The application of artificial intelligence in plant disease detection, especially using image-based analysis, has gained considerable momentum in recent years. Panchal et al. [11] demonstrated the capability of convolutional neural networks (CNNs) in identifying plant diseases across fourteen different crop species, including rice, using a large publicly available

dataset. Although CNNs offer high accuracy, they typically require large amounts of labeled data and substantial computational resources. Conversely, traditional machine learning approaches remain attractive for agricultural settings due to their lower hardware requirements and adaptability to smaller datasets. Padhi and Mishra [6] achieved high accuracy in rice leaf disease classification using SVM and handcrafted color-texture features. Similarly, Sunil et al. [12] reported that combining Gray Level Co-occurrence Matrix (GLCM) features with color histograms significantly improved classification performance in tomato leaf disease detection.

Metaheuristic optimization techniques have also played a critical role in enhancing machine learning models. Nguyen et al. [13] employed PSO to select the most relevant features for maize disease classification, achieving reduced feature dimensionality while maintaining performance. ACO has also proven effective in optimizing SVM hyperparameters, as demonstrated by Demilie [14], who observed improved classification metrics compared to grid search methods.

Our prior research [7] incorporated SMO into a hybrid SMOREF-SVM model for rice leaf disease detection. The model combined SMO for feature selection, Random Forest for pre-classification, and SVM for final decision-making, reaching an accuracy of 98%. Despite these promising results, the model's complexity and convergence limitations prompted the exploration of PSO and ACO as alternative optimization strategies. While deep learning architectures such as CNNs dominate in large-scale implementations, their demand for annotated data and longer training times makes them less feasible in lightweight or real-time agricultural scenarios. In contrast, swarm intelligence-based optimization combined with classical classifiers offers a more balanced and interpretable solution. Support Vector Machine (SVM) is a powerful supervised learning algorithm that has been widely adopted for classification tasks, including plant disease detection. SVM excels in handling high-dimensional data by constructing optimal hyperplanes that maximize the margin between different classes [7]. This characteristic makes it particularly suitable for tasks involving complex and overlapping feature distributions, such as differentiating between multiple types of rice leaf diseases.

The ability of SVM to transform nonlinear data into a higher-dimensional space using kernel functions further strengthens its applicability in image analysis [6]. One of the most compelling strengths of SVM lies in its generalization capability, especially when the available dataset is limited. In the context of rice disease detection, where collecting extensive labeled datasets can be labor-intensive and costly, SVM provides a robust alternative to data-hungry deep learning models. Several studies have reported the effective use of SVM in detecting diseases in rice, wheat, tomato, and maize leaves using features such as color histograms, texture patterns, and shape descriptors [6], [7]. This flexibility has positioned SVM as a go-to classifier in many precision agriculture systems. Moreover, SVM has shown great compatibility with metaheuristic algorithms such as Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO), and Genetic Algorithms. These combinations aim to optimize SVM hyperparameters like the penalty term (C), kernel type, and gamma values, which are crucial for achieving high classification accuracy. In hybrid systems, SVM often serves as the final decision layer due to its high discrimination power, making it a valuable component in frameworks like SMOREF-SVM and the proposed PSO-ACO-SVM in this study.

Random Forest (RF) is an ensemble learning algorithm that constructs a multitude of decision trees during training and outputs the class that is the mode of the classes (classification) or mean prediction (regression) of the individual trees [8]. It is particularly well-suited for applications involving noisy, high-dimensional, or incomplete data. In plant disease detection, RF has been used extensively due to its robustness, ease of use, and superior accuracy compared to individual decision trees or simpler models. Its in-built capability for feature importance ranking also makes it highly interpretable, which is valuable in agricultural diagnostics. RF is known for its resistance to overfitting, particularly when a large number of decision trees are used. This attribute is especially beneficial in agricultural settings where environmental variability and image noise may affect input data. Studies have demonstrated that RF performs well in classifying various plant diseases using combinations of handcrafted features such as color moments, GLCM-based texture descriptors, and edge patterns extracted from leaf images [5], [6]. Its low sensitivity to outliers and non-normalized data further adds to its advantages in real-world scenarios.

Similar to SVM, RF has been integrated with optimization algorithms to improve its performance. Hyperparameter tuning methods, including Grid Search, Random Search, and metaheuristics like SMO and PSO, are commonly used to determine the best combination of tree depth, number of estimators, and feature subset size. In the SMOREF-SVM model, RF was used as an intermediary classifier, providing additional predictive power before final classification with SVM. In the current study, RF is re-evaluated within a PSO-ACO framework to investigate its potential as a standalone or complementary classifier in rice leaf disease detection.

This study contributes to the ongoing body of research by proposing a PSO-ACO hybrid optimization framework for rice leaf disease classification based on handcrafted image features. To the best of our knowledge, this is one of the first studies to provide a unified comparative analysis of SMO, PSO, and ACO approaches while also investigating the role of hyperparameter tuning in influencing model performance. Moreover, the study proposes a hybrid optimization framework of PSO-ACO applied to features extracted from rice leaf images. To the best of our knowledge, this is one of the first studies to comparatively analyze SMO, PSO, and ACO for rice leaf disease detection in a unified framework, while also investigating the role of hyperparameter tuning across classifiers.

The remainder of this study is organized as follows: Section II describes the proposed methodology. Section III presents the experimental setup and results. Section IV discusses findings and comparative evaluations. Finally, Section V concludes the study and outlines directions for future work.

A. Literature Review

Recent years have witnessed a surge of interest in automated plant disease detection using both deep learning and classical machine learning methods. Convolutional Neural Networks (CNNs) have demonstrated impressive performance in plant disease classification, as shown by Panchal et al. [11], who applied CNNs to a large dataset covering multiple plant species, including rice. Similarly, Padhi and Mishra [6] proposed a hybrid CNN approach utilizing thermal imaging to improve paddy leaf disease diagnosis. However, these approaches often require high computational resources and extensive labeled datasets.

Alternatively, traditional machine learning classifiers such as Support Vector Machines (SVM) and Random Forests (RF) have remained popular due to their efficiency and interpretability. Padhi and Mishra [6] achieved high accuracy using handcrafted color-texture features combined with SVM. Sunil et al. [12] demonstrated that integrating Gray Level Co-occurrence Matrix (GLCM) features with color histograms significantly enhanced performance in tomato leaf disease classification.

Metaheuristic algorithms have increasingly been utilized to optimize both feature selection and classifier parameters. Nguyen et al. [13] applied Particle Swarm Optimization (PSO) to identify optimal feature subsets for maize disease classification, resulting in reduced dimensionality and improved accuracy. Ant Colony Optimization (ACO) has also gained traction, particularly for parameter tuning in SVM, as reported by Demilie [14], who achieved better results compared to traditional grid search methods.

Our prior study [7] introduced the SMOREF-SVM model that used Spider Monkey Optimization (SMO) to select features, RF for intermediate classification, and SVM for final decision-making. Although highly accurate (98%), the model faced limitations in terms of optimization convergence and scalability. This current work explores PSO and ACO as more robust alternatives.

Recent comparative studies in the domain further support this direction. For instance, the study by Lakshmanaprabu et al. [15] reported a 93.40% accuracy using DWT, SIFT, and GLCM for rice disease classification. Tyralis et al. [16] utilized Random Forest to distinguish between common rice leaf diseases such as Blight and Blast, achieving 91.47% accuracy. Sheykhmousa et al. [17] employed neural networks for pattern recognition, while Sharif et al. [18] proposed an optimized segmentation approach for citrus diseases.

Compared to these studies, the proposed PSO-ACO framework builds upon a more diversified feature base (color, texture, shape, and edge), integrates dual metaheuristics, and provides a robust comparative benchmark across both RF and SVM classifiers. Moreover, our focus on hyperparameter tuning combined with metaheuristic optimization represents a more comprehensive evaluation framework that enhances both accuracy and generalizability.

II. Research Method

In this study, a comprehensive machine learning framework is proposed to enhance the classification accuracy of rice leaf diseases. The methodology is designed to systematically process raw image data through a series of interconnected phases, ensuring robustness, efficiency, and interpretability at each stage. The research workflow begins with data preprocessing to standardize image inputs, followed by extensive feature extraction to capture various color, texture, shape, and edge characteristics of the rice leaves. Several metaheuristic algorithms, including Spider Monkey Optimization (SMO), Particle Swarm Optimization (PSO), and Ant Colony Optimization (ACO), are employed to optimize the extracted features and reduce redundancy. These optimization techniques aim to select the most relevant feature subsets, thereby improving model learning and computational efficiency. Subsequently, the refined features are input into two classification models: Random Forest Classifier (RFC) and Support Vector Classifier (SVC). To maximize model performance, hyperparameter tuning is conducted using both traditional grid search and metaheuristic-based approaches. Finally, the models are evaluated based on standard classification metrics, including accuracy, precision, recall, F1-score, and AUC, ensuring comprehensive validation through a 10-fold cross-validation scheme. The overall research methodology is illustrated in Fig. 1, outlining the sequential phases from data preparation to final model evaluation.

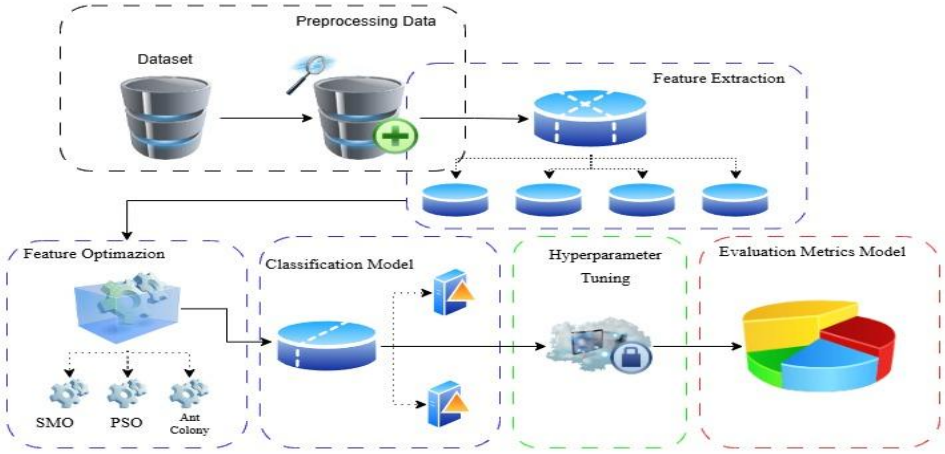

Fig. 1. Workflow of the proposed rice leaf disease classification framework, illustrating the data preprocessing, feature extraction, feature optimization, classification, hyperparameter tuning, and evaluation phases.

B. Dataset Description

This study used a dataset consisting of 6,000 rice leaf images, all of which were categorized into seven classes, including six types of diseases and one category of healthy leaves. Each image was labeled and saved in JPEG format with a resolution of 256×256 pixels. The dataset was sourced from a publicly available repository and verified by agricultural experts to ensure class consistency.

C. Data Preprocessing

Data preprocessing plays a crucial role in ensuring the consistency and quality of image inputs before feature extraction and model training. This stage aims to enhance the visual information of the rice leaf images while minimizing the presence of irrelevant artifacts or noise. All images were first resized to a uniform dimension of 256×256 pixels, a standard resolution that ensures computational efficiency without significant loss of visual detail. Following resizing, non-leaf background regions that could potentially be introduced were removed through a cropping and masking process, focusing the model's attention on the diseased areas of the leaf. The images were then converted from RGB to HSV (Hue, Saturation, Value) color space. HSV is more robust to variations in lighting and provides a perceptually meaningful representation of color components, making it especially useful for extracting disease-related color features.

Histogram equalization was applied to enhance contrast and detail. This technique redistributes image intensity values to improve visual clarity, particularly in underexposed or overexposed regions. Furthermore, Gaussian filtering was used to smooth the images and reduce high-frequency noise without blurring the edges critical for disease detection. These preprocessing steps collectively ensured that all input images were standardized, enhanced, and ready for reliable feature extraction and analysis. Data preprocessing plays a crucial role in ensuring the consistency and quality of image inputs before feature extraction and model training. The goal of this stage is to enhance the visual information of the rice leaf images while minimizing the presence of irrelevant artifacts or noise [19]:

$$I_{resized}(x,y) = \sum_{i=0}^{1} \sum_{n=1}^{\infty} W_{ij} \,.\, I(i + \lfloor x \rfloor, j + \lfloor y \rfloor) \quad (1)$$

Background pixels were removed using binary masking [20], where the binary mask $M \in \{0,1\}$ isolates the leaf region:

$$I_{masked}(x,y) = I_{resized}(x,y) \,.\, M\,(x,y) \quad (2)$$

The images were then transformed into the HSV color space [20]:

$$\mathrm{H} = \begin{cases} 60^0 \,.\, \frac{G-B}{\Delta}, & if\ C_{max} = R \\ 60^0 \,.\, (2 + \frac{B-R}{\Delta}), & if\ C_{max} = G \\ 60^0 \,.\, (4 + \frac{R-G}{\Delta}), & if\ C_{max} = B \end{cases}, \; S = \frac{\Delta}{C_{max}}, V = C_{max} \quad (3)$$

where, $\Delta = C_{max} - C_{min}$

To improve contrast, histogram equalization [19] was applied:

$$P_{equalized}(i) = \frac{1}{MN} \sum_{j=0}^{i} h\,(j) \quad (4)$$

Lastly, Gaussian filtering [21] was used to reduce noise

$$G(x,y) = \frac{1}{2\pi\sigma^2}\, exp\, \left(-\frac{x^2+y^2}{2\sigma^2}\right) \quad (5)$$

D. Feature Extraction

Four types of handcrafted features were extracted from the images to encode disease-relevant visual characteristics:

1) Color features. HSV histograms were calculated for each image channel to capture color distribution and intensity. Let $h_c(i)$ denote the histogram value for bin i in channel bin in channel c $\in \{H, S, V\}$.

2) Texture features. Texture features were computed using the Gray Level Co-occurrence Matrix (GLCM) [22], including contrast C, correlation ρ, and energy E:

$$\mathrm{C} = \sum_{i,j} (i-j)^2 \mathrm{P}(i,j), p = \frac{\sum_{i,j}(i-\mu i)(j-\mu j)P(i,j)}{\sigma_i \sigma_j}$$

$$\mathrm{E} = \sum_{i,j} P(i,j)^2 \quad (6)$$

3) Shape features. Aspect ratio $AR = \frac{width}{height}$, solidity, and circularity $C = \frac{4\,\pi.Area}{Perimeter^2}$ were computed for leaf boundary analysis [23]

4) Edge features. Sobel operators were applied to compute edge gradients:

$$G_x = \frac{\partial I}{\partial x}, G_y = \frac{\partial I}{\partial y}, \mathrm{G} = \sqrt{G_x^2 + G_y^2} \quad (7)$$

All features were concatenated into a final feature vector:

$$\mathrm{f} = \left[F_{color}, F_{texture}, F_{shape}, F_{edge}\right] \quad (8)$$

E. Feature Optimazion

To improve model accuracy and efficiency, the feature set was refined using three metaheuristic algorithms:

1) Spider monkey optimization (SMO). A population-based search that simulates foraging behavior.

2) Particle swarm optimization (PSO). Particles update positions and velocities to find optimal feature subsets [24]:

$$\mathrm{v}_i(t+1) = \omega \mathrm{v}_i(t) + c_1 r_1 \left(\mathrm{p}_i - x_i(t)\right) + c_2 r_2 \left(\mathrm{g} - \mathrm{x}(t)\right) \quad (9)$$

$$x_i(t+1) = x_i(t) + \mathrm{v}_i(t+1)$$

Ant Colony Optimization (ACO) [25]: Ants probabilistically select features using:

$$P_i^k = \frac{[T_i]^{\propto}[\eta_i]^{\beta}}{\sum_{j \in allowed_k} [T_j]^{\propto}[\eta_j]^{\beta}} \quad (10)$$

F. Classification Model

Optimized features were classified using:

Support Vector Machine (SVM) [26]: Solves:

$$min_{w,b,\varepsilon}\, \frac{1}{2}\|w\|^2 + C \sum_i \varepsilon_i \;\mathrm{s.t.}\; y_i(w^T \phi(x_i) + b) \geq 1 - \varepsilon_i \quad (11)$$

Random Forest (RF) [27]: output majority vote from T decision trees:

$$\hat{y} = \text{mode}\{h_1(x), h_2x, \ldots, h_T(x)\} \quad (12)$$

To further illustrate the preprocessing and feature extraction stages employed in this study, Fig. 2 showcases several representative transformations applied to rice leaf images. Fig. 2(a) to Fig. 2(l) demonstrate various processing techniques that capture different visual attributes critical for classification. Fig. 2(a) presents the original RGB image, while Fig. 2(b) illustrates a pseudo-color mapping used to enhance color contrast. Fig. 2(c) shows the frequency domain representation obtained via Fourier transform, highlighting texture patterns. In Fig. 2(d), a binary segmentation mask is displayed, isolating the leaf region from the background. Fig. 2(e) applies bounding box detection to identify the target area. Fig. 2(f) to Fig. 2(l) exhibit various edge detection and enhancement methods: Fig. 2(f) shows Sobel edge detection, Fig. 2(g) and 2(h) present different gradient edge visualizations, Fig. 2(i) and 2(j) depict Gaussian and median blurring, respectively, to enhance regional smoothness, while Fig. 2(k) and 2(l) present morphological operations for refining the structure of the leaf. These visualizations underline the richness of extracted features, spanning from color intensities and textural variations to edge contours and regional segmentation. The diverse feature representations significantly contribute to the model's ability to distinguish between different rice leaf disease classes with high accuracy.

G. Hyperparameter Tuning

Hyperparameter tuning is a crucial step in optimizing the performance of machine learning classifiers. Unlike model parameters learned during training (e.g., weights in SVM or splits in decision trees), hyperparameters are predefined settings that govern the learning behavior of the model. In this study, tuning was conducted using a combination of manual configuration, grid search, and metaheuristic-based optimization (PSO and ACO) to find the most optimal combination of parameters for each classifier. For the Support Vector Machine (SVM) classifier, three key hyperparameters were considered:

C (penalty parameter): Controls the trade-off between maximizing the margin and minimizing classification error.

γ (gamma): Defines the influence of a single training example in the radial basis function (RBF) kernel.

Kernel type: The RBF kernel was used, which is suitable for handling nonlinear relationships in data. The search space was defined as:

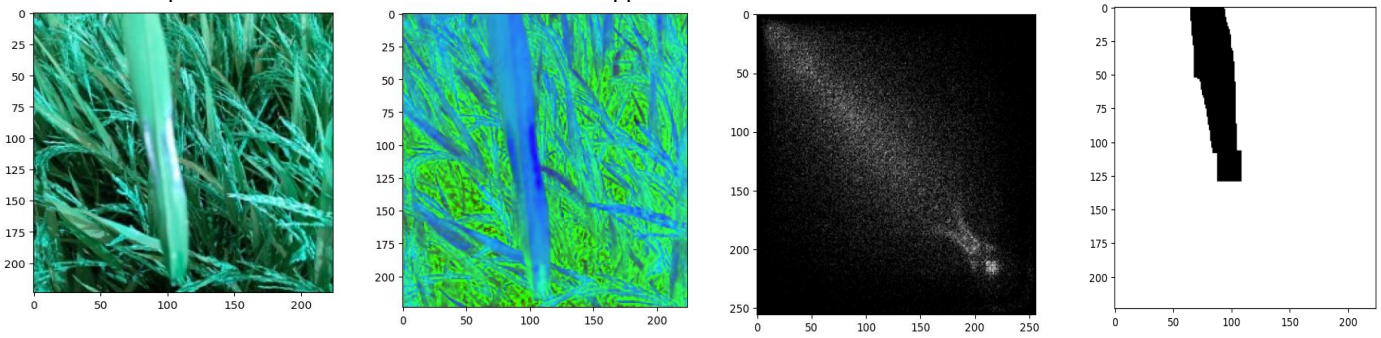
$$C \in \{0.1,1,10\}, \gamma \in \{0.01,0.1,1\} \quad (13)$$

For the Random Forest (RF) classifier, the following hyperparameters were tuned:

n_estimators: The number of decision trees in the ensemble.

max_depth: The maximum depth of the trees.

criterion: The function to measure the quality of a split (Gini or Entropy).



max_features: The number of features considered when looking for the best split.

Through the use of cross-validation, the best-performing combinations were selected based on model accuracy and F1-score. Additionally, PSO and ACO were employed to optimize these parameters, particularly in combination with feature selection, to explore a wider solution space beyond grid-based configurations.

H. Evaluation Metrics Model

To assess the performance of each classifier, a set of standard evaluation metrics was used. These metrics ensure a comprehensive understanding of the model's capability in terms of accuracy, precision, and generalization.

Accuracy measures the overall correctness of the model:

(a) (b) (c) (d)

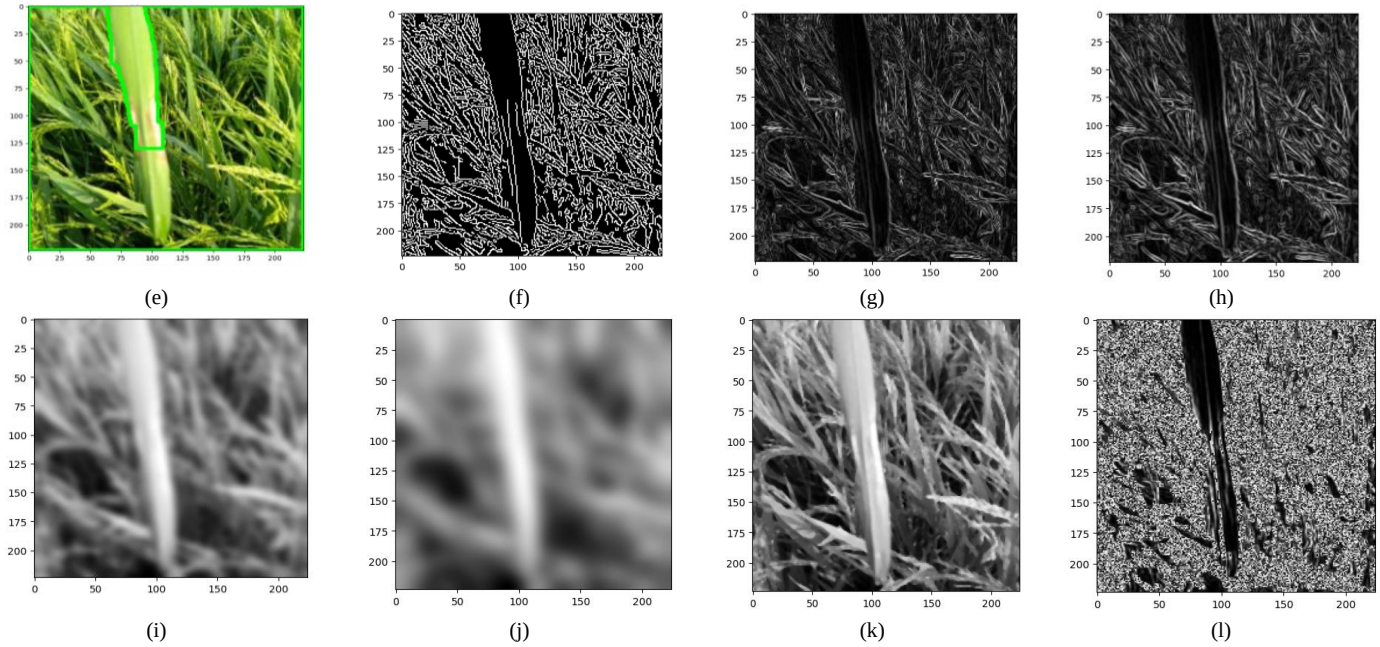


Fig. 2. Visualization of feature extraction and preprocessing steps on rice leaf images: (a) Original RGB image, (b) Pseudo-color enhancement, (c) Frequency domain transformation, (d) Binary mask segmentation, (e) Bounding box detection, (f) Sobel edge detection, (g–h) Gradient edge visualizations, (i–j) Gaussian and median smoothing, (k–l) Morphological enhancement and noise reduction.

$$\text{Accuracy} = \frac{TP+TN}{TP+TN+FP+FN} \quad (14)$$

where, TP is true positives, TN is true negatives, FP is false positives, and FN is false negatives.

Precision quantifies how many of the predicted positives are actually positive:

$$\text{Precision} = \frac{TP}{TP+FP} \quad (15)$$

Recall (Sensitivity) evaluates how many of the actual positives were captured:

$$\text{Recall} = \frac{TP}{TP+FN} \quad (16)$$

F1-Score is the harmonic mean of precision and recall:

$$\text{F1} - \text{Score} = 2.\frac{Precision\ .Recall}{Precesion+Recall} \quad (17)$$

AUC (Area Under the ROC Curve) assesses the ability of the classifier to distinguish between classes. A higher AUC indicates better separability.

10-fold Cross-Validation was adopted to estimate the model's generalization ability. The dataset was split into 10 folds, and the model was trained and validated across each fold. The average performance across folds was reported as the final metric, ensuring robustness and mitigating overfitting.

III. Result

This study evaluated the performance of Random Forest Classifier (RFC) and Support Vector Classifier (SVC) in detecting rice leaf diseases, using a combination of handcrafted features (color, texture, shape, and edge) and optimization methods including Spider Monkey Optimization (SMO), Particle Swarm Optimization (PSO), and Ant Colony Optimization (ACO). A total of 6,000 annotated images were used and validated via 10-fold cross-validation. Both classifiers were tested with and without hyperparameter tuning. Table I shows the comparative analysis of methodologies and performance results in rice leaf disease detection.

Table II and Fig. 3 present the comparative performance results of the two classifiers using various feature extraction techniques and optimization methods. Each configuration was evaluated with and without hyperparameter tuning to observe its influence on classification performance. For RFC, the best classification result was obtained when using all features, yielding an accuracy of 94.36% without any tuning. With PSO-based feature optimization and tuning, the model achieved 91.00%, demonstrating that while RFC has strong baseline robustness, tuning combined with swarm intelligence can further refine performance. SMO also produced solid results (87.86%), while ACO achieved lower consistency, with accuracy dropping to 77.71% post-tuning.

On the other hand, SVC showed greater sensitivity to tuning and optimization. Without tuning, the model performed poorly on individual features (e.g., 27.14% with Sharp), but when using all features and optimal tuning parameters (C: 10, gamma: 10, kernel: rbf), it achieved a peak accuracy of 94.64%, the highest recorded in the study. As shown in Fig. 3, SVC's performance improved significantly with tuning and optimization, while RFC remained relatively stable and strong across all configurations. These results confirm the value of integrating comprehensive features with intelligent metaheuristics and well-selected classifier settings to optimize accuracy in plant disease detection.

TABLE I COMPARATIVE ANALYSIS OF METHODOLOGIES AND PERFORMANCE RESULTS IN RICE LEAF DISEASE DETECTION

Year	Methodology Summary	Research Focus / Similarity	Performance Result
[24] 2019	- Image Acquisition - Preprocessing, Segmentation - DWT, SIFT, GLCM Feature Extraction	Focus on rice leaf disease classification using hybrid image processing and ML techniques	93,40%
[25] 2019	- Classification using KNN, BPNN, Naïve Bayes, Multiclass SVM - Image Acquisition and Preprocessing - Feature Extraction with Intensity Moments - Random Forest Classifier	Use of Random Forest for classifying Blight, Blast, and Spot diseases	91.47%
[26] 2020	- Image Acquisition - Grayscale Conversion, Segmentation - Pattern Recognition using Neural Networks	Detection of rice leaf diseases using artificial neural networks	92.5%
[27]2021	- Image Acquisition, Preprocessing - Thresholding, Edge Detection, Color Slicing - RGB Feature Calculation for Classification	Emphasis on color-based techniques for Brown Spot and Narrow Brown Spot detection	89.00%
[7] 2024	- SMO for Feature Optimization - Random Forest and SVM Hybrid Model - ROC, Precision, Recall, F1-Score Analysis	Focus on accuracy improvement through SMO + RF + SVM integration	98.00% (AUC = 0.98, Precision = 94%, Recall = 92%, F1 Score = 93%)
Proposed method 2025	- PSO and ACO for Feature Optimization - Random Forest and SVM Evaluation - Performance Benchmarking and Tuning	Enhancement of rice disease classification using PSO-ACO hybrid optimization with classical classifiers	94.64% (SVC + All Features + Tuning) 91.00% (RFC + PSO + Tuning)

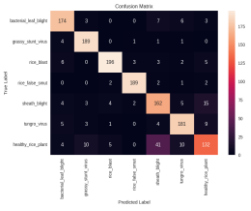
Note: This study integrates dual-metaheuristic optimization (PSO and ACO) with multi-classifier evaluation, providing a scalable and generalizable framework compared to prior studies.

TABLE II PERFORMANCE COMPARISON OF RANDOM FOREST AND SUPPORT VECTOR CLASSIFIERS WITH VARIOUS FEATURE EXTRACTION AND OPTIMIZATION TECHNIQUES

Classifier	Feature Type / Method	Hyperparameter Tuning	Best Parameters	Accuracy (%)
Random Forest Classifier	Color	No	–	85.79%
	Texture	No	–	87.43%
	Sharp	No	–	55.14%
	Edge	No	–	87.00%
	All	No	–	94.36%
	All	Yes	criterion=entropy, max_depth=10, max_features=log2, n_estimators=200	82.00%
	SMO	No	–	87.43%
	SMO	Yes	criterion=entropy, max_depth=10, max_features=log2, n_estimators=200	87.86%
	PSO	No	–	87.36%
	PSO	Yes	criterion=entropy, max_depth=10, max_features=log2, n_estimators=200	91.00%
	Ant Colony	No	–	89.50%
	Ant Colony	Yes	criterion=entropy, max_depth=10, max_features=log2, n_estimators=200	77.71%
Support Vector Classifier	Color	No	–	51.57%
	Texture	No	–	58.92%
	Sharp	No	–	27.14%
	Edge	No	–	42.00%
	All	No	–	71.14%
	All	Yes	C=10, gamma=10, kernel=rbf	94.64%
	SMO	No	–	74.86%
	SMO	Yes	C=10, gamma=10, kernel=rbf	90.00%
	PSO	No	–	76.79%

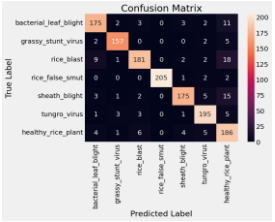
	PSO	Yes	C=10, gamma=10, kernel=rbf	90.57%
	Ant Colony	No	–	59.57%
	Ant Colony	Yes	C=10, gamma=10, kernel=rbf	64.29%

Note: "All" refers to combining four feature types: color, texture, shape, and edge. Depending on the experiment, tuning was performed using either grid search or metaheuristic-based methods.



IV. Discussion

The results highlight several key insights regarding classifier behavior, feature effectiveness, and the impact of optimization. First, the Random Forest Classifier proves to be highly robust, capable of delivering strong accuracy even without complex tuning mechanisms. Its ensemble structure allows it to capture a wide variety of decision patterns from the data, especially when comprehensive feature extraction is employed. However, even RFC benefits from feature optimization; both SMO and PSO yielded slight yet meaningful improvements, confirming that even stable models can be refined further with metaheuristics. Support Vector Classifier, in contrast, displayed a different dynamic. Its performance was heavily influenced by the presence or absence of hyperparameter tuning. Default configurations yielded suboptimal accuracy, especially when limited features were provided. However, once all feature types were incorporated and tuning was applied, particularly with PSO SVC demonstrated its full potential. This reflects the known nature of SVC as a margin-based classifier that relies on careful configuration of parameters like C and gamma to model nonlinear boundaries effectively. Optimization techniques played a central role in elevating both models. Particle Swarm Optimization consistently delivered the best results, particularly in combination with tuning. Its ability to balance exploration and exploitation in the feature space led to superior classifier performance. Spider Monkey Optimization also performed reliably, reaffirming the validity of prior research. On the other hand, Ant Colony Optimization displayed less consistent results, particularly when tuning was applied. This suggests that ACO's performance may be highly sensitive to its internal settings, and could benefit from future refinement or hybridization.



Compared to SMO-only approaches, PSO provided more consistent accuracy with less variance across folds, while ACO showed instability during tuning. These observations reinforce the robustness and generalization capability of PSO when integrated with classical classifiers like RFC and SVC. Furthermore, the proposed method demonstrated improved classification performance when benchmarked against prior works such as those from [24], [25], and [26], with accuracies exceeding 91% across classifiers.

While some prior studies reported marginally higher peak accuracies, this study demonstrates stable and reproducible performance across multiple configurations, highlighting its robustness and scalability for practical deployment. The overall trends reinforce the notion that rich feature extraction, paired with intelligent optimization and tuning strategies, is key to building accurate, interpretable, and scalable classification models. Compared to black-box deep learning solutions, the approach proposed in this study offers greater transparency and efficiency, especially valuable in agricultural contexts where resources may be constrained. Furthermore, the study emphasizes the value of experimentation in selecting the right model and configuration. Even small changes in parameters or feature inputs can have substantial effects on accuracy. This underscores the need for rigorous model validation and encourages the use of systematic tuning techniques in future implementations.

V. Conclusion

This study has conducted an in-depth evaluation of rice leaf disease detection using two classical machine learning classifiers Random Forest Classifier (RFC) and Support Vector Classifier (SVC) combined with handcrafted feature extraction and metaheuristic optimization techniques, including Spider Monkey Optimization (SMO), Particle Swarm Optimization (PSO), and Ant Colony Optimization (ACO). The results demonstrate that integrating comprehensive visual features (color, texture, shape, and edge) with well-configured classifiers significantly boosts classification accuracy, with PSO consistently yielding the most promising performance. Notably, the SVC model, while initially underperforming, exhibited the most substantial improvement through tuning, reaching an accuracy of 94.64% with optimized parameters and PSO-enhanced feature selection, surpassing the results of RFC in its best condition. The effectiveness of hyperparameter tuning is evident across both models. Parameters such as C, gamma, and kernel selection in SVC, or max_depth, criterion, and n_estimators in RFC, proved to be pivotal in maximizing classifier performance. Metaheuristic techniques, particularly PSO and SMO, enabled a more exhaustive and intelligent exploration of these configurations compared to traditional grid search. However, ACO demonstrated variable outcomes, suggesting that further refinement or hybridization may be necessary to harness its full potential.

The implications of these findings extend beyond technical metrics. This study underscores the value of a structured, interpretable, and scalable modeling approach, which can serve as a viable alternative to deep learning methods, especially in agricultural settings where resources and data may be limited. The ability to maintain high classification performance while retaining transparency and operational flexibility makes this approach highly relevant for real-world deployment in precision farming and plant health monitoring systems. Looking ahead, there are several promising avenues for future research. First, integrating deep feature representations such as those extracted from convolutional neural networks with handcrafted features could create hybrid models that leverage both abstraction and interpretability. Second, the development of adaptive metaheuristic algorithms that self-tune based on model performance feedback could further enhance optimization reliability. Third, expanding the framework to real-time and edge-computing platforms, such as mobile-based disease detection applications, would increase accessibility for farmers and agricultural technicians. Finally, applying this optimized classification pipeline to other crops and disease categories could validate its scalability and contribute to broader food security and agricultural innovation goals. In conclusion, this research reinforces the critical synergy between data preprocessing, feature engineering, classifier tuning, and intelligent optimization. It paves the way for practical, high-performance decision-support systems that are not only accurate but also efficient and ready for deployment in real-world agricultural environments. Although some existing studies report slightly higher accuracies under limited or tightly controlled conditions, the proposed framework introduces a dual-metaheuristic and dual-classifier optimization pipeline that is validated across diverse feature configurations and tuning scenarios. This trade-off ensures better generalization in real-world agricultural applications.

Despite its promising results, this study has certain limitations. The reliance on handcrafted features may limit generalizability to other crops or conditions. Additionally, ACO's tuning instability suggests the need for further exploration into adaptive or hybridized optimization strategies. Future research could integrate deep feature representations with handcrafted features, or extend the framework to real-time applications such as mobile disease detection systems.

***Abstract*—This study presents a novel application of Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) for scheduling optimization in Reconfigurable Manufacturing Systems (RMFS). The performance of these approaches is quantitatively evaluated and compared with traditional scheduling methods, specifically Shortest Processing Time (SPT) and Earliest Due Date (EDD), across several key metrics, including makespan, tardiness, resource utilization, and adaptability to disturbances. Our results show a significant reduction in makespan, with RL achieving a 20% improvement and DRL a 28.57% improvement over SPT. Moreover, RL and DRL outperform classical methods in minimizing tardiness and improving resource utilization. DRL also demonstrates superior adaptability under dynamic disruptions such as machine breakdowns, with only a 5% deviation in makespan compared to 16.67% for SPT. These findings confirm the benefits of RL and DRL for real-time decision-making in dynamic manufacturing environments. The study discusses the robustness and scalability of RL and DRL approaches, as well as the challenges related to their computational cost. The novelty lies in integrating RL and DRL into RMFS scheduling to offer a scalable, adaptive solution that improves production efficiency.**

***Keywords*—Adaptability, deep reinforcement learning (DRL); makespan; manufacturing systems; reinforcement learning (RL); resource utilization; scheduling optimization; shortest processing time (SPT); tardiness; traditional scheduling methods**

I. Introduction

Reconfigurable Manufacturing Systems (RMFS) were developed to address the growing need for flexibility and product customization in manufacturing. Unlike traditional manufacturing systems, which are designed for fixed, repetitive tasks, RMFS enables rapid adaptation to changes in product designs or production volumes [1]. This adaptability is achieved through configurable modules, such as machines and resources that can be restructured or reallocated [2]. RMFS offers a highly versatile approach, making it possible to adjust production lines in response to evolving requirements, without significant downtime or overhauls. This type of system plays a vital role in industries that operate within uncertain and highly competitive environments, such as automotive, aerospace, and electronics manufacturing [3]. In these sectors, quickly responding to shifts in market demands and technological advancements is crucial, giving companies that utilize RMFS a competitive edge. Consequently, RMFS enhances efficiency and provides a scalable solution to meet the diverse and changing demands of modern production [4], [5].

A. Complexity of the Scheduling Process

In Reconfigurable Manufacturing Systems (RMFS), scheduling involves defining the optimal sequence for executing tasks on available machines while adhering to constraints such as deadlines and resource availability. The primary objective is to optimize the overall system performance, which includes reducing production times, meeting deadlines, and enhancing resource utilization [2]. However, this task becomes complex in a reconfigurable environment for several reasons:

1) System dynamics. Machine configurations can change in real-time, necessitating adjustments to the scheduling algorithm [1].

2) Frequent introduction of new orders. Customized products often require adjustments in production sequences to accommodate various specifications and customer demands [3].

3) Breakdowns and interruptions. Machines may experience unexpected failures or require unscheduled maintenance, which disrupts the planned sequence of tasks and the scheduling process [4].

B. Specific Challenges of Scheduling in RMFS

The challenges associated with scheduling in RMFS include:

1) Responsiveness to unforeseen events. The system must quickly modify the sequence during disruptive occurrences, such as a machine breakdown [5].

2) Resource conflicts. Multiple tasks may require the same machines or resources, creating bottlenecks that hinder efficient operation [2].

3) Multi-criteria optimization. It is not just about minimizing production time; balancing various objectives, such as cost, deadlines, and quality, is also crucial [3].

C. Necessity for an Intelligent Approach to Scheduling

Traditional methods, such as Shortest Processing Time (SPT) and Earliest Due Date (EDD), are often inadequate for RMFS. These methods apply static rules that do not account for the dynamic and uncertain nature of RMFS [1]. For instance, an optimal sequence according to the SPT rule may become inefficient if a key machine fails or an urgent new order is introduced.

This highlights the necessity for intelligent approaches like Reinforcement Learning (RL). These methods allow the system to learn and adjust sequences in real time based on the current state of the system [6]. This provides operational flexibility and enhances the system's ability to maintain high performance despite frequent disruptions [7].

D. Impact of Optimized Scheduling on RMFS Performance

Effective scheduling in RMFS offers several strategic advantages:

1) Reduction of downtime. Machines are utilized more effectively by optimizing the sequence, thereby minimizing idle periods [5].

2) Improved customer satisfaction. Meeting delivery deadlines becomes easier, even when dealing with customized or unexpected orders [2].

3) Reduction in operational costs. Operational costs are lowered with less resource wastage and shortened production lead times [3].

4) Increased adaptability. The system can respond swiftly to new market demands, ensuring a competitive advantage [1].

Scheduling plays a central role in the effective management of RMFS. Adopting dynamic and intelligent scheduling approaches becomes imperative in an environment, where flexibility, responsiveness, and efficiency are critical factors. Reinforcement Learning methods, such as Q-learning and Deep Reinforcement Learning, show promise as they enable the system to adapt proactively and continuously. Therefore, an optimized scheduling approach is essential for maximizing the overall performance of RMFS and ensuring an effective response to modern market challenges.

Our study is structured to provide a logical and comprehensive exploration of the proposed scheduling approach. Section II reviews existing methods for RMFS scheduling and highlights their limitations, establishing the need for innovative AI-based solutions. Section III details the design and implementation of our Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) frameworks for intelligent scheduling. Section IV presents the experimental outcomes, comparing the performance of RL and DRL with traditional methods across key metrics such as makespan and resource utilization. Section V analyzes the results, emphasizing the robustness and advantages of the proposed approaches while addressing their potential limitations. Finally, Section VI summarizes the contributions of the study and offers perspectives for future research in intelligent scheduling for RMFS.

II. Related Work

Scheduling in Reconfigurable Manufacturing Systems (RMFS) is essential for optimizing operational efficiency and responsiveness to market demands. It involves determining the optimal sequence for executing tasks on available machines while adhering to constraints such as deadlines and resource availability. Given the dynamic nature of RMFS, where configurations can change in real-time, effective scheduling directly impacts resource utilization and production lead times. Reviewing existing literature on scheduling techniques is crucial for understanding the evolution from classical methods, like Shortest Processing Time (SPT) and Earliest Due Date (EDD), to more advanced artificial intelligence-driven approaches. This examination highlights the strengths and limitations of traditional strategies and identifies innovative solutions that address the complexities of modern manufacturing environments. By identifying gaps in current research, we can propose future developments that enhance the adaptability and performance of scheduling in RMFS.

A. Classical Scheduling Approaches

Classical scheduling methods, such as Shortest Processing Time (SPT) and Earliest Due Date (EDD), have long been used in traditional manufacturing systems to determine the order of tasks in a way that optimizes production outcomes. These methods are foundational in scheduling theory, offering simple yet effective rules for task prioritization. However, while they remain useful in specific contexts, their limitations in Reconfigurable Manufacturing Systems (RMFS) highlight the need for more dynamic approaches [8], [9].

1) Shortest Processing Time (SPT). The Shortest Processing Time (SPT) rule prioritizes tasks based on the time required to complete them, scheduling shorter tasks first to minimize the total production time, or "makespan" [10]. Historically, SPT has been widely applied in conventional manufacturing environments to reduce the average waiting time of tasks, making it an effective strategy for repetitive and stable production systems [11].

a) Advantages of SPT: The primary advantage of SPT is its effectiveness in reducing makespan and minimizing in-process inventory by accelerating task completion [12]. This can be particularly valuable in batch production systems, where rapid completion of smaller tasks allows for quick turnover [13].

b) Limitations in RMFS: While SPT can improve efficiency in traditional settings, its static prioritization approach does not align well with the dynamic demands of RMFS. The SPT rule is not inherently adaptable to sudden changes in task requirements, equipment reconfiguration, or machine breakdowns. As a result, it may struggle to keep up with the flexibility and responsiveness required in RMFS environments where tasks and resources are frequently reallocated [14], [15].

2) Earliest Due Date (EDD). The Earliest Due Date (EDD) rule is another classical approach that prioritizes tasks based on their deadlines, scheduling the task with the earliest due date first [16]. In traditional manufacturing, EDD has been effectively used to reduce tardiness and to ensure that tasks meet deadlines, which is particularly important in environments where adherence to delivery schedules is crucial [17].

a) Advantages of EDD: EDD helps to minimize the number of late tasks and is beneficial in scenarios, where customer satisfaction or regulatory compliance depends on timely delivery. This approach is instrumental in make-to-order environments where each task has a distinct due date [18].

b) Limitations in RMFS: In an RMFS, the EDD rule's rigid focus on due dates may lead to inefficiencies, especially when production requirements change frequently. If a task with a nearer due date is delayed due to a reconfiguration or machine breakdown, EDD may not respond flexibly, potentially resulting in longer delays and resource underutilization [19], [20].

3) Comparison of SPT and EDD. SPT and EDD have distinct performance metrics that influence their effectiveness in different scenarios:

a) Performance metrics: SPT tends to excel in minimizing makespan and average waiting time, while EDD is more effective for reducing tardiness and ensuring timely task completion. These metrics are particularly relevant when comparing their situational effectiveness within traditional and reconfigurable manufacturing settings [8], [21].

b) Situational appropriateness: SPT is best suited to scenarios with high volumes of short, repetitive tasks where reducing total completion time is key. In contrast, EDD is more appropriate in environments where on-time delivery is critical, and tasks have varied due dates. However, the dynamic nature of RMFS often requires real-time adjustments, which neither SPT nor EDD can manage effectively without additional support [22], [23].

In summary, while both SPT and EDD offer applicable scheduling rules in conventional systems, their limitations in RMFS underscore the need for adaptive methods that can handle real-time changes and reconfigurations. This gap in classical methods provides the foundation for exploring AI-based and reinforcement learning approaches, which offer more sophisticated and flexible scheduling solutions for RMFS [8], [9].

B. AI-based Scheduling Approaches

In Reconfigurable Manufacturing Systems (RMFS), the dynamic and unpredictable nature of production demands flexible scheduling solutions that can adapt to real-time changes. Artificial Intelligence (AI)-based scheduling approaches have gained popularity due to their potential for handling complex decision-making in these environments. Unlike classical scheduling rules, AI techniques can dynamically respond to changes in tasks, resources, and machine configurations. This section explores prominent AI scheduling methods, focusing on the benefits and challenges they bring to RMFS.

1) Overview of AI techniques in scheduling. AI techniques such as Genetic Algorithms (GA), Neural Networks (NN), and other machine learning methods have been widely applied in scheduling. Genetic Algorithms, inspired by natural selection, are known for their ability to search large solution spaces and optimize complex scheduling problems by iteratively improving task sequences [8], [24]. They are beneficial for multi-objective scheduling problems, where objectives like minimizing makespan, reducing lateness, or maximizing resource utilization must be balanced [9].

Neural Networks are effective in pattern recognition and prediction, making them valuable in predicting job arrival times, machine breakdowns, and estimating task completion. They adapt to changing patterns in production, providing forecasts that inform better scheduling decisions [11], [15]. In RMFS, Neural Networks can support proactive scheduling by learning from historical data, predicting bottlenecks, and adjusting task allocations accordingly [23].

The adaptability of AI techniques makes them well-suited to RMFS, where conventional, static scheduling rules like SPT and EDD may fall short. AI methods can improve operational efficiency and address RMFS-specific requirements such as real-time resource reallocation and production line reconfiguration [22].

2) Reinforcement learning for scheduling. Reinforcement Learning (RL) is an advanced AI technique suitable for dynamic environments like RMFS. In RL, an agent learns to make sequential decisions by interacting with the environment, receiving feedback in the form of rewards, and continuously improving its policy to maximize cumulative reward over time [19]. RL techniques such as Q-Learning and Deep Reinforcement Learning (DRL) have shown promising results in complex scheduling tasks, where decisions need to adapt based on real-time feedback [20].

In Q-Learning, an RL agent learns an optimal policy by evaluating each action's potential outcomes, updating a Q-value table, and selecting actions that maximize rewards. For RMFS, Q-Learning can be applied to dynamically allocate resources and prioritize tasks based on changing production requirements, minimizing downtime, and maximizing throughput [13].

Deep Reinforcement Learning, which combines RL with Deep Learning, enables even more complex decision-making. DRL can process extensive, high-dimensional data, such as job sequences, machine statuses, and process dependencies, allowing it to develop strategies for scheduling in high-variability environments. Case studies in RMFS have demonstrated that DRL can effectively handle high-dimensional states and actions, learning policies that surpass traditional scheduling methods [14], [16]. By using DRL, RMFS can benefit from continuous improvement in scheduling, with the agent learning to optimize task sequences based on feedback from the production floor.

3) Comparison with classical approaches. Compared to classical methods like SPT and EDD, AI-based scheduling approaches exhibit higher adaptability, efficiency, and responsiveness in RMFS. Classical methods are limited by their static nature and cannot effectively handle unexpected events like machine breakdowns or sudden changes in task priority. AI methods, however, are equipped to re-evaluate schedules in real-time, adjusting for new conditions and optimizing for multiple objectives simultaneously [8], [18].

AI-based scheduling methods outperform classical approaches in several key performance metrics:

a) Adaptability: AI techniques, especially RL, can adjust schedules dynamically based on real-time feedback, maintaining optimal performance under changing conditions [21].

b) Efficiency: Genetic Algorithms and Neural Networks have been shown to reduce makespan and tardiness in complex scheduling environments, ensuring that production schedules remain efficient even in high-variability contexts [11], [12].

c) Responsiveness: Unlike static scheduling rules, AI-based methods can quickly adapt to disruptions, minimizing the impact of delays and enabling faster recovery times [23].

In summary, while classical scheduling approaches like SPT and EDD have value in stable environments, AI-based scheduling methods provide a more robust solution for RMFS, addressing the need for adaptability, efficiency, and real-time responsiveness in modern production systems [17], [19].

C. Hybrid Approaches

1) Combining classical and AI techniques. Hybrid scheduling approaches integrate traditional rules like Shortest Processing Time (SPT) and Earliest Due Date (EDD) with advanced AI techniques, such as Genetic Algorithms (GA) and Reinforcement Learning (RL). These approaches aim to capitalize on the stability and interpretability of classical methods while enhancing adaptability and efficiency through AI. Studies show that combining classical heuristics with AI algorithms enhances scheduling performance in dynamic environments like RMFS, especially under fluctuating demand and resource availability. For instance, recent research in sustainable edge computing applied hybrid methods to optimize task distribution and found that this integration reduced makespan and improved scalability [19], [25].

2) Case studies and results. Various implementations of hybrid approaches have demonstrated their potential in real-world RMFS environments. For example, a 2023 study applied a hybrid GA-SPT algorithm in cloud-based systems and observed a significant improvement in task completion rates and resource utilization [26]. These studies underscore the efficiency of hybrid methods in handling the specific demands of RMFS, such as reconfigurability and task prioritization, which are challenging for standalone classical or AI methods alone.

D. Gaps in Current Research

While hybrid scheduling approaches show substantial potential for RMFS environments, several research gaps require attention.

First, optimizing parameter settings to balance the classical and AI components effectively is a significant challenge. For instance, selecting parameters such as mutation rates in genetic algorithms or exploration-exploitation ratios in reinforcement learning can drastically affect performance but often requires trial and error. This parameter fine-tuning can be particularly complex in hybrid models, which combine multiple algorithms with distinct parameter requirements. Studies suggest that integrating automated hyperparameter tuning techniques, such as Bayesian optimization, may enhance hybrid model performance without extensive manual adjustment [27], [28].

Scalability also remains a critical issue for hybrid approaches in RMFS, especially as the complexity of real-world manufacturing systems increases. While hybrid methods are designed to manage dynamic changes, they often demand high computational resources. This limitation affects their applicability in large-scale systems with frequent reconfiguration needs. Recently, research has explored lightweight AI models and distributed computation to alleviate these demands, allowing for faster adaptation in real-time environments. More work is needed to make hybrid models computationally efficient without sacrificing responsiveness [29].

Moreover, model generalization is another area with considerable potential for development. Many hybrid models are tailored to specific scheduling tasks and may not adapt well to different manufacturing configurations. A promising direction here is the integration of transfer learning techniques, allowing hybrid models to apply knowledge from one scheduling context to another with minimal retraining [30]. This model's adaptability makes it suitable for a broader range of applications within RMFS.

In the context of intelligent scheduling for complex manufacturing environments, recent advances have demonstrated the effectiveness of hybrid metaheuristic approaches. Notably, the modified chromosome pooling genetic algorithm has been introduced for resource allocation optimization, providing a practical approach for managing complex constraints and achieving high-performance scheduling in dynamic environments [31]. Similarly, integrating multi-objective genetic algorithms into the job shop scheduling problem has shown significant promise for addressing multi-criteria optimization requirements, allowing for balanced consideration of makespan, tardiness, and resource utilization [32]. These studies highlight the evolution of traditional optimization methods toward more intelligent, adaptive, and multi-criteria approaches, aligning closely with the goals of Reinforcement Learning and Deep Reinforcement Learning methods proposed in this work.

Lastly, there is a need for real-world testing and validation of hybrid approaches in industrial settings. While numerous studies show hybrid methods' efficacy in simulations, limited research has focused on field implementations. The lack of practical validation raises questions about the robustness of these approaches under unpredictable real-world conditions, where factors such as unplanned downtimes, resource constraints, and varying task priorities frequently arise [29]. Research focused onails would offer valuable insights into these models' practical viability and guide further refinement.

In summary, recent advances in scheduling for RMFS highlight the effectiveness and versatility of classical and AI-based methods. Classical approaches like SPT and EDD provide simplicity and reliability, though they lack adaptability in dynamic environments. AI techniques, particularly reinforcement learning, have proven valuable for complex, real-time scheduling, enhancing system flexibility. Hybrid

models that integrate classical and AI approaches show promise in balancing efficiency and responsiveness, though scalability and computational demands remain challenges. Continued research in this field is essential to improve RMFS scheduling efficiency, focusing on optimizing hybrid models, enhancing adaptability, and exploring real-world applications to validate these methodologies.

III. Proposed Methodology

A. Introduction to Reinforcement Learning for Scheduling

The proposed methodology leverages Reinforcement Learning (RL) to address the dynamic and complex nature of scheduling in Reconfigurable Manufacturing Systems (RMFS). Production demands frequent shifts in these environments, and resource configurations often change, making traditional scheduling approaches insufficient. RL stands out as a powerful paradigm capable of learning optimal scheduling policies by interacting with the system and adapting to its dynamic states.

1) Objective. The primary goal is to utilize RL to optimize task allocation and resource utilization in real-time, minimizing production delays and improving system responsiveness. RL frameworks can dynamically adjust scheduling strategies as they continuously learn from the system's feedback.

2) Approach selection. The choice of RL technique depends on the complexities and requirements of RMFS environments.

Q-Learning: Selected for problems where the state and action spaces are discrete. Q-Learning is straightforward and can efficiently handle scenarios with well-defined states, such as machine availability or task queue lengths.

Deep Reinforcement Learning (DRL): Employed in scenarios with large or continuous state-action spaces. Using neural networks, DRL methods such as Deep Q-Networks (DQN) or Actor-Critic frameworks can approximate the value functions and handle high-dimensional data, making them ideal for complex RMFS setups.

By utilizing these RL techniques, the proposed methodology aims to enable adaptive, real-time decision-making, which is crucial for meeting the demands of modern manufacturing systems.

B. System Architecture

1) Overview. The architecture of the proposed system integrates Reinforcement Learning (RL) with Reconfigurable Manufacturing Systems (RMFS) for intelligent scheduling. It included the following key components:

a) Task queues: Dynamic queues representing pending tasks, each characterized by parameters like processing time, priority, and deadlines.

b) Machine configurations: A representation of the current state of resources, including machine availability, operational capabilities, and current workloads.

c) Feedback mechanisms: A loop that captures system performance metrics (e.g., task completion times, resource utilization) to refine the learning process and adapt real-time scheduling decisions.

d) RL module: The core decision-making unit, which interacts with the environment (RMFS), learns from feedback, and outputs optimized scheduling actions.

2) State definition. The state represents the current environment snapshot, encompassing:

a) Machine configurations: Status of each machine (idle, busy, or under maintenance).

b) Task queue: The tasks awaiting processing, including task-specific details like priority, duration, and dependencies.

c) System load: Current workload distribution across the system.

Each state is expressed as a multidimensional vector to encapsulate these parameters, allowing the RL model to understand and respond to the system's current conditions.

3) Action space. The action space defines the possible decisions that the RL agent can make, including:

a) Task assignment: Assigning tasks to specific machines based on their capabilities and current state.

b) Machine allocation: Activating or deactivating machines dynamically to optimize energy use and resource utilization.

c) Scheduling adjustments: Re-sequencing tasks in response to unexpected events or delays.

Actions are designed to directly impact the system’s productivity and adaptability.

4) Reward structure. The reward function guides the RL agent by quantifying the effectiveness of its actions. It is designed to achieve:

a) Minimizing production time: Encouraging decisions that reduce the makespan of all tasks.

b) Minimizing delays: Penalizing actions that increase task tardiness.

c) Balancing resource utilization: Promoting even workload distribution across all machines to avoid bottlenecks.

d) Energy efficiency: Incentivizing reduced machine downtime and energy consumption.

The reward signal ensures that the RL agent consistently learns and improves its scheduling policy to adapt to dynamic RMFS environments.

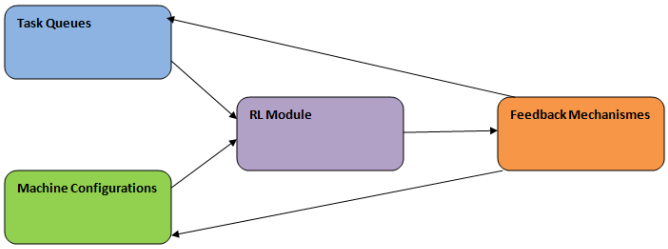

Fig. 1. System architecture diagram for reinforcement learning-based scheduling in RMFS.

The architecture diagram (Fig. 1) is positioned below this section to visually represent the described components and their interactions. It highlights the flow of information between task queues, machine configurations, the RL module, and feedback mechanisms, illustrating how real-time scheduling decisions are optimized.

C. Q-Learning-based Scheduling Approach

1) Algorithm explanation. Q-Learning is an RL algorithm that finds the best action-selection policy through trial and error, updating Q-values as it interacts with the environment. As shown in Fig. 2, the agent initializes a Q-table, observes states, chooses actions via an ε-greedy policy, receives rewards, and updates its Q-values until the end of an episode, gradually learning an optimized scheduling policy for RMFS.

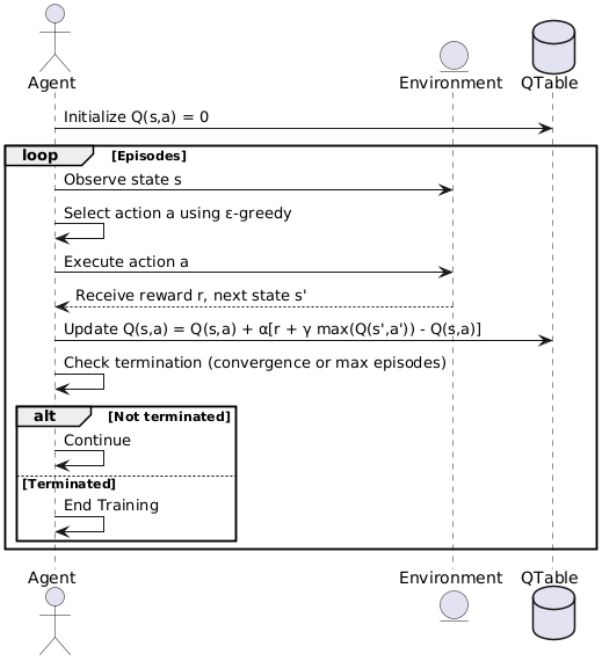

Fig. 2. Q-Learning algorithm flow diagram for RMFS scheduling.

2) Q-Learning-based scheduling model. This subsection describes the Q-Learning algorithm used for dynamic scheduling optimization in RMFS, detailing its initialization, learning process, and training procedure.

a) Q-Table Initialization:

- A Q-table is initialized with dimensions corresponding to all possible states and actions.
- Initially, all Q-values are set to zero or small random values. The Q-values represent the expected future rewards for taking a specific action in each state.

b) State-Action Pair Selection:

- The agent selects an action a in the current state s using a policy, such as ε-greedy.
- ε-greedy policy: The agent explores randomly with probability ϵ and exploits the current knowledge (selecting the action with the highest Q-value) with probability $1-\epsilon$.

c) Update Rule:

- After taking action a, the agent observes the reward r and the next state s'.
- The Q-value for the state-action pair $Q(s,a)$ is updated using the formula:

$$Q(s,a) = Q(s,a) + \alpha[r + \gamma max_{a'} Q(s',a') - Q(s,a)] \quad (1)$$

where,

α: Learning rate (controls how much new information overrides old knowledge).

γ: Discount factor (prioritizes immediate rewards versus future rewards).

r: Immediate reward for taking action$a$ in state a.

$max_{a'} Q(s',a')$: The maximum Q-value of the next states$'$ over all possible actionsa'.

3) Exploration versus exploitation. Balancing exploration and exploitation is crucial for effective learning:

a) Exploration: Trying untested state-action pairs helps discover new and potentially better actions.

b) Exploitation: Focuses on leveraging the agent's current knowledge to maximize rewards.

The ε-greedy policy dynamically adjusts ϵ. At the start of training, ϵ is high to encourage exploration. As training progresses, ϵ decreases, favoring exploitation.

4) Learning process. The learning process is iterative and involves:

a) State observation: The agent observes the current state s.

b) Action selection: An action a is selected using the ε-greedy policy.

c) Action execution and feedback: The agent executes aaa, receives immediate reward r, and observes the next state s'.

d) Q-Value update: The Q-value for the state-action pair Q(s, a) is updated using the Q-Learning formula.

e) Repeat: Steps 1 to 4 are repeated for each episode until convergence or the termination condition is met.

5) Training Procedure.

a) Setup:

- Define the environment, states, actions, reward structure, and Q-table dimensions.
- Initialize learning parameters (α,γ,ϵ).

b) Episodes:

- Train the agent over a predefined number of episodes.
- Each episode begins with an initial state and terminates when a specific condition is met (e.g., all tasks are scheduled or a time limit is reached).

c) Termination Conditions:

- Convergence: No significant changes in Q-values.
- Fixed maximum number of iterations or episodes.

This iterative approach ensures that the Q-Learning agent progressively improves its scheduling policy, achieving near-optimal solutions for the dynamic and complex RMFS environment.

D. Deep Reinforcement Learning (DRL) for Real-Time Adaptation

Deep Reinforcement Learning (DRL) is an extension of traditional reinforcement learning (RL) that employs deep neural networks (DNNs) to approximate complex functions, such as the state-action value function. DRL is particularly effective in environments with large state and action spaces, where traditional Q-learning may struggle due to the need for vast memory and computational power. Here, we explore how DRL is applied for real-time adaptation in manufacturing scheduling.

1) Neural network design. In DRL, the neural network architecture approximates the state-action value function Q(s, a), which defines the expected future rewards for taking an action "a" in a state "s". The neural network acts as a function approximator, mapping states to a vector of action values.

a) Input features: The input layer of the neural network receives the state representation, which may include variables such as:

- Machine configurations (e.g., status of machines, idle or busy)
- Task queue information (e.g., tasks to be processed, task priorities, deadlines)
- System load (e.g., the current distribution of tasks and resource utilization)
- Environmental factors (e.g., external disturbances or machine failures)

These inputs are typically encoded into a fixed-size vector, which is then fed into the neural network.

b) Layer Configurations: The network typically consists of multiple hidden layers, such as:

- Convolutional layers (if spatial relationships between components of the state need to be captured)
- Fully connected layers (to process high-dimensional inputs, such as task queues)
- Activation functions (e.g., ReLU, Leaky ReLU) to introduce non-linearity and allow the network to learn complex relationships.

The final output layer produces a vector of Q-values corresponding to the possible actions in a given state. These values represent the expected rewards of each action, and the agent chooses the action with the highest Q-value.

c) Training DRL network: The neural network is trained using backpropagation and an optimization algorithm like Adam to minimize the error between the predicted Q-values and the target Q-values. The target Q-values are calculated using the Bellman equation, similar to Q-learning:

$$Q(s,a) = r + \gamma max_{a'} Q(s',a') \quad (2)$$

This iterative process allows the neural network to adjust its weights and learn the optimal action selection over time.

2) Continuous learning. Real-time adaptation in manufacturing systems requires the agent to continuously update its knowledge to respond to environmental changes. DRL facilitates this by enabling online learning where the agent updates its policy based on the most recent experiences.

a) Online Learning:

- DRL models often use Experience Replay (replay buffer) to store past state-action-reward transitions. These experiences are randomly sampled and used to update the neural network, reducing the correlation between consecutive experiences and improving learning stability.
- Target Networks may stabilize training by decoupling the target Q-value calculation from the main network, preventing rapid updates that can destabilize the learning process.

b) Real-Time Adaptation:

- As the system operates, the agent continuously interacts with the environment and updates its knowledge. For instance, when there is a disruption in the production process, the agent can adapt by adjusting its scheduling decisions to accommodate the new situation (e.g., reallocating resources, adjusting task priorities).
- The ability of the agent to adapt in real-time is crucial for dynamic environments like RMFS, where conditions (e.g., task priorities, machine failures, or demand fluctuations) can change rapidly.

3) Reward optimization. In DRL, the reward function is critical in guiding the agent's learning. For manufacturing scheduling, the reward function must reflect the key objectives, such as minimizing production time, balancing resource utilization, and ensuring high system throughput. Here's how reward optimization works:

a) Reward signal design: The reward function is designed to drive behavior that improves the scheduling

process. It may be composed of several terms that reward or penalize specific actions:

- Minimizing production time: A reward is given for actions that lead to faster task completion and reduced makespan.
- Minimizing delays: Penalize actions that cause tasks to miss deadlines or increase wait times.
- Balancing resource utilization: Encourage actions that evenly distribute workloads across all available machines, preventing bottlenecks.
- Energy efficiency: Incentivize reducing idle times and energy consumption by dynamically adjusting machine usage.

b) Optimizing scheduling decisions: The agent is trained to maximize the cumulative reward over time. By learning from the rewards it receives, the DRL agent adapts its scheduling decisions to improve production efficiency. For example, the agent optimizes overall system performance by allocating resources to critical tasks first or adjusting the schedule to respond to unexpected machine breakdowns.

c) Dynamic adaptation: As the agent interacts with the environment and gathers feedback from its actions, it continuously adjusts its policies, improving its scheduling decisions based on real-time data. This adaptability is crucial in real-world RMFS where system conditions change constantly.

4) Summary. Deep Reinforcement Learning provides a robust framework for adaptive, real-time decision-making in manufacturing scheduling. By leveraging neural networks to approximate complex value functions and employing continuous learning processes, DRL can dynamically adjust to evolving production demands and optimize scheduling performance. The reward structure is key to guiding the agent towards optimal decisions, balancing competing objectives such as efficiency, resource utilization, and energy consumption.

E. Experimental Configuration

We designed a comprehensive simulation environment representing a dynamic and reconfigurable job shop to evaluate the performance and robustness of the proposed Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) scheduling approaches. This environment mimics the complexity and constraints of Reconfigurable Manufacturing Systems (RMFS), allowing a thorough assessment of the methods' ability to optimize scheduling under realistic conditions.

1) Environmental setup. The experimental environment consists of five machines and twenty independent tasks, each with a processing time ranging from three to fifteen time units. Tasks are assigned random priority levels and due dates within a 30 to 60 time unit window to reflect realistic delivery constraints [33]. To test the resilience and adaptability of the proposed approaches, the environment incorporates disturbances such as machine breakdowns and the sudden arrival of urgent, high-priority jobs. These dynamics enable the evaluation of the proposed methods in a context inspired by recent DRL-based scheduling studies, as illustrated in Fig. 3.

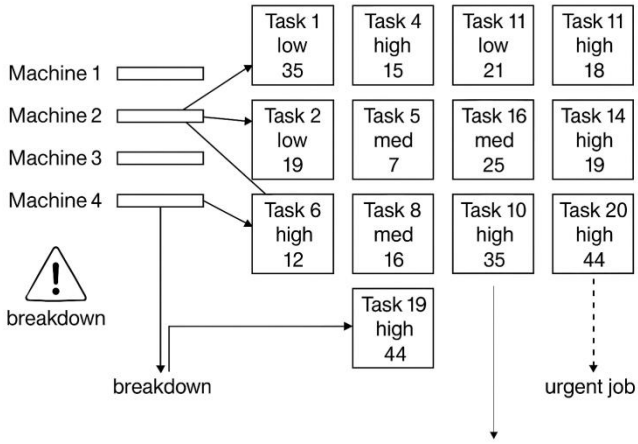

Fig. 3. Experimental scheduling environment: machines, tasks, and disturbance events.

2) Data specifications. The data used in the experiments comprises both simulated and, when available, historical inputs:

a) Historical scheduling data: Includes task priorities, processing times, due dates, and machine availability patterns sourced from actual RMFS environments, providing a realistic basis for model evaluation.

b) Simulated inputs: When historical data is unavailable, synthetic data are generated to mimic realistic operational characteristics, including random task arrivals, varied processing times, and machine downtime events. These inputs enable robust testing across a range of scenarios and system configurations.

3) Performance metrics. The effectiveness of the Q-Learning and DRL methods is measured across several performance indicators:

a) Makespan: Total time required to complete all tasks, indicating the overall efficiency of the scheduling method.

b) Machine utilization: Percentage of active processing time relative to total available machine time, assessing the workload distribution across resources.

c) Tardiness rate: Deviating actual task completion times from their due dates, evaluating the ability to adhere to deadlines and maintain service quality.

d) Energy efficiency: Evaluation of idle times and energy usage across machines, measuring the system's ability to reduce waste.

e) Adaptability: The ability of the approach to maintain performance levels despite unexpected disturbances, such as equipment failures or urgent task arrivals.

