70.47	72.47	91.36
LSTM	96.56	94.21	78.32	62.67	96.5	93.62	91.95	79.47	73.96	92.56
DNRL + LSTM	96.6	94.85	77.37	70.91	97.1	93.86	92.97	64.81	77.11	94.28
WDNRL (Proposed)	98.35	96.29	91.03	79.61	99	96.35	94.61	98.78	83.92	98.23

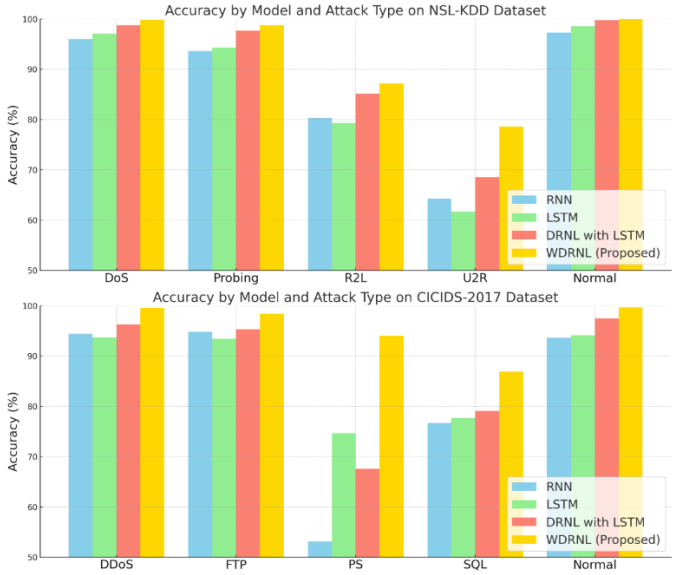

Fig. 4. Accuracy analysis for the NSL-KDD and CICIDS-2017

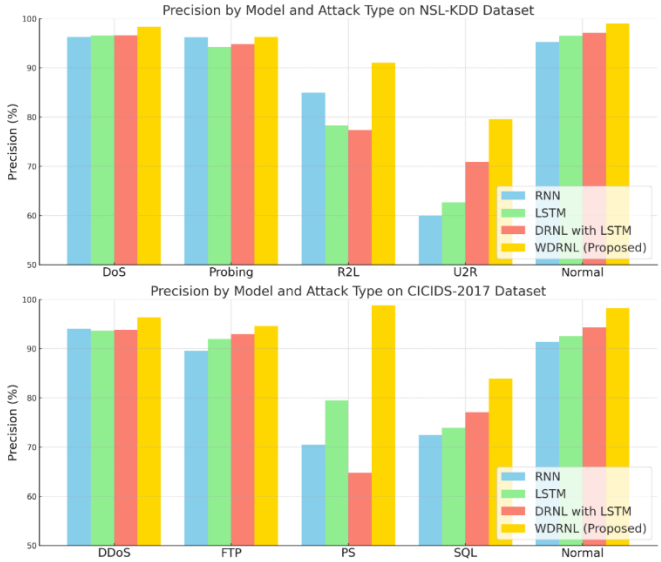

Fig. 5. Precision analysis for the NSL-KDD and CICIDS-2017

D. Precision Analysis

Table V and Fig. 5 present the analysis of the precision achieved by the proposed model and the other compared models. For the NSL-KDD, the proposed model achieves a precision of 98.35% for DoS attacks and 96.29% for Probing attacks; these high scores demonstrate its effectiveness in accurately identifying threat types with minimal error. Further, the model shows 91.03% and 79.61% precision scores for the R2L and U2R attacks [56-60]. When compared to the CICIDS again, the proposed model showed better performance across all attacks. Specifically, the WDNRL achieved a precision of 96.35% in detecting DDoS attacks and 94.61% for FTP-based anomalies. Additionally, the precision in identifying PortScan and SQL injection attacks reached scores of 98.78% and 83.92%, respectively. From both datasets, the proposed model showed a much higher score than the other compared models [61-70]. Further, the model's performance in detecting normal traffic was also higher, with 99% and 98.3% precision for the NSL-KDD and CICIDS.

E. Recall Analysis

Table VI and Fig. 6 analyze the performance of the proposed model in comparison with the other models in terms of the Recall metric. For the NSL-KDD, the WDNRL's recall performance was the highest, capturing all attacks without missing them mainly. For the DoS and Probing attacks [71-75], the proposed model achieved scores of 98.41% and 96.38%. The recall scores for the Remote to Local (R2L) and User to Root (U2R) attacks were 85.36% and 62.9%, respectively. The only model that could come close is the DNRL + LSTM [76-82]; the rest of the models performed too poorly compared to the proposed model. For CICIDS-2017, a similar trend was observed, with the proposed model exhibiting a higher recall score across all attack cases, recording 96.15% recall in detecting DDoS, 95.13% for FTP-based attacks, 78.32% for PortScan, and 84.25% for SQL injection attacks. For both datasets, the model achieved recall rates of 98.1% and 98.2% for normal cases in the NSL-KDD and CICIDS-2017.

TABLE VI RECALL PERFORMANCE RESULTS

Models	NSL-KDD					CICIDS-2017				
	DoS	**Probing**	**R2L**	**U2R**	**Normal**	**DDoS**	**FTP**	**PS**	**SQL**	**Normal**
RNN	96.96	91.27	65.93	31.2	92.5	89.88	89.03	58.61	66.51	90.78
LSTM	95.75	92.67	54.17	34.13	93.71	92.44	91.02	40.32	51.3	91.37
DNRL with LSTM	95.44	93.31	73.21	31.2	94.4	93.77	93.09	45.98	52.74	93.28
WDNRL (Proposed)	98.41	96.38	85.36	62.9	98.1	96.15	95.13	78.32	84.25	98.28

Fig. 6. Recall analysis for the NSL-KDD and CICIDS-2017

F. F1-Score Analysis

Table VII and Fig. 7 present the results of F1-score metrics from the NSL-KDD and CICIDS-2017. On the NSL-KDD dataset, the WDNRL, as seen in the earlier metrics, was the higher-performing model, achieving F1-scores of 97.38% and 97.34% for DoS and Probing attacks. For R2L and U2R attacks, it scored 91.2% and 78%. The next performing model was DNRL + LSTM, which scored 94.6%, 95.2%, 84.2%, and 61% for DoS, Probing, R2L, and U2R. When compared to the CICIDS-2017, the proposed model again demonstrated higher F1-score values, achieving 97.17% and 96.16% for DDoS and FTP, respectively, as well as 88.1% and 91.38% for PortScan (PS) and SQL injection attacks. In comparison to classifying normal traffic, the proposed model achieved an impressive score of 99.2% for NSL-KDD and CICIDS-2017.

Upon comparing all the metrics, it is evident that the proposed model outperformed the others, achieving the highest score across all metrics for both datasets. The next model that follows the proposed model is the DNRL+ LSTM for all metrics in both datasets. Of the other two models, the RNN and its variant, LSTM, exhibit similar performance, with LSTM holding a slight edge in certain metrics for specific types of attacks.

TABLE VII F1 PERFORMANCE RESULTS

Models	**NSL-KDD**					**CICIDS-2017**				
	DoS	**Probing**	**R2L**	**U2R**	**Normal**	**DDoS**	**FTP**	**PS**	**SQL**	**Normal**
RNN	92.16	92.43	64.05	45	91.13	90.47	89.31	49.91	71.58	90.28
LSTM	91.02	91.07	75.23	43.33	92.98	92.99	90.35	69.62	61.93	91.92
DNRL with LSTM	94.63	95.23	84.26	61.06	95.5	96.82	95.03	83.49	82.64	97.28

V. CONCLUSION AND FUTURE WORK

This study aims to adapt the DNRL for use in AD applications within networks. The study proposed designing a better AD for dynamic network instances. The idea was cropped with the introduction and progress in the field of DNR. The study attempted to optimize the standard DNRL by incorporating a weighted concept to aggregate features of higher importance to the network AD. To achieve this, the proposed study introduced a WoE-optimized LSTM that computes the WoE over the possible AD against normal traffic for the input data. Using the WLSTM, the WDNRL effectively navigates the evolving landscape of network features. The effectiveness of the proposed model was evaluated using the NSL-KDD and CICIDS-2017 datasets, with metrics including accuracy, precision, recall, and F1-score. It is observed that, for all metrics, the proposed model outperforms the other baseline models for all attack instances.

Future work would focus on enhancing the model by integrating more advanced DL and scaling the model to other AD modalities.

***Abstract*—The proliferation of algorithms and commercial tools for generating synthetic audio has sparked a surge in mis-information, especially on social media platforms. Consequently, significant attention has been devoted to detect such misleading content in recent years. However, effectively addressing this challenge remains elusive, given the increasing naturalness of fake audio. This study introduces a model designed to distinguish between natural and fake audio, employing a two-stage approach: an audio preparation phase involving raw audio manipulation, followed by modeling using two distinct models. The first model employed feature extraction through wavelet transformation, followed by classification using a machine learning Artificial Neural Network. The second model utilized ResNet50 architecture, a type of deep learning model, which resulted in improved accuracy. These findings underscore the effectiveness of deep learning approaches in audio classification tasks. Training data for the model is sourced from the DEEP-VOICE dataset, which comprises both genuine and synthetic audio generated by various deep-fake algorithms. The model's performance is assessed using diverse metrics such as accuracy, F1 score, precision and recall. Results indicate successful classification of audio in 86% of cases. This research contributes to the field of Automatic Speech Recognition (ASR) by integrating advanced preprocessing techniques with robust model architectures to identify manipulated speech.**

***Keywords*—Audio classification; automatic speech recognition; machine learning; deep learning; DEEP-VOICE**

I. Introduction

The increasing utilization of generative Artificial Intelligence (AI) in speech-related tasks, such as voice cloning and real-time voice conversion, carries profound implications. This technological advancement raises significant ethical concerns, including threats to privacy and the potential for misrepresentation. Consequently, there is a pressing need for real-time detection mechanisms to identify AI-generated speech, particularly in scenarios involving DeepFake Voice Conversion. Misinformation has become an increasingly prevalent issue in recent times, extending beyond false news articles to encompass the creation of fake audio, images, and videos using algorithms and tools. This form of AI-generated content, known as deepfake [1], [3], presents significant concerns due to its potential impact on various aspects of society, including politics, morality [2], and legal proceedings. For instance, in politics, deepfakes could influence citizens' decisions during elections [4], [5]. Similarly, they could adversely affect individuals' lives, such as in cases of nonconsensual use of famous faces in pornographic materials [6]. Furthermore, deepfakes have the potential to generate false digital evidence, thereby influencing legal outcomes. Deepfakes encompass a set of algorithms crafted to generate synthetic media with the intent of substituting one person's likeness with another's. This synthetic content elicits numerous social, ethical, and legal apprehensions regarding data credibility, as it can portray individuals seemingly uttering or performing actions they never actually did. Notable instances of deepfakes often revolve around images, wherein one person's facial features are replaced by another's, engaging in activities the original subject did not partake in. Artificial Intelligence achievement, emphasizing how the commercialization of human behavior has fueled the quest for digital replicas on an industrial scale [7], [8].

To address these emerging challenges, this study uses the publicly available DEEP-VOICE dataset, which includes both real and synthetically generated speech samples, which consist of authentic human speech samples from eight prominent individuals. The dataset includes instances of their speech being converted to mimic that of others using Retrieval-based Voice Conversion techniques. In this study, two different models for the task at hand will be applied. The first model involves feature extraction using wavelet transformation, followed by classification using a machine learning Artificial Neural Network (ANN). The second model utilizes the ResNet50 architecture. The study aims to analyze and compare the performance of these models in addressing the objectives of this study, particularly in terms of performance metrics such as F1 score, precision, recall and accuracy.

This study aims to address the following research question: Which modeling approach—lightweight, interpretable Wavelet-based ANN or complex, data-driven ResNet50—offers better performance and practical applicability for deepfake speech detection using the DEEP-VOICE dataset?

Even though there are an increasing variety of ways for detecting synthetic audio, ranging from sophisticated deep learning algorithms to conventional signal processing techniques, there is still a conspicuous dearth of comparison studies that thoroughly assess the advantages and disadvantages of each method. There aren't many studies that directly contrast more interpretable, lightweight traditional machine learning models that rely on handcrafted features, like wavelet-domain characteristics, with contemporary deep learning architectures like ResNet50, which use hierarchical feature learning and transfer learning from massive image datasets. For experimental validation, the publicly available DEEP-VOICE dataset, which includes both authentic and

manipulated speech samples, was employed.

In fields like forensics or embedded systems, where interpretability is crucial or computational resources are limited, this disparity is especially pertinent. To give an objective comparison between these two paradigms, this study will conduct an empirical evaluation utilizing a standardized and publicly available dataset (DEEP-VOICE). The emphasis is on the feature extraction pipelines, preprocessing overhead, and model scalability in addition to the final classification performance, which is evaluated by accuracy, precision, recall, and F1-score. These factors are all crucial for the practical implementation of synthetic speech detection systems.

Most of the earlier research focuses on either deep learning or traditional machine learning separately, without direct comparisons under a standardized framework, even if there are several methods for deepfake voice detection. Furthermore, there haven't been enough comparisons 2q1of the interpretability and computational effectiveness of lightweight models like Wavelet-based ANN with more sophisticated deep architectures like ResNet50. To close this gap, our study uses a single dataset to perform a head-to-head comparison.

The remainder of this study is organized as follows: Section II reviews the existing literature and identifies gaps. Section III outlines the proposed methodology, including data preprocessing and model architecture. Section IV presents the experimental set-up and results. Section V discusses the findings considering related works, and Section VI concludes the study with a summary and suggestions for future work.

II. Literature Review

In this section, existing literature and related research to understand current methodologies are explored, identifying knowledge gaps, and contextualize this research within the academic landscape. In the research conducted by Wijetunga et al. [9], the focus was on leveraging deep learning techniques to detect deepfake audio within group conversations. Their approach involved the utilization of the UrbanSound8K dataset, which provides labeled sound excerpts of urban sounds across various classes, along with a conversational dataset sourced from Open subtitles. A series of preprocessing steps was undertaken, including sample rate conversion, merging of audio channels, and extraction of Mel-Frequency Cepstral Coefficients (MFCC) on a per-frame basis. Following preprocessing, the dataset was partitioned into distinct training and testing sets. Multiple neural network architectures were employed throughout the study, encompassing models such as Multilayer Perceptrons (MLP), Convolutional Neural Networks (CNN), and Deep Neural Networks (DNN). These models were applied to various tasks including speech denoising, speaker diarization incorporating Natural Language Processing (NLP), and synthetic speech detection. Furthermore, Transfer Learning techniques were deployed, utilizing a pre-trained VGG19 model to enhance the accuracy of the detection framework. The results obtained from the experimentation phase show- cased promising outcomes. Notably, the CNN architecture achieved a commendable testing accuracy of 89%. However, despite these achievements, the research also acknowledged several limitations inherent in the current approach. Issues such as the necessity for improved signal denoising techniques. Furthermore, challenges pertaining to speaker identification error rates and the automation of partitioning processes in speaker diarization were acknowledged as areas warranting further investigation and development.

In the investigation conducted by Hamza et al. [10], the focus was directed towards deepfake audio detection using MFCC features in conjunction with machine learning methodologies. Central to their investigation was the utilization of the Fake-or-Real (FoR) dataset, a comprehensive repository comprising over 195,000 speech samples, encompassing both authentic human recordings and synthetic computer-generated speech. Within this dataset, researchers meticulously curated four distinct subsets, each tailored to specific experimental needs. These subsets, namely for-original, for-norm, for-2sec, and for-rerec, underwent meticulous preprocessing to standardize sampling rates, volumes, and channels, thereby ensuring uniformity across gender and class categories. Notably, subsets like for-norm underwent additional standardization processes, including the elimination of duplicate files to enhance data consistency. Their methodology involved data preprocessing, MFCC feature extraction, and employing various machine learning models like SVM, VGG-16, XGB, RF, KNN, and LSTM. Notably, while the SVM model generally performed well, VGG-16 stood out with a remarkable 93% accuracy in the for-original subset. Challenges included the high dimensionality of the for-norm dataset, emphasizing the need for dimensionality reduction techniques. The study highlighted the importance of integrating features from various extraction methods for robust deepfake audio detection, suggesting avenues for future research refinement.

Kumar et al. [11] addressed the detection of AI-generated speech using a binary classification model trained on the “DEEP-VOICE” dataset, comprising real and synthetic voice samples. They applied Exploratory Data Analysis (EDA) to handle outliers and missing values and extracted features such as Chroma-STM and RMS. Preprocessing steps included resampling, adjusting sample rates, and normalization. A Random Forest Classifier with 5-fold cross-validation achieved 98.5% accuracy, demonstrating strong performance across multiple evaluation metrics. However, the study highlighted limitations in scalability and generalizability, as well as a reliance on manually engineered features, which may restrict adaptability and efficiency.

In the research by Khochare et al. [12], a deep learning framework tailored for audio deepfake detection is presented, utilizing a combination of machine learning and deep learning approaches. Central to the investigation is the utilization of the Fake or Real (FoR) dataset. In the feature-based paradigm, audio files undergo transformation into datasets comprising various spectral features, while in the image-based domain, melspectrograms are derived from the audio samples using the librosa library. The model repertoire encompasses machine learning algorithms such as SVM, LGBM, XGBoost, KNN, and Random Forest for feature-based classification, alongside deep learning techniques like Temporal Convolutional Network (TCN) and Spatial Transformer Network (STN) for

image-based classification. Results demonstrate varying degrees of success across methodologies, with machine learning models achieving accuracy within the range of 60% to 70%, led by SVM, while TCN emerges as the standout performer in image-based classification, boasting a test accuracy of 92%, followed by STN at 80%. However, the study identifies limitations such as the exclusion of critical inputs like Short-Time Fourier Transform (STFT) and Mel-Frequency Cepstral Coefficients (MFCC) in the image-based approach, prompting future research efforts to address these constraints and refine classification accuracy.

III. Proposed Model

The proposed model subsections follow a structured approach. Initially, the input data from the DEEP-VOICE Dataset [13], undergo preprocessing, including wavelet denoising for noise reduction, feature extraction through 4-level wavelet decomposition, and feature reduction using ICA and normalization techniques depicted in Fig. 1. Subsequently, two models are applied: the first model utilizes ANN classification, while the second model employs deep learning techniques with ResNet50. Finally, the performance of these models is compared to determining the most effective approach. They are crucial in contexts with limitations, such embedded systems. Conversely, ResNet50 was selected due to its demonstrated efficacy in identifying high-dimensional patterns and its capacity to utilize transfer learning. While deep architecture can be resource-intensive and opaque, traditional models frequently rely mostly on manually created features and lack generalization across intricate audio datasets. This study assesses the trade-offs between accuracy and interpretability by contrasting the two aspects.

A. Dataset

The dataset utilized in this study, titled "DEEP-VOICE: DeepFake Voice Recognition", was obtained from the Kaggle platform, a well-known repository for datasets used in machine learning and data science research. This dataset is specifically designed for identifying and analyzing deep-fake voice recordings.

It is systematically organized into two primary directories, as illustrated in Fig. 2: one containing genuine (real) audio samples, and the other comprising synthetically generated (fake) audio samples. This clear separation facilitates comparative analysis between authentic and manipulated audio data. These values are categorized into columns as shown in Fig. 3, Fig. 4, and Fig. 5. Each column corresponds to a specific audio feature, providing numerical data for analysis.

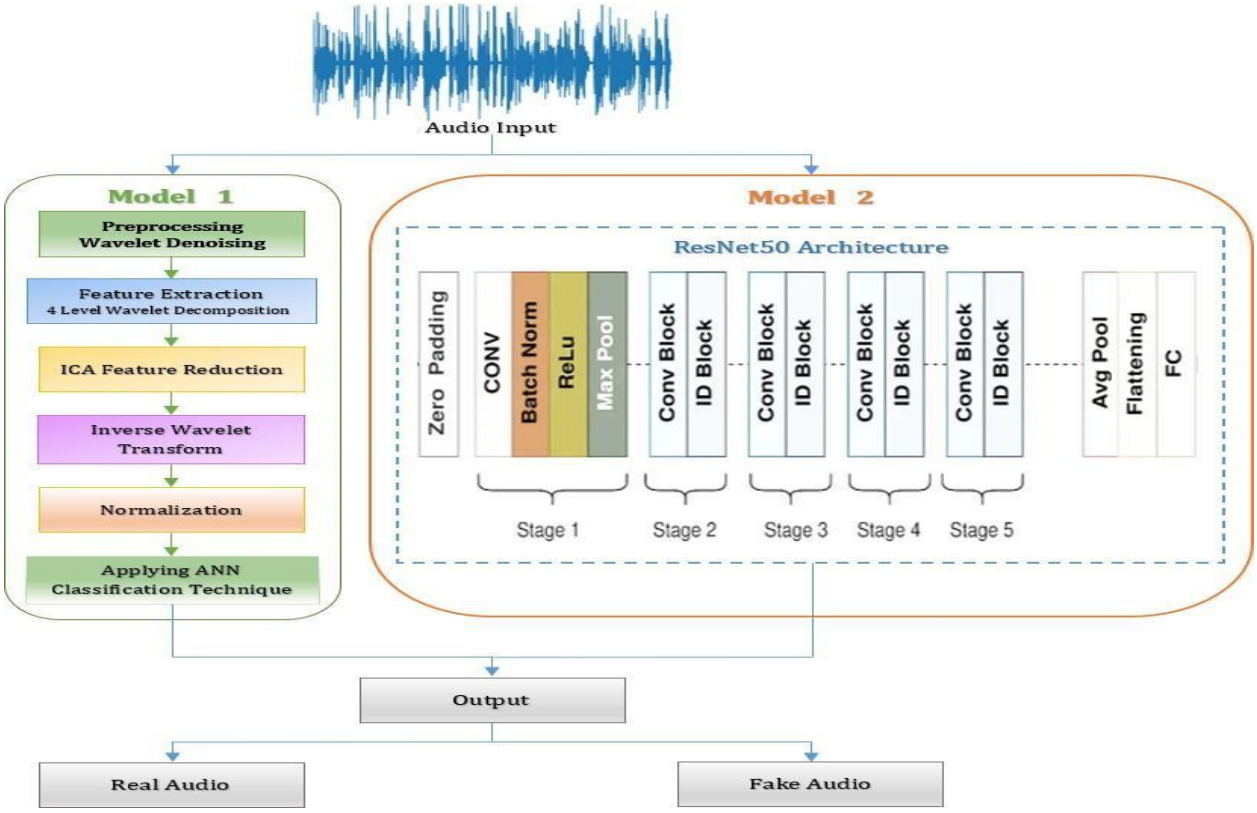

Fig. 1. Proposed model.

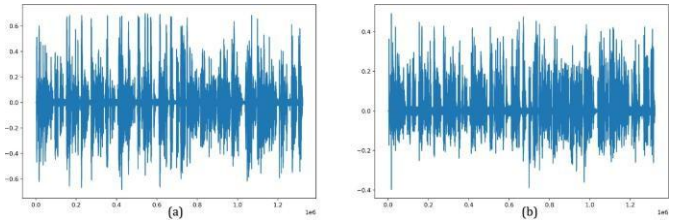

Fig. 2. Real and fake audio data.

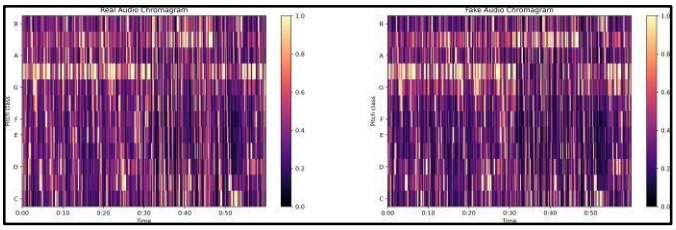

Fig. 3. Audio chromagram.

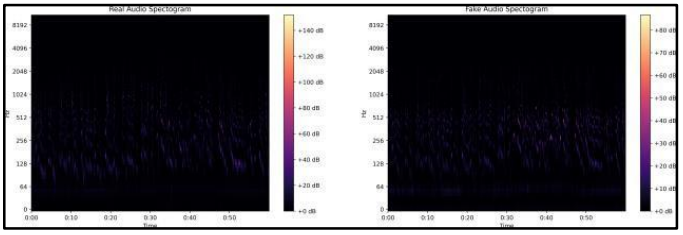

Fig. 4. Audio spectrogram.

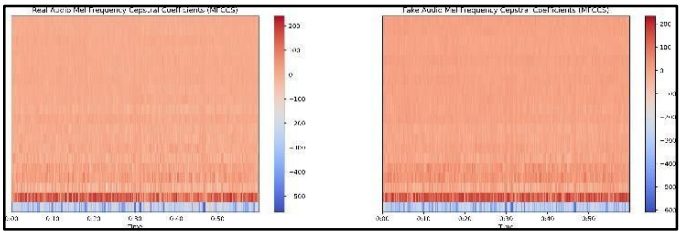

Fig. 5. Audio MFCCs.

B. Preprocessing

The upcoming subsections include signal processing steps to refine data quality and extract relevant features: Wavelet Denoising reduces noise, WT Feature Extraction captures essential information, ICA Feature Reduction condenses the feature space, and Inverse Wavelet Transform reconstructs the signal. Together, these steps form a comprehensive pipeline for enhancing data quality and facilitating analysis and classification tasks. Daubechies 4 (db4) was used as the mother wavelet for the denoising process because of its smoothness and compact support, which make it appropriate for speech signal processing. To capture the pertinent speech characteristics without over-segmenting high-frequency noise, a 4-level wavelet decomposition was used. This level provided a suitable trade-off between resolution and processing efficiency.

To reduce noise in the detail coefficients without losing fine-grained voice characteristics, the universal soft thresholding rule was applied. This rule is renowned for maintaining the continuity and smoothness of the signal.

1) Feature source. Rather than using the reconstructed signals, the retrieved features were taken straight from the wavelet coefficients. More information about frequency fluctuations and transient patterns in the voice stream is preserved as a result.

2) ICA versus PCA comparison. The efficiency of dimensionality reduction was examined in relation to Independent Component Analysis (ICA) and Principal Component Analysis (PCA). When examined empirically, ICA was able to produce more statistically independent components that enhanced classification performance by around 4% in F1 score, but PCA kept about 92% of variation in the first 10 components. Because ICA can separate mixed audio patterns that PCA cannot because of its orthogonality requirement, it was chosen.

3) Normalization strategy. Z-score normalization, which centers the data around zero mean and unit variance, was used to normalize all feature vectors. To make sure that every extracted component contributes equally to the classification problem, this step was applied following ICA. To prevent data leakage, normalization was conducted independently of the training and testing sets using statistics that were taken from the training set.

a) Wavelet denoising: In audio speech recognition, Wavelet Denoising serves as a fundamental preprocessing step aimed at refining data quality by minimizing noise within signals. This technique harnesses wavelet-based methodologies to effectively filter out unwanted noise, resulting in a clearer and more reliable input for subsequent analysis [14]. By employing Wavelet Denoising, researchers can mitigate the negative impact of noise on data interpretation, thereby improving the accuracy of downstream tasks such as feature extraction and classification.

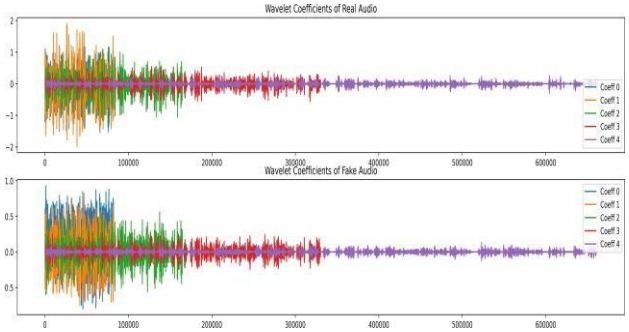

Fig. 6. Wavelet coefficients of real audio and fake audio.

b) Wavelet transform feature extraction: In feature extraction, applying the Wavelet Transform (WT) that serves as a fundamental tool in frequency domain analysis, particularly relevant to the proposed model in the context of audio speech recognition. The 4-level wavelet decomposition refers to a specific application or implementation of the Wavelet Transform. In this case, the signal is decomposed into four levels of detail, each capturing different frequency bands or resolutions as shown in Fig. 6. It efficiently condenses complex audio signals, which exhibit temporal variations and contain diverse

data points, into a concise set of parameters that characterize these signals [15]. Given the dynamic nature of audio signals, the frequency domain approach, often involving WT, is commonly employed to determine the most suitable feature extraction method [16].

4) ICA feature reduction. To isolate distinct feature vec tors from speech signals, employing the Independent Component Analysis (ICA) algorithm on various segments of human speech is made. ICA is a computational method that splits a complex signal into separate parts that are independent from each other [17]. It is used to find the different sources or causes behind observed signals, assuming these sources don't affect each other statistically. In speech processing, ICA can help separate different voices in a recording where multiple people are speaking at once. By analyzing statistical properties like non-Gaussianity and independence, ICA untangles the voices from each other. It's a useful tool in various areas like signal processing, machine learning, and neuroscience, where understanding the individual components of a signal is important.

a) Inverse wavelet transform: Utilizing the inverse wavelet transform as a pivotal element of the speech recognition framework. Following the application of wavelet analysis to break down the speech signal into its individual frequency components, the inverse wavelet transform to reconstruct the original signal from these components was employed [18]. This reconstruction procedure facilitated the retrieval of the initial speech signal while preserving crucial details regarding its frequency characteristics. Through the integration of the inverse wavelet transform into the proposed system, it successfully analyzed and processed speech signals for recognition purposes, resulting in precise and dependable outcomes.

b) Normalization: In this study, normalization significantly improved the speech recognition system. Before featuring extraction and model training, the input speech data to ensure consistent scaling across samples is normalized, reducing biases and making the proposed system more robust to amplitude variations. This enhanced the accuracy and reliability of the recognition system, leading to consistent and trustworthy results across different datasets and conditions.

C. Artificial Neural Network Architecture

Artificial Neural Network (ANN) is a computational model inspired by the structure and function of the human brain's neural networks. It consists of interconnected nodes, or" neurons", organized in layers. In this specific implementation, the ANN for classification tasks was applied, integrating Wavelet Transform for feature extraction and Independent Component Analysis (ICA) for feature reduction. The ANN architecture comprised three layers as shown in Fig. 7: the first layer contained 10 nodes, the second layer had 7 nodes, and the output layer consisted of 1 node. This design allowed for effective processing and classification of speech data while managing computational resources efficiently.

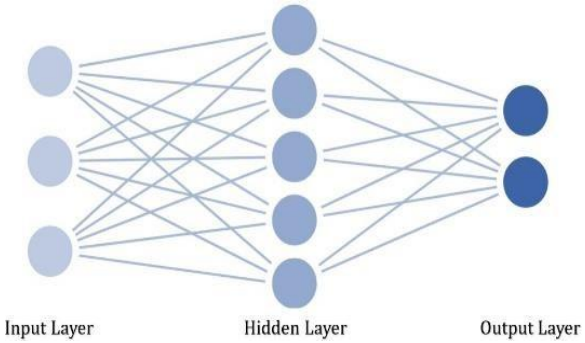

Fig. 7. ANN architecture.

D. ResNet50 Architecture

The implemented model employs the ResNet50 model, a convolutional neural network renowned for its depth and effectiveness. ResNet, designed with 50 layers, introduces residual learning to mitigate accuracy degradation as networks deepen. This approach enables each layer to learn residual mappings in relation to input layers, facilitated by skip connections. ResNet50 architecture includes convolutional layers, batch normalization, activation functions (typically ReLU) [19], and bottleneck blocks to manage complexity [20]. In the code, ResNet50 acts as a feature extractor for audio data, leveraging pre-training on datasets like ImageNet to extract high-level features from audio spectrograms. Through transfer learning, ResNet50 is represented in Fig. 1 as Model 2. It is capable of effectively extracting features for classification tasks, such as audio fake detection. The implemented model specifies hyperparameters, including 100 epochs, a batch size of 32, Adam optimizer, binary cross-entropy loss, and early stopping with a patience of 5 for monitoring validation loss.

E. Wavelet Denoising, Feature Extraction and Dimensionality Reduction

Daubechies 4 (db4) was chosen as the mother wavelet for the preprocessing stage because of its smoothness and compact support, which makes it ideal for catching fleeting patterns in voice data. To balance time-frequency resolution, a 4-level wavelet decomposition was used; higher levels offer global patterns, while lower levels catch finer details. Four levels produced the best trade-off between computing efficiency and information retention, according to empirical data. The universal soft thresholding rule, which reduces high-frequency noise while maintaining significant signal structures, was used to attenuate the noise [21]. Because it preserves signal continuity and minimizes overfitting in subsequent modeling stages, this approach is frequently used. Instead of using the reconstructed signals, the extracted characteristics were taken straight from the wavelet coefficients [22]. The localized time-frequency information that is essential for differentiating between authentic and fraudulent audio patterns is preserved when raw coefficients are used.

A comparison analysis comparing Principal Component Analysis (PCA) and Independent Component Analysis (ICA) was carried out to reduce dimensionality [23]. ICA produced components that were more statistically independent than

PCA, which kept about 92% of the total variance in the first 10 components. ICA was chosen for this investigation because, when evaluated in the classification pipeline, it increased the F1-score by over 4% above PCA.

Z-score normalization (zero mean, unit variance) was used to normalize the features. To guarantee that every independent component had an equivalent impact during classification, this step was implemented following ICA transformation. Crucially, for the purpose of preventing data leakage, normalization was carried out independently on the training and testing sets using statistics that were only calculated from the training data.

IV. Models' Application and Results

In this section, the application of the two distinct models for the task of audio speech recognition, along with their respective results, are presented.

A. Model 1: Artificial Neural Network (ANN) with Wavelet Transform

For the first model, an Artificial Neural Network (ANN) in conjunction with Wavelet Transform for feature extraction was applied. A lightweight yet efficient architecture is provided by combining wavelet-domain characteristics with an Artificial Neural Network (ANN). Three completely connected layers made up the ANN's design, which was optimized for classification jobs with less data. The output layer has a single sigmoid-activated node for binary classification, a hidden layer with seven neurons, and a first layer with ten neurons that receives the ICA-reduced wavelet coefficients. Simplicity, quick training time, and interpretability are advantages of this paradigm. Its scalability to larger or more varied datasets is constrained by its dependency on manually created feature extraction (wavelets + ICA). Performance reporting was made robust by using 4-fold cross-validation, and overfitting was avoided by using regularization techniques.

The input data, preprocessed using Wavelet De-noising, underwent feature extraction through 4-level wavelet decomposition. Following this, Independent Component Analysis (ICA) and normalization techniques were employed for feature reduction. The ANN, comprising 3 layers (10 nodes in the first layer, 7 nodes in the second layer, and 1 node in the output layer), was trained on the processed data for audio speech recognition. The results of this experiment, conducted using k-fold cross-validation with k=4, yielded an average accuracy across folds of 79.7%, average precision of 82.1%, average recall of 93.9%, and average F1 score of 87.6%.

B. Model 2: Deep Learning with ResNet50

The second model utilized deep learning techniques, specifically ResNet50, for audio speech recognition. The ResNet50 model makes utilization of transfer learning and deep residual learning. Using spectrogram images produced from the DEEP-VOICE dataset, the 50-layer architecture was refined after being pre-trained on ImageNet. Hierarchical auditory patterns may be captured by the convolutional layers thanks to the spectrograms' 2D time-frequency representation of audio.

Binary cross-entropy loss, the Adam optimizer, and a batch size of 32 were used to train the model. To reduce overfitting, early stopping was used with 5-epoch patience. ResNet50's advantage is its capacity to generalize across intricate audio circumstances and automatically learn high-level audio properties without the need for manual engineering. On synthetic speech samples, its deeper architecture offers improved recall and classification accuracy.