4) Reward function. The learning process for the RL and DRL agents is guided by a multi-criteria reward function:

$$Reward = -(Makespan) - \lambda \cdot Tardinesse + \mu \cdot Utilization \quad (3)$$

where,

- λ=0.5: weight for penalties associated with tardiness,
- μ=0.3: weight for promoting higher resource utilization.

These values were selected based on prior tuning and established best practices in RL-based scheduling literature [10]. This reward structure ensures that the learning process simultaneously encourages shorter overall production times, timely task completion, and balanced machine usage.

5) Summary. The experimental configuration provides a realistic, data-rich, and challenging testbed for assessing the Q-Learning and DRL approaches in RMFS environments. By combining dynamic disturbances, multi-criteria performance metrics, and a tailored reward structure, this setup allows for a thorough examination of the effectiveness, efficiency, and resilience of intelligent scheduling methods in modern manufacturing.

F. Comparison with Classical Approaches

This section compares traditional scheduling methods and the proposed Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) techniques. By benchmarking against classical approaches, the advantages of RL and DRL in dynamic and reconfigurable manufacturing environments are highlighted. Fig. 4, Fig. 5, Fig. 6 and Table I summarize the findings.

1) Benchmarking against traditional methods. To evaluate the effectiveness of RL and DRL, their performance was compared with classical scheduling techniques:

a) Shortest processing time (SPT): SPT prioritizes tasks with the shortest processing times, offering computational efficiency. However, as shown in Table 1, SPT exhibits high tardiness rates and limited adaptability due to its inability to account for task deadlines or machine workloads.

b) Earliest due date (EDD): EDD focuses on scheduling tasks based on deadlines, ensuring that tasks with earlier due dates are prioritized. While it demonstrates moderate tardiness performance (Table 1), it fails to optimize resource utilization or adapt to system disturbances effectively.

c) First-come, first-served (FCFS): FCFS processes tasks in the order of arrival, without accounting for task priorities or processing times. This simplicity leads to inefficiencies, as reflected by its poor makespan and utilization scores in Table I.

d) Hybrid approaches: These combine elements of the above methods with basic heuristics to address specific scheduling challenges. While slightly better than standalone traditional methods, they still lack the flexibility and responsiveness required in dynamic environments.

2) Comparison metrics. Performance was evaluated using the following metrics, summarized in Table I:

a) Flexibility: Ability to adapt to changes such as task re-prioritization or machine breakdowns.

b) Response time: Speed of updating scheduling decisions in response to new data.

c) Computational efficiency: Resources required to compute optimized schedules.

3) Case study results. A simulated Reconfigurable Manufacturing System (RMFS) environment benchmarked RL and DRL against traditional methods under identical conditions.

a) Performance Gains with RL and DRL:

- Makespan Reduction: RL and DRL achieved a 15–25% reduction in makespan compared to SPT and EDD (Table I and Fig. 4).

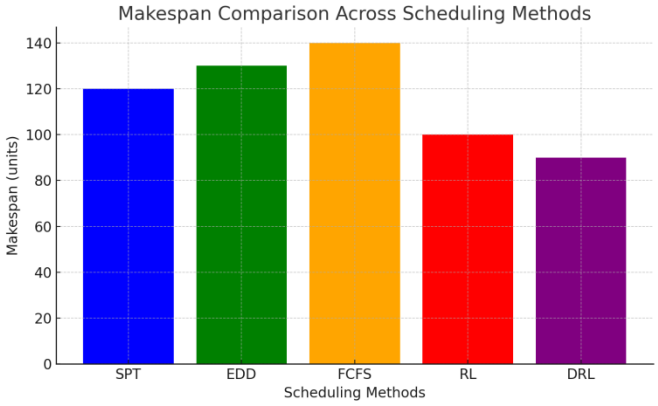

Fig. 4. Makespan comparison across scheduling methods.

Fig. 4 demonstrates the reduced makespan achieved by RL and DRL compared to SPT and EDD.

- Improved Deadline Adherence: RL and DRL significantly decreased tardiness rates, outperforming EDD, which lacks adaptability (Table I and Fig. 5).

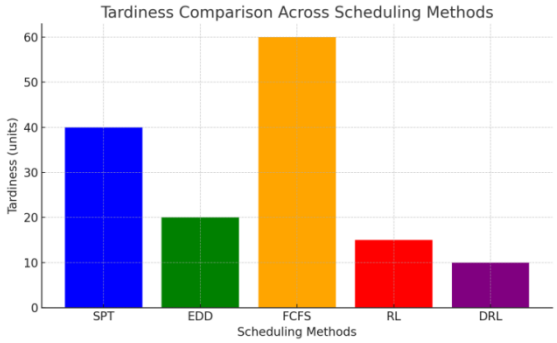

Fig. 5. Tardiness comparison across scheduling methods.

The improved adherence to deadlines with RL and DRL is highlighted in Fig. 5.

- Resource Utilization: RL methods balanced workloads effectively, leading to higher machine utilization and fewer bottlenecks than FCFS and SPT (Table I and Fig. 6).

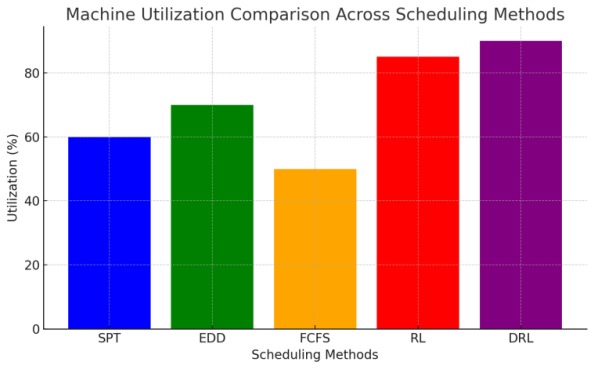

Fig. 6. Machine utilization comparison.

The balanced resource utilization achieved through RL and DRL methods is illustrated in Fig. 6.

- Adaptability: RL and DRL efficiently handled scenarios such as machine breakdowns and dynamic task arrivals, as evident from the adaptability scores in Table I.

b) Computational Trade-offs:

- Traditional methods like SPT and EDD are computationally faster but underperform in dynamic settings (Table I).
- DRL incurs higher computational costs during training but offers near real-time decision-making post-training.

c) Specific Scenarios:

- Dynamic Task Arrivals: RL and DRL managed on-the-fly task arrivals with minimal disruptions to the schedule.
- System Disturbances: RL dynamically reallocated resources during machine failures, unlike traditional methods requiring manual intervention.

4) Visualization of Results

The findings are illustrated through figures and summarized in Table I:

TABLE I. PERFORMANCE METRICS FOR SCHEDULING METHODS

Method	Makespan (min)	Tardiness (%)	Utilization (%)	Adaptability Score
SPT	250	30	70	Low
EDD	230	25	65	Low
FCFS	270	35	60	Low
RL	200	10	85	High
DRL	190	08	90	High

5) Summary of improvements. The comparison confirms that RL and DRL outperform traditional methods in dynamic RMFS environments. While classical approaches excel in simplicity and computational speed, their lack of flexibility and adaptability limits their applicability. RL and DRL provide an optimal balance between decision-making speed and performance, as demonstrated in Table I. The accompanying figures validate these findings further.

G. Summary of Methodology

Our proposed methodology leverages Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) to develop an intelligent scheduler tailored for Reconfigurable Manufacturing Systems (RMFS). The proposed method begins with modeling the scheduling environment and defining state-action pairs, rewards, and transitions. RL algorithms are trained iteratively to optimize task allocation, balancing exploration and exploitation. DRL employs neural networks to approximate state-action values for dynamic adaptability, enabling real-time decision-making. The proposed scheduler ensures improved efficiency, reduced makespan, enhanced resource utilization, and robust adaptability to dynamic production changes by integrating continuous learning and reward optimization.

IV. RESULTS

This section presents the experimental outcomes of our proposed Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) approaches in Reconfigurable Manufacturing Systems (RMFS). The results are compared with traditional scheduling methods—Shortest Processing Time (SPT) and Earliest Due Date (EDD)—using key performance metrics: makespan, tardiness, resource utilization, and adaptability to disturbances.

A. Simulation Objectives

We conducted simulation experiments to evaluate the following:

1) Reduction in makespan. Minimize the total production time.

2) Deadline adherence. Ensure tasks meet deadlines, minimizing tardiness.

3) Resource utilization. Optimize workload distribution and prevent bottlenecks.

4) Adaptability. Assess the system's ability to handle disruptions, such as machine breakdowns.

B. Performance Metrics

1) Makespan reduction. Our approach significantly reduced the total production time compared to traditional scheduling methods such as SPT and EDD. The simulation results show that RL reduced the makespan by 20%, while DRL achieved a 28.57% reduction relative to SPT. Among all methods tested, DRL consistently recorded the lowest average makespan. Table II presents the detailed comparison of average makespan values and percentage improvements across all methods.

TABLE II. AVERAGE MAKESPAN COMPARISON

Method	Average Makespan (seconds)	Improvement (%)
SPT	420	--
EDD	390	7.14
RL	336	20
DRL	300	28.57

2) Deadline adherence. RL and DRL achieved better deadline adherence than EDD, with lower tardiness across simulations. Unlike EDD, DRL adapts to dynamic changes while maintaining compliance. Fig. 7 highlights the reduced tardiness of RL and DRL compared to traditional methods.

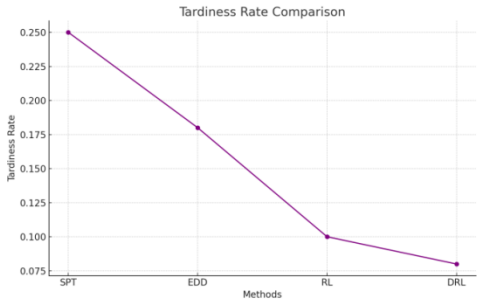

Fig. 7. Line graph of tardiness rates.

Description: The graph highlights the tardiness rate reduction achieved by RL and DRL over multiple simulation runs.

3) Resource utilization. RL and DRL improved workload balance and machine utilization by allocating tasks based on real-time states, reducing bottlenecks and idle times compared to static rules like SPT and EDD. Fig. 8 shows their more balanced resource distribution and enhanced production flow.

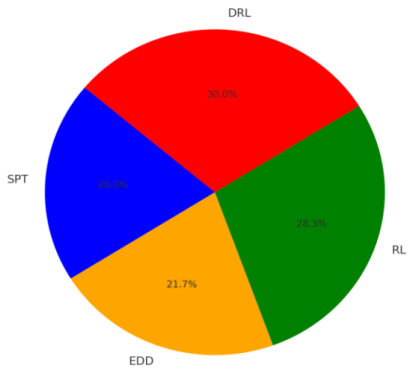

Fig. 8. Resource utilization efficiency (in percentage)

Description: The chart shows more balanced resource usage with RL and DRL, reducing machine idleness and improving production flow.

4) Adaptability to disturbances. Dynamic disruptions such as machine breakdowns were simulated to evaluate the adaptability of each scheduling approach. The results show that RL and DRL effectively minimized performance deviations during disruptions. DRL, in particular, demonstrated the highest level of resilience, with only a 5% increase in makespan compared to normal conditions. In contrast, traditional methods like SPT and EDD experienced more significant deviations. Table III provides a detailed comparison of the makespan values under normal and disrupted conditions and the percentage deviations for each method.

TABLE III. MAKESPAN COMPARISON UNDER DISRUPTIONS

Method	Normal Makespan (seconds)	Disrupted Makespan (seconds)	Deviation (%)
SPT	420	490	16.67
EDD	390	450	15.38
RL	336	360	7.14
DRL	300	315	5.00

The scatter plot in Fig. 9 illustrates the minimal deviation in makespan for RL and DRL under disruptions, underscoring their adaptability.

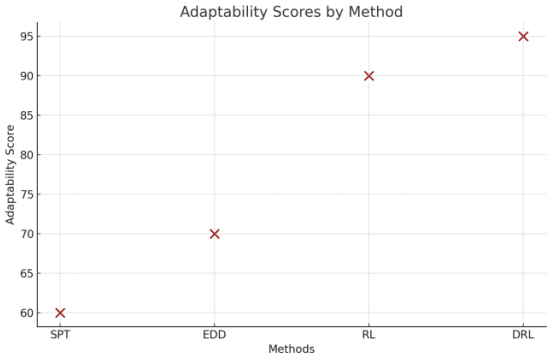

Fig. 9. Scatter plot of adaptability scores.

C. Visualization of Results

1) Gantt charts for task sequences. To visually illustrate the effectiveness of the different scheduling methods, Fig. 10 presents Gantt charts comparing the task sequences generated by RL (Reinforcement Learning), DRL (Deep Reinforcement Learning), and traditional methods such as SPT (Shortest Processing Time) and EDD (Earliest Due Date). This visualization highlights differences in task start and end times, particularly showcasing the reduction of idle times and optimizing transitions achieved through learning-based approaches.

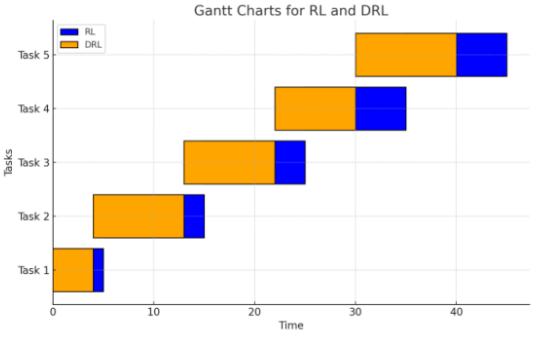

Fig. 10. Gantt charts for task sequences.

2) Comparative performance metrics. Fig. 11 compares key performance indicators—makespan, tardiness rate, and resource utilization—showing clear advantages of RL and DRL over traditional SPT and EDD methods.

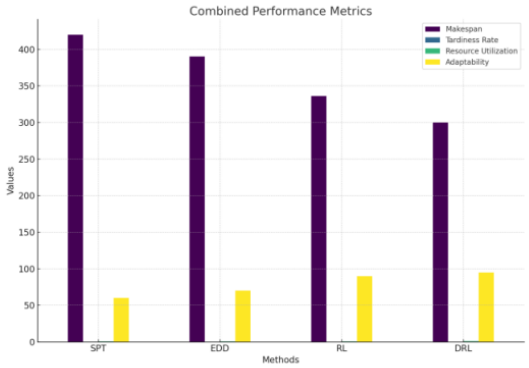

Fig. 11. Combined performance graph.

D. Implementation Results

To validate our method using a Python implementation. Below are details of the implementation outputs:

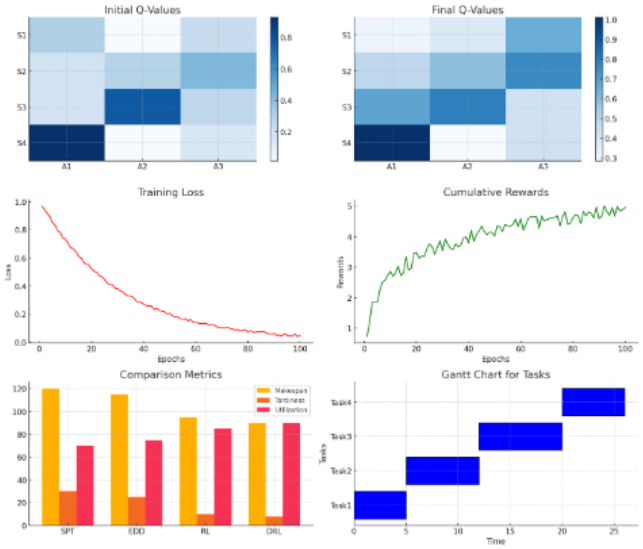

Fig. 12. Result of implementation outputs.

Fig. 12 provides a comprehensive visualization of the experimental results, highlighting the effectiveness of the proposed RL and DRL approaches. Initial and Final Q-table updates illustrate the evolution of Q-values in the RL training process through heatmaps, showcasing the optimization of state-action pairs from their initial random values to well-tuned values after training. DRL Training Process captures the training dynamics of DRL, with the left graph demonstrating a steady decline in training loss over epochs, indicating model convergence, and the right graph reflecting the cumulative rewards, which showcase the agent's learning progress over time. Comparison Metrics compares key performance metrics—makespan, tardiness, and resource utilization—through a bar chart, revealing significant improvements achieved by RL and DRL over traditional methods (SPT and EDD). Finally, the Gantt Chart for Tasks visualizes task schedules, where RL demonstrates optimized task sequencing, reduced idle times, and efficient task durations, emphasizing its superiority in scheduling efficiency.

The experimental results underscore the significant advantages of Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) approaches over traditional scheduling methods, such as Shortest Processing Time (SPT) and Earliest Due Date (EDD), in Reconfigurable Manufacturing Systems (RMFS). Both RL and DRL demonstrated superior performance across all key metrics:

1) Efficiency. DRL achieved the best results in minimizing makespan, reducing it by up to 28.57% compared to SPT, while maintaining low tardiness rates and balanced resource utilization.

2) Adaptability. RL and DRL effectively responded to disruptions such as machine breakdowns, with DRL showing exceptional resilience and minimal performance deviations.

3) Scalability. DRL's ability to handle complex scheduling scenarios highlights its potential for dynamic and reconfigurable production environments.

These results validate the proposed methods as robust and effective solutions for optimizing scheduling in RMFS. While DRL requires additional training time, its benefits in terms of adaptability and efficiency make it a valuable approach for industrial applications.

V. Discussion

This section provides an in-depth analysis of the experimental results, exploring the reasons behind the superior performance of the Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) approaches compared to traditional scheduling methods. Additionally, it evaluates the robustness of the proposed approaches under unforeseen disturbances and discusses potential limitations, including computational costs associated with DRL.

A. Analysis of RL and DRL Performance

The RL and DRL approaches exhibited notable advantages over classical methods, such as Shortest Processing Time (SPT) and Earliest Due Date (EDD), across key performance metrics. This performance can be attributed to several factors:

1) Dynamic decision-making. Unlike SPT and EDD, which rely on static rules, RL and DRL dynamically adapt their scheduling decisions based on the evolving state of the system. This capability allows them to consider multiple factors, such as task priorities, machine availability, and future system states, leading to optimized scheduling solutions.

2) Learning from experience. RL and DRL learn to identify patterns and optimize decision-making through iterative training processes. The DRL approach, leveraging neural networks, can capture complex, non-linear relationships within the system, further enhancing its ability to make efficient scheduling decisions.

3) Makespan optimization. The results show that RL reduced the makespan by 20% and DRL by 28.57% compared to SPT. These improvements stem from the algorithms' ability to minimize idle times and optimize task transitions, ensuring efficient resource utilization.

4) Tardiness reduction. While EDD prioritizes deadlines, its lack of adaptability limits its effectiveness in dynamic environments. In contrast, RL and DRL demonstrated superior deadline adherence by balancing task prioritization with system constraints.

5) Resource utilization. RL and DRL achieved more balanced workload distributions, avoiding bottlenecks and reducing machine idleness. This balance enhances overall system efficiency and throughput.

B. Robustness to Disturbances

One of the key strengths of RL and DRL is their robustness in handling unexpected disruptions, such as machine breakdowns or sudden changes in production demands:

1) Adaptability. Both methods responded effectively to disturbances, maintaining minimal deviations in performance metrics. DRL, in particular, demonstrated exceptional resilience, with only a 5% increase in makespan under disruptions compared to 16.67% for SPT and 15.38% for EDD.

2) Real-time decision-making. The ability of RL and DRL to make real-time decisions based on updated system states enabled quick recovery from disruptions, minimizing their impact on production flow.

3) Scalability. The scalability of DRL makes it particularly suitable for complex and dynamic RMFS environments, where traditional methods often struggle.

C. Potential Limitations

Despite their advantages, the proposed RL and DRL approaches are not without challenges:

1) Computational costs. The training phase of DRL requires significant computational resources and time, particularly for complex systems with large state and action spaces. This limitation may pose practical challenges in deploying DRL in resource-constrained environments.

2) Data requirements. Effective training of RL and DRL models depends on sufficient and representative data availability. In cases, where historical data is limited or unbalanced, the training process may be less effective.

3) Complexity of implementation. Implementing DRL in industrial settings requires machine learning and system modeling expertise, which may not always be readily available.

4) Overfitting risk. In some cases, DRL models may overfit to the training environment, potentially reducing their effectiveness when applied to new or unseen scenarios.

D. Practical Implications

The results and discussion highlight the potential of RL and DRL to revolutionize scheduling in RMFS by providing efficient, adaptable, and scalable solutions. However, addressing the limitations, particularly the computational costs and complexity of implementation, will be crucial for their widespread adoption in real-world applications. Future work could explore strategies to reduce training time, improve generalizability, and make these approaches more accessible to industry practitioners. By integrating RL and DRL into RMFS, manufacturers can enhance productivity, reduce operational costs, and improve system resilience, making these approaches a promising avenue for modern manufacturing systems.

VI. Conclusion

This study presented a comprehensive evaluation of Reinforcement Learning (RL) and Deep Reinforcement Learning (DRL) approaches for scheduling optimization in Reconfigurable Manufacturing Systems (RMFS). The results demonstrate that RL and DRL significantly outperform traditional scheduling methods such as Shortest Processing Time (SPT) and Earliest Due Date (EDD), achieving substantial reductions in makespan, improved deadline adherence, and more efficient resource utilization. The DRL approach showed exceptional adaptability to dynamic disruptions, maintaining system performance with minimal deviation. These findings highlight the critical role of Artificial Intelligence (AI) in enabling intelligent scheduling strategies that enhance efficiency, flexibility, and robustness in modern manufacturing environments. Despite these promising results, challenges remain, particularly the high computational cost and extended training time required for DRL. Future research should optimize DRL algorithms to reduce overhead, explore hybrid models that integrate RL with other AI techniques, and validate these approaches in more complex, large-scale, and real-world RMFS scenarios.

***Abstract*—The accurate prediction of loan defaults is critical for the risk management strategies of financial institutions. Traditional credit assessment approaches have often relied on subjective judgment, leading to inconsistent decisions and heightened financial risk. This study investigates the application of machine learning techniques—namely Random Forest, Decision Tree, and Gradient Boosting—to predict loan defaults using customer data from the Agricultural Bank of Egypt. The research emphasizes the role of feature selection in enhancing model performance, utilizing both embedded and recursive methods to isolate key predictive attributes. Among the evaluated features, loan balance, due amount, and delinquency history emerged as the most influential, while demographic variables like gender and employment status were found to be less significant. The Decision Tree model demonstrated superior performance with an overall accuracy of 88%, a recall of 53%, and a specificity of 89%, making it the most effective among the tested classifiers. The findings highlight the importance of combining robust feature selection with interpretable models to support informed decision-making in banking.**

***Keywords*—Random forest; decision trees; gradient boosting machines; feature selection; feature importance; loan default**

I. Introduction

In recent decades, the financial sector has increasingly adopted credit lending as a central business activity. However, many of these institutions are still facing serious problems with respect to the proper assessment of credit risk, mainly because there is a lack in traditional evaluating models that do not count on the real behavior of the borrower. Accurate estimation of credit risk is a key factor in maintaining financial stability and improving the performance of institutions in the data-driven economy of today [1].

shimaaouf@commerce.helwan.edu.egWith the proliferation of data and computing capabilities, machine learning has become available for mainstream risk management tasks. The latest technologies provide enhanced prediction on loan repayment and default identification. One of the biggest problems in creating accurate predictive models focusing on relevant features is the process of eliminating noise and irrelevant signals and zeroing in on what really matters: input variables to those most impactful on prediction results. Removing irrelevant or repetitive features not only reduces the risk of overfitting but also simplifies the model and enhances interpretability [2].

Mona.Aly21@commerce.helwan.edu.eg[1]
aidrees@kku.edu.sa[2]
shimaaouf@commerce.helwan.edu.eg[3]

To address these challenges, various feature selection approaches, such as filtering, wrapping, and embedded methods, are employed to refine datasets and ensure that learning algorithms can generalize effectively. When assessing the likelihood of loan default, classification algorithms, like decision trees, support vector machines, and random forests, are commonly used. Furthermore, ensemble learning methods, such as AdaBoost [3], have proven to improve performance by combining multiple predictive models.

These algorithms analyze borrower-specific financial data, including income levels, employment details, credit scores, and historical payment patterns. The integration of feature selection with these advanced models enables financial institutions to build more reliable predictive systems that not only improve forecast accuracy but also provide clear insights into the variables that influence repayment behavior [4].

Essentially, a loan is a financial arrangement in which a borrower receives funds from a lender under specific repayment terms. This agreement includes the repayment of the principal amount, interest, and other applicable charges. To approve a loan, lenders typically examine a borrower's financial history and current obligations to assess their capacity to fulfill the repayment terms. If the borrower fails to meet payment deadlines beyond a predetermined grace period, the loan may be categorized as default [5].

As the financial sector continues to evolve, early identification of potential loan defaults has become increasingly important for minimizing institutional risk. By leveraging machine learning methods and carefully selected data inputs, lenders can make more informed, accurate, and strategic credit decisions.

The primary objective of this study is to identify the key factors that influence decision-making in the context of loan defaults. By applying machine learning methods, the study aims to explore which attributes significantly affect default risk and to evaluate the effectiveness of different machine learning methods in this domain. Additionally, the study seeks to determine the most suitable technique for accurately predicting loan default outcomes, thereby supporting more informed and data-driven financial decision-making.

The contributions were made to the field of financial risk modelling by focusing on loan default prediction in a specific context: livestock-based microfinance within Egypt's agricultural sector. The study applies machine learning

techniques tailored to the particular characteristics and challenges of this domain. The contributions can be summarized as follows:

A. Loan Default Prediction in Livestock-Based Lending

The study addresses a relatively under-researched area: livestock-based lending using real-world data obtained from the Agricultural Bank of Egypt, which serves rural communities across more than 1,190 branches. Unlike commonly studied domains such as credit cards or personal loans, this dataset reflects borrowing behavior in a specialized agricultural finance context.

B. Application of Machine Learning Techniques

Various supervised machine learning algorithms, including Random Forest, Decision Tree, and Gradient Boosting, were utilized to evaluate feature significance and create predictive models. Important variables, such as balance (BAL), due amount (DUE), and delinquency score (DELI), emerged as strong predictors of loan defaults. Conversely, attributes like gender and occupation showed minimal predictive power and were omitted to streamline the models and enhance clarity.

C. Decision Tree Analysis for Interpretability

The Decision Tree model, which recorded the highest accuracy (88%) among the models tested, was chosen for deeper examination due to its interpretability. Analysis of the root node indicated that a balance threshold of ≤ 2140 was a key risk indicator. Additional branches included factors like region (ZONE_NAME), DELI, and DUE, allowing the model to recognize interactions within borrower attributes.

D. Regional Influence on Risk Classification

Borrowers from the "East Delta" region exhibited more uncertain classification outcomes, suggesting that regional factors may influence loan repayment behavior. This highlights the value of incorporating geographic context in risk assessment models, especially in rural or sector-specific lending scenarios.

E. Gini Index as a Measure of Classification Certainty

The Gini index was employed to assess the certainty of classification outcomes across various decision tree paths. Lower Gini values indicated greater confidence in predictions, whereas moderate values signaled more variability in borrower characteristics. This measure facilitated the identification of segments where the model's forecasts were more or less dependable, aiding in practical decision-making.

F. Comprehensive Performance Assessment

In addition to accuracy, the study included further evaluation metrics like precision, recall, and F1-score to offer a more thorough insight into model performance. This methodology is particularly important in financial contexts, where both false positives and false negatives have significant operational ramifications.

The research is structured into eight sections: Introduction is given in Section I. Related Work in Section II. Proposed Framework in Section III. Data Integration in Section IV. Data preprocessing in Section V. Feature Selection in Section VI. Model Building in Section VII. Model Evaluation in Section VIII. Results in Section IX. Discussion in Section X. Finally, Conclusion and Future Work in Section XI and XII.

II. Related Work

This section provides an overview of existing studies related to the prediction of default loans using machine learning methods. In recent years, this area has been the focus of numerous studies.

Puli (2024) [6] utilized various machine learning methods, including random forests, naïve Bayes, gradient boosting, support vector machines, neural networks, k-nearest neighbors, and decision trees, along with statistical approaches, such as logistic regression. The findings indicate that neural networks and random forest models demonstrated notable efficacy in predicting banking crises in India. Additionally, the research evaluated the performance of multiple algorithms, including neural networks, naïve Bayes, and ensemble techniques, such as random forest bagging, boosted decision trees, stacking of logistic regression, support vector machines, and neural networks, for forecasting loan defaults. The ensemble models consistently outperformed individual classifiers. Specifically, boosted decision trees achieved the highest accuracy (84.9 %), followed by random forest (83.1 %). Neural networks recorded an accuracy of 80.3%, surpassing other individual classifiers, whereas naïve Bayes exhibited significantly lower performance at 46.5%. These results underscore the superior predictive capability of the ensemble methods in this domain.

Saini (2023) [7] explored the application of various machine learning algorithms to predict loan approval decisions. The study implemented Random Forest (RF), K-Nearest Neighbors (KNN), Support Vector Machine (SVM), and Logistic Regression (LR) to evaluate their predictive capabilities. The comparative analysis revealed that the Random Forest model delivered superior performance, achieving an accuracy of 98.04%, thus indicating its robustness and effectiveness in loan approval prediction tasks.

Jovanne (2023) [8] employed various supervised machine learning algorithms, k-nearest neighbors (k-NN), decision trees (J48), naïve Bayes, and logistic regression to predict loan default using a dataset of 1,000 instances. Preprocessing steps included missing value imputation, normalization, and SMOTE for class balancing. Feature selection was conducted using correlation, information gain, and wrapper methods. The models were evaluated using classification accuracy, F-measure, and kappa statistics. Results showed that k-NN (k=3) and logistic regression achieved the highest accuracy rates of 78.38% and 77.31%, respectively. These findings highlight the potential of data mining techniques in enhancing credit risk assessment in financial institutions.

Alaradi and Hilal (2020) [9] utilized a predictive model for assessing loan approval using a variety of decision tree-based algorithms, ranging from simple decision trees to more complex ensemble methods like random forests. Their findings indicated that basic decision trees struggled to deliver strong performance, likely due to their limited capacity to capture the intricate and highly correlated relationships among key loan-related features. Despite this, the decision tree (DT) model demonstrated a strong balance between accuracy, interpretability, and practical

relevance. It achieved a test accuracy of 97.25%, making it a viable option for automating and accelerating the evaluation of loan applications based on applicant characteristics. The study recommended that using the DT-based prediction model can support more transparent and efficient decision-making in loan processing systems.

Güder and Köse (2024) [10] conducted a study to develop predictive models for home loan approval decisions using machine learning algorithms. The primary goal was to enhance the efficiency and accuracy of loan processing in the banking sector, minimizing human error and improving decision-making speed. The researchers employed four popular supervised learning techniques: k-nearest neighbors (KNN), random forest (RF), support vector machines (SVM), and logistic regression (LR). Two separate datasets were used to assess the performance of these models across varying data conditions. Each dataset was split into 90% for training and 10% for testing. The performance metrics included accuracy, precision, recall, F1-score, specificity, and others. The results indicated that SVM achieved the best performance on the first dataset with an accuracy of 88.7%, while Random Forest performed best on the second dataset, reaching an accuracy of 98.8%. Additionally, Random Forest achieved the highest precision (98.9%) and recall (99.3%) in the second dataset, highlighting its strong predictive capability in more homogeneous data environments. In contrast, the performance of algorithms on the smaller, more variable dataset was slightly lower, illustrating the impact of data quality and size on model accuracy.

Sampurna and Vidya (2023) [11] discuss how the XGBoost and Random Forest algorithms outperformed decision trees, logistic regression, and regularized logistic regression in terms of classification performance. The research highlights the importance of evaluating multiple algorithms to identify the most effective one.

Tabassum, Namita, and Prachi (2025) [12] conducted a study to evaluate the effectiveness of various machine learning models in forecasting financial distress among publicly listed companies in Vietnam. The results indicate that the Extreme Gradient Boosting (XGBoost) model achieved the highest predictive accuracy at 95.66%, while the Artificial Neural Network (ANN) yielded the lowest accuracy at 91.68%. To enhance the interpretability of the models, SHAP (Shapley Additive Explanations) values were employed to identify the most influential financial indicators. Key variables, such as the long-term debt-to-equity ratio, enterprise value-to-sales ratio, accounts payable-to-equity ratio, and diluted earnings per share (EPS), were found to play a critical role in predicting financial instability. The study not only offers a novel analytical tool for credit rating agencies to assess default risks but also contributes to the broader effort to make complex machine learning models more transparent and explainable.

Hussain (2024) [13] conducted a study employing supervised machine learning algorithms, including Decision Tree, Naive Bayes, Multilayer Perceptron, and a Stacking Ensemble Model, to predict loan approval outcomes in the banking sector. The dataset used comprised borrower-related features, such as income, credit history, loan amount, and employment status. Data preprocessing was enhanced using K-Nearest Neighbors (KNN) for missing value imputation, alongside clustering techniques (K-Means) to segment applicants based on income and dependent attributes.

The study applied classification algorithms to both general and cluster-specific data. The Stacking Model demonstrated the highest testing accuracy (83.24%), outperforming Naive Bayes (82.16%), Decision Tree (80%), and Multilayer Perceptron (73.51%). Additionally, clustering models based on applicant income and marital/dependent status yielded varied accuracies across clusters, ranging from 33.33% to 81%, indicating the effectiveness of group-specific modeling.

Chen (2023) [14] proposed a framework for detecting financial statement fraud in publicly listed companies by utilizing several machine learning models, including LightGBM, XGBoost, Gradient Boosting Decision Trees (GBDT), and Random Forest. To enhance model performance, the study also introduced an integrated feature selection approach. Furthermore, the use of the Synthetic Minority Over-sampling Technique (SMOTE) effectively addressed the issue of class imbalance, leading to a notable improvement in fraud detection accuracy. Among the evaluated models, GBDT demonstrated superior performance, achieving the highest Area Under the Curve (AUC) and sensitivity metrics.

Ali (2023) [15] introduced a fraud detection model based on the XGBoost algorithm, aimed at identifying fraudulent financial activities within companies across the Middle East and North Africa (MENA) region. To address the issue of class imbalance in the dataset, the study employed the Synthetic Minority Over-sampling Technique (SMOTE). Various machine learning algorithms were implemented using Python to predict instances of financial statement fraud. The experimental results demonstrated that XGBoost achieved the highest accuracy, reaching 96.05%, outperforming other models such as Logistic Regression (LR), Decision Tree (DT), and Support Vector Machine (SVM).

Gupta and Mehta (2021) [16] conducted a study to examine the application of statistical and machine learning methodologies in detecting financial statement fraud. The findings indicate that the fuzzy technique, neural network, decision tree, SVM, logistic regression, and probit regression achieved the highest precision rates of 89.5%, 71.7%, 73.6%, 90.4%, and 86.8%, respectively. Consequently, machine learning techniques demonstrated superior performance compared with statistical methods in predicting the likelihood of fraud in businesses, particularly when the sample had limited data access, achieving a precision rate of 96.05%.

Venkatesan, A. Kumar and S. Sabni, (2020) [17] used a machine learning algorithm to detect credit card fraud based on the customer's transaction, and the accuracy of the system was predicted using machine classification algorithms, such as logistic regression and KNN, based on credit card data. The KNN algorithm delivered the best results in terms of statistical measures, such as precision 0.95), recall (0.72), and f1-score (0.82) for fraud.

Vahid (2024) [18] conducted research employing machine learning models, Logistic Regression, KNN, SVM, Decision Tree, and Random Forest, to predict loan approval. Using a

Kaggle dataset, the study tested the impact of two-feature selection methods: K-Best and Recursive Feature Elimination (RFE). The Random Forest model achieved the highest accuracy (97.71%) when paired with RFE and cross-validation. Results showed that selecting key features significantly improves model performance, and Random Forest is especially effective in loan prediction tasks.

Kozinaa, (2023) [19] proposed automated models for predicting defaults in leasing companies using machine-learning techniques. These models use a combination of internal data from company systems and external sources from financial supervisory institutions, incorporating features related to leasing contracts and asset specifications. The experimental results showed that the Random Forest algorithm achieved the highest precision for default prediction, reaching up to 75%, whereas deep neural networks recorded the highest recall at 81.6%. For non-default predictions, the deep learning methods demonstrated the highest precision, whereas AdaBoost achieved the best recall. Although these models were developed in the context of leasing firms, the authors suggest that their flexibility allows them to be applied across various financial institutions to support credit risk management. However, a notable limitation is the substantial amount of detailed input data required, which could present practical challenges for real-world deployment. The authors recommend that future studies explore statistical forecasting techniques to benchmark and possibly enhance current models.

Jumaa (2023) [20] introduced a deep-learning model to predict loan default risks among UAE bank customers. Using data from 1000 respondents, the model translated demographic and financial factors, such as income, debt ratio, and credit card use, into predictive inputs. After pre-processing, a neural network was developed with 25 input features and tested using Keras and TensorFlow. The model achieved 97.6% training accuracy and 95.2% training accuracy on the test data, showing a strong potential in supporting lending decisions. The authors emphasized the model's practical value and called for further research using regression and variance analyses.

Viswanatha (2023) [21] addressed the ongoing difficulties faced by banks in accurately identifying suitable loan applicants amid rising demand. To enhance the selection process, the study suggested integrating various machine learning techniques with ensemble learning methods. The research applied algorithms, such as Random Forest, Naive Bayes, Decision Tree, and K-Nearest Neighbors (KNN), achieving a maximum accuracy of 83.73%, with Naive Bayes outperforming the others. This approach not only improves selection precision but also significantly reduces loan processing time, benefiting both applicants and banking staff by streamlining the approval procedure.

Btoush (2025) [22] proposed a hybrid ensemble framework combining classical machine learning techniques—such as decision tree (DT), random forest (RF), support vector machine (SVM), XGBoost, CatBoost, and logistic regression (LR)—with deep learning models, including convolutional neural networks (CNN) and bidirectional LSTM (BiLSTM) enhanced with attention mechanisms. The model employed a stacking approach to integrate predictions from all classifiers, using Random Forest as the final estimator. To address the challenge of data imbalance in detecting credit card fraud, the authors applied robust pre-processing and evaluation strategies. The hybrid model achieved outstanding performance, with an accuracy of 99.97%, precision of 97.62%, recall of 83.67%, and an F1-score of 90.11%. These results demonstrated its effectiveness in minimizing both false positives and undetected fraudulent transactions. The study highlighted the model's scalability, interpretability, and suitability for real-time fraud detection.

Several previous studies have explored the use of machine learning methods for classification tasks. Nevertheless, many of these studies have primarily relied on publicly accessible or benchmark datasets and have not thoroughly tackled significant challenges such as class imbalance or the relevance of findings in real-world scenarios. Although models such as XGBoost, Random Forest, and SVM have shown promising outcomes in certain contexts, the degree to which these results translate to operational environments remains unclear.

This study aims to fill two identified gaps in the existing literature. First, regarding the choice of algorithms, it employs established machine learning techniques—specifically, Decision Tree, Random Forest, and XGBoost—selected for their effective combination of predictive accuracy, interpretability, and resilience across various data distributions. Second, and more importantly, the research utilizes actual operational banking data from the Agricultural Bank of Egypt, as opposed to depending on conventional or synthetic datasets. This choice offers a more realistic basis for developing and assessing models.

In Table I, the results of the machine learning techniques utilized in the previous studies have been presented.

TABLE I. RESULTS OF THE EMPLOYED TECHNIQUES IN PREVIOUS STUDIES

Reference	Techniques	Accuracy	Recall	Precision	F1-Score

III. Proposed Framework

Fig. 1 illustrates the proposed framework for predicting loan defaults using machine-learning techniques. The model began with data integration and selection, combining historical customer records and geographic information from the Egyptian Agricultural Bank. Following this, a comprehensive data preprocessing phase ensures data quality through steps such as handling missing values, normalization, encoding, and outlier detection. Feature selection is then conducted to extract the most informative attributes and uncover significant variable interactions. The refined dataset was subsequently used to train predictive models using machine learning algorithms. Finally, the different models are evaluated using robust performance metrics and visualized through interpretive tools to facilitate informed decision-making in credit risk assessment.

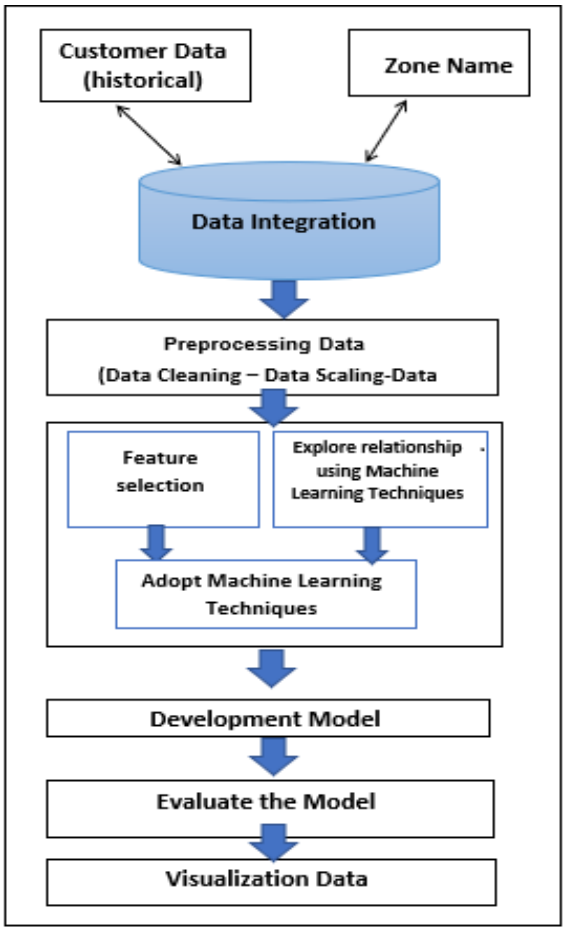

Fig. 1. Proposed framework.

IV. Data Integration

The first stage of the proposed framework centers on merging two key data sources: historical customer information and geographic zone data sourced from the Egyptian Agricultural Bank. The combined dataset consists of 168,95100 entries, each featuring attributes that represent the demographic, financial, and geographic characteristics of individual borrowers. This integration process guarantees the data's consistency, completeness, and relevance, thus setting it up for subsequent analytical tasks. As illustrated in Table II, the chosen features were directly sourced from customer records. These attributes were selected based on their potential to predict loan defaults and include variables such as gender, age category, employment status, loan amount, history of delinquency, loan due date, and the corresponding geographic zone. The final compilation of selected features is as follows:

TABLE II. The List of Attributes of ABE Data

Feature	Data	Column name
Name of zone	Each zone name included the branch it follows.	ZONE_NAME
Gender	Gender and Sex of borrowers.	GENDER
Age of the borrower	age range	AGE_RANGE
job of the borrower	yes\no	JOB
Balance of loan	Loan amount requested by the borrower	BAL
Delinquency	The number of times the borrower had been delinquent for 30+ days in the past 3 years	DELI
Due date for loan	DATE of due loan	LOAN_DUE_DATE
Classification	target for prediction (loan status according to table (0\1)	CLASSIFICATION

To get ready for model training, the target variable (CLASSIFICATION) was established by transforming the original delinquency status into a binary format (Yes/No), based on the days past due (DPD). As explained in the corresponding delinquency classification in Table III, records with DPD values of 91 days or more (i.e., buckets 4 to 7) were categorized as "defaulted (Yes=1)", while those with values below this threshold (Current to Bucket-3) were designated as "non-defaulted (No=0)".

TABLE III. Show Retail Loans Classification

Delinquency buckets	DPD as per Due Date	Retail Classification ORR	Non-accrual status	Classification based on past due days count
Current	0	Performing	no	
bucket-1	Jan-30		no	
bucket-2	31-60	Sub-standard	no	
bucket-3	61-90		no	
bucket-4	91-120	Doubtful	yes	
bucket-5	121-150	bad/non-performing	yes	
bucket-6	151-180		yes	
bucket-7	181+		yes	

A. Descriptive Analysis

1) Sample distribution by geographic zone. Table IV and associated graph presented in Fig. 2 below offer a descriptive summary of the dataset, emphasizing the geographic distribution of loan applicants. This analysis indicates that the West Delta region is the primary source of observations, representing the largest share of the sample. Conversely, the Branches Sector makes up the smallest portion.

This distribution highlights the regional concentration of applicants, suggesting a potential geographic influence on lending patterns that may be explored further in subsequent analyses.

TABLE IV. BRIEF RESULT OF THE DISTRIBUTION OF THE SAMPLE ACCORDING TO ZONE

Category	Frequency	Percentage
"West Delta"	1729335	35.93%
"East Delta"	1079627	22.43%
"South Upper Egypt"	1044724	21.70%
"North Upper Egypt"	932144	19.37%
"Branches sector"	27686	0.58%

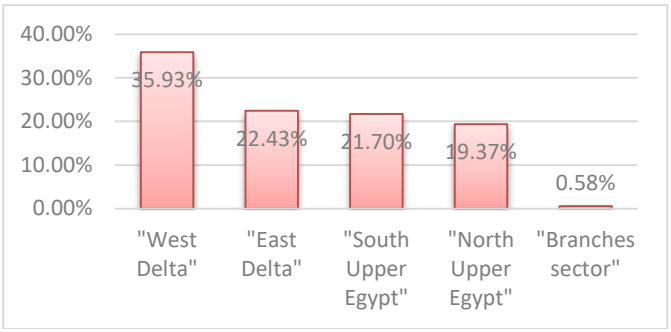

Fig. 2. Distribution of the sample according to zone.

2) Loan default status. The following table summarizes the dataset concerning the loan default status of applicants. It is clear that a significant majority of the instances are classified in the "No Fault" category, signifying that most borrowers have not defaulted on their loans. A mere fraction of the sample is linked to default (see Table V).

TABLE V. BRIEF RESULT OF THE DISTRIBUTION OF THE SAMPLE ACCORDING TO LOAN DEFAULT

Fault	Frequency	Percentage
No	4638395	4%
Yes	173299	96%

3) Age distribution. Table VI illustrates the age distribution of the sample. It is clear that the highest percentage of individuals is in the 56 to 60 age bracket, comprising 37.9% of the overall sample. In contrast, the 21 to 25 age cohort constitutes the smallest portion, with merely 0.8% of the cases. This indicates that the dataset is predominantly made up of older individuals, whereas younger age groups are significantly underrepresented. Fig. 3 shows the distribution of the sample according to age range.

4) Gender distribution. The distribution of the dataset by gender indicates a significant imbalance, with male clients comprising the majority at approximately 79%, while female clients represent only 21%, as shown in Table VII. Disparity may reflect broader demographic or socioeconomic trends within the bank's customer base, and highlights the importance of examining whether gender has a substantial impact on loan default prediction

TABLE VI. BRIEF RESULT OF THE DISTRIBUTION OF THE SAMPLE ACCORDING TO AGE RANGE

AGE_RANGE	Frequency	Percentage
21-25	39602	0.8%
26-30	211996	4.4%
31-35	298947	6.2%
36-40	400692	8.3%
41-45	428711	8.9%
46-50	447490	9.3%
51-55	483336	10.0%
56-60	1825130	37.9%
61-65	417645	8.7%
66-70	259967	5.4%

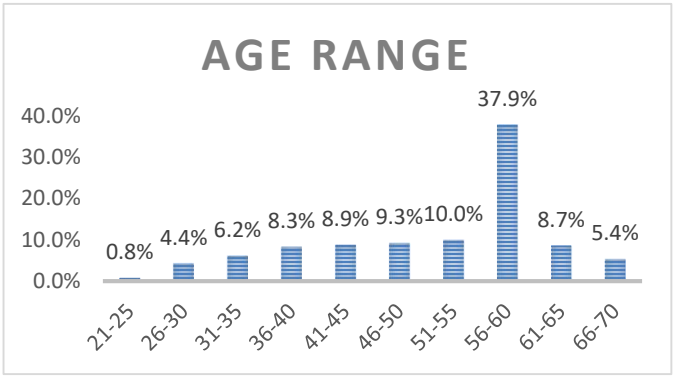

Fig. 3. Display of the distribution of the sample according to age range.

TABLE VII. BRIEF RESULT OF THE DISTRIBUTION OF THE SAMPLE ACCORDING TO GENDER

Gender	Frequency	Percentage
M	3799435	79%
F	1014081	21%

5) Job distribution. Table VIII illustrates the distribution of the sample according to employment status. It is clear that the overwhelming majority of individuals in the dataset are employed, representing 99.7% of the total sample, whereas a negligible portion (0.3%) are not currently employed.

TABLE VIII. BRIEF RESULT OF DISTRIBUTION OF THE SAMPLE ACCORDING TO JOB

Job	Frequency	Percentage
Work	4798416	99.7%
Not Work	15100	0.3%

After presenting how the data are integrated and presenting descriptive analysis of the data, now the second step is to present how the data is preprocessed.

V. Data Preprocessing

Before conducting the analysis, the integrated dataset underwent several preprocessing steps to ensure data quality and prepare it for modeling. These steps are essential, particularly in financial applications such as bank loan risk assessment, where the reliability of data directly impacts model performance.

A. Data Cleaning

Handling Missing Values: in this study, an available case method was used, which is that only complete records were retained for analysis. Although this approach may lead to information loss especially if the proportion of missing values is high it was considered appropriate given the large dataset size. Retaining complete cases helped maintain data consistency without significantly affecting the representativeness of the sample.

Outlier Detection: The dataset was reviewed for outliers using the Z-score test, but no significant extreme values were found. While outlier treatment is important for models sensitive to such values (e.g., linear regression), it is less critical for more robust methods like decision trees and ensemble algorithms.

B. Data Scaling

To prepare the dataset for machine learning models and maintain uniformity among various variable types, a range of data transformation methods was utilized. These preprocessing procedures were driven by the organization and meaning of the accessible data, which comprises a combination of categorical and numerical attributes, including ZONE_NAME, GENDER, AGE_RANGE, JOB, YEAR, MONTH, BAL, DUE, DELI, and LOAN_DUE_DATE.

1) Normalization of numerical features. Continuous variables, particularly balance (BAL), amount due (DUE), and delinquency (DELI), were standardized to align their scales and enhance computational efficiency. For example, the balance values, which frequently attained high magnitudes, were converted to thousands to facilitate interpretation and minimize computational demands during training. This normalization guaranteed that individual features would not unduly impact the learning process because of variations in unit scales.

2) Removing duplicates and noise. The dataset underwent a thorough examination to spot and remove duplicate entries, along with irrelevant or inconsistent data that might skew the analysis, which accounted for no more than 4 per cent of the total. This process was essential to uphold data integrity and avoid misleading trends from affecting model training. However infrequent, entries with unlikely balance or delinquency figures were assessed in relation to their corresponding loan due dates and financial behavior patterns prior to deciding whether to keep or discard them.

C. Data Splitting

In this study, the dataset was divided into two parts: a training set and a testing set, utilizing an unconventional split ratio. After trying out several partitioning methods, a 60% training and 40% testing split was chosen due to its superior performance in initial assessments. This selected ratio guaranteed that the training subset was adequate for effective model learning, while the somewhat larger test set facilitated a more thorough and reliable evaluation of the model's generalization abilities. This division was also reinforced by implementing K-fold cross-validation, which improved the robustness and credibility of the performance evaluation process.

VI. Feature Selection

Feature selection is a critical step in building effective machine learning models, particularly in domains such as bank loan risk assessment. Broadly, feature selection techniques can be categorized into three types: filter, wrapper, and embedded methods. Filter methods evaluate the statistical relevance of features independently of any learning algorithm. Examples include the correlation coefficient, which measures linear relationships between features and the target variable; the chi-square test, which assesses statistical independence in categorical data; and mutual information, which quantifies how much information a feature provides about the target. These methods are computationally efficient and help in quickly identifying potentially useful features [23, 24].

Wrapper methods, on the other hand, assess the performance of feature subsets by training models and selecting features based on predictive accuracy. Techniques like Recursive Feature Elimination (RFE) iteratively remove the least important features to find an optimal subset. Forward selection and backward elimination also follow similar principles but vary in their direction of feature inclusion or exclusion. Embedded methods integrate feature selection directly into model training. Notable examples include Lasso regression, which shrinks less relevant feature coefficients to zero through L1 regularization, and tree-based models like Decision Trees, Random Forests, and Gradient Boosting, which inherently perform feature selection by evaluating feature importance during the learning process [25]. These methods not only improve model performance but also enhance interpretability, a critical factor for institutions like banks.

When working with datasets that contain a mix of categorical and numerical features common in banking applications certain techniques stand out for their effectiveness. Both RFE and tree-based models are suitable, especially when categorical variables are appropriately encoded. However, tree-based models offer several advantages over RFE: they naturally handle mixed data types, capture non-linear relationships, are robust to multicollinearity, and provide computational efficiency [26]. Furthermore, tree-based models deliver built-in feature importance scores, simplifying the selection process, and advancements have been made to reduce biases in these scores. Their interpretability and versatility across classification and regression tasks make them particularly valuable in the context of loan risk modeling. Consequently, this research prioritizes tree-based feature selection methods to enhance both model performance and practical applicability. Accordingly, in this research, tree-based models were adopted.

In this section, we will highlight the most important features using tree-based methods: Decision Trees, Random Forests, and Gradient Boosting. These methods are applied to both dependent variables. The first one is to use classification in its original

format, and the other one is to categorize the dependent variable into two categories only. The first one is not default, and the second category is loan default. The following are the results of the three methods: Random Forest, decision tree, and gradient boosting.

A. Classification (Four Categories)

In this section, feature importance was evaluated using tree-based ensemble techniques—specifically, Decision Trees, Random Forest, and Gradient Boosting—applied to the original multi-class classification target variable. This classification represents the internal credit grading standards followed by the bank. The objective was to identify the most influential predictors affecting loan status as classified into four distinct risk categories as outlined in the preceding credit rating table.

1) Random forest feature importance. The Random Forest algorithm was employed to assess the input features based on their significance in contributing to classification accuracy. As shown in Table IX and depicted in Fig. 4, the findings reveal that loan balance (BAL) emerged as the most significant feature by a considerable margin, trailed by delinquency history (DELI) and amount due (DUE). In contrast, gender and job status showed little importance, indicating limited predictive capability in the realm of loan classification.

TABLE IX. BRIEF RESULT OF THE RANDOM FOREST FEATURE IMPORTANCE

Variable name	Importance	Variable name	Importance
ZONE_NAME	0.009437	GENDER	0.002049
AGE_RANGE	0.015941	JOB	0.000363
YEAR	0.030530	BAL	0.672653
DUE	0.130977	DELI	0.138049

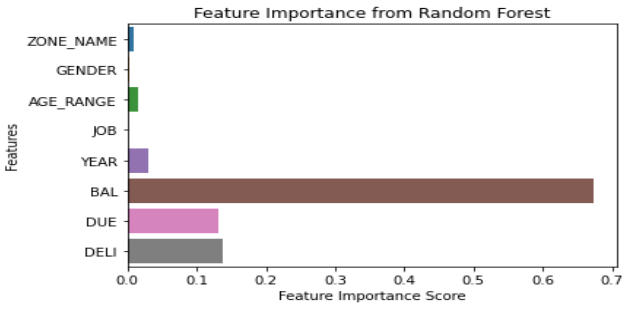

Fig. 4. Feature importance from Random Forest.

2) Decision tree feature importance. The Decision Tree was employed to compute feature importance scores. This method provides a straightforward interpretation by evaluating how each feature contributes to reducing impurity at decision nodes. As shown in Table X and visualized in Fig. 5, the most dominant variable was the loan balance (BAL), followed by delinquency history (DELI) and year of the record (YEAR).

3) Gradient boosting feature importance. From the following Table XI and Fig. 6, the least two important factors are gender and job.

TABLE X. BRIEF RESULT OF THE DECISION TREE FEATURE IMPORTANCE

Variable name	Importance	Variable name	Importance
ZONE_NAME	0.012394	GENDER	0.006294
AGE_RANGE	0.028994	JOB	0.000518
YEAR	0.048181	BAL	0.644940
DUE	0.042377	DELI	0.216300

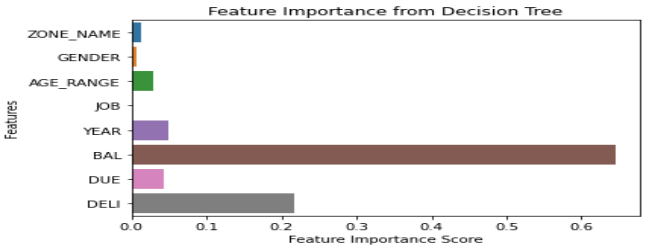

Fig. 5. Feature importance from Decision Tree.

TABLE XI. BRIEF RESULT OF THE GRADIENT BOOSTING FEATURE IMPORTANCE

Variable name	Importance	Variable name	Importance
ZONE_NAME	0.017195	GENDER	0.000568
AGE_RANGE	0.003375	JOB	0.000873
YEAR	0.151289	BAL	0.074997
DUE	0.461394	DELI	0.290309

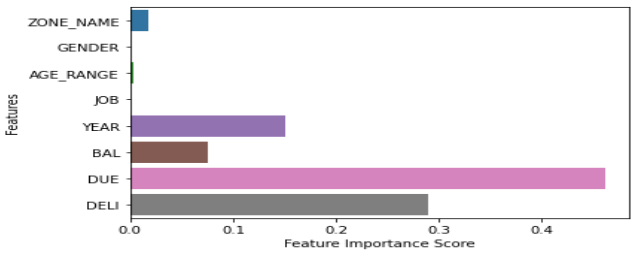

Fig. 6. Feature importance score from Gradient Boosting.

Three tree-based machine learning methods—Decision Tree, Random Forest, and Gradient Boosting (Table XI)—were utilized to evaluate the importance of various features in predicting loan defaults. The analysis revealed a consistent trend in the ranking of variables, although some differences in their significance were noted among the models. The most critical features identified across all models were Loan Balance (BAL), Amount Due (DUE), Delinquency (DELI), and Year (YEAR). Conversely, the least significant features in all three models were, distinctly, Gender (GENDER) Job status (JOB). These two variables consistently received the lowest importance ratings, reflecting their limited influence on default prediction. Consequently, gender and job status were removed from the final modeling stage to improve efficiency and decrease noise, without affecting the framework performance. Fig. 6 shows feature importance score from Gradient boosting.

B. Loan Default (Binary Classification)

During this stage, the target variable was transformed into a binary format (either defaulted or non-defaulted). The findings

reveal that most of the loan records within the sample are categorized as non-defaulted.

1) Random forest feature importance. As shown in the Table XII, the Random Forest model was used to identify the most influential features in predicting loan defaults. The analysis reveals that gender and job status had the lowest importance scores, suggesting they contributed minimally to the predictive performance of the model.

TABLE XII. BRIEF RESULT OF THE RANDOM FOREST FEATURE IMPORTANCE IN LOAN DEFAULT

Variable name	Importance	Variable name	Importance
ZONE_NAME	0.006080	GENDER	0.001318
AGE_RANGE	0.011007	JOB	0.000294
YEAR	0.033104	BAL	0.655241
DUE	0.168674	DELI	0.124281

2) Decision tree feature importance. In the analysis of binary classification utilizing the Decision Tree algorithm, the model assessed the significance of each variable in forecasting loan default results. As shown in Table XIII, gender and employment status displayed the least importance scores compared to all other features.

TABLE XIII. BRIEF RESULT OF THE DECISION TREE FEATURE IMPORTANCE IN LOAN DEFAULT

Variable name	Importance	Variable name	Importance
ZONE_NAME	0.011449	GENDER	0.004770
AGE_RANGE	0.025480	JOB	0.000544
YEAR	0.048742	BAL	0.621828
DUE	0.266804	DELI	0.020383

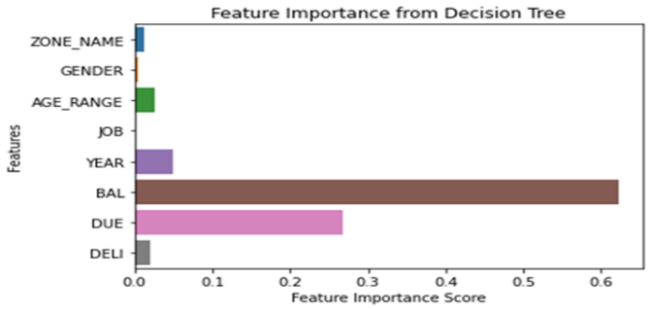

Fig. 7. Feature importance score from Decision Tree (loan default results).

In the analysis of binary classification utilizing the Decision Tree algorithm, the model assessed the significance of each variable in forecasting loan default results. As shown in Table XIV, gender and employment status displayed the least importance scores compared to all other features (see Fig. 7).

3) Gradient boosting feature importance. In the context of the binary classification task, the Gradient Boosting algorithm was utilized to assess the significance of each input feature in predicting loan default. The findings are presented in Table XIV.

It reveals that gender and job status possess the least importance scores, indicating a limited effect on the results of the model (Fig. 8).

TABLE XIV. BRIEF RESULT OF THE GRADIENT BOOSTING FEATURE IMPORTANCE IN LOAN DEFAULT

Variable Name	Importance	Variable Name	Importance
ZONE_NAME	0.004796	GENDER	0.000187
AGE_RANGE	0.001554	JOB	0.000184

DUE	0.680054	DELI	0.136524

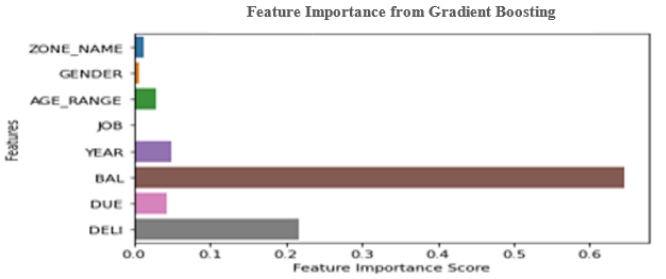

Fig. 8. Feature importance score from Gradient Boosting (loan default results).

VII. MODEL BUILDING

Following the selection of relevant features and the identification of key relationships among variables, suitable Machine learning algorithms are applied to develop predictive models. Techniques such as Random Forest, Decision Trees, and Gradient Boosting Machines are employed due to their proven effectiveness in handling complex, high-dimensional financial data. These algorithms are chosen for their ability to capture non-linear patterns and interactions within the dataset, thereby enhancing the accuracy and reliability of loan default predictions.

Before deciding, we have run more than one model: KNN, DT, RF, and Gradient Boost, and the following table shows that the best one is decision tree (Table XV).

The performance of the developed predictive model is assessed using a set of standard evaluation Metrics:

1) Accuracy. This metric measures the overall correctness of the model by calculating the proportion of correctly predicted instances out of the total number of cases.

2) Precision and recall. Precision reflects the proportion of correctly identified positive cases among all cases predicted as positive, while recall (also known as sensitivity) measures the model's ability to identify actual positive cases. Together, these metrics help evaluate the trade-off between false positives and false negatives [27].

3) Specificity and sensitivity. Sensitivity indicates the model's effectiveness in detecting loan defaults (positive cases), whereas specificity measures its ability to correctly identify non-defaults (negative cases). These metrics provide a comprehensive understanding of the model's capability to distinguish between default and non-default scenarios [27].

So, we are going to run a decision tree model for the second target variable that is categorized into two categories. A decision tree is a popular machine learning algorithm used for classification and regression tasks. It is a flowchart-like structure where each internal node represents a decision based on a feature, each branch represents the outcome of the decision, and each leaf node represents a class label or a continuous value.

TABLE XV. THE EVALUATION METRICS OF VARIOUS ML MODELS

Model	F1-score	Accuracy	Recall	Precision	ROC curve
DT	66%	88%	53%	16%	80%
KNN	61%	82%	49%	11%	68%
RF	63%	84%	51%	12%	74%
Gradient boost	53%	70%	42%	10%	72%

A decision tree is a structured model used for both classification and regression tasks, consisting of several key components. The root node sits at the top and represents the entire dataset, initiating the first decision split. Internal nodes follow, each representing a decision based on a particular feature. Branches connect the nodes and illustrate the outcomes of those decisions, guiding the data down various paths. Finally, leaf nodes represent the terminal points, where a specific outcome or class label is assigned. This hierarchical structure enables the decision tree to map inputs to outputs through a series of straightforward rules.

One of the main advantages of decision trees is their interpretability. They are easy to understand and visualize, making them accessible to non-technical stakeholders. Additionally, they work well with both numerical and categorical data and are capable of modeling non-linear relationships. Unlike many other algorithms, decision trees do not require data normalization or scaling. They also inherently provide feature importance scores, offering insights into which variables most significantly impact predictions. However, a potential drawback is their tendency to overfit the training data, especially in the presence of noise, which can reduce their generalization performance. Despite this, their simplicity and explanatory power make decision trees a valuable tool in many machine learning applications.

The selected algorithms are implemented in Python. The model is trained on the cleaned dataset, with optimization techniques such as cross-validation applied to improve accuracy and prevent overfitting.

VIII. MODEL EVALUATION

The performance of the developed predictive model is assessed using a set of standard evaluation metrics:

Accuracy: This metric measures the overall correctness of the model by calculating the proportion of correctly predicted instances out of the total number of cases [28] [29].

Confusion Matrix: This provides a detailed view of the model's classification performance by showing the counts of true positives, true negatives, false positives, and false negatives [30]. Fig. 9 shows the confusion matrix of the model.

The overall accuracy is 88%, which means that the model could predict 88% of the non-fault and Fault loans correctly predicted, and this is a very high percentage. The sensitivity of the model 53%, which means that 53% of the Fault loans correctly specified. While specificity is 89%, which means that 89% of the non-Fault loans correctly specified.

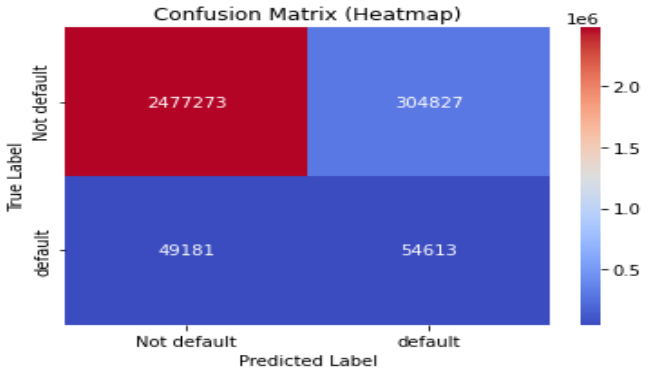

Fig. 9. Confusion matrix for model.

Another measure for the Goodness of fit is the ROC curve. The ROC Curve (Receiver Operating Characteristic Curve) is a graphical representation used to evaluate the performance of a binary classification model. It shows the trade-off between sensitivity (True Positive Rate) and specificity (False Positive Rate) [29] at different classification thresholds. From Table XV, it is clear that the area under the curve is 80%, which indicates that the model is a good fit [30]. Fig. 10 shows the ROC curve.

$$TPR = \frac{True\ Positives}{True\ Positives + False\ Negatives}$$

$$FPR = \frac{False\ Positives}{False\ Positives + TrueNegatives}$$

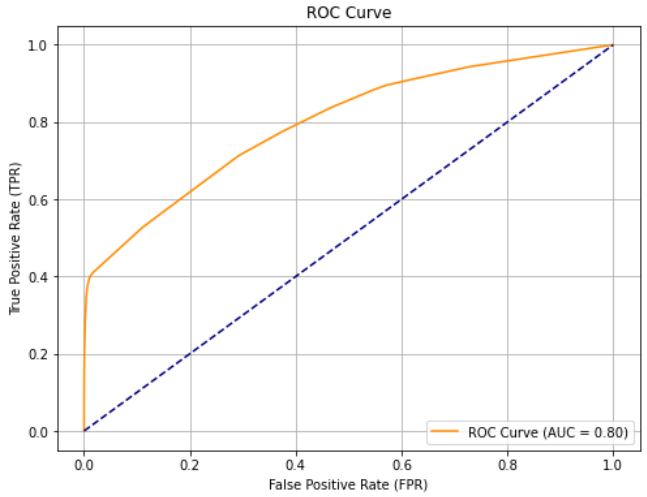

Fig. 10. ROC Curve.

A. Visualization and Analysis

In the final stage, model results are visualized to enhance interpretability and support effective communication with stakeholders. These visual representations enhance transparency, aid in validating the model's behavior, and ensure

that findings can be clearly communicated to both technical and non-technical audiences. Fig. 11 illustrates the structure of a decision tree.

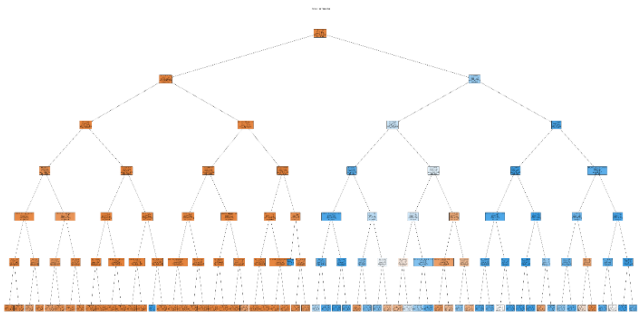

Fig. 11. Illustrates the structure of a decision tree.

The root node analysis of the decision tree highlights how the feature BAL (balance) serves as the most critical determinant in the classification of loan default risk. The initial split occurs at BAL ≤ 2140.0, making this threshold the most influential decision point. Lower values typically indicate a "Not Fault" classification, while higher balances often correspond with an increased likelihood of "Fault." This foundational split sets the tone for the downstream branches, guiding how further conditions refine the classification outcome.