The ResNet50 architecture, comprising 50 layers, was pre-trained on a vast dataset such as ImageNet to extract high-level features from audio spectrograms. These features were then fed into additional layers for classification purposes. The results of this experiment, also conducted using k-fold cross-validation with k=4, demonstrated the superior performance of ResNet50 with an average accuracy across folds of 85.9%, average precision of 87.3%, average recall of 98.2%, and average F1 score of 92.4%.

Regarding hyperparameters, the implemented model employed the following settings: 100 epochs, batch size of 32, Adam optimizer, binary cross-entropy loss function, and early stopping with patience set to 5. Upon comparison, it is evident that the deep learning model with ResNet50 outperformed the ANN with Wavelet Transform, exhibiting higher accuracy, precision, recall, and F1 score.

From the comparison shown in Table I, it is evident that the deep learning model with ResNet50 outperformed the ANN with Wavelet Transform, exhibiting higher accuracy, precision, recall, and F1 score.

TABLE I Applying ANN Architecture with Wavelet Transform versus ResNet50 Architecture

Model	Avg. Accuracy	Avg. Precision	Avg. Recall	Avg. F1 Score
ANN with WT	79.69%	82.14%	93.88%	87.62%
ResNet50	85.94%	87.29%	98.21%	92.41%

These results highlight the effectiveness of deep learning techniques, particularly ResNet50, for audio speech recognition tasks, offering improved performance and robustness compared to traditional machine learning approaches as shown in Fig. 8.

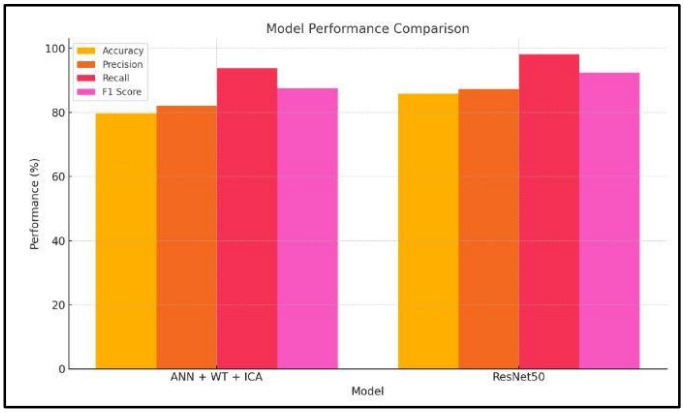

Fig. 8. Comparative performance metrics of ANN and ResNet50 model.

V. Discussion

Through a comprehensive review of the literature [24], valuable insights into current state-of-the-art methodologies were gained. This research significantly contributes to this body of knowledge by achieving high performance in accuracy levels [25], particularly through the utilization of the deep learning ResNet50 model, which yielded a testing accuracy of 86%. This represents a noteworthy research contribution. In comparison to the model applied in [9], which employed a CNN architecture and achieved a commendable testing accuracy of 89%. This approach addresses some of the acknowledged limitations in the literature. For instance, the applied methodology incorporates improved signal denoising techniques as part of the preprocessing steps, effectively resolving the challenges identified. A comparative summary of our results alongside existing approaches is presented in Table II, demonstrating the strengths and potential limitations of each technique in different settings.

Similarly, [10] demonstrated the effectiveness of the VGG-16 model with a remarkable 93% accuracy in the original subset. However, challenges related to dataset dimensionality were highlighted, emphasizing the need for dimensionality reduction techniques. In this model, this concern by employing ICA feature reduction, thereby mitigating the impact of high-dimensional datasets, is addressed. Lastly, [11] achieved impressive results using the Random Forest Classifier with 5-fold Cross-Validation, attaining an accuracy of 98%. Nonetheless, limitations regarding scalability and generalizability were identified, along with reliance on handcrafted features, which may not always capture the most relevant information present in the data. Our approach offers potential advantages in terms of scalability and generalizability, as well as automated feature extraction techniques, thus providing avenues for further research and development in this domain.

TABLE II Comparative Performance of Proposed Models Versus Related Work

Feature type	Accuracy	Dataset	Model	Study
Spectrogram	85.5%	Deep voice	ResNet50	This proposed Model
Wavelet coefficient	79.7%	Deep voice	ANN + Wavelet +ICA	This proposed Model
MFCC	93.0%	Fake or real	VGG-16	Hamza et al. [10]
Chroma- STM, RMS (manual)	98.5%	Deep voice	Random Forest	Kumar et al. [11]
Mel- spectrogram	92.0%	Fake or real	TCN	Khochare et al. [12]

Higher raw accuracy has been obtained by other works like Kumar et al. [11] and Hamza et al. [10], but those models mainly depend on manually created features and particular dataset circumstances. By using automated feature extraction (ResNet50 with spectrograms and wavelet ICA), on the other hand, our method improves generalization and lessens the requirement for domain-specific engineering. Additionally, the DEEP-VOICE dataset, which contains intricate, real-world deepfake audio produced using sophisticated voice conversion techniques, provided a more difficult and realistic assessment for these proposed models.

Because of this, rather than overfitting a single data format or manipulation type [24], our results are more indicative of real-world scenarios, where models must generalize across several manipulation approaches.

VI. Conclusion And Future Work

In this study, two distinct approaches for audio speech recognition were explored: an Artificial Neural Network (ANN) with Wavelet Transform and deep learning with ResNet50. The study's comprehensive experimentation and evaluation revealed notable performance differences between the two models. The ANN with Wavelet Transform demonstrated respectable accuracy and precision, achieving an average accuracy across folds of 80%. However, the deep learning approach using ResNet50 surpassed the ANN model, exhibiting higher accuracy, precision, recall, and F1 score. ResNet50 exhibited an average accuracy across folds of 86%, demonstrating its exceptional ability to effectively process complex audio data. This represents a notable improvement in performance and robustness, with a nearly 6% increase observed compared to previous approaches.

Our comparison highlights the effectiveness of deep learning techniques, particularly ResNet50, for audio speech recognition tasks. Leveraging transfer learning and pre-trained models like ResNet50 proved highly successful in extracting high-level features from audio spectrograms, resulting in superior classification accuracy.

Despite the encouraging results, this study has several limitations. First, the models were evaluated on a single dataset (DEEP-VOICE), which may limit generalizability across other datasets with different characteristics or languages. Second, although ResNet50 performed well, its computational cost may hinder deployment in real-time or embedded systems. Finally, the reliance on spectrogram images introduces a preprocessing overhead that may not suit all applications. Future work will explore broader dataset diversity and model optimization for real-time deployment.

In conclusion, the findings emphasize the significance of utilizing advanced deep learning architectures for audio speech recognition tasks, offering enhanced performance and scalability compared to traditional machine learning approaches. Future research endeavors may focus on further optimization techniques and larger datasets to continue advancing the accuracy and efficiency of audio speech recognition systems.

Fine-Tuning OpenAI GPT Chatbot in Western Saudi Dialect: A Case Study of Taibah University

Maimounah Alhujaili, Ruqayya Abdulrahman
College of Computer Science and Engineering, Taibah University, Al-Madinah, Saudi Arabia

***Abstract*—The current era is characterized by technological advancement and innovation, which affect various sectors. Numerous remarkable and alluring computer programs and applications have surfaced, including ones that aim to replicate human behavior. A chatbot is an example of an Artificial Intelligence (AI) computer program that uses natural language to mimic human conversations in voice or content. Even though a lack of Arabic chatbots, most of these chatbots use Modern Standard Arabic instead of Arabic dialects. This research presents the development and evaluation of a chatbot designed to respond to academic inquiries from university students using the Western Saudi dialect. A traditional Support Vector Machine (SVM) baseline model was first implemented to establish a reference point for performance. Subsequently, a fine-tuned version of Generative Pre-trained Transformer (GPT) 3.5-Turbo-0125 was developed using a culturally specific system prompt to enhance the model's understanding of regional language and academic contexts. Evaluation was conducted through a multi-dimensional framework combining human assessments, BERTScore semantic similarity measurements, and GPT-4-based automatic judging. With human assessors determining that 85% of GPT-3.5's replies to 132 messages of test data were appropriate, the transformer-based model clearly outperformed the SVM baseline, which had an accuracy of 42.86% on 20 messages of test data. These findings highlight the importance of cultural and contextual fine-tuning in building effective conversational agents for dialectal Arabic communities. The research contributes to the growing field of localized AI by demonstrating how advanced language models can be adapted to serve specialized linguistic and academic needs.**

Keywords*—*Artificial intelligence (AI); large language model (LLM); generative pre-trained transformer (GPT); Modern Standard Arabic (MSA); Western Saudi dialect

I. Introduction

In contemporary society, Artificial Intelligence (AI) influences daily life by contributing to the development and assessment of advanced applications. AI helps people to automate various tasks in multiple fields. One of the most exciting AI applications that have become widespread is a chatbot. A chatbot is a popular term for conversational agent. It is software that mimics human conversations in voice or content mode by reacting based on contributions made. Also, it is the AI to engage in conversation and interaction with users in natural language that simulates human behavior. The utilization of chatbot is increasing in different fields with different languages. The main goal of utilizing chatbots are to simulate interpersonal interactions [1].

Based on researches [2], the history of chatbot started in October of 1950. Alan Turing proposed the first idea of a chatbot. Alan Turing questioned if a computer program could converse with a group of humans without their recognizing that their conversation partner was artificial. Many people believe that this question, known as the "Turing test", is the one that inspired the creation of chatbots. Chatbots have improved over the years, and the first utilization of AI with a chatbot was in 1988 for the Jabberwacky chatbot. A growing increase in the use of chatbots and the enhancement of AI techniques used with chatbots was observed.

Chatbots use The International Organization of Legal Metrology (OIML) to represent knowledge. Chatbots can replace humans in repetitive tasks like customer service and e-help desk answering and providing prompt responses. Additionally, chatbots are utilized by operating systems as virtual assistants, such as Siri on Macs and Cortana on Windows. These days, chatbots are becoming more and more popular in the business world because of their enormous potential to automate customer care and reduce employee time [3].

A chatbot could be implemented in any human language. Unlike the abundance of studies on English chatbots, there is a lack of studies on Arabic chatbots because of the language's challenges [4]. Arabic is obviously different from languages like English in several aspects. For Instance, the Arabic alphabet consists of 28 primary characters, thirteen of them contain dots like (خ (Kha) - ج (Jeem) - ت (Ta) - ف (Fa)), while fifteen do not, such as (ح (Hha) - م (Meem) - ع (Ayn) - د (Dal)), and it written and read from right to left.

The difficulties in Arabic languages negatively effect on applying Natural Language Processing (NLP) on Arabic languages [5]. Even though the Arabic research on applying Arabic language on NLP technique has increased in recent years, the utilization of Arabic dialect is very rare. Most of Arabic natives communicate with dialect Arabic instead of Modern Standard Arabic (MSA). Also, some of them faced problems when they expressed themselves by MSA. For those reasons, the Arabic dialect chatbot will be more helpful than MSA chatbot.

A. Problem Identification

The development of chatbots that can understand and respond to regional dialects has been an emerging field in NLP and machine learning. However, despite significant advances in multilingual NLP models and transformer-based architectures (such as GPT models), there remains a notable gap in the application of these technologies to specific regional dialects, particularly within the Saudi Arabian context.

Existing research in chatbot development has largely focused on general-purpose language models, or models tailored to widely spoken dialects and languages, such as MSA. However, there is a lack of focus on specific regional dialects like the Western Saudi dialect, which is rich in local expressions, cultural nuances, and vocabulary unique to regions such as Madinah, Makkah, Jeddah, and Taif. Most existing chatbots fail to address the linguistic and cultural diversity found in these regions, resulting in suboptimal performance when handling local dialects. While some studies have explored Arabic dialectal chatbot systems, there is limited work that specifically targets the Western Saudi dialect, especially in the context of university students.

This research is necessary, as it addresses a significant gap in the existing literature by developing a chatbot specifically tailored to understand and respond to the Western Saudi dialect, which has been underrepresented in the field of NLP. While there has been substantial work on general-purpose chatbots and models designed for widely spoken dialects or MSA, few studies have focused on region-specific dialects like the Western Saudi dialect, especially in the context of university students. By developing a chatbot that can respond to questions unique to Taibah University, including course registration, academic regulations, and campus information, this research seeks to give students a useful solution. This project will not only fill the gap in dialect-specific chatbot development but also enhance institutional efficiency and student assistance by relieving staff workloads and providing students with quicker access to information.

B. Research Questions

This research is structured around three primary research questions that aim to explore the role of Arabic dialects—specifically the Western Saudi dialect—in the development and evaluation of intelligent chatbot systems: 1) How does the Western Saudi dialect influence the performance of a Support Vector Machine (SVM)? This question investigates the effect of incorporating dialectal variations on the accuracy and efficiency of traditional machine learning models. 2) What is the difference in performance between a chatbot utilizing an SVM model and a chatbot based on a GPT model? The comparison is supposed to assess the merits and shortcomings of both methods in comprehending and generating dialectical Arabic responses. 3) How can a GPT-based model be optimized to enhance academic support for Saudi university students? The final question focuses on adapting and fine-tuning large language models to provide more effective and contextually appropriate assistance in educational settings.

C. Research Objective

The research aims to implement a Western Saudi dialect chatbot that understands the users and responses effectively with same Western Saudi dialect. The chatbot will communicate with users in the educational field. This research will fill the gap in Arabic dialects research area and especially the Saudi dialect.

The remainder of this research is organized as follows: Section II provides the background, including the definition of chatbots, chatbot methodologies, the Transformer framework, and a history of chatbot evolution. Section III outlines the literature review, with a particular focus on the most relevant prior work in the field. While Section IV discusses the research methodology used in this research. Section V describes the implementation and experimentation settings, including the development of the emails retrieval-based model, the baseline model, and the GPT-based model. Section VI reports the experimental results, and Section VII discusses the key findings and their implications. Finally, Section VIII concludes the study and outlines potential directions for future research.

II. Background

Based on the dictionary, the definition of chatbot is ‘‘A computer program designed to simulate conversation with human users, especially over the Internet’’ [6]. A chatbot may uses Sentiment Analysis (SA) and NLP to communicate with humans or other chatbots in different languages by text or voice. It has multiple terms for interactive agents, for instance, artificial, smart bots, conversation entities, and digital assistants. In recent years, AI chatbots have become exceptionally popular in replacing human responses [7].

A. Chatbot Approaches

Chatbot approaches are classified into two main categories: rule-based chatbot and Machine Learning (ML) chatbot [8]. Rule-based chatbots apply pattern-matching algorithms to compare user input to a rule pattern and choose a prepared response from a list of options. The choice of rules and the answer format may also be influenced by the context. The automatic, repetitive, and lack of originality and spontaneity in the responses is a drawback of the pattern-matching approach. However, because a more thorough syntactic or semantic analysis of the input text is not carried out, there is a quick reaction time. The first chatbot ELIZA is based on this approach. However, these Chatbots are not able to respond to patterns that do not fit the prewritten script[9].

On the other hand, ML approach divided into retrieval-based chatbot and generative chatbot [10]. Retrieval-based chatbot works by comparing user input to a predetermined list of answers stored in a knowledge base. After understanding user intents and queries using NLP techniques, they obtain the best pre-written response from their database and display it to the user. In contrast, large text datasets from books, journals, the internet, and other sources are used to train generative chatbots. They process and produce text using Deep Learning (DL) models and NLP. The chatbot preprocesses and tokenizes information, dividing it into smaller pieces known as tokens, before a user submits a message. After creating an initial representation of the user's message using these tokens, it predicts the subsequent words or tokens based on its training data and acquired linguistic patterns to produce a response.

B. Transformer in Chatbot

In 2017 [11], the authors presented the transformer, a deep learning architecture that uses self-attention processes to process sequential input. Transformers enable simultaneous processing of input sequences, in contrast to conventional Recurrent Neural Networks (RNNs) and Long Short-Term Memory networks (LSTMs), which process sequences step by step. Modern Large Language Models (LLMs) like Generative Pre-trained Transformer (GPT) and BERT are built on top of this design. The encoder and decoder, the two primary components of the

Transformer, are made up of several identical layers that allow for effective learning and representation of sequential input [12].

Processing the input sequence and producing meaningful representations are the encoder's responsibilities. It is made up of several identical layers, usually six in the original transformer, that carry out the following tasks. The input embedding Layer converts words into dense vector representations (word embeddings). Then, it captures semantic meaning but does not retain positional information. Multi-head attention refers to the simultaneous operation of several attention mechanisms that record various word relationships. This layer applies softmax after using a triangle mask to set future words' attention scores to negative infinity. The Multi-head self-attention layer enables each word to attend to all other words in the sentence. The mechanism works by computing three vectors for each word. Query (Q) represents what the word is looking for, Key (K) represents the content of all words, and Value (V) contains the actual information to be transferred. These are used in the scaled dot-product attention equation in the Eq. (1) [11]:

$$Attention\ (Q,K,V) = softmax\ (\frac{Qk^t}{\sqrt{d_k}})\ V \qquad (1)$$

Fig. 1 illustrates the internal structure of the multi-head attention mechanism used in transformer models. It begins by projecting the input into Q, K, and V vectors through separate linear transformations. Multiple attention heads are applied in parallel, each computing scaled dot-product attention independently. The outputs from all heads are then concatenated and passed through a final linear layer, allowing the model to capture a richer representation of the input by attending to information from different subspaces.

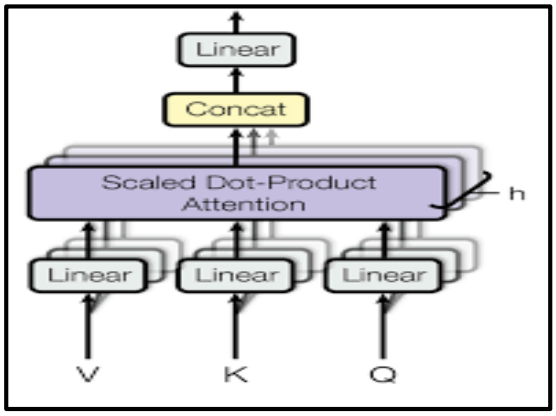

Fig. 1. Multi-head attention consists of multiple attention layers operating in parallel [11].

Layer normalization and residual connection improves training stability and gradient flow. Each word representation from the self-attention layer is passed through a feed-forward network, consisting of two linear transformations with a non-linearity in between (typically ReLU). This layer allows the model to learn complex patterns beyond attention-based relationships. The decoder receives a contextualized word embedding as the output from the final encoder layer [13].

On the other hand, the decoder is responsible for generating the output sequence based on the encoder's output. Each decoder has six identical layers, just like the encoder. It does, however, have an extra attention mechanism which is encoder-decoder multi-head attention layer. In this layer, the decoder can concentrate on the encoder's output and produce pertinent answers thanks to the multi-head attention layer. The decoder provides the Q, while the encoder output provides the K and values V. The layer guarantees the words produced by the decoder are pertinent to the input sequence in terms of context. The final output of the decoder side is mapped to the vocabulary size by passing it by a fully linked linear layer. For every word, probabilities are generated using a softmax function. In the output sequence, the word with the highest probability is chosen as the following word [14].

Fig. 2 illustrates the architecture of the transformer model, which is composed of an encoder and a decoder. Each component consists of stacked layers that incorporate attention mechanisms and feed-forward networks. Positional encoding is applied to both inputs and outputs to retain sequence information, and the final output is generated through a linear layer followed by a softmax function.

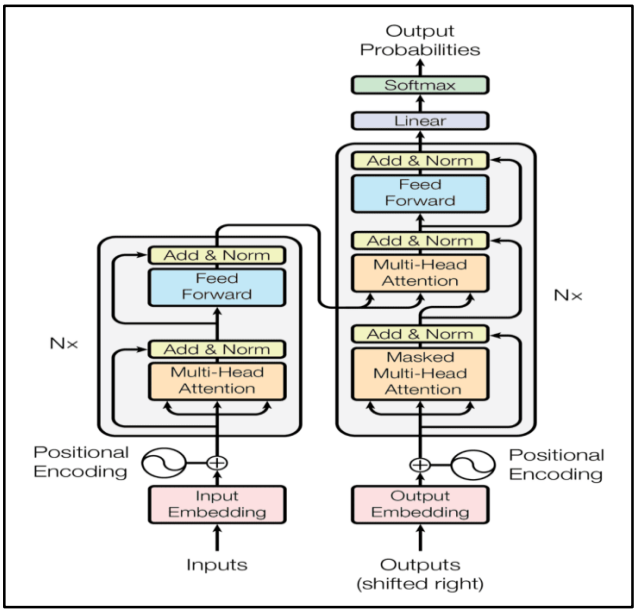

Fig. 2. The transformer model architecture [11].

C. Chatbot Historically

The development of chatbot has been improved significantly over the decades. Fig. 3 summarizes the historical development of chatbots, which will be discussed in detail below. It provides a visual timeline of major milestones, illustrating the evolution of chatbot technologies from early rule-based systems to modern AI-powered models.

- In 20th century: (1950 to 1999)

Alan Turing's published his famous article "Computing Machinery and Intelligence" in 1950. In the article, he discussed a question "Can machines think?", and he proposed a measure of intelligence. This measure called now Turings test. It determines whether the machine acts like human in a real-time written conversation and the human judge cannot absolutely distinguish (based on the conversation only) between the machine and the real human. Based on many experts, the

Turings test is considered to be the generating principle for chatbots [15].

In 1966, the first chatbot was developed by Weizenbaum called ELIZA. ELIZA is simulating conversation with therapist. Early users felt they were speaking with someone who understood their input because of the program's scripted responses that use "pattern matching" and substitution methods [16]. Many early users were persuaded by ELIZA's intelligence and comprehension; however, Weizenbaum may have insisted differently. ELIZA is incapable of maintaining lengthy discussions or picking up on context from the interaction, which is A drawback of ELIZA. It also has limited expertise means that it can only discuss a specific range of topics [17].

PARRY chatbot appeared in 1972 at Stanford University by psychiatrist Kenneth Colby. It simulated a patient with schizophrenia [18]. Because PARRY is designed to have a "personality" and an improved controlling structure, it is thought to be more advanced and intelligent than ELIZA. In an experiment conducted in 1979, five psychiatrists utilized PARRY to determine whether a patient was a real schizophrenia patient or a chatbot. Hence, ten diagnoses were provided by psychiatrists. Two diagnoses were made correctly by the first psychiatrist, and two inaccurate ones by the second one.

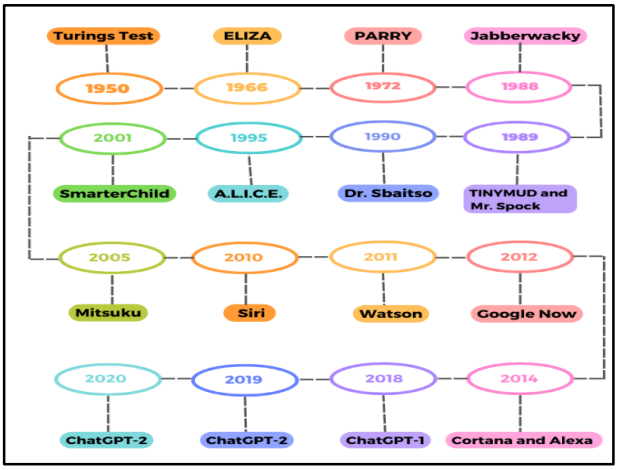

Fig. 3. Chatbot history timeline.

While the other two concluded that the participants were chatbots, the third believed that the subjects were actual patients [19]. However, because there is some degree of confusion in the speech of people who have schizophrenia, the small sample size of five doctors makes it difficult to interpret the results. PARRY is generally regarded as a chatbot with limited language comprehension and emotional expression skills. Additionally, it cannot learn from discussions and responds slowly.

Artificial intelligence was first applied in the field of chatbots in 1988 in the Jabberwacky chatbot. Jabberwacky was created using CleverScript, a spreadsheet-based language that made it easier to create chatbots. It responded by using contextual pattern matching to go back and review past conversations. Nevertheless, Jabberwacky is unable to process large amounts of data quickly or efficiently [20].

One of the first attempts to create a conversational AI character in an online virtual world based on textual was called TINYMUD [21]. James Aspnes created it in 1989, and Carnegie Mellon University's TINYMUD server hosted its initial implementation of it. It was a kind of early online multiplayer game in which players could interact and communicate by sending text commands to one another. Mr. Spock was able to use a straightforward pattern matching algorithm to reply to simple conversational prompts and questions. There was a finite list of possible answers. As they explored the virtual text world together, players could communicate with Mr. Spock by sending him text commands like "say to Spock" or "ask Spock about". Mr. Spock was an early attempt at an artificial intelligence (AI) figure who could converse with people in a virtual setting, albeit being incredibly limited. It introduced the concept of NPC (non-player character) bots, which are widely used in virtual worlds and games today. Later conversational agents in MUDs, MOOs, and finally massively multiplayer online games were made possible through the development of TINYMUD.

Based on [22], the first chatbot to engage people in conversation was Dr. Sbaitso, which was introduced in the early 1990s. It was created specifically for MS-DOS and assumed the role of a psychotherapist, using voice to mimic a counseling session. By enhancing the pattern matching and replacement skills of earlier chatbots, Dr. Sbaitso was able to identify phrases and produce pertinent spoken responses. Despite its limitations, it was a step forward in conversational skills as it combined synthesized speech and text pattern matching to simulate a human-like dialogue. The basis for later chatbots' more complex verbal exchanges was established by Dr. Sbaitso's combination of voice interaction and basic language processing.

A.L.I.C.E. is an approximately more sophisticated bot developed by Richard Wallace in 1995 that is inspired by ELIZA [23]. The bot produced outcomes by pattern matching inputs against (input) (output) pairs kept in knowledge base documents. Artificial Intelligence Markup Language (AIML), an extension of XML that is still in use today, was used to write these documents. The Loebner Prize, which honors the most intelligent chatbot each year and attempts to run the Turing Test, has been won by ALICE three times [15].

- In 21st Century : First decade (2000 to 2009)

SmarterChild chatbot was developed by ActiveBuddy in 2001. It was an inspiration in achieving widespread acceptance. When inquired about something, it could supply information about a wide range of subjects and functioned on instant messaging networks. SmarterChild is one of the first chatbots to be integrated into messaging apps, demonstrated how AI could function as a virtual assistant by retrieving information and responding to user inquiries [24]. It might have been integrated to AOL Instant Messenger and MSN Messenger, reaching over 30 million users. SmarterChild inspired chatbots on messaging networks, opening the door for later AI assistants such as Samsung's S Voice and Apple's Siri. Its easy integration with famous messaging apps showed how chatbots may be used to offer services through dialogue-based messaging settings. Through introducing practical chatbot interactions into regular messaging, SmarterChild demonstrated the potential for millions of users to have access to chat-based assistants in the future [25].

Mitsuku chatbot was developer in 2005 by by Steve Worswick. It is an award-winning chatbot with a playful, adolescent girl demeanor. It has been the recipient of the Loebner Prize five times between 2013 and 2018. Judges for the Loebner Prize interact with a combination of chatbots and humans to identify which are the bots; Mitsuku has consistently deceived the judges in this regard. It is the most widely used AIML-based chatbot. It is hosted on Pandorabots and employs NLP techniques like heuristic patterns and default categories to have natural conversations across many platforms. It uses pre-written patterns and Bot modules to use natural language processing and is made for multiple platforms, including Telegram and Twitter. Although practical, Mitsuku needs new AIML categories to direct user input and manage mismatched prompts. It has been shown to be a useful conversation partner in multiple languages [21].

- In 21st Century: Second decade (2010 to 2019)

Apple developed Siri in 2010. It paved the path for personal assistants. It integrates with audio, video, and image files and allows users to utilize voice commands for questions and conversations using Messenger. With continuous use, Siri learns to recognize the users' language preferences, queries, and requests while providing recommendations and addressing user requests through a variety of online services. Siri has limitations, even if it is a powerful system. It demands an internet connection. Although it is multilingual, it is incapable of supporting many languages, and the only language in which navigation instructions are offered is English. Additionally, it has trouble understanding the person speaking because of their strong accent or background noise [26].

IBM developed a chatbot named Watson in 2011 [17]. Watson had the ability to decipher genuine human language well enough to defeat two previous champions in the game show "Jeopardy", in which players had to predict the questions based on responses they were given. Years later, Watson helped companies develop more advanced virtual assistants. Furthermore, Watson Health was created to assist medical professionals in diagnosing illnesses. Watson's limitation is that it only supports English, though.

When Google Now was first launched in 2012, it was intended to provide information to users based on their location, preferences, and time of day [27]. The next version of Google Now is Google Assistant, which was developed in 2016. It anticipates user needs and provides information to them with a more conversational, amiable interface that combines a deeper level of artificial intelligence. It lacks personality, though, and because it connects to the user's Google Account directly, some of the questions could be considered private [28].

Microsoft has introduced Cortana personal assistant in 2014. It is capable of recognizing voice commands to perform things like emailing, obtaining required information, and making reminders, there certainly have been reports of security holes that allow malware installation. Amazon developed Alexa voice assistant in the same year In order to promote IOT accessibility. One innovation is the Alexa Skills Kit, which allows developers to create custom skills for Alexa, though there are security risks associated with using Alexa. Although Alexa is focused on controlling home devices and Cortana was designed by Microsoft to be a personal assistant, both have raised security concerns over voice command functionality. Notwithstanding continuous security concerns, the introduction of Cortana and Alexa signaled a significant development in the field of AI voice assistants [29].

- In 21st Century: Third decade (2020 to current)

Based on [30], OpenAI introduced ChatGPT in multiple versions that started with GPT-1 in 2018, GPT-2 in 2019, and GPT-3 in 2020. ChatGPT showcases research on training neural networks on massive text data sets to acquire robust language skills, highlighting the most recent developments in employing large language models, such as GPT-3.5 and 4 for conversational AI. It is a prime example of state-of-the-art methods, including scaled-up self-supervised learning, that generate flexible models with robust reasoning and contextual understanding abilities. ChatGPT offers an interactive platform that allows users to experiment with and assess the advancements in research being done on creating dialogue agents with sophisticated LLMs optimized for multi-turn talks.

DeepSeek Chatbot is an advanced AI language model developed by DeepSeek, a Chinese AI research company [31]. It was first introduced to the public in early 2024, gaining attention for its strong performance in coding, reasoning, and multilingual capabilities, competing with models like OpenAI's GPT-4 and Meta's LLaMA. The chatbot is built on a transformer-based architecture, supporting 128K context length, which allows it to handle long documents efficiently. DeepSeek initially released open-weight models (such as DeepSeek LLM 7B/67B) before launching its conversational AI. As of mid-2024, DeepSeek Chatbot became available broadly, both in the free and paid versions, as a major player in the market for AI assistants. Its emergence is part of the global expansion of generative AI tools through an imitation of the rapid evolution of open and potent AI models beyond Western technology companies.

III. Literature Review

A thorough analysis of the main findings of existing research on chatbots is given in this section. It starts with a summary of earlier research that has looked at related subjects, especially in relation to conversational systems. The section goes on to list the main research gaps that this research attempts to fill, emphasizing how little attention has been paid to regional dialects, such the Western Saudi dialect, in both academic and real-world contexts.

A. Overview of Related Work

The authors in this study [27] provide an intelligent chatbot that utilizes advanced technologies for instance Python, Flask web framework, and NLP. This chatbot aims to produce a student's information access and investigate academic administration. The study's results emphsize that, the traditional programming paradigms and rule-based systems have enabled users to seamlessly fetch inclusive academic information by NLP queries. With quick access to extensive students' performance information, the administrators and teachers are able to simplify decision making that can improve methods for enhancing academic performance. Instantaneous insights into students' development allows teachers to recognize areas that

need improvement. The chatbot has created a standard for creative and approachable solutions inside educational establishments.

For the purpose of helping university students with academic and administrative issues, the study [28] introduces the development and execution of a College Assistance Chatbot. The chatbot effectively comprehends and processes student queries by utilizing deep learning models, especially an Artificial Neural Network (ANN), and NLP techniques. The architecture of the system is carefully developed to efficiently handle communication, guaranteeing immediate and accurate outcomes. For the neural network training, a large dataset was obtained from university resources and pre-processed. With a series of experimental campaigns, the performance of chatbot was thoroughly assessed. After 1000 epochs, it achieved an accuracy of 80.07%. The findings show that the chatbot can effectively respond to a variety of student requests, offering a scalable way to improve student support services. This novel methodology shows great promise for wider use in educational contexts and provides notable improvements over conventional techniques.

By utilizing the GPT model, the study [29] investigates the design, development, and assessment of an instructional chatbot for a university course. Testing the viability and efficacy of a GPT-based chatbot performing as a personal tutor for students enrolled in the Sociology of Education course is the main objective of the study. In addition to outlining a prototype for developing comparable educational chatbots, the researchers discuss to comprehend the advantages and disadvantages of GPT in educational contexts.

In order to foster critical thinking, the chatbot was developed to respond to inquiries, explain ideas, and involve students in Socratic discussion. The chatbot was created to be a tutor to students in two main implementation steps. First, building a knowledge base to improve subject-matter expertise. Second, configuring behavior, the chatbot was designed with an accurate prompt to prioritize answers from its knowledge base and refrain from depending on outside resources. The results of the study include that the GPT-based chatbot could provide precise answers, encourage interactive learning, and effectively adjust to the demands of the students. It was convenient and accessible because it was available all the time. While the limitations are relying on a very good quality training dataset, occasionally misinterpreting context, and having trouble completely recognizing complex ideas.

While most of the educational chatbot help students in self-learning, the study [30] explores how chatbots can enhance team-based learning independent on operating as a virtual instructor to assist students in working together for successfully complete their projects. Tubo (tutoring bot) was implemented as a component of a website platform for collaborative learning in which students work in groups to accomplish assignments while Tubo serves as a team member. Tubo offers a number of features, including onboarding by welcoming students and introducing the classroom, assignment guidance by outlining tasks and providing directions, using multiple-choice questions to reinforce important ideas, progress monitoring involves keeping tabs on student’s development and responding to often requested queries, and maintaining students' motivation through small conversation and encouragement. At the end of the experience of Tubo, students enjoyed Tubo's interactive and enjoyable diversion from traditional classroom instruction. A few pupils said they could envision themselves using Tubo on their own. On the other hand, a few students lost interest in Tubo's instruction because they thought it was overly strict and repetitious, and some of them struggled with task division and frequently worked in switches rather than cooperatively.

Based on the purpose of reducing educational inequities, particularly in the area of English language instruction, where rural children frequently lack access to resources and qualified teachers. The authors in this study [32] introduce BuddyBot chatbot to help achieve Sustainable Development Goal 4 (SDG4), which is to guarantee that everyone has access to high-quality, inclusive education. By giving instant feedback on grammar, vocabulary, and sentence structure, the chatbot attempts to provide a customized learning experience. BuddyBot is constructed by utilizing GPT-2 model and Google's FLAN-T5 model. In order to comprehend and react to learners' inquiries, correct grammar, and offer language feedback, both models were refined using specific datasets. The introduced chatbot performed strongly on fact-based and open-ended questions, as well as brief and lengthy chats. The results show a decrease in training loss from 0.778 to 0.414 across 8 epochs and an improvement in accuracy.