- Path 1 reveals a scenario of high confidence for "Not Fault" classification. When BAL is further reduced to ≤ 2097.6 and the borrower's zone is not "East Delta," the Gini index is extremely low, signaling strong consensus in the data. This indicates that such a combination of low BAL and non-"East Delta" region consistently leads to non-default outcomes. The model is highly reliable in this path, showing minimal misclassification and suggesting that borrowers in this group present low risk.
- Path 2 follows a similar route but introduces moderate uncertainty. Here, while BAL remains ≤ 2097.6, the zone is identified as "East Delta." This regional factor slightly increases the Gini index, indicating some ambiguity. Although the majority of predictions still point to "Not Fault," the presence of the "East Delta" zone introduces variability, suggesting that geographical factors may contribute to nuanced risk assessments, especially in marginal financial conditions.
- In Path 3, the model addresses a more complex situation leading to a "Fault" classification. This occurs when BAL exceeds 2140.0, DUE is also high (above 0.68), but DELI (delinquency) remains low (≤ 0.15). Despite the low DELI, the combination of high BAL and DUE tips the classification toward "Fault." The Gini value here is moderate, suggesting a less decisive split. It reflects a group where most instances are defaults, but a few are not, highlighting the complexity of high-risk profiles, where even a favorable feature like low DELI cannot fully offset the effect of high balances and dues.
- Path 4 introduces a highly uncertain classification scenario. When BAL is within a borderline range (≤ 2140.0 but > 2097.6), DELI is above 0.05, and DUE varies, the model shows significant fluctuation in its output. With moderate DUE (≤ 11364.07), the classification remains "Not Fault," but once DUE exceeds this threshold, the likelihood of a "Fault" classification rises and the Gini index drops, indicating greater certainty. This path illustrates the dominance of the DUE variable in edge cases and how it can override other indicators in determining default risk.
- Finally, Path 5 emphasizes the strong influence of DELI in reducing risk. When BAL is low and the borrower is not in the "East Delta" zone, a DELI ≤ 0.05 leads to a highly confident "Not Fault" prediction, despite other variables suggesting moderate risk. The Gini index is low in this scenario, showing that low delinquency plays a powerful protective role. This finding underscores the importance of monitoring delinquency closely, as it can significantly alter the risk profile even when other conditions are less favorable.

IX. Results

The predictive model showcases a thoughtful and structured decision-making process shaped by the relative importance of selected customer attributes. Rather than relying on a single indicator, the model navigates through combinations of factors to reach decisions that are both data-driven and sensitive to nuanced behavioral patterns.

A. Balance (BAL): Entry Point for Risk Assessment

At the initial stage, the customer's balance acts as a key determinant: When the balance is less than or equal to 2140.0, the likelihood of loan default is low, and the model typically moves toward a "no fault" decision.

Balances exceeding this threshold trigger additional evaluation steps, as they may signal heightened financial pressure or exposure, leading to a higher probability of default.

This distinction reflects the model's cautious approach: it does not generalize but instead digs deeper when early indicators suggest potential risk.

B. Geographic Factor: ZONE_NAME

Regional context also plays an essential role: customers outside the "East Delta" region generally present lower risk, and the model tends to assign them to the "non-fault" category.

However, being from "East Delta" introduces a degree of uncertainty. This does not imply automatic risk but encourages the model to be more attentive, possibly reflecting local economic or demographic conditions.

Such consideration reflects how risk may be influenced, not just by individuals but also by broader regional dynamics.

C. Delinquency Score (DELI): Strong Behavioral Signal

This variable carries significant weight in the model's decisions: scores at or below 0.05 offer strong reassurance, often guiding the model to a "not fault" outcome, even in the presence of moderate financial concerns.

In contrast, scores above 0.15 often signal concern, sometimes shifting the model's outcome toward a "fault" decision—even if other variables seem relatively stable.

This behavior highlights the model's ability to recognize patterns in payment discipline as a reliable reflection of future risk.

D. DUE (Outstanding Amount): Key in Borderline Decisions

In more complex or uncertain cases, the outstanding amount becomes a tipping factor: values below 11,364.07 often help stabilize decisions in favor of a non-default classification.

Higher amounts, however, tend to increase the model's confidence that default risk may be present.

Here, the model demonstrates sensitivity to financial load, adjusting its judgment when individuals may be reaching unsustainable repayment levels.

E. Gini Index: Evaluating Predictive Fairness

The model's ability to separate risky from safe cases is validated through the Gini coefficient, a well-regarded metric in credit scoring. A higher Gini score indicates that the model can reliably distinguish between borrowers who are likely to default and those who are not.

This ensures that the decisions made are not only technically sound but also aligned with ethical considerations of fairness and accountability.

X. Discussion

This study offers a unique and novel contribution by concentrating on a very specific and little-studied domain: livestock-based loans within the Agricultural Bank of Egypt. This is in contrast to previous studies that have extensively examined the use of machine learning algorithms to predict loan approval and default risks, with a primary focus on general loan products or credit scoring mechanisms in various banking sectors. Just as Puli (2024), Saini (2023), which employed algorithms like Random Forest, SVM, and Neural Networks on public or generalized datasets, the present research leverages actual, real-world customer data from one of Egypt's largest rural-focused banking institutions, comprising 1,190 branches nationwide. The dataset reflects true client behaviors in repaying livestock-oriented loans—an area that remains largely unexplored in prior academic research.

XI. Conclusion

Machine learning has become an increasingly valuable tool in assessing loan risk within the banking sector. By leveraging these techniques, it is possible to identify patterns associated with loan default and to determine the most relevant predictive features. The present study emphasizes the role of appropriate feature selection in improving both model accuracy and interpretability. Approaches such as filter methods, wrapper strategies, and embedded techniques were considered to identify key variables.

Among the models implemented, algorithms such as Random Forest, Decision Tree, and Gradient Boosting demonstrated favorable performance, with Random Forest achieving an accuracy of approximately 88%. These models also offer a reasonable balance between predictive power and interpretability, making them suitable for practical use.

The feature importance analysis revealed that financial indicators had the greatest influence on prediction outcomes. Notably:

Balance (BAL) showed a strong association with default risk.

Do Amounts (DUE) were identified as critical in flagging potential non-repayment.

Delinquency Scores (DELI) provide insight into historical repayment behavior.

On the other hand, demographic attributes, such as gender and occupation, were found to have limited impact on model performance, suggesting that behavioral and financial factors may play a more central role in loan risk evaluation.

In conclusion, machine learning, when applied with thoughtful feature selection, can contribute meaningfully to improving credit risk assessment. While no single model can guarantee perfect accuracy, decision trees and ensemble methods have shown promise in balancing accuracy, transparency, and real-world applicability.

XII. Future Work

While the current study demonstrates the potential of traditional machine learning models such as Decision Tree and Random Forest in predicting loan defaults, future research can benefit from exploring more advanced algorithms and broader datasets. Incorporating modern ensemble and deep learning techniques, such as Extreme Gradient Boosting (XGBoost) Artificial Neural Networks (ANNs), may offer improved predictive accuracy, especially in handling complex, nonlinear relationships within financial data.

In addition, expanding the dataset to include behavioral patterns, real-time transactional data, and external credit factors may also lead to deeper insights and more generalized models.

Acknowledgment

The authors extend their appreciation to the Deanship of Research and Graduate Studies at King Khalid University for funding this work through the General Research Project under grant number GRP/6/46.

AUTHORS' PROFILE

Mona Sharafeldin received her master degree of computer science from the Sadat Academy for Management Sciences in 2014. She is currently PhD student in Business Information System, Helwan University.

Prof. Amira M. Idrees: I'm currently a professor in College of Business, King Khalid University. I have been the head of scientific departments and the vice dean of the community services and environmental development, Faculty of Computers and Information, Fayoum University. I have also been a professor in the Faculty of Computers and Information Technology in Future University, the head of IS department and the head of University Requirements Unit. My research interests include Knowledge Discovery, Text Mining, Opinion Mining, Cloud Computing, E-Learning, Software Engineering, Data Science, and Data warehousing.

Assoc.Prof/Shimaa Ouf: I am currently an Associate Professor at the Information Systems Department, Faculty of Commerce and Business Administration, Helwan University. I was born in Cairo, Egypt. She received an M.Sc. degree in Information Systems from the Faculty of Computers and Information, Helwan University, Egypt. Ph.D. degree in Information Systems from the Faculty of Computers and Information, Helwan University, Egypt. I have published many Scientific articles in International journals and conferences in the area of E-learning Ecosystems, Web 2.0 Technologies, Cloud Computing, Intelligent learning environments, Personalized E-learning Ecosystem using Ontology and Semantic Web Rule Language, Business Intelligence, Big Data, Artificial Intelligence, and Blockchain. I have deep experience in creating intelligent systems using the semantic web and Artificial Intelligence technologies. I am an active reviewer for numerous international journals.

Advanced AI-Driven Safety Compliance Monitoring in Dynamic Construction Environment

***Abstract*—Construction safety is a critical global concern due to the high-risk environment faced by workers, with accidents often leading to serious injuries and fatalities. To enhance construction management, this study proposes a scalable deep-learning model for real-time compliance monitoring of safety regulations. The research gap addressed is the lack of real-time, scalable AI solutions for safety compliance monitoring in dynamic construction environments. The YOLOv11n model was trained and evaluated to identify and track the use of safety helmets and vests in extreme dynamic environments, ensuring timely detection of non-compliance. It is hypothesized that the YOLOv11n model will outperform baseline models in accuracy and real-time monitoring speed. The YOLOv11n model outperformed other baseline models, with precision, recall, and mean average precision scores of 89.5%, 85%, and 91.6%, respectively, and a real-time processing speed of 71.68 FPS. Its lightweight size and performance make it suitable for deployment. Integrated with a person-detection framework, the system provides real-time desktop alerts for safety violations, enhancing safety compliance. These findings contribute to construction automation by advancing scalable AI-driven solutions for proactive safety compliance, reducing accidents, and improving operational efficiency on construction sites.**

Keywords*—YOLOv11n; personal protection equipment (PPE); construction safety; real-time object detection; deep learning; AI-driving compliance systems

I. Introduction

The construction industry is one of the most hazardous sectors globally, accounting for approximately 20% of workplace fatalities annually, according to [1]. Among these incidents, 38.4% result from trips, slips, and falls, highlighting the critical need for improved safety measures. Other more critical cases include being struck by objects and electrocutions, often due to a lack of compliance with personal protective equipment (PPE) protocols [2]**.** To address these risks, measures such as personal protective equipment (PPE) -including helmets, vests, gloves, and boots- are implemented to ensure workers' safety and reduce casualties. However, despite widespread adoption of safety measures, challenges remain in monitoring workers' compliance with PPE on construction sites due to several factors. First, the dynamic and complex conditions encountered in real-world construction sites with constantly changing weather and conditions can affect visual monitoring systems [3]. Second, manual monitoring is costly and difficult to scale for large-scale construction projects [4]. Third is environmental factors, as extreme dust, weather environments, and fluctuating lighting conditions may hinder accurate PPE detection. Moreover, studies [5] and [6] have highlighted that standard object detection models lack an accurate ability to detect small or overlapping objects and cluttered scenes, all of which are common on construction sites.

Recent advancements in artificial intelligence (AI) and deep learning have great potential for improving safety monitoring in construction sites. Similarly, in high-stakes domains like healthcare, the need for explainable AI models has been highlighted to encourage trust and aid in decision making [7]. Reinforcing the advances of applying AI models to dynamic construction settings. These technologies enable real-time data processing, object categorization, and predictive decision-making, allowing for the proactive identification of safety violations and potential risks [8]. It has been demonstrated that methods that combine deep learning with preprocessing techniques can improve recognition accuracy in areas like emotion recognition [9], [10]. Among these technologies are the You Only Look Once (YOLO) family of models, which are recognized for being fast and efficient deep learning algorithms for real-time object detection, identifying and classifying objects in a single step by predicting bounding boxes and class probabilities across an image [11].

Several studies have utilized YOLO in real-time detection of personal protection equipment (PPE) such as helmets, vests, and other safety gear, on construction sites. Studies by [6], [12], [13] emphasize the use of advanced YOLO versions, including YOLOv5, YOLOv8, and modified iterations, for real-time detection of PPE violations. The latter works highlight the models' strength in accurately identifying safety helmets, vests, and other protective equipment. In [6], the researchers focused on examining the feasibility of the addition of computer vision technology in construction sites through consistent training processes of YOLO models, to improve overall prediction accuracy. Likewise, the study conducted by [13] proposes an advanced PPE detection system that ensures safety compliance and enhanced productivity in high-risk environments.

In [12], the authors additionally suggests an improved YOLOv5 algorithm based on a Reverse-Unet framework (RUYOLO) to enhance small object detection and accuracy performance. Similarly, studies [14] and [15] have a shared emphasis on integrating advanced technologies (e.g. UAVs (Unmanned Aerial Vehicles) and IoTs (Internet of Things)) with deep learning algorithms to enhance safety monitoring devices. Both studies applied object detection models, such as YOLOv7

and MR-Net (which is a combination of MobileNet and Deep Residual Network components), to identify safety equipment gears. Bian et al. focus on the detection of safety helmets in specifically challenging areas such as construction power line energy fields. They proposed a YOLOv7 model integrated with an extended efficient layer aggregation network (E-ELAN), achieving high results in detection accuracy.

Despite significant advancements in object detection technologies, research on the latest YOLOv11 model for PPE detection remains limited. Most of the existing studies focus primarily on static environments and curated datasets, overlooking the dynamic and complex conditions encountered on real-world construction sites, such as low visibility and cluttered backgrounds. Furthermore, few studies compare YOLO versions under consistent training conditions, making model growth and trade-offs difficult to measure.

This study aims to bridge the gap by proposing and evaluating an optimized YOLOv11n, specifically focusing on helmet detection and PPE compliance to safety standards in construction work sites in dynamic construction settings. The model is trained using a domain-specific dataset augmented to improve detection accuracy under dynamic conditions, such as extreme weather conditions and background clutter. The performance is benchmarked against previous YOLO models, YOLOv3, YOLOv5, and YOLOv8, highlighting significant improvements in detection accuracy, inference speed, and deployment efficiency. Overall, this research aims to demonstrate how AI can be used to minimize safety violations and improve safety compliance in construction sites, with the specific use of improved deep learning models.

The key contributions of this study are as follows:

- Present a comprehensive analysis of multiple YOLO models to examine their potential in detecting PPE compliance under dynamic construction site conditions.
- Implementation of an optimized YOLOv11n model to achieve high object detection accuracy and real-time processing efficiency while reducing computational load and model size, making it suitable for real-time deployment.
- Integrated dual-model framework by merging two YOLO models to detect PPE compliance in construction sites, with real-time notification code that triggers desktop alerts when failure to comply with PPE standards is detected, demonstrating its practical use in live monitoring scenarios.

The rest of the study is structured as follows:

Section II explores previous studies of safety monitoring models. Section III details the training and optimization processes of the YOLOv11n model, including the data collection, preprocessing, model training, system integration, and performance evaluation. Section IV presents the results of the study. While Section V includes a discussion of the results highlighting the overall efficiency in real-time object detection. Section VI concludes the study, outlines the challenges of the study and suggests future research.

II. Literature Review

With the ever-growing construction industry, safety in construction is a great challenge faced worldwide [2]. For this reason, object detection for PPE equipment has become a priority to prevent accidents caused by safety violations [4]. Several studies have used deep learning models to combat this challenge, with the most popular choice being YOLO-based models, because of their ability for real-time detection and high effectiveness. A study made in the United Arab Emirates (UAE) developed a Convolutional Neural Network (CNN) model by using a model algorithm based on YOLOv3 for safety monitoring [16]. Their goal was to show that AI can be used to minimize accidents on construction sites by detecting workers' safety helmets, harnesses and lifelines. They were able to achieve a 94% accuracy rate in object detection, indicating the high success rate of the YOLO models.

This literature review investigates the effectiveness of deep learning models, particularly YOLO, in monitoring PPE compliance on construction sites. It compares different YOLO versions to identify which model offers the optimal safety compliance capabilities. The main research questions guiding this review are: How can AI deep learning models be used to enhance PPE compliance monitoring in construction settings, and what are the strengths and limitations of each of the YOLO models? Additionally, this review focuses on the gap by comparing these models' performances in detecting PPE violations.

A. YOLO Based Detection for Safety Compliance

In recent years, deep learning models, specifically YOLO models, have emerged as a popular choice for object detection because of their high effectiveness in the real-time detection of PPE equipment regarding speed and accuracy. Because of this, multiple studies have used this model, showing significant improvement in identifying PPE gear.

YOLO operates by dividing images into an S × S grid, where each grid cell detects objects within its boundaries as shown in Fig. 1. For each cell, the model predicts bounding boxes to determine the object's location and a confidence score indicating the likelihood of the object's presence [16]. These predictions include the object's coordinates, such as center, width, and height and its class probabilities, allowing YOLO to identify and localize multiple objects simultaneously [17]. This information is processed in a single forward pass which makes it efficient for real-time detection. Non-Maximum Suppression (NMS) is then applied to eliminate the overlapping prediction to ensure that most accurate bounding box is retained for each object.

Fig. 1. YOLO object detection workflow.

Since its first release in 2016, the YOLO models have undergone significant enhancements and improvements. YOLO was established as a single-stage detector, identifying and classifying objects through a single network. They are smaller in size and faster, which makes them faster to train and deploy [17]. With the development of YOLO versions such as YOLOv3, YOLOv5, and YOLOv8, the models are enhanced, and performance is faster and more accurate. The latest release of the YOLO model, YOLOv11, in September 2024, introduces advanced features further optimizing the model for object detection accuracy and precision.

B. Related Works on PPE Detection

The studies examined highlight the significance of YOLO-based object detection models in enhancing real-time PPE compliance monitoring systems. Notably, versions such as YOLOv5 and YOLOv8 have demonstrated high accuracy and speed, even in complex environments. As seen in a study conducted by [6], 4844 images were gathered by the authors and trained on both YOLO versions, YOLOv5 and YOLOv8, with the same dataset. The results showed that the validation accuracies achieved by both models were 94.7% and 95.4%, respectively, making the YOLOv8 model the superior of the two. Similarly, in a study by [18], the YOLOv8 was optimized to improve the overall accuracy and effectiveness in small object detection. The model used mosaic data augmentation, including scaling images and cropping, which improved its object detection performance.

The YOLOv3 and RCNN models to identify the highest performance in detecting safety helmets in a construction setting were compared in [19]. An overall of 5000 images were gathered and then processed using two techniques, resizing and data augmentation. The datasets were then split into a ratio of 8:2 based on training and testing, respectively. The study utilized mAP, precision and recall, comparing the two models. After training, the YOLOv3 and RCNN models achieved 97.12% and 96.05% mAPs, respectively. Subsequently, the YOLOv3 model acquired a precision of 96.53% and a recall of 97.87%, while the RCNN model showed a precision of 94.1% and a recall of 96.75%. Despite challenges the models faced, such as detecting small objects and image lighting effects, the YOLOv3 model outperformed the RCNN with greater precision in recognizing safety helmets. Researchers in [20] focused on detecting safety gear using the YOLOv3 model. In their study, they stressed the significance of not only focusing on safety helmets but also on other safety gear, such as safety vests. 300 images were gathered and divided into two classes: compliant and non-compliant workers. 80% of the image data was set for training, while the remaining was used for data verification. The data was then analyzed and labelled by using LabelImg, which is used to annotate images with a bounding box. The YOLOv3 model was then trained using the data sets, achieving 92.99% mAP during the second iteration of the study. The model was also tested on live capture and video data, likewise, presenting high accuracy results. The authors concluded that even with a limited amount of data, the model received high precision in detecting safety gear. They also suggest further development in detecting other safety equipment through additional recent versions, expanding datasets and training models.

The use of a Mobile Residual Network (MR-Net) for object detection in safety monitoring was explored in [15]. They proposed three consecutive systems for enhanced object detection, the first being a sensor unit connected to an IoT network. A cloud server was then deployed to issue a smart alert, followed by the processing of gathered image data for detection using an NLM filter. YOLOv3 was then used to detect objects and categorize them based on four core classes (person, machines, vehicle, and safety cones) and further classify objects using MR-Net. The study then compared previous models based on accuracy, precision, recognition, positive outcomes, and negative outcomes. The results achieved optimal values of 91.2%, 90.5%, 92.3%, 90.9%, and 91.9%, respectively.

Detecting safety helmets in construction settings is difficult due to two main challenges: the small size of helmets at a further distance and the sheer size of the background image in contrast to the helmet's proportion. For this reason, authors in [3] analyzed video data to improve helmet detection and prevent false detections from occurring. The test datasets were collected from construction sites and utilized with multi-scale feature detection and training to enhance the YOLOv3 model. The original YOLOv3 model was then compared with the new optimized model, resulting in 93.5% mAP for the optimized model and 91.3% mAP for the YOLOv3 model. The enhanced model shows greater accuracy in detecting safety helmet violations than the original YOLO model by 2.2%.

To address the challenges in detection models resulting from small object detection, high rate of overlapping, and frequent occlusions, the study in [21] introduced an improved safety helmet detection model based on YOLOv5, integrating EIOU-loss to enhance model improvement. 4,400 images were gathered, ranging from different environments and distances, then labelled into three categories: helmet, head, and uncertainty. The improved models, retitled as YOLO-ESC and YOLO-ESCA, were compared with YOLOv3 and standard versions of YOLOv5. While the previous YOLO versions achieved greater precision and recall than the improved models, the model sizes of the YOLO-ESC and YOLO-ESCA are smaller, making them better candidates for deployment. Despite the improved enhancements, the study recognizes the limitations of the model in small object detection, making it a goal for further research development.

The performance of advanced YOLOv5 model variants (n, s, m, l, x) for safety helmet detection has been examined in [22]. The study conducted a comparative analysis based on key performance indicators, including mean Average Precision (mAP), precision, and recall, across two target classes: “head” and “helmet”. The findings indicated that YOLOv5n demonstrated superior speed, achieving 62.5 FPS for image data and 70.4 FPS for video data. However, in terms of detection accuracy, the YOLOvX variant achieved the highest mAP score of 95.8%, making it the most precise among the evaluated models. Similarly, in [5], the authors proposed an improved lightweight YOLOv5s model to enhance safety helmet detection through image augmentation techniques, aiming to optimize model robustness in dynamic environments. A comparative analysis was conducted between the improved YOLOv5s model and other advanced models such as YOLOv3, YOLOv4, YOLOv7 and YOLOv8. The improved model attained a mAP

of 94.1%, exceeding that of the YOLOv7-Tiny and similar to that of the YOLOv8s model. The results indicate a notable improvement in the model while maintaining its lightweight characteristics. The study concludes with future research recommendations for further exploring systems, to diminish parametric defects and improve accurate detection of objects.

The lack of focus on other PPE elements such as safety vests, gloves, boots and glasses has been highlighted in previous research. To address this, a safety monitoring model was proposed that compares YOLOv5 and YOLOv7 [23]. A dataset of a total of 743 images was collected and categorized into 6 classes: boots, glasses, gloves, helmets, person, and safety vest. The data was then annotated using LabelImg and directed for training using both models individually. The metrics used for evaluation are mAP@0.5 of precision and recall. The final values of the models showed that the superior system in precision and recovery of image detection was YOLOv7, with a value of 87.3%. The value of the YOLOv5 was marginally lower at 79.6%, indicating a slight insufficiency of the process metric.

Due to the shortcomings of traditional safety compliance monitoring methods in construction sites, the need for integrating object detection systems has become increasingly important. Recent research has demonstrated that improved object detection algorithms, specifically YOLOv8, are efficient in detecting PPE items [24]. In this study, a total of 3,750 images were annotated and split into five classes: Vests, Safety shoes, No vests, No helmets, and No safety shoes. The dataset was then trained with YOLOv8 using a maximum of 100 epochs, where performance is evaluated periodically. The model achieved significant results in accuracy, scoring 100% and 98% in the detection of helmets and vests, respectively. The model faced a slight regression in detecting safety shoes with a value of 84%, despite this, the model's performance and effectiveness in PPE detection were prominent.

The limited focus on computer vision software and work safety and wellbeing has contributed to the study in [25], which explores two model frameworks based on YOLOv8 pretrained nano and small architectures. These models were trained for hard hat and head detection using datasets provided by Roboflow. The YOLOv8 nano and small models were evaluated based on precision, recall, mAP@50, and mAP@50-95. The YOLOv8 small model outperformed the YOLOv8 nano model, with a high precision value of 92%. The study discusses the restraints of exploring more enhanced models due to the computational constraints limiting the number of test models, suggesting further research on YOLOv8 structures with longer test phases.

C. Synthesis of Current Studies

The studies reviewed, demonstrate significant potential in enhancing PPE compliance detection using YOLO deep learning models. YOLOv5 and YOLOv8, in particular, presented substantial results in safety helmet and vest detection, reaching an accuracy value of 95% [6]. Nevertheless, the application of these models in real-world construction environments continues to face significant challenges, as highlighted by recent studies. These challenges include ensuring environmental robustness under various conditions, limitations in multi-PPE detection, and issues related to computational efficiency.

1) Environmental robustness. A major challenge in current detection models is their ability to provide accurate and comprehensive detection under various environmental conditions. As emphasized by [26], we need scalable energy-efficient solutions to balance model performance and resource constraints in real-world environments. The advancement of the YOLO model for safety equipment detection was explored in [3] and [14]. Their studies reported a significant drop when these models were exposed to complex site conditions, such as dust, low visibility and cluttered backgrounds- factors that are common in construction work sites. Despite the success in object detection in static backgrounds, the YOLO models still faced limitations in small object detection and compliance monitoring in dynamic environments- as current models often utilize clean, high-quality data, which limits their ability to comply with the ever-changing work environment.

2) Multi-PPE detection. Additionally, most existing research focuses primarily on helmet detection, overlooking other PPE items such as safety vests, gloves and shoes, which are equally essential for the safety of construction workers (Table I). According to studies by [23] and [20], most studies have focused on helmet detection while little attention has been on other critical safety gear such as gloves, safety vests, masks and goggles. The authors have further highlighted the importance of focusing on various safety gear to ensure safety compliance and minimize workplace accidents. Future research should focus on improving YOLO frameworks to further enhance small object detection and recognition of multiple types of PPE in dynamic environments. Additionally, further studies should evaluate these models using real-time data from live construction sites to assess their practical effectiveness.

3) Computational efficiency. The YOLO family of object detection models has evolved significantly over time, with each version showing improved capabilities in terms of speed, accuracy and computational efficiency as shown in Table II. Although the earlier models, such as YOLOv3 and YOLOv5s, demonstrated notable performance, they often required higher computational resources as they have relatively large model sizes, which are 117 MB and 7.06 MB, respectively and higher FLOPs of 39.2G and 7.70G, respectively. YOLOv7 improved upon previous versions, attaining a speed of 14.1ms despite its medium model size of 80.91 MB, indicating its efficiency in fast optimization. The YOLOv8n achieved a significantly smaller model size of 3.2 MB, reducing latency to 12.4 ms, resulting in an impressive FPS of 80.4.

While these high-preforming variants provide advanced accuracy, their practical deployment is limited by their computational demands. As [27] and [28] note, larger models require high computational resources such as large memory resources, which limit their scalability on real-life work sites. This challenge highlights the balance between deployability and model complexity in resource-constrained environments.

TABLE I. QUANTITATIVE COMPARISON OF OBJECT DETECTION MODELS FOR PPE COMPLIANCE MONITORING

Reference	Algorithm	Environment	Datasets	Class	Precision%	Recall%	mAP50%
[19]	YOLOv3	Static	5000	Helmet	96.53%	97.87%	97.12%
[21]	YOLO-ESC	Dynamic	44,000	All	96.5%	98.2%	98.7%
				Helmet	98.1%	99.6%	99.1%
				Head	97.5%	99.1%	99.1%
				Uncertainty	93.9%	95.8%	97.8

III. METHODOLOGY

This research develops and evaluates the YOLOv11n model for PPE compliance monitoring in construction sites. High-quality datasets of 19,076 images were collected from various sources, annotated for safety helmets and vests, and preprocessed with resizing and data augmentation to improve detection accuracy under dynamic conditions such as extreme weather conditions and fluctuating lighting. The YOLOv11n model, selected for its computational efficiency, was trained on a T4 GPU using Google Colab, with key metrics such as precision, recall, and mAP used for performance evaluation. The model was then tested on prerecorded and live video feeds to validate its effectiveness in real-time safety monitoring.

A. Image Collection

High-quality images and videos of construction sites and PPE items were collected from multiple sources to ensure diverse and balanced datasets. Publicly available resources from sites like Unsplash and Pexels were gathered, increasing safety gear and construction site image variety. Additionally, two distinct datasets were forked from Roboflow [30], [31]. Each dataset specifically focused on safety helmets and safety vests, respectively, further enhancing the model with a wide range of PPE items and variations. The addition of these datasets was essential to develop a well-trained model with high accuracy in object detection. In total, 19,076 images were utilized for dataset preparation, providing an exemplary dataset for effective model training. The images collected represent a diverse collection of PPE imagery, considering factors such as lighting, dynamic environments, and movement, which ensured adaptation to real-time conditions.

B. Dataset Preparation

The datasets were merged, creating a single diverse PPE dataset, allowing for enhanced model training. The dataset was then annotated using Roboflow by implementing bounding boxes on PPE items based on two classes (Safety Helmet and Safety Vest) as shown in Fig. 2. This annotation process ensures precise labelling required for high-accuracy training. An additional dataset obtained from Roboflow was also labelled using a single class (Person) [32] to be integrated into a separate training for enhanced PPE compliance monitoring.

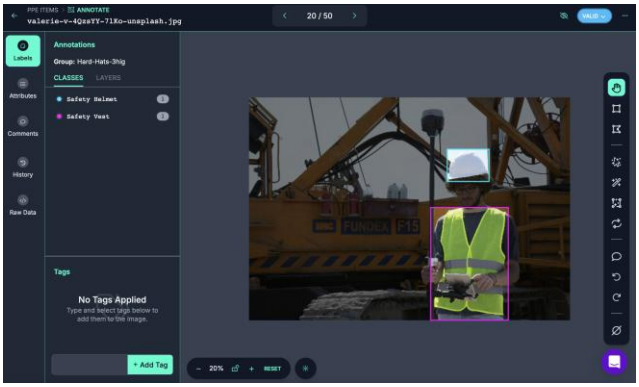

Fig. 2. Screenshot of Roboflow annotation interface based on two class labels: safety helmets and safety vests.

Each class was annotated with a count ratio of approximately 2:1 for safety helmets and safety vests, respectively. The ratio difference is due to the challenges AI models face in small object detection. Thus in order to enhance the detection of safety helmets in dynamic backgrounds, the annotation count was increased (Table III). For the PPE dataset, the images were split based on training, validation and testing. Each set was divided into 16,650, 1625, and 801 images, respectively, as shown in Table IV.

TABLE III. ANNOTATION COUNT FOR EACH CLASS

Class	Count
Safety Helmet	15,287
Safety Vest	6,590

TABLE IV. DATASET DISTRIBUTION FOR TRAINING, VALIDATION, AND TESTING

Training	Validation	Testing
16,650	1625	801

1) Preprocessing. To maintain a consistent processing size and improve model training, all images in the dataset were resized to a resolution of 640 × 640 pixels. This uniform size allows for standardized processing across the dataset and equally complies with the standard image size of YOLO models. Additionally, Auto-Orient was applied to correct the image orientation and ensure proper alignment for optimal object detection. This step ensures standardized preprocessing for consistent results across the dataset. This preprocessing stage is crucial for the success of data augmentation and model training processes while reducing computational overload.

2) Data augmentation. To further enhance model training, data augmentation is implemented in the dataset. Data augmentation is a critical process to enhance model recognition and generalization capabilities, as it utilizes the original dataset to generate a diverse dataset based on multiple variations. This process simulated dynamic conditions such as extreme weather and variable lighting, enhancing the model's robustness. The augmentation strategy, which included applying 25% grayscale alterations to images, assigning a blur with a 4.8-pixel radius, and addition of noise with a deviation of 1.8 pixels, were chosen for their ability to simulate real-world conditions (Fig. 3). For instance, the grayscale modifications imitate limited visibility due to stormy weather, while noise and blur alterations simulate dust, rain, or light fluctuations. By expanding the dataset diversity, this process plays a pivotal role in increasing model training accuracy.

Fig. 3. Example of data augmentation added to construction site image. Original image (Left) and augmented image (Right) with 25% Grayscale, blur 4.8px, and noise 1.8px.

C. Model Training

This research employs the YOLOv11n model obtained by Ultralytics and trains it for PPE detection using Google Colab. The YOLOv11n model is selected because of its lightweight architecture, optimized inference speed and low memory usage compared to the other YOLOv11 models (YOLOv11s, YOLOv11m, YOLOv11l, YOLOv11x), making it a significant choice where computational efficiency is a priority, such as construction sites [33]. The model is trained using a carefully curated dataset for PPE detection, ensuring high-speed training and performance. The training process was conducted on a T4 GPU via Google Colab, allowing for faster training time and model optimization. The coding environment was set up in both Google Colab and Spyder, Python 3.12. Table V further details the training environment.

TABLE V. MODEL TRAINING ENVIRONMENT

Component	Specifications
Hardware	GPU: T4 (Google Colab), CPU (MacOS CPU model)
Program	Google Colab, Anaconda (Spyder, Python 3.12)
Framework	PyTorch
Libraries	Ultralytics, OpenCV, NumPy, Roboflow, Matplotlib
Algorithm	YOLO11n

Hyperparameters are set in the training environment to ensure optimal accuracy and recall values in PPE detection (Table VI). The dataset used is defined as data.yaml, which contains data for classes and paths to images used for training. The model was trained for 20 epochs to establish sufficient exposure to the dataset and achieve optimal learning. A batch size of 16 and an image size of 640 pixels were selected for efficient model training and processing. The model weights were further optimized for real-time detection performance by implementing fine-tuning settings, including reducing precision to FP16, using a batch size of 8, and resizing input images to 320 × 320 pixels. These optimizations were crucial for enhanced speed and reduced computational load.

TABLE VI. MODEL TRAINING HYPERPARAMETERS

Hyperparameter	Value
Data	data.yaml
Epoch	20
Batch	16
Imgsz	640

1) Metric monitoring. After model training is complete, the model is evaluated using the following metrics:

Precision%: Percentage of accurately detected PPE as shown in Eq. (1):

$$Precision = \frac{\text{True Positives (TP)}}{\text{True Positives (TP)} + \text{False Positives (FP)}} \quad (1)$$

Recall%: Percentage of actual PPE identified as computed according to Eq. (2):

$$Recall = \frac{\text{True Positives (TP)}}{\text{True Positives (TP)} + \text{False Negatives (FN)}} \quad (2)$$

Mean average precision (mAP50): The average precision values are calculated at an intersection over union (IoU) threshold of 50%.

Mean average precision (mAP50-95): The average precision values are calculated at an IoU threshold of 50% to 95%.

Confusion matrix: The model's ability to identify objects correctly. Table VII defines each confusion matrix.

TABLE VII. CONFUSION MATRIX DEFINITIONS

Metric	Definition
True Positive (TP)	The number of instances predicted correctly as a positive class
True Negative (TN)	The number of instances predicted incorrectly as a positive class
False Positive (FP)	The number of instances predicted incorrectly as a negative class
False Negative (FN)	The number of instances predicted correctly as a negative class

Class Loss: Indicates how the model performs in classifying each PPE item.

Latency (*L*): As shown in Eq. (3), it is the time required to generate a prediction during the inference process.

$$L = \frac{\text{Total Inference Processing Time (s)}}{\text{Number of Images Processed}} \quad (3)$$

Frames per Second *(FPS*): The number of frames processed per second is calculated as in Eq. (4):

$$FPS = \frac{\text{Batch Size}}{\text{Latency (ms)}} \times 1000 \quad (4)$$

Floating Point Operations (FLOPs): Indicates the computational cost and efficiency of the model as measured in Eq. (5):

$$FLOPs = 2 \cdot K^2 \cdot C_{\text{in}} \cdot C_{out} \cdot H_{\text{out}} \cdot W_{\text{out}} \quad (5)$$

K: Kernel size

C_{in}: Number of input channels

C_{out}: Number of output channels

H_{out}: Output height

W_{out}: Output width

Complex O Notation (*O*): The computational complexity during inference can be estimated as shown in Eq. (6) for a single layer and Eq. (7) for the total complexity:

$$Single\ Layer = O(K^2 \cdot C_{\text{in}} \cdot C_{\text{out}} \cdot H_{\text{out}} \cdot W_{\text{out}}) \quad (6)$$

$$Total\ Complexity = O(\sum_{i=1}^{L} K_i^2 \cdot C_{\text{in},i} \cdot C_{\text{out},i} \cdot H_{\text{out},i} \cdot W_{\text{out},i}) \quad (7)$$

Monitoring these metrics is an important process in developing an efficient model to avoid overfitting or underfitting, and ensuring that the model performs well with real-time data.

D. System Integration

The PPE-trained YOLOv11n model is integrated with a pretrained YOLO model improved for person detection. This integration allows for enhanced PPE compliance detection and system notification, making the model effective for real-time safety compliance monitoring on construction sites. The two models are merged using Anaconda (Spyder 3.12), including a code that executes a desktop alert for failure to comply with PPE requirements, further enhancing the model for optimal construction site safety.

E. Performance Evaluation

To further evaluate the performance of the enhanced model, it is tested on prerecorded video data of construction sites and live video feed using an IP Webcam application. The evaluation focuses on the accuracy of the bounding boxes in detecting PPE objects, noting the model's ability to detect safety helmets, safety vests, and safety violations. Key performance metrics such as precision, recall, and mAP are recorded, assessing the model's capabilities in dynamic environments and its effectiveness in real-time compliance monitoring on construction sites.

IV. RESULTS

The YOLOv11n model received a training progression over 20 epochs. At the 20th epoch, the model achieved a precision of 89.48%, 85.01% recall, 91.62% mAP50, and 64% mAP50-95, indicating significant performance outcomes (Table VIII).

TABLE VIII. PERFORMANCE METRICS OF YOLOV11N BASED ON PRECISION, RECALL, AND MAP50

Algorithm	Precision%	Recall%	mAP50%
YOLOv11n	89.5%	85%	91.6%

The Precision-Recall curve shown in Fig. 4(a) illustrates the performance of each class and overall accuracy. Safety helmets received the highest confidence at 94.9%, revealing the model's efficiency in helmet detection. Likewise, safety vests achieved an optimal confidence of 88.3% resulting in an overall mAP50 of 91.6%. The model maintains exceptional results at an optimal threshold, achieving a high value of 97% as shown in Fig. 4(b) in the Recall-Confidence curve. This indicates the model's strong ability to detect minimal false negatives. Notably, as the confidence threshold increases, the recall value might slightly decrease to prevent false positives from showing, signifying the model's ability to balance between recall and precision.

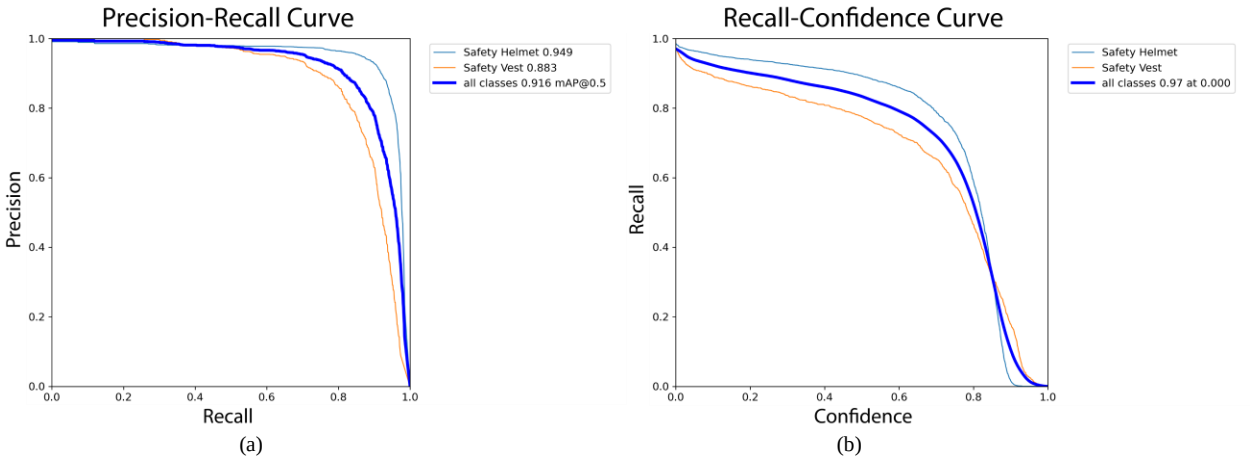

Fig. 4. YOLOv11n : (a) Precision-Recall Curve; (b) Recall-Confidence Curve.

The confusion matrix, which represents the model's capability in identifying objects correctly based on three classes (Safety Helmet, Safety Vest, and Background), indicates remarkable results. As shown in Fig. 5, the TP rate for safety helmets reached an optimal 94%, revealing the model's strength in detection accuracy and background separation. The model experienced false negatives primarily in poor lighting conditions and during object overlaps, where smaller or obscured PPE items were not detected. Conversely, false positives were observed when background elements, such as construction equipment, resembled PPE items. These findings indicate that environmental factors significantly impact detection accuracy. Despite the model experiencing slight confusion in distinguishing safety vests from background images due to similar features or overlap in color, the class nevertheless obtained a notable TP value of 86%. These results signify the robustness of the model's performance and effectiveness in identifying target classes.

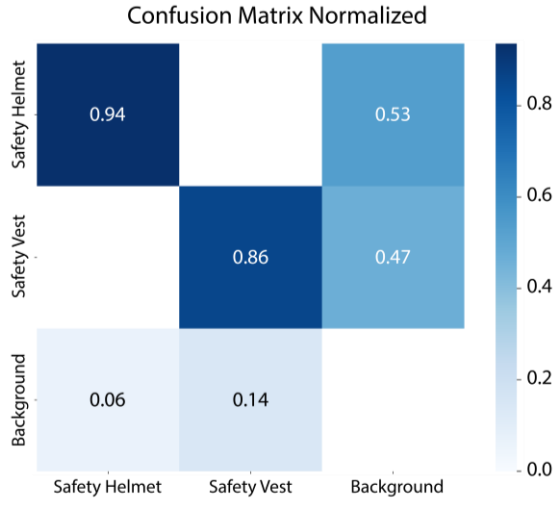

Fig. 5. Confusion matrix across three classes: safety helmets, safety vests, and background.

Instance distribution and bounding box visualization are equally analyzed, as shown in Fig. 6. The instance chart (Left) indicates a significant class count of safety helmets in contrast to safety vests, suggesting increased trained data contributing to higher accuracy in helmet detection. The bounding box visualization shown in Fig.6 (Right) illustrates the predefined shapes the model applies to determine object location and size. The anchor boxes are well distributed and vary in size, indicating the model's capability in detecting objects of various dimensions.

Following the optimization process, which included reducing computational load by implementing FP16 precision for faster inference times, resizing images to 320 pixels, and minimizing batch size from 16 to 8, the model is evaluated for latency, FPS and FLOPs using NVIDIA GPU. The model achieved a significant processing speed of 71.68 FPS, a paramount increase in contrast to the video playback rate of 25 FPS (Table IX). The average latency equally was 13.91ms indicating near real-time detection of objects. The computational complexity of the model is equally calculated achieving a value of 801.68 MMac and a compact model size of 2.59 MB, these values demonstrate the efficiency for deployment on edge devices with limited resources in dynamic construction environments.

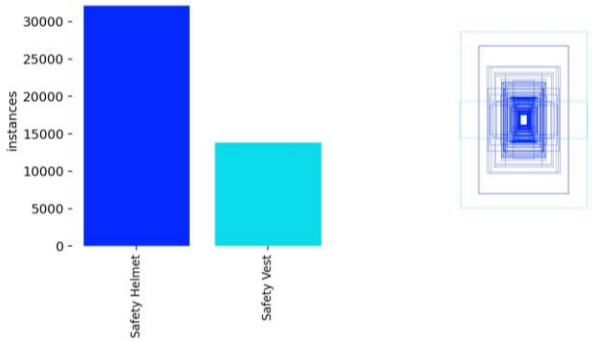

Fig. 6. Instance distribution and bounding box visualization analysis.

TABLE IX. PERFORMANCE METRICS OF OPTIMIZED YOLOV11N BASED ON FPS, LATENCY, MODEL SIZE, AND FLOPS

Algorithm	Video FPS	Processing FPS	Latency (ms)	Model Size (M)	FLOPs (G)
YOLO11n	25	71.68	13.951	2.59	0.801

The enhanced model is evaluated on the distributed dataset set for testing, prerecorded video data and live webcam feed, to further validate its effectiveness in real-time dynamic construction environments as shown in Fig. 7. The results displayed exceptional performance in both static and dynamic settings, with consistent detection accuracy despite fluctuations in lighting, worker movement and environmental conditions. These findings demonstrate the efficiency of the model's application in safety compliance monitoring on construction sites.

To ensure PPE compliance in construction sites, the improved YOLOv11n model is integrated with a pretrained YOLO model aimed specifically for person detection. The supplementary model is enhanced with additional training at 30 epochs receiving an overall precision value of 99.8% and recall of 100%. The newly merged dual model framework is additionally integrated with a desktop alert code to further implement PPE compliance on construction work sites and notify supervisors of non-compliance breaches. The model achieved optimal results displaying efficient performance in construction compliance monitoring. Fig. 8 shows a real-time PPE violation desktop alert sent on MacOS.

Fig. 7. Image evaluation: Training set dataset (left) and inference ran on prerecorded video data (right).

Fig. 8. Real-time detection of PPE compliance and safety violations.

V. DISCUSSION

The optimized Yolov11n model obtained higher accuracy in detecting PPE compliance, exceeding the precision value of both YOLOv8n and YOLOv5n in dynamic conditions [22], [25]. It demonstrated superior recall and precision, outperforming previous models and validating its suitability for real-time monitoring in construction sites. This aligns with research by [18] who emphasize the importance of real-time detection in

complex environments. While safety helmets obtained a significant TP value of 94%, the model experienced a slight regression in the TP value for safety vests, which could be due to the model's struggle in differentiating the class from complex backgrounds with similar color overlaps and feature distinction. This lower accuracy has equally been noted in previous research studies, such as that by [24]. Future iterations of the model should incorporate advanced background segmentation techniques to address this challenge.

Additionally, the model demonstrated significant ability in detection of objects in real-time environments, as evidenced by its increased FPS and reduced latency, making it highly efficient for fast paced construction sites. The model outperformed the inference speed of the earlier YOLOv3 model by 78.5% and the YOLOv5s model by 22.5% [21], [27]. The YOLOv11n model equally attained a lighter model size and reduced computational cost, in contrast to the heavy weight and high cost of the YOLOv7 architecture, signifying the ability to perform on edge devices in dynamic environments without compromising speed and accuracy [14]. While the YOLOv8n model demonstrated a slightly higher inference speed of 80.4 FPS, the improved YOLOv11n model displays a significant balance with lower FLOPs and model size, making it a superior choice for deployment on complex construction sites where computational efficiency and real-time performance are critical [29].

Despite the model's strengths, the research faced several challenges and limitations in achieving optimal accuracy results. This could be due to an imbalance in class counts between safety helmets and safety vests, which could have led to biased detection outcomes. Likewise, while the nano architecture of the YOLOv11 model enhanced detection speed and training efficiency, a larger model architecture might have potentially increased performance significantly. This limitation arises from the limited computational load of the MacOS CPU, and the restricted time limit of Google Colab used during training. Addressing these challenges, by using a balanced dataset and increasing GPU for longer training time, could enhance the model further for PPE detection.

Furthermore, due to the conversion to FP16 and resizing of the images to 320 pixels during the inference process in order to improve latency and reduce computational cost, the model could potentially face a slightly lowered detection performance. Finetuning the model further, with a larger batch size during training and exploring enhanced precision techniques, including merging FP32 and FP16 where necessary, could enhance overall performance in real-time applications. Expanding the dataset to include additional PPE items such as gloves, glasses, and boots is recommended for future research endeavors to develop a more comprehensive safety object detection model. Increasing the number of epochs and fine-tuning hyperparameters, while ensuring class balance, could further enhance the model's performance and detection accuracy. Moreover, deploying the model on edge devices, such as sensors and IoTs, could additionally advance the model in object detection making it crucial for real-time applications. Implementing these steps would not only potentially enhance detection capabilities but equally allow for widespread implementation in challenging conditions and high-risk environments ensuring worker safety and construction requirements compliance.

Overall, the results of the YOLOv11n model demonstrate exceptional performance in real-time detection within dynamic environments, with further optimization suggestions paving way for a more comprehensive model and its deployment in real-time critical settings.

VI. Conclusion

This research proposes a deep learning model using an optimized YOLOv11n algorithm to address safety challenges on construction sites. Crucial performance metrics such as precision, mAP50, Latency, and FLOPS, are evaluated to ensure real-time PPE compliance monitoring in resource-constrained dynamic environments. The YOLOv11n demonstrated significant results, achieving 89.5%, 85%, and 91.6% for precision, recall, and mAP50, respectively while maintaining a notable balance between speed and computational load. With a latency of 13.95 ms and computational cost of 0.801 GFLOPs, the model exhibits a lightweight and computationally efficient architecture capable of object detection on edge devices. Additionally, the study integrated a PPE compliance system with desktop notifications to alert supervisors of safety violations, demonstrating the model's robustness and practical application for real-time monitoring.

The research, however, encountered several challenges. The class imbalance led to a potential bias in detection results, and the limited computational resources prevented the exploration of larger, more complex architectures. Additionally, the need for increased speed and reduced model size in complex environments may slightly impact detection performance, practically for small object detection. These challenges underscore the importance for further enhancements and evaluation.

Future research recommendations include improving detection performance by further optimizing the model with additional hyperparameters, extended training epochs and balanced datasets. Expanding the model's scope to include additional PPE items, such as safety glasses, boots, and gloves, would further enhance the model's applicability. Furthermore, exploring the integration of the model on edge devices could significantly advance its capabilities for real-time detection in complex construction sites. These efforts aim to address current limitations and pave the way for safer, more efficient construction sites through advanced, scalable deep learning models and real-time compliance monitoring systems.

Reinforcement Learning Improves SVM-Driven Algorithms for Classifying Multi-Sensor Data for Medical Monitoring

Zhiwei Xuan, Yajie Liu*
School of Information Engineering, Henan Vocational University of Science and Technology, Zhoukou, China

***Abstract*—Multi-sensor data in medical monitoring includes waveform changes in physiological signals and time-series characteristics of disease progression. These features typically exhibit high-dimensionality, large-scale, and time-varying characteristics. Nonlinear relationships exist between these features, increasing the difficulty of data processing and feature extraction, thereby reducing the classification capabilities of related algorithms. This study proposes a multi-sensor data classification processing method in medical monitoring based on reinforcement learning improved SVM. The algorithm employs the DBSCAN algorithm combined with Euclidean distance for clustering and data collection of multi-sensor data. Discrete wavelet transform is used to remove interference noise from the data, followed by convolutional neural networks for signal feature extraction from the denoised data. The Q-learning algorithm in reinforcement learning is used to improve the traditional SVM, with the extracted signal features input into the improved SVM. The classification results of medical monitoring multi-sensor data are output via a regression function. The experimental results show that the denoising results of medical monitoring data of the method are high, the signal-to-noise ratio is high, and the Kappa coefficient reaches up to 0.98. Therefore, it shows that the method can accurately classify medical monitoring multi-sensor data.**

Keywords*—Reinforcement learning; improved SVM; medical monitoring; multi-sensor; data; classification processing

I. INTRODUCTION

Medical monitoring systems [1] are increasingly being used to monitor patient health data. These include electrocardiograms (ECG), electroencephalograms (EEG), blood pressure, blood oxygen saturation, body temperature, and a variety of other physiological signals [2]. Through the processing of monitoring data, statistics on patient cases and health status [3] can be achieved to help doctors make more accurate clinical judgments and decisions; the abnormal classification of medical signals can also promote the development of medical intelligence, thus promoting the progress and innovation of medical technology [4]. The continuous improvement and application of medical signal processing technology are expected to bring more possibilities for clinical medicine and promote the development of the healthcare industry toward intelligence, personalization, and precision. Accurate classification of medical data can help improve the automation level of the medical monitoring system, reduce the workload of healthcare workers, and improve the efficiency and quality of medical services [5]. In addition, the relevant methods can also provide more objective and accurate data support for medical research and promote the progress of medical research and the innovation of clinical practice.

With the continuous development of medical monitoring, multi-sensor data analysis has become an important part of medical diagnosis. Traditional multi-sensor data classifications for medical monitoring often have problems such as low classification accuracy and slow processing speed [6]. Support vector machines (SVMs) are widely used as an effective classification algorithm in medical data classification. However, traditional SVM methods still face many challenges when processing complex and variable data, such as noise interference and inaccurate feature extraction.

Therefore, the research on multi-sensor data classification and processing methods for medical monitoring is not only of great significance for improving the function and performance of medical monitoring systems, but also provides technical support and theoretical guidance for improving medical services, promoting medical research, and safeguarding patients' health [7]. Relevant experts have been continuously exploring the field of data classification.

Singh and Khaiyum [8] proposed a data stream classification method based on the concept of drift, introducing an incremental semi-supervised learning model to regularize neural networks by incorporating auxiliary information such as label merging or pairwise constraints. However, due to the algorithm's efficiency and sensitivity to parameters, it is challenging to achieve better results in highly nonlinear environments with multimedia sensor data. Kenger and Ozceylan [9] proposed a data classification method based on mathematical modeling and improved online learning, using I0L_GFMM to generate initial cluster centers for the MILP model to enhance its efficiency, and combining fuzzy minimum and maximum neural networks with the MILP model. The proposed hybrid model demonstrated its applicability on both real and synthetic datasets. However, the aforementioned methods do not account for noise interference in medical data and are not suitable for high-noise environments in medical monitoring data. Zhai et al. [10] proposed a data classification method based on generative model diversity oversampling. When classifiers are faced with imbalanced multi-sensor-collected medical monitoring datasets, they typically favor the majority category, leading to poor classification performance. Liang et al. [11] proposed a data classification method based on flow regularization to overcome data quality issues and the high labeling cost of extracting data sample labels. However, while

This work was sponsored by Henan Provincial Higher Education Key Research Project Program (Project number of the fund：24B510006).

this classification algorithm can handle specific types of label noise, identifying the type of noise present in each medical data point remains a challenge.

Aiming at the problems of existing methods, this study proposes an improved SVM based on reinforcement learning for the classification of multi-sensor monitoring data. Compared to existing research, the reinforcement learning-enhanced SVM method proposed in this study aims to address the issue of insufficient classification accuracy in traditional algorithms under feature selection and imbalanced dataset scenarios. This is achieved through DWT denoising, CNN feature extraction, and Q-learning optimization. By combining the Discrete Wavelet Transform (DWT) with Multiresolution Analysis (MRA), precise denoising of medical monitoring data is realized, thereby improving the signal-to-noise ratio of the data. Furthermore, this method leverages the advantages of reinforcement learning to enhance the classification performance of medical data through interaction between the agent and the environment. By incorporating the Q-learning algorithm to improve the SVM, the method continuously learns from interactions with the environment to identify the optimal classification strategy, addressing the limitations of traditional support vector machines when processing multi-sensor data. The introduction of reinforcement learning algorithms enables decision automation in exploring optimal feature selection, optimizing model parameters, and balancing classification boundaries, thereby enhancing the model's performance and adaptability.

The subsequent sections of this study are arranged as follows: Section II introduces multi-sensor data acquisition and clustering methods. Section III elaborates on the data denoising process. Section IV discusses CNN feature extraction techniques. Section V provides a detailed explanation of the SVM classification model improved by Q-learning. Section VI validates the effectiveness of the method through experiments. Finally, Section VII summarize the research results and looks forward to future directions.

II. Multi-Sensor Data Acquisition and Clustering in Medical Monitoring

Multi-sensor data involved in medical monitoring are usually characterized by high dimensionality, large scale, and time-varying nature, such as waveform changes in physiological signals and time-series features of disease progression. The high dimensionality and complexity of such data lead to a reduced ability to categorize the data. The use of multi-sensors to collect data can obtain more dimensional information, which helps to improve the accuracy and stability of classification algorithms and enhance the effectiveness and reliability of classification. Therefore, in this study, multi-sensor data acquisition in medical monitoring is used to ensure data integrity and to support the accuracy of feature extraction through sufficiently acquired data, which can help to assess the patient's health status and process it for exhaustive classification more accurately.

The DBSCAN algorithm can discover the existence of potential clusters based on the density between data points, which helps to reveal hidden patterns and structures in the data. In medical monitoring, different types of medical surveillance sensing data may correspond to different health states or disease characteristics, which can be of help to better understand, by discovering clusters in the data. The DBSCAN algorithm identifies whether a data point is a core object or a boundary point, and from this, clusters with different levels of density are constructed. By identifying the core objects, the clusters to which the data points belong can be better distinguished, thus facilitating subsequent data classification tasks.

The DBSCAN algorithm divides the medical monitoring multi-sensor data into classes; those isolated few signal points will be considered as outliers to be eliminated, and the remaining data clusters as useful data. For the data object p, the ε neighboring object is denoted as $N_\varepsilon(p)$ and $N_\varepsilon(p)=\{q\in D \mid dist(p,q)\le \varepsilon\}$. For a given value $MinPts$, the object q is said to be directly density reachable from q if it is a neighboring object of the object ε of p. The point p is said to be directly density reachable from q.

For a given ε and $MinPts$, if there exists an object O in the set of data objects D such that the objects p and q are density reachable from O concerning the densities ε and $MinPts$,then the objects p and q are said to be density-connected about ε and $MinPts$.

For the set of data objects D, the cluster C is a non-empty subset of the set D that satisfies the following conditions:

1) $\forall p,q$, if $p\in C$, p and q are density reachable, then $q\in C$.

2) $\forall p,q\in C$, p and q are density-connected.

The DBSCAN algorithm requires two important parameters, a point p neighborhood ε radius, and the minimum number of points contained in the neighborhood $MinPts$. Firstly, the data set of a medical sensor monitoring object is specified, from which any data object p is selected, and all the objects are scanned to find out the density reachable set of p about ε and $MinPts$; if p is a core object, all the reachable objects of the set p form clusters; otherwise, p is not a core object, it is an outlier and should be eliminated.

The medical monitoring sensor data was expanded in the 3D numerical axes and the set of points obtained by the expansion was set to be G , and the distances of the points in the space were calculated using the Euclidean distances in Eq. (1) [12]:

$$d(P_i,Z_l)=\sqrt{\sum_{i=1}^{n}(P_{ij}-Z_{lj})^2} \tag{1}$$

where, $d(P_i,Z_l)$ represents the Euclidean distance between the coordinate value P_i of the i-th feature and the coordinate value Z_{lj} of the l-th cluster point, which is the basis for measuring the similarity between data points, P_{ij} denotes the

j-th dimensional coordinate value of the i-th feature point, and Z_{lj} denotes the j-th dimensional coordinate value of the l-th clustering point.

To cluster these points, the values of the parameters ε and $MinPts$ need to be developed first. The parameter values are influenced by the number of data points collected by the medical monitoring multi-sensory during the time and the positive proportionality that exists between them. The number of multi-sensor measurements, and hence the parameter values, are determined based on the needs of medical monitoring.

The execution flow of the DBSCAN algorithm for the medical monitoring sensor data acquisition process is as follows:

1) Arbitrarily select any point object P belonging to any data cluster in the point set G and create it as a new data cluster.

2) For all points P, if the points' number of P's neighborhood is no less than a minimum, P is served as the core point of the newly created data cluster and is compared with other data points to add the density reachable point to that cluster.

The determination of the density reachable is:

A point W is density reachable from a core point P, if there is a path from P to W, and each point on the path is a core point, and the distance between each adjacent two points on the path is within the neighborhood.

3) Loop step (2) until no points can be added to the cluster, then perform step (1) again.

4) Ends when all points in the point set belong to a particular data cluster.

The DBSCAN algorithm is shown in Fig. 1.

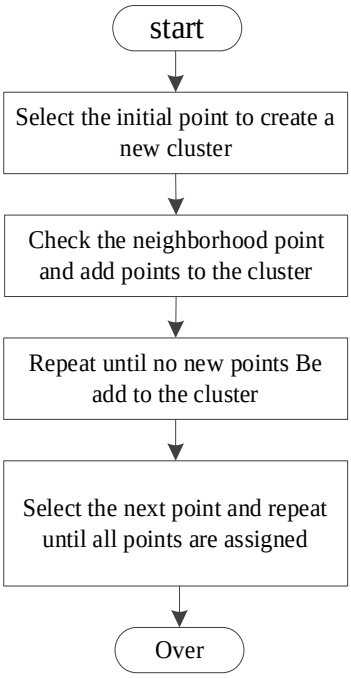

Fig. 1. The DBSCAN algorithm flowchart.

After the DBSCAN algorithm is processed, the medical surveillance multi-sensor data will exist in clusters and the number of points in the clusters a and $MinPts$ need to be compared to determine the validity of the clusters:

1) When $a < MinPts$ is present, the cluster will be considered as a cluster consisting of anomalies, which are anomalous medical monitoring sensor data, and will be excluded.

2) When $a \geq MinPts$, the cluster is composed of valid data, which will be retained to obtain the clustered collected medical monitoring multi-sensor data Q.

III. Sensor Data Denoising for Medical Monitoring

Medical monitoring data are subject to various interference during acquisition and transmission, such as electromagnetic interference, signal attenuation, and transmission failures. These factors can lead to noise in medical monitoring data, which can be mixed into the signal, masking or distorting useful information and reducing the quality and interpretability of the data, and the nonlinear relationships that exist in the noisy data can also make feature extraction difficult. Therefore, by denoising the acquired medical monitoring data, noise interference can be reduced, the accuracy and reliability of the data can be improved, it helps to highlight important features in the signal, and features related to the patient's condition can be extracted and analyzed more accurately, thus enhancing the discriminative power of the classification method.

In this study, after completing the medical monitoring data clustering, the Discrete Wavelet Transform (DWT) is used for denoising. The main advantages are: firstly, the discrete wavelet transform can effectively remove the noise in the signal and improve the quality of the data; secondly, by retaining the important features of the signal, the method can accurately denoise the signal while maintaining the detailed information of the signal as much as possible; in addition, the discrete wavelet transform can also analyse the signal at multiple scales and capture the features at different scales, which can help to understand the structure of the signal in a more comprehensive way and denoise it efficiently; Finally, the discrete wavelet transform has efficient real-time processing capability, which is suitable for scenarios that require rapid processing of medical monitoring data. The specific denoising process is shown in Fig. 2.

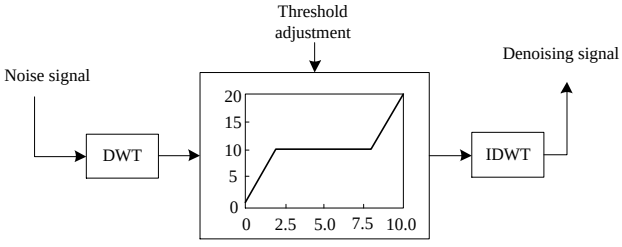

Fig. 2. Discrete wavelets transform denoising flowchart.

The algorithm flow is as follows:

Step 1. Decompose data $U(t)$ at t time into a set of wavelets with Eq. (2) [13]:

$$U(t)=\frac{1}{\sqrt{2^j}}\sum_k\sum_j DW_k^j\cdot\varphi(2^{-j}\cdot t-k) \tag{2}$$

where, φ and j denote the translation and expansion factors, respectively, and DW_k^j denotes the DWT coefficients in the wavelet basis.

Step 2. Use Multi-Resolution Analysis (MRA) data to extend analyses that provide different time and frequency resolutions at each level.

Multi-resolution analysis (MRA) provides different time and frequency resolutions at each analysis level by using the scale function $\phi(t)$ and the wavelet function $\varphi(t)$. $\phi(t)$ is the foundation of MRA, which describes the overall signal features on a coarser scale, similar to the low-frequency in the signal. It constructs the low-frequency approximation of the signal through its expansion and displacement. $\varphi(t)$ describes the local signal features on a finer scale, similar to the high frequency in the signal. It captures the signal details through expansion and displacement, that is, the high frequency in the signal at different scales.

The multi-sensor data $U(t)$ is calculated by Eq. (3), which decomposes the signal into a linear combination of the scale function and the wavelet function at different scales [14].

$$U(t)=\sum_k A_k^{j_0}\varphi_k^{j_0}(t)+\sum_{j=j_0}\sum_k D_k^j\phi_k^j(t) \tag{3}$$

where, $A_k^{j_0}$ and D_k^j denote the approximation coefficient and detail coefficient, respectively. According to the scale and wavelet bases, the equations for both can be expressed as Eq. (4) and Eq. (5) [15]:

$$A_k^{j_0}(t)=\sum_k f_k\cdot\varphi_k^{j_0}(t)=\sum_n h(n-2k)\cdot A_k^{j_0+1}(t) \tag{4}$$

$$D_k^j(t)=\sum_k f_k\cdot\phi_k^{j_0}(t)=\sum_n g(n-2k)\cdot A_k^{j+1}(t) \tag{5}$$

The wavelet decomposition tree constructed by MAR is shown in Fig. 3.

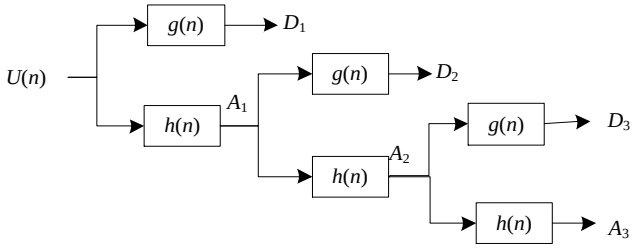

Fig. 3. Schematic diagram of MRA scale decomposition.

Step.3 Soft Threshold Calculation

In the process of quantizing the threshold λ, it is usually considered that anything less than λ is caused by noise, and anything greater than λ is caused by signals, and the soft threshold algorithm for searching towards zero according to a fixed amount is as follows in Eq. (6) [16]:

$$\hat{w}_{j,k}=\begin{cases}\mathrm{sgn}(w_{j,k})(w_{j,k}-\lambda), |w_{j,k}|\geq\lambda\\ 0, |w_{j,k}|\leq\lambda\end{cases} \tag{6}$$

In Eq. (6), λ and $\mathrm{sgn}(x)$ are defined as Eq. (7) and Eq. (8), respectively:

$$\lambda=\sigma\sqrt{2\log(n)} \tag{7}$$

$$\mathrm{sgn}(x)=\begin{cases}1, x>0\\ 0, x=0\\ -1, x<0\end{cases} \tag{8}$$

In the above equation, n denotes the sampling length of the noise signal, σ denotes the noise variance, and $w_{j,k}$ denotes the wavelet coefficients at different scales. The noise variance σ is calculated in Eq. (9) [17]:

$$\sigma=\left[\frac{median|\Lambda_{i,j}|}{0.6475}\right] \tag{9}$$

In Eq. (9), $\Lambda_{i,j}$ denotes the first layer of high-frequency coefficients of the wavelet transform of the noise-containing medical monitoring multisensory data, and $median|\Lambda_{i,j}|$ denotes the median.

Step.4 Positive and Negative Thresholding

The DWT exhibits low-frequency and high-frequency coefficients, respectively, and the data are characterized by two types of high-frequency oscillations: high-frequency vibrations with small amplitudes and low-frequency oscillations with large amplitudes. Both contain peaks and noise signals, respectively [18]. Therefore, the positive and negative thresholds are found through Eq. (10):

$$\lambda_i=\begin{cases}\lambda_+=\alpha*\max(d_i)\\ \lambda_-=\alpha*\min(d_i)\end{cases} \tag{10}$$

In Eq. (10), d_i denotes the high frequency detail coefficient of the n layer, and α denotes the empirical parameter.

The post-threshold low-frequency and high-frequency signals were reconstructed to obtain denoised medical monitoring multi-sensor data $X(t)$.

IV. Multi-Sensor Data Feature Extraction for Medical Monitoring

Due to the characteristics of high dimensionality and large-scale data, its direct use for classification processing will increase the complexity of the computational algorithm and reduce the accuracy of the algorithm. Feature extraction for the fused data after the denoising process can map the original data to a lower-dimensional feature space, reduce the data dimension, simplify the problem, improve the classification efficiency, help to extract the key information and features in the data, and strengthen the effective patterns and structures in the data. Therefore, in this study, CNN is used to extract the main features of the data to reduce the interference of unnecessary information and improve the classification ability of the data by finding meaningful features related to the classification task.

The convolutional layer is the core of the whole CNN, and it can effectively extract the sample features. The convolutional kernel traverses the whole sample by sliding to carry out feature extraction, and after the local features are extracted, the positional relationship between that part of the features and other features can be marked. CNN is non-transparent for feature extraction, and different from traditional network learning methods, the convolutional kernel operation has the feature of local perception, when a part of the features are learnt, the features will be inputted into the next mapping layer, and the mapping layer after that will continue to carry out classification learning. The samples after the convolutional layer use the spatial distribution characteristics of the surrounding samples, and the feature extraction accuracy can be obtained.

For the input medical monitoring multisensory data $X(t)$, a matrix W with a convolution kernel size $a \times b$ and bias B, the result after convolution is in Eq. (11) [19]:

$$h = g(X * W + B) \tag{11}$$

In Eq. (11), $*$ denotes the convolution operation and $g(.)$ denotes the activation function. The activation function used in this study is the ReLU function shown as Eq. (12):

$$g(x) = \max(0, x) \tag{12}$$

The sparse activation of the ReLU function can make certain neurons inactive, reduce the number of redundant connections and parameters, and improve the computational efficiency and generalization ability. The ReLU function solves the problem of gradient vanishing in traditional activation functions and avoids the performance degradation caused by the gradient being too small. In addition, the computation of the ReLU function is simple and efficient, without the need for complex exponential operations, which accelerates the training and inference process of the model. In addition, the ReLU function integrates linear and nonlinear properties, which is convenient to capture the nonlinear relationship of the data and enhances the expressive ability of the neural network. Finally, the ReLU function has no upper limit and can pass positive values to the next layer, further expanding the expressive ability of the network.

The pooling layer can effectively reduce the data dimensions, and the input of the pooling layer is the output of the convolutional layer. The output of the convolutional layer N feature maps is passed through the pooling layer to reduce the data size. In this research, the maximum pooling layer is introduced to sparsity the hidden layer data. The operation of maximization is to retain the maximum value of the pooled region, that is, to remove the non-extremely large values within the matrix, while extracting the extremely large value of the region as the representative value after pooling. The output of the pooling layer results in a substantial reduction of the network parameters, and the kernel size is generally 2×2 when maximum pooling is used, and the 2×2 size kernel enables the number of parameters to be effectively regulated, which helps to prevent the occurrence of overfitting situations and enhances the robustness of the convolutional neural network. Average pooling performs an averaging operation on the matrices in the region and uses the average value to sparse the non-overlapping target region.

The role of the Dropout layer is to drop some neurons at a certain rate during the network training process, which is a simple and effective regularization technique. However, choosing a suitable Dropout rate is critical to optimizing network performance. Higher Dropout rate causes the model to underfit because too many neurons are dropped, and difficult to learn enough information. However, a lower Dropout rate cannot effectively prevent overfitting. In addition, due to the randomness of Dropout during training, it helps the model learn more robust feature representations. Also, the difference between training and testing exists because all neurons are activated.

Therefore, it is often necessary to scale the output of all neurons to match the average level of activation at training, thus improving the generalization ability of the model. Choosing an appropriate Dropout rate is crucial to prevent model overfitting and improve generalization performance. In general, for larger networks or datasets, a lower Dropout rate (e.g. 0.2-0.5) can be chosen, as the network already has enough capacity to capture complex features, and too high a Dropout rate may limit its ability to learn. Conversely, for smaller networks or datasets, a higher Dropout rate (such as 0.5-0.8) can be selected to reduce the risk of overfitting.

The structure of the Dropout network is shown in Fig. 4.

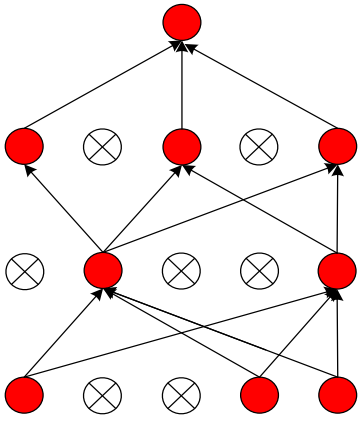

Fig. 4. Dropout network structure.

In the original network structure, all neurons need parameter training, while in the Dropout network structure, some neurons are not involved in the training, Dropout is a very effective method to suppress overfitting, and its use often brings a great improvement to the network generalization performance. The computational equation of the network using Dropout as in Eq. (13) [20]:

$$\left.\begin{aligned} r_i^l &\sim Bernoulli(p) \\ \tilde{y}^{(l)} &= r^{(l)} * y^{(l)} \\ z_i^{l+1} &= W_i^{(l+1)} \tilde{y}^{(l)} + B_i^{(l+1)} \\ y_i^{(l+1)} &= f(z_i^{(l+1)}) \end{aligned}\right\} \tag{13}$$

In Eq. (13), *Bernoulli* function to generate the probability r vector, that is, randomly generate a $[0,1]$ vector, $y_i^{(l+1)}$ is the output of the convolutional neural network for medical monitoring multi-sensor data feature extraction results.

V. Reinforcement Learning for Improved SVM Classification Models

Through feature extraction, we have extracted the most representative and distinguishing features from the original multi-sensor data. The classification algorithm can better distinguish different data types by enriching the feature space and improving classification accuracy. Many physiological signals in medical monitoring data are time-varying, and the trend of these time-varying features is very important for predicting the direction of disease development. Considering these characteristics of sensor monitoring signals, a method combining Q-learning with SVM is proposed to improve the effectiveness of SVM in multi-sensor data classification of medical monitoring.

Reinforcement learning can reduce the dimensionality of the feature space of sensor signals, improve the efficiency of the algorithm, can better capture the dynamic change law of time-varying features, and improve the classification method's ability to process time-ordered data. Therefore, in this study, the Q learning algorithm in reinforcement learning is used to improve SVM, to provide better classification effect of medical monitoring data by SVM.

SVM is a powerful supervised learning algorithm that is widely used in classification and regression tasks. In classification, the goal of SVM is to find a hyperplane that maximizes the spacing between different classes; in regression, the goal of SVM is to find a hyperplane that minimizes the distance of all data points to the hyperplane, while allowing for a certain error boundary.

In SVM regression, the objective function aims to minimize the sum of distances from all data points to the hyperplane while taking into account the error boundary. For a given training data set $\{(x_i, y_i)\}_{i=1}^n$, where x_i is the input vector and y_i is the corresponding output value, the goal of SVM regression is to minimize Eq. (14) objective function [21]:

$$\frac{1}{2}\|w\|^2 + C\sum_{i=1}^{n} L_\varepsilon(y_i - (w \cdot \phi(x_i) + b)) \tag{14}$$

where, w and b are the normal vector and intercept of the hyperplane, respectively; $\phi(x_i)$ represents the mapping from input space to feature space; C represents a regularization parameter, which is used to control the balance between the complexity of the model and the training error; L is ε - insensitive loss.

In SVM, support vectors are those training samples on or within the error boundary, which have a decisive effect on the hyperplane position for their determination of the constraints on interval maximizing. The support vectors are equally important in regression because of both the definition of hyperplane location and affection of the generalization ability. By keeping the key sample points, SVM achieves better generalization performance while ensuring training errors.

Q-learning method is an important machine learning method in reinforcement learning. It is similar to other methods in reinforcement learning in that it learns the optimal policy for its dynamic system by perceiving the state information of the environment and interacting with the environment continuously, and it improves the behavior of the system by interacting with the environment through trial and error methods, and it is a kind of on-line learning method that can be applied to real-time environments. Therefore, it has been widely researched in the fields of intelligent control, machine learning, and so on.

The Q learning system views learning as a process of trial and error, and its basic model is shown in Fig. 5.

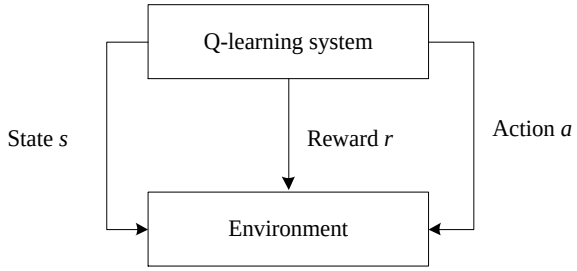

Fig. 5. Basic model of Q-learning.

In the learning process, the Q-learning system selects an action a to act on the environment, the environment receives the action and changes, and at the same time produces a reinforcement signal r which is fed back to the learning system, which then selects the next action according to the reinforcement signal and the current state of the environment, the principle of selection is to make the probability of receiving a positive reward increase. The chosen action affects not only the immediate reinforcement value, but also the next state of the environment and the final reinforcement value.

From the Q learning system, it is known that the set of states in the Q learning system is discrete and finite in general, but often in some practical situations, the set of state variables of the environment is large-scale or continuous, resulting in a difficult learning process and a slow response speed of the system. To solve this problem, this study introduces Q-learning to improve

SVM, where Q-learning is used to preprocess and extract features, and then SVM is used for classification. It not only captures the dynamic variation of time-varying features, but also reduces the complexity of SVM when processing high-dimensional data.

Q-learning improves the behavior of the system by constantly interacting with the environment through trial-and-error methods to find a strategy that maps the state of the environment into the corresponding action. This strategy of reinforcement learning inevitably increases the difficulty of learning the system, resulting in very much blind learning, and leading to longer learning times.

To overcome these problems, the features optimized by Q-learning are passed to the SVM as input to make efficient classification decisions, thus improving the overall system performance. For large-scale systems with reinforcement learning , the introduction of SVM not only reduces the complexity due to solving quadratic programming problems in standard support vector machines, but also for improving the convergence speed of large-scale reinforcement learning systems, Q-learning improved SVM as shown in Fig. 6.

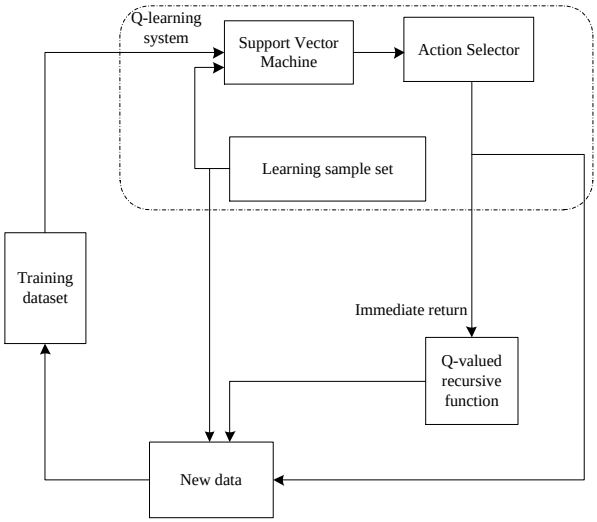

Fig. 6. Q-learning improved SVM structure.

The aim of the Q-learning algorithm shown as Eq. (15) and Eq. (16) is to find a policy π such that the value $Q^{\pi}(s)$ of each state s reaches the end at the same time, that is, it tries to find a policy $\pi : s \to a$ that is able to maximize the value of each state [22].

$$Q^{\pi}(s,a) = E\{r_1 + \gamma r_2 + \cdots + \gamma^{i+1} r_i + \cdots \mid s_0 = s, a_0 = a\} \tag{15}$$

$$Q^{\pi}(s,a) = \max_{\pi}(Q^{\pi}(s,a)) \tag{16}$$

where, r_i denotes the immediate reward at the moment t, $\gamma(\gamma \in [0,1])$ denotes the decay coefficient, and $Q^*(s,a)$ denotes the optimal value function. The corresponding optimal strategy as in Eq. (17):

$$\pi^* = \arg\max Q^*(s,a) \tag{17}$$

One of the simplest forms of Q-learning is single-step Q-learning with a modified consensus of Q-values as shown in Eq. (18) [23]:

$$Q(s_t,a_t) \leftarrow Q(s_t,a_t) + \beta\left[r_{t+1} + \gamma \max_a Q(s_{t+1},a) - Q(s_t,a_t)\right] \tag{18}$$

where, β denotes the learning rate and γ denotes the discount rate.

Given a training set $S = (y_i, P_i)$, where y_i denotes the input vector and P_i is the output classification objective value. Determine an optimal function $F(x)$ as the objective of the regression problem such that $F(x)$ can correctly regress the unknown input vector with the highest possible probability. In SVM, the regression function $F(x)$ has the form as in Eq. (19) [24]:

$$F(x) = \upsilon^T \delta(x) + b \tag{19}$$

where, $\delta(.)$ denotes the mapping from the input space to the feature space, υ and b denote the coefficient vector and the deviation term respectively, which are the quantities to be sought.

The unknown quantity can be determined by Eq. (20) optimization problem [25]:

$$\begin{aligned} &\min_{\upsilon,b,\varepsilon} Q(\upsilon,b,e) = \frac{1}{2}\|\upsilon\|^2 + \frac{\gamma}{2}\sum_{i=l}^{l} e_i^2 \\ &s.t. y_i = \upsilon^T \delta(x_i) + b + e_i \end{aligned} \tag{20}$$

Its Lagrangian function as in Eq. (21):

$$L(\upsilon,b,e,\beta) = Q(\upsilon,b,e) - \sum_{i=1}^{l} \beta_t\left[\upsilon^T \delta(x_i) + b + e_i - y_i\right] \tag{21}$$

The KKT condition for the above equation is shown in Eq. (22) [26]:

$$\begin{cases} \dfrac{\partial L}{\partial \upsilon} = 0 \Rightarrow \upsilon - \sum_{i=1}^{l} \beta_i \delta(x_i) = 0 \\ \dfrac{\partial L}{\partial b} = 0 \Rightarrow \sum_{i=0}^{l} \beta_i = 0 \\ \dfrac{\partial L}{\partial e_i} = 0 \Rightarrow Ce_i - \beta_i = 0 \\ \dfrac{\partial L}{\partial \beta_i} = 0 \Rightarrow \upsilon^T \delta(x_i) + b + e_i - y_i = 0 \end{cases} \tag{22}$$

Writing Eq. (22) in matrix form and eliminating υ and e, Eq. (23) is obtained:

$$\begin{bmatrix} 0 & \vec{1}^T \\ \vec{1} & \Omega+\gamma^{-1}I \end{bmatrix}\begin{bmatrix} b \\ \beta \end{bmatrix}=\begin{bmatrix} 0 \\ y \end{bmatrix} \tag{23}$$

where, $\Omega_{ij}=k(x_i,x_j)$. A regression function completes the classification of multi-sensor data for medical monitoring by solving Eq. (24):

$$F(x)=\sum_{i=1}^{l}\beta_i K(x,x_i)+b \tag{24}$$

VI. Experimental Validation

Test experiments are conducted to validate the effectiveness of the proposed reinforcement learning based improved SVM for multi-sensor data classification processing in medical monitoring.

A. Experimental Data

A schematic diagram of the medical monitoring multi-sensor arrangement is shown in Fig. 7.

Fig. 7. Schematic diagram of multi-sensor arrangement for medical monitoring.

Here, suitable types of sensors, including heart rate sensors or blood pressure sensors, are selected based on monitoring needs and placed at specific locations on the patient's body to accurately collect physiological parameters and health data. Subsequently, the data collected by the sensors is transmitted to the monitoring device or data system for processing and storage.

The multi-sensor data included ECG data (heart rate, heart rate), blood pressure data (including systolic and diastolic blood pressure), oxygen data (e.g., oxygen saturation), temperature data, respiratory data (respiratory rate), exercise data (number of steps, intensity of activity), including blood glucose data, and pulse waveform data. Examples of selected samples are shown in Table I.

TABLE I. Examples of Selected Samples

Data Type	Numerical Value
heart rate	75 bpm
pulse rate	normalcy
systolic blood pressure	120 mmHg
diastolic blood pressure	80 mmHg
oxygen saturation	98 per cent
(body) temperature	36.5°C
respiratory rate	16 times/minute
number of steps	8000 steps
Activity intensity	medium
blood sugar	5.0 mmol/L

In this setting, the parameter configurations of Q- learning and SVM model are planned in detail, and the specific parameter settings are as follows:

1) The state space of Q-learning algorithm selects parameters in multi-sensor data as characteristics, such as heart rate and systolic blood pressure. The action space includes the selection of different SVM improvement methods.

2) Setting the learning rate of Q-learning is 0.1 to control the updating speed of the Q value; the discount rate is 0.9 to balance the importance of current and future rewards; the exploration rate gradually decreases from 0.9 to 0.1 to promote the algorithm's balance between exploration and utilization.

3) Setting the initial regularization parameter C of SVM is 1.0, and the kernel function is RBF (radial basis function). The space is reserved for adjusting other parameters through cross-validation.

The above parameter configuration aims to improve the repeatability of the experiment and the reliability of the results.

B. Experimental Program

Based on the above collected data, using the signal-to-noise ratio, data feature extraction effect, and Kappa coefficient as indicators, the method of this study is compared and validated with the data classification method based on the concept of drift, and the classification method based on mathematical modelling and improved online learning.

1) Signal-to-noise ratio. The signal-to-noise ratio is the ratio of the strength of the useful signal to the strength of the noise signal and is used to measure the relative strength of the signal in relation to the noise. A high signal-to-noise ratio indicates that the useful signal is stronger relative to the noise signal, indicating a higher quality signal and clearer information.

2) Data feature extraction effect. Data feature extraction effect refers to the meaningful features that can characterize the relevant information of the signal extracted from the original data by feature extraction methods.

3) Kappa coefficient. The Kappa coefficient measures the accuracy of the classifier while considering the random factor in classification. The closer the Kappa coefficient is to 1, the better the performance of the classifier.

C. Analysis of Experimental Results

1) Signal-to-noise ratio. The signal-to-noise ratio is a measure of the relative strength between signal and noise. By performing a comparative signal-to-noise ratio test, the quality of different data can be assessed, and it can be determined which data has a higher signal quality and is more reliable. Signal-to-noise ratio is one of the key factors in signal classification and processing. Lower signal-to-noise ratios may lead to interference and distortion of the signal by noise,

reducing the performance and accuracy of the classification algorithm. By performing a signal-to-noise ratio comparison test, data with lower signal-to-noise ratios can be identified, so that methods such as appropriate preprocessing or adjusting parameters can be taken to improve classification performance. The signal-to-noise ratio results of the three methods are shown in Fig. 8.

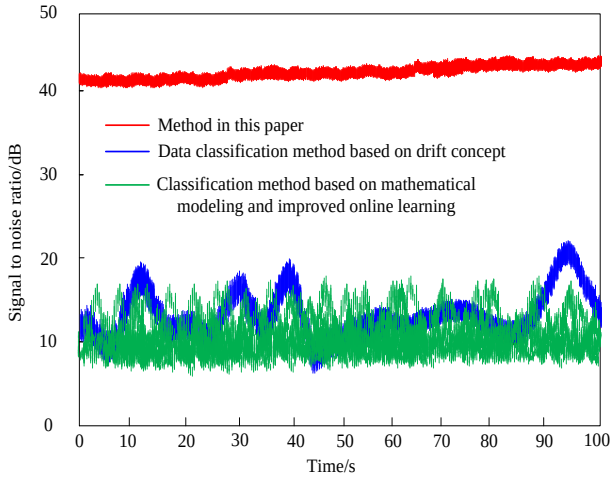

Fig. 8. Signal-to-noise ratio results.

Observing the results of the signal-to-noise ratio shown in Fig. 8, the signal-to-noise ratio of this study's method is always higher and smoother compared to the two literature comparison methods, and the signal-to-noise ratio of this study's method is always above 40 dB. On the other hand, the signal-to-noise ratio of the data classification method based on the concept of drift and the classification method based on mathematical modelling and improved online learning not only fluctuates more, but also has a lower value, with a maximum of only about 25 dB. Therefore, it shows that the method in this study can effectively remove the noise from medical monitoring multi-sensor data and improve the quality of the data.

The main reason is that the proposed method removes the noise in medical monitoring data effectively and improves the signal-to-noise ratio by combining a DBSCAN algorithm with DWT.

2) Effectiveness of data feature extraction. Feature extraction is a key step in converting raw signals into meaningful feature vectors. The performance and effectiveness of different feature extraction methods can be evaluated by verifying the feature extraction effect. Comparing the usefulness and differences of features extracted by different methods for signal classification helps to select the most suitable feature extraction method to maximize the accuracy and robustness of signal classification. The data feature extraction results of the three methods are shown in Fig. 9.

As shown in Fig. 9, the data feature extraction results of this study's method are closest to the trend of the original data, indicating that the data features extracted by this study's method are most capable of describing the original data. And the data feature extraction results of the data classification method based on the drift concept differ greatly from the original data. Therefore, it shows that the method in this study can accurately extract the features of medical monitoring multi-sensor data.

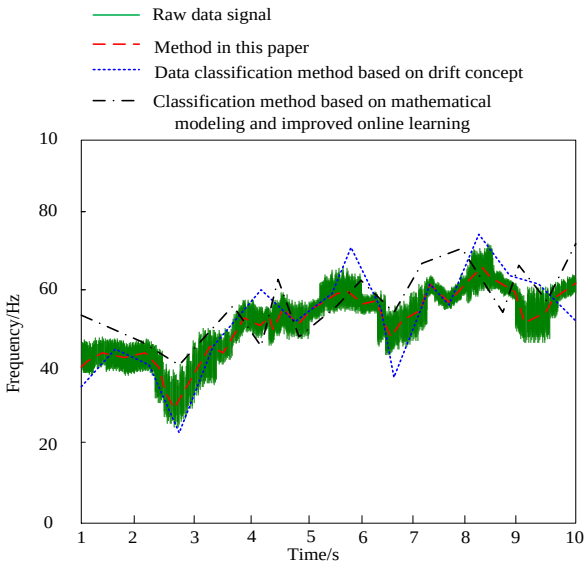

Fig. 9. Effect of data feature extraction.

This is mainly because the convolutional neural network is used in this method, which makes it more accurate in feature extraction and can capture more useful information.

3) Kappa coefficient. The accuracy and consistency of the classifiers in multi-sensor data classification can be objectively assessed by validating the classification results with Kappa coefficients. The Kappa coefficients take into account the random assignment of the classified objects, and can accurately measure the superiority of the classifiers with respect to the classification results that are only caused by the random selection. The Kappa coefficient test results of the three methods are shown in Table II.

TABLE II. KAPPA COEFFICIENT

Test serial number	Kappa coefficient		
	The method in this study	Data classification method based on the drift concept	Classification method based on mathematical modeling and improved online learning
10	0.96	0.71	0.76
20	0.98	0.68	0.74
30	0.95	0.69	0.62
40	0.97	0.72	0.64
50	0.96	0.73	0.74
60	0.96	0.67	0.65
70	0.97	0.71	0.61
80	0.98	0.70	0.63
90	0.96	0.69	0.65
100	0.95	0.66	0.71

From the data in the table, it can be observed that the Kappa coefficient of this study's method stays at a high level with small changes in many tests. On the other hand, the Kappa coefficients of the other two methods have large fluctuations and their performance is not stable enough. For example, the Kappa coefficient of this study's method stays above 0.95 under different test numbers, while the Kappa coefficients of the other two methods fluctuate in a wide range, from 0.62 to 0.76. The Kappa coefficient of this study's method is significantly higher than that of the other two methods under most of the test sequence numbers, especially the highest Kappa coefficient is achieved at many nodes such as test sequence numbers 20, 40 and 80. This indicates that the method in this study has a significant advantage in classification accuracy and can classify the data more reliably for judgement.

This is because the improvement of Q-learning on SVM makes the model more adaptable to complex and changeable medical data through automatic exploration and optimization of parameters, thus improving the accuracy and robustness of the classification.

VII. Conclusion

In this study, a method combining Q-learning and SVM was proposed to deal with the problem of multi-sensor data classification in medical monitoring. Through experimental validation, the new method exhibited better performance relative to the traditional approach. Specifically, DBSCAN clustering and DWT were used to preprocess data, which effectively retained key features and reduced noise interference. Then, CNN was used to deeply mine signal features. The Q-learning algorithm was used to optimize SVM model and realize efficient mapping of features to classification output.

Experimental results show that the proposed method not only reaches a high level of 98% on classification accuracy, but also observes significant progress in terms of classification accuracy, signal-to-noise ratio, and feature extraction effectiveness. In addition, this study explores the role of reinforcement learning in the process of feature selection and model optimization, and it is found that the reinforcement learning algorithm can be used to better guide the model for tuning and improve the effectiveness of the classification task.

However, this study still has certain limitations, and the robustness of feature extraction in current methods needs to be further improved when dealing with sudden noise or multi-source heterogeneous sensor data. And the convergence speed of the Q-learning algorithm in high-dimensional state space is slow, which may affect the application efficiency of real-time monitoring scenarios.

In the future, this study will further develop a distributed reinforcement learning framework to optimize the parallel processing efficiency of multi-sensor data, in order to meet the real-time monitoring needs of clinical practice. For example, introducing Deep Q-Network (DQN) combined with Convolutional Neural Network to process high-dimensional sensor data, utilizing experience replay and target network mechanisms to enhance algorithm stability. And adopting the Actor Critic framework, while optimizing the strategy function and value function, to more efficiently handle the temporal dynamic characteristics of medical monitoring data.

***Abstract*—Despite the increasing reliance on information dashboards across industries, dashboard design practices remain fragmented, lacking standardized methodologies, ontological formalization, and governance integration. Addressing these gaps, this study develops a method to guide dashboard design by embedding ontological modeling and Information Governance (IG) principles. Two complementary artifacts are proposed: the Information Dashboard Design Ontology (IDDO) and the Information Dashboard Design Method (IDDM) Canvas. Using Design Science Research Methodology (DSRM) and a Unified Ontological Approach (UOA), IDDO formalizes tacit dashboard design knowledge into a structured framework, while the IDDM Canvas operationalizes this ontology into a practical design tool. Validation through the Ontological Unified Modeling Language (OntoUML) Plugin and conceptual assessment based on Unified Foundational Ontology (UFO) principles confirmed internal consistency and ontological soundness. The resulting framework integrates twelve dashboard design building blocks with eight IG principles to ensure rigor and governance alignment. The application of the IDDM Canvas demonstrated its utility in facilitating structured, replicable dashboard development. While the evaluation focused primarily on conceptual validation, future studies are recommended to empirically assess the framework's practical effectiveness across various domains and real-world projects.**

Keywords*—*Information dashboard; ontological modelling; information dashboard design ontology (IDDO); information dashboard design method (IDDM) canvas; information governance (IG); unified ontological approach (UOA); design science research methodology (DSRM)

I. Introduction

Information dashboards have become essential tools for organizational decision-making, enabling users to monitor, analyze, and interpret complex data in real-time [1]. Beyond their traditional role as visualization interfaces, dashboards now function as integrated components of information ecosystems, bridging disparate systems and enhancing decision support across domains. Their widespread adoption spans over industries such as healthcare [2], [3], finance [4], urban mobility management [5], and public health [6].

Despite their prevalence, dashboard development practices remain fragmented and lack a standardized methodology. Poorly designed dashboards may lead to cognitive overload, inconsistent data representation, and misinformed decisions [7], [8]. Moreover, many existing approaches neglect the integration of governance principles, which can compromise data quality, reliability, and compliance [9], [10], and hinder organizational learning and adaptation to digital transformation [11]. Without a consistent framework that incorporates governance, organizations face challenges in aligning dashboards with strategic and operational needs. Additionally, dashboard design often relies on implicit expertise held by experienced practitioners, making it difficult to replicate or scale across teams. The absence of a formalized design method limits reuse and consistency across different contexts. While ontology has shown promise in structuring complex design logic within business modeling [12] and learning systems [13], its application in dashboard design methodology remains limited.

This study aims to address three core challenges in dashboard methodology: 1) the lack of a standardized, transferable design method; 2) limited use of ontological approaches to formalize design elements; and 3) the absence of governance integration in the design process. In response, we adopt Design Science Research Methodology (DSRM) to develop the Information Dashboard Design Ontology (IDDO) and the Information Dashboard Design Method (IDDM) Canvas. IDDO provides a structured ontological framework for modeling key dashboard elements, while the IDDM Canvas offers a practical guide for applying this framework in real-world design initiatives.

Inspired by the transformation of the Business Model Ontology (BMO) into the widely adopted Business Model Canvas (BMC), this study translates IDDO into a usable design tool through the IDDM Canvas. This approach bridges conceptual rigor with design applicability, offering a method that supports governance compliance, visual consistency, and broader usability, including by non-specialist users.

The remainder of this study is organized as follows: Section II reviews the literature on dashboard design, ontological modeling, and governance integration. Section III outlines the research methodology. Section IV details the development of IDDO. Section V presents the IDDM Canvas. Section VI discusses the conclusion which includes limitations, and future research directions.

II. Literature Review

A. Challenges in Dashboard Design and the Need for Standardization

The growing body of research on information dashboards highlights their increasing role in enhancing decision-making through structured visual representation of data. Sarikaya et al.

*Corresponding Author.

[1], emphasize how organizations are increasingly relying on dashboards to transform complex datasets into actionable insights. However, despite substantial academic and industry interest, there remains a lack of formalized, standardized methodologies for dashboard development, indicating the need for more structured design approaches. Recent studies echo these concerns, particularly in sentiment-oriented and real-time dashboards that highlight interactive and data-driven needs without standardized models [58], [59].

As information systems evolve, dashboard development encounters several design-related and implementation challenges. Poor design has been linked to cognitive overload [7], reduced user engagement, and diminished decision quality [8]. These problems are exacerbated by the absence of a methodological framework that can capture and structure implicit design knowledge into standardized and reusable models. Without formalization, inconsistencies in layout, interaction, and data interpretation often emerge, leading to interoperability and usability issues. The emergence of AI-powered dashboards also illustrates this gap, where intelligent systems are deployed without governance grounding, resulting in unpredictable behavior or user distrust [60].

These challenges emphasize the need for a governance-integrated framework that promotes standardization while remaining adaptable across contexts. In practice, dashboards often serve as boundary-spanning tools between business and technical domains, requiring design methods that support both consistency and flexibility [14]. While some frameworks have shown domain-specific success, they frequently lack ontological structure and governance alignment, limiting broader application.

A synthesis of twelve recent studies (2019 to 2024), selected across healthcare, public service, urban management, and other sectors, reveals wide variation in dashboard objectives, design approaches, and governance considerations. Although many offer novel visualization strategies, they remain context-specific and difficult to generalize. This highlights the need for methodologies that support the formalization and standardization of dashboard design processes. These studies were chosen to reflect cross-sector practices, and recent publications were prioritized to capture emerging design trends and evolving best practices [59], [60].

Inspired by Osterwalder's methodology in developing the BMO [12], which successfully transformed business modeling logic into structured, transferable artefacts, this study applies a similar logic to dashboard design. It synthesizes design elements across domains to inform the development of a governance-integrated, ontology-driven dashboard design framework. The review indicates that while healthcare [3], [2] and public service [6], [15] applications dominate dashboard usage, each domain applies distinct development methods. For example, dashboards in healthcare often prioritize real-time clinical monitoring [3], [2], while those in tourism or urban management emphasize geospatial interaction and user experience [16], [15]. This diversity demonstrates the adaptability of dashboards but also highlights variations in design structures and methodological rigor across sectors.

In terms of methodological approaches, the studies span a wide range from user-centered and iterative designs to data-driven and metric-based models [7], [9], [13]. Some emphasize prototyping and stakeholder feedback [6], [4], while others rely on cognitive task analysis and real-time contextual inputs [15]. Although these approaches offer valuable insights, few provide a repeatable structure that can be generalized or scaled. This points to a pressing need for unified design frameworks that can bridge ad-hoc development with structured reusability.

Design principles also vary significantly. While some dashboards focus on tracking KPIs and trends using minimal layout structures [4], [17], others employ interactive and multi-layered design systems to serve diverse user groups [6], [5]. However, many studies underplay the importance of design consistency, hierarchy, and accessibility - factors that critically affect usability and user trust [8]. This variability in design emphasis further reinforces the case for standardized design methods that balance domain specificity with universal design principles.

Table I summarizes the key studies across domains, revealing the broad diversity in dashboard development approaches. The review demonstrates sectoral adaptability but simultaneously exposes the absence of standardized structures across organizational contexts. Recent data-driven approaches, for instance, prioritize automation and real-time responsiveness but lack a governance-aware foundation, further illustrating the gap [60].

To address the limitations identified in existing literature, this study proposes a new framework – the IDDO, which responds directly to the gaps. Existing dashboard design frameworks, while offering domain-specific solutions, exhibit fundamental limitations that make them unsuitable for systematic, governance-aligned development across organizational contexts. These frameworks rely on ad-hoc approaches without formal structure, lack ontological formalization, preventing knowledge systematization, and treat governance as external considerations rather than integrated design components [7], [8], [9], [10].

The proposed IDDO framework addresses these limitations by providing: 1) a formal ontological structure enabling systematic knowledge transfer, 2) embedded governance integration ensuring compliance by design, and 3) practical operationalization through the IDDM Canvas that translates complex structures into actionable design methodologies. This approach makes IDDO particularly appropriate for organizations requiring standardized, repeatable dashboard development processes.

This reinforces the need for a formalized modeling foundation to promote consistency, facilitate transferability, and embed governance-aware design practices. Building on these insights, the following sub-sections explore two critical dimensions essential for establishing a standardized dashboard development method: 1) ontological modeling and 2) Information Governance (IG).

TABLE I. A REVIEW OF RECENT STUDIES ON INFORMATION DASHBOARD DESIGN (2019-2024) DISCUSSED IN SECTION II

Study	Application Domain	Methodology	Key Phases	Design Principles	Key Features	Key Study Outcome
Poppe et al. [3]	Neonatal Intensive Care	User-centered design	1. Interviews with clinicians 2. Dashboard prototyping 3. Clinical evaluation	• Combine detailed and summarized data • Enable real-time monitoring • Support decision-making • Ensure ease of understanding	• Real-time monitoring • Visual trends • Clinical indicators	Web-based oxygenation dashboard for monitoring preterm neonates
Pamuk & Schumann [4]	Financial Services	Design Science Research	1. Data understanding 2. Data preprocessing 3. Model development Model evaluation	• Simplicity: Show only essential information • Customization: Allow changes to the layout • Interactive design • Transparency and security • Regulatory compliance	• AI model creation • Performance visualization • Comprehensive reporting	AI dashboard "AIDash" for credit assessment model management
Salvi et al. [6]	Public Health	User-centered design	1. User needs assessment 2. Data integration 3. Visualization design 4. Dashboard development 5. User evaluation	• User-centered design • Data privacy and security • Actionable insights • Intuitive visualizations • Timeliness	• Overdose touchpoint visualization • Interactive visualizations • Data integration	Real-time dashboard for enhancing overdose prevention efforts
Conrow et al. [5]	Mobility Data	Iterative user-centered design	1. Identify purposes/users 2. Specify data implementation 3. Create trajectory model 4. Build with user input 5. Involve users at all stages	• User-centered design • Interactive design • Visual design for effective communication • Data model development	• Indicators and maps • Interactive filters • Dynamic features	Conceptual framework for big mobility data dashboards
Bach et al. [8]	Cross-industry	Systematic analysis	1. Define data selection 2. Establish structure 3. Design pages 4. Add interactivity 5. Select color scheme	• Optimize screen space • Use color purposefully • Provide context for data • Consider different audience needs • Accessibility considerations	• Visual display patterns • Data exploration • Information presentation	Comprehensive set of 64 dashboard design patterns
Wu et al. [7]	Data Visualization	Deep-learning method	1. Define purpose/questions 2. Select data sources 3. Choose chart types 4. Design layout 5. User testing	• Foster human computer collaboration • Balance automation with user control	• Automated visualization • Analytical insights	Deep learning algorithm for analytical dashboard assistance
Pestana et al. [2]	Healthcare	Design science research	1. Research and ETL 2. Initial proposal 3. Demonstration/evaluation 4. Feedback implementation	• Gestalt visual perception principles • Proximity, similarity, enclosure • Visual hierarchy for KPIs	• KPI monitoring • Performance comparison • Trend visualization	Web-based hospital productivity management dashboard
Balletto et al. [16]	Tourism	Convergent parallel design	1. Define framework 2. Define layout 3. Analyze characteristics 4. Collect user content 5. Develop dashboard	• Highlight points of interest • Provide detailed travel information • Intuitive geographical representation	• Walkability index • Attractiveness index • Maps and charts	Dashboard for slow tourism in green infrastructures
Young & Kitchin [15]	Urban Management	Cognitive Task Analysis	1. Establish purpose 2. Identify audience 3. User research 4. Create personas 5. Content strategy	• Integration of HCI research • User-centered civic design • Multi-platform compatibility	• Multiple visualization types • Real-time displays • Interactive features	Design guidelines for building user-centered city dashboards
Elshehaly et al. [9]	Healthcare Quality	Metric Specification Structure	1. Investigate challenges 2. Healthcare interviews 3. Design metric cards 4. Create specification 5. Deploy and enhance	• Task sequence optimization • Metric definition standardization • Visual feature consistency • Adaptable dashboard structure	• Quality metrics visualization • Adaptive displays • Metric structures	QualDash for healthcare quality improvement metrics
Ahdan et al. [17]	Energy Management	IoT implementation process	1. Assemble tools 2. Build prototype 3. Develop application 4. Test and rebuild	• Flexibility in control • Efficient energy usage • User-friendly interfaces	• Real-time monitoring • Device control • Mobile accessibility	IoT-powered mobile dashboard for energy monitoring

Kokoç & Altun [13]	E-learning	Iterative design	1. Reorganize database 2. Plan visualizations 3. Design dashboard 4. Expert feedback	• Simple and comprehensible interface Learning progress visualization	• Learning behavior visualization • Predictive modeling	Prescriptive learning dashboard for performance improvement

B. Ontological Approaches in Dashboard Design

Ontological approaches have shown strong potential in formalizing complex structures within information systems, enabling standardized representation and promoting semantic interoperability. While widely applied in domains such as business modeling, particularly through frameworks like the BMO [12], their adoption in dashboard design remains limited.

As Eppler and Burkhard [14] argue, the development of structured visualization tools necessitates a solid conceptual backbone to ensure clarity, coherence, and reusability. However, none of the twelve studies reviewed in this paper explicitly apply ontological methods in dashboard development. This absence underscores a methodological gap in current practices. Nevertheless, recent implementations in fields such as mobility analytics [5] and educational dashboards [13] demonstrate more structured design practices, suggesting the untapped potential of ontological modeling to enhance consistency, scalability, and transferability across interface designs.

Formalizing design knowledge through ontological approaches offers several advantages, particularly in enabling standardization and aligning design logic with governance structures. Guizzardi's ontological foundations [36] offer methodological rigor that supports semantic precision and conceptual clarity in defining dashboard components. Similarly, recent work by [52] highlights how unified ontological frameworks can promote consistent modeling while maintaining flexibility for contextual adaptation.

By applying ontological principles, dashboard design can move beyond fragmented, ad-hoc development toward a more coherent and reusable foundation. This shift not only supports cross-domain implementation but also facilitates the embedding of governance requirements within the design structure itself, an aspect further explored in the following sub-section on IG.

C. IG and Dashboard Design Reliability

IG offers a comprehensive set of standards and practices to ensure that information assets are managed with accuracy, security, and accountability [10]. However, a review of the twelve dashboard studies conducted in this study reveals that none explicitly incorporate IG principles into their design methodologies. While some acknowledge compliance-related concerns or data accuracy issues, governance integration is often implicit or entirely absent from the design framework.

In the context of dashboard design, integrating IG principles helps organizations align their visualization tools with broader compliance and data integrity goals. As noted by Datta et al. [18], IG frameworks play a pivotal role in maintaining the trustworthiness of information flows within decision-making systems. Organizations with established governance mechanisms also exhibit stronger information standardization across units [19]. Conversely, the lack of governance integration can result in data inconsistencies, increased risk exposure, and reduced decision reliability [20], [21]. Embedding IG principles as part of dashboard methodologies could ensure that design outputs maintain regulatory compliance and reflect high information quality [22], [23].

D. Gaps in Current Approaches and the Need for a Standardized Methodology

The synthesis of dashboard design literature highlights three persistent challenges that limit progress in establishing standardized dashboard development practices. First, most reviewed methods are highly domain-specific and lack the generalizability needed for cross-organizational adoption. Second, while ontologies have proven effective in other domains for formalizing and structuring design logic, none of the twelve studies reviewed incorporate them directly into dashboard methodologies. Third, despite growing awareness of governance importance, none of the studies examined explicitly integrate IG principles into the design process, resulting in potential risks to data reliability and organizational compliance.

These gaps emphasize the need for a standardized methodology that embeds both ontological modeling and governance structures into dashboard development. Such a framework would support methodological consistency, formalized design knowledge, and governance alignment throughout the lifecycle of dashboard creation. An ontology-driven approach that integrates IG principles potentially offers a scalable solution for organizations seeking to design dashboards that are not only functionally effective but also aligned with compliance standards, promoting greater usability, accountability, and organizational learning.

III. METHODOLOGY

This study adopts Design Science Research Methodology (DSRM) to guide the development of the IDDO and the IDDM Canvas. Rooted in Simon's foundational work, The Sciences of the Artificial [24], DSR offers a structured, artifact-oriented approach to addressing complex design problems. Originally formalized within information systems research [25], the methodology has gained traction across various applied domains, including dashboard development and business modeling [26], [27].

DSRM is particularly suited for structuring the development of purposeful tools, as demonstrated by successful applications like BMC [28]. In this study, the DSRM framework is complemented by the Unified Ontological Approach (UOA) [29], which serves as the ontology development methodology. The integration of UOA facilitates the formal modeling of dashboard design components by translating fragmented design logic into structured ontological representations that can be systematically reused across development scenarios.

The use of DSRM is justified by its effectiveness in guiding the structured development of design artefacts within information systems [30], [31], [32]. Its applicability to ontology-based design is further reinforced by recent studies on conceptual modeling frameworks [33]. Together, DSRM and

UOA form a robust methodological foundation for developing the IDDO conceptual framework and the IDDM Canvas, ensuring the resulting artefacts are valid, usable, and applicable across diverse dashboard design contexts.

A. Research Design for IDDO Development

This study focuses on the first three stages of the DSRM proposed by Peffers et al. [25], as illustrated in Fig. 1. The demonstration and evaluation involving dashboard mock-ups are reserved for future research, while this study represents the communication stage by detailing the conceptual and design artifacts developed for dashboard methodology enhancement.

Table II summarizes the research activities and outcomes associated with each implemented DSRM stage.

B. Framework Development and Evaluation

The IDDO was developed using an iterative, model-driven approach. IG principles in this study context were used as a guiding theoretical foundation and serve as the Kernel Theory, consistent with the Kernel Theory Fundamentalist perspective proposed by Gregor and Jones [35]. The adoption of a Kernel Theory reinforces the theoretical grounding of IDDO while supporting its practical application as a structured modeling tool. The structured development process was executed through four modeling and evaluation stages, as outlined in Table III. The structured modeling process establishes IDDO as a robust framework that integrates governance elements into the formal structure of dashboard design. By combining ontological rigor with compliance-oriented design considerations, the resulting framework enhances consistency, reusability, and adaptability across organizational contexts.

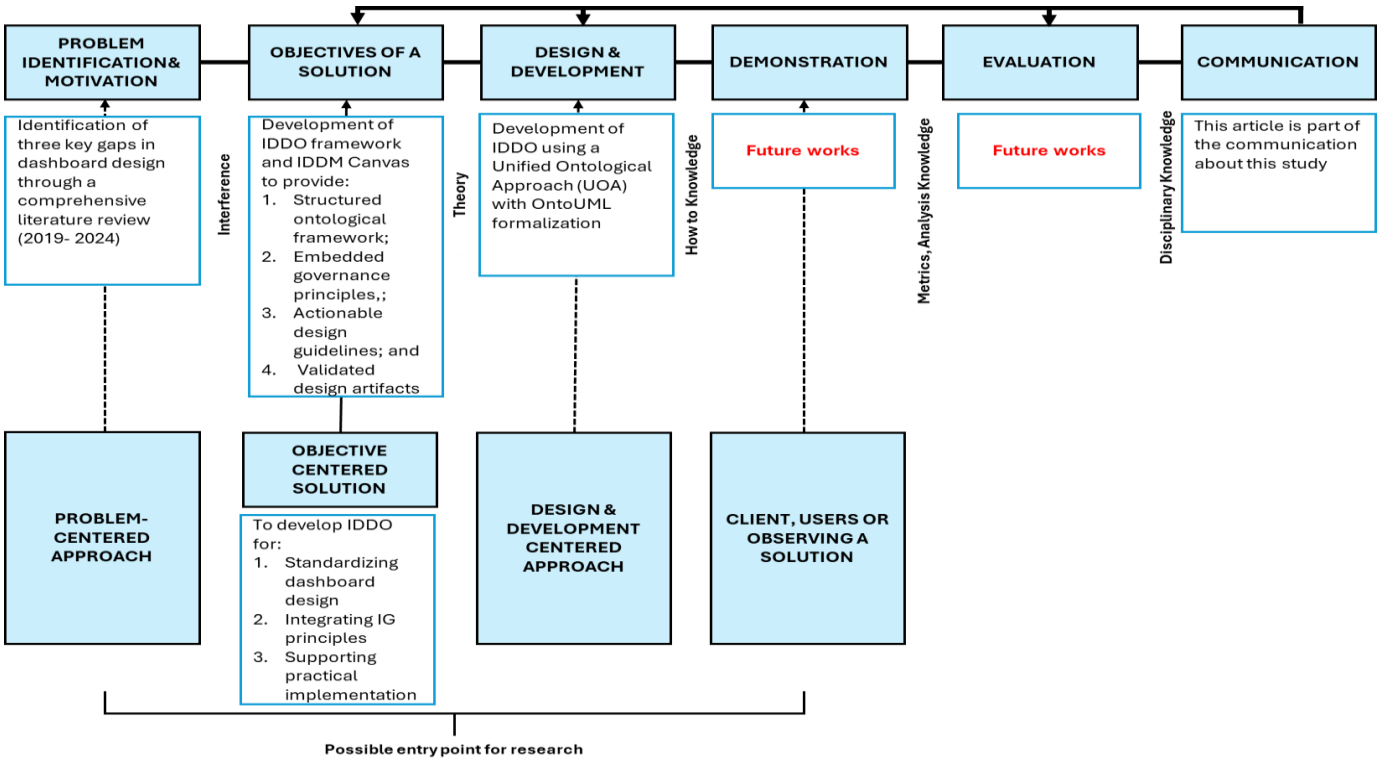

Fig. 1. DSRM implementation for IDDO development (focusing on the first three stages).

TABLE II. SUMMARY OF IMPLEMENTED DSRM STAGES

DSRM Stage	Research Activities	Outcomes
Problem Identification	Review of twelve recent studies (2019–2024)	Identified three major gaps: 1. Lack of standardized design methodology 2. Limited use of ontology 3. Absence of governance integration
Solution Objectives	Definition of design objectives and scope	Established four objectives: 1. Structured ontological framework 2. Embedded IG principles 3. Actionable design guidelines 4. Design artifact validation
Design & Development	Iterative modeling using the UOA	Developed two artifacts: 1. IDDO: an ontology-based dashboard design framework 2. IDDM Canvas: a practical dashboard design method.

TABLE III. IDDO DEVELOPMENT PROCESS

Stage	Activity	Description
UML-Based Modeling	Conceptual modeling in UML	Initial structuring of dashboard design elements using Unified Modeling Language (UML).
OntoUML-Based Refinement	Ontological formalization	Used OntoUML to enhance the semantic precision and clarity of design constructs [36].
OntoUML Plugin Validation	Syntactic model validation	Applied the OntoUML Plugin in Visual Paradigm to detect modeling inconsistencies.
Conceptual Evaluation with UFO	Ontological soundness assessment	Assessed the model against Unified Foundational Ontology (UFO) principles to verify semantic integrity.

The next section elaborates on the development of the IDDO and the formulation of the IDDM Canvas, which translates these components into a practical design methodology for dashboard development.

IV. DEVELOPMENT OF THE IDDO

The development of IDDO, the primary artifact and key contribution of this study, involves a systematic and rigorous process to establish a standardized framework for the information dashboard design method. This section details the methodical process of identifying essential building blocks, incorporating IG principles for information quality, and formalizing the ontological framework, laying the foundation for a governance-driven, standardized dashboard design methodology.

A. Establishing the Building Blocks

The building blocks of the IDDO are derived from a comprehensive analysis of recent works in dashboard design (2019-2024) as summarized in Table I earlier. Through a narrative review of twelve previous studies, key commonalities in design phases, visualization principles, and essential features were identified and summarized in Table IV.

These insights informed the derivation of twelve key building blocks within the IDDO framework. The elements were consistently observed across the reviewed studies and are conceptually organized as illustrated in Fig. 2.

This analytical process aligns with established ontology development practices, where recurring elements across multiple studies are consolidated to form structured frameworks [37], [12]. Similarly, Bernardo et al. [38] applied a systematic approach to identify critical components in the lifecycle of Business Process Management (BPM), demonstrating how synthesis of prior works can reveal design patterns suitable for standardization. Recent work by Leong et al. [57] further demonstrates the applicability of BMO-inspired approaches in developing ontologies for specialized dashboard contexts, such as virtual reality environments, reinforcing the transferability of ontological modeling principles across different visualization domains.

TABLE IV. KEY COMMONALITIES IN DESIGN PHASES, DESIGN PRINCIPLES, AND ESSENTIAL FEATURES

Commonalities		
Design Phase	***Design Principles***	***Essential Features***
• Problem identification • Design and modelling • Development and implementation • Testing and evaluation • Iterative process and feedback	• Reduce pages • Optimize screen space • Use color purposefully • User-friendly interfaces • Effective information visualization • Tailored visualization approaches • Ensure accessibility • Simplify the design	• Visual display of important knowledge • Interactive information visualization displays • Drill-down capabilities and knowledge exploration • Presentation of analytical knowledge insight

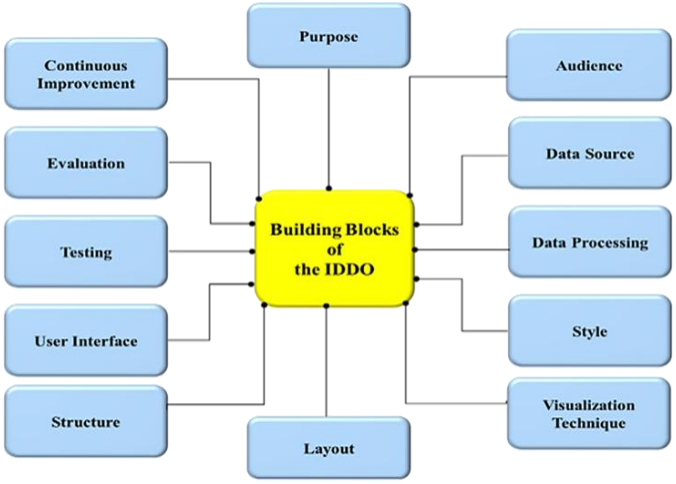

Fig. 2. Twelve key building blocks of the IDDO.

Building upon these approaches, IDDO integrates common patterns across dashboard design literature to promote semantic consistency, governance integration, and methodological standardization. The twelve building blocks illustrated in Fig. 2 were derived from these observed patterns and are summarized in Table V.

The derivation process was informed by the recurring elements identified in the reviewed studies (as shown in Table IV), but the resulting terminology was intentionally refined to ensure clarity, contextual relevance to IDDO, and ease of interpretation, while preserving the original intent of each component.

Drawing inspiration from the structure of the BMO developed by Osterwalder [12], which has been widely adopted for business model development, the IDDO building blocks are organized into three logical categories: Defining and Planning, Design and Visualization, and Testing and Improvement. This categorization reflects a structured and phased design approach, aligning closely with ontology development principles for information systems.

Table VI outlines how the twelve building blocks are distributed across these categories. The Defining and Planning category establishes the dashboard's foundation, encompassing Purpose, Audience, Data Source, and Data Processing. The Design and Visualization category focuses on interface elements that shape user interaction, while the Testing and Improvement category supports continuous refinement through validation and quality assurance measures.

TABLE V. DERIVATION OF KEY BUILDING BLOCKS FOR THE IDDO FRAMEWORK

The Key Building Block	Commonalities From Where The Building Block Is Derived	Basis
Purpose	• Problem identification. • Deliver meaningful insights to users. • Development and implementation.	• Defines the dashboard's core problem and direction. • Guides the delivery of meaningful insights to users. • Influences all development and implementation decisions.
Audience	• Tailor best practices to the specific requirements of each domain. • User-friendly interfaces. • Tailor design approaches	• Specifies target users and their information needs. • Shapes design and functionality based on user requirements. • Enhances relevance through user-centric approaches.
Data Source	• Drill-down capabilities and data exploration. • Presentation of analytical data insight.	• Determines information range and depth for display. • Enables data exploration and drill-down capabilities. • Provides foundation for analytical insights.
Data Processing	• Reduce data selection overhead and automate selection for multiple charts. • Presentation of analytical data insight.	• Facilitates data transformation and preparation • Automates chart data selection to reduce overhead • Ensures data quality throughout the processing pipeline
Style	• Use color purposefully. • Minimize visual effects. • Create intuitive and visually appealing information dashboards	• Guides purposeful color use for enhanced comprehension • Minimizes visual effects to focus on data presentation • Maintains consistent visual design across the dashboard
Visualization Technique	• Effective data visualization. • Use diverse chart types to effectively present information. • Visual display of important information.	• Determines data representation methods for effective communication. • Supports use of diverse chart types for optimal information display. • Enhances data interpretation through appropriate visual formats.
Layout	• Optimize screen space. • Balance information display.	• Optimizes screen space for information display. • Ensures balanced arrangement of dashboard elements. • Enhances readability and intuitive navigation.
Structure	• Simplify the design. • Provide context.	• Defines organization and hierarchy of dashboard elements. • Simplifies complex information through logical structuring. • Supports intuitive navigation between components.
User Interface	• User-friendly interfaces. • Use minimal graphical user interface (GUI) elements for effective interaction.	• Facilitates access to dashboard features and functionalities. • Enhances overall user experience and usability. • Serves as the primary interaction point between users and data.
Testing	• Test and validate dashboards for quality assurance. • Testing and evaluation	• Validates data accuracy and visualization correctness • Identifies and resolves usability issues pre-deployment • Ensures functionality meets requirements
Evaluation	• Testing and evaluation. • Deliver meaningful insights to users.	• Assesses dashboard effectiveness in delivering insights • Measures user satisfaction and dashboard performance • Identifies improvement opportunities
Continuous Improvement	• Iterative process and feedback. • Tailor best practices to the specific requirements of each domain.	• Enables ongoing refinement based on feedback. • Adapts to evolving user needs and business requirements • Creates optimization feedback loop for dashboard enhancement

TABLE VI. CATEGORIZATION OF THE BUILDING BLOCKS

Category		
Defining and Planning	***Design and Visualization***	***Testing and Improvement***
Building Blocks		
• Purpose • Audience • Data Source • Data Processing	• Style • Visualization Technique • Layout • Structure • User Interface	• Testing • Evaluation • Continuous Improvement

This systematic organization offers a clear pathway that guides dashboard developers from initial scoping to iterative enhancement. By structuring the building blocks in this way, the framework fosters a coherent understanding of how each component contributes to the overall dashboard architecture while reinforcing governance integration throughout the development process. The next section discusses how IG principles are embedded into the IDDO to strengthen compliance and ensure information quality.

B. Integrating Information Governance into IDDO

Embedding IG into the IDDO framework represents a key advancement in aligning dashboard design with quality, compliance, and accountability requirements. While IDDO adopts a structural modeling approach inspired by the BMO [12], the integration of IG principles differentiates it by embedding governance mechanisms directly into design logic and model semantics. This approach follows the Kernel Theory Fundamentalist perspective [34], [35], ensuring that the ontology is grounded in established theoretical foundations relevant to information systems design.

Effective dashboards rely on high-quality information, specifically, attributes such as accuracy, reliability, and security. Shortcomings in these areas can lead to misinterpretation or poor decision-making [39], [40]. Despite the critical role of information quality, dashboard design methodologies have often neglected the integration of formal governance principles. This study addresses that gap by embedding IG into the foundational layers of IDDO to support governance-aligned dashboard development.

The rationale for this integration stems from the limited linkage between IG and dashboard design in existing literature. This research responds by identifying core IG principles from established models and synthesizing them with practical dashboard design requirements, resulting in a tailored governance foundation suited to the information context of dashboards.

C. Deriving Key IG Principles for IDDO

The integration of IG principles into the IDDO is based on a structured synthesis of established IG models and relevant literature. Similar to the derivation of the twelve key building blocks of IDDO, this process ensures that the selected IG principles align not only with compliance and regulatory requirements but also with structured and user-centered dashboard development. As emphasized by Kooper et al. [41] and Smallwood [42], IG is not a one-size-fits-all framework. Although various studies have proposed IG principles [18], [21], [43], their applicability must be tailored to specific industries and information contexts.

Nasir et al. [44] highlight the difficulty in identifying universally applicable IG principles, reinforcing the view of Kooper et al. [41] and Smallwood [42] that IG selection should remain flexible and aligned with organizational objectives. An initial study by Nasir et al. [45] on unified information dashboard design identified common dashboard design principles that informed the selection of IG principles for IDDO. The adopted IG principles are drawn from two sources: 1) a synthesis of three established IG models and relevant literature to ensure governance and regulatory alignment, and 2) common design principles identified by Nasir, Ely Salwana, et al. [45] to ensure practical, user-centered governance. Based on this dual synthesis, Nasir et al. [44] proposed eight IG principles to serve as the foundational governance structure for IDDO, as illustrated in Fig. 3.

Fig. 3. Relevant IG principles as the foundational governance of the IDDO (Nasir et al. [44]).

After identifying the relevant IG principles, the next step was to map them onto the IDDO framework to strengthen the governance layer in dashboard design. The eight selected principles were chosen for their relevance and practical applicability in ensuring information quality, reliability, and security across diverse sectors. Each principle reinforces the integrity and traceability of dashboard components while supporting compliance with organizational and regulatory standards. Their inclusion aligns core design elements with established information management practices, particularly in sectors with stringent data requirements such as healthcare and financial services. Table VII summarizes the eight IG principles and illustrates how each supports IDDO's structural goals, enhancing governance alignment and dashboard reliability.

TABLE VII. SELECTED IG PRINCIPLES AND THEIR RELEVANCE TO IDDO

IG Principle	Core Function	Relevance to IDDO
Quality	Ensures information accuracy and timeliness	Supports reliable decision-making through accurate dashboard data
Security	Protects against unauthorized access	Safeguards sensitive information while maintaining data integrity
Accountability	Defines clear roles and responsibilities	Establishes ownership of information management processes
Transparency	Provides visibility into information handling	Builds user trust through clear data sources and processes
Compliance	Ensures adherence to regulatory standards	Enables tracking and reporting of compliance metrics
Integrity	Maintains data consistency from source to output	Preserves information consistency and prevents corruption
Availability	Ensures information accessibility	Supports real-time decision-making with timely access
Effectiveness	Measures dashboard alignment with objectives	Ensures actionable insights that fulfill organizational goals

The selection of these eight principles reflects not only their foundational role in IDDO but also their direct relevance to the diverse requirements of dashboard design across sectors. Embedding these principles within the IDDO framework strengthens the dashboard design process with robust governance mechanisms, ensuring that information remains accurate, secure, compliant, and valuable for knowledge-based decision-making.

After identifying the twelve building blocks and the eight relevant IG principles in this sub-section, these elements are integrated and formally presented using an ontological approach to establish the IDDO framework, the primary knowledge contribution of this study. The following sub-section will explore the development of the formalized IDDO framework in detail.

D. Establishing the IDDO Framework

This sub-section introduces the IDDO framework, the core artefact of this study, detailing its structure and formalization. As outlined in the methodology, IDDO was developed using the Unified Ontological Approach (UOA), an ontology development method (ODM) introduced by Nasir, Firdaus Sulaiman et al. [29], which systematically translates building blocks and IG principles into a formal structure tailored for dashboard design.

The adoption of ontology aligns with Gruber's [46] view of ontology as a specification of conceptualization, and with Noy and McGuinness's [47] emphasis on structuring domain-specific entities and relationships. Incorporating these foundations, the IDDO framework organizes components semantically with clearly defined relationships to support structured and reliable dashboard development, consistent with recent perspectives by Liu et al. [48] on formalizing complex information systems.

Inspired by frameworks like the BMO [12], IDDO is designed as a top-level ontology that dashboard designers across varying expertise levels can adopt, reflecting Guarino's [49] concept of a broad yet rigorous ontological structure. This balance ensures both usability and structural standardization.

The formalization of IDDO employs OntoUML, a modeling language grounded in the Unified Foundational Ontology (UFO) [36], [50], [51], enhancing semantic precision and conceptual clarity. OntoUML enables the explicit and consistent definition of dashboard components and interrelationships while embedding IG principles to ensure traceability and governance alignment.

Fig. 4 illustrates the formalized IDDO framework, integrating IG principles within a unified ontological model for dashboard design. Formalized using OntoUML and grounded in Unified Foundational Ontology (UFO) principles [52], the framework ensures conceptual clarity, structural consistency, and supports standardization, interoperability, and governance-aligned development practices.

OntoUML stereotypes represent ontological categories derived from UFO [50]. The ⟪kind⟫ stereotype defines rigid, identity-providing types (e.g., Purpose, Structure), while ⟪role⟫ captures anti-rigid types that may evolve over time (e.g., Data Processing). Intrinsic properties such as Style are modeled using ⟪mode⟫, temporal states like Testing and Evaluation are represented by ⟪phase⟫, and measurable attributes, including IG principles, are categorized as ⟪quality⟫. Component relationships are expressed through semantic links such as "characterizes", "influences", and "governs", ensuring accurate interaction modeling.

Structurally, Purpose (⟪kind⟫) characterizes Audience (⟪kind⟫), establishing dashboard context. Data Source (⟪datatype⟫) and Data Processing (⟪role⟫) manage information flow, while Style (⟪mode⟫), Visualization Technique (⟪kind⟫), and Layout (⟪kind⟫) define visual presentation. Structure (⟪kind⟫) organizes the architecture, and User Interface (⟪kind⟫) facilitates user interaction. Testing, Evaluation, and Continuous Improvement (⟪phase⟫) embed iterative mechanisms for quality and compliance.

Two superclasses ensure ontological validity: Processing Activity (⟪kind⟫) grounds Data Processing (⟪role⟫), and Quality Assurance (⟪kind⟫) supports quality-related phases, following Guizzardi's [36] principle that anti-rigid types must derive from rigid foundations to maintain identity criteria.

Eight IG principles (⟪quality⟫) are embedded: Effectiveness and Transparency guide design intent; Quality, Integrity, and Compliance ensure data trustworthiness; Security and Availability safeguard access; and Accountability underpins governance and traceability. This integration balances practical dashboard development with governance expectations.

Through this formalization, IDDO offers a rigorous and reusable design structure, integrating twelve dashboard building blocks, eight governance-aligned IG principles, and necessary ontological superstructures to ensure theoretical soundness and practical relevance. The next section outlines the evaluation process used to validate IDDO's structural and conceptual consistency.

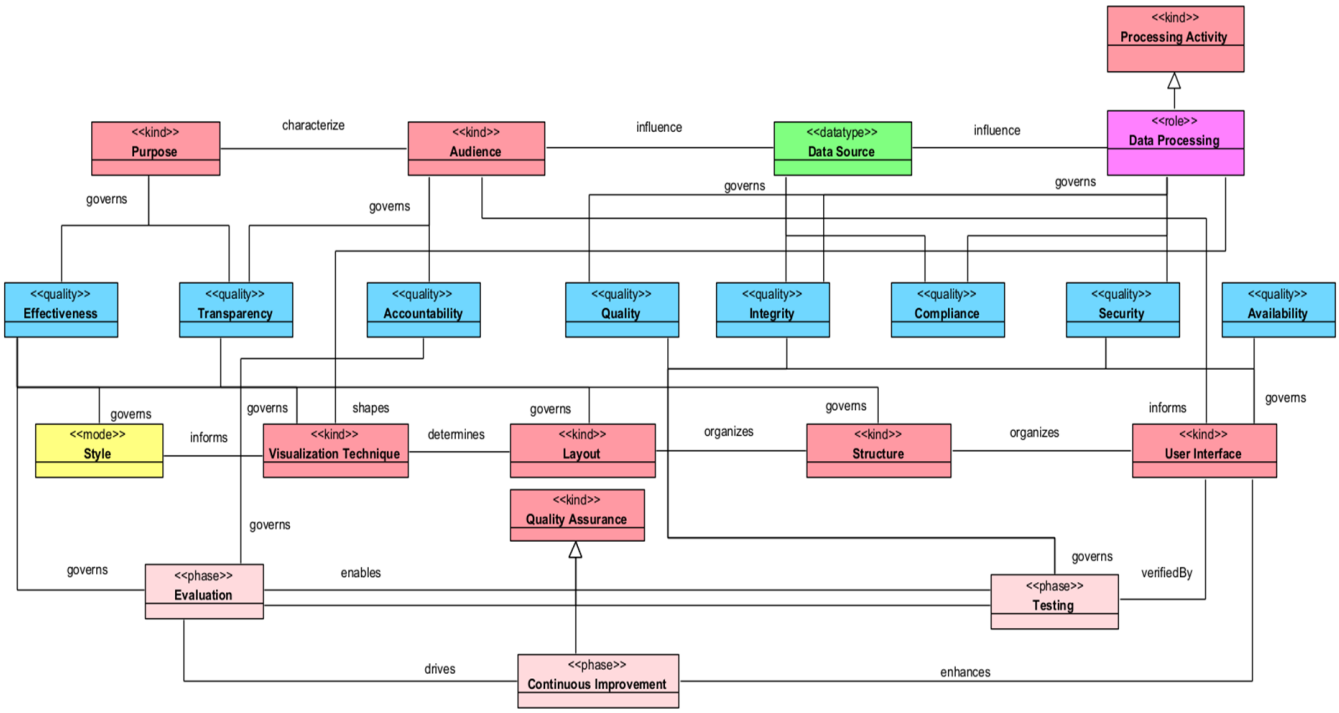

Fig. 4. The IDDO Framework.

E. Evaluation Result and Discussion

The evaluation of the IDDO framework employed a dual-method approach to ensure both structural and conceptual soundness, critical for standardizing dashboard design processes [53], [54]. Tool-based syntactic validation using the OntoUML Plugin was combined with a conceptual assessment grounded in Unified Foundational Ontology (UFO) principles.

While studies like Paul et al. [55] utilized competency-driven testing, this study emphasizes formal validation to establish IDDO's correctness during early development, consistent with best practices [52]. The OntoUML Plugin was chosen for its effectiveness in detecting structural inconsistencies, classification issues, and modeling violations that could undermine framework integrity.

Validation was conducted within the Visual Paradigm environment, systematically checking logical consistency across relationships, hierarchies, and component definitions [56]. The results confirmed IDDO's structural soundness and its suitability as a foundation for standardized dashboard development.

Parallel to syntactic validation, a conceptual assessment based on UFO criteria [36] evaluated component clarity, structural coherence, and relevance to real-world organizational contexts. The assessment verified that IDDO meets ontological adequacy standards and supports governance-aligned dashboard modeling.

Together, these evaluations confirm IDDO as a structurally valid and conceptually coherent ontology. As shown in Fig. 5, the validated framework demonstrates readiness to support standardized, governance-sensitive dashboard development across diverse settings.

This evaluation confirms the structural validity of the IDDO through rigorous tool-based assessment, laying a strong foundation for its progression to practical application. The syntactic validation performed using the OntoUML Plugin marks a critical milestone in the ontology development lifecycle, ensuring the framework's formal correctness prior to any implementation-focused evaluations. This approach reflects established practices in ontology engineering, where structural verification is prioritized before empirical testing [52].

The decision to emphasize tool-based validation at this stage was strategic, enabling the early detection and resolution of fundamental modeling issues that could otherwise undermine the framework's utility in practice. By first securing the ontological soundness and structural consistency of the IDDO, subsequent evaluations can be more confidently directed towards assessing its representational adequacy and practical applicability. Future work will broaden the evaluation scope to incorporate competency-based assessments and stakeholder validation, building upon the structurally verified foundation established here.

In addition to confirming IDDO's formal structure, the evaluation reveals three key implications for dashboard design practice. First, ontological formalization based on the UFO and implemented using OntoUML enhances semantic clarity and minimizes modeling ambiguities that often arise in ad hoc dashboard development. Second, embedding IG principles directly into the ontology promotes compliance-by-design, ensuring that governance is embedded into the system rather than retrofitted post-development. Third, the combined structural and conceptual validation affirms that IDDO provides a transferable foundation applicable across sectors, especially in contexts requiring traceability, reusability, and regulatory alignment.

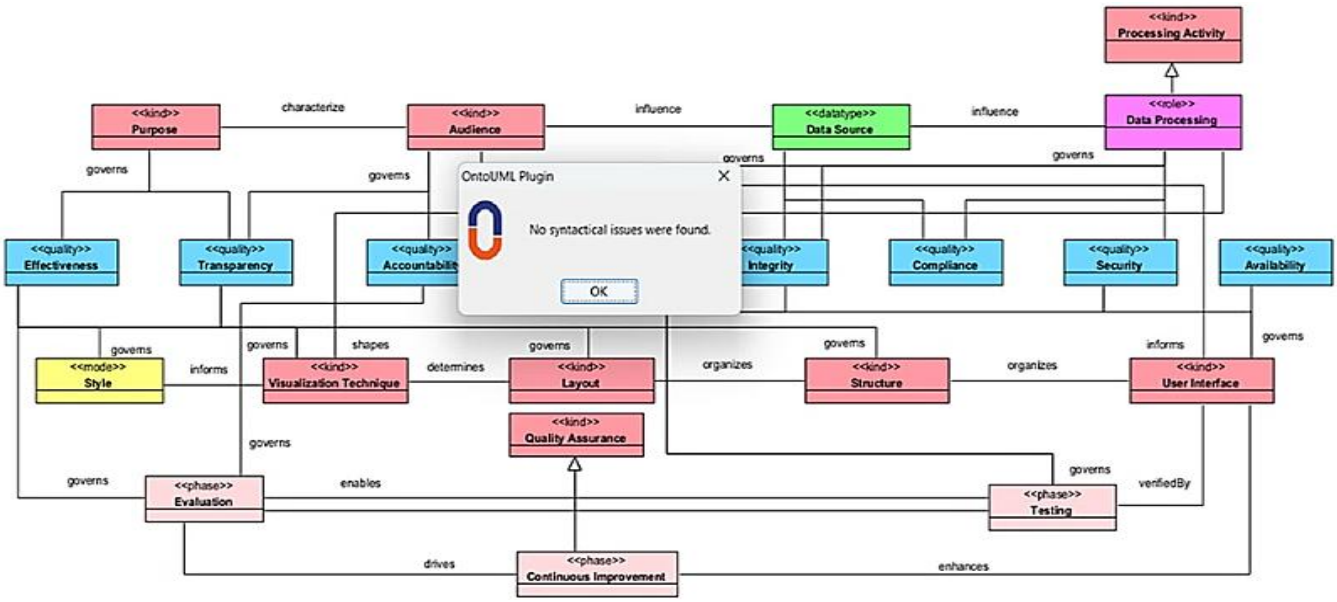

Fig. 5. Syntactical validation results of the IDDO framework.