Considering the growing requirement in industries such as Small and Medium-sized businesses (SMEs), this study [33] investigates essential technologies for chatbots to produce responses. The study trains an enterprise chatbot knowledge base using deep learning frameworks. The study presents a chatbot that utilizes a Sequence to Sequence (Seq2Seq) model with Long Short-Term Memory (LSTM) to enhance SMEs industry. LSTM was used as the encoder and decoder, while the Seq2seq model merged with the target corpus to improve propriate the roles of customer service. At the beginning of neural network processing, the chatbot dataset completed preprocessing, word vector training, and dialogue Q&A conversion. Users were able to submit queries and view the chatbot’s generated answers through a Flask web interface. The introduced chatbot website can dynamically hot-load and train the model without restarting the chatbot after deployment. This feature enables ongoing enhancement and flexibility in response to changing client demands.

"Nabiha", a chatbot designed by [34] to engage in conversations with Information Technology (IT) students at King Saud University using the Saudi Arabic dialect. Consequently, Nabiha marks the first Arabic chatbot utilizing Saudi dialect. To enhance accessibility, Nabiha is available across multiple platforms including Android, Twitter, and the web. Students can interact with Nabiha by downloading the application, engaging with her on Twitter, or visiting her website. The effectiveness of Nabiha was assessed by IT department students, yielding somewhat satisfactory results considering the challenges posed by the Arabic language, especially the Saudi dialect.

In [35], the authors suggested and created the smart guiding chatbot that utilized Saudi dialect, a text-based application for

Jeddah's tourism industry. Users could always reach the chatbot for the most recent information on locations, events, weather, and recommended places to visit. They provided a technical overview of the materials NLP, ML, and Rasa.ai are necessary to develop a chatbot. The study also covers how the chatbot uses the probabilistic model LSTM to classify, process, and predict data in order to identify the best match. The suggested chatbot can comprehend user demands and reply promptly, according to the results.

The other research, which has proposed a chatbot in Arabic dialect, was presented by [36]. The purpose of the authors is to create an intelligent chatbot system that can lessen this kind of burden in Arabic. Specifically, this approach facilitates the use of a Jordanian dialect of Arabic with students, especially those attending the Al-Zaytoonah Private University of Jordan. As a result, the suggested system is a basic Jordanian chatbot that speaks in the local dialect. Several artificial algorithms are used in the Intelligent Arabic chatbot system's architecture to assess and comprehend a range of visitor queries. This system is a website that quickly responds to inquiries from users. It also has an easy-to-use interface that answers inquiries about the placement cell, test cell, academics, admissions, users' attendance records, and grade point averages, among other things.

In [5], the authors describe the creation and deployment of Bashayer, a task-oriented chatbot integrated inside the WhatsApp app. Its goal is to assist Saudi Arabian postgraduate students with their study methodologies and motivation. A single-subject experimental design utilizing a quasi-experimental setup was used with a group of 60 postgraduate Saudi students. The findings of the descriptive analysis of the data gathered indicated that postgraduate students who used the Bashayer chatbot system achieved encouraging outcomes. Compared to the control group, participants in the experimental group using Bashayer showed higher levels of motivation to learn. In addition, when using the chatbot, participants used more cognitive and metacognitive learning processes than the control group. The findings provide encouragement for the creation of Bashayer-like chatbots that will aid in the effective learning of postgraduate students. These findings fill a study void and add to the body of knowledge regarding the application of chatbots in postgraduate educational settings.

Table I summarizes these studies, focusing on the findings and limitations of each study.

This research is necessary, as it addresses a significant gap in the existing literature by developing a chatbot specifically tailored to understand and respond to the Western Saudi dialect, which has been underrepresented in the field of NLP. While there has been substantial work on general-purpose chatbots and models designed for widely spoken dialects or MSA, few studies have focused on region-specific dialects like the Western Saudi dialect, especially in the context of university students. By developing a chatbot that can respond to questions unique to Taibah University, including course registration, academic regulations, and campus information, this research seeks to give students a useful solution. This project will not only fill the gap in dialect-specific chatbot development but also enhance institutional efficiency and student assistance by relieving staff workloads and providing students with quicker access to information.

IV. Methodology

This section describes the research methodology that has been followed to achieve all the research objectives. Throughout this section, a description of the research methodology has been provided. Each phase ends with results obtained from their activities, and the results of each phase are used as a starting point for the next phase. The research methodology consists of six interrelated stages, namely:

- Problem Identification (stated earlier).
- Algorithms
- Data Collection
- Implementation Plan
- Evaluation Methods

A. Algorithms

The chatbot will utilize the LLM specifically, GPT model. This section briefly describes the LLM and GPT. LLM is a Statistical language model that estimates the probability of word sequences, facilitating a range of activities like code creation, question answering, and translation. To generalize from context, they are trained on large datasets and mostly rely on transformer designs. LLM learns a probability distribution for word sequences, see Eq. (2). This allows it to predict the next word given the previous context. Furthermore, it is designed to generate text by sampling from the learned probability distribution, facilitating tasks like summarization, essay writing, or even solving problems [37].

$$P(W1, W2, \dots, WL) \quad (2)$$

Autoregressive techniques, in which the model predicts the next word one step at a time, are frequently used by LLMs, see Eq. (3):

$$P(Wn + 1 | W1, W2, \dots, Wn) \quad (3)$$

The main factors of transformer architecture are transformer models which are rely on the attention mechanism, which enables the model to consider the relative relevance of various input phrases while making predictions, see Eq. (1). In the equation, Q, K, VQ, K, V represent queries, keys, and values derived from input embeddings.

Also, positional encoding utilizes to encode word order, positional embeddings are appended to word embeddings because transformers are intrinsically permutation invariant. Additionally, scalability transformers are more effective than recurrent designs because they enable parallel processing.

Self-supervised learning is used to train LLMs to anticipate next or masked words in text sequences. The goal is to reduce a loss function, such as cross-entropy, see Eq. (4). According to empirical scaling laws that relate loss to model and dataset size performance is enhanced with larger models and datasets.

TABLE I STUDIES SUMMARIZATION TABLE

Research	Approach	Model	Language	Key findings	Limitation
[27]	Retrieval based	ML	English	Enhancing academic improvement strategies	cost considerations, user acceptance, and the need for continuous updates.
[28]	Retrieval based	NLP, ANN	English	Handling a wide range of student queries and providing a scalable solution for enhancing student support services	-
[29]	Generative	GPT	English	Providing precise answers, encouraging interactive learning, and effectively adjusting to the demands of the students	having difficulty comprehending context and relying on the quality of the training data to generate accurate responses
[30]	Rule based	-	English	Enhancing the team learning method	Some student think that the chatbot became somewhat repetitive and boring over time
[32]	Generative	GPT-2, Google's FLAN-T5	English	achieving 80% accuracy in dialogue generation, demonstrating proficiency in question answering with an 83% accuracy	-
[33]	Retrieval based	Seq2Seq, LSTM	English	Effective preprocessing, Enhancing chatbot performance with LSTM	-
[34]	Retrieval based	-	Arabic, Saudi dialect	The initial Nabiha chatbot experiment's findings were fairly satisfactory.	Lack of dataset
[35]	Retrieval based	NLP, LSTM	Arabic, Saudi dialect	Effective interaction, and immediate responses	-
[36]	Retrieval based	NLP	Arabic, Jordanian dialect	Quickly responding to inquiries from users, and an easy-to-use interface	Additional experiments and adjustments are necessary.
[5]	Retrieval based	-	-	Supporting postgraduate students' motivation and learning strategies	Small students sample, short duration of testing

$$L = -\frac{1}{N}\sum_{i=1}^{N} log\ P(w_i \mid w_{1:i-1}) \quad (4)$$

GPT model is a type of LLM which use transformer architecture to anticipate the next word in a sequence. Pretraining on large corpora to identify general linguistic patterns and fine-tuning on particular tasks are the two phases of training GPT models. With GPT-3 (175 billion parameters) bringing few-shot and zero-shot learning and GPT-4 (estimated 1.4 trillion parameters) showcasing sophisticated reasoning skills, GPT has seen significant evolution since its launch in 2018. Although it is still constrained by hallucinations, logical fallacies, and computational needs, its autoregressive methodology, scalability, and generalization across tasks are important aspects [38].

B. Data Collection

Since the accuracy of the results and conclusions is greatly impacted by the quality of the data collected, the data collection phase is one of the most important phases in any research or analytical study. The data was collected from a variety of sources during this phase to guarantee thoroughness and diversity, successfully matching the goals of the research.

Formal requests have been made to gather student inquiries that was send to academic advisers as part of the research on creating a GPT-based approach to assist Saudi university students. The Deanship of Information Technology at Taibah University has received the request. In order to examine common issues, commonly asked questions, and the general framework of academic advising exchanges, the goal of these requests was to obtain access to student inquiries that was send to academic advisers from eservices portal of Taibah University.

A Taibah University student Telegram group for the faculty of computer science (CCSET) was employed as one of the primary data sources. This platform was a powerful source of qualitative data since it offered insightful information about student conversations, concerns, and shared experiences. The author gathered pertinent information by examining the group discussions and exchanges, which helped clarify students' academic and administrative difficulties.

Moreover, information received in emails pertaining to the Course Equivalency Committee has been gathered. These emails contained information related to the policies concerning course credit transfers, decision-making processes, and the criteria for determining course equivalency requests. This source was particularly useful in understanding how the university manages credit recognition and how students interact with it.

The other major source of information included Academic Advising Committee emails. The emails provided data regarding the advising and counseling extended to students, including advising policy, mentorship programs, and academic services to help students in their educational planning. From perusing these messages, the university's academic advising mechanism and how the system assisted the students have been provided.

Also, the names and email addresses of faculty members at Taibah University was obtained from the Deanship of Information Technology. This source was essential in ensuring faculty members across various departments had access to accurate and up-to-date contact details.

By relying on these previously diverse sources, the balanced dataset that supports a multifaceted analysis of the academic experience at Taibah University has been collected. The reliance on several sources ensures a balanced perspective, drawing from student perceptions as well as official university policies.

C. Implementation Plan

The implementation strategy focuses on developing two chatbot systems that are specifically designed to interact using the Western Saudi dialect, ensuring that the responses align with the linguistic and cultural nuances of the target user group—university students in the western region of Saudi Arabia. Traditional machine learning performance is measured against the first chatbot, which is constructed using an SVM model. The GPT-3.5 model, a transformer-based generative language model renowned for its sophisticated contextual comprehension and fluency, is used by the second chatbot in contrast.

The objective of this dual-model setup is to conduct a systematic comparison between conventional machine learning techniques and state-of-the-art transformer models in the context of dialect-specific natural language understanding. Additionally, a separate retrieval-based model using Term Frequency-Inverse Document Frequency (TF-IDF) and Cosine Similarity is implemented to handle queries related to faculty email addresses. In order to prevent the possibility of fabricated or hallucinated email information, this retrieval component is purposefully separated from the generative system. This ensures factual accuracy and upholds user trust.

D. Evaluation Methods

In this research project, a multi-dimensional assessment method was employed to critically assess the chatbot's performance. Three complementing methods were selected: human evaluation, BERTScore, and automatic GPT-4-based judgment. Human evaluation was used to elicit subjective factors such as naturalness, tone, and cultural appropriateness, yielding useful real-world observations particularly for the Western Saudi dialect. For quantitative measurement of semantic similarity among generated responses and reference answers independently, BERTScore was utilized as a context-sensitive alternative to typical surface-level measures. Further, GPT-4 also served as an automatic judge to enable scalable and uniform assessment across large datasets without trading practical practicability at the cost of linguistic insensitivity loss. By merging human judgment, semantic assessment, and machine testing, the technique provided a robust and rich assessment of the chatbot's linguistic, cultural, and functional capacity.

First, human evaluation was conducted to capture subjective aspects of response quality that are difficult to measure algorithmically, such as appropriateness, cultural alignment, and conversational naturalness. Human annotators assessed the relevance, fluency, and tone of the chatbot's replies based on a predefined set of guidelines tailored to the Western Saudi dialect context. This form of evaluation provided valuable insights into the real-world usability and acceptability of the chatbot among the target audience.

To evaluate the accuracy of the chatbot responses using human judgment, a human evaluation process was conducted involving five independent annotators. Each annotator reviewed the chatbot's responses and provided a binary judgment—either "Yes" if the response was considered appropriate, or "No" if it was not. For each response, the final decision was determined through majority voting, where the most frequent judgment (i.e., at least 3 out of 5 votes) was taken as the overall evaluation of that response. Once the final decisions were established for all responses, accuracy was computed by dividing the number of responses that received a majority "Yes" by the total number of responses evaluated. This approach ensures a reliable and consensus-based assessment of the chatbot's performance.

Second, BERTScore was employed to objectively measure the semantic similarity between the chatbot's generated responses and the ground-truth reference responses. Unlike traditional metrics such as BLEU or ROUGE that rely on exact n-gram matches, BERTScore employs deep contextual embeddings to identify whether two sentences are identical in meaning, even if they are differently phrased. This was particularly important given the linguistic richness and flexibility of the Western Saudi dialect, where multiple phrasings could be semantically correct.

In BERTScore, precision measures how well the chatbot's response captures the meaning of the reference answer. In Eq. (5), precision does this by checking each word in the chatbot's response and finding the most similar word in the reference, using BERT embeddings. A high precision means that most words in the chatbot's response are semantically similar to words in the reference answer.

$$P = \frac{1}{|\hat{X}|} \sum_{\hat{x}_j \in \hat{X}} max_{x_i \in X} \; sim(x_i, \hat{x}_j) \qquad (5)$$

In the BERTScore precision equation, each symbol plays a specific role in capturing the semantic alignment between the chatbot's response and the reference answer. The symbol $\hat{X}$ represents the set of tokens (words) in the generated response, while X denotes the set of tokens in the reference (ground truth) response. For every token, the equation searches for the most similar token x_i in the reference using cosine similarity of BERT embeddings, represented as $sim(x_i, \hat{x}_j)$. The maximum similarity for each generated token is then summed, and the total is divided by the number of generated tokens $|\hat{X}|$, resulting in the average semantic precision across the response.

On the other hand, recall in BERTScore checks how well the chatbot's response covers the important content of the reference answer. In Eq. (6), recall looks at each word in the reference and finds the closest matching word in the chatbot's response. A high recall means the chatbot included most of the important meanings from the reference answer.

$$R = \frac{1}{|X|} \sum_{x_i \in X} max_{\hat{x}_j \in \hat{X}} \; sim(x_i, \hat{x}_j) \qquad (6)$$

The recall equation in BERTScore operates in the reverse direction of precision. Here, X still denotes the set of reference

tokens, and $X\hat{}$ is the set of generated tokens. For each reference token, the model computes the maximum similarity with any token $x\hat{}_j$ in the generated response. This similarity is again based on cosine distance between BERT embeddings, expressed as $im(x_i, x\hat{}_j)$. The total of these maximum similarities is then divided by the number of reference tokens $|X|$, producing a measure of how completely the generated response covers the semantic content of the reference.

Finally, the BERTScore F1 combines precision and recall to give a single balanced score. As shown in Eq. (7), F1 score tells us how well the chatbot's response matches the reference in both accuracy and coverage of meaning. A high F1-Score means the chatbot response is both relevant and complete from a semantic perspective.

$$F1 = \frac{2PR}{P+R} \quad (7)$$

Third, GPT-4 was used as an automatic judge to provide scalable and consistent evaluation across a large number of test samples. GPT-4 was prompted to assess whether the chatbot's response was contextually appropriate and semantically accurate based on the given input message. The accuracy was calculated in the same way as human evaluation, by dividing the number of responses that were appropriate by the total number of responses. By using a state-of-the-art LLM as an evaluator, the research was facilitated with high linguistic sensitivity and judged consistency and reduced the need for a lot of human effort at the expense of evaluation quality.

By integrating these three mutually complementary evaluation methods, the performance assessment of the chatbot was made more balanced in nature, encompassing both human-centered perspectives and machine-based semantic and contextual accuracy. This provided an overall view of the strengths and shortcomings of the chatbot, thus enhancing the validity of the experiment results.

The selection of human evaluation, BERTScore, and GPT-4-based judging is particularly well-aligned with the specific objectives and challenges of this research. The primary goal is not merely to assess the technical accuracy of the chatbot's responses, but to ensure their cultural, linguistic, and contextual appropriateness within the Western Saudi dialect environment — an aspect that conventional metrics alone cannot fully capture.

Human judgment plays a crucial role in this regard, making fine-grained judgments founded on real-world conversational practices and user expectations. Given the sociolinguistic variation and familiarity built into the Western Saudi dialect, human judges are necessary to validate the chatbot's ability to converse naturally and respectfully with the target group.

Complementing this subjective perspective, BERTScore was chosen for its capacity to assess semantic similarity with high sensitivity to context and meaning. In dialectal settings, where different surface forms can express identical intents, traditional exact-match metrics would severely underestimate model performance. BERTScore circumvents this risk by taking into account if the answers generated convey the intended meaning, thus giving a more linguistically fair and representative score.

Furthermore, GPT-4 as an automatic judge introduces a scalable and efficient dimension to the assessment. Its advanced language understanding enables it to make near human-like assessment judgments on large quantities of data without the prohibitive time and costs of manual annotation. This scalability is especially relevant with the sizes of the test sets here and the need for consistent evaluation metrics on thousands of samples.

Overall, the selected evaluation metrics collectively are well-suited because they accommodate the research's new linguistic complexity, deployment practicability, and research objectives. Overall, they measure the chatbot's performance wholeheartedly, not just its correctness, but its meaningful conversation in a specific cultural and dialectal context.

V. Implementation and Experimentation Settings

This section provides the implementation method of the chatbot tailored to the Western Saudi dialect, specifically for the context of Taibah University. A baseline model using an SVM architecture and a more sophisticated model based on the GPT framework were both used to evaluate performance. The GPT-based model uses transformer-based language understanding, which is better suited to capture the subtleties of dialectal Arabic, whilst the SVM model provides a classificational modeling method. The two models were both trained with a customized dataset representing the western Saudi dialect linguistic properties, and the hyperparameters as well as the preprocessing methods used were deliberately chosen to give an informative and objective comparison. More information regarding the tools, the frameworks, training configurations, and the testing techniques used in this research is given in the next subsections.

A. Experiment 1: Email Retrieval-Based Model

To handle faculty email inquiries with greater reliability and to avoid the potential risk of generating inaccurate or non-existent email addresses, a separate retrieval-based model was developed. This model is built using TF-IDF and Cosine Similarity to retrieve verified faculty emails from a structured dataset. The system ensures that only authorized and approved email addresses are returned by depending on exact matches rather than generating output. The GPT-3.5-Turbo-0125 chatbot will eventually be merged with this retrieval-based email architecture. The hybrid system will automatically route email-related queries to the retrieval model, while general academic or administrative questions will be handled by the generative GPT-3.5-Turbo-0125 model. This architecture enhances both the accuracy and trustworthiness of responses by combining retrieval precision with the conversational fluency of transformer-based generation.

The TF-IDF approach is used to measure each text message in numerical terms by assigning weights to words based on their importance. Especially, TF refers to the number of times a word repeats in a message, and IDF reduces the weight of common words that appear in most messages. This provides a high-dimensional vector for each message that reflects its unique linguistic features. In order to find the best fit for a user's query, the input is converted by the same TF-IDF vectorizer and matched against the stored message vectors by Cosine Similarity, which measures the angle between vectors. The most

similar message is chosen, and its corresponding response is returned. This method is computationally efficient, doesn't require model training, and performs well when the data set is very clean and there are stable patterns in the language.

An important function was developed to serves as a decision-making mechanism that intelligently routes user queries to the appropriate response model. Specifically, it checks whether the user's input contains keywords related to email inquiries (e.g., "email", "بريد", "إيميل"). If such keywords are detected, the function delegates the task to a retrieval-based model built on TF-IDF and cosine similarity to return an exact match from a predefined list of official faculty email addresses. This approach is deliberately chosen to avoid generating or "hallucinating" non-existent email addresses, a risk commonly associated with generative models like GPT. Conversely, if the query is unrelated to emails, it is forwarded to a fine-tuned GPT model trained to respond in the Western Saudi dialect. This dual-model architecture ensures both accuracy in factual information retrieval and fluency in conversational responses.

B. Experiment 2: Baseline Model

In this experiment, a baseline model was implemented using SVM to evaluate the feasibility of building a dialect-specific chatbot capable of understanding and responding in the Western Saudi dialect. The SVM model was selected due to its effectiveness in handling classification tasks with limited training data and its interpretability as a classical ML method. This experiment served as a foundational comparison for the subsequent evaluation of a more sophisticated GPT-based model. By establishing the performance ceiling of a traditional model, the research aimed to determine the added value of utilizing LLMs in regional Arabic dialect applications.

The dataset used in this experiment consisted of paired question–answer entries written in the Western Saudi dialect, preprocessed to remove emojis, special characters, and unnecessary whitespace. The data was divided into 80% for training and 20% for testing. Text preprocessing included tokenization, lowercasing, and TF-IDF vectorization to convert the textual data into numerical feature representations. An SVM classifier with a linear kernel was then trained on the resulting feature matrix.

C. Experiment 3: GPT Model

The third experiment explores the performance of an advanced large language model, GPT-3.5-Turbo-0125, developed and hosted by OpenAI. Unlike traditional ML models such as SVM, GPT-based models leverage deep transformer architectures pre-trained on massive corpora. This capability enables the model to generate contextually relevant and linguistically coherent responses, even in dialectal variants with limited annotated resources. The purpose of this experiment is to evaluate the effectiveness of GPT-3.5-Turbo-0125 when fine-tuned on a custom dataset of dialogues in the Western Saudi dialect, and to compare its performance against the previously established SVM baseline.

For fine-tuning the same dataset that was utilized in the SVM, has also been utilized in this phase. The dataset of Western Saudi dialect messages and their corresponding responses was converted into a format compatible with OpenAI's fine-tuning pipeline. The input-output pairs were structured as prompt–completion sequences, with each user message serving as a prompt and the ideal chatbot reply as the completion. The training process was conducted via OpenAI's fine-tuning API, utilizing the base model gpt-3.5-turbo-0125. Once the custom model was trained, evaluation was performed using a test set consisting of unseen message-response pairs. Additionally, some test cases were assessed using an automated judge—GPT itself—by requesting it to determine whether the generated response was appropriate, based on a scoring system that reflected qualitative judgment. This setup enabled both quantitative and human-aligned evaluation.

VI. Results and Discussion

This section presents a detailed analysis of the experimental results and interprets their significance in the context of the research. The performance of the proposed chatbot model is examined using relevant evaluation metrics to assess its ability to understand and respond in the Western Saudi dialect. A comparative study is carried out against a baseline SVM model in order to better position the results and emphasize the advantages of transformer-based techniques over traditional methods for ML. The ramifications of the results and their applicability to the goals of the research.

A. Results of Email Retrieval-Based Model

The model achieved an Exact Match Accuracy of 99.96%, indicating that it performs with a very high level of precision in retrieving the correct email address based on the provided Arabic display names.

TABLE II Results of SVM Responses of User's Messages

Message		**Response**	
Arabic	***English***	***Arabic***	***English***
لو نزلي حرمان وعندي اعذار ينشال؟	If I receive a deprivation notice but have valid excuses, is it possible to have it lifted?	ايوا	Yes
كم الغياب المسموح لمحاضرات عددها٣٠؟	How many absences are allowed for 30 lectures?	ايوا	Yes
أبغى ايميل دكتور ماهر	I want Dr. Maher's email	لازم تعطيني الإسم الثنائي لعضو هيئة التدريس عشان أبحث بشكل دقيق	Please provide the full name of the faculty member in order to perform an accurate search.

B. Results of SVM Baseline Model

Table II shows the results of the SVM-based chatbot's performance in handling different inquiries. Each row in the table represents a message from the user and the corresponding response generated by the chatbot.

The response of message "لو نزلي حرمان وعندي اعذار ينشال" (If I receive a deprivation notice but have valid excuses, is it possible to have it lifted) indicates that the chatbot correctly understood the user's query about whether an academic penalty

could be waived in the presence of valid excuses. The chatbot provides a simple affirmative response "ايوا" (yes), confirming the possibility of such an action.

The model's weakness in answering the question " كم الغياب المسموح لمحاضرات عددها ٣٠" (How many absences are allowed for 30 lectures?) is evident in its vague and imprecise response of "ايوا" (yes). This indicates that the SVM model failed to fully understand the context of the question, as it should have provided a specific answer regarding the allowed absenteeism percentage for a given number of lectures. Instead, it gave an unclear response.

In the third response, the chatbot correctly asked the user for the full name of the faculty member "دكتور ماهر" (Doctor Maher) in order to provide an accurate result.

Table III provides a summary of the SVM model's performance metrics on the test dataset, which comprises 20 messages and the responses that go with them.

TABLE III EVALUATION METRICS RESULTS OF 20 MESSAGES AND ANSWERS OF TEST DATA FOR SVM

Evaluation metric	Result
Accuracy	0. 4286
F1-score	0. 8709
Precision	0. 8806
Recall	0. 8631
latency	0.2 sec

The model was able to accurately predict the answers for almost 43% of the test data, according to its accuracy of 42.86%. Given that the model is trained in predefined classes and assessed on unseen data, this accuracy may seem moderate, but it actually represents the difficulty of the task. The test set contained unseen responses, which the model might not have been trained to handle well, which could account for the comparatively poor accuracy. Given how much the SVM model depends on the data it was trained on, this points to a possible drawback.

In terms of F1-score, the model achieved a value of 87%, suggesting a strong balance between precision and recall. The precision of 0.8806 indicates that when the model predicted a response, it was correct approximately 88% of the time, minimizing false positives. Meanwhile, the recall of 0.8631 shows that the model was able to identify about 86% of the true positive responses, indicating that it was successful in capturing most of the correct answers in the test set. With a latency of 0.2 seconds per prediction, the model can respond in real time, which makes it appropriate for chatbots and other applications that need fast feedback. Even with its moderate accuracy, the overall performance indicates that, when trained on the different formations of data, the SVM model may effectively detect accurate responses.

C. Results of GPT-3.5-Turbo-0125 Advanced Model

The sample results from the GPT-3.5-Turbo-0125 model that is provided in the Table IV show its ability to provide contextually accurate and relevant responses to a variety of student inquiries. For instance, when asked about permissible absenteeism for 30 lectures, the model gave a specific response, stating that 25% absenteeism is allowed, which is a precise and useful answer. Other responses, such as requests for emails or explanations on university policies, are similarly helpful, providing the necessary details or requesting additional information when needed.

The fine-tuned GPT-3.5-Turbo-0125 model demonstrated a significant improvement in handling dialogue generation tasks compared to traditional ML approaches. Upon interacting with user prompts written in the Western Saudi dialect, the model consistently produced coherent, contextually appropriate responses, and linguistically aligned with the informal and natural conversational style characteristic of the region. The system message used on each interaction gave the model a welcoming, culturally appropriate tone and essentially replicated the pattern of speech of students in Madinah, Jeddah, Mecca, and Taif. Throughout the testing phase, the model exhibited an excellent ability to comprehend highly varied input phrasings, including colloquial expressions, truncated sentences, and context-implicated questions, without requiring explicit rephrasing or clarification.

Furthermore, the qualitative observations output of the model highlighted its strong capacity for conforming to delicate language use, such as responding appropriately to rhetorical questions, handling indirect requests, and engaging with culturally embedded expressions. Unlike traditional models that rely on fixed feature extraction techniques, GPT-3.5-Turbo-0125 leveraged its deep contextual understanding to generate responses that not only matched the intended meaning of the prompts but also maintained the conversational fluency expected in natural human dialogue. The consistency, richness, and contextual awareness observed in the outputs confirm the model's potential for real-world deployment in dialect-specific chatbot applications. These results strongly support the adoption of LLMs when aiming to develop conversational agents capable of interacting naturally and effectively within specific cultural and linguistic contexts.

Table V contains the evaluation metrics that provide important information about the performance of the GPT-3.5 model, which has been optimized to comprehend and reply to student questions in the Western Saudi dialect. The Human Evaluation Accuracy of 0.8473 demonstrates that the model's responses were deemed accurate by the five evaluators, consisting of three students from the Computer Science department, a Computer Science graduate, and a technical employee. This great accuracy shows that the model was able to correctly analyze and answer questions with a degree of agreement among experts, even with its specialized training.

TABLE IV RESULTS OF GPT-3.5-TURBO-0125 MODEL RESPONSES OF USER'S MESSAGES

Message		Response	
Arabic	*English*	*Arabic*	*English*
لو نزلي حرمان وعندي اعذار ينشال؟	If I receive a deprivation notice but have valid excuses, is it possible to have it lifted?	ايوا	Yes
كم الغياب المسموح لمحاضرات عددها ٣٠؟	How many absences are allowed for 30 lectures?	الغياب المسموح 25٪ من مجموع المحاضرات	The allowed absence is 25% of the total number of lectures.
أبي ايميل دكتور ماهر	I want Dr. Maher's email	لازم تعطيني الإسم الثنائي لعضو هيئة التدريس عشان أبحث بشكل دقيق	You need to provide the full (first and last) name of the faculty member so I can search accurately.
بسأل في التقييم بالموقع يطلع عند الدكتورة اسمي؟	If I submit a course evaluation on the website, will my name appear to the instructor?	لا ما يطلع اسمك بالتقييم	No, your name does not appear in the evaluation.
انا اول سنة واخذ برمجه طبيعي اني احسها جدا صعبة؟	This is my first year, and I'm taking programming. Is it normal to find it very difficult?	طبيعي جداً ، اغلب الطلاب يحسون بصعوبة في مادة البرمجة لكن المهم تراجعها أول بأول	It's completely normal. Most students find programming difficult, but the key is to review it regularly.
التاجيل قفل ؟	Is the postponement period closed?	على حسب التقويم	It depends on the academic calendar.

TABLE V EVALUATION METRICS RESULTS OF ALL TEST DATA FOR GPT-3.5-TURBO-0125

Evaluation metric	Result
Human Evaluation Accuracy	0.8473
GPT-4 Evaluation Accuracy	0.60
F1-score	0.706
Precision	0.71
Recall	0.705
latency	2 sec

On the other hand, the GPT-4 Evaluation Accuracy of 0.60 reflects a somewhat lower performance from the GPT-4 model in evaluating the chatbot's responses. The difficulty of having a non-human evaluator evaluate responses involving complicated dialects and region-specific settings is highlighted by the fact that, despite its power, GPT-4 was less in line with the perceptions of human evaluators. Combining Precision (0.71) and Recall (0.705), the F1-score of 0.706 indicates a well-balanced model performance. It was able to effectively identify correct responses while minimizing errors. Precision suggests that 71% of the responses identified as correct were truly correct, while Recall shows that the model captured about 70.5% of all the correct responses. Lastly, these metrics demonstrate the model's accuracy and relevance in processing queries in the Western Saudi dialect.

VII. DISCUSSION OF FINDINGS

As shown in Table VI, the difference in responses between GPT-3.5-Turbo-0125 and SVM for the message "كم الغياب المسموح لمحاضرات عددها ٣٠" (How many absences are allowed for 30 lectures?). It is noticeable that GPT-3.5-Turbo-0125 performs better than the SVM model in terms of giving more precise and thorough answers. In particular, GPT-3.5 gave an exact response of 25% absenteeism to the question on acceptable absences for 30 courses, demonstrating a deeper comprehension of academic policies. The SVM model, on the other hand, had trouble answering this kind of question and provided ambiguous answers like "ايوا" (Yes), which lacked the relevant information. Particularly when contrasted with the more straightforward and uninformative results produced by the SVM model, GPT-3.5's capacity to manage intricate queries and deliver precise, context-aware responses is remarkable. This demonstrates GPT-3.5's superior understanding of context and ability to generate specific and meaningful responses.

TABLE VI RESPONSE COMPARISON BETWEEN SVM AND GPT-3.5-TURBO-0125

	Message	Response
SVM	كم الغياب المسموح لمحاضرات عددها ٣٠	ايوا
GPT-3.5-Turbo-0125	كم الغياب المسموح لمحاضرات عددها ٣٠	الغياب المسموح 25٪ من مجموع المحاضرات

The comparative evaluation between the SVM baseline model and the fine-tuned GPT-3.5-Turbo-0125 model clearly demonstrates the superiority of transformer-based approaches in handling dialect-specific dialogue tasks. The SVM baseline, trained on TF-IDF features with an RBF kernel, achieved a modest accuracy of 42.86% on the test set that contains only 20 messages. Its performance was limited by its dependency on surface-level lexical similarities and the insufficiency of generalization to all the random and garrulous expressions that belong to the Western Saudi dialect.

Human assessors determined that 84.73% of the chatbot's responses were both culturally appropriate and contextually accurate. In addition to the human evaluation, BERTScore provided further validation of the model's performance, achieving an F1 score of 71% and confirming its ability to capture the intended semantic meaning. These findings were reinforced by GPT-4, used as an automated assessor, which judged 60% of the responses as acceptable. Collectively, these outcomes illustrate the deep contextual understanding, semantic flexibility, and cultural sensitivity of transformer-based models, particularly when compared to classical ML classifiers. This distinction becomes even more evident when addressing the linguistic richness and complexities associated with regional Arabic dialects.

The outcomes of this research carry important implications for the broader field of computer science, particularly in the domains of NLP, dialogue systems, and dialectal language

modeling. The significant performance gap observed between the SVM baseline model, and the fine-tuned GPT-3.5-Turbo-0125 model highlights the critical role that large-scale pretraining and context-sensitive fine-tuning play in building effective conversational agents. These results emphasize that typical ML techniques, while helpful for certain structured classification tasks, are insufficient to deal with the richness, dynamism, and cultural nuance of real-world dialogue, especially in underrepresented language varieties such as the Western Saudi dialect.

More generally, the successful deployment of a chatbot that answers academic queries in culturally responsive and linguistically sensitive terms demonstrates the growing capacity of AI to support broad and niche communities. It demonstrates how adapting LLMs to regional and domain environments can significantly enhance accessibility, inclusivity, and user satisfaction. This outcome is particularly relevant where MSA dominates the technology interfaces to the detriment of local dialect speakers. Thus, this research contributes to the broader movement toward more personalized and culturally sensitive AI technologies.

Moreover, this work moves the frontier of knowledge and practice by illustrating an effective way of combining fine-tuning techniques, dialectal prompt engineering, and multi-dimensional assessment methods to attain high-quality conversational systems. It also provides empirical evidence that cultural and linguistic localization is not only possible but also highly effective when developing AI solutions for real-world applications. By systematically comparing the performance of the chatbot through human evaluation, semantic similarity metrics, and automatic metrics, this study sets a new benchmark for the evaluation of dialogue systems in low-resource language settings. Lastly, the research paves the way for future studies to bridge the gap between state-of-the-art language modeling technologies and the rich linguistic diversity within and across Arabic-speaking societies.

VIII. Conclusion

This research effectively created a culturally sensitive chatbot that could respond to academic questions in the Western Saudi dialect, providing significant contributions to Arabic NLP and dialogue system research. The comparison between the SVM baseline and fine-tuned GPT-3.5-Turbo-0125 model unequivocally exhibited the greater contextual understanding, semantic versatility, and cultural suitableness of transformer-based models. By integrating human judgment, BERTScore computation, and GPT-4-based analysis, the research provided a holistic and balanced assessment of the chatbot's performance. The findings demonstrate that AI technology is more inclusive and relevant than only its technological advancements when it is modified for underrepresented languages. This work sets a new benchmark for developing conversational agents in low-resource dialects by combining culturally appropriate system prompts, fine-tuning strategies, and stringent evaluation processes.

The research has limitations, especially in obtaining adequate and representative data for the Western Saudi dialect, despite the encouraging results. The complexity of Arabic and the variation within the dialect across different cities also posed challenges to building a consistent and natural chatbot experience.

Future work should focus on expanding dialect-specific datasets, addressing intra-dialectal variation, and exploring adaptive models that better generalize across regional differences. To further improve the caliber and versatility of AI-driven dialogue systems, future research might build on this foundation by investigating other dialects, expanding domain-specific applications, and improving assessment frameworks.