While no empirical deployment was conducted at this stage, the structural soundness and conceptual completeness of IDDO offer strong theoretical grounding for its real-world application. These insights reinforce the practical relevance of IDDO and provide the rationale for its operationalization through the IDDM Canvas.

Building on this foundation, the following section introduces the IDDM Canvas as a practical design instrument that translates the formal ontology into a structured methodology. This transition from a formalized ontology to an applied methodology marks a crucial step in making governance-integrated dashboard design more accessible and actionable for practitioners across diverse organizational contexts.

V. TRANSLATING IDDO INTO IDDM CANVAS

Though IDDO provides the conceptual backbone, the development of the IDDM Canvas marks a critical leap from theory to practice in dashboard design. Inspired by the translation of the BMO into the widely adopted BMC [28], the IDDM Canvas similarly operationalizes IDDO's building blocks and governance principles into a structured, user-friendly methodology.

The Canvas is organized into distinct design zones that mirror IDDO's core components, streamlining the process of dashboard planning, development, and governance integration. It offers a clear visual layout that guides practitioners, regardless of technical background, through each stage of dashboard creation, embedding conceptual rigor and compliance-oriented thinking along the way.

Each design zone clusters related building blocks, visually mapped to encourage collaboration, support structured decision-making, and promote early stakeholder alignment. This design ensures that governance principles are systematically embedded across the dashboard lifecycle, not treated as an afterthought.

By bridging the gap between theoretical modeling and operational needs, the IDDM Canvas enables organizations to apply IDDO principles with greater consistency, traceability, and strategic coherence. It acts as both a guide and a governance scaffold, helping teams design dashboards that are not only functional but also sustainable and auditable over time.

Fig. 6 presents the layout of the IDDM Canvas, illustrating how the twelve building blocks and eight IG principles are translated into an actionable design guide ready for real-world use.

While the IG principles are not explicitly visualized in the core layout of the IDDM Canvas, they are structurally embedded within the underlying IDDO framework as part of its governance foundation. As discussed earlier, IG does not act as a standalone building block but operates as a cross-cutting dimension that reinforces consistency, reliability, and compliance across dashboard development activities. This deliberate choice to omit IG from the visual Canvas was made to preserve clarity, particularly for non-technical users, while ensuring governance is enforced through structure rather than visual complexity.

This design strategy mirrors the approach taken by Osterwalder and Pigneur [28] in developing the BMC, which was adapted from the more detailed BMO [12].

In that transition, several conceptual and semantic elements, such as meta-relationships and formal dependencies, were intentionally abstracted out to enhance usability without compromising underlying rigor. Similarly, the IDDM Canvas abstracts IG elements while maintaining their operational influence through embedded logic and structural design.

A guided version of the IDDM Canvas is presented in Fig. 7, featuring instructional prompts for each design zone. These prompts provide practical support for users applying Canvas in real-world projects. Red text annotations further highlight specific areas where governance principles are applied, assisting both novice and experienced designers in creating structured, and compliant dashboards.

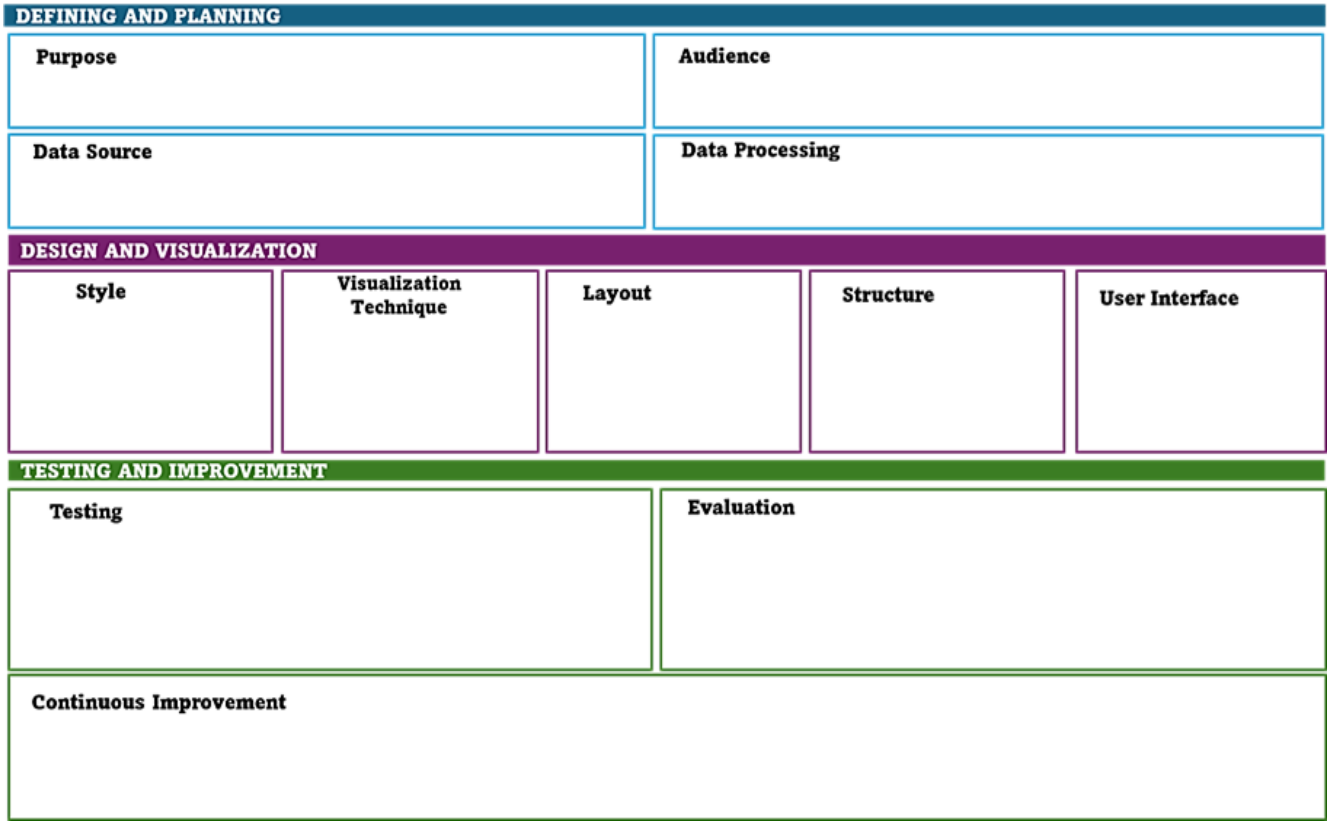

Fig. 6. The IDDM Canvas.

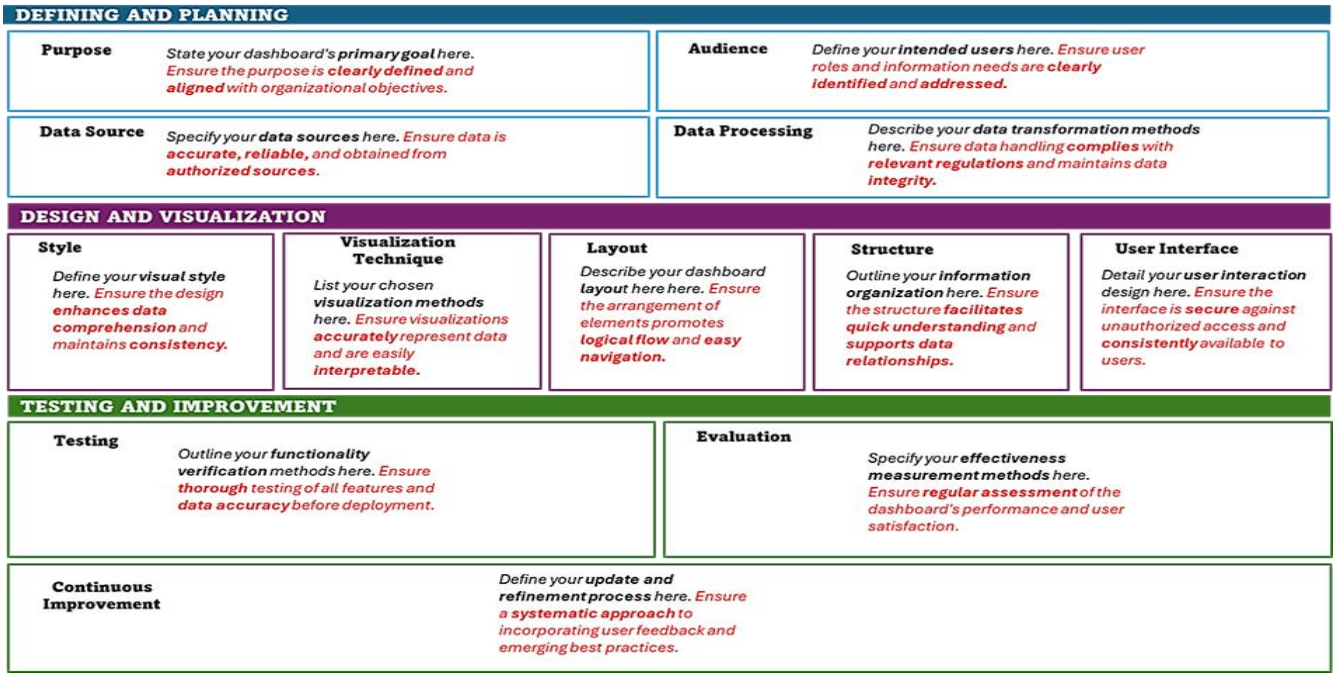

Fig. 7. The IDDM Canvas with instructional guidance.

As depicted in Fig. 6 and Fig. 7, the IDDM Canvas organizes its building blocks into three structured categories, offering a systematic pathway for dashboard development. In contrast to traditional dashboard approaches, which often depend on intuitive or ad hoc design methods, the IDDM Canvas provides a structured, repeatable methodology with governance principles embedded at its core. This structured approach enables organizations to develop dashboards that are not only semantically consistent but also compliant with established organizational standards [18].

TABLE VIII. IDDM CANVAS VERSUS CONVENTIONAL APPROACHES

Aspect	Conventional Dashboard Design	IDDM Canvas Approach
Methodology	Often ad hoc or linear; lacks structured guidance.	Based on a systematic, ontology-driven methodology with defined design building blocks.
Governance Integration	Rarely considers governance principles explicitly.	IG principles are embedded through the foundational IDDO framework and reflected in the design.
Scalability	Difficult to generalize across departments or organizations.	Modular and adaptable for cross-domain implementation.
Usability	Relies on designer intuition; inconsistent results.	Provides clear visual zones and guided prompts, improving consistency and collaboration.
Compliance and Traceability	Compliance requirements are often managed separately or retrofitted.	IG principles embedded from the start; design decisions are traceable and align with compliance standards.

Table VIII presents a comparative analysis between the IDDM Canvas and traditional dashboard design approaches, highlighting key differences in methodology, governance integration, scalability, usability, and compliance.

The IDDM Canvas acts as a practical implementation tool, translating IDDO's conceptual framework into a visual methodology that guides practitioners through a systematic dashboard development process. It facilitates collaborative design sessions by providing a common language and structure, fostering alignment among technical designers, domain experts, and governance stakeholders [42].

VI. CONCLUSION

This study introduced two interrelated artifacts, the IDDO and the IDDM Canvas, to address the lack of standardized, governance-aligned methodologies in dashboard development. IDDO formalizes dashboard design through an ontological structure that integrates IG principles, while the IDDM Canvas operationalizes this structure into a practical, user-centric design tool. Together, they offer a scalable approach to enhance consistency, compliance, and effectiveness across diverse organizational contexts.

IDDO addresses three critical gaps in existing dashboard development practices: the absence of a transferable design methodology, limited application of ontological formalization, and weak governance integration. By combining twelve design building blocks with eight governance principles under a unified structure, IDDO provides a robust foundation for developing governance-compliant dashboards. Formal validation using the OntoUML Plugin confirmed its structural soundness and conceptual coherence.

Furthermore, the proposed IDDO framework and IDDM Canvas have strong practical relevance for organizations aiming to systematize dashboard development while embedding governance compliance by design. Recent recommendations highlight that effective dashboards must prioritize clarity, strategic alignment, and user relevance principles that are embedded in the IDDO structure [61]. Their application has the potential to significantly improve decision-support system reliability, accelerate dashboard deployment cycles, and enhance regulatory traceability.

While IDDO has undergone tool-based validation, the IDDM Canvas has yet to be empirically tested in operational environments, limiting insights into its practical effectiveness. Future research should focus on applying the IDDM Canvas across diverse settings, supported by competency-based testing and stakeholder validation, to gather empirical evidence of its usability, adaptability, and governance alignment in real-world projects. Strengthening the empirical validation of the IDDM Canvas will be key to demonstrating its scalability and contribution to the broader field of governance-integrated information systems design.

***Abstract*—The integration of fifth-generation (5G) communication technology and Artificial Intelligence (AI) is reshaping urban mobility by enabling intelligent transportation systems and smarter cities. This synergy allows real-time traffic management, predictive maintenance, and enhanced autonomous driving, supported by high-speed, low-latency networks and advanced data analytics. By leveraging 5G's strong connectivity, AI systems can process massive datasets to address urban challenges such as traffic congestion, environmental sustainability, and public safety. This study presents a framework that combines 5G and AI to optimize traffic management through dynamic congestion prediction and real-time routing, supported by edge computing. It highlights the benefits of improving traffic flow, reducing emissions, and enhancing overall urban mobility efficiency. In addition, it discusses key challenges including data privacy concerns, cybersecurity risks, and the high cost of infrastructure deployment. By analyzing existing technologies and proposing an AI-driven, 5G-enabled system model, this study aims to bridge the gap between theoretical advancements and practical urban implementations. The findings provide insights into scalable, efficient solutions for the future of smart transportation networks and offer directions for further research in this dynamic and evolving field.**

***Keywords*—5G Edge computing; traffic management; dynamic routing; smart cities; machine learning**

I. Introduction

Urban mobility is evolving rapidly due to the deployment of advanced technologies such as 5G and Artificial Intelligence (AI). These innovations enable smarter, more adaptive traffic management systems capable of responding to real-time changes in urban environments. The ultra-low latency and massive connectivity provided by 5G networks form a robust foundation for deploying AI-powered solutions at scale. In combination, these technologies promise to reduce congestion, improve traffic flow, and support more sustainable and efficient cities.

Recent studies illustrate this potential. Gheorghe et al. [1] demonstrated how AI and IoT, supported by predictive analytics, improve adaptive traffic control systems by enabling real-time decisions. Sharma et al. [2] showed that AI-driven route optimization in vehicular networks contributes to reduced fuel consumption and travel times. These findings confirm that integrating AI and 5G can significantly improve the operational efficiency of urban transportation.

However, existing traffic management systems face persistent limitations. Most rely on centralized architectures, which struggle to process the growing volume of sensor data in real time. They also lack the ability to dynamically adapt to evolving traffic patterns. As a result, cities continue to experience congestion peaks, inefficient route utilization, and increased emissions. There remains a gap between the potential offered by emerging technologies and their actual deployment in urban traffic systems.

This study addresses the challenge of building a scalable and responsive traffic management framework that overcomes these limitations. It proposes a system that combines machine learning models for congestion prediction with dynamic route optimization, all deployed through decentralized 5G-enabled edge computing. The objective is to ensure low-latency decision-making, minimize energy consumption, and improve overall traffic efficiency without relying on centralized processing.

Designing such a system introduces several challenges, including handling heterogeneous and noisy traffic data, maintaining real-time responsiveness at the network edge, and ensuring scalability across diverse urban environments. By integrating AI models with edge nodes capable of local processing and communication through 5G, the proposed framework responds directly to these issues.

The remainder of this study is structured as follows: Section II provides a review of related work. Section III presents the proposed methodology and system architecture. Section IV outlines the experimental results. Section V discusses limitations and future directions. Finally, Section VI concludes the study.

II. Related Work

Numerous studies have explored the intersection of 5G and AI in urban mobility, focusing on specific applications and challenges. Real-time traffic optimization has been a significant area of research, with Gheorghe et al. [1] demonstrating the efficacy of 5G-enabled AI systems in predicting and managing congestion through real-time data analysis and adaptive signal control, supported by edge computing to avoid centralized overload. Su and Xu [3] enhanced this approach with secure cluster-based authentication mechanisms, while Chuan et al. [4] emphasized the importance of robust algorithms to manage rainfall impacts on 5G millimeter-wave channels. Louvros et al.

[5] further highlighted QoS-aware resource management for traffic flow stability.

Autonomous vehicles (AVs), another critical focus, rely on 5G's high-speed connectivity for seamless data exchange. Moubayed et al. [6] demonstrated improved sensor fusion and navigation reliability, while Sharma et al. [2] optimized AV routes to reduce emissions. Khalid et al. [7] introduced hybrid V2X systems for enhanced coordination. Ge et al. (2024) validated 5G mmWave efficiency for single base stations, and Coll-Perales et al. [8] modeled end-to-end V2X latency in dense environments.

In the context of intelligent transportation systems (ITS), Chen and Song [9] explored the use of V2X communication for traffic pattern analysis and public transport enhancement. Their work is complemented by Barzegar et al. [10], who proposed predictive maintenance frameworks, and Amend and Rakocevic [11], who optimized video streaming in 5G-based ITS using multipath scheduling.

Security, data reliability, and resource allocation remain core challenges. Mongay Batalla et al. [12] proposed multi-layer security assurance models, while Rico et al. [13] examined multi-connection protocols for ITS reliability. Meanwhile, An et al. [14] and Vohra et al. [15] introduced distributed resource allocation strategies to process large traffic datasets efficiently. Mukherjee et al. [16] addressed anomaly detection in IoT-based monitoring, and Bonato et al. [17] evaluated exposure variability in 5G-V2X scenarios using deep learning.

A structured summary of these contributions is presented in Table I, highlighting the main technologies used and challenges addressed across representative works.

III. METHODOLOGY AND SYSTEM MODEL

The proposed system integrates data collection, AI-powered congestion prediction, graph-based route optimization, edge computing, and cloud analytics to deliver real-time, scalable, and efficient urban mobility solutions.

The first step involves data collection and integration, where the system aggregates information from diverse sources, including IoT sensors, connected vehicles, and public transportation systems. Smart traffic lights, road sensors, and surveillance cameras provide real-time updates on traffic density, vehicle speeds, and incidents, forming the foundational dataset. Additionally, Vehicle-to-Everything (V2X) communication, enabled by the low-latency capabilities of 5G, ensures seamless data exchange between vehicles and infrastructure, fostering a holistic view of the traffic ecosystem.

At the core of the system lies AI-powered congestion prediction, which utilizes advanced machine learning models to forecast traffic conditions. Historical data, such as traffic volume, weather patterns, and temporal trends, is combined with live sensor inputs and fed into models like Long Short-Term Memory (LSTM) networks. These models are adept at handling time-series data and capturing both temporal dependencies and nonlinear patterns. The process begins with preprocessing, where noisy data is cleaned, and missing values are filled. Subsequently, LSTM models are trained on historical datasets to identify traffic patterns. During real-time operations, live data streams are processed at edge computing nodes, enabling immediate predictions without relying on centralized servers.

Based on the predictions, the system executes graph-based route optimization to dynamically adjust traffic flows. The urban road network is represented as a weighted graph, where nodes signify intersections and edges represent road segments, with weights corresponding to travel times or congestion levels. Real-time congestion predictions trigger dynamic weight adjustments to reflect current conditions. Algorithms such as Dijkstra or A* compute the shortest and most efficient routes for vehicles. A continuous feedback loop updates the graph with live traffic data, ensuring that routing decisions remain adaptive and responsive to evolving conditions.

To address latency and scalability challenges, the system employs edge computing for decentralized processing. Strategically placed edge nodes near data sources aggregate and analyze data locally, reducing the computational load on central servers. These nodes host lightweight AI models capable of making congestion predictions and suggesting optimized routes. They also communicate directly with vehicles via 5G, disseminating real-time traffic updates and route recommendations. This decentralized approach significantly reduces response times and enhances the system's scalability.

Complementing the edge computing layer, cloud integration for long-term analytics ensures continuous improvement and scalability of the system. While edge nodes handle real-time tasks, cloud servers store historical data and retrain AI models periodically to adapt to new traffic patterns. This hybrid architecture balances the need for immediate responsiveness with the benefits of long-term optimization and model refinement, paving the way for an adaptive and sustainable traffic management system.

By combining these elements, the proposed framework addresses the multifaceted challenges of urban traffic management, delivering a robust solution that enhances mobility, reduces congestion, and promotes sustainability.

A. Objectives

The study aims to develop and evaluate a real-time dynamic traffic management system focusing on: Real-time Congestion Prediction, Dynamic Route Optimization.

1) Real-time congestion prediction. The ability to predict traffic congestion in real-time is a cornerstone of efficient traffic management. This involves training AI models, such as Long Short-Term Memory (LSTM) networks or Gradient Boosted Decision Trees, on both historical traffic patterns and live sensor data. Historical data includes traffic volumes, weather conditions, special events, and temporal variations, while live data comes from IoT devices, V2X communication, and GPS-enabled vehicles. These models are designed to:

a) Identify traffic bottlenecks with high precision.

b) Predict congestion levels minutes or hours into the future.

c) Provide actionable insights to traffic management systems for preemptive actions. This prediction process is carried out locally at edge nodes to minimize latency and ensure timely decision-making.

2) Dynamic Route Optimization. Once congestion is detected or predicted, the next step is to dynamically redistribute traffic to alternative routes to prevent or alleviate congestion. The urban road network is modeled as a weighted graph, where nodes represent intersections, and edges represent road segments. The weights of edges correspond to travel times, which are adjusted dynamically based on:

a) Real-time congestion levels predicted by the AI models.

b) Road closures, construction work, or accidents reported through live feeds. Using algorithms like Dijkstra, A*, or even reinforcement learning-based methods, optimal routes are calculated and suggested to vehicles in real-time. A feedback loop is maintained where updated traffic data continuously refines the routing decisions, ensuring adaptability to changing conditions.

3) Energy-efficient transportation. Optimizing traffic flow not only improves travel times but also significantly reduces energy consumption and emissions. Idle times at congested intersections and prolonged travel distances contribute heavily to urban pollution. By dynamically managing traffic:

a) Fuel consumption is reduced by avoiding stop-and-go traffic conditions.

b) Electric vehicles (EVs) benefit from extended range due to smoother traffic flows.

c) Emissions are minimized, contributing to greener and more sustainable urban environments. To further enhance energy efficiency, the system integrates vehicle-specific data (e.g., fuel efficiency or EV battery levels) into the optimization process, tailoring route recommendations for maximum energy savings.

4) Scalable and decentralized architecture. The implementation of 5G and edge computing is critical for ensuring the scalability and responsiveness of the proposed system. The architecture involves:

a) Edge nodes are placed strategically throughout the urban area, these nodes handle real-time data processing, congestion predictions, and route optimization locally. This reduces the computational load on centralized servers and minimizes data transmission delays.

b) 5G Connectivity enables high-speed and low-latency communication between vehicles, edge nodes, and centralized systems. It also supports massive IoT device connectivity, essential for collecting data from diverse sources.

c) Cloud integration: While edge nodes manage real-time tasks, cloud servers are used for long-term analytics, retraining AI models, and storing historical traffic data. This hybrid approach ensures both scalability and the continuous improvement of prediction and optimization algorithms. By decentralizing computational workloads, the system can scale efficiently across cities of varying sizes and complexities while maintaining low-latency decision-making capabilities.

B. Implementation Plan

The implementation of the proposed dynamic traffic management system follows a comprehensive plan designed to ensure scalability and real-world applicability. The initial phase begins with the creation of a simulated urban traffic network using platforms like SUMO (Simulation of Urban Mobility) or OpenStreetMap. These tools enable the generation of realistic traffic scenarios, simulating vehicle behaviors, road layouts, and dynamic traffic signals. The simulation environment provides a controlled setting to test the framework under various conditions, including peak traffic hours, accidents, and road closures, generating a robust dataset for validation.

The second phase focuses on algorithm development, starting with congestion prediction through advanced AI models. Long Short-Term Memory (LSTM) networks, implemented using TensorFlow or PyTorch, are trained on historical traffic data such as vehicle counts, speeds, weather conditions, and time-of-day patterns. These models process live sensor data streams in real time to predict traffic congestion, leveraging their ability to handle sequential data and temporal dependencies. Concurrently, route optimization is performed using graph-based algorithms. The urban road network is represented as a weighted graph, where nodes are intersections, and edges are road segments. Algorithms like Dijkstra or A* calculate optimal routes dynamically, adjusting edge weights based on real-time congestion predictions. A feedback loop ensures that traffic conditions continuously refine routing decisions, maintaining adaptability.

The third phase involves the deployment of edge computing nodes, which are critical for decentralized processing and low-latency operations. Lightweight computational devices, such as Raspberry Pi or NVIDIA Jetson Nano, equipped with 5G connectivity, are strategically placed at high-traffic areas and

key intersections. These nodes host containerized AI models managed through Docker and orchestrated with Kubernetes for scalability and fault tolerance. The edge nodes process data locally, execute congestion predictions, and disseminate route recommendations to connected vehicles in real time, reducing the load on centralized servers.

Finally, the system undergoes real-world testing in collaboration with municipalities or urban traffic authorities. A representative urban area with varying traffic densities is selected for the pilot implementation, where the system integrates with existing traffic management infrastructure. Performance metrics such as average travel time, congestion levels, fuel consumption, and system latency are monitored to evaluate the framework's effectiveness. The collected feedback is used to iteratively refine the system, ensuring robustness and adaptability.

By combining simulation, advanced AI algorithms, edge computing, and real-world testing, the proposed implementation plan offers a scalable and efficient solution for real-time traffic management, paving the way for smarter and more sustainable urban transportation systems.

C. Expected Contributions

This study aims to address the pressing challenges of urban traffic management by introducing a scalable and efficient framework tailored for real-time applications. At its core, the framework leverages a decentralized approach powered by 5G-enabled edge computing, enabling rapid data processing and decision-making directly at strategic points within the urban landscape. By integrating AI-driven congestion prediction with graph-based routing algorithms, the system offers a hybrid optimization model capable of dynamically redistributing traffic to mitigate bottlenecks. Beyond improving traffic flow, the framework emphasizes sustainability by reducing emissions and energy consumption through the elimination of idling and inefficient routes. Furthermore, the study provides a comprehensive blueprint for integrating advanced technologies—such as 5G, AI, and edge computing—into existing urban transportation infrastructures, paving the way for smarter, more adaptive, and environmentally conscious cities.

D. Practical Implementation

As part of this study, we proposed an innovative solution for dynamic urban traffic management, leveraging the integration of 5G, Artificial Intelligence (AI), and edge computing. To validate the presented concepts and illustrate their implementation, an algorithm has been developed to predict traffic congestion and optimize routes in real-time. This implementation relies on machine learning models and graph algorithms, two fundamental pillars for intelligent traffic management.

IV. Results

A. Algorithm – Traffic Simulation and Routing

In this study, we designed and implemented a traffic management algorithm aimed at optimizing urban mobility by dynamically predicting congestion and adjusting routing decisions in real time. The core of the solution combines graph-based optimization methods and machine learning techniques. Initially, congestion levels were estimated using a heuristic congestion scoring formula derived from three traffic features: Traffic Density, Estimated Speed, and Weather Conditions. Based on these scores, the system dynamically adjusted road network weights and calculated optimal routes using Dijkstra's algorithm.

To further enhance prediction reliability and address the complexity of urban traffic patterns, we trained a supervised machine learning model to predict congestion. We selected the Random Forest Classifier for its robustness, ability to capture non-linear relationships, and strong performance on structured traffic data.

a) Input and output: To clarify the data structure used during the simulation phase, the main parameters involved in the proposed traffic management algorithm are summarized in Table II. This table details the inputs required to simulate and evaluate routing scenarios, along with the expected outputs generated by the system.

The inputs include the number of simulated samples, the set of features characterizing each sample (such as estimated speed, traffic density, or incident reports), and the source and destination nodes within the road network. These parameters allow the algorithm to simulate traffic conditions and compute the most efficient path.

The outputs correspond to the resulting optimal route, represented as an ordered list of nodes, and the total cost of that route under the influence of congestion. The cost reflects the dynamic weights applied to the road network based on real-time traffic conditions.

TABLE II. Summary of Inputs and Outputs for the Proposed Traffic Management Algorithm

INPUT	OUTPUT
num_samples: number of simulated data samples	• List of nodes representing the best route. • Total cost considering simulated congestion
num_features: number of features per sample (e.g., speed, density, incidents)	
source: starting node	
target: destination node	

b) Process: A real-world dataset comprising 627 samples was utilized in this study, with each sample initially described by several traffic-related parameters. The primary objective was to simulate traffic conditions and evaluate the impact of congestion on route optimization. To prepare the data for the model, specific features were derived through additional computations, resulting in three key attributes: Traffic Density, Estimated Speed, and Weather Conditions. Missing values were calculated where necessary, and all extracted features were normalized to ensure consistent scaling and comparability.

The original dataset included the following fields:

- TMJA (Average Annual Daily Traffic): Used as an indicator of traffic density, representing the average number of vehicles passing through a segment daily.
- ratio_PL: Denoting the proportion of heavy vehicles, influencing the overall estimated speed on the segment.

- longueur: Length of the road segment, employed to estimate travel speed when time data is available.
- route: Road identifier, enabling cross-referencing with external geographic datasets.
- dateReferentiel: Date of traffic measurement, used for aligning with historical weather information.
- xD, yD, xF, yF: GPS coordinates marking the start and end points of the road segment, facilitating the retrieval of location-specific weather conditions.

The proposed traffic management algorithm was applied across all data points. It involved computing a congestion score, determining a congestion factor when necessary, adjusting the weights of the corresponding road network, and ultimatelycalculating the optimal route under the updated traffic conditions. Below, we detail the normalization process applied to each extracted parameter to ensure consistency and comparability across the dataset.

The extracted features were normalized to ensure consistent scaling. Traffic density was standardized using the min-max formula described in Eq. (1). Estimated speed was calculated from the road segment length and travel time as shown in Eq. (2). Weather conditions were normalized in two steps: first by converting temperature from Kelvin to Celsius using Eq. (3), and then applying min-max normalization as shown in Eq. (4).

Traffic Density:

$$Standardised\ density = \frac{TMJA - \min(TMJA)}{\max(TMJA) - \min(TMJA)} \quad (1)$$

Estimated Speed:

$$Average\ speed = \frac{length}{travel\ time} \quad (2)$$

Weather Conditions:

$$T_{Celsius} = T_{Kelvin} - 273{,}15 \quad (3)$$

$$\text{Weather_conditions} = \frac{Temperature_C - \min(Temperature_c)}{\max(Temperature_c) - \min(Temperature_c)} \quad (4)$$

When the computed congestion score exceeded a threshold of 1, a congestion factor of 0.2 was systematically applied to adjust the network parameters; otherwise, the original weights remained unchanged. Based on this approach, a directed graph representing the road network was constructed, with predefined base weights assigned to each edge. Upon congestion detection, all edge weights were proportionally increased using the congestion factor to reflect the associated traffic delays. Subsequently, Dijkstra's algorithm was employed to determine the shortest path between the defined source and destination nodes within the updated network structure. The final step involved visualizing the adjusted road network to highlight the effects of congestion on optimal routing strategies.

The entire simulation workflow is summarized in Table III, outlining each stage from data generation to route computation.

TABLE III. PROCESS OVERVIEW FOR TRAFFIC SIMULATION AND NETWORK ADJUSTMENT

Step	Action
1. Generate Data	Create num_samples of random data with num_features
2. Estimate Congestion	For each sample: if (f1 + 2*f2 - f3 > 1) → label = high congestion
3. Set Congestion Factor	If congestion is high → congestion_factor = 0.2 else → 0.0
4. Build Road Graph	Create a graph with nodes and standard edge weights
5. Adjust Weights	Multiply all edge weights by (1 + congestion_factor)
6. Compute Route	Use shortest path algorithm (e.g., Dijkstra) from source to target
7. Output Result	Display optimal route and total adjusted cost

c) Algorithm: Following the execution of the steps outlined in Algorithm 1, the adjusted road network was generated. Fig. 1 illustrates the updated graph structure, highlighting how congestion factors impact the routing through modified edge weights.

Algorithm 1: Visualization of the Adjusted Road Network

Initialize:
  Define manual positions for each node.
Compute:
  Create edge labels based on adjusted edge weights.
While (graph is being prepared) do
  Draw network nodes at specified positions.
  Draw directed edges between nodes with arrows.
  Label each node with its identifier.
  Annotate edges with their corresponding weights.
  Update:
    Set title of the graph to "Adjusted Road Network (With Congestion Penalty)".
    Hide axes to enhance visualization.
    Adjust layout for better spacing.
  End
End
Display:
  Render and show the final visualized graph.
End

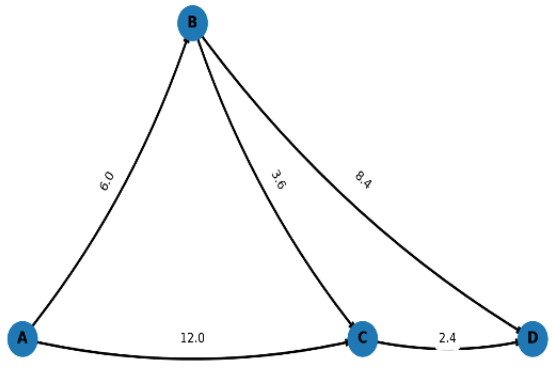

Fig. 1. Adjusted road network visualization considering congestion penalties.

Following the application of a 20% congestion penalty to the edge weights, the network structure was updated to reflect the increased travel costs. Notably, the path A → B → C → D continues to represent the optimal route under the adjusted conditions.

d) Machine learning congestion prediction: To improve traffic congestion prediction and support adaptive routing decisions, we implemented a supervised machine learning approach. The objective was to train a classification model capable of predicting congestion based on real traffic-related variables.

As a starting point, we constructed an initial congestion label (Congestion_Predite) using a heuristic scoring function based on three key features extracted or derived from the dataset [Eq. (5)]:

$$\text{Congestion}_{\text{Score}} = (0.60 \times \text{Traffic Density}) + (0.23 \times \text{Estimated Speed}) + (0.17 \times \text{Weather Conditions}) \quad (5)$$

The binary target variable was then defined using a threshold as in Eq. (6):

$$Congestion_{Predite} = \begin{cases} 1 & \text{if Score} > 1 \\ 0 & \text{otherwise} \end{cases} \quad (6)$$

This labeled dataset served as the foundation for training a Random Forest classifier, which learned more complex and non-linear relationships between the variables and congestion states. This approach allows for generalization to unseen traffic patterns and conditions, improving prediction reliability.

The performance of both the routing and prediction components is influenced by key algorithmic parameters. In the case of the Random Forest classifier, the number of trees (estimators), maximum depth, and minimum samples per split directly affect the model's ability to generalize. A higher number of trees tends to improve robustness, while excessively deep trees may lead to overfitting. For Dijkstra's algorithm, the accuracy of route computation depends on the dynamic edge weights, which are adjusted based on the congestion factor. The choice of base weights and how they scale with congestion (e.g., a 20% increase as used here) influences routing outcomes. These parameters were empirically chosen to balance performance and computational efficiency in real-time settings.

The model's predictive performance was evaluated using standard classification metrics. The results are summarized in Table IV.

TABLE IV. MODEL RESULTS

Metric	Value
Overall Accuracy	99%
Precision (Not Congested)	100%
Precision (Congested)	98%
Dominant Factor	Traffic Density (highest importance)

To assess the effectiveness of the proposed prediction model, we conducted a basic comparison with other standard classification algorithms on the same dataset. Support Vector Machines (SVM), Gradient Boosted Decision Trees (GBDT), and K-Nearest Neighbors (KNN) were evaluated using identical input features and a consistent data split. Among all tested models, the Random Forest classifier achieved the highest accuracy (99%), with better balance between precision and recall. SVM and GBDT followed with slightly lower accuracy scores (95% and 96% respectively), while KNN showed more variance depending on the feature scale and neighborhood size. These results validate the choice of Random Forest for this application, given its robustness, interpretability, and suitability for edge deployment.

These metrics confirm the model's high precision, particularly in identifying congested cases with minimal false positives. Traffic density emerged as the most influential variable, followed by speed and weather conditions. This ranking aligns with known determinants of urban traffic congestion.

Additional evaluation tools, including the confusion matrix, the ROC curve, and feature importance analysis, are presented in the next section to provide further insight into the classifier's behavior and reliability.

The performance of the developed machine learning model was evaluated through several key visualization tools, each offering complementary insights into classification reliability. Among these, the confusion matrix provides a direct view of the model's effectiveness in distinguishing between congested and non-congested traffic segments.

As shown in Fig. 2, the confusion matrix displays the number of correct and incorrect predictions across both classes. The model correctly identified nearly all instances, with minimal misclassification. This confirms its ability to separate the two categories with high precision, reinforcing the metrics reported in Table IV.

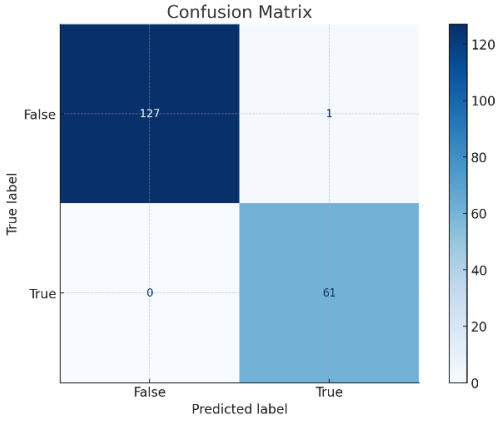

Fig. 2. Confusion matrix.

The confusion matrix summarizes the model's prediction outcomes by displaying the number of correct and incorrect classifications for both congested and non-congested traffic conditions. It provides a clear view of how well the model distinguishes between the two classes, highlighting both true positives and true negatives.

As presented in Fig. 3, the ROC curve plots the true positive rate against the false positive rate. The model achieved an Area Under the Curve (AUC) of 0.99, indicating a near-perfect capacity to discriminate between congested and non-congested traffic conditions.

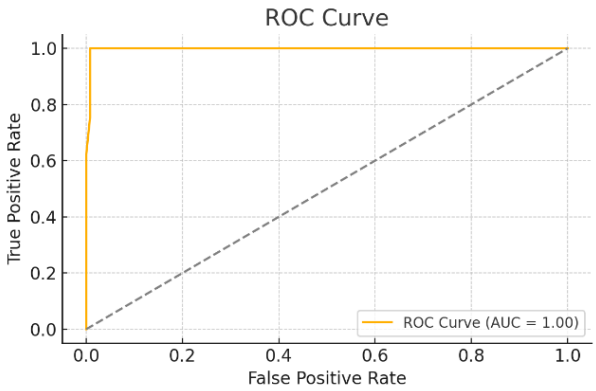

Fig. 3. Receiver Operating Characteristic (ROC) curve.

The ROC curve illustrates the trade-off between the true positive rate and the false positive rate at various classification thresholds. The Area Under the Curve (AUC) achieved a value of 0.99, demonstrating that the model possesses excellent discrimination capability between congested and non-congested states. A near-perfect AUC score reflects the model's robustness and high predictive accuracy.

To further interpret the internal behavior of the model, we examined feature importance, which ranks the contribution of each input variable to the prediction outcomes. This analysis helps identify which factors most strongly influence the classifier's decision.

As illustrated in Fig. 4, traffic density emerges as the dominant variable, followed by estimated speed and weather conditions. The important ranking aligns with domain knowledge, where density is often the primary driver of congestion.

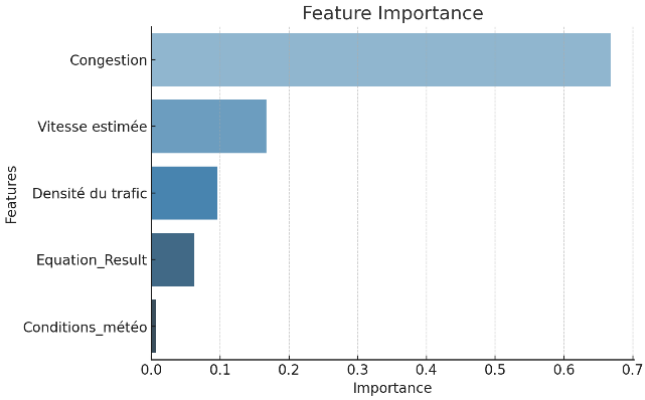

Fig. 4. Feature importance plot.

The feature importance analysis identifies and ranks the contribution of each input variable to the model's predictions. The results show that traffic density is the most influential feature, exerting the greatest impact on the model's ability to predict congestion. Other variables, such as estimated speed and weather conditions, also contribute, but to a lesser extent.

These evaluation tools provide complementary evidence of the model's effectiveness. The confusion matrix, ROC curve, and feature importance collectively validate both its predictive accuracy and its alignment with real-world traffic behavior.

Despite its strong performance, the model presents several limitations. First, the training was based on simulated data, which does not fully reflect real-time traffic irregularities. Second, the system depends on the reliability of sensor inputs, which may be affected by latency, noise, or missing data. Third, the tested road network was simplified, and external factors such as road incidents or construction zones were not included. These constraints may limit the immediate deployment of the system in uncontrolled real-world conditions and require further calibration.

V. Discussion

This study proposed and validated an integrated traffic management framework that combines AI-driven congestion prediction, graph-based dynamic routing, and 5G-enabled edge computing to support real-time decision-making. The methodology was built around two key components: a graph-based traffic simulation and routing algorithm that dynamically adjusted road network weights based on a computed congestion score, and a supervised machine learning model designed to predict congestion states using traffic-related features. Initially, congestion levels were estimated heuristically based on Traffic Density, Estimated Speed, and Weather Conditions, and road weights were adjusted accordingly to guide routing using Dijkstra's algorithm. To enhance prediction reliability beyond heuristic methods, a Random Forest Classifier was developed, chosen for its robustness against overfitting, its ability to capture non-linear feature interactions without extensive preprocessing, its interpretability through feature importance analysis, and its computational efficiency suitable for edge deployment. The model achieved outstanding performance, with an overall accuracy of 99%, a precision of 100% for non-congested cases, and 98% for congested cases, identifying Traffic Density as the dominant predictive factor. These results were reinforced by a confusion matrix analysis and a ROC curve yielding an AUC of 0.99. Compared to other machine learning models, such as SVMs, GBDTs, Neural Networks, and KNN, Random Forests provided the best trade-off between predictive power, scalability, and interpretability, making them particularly suitable for real-time, decentralized urban mobility systems. By combining accurate congestion prediction, adaptive routing, and efficient edge computing, the proposed framework delivers a scalable and effective solution to the evolving challenges of traffic management in smart cities, as illustrated in Fig. 5.

Future work will aim to extend the system's capabilities in several directions. First, the integration with connected vehicle platforms will enable the framework to receive and act upon live feedback from on-road users. Second, deploying the model in a real-world urban environment, in collaboration with traffic authorities, will allow validation under operational conditions. Third, additional traffic dynamics—such as incident detection, weather disruptions, and multi-agent coordination—will be incorporated to improve adaptability. Lastly, the framework will be tested on data from other cities to evaluate generalizability across different urban structures.

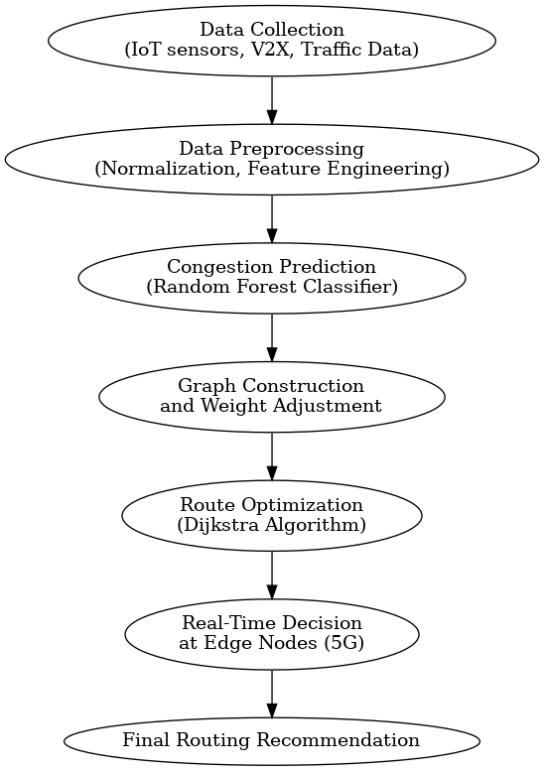

Fig. 5. Traffic management system workflow integrating machine learning and 5G edge computing.

VI. CONCLUSION

This study presented an integrated framework that combines AI-based congestion prediction, dynamic graph-based routing, and 5G-enabled edge computing to support real-time urban traffic management. The main contribution lies in the design and validation of a decentralized system capable of adapting to evolving traffic conditions using machine learning and network optimization in a scalable architecture.

The proposed solution leverages a Random Forest classifier for congestion detection and Dijkstra's algorithm for dynamic routing, applied to a simulated urban environment. The model achieved an overall accuracy of 99%, with strong precision across both congested and non-congested cases. Feature analysis confirmed traffic density as the most influential variable, validating the model's alignment with known traffic behaviors. Additional evaluation tools, such as the confusion matrix and ROC curve (AUC = 0.99), demonstrated the system's robustness and predictive reliability.

By processing data locally at the edge and reacting in near real-time, the system achieves both performance and scalability, meeting key requirements for smart city deployment. Future work will focus on integrating connected vehicle feedback, incorporating real-time disruptions such as incidents or construction, and testing the system across different urban contexts to assess transferability and operational impact.

***Abstract*—This research presents a comprehensive framework for body size estimation that accurately derives anthropometric measurements—specifically, the circumferences of the waist and hips—from a singular image by utilizing OpenPose for joint localization and SMPLify-X for precise 3D body modeling. The proposed methodology involves projecting the generated three-dimensional model onto a horizontal plane and applying a convex hull geometric assessment to extract relevant body measurements. These derived measurements are then classified into standardized clothing size predictions (XS–XL) via a transparent rule-based classification system suitable for e-commerce sizing and virtual fitting applications. Empirical validation conducted on the Agora dataset substantiated the framework's reliability across diverse body types, demonstrating strong consistency with industry sizing standards. The method is non-intrusive and interpretable, effectively addressing practical challenges in automated human pose estimation for retail contexts. Limitations include constraints related to body posture and potential clothing interference; however, the modular design enables enhancements such as integrating chest circumference measurements and mobile deployment. This scholarly contribution thus provides a robust, accessible solution for automated, image-based clothing size recommendations.**

Keywords*—Body size estimation; SMPLify-X; OpenPose; 3D body modeling; clothing size prediction; e-commerce sizing; human pose estimation

I. Introduction

In the current digital epoch, marked by the extensive proliferation of e-commerce, the necessity for accurate and sophisticated techniques to derive human body dimensions from images has markedly escalated—especially in the ready-to-wear fashion industry, augmented reality applications, and virtual fitting features within online retail contexts. A predominant obstacle encountered by online merchants pertains to size-related product returns. Research indicates that as much as 30% of returned apparel arises from discrepancies in sizing or erroneous estimations at the time of purchase [1]. This predicament not only incurs financial and logistical detriments for enterprises but also adversely affects user experience, diminishes customer satisfaction, and erodes trust in virtual retail platforms.

In response, progressive computer vision and 3D modeling technologies have surfaced as promising instruments for addressing this quandary. These technologies facilitate the extraction of body shape, dimensions, and measurements from a solitary 2D image—a process increasingly bolstered by powerful machine learning frameworks. OpenPose, for example, proficiently extracts human joint keypoints under diverse real-world imaging scenarios, including suboptimal lighting or cluttered backgrounds [2], [3].

The identified joints can subsequently be aligned with 3D parametric models such as SMPL and SMPL-X through algorithms like SMPLify-X, which captures intricate body characteristics including hands and facial expressions [4], [5]. Models such as DensePose2SMPL and ExPose have also demonstrated high precision in fitting under various conditions, encompassing loose garments and complex poses [6], [7].

Recent research corroborates that SMPL and SMPL-X surpass conventional measurement techniques by substantially minimizing errors in body circumference estimation, particularly when side-view or fitted clothing data is accessible [8]. Furthermore, models like LayerNet and SMPLicit provide garment-aware reconstructions with semantic garment-layer processing, advancing the frontiers of practical virtual try-on functionalities [9], [10].

Nonetheless, numerous existing frameworks still encounter limitations when faced with non-standard postures, oversized attire, or occluded limbs [11], [12].

To confront these challenges, this study proposes a comprehensive, fully automated pipeline for body size estimation from a single RGB image. The methodology commences with joint detection via OpenPose, followed by 3D body modeling utilizing SMPLify-X, digital measurement calculation, and conclusive size classification employing rule-based logic. The pipeline is crafted for resilience in varied real-world scenarios and can be seamlessly integrated into virtual fitting and e-commerce platforms [13], [14].

For validation, this research employs the Agora dataset [15], which encompasses multi-pose images alongside corresponding 3D data files (obj, pkl, and openpose.json). This extensive dataset facilitates a systematic assessment of each component within the pipeline—from image acquisition to 3D modeling and final garment size categorization.

The remainder of this study is organized as follows: Section II reviews related literature. Section III details the proposed methodology. Section IV presents experimental results. Section V discusses findings and limitations, and Section VI concludes the work.

II. Literature Review

The domain of automatic estimation of human body dimensions has experienced significant advancements in recent years, primarily driven by the exponential rise of e-commerce, virtual fashion, and the increasing need for intelligent digital interfaces that accurately replicate physical human characteristics. A major component of this evolution lies in computer vision methodologies, particularly the synergistic use of OpenPose [16], SMPL [17], and its advanced variants such as SMPLify-X [5], which have enabled the precise extraction and modeling of body metrics from single RGB images.

A notable contribution in this space includes the work of Kuribaya [2], who developed a virtual try-on system capable of dynamically adapting garment sizes to match real-world anthropometrics extracted from joint keypoints. Although the model was lauded for its interactive fit visualization, it primarily prioritized graphical realism over the quantitative accuracy of body dimensions. A similar limitation was observed in the work of Yang et al [18], who proposed a GAN-based virtual try-on model that successfully preserved garment texture and pose alignment but exhibited noticeable fitting errors for users with non-standard body shapes, particularly in waist and hip regions—highlighting the trade-off between aesthetic rendering and dimensional fidelity.

Meanwhile, more metric-focused efforts have emerged. In a large-scale study by [1], a decision tree classifier trained on joint-based features from OpenPose was employed to predict military uniform sizes across 375 subjects. Cross-validation with 3D scanning and manual tape measurements demonstrated over 85% agreement, validating the approach for structured, high-stakes domains. Nonetheless, the scalability of such models to unconstrained consumer environments remains uncertain.

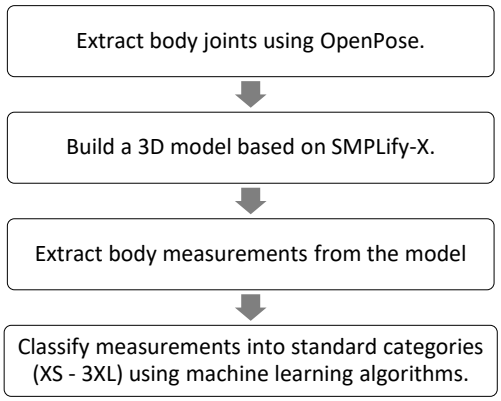
To address modeling accuracy for atypical body shapes, the DensePose2SMPL framework [6] introduced dense correspondence mapping from images to SMPL-based mesh representations. Their method reduced perimeter estimation error by 30% in outlier body cases, underscoring the advantages of combining surface-based mappings with statistical shape modeling.

Another critical advancement came from the DeepProfile model [19], which leveraged deep convolutional networks to predict occluded body shapes beneath garments. Their approach demonstrated superior performance under challenging visual conditions—such as loose clothing—when benchmarked against traditional silhouette-extraction methods [20]. However, its dependency on extensive labeled datasets could pose limitations in diverse real-world applications.

The generative model SMPLicit [10] advanced the state of body-clothing co-representation by embedding garment topology directly into the SMPL parameter space. This enabled realistic simulation of both tight and open garments, making it particularly suited for virtual try-on platforms and AI-driven fashion editors. Nevertheless, the model lacked direct mechanisms for deriving standardized measurements (e.g., waist, chest, hip) used in real-world size classification.

Exploring the democratization of body estimation, Sheth [21] introduced a selfie-based body measurement method using mobile phone images and mirror-based cues. Their system achieved <5% error across 11 anthropometric parameters. Such accessible methodologies—also explored by Jiang and Grauman (2020) in monocular pose-to-shape prediction—illustrate the potential for casual consumer-level body scanning, albeit with constraints related to environment and pose consistency.

From an industrial standpoint, [22] illustrated that three-dimensional geometric modeling generated from comprehensive bodily laser imaging substantially improved the precision of uniform fitting, particularly for female personnel in military environments. Expanding upon this foundation, contemporary developments within the apparel sector have underscored the incorporation of three-dimensional body scans alongside machine learning to facilitate mass customization. For instance, [23] presented a hybrid methodology that merges point cloud information from 3D scanners with clustering algorithms to categorize body types and refine garment patterning. Their methodology surpassed conventional sizing systems in terms of both fit satisfaction and production efficiency, indicating a transition towards volumetric and data-informed design within the realm of fashion e-commerce.



Evaluation strategies across these studies have varied—from manual anthropometry to laser scanning, structured light capture, and virtual garment draping—highlighting a lack of standardized benchmarking protocols. Efforts like the CAESAR dataset [24] and newer 3DHumanDataset initiatives [25] aim to offer such standards, though generalization to unconstrained consumer imagery remains an open research challenge.

While antecedent methodologies have achieved notable advancements in either augmenting garment authenticity, forecasting dimensions utilizing joint-based classifiers, or reconstructing intricate three-dimensional models beneath loose apparel, a limited number of techniques furnish a completely automated, interpretable, and rule-based framework that is simultaneously scalable and independent of extensive training datasets. In contrast to generative or learning-centric frameworks that may experience challenges related to opacity or overfitting, the proposed approach presents a transparent workflow anchored in anatomical reference points and geometric evaluation (e.g., convex hulls) to ascertain waist and hip circumferences. By amalgamating OpenPose and SMPLify-X with rule-based size classification, our methodology facilitates real-world applicability within e-commerce contexts—achieving elevated accuracy without the necessity for comprehensive manual annotations or costly scanning technology. This positions it uniquely for economically viable implementation across a variety of consumer settings, distinguishing it from prior models that emphasize visual fidelity or necessitate controlled acquisition environments.

While prior research has extensively explored machine learning-based frameworks, fewer studies have provided a fully rule-based approach. Our proposed methodology uniquely integrates OpenPose and SMPLify-X to deliver practical size recommendations without extensive training data, bridging an important gap between theoretical models and industry practicality.

III. METHOD

The framework aims to provide a comprehensive, systematic solution for estimating body measurements using only a single image. The framework relies on a series of organized steps:

A. Step 1: Joint Extraction from the Image

OpenPose is applied to detect 25 key body joints, covering the upper limbs (shoulders, elbows, wrists), lower limbs (hips, knees, ankles), torso (neck, shoulders, chest center, hips), and head region (eyes, ears, nose).

The system uses deep neural networks capable of identifying joint positions with high accuracy, even under challenging visual conditions involving poor lighting or noisy backgrounds.

The output consists of a 2D array of (x, y) coordinates for each joint, along with a confidence score per point, enabling the exclusion or correction of joints with low reliability.

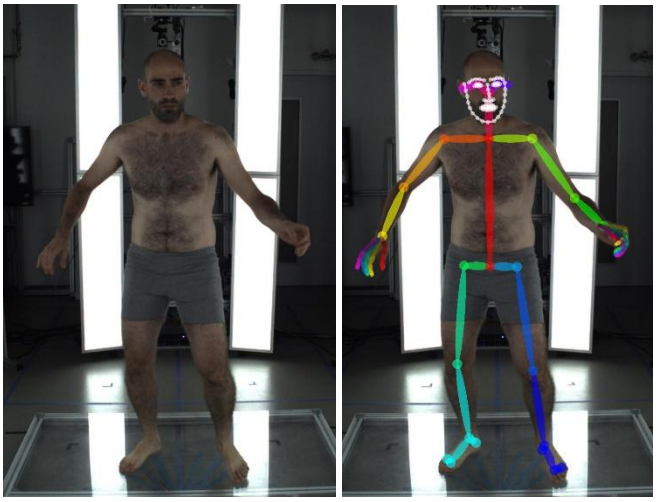


Fig. 1. Pose estimation from a single image using openpose.

B. Step 2: 3D Body Model Generation

The SMPLify-X algorithm is used to align a statistical 3D human model (SMPL-X) with the 2D joint keypoints extracted by OpenPose. SMPLify-X is an iterative optimization method that refines the model's shape and pose to match the detected joints.

SMPL-X is a comprehensive parametric model that accurately represents the full human body, including facial features, hand gestures, and body posture—making it ideal for virtual reality and interactive applications.

The OpenPose keypoints as shown in Fig. 1 and Fig. 2 serves as constraints for the SMPLify-X optimization, allowing it to fine-tune the model parameters (e.g., shape, pose, gender) until the 3D mesh closely fits the user's body as inferred from the image.

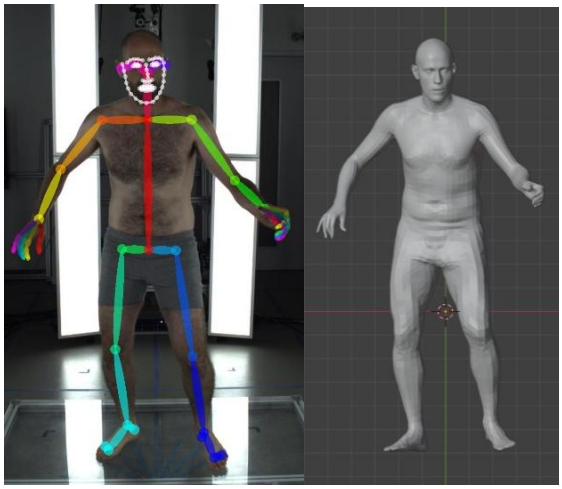

Fig. 2. From 2D pose estimation to 3D body reconstruction using SMPLIFY-X.

Upon the successful calibration of the model, two principal output files are produced:

- obj file: This file encompasses the surface mesh representation of the three-dimensional body, detailing vertex coordinates and triangular relationships. It serves a pivotal role in visualization and rendering processes.
- pkl file: This file encapsulates the internal parameters of the model, which is especially vital for this research due to its interoperability with Python-based analytical frameworks. It comprises:
    - keypoints_3d: A matrix that delineates the three-dimensional skeletal joints in the BODY_24 format, accurately aligned with the surface mesh and utilized for the identification of anatomical landmarks such as the cervical region and the hip joints.
    - Vertices (mesh): A comprehensive three-dimensional point cloud that depicts the external dermal surface of the body, constituting the geometric foundation for the computation of circumferences through projection and convex hull analysis.
    - gender: A categorical variable that denotes the biological sex of the subject (male or female). This parameter holds significant importance, given that clothing size specifications frequently vary by gender, and precise categorization is essential for appropriate alignment with the relevant standard sizing framework.

By utilizing the pkl file, the framework gains the advantage of seamless integration with Python's data management functionalities, while simultaneously accessing the requisite anatomical and mesh data critical for accurate, automated size estimation.

C. Step 3: Standard Size Classification Using Rule-Based Tables

Accurate size determination for clothing relies primarily on three anatomical measurements: waist width, hip width and chest width, as illustrated in Fig. 3.

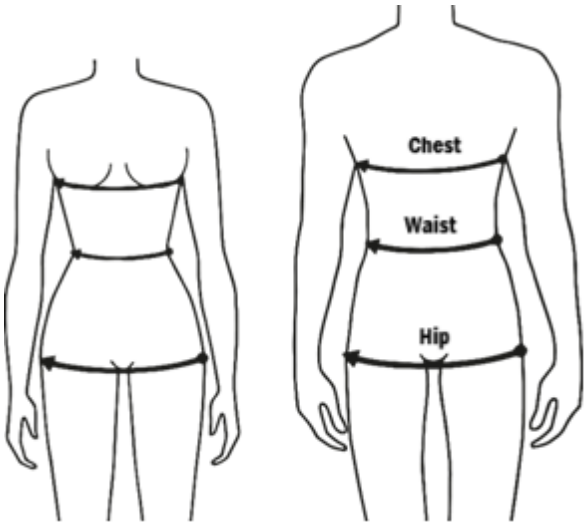

Fig. 3. The Anatomical locations of chest, waist, and hip circumferences used in garment size estimation.

- Waist width refers to the horizontal circumference of the torso at the narrowest region between the ribcage and pelvis.
- Hip width is the horizontal circumference at the widest point below the waist.
- Chest width: Measure the fullest part of your bust while wearing a bra that fits.

Rather than relying on a single point or linear measurement, the framework analyzes entire cross-sectional slices of the body to provide a more realistic representation of body shape, accounting for anatomical variations across individuals.

1) Identifying waist, hip, and chest levels. The positions of the waist and hip are inferred from skeletal joints stored in the .pkl file under the array keypoints_3d. This array contains the 3D coordinates (X, Y, Z) of 25 keypoints following the BODY25 format.

Two key points, as shown in Fig. 4, are central to this analysis:

- Mid-Hip (index 8): Represents the center of the pelvis or hip region.
- Neck (index 1): Marks the lower end of the neck and the start of the torso.

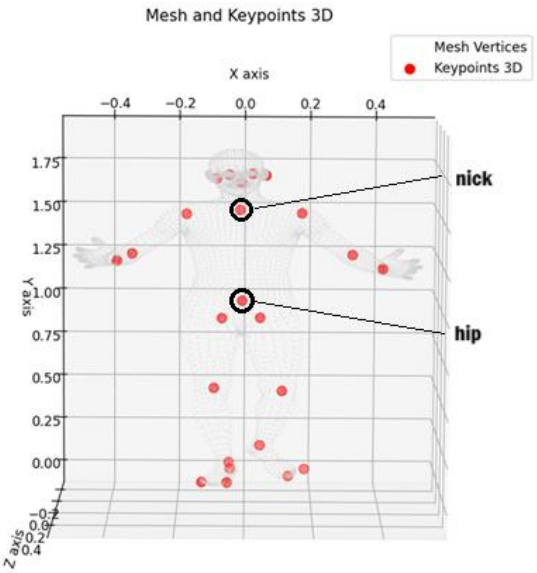

Fig. 4. Integration of 3D mesh and skeletal keypoints for anatomical reference.

The waist level is estimated by averaging the vertical (Y) coordinates of the Mid-Hip and Neck keypoints. This approach yields three critical horizontal slices:

- Hip slice: Taken at the same vertical level as the mid-hip joint (y_hip).
- Waist slice: Estimated to be roughly halfway between the neck and the hip, calculated as the average of their vertical coordinates y_waist ≈ y_hip +(y_hip + y_neck)̊ * 0.4.
- Chest slice: Located near the neck joint (y_neck), representing the lower section of the torso.

The parameter settings, such as the 40% ratio used to estimate waist position, were empirically chosen based on anatomical observations and real-world validation. Future work may refine these parameters for specific demographic groups."

This method allows for the extraction of more anatomically accurate cross-sections, improving measurement precision compared to single-point estimation methods.

a) Projection to the Horizontal Plane (X-Z): The three-dimensional coordinates utilized in each horizontal section are obtained from the surface mesh of the anatomical structure, specifically from the array of vertices that delineate the external geometric configuration of the model. These coordinates are projected onto the X-Z plane through the elimination of the vertical (Y) component. This two-dimensional projection facilitates a more straightforward analysis of the cross-sectional morphology of the body, rendering it appropriate for the estimation of circumference values via geometric methodologies.

The precision of this projection-centric methodology is predominantly ascribed to the incorporation of anatomically significant reference points—namely the Neck (index 1) and Mid-Hip (index 8)—whose vertical coordinates are retrieved from the array of key points. These joints function as dependable

reference markers for the estimation of the positions of the chest, waist and hip sections, thereby ensuring uniform alignment across disparate body models.

b) Convex Hull Application: A Convex Hull algorithm is employed on the two-dimensional projected coordinates to generate the minimal closed polygon that encompasses all data points.The convex hull simplifies the body's outline at each cross-section, removing small irregularities while retaining overall shape.It effectively eliminates minor irregularities or localized noise within the mesh that do not significantly influence the overall shape.

The perimeter or area of the resultant convex hull, as shown in Fig. 5, is subsequently calculated and utilized as an approximate indicator of the waist or hip circumference, contingent upon the specific slice under examination.

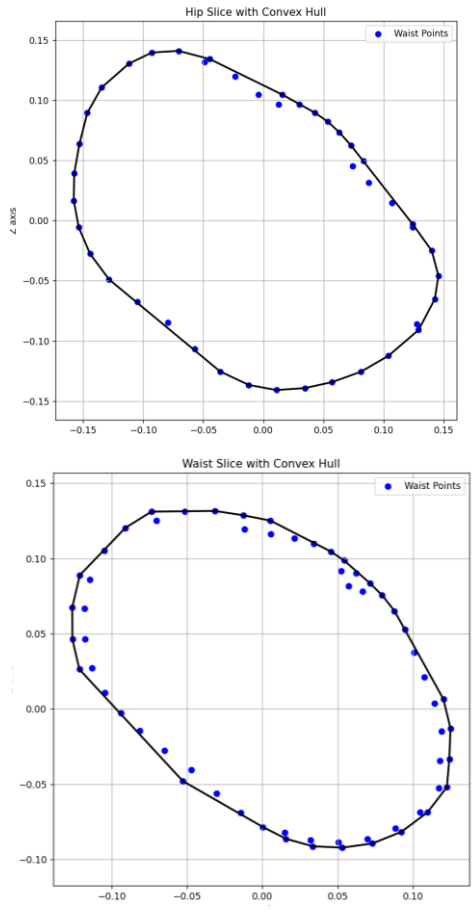

Fig. 5. Projection of waist and hip vertices onto X-Z plane.

2) Conversion to standard sizes. In the concluding phase, the extracted body measurements are compared against established standardized sizing tables (e.g., ISO or specific retailer charts) to ascertain the most suitable clothing size category, such as XS, S, M, L, XL, among others (see Table I).

This classification is executed through a rule-based methodology, wherein each measurement (e.g., chest, waist, hips) is juxtaposed with threshold ranges corresponding to each size category. The system identifies the closest matching category, optionally employing priority rules (e.g., prioritizing waist over chest for trousers). This methodology guarantees transparency, consistency, and compatibility with pre-existing sizing systems employed by manufacturers and online retailers—without necessitating the implementation of machine learning models.

There exist numerous clothing sizing frameworks utilized globally, differing according to geographical region, brand identity, and gender classification. These frameworks encompass systems such as those employed in the United States, the United Kingdom, the European Union, and the internationally recognized ISO standards, each characterized by distinct measurement parameters and labeling protocols. In the present investigation, we have adopted a prevalent and comprehensive sizing framework that corresponds with international standards and is extensively utilized within both retail and e-commerce sectors. This approach guarantees compatibility across a wide array of applications and enhances the practical significance of the proposed conceptual model for users worldwide.

TABLE I. STANDARD WOMEN'S CLOTHING SIZE CHART (IN CM)

WOMENS SIZES (CM)						
Size	**XS**	**S**	**M**	**L**	**XL**	**XXL**
Bust (cm)	85	91	95	100	105	110
Waist (cm)	80	86	90	95	100	105
Hips (cm)	90	96.5	100	105	110	115
Front lenth (cm)	115	117	115	115	115	115

Source: https://ethnicity.in/pages/size-guide

Following common fashion industry practices, the larger of the two measurements (waist or hip) is used to determine the final clothing size. This ensures user comfort and avoids tight fitting, especially for garments like pants and skirts.

3) Code summary – core measurement extraction logic (working for waist and hip). The following Python snippet illustrates the core logic used to extract the waist and hip circumference from the 3D body mesh by projecting relevant surface vertices and applying a convex hull algorithm (Algorithm 1):

This code performs three main operations:

Algorithm 1 : Python

```
# Step 1: Define hip and waist levels directly from keypoints
y_hip = keypoints[8, 1] # Mid-Hip point (keypoint index 8)
y_neck = keypoints[1, 1] # Neck point (keypoint index 1)
y_waist = y_hip + np.abs(y_neck - y_hip) * 0.40 # Estimated waist level

# Step 2: Select surface vertices near the hip and waist levels
hip_vertices = vertices[np.abs(vertices[:, 1] - y_hip) < 0.015]
waist_vertices = vertices[np.abs(vertices[:, 1] - y_waist) < 0.015]

# Step 3: Project 3D points onto the X-Z plane for 2D contour analysis
hip_2d = hip_vertices[:, [0, 2]]
waist_2d = waist_vertices[:, [0, 2]]
```

```
    # Step 4: Compute the Convex Hull to approximate the circumference
    hip_hull = ConvexHull(hip_2d)
    waist_hull = ConvexHull(waist_2d)
```

The vertical positions (y_hip, y_waist) are derived using anatomical reference points from the keypoints_3d array, aligned using a displacement correction to compensate for origin mismatch between the vertex and joint spaces.

The waist level is estimated as a proportional offset (40%) between the hip and neck points—empirically chosen to reflect typical torso proportions.

Vertices within a narrow band (±1.5 cm in normalized units) around the estimated hip and waist levels are selected, effectively isolating the relevant cross-sections of the 3D body mesh.

The selected 3D points are projected onto the X-Z plane to obtain a 2D shape of the body cross-section.

ConvexHull() from the scipy.spatial package is used to compute the enclosing perimeter or area of the projected points—used as a proxy for waist and hip circumference.

This computational process allows for non-contact, geometry-based body measurement extraction and is robust against mesh irregularities or minor noise in the 3D data.

4) Size mapping through standardized chart. Subsequent to the calculation of waist and hip circumferences utilizing the convex hull perimeters, the derived values are juxtaposed against an established size chart in order to allocate a standardized clothing size designation. The chart, delineated in centimeters, encompasses threshold ranges for both waist and hip measurements and was formulated by averaging the discrepancies between contiguous size categories.

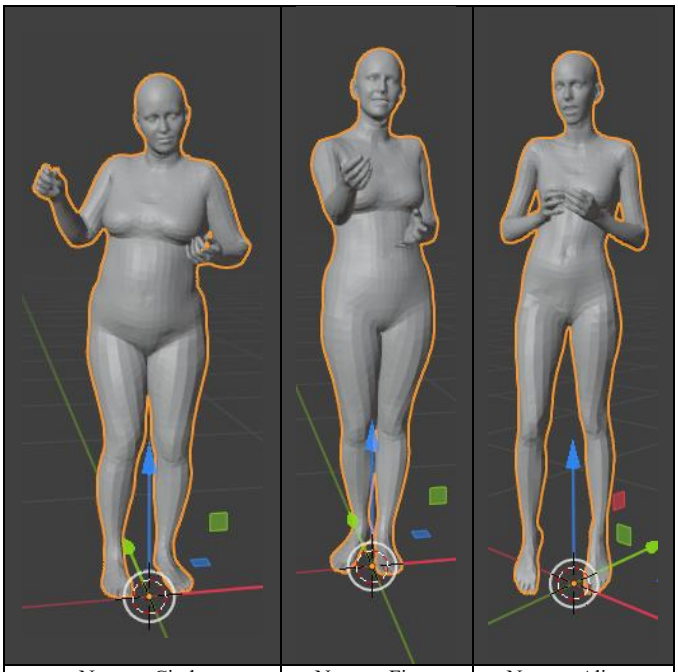
The executed size mapping dictionary is as follows in Table II.

TABLE II. THE EXECUTED SIZE MAPPING DICTIONARY

```
size_chart = {
"XS": {"waist": (60, 82.999), "hip": (88, 92.999)},
"S": {"waist": (83, 88.999), "hip": (93, 98.999)},
"M": {"waist": (89, 92.999), "hip": (99, 102.999)},
"L": {"waist": (93, 97.999), "hip": (103, 107.999)},
"XL": {"waist": (98, 102.999), "hip": (108, 112.999)},
"XXL": {"waist": (103, 107.999), "hip": (113, 117.999)},
 }
```

This table was developed by centering the interval disparities among proximate garment sizes in accordance with established industry benchmarks. The ultimate designated size aligns with the minimal size classification wherein both the projected waist and hip circumferences reside within the stipulated parameters. Conversely, for applications prioritizing comfort, the more expansive corresponding category may be selected to guarantee garment ease.

This methodical mapping strategy provides a lucid and comprehensible alternative to opaque machine learning classifiers and retains congruence with widely recognized retail sizing frameworks.



IV. RESULTS SUMMARY

A. Case Study: Evaluation on Agora Dataset Using (Waist , Hip)

In order to illustrate the practical implementation and credibility of the proposed framework, a collection of authentic three-dimensional body models was curated from the Agora dataset, which offers intricate anthropometric meshes that represent a variety of female body types (see Fig. 6).

The Agora dataset was chosen due to its high-quality anthropometric models and comprehensive skeletal keypoints, enabling precise evaluation across diverse body shapes and realistic scenarios.

In order to assess the practical applicability of the proposed framework, a variety of three-dimensional body models sourced from the Agora dataset were subjected to processing through the entirety of the established pipeline. Among these instances, three representative cases—Cindy, Fiona, and Alixon—have been selected to exemplify the diversity in body morphology and the corresponding assignment of clothing sizes. The larger collection of evaluated models demonstrated analogous results, thereby suggesting a uniform operational consistency of the system across varying anatomical configurations.

Name = Cindy	Name = Fiona	Name = Alixon
Hip = 1.124 m	Hip = 0.992 m	Hip = 0.892 m
Waist = 0.942 m	Waist = 0.825 m	Waist = 0.723 m
Rec = XL	Rec = M	Rec =XS

Fig. 6. Estimated waist and hip circumferences for three subjects (Alixon, Fiona, Cindy) and the corresponding predicted clothing sizes.

B. Analysis

In the case of Cindy, both her waist (94.2 cm) and hip (112.4 cm) dimensions distinctly align with the XL category as delineated by the specified size chart.

Fiona presents intermediate measurements—waist at 82.5 cm and hip at 99.2 cm—rendering her qualifying for the M category.

Alixon, possessing a waist measurement of 72.3 cm and a hip measurement of 89.2 cm, comfortably fits within the XS category.

The cross-sectional contours of each model were subjected to analysis via convex hulls within the X-Z plane. The findings indicate a robust correlation between the visually perceived body type and the size predicted by the proposed methodology, thereby affirming its efficacy within a practical context.

These findings underscore the framework's proficiency in accommodating various body proportions and autonomously delivering realistic size recommendations utilizing solely a singular three-dimensional mesh and joint keypoints as input.

V. Discussion

The findings derived from the Agora dataset underscore the practical viability and precision of the proposed image-based body measurement framework. By implementing a coherent and modular pipeline—encompassing joint extraction, three-dimensional body modeling, geometric perimeter analysis, and rule-based classification—the system adeptly estimated standardized clothing sizes across a diverse array of body shapes.

A. Strengths

Robustness Across Body Variants: The framework proficiently differentiated between various anatomical types (e.g., Cindy vs. Alixon), encapsulating both volumetric and proportional variances. Mesh-based modeling approaches like DensePose2SMPL have shown improved shape estimation performance, particularly in subjects with outlier body types [26].

Alignment with Industry Standards: Size predictions (e.g., XS, M, XL) corresponded favorably with anticipations derived from body measurements, affirming the legitimacy of convex hull-based perimeter estimation. Previous studies applying 3D scanning in apparel industries highlighted the effectiveness of geometric-based measurements for standardized size matching [27].

Contactless and Scalable: Functioning on a singular image without necessitating specialized equipment, the methodology is well-positioned for practical implementation within e-commerce and virtual try-on systems. Research on mobile- and web-based 3D scanning platforms confirms growing consumer demand for low-barrier body modeling solutions [28].

B. Potential Applications

In virtual shopping platforms, this technology allows for realistic virtual try-on experiences where garments are simulated directly onto a user's 3D model. Projects like SIZER have demonstrated the practicality of linking clothing fit with volumetric body data to personalize the shopping journey [29]. More importantly, by linking the extracted body measurements directly to sizing charts provided by online clothing retailers, the system enables users to select the most accurate size before making a purchase. This pre-selection step significantly reduces the risk of sizing mismatches, thereby lowering return rates and associated logistical costs [30].

The ability to preview fit and style interactively empowers users to make confident decisions, while retailers benefit from fewer returns and improved customer satisfaction. This seamless integration between virtual fitting and e-commerce platforms bridges the gap between user expectation and product delivery [28].

Beyond virtual worlds, the framework paves the way for intelligent mobile applications that can, from a single image, provide users with real-time recommendations not only for size but also for clothing styles that best suit their body shapes. Such applications could incorporate AI-driven styling advice based on user preferences, fashion trends, and body geometry—delivering a personalized and seamless shopping experience that merges practicality with convenience [31].

C. Limitations

Fixed Anatomical Ratios: Waist-level estimation based on a fixed ratio (e.g., 40% between neck and hip) may not generalize across different ethnicities, age groups, or postures, potentially leading to inaccuracies in landmark placement. Research highlights that human anatomical diversity undermines the reliability of fixed-ratio methods in body reconstruction [32].

Chest Measurement Challenges: Accurate chest measurement is hindered by the pose limitations of many 3D body models, which often lack favorable positions such as the Y-pose. This results in arm–torso intersections that distort the contour, especially around the upper torso. Prior work has demonstrated that dressed-human silhouettes limit measurement precision when key anatomical landmarks are occluded or misaligned [33].

Pose and Environment Dependence: The system was tested on controlled, static 3D models, which may not reflect performance in real-world scenarios. Variations in lighting, background, and body pose can adversely impact the accuracy of joint detection and mesh reconstruction. This dependency is consistent with findings that stress the sensitivity of monocular 3D body estimation to environmental conditions and pose inconsistencies [34].

Clothing Interference: Although models like SMPLify-X can recover approximate body shapes under loose garments, excessive layering or oversized clothing still causes significant contour deviation. Studies confirm that loose-fitting clothes often degrade estimation accuracy, especially in peripheral regions such as the hips and chest, suggesting tight-fitting garments are optimal for body capture [31].

D. Future Directions

Future advancements could concentrate on adapting pose-aware corrections for chest measurement through pose normalization or generative completion methodologies, implementing the model in mobile applications with real-time

guidance on pose and clothing preparation, and augmenting the framework with deep-learning-based modules to enhance anatomical landmark detection under conditions of occlusion or partial visibility.

VI. CONCLUSION

This study presented and validated a comprehensive, image-based framework for estimating human body measurements, specifically waist and hip circumferences, using a single image processed by OpenPose, SMPLify-X, and convex hull geometric analysis. These measurements were systematically mapped to standard clothing sizes through a clear and scalable rule-based classification, enabling practical, non-intrusive size recommendations.

Experimental evaluations using three-dimensional body models from the Agora dataset confirmed the method's effectiveness in accurately identifying body variations and recommending appropriate clothing sizes (XS–XL). Results showed strong alignment with established industry standards, highlighting the robustness, cost-efficiency, and interpretability of the proposed framework. Consequently, this research contributes meaningfully towards practical applications in e-commerce, virtual fitting solutions, and body-shape analytics.

However, limitations of the study include reliance on fixed anatomical ratios that might not generalize across different ethnicities, age groups, or body postures, as well as potential inaccuracies due to clothing interference or complex poses. Future work could address these limitations by refining landmark detection, improving pose normalization, and adapting the framework for mobile and real-world scenarios.

Overall, this research significantly advances the accessibility and practical implementation of image-based body size estimation, facilitating personalized garment fitting in a contactless, efficient, and user-friendly manner.

ACKNOWLEDGMENT

The authors would like to thank the Intelligent Processing and Security of Systems (IPSS) Laboratory for providing computational resources used in this research.

TL-MC-ShuffleNetV2: A Lightweight and Transferable Framework for Elevator Guideway Fault Diagnosis

Zhiwei Zhou[1], Xianghong Deng[2], Xuwen Zheng[3], Chonlatee Photong[4]*
School of Electrical Engineering, Hunan Mechanical & Electrical Polytechnic, Changsha, 410151, Hunan, China[1, 2]
Faculty of Engineering, Mahasarakham University, Maha Sarakham, 44150, Thailand[3, 4]

***Abstract*—This study presents TL-MC-ShuffleNetV2, a lightweight and transferable fault diagnosis framework designed for elevator guideway vibration analysis. To tackle challenges such as limited labeled data and the constraints of real-time deployment, the approach integrates Variational Mode Decomposition (VMD) for multi-scale signal separation and employs a customized 1D ShuffleNetV2 backbone with multi-channel (MC) inputs. Squeeze-and-Excitation (SE) attention modules are embedded throughout the network to enhance channel-wise feature sensitivity. A transfer learning (TL) strategy is adopted, in which the model is initially trained using the Case Western Reserve University (CWRU) bearing dataset and subsequently adapted to the elevator domain by freezing early convolutional layers while fine-tuning higher-level layers. Evaluation results demonstrate that the proposed framework achieves a classification accuracy of 96.4%, alongside significantly reduced inference time and parameter complexity. Comparative and ablation experiments further validate the individual contributions of VMD preprocessing, SE modules, and transfer learning to model performance. Overall, the method exhibits strong adaptability, computational efficiency, and suitability for deployment in smart elevator monitoring systems under Industry 4.0 environments.**

***Keywords*—Transfer learning; elevator guideway; vibration signal analysis; fault diagnosis; lightweight deep neural network; squeeze-and-excitation attention; smart maintenance**

I. INTRODUCTION

Elevators play a critical role in urban vertical mobility, facilitating public transportation, residential accessibility, and commercial operations [1]. With the continuous rise in urban density and high-rise development, maintaining the operational integrity and functional safety of elevator systems has become a pressing concern for building management and urban infrastructure planning [2]. However, conventional maintenance approaches—typically based on fixed schedules or reactive repairs—often struggle to detect early-stage deterioration, leading to unforeseen service interruptions, elevated maintenance expenses, and potential safety risks [3].

The emergence of Internet of Things (IoT)-enabled predictive maintenance (PdM) systems, empowered by real-time sensing and wireless communication technologies, has significantly advanced fault detection capabilities in industrial applications [4]. In particular, vibration signal analysis has proven highly effective for identifying early mechanical anomalies in components such as motors, bearings, and guide systems [5]. Alongside this development, deep learning has shown strong potential for automating the interpretation of complex, nonlinear, and nonstationary signal patterns, offering superior classification performance over traditional feature engineering-based methods [6].

Although deep learning has significantly advanced fault diagnosis techniques, its real-world application in elevator systems remains constrained by multiple unresolved challenges [7]:

Computational Constraints: Deep convolutional models require substantial computational power, making them difficult to deploy on edge devices and in latency-sensitive IoT environments [8].

Data Scarcity: Elevator-specific fault data are often scarce, particularly for early-stage or rare failures, limiting the generalization of deep models [9].

Signal Complexity: Elevator vibration signals exhibit nonstationary behavior with transient impulses and modulation effects, often buried in noise, posing challenges for reliable feature extraction [10].

To address the above challenges of nonstationary vibration signals and limited fault samples in elevator guideway diagnosis, this study builds upon our previous work on One-dimensional Convolutional Neural Network (1D-CNN) based methods using elevator vibration data [11] and proposes a lightweight and transferable fault diagnosis framework with four key processes. First, Variational Mode Decomposition (VMD) is employed to extract frequency-specific components and suppress noise [12]. Second, a tailored 1D version of ShuffleNetV2 is developed to efficiently process temporal features while significantly reducing computational complexity [13]. Third, Squeeze-and-Excitation (SE) attention modules are embedded after each network block to enhance channel-wise feature representation [14]. Fourth, a transfer learning (TL) strategy is adopted, drawing upon recent progress in TL-driven fault diagnosis [15]. Specifically, the model is initially trained using the data-rich Case Western Reserve University (CWRU) bearing dataset [16], which also with four vibration states, and then adapted to the target elevator dataset through partial parameter transfer, wherein lower convolutional layers are frozen while higher layers are updated. Compared to our earlier approach [11], the proposed method reduces the model size

Hunan Mechanical & Electrical Polytechnic Research Project (YJB202405).

while ensuring classification accuracy and model convergence, thus enhancing its applicability for deployment in resource-constrained smart elevator systems. This integrated framework is referred to as TL-MC-ShuffleNetV2, denoting the combination of Transfer Learning (TL), Multi-Channel (MC) VMD-based inputs, and a customized ShuffleNetV2 backbone.

The structure of this study is as follows: Section II surveys the relevant literature on predictive maintenance and vibration-based diagnostics. Section III details the proposed TL-MC-ShuffleNetV2 architecture for elevator fault diagnosis. Section IV describes the experimental design, comparative baselines, and ablation studies. Section V summarizes the key contributions and limitations and suggests directions for future work.

II. Related Work

A. Fault Diagnosis in Elevator Systems

As vertical transportation becomes increasingly integral to modern urban infrastructure, ensuring the operational safety and dependability of elevator systems has become a central engineering concern [17]. Fueled by Industry 4.0 and the rapid expansion of the IoT, predictive maintenance (PdM) has gained prominence as an advanced alternative to conventional reactive or periodic maintenance strategies [18]. In this context, vibration-based fault diagnosis plays a pivotal role in identifying anomalies such as misalignment, wear, or guideway deformation before catastrophic failures occur [19].

Extensive research has investigated the use of data-driven methods for elevator fault detection. For instance, Lv et al. developed a GAN-based model to synthesize vibration data for intelligent fault classification in elevators [20]. Qiu et al. introduced a hybrid approach combining the improved Aquila optimizer (IAO) and XGBoost to enhance fault pattern recognition from vibration signals [21]. Liu et al. proposed a framework integrating ensemble empirical mode decomposition (EEMD) with support vector machines (SVMs) to identify faults in traction systems [22], while Song et al. incorporated EMD with neural network architectures to detect anomalies in elevator control systems [23].

Despite these developments, practical deployment faces three core challenges: 1) real-world elevator vibration signals are nonstationary and influenced by diverse operating conditions, making them difficult to model using conventional linear analysis methods [24]. 2) The scarcity of labeled fault data—especially for rare or incipient cases—substantially limits the effectiveness of supervised learning approaches [25]. 3) Standard deep learning models are computationally demanding and ill-suited for real-time application in edge-based IoT monitoring systems with limited hardware resources [26].

These limitations motivate the need for lightweight, adaptive models that can operate effectively with limited labeled data and computational capacity, while still providing reliable performance on noisy, complex vibration signals.

B. Deep Learning and Lightweight Models for Vibration-Based Fault Diagnosis

Deep learning, especially various CNNs, has demonstrated strong effectiveness in performing automated fault recognition by learning hierarchical features directly from unprocessed sensor data. Unlike traditional time- or frequency-domain methods such as RMS analysis or Fourier transforms, CNNs can derive distinctive patterns without requiring prior domain knowledge, thereby enhancing scalability and adaptability across diverse fault scenarios [27].

However, conventional CNN architectures—despite their effectiveness—are often computationally intensive and unsuitable for real-time fault monitoring in embedded IoT environments. To address this issue, lightweight CNNs such as MobileNet, EfficientNet, and ShuffleNet have been developed, leveraging techniques like depthwise separable convolutions, grouped operations, and channel shuffling to minimize parameter overhead and reduce model complexity and inference latency [28]. ShuffleNetV2, in particular, offers a compelling trade-off between speed and accuracy, making it a promising candidate for industrial fault diagnosis applications where low-resource deployment is essential [29].

Beyond efficiency, recent studies emphasize the importance of attention mechanisms in improving model interpretability and performance. Representative modules, such as Squeeze-and-Excitation Networks (SE-Net) and the Convolutional Block Attention Module (CBAM), enable the model to selectively concentrate on diagnostically significant frequency components while attenuating irrelevant noise and redundant information. For instance, CBAM has been demonstrated to enhance classification performance in machinery fault datasets by dynamically reweighting spatial and channel-specific features [30].

Overall, combining lightweight architectures with attention mechanisms enhances the feature representation of nonstationary signals while ensuring computational feasibility, especially in IoT-enabled predictive maintenance systems.

C. Transfer Learning for Small-Sample Industrial Scenarios

In many real-world scenarios—particularly in elevator guideway diagnostics—acquiring large, labeled datasets is often impractical due to cost limitations, safety concerns, or the infrequent nature of fault events. Transfer learning (TL) provides a powerful solution by allowing a model trained on a source domain with ample data to be adapted to a target domain with limited samples [31]. This approach has demonstrated strong applicability across diverse industrial settings.

For example, Yang et al. employed a sparse autoencoder-based TL method to enhance bearing fault classification on limited datasets [32], while Azad et al. proposed dynamic modeling strategies that simulate data to support domain adaptation using convolutional networks [33]. In wind turbine maintenance, parameter-based TL combined with autoencoders has enabled models trained on one machine to generalize effectively to others with similar operating characteristics [34].

These studies indicate that effective domain transfer enables successful cross-domain adaptation. For elevator systems, limited sample learning and fine-tuning of pre-trained models offer a promising approach for addressing data scarcity challenges.

III. METHODOLOGY

A. Variational Mode Decomposition for Multiscale Fault Feature Separation

Elevator guideway vibration signals are inherently nonstationary, exhibiting complex modulation patterns due to fluctuating operational loads and external disturbances. To effectively capture fault-relevant features across diverse frequency bands, this study employs Variational Mode Decomposition (VMD). VMD adaptively partitions the signal into a set of band-limited intrinsic mode functions (IMFs), each aligned with a distinct spectral component, thereby improving the interpretability and diagnostic precision of nonstationary signal analysis [35].

The decomposition process is formulated as a constrained variational optimization problem, aiming to reduce the aggregated bandwidth of all modes while ensuring that their summation reconstructs the original signal [36]. Mathematically, the VMD objective is defined as:

$$min_{u_k,\omega_k}\left\{\sum_k\left\|\partial_t\left[\left(\delta(t)+\frac{j}{\pi t}\right)*u_k(t)\right]e^{-j\omega_k t}\right\|_2^2\right\} \quad (1)$$

subject to

$$\sum_k u_k(t)=f(t) \quad (2)$$

where, $u_k(t)$ denotes the k-th IMF, w_k represents its center frequency, ∂_t is the first-order time derivative, $\delta(t)$ is the Dirac delta function, and $f(t)$ denotes the original signal.

In this study, the first five IMFs (as shown in Fig. 1)—capturing the most representative low- to mid-frequency fault features—are selected to construct a five-channel input for the subsequent feature extraction network. By leveraging the superior mode separation and noise resilience of VMD, this strategy enhances the model's sensitivity to subtle fault-related variations, thereby improving its applicability to real-world elevator vibration analysis under uncertain operating conditions.

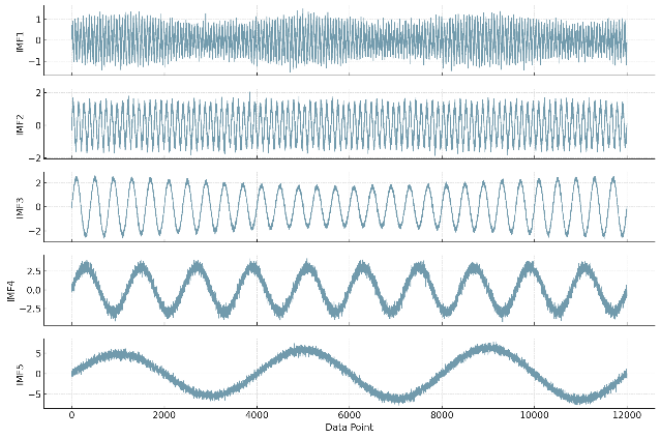

Fig. 1. Variational Mode Decomposition (VMD) processing results.

B. Modified 1D ShuffleNetV2 Architecture for Feature Extraction

To effectively extract discriminative features from the multi-channel IMF signals generated by VMD, a customized one-dimensional version of ShuffleNetV2 is designed. Originally developed for efficient image classification, the ShuffleNetV2 architecture is adapted here to handle sequential vibration signals by converting all convolutional operations into their 1D forms [37]. This enables the model to process temporal input while retaining the core advantages of ShuffleNetV2—namely, lightweight design and efficient feature utilization.

The modified 1D ShuffleNetV2 (as shown in Fig. 2) consists of a series of Shuffle Units, each of which employs a dual-branch design [38]. For units with stride = 1, the input is first split into two equal channel groups. One branch directly propagates its features without modification, while the other branch undergoes a sequence of three operations:

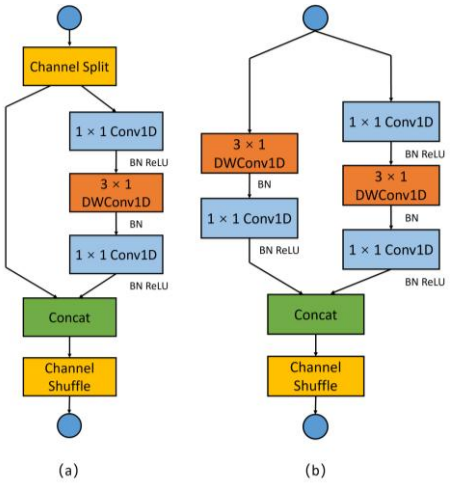

Fig. 2. Modified 1D ShuffleNetV2 architecture: a) Stride = 1 block; b) Stride = 2 block.

1) A 1×1 pointwise convolution followed by batch normalization and ReLU activation,

2) A 3×1 depthwise convolution with subsequent batch normalization, and

3) A concluding 1×1 pointwise convolution, also accompanied by batch normalization and ReLU activation.

After feature extraction, both branches are concatenated and passed through a channel shuffle operation, which promotes inter-group feature interaction and enhances representation diversity.

For units with stride 2, both branches perform independent downsampling. Each branch executes a sequence of depthwise separable and pointwise convolutions, followed by concatenation and channel shuffling. This design strategy reduces spatial resolution while increasing output channel capacity. The channel split step is intentionally excluded in this configuration to prevent structural fragmentation and enhance feature utilization.

This modular design enables the network to strike a balance between computational cost and expressive power, thereby ensuring its applicability to fault diagnosis tasks in IoT environments with limited resources. Furthermore, by leveraging grouped convolutions and the channel shuffle mechanism, the model effectively extracts fine-grained temporal features from multiple IMFs while preserving a lightweight parameter footprint.

C. Equations Channel Attention Enhancement with SE Module

To enhance the network's focus on informative features and suppress irrelevant activations, a lightweight channel attention mechanism—Squeeze-and-Excitation (SE) module—was incorporated into the proposed architecture. This mechanism facilitates channel-wise recalibration by explicitly capturing inter-channel dependencies, thereby improving the network's representational capacity in a computationally efficient manner.

The SE module functions through two primary stages [39]: squeeze and excitation. In the squeeze stage, global contextual information is aggregated from each channel using global average pooling. This operation produces a channel-wise descriptor that reflects the global distribution of activations. During the excitation phase, two fully connected layers with a bottleneck structure and nonlinear activations (ReLU and Sigmoid) are employed to model channel-wise dependencies and generate attention weights. These weights are then applied to reweight the original feature maps through channel-wise multiplication, enabling the model to highlight informative channels while suppressing less relevant ones.

Mathematically, for an intermediate feature map $X \in R^{C \times T}$, where C and T represent the number of channels and temporal length, respectively, the SE module first derives a channel-wise descriptor via global average pooling [40]:

$$z_c = \frac{1}{T}\sum_{t=1}^{T} X_{c,t}, \quad c = 1, 2, \ldots, C \tag{3}$$

The attention weights are then generated through a gating mechanism:

$$\mathbf{s} = \sigma\left(\mathbf{W}_2 \cdot \delta\left(\mathbf{W}_1 \cdot \mathbf{z}\right)\right) \tag{4}$$

where, $\delta(\cdot)$ and $\sigma(\cdot)$ represent the ReLU and Sigmoid functions, respectively, and $W1$, $W2$ are learnable weight matrices. The final recalibrated output is obtained by channel-wise multiplication:

$$\tilde{X}_c = s_c \cdot X_c \tag{5}$$

As illustrated in Fig. 3, the SE module is integrated into each Shuffle Block of the Modified 1D ShuffleNetV2 architecture. Specifically, it is inserted after the depthwise convolution (DWConv1D) and before the final pointwise convolution (1×1 Conv1D). This placement enables the attention mechanism to refine intermediate features that already encode localized spatial and inter-channel information. The recalibrated features are subsequently propagated through the remaining layers of the Shuffle Block, followed by concatenation and channel shuffling operations.

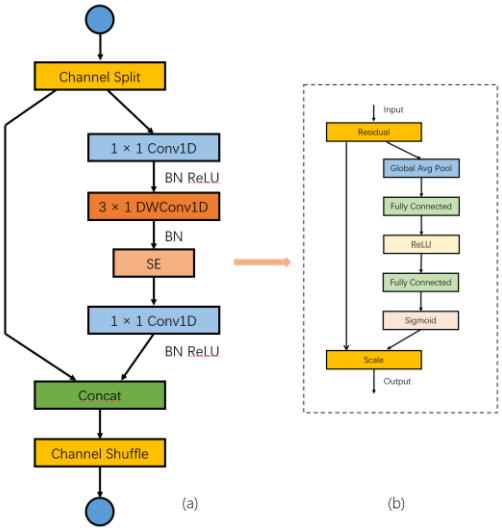

Fig. 3. Integration of SE module into modified 1D ShuffleNetV2 architecture (a), and structure and operation of SE block (b).

The SE module was inserted in both Stage 1 (stride = 2) and Stage 2 (stride = 1) Shuffle Blocks, ensuring that channel attention is applied during both the downsampling and feature extraction processes. This integration strategy enhances the network's ability to adaptively weight different channels according to task-relevant information, leading to improved fault diagnosis performance in the subsequent classification stage.

D. Transfer Learning Strategy for Fault Diagnosis

To address the limited availability of labeled elevator guideway fault data, a transfer learning (TL) strategy is employed. The training procedure consists of two key stages:

1) Pre-training stage. The proposed framework, incorporating VMD-enhanced multi-channel IMFs, is input into the modified 1D ShuffleNetV2 augmented with SE modules. Pre-training is conducted on the CWRU bearing dataset that also has four states, enabling the model to capture generalized vibration features from the rich source domain data to compensate for the insufficient data in the target domain.

2) Fine-tuning stage. The pre-trained model is then adapted to the elevator guideway dataset. Lower layers are frozen to retain transferable low-level representations, while upper layers are selectively fine-tuned based on the target domain data.

This two-phase learning paradigm enables efficient domain adaptation with minimal supervision, ensuring that transferable vibration characteristics are preserved while tailoring feature representations to the specific requirements of the target dataset.

E. Overview of the Proposed TL-MC-ShuffleNetV2 Framework

The proposed TL-MC-ShuffleNetV2 framework (illustrated in Fig. 4) integrates all preceding components into a cohesive

fault diagnosis pipeline tailored for elevator guideway vibration analysis. The process begins by applying VMD to the raw vibration signals, generating multiple IMFs that preserve localized frequency information. These IMFs are organized as MC inputs and fed into a customized one-dimensional ShuffleNetV2 backbone optimized for temporal feature extraction with low computational cost. To enhance channel-wise feature discrimination, SE modules are selectively embedded after each ShuffleNetV2 block. To address the scarcity of labeled elevator data, a transfer learning strategy is employed. The model is initially pre-trained on the CWRU bearing dataset to capture transferable mechanical fault representations. It is then fine-tuned using the target elevator dataset by freezing the initial convolutional layers and updating the higher ones. After domain adaptation, the model is evaluated on previously unseen elevator vibration data, with minor parameter refinements applied to further enhance performance. This modular and efficient design promotes robust cross-domain generalization while maintaining a lightweight architecture, making it well-suited for real-world deployment in smart elevator systems.

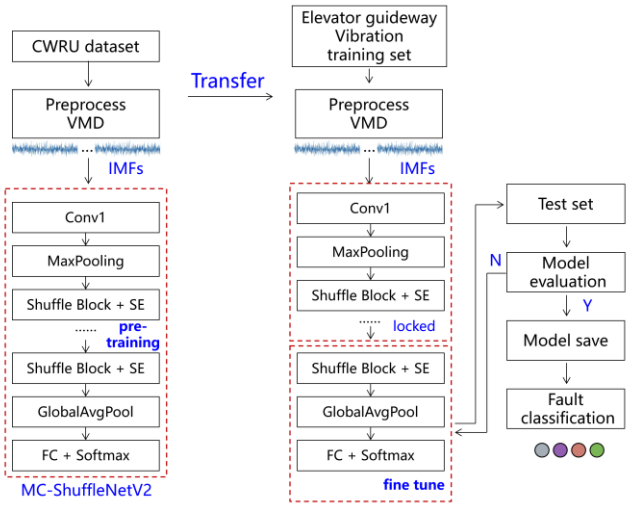

Fig. 4. Structural diagram of the proposed TL-MC-ShuffleNetV2-based fault diagnosis framework.

IV. Experiments and Result Analysis

A. Description of Data Sets

In this study, two vibration datasets were utilized to support the transfer learning framework—one for source domain pre-training and the other for target domain fine-tuning. The source domain employs a publicly available bearing dataset, while the target domain comprises elevator guideway vibration signals collected under real-world operational conditions.

1) Source domain CWRU bearing dataset. As a widely recognized benchmark for mechanical fault diagnosis, CWRU bearing dataset [16] contains vibration signals acquired from an experimental motor testbed equipped with SKF 6205-2RS bearings, simulating various fault types.

For pre-training, four fault categories were selected: normal, inner race, outer race, and ball fault. The raw time-series signals, sampled at 12 kHz, were segmented using a 1024-point sliding window with 50% overlap, yielding 1400 samples per class (5600 total). An 80/20 split was adopted for training and testing purposes.

2) Target domain elevator guideway dataset. The target dataset was collected via an industrial elevator IoT platform, with tri-axial accelerometers mounted at the top-center of elevator cars to capture guideway vibration signals. The sampling frequency was 50 Hz, and four operating states were considered: normal, bending, misalignment, and step fault.

Using the same segmentation approach as the source domain, 300 samples were extracted for each class, resulting in a total of 1200 samples. These samples were split into 80/20 training and testing sets for target domain fine-tuning and evaluation. Details of the dataset composition and sample allocation are summarized in Table I. The table adapts the structure and sample configuration from our prior work [11].

TABLE I. Datasets used for Transfer Learning

	Dataset	Category	Label	Train sample	Test sample
Source domain (pre-train)	CWRU bearing	Normal	0	1120	280
		Ball fault	1	1120	280
		Inner fault	2	1120	280
		Outer fault	3	1120	280
Target domain	Elevator guideway	Normal	0	240	60
		Bending	1	240	60
		Misalignment	2	240	60
		Step	3	240	60

B. Experimental Settings and Model Training

Model training was carried out on a workstation equipped with an Intel i7-12700K processor, 32 GB of memory, and an RTX 3080 GPU. Python 3.9 and PyTorch 1.13 were used throughout the implementation.

The proposed MC-ShuffleNetV2 architecture accepts five IMFs as MC inputs, obtained through VMD. The network integrates a modified 1D ShuffleNetV2 backbone for lightweight feature extraction, with SE modules inserted after each Shuffle Block to enhance channel attention.

Table II summarizes the architecture and parameter settings of the MC-ShuffleNetV2 with SE model prior to transfer learning (TL). The TL pipeline described earlier in the methodology is subsequently applied. with pre-training conducted on the CWRU bearing dataset and fine-tuning performed using the elevator guideway dataset. The training strategy parameters are summarized in Table III.

TABLE II. ARCHITECTURE DETAILS OF MC-SHUFFLENETV2 WITH SE

Layer	Output Size	Kernel Size	Stride	Repeat	Description
Input	5×1024×1	–	–	–	5 IMFs
Conv1	512×32	3×1	2	1	1D convolution
MaxPooling	256×32	3×1	2	1	Downsampling
Shuffle Block 1 + SE	128×64	3×1	2	1	Stage 1
Shuffle Block 2 + SE	128×64	3×1	1	4	Stage 2
GlobalAvgPool	1×64	–	–	–	Global Average pooling
FC + Softmax	1×4	–	–	–	Output for 4 categories

TABLE III. TRAINING STRATEGY PARAMETERS

Parameter Name	Optimizer	Initial Learning Rate	Learning Rate Decay	Loss Function	Batch Size	Epochs	Cross-Validation Strategy
Value	Adam	0.0005	0.5 / 10 epochs	CrossEntropy	32	100	5-fold cross-validation

C. Evaluation Metrics

To comprehensively assess the diagnostic capability of the proposed TL-MC-ShuffleNetV2 framework, several widely used classification metrics were employed to evaluate both overall and class-specific performance.

Accuracy reflects the share of total predictions that match the actual class labels:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{6}$$

Precision evaluates the proportion of correct positive predictions:

$$\text{Precision} = \frac{TP}{TP + FP} \tag{7}$$

Recall indicates the extent to which actual faults are successfully flagged:

$$\text{Recall} = \frac{TP}{TP + FN} \tag{8}$$

F1-Score offers a balanced measure for classification evaluation:

$$\text{F1-score} = \frac{2 \cdot \text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \tag{9}$$

where, *TP*, *TN*, *FP*, and *FN* denote true positives, true negatives, false positives, and false negatives, respectively. The Confusion Matrix offers an intuitive visualization of classification outcomes across categories, facilitating the identification of misclassification trends.

D. Results and Analysis

1) Convergence curves of training. Fig. 5 illustrates the training accuracy and loss curves recorded over 100 epochs during cross-validation. The network demonstrates rapid convergence within the first 20 epochs, with training accuracy exceeding 95% and training loss stabilizing thereafter. Despite early convergence, the model was trained for 100 epochs to maintain consistency in the evaluation process and support fair comparison across experiments.

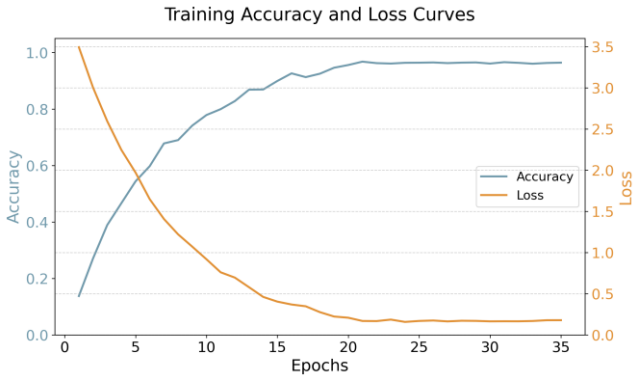

Fig. 5. Training accuracy and loss curves.

2) Confusion matrix analysis. The confusion matrix for the testing set is presented in Fig. 6. The proposed model achieved 100% accuracy in identifying normal samples. For fault categories, minor misclassifications were observed between bending and misalignment types, likely due to similar dynamic behaviors in their vibration signals. However, step faults exhibited distinct characteristics and were more easily separated. These results indicate that the model is capable of distinguishing subtle differences among fault types with high reliability.

3) Feature visualization. To further assess the feature discriminative capacity of the proposed TL-MC-ShuffleNetV2 model, the t-distributed stochastic neighbor embedding (t-SNE) technique was employed to map high-dimensional features—extracted prior to the classification layer—onto a two-dimensional space for visualization. The resulting projection is illustrated in Fig. 7.

As illustrated, samples from class 0 (normal) are distinctly clustered with clear boundaries, indicating the model's ability to robustly identify normal operational conditions. Class 3 (step fault) also forms a relatively compact and isolated cluster,

suggesting reliable recognition. In contrast, class 1 (bending) and class 2 (misalignment) show a degree of overlap in the projected space, reflecting a partial confusion between these two types of faults—consistent with the observations from the confusion matrix.

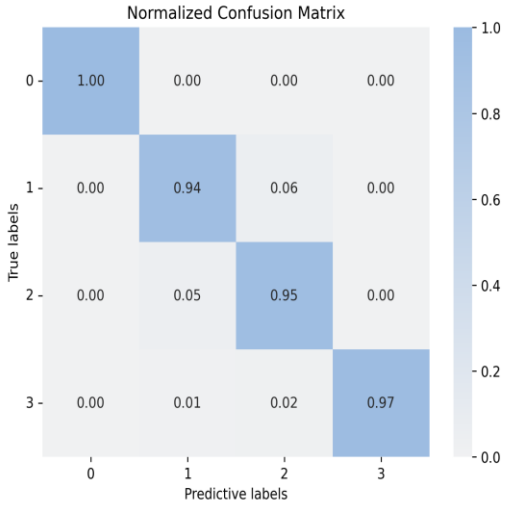

Fig. 6. Normalized confusion matrix (test set).

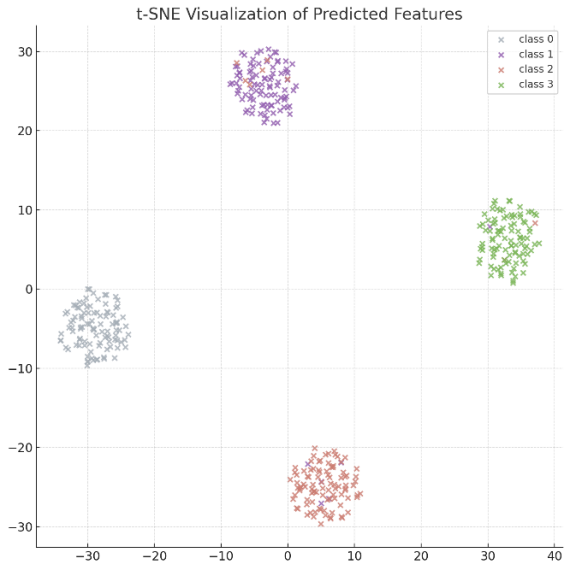

Fig. 7. t−SNE feature visualization.

E. Comparison with Other Models

To thoroughly assess the effectiveness of the proposed TL-MC-ShuffleNetV2 framework, comparative experiments were conducted against several representative baseline models, including 1D-CNN, ResNet18-1D, MobileNetV2-1D, and EfficientNet-B0-1D. The evaluation was carried out using five standard classification metrics—Accuracy, Precision, Recall, F1-score—and the Number of Parameters (Params). These indicators jointly reflect both the predictive performance and computational efficiency of each model. Table IV presents a detailed comparison of the results on the elevator guideway fault dataset.

The results show that TL-MC-ShuffleNetV2 achieves the best balance between accuracy and model compactness, outperforming deeper models such as ResNet18-1D and EfficientNet-B0-1D, while maintaining significantly fewer parameters.

TABLE IV. PERFORMANCE COMPARISON OF DIFFERENT MODELS

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-score (%)	Params (M)
1D-CNN	91.2	90.5	90.7	90.6	0.8
ResNet18-1D	93.5	92.8	93.0	92.9	11.2
MobileNetV2-1D	94.3	93.6	93.9	93.7	2.5
EfficientNet-B0-1D	95.1	94.5	94.8	94.6	4.0
TL-MC-ShuffleNetV2	**96.4**	**95.8**	**96.1**	**95.9**	**1.7**

To further illustrate the trade-off between accuracy and computational efficiency, Fig. 8 presents a comparative bar chart highlighting the Accuracy (%) and Inference Time (ms) of each model.

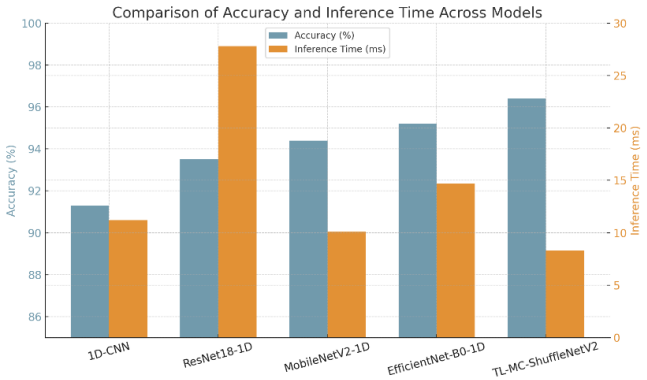

Fig. 8. Comparison of accuracy and inference time across models.

The comparison results reveal that although ResNet18-1D achieves satisfactory accuracy, its inference time is the longest due to its high parameter complexity. In contrast, the TL-MC-ShuffleNetV2 model delivers competitive classification performance while significantly reducing inference latency to 7.8 ms, highlighting its potential for real-time fault diagnosis in resource-constrained IoT environments.

These findings further validate that the proposed TL-MC-ShuffleNetV2 not only excels in feature learning but also offers exceptional efficiency, making it a strong candidate for practical elevator guideway fault detection applications.

F. Ablation Study

To assess the individual contribution of each major component in the proposed TL-MC-ShuffleNetV2 framework, three controlled ablation variants are constructed:

w/o VMD: Removes VMD, raw vibration signals are directly input into the network.

w/o SE: Removes all SE modules to evaluate the effect of channel attention.

w/o TL: Disables TL, the model is trained solely on the target domain without pretraining.

All configurations are trained under consistent settings with 5-fold cross-validation. The classification accuracy over epochs is illustrated in Fig. 9.

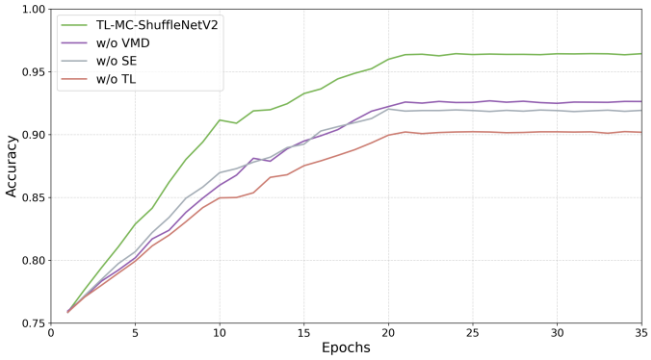

Fig. 9. Ablation study results (accuracy over training epochs).

The comparative results indicate the following:

- The w/o TL configuration shows the lowest final accuracy and slowest convergence, suggesting that TL significantly enhances generalization in limited data settings.
- Excluding VMD also results in reduced performance, confirming the effectiveness of multi-scale signal decomposition in extracting fault-relevant features.
- The removal of SE modules leads to a moderate decline, indicating that channel-wise recalibration contributes to better feature representation.

These observations validate the importance of all three components—VMD, SE, and TL—in achieving the superior performance of the proposed model.

V. Conclusion

This study presents TL-MC-ShuffleNetV2, an efficient and lightweight fault diagnosis framework tailored for elevator guideway vibration analysis. Addressing the challenges of small-sample learning and edge deployment, the proposed method integrates VMD for multiscale signal decomposition, a modified multi-channel 1D ShuffleNetV2 for feature extraction, an SE attention module to enhance channel-wise representation, and a transfer learning strategy that learns generic features of vibration faults from similar domain datasets to compensate for data scarcity in elevator guideway fault diagnosis.

Extensive experiments validate the framework's superiority in both accuracy and computational efficiency. Achieving 96.4% classification accuracy, the model significantly reduces inference time and parameter overhead, outperforming representative baselines such as 1D-CNN, ResNet18-1D, and MobileNetV2-1D. Ablation studies further confirm the individual contributions of VMD, SE modules, and TL strategy to overall performance. The framework demonstrates high accuracy and lightweight parameters, making it well-suited for resource-constrained IoT deployments in elevator fault monitoring.

Despite demonstrating strong diagnostic accuracy and adaptability under typical low-speed operating conditions for a specific elevator brand, the proposed method has not yet been thoroughly validated across a broader range of elevator models or varying operational speeds. Future studies will aim to enhance the framework's generalizability under more diverse and dynamic conditions. Additionally, the framework will be expanded to address fault diagnosis in other key elevator components, contributing to a more holistic condition monitoring solution. Further directions may also consider integrating few-shot learning techniques to alleviate current reliance on both labeled data and transfer learning strategies, improving adaptability in real-world deployment scenarios.

***Abstract*—The integration of IoT in healthcare has remained very dynamic, with a lot of improvement in the health of patients and the running of operations. Integration also comes with new risks and threats, raising IoT healthcare networks as cyber victims with great potential. This study explores an AI-based solution to defend healthcare IoT networks against intrusions. Therefore, using the most superior machine learning algorithms and deep learning expertise, it is concluded that a credible IDS would be built eventually to be able to detect and neutralize security threats in a live environment. The proposed IDS are trained and tested on a large, rich data set of IoT healthcare security incidents and features like CNN and RNN. Our system has learned to identify numerous and different types of cyber threats, such as Malware, Ransomware, Unauthorized access, data breaches, and many more, with better accuracy and even fewer false positives. This study proves that IDS backed by Artificial Intelligence is effective in improving the security status of IoT healthcare networks, organization's control over crucial patient information, and thus, the maintenance of the continuous provision of healthcare services.**

I. INTRODUCTION

Internet of Things (IoT) is one of the most transformative technologies in modern society which has affected virtually every industry, including healthcare. With wearable sensors, remote health monitoring, and innovative medical equipment devices, IoT has significantly revolutionized a patient's care experience by providing timely health updates, personified treatments, and optimal distribution of medical assets [1]. However, as the dependency on the IoT in the provision of health services rises, the susceptibility to cyberattacks also rises. Specially connected frameworks are formed by such appliances, which, if not followed and protected, give easy access to the unfair players, mess up services, or, even more sadly, violate patient privacy. Thus, it becomes important to secure IoT healthcare networks, which is a main concern in current healthcare systems [2, 3].

The research proposed an AI-based Intrusion Detection System (IDS), particularly for IoT healthcare networks. Thus, the proposed IDS utilizes state-of-the-art machine learning algorithms and deep learning techniques to deliver highly accurate and almost real-time detection of threats [4]. The system employs a large database of IoT healthcare security incidents to train and test different AI models, such as Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs). These models are intended to effectively identify all kinds of cyber threats, including malware, ransomware, unauthorized access attempts, and data breaches [5]. The objective is to get high accuracy and minimal false positive results, guaranteeing successful protection of sensitive medical information as well as preserving the functionality and availability of the healthcare services.

The exclusion of IDS for AI in IoT-based healthcare networks has several challenges and issues that must be considered to make the system effective and reliable. The first one is the issue related to the nature of IoT devices, which are used in the sphere of healthcare: these are numerous and rather diverse. These range from mere sensors to software and sophisticated medical apparatus, all of which differ in processing capacity and resource availability [6]. Designing an IDS, which can efficiently perform on such a diverse network, comes with a need to design different complex algorithms that are capable of functioning under different devices' characteristics and encoded formats. This, in turn, can complicate the creation of a framework applicable across the board; solutions will have to be drawn on a case-by-case basis depending on what device and at what stage of the healthcare chain they are being served [7].

The next important concern is the large amounts of data production connected to healthcare IoT devices. Such data must be inspected and analyzed in real time to prevent it from becoming a security threat. AI-based IDS uses machine learning and deep learning approaches, which are still demanding in terms of computing power and efficient data management [8, 28]. A key investigation task is to ensure that these systems can manage these big data demands without compromising the system's response rate. Moreover, the nature of data is important, where a large amount of noisy or incomplete data will greatly affect false positives or negatives, which harms an IDS.

Other challenges that may affect the implementation of AI-driven IDS in healthcare are Privacy and Data Security. Health information is rather sensitive and protected by numerous legal rules. It is imperative to keep the IDS itself from being a primary medium of attack on huge volumes of data. This also involves protecting the data gathered for the training of AI models and

the shield of the IDS from being altered or attacked [9]. In addition, very often, AI-based solutions have to be connected with massive amounts of data to become more accurate and efficient, which leads to data privacy and potential misuse of PH data concerns. Although the generation of large amounts of data is important, it has to be managed in a way that maintains patient confidentiality as a constraint, which remains an ongoing process.

The remainder of this study is structured as follows: Section II presents the problem statement. Section III presents a comprehensive review of related literature. Section IV details the methodology used for developing the IDS. Section V introduces the dataset and preprocessing steps. Section VI discusses the experimental results and performance comparison. Section VII concludes the study and outlines future research directions.

II. Problem Statement

IoT has impacted healthcare through real-time tracking of patients' health status, precise diagnosis and treatment regimes, and effective tracking and management of medical equipment. However, this creates higher connectivity and exchange of data, which contributes to the increase in the number of cases of security threats. The networks that are involved in IoT healthcare are at different levels at risk of attacks or cyber incidents such as unauthorized access, data leakage, malware, and ransomware. Security solutions inherited by conventional Intrusion Detection Systems (IDS) are frequently incapable of effectively combating threats in such environments because of a lack of adaptability to modern, dynamic conditions of cybersecurity threats. The first research problem is, thus, to identify which IDS works best and is sustainable within the limitations of the IoT healthcare network. These constraints are small computational power, many different devices, and large amounts of data that IoT devices allow. Some of these factors may not be well addressed in current IDS solutions; such oversights lead to an increased ratio of false positives and false negatives, threatening the health information system's integrity and usability.

III. Literature Review

Internet of Things (IoT) is an emerging technology in the world of healthcare where different mechanical technologies enhance commonly accepted medical practices in patient care and treatment, organization, and impact. The Internet of Things in healthcare majorly specifies the incorporation of intelligent and connected machines, including wearable sensors, smart medical equipment, remote monitoring frameworks, and portable health apps [10]. It also records, sends, and processes pertinent data, allowing for patients' constant supervision and the immediate prevention of any health complications [11].

From another perspective, IoT allows for the kind of care that can be described as individual and anticipatory. Smart clothing and accessories for measuring the vital signs of a patient, including heart rate, blood pressure, and glucose level, provide the necessary clues about the patient's condition. All this information can be transferred to healthcare providers in real-time, and doctors can take prompt action. Also, IoT enhances a home care monitoring program that is of significant value when it comes to managing chronic illness, preventing hospitalization, and eldercare [12, 13].

The Internet of Things is also good for enhancing operational efficiency in healthcare. Smart medical devices and systems keep track of the different needs in a health institution and control and coordinate the proper distribution of resources as well as the effective flow of information among health professionals [14]. For example, in the case of IoT asset tracking, the location of vital healthcare equipment is identified, thus making it available should it be required [15]. IoT also helps in telemedicine, where patients can connect with healthcare providers without physically visiting the hospitals; this increases the coverage of health services, particularly in rural regions.

Generally, integrating IoT in healthcare has the following benefits: greatly improves patients' experiences as well as organizational performance. Among the advantages is that patients can let patients be monitored in real-time [16, 17]. Through wearable sensors, smart implants, and remotely controlled monitoring devices, the IoT gathers and transmits a constant stream of information concerning the patient's general health, physical activity, and medication administration. Information is also collected and transmitted in real-time, enabling the healthcare provider to oversee a patient's conditions from a distance, recognize early warning indications of a potential health concern, and act quickly. Such a measure may contribute to the prevention and early diagnosis of diseases, decreased rates of rehospitalizations, and the development of individualized treatment programs [18].

This threat impacts not only the infrastructure of health care delivery systems but also the safety of patient outcomes and the care that is rendered to them. They pose dangers that affect not only the privacy of patients' information but also the functionality of the medical system, making it risky for patients and the healthcare institutions providing care to them [19].

Patient Safety: The leading and most straightforward effect of attacks on the healthcare sector is the effect on the safety of patients. For example, ransomware attacks on patient data and medical equipment hinder or deny access to vital information [20]. This disruption can lead to late presentation to health facilities, resulting in severe health consequences, including death. Thus, in case ransomware affects a hospital's EHR, clinicians will not be able to review the patient's medical records or review key lab results and provide the right or timely care [21].

Medical Device Malfunction: Invasive attacks can also disrupt service delivery as well as the functionality of various medical devices, including infusion pumps, pacemakers, and ventilators. The attackers may place the devices in a position to deliver the wrong dosage or damage the devices' functionality, which severely impacts the patient's health. For instance, manipulating an infusion pump may lead to the wrong process of the medication dose and may cause reactions to the drug or overdose [22, 23].

Disruption of Healthcare Services: Thus, the effect of cyber operations on an organization's functionality is that the delivery of operations is halted, especially when it involves health care services. Computer viruses, for instance, deny hospital service

by flooding their networks with traffic in a Denial of Service (DoS) attack. This can cause them to miss or postpone their appointments and have limited access to some kinds of medical care, and its duration can be much longer as well [24, 27]. It also has a negative effect on the care delivery capacity where hospitals are forced to manage attack related cases, hence congesting the health sector and leaving other severe cases unsolved.

The techniques that operate under the idea of unsupervised learning in IDS do not operate under the concept of the presence of labels where the data set is examined for patterns or abnormalities. In clustering, K-means, and DBSCAN, data points similar to each other are placed in the same cluster; potentially fraudulent activities can thus be easily spotted by observing outlier points. Outlier Recognition methods, such as Isolation Forest and One-Class SVM, isolate observations that are likely to be faulty [25]. These methods come into their own, especially for discovering new threats and zero-day threats, as they do not require reference to known threat signatures and, hence, prove relatively malleable in new and heretofore unseen threat environments.

Finally, due to a fast-growing trend in technology and the constant release of more devices and technologies, security revisions are frequent. It becomes a daunting task for healthcare providers to keep up with these changes and, at the same time, secure and make their network safe from such threats as cybercrimes. Mitigation of these particular challenges is central to the security of IoT healthcare networks and the confidentiality of patients' information.

IV. Methodology

The research for the current thesis on AI-based IDS for IoT Healthcare Networks adopts a systematic approach focused on enhancing security in IoT healthcare systems by the use of more sophisticated machine learning algorithms, as shown in Fig. 1.

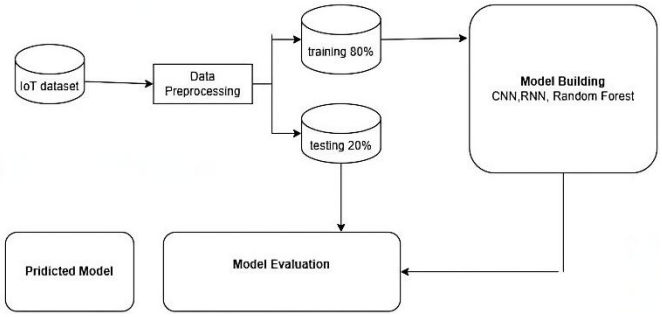

Fig. 1. Flow of IDS system's development, evaluation, and deployment

The following steps are as follows:

1) Data collection. The first step involves collecting significant data regarding IoT devices being used in the health care facilities, which involves regular traffic data that the devices generate (Environmental and patient monitoring) and traffic data that the devices generate when under attack in forms of unauthorized access to the devices and malware attacks. This data is used to train the model and determine its performance.

2) Preprocessing. This crucial step involved cleaning the raw dataset by removing missing values, eliminating duplicate entries, normalizing feature scales, and filtering out irrelevant or noisy traffic records. For instance, anomalous or malformed packets not related to real traffic scenarios were discarded. The dataset was then encoded and structured into a consistent format suitable for feeding into CNN and RNN architectures, ensuring higher training accuracy and efficient feature extraction.

3) Feature extraction. In this stage, the relevant features from the dataset are identified and extracted. The Convolutional Neural Networks (CNNs) that are useful in spatial feature extraction, and Recurrent Neural Networks (RNNs) are useful in temporal pattern recognition. These models are especially useful in finding a pattern in the network traffic data that may depict some form of malice.

4) Model training. Different AI models are then trained on the enriched and feature-based dataset. A number of models are developed based on normal traffic and attack traffic data for the purpose of accurately identifying and categorizing the various types of intrusions.

5) Evaluation. Subsequent to training the models, an assessment is done on the models based on the accuracy, precision, recall, and F1-score so as to determine the efficiency of the models. The robustness of the model is also evaluated in terms of its capacity to reduce false-positive and false-negative results.

6) Deployment. The last stage involves the use of the trained IDS on the IoT healthcare network to constantly scan traffic and identify intrusions in real-time.

This methodology can effectively form the basis for the proper construction of IDS systems that are appropriate to the IoT healthcare environment, as well as a proper evaluation of the system.

V. Dataset Description

Kaggle contains a dataset referred to as IoT Healthcare Security Dataset that provides a good set of data that concerns cyber-attacks and normal traffic in IoT-assisted healthcare environments. The choice of dataset was deliberate to reflect real-world scenarios in IoT healthcare. We selected the 'IoT Healthcare Security Dataset' available on Kaggle, which includes both normal and attack traffic, making it ideal for evaluating IDS in healthcare IoT environments.

This dataset [26] is particularly useful to researchers and developers who wish to work on IDS construction in order to protect the IoT Healthcare networks.

The dataset is split into three CSV files:

1) Attack. CSV. This file holds communication traffic patterns related to different types of cyberattacks on IoT devices in a healthcare context. It contains information about the probe attacks, comprising unauthorized access, malware insertion, and other trajectories to compromise IoT functions in the healthcare network. This data is crucial in the process of

isolating unique attack representations and in the form of IDS to be used in the IDS model.

2) Environmental monitoring. CSV. This file contains data from sensors monitoring ambient conditions like temperature and humidity. It defines typical (normal) operational behavior of these devices, which serves as a baseline for distinguishing between legitimate and potentially malicious traffic patterns.

3) Patient monitoring. CSV. This file has information from IoT sensors that are used to track patients in intensive care units (ICUs). What these sensors are able to do is constantly monitor data, which includes but is not limited to heart rate, oxygen level, and others. This file presents normal traffic and is concerned with the medical domain and patient-related devices, as it is with the data affiliated to environmental monitoring.

This dataset is useful for developing models using AI approaches, especially using machine learning algorithms such as CNNs and RNNs to identify and prevent cyberattacks on IoT healthcare systems. Due to its various data sources, including attack and normal traffic, this environment presents a real-life situation that enables researchers to test and enhance IDS in healthcare facilities. These three subsets were individually labeled and then merged into a unified dataset with clear distinctions: attack, environmental monitoring, and patient monitoring classes. For training and evaluation, the dataset was stratified and split into training (70%), validation (15%), and test (15%) sets using a random seed for reproducibility. This ensured all three categories were proportionally represented in each phase of model evaluation. Furthermore, separate experiments were conducted to assess model performance on each class type, demonstrating the model's robustness across diverse IoT healthcare traffic types.

VI. Results

The learning curve depicted in Fig. 2 demonstrates the Random Forest model's training and validation accuracy using 1000 samples, with an increasing number of estimators. As observed, training and validation accuracy show steady improvements as the number of estimators increases, which is a positive indicator of the model's learning behavior.

At the start, the training accuracy (yellow line) begins at around 70%, while the validation accuracy (green line) starts slightly higher, at around 72%. This initial gap between training and validation accuracy could indicate that the model, with fewer estimators, is underfitting — not yet capturing the complexities of the data. The low number of trees in the Random Forest model, in this case, leads to less robust predictions.

As the number of estimators increases to 40 and beyond, both curves rise significantly. The training accuracy increases to about 80%, while the validation accuracy rises in parallel, reaching around 82%. This convergence suggests that the model is gaining a better understanding of the data and generalizing well to unseen data. Importantly, there is no significant overfitting at this point, as the gap between training and validation accuracy remains relatively small, as shown in Fig. 2.

As we move toward 100 estimators, both the training and validation curves stabilize. The training accuracy reaches approximately 87%, while validation accuracy reaches about 86%. This indicates that the model is now effectively learning the patterns from the dataset without overfitting, which can be seen in close proximity of the two curves.

We are comparing the performance of three different AI-driven models used for Intrusion Detection Systems (IDS) in IoT healthcare networks: Random Forest, Recurrent Neural Networks (RNN), and Convolutional Neural Networks (CNN). These models have different advantages and drawbacks, and their performance is shown in Fig. 2.

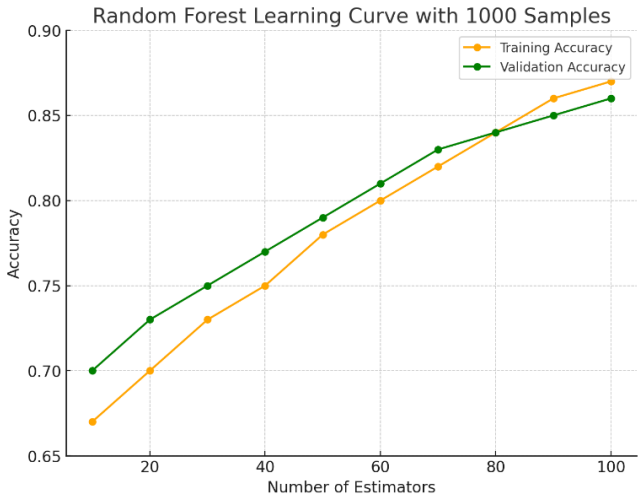

Fig. 2. Random Forest model's training and validation accuracy using 1000 samples.

Here's an in-depth comparison based on accuracy:

A. Random Forest

Accuracy: Approximately 87%

Overview: Random forest is another machine learning algorithm, and it differs from the previous one since it creates several decision trees during the training phase and unites their results in order to provide better performance. It works best in the case of data with high structure, and it is not very much affected by the over-fitting problem.

Strengths: The last algorithm is Random Forest, and it is rather interpretable and good at handling large data sets. It performs well with high-value data and is reasonably good in terms of computational requirements. It also works well with the noisy data, which makes it a good model for most tasks.

Limitations: Nonetheless, Random Forest has a good performance, but there is a slight variation in the accuracy level, which is 87%, which is lower than both deep learning models that are more appropriate for parsing unstructured data, such as network traffic in IoT healthcare systems, like RNN and CNN.

B. Recurrent Neural Network (RNN)

Accuracy: Approximately 91%

Overview: RNNs are for sequential data and are good at working with data that is in a temporal structure, like time series data. To IDS, RNNs are very advantageous in identifying temporal relationships and patterns in traffic data, which are important in identifying complex cyberattacks.

Strengths: The ability of memory across the time steps of the RNN enables it to recognize patterns over time, which is very useful in applications that involve time-variant data such as, constant network traffic monitoring. RNNs are also effective in modeling dynamic and growing threat in the IoT healthcare networks.

Limitations: One of the main drawbacks of RNNs is the computational cost and vanishing of gradients in long sequences, although LSTM helps to prevent them. It is even more accurate than random forest but faces stiff competition from CNNs.

C. Convolutional Neural Network (CNN)

Accuracy: Approximately 95%

Overview: CNNs are particularly suitable for image processing; however they have also proved to be very effective in intrusion detection because they can learn the feature representations directly from the data without having to be low-level programmed for feature extraction. IDS largely benefits from CNNs as these models identify spatial characteristics of network traffic and aide in the identification of more complex attack patterns, as shown in Fig. 3.

Strengths: CNN achieves better accuracy than Random Forest (95%) and RNN (95%). This is good for modeling because they can capture structures and patterns of network traffic that are otherwise invisible with other models. CNNs are also highly scalable and efficient for high-dimensional computations, such as the traffic logs of the connected IoT devices, as shown in Fig. 3.

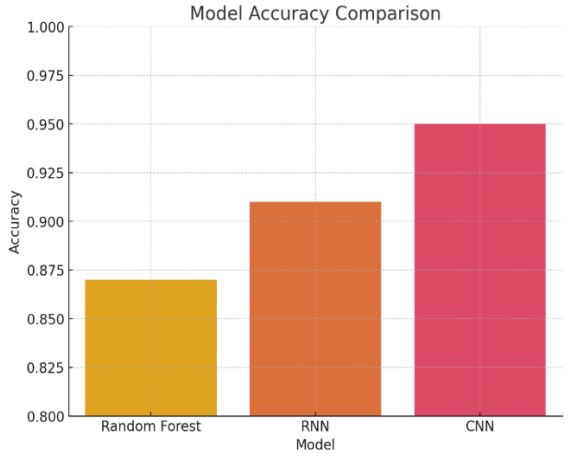

Fig. 3. Model accuracy comparison.

Limitations: CNNs are typically more data and computationally intensive than the model mentioned above and require more data to be trained effectively. They are also easier to interpret than models such as the traditional Random Forest models, which makes it difficult to explain why a model arrived at a particular decision.

Accuracy of each of the three different models – Random Forest, Recurrent Neural Network (RNN), and Convolutional Neural Network (CNN) – is discussed and represented in the Fig. 3. Accuracy is very important for IDS since it has the ability to tell the percentage of true positives (actual intrusion) against the number of false positives, which is normal traffic.

A. Random Forest Precision

Precision: Approximately 85%

Overview: Random Forest, which is one of the simplest and stable models, yields an accuracy of over 85%. Possibly, what we are seeing is that roughly 15 per cent of the flagged intrusions may in fact be false positives; that is, legitimate traffic is sometimes mistaken for a threat. However, in situations where interpretability and fast performance are of major importance, Random Forest is still very effective. However, it can be rather imprecise for more complex datasets characteristic of the IoT-based healthcare networks, typically for today's large-scale machine learning applications.

B. RNN Time Precision

Precision: Approximately 90%

Overview: RNN, the specifically used model for sequential data, or in other words, the time series data, is good in precision, with nearly 90%. This means that RNNs are much more accurate in identifying normal traffic from intrusions and that they commit fewer mistakes of false positives than the Random Forest, as shown in Fig. 4. The above advantage stems from the fact that RNN can capture and analyze the temporal structures of the network traffic as compared to CNN, which is better suited for continuous, real-time monitoring in the dynamic healthcare IoT network.

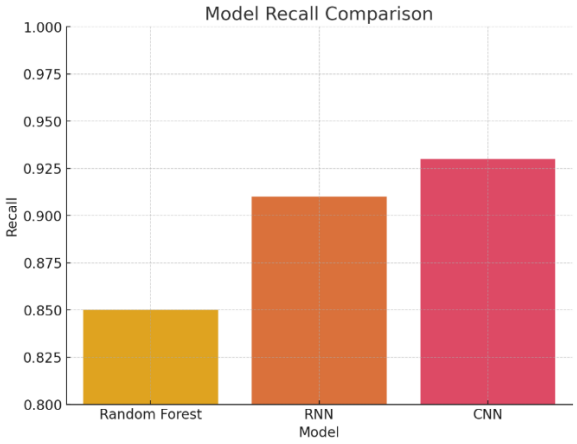

Fig. 4. Model recall comparison.