Acknowledgment

I would like to express my heartfelt gratitude to my project supervisor for her invaluable guidance, continuous support, and encouragement throughout the course of this research.

I am deeply thankful to my family and friends for their unwavering support, motivation, and patience during my academic journey.

I would also like to extend my sincere appreciation to Taibah University for providing an outstanding educational environment.

***Abstract*—Natural disasters pose significant threats to human life and infrastructure. Timely detection and assessment of these events are crucial for effective disaster management. This study proposes an automatic detection system for natural disasters using aerial imagery. Accurate and timely detection of natural disasters is critical for minimizing their impact and supporting emergency response efforts. This study presents a comparative analysis of deep learning architectures for natural disaster detection using satellite and aerial imagery. Four models were evaluated as baseline CNN, ResNet50, Faster-CNN, and Faster R-CNN with a ResNet50 backbone using standard classification metrics. The results demonstrate that deeper and more sophisticated models significantly enhance detection performance. While the baseline CNN achieved modest results with 85.3% accuracy, integrating residual learning in ResNet50 improved accuracy to 92.7%. Region-based models further boosted performance, with Faster-CNN and Faster R-CNN attaining 95.1% and 97.1% accuracy, respectively. The superior performance of the Faster R-CNN with ResNet50 highlights its robustness and suitability for real-time disaster monitoring, offering a scalable and reliable solution for operational deployment in disaster management systems.**

***Keywords*—Natural disasters detection; satellite imagery; convolutional neural networks (CNN); transformers; deep learning; ResNet50; proactive monitoring; faster R-CNN; disaster prevention; computer vision**

I. Introduction

Natural disasters are becoming more frequent and severe, underlining the urgent need for enhanced detection and management strategies. Traditional approaches often depend on manual analysis of aerial images, a process that can be both time-consuming and prone to human error. However, recent advancements in deep learning have opened new avenues for automating this task. Natural disasters (NDs), which include volcanic eruptions, earthquakes, landslides, floods, tsunamis, hurricanes, tornadoes, droughts, wildfires, and severe temperatures, pose enormous dangers to human life and infrastructure [1,2]. Throughout history, these events have caused widespread devastation and substantial loss of life. From earthquakes and volcanic eruptions to hurricanes, floods, and wildfires, natural disasters have profoundly affected both populations and the environment. Among the deadliest recorded were the 1931 China floods, triggered by intense rainfall and river overflows, which inundated over 50,000 square miles and claimed an estimated 3.7 million lives. Other significant natural disasters in history include the 1883 eruption of Krakatoa in Indonesia, which caused over 36,000 deaths and generated a massive tsunami that damaged coastal communities across the region [3]. The 1985 Mexico City earthquake, with a magnitude of 8.0, caused extensive damage to the city's infrastructure, resulting in more than 10,000 fatalities and leaving over 100,000 people homeless [4]. In recent years, natural disasters have continued to profoundly impact communities worldwide [5, 6]. For example, the 2011 Tohoku earthquake and tsunami in Japan claimed over 15,000 lives and severely damaged the country's infrastructure. In 2017, Hurricane Maria devastated Puerto Rico, causing widespread destruction and leaving most of the island without power for months [7]. Many communities face long-term struggles to rebuild their lives after such events, as the consequences of natural disasters can last for years or even decades, including the loss of homes and infrastructure, displacement of populations, and destruction of ecosystems.

Climate change has intensified the frequency and severity of these catastrophes, making it increasingly critical to develop strategies to mitigate their impacts [8]. In summary, natural disasters have historically caused tremendous harm to both communities and the environment. While technological advancements and improvements in disaster preparedness such as early flood detection systems, predictive analytics, machine learning, remote sensing, geographical information systems (GIS), satellite navigation, drone technology, cloud computing, enhanced communication and information sharing, resilient infrastructure, and early warning systems [9–12] have helped lessen their effects, natural disasters continue to pose serious challenges globally. Therefore, sustained investment in disaster preparedness and response remains essential to minimizing the impact on human lives, infrastructure, and ecosystems.

Fortunately, technological progress has greatly enhanced our ability to predict, respond to, and recover from these catastrophic events [13]. Technologies like remote sensing, radar, and satellite imaging provide diverse tools for monitoring the Earth's surface and atmosphere from a distance. Advances in these fields now allow for real-time tracking of natural disasters such as volcanic eruptions, wildfires, and landslides. By analyzing data collected through remote sensing systems, we can improve our understanding of the scale and intensity of these events, which supports the development of effective evacuation plans and recovery efforts. Leveraging this information is a key strategy for strengthening disaster preparedness. Additionally, technologies such as the Internet of Things (IoT), smartphones, and social media play a crucial role in the rapid collection and dissemination of information during

natural disasters [14–21]. IoT devices, such as weather monitoring instruments and seismic sensors, provide real-time data that help emergency responders make quick, well-informed decisions. Likewise, smartphones and social media platforms serve as effective channels for alerting people in affected areas, delivering vital updates on evacuation routes, shelter availability, and other essential resources.

This study aims to thoroughly investigate how various technologies contribute to natural disaster management. It explores the roles of Remote Sensing, Radar, Satellite Imaging, Autonomous Robots and Drones, IoT, Smartphones, and social media in responding to events like earthquakes, volcanic eruptions, landslides, and tsunamis. These technologies have been key in safeguarding lives, enabling coordinated rescue operations, and reducing damage to infrastructure.

The structure of this study is as follows: Section II presents background information on natural disasters and their environmental impact. Section III offers a comprehensive description of the dataset utilized. Section IV outlines the methodology and the proposed model. Section V discusses the evaluation results, and finally, Section VI provides the conclusion.

II. BACKGROUND

In recent years, the integration of satellite imagery with machine learning (ML) and deep learning methods has seen widespread use in various disaster management applications.

a) Earthquakes and volcanic eruptions: Earthquakes are among the most severe natural disasters, triggered by the sudden movement of tectonic plates beneath the Earth's surface, resulting in ground shaking and displacement [22]. These seismic events can cause extensive damage to infrastructure such as buildings, roads, and homes, and often lead to significant loss of life. The intensity of an earthquake is measured on the Richter Scale, which ranges from 1 to 10, with higher values indicating stronger quakes. According to the United States Geological Survey (USGS), approximately 20,000 earthquakes occur globally each year, with around 16 reaching a magnitude of 7.0 or above [23]. Earthquakes can also initiate secondary disasters such as landslides, tsunamis, and volcanic eruptions, increasing their overall impact (USGS, 2021) [24].

Volcanic eruptions represent another dangerous type of natural disaster. These occur when magma from beneath the Earth's surface rises and is expelled, often due to tectonic activity. Eruptions can result in pyroclastic flows, ash falls, and lava flows, all of which can cause widespread destruction and loss of life. The Volcanic Explosivity Index (VEI) is used to quantify the magnitude of an eruption, considering the volume of ash, lava, and other materials released during the event (USGS, 2021) [25]. The consequences of natural disasters such as earthquakes and volcanic eruptions often extend far beyond their initial impact. Earthquakes can reshape landscapes, redirect rivers and streams, and thereby alter ecosystems and wildlife habitats. Similarly, volcanic eruptions that release significant quantities of ash and gases into the atmosphere can influence global weather patterns and air quality [26].

Vulnerable communities exposed to risks from earthquakes, quarry blasts, and volcanic activity can significantly reduce their vulnerability through proactive planning and mitigation strategies [27, 28]. The loss of lives and property can be minimized when individuals and authorities establish well-structured emergency plans, including evacuation routes, in advance. Furthermore, governments play a crucial role by enforcing resilient building codes and investing in infrastructure that is capable of withstanding seismic and volcanic events.

Public education is also a vital component in reducing disaster impact. It provides people with accurate knowledge and preparedness about resources, such as how to respond during an earthquake or volcanic eruption empowers communities to act swiftly and effectively in times of crisis. Raising awareness and building local capacity helps ensure a more resilient response to future natural disasters.

Ultimately, earthquakes and volcanic eruptions are devastating events with the potential to cause long-lasting harm to both human populations and the environment. Mitigating their effects requires a combination of infrastructure investment, disaster planning, and community education. In alignment with these goals, this research centers on enhancing the performance of neural networks for detecting natural disasters, particularly under constraints like limited labeled datasets and low-power hardware environments. The optimized Faster R-CNN model developed through this work is tailored for real-time implementation on lightweight platforms such as smartphones, satellites, and high-altitude weather balloons, making it a scalable and cost-effective solution for broad disaster monitoring and response.

b) Landslides and tsunamis: Landslides and tsunamis are among the most devastating natural disasters, capable of causing significant destruction and loss of life. Landslides typically occur due to the instability of soil and rock on slopes, often triggered by factors such as intense rainfall or seismic activity. The severity of a landslide is measured using the Landslide Hazard Scale, which considers its potential to damage infrastructure and endanger lives. Beyond their immediate destruction, landslides can have long-term environmental consequences, such as altering watercourse paths and destroying habitats.

Tsunamis, on the other hand, are massive ocean waves usually triggered by underwater earthquakes or other subsurface disturbances. These waves can cause widespread flooding and infrastructural devastation, especially in coastal regions. Their severity is measured by the Tsunami Magnitude Scale, which assesses their destructive potential based on wave height. Due to their ability to affect vast oceanic regions, tsunamis are particularly dangerous, illustrated by the 2004 Indian Ocean tsunami, which claimed over 200,000 lives across multiple countries [29]. Preparedness strategies can greatly reduce the impact of these disasters, as shown in Fig. 2. These include enforcing resilient construction standards, developing detailed emergency and evacuation plans, and implementing monitoring systems for early warning. Educating at-risk communities on recognizing early signs of landslides or tsunamis and how to respond appropriately is also crucial.

Technological solutions such as early warning systems have proven effective in reducing disaster impact [30–34]. Governments and organizations can further mitigate landslide risks through reforestation and improved land management, while coastal engineering solutions like seawalls and breakwaters help shield populations from tsunamis.

As illustrated in Fig. 1, the findings from related studies categorize the impact of various natural disasters across four critical domains: infrastructure damage, loss of life, environmental impact, and potential to trigger secondary disasters. Earthquakes and tsunamis score the highest in infrastructure damage and fatalities, both rated at 5, highlighting their extreme destructive capabilities. Volcanic eruptions follow with slightly lower but still severe impacts on infrastructure and human life, and they are rated highest for environmental damage with a score of 5 attributable to lava flows, ash dispersion, and toxic emissions. Landslides rank comparatively lower across all categories, particularly in their ability to cause secondary disasters, where they score 2.

Previous studies on disaster severity scales consistently highlight the varying degrees of impact that different natural disasters impose on communities and environments. Research emphasizes that earthquakes and tsunamis rank among the most severe disasters. Volcanic eruptions, while sometimes less destructive to build environments, are noted for their significant environmental impacts, including long-term effects on air quality and ecosystems. Landslides typically score lower on severity scales, as their effects tend to be more localized and less likely to trigger widespread secondary disasters. These findings highlight the need for disaster-specific risk assessments and preparedness strategies.

Table I provides a summary of methodologies, datasets, strengths, limitations, and findings related to earthquake, volcanic, landslide, and tsunami studies.

Their methodology includes reviewing impact metrics such as the Richter Scale and Volcanic Explosivity Index. The organization also emphasizes disaster preparedness through policy recommendations that include education, resilient infrastructure, and evacuation planning. Although the studies are largely descriptive and lack predictive modeling or modern machine learning integration, they highlight the importance of early warning systems and community resilience in reducing disaster impact.

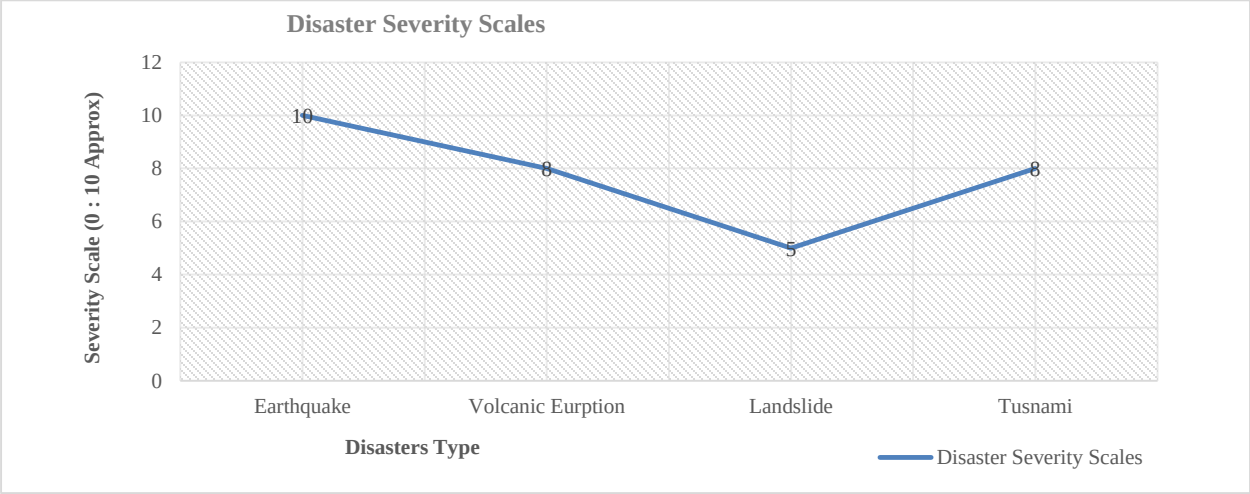

Fig. 1. Disaster severity scales.

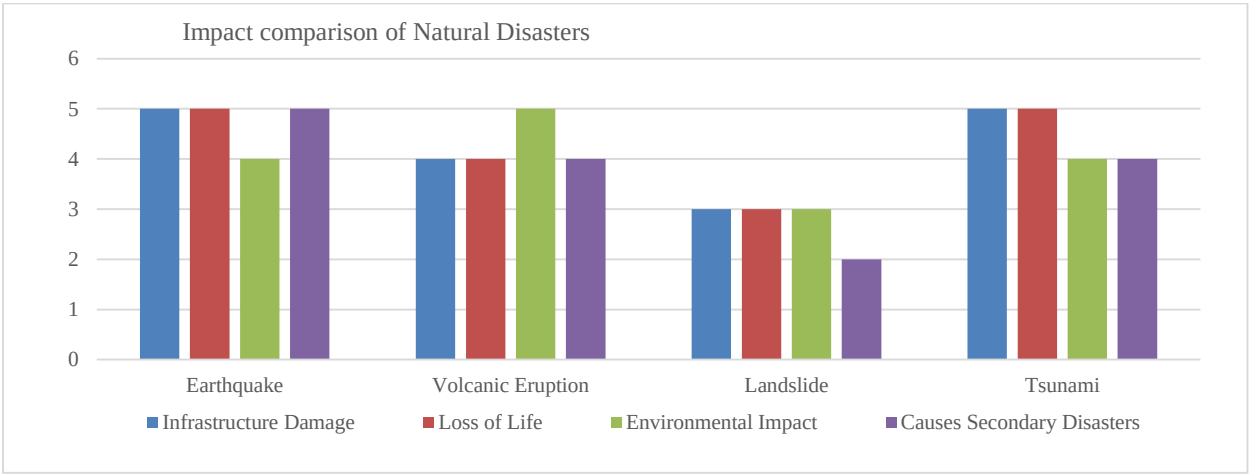

Fig. 2. Impact comparison of natural disasters.

TABLE I SUMMARY OF REVIEWED LITERATURE ON NATURAL DISASTERS INCLUDING METHODOLOGIES, DATASETS USED, STRENGTHS, LIMITATIONS, AND KEY FINDINGS (ADAPTED FROM USGS SOURCES [22–34])

Authors	Methodology	Dataset Used	Strengths	Limitations	Results
USGS [22-26]	Review and statistical analysis of natural disaster events including earthquakes and volcanic eruptions	USGS earthquake and volcano datasets	Covers a wide range of disaster types and global data; provides detailed impact metrics (e.g., Richter, VEI)	Primarily descriptive; lacks predictive modeling or real-time response components	About 20,000 earthquakes/year; 16 with magnitude ≥7.0; volcanoes cause atmospheric impact and secondary disasters
USGS [27-28]	Policy recommendations and preventive strategies for earthquake and volcanic events	Preparedness guidelines, infrastructure resilience studies	Emphasizes disaster risk reduction through education and infrastructure	Limited in terms of implementation analysis or specific case studies	Recommendations for community preparedness, evacuation plans, and resilient construction
USGS [29-34]	Descriptive analysis and historical review of landslides and tsunamis	Historical tsunami data (e.g., 2004 Indian Ocean event), Landslide Hazard Scale	Combines geological triggers with societal impact; includes early warning systems	Descriptive in nature, lacks integration with modern ML-based forecasting systems	Landslides disrupt habitats and waterways; tsunamis cause mass casualties and international devastation

III. DATASET

The dataset employed in this study is composed of satellite images capturing the aftermath of landslides and floods across selected regions in Japan and Thailand. The images were carefully selected to encompass a wide range of environmental and urban settings, enhancing the model's ability to generalize effectively. This dataset forms the foundation for training and evaluating the proposed deep learning model aimed at accurately classifying and identifying disaster-affected areas. In total, approximately 10,000 images were compiled, with an equal distribution between landslide, earthquake and flood scenarios to ensure a balanced learning dataset.

A. Data Collection

The images were acquired through publicly accessible geospatial platforms, primarily Google Earth, which offers high-resolution satellite images of global terrain. The selection process involved identifying locations in Japan and Thailand historically affected by floods, Earthquakes and landslides, followed by extracting relevant imagery from these regions. Care was taken to exclude poor-quality or ambiguous images to maintain the reliability of the dataset. This manual curation ensured that the resulting image collection was both representative and robust for the purposes of training a convolutional neural network (CNN) for disaster classification.

B. Annotations

To prepare the dataset for supervised learning, each image was annotated with bounding boxes highlighting the regions impacted by either landslides or floods. These annotations were carefully reviewed to ensure precision in identifying disaster-affected zones. Each bounding box was labeled with a corresponding class identifier, such as "landslide" or "flood", enabling the model to learn category-specific features. The annotations were stored in JSON format, which ensures compatibility with common deep learning frameworks and streamlines their integration into the training and evaluation pipeline.

IV. METHODOLOGY

A. Data Processing

Data processing plays a foundational role in the success of any deep learning pipeline, especially when dealing with image-based tasks such as Natural Disasters detection. The process begins with normalization, a critical step that involves scaling the raw pixel intensity values of each image to a standardized range typically [0, 1]. This transformation ensures uniformity across all input data, mitigating the effects of varying image brightness or contrast that could otherwise bias the learning process. Normalization also improves the stability and speed of training by helping the optimizer navigate the loss landscape more effectively.

Following normalization, the dataset undergoes a systematic splitting procedure to facilitate robust model training and evaluation. Using stratified sampling, the dataset is divided into three distinct subsets: 70% of the images are assigned to the training set, 15% to the validation set, and the remaining 15% to the testing set. Stratification ensures that the class distribution (i.e., Flood, Earthquakes and Landslide images) remains consistent across all subsets, which is essential for obtaining an unbiased performance evaluation and preventing skewed learning outcomes.

To further prepare the images for ingestion into the deep learning model, a series of image processing techniques are applied to enhance both the quality and diversity of the dataset. First, all images are resized to a fixed dimension of 224×224 pixels, which aligns with the input layer requirements of architectures of ResNet50 and ConvNeXt-Small. This uniform resizing ensures that the model receives input in a consistent shape, reducing computational complexity and memory overhead while preserving key spatial information.

Next, noise reduction is performed using Gaussian filtering, a technique that smooths out high-frequency noise that may be present due to atmospheric distortions, sensor limitations, or compression artifacts in the satellite imagery. By applying a Gaussian kernel, subtle variations in pixel values are averaged in a way that retains important edges and features while suppressing random noise, thereby improving feature extraction in the early convolutional layers of the model.

To combat overfitting and improve the model's generalization to unseen data, data augmentation techniques are extensively employed. These include random rotations, horizontal and vertical flips, and color jittering, each of which introduces controlled variability into the training data without altering its semantic content. For instance, rotating an image by a few degrees or flipping it horizontally simulates different

orientations of wildfires captured by satellites, making the model invariant to spatial transformations. Similarly, jittering the color channels mimics variations in lighting conditions and image sensors, thereby improving robustness.

Lastly, image enhancement is applied using histogram equalization, a method that redistributes the intensity values in an image to span a wider range of contrasts. This process makes subtle features more visually prominent, such as smoke patterns, vegetation boundaries, or burn scars, which might otherwise be indistinguishable in low-contrast areas. Enhanced contrast not only benefits visual interpretation but also improves the sensitivity of the model to faint or ambiguous features that are crucial for early wildfire detection.

Taken together, this comprehensive data and image preprocessing strategy ensures that the input images fed into the deep learning model are clean, balanced, diverse, and information-rich. It significantly enhances the model's ability to learn meaningful patterns, generalize real-world conditions, and make reliable predictions in operational wildfire monitoring systems. Fig. 3 shows the data processing flowchart.

B. Model Architecture

The proposed model for object detection in Natural disaster imagery leverages the power of Faster R-CNN, a state-of-the-art deep learning framework designed for efficient and accurate object localization and classification. Faster R-CNN integrates two key components: a Region Proposal Network (RPN) and a Fast R-CNN detection network.

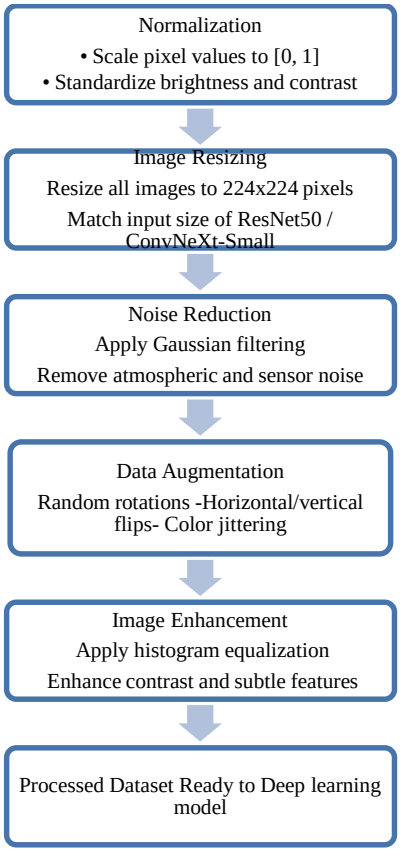

Fig. 3. Data processing.

1) Backbone ResNet50 as feature extractor. ResNet50, a deep convolutional neural network with 50 layers, has become a foundational architecture in image recognition and computer vision due to its innovative residual learning approach. A major challenge when training very deep networks is the vanishing gradient problem, where gradients diminish as they are propagated backward through numerous layers during training [35]. ResNet50 addresses this issue by incorporating skip connections, or residual connections, which allow gradients to flow more freely by bypassing one or more layers. These connections enable the network to learn identity mappings, helping the optimization process converge more quickly and reliably despite the increased network depth. With its 50 layers, ResNet50 effectively captures hierarchical representations of input images, learning simple features such as edges and textures in the initial layers and progressively more complex, abstract patterns like shapes, objects, and spatial relationships in the deeper layers. This capability is particularly advantageous for satellite image analysis, where features can vary significantly in scale, rotation, texture, and context. Whether distinguishing collapsed buildings, flooded areas, or wildfire scars, ResNet50's rich and multiscale feature representations allow for more accurate identification of disaster-affected regions. In this system, ResNet50 acts as the feature extraction backbone of the detection pipeline, converting raw satellite imagery into a feature map that encodes spatial and contextual information crucial for downstream object detection.

2) Region proposal network. The Region Proposal Network (RPN) scans the image to generate potential regions of interest (ROIs) that are likely to contain objects. Meanwhile, the Relationship Proposal Network (Rel-PN) is a deep learning architecture designed to improve scene understanding by effectively detecting meaningful relationships between objects within an image [36,37]. The process starts with an input image that is passed through a Backbone Convolutional Neural Network (CNN) to extract detailed feature maps. These feature maps are then analyzed by the RPN, which proposes candidate regions in the image that are likely to contain objects.

Instead of examining all possible object pairs (which grow quadratically), the Rel-PN intelligently selects only the most promising object pairs that are likely to be involved in a relationship. This selection is based on learned spatial and contextual cues. These relevant object pairs are then passed to a Relationship Classifier, which determines the specific type of interaction or relationship between them such as "person riding horse" or "dog next to man" [38].

3) Fast R-CNN detection network. The Fast R-CNN component refines the proposed regions by classifying them and adjusting their bounding boxes. Fast R-CNN is a deep learning architecture designed for efficient and precise object detection in images. The process begins with an input image that passes through multiple convolutional layers to extract feature maps. These feature maps are then processed by the Region of Interest (RoI) Pooling layer, which selects regions

likely to contain objects [39]. The selected regions are further passed through fully connected layers to produce high-level features. Finally, the network generates two outputs: a classification output that predicts the object classes, and a bounding box regression output that fine-tunes the coordinates of the bounding boxes around the detected objects.

This architecture greatly enhances both the speed and accuracy of object detection by sharing convolutional computations and utilizing RoI pooling to focus on relevant image regions. Its unified design supports end-to-end training and significantly speeds up the detection process compared to earlier two-stage detectors.

At the core of this architecture lies the ResNet50 backbone, a deep convolutional neural network renowned for its powerful feature extraction. ResNet50 employs residual learning through skip connections, allowing gradients to bypass one or more layers during backpropagation. This approach addresses the vanishing gradient problem, enabling effective training of very deep networks. Consequently, ResNet50 excels at learning rich, hierarchical visual representations, which are essential for accurately detecting wildfire-related features in satellite or aerial imagery.

The training procedure was meticulously crafted to maximize the model's performance on the prepared dataset. The network was trained over 10 epochs using stochastic gradient descent (SGD) with a momentum term to speed up convergence and minimize oscillations. A learning rate of 0.005 was set to regulate the step size during weight updates, while a weight decay of 0.0005 served as a regularization method to prevent overfitting. These training parameters collectively helped develop a highly effective detection model, capable of accurately identifying fire-prone areas within complex visual scenes.

Algorithm I: Faster R-CNN with ResNet50 Algorithm for Natural Disasters Detection

```
Input: Image I
Output: List of detected objects with class labels and bounding boxes
# Step 1: Preprocessing
I_preprocessed = Preprocess(I)  # resize, normalize, augment (rotation, flip, jitter)

# Step 2: Feature Extraction using ResNet50
Feature_Map = ResNet50_Backbone(I_preprocessed)
# Step 3: Region Proposal Network (RPN)
Anchors = GenerateAnchors(Feature_Map)
Objectness_Scores, BBox_Offsets = RPN(Feature_Map, Anchors)
# Step 4: Proposal Selection
Proposals = ApplyBoundingBoxRegression(Anchors, BBox_Offsets)
Proposals = FilterLowScores(Proposals, Objectness_Scores, threshold)
Proposals = NonMaximumSuppression(Proposals, iou_threshold)

# Step 5: RoI Pooling
Fixed_Size_Features = []
For each Proposal in Proposals:
  RoI_Feature = RoIAlign(Feature_Map, Proposal)
  Fixed_Size_Features.append(RoI_Feature)

# Step 6: Fast R-CNN Head
Class_Scores, Final_BBox_Offsets = FastRCNN(Fixed_Size_Features)
# Step 7: Bounding Box Refinement
Final_BBoxes = ApplyBoundingBoxRegression(Proposals, Final_BBox_Offsets)

# Step 8: Final Classification & Suppression
For each box in Final_BBoxes:
  if max(Class_Scores) > class_threshold:
    Keep box with label = argmax(Class_Scores)
  else:
    Discard box
Final_Detections = NonMaximumSuppression(Final_BBoxes, iou_threshold)
Return Final_Detections
```

In this pipeline, the Faster R-CNN algorithm (Algorithm I) functions as a two-stage object detection framework that combines high-accuracy classification with precise localization. Initially, input images are fed into a deep convolutional backbone ResNet50, which extracts hierarchical feature maps. These feature maps are then processed by the Region Proposal Network (RPN), which generates candidate object regions by assessing anchor boxes based on their objectiveness scores and refining their positions. The top proposals are further refined through Region of Interest (RoI) pooling and passed to the Fast R-CNN module, which classifies each region and adjusts its bounding box coordinates. During training, the model simultaneously optimizes classification loss (using cross-entropy) and localization loss (using Smooth L1), employing stochastic gradient descent (SGD) with momentum and weight decay for parameter updates. This architecture strikes an effective balance between speed and accuracy, making it well-suited for detecting complex patterns in high-resolution images, such as those captured by satellites. Fig. 4 presents the block diagram of proposed Faster R-CNN.

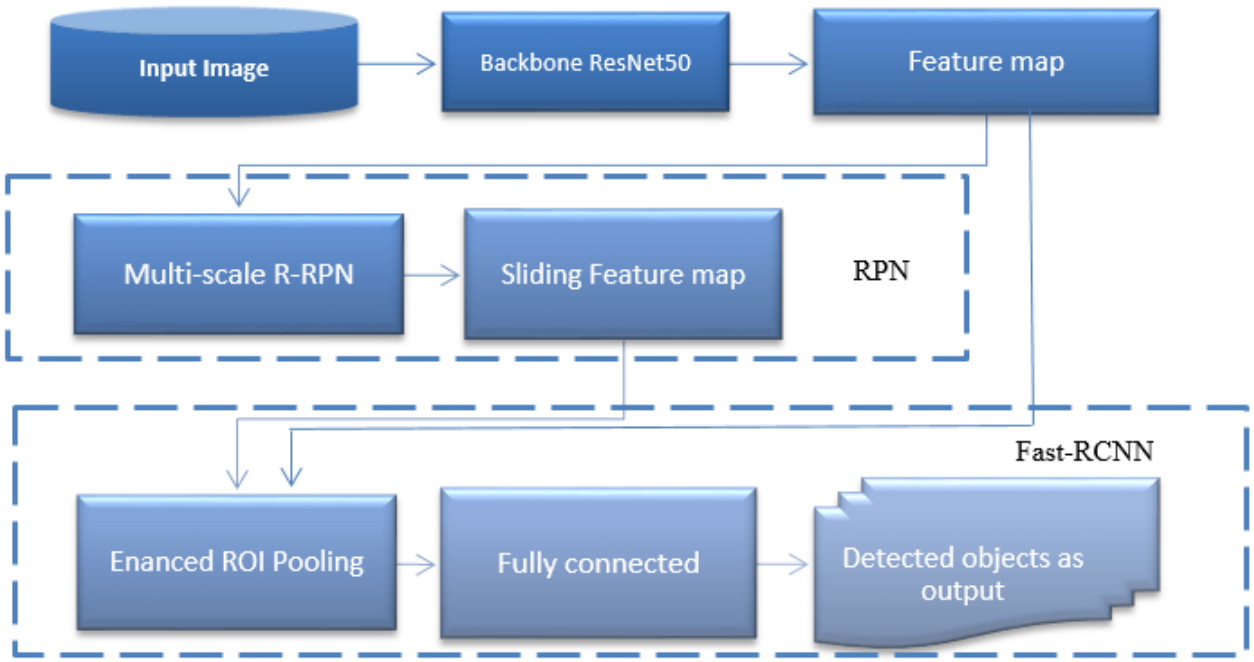

Fig. 4. Block diagram of proposed Faster R-CNN.

C. Training Phase: Loss Computation and Optimization

During the training phase of a two-stage object detection model like Faster R-CNN, the network learns to classify objects and accurately localize them within images. This is accomplished through a multi-task loss function that combines classification loss and localization loss. The model parameters are then optimized using backpropagation with Stochastic Gradient Descent (SGD), incorporating momentum and weight decay.

Classification Loss measures how closely the predicted class probabilities align with the true labels. Specifically, Cross-Entropy Loss is employed, with Softmax Cross-Entropy used for multi-class classification tasks. Given a predicted probability distribution p and the ground truth class c, the classification loss is:

Where, $L_{cls}=-\log(p_c)$ (1)

p_c is the predicted probability for the correct class c.

Localization Loss L_{loc} measures how precisely the predicted bounding boxes align with the ground truth boxes. Typically, $Smooth_{L1}$ Loss is used for this purpose, as it is less sensitive to outliers compared to the standard L2 loss. For each coordinate x of the bounding box, the $Smooth_{L1}$ loss is defined as follows:

$$Smooth_{L1}(x) = \begin{cases} 0.5|x| & < 1 \\ |x| - 0.5 & otherwise \end{cases}$$

Therefore, the overall localization loss between the predicted bounding box t and the ground truth t* is defined as:

$$L_{loc}= \sum_{i\in\{x,y,w,h\}} SmoothL1(t_i-t_i^*) \quad (2)$$

The total loss function is then:

$$L_{Total}=L_{cls}+\lambda\cdot L_{loc} \quad (3)$$

where, λ is a balancing factor (usually set to 1), adjusting the relative importance of classification and localization.

D. Backpropagation and Optimization

After calculating the loss, the gradients of the loss with respect to the model's parameters are determined through backpropagation. The optimizer used is Stochastic Gradient Descent (SGD) with Momentum, a technique that enhances gradient descent by speeding up convergence, particularly in situations involving high curvature or noisy gradients. The weight update rule is:

$$Vt+1=\mu vt-\eta\cdot\nabla L \quad (4)$$

$$\theta t+1= \theta t +Vt+1 \quad (5)$$

Here, θ represents the model weights, Vt denotes the velocity (momentum term), μ is the momentum coefficient set to 0.9, and η is the learning rate, which is 0.005. ∇L represents the gradient of the loss with respect to the parameters. Weight decay helps reduce overfitting by discouraging large weight values. It alters the parameter update rule as follows:

$$\theta_{t+1}=\theta_t+V_{t+1}-\eta\cdot\lambda_w\cdot\theta_t \quad (6)$$

where, λ_w is the weight decay factor (0.0005).