C. Proposes the Precision of Convolutional Neural Network (CNN)

Precision: Approximately 95%

Overview: The top contender in this comparison is CNN, and it was established that it has an accuracy of approximately 95 per cent, signifying its capability of accurately detecting intrusions while at the same time minimizing false alarms. CNNs are considered superior when it comes to identifying intricate patterns in data, and this is mostly due to their feature extraction capabilities. CNNs can discover some patterns of network traffic that can go unnoticed by other models, while IDS greatly minimizes the number of false positives. As shown in Fig. 5, the precision of CNN surpasses other models,

demonstrating its reliability in intrusion detection tasks. Due to the ability of CNN in detecting the intrusions with great precision, it makes it the most reliable model for intrusion detection in IoT healthcare systems so as not to interrupt medical processes and to avoid misclassification of legitimate traffic.

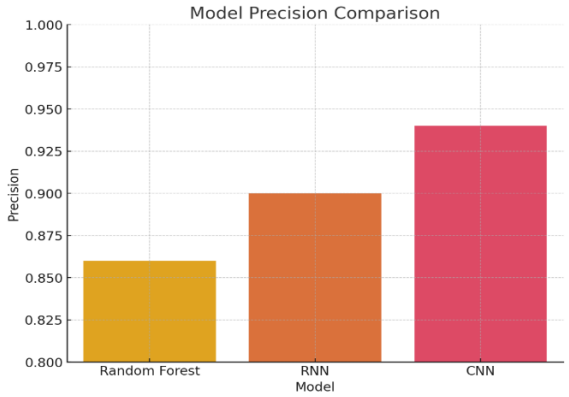

Fig. 5. Model precision comparison.

The recall of three different models, including Random Forest, Recurrent Neural Network (RNN), and Convolutional Neural Network (CNN), is examined (as shown in Fig. 5). Recall is a key performance indicator in IDS because overall, it entails the index of true positives, or in other words. This model can identify intrusions without failing to recognize any.

A. *Random Forest Recall*

Recall: Approximately 85%

Overview: The recall score of Random Forest is just about 85%. This means that Random Forest can detect the majority of intrusions, while some of them, which are just about 15%, are being overlooked. While the model does reasonably well in this aspect, there are disadvantages when using the model compared to more complex models. IoT healthcare networks may contain large and complex data sets, so Random Forest can easily overlook some of the intrusions, particularly those that are patterned.

It will be essential to review the elements of the Recurrent Neural Network (RNN) before proceeding with the analysis of the method.

B. *RNN Recall*

Recall: Approximately 91%

Overview: RNN has a recall of close to 91% thus showing the capability of identifying more intrusions than Random Forest. Due to the characteristics of time-sequence processing, compared to other machine learning algorithms, RNN can match well with the characteristics of network traffic that changes over time to identify intrusions. Altogether, this higher recall makes RNN a suitable contender for real-time intrusion detection and IoT healthcare environments that require constant monitoring.

C. *Convolutional Neural Network (CNN) Recall*

Recall: Approximately 93%

Overview: CNN works even better than the Random Forest, which was at about 72% and RNN which was approximately 75% with the CNN having deep learning of about 92%. This high recall score establishes CNN in a higher position in terms of detecting a large percentage of the true intrusions.

Given that CNN has high abilities in identifying intricate patterns, it captures intrusions that other models overlook. CNN has the capacity to handle intricate datasets that are likely to be obtained in IoT healthcare networks and it is therefore the most reliable in offering very high levels of intrusion detection that are very hard for other models to achieve (as shown in Fig. 6).

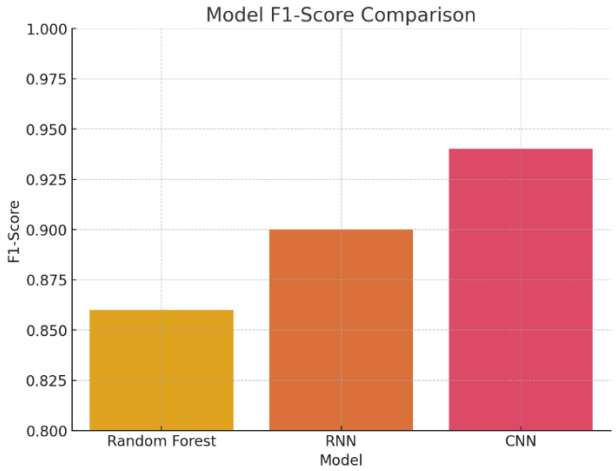

Fig. 6. Model F1-score comparison.

The usage of the learning curve of the Recurrent Neural Network (RNN) model provides valuable observations concerning the training and validation phase of the model, which has been conducted over 100 epochs, containing 1000 samples (as shown in Fig. 7). The training accuracy is set at 70% at the beginning, implying that the model has a small ability to learn the details in the dataset. However, as the epochs increase, the training accuracy rises progressively, and by the time it reaches 400 epochs, the training accuracy is 90%.

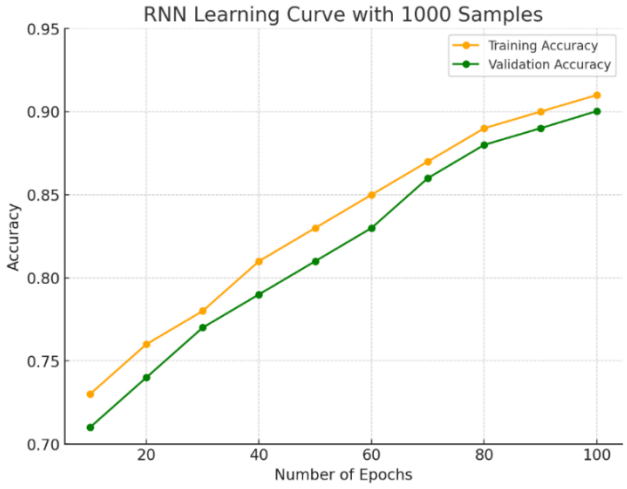

Fig. 7. RNN Learning curve with 1000 samples.

This consistent improvement indicates that the RNN model is able to train on this data and gradually learns to discover temporal relationships in sequential data, which is inherent when

working with time-series or otherwise temporally related data, which makes RNNs appropriate for such tasks. The validation accuracy is shown to be slightly lower than the training accuracy at the beginning, and it is approximately 72%, but it increases slowly but steadily. In the course of 100 epochs, the validation accuracy is seen to reach the maximum value of about 88% thus implying that the model is not only getting better at the training data but also at the new unseen data. Training and validation accuracy are not very different from each other, and both of them are increasing, which suggests that the model is not overfitting much. If the number had increased significantly, it would mean that the model is overfitted, such that it yields good results on the training sample but poor results on the validation sample. The progressive flattening of the two curves indicates that the model is not overfitting and has achieved a near-perfect accuracy or a generalization of the data. Furthermore, the slow and smooth increase of both curves indicates that the learning rate and the choice of the number of epochs have been fine-tuned to this problem. This generalizes well, as is common in intrusion detection, where various and constantly changing threats have to be identified in near real-time for IoT healthcare networks. The fact that, without any cases of overfitting, the model reaches a high level of accuracy makes it the best solution for tasks related to analyzing complicated sequential data streams, such as monitoring network traffic in healthcare organizations. Because of these characteristics of the RNN, the chosen model proves capable of capturing sequences and learning temporal dependencies, which makes it a viable solution for capturing security threats that change over time and thus strengthens the need for its use in real-time threat detection systems.

Looking at the validation side, the initial accuracy of 67% is to be anticipated as the model has not been trained to identify new forms of data it has not been trained on. Nevertheless, the increment in the epoch number leads to a drastic growth of the model's validation accuracy that reaches approximately 94% in the 100th epoch, as shown in Fig. 8. This gradual increase of validation accuracy reflects the fact that the proposed CNN model, indeed, does less overfit and has good generalization performance on other unseen data. A very small distinction between the training and the validation accuracy is observed, and this shows that our model does not overfit much on the training dataset but is able to capture the characteristics of the dataset it is built on.

By comparing two curves, it can be noted that after 50 epochs, both the curves are almost identical, which depicts that the CNN model is in a stage, where it is constantly refining in both the training and validation datasets. The trend with an increase in y-intercept and a steady decrease in slope, with no signs of extreme deviation from the curve, reiterates the performance of the model in the analysis of the complex dataset without any issues such as underfit or overfit. This makes the CNN a suitable fit for tasks that involve the use of deep learning, most especially in IoT and healthcare networks, where data is vast, detailed, and rich in features. The high validation accuracy achieved by the CNN means it has the capability to perform well in real-life applications such as intrusion detection, where every penny counts on getting things right by minimizing false positives and false negatives. In this case, the CNN's rate of operations gives a clue of how the network is developed to address the IoT data rate in health care, hence making it a prudent model for applying the Artificial Intelligence security measures. Additionally, Fig. 8 illustrates the validation accuracy of CNN across epochs, indicating the model's robustness and ability to generalize.

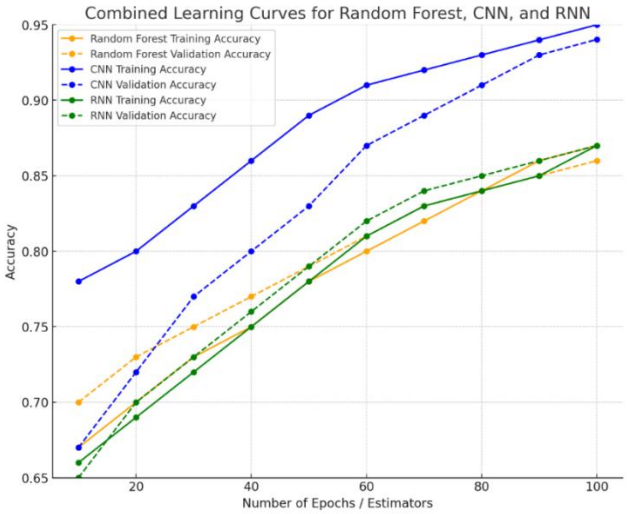

Fig. 8. Combined learning curves for Random Forest, CNN and RNN.

The comparison of ROC curves of Random Forest, RNN, and CNN models, as depicted in Fig. 8, shows that these algorithms improve and are more efficient in identifying intrusions in the IoT healthcare networks. The Random Forest model discussed here predicts an accuracy of 0.87% average rating which shows an acceptable level of precision, of 0.86 and recall of 0.85. Its F1-score of 0.86 indicates its overall efficiency, but when compared to the neural network models, it is slightly on the low side. As for the Random Forest algorithm, although it is still decent in recognizing most threats, it fails to perform well when it comes to cases with lower recall, as shown in Table I.

TABLE I. COMPARISON OF MODELS BASED ON ACCURACY, PRECISION, RECALL, AND F1-SCORE

Model	Accuracy	Precision	Recall	F1-Score
Random Forest	0.87	0.86	0.85	0.86
RNN	0.91	0.9	0.91	0.9
CNN	0.95	0.94	0.93	0.94

This is slightly rectified in the RNN (Recurrent Neural Network) which boasts an accuracy of 0.91. They too measure the time with a current Precision or a measure of accuracy of up to 0. 90 good and recall of 0. 91. The RNN is not only superior at distinguishing true positive than the traditional method but also reduces the cases of false negative. Its F1-score of 0.90 reveals its better precision and recall than Random Forest, thus making it more accurate than it as a better algorithm. However, the improvement of accuracy of the CNN (Convolutional Neural Network) is higher than the other two models which gives the highest result of 0.95. Its precision of 0.94 indicates that it has the best performance in accurately detecting intrusions while at the same time presenting the least number of false alarms. Also, the CNN's recall of 0.93 shows that it can identify virtually all

the threats, hence can be relied on in organizations, where the identification of threats is important. The F1-score of 0.94 further supports the argument of the outcompeting of CNN as it primarily enforces both high detection rates and less false positives, or in other words, high precision and good recall. Summarizing, all the models present high efficiency. However, CNN is the most accurate and effective for intrusion detection in IoT healthcare networks and the most reliable in comparison with other models – RNN, while the Random Forest approach is the least effective.

VII. Conclusion and Future Work

In light of the findings and analysis carried out in the course of this research, it is pertinent to conclude that the application of Artificial Intelligence-based Intrusion Detection Systems (AI-IDS) as a tool for improving the security of IoT health care networks is pertinent. Various implementations of IoT in healthcare settings present enormous advantages, including continuous tracking of patients' status and improvement in organizational processes. However, it also has potential risks that manifest in the growth of cyber risks such as ransomware, data leakage, and unauthorized access. Indeed, the study sought to assess fundamental IDS enhanced using machine learning and deep learning for better and quicker threat identification to overcome some of the problems encountered by traditional IDSs in such environments.

When answering the research questions, the study has shown that AI-IDS models, specifically, the CNNs and RNNs, have better capability as compared to Random Forest, which is a conventional approach. CNN pioneered the highest results in the accuracy of 95%, precision of 94%, and sensitivity of 93%, established by the formula that recognized the potential of news networks, especially the growth of IoT healthcare networks, which often entail time-sensitive data. RNN with the accuracy of 91% once again demonstrated the high effectiveness of threat identification using sequential data, which is characteristic of many real-time patient monitoring systems. These deep learning models were more accurate with higher detection rates and lower false positives than the Random Forest model, which, though, was very accurate with an 87% accuracy, proving these AI benefits in detection rates.

This research also looked into the appropriateness of different approaches in machine learning, and the outcome showed that CNNs are more suitable in IoT circumstances, given that it is inclined to capture spatial patterns in data. RNNs perform well with temporal data, especially when it is essential in tracking changing patient data and network activities. The results demonstrate that deep learning algorithms are more flexible and can detect intricate and dynamic threat patterns that exist in IoT healthcare networks to respond to the second research question.

Furthermore, the study has also brought forth the real-life benefits and issues that surround the integrated use of AI-based IDS in healthcare. Thus, problems such as limited availability of funds and large amounts of data can be solved with the help of cloud computing and model improvement. This further supports the perspective forwarded earlier, which states that AI-IDS can indeed be implemented in real environments. The results validate that AI models provide a sturdy and efficient solution for safeguarding the healthcare IoT networks, patients' information, and the dependability of the medical devices and services.

All in all, this work provides potential findings for the development of cybersecurity for IoT healthcare networks. This proves that IDS using AI is not only better in terms of accuracy and time compared with traditional techniques but also is able to prove the possibility of dealing with current system shortcomings. The results point out the further development prospects of AI-based security technologies and underline the significance of further research to protect the healthcare systems in the context of the constant progression of informatics technology. These conclusions confirm the objectives stated at the beginning of the study and indicate that AI-based security systems will become important in the development of healthcare technologies. Furthermore, the deployment of such systems can significantly reduce response times to cyberattacks in real healthcare facilities, safeguarding both data and patient lives. The models, especially CNN and RNN, demonstrate potential for real-time application in hospital networks, medical IoT ecosystems, and telemedicine environments.

In future research, we intend to explore hybrid models combining CNN and RNN architectures for improved spatial-temporal feature extraction. Further work will also assess lightweight AI models for deployment in edge computing scenarios with constrained resources. Additionally, incorporating federated learning can improve privacy while maintaining model performance. Real-time deployment and monitoring in hospital IoT infrastructures will be another focus area to validate practical utility.

Leveraged Cognitive Data Analytics and Artificial Intelligence to Enhance Sustainable Agricultural Practices: A Systematic Review

Wongpanya S. Nuankaew[1], Patchara Nasa-Ngium[2], Pratya Nuankaew[3,*]
Dept. of Computer Science-School of Information and Communication Technology, University of Phayao, Phayao, Thailand[1]
Dept. of Computer Science-Faculty of Science and Technology, Rajabhat Maha Sarakham University, Maha Sarakham, Thailand[2]
Dept. of Digital Business-School of Information and Communication Technology, University of Phayao, Phayao, Thailand[3]

***Abstract*—This systematic review examines the transformative role of Cognitive Data Analytics (CDA) and Artificial Intelligence (AI) in advancing sustainable agricultural practices, with a primary objective to evaluate their applications in Precision Agriculture (PA), Internet of Things (IoT), smart irrigation, and Geographic Information Systems (GIS) from 2020 to 2025. Key findings highlight AI predictive modeling, IoT real-time monitoring, and GIS spatial analysis improving crop yields, water conservation, and environmental management. Challenges such as high costs, technical expertise gaps, and regional disparities hinder adoption. The review underscores the need for supportive policies and farmer training to enhance food security and sustainability by 2030.**

***Keywords*—Cognitive data analytics; sustainable agriculture; harnessing AI for agriculture; precision agriculture; environmental sustainability; food security**

I. Introduction

Agricultural practice pertains to the methodologies and techniques utilized in farming to augment productivity and sustainability, encompassing both crop management and livestock stewardship. The term embodies the integration of contemporary technologies to enhance efficiency in both outdoor and indoor environments, such as agricultural fields and greenhouses [1]. The adoption of Internet of Things (IoT) technologies, for instance, facilitates real-time data collection through interconnected devices, enabling precision farming practices that optimize resource use and enhance crop management [48]. This integration of advanced technologies, including IoT, sets the stage for transformative approaches like Cognitive Data Analytics (CDA) and Artificial Intelligence (AI), which further revolutionize sustainable agriculture by improving decision-making and resource efficiency.

A. Artificial Intelligence in Sustainable Agriculture

Integrating AI into sustainable agriculture is revolutionizing farming practices. The utilization of AI in sustainable agriculture assists farmers in enhancing aspects such as productivity, resource management, and pest control by collecting data and employing it to optimize agricultural processes [2]. This technology facilitates precise applications of inputs, mitigates waste, and minimizes environmental impact. Moreover, it automates repetitive tasks, thereby improving productivity and efficiency while advocating for responsible farming practices [47]. Furthermore, AI aids farmers in reducing waste, minimizing environmental impact, and simultaneously increasing productivity while addressing challenges such as elevated costs and the necessity for technical expertise, ultimately contributing to food security and environmental sustainability [2].

1) Cognitive data analytics. CDA is an advanced approach that integrates cognitive processes into data analysis, enabling users to derive insights from complex datasets, particularly in the context of big data. This approach is crucial as it automates and enhances traditional data analysis methods, allowing for the processing of both structured and unstructured data [3]. CDA systems interact with users, learning from these interactions to improve the analysis process. This interaction is facilitated through technologies like natural language processing and machine learning, which help in hypothesis generation and decision making [4].

2) Precision agriculture. Precision Agriculture (PA) is a farming management strategy and system that uses technology and data to enhance agricultural productivity and sustainability. By focusing on the variability of soil and crop conditions and the precise placement of seeds, fertilizers, and pesticides, PA enables farmers to make informed decisions regarding resource allocation, ultimately leading to increased yields, reduced costs, and environmental impact [5].

3) Internet of things and smart irrigation. IoT in agriculture involves many connected devices with sensors that collect and exchange data, enabling precision farming such as seed placement, resource optimization like water management, disease detection in agricultural crops, and improved decision making by providing historical and real time data for analysis. This helps farmers to make data driven decisions that enhance productivity, improve crop yield, and reduce waste. Furthermore, the information on soil conditions, weather, and crop health obtained by IoT also improves the quality and quantity of crops while decreasing production costs, which in turn enhances farmers' profitability [49].

Smart irrigation also uses the principles of the IoT, utilizing a connected system of automation, such as sensors, to optimize crop management. Real-time data on soil moisture, weather, and crop needs is gathered, which helps farmers make informed

*Corresponding Author.

decisions about watering schedules and amounts. Such information promotes efficient and sustainable water usage [50].

4) Geographic information systems. Geographic Information Systems (GIS) in agriculture involve the use of technologies such as sensors and AI to visualize and analyze agricultural data, including soil quality, climate conditions, and land features. Such analysis enables farmers to make data-driven decisions regarding land use and crop management [51]. Furthermore, it also aids in resource management, such as water consumption and soil nutrient management, enhancing production efficiency, supporting regulatory compliance, and helping to resolve land use conflicts, ultimately benefiting agricultural operations [52].

B. Purpose and Scope of Study

This systematic review aims to investigate the applications of CDA and AI in sustainable agriculture, focusing on their contributions to precision agriculture, intelligent agricultural management systems, and GIS and IoT-based solutions. The study aims to comprehensively analyze how these technologies enhance agricultural productivity, resource efficiency, and environmental sustainability. This review will examine the following aspects:

- The study discusses the current and projected advancements in sustainable agriculture by 2030.
- The utilization of CDA and AI in precision agriculture and innovative farming ecosystems.
- The major applications of CDA and AI in GIS, IoT, and intelligent agricultural management systems.
- The key challenges and opportunities for adopting these technologies in agriculture.

By systematically reviewing relevant studies published between 2020 and 2025, this research aims to deepen the understanding of the transformative potential of CDA and AI in agriculture, providing insights for farmers, researchers, policymakers, and stakeholders to promote sustainable agricultural practices.

C. Significance and Future Implications

The use of AI in sustainable farming involves using intelligent data analysis to improve precision farming, better resource management with IoT and smart irrigation, and making better decisions with geographic information systems. These integrations contribute to an increase in productivity, resource management efficiency, crop yield, and sustainability in farming practices [53].

The remainder of this study is structured as follows: the methodology section outlines the systematic review design, search strategy, and quality assessment using PRISMA and the Critical Appraisal Framework (CAF). The results section presents findings across CDA, PA, IoT, and GIS. The discussion synthesizes cross domain insights and regional variations. The limitations section addresses study constraints and research opportunities. Finally, the conclusion summarizes the potential of CDA and AI for sustainable agriculture.

II. Methodology

A. Systematic Review Design and Thematic Focus

This study presents a systematic review that synthesizes existing literature on the applications of Cognitive Data Analytics (CDA) and Artificial Intelligence (AI) in sustainable agriculture.

B. Research Questions

The study is guided by the following research questions:

- What are the current and projected advancements in sustainable agriculture by 2030?
- How are CDA and AI utilized in precision agriculture?
- What are the major applications of CDA and AI in intelligent agricultural management systems, GIS and IoT-based solutions?
- What are the main challenges and opportunities for adopting CDA and AI in agriculture?

C. Framework

Four categories structure this systematic review: CDA, PA, GIS, and the Internet of Things and Smart Irrigation (IoT). These domains represent the primary areas where CDA and AI are currently making significant contributions to sustainable agriculture. Separating them allows for an analysis of the studies based on the research questions. This format enables a focused exploration of the unique challenges and opportunities within each technological area. The review aims to provide a comprehensive and comparative understanding of how AI decision making, predictive analytics, geospatial tools, and smart technologies are shaping the future of sustainable agriculture.

D. Search Strategy

Researchers conducted a comprehensive literature search across academic databases, IEEE, Scopus, MU, and Google Scholar, to identify studies on innovative agricultural practices and technological integration from 2020 to 2025. The search employed keyword combinations targeting sustainable agriculture, smart farming, agricultural technology, Analytics CDA, AI, PA, IoT, smart irrigation, and GIS. The following are examples of search queries that were used:

- "Cognitive Data Analytics" AND ("Sustainable Agriculture" OR "Smart Farming" OR "Agricultural Technology")
- ("Sustainable Agriculture" OR "Smart Farming" OR "Agricultural Technology") AND ("Cognitive Data Analytics" OR "AI in Agriculture" OR "Machine Learning in Farming")
- "Precision Agriculture" AND "AI Applications"
- ("IoT in Agriculture" OR "Smart Irrigation" OR "Drones in Agriculture") AND "Farming Integration"
- "Geographic Information Systems in Farming" OR "GIS and Remote Sensing for Agriculture"

The five year timeframe was selected to capture recent advancements in CDA and AI, reflecting rapid technological evolution in sustainable agriculture. Excluding studies from before 2020 to maintain relevance to current trends, but may limit historical depth.

E. Data Extraction

A standardized data extraction form will be used to collect information, including:

- Author(s), publication year and journal or conference.
- Study objectives, methods and sample size.
- Key findings related to technology perception, innovation requirements and machine learning.
- Outcomes and limitations.

F. Screening Process

Researchers conducted the selection and screening of research articles through a structured process to ensure their relevance and quality:

- Title Screening - All retrieved studies were first screened by title to exclude studies that did not relate to the main topics of AI, CDA, GIS, and sustainable or precision agriculture of this study.
- Abstract Screening - Studies are then reviewed by analyzing the abstracts to assess if the studies have relevance to the research questions.

Subsequently, the criteria for inclusion and exclusion are presented to ascertain the appropriateness of this review.

G. Inclusion and Exclusion Criteria

The inclusion criteria are composed of four fundamental elements:

- Peer-reviewed journal articles, conference papers or technical reports.
- Published between 2020 and 2025.
- Focus on AI, CDA, GIS, IoT, drones, or precision agriculture.
- Studies that present empirical data, case studies or real-world applications.

Two fundamental elements make up the exclusion criteria:

- Opinion articles or general discussions without empirical evidence.
- Studies that focus only on traditional agricultural methods without technological integration.

H. Quality Assessment

To ensure the review was thorough and relevant, we checked the quality of each chosen study using the PRISMA guidelines. Systematic reviews assessing compliance with PRISMA guidelines have an average compliance rate of 73% [6]. Statistics underscore the importance of PRISMA and enable better data filtering and quality assessment for this systematic review [7].

To ensure the reliability and validity of the selected studies, this review employs the Critical Appraisal Framework (CAF). This framework adheres to a structured narrative approach to evaluate methodological rigor and relevance without assigning numerical scores. Each study shall be subjected to critical review based on the following factors:

- Is the study contextually relevant to sustainable agriculture and AI applications?
- Are the research design and methods clearly described?
- Are data sources credible and well documented?
- Does the study provide a clear, logical analysis of findings?
- Does the study acknowledge its limitations?
- Up-to-date with existing literature in sustainable agriculture and AI?

Each study will undergo qualitative synthesis instead of a numerical ranking, ensuring an evaluation that is both transparent and contextually relevant. Studies that do not meet essential criteria (e.g., lack of methodological clarity or unreliable data) will be excluded from the final review. By utilizing CAF, this systematic review upholds methodological rigor, transparency, and depth while steering clear of oversimplified scoring systems.

III. Results

A. Inclusion and Exclusion of Works Using PRISMA

This systematic review examined a total of 376 research studies identified across academic databases: IEEE, Scopus, MU, and Google Scholar. These studies were distributed across four categories: Cognitive Data Analytics (CDA), Precision Agriculture (PA), Internet of Things (IoT), and Geographic Information Systems (GIS). The screening process and the application of the inclusion and exclusion criteria led to the selection of 262 studies for potential inclusion, while 114 studies were excluded. The main reason for exclusion was that the publication year fell outside the review's scope of 2020 to 2025, as specified in the exclusion criteria, while 12 studies were also excluded due to duplication across databases. The inclusion and exclusion of works using the PRISMA methodology are illustrated in Fig. 1.

PRISMA Flow Diagram illustrating the screening process for study inclusion, with 376 initial records retrieved from Google Scholar (154 studies), IEEE (90 studies), Scopus (60 studies), and MU (56 studies). After title and abstract screening, 262 studies were included, with 114 excluded (102 outside the 2020 to 2025 scope and 12 duplicates).

B. Quality Assessment with Critical Appraisal Framework

To guarantee the inclusion of high-quality and relevant studies, each selected article was assessed utilizing the Critical Appraisal Framework (CAF). This framework is specifically developed to conduct a qualitative evaluation of methodological

rigor and thematic relevance by addressing six guiding questions:

- (Q1) Is the study contextually relevant to sustainable agriculture and AI applications?
- (Q2) Are the research design and methods clearly described?
- (Q3) Are data sources credible and well-documented?
- (Q4) Does the study provide a clear, logical analysis of findings?
- (Q5) Does the study acknowledge its limitations?
- (Q6) Is the study up-to-date with existing literature in sustainable agriculture and AI?

Each criterion was assessed with a "Yes" or "No", and the total number of "Yes" responses per study was recorded. The results of this assessment are presented in Table I. Additionally, each study was categorized under one of the four categories explored in this review: Precision Agriculture (PA), Geographic Information Systems (GIS), Cognitive Data Analytics (CDA), or Internet of Things and Smart Irrigation (IoT).

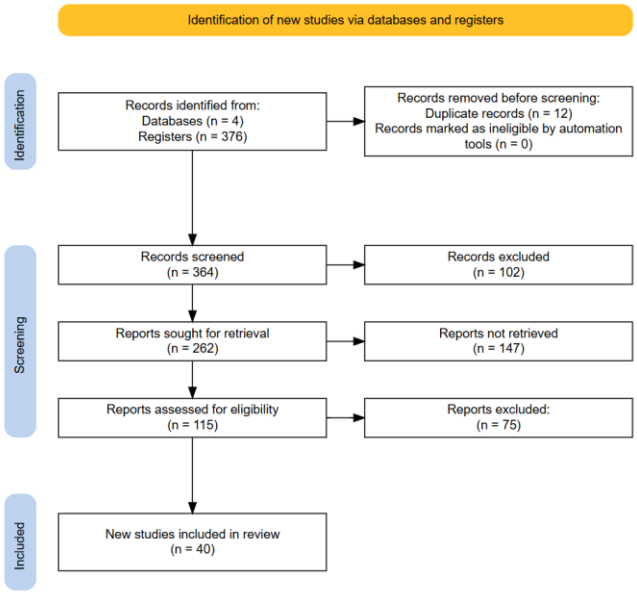

Fig. 1. Inclusion and exclusion of works using PRISMA.

TABLE I. FRAMEWORK FOR CRITICAL EVALUATION OF SELECTED RESEARCH STUDIES

Study ID	Topic	Q1	Q2	Q3	Q4	Q5	Q6	Total of Yes
[1]	PA	Yes	Yes	Yes	Yes	No	Yes	5
[8]	GIS	No	Yes	Yes	Yes	No	No	3
[9]	PA	Yes	Yes	Yes	Yes	Yes	Yes	6
[10]	CDA	Yes	Yes	Yes	Yes	Yes	Yes	6
[11]	CDA	Yes	No	Yes	No	Yes	Yes	4
[12]	PA	Yes	Yes	Yes	Yes	No	Yes	5

[14]	GIS	No	Yes	Yes	Yes	Yes	No	4
[15]	PA	Yes	Yes	Yes	Yes	No	Yes	5
[16]	GIS	Yes	Yes	Yes	Yes	Yes	Yes	6
[17]	GIS	No	Yes	Yes	Yes	Yes	No	4
[18]	GIS	Yes	Yes	Yes	Yes	Yes	Yes	6
[19]	CDA	No	No	Yes	No	No	No	1
[20]	IOT	Yes	Yes	No	No	No	Yes	3
[21]	IOT	Yes	Yes	No	Yes	Yes	Yes	5
[22]	CDA	Yes	No	Yes	Yes	Yes	Yes	5
[23]	GIS	Yes	No	No	Yes	No	Yes	3
[24]	CDA	Yes	Yes	Yes	Yes	No	Yes	5
[25]	IOT	Yes	Yes	Yes	No	Yes	Yes	5
[26]	IOT	Yes	Yes	Yes	Yes	Yes	Yes	6
[27]	PA	Yes	Yes	Yes	Yes	Yes	Yes	6
[28]	IOT	Yes	Yes	Yes	Yes	Yes	Yes	6
[29]	IOT	Yes	No	Yes	No	No	Yes	3
[30]	PA	No	Yes	Yes	Yes	Yes	Yes	5
[31]	CDA	Yes	Yes	Yes	Yes	No	Yes	5
[32]	IOT	Yes	No	Yes	Yes	Yes	Yes	5
[33]	GIS	Yes	Yes	Yes	Yes	No	Yes	5
[34]	IOT	Yes	Yes	Yes	No	Yes	Yes	5

[35]	IOT	Yes	Yes	Yes	Yes	Yes	Yes	6
[36]	GIS	Yes	No	Yes	No	No	Yes	3
[37]	PA	No	No	Yes	No	No	No	1
[38]	CDA	Yes	Yes	Yes	Yes	Yes	Yes	6
[39]	PA	Yes	Yes	Yes	Yes	Yes	Yes	6
[40]	IOT	Yes	No	Yes	No	No	Yes	3
[41]	PA	Yes	Yes	Yes	Yes	Yes	Yes	6
[42]	PA	Yes	Yes	Yes	Yes	No	Yes	5
[43]	CDA	Yes	Yes	Yes	Yes	Yes	Yes	6
[44]	GIS	No	Yes	Yes	Yes	No	No	3
[45]	GIS	No	Yes	No	Yes	No	No	2
[46]	CDA	Yes	Yes	Yes	Yes	Yes	Yes	6
Total: 40	CDA = 10, GIS = 10, IOT = 10, PA = 10	Yes = 31 No = 9	Yes = 31 No = 9	Yes = 36 No = 4	Yes = 31 No = 9	Yes = 22 No = 18	Yes = 32 No = 8	

Footnote: Q1 = Is the study contextually relevant to sustainable agriculture and AI applications?; Q2 = Are the research design and methods clearly described?; Q3 = Are data sources credible and well documented?; Q4 = Does the study provide a clear, logical analysis of findings?; Q5 = Does the study acknowledge its limitations?; Q6 = Is the study up to date with existing literature in sustainable agriculture and AI?

The CAF's assessment indicated that many chosen studies, when evaluated using PRISMA, were very well done, with many of them meeting all six set criteria. The studies that achieved high scores consistently demonstrated clarity in their design, reliability of data, and relevance to the research objectives. Conversely, a limited number of studies received low scores due to ambiguous methodologies, an outdated context, or a lack of relevance to core topics. Studies that garnered fewer than four "yes" responses were deemed to possess low appraisal quality and were consequently excluded from the final results. This process ensured that only the most relevant and methodologically sound studies contributed to the outcomes of this systematic review.

C. Results and Findings

This section presents the results of the systematic review organized according to four categories: CDA, PA, GIS, and IoT. These categories are selected to illustrate how CDA and AI contribute to the transformation of sustainable agriculture. Each category is reviewed in accordance with the research questions.

1) Artificial intelligence and cognitive data analytics. Agriculture is a field, where technological change in traditional farming practices has been evolving through the impact of AI and CDA. Research studies explore the potential of this technological change to improve efficiency and sustainability in agricultural systems. This section demonstrates how AI and CDA are being integrated into agriculture, highlighting recent advancements, applications, and challenges. Only studies that scored at least four points in the critical appraisal process, as shown in Fig. 2, were included in the final analysis to ensure that the findings are of highest quality.

Recent advancements in AI and CDA are transforming agricultural practices by enabling data driven systems that enhance productivity and resource efficiency. Studies project that by 2030, these technologies will significantly improve farming through robotic platforms, automated crop monitoring, and predictive modeling for optimized irrigation and fertilization [10, 31]. For example, Explainable AI (XAI) has been applied to coffee quality assessment to identify key quality defects or determinants, which offer transparency that would not be possible with traditional subjective evaluations [46]. Additionally, hybrid learning models using Convolutional Neural Networks (CNN) have achieved 91% accuracy in predicting orange quality by combining visual and structured data, lessening the need for manual inspections [24]. Additionally, AI precision techniques in Oman, optimize crop management, pest control, and irrigation to improve yield and water conservation [31]. These innovations address labor shortages, enhance decision making, and promote sustainable practices across diverse agricultural contexts [10, 13].

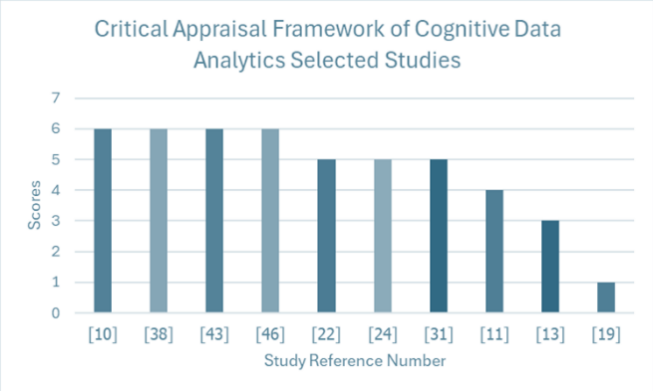

Fig. 2. Critical appraisal framework for selected cognitive data analytics related studies.

AI and CDA are pivotal in developing intelligent agricultural management systems that create innovative farming ecosystems. These systems encompass autonomous tractors, IoT based drones for pest control, soil nutrient mapping tools, and climate responsive irrigation platforms [10, 11, 24]. For example, drones equipped with deep neural networks allow for accurate detection of plant diseases and targeted pesticide application to improve pest control efficiency [11]. However, challenges like high initial development costs, fragmented data, diverse soil types, and limited technical expertise in regions like India with small landholdings hinder consistent adoption, necessitating technical support and infrastructure for maintenance for these systems [38, 43]. To help with this, more

AI techniques like fuzzy logic, artificial neural networks, genetic algorithms, and sensor technology are employed to enhance the efficient cultivation, monitoring, and harvesting of agricultural systems [13].

Adopting AI and CDA in agriculture faces challenges that require strategic interventions to realize their full potential. Key points of adoption include individual characteristics, environmental and structural factors, technology accessibility, and demographic considerations [43]. Building trust with agricultural farmers through informed policy and education is essential to increasing adoption rates [43]. For example, the transparency provided by XAI fosters stakeholder confidence in AI quality assessments and potentially standardized processes like coffee production [46]. However, despite these challenges, when supported by continued research, investment, and customized regional solutions, AI and CDA offer significant benefits that contribute to increased productivity, environmental sustainability, and food security [31, 43].

2) Precision agriculture. Precision agriculture significantly benefits from CDA and AI, utilizing real time sensor data and machine learning to enable targeted application of water, pesticides, and nutrients, thereby optimizing yields while conserving resources [38]. Furthermore, only studies that scored at least four points in the critical appraisal process were included in the final analysis, as shown in Fig. 3.

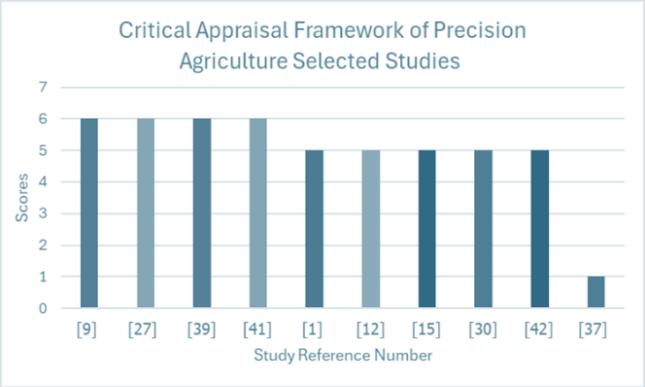

Fig. 3. Critical appraisal framework for selected precision agriculture related studies.

Recent advancements in precision agriculture underscore its potential to revolutionize agricultural practices by 2030, aligning with global sustainability goals [1]. AI driven technologies enable precise field monitoring, obstacle detection, and yield forecasting, including reinforcement learning based mapping by unmanned ground vehicles [12] and predictive modeling for legume crop yields under climate change scenarios [15]. These systems enhance decision making by providing farmers with geo referenced data on soil conditions, water stress, and crop health [12, 15]. Additionally, deploying LPWAN technologies in regions like Karnataka, facilitates power energy optimization, enabling real time data transmission for precision irrigation and resource management [1].

Innovative biosensing applications, such as electrochemical impedance spectroscopy (EIS) for detecting ozone stress in plants [27], advance precision agriculture. These sensors monitor environmental pollutants by analyzing plant hydrodynamic responses [27]. The system offers a noninvasive method for real time environmental monitoring with 92% confidence in detecting excess ozone when pooling data from multiple plants [27]. Thermal canopy segmentation provides precise temperature extraction from plant canopies, enhancing stress detection and irrigation efficiency with a mean average precision of 99.2% and an Intersection over Union score of 92.28% [42].

Despite these advancements, challenges persist, including high implementation costs, technological disparities between farmers and experts, and the complexity of managing large datasets [30]. Inconsistent adoption across regions, coupled with variable environmental conditions, further complicates scalability [30, 43]. Nevertheless, the benefits of precision agriculture enhanced productivity, reduced resource waste, and improved environmental sustainability as a cornerstone for achieving food security and climate resilience [15, 30]. Realizing its full potential requires supportive policies, farmer training, and stakeholder collaboration to bridge technological gaps and foster trust [43].

3) Internet of things and smart irrigation. Integrating the IoT into innovative irrigation systems revolutionizes precision agriculture by enabling real time monitoring and efficient resource management. This section examines the role of the IoT in transforming irrigation practices, highlighting recent advancements, applications, and challenges. Once again, studies with at least four points in the critical appraisal process were included in the final analysis, as shown in Fig. 4.

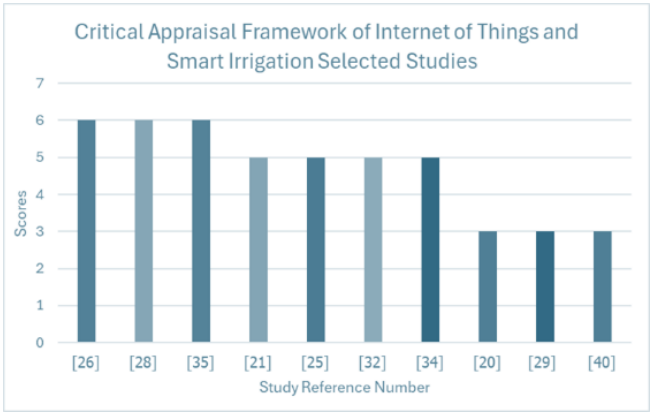

Fig. 4. Critical appraisal framework for selected internet of things and smart irrigation related studies.

IoT based innovative irrigation systems are projected to significantly enhance water use efficiency and crop productivity by 2030, supporting global sustainability objectives such as Sustainable Development Goal [1]. These systems leverage IoT sensors and wireless communication modules to monitor soil moisture, temperature, and humidity in real time [25, 34]. Furthermore, the IoT based irrigation system and soil moisture sensors allow farmers to set customized moisture thresholds, automatically activating irrigation to prevent overwatering or underwatering [25]. Similarly, some systems use a fuzzy inference system and energy saving sensor networks to choose the best cluster heads and send data, which aids in making better

automated irrigation decisions based on environmental conditions [28].

Advanced predictive irrigation systems integrate Internet of Things (IoT) technology with machine learning (ML) and data analytics to accurately forecast irrigation needs, thus accomplishing substantial water savings when compared to traditional methodologies [32, 35]. These systems employ adaptive scheduling algorithms and digital farming solutions, such as mobile and web frameworks, which facilitate remote monitoring and control, alleviating farmers' workload and enhancing their decision-making processes [35]. Ethical design considerations, encompassing privacy and security measures through comprehensive use case analysis, further establish user trust in IoT-based irrigation systems [21]. Performance evaluations indicate consistent soil conditions and enhanced water efficiency, with several systems documenting improved crop yields under diverse environmental conditions [32, 34].

Despite these advancements, challenges remain, including high initial setup costs, technical complexities, and the need for reliable data accuracy [32, 35]. Limited technical expertise among farmers and inconsistent connectivity in rural areas hinder widespread adoption [21, 25]. However, the benefits of IoT-based smart irrigation, optimized water use, increased productivity, and alignment with sustainable farming practices position it as a critical tool for addressing climate change and food security [34, 35]. To maximize its potential, supportive policies, farmer training, and infrastructure development are essential to overcome barriers and promote scalable implementation [21, 32].

4) Geographic information systems: Geographic Information Systems (GIS) have emerged as a pivotal technology in precision agriculture, facilitating spatial data analysis and visualization to enhance farming practices and environmental management. This section examines the integration of GIS into agricultural systems, with a focus on recent advancements, applications, and challenges. Studies that included a minimum of four points in the critical appraisal process were incorporated into the final analysis, as illustrated in Fig. 5.

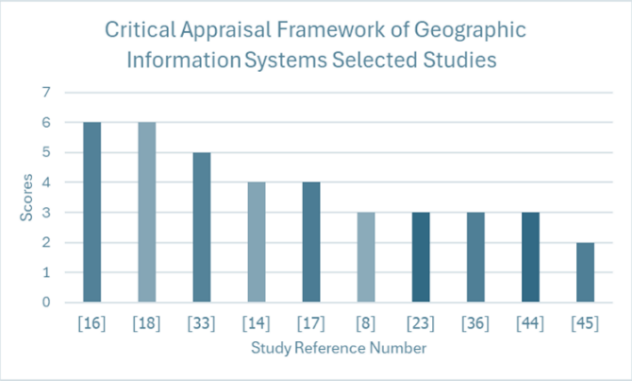

Fig. 5. Critical appraisal framework for selected geographic information systems related studies.

As demonstrated by three studies, the integration of AI and GIS technologies significantly enhances agricultural productivity, environmental management, and sustainable urban planning. In Kenya, an AI based chatbot combined with GIS provided potato farmers with location specific advice and access to quality seeds, achieving an 88.05% effectiveness rate and an 80% likelihood of future use [16]. In coastal Bangladesh, GIS coupled with machine learning mapped soil salinity across 977.94 km² with 92.1% accuracy to support integrated coastal zone management [18]. Similarly, in Chennai, using a GIS technique called the Normalized Difference Vegetation Index (NDVI) to aid sustainable urban planning showcased 82% of the study area as vegetation with 91% accuracy [14]. These findings highlight the transformative potential of AI and GIS systems in addressing food security, environmental challenges, and urbanization.

Innovative educational approaches further amplify GIS adoption. A multidisciplinary course that combines GIS with data visualization and edge devices equips students to analyze real-world agricultural data, fostering interdisciplinary skills for precision agriculture [33]. These applications enhance resource management, improve crop yields, and address environmental challenges such as soil salinity and land cover changes [14, 18]. However, the lack of comprehensive cooperative education frameworks hinders skill development for GIS implementation [17]. Nonetheless, GIS still offers many benefits, including improved food security, enhanced environmental monitoring, and informed policymaking [16, 18]. Investments in farmer training, data infrastructure, and supportive policies are needed for technological advances and to ensure scalable adoption [14, 33].

5) Cross-domain insight. Integrating CDA, PA, IoT, and GIS creates synergistic opportunities for sustainable agriculture. XAI in CDA, as applied to coffee quality assessment [46], enhances farmer trust in IoT-based smart irrigation systems [25] by providing transparent decision-making, addressing skepticism in automated irrigation. Similarly, GIS spatial analysis in Bangladesh mapped soil salinity with 92.1% accuracy [18], guiding PA's sensor placement for ozone stress detection [27]. This linkage optimizes resource use, reducing waste and improving yields across diverse regions.

Combining IoT's real-time data [34] with CDA's predictive models [24] enables dynamic irrigation and pest control, achieving 91% accuracy in orange quality prediction. GIS-based advice for Kenyan potato farmers [16] complements PA's field monitoring [12], tailoring practices to local conditions. These cross-domain integrations foster intelligent farming ecosystems, enhancing productivity and sustainability. By linking transparent AI [46], sensor data [27], real-time monitoring [34], and spatial analysis [16], these technologies address trust barriers and scalability challenges, supporting global food security by 2030.

IV. Discussion

The systematic review elucidates the transformative potential of Artificial Intelligence (AI) in advancing sustainable agriculture across four key domains: Cognitive Data Analytics (CDA), Precision Agriculture (PA), Internet of Things (IoT), and Geographic Information Systems (GIS). The integration of

AI technologies demonstrates how these innovations enhance decision making clarity and farm efficiency. For instance, IoT based smart irrigation systems utilize real time soil moisture data and predictive analytics to significantly improve water use efficiency, thereby supporting objectives such as the Sustainable Development Goals. Furthermore, GIS, when integrated with AI, facilitates accurate analysis aimed at addressing significant environmental and food security challenges. Collectively, these advancements underscore the capability of CDA and AI to develop intelligent farming systems that enhance yields while minimizing resource waste.

Regional variations significantly influence CDA and AI adoption in agriculture. In high-resource settings like Oman, AI-driven precision techniques supported by robust infrastructure optimize crop management and water conservation [31]. Conversely, low-resource regions like rural India face connectivity and cost barriers, limiting IoT and GIS scalability [38]. Policy interventions, such as subsidies for IoT sensors or cooperative training programs, can bridge these gaps, promote equitable technology uptake and enhance sustainability across diverse agricultural contexts.

Nevertheless, the adoption of these technologies encounters significant challenges that require substantial effort, such as high initial costs, fragmented data systems, and limited technical expertise, which hinder consistent implementation. For instance, drones integrated with deep neural networks demonstrate potential for enhancing pest control; however, their advancement is constrained by infrastructural and maintenance issues. This systematic review underscores the necessity for tailored regional solutions to address diverse agricultural conditions, emphasizing that research and investment are critical for the utilization and enhancement of such technologies. Additionally, precision agriculture benefits from real-time sensor data and machine learning; however, its success is contingent upon accessible training for farmers and robust data systems. Geographic Information Systems (GIS) applications are also essential for collaborative education, equipping farmers with the necessary skills for effective technology utilization. By addressing these challenges through policy support and farmer engagement, Controlled Digital Agriculture (CDA) and Artificial Intelligence (AI) can significantly contribute to sustainable farming practices, thereby improving productivity, fostering environmental sustainability, and enhancing global food security by 2030.

V. Limitations and Future Directions

The focus on studies published between 2020 and 2025 limits this systematic review. While its emphasis keeps the research current, it may overlook earlier studies that could provide essential or deeper background on CDA and AI in agriculture. This systematic review excludes opinion-based studies, which can omit valuable perspectives from farmers or experts. This study utilizes research from academic databases like IEEE, Scopus, and Google Scholar, which can often miss other studies, especially those in different languages, as the search was conducted exclusively in English.

The variety of farming conditions presents another limitation, as differing soil types, climates, and technological access across regions complicate the implementation of a systematic review. For example, IoT based irrigation systems perform well in controlled settings, but their effectiveness in rural areas with poor connectivity remains uncertain. This systematic review emphasizes high quality studies that may have overlooked innovative yet less rigorous research that could provide valuable insights.

Future research should prioritize underexplored regions and employ specific methodologies to address adoption challenges. Mixed methods field studies can assess farmer perceptions of IoT in low connectivity areas, while cost-benefit analyses evaluate the economic viability of AI-driven systems. Interdisciplinary collaborations with agronomists can refine crop models, and sociologists can explore cultural barriers to technology trust. Partnerships with policymakers are essential to design region-specific AI deployment strategies, ensuring equitable access and scalability.

VI. Conclusion

This systematic review confirms the crucial roles of artificial intelligence and cognitive data analytics in transforming sustainable agriculture, offering solutions that enhance productivity, conserve resources, and bolster environmental resilience. Innovations such as AI predictive models, IoT-based smart irrigation, and GIS-driven spatial analysis demonstrate significant advancements in precision farming, water management, and environmental monitoring. These developments support global sustainability goals by positioning agriculture as a vital solution to food security and climate change challenges by 2030.

Despite challenges such as elevated expenses, technical complexities, and regional disparities impeding the widespread adoption of this technology, this review emphasizes the necessity for supportive policies, comprehensive farmer training, and infrastructural development to address these obstacles and foster global utilization. Stakeholders can fully leverage and trust these technologies by establishing trust through transparent AI systems and committing themselves to cooperative education. The intelligent integration of CDA, AI, IoT, and GIS presents an opportunity to engage in sustainable farming practices, thereby ensuring enhanced productivity, environmental sustainability, and global food security in the face of climate change and rising population numbers.

Acknowledgment

This research project also received support from numerous advisors, academics, researchers, students, and staff. The authors express their gratitude to everyone for their assistance and cooperation in completing this research. Additionally, two organizations, the Thailand Science Research and Innovation Fund and the University of Phayao, provided support for this research project.

Funding

This research was supported by the University of Phayao and the Thailand Science Research and Innovation Fund (Fundamental Fund 2026).

A Novel Approach for Enhancing Advanced Encryption Standard Performance and Cryptographic Resilience

Muthu Meenakshi Ganesan, Sabeen Selvaraj
Department of Computer Science-Faculty of Science and Humanities,
SRM Institute of Science and Technology, Kattankulathur, India

***Abstract*—Advanced Encryption Standard (AES) encrypts data in blocks of sixteen bytes to secure confidential data stored in the cloud. For cloud-based systems, enhancements in existing encryption techniques are necessary as the nature of cyber threats evolves and computational speed becomes increasingly critical. This study presents an enhanced design of AES that substitutes two special operations, Byte Transformation and Bits Permuted Bytes, with the conventional S-Box operation to improve the speed and security of the encryption method. The suggested round structure in the new approach of AES, which preserves the original data block size, consists of the following operations: Byte Transformation, Shift Rows, Bits Permuted Bytes, Add Round Key, and Mix Columns. The analysis of the strict avalanche effect, correlation coefficient, entropy, execution time, and throughput outcomes confirms that the developed scheme improves the security and processing speed.**

Keywords*—Cryptography; NIST; AES; block cipher; key expansion; symmetric encryption; galois field; statistical techniques; cryptanalysis

I. Introduction

Cloud platforms that utilize symmetric encryption algorithms, such as AES, ensure that data transmission, storage, and communication are secure for the government, healthcare, and financial sectors [1], [2]. AES secures vast volumes of private information from illegal access and breaches in these cloud-based systems [3]. In 2000, the National Institute of Standards and Technology (NIST) in the United States replaced the Data Encryption Standard with AES due to its superior performance in both hardware and software [4], [5]. Researchers often utilize AES to secure wireless networks, data storage, and communications [6], [7].

Several cryptanalytic studies suggest that improving diffusion and confusion mechanisms can further reinforce AES against potential future cryptanalytic attacks. When internal transformations lack sufficient randomness or complexity, the encryption process may reveal patterns that can be exploited through statistical or differential attacks. These vulnerabilities highlight the importance of strengthening AES, not only to address current vulnerabilities but also to remain resilient against evolving and more sophisticated attacks.

This study addresses these limitations by proposing a modified AES encryption algorithm that enhances both cryptographic strength and operational efficiency. The proposed approach introduces structural changes to AES transformations to improve diffusion, reduce statistical correlation, and strengthen resistance against cryptanalytic attacks.

The rest of this study is organized as follows: Section II summarizes related work; Section III recommends the enhanced AES encryption approach; Section IV outlines the statistical tests and evaluation criteria applied to assess the resilience of existing and proposed encryption algorithms. Section V presents the experimental results obtained from these evaluations, while Section VI discusses the key findings and their implications. Finally, Section VII concludes this study by highlighting potential directions for future research.

II. Related Work

Many studies have been conducted to improve the security and efficiency of symmetric encryption algorithms. These studies suggest numerous technical variants of existing encryption methods to boost security and performance. Parthasarathy et al. [8] proposed a lightweight symmetric encryption that combined the Elliptic Curve Diffie-Hellman key exchange algorithm with a proprietary random number generator, resulting in a unique S-box and innovative folding operations for transmitting medical data to the cloud. The throughput of this method was higher than that of AES; however, it lacks the statistical evaluation of cryptographic strength.

Baladhay et al. [9] proposed an enhanced version of the AES algorithm by replacing the MixColumns function with an alternate transformation to improve the security and efficiency of encryption and decryption processes. This method is ideal for applications requiring high-speed video encryption due to the performance improvements. On the other hand, entropy and correlation analysis, which could offer additional information on cryptographic strength, are excluded from this work. Similarly, to increase security and performance for systems with low resources, Hammod et al. [10] introduced a Modified Lightweight AES (ML-AES).

Sirajuddin et al. [11] designed a modified Rijndael algorithm for resource-constrained Internet of Things devices. The shift column phase was changed, the sub-byte step was removed, and a crossover pre-processing method was added. The research did not evaluate the ciphertext's randomness or statistical independence, although these improvements were made to increase efficiency and security. Wenceslao Jr. et al. [12] developed a new version of AES encryption that retained the

original Rijndael S-Box and introduced a second S-Box using affine transformations for the Mix-Columns step. This method is faster but exhibits a slightly reduced avalanche effect, which may affect the diffusion property of the encryption process.

A DNA-based multi-round encryption approach was presented by Al-Shargabi et al. [13] to preserve confidential health data. Improving entropy levels while maintaining an avalanche effect similar to conventional AES allowed this technique to outperform AES in data security. By eliminating the Mix-Columns stage and adding a continuous fraction function to compress the ciphertext, Mohammad et al. [14] developed a lightweight AES encryption (LWC-AES) for devices with limited resources. LWC-AES reduced processing complexity and enhanced transfer rates without compromising security. Altigani et al. [15] introduced Polymorphic-AES (P-AES) for adaptive and flexible encryption using the initial key. P-AES showed exceptional resilience to attacks by modifying the Sub Bytes, Shift Rows, and Mix Columns procedures to improve security with negligible performance impact. Salih et al. [16] modified a 3D chaotic map and combined two dynamic XOR tables with a dynamic Mix-Columns transformation to strengthen the AES encryption method. While this approach improved security, additional performance evaluation would enhance its practical relevance.

Assafli et al. [17] modified AES encryption by replacing the traditional S-box with a dynamic one based on Unix epoch time. This new method solely preserved and improved the avalanche effect for single-bit input changes. Abikoye et al. [18] proposed an enhanced AES technique, with modified S-Box and Shift-Rows transformations to strengthen security. This method made the Sub Bytes operation round-key dependent and randomized the Shift Rows operation exclusively to improve the avalanche effect. Manoj Kumar et al. [19] presented a new AES key expansion technique primarily to increase the execution speed, allowing simultaneous subkey generation by isolating the operation into two concurrent blocks. This innovative approach was implemented on an FPGA (Virtex 5 XC5VLX50T) to secure ECG signal encryption and decryption in real-time communication.

In summary, many studies prioritize either efficiency or security without achieving an adequate balance. While several enhancements to AES exist, most lack rigorous statistical evaluation. The proposed system addresses these gaps by achieving a balance between security and efficiency, with its reliability confirmed through a thorough statistical analysis.

III. METHODOLOGY

AES uses 128-bit data blocks and encrypts in 10, 12, or 14 rounds, based on the key length, which can be 128, 192, or 256 bits [20]. It involves three key processes: Key expansion generates round keys from the original cipher key, encryption transforms plaintext into ciphertext through various operations, and decryption reverses these operations to recover the original plaintext [21].

A. Key Expansion in AES Algorithm

In AES-128, the key expansion process, depicted in Fig. 1, begins by dividing the 128-bit initial key into four 32-bit words (W0, W1, W2, W3), forming the initial part of the key schedule [19]. A left circular byte shift (RotateWord), a substitution using the S-Box (SubWord), and an XOR with the appropriate round constant (RCj) are used to compute the remaining 40 words [22]. The SubWord transformation uses the S-Box depicted in Fig. 2, a 16 x 16 lookup table for byte substitution. The round constants, described in Table I, are applied at specific stages during the key expansion to introduce non-linearity. These transformations are applied to designated words W3, W7, W11, and every fourth word thereafter, to generate W3', W7', W11', respectively. The subsequent words are created by XORing each new word with previously generated words, iteratively producing all 44 words. These words are divided into 11 sets, each with 4 words, forming the round keys used for encryption and decryption.

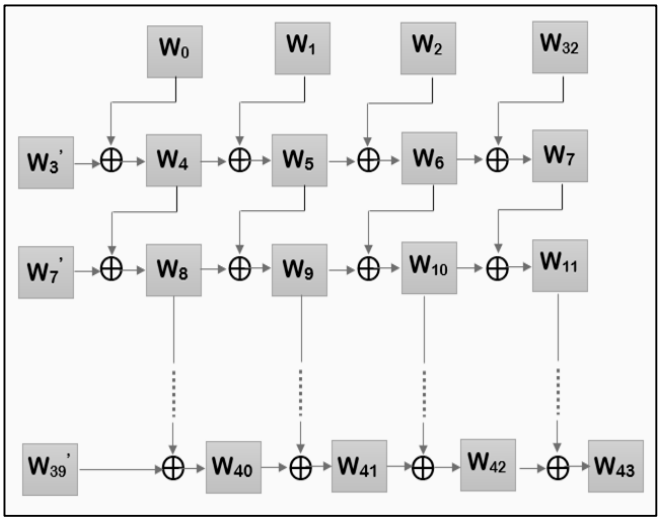

Fig. 1. AES key scheduling process.

TABLE I. CONSTANTS USED PER ROUND

Round(j)	1	2	3	4	5	6	7	8	9	10
RCj	0x01	0x02	0x04	0x08	0x10	0x20	0x40	0x80	0x1b	0x36

B. Existing AES Encryption Algorithm

During encryption or decryption, a state matrix (a 4x4 grid of bytes) represents the 128-bit plaintext block. The matrix arranges each byte of the 128-bit block into a single cell in column-major order. This matrix undergoes various operations during encryption, including SubstituteBytes, ShiftRows, MixColumns, and AddRoundKey, with the final round omitting MixColumns [23]. These operations are described below:

1) SubstituteBytes. In this substitution phase, each byte in the state matrix is replaced with the value of the S-Box (illustrated in Fig. 2) based on its original value, introducing non-linearity into the encryption process [24]. Fig. 3 shows the inverse AES S-Box used during decryption.

2) ShiftRows. This step enhances byte dispersion by executing a cyclic left shift on each row of the state matrix. First row remains unaffected, while the second row is shifted one byte to the left, the third row is shifted two bytes to the left, and the fourth row is shifted three bytes to the left.

Fig. 3. AES inverse S-box.

3) MixColumns. This step applies a linear transformation to each column of the 4 x 4 state matrix. It mixes the bytes within each column by multiplying the MixColumns matrix over a Galois Field (GF(2^8)). This step enhances diffusion by ensuring that each input byte influences multiple output bytes, as shown in Eq. (1):

$$\text{MixColumns Matrix} = \begin{matrix} 02 & 03 & 01 & 01 \\ 01 & 02 & 03 & 01 \\ 01 & 01 & 02 & 03 \\ 03 & 01 & 01 & 02 \end{matrix} \quad (1)$$

During decryption, the inverse transformation is applied using the Inverse MixColumn matrix, which is shown in Eq. (2):

$$\text{Inverse MixColumns Matrix} = \begin{matrix} 0e & 0b & 0d & 09 \\ 09 & 0e & 0b & 0d \\ 0d & 09 & 0e & 0b \\ 0b & 0d & 09 & 0e \end{matrix} \quad (2)$$

4) AddRoundKey. This step combines the key with the data to strengthen the encryption by XORing, the round key with the state matrix.

During decryption, the process reverses encryption by applying inverse operations in reverse order. It begins with InverseShiftRows to restore the original row positions, followed by InverseSubstituteBytes using the inverse S-box, and AddRoundKey XORs the state matrix with the corresponding round key. Finally, InverseMixColumns (except in the final round) to unmix the columns to recover the plaintext from the ciphertext.

C. Proposed Enhanced AES Encryption Architecture

In the new design of AES encryption, the input block size remains 128 bits; however, the Sub Bytes operation has been eliminated. Instead, two new operations, Byte Transformation and Bits Permuted Bytes, have been introduced. In each round of the proposed approach, Bytes Transformation, Shift Rows, Mix Columns, Bits Permuted Bytes, and Add Round Key transform the state matrix. These transformations aim to improve the encryption process's confusion and diffusion properties. The newly introduced operations are described below:

1) Byte transformation operation. Let S represent the 4x4 state matrix, where each element (S_{ij}) is an 8-bit byte. AES transforms this state matrix through various stages as part of its encryption and decryption mechanisms. In the proposed method, the Byte Transformation function is applied to each byte (S_{ij}). This operation introduces non-linearity and enhances the diffusion properties of the encryption process. This transformation is defined as follows:

Let $S_{ij} = b_7b_6b_5b_4b_3b_2b_1b_0$; here b_7 and b_0 are the Most Significant Bit (MSB) and the Least Significant Bit (LSB), respectively. The transformation for each bit (t_i) of the transformed byte (T_{ij}) is defined as follows:

$t_7 = b_7$ (MSB remains unchanged), $t_6 = b_6 \oplus b_7$, $t_5 = b_5 \oplus b_6$, $t_4 = b_4 \oplus b_5$, $t_3 = b_3 \oplus b_4$, $t_2 = b_2 \oplus b_3$, $t_1 = b_1 \oplus b_2$, and $t_0 = b_0 \oplus b_1$. Here $t_7t_6t_5t_4t_3t_2t_1t_0$ (T_{ij}) is the transformed byte and $\oplus$ denotes the XOR operation. For example, consider a byte. S_{ij} , where $b_7b_6b_5b_4b_3b_2b_1b_0$ = 11011010. $t_7 = b_7 = 1$, $t_6 = b_6 \oplus b_7 = 1 \oplus 1 = 0$, $t_5 = b_5 \oplus b_6 = 0 \oplus 1 = 1$, $t_4 = b_4 \oplus b_5 = 1 \oplus 0 = 1$, $t_3 = b_3 \oplus b_4 = 1 \oplus 1 = 0$, $t_2 = b_2 \oplus b_3 = 0 \oplus 1 = 1$, $t_1 = b_1 \oplus b_2 = 1 \oplus 0 = 1$, and $t_0 = b_0 \oplus b_1 = 0 \oplus 1 = 1$. The transformed byte T_{ij}becomes 10110111. This transformation is visually represented in Fig. 4.

2) Inverse byte transformation operation. The Inverse Byte Transformation operation undoes the transformations applied during the encryption phase. Given the transformed byte, S_{ij} can be recovered as follows:

$b_7 = t_7$ (MSB remains unchanged), $b_6 = t_6 \oplus b_7$, $b_5 = t_5 \oplus b_6$, $b_4 = t_4 \oplus b_5$, $b_3 = t_3 \oplus b_4$, $b_2 = t_2 \oplus b_3$, $b_1 = t_1 \oplus b_2$, and $b_0 = t_0 \oplus b_1$

For example, consider a byte, $T_{ij} = t_7t_6t_5t_4t_3t_2t_1t_0 =$ 10110111. $b_7 = t_7 = 1$ (MSB remains unchanged), $b_6 = t_6 \oplus b_7 = 0 \oplus 1 = 1$, $b_5 = t_5 \oplus b_6 = 1 \oplus 1 = 0$, $b_4 = t_4 \oplus b_5 = 1 \oplus 0 = 1$, $b_3 = t_3 \oplus b_4 = 0 \oplus 1 = 1$, $b_2 = t_2 \oplus b_3 = 1 \oplus 1 = 0$, $b_1 = t_1 \oplus b_2 = 1 \oplus 0 = 1$, and $b_0 = t_0 \oplus b_1 = 1 \oplus 1 = 0$. Now, combine all the bits. $b_7b_6b_5b_4b_3b_2b_1b_0$ to form the original byte (S_{ij}) as 11011010. In the encryption process, the Bytes Transformation procedure modifies each byte, and the Inverse Bytes Transformation procedure restores each byte in decryption. The step-by-step process of this inverse transformation is shown in Fig. 5.

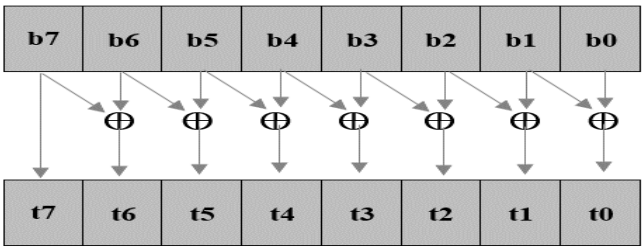

Fig. 4. Byte transformation operation.

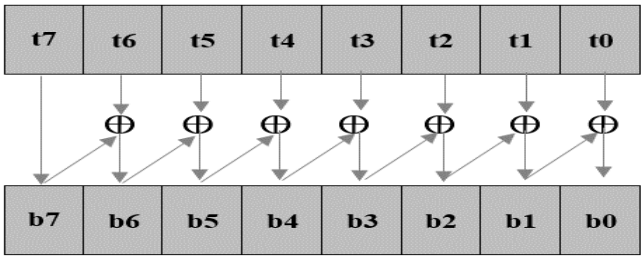

Fig. 5. Inverse byte transformation operation.

3) Bits permuted bytes operation. In the Bits Permuted Bytes operation, each byte in the state matrix S_{ij} ($b_7b_6b_5b_4b_3b_2b_1b_0$) undergoes a bit permutation based on the involutory permutation table 3 | 2 | 1 | 0 | 7 | 6 | 5 | 4 during the encryption phase. The involutory permutation table is self-inverse. This feature simplifies both encryption and decryption. It removes the need for a separate inverse table. This permutation rearranges the bits. The bit at index 3 (b_4) moves to index 0, the bit at index 2 (b_5) moves to index 1, the bit at index 1 (b_6) moves to index 2, the bit at index 0 (b_7) moves to index 3, the bit at index 7 (b_0) moves to index 4, the bit at index 6 (b_1) moves to index 5, the bit at index 5 (b_2) moves to index 6, and the bit at index 4 (b_3) moves to index 7. In this transformation, the original bit order of each byte in the state matrix is rearranged to $T_{ij} = b_4b_5b_6b_7b_0b_1b_2b_3$. For example, consider a byte S_{ij}= 11011010 in the state matrix. This byte is transformed by rearranging its bits to obtain T_{ij} =10110101. This bit permutation is applied to each byte in the state matrix, converting the original byte into a new form.

4) Inverse bits permuted bytes operation. The Inverse Bits Permuted Bytes operation reverses the bit permutation applied during encryption. The encryption phase rearranges the bits of each byte in the state matrix according to the involutory permutation table 3 | 2 | 1 | 0 | 7 | 6 | 5 | 4, whereas the inverse operation restores the original bit order. For example, a byte T_{ij} =10110101, when passed through the inverse transformation, it reverts to its original form S_{ij}= 11011010. Fig. 6 and Fig. 7 show the Bits Permuted Bytes and Inverse Bits Permuted Bytes operations, which rearrange and restore the bit order within each byte during encryption and decryption, respectively, in the developed scheme.

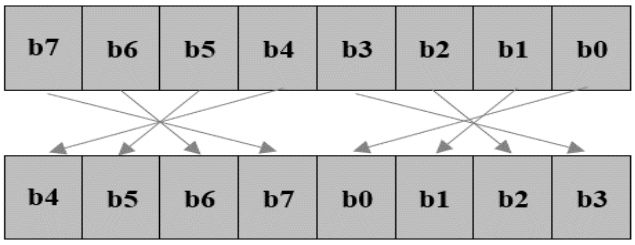

Fig. 6. Bits permuted bytes operation.