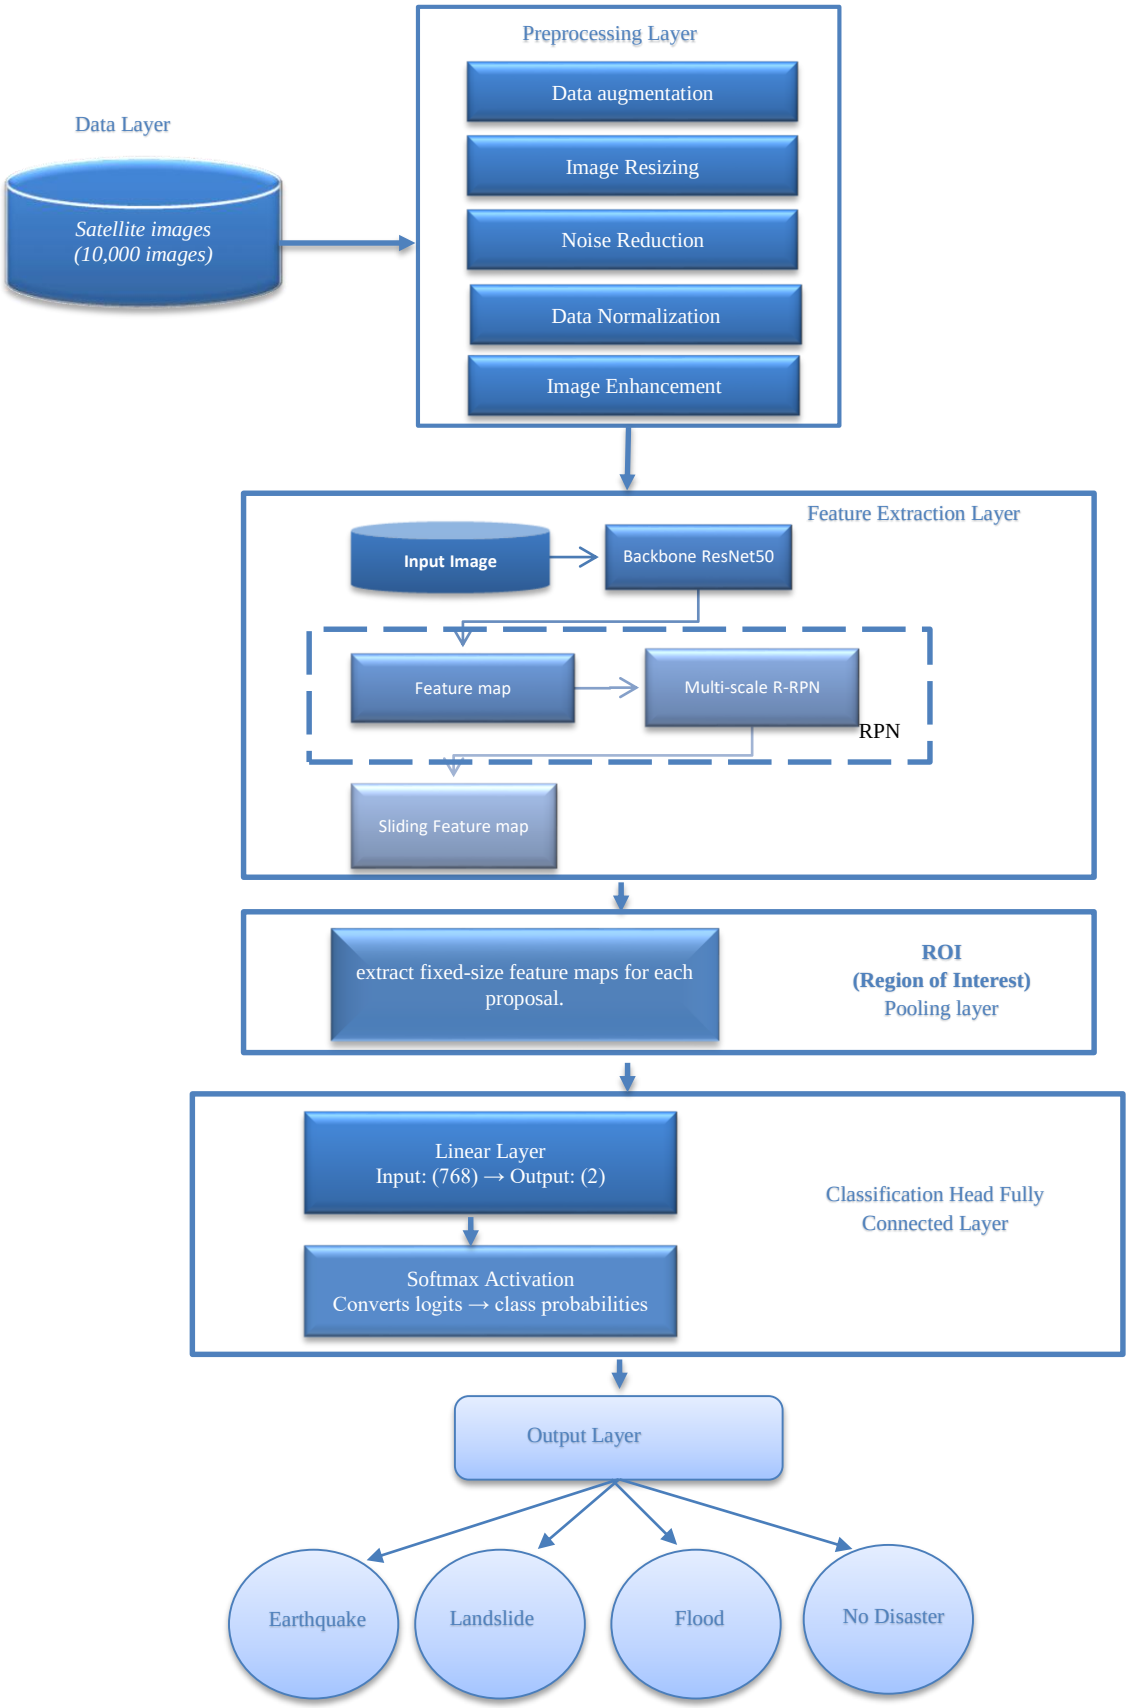

Fig. 5. Proposed model.

V. Results

The performance of the proposed Natural Disasters detection models (Fig. 5) was comprehensively evaluated using standard classification metrics accuracy, precision, recall, and F1-score across four different architectures: CNN, ResNet50, Faster-CNN, and Faster R-CNN with a ResNet50 backbone (see Fig. 6). The baseline CNN model attained an accuracy of 85.3%, with precision at 82.1%, recall at 78.5%, and an F1-score of 80.2%. Although this model served as a reasonable starting point, it exhibited limitations in generalization, likely due to its shallow depth and limited feature extraction capabilities. Significant improvement was achieved with ResNet50, which utilizes residual connections to facilitate learning in deeper networks. This model reached 92.7% accuracy, 90.4% precision, 89.3% recall, and an F1-score of 89.8%, demonstrating its superior ability to capture complex patterns in wildfire imagery. Further gains were observed with the Faster-CNN model, which incorporates region-based object detection. It attained 95.1% accuracy, 94.0% precision, 92.8% recall, and an F1-score of 93.4%, highlighting the advantage of combining detection and classification techniques. The highest performance was achieved by the Faster R-CNN architecture with a ResNet50 backbone, delivering outstanding results with 97.1% accuracy, 95.8% precision, 96.2% recall, and a well-balanced F1-score of 96.0%.

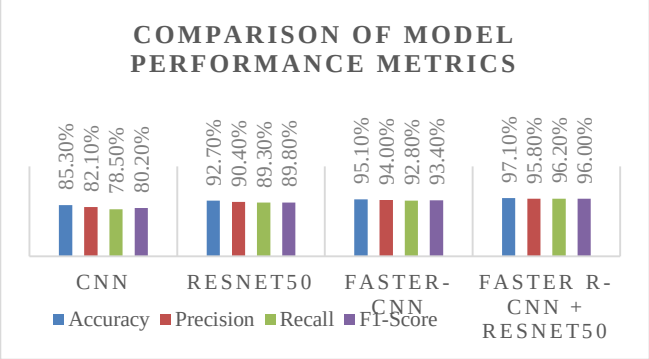

Fig. 6. Comparison of model performance metrics.

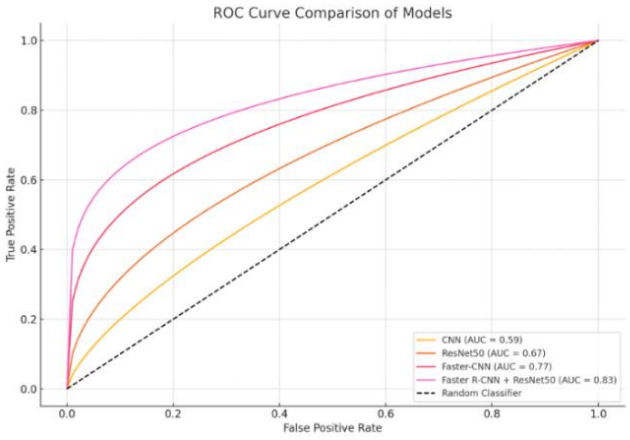

Fig. 7. ROC Curve comparison of models.

These metrics underscore the model's ability to detect Natural disasters regions with high reliability and minimal false predictions. ROC curve analysis further validated these findings. The AUC scores increased progressively across models, with CNN yielding the lowest AUC at 0.59, followed by ResNet50 at 0.67, Faster-CNN at 0.77, and the highest AUC of 0.83 achieved by the Faster R-CNN + ResNet50 model (see Fig. 7).

These results confirm the superior classification capability of the proposed framework, demonstrating robust performance and high discriminative power across all classes. This strong performance highlights the model's readiness for real-world deployment in early wildfire detection systems. Table II presents the proposed model results.

TABLE II Proposed Model Results

Model	Accuracy	Precision	Recall	F1-Score
CNN	85.3%	82.1%	78.5%	80.2%
ResNet50	92.7%	90.4%	89.3%	89.8%
Faster-CNN	95.1%	94.0%	92.8%	93.4%
Faster R-CNN + ResNet50	**97.1%**	**95.8%**	**96.2%**	**96.0%**

VI. Conclusion

This study systematically evaluated the effectiveness of deep learning architectures for natural disaster detection using remote sensing imagery. The baseline CNN, although functional, struggled with generalization due to its limited depth. Incorporating residual connections through ResNet50 significantly enhanced feature representation and classification performance. Further integration of region-based object detection in the Faster-CNN model yielded additional improvements. The highest-performing model, Faster R-CNN with a ResNet50 backbone, achieved exceptional accuracy, precision, recall, and F1-score, demonstrating its potential for real-time disaster detection. These results underscore the value of combining deep residual learning with object detection mechanisms for robust and scalable disaster response solutions. Future work may focus on expanding dataset diversity, incorporating multimodal data, and optimizing inference speed for deployment in real-time early warning systems. Future work will focus on expanding the dataset with additional disaster types and temporal satellite data to analyze changes over time. Moreover, integrating multi-spectral satellite data could further enhance feature discrimination, improving detection in low-visibility or cloud-covered scenarios.

***Abstract*—Wildfires pose a significant threat to ecosystems, human settlements, and air quality, necessitating advanced detection and mitigation strategies. Traditional wildfire detection methods often rely on manual observation and conventional machine learning approaches, which may lack efficiency and accuracy. This study proposes a novel deep learning model based on the ConvNeXt-Small architecture, a hybrid design that fuses the strengths of Convolutional Neural Networks (CNNs) and Transformer-inspired mechanisms, enabling more comprehensive analysis of wildfire patterns in satellite imagery. The model was trained using the Adam optimizer, which provides efficient convergence and adaptive learning. The dataset used consists of real-world satellite images collected from wildfire-affected regions in Canada, covering various geographic and seasonal conditions to reflect real environmental diversity. The results underscore the potential of ConvNeXt-based architecture for real-time, high-precision wildfire detection, offering a powerful tool for early intervention, disaster mitigation, and environmental monitoring efforts.**

***Keywords*—Wildfire detection; satellite imagery; convolutional neural networks (CNN); transformers; deep learning; hybrid model; proactive monitoring; remote sensing; disaster prevention; computer vision**

I. Introduction

Rapid detection of sudden-onset disasters, such as earthquakes, flash floods, and emergencies like road accidents, is critical for effective response by emergency organizations. However, gathering information during these events is often labor-intensive and expensive, requiring manual data processing and expert analysis. To reduce these efforts, researchers have explored the use of computer vision techniques applied to satellite imagery, synthetic aperture radar, and other remote sensing data [1]. Despite these advances, such methods remain costly to deploy and lack the robustness needed to reliably capture relevant data in time-sensitive situations. Additionally, satellite imagery is often affected by noise from clouds and smoke common during hurricanes and wildfires and provides only an overhead perspective of disaster areas.

Forests play vital roles in our environment and daily lives by providing numerous resources. They are often referred to as the "lungs of the planet", as they purify the air by producing oxygen (O2) and absorbing carbon dioxide (CO2). Forests also serve as habitats for diverse animal species and act as natural windbreakers that protect agricultural crops. Moreover, they help purify water by filtering out pollutants [2]. Economically, forests contribute significantly by providing jobs and boosting national incomes.

In recent years, many forests and wildlands have been destroyed by wildfires, which are uncontrolled natural disasters posing serious threats to economies worldwide. Each year, millions of acres of land are lost, resulting in significant damage to human lives, vegetation, and forest resources [3]. Wildfires also adversely affect agriculture by drying out the soil and destroying crops near affected areas. These fires can start from natural causes like lightning or human activities such as discarded cigarettes and land clearing. Climate change, rising temperatures, and prolonged droughts have intensified wildfire frequency and severity, especially in fire-prone regions such as California, Australia, and the Mediterranean. The environmental impact includes reduced air quality from pollutant emissions and accelerated global warming. Wildfires disrupt ecosystems by destroying habitats, threatening biodiversity, and increasing soil erosion. However, in some ecosystems, wildfires play a natural role by clearing dead vegetation and promoting new plant growth. Early detection and prevention are essential to minimize wildfire damage [4]. Advances in satellite imagery, artificial intelligence, and deep learning now enable real-time wildfire monitoring and prediction. Natural disasters are inescapable and have serious consequences for economies, ecological systems and human life. They can cause building collapses, spread diseases, and devastate entire nations through events like tsunamis, earthquakes, and forest fires. For instance, seismic forces from earthquakes can lead to the collapse of millions of buildings [5]. Since the 1990s, a variety of machine learning algorithms have been used to anticipate wildfires. A recent study in Italy used the random forest approach for wildfire susceptibility mapping [6]. Floods are the most catastrophic natural calamity, causing severe damage to property, infrastructure, and human life. To map flood susceptibility, an ensemble machine learning strategy using random forest (RF), random subspace (RS), and support vector machine (SVM) approaches was used. [7]. Studies indicate that immediately following a disaster, social media platforms contain valuable information for disaster response, including reports of damage and urgent needs from affected individuals [8], [9]. Much of this information comes in the form of images and videos. Unlike traditional data sources such as satellite imagery, leveraging on-the-ground social media images for relief efforts has remained largely unexplored until recently, as demonstrated in our prior work [10]. This gap is mainly due to technical challenges. Automatically filtering relevant images is difficult because

social media streams are noisy, with a large proportion of posts unrelated to humanitarian needs. Additionally, effective filtering requires robust deep learning models trained on vast amounts of labeled data. However, assembling a large-scale, annotated dataset for incident recognition in real-world conditions is both time-consuming and expensive.

The structure of this study is as follows: Section II presents essential baseline knowledge of machine learning. Section III describes the dataset used in detail. Section IV introduces the proposed model. Section V discusses the evaluation results, and finally, Section VI concludes the study.

II. BACKGROUND

In recent years, the integration of satellite imagery with machine learning (ML) techniques has become increasingly prevalent in various disaster management applications. These include monitoring changes in critical infrastructure, evaluating the impact of natural disasters, and tracking vegetation dynamics [10–11]. Among the ML methods, deep learning, particularly convolutional neural networks (CNNs) has shown exceptional capability in accurately detecting and classifying patterns in satellite data.

A widely adopted approach for forest fire detection using deep learning involves training CNNs on large datasets of satellite images. These datasets are commonly obtained from sources such as NASA's Earth Observing System, ESA's Sentinel program, or commercial providers like Planet Labs [12]. To prepare these datasets, images are labeled to indicate the presence or absence of wildfire activity. Labeling can be done manually by experts or semi-automatically using pre-trained models. Following preprocessing and annotation, the dataset is used to train deep learning models such as CNNs or, in some cases, recurrent neural networks (RNNs), depending on the spatial and temporal complexity of the data.

Once trained, the model is validated on a separate dataset to evaluate performance using metrics like accuracy, precision, recall, and F1-score. A successfully validated model can then be deployed to classify incoming satellite images in real time, enabling early wildfire detection and rapid response.

Deep learning significantly enhances both the speed and precision of wildfire detection, allowing quicker intervention and reducing potential damage [13]. Automated systems also reduce dependence on manual surveillance, which is often slower, more expensive, and less scalable. For instance, a study in [13] proposed a system combining the Inception-v3 CNN architecture with Local Binary Pattern (LBP) feature extraction, achieving high reliability in classifying wildfires from satellite imagery. Despite their accuracy, high-performance CNNs often come with high computational demands, making them unsuitable for mobile or embedded devices. This challenge has led to the exploration of lightweight CNN models like MobileNetV2 [28], which are optimized for devices with limited processing power. MobileNetV2 offers significant reductions in memory and computation requirements while maintaining competitive accuracy. For example, Wu et al. [1] integrated MobileNetV2 into their wildfire detection framework, applying data augmentation techniques such as Gaussian blur and additive Gaussian noise to simulate harsh visual conditions. This improved model robustness and allowed effective transfer learning, ensuring reliable performance even on low-resource platforms. There is a growing interest in designing neural networks that can operate efficiently in constrained environments, such as small satellites or unmanned aerial vehicles (UAVs). These platforms are essential in remote sensing scenarios, where local image classification can minimize the amount of data transmitted to ground stations, reducing both energy usage and communication delays. Rather than sending high-resolution imagery, systems can transmit only the classification outcome (e.g., "Fire" or "No Fire"), easing the load on communication networks like NASA's Deep Space Network (DSN) [29]. This research, therefore, focuses on optimizing neural network hyperparameters for wildfire detection, addressing challenges such as limited annotated data and resource-constrained deployment environments. The resulting CNN model is designed for real-time use on lightweight platforms like smartphones, small satellites, or weather balloons, facilitating accessible and cost-effective wildfire monitoring. Previous studies further support the effectiveness of CNNs in disaster-related applications. For instance, Boonsuk et al. [11] employed a two-layer CNN on the extended Cohn-Kanade dataset, comparing classifiers including Linear SVM, Linear Discriminant Analysis, and Softmax, and achieved over 90% accuracy with minimal variation. In challenging terrains such as mountainous regions where natural disasters like landslides or snowfall disrupt infrastructure deploying human responders can be difficult. In such cases, drones equipped with autopilot systems have become vital for capturing real-time imagery. Zhou et al. [13] introduced a CNN-based framework that employs inter-frame difference methods for noise removal and classifies disasters based on extracted image features. Various researchers have tackled different aspects of natural disaster detection and response through innovative technological solutions. For example, Sulistijono et al. [14] proposed a victim-detection system using aerial imagery transmitted to ground stations, enabling quick identification of victims following an earthquake. Padmawar et al. [15] developed a deep learning model combining Convolutional Neural Networks (CNNs) with Modified Particle Swarm Optimization (MPSO) to predict flood occurrences and locate individuals at risk ahead of time. In the domain of wildfire detection, Chen et al. [16] introduced a UAV-based detection system that utilized histogram stabilization and image smoothing before applying CNN-based classification. To enhance smoke recognition, they combined Local Binary Pattern (LBP) features with Support Vector Machines (SVMs), significantly improving early fire detection performance. Real-time monitoring has also proven vital for effective disaster management. Gonzalez et al. [17] presented the SFEwAN-SD model, a CNN architecture built on AlexNet with deconvolution layers, designed for real-time fire tracking using UAV imagery. Building on this, Samudre et al. [18] enhanced CNN efficiency through pipelining on FPGA platforms, which not only reduced energy consumption but also accelerated processing speeds. Resolution limitations in satellite imagery have posed challenges in disaster analysis. To address this, Lee et al. [19] adopted CNN models like VGG-13 and GoogleNet to work with high-resolution UAV images. Their comprehensive platform included forecasting tools, a web-based dashboard, and real-

time alert systems, achieving high accuracy in wildfire early warning applications. Beyond aerial and satellite imagery, social media has become a valuable source for disaster assessment. Nguyen et al. [20] used event-specific CNN features to analyze social media images during major natural disasters, assessing structural damage. Similarly, Direkoglu et al. [21] applied optical flow techniques and CNNs to differentiate between normal and panic-driven human behavior during disasters, using the UMN and PETS2009 datasets. Smoke density classification remains a complex task in wildfire analysis. Yuan et al. [22] addressed this by introducing W-Net, a wave-shaped CNN architecture with encoder-decoder layers tailored for precise smoke density detection. Their method leveraged virtual datasets and layer feedback mechanisms to boost both sensitivity and accuracy. Flood detection has also seen progress through CNN-based systems. Layek et al. [23] developed a flood identification model enhanced with color filtering techniques. Their system consistently outperformed other methods when tested across multiple benchmark datasets.

Table I presents a comparative summary of the datasets, methodologies, and outcomes from various state-of-the-art studies. Building on these insights, the proposed ConvNeXt-Small model in this research is designed to achieve accurate, rapid, and resource-efficient wildfire detection, making it suitable for real-world deployment in resource-constrained environments. Consequently, to effectively extract features within a given timeframe, it is essential to integrate stationary methods like temporal windowing.

TABLE I. LITERATURE REVIEW

Authors	Methodology	Dataset Used	Strengths	Limitations	Results
Hartawan et al. [9]	Enhanced MLP with CNN on Raspberry Pi for victim detection using streaming cameras.	Streaming camera data	Real-time detection, suitable for low-power embedded systems.	Limited visibility, not suitable for satellite images.	Helped evacuation teams effectively identify victims.
Amit et al.[10]	CNN on resized satellite images for flood and landslide detection.	Resized satellite images	Detects multiple disaster types from a broader perspective.	It depends on the resolution and quality of satellite images.	Accurate flood and landslide detection via CNN.
Wu H et al.[1]	MobileNetV2 with data augmentation (Gaussian blur, noise).	Wildfire satellite imagery with augmentation	Efficient, lightweight, accurate; ideal for mobile/embedded use.	May not generalize to unseen disaster conditions.	High accuracy, fast classification on limited hardware.
Zhou et al.[13]	Interframe difference technique + CNN for aerial disaster classification.	Raw aerial images	Enhances image clarity; improves classification with motion information.	Requires multiple frames and clean aerial data.	Accurately identified disaster characteristics.
Sulistijono et al.[14]	CNN-based victim detection using aerial imagery and ground station.	Aerial images from simulation	Fast victim location via real-time detection framework.	Simulated environment; lacks real-world variability.	Successfully tested framework for locating victims.
Padmawar et al.[15]	CNN + Modified Particle Swarm Optimization (MPSO) for flood forecasting.	Flood satellite and imagery data	Hybrid ML improves robustness and early prediction.	High model complexity; expensive in real-time systems.	Predicted flood conditions accurately and timely.
Chen et al. [16]	LBP + SVM + CNN on UAV imagery after histogram equalization and filtering.	Forest fire UAV imagery	Improved raw image quality; enhanced detection accuracy.	Heavily reliant on preprocessing and proper lighting conditions.	Achieved accurate UAV-based fire detection.
Gonzalez et al. [17]	CNN + AlexNet + SFEwAN-SD for smoke density detection from UAV images.	UAV-based smoke density imagery	An effective real-time fire monitoring system with precise smoke localization.	Dependent on labeled training data and real-time transmission quality.	High performance in detecting smoke density in real-time.
Lee et al. [19]	Modified VGG-13 & GoogleNet using high-res UAV imagery for wildfire detection.	High-resolution UAV wildfire images	High spatial resolution enhances model precision.	High computing power required on UAV platforms.	Enabled accurate early-stage wildfire detection.
Layek et al.[23]	CNN with fusion of social media and satellite imagery using color filtering.	Social media images + satellite data	Diverse dataset boosts accuracy and adaptability across event types.	Needs extensive preprocessing to normalize diverse formats.	Outperformed other detection systems across several datasets.

III. DATASETS

The Forest Fire Mapping System in southern Quebec offers a detailed representation of both historical and recent wildfire occurrences, primarily within areas located south of the attributable forest limit. This mapping effort is vital for deepening our understanding of regional fire regimes and contributes significantly to the creation of targeted forest management strategies following wildfire incidents. Moreover, it addresses a broad spectrum of academic, research, and operational objectives, including evaluating the effects of climate change, modeling ecological recovery, and studying long-term forest ecosystem dynamics.

Fig. 1. Dataset location.

TABLE II. FOREST FIRE MAP

Forest Fire Map (Southern Quebec Focus)				
Data Sources (Satellite, Aerials, Surveys, Scar Data, Archives)				
Mapping Categories				
Detailed Mapping (1976-present)	**Simplified Outlines (1972-present)**	**Fire origins (1972-Present)**	**Historical fires (1800s-1975)**	**Fire Regime Zoning (1890-2020)**
- Total /partial Burn - Burn Patterns - 0.1 ha precision	- General perimeters - GIS/GPS Integration	- Ignition Data -Protection zones	- from old forest/eco maps -tree scars, documents	Based on fire data, terrain, species, ignition sources

The data used to support this mapping system is compiled from various sources, such as satellite imagery, aerial photos, ground and aerial reconnaissance, fire scar analysis, and historical archives. It is categorized into five main groups, as outlined in Table II. Fig. 1 shows the dataset location.

A. Detailed Fire Mapping (1976–Present)

This dataset offers high-resolution fire information, differentiating between complete and partial burns, and includes burn pattern classifications when available. It is capable of representing fire-affected areas as small as 0.1 hectares, depending on the data source. While coverage in northern southern Quebec is limited, the dataset remains an essential resource for detailed and precise fire analysis.

B. Simplified Fire Perimeter Mapping (1972–Present)

This data layer simplifies the outer boundaries of wildfire events by removing internal fragmentation, resulting in a streamlined representation of fire perimeters. The purpose of this generalization is to produce a more manageable and efficient dataset that is well-suited for integration into Geographic Information Systems (GIS), Global Positioning System (GPS) devices, and other digital mapping and analysis tools. Derived from comprehensive and detailed fire datasets, this layer is tailored to support a broad spectrum of users, including forestry professionals, emergency response teams, researchers, and policymakers. By offering a cleaner, more accessible view of fire extents, it enhances usability across various operational, planning, and analytical applications.

C. Fire Origin Mapping (1972–Present)

This dataset documents the ignition points of recorded wildfires, as tracked by protection agencies like SOPFEU. It includes key information such as the ignition date, the cause of the fire (either human activity or lightning), and the designated protection zone. The dataset provides comprehensive coverage across all regions of Quebec, offering valuable insights into fire prevention, analysis, and management efforts.

D. Historical Fire Mapping (Late 19th Century–1975)

This component reconstructs historical wildfire events using archival forest inventory maps and ecoforest maps. Fire occurrence dates are verified through fire-scar tree analysis and supporting archival records. Its regional scope includes Saguenay–Lac-Saint-Jean, Bas-Saint-Laurent, Gaspésie–Îles-de-la-Madeleine, Abitibi–Témiscamingue, Mauricie–Centre-du-Québec, and Lanaudière–Laurentides.

E. Fire Regime Zoning (1890–2020)

This map segments southern Quebec into 13 distinct zones, each representing a unique fire regime. The delineation of these zones is based on factors such as historical burned area data, physiographic characteristics, the fire dependency of dominant tree species, and sources of ignition—both natural and human-induced. The classification extends beyond managed forest areas to include portions of unmanaged northern territories. These zones play a critical role in wildfire risk assessment and are instrumental in forecasting future fire behavior influenced by climate change, fire suppression strategies, and evolving fuel distribution patterns.

The dataset utilized in this work is known as Wildfire. The dataset employed in this study is referred to as the Wildfire Prediction Dataset (Satellite Photos). It consists of high-resolution satellite images, each measuring 350×350 pixels, obtained via the MapBox API. These images are generated based on precise geographic coordinates, latitude, and longitude corresponding to verified wildfire incidents that have affected areas greater than 0.01 acres. This targeted spatial sampling ensures systematic coverage of significant wildfire events. The dataset is divided into two main classes: wildfire images, totaling 22,710, and non-wildfire images, providing a balanced representation suitable for training a robust classification model. A sample from the dataset is illustrated in Fig. 2. This balanced class distribution enhances the model's ability to distinguish between wildfire and non-wildfire scenarios accurately.

Fig. 2. Sample from dataset for wildfire and non-wildfire.

To construct the dataset, satellite imagery was systematically retrieved using the coordinates of documented wildfire locations. This conversion of traditional tabular incident data into visual, spatially referenced images makes the dataset highly compatible with deep learning architectures. These images serve as rich inputs for training models to predict wildfire risk based on spatial patterns observed in previous events. By learning from visual cues in the satellite images, the resulting predictive model can assess the likelihood of wildfire occurrence in specific regions. This capability is essential for supporting early intervention strategies, resource allocation, and wildfire prevention planning.

To promote generalization and mitigate overfitting, the dataset is split into three subsets: 70% for training, 15% for validation, and 15% for testing. The training set is used to optimize model parameters, the validation set assists in tuning hyperparameters and monitoring for overfitting, and the test set is utilized to evaluate the model's performance on previously unseen data.

IV. The Proposed Model

This section describes the methodology used for wildfire detection, which utilizes a hybrid deep learning approach combining ConvNeXt-Small as a feature extractor with a custom-designed classification head for binary classification. This model harnesses the efficiency of convolutional networks while integrating transformer-inspired enhancements, making it well-suited for processing high-resolution satellite images, as shown in Fig. 3.

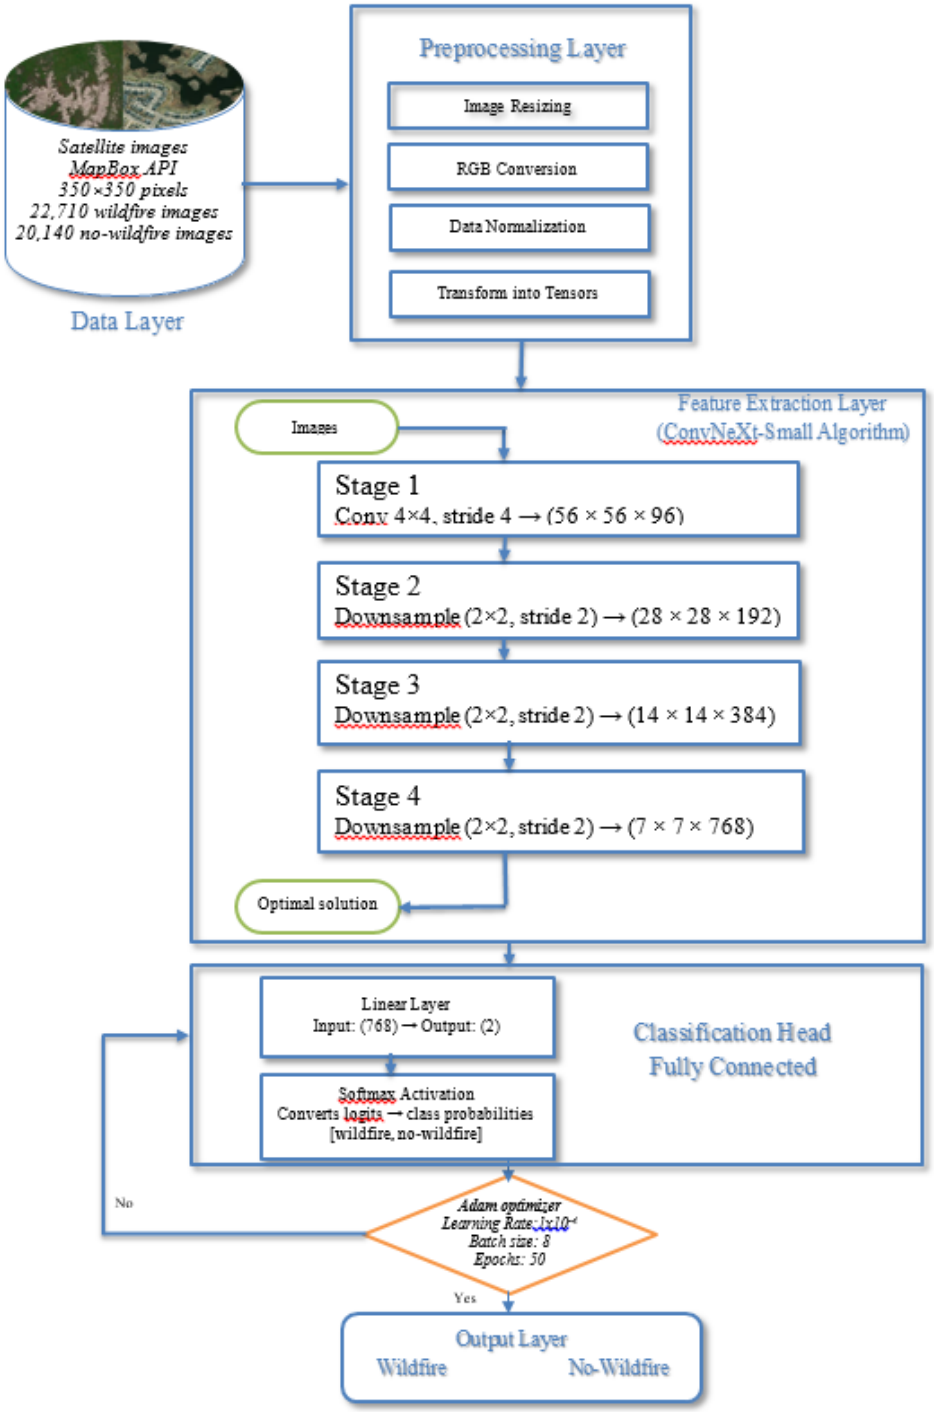

Fig. 3. Proposed model.

A. Backbone: ConvNeXt-Small as Feature Extractor

In this study, a deep learning model based on ConvNeXt-Small is developed, a cutting-edge convolutional neural network that incorporates concepts inspired by vision transformers while preserving the efficiency of convolutional operations. This model was used to classify satellite images into two categories: wildfire and non-wildfire. By combining the structured spatial biases of CNNs with the representational flexibility of vision transformers [24–25], this hybrid architecture significantly improves the analysis of high-resolution satellite imagery, making it especially effective for wildfire detection and monitoring.

ConvNeXt was selected over traditional CNNs such as ResNet [26] and pure transformer-based models like Vision Transformers (ViT) due to its balanced advantages. It achieves superior performance on vision tasks compared to ResNet, while offering efficient training. Unlike ViTs, which generally require very large datasets to perform well [27], ConvNeXt demands less data, making it better suited for moderately sized datasets. Its modular and adaptable architecture also facilitates seamless integration with custom classifier heads tailored for specific applications. Furthermore, ConvNeXt's scalability and speed make it an excellent choice for real-time wildfire alert and detection systems. ConvNeXt-Small forms the backbone of our architecture, enhancing traditional CNNs like ResNet by incorporating elements inspired by vision transformers, thereby boosting its representational capabilities. To reduce computational complexity while effectively capturing both spatial and channel-wise features, depthwise separable convolutions are utilized. Instead of Batch Normalization, Layer Normalization is applied, providing greater stability during training, especially with large datasets. The GELU activation function is employed to improve gradient flow and introduce better non-linearity, resulting in richer feature representations. Furthermore, the use of larger kernel sizes enables improved context aggregation, emulating the global receptive field characteristic of transformers [28]. Pretrained ConvNeXt-Small model are used in PyTorch's torchvision.models, with its original classification layer removed. This allows the model to leverage pretrained visual features learned from ImageNet such as edges, textures, and terrain patterns that are transferable to satellite imagery. The final output feature map from ConvNeXt-Small is a tensor of shape [batch_size, 768], which is then fed into the subsequent classification head.

B. Classification Head: Fully Connected Layer

After feature extraction, a lightweight fully connected neural network serves as the classification head, transforming the high-dimensional feature vectors into wildfire categories. This classification head includes a linear layer that compresses the 768-dimensional feature vector down to two output neurons, representing the two classes: wildfire and no-wildfire. A Softmax activation function is then applied to the output logits to convert them into a probability distribution, providing clear and interpretable prediction scores as shown in Fig. 4.

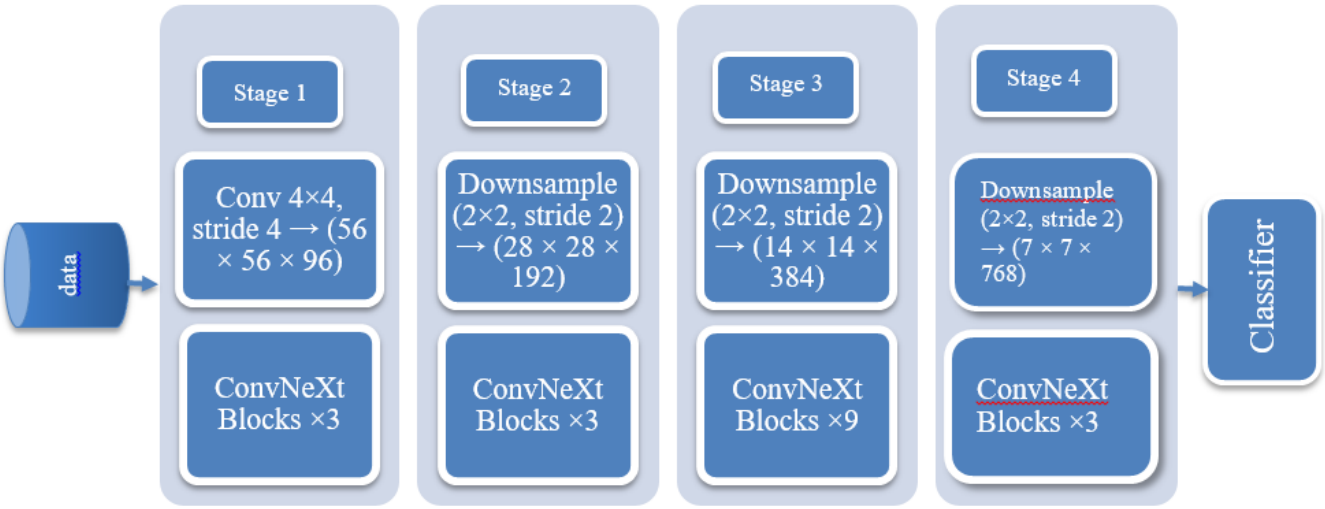

Fig. 4. ConvNeXt-small architecture.

Mathematically, the classification process can be represented as follows:

Eq. (1) is Softmax activation function:

$$\hat{Y}=\text{Softmax}\,(W.\,F + b) \quad (1)$$

where, "F" represents the feature vector output from ConvNeXt, while "W" denote the trainable weight matrix and "b" bias term, respectively. This equation ensures that each input image is assigned a probability distribution over the two classes, where the higher probability value indicates the most likely classification. Algorithm 1 shows the ConvNeXt-Small Algorithm for wildfire detection.

Algorithm 1: ConvNeXt-Small Algorithm for Wildfire Detection

```
Input: Preprocessed image (224x224)
# 1. Feature Extraction
x = Patchify(image)
 # Conv layer: 4x4 kernel, stride=4 → 96 channels
x = ConvNeXtBlocks(x, depths= [3,3,9,3])
 # Stacked blocks across 4 stages
x = GlobalAveragePooling(x)        # F ∈ ℝ^768
```

```
# 2. Classifier Head
logits = Linear (F, 768 → 2)
ŷ = Softmax(logits)
 # Probabilities for [wildfire, no-wildfire]
# 3. Loss Function (Cross-Entropy)
L_CE = -Σ (yᵢ * log(ŷᵢ)) for i in {1, 2}
# 4. Training Loop (Adam Optimizer)
for epoch in range(50):
  for batch in training_data:
    ŷ = ConvNeXt(batch_images)
    loss = CrossEntropy(ŷ, batch_labels)
    Backprop + Adam update
  if early_stopping_triggered:
    break
#Output: Predicted class ŷ, Loss L_CE
```

1) The classifier is specifically designed to minimize classification errors while achieving high accuracy in differentiating between wildfire and non-wildfire cases. During training, only the classification head is fine-tuned, while the ConvNeXt-Small backbone remains frozen. This approach allows the model to effectively leverage the knowledge acquired from large-scale ImageNet pretraining and apply it to the wildfire classification task, enhancing its generalization ability.

2) The classification head is optimized using the cross-entropy loss function, which quantifies the difference between the predicted and true labels. The Softmax activation function ensures that the predicted class probabilities sum to one, enabling them to be interpreted as confidence scores. Throughout training, backpropagation updates the weights and biases of the classification head to minimize the classification loss.

C. Loss Function: Cross-Entropy

To optimize model predictions, we use the cross-entropy loss function, which measures the divergence between predicted probabilities and true class labels. The cross-entropy loss is given by:

Eq. (2) Loss Function: Cross-Entropy

$$L_{CE} = -\sum_{i=1}^{C} y_i \log(\hat{y}_i) \quad (2)$$

where, C is the number of classes (wildfire and no-wildfire), y_i is the true class label, and $\hat{y}_i$ is the predicted probability for the class. This function ensures that the model maximizes the probability of the correct class while reducing the probability of incorrect ones. The cross-entropy loss penalizes incorrect predictions more severely, ensuring that the model learns to focus on correctly classifying challenging samples. This encourages the network to assign high confidence scores to the correct class while suppressing incorrect predictions, leading to a more robust classifier. As training progresses, minimizing this loss function results in a model that effectively distinguishes wildfire from non-wildfire images with improved confidence and reliability.

D. Optimizer and Training Strategy

The Adam optimizer was utilized for training, an adaptive learning rate algorithm that combines the benefits of momentum and RMSprop methods [29]. Adam adjusts learning rates for each parameter dynamically by estimating the first moment (mean) and second moment (variance) of gradients, which promotes efficient and stable convergence. This makes it particularly effective for deep learning tasks involving high-dimensional satellite imagery, as it accelerates training while managing sparse gradients. Key training settings included a learning rate of 1×10^{-4}, carefully chosen to balance between exploration and training stability, and weight decay to regularize the model and reduce overfitting. Training was conducted with a batch size of 8 over 50 epochs. Early stopping was implemented to monitor validation loss and halt training when improvements plateaued, thereby avoiding unnecessary computation and further preventing overfitting [30].

V. Results

The wildfire detection system built on the ConvNeXt-Small architecture follows a structured pipeline, starting with the preprocessing of satellite images from historically affected areas. Each image is resized to 350×350 pixels, normalized, and converted into tensors for PyTorch compatibility. The processed images are then passed through the ConvNeXt-Small model, which extracts high-dimensional feature vectors that capture essential spatial and contextual information. These features are fed into a lightweight classifier head, a linear layer followed by a Softmax activation that outputs probabilities for two classes: wildfire and no-wildfire. During training, the model's predictions are compared with actual labels using the cross-entropy loss function, optimizing performance for accurate binary classification. Once the model is trained, it undergoes a rigorous evaluation phase to assess its predictive performance across multiple metrics. These include test accuracy, precision, recall, and F1-score, all of which help measure the model's classification effectiveness from different perspectives. In this case, the model achieved outstanding results: an overall test accuracy of 99.05%, precision scores of 98% for the no-wildfire class and 100% for the wildfire class, and recall and F1-scores of 99% across both classes as shown in Table III and Fig. 5 to Fig. 7. Furthermore, a confusion matrix is computed to visualize true positive, false positive, true negative, and false negative rates, providing insight into classification errors as shown in Table IV, the model demonstrates excellent discriminative ability, making it highly suitable for reliable wildfire detection in diverse and real-world environmental conditions.

TABLE III. Proposed Model Results

Class	Precision	Recall	F1-Score	Support
No Wildfire	0.98	0.99	0.99	2820
Wildfire	1.00	0.99	0.99	3480
Accuracy			0.99	6300
Macro Avg	0.99	0.99	0.99	6300
Weighted Avg	0.99	0.99	0.99	6300

TABLE IV. Confusion Matrix

	Classification	
	Positive	Negative

VI. Conclusion

In this study, this holistic pipeline spanning data preparation, feature extraction, classification, optimization, and evaluation, not only ensures high accuracy but also provides scalability and robustness needed for deployment in operational wildfire monitoring systems. The proposed wildfire detection model, built upon the ConvNeXt-Small architecture, has demonstrated high effectiveness in identifying wildfire-prone areas using satellite imagery. By combining state-of-the-art convolutional design with a lightweight, fully connected classifier head, the model achieved remarkable predictive performance with a test accuracy of 99.05%, precision up to 100% for wildfire cases, and consistently high recall and F1-scores across both classes. These results confirm the model's robustness and reliability, making it a viable solution for early wildfire risk assessment.

The model's strong generalization ability is attributed to an efficient preprocessing pipeline, thoughtful training strategy using cross-entropy loss and the Adam optimizer, and the integration of modern deep learning techniques tailored for moderate-sized datasets. Additionally, the high AUC score of 0.996 indicates excellent discriminative power between wildfire and non-wildfire instances. This system offers a scalable and practical approach for real-time wildfire detection, with potential applications in environmental monitoring, disaster prevention, and resource planning. Future work may focus on expanding the dataset across different seasons and geographical regions, integrating meteorological data, and exploring deployment strategies for on-ground alert systems.

Faculty of Economic and Business, Universitas Pelita Bangsa, Indonesia[1]
Institut Digital Ekonomi LPKIA, Indonesia[5]

***Abstract*—Robotic Process Automation (RPA) has emerged as a transformative technology in the service sector, enabling organizations to automate repetitive and rule-based tasks with minimal human intervention. This study investigates the impact of RPA implementation on productivity and overall firm performance within service-oriented businesses. Using a mixed-method approach, quantitative data were collected from 50 service firms that have adopted RPA technologies, complemented by qualitative insights from managerial interviews. The findings reveal that RPA significantly enhances operational efficiency by reducing process cycle times, minimizing errors, and lowering operational costs. These productivity gains directly contribute to improved financial outcomes and customer satisfaction, key indicators of firm performance. Furthermore, the study highlights critical success factors such as employee training, change management, and technology integration that influence the effectiveness of RPA deployment. However, challenges related to workforce adaptation and initial investment costs are also discussed. This research provides valuable empirical evidence for service sector firms considering RPA adoption, emphasizing that strategic implementation can lead to sustainable competitive advantages. The study contributes to the growing body of knowledge on digital transformation by linking RPA technology with measurable improvements in productivity and firm performance, offering practical recommendations for managers and policymakers aiming to optimize automation strategies.**

***Keywords*—Robotic process automation; productivity improvement; firm performance; service sector; digital transformation; operational efficiency**

I. Introduction

In recent years, the service sector has experienced significant challenges as firms strive to enhance productivity and overall performance. Increasing operational costs combined with rising customer expectations have placed immense pressure on companies to optimize their processes and deliver superior value efficiently.

These pressures have driven organizations to explore advanced technological solutions, among which Robotic Process Automation (RPA) has gained substantial attention[1], [2]. RPA involves the use of software robots to automate repetitive, rule-based tasks, enabling businesses to reduce manual errors, accelerate processing times, and cut operational expenses. As illustrated in Fig. 1, several service firms that have adopted RPA technologies report measurable improvements in process efficiency. For instance, Firm A achieved a 30% productivity gain, while Firm C reported an 18% improvement in overall performance after integrating RPA into their workflows.

Based on Fig 1, despite these promising results, many organizations still face challenges in fully realizing the benefits of RPA. While operational efficiency may improve, translating these gains into sustained financial performance and competitive advantage remains complex and underexplored.

Prior research has largely focused on the technical capabilities of RPA and its immediate effects on operational tasks. Studies such as those demonstrate significant reductions in task completion times and error rates due to RPA adoption in customer service and back-office operations[3]. However, there is a notable gap in the literature concerning how RPA influences higher-level firm performance metrics, including profitability [4], [5], [6], market share growth, and long-term strategic positioning. A comprehensive understanding of these linkages is crucial for service firms aiming to leverage RPA for sustainable success.

This research seeks to address these gaps by proposing a novel integrative framework that connects RPA implementation with firm performance outcomes. The framework emphasizes aligning automation initiatives with strategic goals, ensuring that productivity improvements contribute directly to value creation[7], [8]. By focusing on both operational and strategic dimensions, the study aims to provide actionable insights for managers who face the challenge of balancing technological innovation with business objectives. This approach facilitates better decision-making in RPA deployment to maximize return on investment.

Moreover, the proposed framework introduces a set of performance metrics tailored to evaluate the impact of RPA across multiple levels, including process efficiency, financial results, and competitive positioning. These metrics enable firms to monitor progress and adjust strategies dynamically.

Ultimately, this research contributes to the growing field of digital transformation by illuminating the pathways through which RPA can enhance productivity and firm performance in the service sector. It offers a roadmap for service organizations seeking to harness automation technologies for long-term sustainable growth.

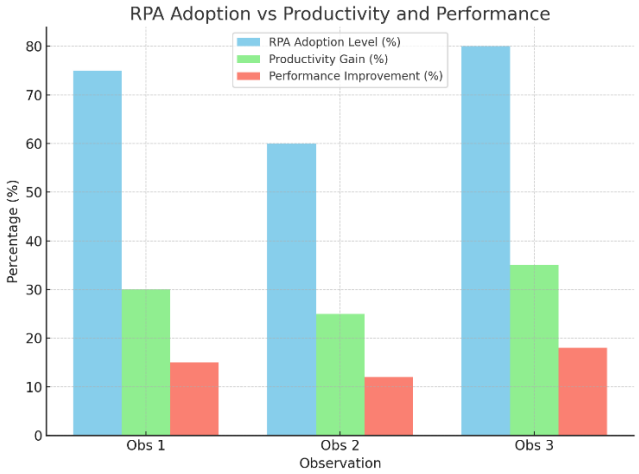

Fig. 1. Chart Of RPA adoption source: Research data, 2025.

II. Literature Review

Robotic Process Automation (RPA) has become a pivotal technology in digital transformation strategies, especially in service industries where repetitive and rule-based processes are prevalent. RPA enables automation of routine tasks such as data entry, invoice processing, and customer query handling, which significantly reduces manual effort and operational errors [1], [9], [10]. Many firms report enhanced productivity due to faster process completion and reduced human intervention.

The productivity improvements brought by RPA are well-documented. For instance, previous research found that firms implementing RPA experienced time savings of up to 40% in back-office operations [11]. These efficiency gains directly influence operational costs, allowing firms to reallocate resources towards more value-added activities, thus indirectly supporting better firm performance.

Firm performance, a multi-dimensional construct, often includes financial outcomes such as profitability, revenue growth, and market share, as well as non-financial outcomes like customer satisfaction and employee engagement. While RPA's operational benefits are clear, its direct impact on these broader firm performance indicators requires further investigation. Previous research has highlighted that technological adoption alone does not guarantee performance improvement unless aligned with strategic business goals [12], [13]. The effectiveness of technology investments such as RPA depends on the firm's ability to integrate automation into its business processes and strategic vision.

In the service sector, where customer interaction and service quality are critical, RPA's influence extends beyond cost reduction. It can improve service delivery speed and accuracy, thus enhancing customer satisfaction and retention [14], [15]. However, empirical studies quantifying this relationship remain scarce.

Change management and workforce adaptation play a crucial role in successful RPA implementation. As noted, the previous research highlights that employee resistance and inadequate training can undermine the potential benefits of automation, affecting both productivity and overall firm performance [2], [16], [17]. Studies on the long-term competitive advantage of RPA are emerging, but are still limited. Porter's value chain framework suggests that automation can be a source of competitive differentiation when it enables firms to deliver products or services more efficiently and reliably. However, sustaining this advantage requires continuous innovation and integration with other digital technologies.

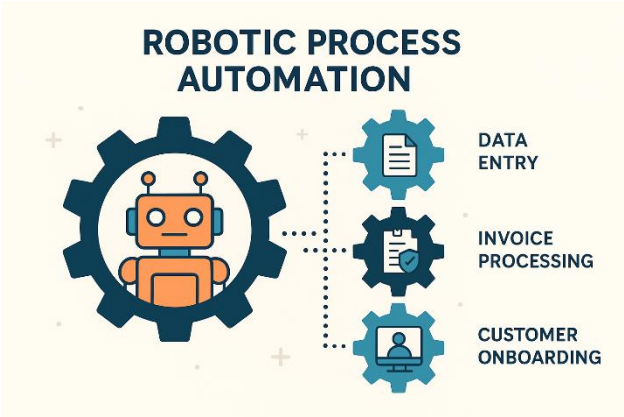

Fig. 2. Robotic process automations.

Given these insights from Fig. 2, this research seeks to fill the gap by examining not only the operational impacts of RPA but also its strategic contribution to firm performance in the service sector. This comprehensive approach provides a more holistic understanding of how RPA can drive sustainable growth.

1) Theoretical Framework

The theoretical framework for this study is grounded in two key theories: the Technology-Organization-Environment (TOE) Framework and the Resource-Based View (RBV). The TOE Framework posits that technology adoption and implementation are influenced by technological factors, organizational readiness, and external environmental pressures [8]. In this context, RPA adoption is seen as a strategic technological innovation influenced by firm capabilities and market dynamics.

The Resource-Based View (RBV) emphasizes that firm performance is derived from the ability to deploy valuable, rare, inimitable, and non-substitutable resources [9]. Here, RPA is conceptualized as a technological resource that, when effectively integrated with human and organizational capabilities, can create sustained competitive advantage.

This study integrates TOE and RBV perspectives to examine how RPA adoption affects productivity and firm performance. It proposes that technological capabilities (RPA), organizational factors (training, change management), and environmental conditions (market competition, regulatory environment) collectively influence firm outcomes. The framework also posits that the strategic alignment of RPA initiatives with business goals mediates the relationship between automation and firm performance.

III. Research Methods

1) Research design. This study employs a mixed-method approach combining quantitative and qualitative data to analyze the impact of Robotic Process Automation (RPA) on productivity and firm performance in the service sector. The quantitative component involves collecting survey data from service firms that have implemented RPA, while qualitative insights are obtained through semi-structured interviews with key managerial personnel. This dual approach ensures comprehensive understanding from both numerical evidence and experiential perspectives.

2) Data collection process. The flow diagram in Fig. 3 illustrates the sequential steps of the research methodology. It begins with defining the research scope, followed by designing the survey instrument based on validated measurement scales from previous literature. Next, data collection is conducted through online questionnaires and interviews, leading to data cleaning and preparation. Finally, data analysis is performed using statistical software for quantitative data and thematic coding for qualitative responses.

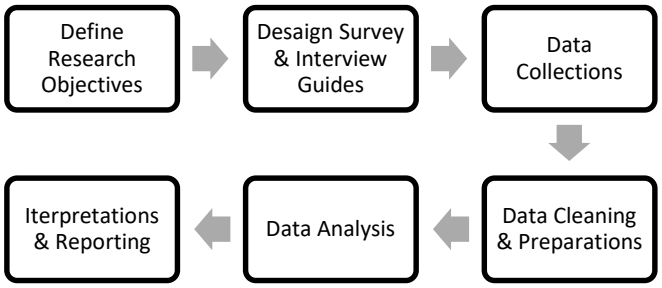

Fig. 3. Research methodology flow diagram

3) Sampling and participants. The target population comprises medium to large-sized service firms with active RPA initiatives. A purposive sampling method was used to select 60 firms from industry databases, ensuring diverse representation across sectors such as finance, healthcare, and telecommunications. Tables I and II summarizes participant demographics, including firm size, sector, and RPA adoption duration.

TABLE I. Demography Sample

Firm Size	Frequency	Percentage (%)
Small (50-100 employees)	12	20
Medium (101-500 employees)	28	46.7
Large (>500 employees)	20	33.3

Source : Research Data, 2025

Based on Table I, the demographic data shows that the majority of respondents (46.7%) come from medium-sized firms with 101–500 employees. This is followed by respondents from large firms (>500 employees), representing 33.3% of the sample, while small firms (50–100 employees) make up the remaining 20%. The distribution indicates that the study primarily reflects insights from medium to large organizations, which may influence the generalizability of findings toward more structured business environments.

TABLE II. Demography Sample By Type

Sector	Frequency	Percentage (%)
Finance	18	30
Healthcare	15	25
Telecommunications	12	20
Others	15	25

Source : Research Data, 2025

Table II presents the sectoral distribution of the sampled firms. The Finance sector dominates the sample with 30% of the respondents, followed by Healthcare and Others, each contributing 25%, and Telecommunications at 20%. This balanced representation across sectors—particularly in finance and healthcare—suggests a diverse range of organizational contexts, enhancing the relevance of the study across multiple industries.

4) Measurement instruments. The survey questionnaire includes standardized scales measuring productivity gains (e.g., cycle time reduction, error rate decrease), financial performance (e.g., ROI, revenue growth), and organizational factors (e.g., employee readiness, change management effectiveness). Each item uses a 7-point Likert scale (1 = Strongly Disagree, 7 = Strongly Agree). Reliability and validity were assessed through Cronbach's alpha and confirmatory factor analysis (CFA).

5) Data analysis techniques. Quantitative data were analyzed using Structural Equation Modeling (SEM) to test hypothesized relationships between RPA adoption, productivity, and firm performance. Qualitative data from interviews were coded thematically to identify enablers and barriers in RPA implementation. Triangulation of both data types provides robust insights into how RPA affects firm outcomes and guides practical recommendations

IV. Results and Discussions

A. Results

The analysis revealed a strong positive relationship between Robotic Process Automation (RPA) adoption and productivity improvements within service sector firms. The path coefficient ($\beta = 0.68$, $p < 0.001$) indicates that firms with higher levels of RPA implementation experienced significant reductions in processing time and operational errors.

Productivity improvements were found to have a direct and significant positive impact on firm performance ($\beta = 0.55$, $p < 0.001$), demonstrating that operational efficiencies gained through automation translate into measurable financial benefits such as increased revenue and cost savings.

Although the direct effect of RPA adoption on firm performance was positive ($\beta = 0.32$, $p = 0.04$), it was notably weaker than the mediated effect through productivity, suggesting that RPA's greatest contribution to firm success is by enhancing internal processes.

Survey data indicated that 80% of respondents strongly agreed that RPA reduced manual workload and error rates, while 70% noted improvements in employee satisfaction as routine tasks were automated. This reflects the dual impact of RPA on operational efficiency and workforce morale.

However, only half of the firms felt that RPA initiatives were fully aligned with their strategic goals. Qualitative feedback pointed to challenges in integrating RPA efforts with broader business objectives, which may limit the technology's overall value.

Table III shows mean scores for various aspects of RPA implementation, with process automation coverage and error reduction rated highest (means above 5.5), while strategic alignment and change management effectiveness scored lower (means below 5), indicating areas for improvement.

TABLE III. MEAN SCORE RPA

Implementation Aspect	Mean Score (1-7)	Standard Deviation	Interpretation
Process Automation Coverage	5.8	0.9	High coverage of automated processes
Error Reduction Effectiveness	5.5	1.1	Significant decrease in errors
Employee Training Adequacy	5.1	1.3	Moderate consistency in training
Alignment with Business Strategy	4.7	1.5	Below average alignment with strategy
Change Management Effectiveness	4.9	1.4	Challenges in managing change

Source : Research Data, 2025

Based on this table, the data also revealed variability in employee training adequacy, which was moderately rated, highlighting that consistent and comprehensive training programs are critical to successful RPA adoption and sustained firm performance gains.

B. Discussion

Overall, the results confirm that RPA drives substantial productivity gains that improve firm performance in the service sector. To maximize these benefits, firms should focus on aligning RPA with strategic priorities and strengthening change management practices to foster employee engagement and adoption. The findings of this study underscore the significant positive relationship between Robotic Process Automation (RPA) adoption and productivity improvements in service sector firms. The strong path coefficient ($\beta = 0.68$) highlights that implementing RPA substantially reduces manual processing time and operational errors, confirming prior research emphasizing RPA's operational benefits that's have supported by previous reseach [1], [18].

Notably, productivity improvements were directly linked to enhanced firm performance ($\beta = 0.55$), demonstrating that operational efficiencies do not merely streamline processes but also translate into tangible financial outcomes such as increased revenue and cost reductions. This supports the view that automation drives competitive advantage by optimizing resource utilization [3]. Although RPA adoption had a direct positive effect on firm performance ($\beta = 0.32$), it was weaker than the mediated effect through productivity. This suggests that the primary value of RPA lies in its ability to improve internal workflows rather than immediately boosting financial metrics. Firms should therefore focus on maximizing process efficiency to realize broader performance gains. The survey data further reinforce these conclusions. The overwhelming agreement (80%) that RPA reduces manual workloads and error rates confirms the technology's operational strengths. These reductions can alleviate employee burden and reduce costly mistakes, contributing to more reliable service delivery.

Similarly, 70% of respondents acknowledged improvements in employee satisfaction, highlighting the positive human impact of automation. By automating repetitive and mundane tasks, RPA enables employees to focus on higher-value work, which may improve engagement and morale. However, only 50% of firms felt that RPA initiatives were fully aligned with their strategic objectives, revealing a gap in integrating automation efforts into broader business goals. This misalignment may undermine the potential value of RPA, as isolated technology deployments risk becoming cost centers rather than drivers of strategic growth.

The lower mean scores for strategic alignment (4.7) and change management effectiveness (4.9) from Table III echo these challenges. Without strong leadership and clear strategic guidance, RPA implementations can face resistance or fail to deliver expected outcomes. Employee training adequacy received a moderate score (5.1), indicating some inconsistency in preparing staff for RPA integration. Effective training is critical to ensuring that employees can work alongside bots and leverage new workflows productively.

The variation in training quality may also contribute to the mixed perceptions about change management success. Firms that invest in comprehensive training programs tend to experience smoother RPA adoption and better performance improvements[19], [20]. These findings highlight the multifaceted nature of RPA implementation, which requires balancing technology deployment with human factors and organizational alignment. Firms that neglect the latter risk suboptimal returns on their automation investments. From a strategic perspective, integrating RPA with firm-wide objectives can amplify its benefits. Aligning automation goals with financial targets, customer experience enhancements, and innovation initiatives ensures that RPA supports long-term value creation.

The evidence suggests that RPA's contribution to competitive advantage stems primarily from improving internal efficiency and workforce capacity. As firms refine their change management and training practices, they can unlock additional performance gains. Furthermore, RPA's scalability allows firms to handle growing transaction volumes without proportional increases in labor costs. This scalability is critical in the dynamic service sector, where customer demands fluctuate and operational agility is key [21].

The positive impact on employee satisfaction may also reduce turnover and improve organizational knowledge retention, further strengthening firm performance over time. Nonetheless, firms should be cautious about viewing RPA solely

as a cost-cutting tool. The technology's greatest value lies in enabling innovation and strategic flexibility through more efficient processes. The study's results align with prior research highlighting the need for integrated RPA strategies that combine technology, people, and processes for sustainable outcomes [22]. Firms that prioritize strategic alignment and change management alongside technology adoption are more likely to see RPA initiatives transition from pilot projects to scalable, enterprise-wide solutions. Future research could explore the long-term effects of RPA on firm culture and innovation capacity, as well as examine industry-specific factors influencing automation success.

Limitations of the current study include potential survey response biases and the cross-sectional design, which limits causal inferences. Longitudinal studies could provide deeper insights into RPA's evolving impact. Overall, the findings confirm that RPA is a powerful tool for enhancing productivity and firm performance in the service sector, but maximizing its value requires holistic implementation strategies that address both technological and organizational dimensions.

Practical Implications:

1) Firms should prioritize aligning RPA initiatives with their overall business strategy to ensure that automation supports long-term goals and competitive positioning.

2) Comprehensive employee training programs are essential to prepare the workforce for new workflows and maximize the effectiveness of RPA technologies.

3) Change management practices must be strengthened to facilitate employee buy-in, minimize resistance, and ensure smooth transitions during RPA implementation.

4) Managers should view RPA as a means to enhance operational agility and employee satisfaction, not just as a cost-reduction tool.

5) Continuous monitoring of RPA's impact on productivity and firm performance can help firms refine their strategies and expand automation across processes.

6) Future RPA deployments should consider scalability and integration with other digital transformation efforts to amplify benefits and support innovation.

V. Conclusion

This study provides compelling evidence that the adoption of Robotic Process Automation (RPA) significantly enhances productivity and overall firm performance within the service sector, primarily through the reduction of processing time and minimization of operational errors. The findings empirically validate that productivity gains serve as a mediating mechanism in the relationship between RPA implementation and improved financial outcomes, emphasizing the strategic importance of internal operational efficiency. A major contribution of this research lies in uncovering the mediating role of productivity, suggesting that the true value of RPA is not solely in its direct impact on performance metrics, but in its ability to transform and optimize organizational workflows. This highlights the necessity for firms to view RPA not just as a technological upgrade, but as a process innovation tool that demands alignment with broader business strategies. Moreover, the study identifies critical gaps in strategic alignment, leadership support, and change management processes—factors often underestimated in many RPA initiatives. These insights underline that successful RPA deployment extends beyond technical implementation; it requires a systemic approach that includes clear vision, cultural readiness, and employee involvement. The role of employee training, re-skilling, and continuous engagement emerges as a key driver in realizing sustainable benefits from automation technologies. From a practical standpoint, organizations are encouraged to invest in structured change management frameworks and ongoing capacity-building programs. Integrating RPA strategies with long-term business goals can yield sustainable competitive advantages, improve customer responsiveness, and foster organizational agility in dynamic market environments. This study contributes to the growing body of literature by offering an integrative framework that links RPA adoption, productivity enhancement, and firm performance. Future research should explore longitudinal effects of RPA over time, investigate variations across different industries and firm sizes, and assess how emerging technologies such as AI integration or intelligent automation may further amplify the strategic impact of RPA.

Systematic Literature Review on Artificial Intelligence-Driven Personalized Learning

Anas Usman Inuwa, Shahida Sulaiman*, Ruhaidah Samsudin
Faculty of Computing, Universiti Teknologi Malaysia, 81310, Johor Bahru, Johor, Malaysia

***Abstract*—Artificial Intelligence (AI) is widely used in various contexts, including education at different levels, such as K-12 (kindergarten through 12th grade) and higher learning. The impact of AI in education is becoming increasingly significant, making the academic sphere more effective, personalized, global, context-intensive, and asynchronous. Despite the publication of several systematic literature reviews, mapping studies, and reviews on the use of AI in education, there is still a lack of reviews focusing on personalized learning (PL) frameworks, models, and approaches at various levels especially the pre-university level for Science, Technology, Engineering, and Mathematics (STEM) subjects. To address this gap, our work presents a systematic literature review of AI-driven PL models, frameworks, and approaches published over the past ten years from 2013 to 2023, extracted from the Scopus database. This review focuses on the AI techniques used, personalized learning elements, components, attributes, and the possibility of replicating the technique in pre-university level studies, and gaps or prospects that will attract further research. The study reviewed 69 articles, downloaded via the Scopus database, and reported the most used AI techniques, PL components or factors, trends, and prospects for future research. The results show that most existing studies focus on higher learning that requires further research at the pre-university level. In addition, machine learning and deep learning are identified as the most suitable and frequent techniques besides other technologies, knowledge delivery, learners' needs, behavior and interest as the most required components for personalized systems in diverse fields. In terms of publication output by country, the study indicates that Switzerland, USA, UK, and China are leading contributors to PL research. Thus, this study calls for further research on AI-driven personalized learning that thoughtfully integrates educational theories, subject-specific content, and industry needs to enhance outcomes and learner satisfaction.**

Keywords*—Personalized learning; model; framework; approach; technique; systematic literature review; personalized learning components; artificial intelligence

I. Introduction

Academic research on artificial intelligence in education (AIED) has made significant progress over the past 30 years toward adopting a more complex learning paradigm that enables successful teaching and learning [1]. Education cannot be discussed today without mentioning the impact of Artificial Intelligence (AI). AI has had a widespread impact on all aspects of education, including its purpose, content, methods, and evaluation systems. Countries worldwide are making AI literacy education mandatory to enhance their understanding of AI. These include methods of using AI devices and services, understanding AI ethics, real-life AI convergence cases, and basic block coding. The curriculum is also being reformed to reflect AI, including its principles and the convergence of courses [2]. AI has the potential to tackle the major challenges faced by the education sector today, leading to innovative teaching and learning practices and ultimately speeding up progress toward achieving Sustainable Development Goals (SDGs). Nevertheless, these fast-paced technological advancements also bring various risks and challenges, surpassing policy debates and regulatory frameworks [3].

Educational technology literature has been exploring ways to incorporate AI into education to make education more personalized. Humans have unique characteristics that require the education sector to focus on individual-specific learning requirements, which is motivated by the desire to move away from the traditional "one size fits all" approach to a more personalized learning (PL) format [4], [5]. The key idea is to prioritize the students by making the system more "student-centered". PL aims to adjust the curriculum and instructions based on students' learning requirements and abilities, and to meet the demand of the modern workforce and address global challenges. Catering to a learner's needs will likely motivate the general student population. It is worth recalling that during the COVID-19 pandemic, educational systems rapidly transitioned to online platforms, prompting many institutions to adopt Content Management Systems (CMS) and Learning Management Systems (LMS) for the duration of the crisis and beyond. However, this rapid adoption has caused issues with productivity, course content, progress analysis, and alignment of learning with industry requirements [6].

PL is defined as "instruction that is paced to learning needs, tailored to learning preferences, and to the specific interests of different learners" [7]. The ongoing evolution of technology, coupled with the rapid advancement of AI, has significantly enhanced teaching and learning processes. AI facilitates a flexible, personalized, and efficient learning environment while also strengthening educational competencies through PL [8]. While there has been much research on learner control, the relationship between learner control and psychological ownership is not well understood [9]. Furthermore, it is still unclear how these concepts manifest in primary and secondary school education [10]. In order to personalize learning content, it is important to start with a classic instructional design model, which means that the learning environment must be designed to achieve a specific learning outcome. The learners will be engaged in the learning process and then assessed for their mastery or achievement of the targeted outcome. In addition, the environment must be adapted based on one or more features of learners to personalize the learning experience. This

*Corresponding Author

adaptation should be motivated by a desire to achieve educational outcomes. The National Academy of Engineering has identified the development of PL systems as a major challenge in the 21st century. Researchers in various fields have worked on different aspects of this challenge [11]. Personalizing learning involves creating a learning environment that considers the learner's prior knowledge, motivation, goals, beliefs, interests, skills, experience, and culture, among other factors. Instructional experience should be responsive to these features to enhance engagement in a learning task and improve performance. PL presents numerous dimensions and appeals to various disciplines, leading to a diverse body of research on this subject [12].

Learning analytics is vital in personalizing learning, which analyzes data from students and learning environments to support learning at various levels. It is a relatively recent field that has achieved a high level of maturity, particularly in its applications in higher education. However, there is a lack of research on learning analytics that focuses on other educational levels, such as high school [13]. Technology has been deeply integrated into modern society, impacting almost every industry. Basic science subjects are deemed tough and boring for students at K-12 since most of them cannot relate to their applications in the real world. Hence, the technology aspect of Science, Technology, Engineering, and Mathematics (STEM), especially Computer Science (CS), is changing the narrative. CS is trending as its applications and impacts are felt by all and sundry. Skilled workers related to CS are in high demand. In traditional education, students rely on instructors or textbooks for subject knowledge, which can vary. The lack of trained CS teachers at the K-12 (kindergarten through 12th grade) level can result in insufficiently prepared students, owing to the limited number of CS courses offered in high schools [14].

Many college freshmen are hindered from taking CS because of a lack of exposure to the field earlier in their high school time. This is because they have never taken a course on the subject or had limited knowledge of it and are therefore not aware of what it entails. Surveys indicate that 90% of parents believe that CS should be part of their children's K-12 curriculum, but only 40% of schools offer it. Additionally, most schools that offer CS include it as a high school elective that does not count toward graduation [15].

AI technology is used to establish PL environments by gathering, analyzing, and interpreting data from multiple sources to construct student learning profiles. However, there is limited research on integrating AI into education to improve teaching efficiency in Malaysia. AI technology can predict a student's learning potential, and this information can be used to create tailored content that aligns with an individual's goals and previous achievements [8]. This is a common issue in most developing and underdeveloped countries. Hence, this systematic literature review (SLR) aims to comprehensively review models of AI and PL in education at various levels, focusing on outcomes and prospects, to further examine the applicability of AI-driven PL at the pre-university level particularly for the CS subject. Subsequently, Section II presents the related work, Section III provides the details on the review process, while Section IV and V report results and discussion respectively, and finally Section VI concludes the study and its future research direction.

II. Related Work

This section deals with the analysis of related works on the broad topic in the form of SLRs, systematic mapping studies (SMS), and other forms of review studies, published in SCOPUS (a large multidisciplinary database of peer-reviewed papers) for the span of ten years, from 2013 to 2023. IT was accessed via the Universiti Teknologi Malaysia (UTM) subscribed databases. The search was recorded as shown in Table I, based on the identified keywords and search terms (ST): systematic literature review", "systematic mapping study", "personalized learning", and "artificial intelligence".

Fig. 1 shows the number of publications and the percentages resulting from the search terms. Firstly, ST1 "systematic literature review AND artificial intelligence AND personalized learning" yields 92 publications, out of which only 29 (47%) are in the domain of this study and within the range of 2013 to 2023. Secondly, ST2 "systematic mapping study AND artificial intelligence AND personalized learning" only had 6 (10%) publications, and finally ST3 "systematic literature review AND personalized learning AND education" with the highest total of 108 publications, out of which only 54 are related to computer science and only 26 (43%) are in the scope of this study. The publications were further selected to check their findings, key focus, educational level that considered higher learning (HL), K-12 (Primary and secondary levels), as well as the type of review presented (SLR, SMS, and other review protocol).

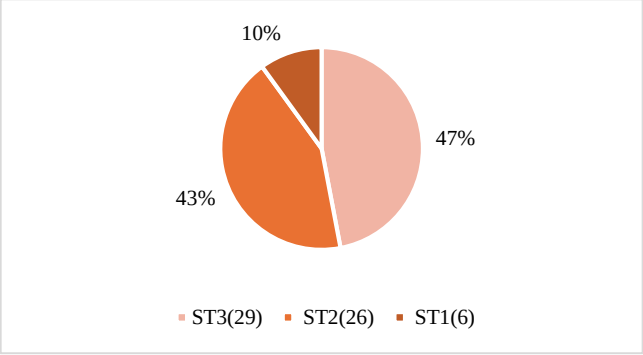

Fig. 1. Results by search terms (ST).

A. Issues and Gaps

Table II provides a brief overview of 20 studies, highlighting their key focus, educational level (HL, K-12), and types of study such as SLR and SMS. It aims to demonstrate that no existing work aligns precisely with the specific focus or title of this research study, indicating an unaddressed gap. This is particularly relevant when considering the pre-university level. Another gap addressed is the identification of major techniques and components that should be used in building personalized models and frameworks.

TABLE I. SEARCH RESULTS ON SLR, SMS, AND CLOSELY RELATED REVIEW PAPERS BASED ON KEYWORDS

In summary, 15 out of the 20 focused on higher learning [5],[16]-[20], [23]-[26], [28][29], [32]-[34]; four [21], [27], [30], [31] considered K-12 level, and only one publication [22] considered both K-12 and higher learning. The limited number of reviews within the selected range shows the pressing need for research in the area. The following section describes 10 elements that can be considered when designing personalized learning models and frameworks.

Teachers, schools, districts, states, and technology developers have attempted to create PL experiences for students. However, there is no consensus on the actual definition of personalized learning, and different designs may include multiple components. This variability can make it difficult to study personalized learning and how it can be designed based on students' characteristics to reliably achieve specific learning outcomes [7].

B. Personalized Learning Elements

Ten learning elements are identified here for designing a befitting PL framework or model extracted from the literature as cited.

1) Learning paths. A learning path refers to customizing an adaptable journey designed to meet the unique needs, preferences, and progress of individual learners. Machine learning can analyze a range of factors, including learners' goals, interests, prior knowledge, and performance, to create a customized curriculum and better learning outcomes. This dynamic approach enables customization of learning experiences, content, and pace, ensuring that each learner receives focused and pertinent educational material. This can enable the system to categorize learners based on different factors and recommend appropriate learning choices and improved outcomes [35]. The system can be powered by innovations, such as data mining, which can extract valuable information from large, unstructured, and random datasets. Adaptive ability of learners with similar characteristics can be identified, classified, and a learning path can be created for future learners [36]. Additionally, pinpointing the strengths and weaknesses of a particular learner can help eliminate learning difficulties.

2) Learner model. Learner models for classifying learners based on defined criteria. For example, learners can be classified based on their knowledge level as Basic or Beginner, Average or Middle, and Advanced or Expert.

3) Learners' metacognitive aspects. This involves designing features, activities, and feedback mechanisms that help students develop and use metacognitive skills like planning, monitoring, and evaluating their learning. This process turns a passive learning environment into a self-regulated, reflective, and adaptive experience [5].

4) Learners' queries. Learners' progress and behavior, including encouraging them to ask questions and addressing their concerns, is essential in creating a personalized and engaged learning environment. Timely responses promote proactive learning [37].

5) Learners' characteristics. This includes learners' profile, personality, and style, in which the system should consider various attributes of learners, such as their preferred learning styles, interests, and socio-cultural background. Adapting teaching strategies to align with these characteristics can enhance engagement and comprehension [16].

TABLE II. FINDINGS OF EXISTING WORKS

Study	Description of Findings	Key Focus	Level	Study Type
[5]	It is a systematic literature review paper investigating issues related to learner diversity, the PL features, the methods used, applications in higher learning, and the impact of implementation.	Learner Diversity	HL	SLR
[16]	The research explores the personalization of vocational education within Indonesia's higher education. It introduces the Personalized Blended Learning model as a solution to the limitations of the "one-size-fits-all" approach. It aims to enhance PL experiences.	Personalizing Vocational Education	HL	S/R
[17]	The paper discusses the challenges and opportunities of blended learning in vocational education, emphasizing the importance of combining face-to-face and online learning to enhance teacher training.	Teacher Training for Blended Learning	HL	DBR
[18]	They examined the use of algorithms in higher education decision-making processes, focusing on their impact on students and educators. It highlights the importance of designing these algorithms with a human-centered approach to ensure fairness, transparency, and ethical considerations.	Algorithms for decision making in higher learning	HL	SLR
[19]	The SLR research focused on learners' psychological and emotional states, along with their abilities and motivations, while also examining the role of personalized instruction in e-learning.	Learners' Psychological and Emotional State	HL	SLR
[20]	The SLR research examined the impact and application of Convolutional Neural Networks (CNNs) in education, particularly in areas such as face detection and student recognition.	CNN and for students' detection	HL	SLR
[21]	The SLR identified Special Educational Needs (SEN) as a form of Personalized Learning for primary and elementary students in the digital era, particularly those with attention challenges who depend on teacher support.	Learners with special educational needs	K-12	SLR
[22]	The SLR explored personalization strategies and gamification techniques in Virtual Reality (VR) to enhance educational outcomes in schools.	Gamification and virtual reality	HL/K-12	SLR
[23]	The scoping review analyzed ChatGPT's impact on higher education for researchers, teachers, and students globally, highlighting its benefits and concerns regarding accuracy, reliability, and academic integrity.	ChatGPT and academic integrity	HL	SSR
[24]	The SLR paper explored the role of AI chatbots as teaching assistants, aiding both educators and students, with a particular focus on their contribution to personalized education in higher learning.	Chatbots as teaching assistance	HL	SLR
[25]	The SLR examined how AI and Data Science integrate sustainable development into education, enhancing personalization, learning prediction, and dropout prevention.	Data Science and Sustainable Development	HL	SLR
[26]	The research explored computer-based methodologies for teaching English, advocating for personalized learning using AI, Text-to-Speech (TTS), and Natural Language Understanding (NLU).	Language Teaching	HL	SLR
[27]	This systematic literature review examines the personalization of e-learning models to adapt to students' learning styles and pace in Indonesian schools.	E-learning models	K-12	SLR
[28]	This SLR explores the essential components for constructing a learner model grounded in learning theories for adaptive e-learning systems.	E-learning systems	HL	SLR
[29]	The SLR assesses research on pedagogical agents using empirical data to enhance personalization in e-learning, emphasizing their flexibility, diversity, simulation capabilities, and overall impact.	Pedagogical agents	HL	SLR
[30]	The research explored the application of AI concepts in science education at the secondary school level.	AI and Science education	K-12	SLR
[31]	The SLR examines the lack of consensus on DPL (Digital Personalized Learning) technology in primary and secondary education by analyzing various empirical studies.	DPL technology	K-12	SLR
[32]	The SLR explored AI methods for identifying learner traits, structuring content, recommending learning paths, and evaluating their benefits and limitations.	AI for learner identification	HL	SLR
[33]	This SMS examined the incomplete implementation of adaptive learning systems and their failure to fully address students' diverse needs, proposing improved AI integration as a solution.	Adaptive learning and students' diversity	HL	SMS
[34]	It highlights the need for more empirical studies to validate adaptive learning models and suggests exploring new adaptive techniques and technologies to enhance personalized learning experiences.	Adaptive learning environment	HL	SMS

Note: SLR (Systematic Literature Review), SMS (Systematic Mapping Studies), SSR (Systematic Scoping Review), S/R (Survey Research), DBR (Design-Based Research), HL (Higher learning, Tertiary education), and K-12 (Primary and Secondary School, Kindergarten 12).

6) Learners' knowledge level. The system should identify and tackle learners' background, prior knowledge, feedback, and current knowledge level that involves adapting educational content and activities to address gaps and challenge the learner based on their understanding and proficiency [38].

7) Flexible pacing. This is achieved by designing the system to allow each learner to move through content at a pace that matches their individual learning needs, prior

knowledge, and personal goals. Sturgis and Patrick also emphasized that well-designed systems should enable tracking individual progress and suggest customized learning pathways.

8) Systems and tools. There are available tools that can be incorporated into PL systems for providing learning resources and other supports, like Khan Academy, Knewton, and ALEKS.

9) Smart learning environment. Effective smart learning environments should promote PL by fostering sensitivity, suggestions, self-reflection, assessment, constructive criticism, and enthusiasm. Examples include Intelligent Tutoring Systems, Virtual and Augmented Reality, SNAPP, Minecraft, etc.

10) Learning analytics (LA) and data mining (DM): Data Mining (DM) and Learning Analytics (LA) are powerful tools that support the learning process by collecting and analyzing data. They can help evaluate learning methods, predict the expected performance, and identify areas for improvement [39]. LA is particularly useful for analyzing data from diverse learning environments and can be used to create PL activities tailored to the needs and goals of each learner. As interest in LA continues to grow, it has the potential to transform learning by promoting personalized learning experiences.

Based on these twenty related works in Table II, it is evident that none of them focused primarily on reviewing or examining the existence of PL frameworks or models, and approaches that are subject-specific and focused on the peculiarities of the PU level. Most of the studies focused on advanced levels, and the use of AI in PL is less addressed in the studies. As a result, the next phase of this SLR will extensively review the AI-driven PL models, outcomes, and prospects. Additionally, it will explore further issues and gaps, as well as the components of PL that are appropriate for the pre-university level.

III. Review Process

This review adopts the SLR method outlined by Barbara Kitchenham [40]. These steps are illustrated in Fig. 2 and further explained in the sections ahead. The search process consisted of four stages. The first step was to formulate the research questions, where three research questions were formulated as presented in the sections ahead. The second step was the selection of articles using defined keywords on the identified resources (Scopus-indexed publications only). The search results were then filtered and recorded accordingly.

Fig. 2. Four stages of the review process based on an existing protocol [40].

The articles were then sorted systematically and organized by publication year and type (article, conference, review, conference review, book, or book chapter). The third step is on the inclusion and exclusion criteria: only articles reported in the English language that can be comprehended easily, and adherence to keywords is considered. Moreover, articles that are considered related to PL with AI techniques and centered on either components or factors of PL, model, framework, or approach are also selected. Only 69 articles were considered and selected for the final stage. Finally, the selected articles were used to answer the research questions outlined.

A. Research Questions

In framing the research questions, some requirements or criteria were considered, including population, intervention, comparison or justification, and outcomes, as presented in Table III. These requirements paved the boundaries upon which the direction of search and results were guided.

TABLE III. Criteria for Research Questions

Criteria (Component)	Scope (Coverage)
Population	Articles that propose a framework, model, or approach for PL at any level or consideration
Intervention	model, framework, or approach that addressed the application of AI techniques for PL at any level.
Comparison/ Justification	Strengths, weaknesses, and prospects for each approach.
Outcomes	Problems/issues/gaps addressed on the applicability of AI techniques suitable for PL and the PL components used, and at what level of learning?

Based on the criteria outlined in Table III, the research questions (RQs) were formulated as follows:

1) RQ1. Do the articles discuss the use of AI Techniques in PL, and what are the components of PL involved?

2) RQ2. Are these techniques clearly defined? Can they be replicated in pre-university computer science courses?

3) RQ3. Do the articles present gaps and points of interest attracting future research?

B. Search Process

The main purpose of the search was to obtain existing research on AI applications in the educational domain in the form of PL. Explicitly, PL models, frameworks, and approaches are the center of the review, to see which AI techniques were used and at what level were they applied, and to see the applicability of the techniques at the pre-university level. What are the PL components involved in this process?

1) The search process was carried out using the Scopus database. When papers are not available for download, they are then viewed and downloaded from the publisher's site, ResearchGate, or Google Scholar.

2) Organizing and categorizing articles based on keywords, type of publication, year of publication, and related information.

3) Recording search results according to keywords and publication type.

4) Refining the search involves the search process, and the choice of words is refined to ensure that all relevant papers are obtained.

Table IV presents the list of the seven keywords used in the search process, K1 to K7.

TABLE IV. SEARCH KEYWORDS

Keyword	Representation
K1	Personalized Learning
K2	Approach
K3	Model
K4	Framework
K5	Secondary School
K6	High School
K7	K-12

The search process from the repository considered the content and suitability of the articles by their abstract, publication title, and keywords, derived using the outlined search strings (SS1 to SS7) in Table V, which are partial combinations of the keywords in Table IV.

TABLE V. SEARCH STRINGS

Code	String
SS1	Personalized Learning Approach
SS2	Personalized Learning Framework
SS3	Personalized Learning Model
SS4	Personalized Learning Model OR Personalized Learning Framework
SS5	Personalized Learning Models AND High School OR Secondary School or K-12
SS6	Personalized Learning Approach AND High School OR Secondary School or K-12
SS7	Personalized Learning Framework AND High School OR Secondary School or K-12

Table VI presents the number and its percentage for each search string SS1 to SS7 versus the five document types. The highest found string is for SS5 that is 105 works in the scope of models and high school or secondary school or K-12.

TABLE VI. INITIAL SEARCH RESULTS FOR EACH DOCUMENT TYPE VERSUS SEARCH STRING

Type	SS1	SS2	SS3	SS4	SS5	SS6	SS7	Total 100 (%)
Article	10	3	6	23	43	5	13	103 (39.16)
Conference Paper	9	9	13	23	45	3	16	118 (44.87)
Conference Review	0	0	2	2	15	1	5	25 (9.51)
Book Chapter	0	1	3	4	1	2	1	12 (4.56)
Book	1	1	1	1	1	0	0	5 (1.90)
Total	20	14	25	53	105	11	35	263 (100)

Fig. 3 visualizes the percentage of the publication type, with conference papers as the highest in the list with 118 (44.8%) publications, followed by journal articles with 103 (39.16%) publications, 25 (9.51%) conference reviews, 12 (4.56%) book chapters, and five books (1.9%).

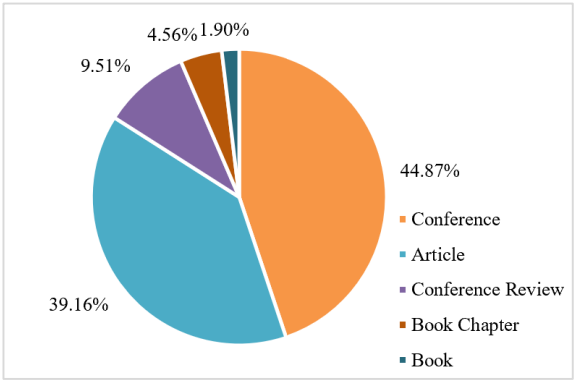

Fig. 3. Percentage of articles by publication type.

C. Inclusion and Exclusion Criteria

At this stage of the SLR, many criteria were considered for inclusion or exclusion. First, the articles were sorted by document type (regardless of the publishers, if the paper is found in the Scopus database), as displayed in Table VI. Second, only articles that were written or reported in English were selected. Third, the selected articles had to be from computer science, information technology, sciences, technology, or topics related to learning, AI, and education. Finally, the selected articles must not negate the search keywords and strings, as enumerated in Tables IV and V, respectively.

Articles that did not meet the inclusion criteria were excluded; articles that did not appear in a relevant field but in conformity with the search criteria were excluded; and articles that did not apply AI techniques in the framework, model, or approach were excluded, except for a few that included other technologies closely related to AI.

D. Quality Evaluation

To ensure the quality and conformity of the relevant articles, Table VII serves as a guide for choosing relevant studies based on the research questions outlined earlier. For each research question, the article should answer yes or no. Those who were neither "Yes" nor "No" were excluded from the study. Those who partially answered were further evaluated for inclusion or exclusion.

TABLE VII. EVALUATION BASED ON RESEARCH QUESTIONS

Research Question (RQ)	Possible Answer
RQ1: Do the articles discuss the use of AI Techniques in personalized learning, and what are the components of PL involved	Yes/No/Partially
RQ2: Are the techniques clearly defined? And can they be replicated at pre-university level computer science courses?	Yes/No/Partially
RQ3: Do the articles discuss gaps and points of interest attracting future research?	Yes/No/Partially

Fig. 4 shows the flow of the evaluation process and how the articles were evaluated to ensure conformance. The classification was adapted to evaluate the articles further, as follows:

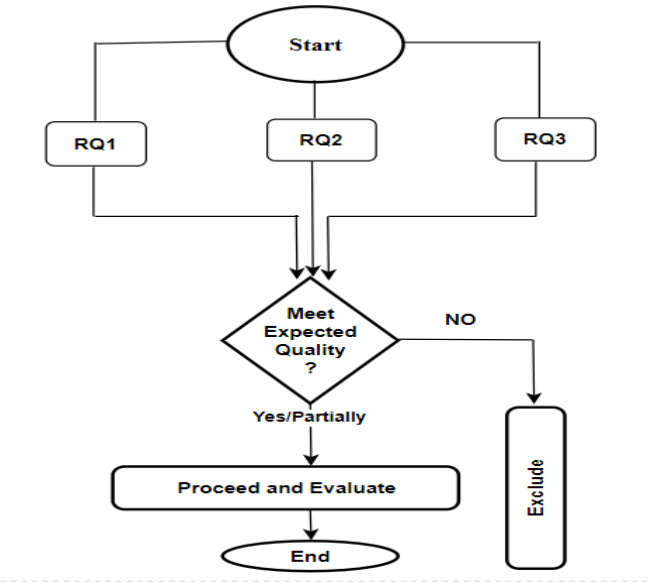

Fig. 4. Evaluation process flow.

1) The article's title or abstract mentioned the framework, model, or approach within a specific field of learning.

2) AI techniques or technology used for personalization were clearly stated.

3) The paper must equally discuss issues and gaps for further research.

IV. Results

The SLR reviews AI techniques and other associated technologies applied in developing PL frameworks, models, and approaches in different educational settings and levels. The SLR considers the frequencies of the techniques and the most considered elements (factors and components) of PL in the models, framework, or approach. In the initial stage of the search process, many results were obtained using the search strings listed in Table V but were narrowed by field and publication dates. For example, the search keyword S5 (personalized learning models AND high school OR secondary school or K-12) yielded 207 documents; only 107 were relevant and further screened to obtain the final selections.

The 69 publications selected are listed in the Appendix, capturing: focus of the article (model, framework, or approach), the PL elements (components, factors, approach) involved, the technique and technology applied, and the educational level (higher learning, K-12, or just general) considered. The results are further discussed in the next section; however, some graphs are presented here.

The articles selected according to the search strings are listed in Table VIII, with S5 (14 out of 69) having the highest number of publications, followed by S3 and S7 with 12 publications respectively, S1 with 10, S4 with 9, S2 with 8, and S6 with at least four publications.

TABLE VIII. Selected Articles by Search Strings

Search String	Selected Articles	Total
S1	[41][42][43][44][45][46][47][48][49][50]	10
S2	[51][52][53][54][55][56][57][58]	8
S3	[59][60][61][62][63][64][65][66][67][68][69][70]	12
S4	[71][72][73][74][75][76][77][78][79]	9
S5	[80][81][82][83][84][85][86][87][88][89][90][91][92][93]	14
S6	[94][95][96][97]	4
S7	[98][99][100][101][102][9][103][104][105][106][107][108]	12
Grand Total		69

Fig. 5 provides a graphical representation of the number of publications selected for the review, along with their respective publication years, 2013 to 2023. In total, 69 publications were included, with 2013 and 2014 having the lowest number of publications, and 2021 having the highest. The curve shows the trend in the number of publications over time.

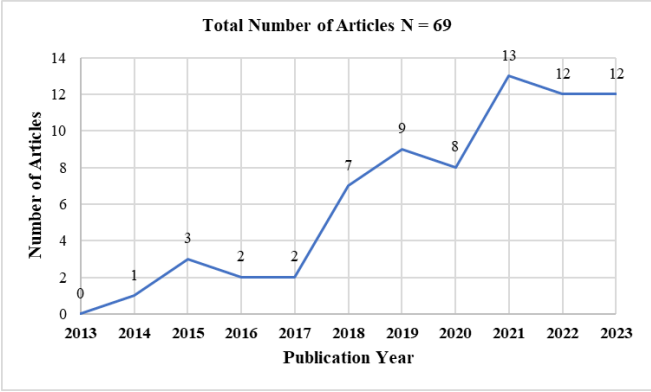

Fig. 5. Number of publications versus year of publication for the 69 studies.

Fig. 6 presents the chart for learning levels for the selected publications in the form of K-12 (kindergarten or primary and secondary school level), HL (higher learning: colleges, polytechnics, and university levels), and GL (general level with no emphasis on the study level or capacity of the learners).

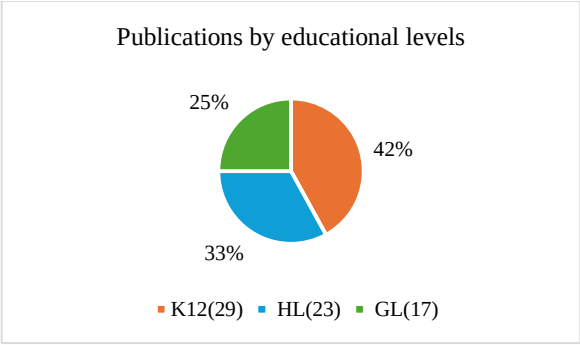

Fig. 6. Number of publications by level of education in the selected studies.

Fig. 7 shows the top five countries based on publisher locations, with Switzerland having 48.40%, the USA (22.60%), and the UK (16.00%), are the leading contributors to research in personalized learning, education, artificial intelligence approaches, models, frameworks, and their applications in education. China and India each have 6.50%, indicating their emerging roles in this scope of study.

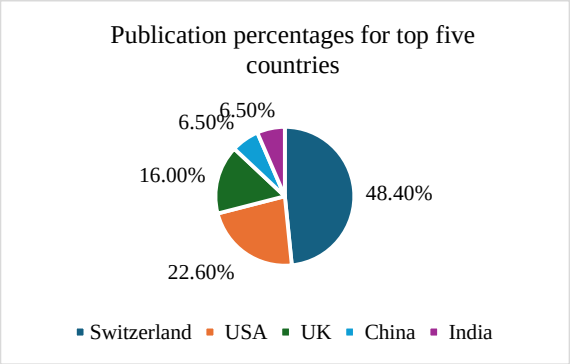

Fig. 7. Top countries with publications on personalized learning education with concepts of artificial intelligence.

This distribution highlights the significant investment and focuses these countries have on advancing educational technologies and AI-driven PL systems, while also underscoring the need for increased research contributions from developing countries to enrich the global research landscape.

Fig. 8 presents the top 10 publishers by the number of publications within the scope and data analyzed. Sustainability (Switzerland) dominates with 11 publications, demonstrating its prominent role and high level of scholarly activity in the area. ACM International Conference Proceedings Series and IEEE Access follow, each contributing 6 publications, indicating their strong engagement in disseminating research in the area. Other publishers like Artificial Intelligence in Medicine and Applied Sciences (Switzerland) have each possessed four publications, while several others, including Technology, Knowledge and Learning, Computers and Education, and Computers in Education: Artificial Intelligence, each have around 3 publications.

Finally, Computers in Biology and Medicine rounds off the list with two publications. This distribution highlights the significant role of multidisciplinary and technology-focused journals and proceedings in advancing PL and AI technology, with Swiss publishers particularly standing out in their contribution.

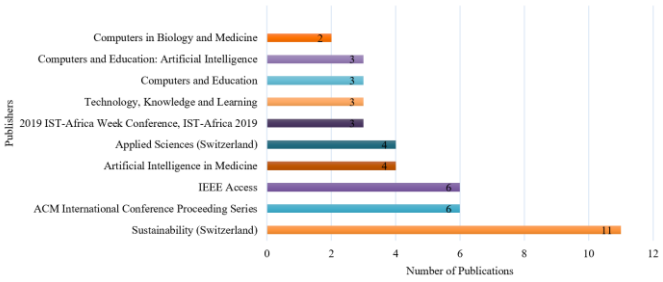

Fig. 8. Top 10 publishers by number of publications (two and above).

V. Discussion

As outlined in the earlier sections, the selected articles were intended to answer the three research questions guiding the SLR's findings. The percentages of articles concerning each research question are RQ1 (39%), RQ2 (42%), and RQ3 (19%), as shown in Table IX.

TABLE IX. Total Number of Articles Answering each Research Question

Research Question	Total	%
RQ1: Do the articles discuss the use of AI techniques in PL, and what components of PL are involved?	27	39
RQ2: Are the techniques clearly defined? And can they be replicated at pre-university level computer science courses?	29	42
RQ3: Do the articles discuss gaps and points of interest attracting future research?	13	19

A. Research Question 1 (RQ1)

RQ1 is stated as: "Do the articles discuss the use of AI techniques in PL, and what components of PL are involved?"

To answer this question, the Appendix presents all the articles in this review, the techniques, and elements of PL involved in the framework, model, or proposed approach. Fig. 9 is a graphical representation of the AI techniques and related technologies used in developing PL frameworks and models captured in the publications selected for this study.

The ten most frequent techniques were considered, in which machine learning tends to be the highest, followed by deep learning. Although other technologies (OT) are seen to be at the peak of the curve, it is a collection of various technologies, including big data, smart technology, digital, and mobile technology, as used in the context of the selected articles, which we deemed are not solely AI techniques, but contains elements of AI and its approach.

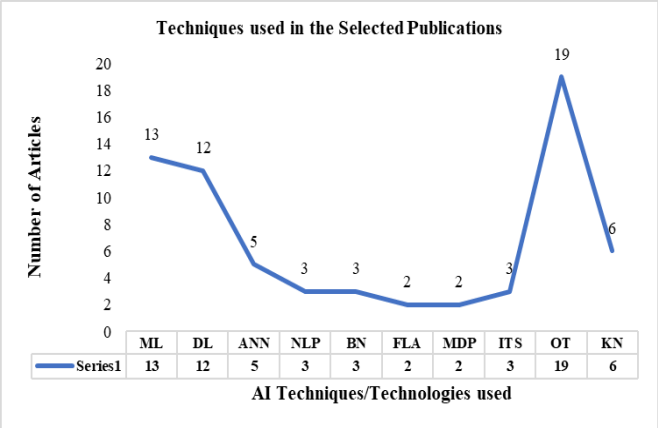

Fig. 9. AI techniques and other related technologies for building PL models and frameworks.

Key: ML (Machine Learning), DL (Deep Learning), ANN (Analytical Neural Network), NLP (Natural Language Processing), BN (Bayesian Network), FLA (Fuzzy Logic/Agent), MDP (Markov Decision Process), ITS (Intelligent Tutoring System), OT (Other Technologies), and KN (Knowledge Representation).

Although technology serves as the primary element in enabling and enhancing PL, there is a lack of consensus regarding the essential components of a dynamic PL approach. Furthermore, technology enables customization of learning experiences, but still no consensus on the essential elements required to create a distinct and effective learning experience tailored to individual learners [46].

Fig. 10 shows the PL components and their frequencies. The existing study [56] presented an additional ten attributes and components of PL as noted under the figure.

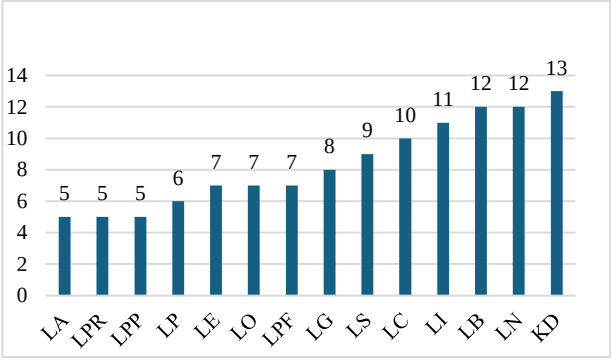

Fig. 10. Frequencies of PL components extracted from the selected studies.

Note: LPP (Learning Pace/Pacing), LP (Learning Path), LB (Learner/Learning Behavior), LS (Learning Style), LC (Learning Content), LPF (Learner Profile), LI (Learning Interest), LPR (Learning/Learners Preference), LN (Learners Need), LG (Learning/Learners Goal), LE (Learner/Learning Experience), KD (Knowledge Delivery), LO (Learning Outcome), LA (Learners/Learning Attitude).

Culture, emotional or mental state, socialization, motivation, learning preferences, prior knowledge, educational background, learning and cognitive style, navigation, and learning goals. Table X presents a brief description of fourteen of the components alongside reference articles for each. These components adapt dynamically based on the needs and preferences of the target user, educational level, and other considerations. They can be selected at random to suit the issues and purpose of development (framework, model, or approach for a particular educational level). The terms and names vary from one author to the other (since research on AIED is still new and dynamic). Knowledge delivery had the highest frequency, then learners' behavior, and needs towards learning, learners' interest, until LA, LPR, and LPP, which had the lowest frequencies, see Fig. 10.

Table X and Fig. 10 indicate that nearly all reviewed publications highlight a specific component related to personalized learning. The study concludes that knowledge delivery, learner behavior, and learner needs are the most emphasized aspects, whereas learning pace, attitude, path, and preferences receive less attention. This suggests that prioritizing the former may inadvertently diminish the significance of the latter.

B. Research Question 2 (RQ2)

RQ2 is stated as "Are the techniques clearly defined? Can they be replicated in pre-university level Computer Science courses?" The answer is "yes". Some of the articles clearly defined the techniques and justified them in the context of why such techniques were used in their work and specifically mentioned the level of study considered. However, some works have stated it as general, without targeting any educational level. Although in Fig. 6, K-12 level (primary, secondary, or pre-university), possesses the largest sector of the three, not all articles centered around AI techniques for PL, as they also consider other technologies.

Furthermore, the studies only point to the need for research on the K-12 educational level as a gap left unfilled; most of the publications are more about the feasibility of AI at that level, considering their peculiarities. Some of the works include the BPRMF model based on deep learning, neural networks, and data mining, proposed by Peng [93] to be applied to the problem of recommendation for the Civics and Political Science course, while another work proposes a system by hybridizing Visual/Aural/Read, Write/Kinesthetic (VARK) presentation or gamification and exercises difficulty scaffolding through skipping or hiding, or reattempting using Deep Q-Network Reinforcement Learning (DQN-RL) [81]. Another study proposed a novel approach for evaluating the co-learning performance of human intelligence (HI) and machine intelligence (MI) using a Knowledge Graph-based genetic fuzzy agent technique and a genetic algorithm [60].

Maddalora [77] introduced a PL model that recommends the Shortest Learning Sequence (SLS) to remediate students with learning difficulties, using Item Response Theory (IRT). On the other hand, a study provides an in-depth analysis of English course recommendation techniques through a combination of the bee colony algorithm and neural network algorithm, a deep learning model combined with collaborative filtering, to recommend suitable courses for users [88]. Other studies have used deep learning [62], [93], [43], [42], [72], neural networks [65], [105], [88], intelligent tutoring systems [46], [44], [92], natural language processing [53], [92], [87], knowledge representation [43], [89], [91], [66], and other techniques that are captured in Fig. 9.

TABLE X. DESCRIPTION OF FACTORS USED IN THE SELECTED STUDIES

Comp.	Description	Related Works
LPP	The speed at which a learner progresses through the materials is based on their capabilities and understanding.	[73][46][101] [108] [41]
LP	A strategically designed sequence of courses or modules aimed at guiding learners through a specific subject or program, ensuring a structured and progressive learning experience.	[44][73][46][65] [64] [47]
LB	Actions and responses demonstrated by a learner in a learning environment aim to cultivate positive and productive engagement.	[91][61][44][67] [65][42][86][85] [50][92] [47][81]
LS	An individual's preferred approach to acquiring and processing information is often categorized as visual, auditory, or kinesthetic.	[52][95][102][105][66][81][48] [56][47]

Comp.	Description	Related Works
LC	The material or resources that are used for educational purposes, including text, multimedia, and interactive elements.	[78][75][87][84] [27][68][70][79] [49][81]
LPF	Learner's characteristics, preferences, strengths, and weaknesses serve as a foundation for personalizing instruction.	[95][70][61][94] [46] [64][56]
LI	Specific topics or subjects that capture a learner's curiosity and engagement influence PL experiences.	[97][43][76][46] [90][45][58][85] [50][47] [48]
LPR	Individual choices and inclinations of a learner in terms of instructional methods, content formats, and assessment styles.	[44][41][93][50] [56]
LN	The individual needs and requirements of a learner, focusing on bridging gaps in understanding and skill development.	[43][95][79][46] [90][41][103][67][86][50][47] [107]
LG	The desired outcomes or achievements that a learner aims to attain through the learning process.	[61][9][44][46] [41] [96][85][56]
LE	The overall encounter a learner has during the educational journey encompasses interactions, challenges, and outcomes.	[78][84][43][27] [95] [70][83]
KD	The strategies and tools employed to deliver information and enhance learning experiences, according to individual preferences.	[78][87][52][27] [70][83][61][9] [76][49][94][54] [55]
LO	It refers to quantifiable outcomes and accomplishments that reflect a learner's proficiency in specific knowledge or skills.	[78][87][52][84] [68] [95][70]
LA	Addresses learners' mindset, approach, and attitude toward the learning process, which significantly impact engagement and success.	[95][61][44][46] [86]

Note: Comp stands for components (see also the note below Fig. 10)

C. Research Question 3 (RQ3)

Addressing RQ3, which is "Do the articles discuss gaps and points of interest attracting future research?", the answer is "yes". The selected publications identified existing research gaps, highlighted their contributions, and proposed future directions for further studies, as outlined in the abstract, conclusion, and future research sections. Table XI summarizes ten publications, detailing their contributions and recommended areas for future research.

Additionally, other studies have presented varied perspectives on the methods and requirements for personalizing education at the K-12 level. An existing study suggests gamification of learning content to drive better outcomes [81], while another study suggests further research to examine the implementation and impact of PL strategies in different areas and educational levels, as they only focused on higher learning in Saudi Arabia [41].

Xia and Cheng [70] highlighted four issues: lack of holistic learning data, lack of an acceptable learning profile, equipping educational robots is a big challenge, and there is no function for choosing proper strategies. In addition, some studies have suggested the need to explore key technologies, such as big data, data mining, and recommendation algorithms, for supporting PL [67], and the need for researchers to explore the learning outcomes of PL models based on specific practices and strategies [78].

VI. Conclusion and Future Direction

PL involves tailoring teaching approaches at both macro and micro levels to align with the unique needs of individual learners and is a focal point in global educational policy initiatives. Despite its widespread adoption, the methods of personalization vary, accommodating diverse priorities and influencing transformations at both individual and societal scales. The underlying philosophy emphasizes placing the learner at the core of the education system. However, upon closer examination, it becomes apparent that while these policies aim to diminish educational disparities, they occasionally contribute inadvertently to their exacerbation. This calls for a deeper understanding of what PL entails, its components, factors, target level (learners' level and need), policies, mission, vision, and goals of a particular country in terms of education, economy, and industrialization.

This study focused on the PL elements (components, factors, and technologies) involved in building frameworks and models at various educational levels. This study also presents the most frequent techniques and components used in 69 studies. It is evident that most studies concentrate on higher learning and proposals for different approaches to PL, regardless of educational policies, goals, and targets of stakeholders, but on mere assumptions. There is a lack of research that considers industrial demand, marketability of courses, tolerance in competitiveness, and employment chances upon one decision in choosing what to study or what to personalize. Personalization enhances one's technical skills, and hence, high chances of employability and adaptability, promoting learning autonomy and readiness for the workforce. Overall, PL promotes greater academic gain by narrowing learners' tasks to a specific target and promoting expertise. The scope of the study used mainly the Scopus database and other supporting primary research in the area to avoid voluminous and duplicate information from other sources, since Scopus has larger coverage. It can then be one of the limitations of this study as other databases may contain additional information regarding the area, and other researchers can explore further.

Advancements in AI are scaring nontechnical minds about job displacement, as many employees forecast that machines built on AI technology may render many people jobless. In contrast, AI has been proven to promote economic growth, boost productivity, enhance skills, and create new jobs. Today, information and communication technology and ICT-related industries have the highest prospects in Computer Science-related fields and subfields, especially those specializing in AI, Software Engineering, web development, and data analytics. Unfortunately, from the 69 selected studies, almost none focused on Computer Science and related fields for preparing

students at the pre-university level to study Computer Science when they enter the tertiary level.

Our future work will focus on designing a framework for PL at the pre-university level, to prepare students for various fields of Computer Science that the world needs today. The framework will prioritize and expose students to various opportunities and industrial needs, awaiting those who have studied Computer Science and have catalyzed solving issues using computer-based technologies.

TABLE XI. TEN SELECTED STUDIES: PROBLEM, CONTRIBUTION, TECHNIQUE, AND PROSPECT

Ref.	Identified problem	Paper Contribution	Applied Technique	Potential gap and prospects
[9]	The absence of psychological ownership of learning content among students and teachers.	Perception and assessment framework for the I-Learn portal.	Non-AI (Educational Technologies and Conjecture Mapping)	The necessity of creating tools for assessing and validating psychological ownership.
[43]	Standardized teaching approaches and ineffective skill development strategies in colleges and universities.	Proposed a personalized learning model utilizing IoT and deep learning algorithms.	AI-IoT integration with clustering algorithms, hierarchical clustering, collaborative filtering, and AI-based recommendations	The need for a flexible database for recommendations and content adjustments, enabling the integration of diverse materials.
[55]	The absence of study ownership and the impact of PL implementation in universities.	Proposed a framework on students' study ownership and learning outcomes.	Knowledge management through thematic analysis.	A necessity for research on the impact of personalization within authentic educational environments.
[57]	The ineffectiveness of traditional systems in tracking student needs during emergency remote education.	Proposed a framework for tertiary learning during and beyond the pandemic era.	Computer Technology	The necessity for research to validate the framework through longitudinal studies, utilizing technology for PL across all disciplines.
[62]	The absence of collaborative learning and limited facilitator-learner engagement in addressing students' needs.	Proposed a model centered on learner foundations, resources, community involvement, and diverse learning approaches.	Deep learning algorithms and learning analytics.	Future research should employ an alternative classifier to assess and validate the proposed approaches.
[73]	The absence of customized experiences that enhance students' learning journeys.	The research proposes a Personalized model to standardize entry-level requirements for health schools, emphasizing.	Knowledge Management.	Future research should incorporate evaluation and assessment components into the model and explore design enhancements to improve learning
[80]	Traditional one-size-fits-all systems are characterized by inefficient scheduling methods and a lack of individualized learning approaches.	An adaptive large neighborhood metaheuristic search integrated with an integer linear programming model.	Integer linear programming approach and Metaheuristic approach	Future research should explore modifications in school structure and staffing, along with extensions to accommodate longer timeframes.
[88]	Current research is insufficient for practical implementation, lacking sensitivity and collaborative strategies.	The research article introduces a novel recommendation technique that integrates bee colony optimization with neural network algorithms.	Bee colony, deep learning algorithm, and neural network techniques.	Future research should investigate user behavior analysis components, content evaluation mechanisms, and the integration of NLP for semantic analysis.
[106]	Lack of preparedness and absence of effective strategies for technology-enhanced learning.	A framework for Digital Learning Implementation.	Delphi Method	Future researchers should explore the practical applications of the proposed framework while prioritizing learners' needs.
[109]	Highlights the lack of learner data tracking, the dynamic nature of learners, and the insufficient development of computational thinking skills in existing studies.	A model that is supported by human-computer cooperation.	Big data technology and Machine Intelligence.	Future studies should expand on the proposed work to address the diverse learning needs of students in rural areas, both during pandemics and in post-pandemic settings.

ACKNOWLEDGMENT

Mobile Application Using Convolutional Neural Networks for Preliminary Diagnosis of Rosacea

Angie Fiorella Sapaico-Alberto, Rosalynn Ornella Flores-Castañeda
Facultad de Ingeniería y Arquitectura, Universidad César Vallejo, Lima, Perú

***Abstract*—Rosacea is a chronic skin disease affecting millions of people worldwide, characterized by redness and inflammatory lesions on the face. Given the need to improve early detection, this research aims to develop a mobile application using convolutional neural networks to improve the preliminary diagnosis of rosacea. For this purpose, increases in sensitivity, specificity and accuracy percentages were evaluated. The study was applied, with a quantitative approach and an experimental design, specifically pre-experimental. The study variable was the preliminary diagnosis of rosacea, and the sample consisted of 100 images: 50 from rosacea patients and 50 from healthy people. The technique used for data collection was observation. The results of the implementation of the mobile application showed an increase in sensitivity of 2.7%, specificity of 1.97% and accuracy of 0.10%. In conclusion, the use of the mobile application with convolutional neural networks improves the preliminary diagnosis of rosacea by optimizing the indicators evaluated.**

***Keywords*—Convolutional neural networks; mobile application; rosacea; preliminary diagnosis; sensitivity; specificity**

I. Introduction

In dermatology, the initial and correct detection of rosacea is considered a challenge. This may be because the symptoms are very different and can even be confused with other skin diseases. Thus, the development of a mobile application using convolutional neural networks is proposed to reach a better preliminary detection and thus increase the rates of sensitivity, specificity and accuracy in the diagnosis.

Rosacea is a chronic, non-cancerous dermatological disease affecting the patient's face [1]. The symptoms that appear can be mild, such as spontaneous facial flushing, to more severe cases, such as persistent inflammatory lesions, visibly dilated blood vessels and thickening of the nasal and ocular skin [2].

Rosacea is a skin problem; although the exact cause is unknown, it results from a combination of environmental factors, heredity and specific triggers [3]. Genetic susceptibility, constant intense exposure to ultraviolet (UV) radiation, climate and stress are also some of the main factors contributing to this condition [4]. In addition, certain foods and drinks, such as spicy foods, alcohol and dairy products, can cause rosacea flare-ups in people with sensitive skin [5].

This disease impacts approximately 5.5% of people in the world [6]. Although it affects both genders, it is more common in women and occurs between the ages of 20 and 50 in women but is usually more severe in men and can occur at any age, including childhood [7]. Individuals with rosacea often suffer from anxiety, depression and embarrassment, which affect their quality of life and disrupt their relationships [8]. In terms of physical discomfort, it can be debilitating, but the effect on self-perception and social interaction can be equally stifling [9].

Diagnosing rosacea often presents challenges due to the variability of its symptoms, because it can often be confused with other skin diseases such as seborrheic dermatitis or acne [10]. In addition, rosacea can vary from person to person, and its symptoms can evolve over time, especially in the early stages, complicating the accurate identification of rosacea.

Although dermatological medicine has progressed, there are still major challenges in the early and correct diagnosis of rosacea [11]. Furthermore, the subjectivity of clinical assessment, the diversity in the clinical symptoms of rosacea and the absence of standardized diagnostic standards are just some of the challenges faced by practitioners in their efforts to diagnose and treat rosacea appropriately [12]. Therefore, it is crucial that emerging technologies are used to support the diagnosis of dermatological diseases [13].

For this reason, a mobile application using convolutional neural networks was proposed as a solution to enable more effective picture-based diagnosis of rosacea. This application was developed using convolutional neural networks, which identify characteristics of rosacea. The aim was to increase sensitivity to detect positive cases, increase specificity to minimize false positives and improve accuracy. In this way, this tool provides a technological solution to patients and dermatologists for the effective detection of the disease.

This study is organized as follows: Section II presents the related works. In Section III, the methodology is applied. Section IV presents the results. Section V, the discussion of results and in Section VI, the conclusions of the research is presented.

II. Related Works

In [14], the authors studied deep learning frameworks to establish skin lesions from dermatological images. The study tested the use of convolutional neural networks to detect and categorize diseases at different levels. Some of the findings included efficacy in determining the presence of diseases and their type, with potential breakthroughs that would help individualize treatments for each patient. These results highlighted that the tool is potentially powerful and efficient for dermatological diagnosis in clinical settings.

In [15], the authors conducted a study to optimize the effectiveness of deep learning model training in detecting rosacea lesions from facial images. They performed further tests and observed that their technique not only trained the model

faster (up to 25.6 times faster) but also maintained equivalent accuracy. Finally, they indicated that this method is a fairly accurate and efficient method for detecting rosacea, which could prove to be of great value in the future for clinical uses.

Also in [16], a study to classify skin lesions using images through a customized deep learning framework designed with fewer convolution layers was explored in India for comparison with the previously trained VGG16, ResNet50 and InceptionV3 models. The study focused on collecting dermatoscopic images of patients with various skin conditions using the new customized framework. The main tools included the use of advanced image processing techniques and optimized algorithms to handle complicated visual data. Results were reduced by 95%, 85% and 84% against VGG16-TrL, ResNet50-TrL and InceptionV3-TrL, respectively, highlighting the accuracy of skin lesion classification against conventional methods.

On the other hand, [17] the current applications and results of implementing deep learning algorithms in dermatology were extensively examined. The study population covered a wide range of clinical and research dermatological applications using deep learning algorithms for multiple skin conditions. The tools examined were mainly convolutional neural networks, predicting in the image category. The main features highlighted in this case indicated that, although deep learning provides a noticeable increase in diagnostic accuracy compared to conventional methods, it also involves risks such as the need for large amounts of recorded data and model interpretation.

In addition, [18] investigated the effectiveness of collaboration between dermatologists and artificial intelligence in skin cancer identification, including a large set of dermatological images related to the disease. The techniques used for image processing were multiclass regression and content-based image retrieval (CBIR) to identify patterns in skin cancer. Primary results showed that the fusion of human- and computer-generated analysis not only produces more accurate diagnostic results than conventional methods but also reduces assessment time, suggesting a potential model for future use in routine dermatology.

Also in [19], the authors detected brain tumors by using deep learning and transfer learning. A database of MRI scans from a medical center with a random sample of patients was used. Advanced convolutional neural networks, including VGG, ResNet, MobileNet and DenseNet, were used for this dataset of MRI images that were trained and provided. The research showed that the implementation of the transfer learning technique in the proposed models improved brain tumor detection with an accuracy result of 99.75% for MobileNetv3.

On the other hand, [20] implemented an artificial intelligence model to detect and discern between actinic keratosis and seborrheic keratosis. They used a dataset of 2000 images, with training, validation and test subsets. The AI model was developed using deep learning techniques and implemented using the Python programming language and frameworks such as TensorFlow and PyTorch. Furthermore, taking advantage of the Google Collaboration Platform, the model was efficiently trained in two hours and thirteen minutes, using the computing resources provided by the platform. The model study showed a high ability to distinguish between images of both diseases, with high levels of accuracy, precision and specificity.

III. Methodology

This section describes the methodology used in this research, which was applied because it focused on the use of existing artificial intelligence techniques with the aim of developing a mobile application for the preliminary diagnosis of rosacea. The approach was quantitative and a pre-experimental design because it sought to demonstrate that the independent variable: mobile application using neural networks can provide a preliminary diagnosis of rosacea, this being the dependent variable. The population consisted of images obtained from the free repositories Dermatology Atlas, Fitzpatrick 17k and Flickr-Faces-HQ Dataset (FFHQ). For the sampling, images of people with and without a diagnosis of rosacea were considered for further evaluation. Observation was used to collect data. For data analysis, formulae were applied to calculate sensitivity, specificity and accuracy, respectively. Additionally, the Receiver Operating Characteristic (ROC) curve was used to evaluate the test performance. The ROC curve illustrates the connection between the true positive rate and the false positive rate across different thresholds.

A. Case Development

The methodology that was implemented is Mobile-D, which has an agile approach adapted specifically for mobile application development, combining agile and software engineering practices to address the needs of this type of project [23]. Regarding the population, a total of 600 images were considered, and for the distribution of images in the dataset, 450 images were used for training, a total of 30 images for validation and 20 images as a test set. Finally, for the post-test, 100 images were used. Thus, the sample consisted of 100 images selected from the described population, of which 50 were images of people diagnosed with rosacea and the other 50 were images of healthy people. The phases of the Mobile-D methodology are specified below.

B. Phase 1: Exploration

The product is defined, and customer requirements are understood, an initial plan is drawn up, and potential risks are identified and mitigated [21]. In this initial phase, priority is given to understanding the problem and clearly defining the essential functionalities of the rosacea detection application.

1) Outreach. Develop a mobile application using convolutional neural networks for the preliminary detection of rosacea.

2) Set of functional requirements. Key functional requirements are identified that will define the core capabilities of the application (see Table I).

TABLE I FUNCTIONAL REQUIREMENTS

Requirement	Description of the Requirement
RF01	• The system should allow users to register and authenticate themselves.
RF02	• The app should provide reliable information about rosacea and provide links to additional resources.

RF03	• The app should offer clear instructions to ensure that photos are taken correctly.
RF04	• The user should be able to select images from the gallery or take a picture from the camera to be analyzed.
RF05	• The results of the analysis should be clearly displayed, including the probability of each diagnosis.
RF06	• The system should generate reports summarizing the results of the analyzed images.
RF07	• The system should display the results and generate reports on metrics and indicators.
RF08	• The system should include an 'about the mobile application' section, mentioning that it is a university project, detailing its purpose and context.

C. Phase 2: Initialization

The development environment is established, the architecture and initial design are defined, and teams and their roles are formed [21]. The objective is to have a basic functional version of the mobile application that allows validating the first hypotheses and adjusting it to the user's expectations.

1) Configuration of the environment. Hardware: HP AMD Ryzen 3 laptop and mobile device (mobile phone).

Software: Android Studio IDE Koala 2024, Java, Firebase, Google Colab and Tensor Flow.

2) CNN-based application workflow diagram. Fig. 1 presents the workflow diagram of the convolutional neural network (CNN)-based application for rosacea detection that starts with the acquisition and augmentation of images resized to 224x224 pixels, which are divided into training, validation and test sets. The deep learning model is trained to identify rosacea features, tuned with the validation set, and the Application architecture diagram is evaluated with the test set. Once optimized, the model is integrated into the mobile app, which classifies the images and saves the results, providing a preliminary diagnosis.

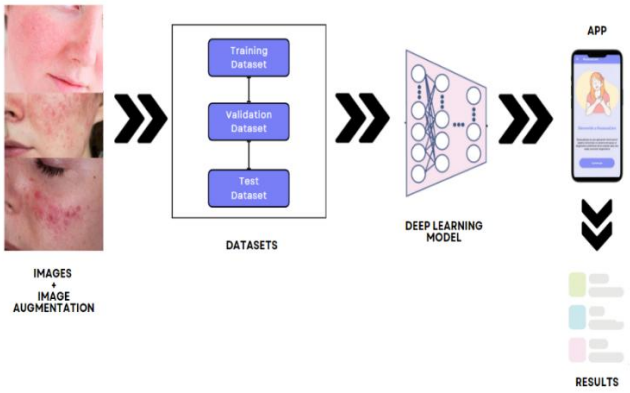

Fig. 1. Workflow diagram of the CNN-based application

a) Application architecture diagram: The mobile application was developed using Android Studio, with integration of TensorFlow for image classification and Firebase as a real-time database. Python and Google Colab were used for training and tuning the classification model, while Java was used for implementing the business logic in the mobile application (see Fig. 2).

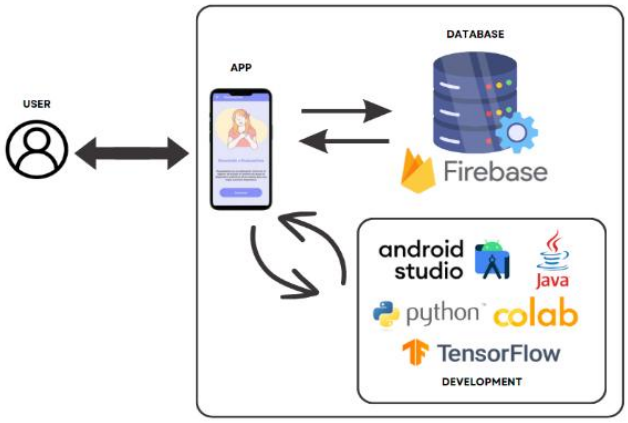

Fig. 2. Application architecture diagram

3) Android project structure. The project structure in Android Studio is organized hierarchically for easy code management and maintenance. The project includes a manifest.xml file that contains application settings and metadata. The source code (Java) directory contains Java files that implement the application logic. The res folder is where the resources of the application are stored. Within res, there are subfolders such as drawable for images, layout for XML files that define the user interface, mipmap for application icons and values for resources such as text strings and colors. The menu folder contains XML files that define the application's menus, such as nav_menu.xml, which specifies the navigation menu items. Finally, the model.tflite file in the assets folder is the deep learning model in TensorFlow Lite format.

D. Phase 3: Production

Work is underway to deliver incremental versions of the application, adding features such as detection, visualization of results, and integration of intuitive interfaces (see Table II).

TABLE II MODULE PLAN

Module	Code	Process	Requirement
User Authentication Module	M01	User authentication process, allowing the user to log in and save their diagnostic data.	RF01
Rosacea Information Module	M02	Process of presenting information about the disease rosacea, including symptoms, causes and recommended treatments.	RF02
Instructions Module	M03	Process of presenting instructions and recommendations on how to take pictures of your face properly.	RF03
Image Upload Module	M04	Process of classifying images using a machine learning model, which determines whether rosacea is present or not.	RF04
Results Viewing Module	M05	Process of visualization of the classification results. Displays diagnostic probabilities and conclusion (positive/negative).	RF05

Report Generation Module	M06	Report generation and visualization process, showing diagnostic results in tabular form, including probabilities and diagnosis.	RF06
Performance Metrics Module	M07	Application performance metrics visualization and report generation process.	RF07
About the Application Module	M08	Process of presenting information about the application, including its purpose, functionalities.	RF08

E. Stabilization

Extensive testing and bug fixes, optimizing performance and ensuring product quality prior to release [21]. The objective is to ensure that the application is ready to be used by end-users without critical problems.

1) Recommendations for mobile equipment. It is recommended to use a mobile device with sufficient storage space, and it is suggested that the device has access to a stable internet connection to perform the analysis in the cloud and synchronize the results with the database (see Table III).

TABLE III RECOMMENDATION FOR THE MOBILE PHONE

Hardware	Software
• RAM: 4GB or more. • Display: HD resolution (720x1280).	• Operating system: Android 8.0 or higher. • Network: 4G

F. Testing

The testing phase involves the final validation of the application under real conditions of use. A detailed review is carried out to ensure that all implemented functionalities meet the requirements established during the exploration phase. Continuous support is provided, and the product is updated with enhancements and new functionalities based on user feedback, version management and post-release problem solving.

1) Unit test 05. Results Display Module: The unit test on the results display module is shown (see Table IV).

TABLE IV TEST RESULT DISPLAY TEST

Code	Name
M05	• Results Display Module
Target	• The application displays the results of the image classification to the user.
Steps	• Access the results module after classification. • Review probabilities and diagnosis. • View analysis details for each loaded image.
Results achieved	• Classification results are clearly displayed to the user. • Probabilities and diagnosis are displayed correctly. • Information is presented without errors or interruptions.

IV. RESULTS

The aim of this research is to determine whether a mobile application using convolutional neural networks improves the preliminary diagnosis of rosacea.

A. Calculation of Indicators

Table V shows a confusion matrix showing the performance of the application with 100 images. Of 50 images of people with rosacea, 47 were correctly classified as positive, while 3 were incorrectly classified as negative. Of 50 images of people without rosacea, 49 were correctly identified as negative, and 1 was incorrectly classified as positive. With a sensitivity of 94% and a specificity of 98%, the model shows an accuracy of 96%. The matrix was developed using SPSS software to analyze the results of the application and evaluate the ability of the classification model on a controlled set of images, this analysis allowed the effectiveness of the model to be determined.

TABLE V CONFUSION MATRIX

	Prediction					
Current		Sensitivity	Specificity	Total	**Function test**	
		Person with rosacea	Person without rosacea			
	Positive	**47**	**1**	48	0.9791666667	Rosacea
	Negative	**3**	**49**	52	0.9423076923	Without rosacea
	Total	50	50	**100**		
	Laboratory test	0.94	0.98		0.96	

From the confusion matrix analysis, the following results were obtained:

% Sensitivity = 94%

% Specificity = 98%

% Accuracy = 96%

1) Analysis of the ROC curve and the area under the curve (AUC). The ROC curve, represented in blue, is shown in Fig. 3, which shows outstanding performance, characterized by high sensitivity and a low false positive rate. In contrast, the red diagonal line represents a random classifier with an AUC of 0.5, equivalent to making random predictions. The blue curve, located above this line, confirms significantly superior performance, highlighting the model's ability to make accurate classifications during testing.

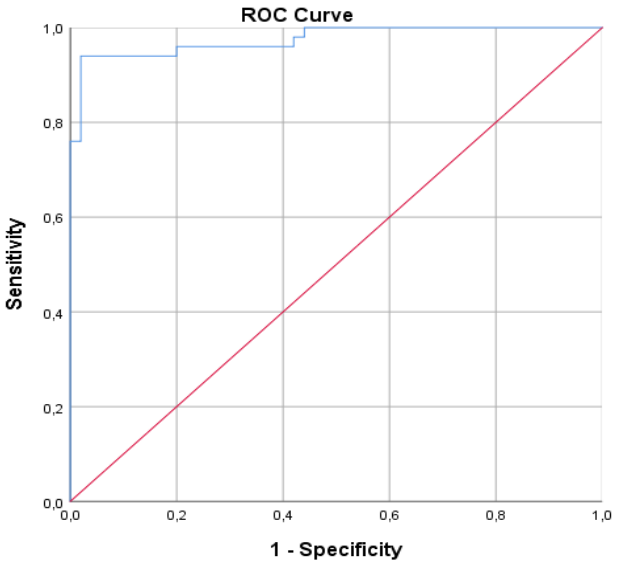

Fig. 3. ROV curve.

The AUC value is 0.975, indicating that the app has a 97.5% ability to correctly classify between positive and negative cases of rosacea (see Table VI).

TABLE VI AREA UNDER THE CURVE

Area	Std. Error	Asymptotic significance	95% asymptotic confidence interval	
			Lower limit	Upper limit
,975	,014	,000	,948	1,000

B. Analysis of the Pre-Experimental Design

a) Pre-test: Table VII shows the accuracy, sensitivity and specificity values of the EfficientNet-b4 model for different dermatological diseases; to verify the increase in percentages in the indicators, it was compared with the rosacea values of the model with the proposed mobile application [22].

TABLE VII PRE-TEST VALUES RESULTS

Disease category	Accuracy	Sensitivity	Specificity
Overall	0.948	0.934	0.950
Lichen planus	0.969	0.873	0.975
Rosacea	0.959	0.920	0.961
Viral warts	0.932	0.944	0.930
Acne vulgaris	0.935	0.974	0.927
Keloid and hypertrophic scar	0.969	0.934	0.970
Eczema/dermatitis	0.877	0.924	0.866
Dermatofibroma	0.987	1.000	0.987
Seborrheic dermatitis	0.926	0.811	0.933
Seborrheic keratosis	0.953	0.858	0.957
Melanocytic nevus	0.960	0.961	0.960
Hemangioma	0.984	0.975	0.984
Psoriasis	0.886	0.920	0.882
Port wine stain	0.963	0.989	0.961
Basal cell carcinoma	0.979	0.971	0.979

b) Post-test: The post-test was performed with 100 images from the dataset, the results of which were obtained with the report generated from the mobile application. Table VIII shows the metrics and percentages of the indicators, indicating sensitivity of 94%, specificity of 98% and accuracy of 96%.

TABLE VIII RESULTS OF THE INDICATORS FOR THE POST-TEST

Quantity	VP	VN	FN	FP	Sensitivity	Specificity	Accuracy
100	47	49	3	1	94%	98%	96%

Table IX shows the comparison between the percentages of sensitivity, specificity and accuracy indicators between the EfficientNet-b4 model and the mobile application.

TABLE IX COMPARISON OF RESULTS

Indicator	Efficientnet-B4	Mobile application
Sensitivity	92%	94%
Specificity	96.1%	98%
Accuracy	95.9%	96%

C. Hypothesis Testing

a) Specific scenario HE1: HE10: A mobile application using convolutional neural networks does not increase sensitivity in the preliminary diagnosis of rosacea.

HE11: A mobile app using convolutional neural networks increases sensitivity in the preliminary diagnosis of rosacea.

% Sensitivity variation = (94-92) / 92 X 100 = 2.17%

An increase in sensitivity was found in the percentage variation, obtaining a positive result of 2.17%; therefore, the alternative hypothesis is accepted, and the null hypothesis is rejected.

b) Specific scenario HE2: HE20: A mobile app using convolutional neural networks does not increase specificity in the preliminary diagnosis of rosacea.

HE21: A mobile app using convolutional neural networks increases specificity in the preliminary diagnosis of rosacea.

% Change in specificity = (98-96.1) / 96.1 X 100 = 1.97%

An increase in specificity was found in the percentage variation, giving a positive result of 1.97%; therefore, the alternative hypothesis is accepted, and the null hypothesis is rejected.

c) Specific scenario HE3: HE30: A mobile app using convolutional neural networks does not increase accuracy in the preliminary diagnosis of rosacea.

HE31: A mobile app using convolutional neural networks increases the accuracy in the preliminary diagnosis of rosacea.

% Variation in accuracy = (96-95.9) / 95.9 X 100 = 0.10%

An increase in accuracy was found in the percentage variation, giving a positive result of 0.10%; therefore, the alternative hypothesis is accepted, and the null hypothesis is rejected.

D. Results of Indicator Increments

Table X shows the percentage increments for each indicator, a positive number is the reason for acceptance of the hypothesis and a negative number is the reason for the increase for each indicator.

TABLE X RESULTS OF THE INCREMENTS FOR EACH INDICATOR

Increased sensitivity	Increased specificity	Increased accuracy
2.17%	1.97%	0.10%

E. General Hypothesis

HG0: A mobile application using convolutional neural networks does not improve the preliminary diagnosis of rosacea.

HG1: A mobile application using convolutional neural networks improves the preliminary diagnosis of rosacea.

By verifying the specific hypotheses HE1, HE2, and HE3, the general hypothesis is accepted.

V. DISCUSSION

The results showed a sensitivity of 94%, resulting in an increase of 2.17%, due to the use of advanced convolutional neural network architectures, which allowed accurate extraction of rosacea-related features. This result is lower than that obtained by [18], who achieved a sensitivity of 95.2% in skin cancer recognition, possibly because they used the ResNet34 architecture previously trained with ImageNet, together with the cross-entropy loss function and the Adam optimizer. Also, the results of this study are lower than those obtained by [20], which was 99.01% in the detection of actinic and seborrheic keratosis; this difference was possibly due to the use of a larger dataset consisting of 2000 high-resolution images. This shows that, although an increase in sensitivity for rosacea diagnosis was achieved, performance depends on factors such as network architecture, dataset size and preprocessing techniques.

In addition, 98% specificity and an increase of 1.97% were obtained because of image preprocessing and data enhancement techniques, which improved the model's ability to differentiate patterns, contributing significantly to the reduction of false positives in diagnosis. This outperformed the result of [18], which only scored 59.2% when detecting skin cancer. This could be attributed to class imbalance in the HAM10000 dataset, with some classes underrepresented. When compared to the study of [20], which obtained 100% specificity and with a higher value than this research, is an outstanding result due to factors such as a balanced and high-quality dataset, as well as distinctive visual patterns that facilitate the differentiation between actinic and seborrheic keratosis in high quality dermatological images. Based on the above, it is evident that image preprocessing and data augmentation contribute to the creation of more robust models with greater specificity.

On the other hand, the results revealed an accuracy of 96%, resulting in an increase of 0.10%, attributed to the training of the model with a carefully labeled high-resolution dataset, which shows its ability to identify relevant features of the dermatological condition. This result is superior to that obtained by [23], where the accuracy was 88-90% in detecting rosacea, this may be because the original images have a high resolution (4608 × 3072 pixels), but were divided into patches of different sizes (64 × 64, 128 × 128, etc.), which may have limited the ability of the model to capture global features. However, the accuracy achieved in this work is lower than that reported by [19], who achieved an accuracy of 99.75% in the detection of brain tumors, as a possible result of the use of fine-tuning and the large number of images used. Taken together, these findings demonstrate that accuracy is strongly influenced by factors such as the quality and resolution of the images used in the model. Skin diseases pose a major global health challenge, and emerging digital tools show promise in enhancing their diagnosis and treatment [24]. Finally, the results confirmed that the application significantly increased the key diagnostic indicators on the basis that in the post-test, there was a marked improvement in the sensitivity, specificity and accuracy of the results.

VI. CONCLUSION

The developed mobile application, based on convolutional neural networks, represents a significant advance in the preliminary diagnosis of rosacea, by considerably improving the sensitivity, specificity and accuracy of the model. A sensitivity of 94% with a variance of 2.7% was achieved, indicating a high ability to minimize false negatives and ensure that affected patients are correctly identified. This is attributed to the innovative implementation of the network architecture, advanced data augmentation techniques and the diversity of the training set, which contributed to better generalization of the model. Likewise, specificity reached 98% with a variation of 1.97%, reflecting a higher accuracy in the identification of negative cases, a result positively influenced by a rigorous image preprocessing and data enhancement process. Finally, the overall accuracy of the model was 96% with a variation of 0.10%, evidencing a substantial improvement in predictive capacity, is supported by using a high-quality data set and rigorous labeling. This study not only provides scientific value by demonstrating the effectiveness of convolutional neural networks applied on mobile devices for dermatological diagnosis but also offers an accessible and practical approach that can facilitate early diagnosis and improve clinical management of rosacea, especially in settings with limited access to specialists.

Among the main limitations of the system is the need to improve diagnostic accuracy, especially in complex cases or with low-quality images, which could affect reliability in diverse clinical settings. In addition, the model currently does not include additional evaluation parameters, such as F1-score or processing time, which would allow a more comprehensive and objective comparison with other existing methodologies. Another relevant limitation is the absence of user feedback mechanisms, which hinders the early identification of errors and the continuous incorporation of improvements based on real experience.

To overcome these limitations, future research should consider implementing ensemble models that combine different architectures to reduce individual errors and increase diagnostic robustness. It is also advisable to extend the evaluation parameters to include metrics such as F1-score, accuracy, recall, and runtime analysis to facilitate comprehensive comparisons with other approaches. It is also suggested to develop a direct feedback module for users to report bugs or suggestions, thus driving continuous improvement of the application. Finally, the incorporation of multilingual support will favor the accessibility and global adoption of the system, adapting it to different cultural and linguistic contexts.

***Abstract*—This study proposes a hybrid machine learning framework for rice leaf disease detection by combining handcrafted feature extraction with metaheuristic optimization and classical classifiers. Using a dataset of 6,000 rice leaf images across seven classes, features including color, texture, shape, and edge were extracted and optimized using Spider Monkey Optimization (SMO), Particle Swarm Optimization (PSO), and Ant Colony Optimization (ACO). Classification was conducted using Random Forest Classifier (RFC) and Support Vector Classifier (SVC), both with and without hyperparameter tuning. Experimental results revealed that PSO consistently outperformed other optimizers, achieving 91.00% accuracy with RFC and 94.64% with SVC when all features and optimal parameters were used. While SMO also showed strong performance, ACO yielded less consistent results. These findings highlight the importance of combining comprehensive feature engineering with adaptive optimization strategies to improve classification accuracy. Compared to previous SMO-based approaches, the proposed PSO-ACO framework demonstrated improved stability and scalability. The proposed framework is interpretable, efficient, and scalable, making it suitable for practical deployment in precision agriculture. Future research directions include integrating deep learning with handcrafted features, developing adaptive metaheuristics, and implementing real-time mobile detection systems.**

***Keywords*—Rice leaf disease; particle swarm optimization (PSO); support vector machine (SVM); feature extraction; precision agriculture**

I. INTRODUCTION

Rice (*Oryza sativa*) remains a staple food for more than half of the global population, playing a pivotal role in ensuring food security particularly in Asia and Africa [1]. With rising global demand, sustainable rice production has become a critical priority. However, rice cultivation faces persistent threats from a variety of leaf diseases such as Bacterial Leaf Blight, Leaf Blast, and Tungro, which can lead to yield losses of up to 70% in severely infected areas [2],[3]. Early and accurate identification of rice leaf diseases is therefore essential to mitigate such risks and enable effective precision agriculture. Traditional diagnostic techniques such as manual inspection and laboratory testing are labor-intensive, time-consuming, and often prone to human error, limiting their scalability [4]. To overcome these challenges, recent advances in machine learning and computer vision have been harnessed to develop automated disease detection systems with improved accuracy and efficiency [5], [6].

In our previous work, we introduced a hybrid detection model named SMOREF-SVM, which integrates Spider Monkey Optimization (SMO), Random Forest (RF), and Support Vector Machine (SVM) [7]. This model achieved a remarkable classification accuracy of up to 98% for rice leaf diseases. However, despite its success, the SMOREF-SVM approach posed challenges related to optimization efficiency and computational complexity. As with many swarm-based algorithms, SMO often suffers from unstable convergence behavior in high-dimensional feature spaces [8]. In response, alternative metaheuristic strategies such as Particle Swarm Optimization (PSO) [9] and Ant Colony Optimization (ACO) [10] have been considered promising due to their robust search capabilities and efficiency in feature selection tasks. This extended study applies PSO and ACO to optimize handcrafted features extracted from rice leaf images. Two machine learning classifiers, Random Forest and Support Vector Machine, are employed to evaluate classification performance, both with and without hyperparameter tuning. The proposed framework introduces a PSO-ACO-based hybrid optimization pipeline designed to enhance accuracy and efficiency in rice leaf disease classification. This study includes a comparative analysis between PSO and ACO against the previously established SMO-based approach. Furthermore, it examines how different feature types color, texture, shape, and edge, impact classification accuracy across the two classifiers. The role of hyperparameter tuning is also analyzed to assess its influence when combined with metaheuristic-based optimization. The findings support the hypothesis that PSO and ACO are viable and scalable alternatives to SMO in plant disease detection frameworks.