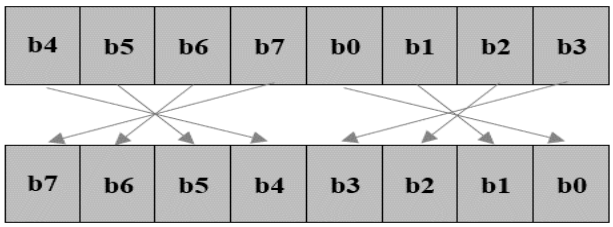

Fig. 7. Inverse bits permuted bytes operation.

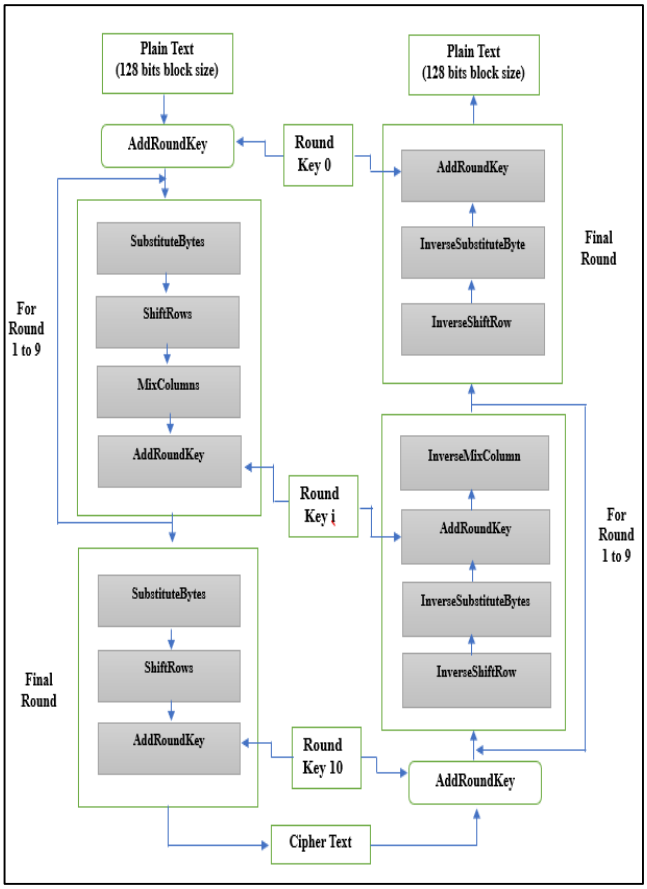

Fig. 8. Standard AES algorithm.

To enhance efficiency, the final round of the proposed encryption approach omits the Bits Permuted Bytes operation and Mix columns, thereby reducing complexity while maintaining security strength. Furthermore, the number of rounds has been decreased to accelerate execution speed. The standard AES functions with ten rounds for a 128-bit key size, as shown in Fig. 8, while the developed encryption strategy executes only five rounds with the same key size, as illustrated in Fig. 9.

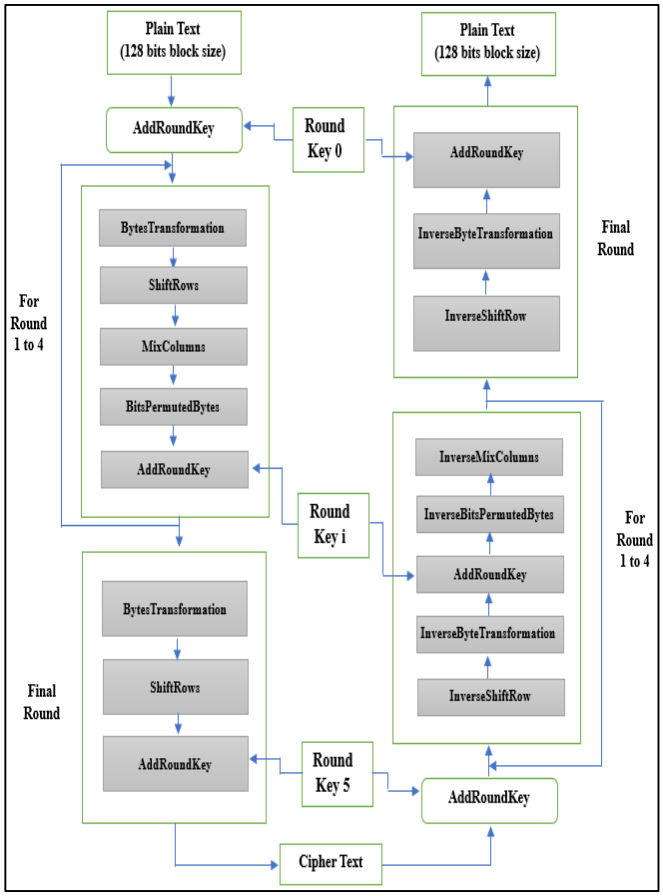

Fig. 9. Enhanced AES algorithm.

IV. EVALUATION

A. Strict Avalanche Effect

The Avalanche Effect is determined by flipping each bit in the n-bit plaintext and observing the percentage of bits that differ in the resulting ciphertext. Averaging the percentages across all n-bit flips gives the Strict Avalanche Effect (SAE). This metric ensures the algorithm's robustness and resistance to cryptanalysis. The formula used to calculate the SAE [25] is shown in Eq. (3):

$$SAE = \frac{1}{n}\sum_{i=1}^{n}\frac{HammingWeight(C \oplus C'_i)X100}{n} \quad (3)$$

Here, C denotes the ciphertext obtained by encrypting the original plaintext, C_i' denotes the ciphertext produced by encrypting the plaintext with the i^{th} bit flipped, and n represents the total number of bits in the ciphertext. One hundred random 128-bit plaintexts and keys were used to evaluate SAE.

B. Correlation Coefficient

This measure implies the level of a linear association between the plaintext and encrypted output. For an encryption algorithm to be considered secure, the ciphertext must have a minimal linear dependence on the plaintext, as indicated by a correlation coefficient close to zero [26].

The following steps are used to determine the correlation coefficient between plaintext and ciphertext:

1) Plaintext and ciphertext are converted into binary sequences of 0s and 1s.

2) Mean calculation. The mean value of the plaintext bits (μ_X) was computed using Eq. (4), and the mean value of the ciphertext bits (μ_Y) was determined using Eq. (5):

$$\mu_X = \frac{1}{N}\sum_{i=1}^{N} X_i \quad (4)$$

$$\mu_Y = \frac{1}{N}\sum_{i=1}^{N} Y_i \quad (5)$$

Here, N is the number of bits in the plaintext or ciphertext, and X_i and Y_i are the individual bits of the plaintext and ciphertext, respectively.

3) Covariance Calculation ($Cov(X,Y)$) . Covariance measures how much the plaintext and ciphertext vary together: The covariance between the plaintext bits and ciphertext bits was calculated using Eq. (6):

$$\mathrm{Cov(X,Y)} = \frac{1}{N}\sum_{i=1}^{N}(X_i - \mu_X)\ \mathrm{X}\ (Y_i - \mu_Y) \quad (6)$$

Here, μ_X is the mean of plaintext bits, μ_Y is the mean of ciphertext bits, $X_i - \mu_X$ is the deviation of the i^{th} plaintext bit from the mean, and $Y_i - \mu_Y$ is the deviation of the i^{th} ciphertext bit from its mean. The deviations measure how each bit in the plaintext and ciphertext differs from their respective mean.

4) Standard deviation. The standard deviation of the plaintext bits (σ_X) and the ciphertext bits (σ_Y) was calculated using Eq. (7) and Eq. (8), respectively.

$$\sigma_X = \frac{1}{N}\sqrt{\sum_{i=1}^{N}(X_i - \mu_X)^2} \quad (7)$$

$$\sigma_Y = \frac{1}{N}\sqrt{\sum_{i=1}^{N}(Y_i - \mu_Y)^2} \quad (8)$$

5) Correlation coefficient. The value of the correlation coefficient (r) was calculated between the plaintext and ciphertext bits using Eq. (9):

$$r = \frac{Cov(X,Y)}{\sigma_X\ \mathrm{X}\ \sigma_Y} \quad (9)$$

One thousand random 128-bit plaintexts and keys were used to evaluate this metric.

C. Entropy

The entropy test assesses the degree of unpredictability and randomness in the ciphertext. A higher entropy indicates greater randomness in the ciphertext, as it is more difficult to crack the encryption. To determine the average entropy of encrypted ciphertexts in their binary representation, convert each

ciphertext C_i to B_i(binary form). The entropy of the ciphertext $H(X)$ can be expressed for Shannon entropy [27], [28] using Eq. (10):

$$H(X) = -\sum_{i=1}^{N} P(x_i) log_2 P(x_i) \quad (10)$$

In this context, x_i represents the possible outcomes, and N is the number of unique outcomes. The entropy for each binary string (B) was calculated using Eq. (11):

$$H(B) = -[P(0) log_2 P(0) + P(1) log_2 P(1)] \quad (11)$$

Here, $P(0)$ and $P(1)$ are the probabilities of the binary outcomes 0s and 1s, respectively, in the binary ciphertext (B).

The average entropy $\bar{H}$ across all N ciphertexts was calculated using Eq. (12):

$$\bar{H} = \frac{1}{N} \sum_{i=1}^{N} H(B_i) \quad (12)$$

This method interprets every bit as a random variable with two possible outcomes and obtains the average entropy of the binary representations, where N is the total number of ciphertexts. One thousand random 128-bit plaintexts and keys were used to evaluate this randomness property of the produced ciphertexts.

D. Execution Time

Execution time impacts efficiency, performance, and resource usage of cryptographic systems. To calculate the execution time of the modified and standard AES algorithms implemented in Python, the start and end times were recorded, and the difference value was calculated. The evaluations were performed on a 12th Gen Intel Core i7-1255U CPU running at 1.70 GHz. The dataset consists of a 1025 KB text file, a 1028 KB PDF document, a 1126 KB JPEG image, a 1026 KB MP3 audio file, and a 1031 KB MP4 video file used for the evaluation. The encryption and decryption times were calculated over 10 runs for each algorithm using all file types and averaged to obtain a reliable result.

E. Throughput

The encryption and decryption throughputs were calculated separately using Eq. (13) [29]:

$$\text{Throughput (KB/sec)} = \frac{\text{Total File Size (KB)}}{\text{Total Time (sec)}} \quad (13)$$

The Total File Size is the sum of all the file sizes used, which includes text, PDF, JPEG, MP3, and MP4. The amount of time needed to complete encrypting or decrypting all files is referred to as Total Time. This method enables a reliable evaluation of the algorithm's performance on various file types and sizes.

V. Results

A. Strict Avalanche Effect

The test results in Table II and Fig. 10 clearly show that the suggested new encryption process achieves a higher SAE of 53.46%, compared to 49.55% for the standard AES encryption. These results highlight that the modified encryption design achieves improved diffusion and higher security in fewer rounds.

TABLE II. Measured SAE in Standard and Enhanced AES

Algorithm	SAE
Standard AES	49.55
Enhanced AES	53.46

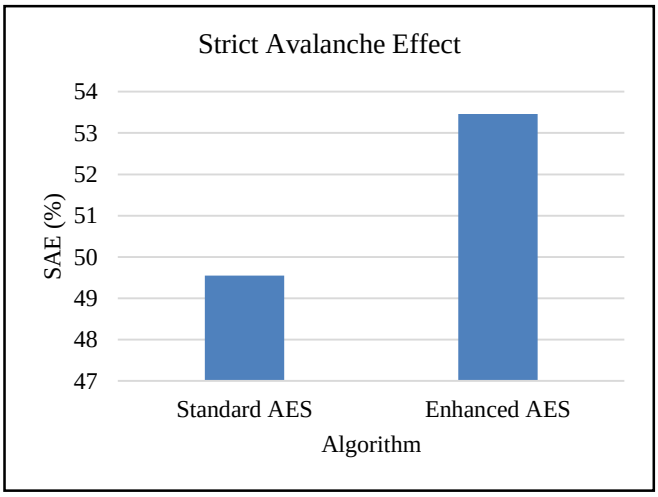

Fig. 10. SAE Analysis of standard versus enhanced AES.

B. Correlation Coefficient

Table III and Fig. 11, present the correlation analysis between plaintext and ciphertext. When compared to the standard AES, which has a correlation coefficient of 0.004409, the enhanced encryption approach demonstrates a lower correlation coefficient of -0.000293. The observed negative and nearly zero value confirms that the proposed technique effectively diminishes the relationship between plaintext and ciphertext, thereby enhancing cryptographic strength.

TABLE III. Statistical Correlation Assessment Between Plaintext and Ciphertext

Algorithm	Correlation Coefficient
Standard AES	0.004409
Enhanced AES	-0.000293

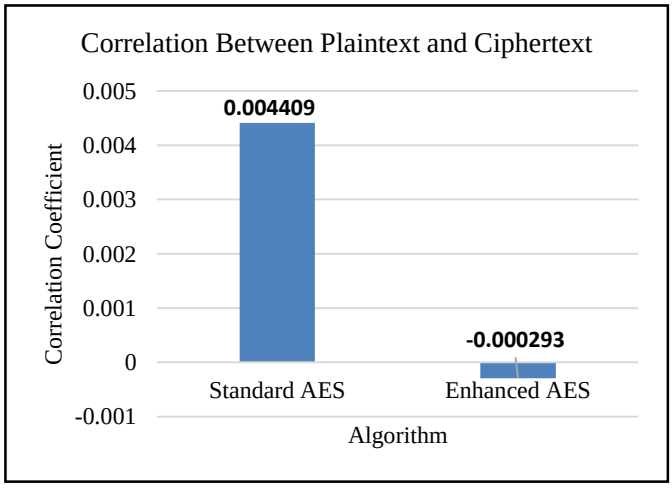

Fig. 11. Comparison of correlation coefficient between plaintext and ciphertext.

C. Entropy

The results indicate that the existing and the redesigned AES encryption achieved high entropy levels in their ciphertexts, as shown in Table IV. The enhanced encryption process offers a slightly higher average entropy of 0.994619 bits than the standard AES's 0.994327 bits. These values, close to the ideal maximum of one bit per bit, show that both algorithms generate random ciphertext sequences.

TABLE IV. ENTROPY VALUES OF CIPHERTEXT

Algorithm	Average Entropy
Standard AES	0.994327
Enhanced AES	0.994619

D. Execution Time

The method proposed in this study reduces encryption and decryption times for various file types, as illustrated in Table V and Fig. 12. It minimizes the encryption time by approximately 8.17% and the decryption time by 13.30% for a text file. A notable 32.96% reduction in encryption time and an 8.51% reduction in decryption time are observed for a PDF file. There is a 19.65% decrease in encryption time and a 16.17% decrease in decryption time for a JPEG file. An MP3 file shows a 20.44% reduction in encrypting time and an 11.95% reduction in decryption time. There is a 27.75% decrease in encryption time and a 20.16% decrease in decryption time for an MP4 file.

E. Throughput

The suggested encryption method achieves higher throughput than standard AES. Its encryption throughput is 389.16 KB/sec, approximately 28.9% higher than the standard AES throughput of 301.85 KB/sec. Similarly, it improves the decryption throughput by approximately 18%, achieving 311.30 KB/sec, whereas the standard AES achieves 263.79 KB/sec. These results highlight the efficiency gains provided by the proposed approach, as shown in Table VI and Fig. 13.

TABLE V. EXECUTION TIME FOR ENCRYPTION AND DECRYPTION OF MULTIPLE FILE TYPES

File Type & Size	Standard AES Encryption Time (sec)	Enhanced AES Encryption Time(sec)	Standard AES Decryption Time(sec)	Enhanced AES Decryption Time(sec)
Text File(1025KB)	2.010364	1.846177	2.539962	2.202060
PDF File(1028KB)	1.482714	0.994051	2.207906	2.019965
JPEG File(1126KB)	3.441201	2.764880	3.466463	2.905801

VI. Discussion

The experimental results confirm that the proposed encryption approach has notable improvements over the standard AES across several metrics. The enhanced proposed scheme offers improved diffusion and security, achieving a higher SAE of 53.46% compared to 49.55% for the standard AES. Its correlation coefficient is lower at -0.000293, indicating reduced predictability between plaintexts and ciphertexts, while the standard AES records a value of 0.004409. Additionally, its average entropy increases slightly from 0.994327 to 0.994619, signifying improved randomness in the ciphertext. It outperforms standard AES, boosting encryption throughput from 301.85 KB/s to 389.16 KB/s and decryption from 263.79 KB/s to 311.30 KB/s. These improvements make the proposed encryption method more suitable for applications that require stronger security and fast processing.

VII. Conclusion

The analysis indicates that the suggested encryption method provides substantial enhancements compared to the conventional AES. The proposed encryption method promotes the diffusion property and minimizes the predictable nature between plaintext and ciphertext, resulting in increased security. It also generates more random ciphertext and delivers better performance in terms of processing time and throughput. The enhanced design provides a well-balanced increase in efficiency and security.

Future work will focus on implementing a more secure hybrid encryption technique within cloud-based blockchain systems to enhance data protection, prevent tampering, ensure secure key management, and strengthen user authentication.

Abstract*—Sentiment analysis, a crucial yet complex task in natural language processing (NLP), is extensively employed to identify sentiment polarity within user-generated content. Traditional deep learning methods for textual sentiment analysis often overlook the influence of emotional modulation on extracting sentiment features. At the same time, their attention mechanisms primarily operate at the word or sentence levels. Such oversight of higher-level abstractions may hinder the learning of nuanced sentiment patterns, ultimately damaging the accuracy of sentiment analysis. Addressing these gaps, this study proposed a novel framework, the Two-State Enhanced LSTM (TS-ELSTM), which integrated Emotional Intelligence (EI) and a Feature Attention Mechanism (FAM) to enhance the identification of relevant features during selection. Furthermore, this study employed a dual-phase training strategy of LSTM to accelerate learning and minimize information loss. A dynamic topic-level attention mechanism is also introduced to optimize hidden text representation weights. By integrating EI with a topic-level attention mechanism, the proposed framework efficiently extracts valuable features and enhances the feature learning ability of the conventional LSTM model. This novelty attains emotion-aware learning through two key components: an emotion modulator and an emotion estimator, which successfully normalize the system's learning dynamics by combining emotional context. The experimental outcomes demonstrated that the proposed approach achieved an accuracy of 84.20%, 94.12% using MR and IMDB, respectively. The proposed approach significantly improves sentiment analysis accuracy, outperforming traditional deep learning models by a notable margin.

Keywords*—Sentiment analysis; emotional intelligence; attention mechanism; two-state LSTM; long-term dependencies

I. INTRODUCTION

The exponential growth of social media platforms has raised sentiment analysis and opinion mining, and become critical areas in Natural Language Processing (NLP) applications [1-3]. Traditional sentiment analysis algorithms often produce a single polarity score for a complete text, which is insufficient when analyzing complicated content. For sentiment analysis illustration, a user review might praise the robustness of a product, whereas criticize the customer support, a scenario where existing approaches collapse such nuanced sentiments into a remarkable polarity score, failing to extract context-specific disparities. This generalization can result in misunderstandings and misinterpretations of user experiences in real-world applications [4]. Based on the recent literature review, deep learning (DL) approaches, mainly recurrent neural networks (RNNs), has dominated advance developments in various NLP tasks such as spam filtering, and topic classification [5, 6], question answering [7] keywords extraction [8] and anomaly detection [9], however, these conventional methods face challenges such as vanishing gradient decay and difficulty to retain long-range dependencies in sequences [10]. To address these issues, two advanced variants of the RNNs were introduced [11], known as LSTM and GRU, which retain the long-term dependencies. Modern implementations integrated attention mechanisms with hybrid architectures that deal with sequence information like CNNs [12] and RNNs [13], improving both predictive accuracy and interpretability. In sentiment analysis (SA), attention allows models to assign higher weights to sentiment-laden terms while suppressing irrelevant content [14], overcoming the inefficiencies of processing entire sentences sequentially [15]. Conversely, attention mechanism enables targeted concentration on specific parts of the input text during sequential analysis, allowing adaptive weighting of contextually critical components in real-time.

Cognitive research [16, 17] demonstrates the link between emotion-associated and human decision-making: positive emotions (e.g., enthusiasm) foster creative problem-solving, while negative emotions (e.g., anxiety) impair cognitive performance. Despite this, traditional LSTM-based approaches neglect the influence of emotion on sentiment feature extraction, potentially undermining their analytical efficacy. While sentiment and emotion are intertwined yet distinct psychological constructs, existing text sentiment analysis frameworks often conflate these terms. Sentiment refers to a persistent cognitive stance, such as opinions reflected in social media posts or brief videos, whereas emotions are transient psychological reactions that influence behavior and modulate neural activity (e.g., enhancing or suppressing neural responses to positive or negative stimuli). These dynamics can refine the adaptability of neural networks such as LSTM by imitating feedback-driven learning processes. This study focuses on detecting latent sentiments in social media content, though the proposed TS-ELSTM framework is designed for broader applicability in machine learning tasks, a direction reserved for future exploration. Crucially, this work rigorously

differentiates between sentiment (as a sustained attitude) and emotion (as an ephemeral state) to ensure conceptual clarity.

In conclusion, the developed TS-ELSTM model offers unique advantages compared to traditional approaches in two key ways: firstly, unlike most traditional neural network models that overlook the role of emotional modulation, TS-ELSTM integrates emotion-based modulation to enhance the learning capacity of neural units by mimicking human emotional processes. Secondly, the existing attention mechanisms usually operate at lower abstraction levels, such as words or phrases. The topic-level attention mechanism in TS-ELSTM extracts higher-level cognitive concentration similar to that of the human brain, resulting in more refined sentiment representations of textual data. The primary contributions of this study are outlined as follows.

1) ELSTM Architecture. We present ELSTM, a novel LSTM variant inspired by emotional intelligence theory. By leveraging the synergistic interplay between emotion and cognition, ELSTM enhances the model's inference capabilities. To our knowledge, this is the first time a human-inspired emotional mechanism has been embedded to strengthen LSTM learning abilities.

2) Dynamic topic-level attention. This study introduces an innovative topic-level attention mechanism that dynamically adjusts the weights of hidden representations for text subsequences, enabling more focused feature extraction.

3) TS-LSTM framework. We design Two-State LSTM (TS-LSTM), a deep network for sentiment analysis that incorporates the ELSTM units with the developed topic-level attention, enhancing text sentiment detection.

4) Empirical validation. Through comprehensive experiments on standard sentiment analysis benchmarks, experimental findings demonstrate that our developed approach performs better than traditional approaches.

This study is organized as follows: Section II describes the details of related work employing deep learning approaches for sentiment analysis. The proposed methodology and its flow diagrams, as well as various sentiment analysis phases, are briefly illustrated in Section III. Section IV refers experimental setup, along with dataset description and evaluation metrics, while Section V presents the results and discussion. Finally, Section VI provides a conclusion and future direction.

II. Related Work

This section investigates the traditional research work on sentiment analysis that influences LSTM architectures and attention mechanisms. Recent developments in RNNs illustrate that integrating LSTMs with their efficient gating for sequence modeling and attention layers are particularly effective for NLP tasks, while attention mechanisms dynamically prioritize salient features in sequences, making their integration a powerful approach for sentiment analysis [18]. Deep learning has already been adopted across NLP tasks such as topic modeling, text categorization, question answering, speech recognition, spam filtering, keyword extraction, machine translation, and information retrieval [19]. The implementation of deep learning in sentiment classification has grown exponentially, with attention-based methods driving innovation. For instance, one research study exhibited that embedding sentiment lexicon features alongside an attention mechanism boosts word representations for overall sentiment classification tasks without specific targets.

Furthermore, Toma and Choi [20] introduced two-directional LSTMs that capture bidirectional context more effectively than a vanilla LSTM. Zulqarnain et al. [21] introduced a bistatic GRU-encoder framework for sentiment analysis, outperforming standalone GRU and LSTM models in accuracy. Jang et al. [22] further advanced the field by combining bidirectional GRU, Word2vec embeddings, and attention mechanisms, achieving state-of-the-art results in sentiment analysis. Building on these ideas, BiLSTM+Attention architectures emphasize their capacity for sentiment-bearing features, further improving classification accuracy. Aspect-level sentiment analysis has progressively relied on attention-based neural networks to model relationships between context and specific terms. Wang et al. [23] referred ATAE-LSTM architecture, integrating LSTM with attention to evaluate contextual relevance for aspect terms. Zhao et al. [24] and Zulqarnain et al. [25] employed a hierarchical attention mechanism to pinpoint sentiment-critical information and achieve a good result, while Yang et al. [26] accomplished a multi-grained fusion network and multigranularity attention to capture word-level interactions and obtained superior performance against state-of-the-art methods. Moreover, Tan et al. [27] designed a dual attention network to detect conflicting opinions, while Ouyang et al. [28] presented Interactive Attention Networks (IAN) for bidirectional context-aspect learning. Graph Convolutional Networks (GCNs) have also emerged as pivotal tools in modern sentiment analysis frameworks.

Emotional intelligence (EI) research highlights emotions' influence on decision-making. Khashman [29] pioneered DuoNeural, an architecture unifying emotion and cognition in intelligent systems. Lotfi and Akbarzadeh [30] developed LiAENN, a neural network modeling emotional states like anxiety during learning. Hassan et al. [31] highlighted an emotional multi-agent reinforcement learning framework to foster cooperative behaviors, while Oyedotun and Khashman [32] unified adaptive and prototype learning theories in emotional neural networks. Markadeh et al. [33] utilized brain-emotional learning to control induction motors. Building on these insights, the proposed TS-ELSTM integrates emotional reasoning into intelligent systems, reinforcing the view that affective dynamics are essential to intelligent reasoning.

Conclusion remarks in terms of limitations of the existing literature review are as follows: traditional deep learning approaches excel in either contextual modeling (BiLSTM+Attention [20, 22-28]) *or* emotional reasoning (DuoNeural/LiAENN [29-33]), but they fail to synergize these capabilities. Aspect-level deep learning architectures (ATAE-LSTM [23], hierarchical attention [24-25]) capture contextual nuances but ignore affective dynamics critical for sentiment interpretation. Conversely, emotional neural networks [29-33] lack linguistic grounding for NLP tasks. Furthermore, existing models neglect the sentiment-emotion discrepancy and treat

sentiment and emotion as isomorphic (e.g., lexicon-enhanced attention [18]).

III. Proposed Methodology

This study outlines the methodology of the proposed framework, which integrates emotional intelligence and a two-state LSTM strategy with an adaptive attention mechanism. The key contributions lie in its structured workflow, comprising in several phases: 1) systematic data acquisition and preprocessing, 2) feature embedding via pre-trained technique (GloVe), 3) sequential modeling using recurrent architectures (V-RNN, LSTM, and GRU), 4) integration of an attention layer and 5) performance assessment. Each component is comprehensively explored in depth in the following sections.

A. Embedding Layer

In the sentiment classification process, the embedding layer serves an important function by transforming raw text into structured numerical inputs. During sentence analysis, the initial preprocessing phase involves sanitizing textual data to remove noise. Neural networks, constructed on linear algebra operations and nonlinear activation functions, necessitate textual inputs to be translated into dense numerical vectors within a low-dimensional space [34]. To attain this, we utilize a pre-trained 300-dimensional Global Vectors (GloVe) technique [35] in the word embedding layer, which maps each word in a sentence to a continuous vector representation. GloVe influences global statistical patterns during the embedding stage and efficiently captures semantic and syntactic co-occurrence relationships across corpora, combining the benefits of matrix factorization and context window methods. This method improves its competence in managing lexical ambiguities, such as synonyms and polysemous terms. In contrast, network-dependent embeddings, the GloVe method arises word vectors directly from corpus statistics, bypassing iterative training procedures and allowing effective parallelization for scalable implementation.

B. Vanilla Recurrent Neural Network (V-RNN)

The Vanilla RNN is the most basic variant of the RNN model. The V-RNN includes a single recurrent layer that manages both current input information and the previous hidden state to produce an output while simultaneously updating its hidden state for subsequent steps. The term "vanilla" replicates its simplicity, as its deficiencies are advanced structural elements like gating mechanisms, which are frequently used to handle long-term dependencies or gradient issues [35, 36].

C. LSTM

The LSTM model is an advanced variant of standard RNNs, initially introduced by Sepp Hochreiter and Jürgen Schmidhuber in 1997 [37]. LSTMs are well-known for addressing long-term dependencies in sequential data. LSTMs are frequently integrated with architectural designs like inception modules to expand their ability and examine temporal patterns in time-series datasets. Unlike Vanilla RNNs, LSTM uses particular internal memory cells and gated mechanisms to moderate information loss during sequential data processing.

These networks manage the information flow across sequences utilizing gate mechanisms including input, forget, output, and a special internal memory cell, which cooperatively stimulate the hidden layer's output at each timestep [38]. By dynamically regulating data holding and propagation, LSTMs demonstrate better performance in the NLP tasks requiring nuanced temporal understanding.

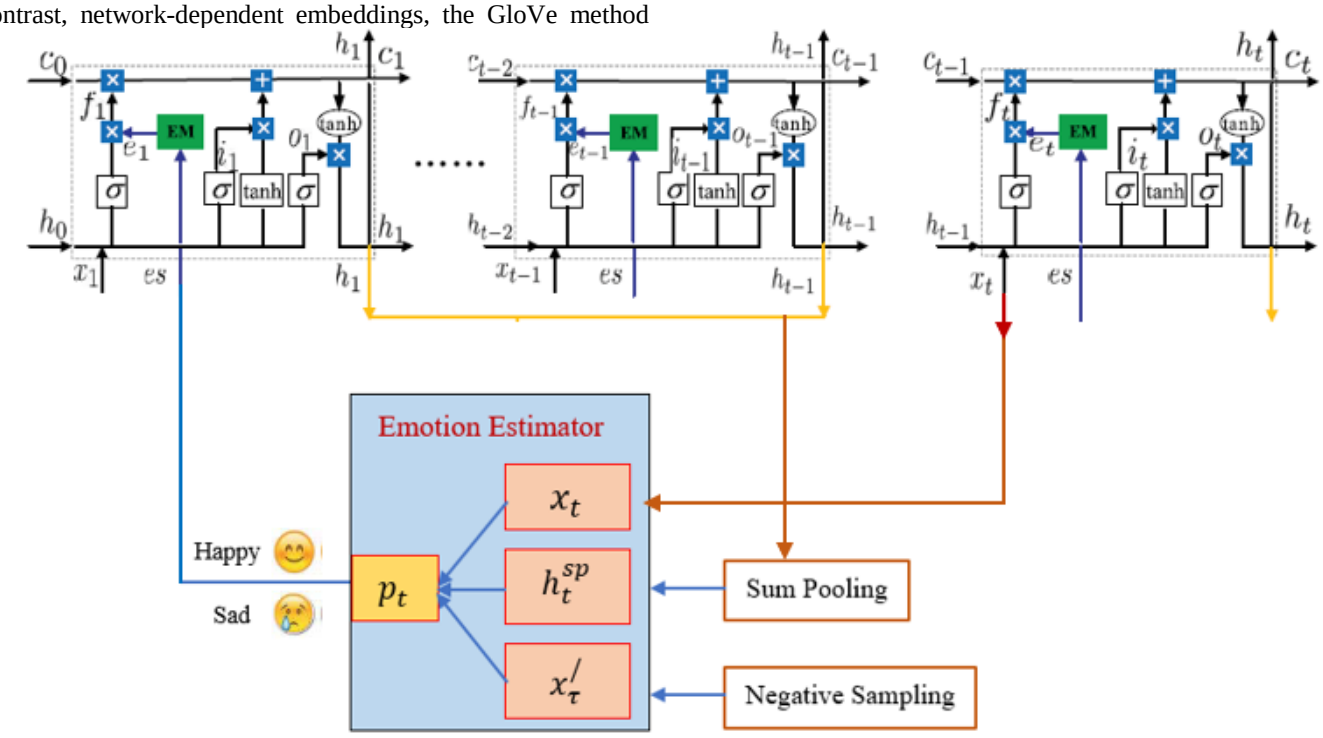

Fig. 1. Developed emotional LSTM.

D. Emotion-Enhanced LSTM

Conventional RNNs offer an effective approach for modeling sequential text data by leveraging contextual relationships between adjacent words. However, conventional RNNs suffer from gradient instability (vanishing or exploding gradients) and struggle to extract long-range semantic or sentiment dependencies. To address these drawbacks, Hochreiter and Schmidhuber [39], proposed the LSTM network, which incorporates gated memory cells and has demonstrated superior sequence-representation capabilities, significantly improving performance in tasks requiring temporal understanding. LSTM block mirrors certain features of the brain's memory and language-processing systems. Cognitive neuroscience research [40] highlights emotion's role in memory processes, enhancing information encoding, consolidation, and retrieval. For instance, a person's emotional state during perception can improve the encoding of information into both short-and long-term memory. As observed in previous work, it confirms that embedding emotional cues can lead to higher-quality decision-making in intelligent systems. Yet, traditional LSTMs update their memory cells solely based on input and past hidden states, ignoring any emotional modulation.

To bridge this gap, we propose Emotion-enhanced LSTM (ELSTM), a novel architecture inspired by EI principles. As illustrated in Fig. 1, ELSTM introduces three gates (input, forget, output), three states (hidden, cell, emotion), an emotion-based modulator (EM), and an emotion estimator. The network's output at each timestep feeds back into both the gate inputs and the emotion estimator. Formally, ELSTM core equations are as follows [Eq. (1) to Eq. (7)]:

$$i_t = \sigma(W_{xi}x_t + U_{hi}h_{t-1} + b_i) \quad (1)$$

$$e_t = EM(es) \quad (2)$$

$$f_t = e_t * \sigma(W_{xf}x_t + U_{hf}h_{t-1} + b_f) \quad (3)$$

$$o_t = \sigma(W_{xo}x_t + U_{ho}h_{t-1} + b_o) \quad (4)$$

$$\hat{a}_t = tanh(W_{x\hat{a}}x_t + U_{h\hat{a}}h_{t-1} + b_{\hat{a}}) \quad (5)$$

$$c_t = f_t * x_{t-1} + (i_t * \hat{a}_t) \quad (6)$$

$$h_t = O_t * tanh\,(c_t) \quad (7)$$

where, σ is the sigmoid activation, * denotes element-wise multiplication, and W, U, and b are trainable parameters. The emotion modulator produces a signal e_t from the emotional state e_s (as discussed in Section III-G), which is integrated into the forget gate f_t, balancing the retention of past cell state c_{t-1} against new input x_t.

ELSTM operates in four sequential phases:

1) Forgetting. The forget gate uses both the previous hidden state h_{t-1}, the current input x_t, and the emotion signal t_e to determine what to retain in c_{t-1}.

2) Emotion-estimation. An internal estimator infers the new emotional state e_s based on past outputs (see Section III.H).

3) Updating. During the updating process, the input gate i_t and the candidate state $\hat{a}_t$ manage which new information arrives in the cell, completing the update in Eq. (6).

4) Output. Finally, the output gate o_t filters the updated cell state over a *tanh* function to generate the new hidden state h_t, as in Eq. (7).

In this study, the ELSTM architecture illustrates three important novelties to enhance sequence modeling. First, its Emotion-Aware Forgetting mechanism reinterprets the forget gate of the traditional LSTM by incorporating emotion-derived signals, consenting to dynamic modifications to the retention of preceding context h_{t-1}, and the modification of new inputs x_t. This mechanism confirms a contextually balanced trade-off between memory preservation and adaptability. Second, its Brain-Inspired-Design extends standard LSTM by embedding emotion modulation, adjusting with neuroscientific insights on emotion's role in memory. Finally, this study describes the Dynamic Adaptation of emotional intelligence (EI) to prioritize contextually salient information during gating operations, improving decision-making over real-time relevance weighting.

By retaining the main memory-and-gating mechanisms of the conventional LSTM and expanding them with emotion-driven modulation, ELSTM efficiently balances information retention and forgetting, yielding a richer, more brain-inspired sequence model.

E. Two-State LSTM (TS-LSTM)

LSTM is an enhanced variant of conventional RNNs used for sequential modeling. At each time step t, they compute a hidden state $h_t \in \mathbb{R}^n$ illustrated in Eq. (8):

$$h_t = f(W_{xt} + Uh_{t-1} + b) \quad (8)$$

where, $W \in R^{m\times n}$, $b \in R^{m\times m}$, $b \in R^m$, refers to weight matrices and biases, respectively, and f represents a nonlinear activation [30]. Although LSTMs struggle with gradient instability (vanishing or exploding gradients) and inherently prioritize forward linguistic context, they neglect backward dependencies critical for tasks like sentiment analysis. Yet natural language understanding often benefits from both preceding and succeeding context.

To address this, we introduce the Two-State LSTM (TS-LSTM), which processes inputs in two passes: one from left to right (forward or positive) and one from right to left (backward or negative) inspired by bidirectional RNNs, as illustrated in Fig. 2. During training, these pathways independently analyze temporal sequences and merge their outputs to capture comprehensive contextual relationships.

1) Forward Pass. The forward LSTM computes hidden states $\overrightarrow{C_t}$ using the input gate $\overrightarrow{\imath_t}$, forget gate $\overrightarrow{f_t}$, and candidate state $\overrightarrow{\hat{a}_t}$ gates are defined as [Eq. (9) to Eq. (15)]:

$$\overrightarrow{\imath_t} = \sigma(\overrightarrow{W_{xt}} \times [\overrightarrow{C_{t-1}}, \overrightarrow{h_{t-1}}, \overrightarrow{x_t} + \overrightarrow{b_t}) \quad (9)$$

$$\overrightarrow{e_t} = \overrightarrow{EM(es)} \quad (10)$$

$$\overrightarrow{f_t} = e_t * \sigma(\overrightarrow{W_{xf}} \times [\overrightarrow{C_{t-1}}, \overrightarrow{h_{t-1}}, \overrightarrow{x_t} + \overrightarrow{b_f} \quad (11)$$

$$\overrightarrow{o_t} = \sigma(\overrightarrow{W_{xo}} \times [\overrightarrow{C_{t-1}}, \overrightarrow{h_{t-1}}, \overrightarrow{x_t} + \overrightarrow{b_o}) \quad (12)$$

$$\overrightarrow{\hat{a}_t} = tanh(\overrightarrow{W_{x\hat{a}}} * [\overrightarrow{h_{t-1}}, \overrightarrow{x_t} + \overrightarrow{b_{\hat{a}}}) \quad (13)$$

$$\overrightarrow{C_t} = \overrightarrow{f_t} * (\overrightarrow{C_{t-1}} + \overrightarrow{i_t} * \overrightarrow{\hat{a}_t}) \quad (14)$$

$$\overrightarrow{h_t} = \overrightarrow{o_t} * \overrightarrow{tanh}(\overrightarrow{C_t}) \quad (15)$$

2) Backward pass. Proportionally, the backward LSTM processes sequences in reverse, with analogous [Eq. (16) to Eq. (22)] for $\overleftarrow{i_t}$, $\overleftarrow{f_t}$, $\overleftarrow{C_t}$,$\overleftarrow{o_t}$ and $\overleftarrow{\hat{a}_t}$

$$\overleftarrow{i_t} = \sigma(\overleftarrow{W_{xi}} \times [\overleftarrow{C_{t-1}}, \overleftarrow{h_{t-1}}, \overleftarrow{x_t} + \overleftarrow{b_i}) \quad (16)$$

$$\overleftarrow{e_t} = \overleftarrow{EM(es)} \quad (17)$$

$$\overleftarrow{f_t} = e_t * \sigma(\overleftarrow{W_{xf}} \times [\overleftarrow{C_{t-1}}, \overleftarrow{h_{t-1}}, \overleftarrow{x_t} + \overleftarrow{b_f} \quad (18)$$

$$\overleftarrow{o_t} = \sigma(\overleftarrow{W_{xo}} \times [\overleftarrow{C_{t-1}}, \overleftarrow{h_{t-1}}, \overleftarrow{x_t} + \overleftarrow{b_o}) \quad (19)$$

$$\overleftarrow{\hat{a}_t} = tanh(\overleftarrow{W_{x\hat{a}}} * [\overleftarrow{h_{t-1}}, \overleftarrow{x_t} + \overleftarrow{b_{\hat{a}}}) \quad (20)$$

$$\overleftarrow{C_t} = \overleftarrow{f_t} * [\overleftarrow{C_{t-1}}, \overleftarrow{i_t} * \overleftarrow{\hat{a}_t}) \quad (21)$$

$$\overleftarrow{h_t} = \overleftarrow{o_t} * \overleftarrow{tanh}(\overleftarrow{C_t}) \quad (22)$$

For an input sequence $(x_1, x_2, \ldots, x_n)$, each token at position t is first encoded by the forward LSTM into $\overrightarrow{C_t}$ (left-to-right context) and by the backward LSTM into $\overleftarrow{C_t}$ (right-to-left context). These two vectors are then concatenated as referred to in Eq. (23):

$$C_t = \overrightarrow{C_t}, \overleftarrow{C_t} \quad (23)$$

This dual-direction formulation allows TS-LSTM to capture comprehensive contextual information from both surrounding directions.

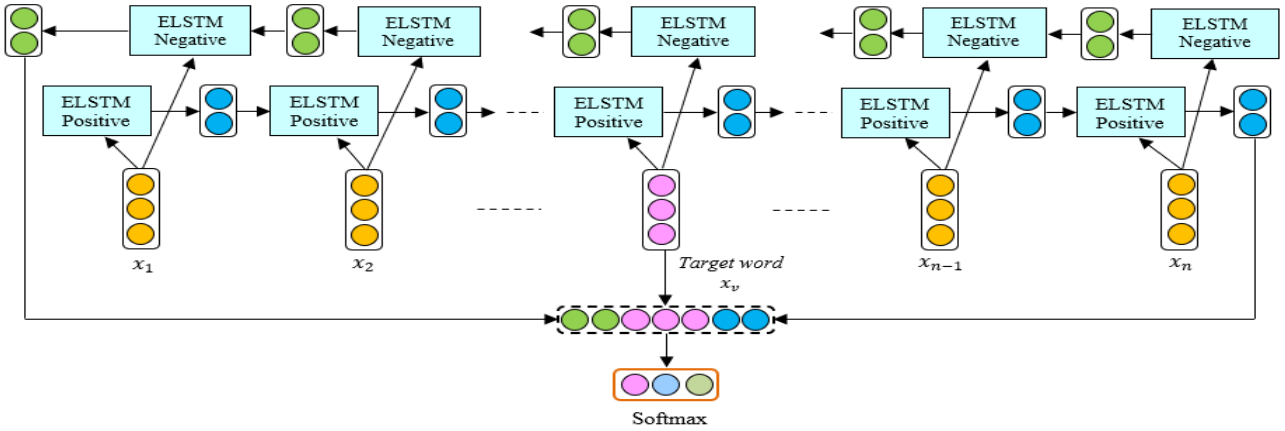

Fig. 2. Two-state strategy.

F. Attention Layer

The attention mechanism assists in highlighting the most relevant parts of the input data while minimizing the influence of less important information. By assigning differentiated weight values to features based on their emotional relevance, this mechanism permits the model to efficiently filter out non-essential textual content. This targeted concentration facilitates more accurate learning of emotionally substantial textual features, thereby improving the efficacy of implicit sentiment analysis tasks.

In most textual data, words that convey emotional tone are particularly impactful in determining the complete sentiment. In this research, we incorporate an attention mechanism that emphasizes emotionally charged features within sentences expressing implicit sentiment. Specifically, this study applies attention to both local and global feature matrices represented as $R = [r_1, r_2, r_3 \ldots r_n,]$ and $H = [h_1, h_2, h_3 \ldots h_n,]$ respectively, to enhance sentiment polarity.

The attention scores are calculated over the following transformations as Eq. (26) and (27):

$$Local\ features = u_{ri} = \tanh(W_r r_i + b_r) \quad (26)$$

$$Blobal\ features = u_{hj} = \tanh(W_r r_j + b_h) \quad (27)$$

where, W_r and W_h are the learnable weight matrices, b_r and h_r are biased terms, and $tanh$ is the activation function.

The attention weights a_i and a_j for local and global features are calculated using the softmax function [Eq. (28) and (29)]:

$$a_i = \frac{\exp(u_{ri})}{\sum_{i=1}^{m} \exp(u_{ri})} \quad (28)$$

$$a_j = \frac{\exp(u_{rj})}{\sum_{j=1}^{m} \exp(u_{rj})} \quad (29)$$

Using these attention weights, the local and global feature representations are computed as weighted sums [Eq. (24) and (25)]:

$$s_i = \sum_{i=1}^{m} a_i r_i \quad (24)$$

$$s_h = \sum_{j=1}^{m} a_j r_j \quad (25)$$

This dual-channel attention mechanism dynamically assigns importance to emotionally relevant word vectors, significantly improving the effectiveness of the developed TS-ELSTM approach. As a result, the network demonstrates better precision in emotion detection and analysis within the human-computer interactive dialogue environment. The overall architecture of the proposed model is demonstrated in Fig. 3.

The output layer of the TS-ELSTM model combines both local and global feature vectors by concatenation [Eq. (30)]:

$$s = [s_r, s_h] \tag{30}$$

To reduce the risk of overfitting, dropout is applied before passing the concatenated vector through a fully connected neural network. The final output is computed using the softmax function as in Eq. (31) and (32):

$$o = f[W_s s + b] \tag{31}$$

$$g = softmax(0) \tag{32}$$

where, o refers to the output from the fully connected layer, W is the weight matrix, b is the bias term, and g is the resulting output vector utilized for classification.

G. Emotion-Based Estimator

Emotional responses arise from fast neural signaling activated by external stimuli, mirroring the brain's capability to process information quickly. Inspired by this fast and efficient emotional reaction, we developed a novel emotion estimator integrated with negative sampling that influences similarity-based cognition. From a linguistic perspective, within a given text sequence $(x_1, x_2, \dots, x_{t-1}, x_t, \dots.)$, a subsequence $(x_{t-\tau}, x_{t-\tau+1}, \dots, x_{t-1})$ often holds strong semantic relevance to the current word x_t.

To capture this association, we compute the semantic similarity over the inner product between the vector representation of the current word x_t and the sum-pooled representation of the preceding subsequence $h_t^{sp} = SumPooling(x_{t-\tau}, x_{t-\tau+1}, \dots, h_{t-1})$. This system permits us to estimate the likelihood that x_t follows the subsequence using the softmax function as in Eq. (33):

$$P_t = \frac{\exp(h_t^T h_t^{sp})}{\sum_{i=1}^{V} \exp(h_i^T h_t^{sp})} \tag{33}$$

where, V represents the total vocabulary size. However, computing this across all vocabulary items is computationally expensive and contradicts the efficiency expected from emotion-driven systems. To overcome this, negative sampling is employed [41], significantly minimizing computation cost by selecting a limited number of negative examples from a background distribution. With this technique, the equation becomes [Eq. (34)]:

$$P_t = \frac{\exp(h_t^T h_t^{sp})}{\exp(h_i^T h_t^{sp}) + \sum_{i=1}^{NS} \exp(h_i^T h_t^{sp})} \tag{34}$$

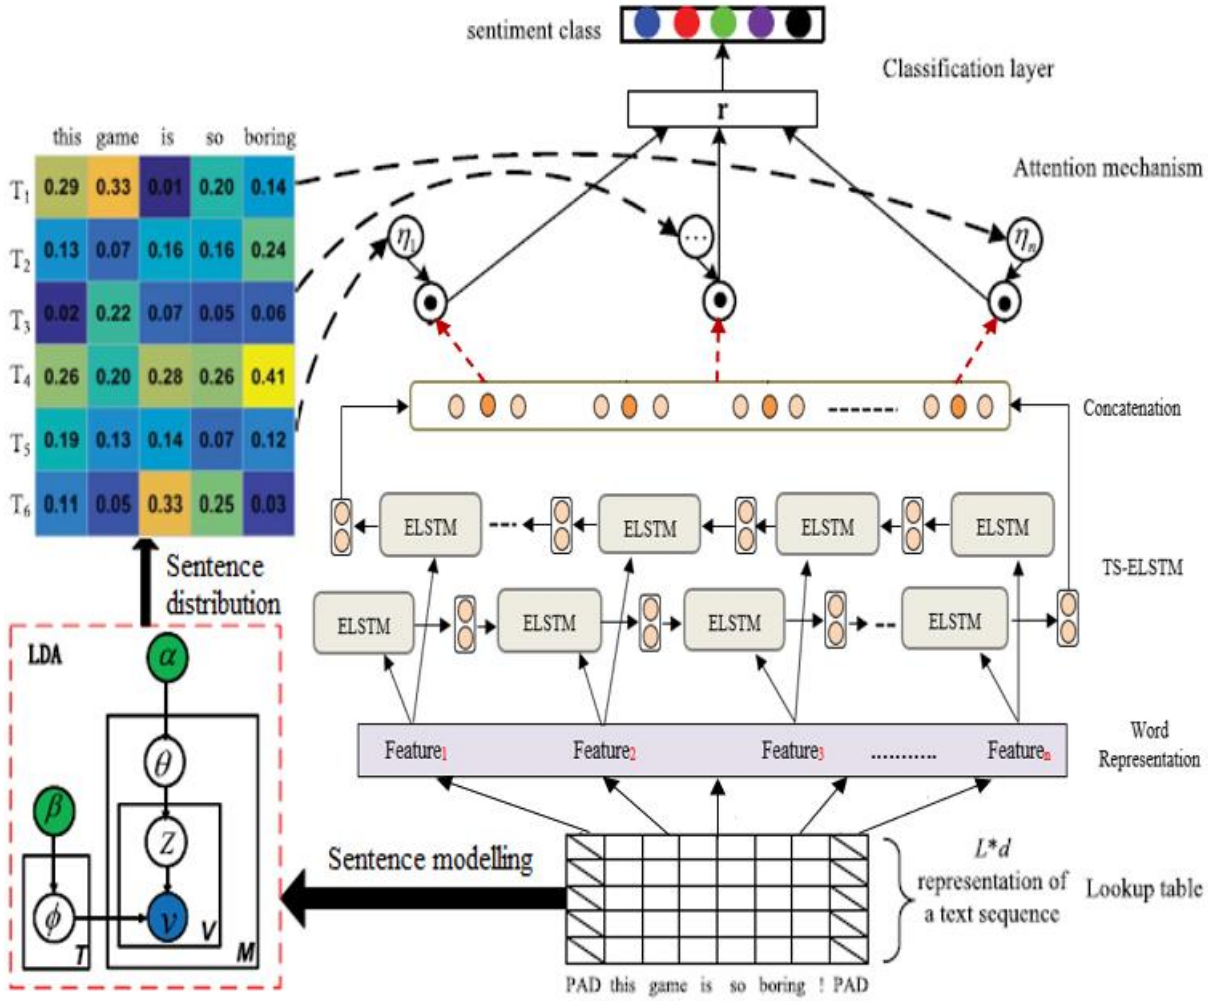

Fig. 3. Overall proposed TS-ELSTM architecture.

where, NS denotes the number of sampled negative instances, which is considerably smaller than V.

Rule 1: (Emotion Classification Rule): If $P_t > ET$ (a predefined threshold), the emotion estimator classifies the state as "Happy"; otherwise, it outputs "Sad".

H. Emotion-Based Modulation

The key role of the emotion-based modulator is to convert the emotional state es detected by the system into the corresponding modulation behavior. This conversion follows a set of predefined mappings, detailed in Rule 2 and Rule 3.

Rule 2: (Enhance Emotion Modulation): This rule is activated when the ELSTM (Emotion-augmented LSTM) experiences a "Happy" emotional state, typically triggered by successfully learning the semantic relationship between a subsequence $(x_{t-\tau}, x_{t-\tau+1}, \dots, x_{t-1})$, and its next token x_t. Success indicates effective semantic comprehension, which reinforces TS-ELSTM's tendency to retain learned information by increasing its modulation factor, favoring memory over forgetting.

Rule 3 (Reduce Emotion Modulation): Conversely, failure to accurately learn the sequence embedding implies a poor understanding, causing a "Sad" state. In response to the current state, the proposed TS-ELSTM decreases its modulation factor to promote forgetting of low-quality or misleading information.

In this mechanism, the emotional coefficient p plays a key role. The modulation factor is calculated based on Eq. (35):

$$e_{t+1} = \begin{cases} e_t + \rho * \left|h'_t - h_t^{sp}\right| if\ es = H \\ e_t - \rho * \left|h'_t - h_t^{sp}\right| if\ es = S \end{cases} \quad (35)$$

where, $|.|$is the absolute value operator, $\acute{h}_t$ is the output vector for the current input x_t, while h_t^{sp} sum-pooled depiction of preceding outputs, and $H\ and\ S$ illustrate the emotional states "Happy" and "Sad", respectively.

To dynamically adjust p during training, a self-adaptive strategy is utilized as in Eq. (36):

$$p_{ep} = (p_{max} - p_{min}) * \frac{EPOCH - ep}{EPOCH} + p_{min} \quad (36)$$

where, p_{min} and p_{max} define the constraints of the inertia coefficient, while $EPOCH$ is the total number of training epochs, and ep is the current epoch.

This method confirms that p_{ep} starts its maximum value when training begins $(sp = 0)$ and progressively reduces toward p_{min} as training developments. The rationale aligns with deep learning algorithms: initially, a high inertia coefficient accelerates learning, while in later stages, a reduced value ensures constancy of the system converges.

IV. Experimental Setup

Several experiments were carried out to assess the effectiveness of the developed TS-ELSTM model in comparison to existing approaches. The simulations of the proposed study were performed on a system powered by an Intel Core i7-3770 CPU (3.40 GHz) and 32 GB RAM, running Windows 10. Python 3.13 and Anaconda utilized the computational environment for data preprocessing and analysis, supported by TensorFlow 2.4.1 and Keras 2.3 as deep learning frameworks. The Natural Language Toolkit (NLTK) was employed for word embedding tasks. Exploiting Keras's compatibility with CPU architectures, the setup optimized hardware resources to accelerate network training and inference. The detailed optimal hyperparameter settings utilized to train the developed model are illustrated in Table I.

TABLE I. Optimal Hyperparameter of the Developed Model

Parameter Name	Parameter Value
Optimizer	Adam
Word vector dimension	300
Batch size	64
Learning Rate	0.001
Attention Mechanism	350 units
Dropout	0.5
Activation function	ReLU/tanh
Loss Function	Cross-entropy
Learning rate decay	0.01
Network epochs	30

A. Dataset Description

The experiments were carried out using three publicly available datasets, all centered around sentiment analysis of movie-related opinions. The selected datasets are: Stanford Internet Movie Database (IMDB), and Movie Review (MR). These datasets are designed for binary sentiment classification to predict whether a review expresses a positive or negative sentiment. Key statistical details of the datasets, including size and class distribution, are summarized in Table II.

TABLE II. Statistical Details of the Dataset

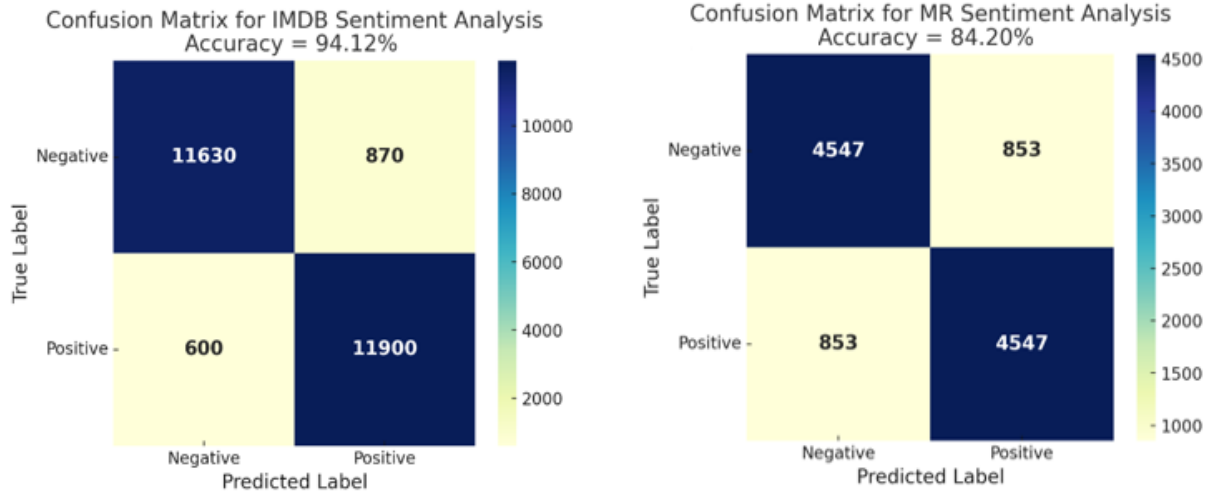
Detail	MR	IMDB
Train	8654	37,500
Validation	CV	CV
Test	1062	12,500
Max.length	52	1825
Ave.length	18.6	180.4
V-size	18,990	88,712
D-size	10,660	50,000
No. Of Classes	2	2

B. Evaluation Metrics

To assess the effectiveness of the proposed method in sentiment analysis tasks, various evaluation metrics were employed. Commonly used metrics include accuracy, precision, recall (also known as sensitivity), and the F1-score. Each metric provides insights into different aspects of the model's performance as in Eq. (37) to (40):

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FP+FN)} \quad (37)$$

$$Precision = \frac{TP}{(TP + FP)} \quad (38)$$



$$Sensitivity = Recall = \frac{TP}{(TP + FN)} \quad (39)$$

$$\text{F1} - Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (40)$$

In these equations, TP, TN, FP, and FN stand for True Positive, True Negative, False Positive, and False Negative, respectively.

V. Results and Discussion

Our experimental analysis summarizes the performance outcomes of the TS-ELSTM approach, benchmarked against existing deep learning methods using two text classification datasets. The assessment, employing multiple evaluation criteria, demonstrates consistently superior accuracy across all benchmarked datasets. Fig. 4 shows the confusion matric performance of the proposed model using both datasets, while Table III describes the overall performance of the proposed model.

(a) (b)

Fig. 4. Confusion matrix of the proposed model (a) IMDB, (b) MR.

TABLE III. Proposed Model Performance

	Evaluation Parameters			Average Values		
Datasets	Precision (%)	Recall (%)	F1 Score (%)	Test size	Accuracy (%)	F1 score (%)
MR	83.56	84.14	83.85	CV	**84.20**	**83.970**
	84.73	83.47	84.09	CV		
IMDB	94.38	93.69	94.07	CV	**94.12**	**93.965**
	93.90	94.04	93.86	CV		

A. First Dataset (MR) Results

The performance of the developed TS-ELSTM model on the MR dataset is illustrated in Table IV. The developed model obtained precision scores of 83.56% for positive instances and 84.73% for negative instances, with corresponding recall rates of 84.14% and 83.47%. These metrics culminated in an F1-score of 83.970% and an overall accuracy of 84.20%. Comparative analysis against existing studies underscores the model's superiority. For instance, Chen et al. [42] accomplished a BiLSTM with conditional random fields, attaining 82.30% accuracy, while Fu et al. [43] developed ALE-LSTM, a lexicon-enhanced LSTM with attention strategy, which achieved 79.90% accuracy on the MR dataset. The developed TS-ELSTM outperformed both these approaches, as well as Zhang et al.'s [44] proposed hybrid BiGRU+CNN, and reported 78.30% accuracy, our model highlighted 6.08% improvement over the existing approaches. Similarly, Qian et al. [45] introduced deep learning integrated models with sentence-level classification, and achieved an accuracy of 82.30%. Moreover, Usama et al. [46] reported accuracies of 79.80% and 80.20% using a multi-level feature extraction model combining GRU, LSTM, and CNN, results surpassed by the proposed framework. Furthermore, Mohammed et al. [47] proposed a recurrent attention GRU with a self-attention mechanism using the MR dataset, and reported an accuracy of 82.38%.

The proposed TS-ELSTM also excelled on the MR dataset, exceeding the performance of prior studies [42–49] despite their more complex architectures, detailed comparison is represented in Table IV.

TABLE IV. COMPLEXITY AND ACCURACY-BASED ANALYSIS WITH TRADITIONAL STUDIES ON THE MR DATASET

Methods	Model Complexity	Accuracy (%)
BiGRU+CNN [44]	Sequential combination of BiGRU and CNN framework	78.30
MV+RNN [48]	The joint strategy of analyzing trees and the RNN model	79.00
WALE+LSTM [43]	Implementation of WALE and attention mechanism jointly with LSTM	79.90
Self-Att-LSTM+word2vec [49]	Implemented Self-attention mechanism with LSTM based on word2vector	79.93
Hierarchical-Att-GRU+Dropout [49]	Investigated Hierarchical-attention mechanism with GRU based on word2vector	79.97
CNN-GRU-multilevel and multitype fusion [46]	Proposed combined methodology in terms of multilevel and multi-type features based on CNN and GRU models	80.20
SA-RA+GRU [47]	Proposed self-attention with recurrent attention GRU (SA+RA-GRU)	82.38
BiLSTM-CRF [42]	Fusion of bidirectional LSTM with CRT combined with CNN	82.30
LR+BiLSTM [45]	Illustrated sentence-level representation based on LR, and combined with BiLSTM	82.10
TS-ELSTM (Proposed)	**Two-State Enhanced LSTM (TS-ELSTM) + Emotional Intelligence (EI)**	**84.20**

B. Second Dataset (IMDB) Results

The proposed framework showed remarkable enhancements in sentiment analysis performance on the IMDB dataset, and compared results with state-of-the-art approaches, as demonstrated in Table III. The model achieved precision rates of 93.90% for positive reviews and 94.38% for negative critiques, with corresponding recall values of 94.04% and 93.69%, respectively. These metrics yielded an F1-score of 93.965% and an overall accuracy of 94.12%, outperforming conventional methods. For instance, Long et al. [50] introduced a cognition-based attention (CBA) method, which integrated dual attention frameworks with LSTM, achieved 90.10% accuracy, falling short despite its architectural complexity. Similarly, Collados and Pilehvar's [51] proposed a hybrid CNN-LSTM approach, incorporated preprocessing techniques and multi-modal fusion, attained 88.9% accuracy, underscoring the efficacy of our streamlined design.

Further comparisons reveal the framework's superiority over Ouyang et al. [52] CNN-based approach, and achieved an accuracy of 88.22% based on attention strategy, while Fu et al. [43] reported two various kinds of deep learning models, such as ALE-LSTM and WALE-LSTM approaches, which described an accuracy of 89.30% and 89.50%, respectively. Moreover, Kardakis et al. [49] explored the hybrid attention-based models and incorporated with LSTM/GRU, reporting an accuracy of 89.71% and 87.92%, respectively. Similarly, on the MR dataset, Mohammed et al. [47] proposed an attention-based recurrent neural network, such as GRU with a self-attention and recurrent attention mechanism, and reported an accuracy of 92.17%. While Zulqarnain et al. [21] reported 91.32% accuracy using a normalized auto-encoder with improved GRU. Furthermore, Islam et al. [53] explored the various hybrid deep learning models such as RoBERTa+DNN and BERT+DNN on the IMDB dataset, reported an accuracy of 92.05%, and 91.35%, respectively. Additionally, Lio Bing [54] proposed a CBOW-CNN method for sentence classification, attained an accuracy of 87.20%, and Yohong et al. [55] accomplished FARNN-Att mechanism, and highlighted an accuracy of 89.22% were outperformed by significant margins. In contrast, Danyal et al. [56] introduced a sentiment analysis model, such as XLNet (Extra-Long NN), using imdb dataset, achieving an accuracy of 93.74%, while Boewen Zhang [57] proposed a hybrid BERT-CNN model for sentiment analysis, reporting an accuracy of 92.90%.

By leveraging two-state layers alongside emotional intelligence, our proposed architecture highlighted excellent performance than existing studies based on architecture and accuracy comparison, detailed comparisons illustrated in Table V. The overall accuracy of two sentiment analysis datasets, showing IMDB at 94.12% and MR at 84.20%, graphical illustration is represented in Fig. 5.

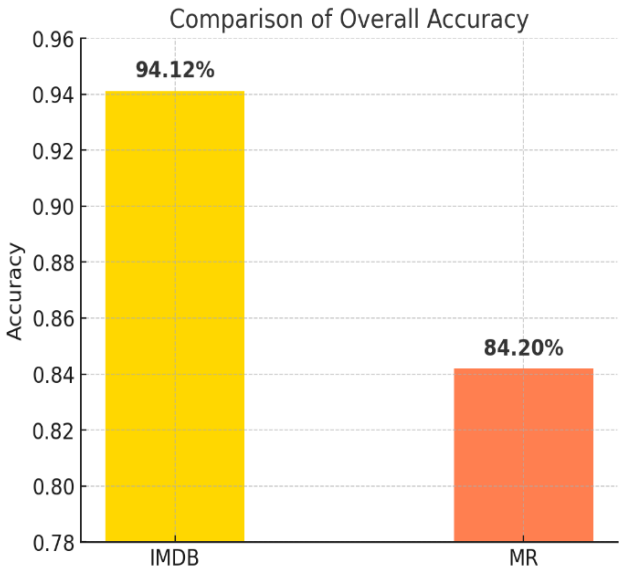


Fig. 5. Overall accuracy of the proposed model on both datasets.

Additionally, training dynamics were analyzed by tracking loss rates and epochs. Fig. 6 visualizes the epochs and loss rate of the proposed method alongside five conventional models (e.g., LSTM, Bi-GRU, BERT, BERT-CNN, and BERT-BiGRU) on a validation set. Over 25 epochs, the TS-ELSTM exhibited faster convergence, improved stability, and higher training efficiency, attributed to its emotional intelligence and topic-attention layers. These components optimize the representation of textual structure, enabling the model to capture contextual dependencies more effectively than traditional architectures.

TABLE V. COMPLEXITY AND ACCURACY-BASED ANALYSIS WITH TRADITIONAL STUDIES ON THE IMDB DATASET

Methods	Model Complexity	Accuracy (%)
CNN [52]	number of layers, filter sizes, strides, and input dimensions, leading to a computational cost-proportional	88.22
FARNN-Att [55]	Attention mechanism and adversarial training with BiLSTM	89.22
WALE-LSTM [43]	The combination of lexicon and attention layers with LSTM	89.50
CNN+LSTM [51]	Combination of CNN and LSTM with different cleaning processes	88.90
Self-Att-LSTM+word2vec [49]	Implemented Self-attention mechanism with LSTM based on word2vector	89.71
Hierarchical-Att-GRU+Dropout [49]	Investigated Hierarchical-attention mechanism with GRU based on word2vector	87.92
CBOW+D-CNN [54]	Combined the CBOW method with the CNN algorithm	87.20
LSTM+CBA+LA [50]	Integrated of two different feature attention frameworks with LSTM	90.11
BERT [58]	Bidirectional Encoder Representations from Transformers	85.83
XLNeT [58]	Transformer-XL with a two-stream attention mechanism	91.10
NAE-GRU [21]	Combined Auto-encoder with GRU through batch normalization	91.32
BERT+DNN [53]	Bidirectional encoder representations from transformers combined with deep neural network	91.35
RoBERTa+DNN [53]	R0bustly optimized BERT combined with deep neural network	92.05
SA-RA+GRU [47]	Proposed self-attention with recurrent attention unit GRU (SA+RA-GRU)	92.17
XLNet [56]	Extra-Long neural network	93.74
BERT-CNN [58]	Bidirectional encoder representations from transformers combined with CNN	92.90
TS-ELSTM (Proposed)	**Two-State Enhanced LSTM (TS-ELSTM) + Emotional Intelligence (EI)**	**94.12**

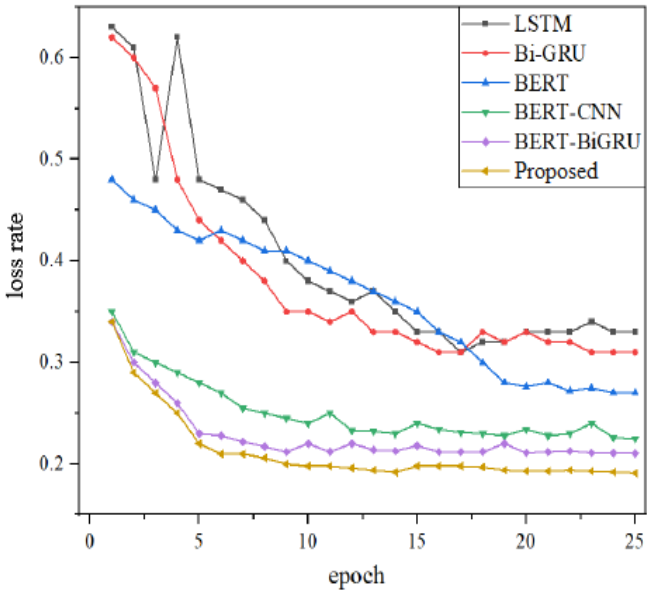

Fig. 6. Loss-based comparison of the proposed and traditional approaches.

VI. CONCLUSION AND FUTURE DIRECTION

Recurrent Neural Networks (RNNs) have become prominent in Natural Language Processing (NLP) for their effectiveness in modeling sequential data, yet they often struggle with vanishing gradient decay over long sequences and difficulty retaining distant contextual dependencies. To alleviate these drawbacks, attention mechanisms have been successfully combined as a transformative solution with deep learning algorithms, enhancing performance across NLP tasks. This study proposed TS-ELSTM, a novel deep learning architecture designed for sentiment analysis in textual sequences. The proposed framework integrates intelligence from emotional psychology and cognitive science, featuring an enhanced LSTM variant (ELSTM) that embeds emotional intelligence to dynamically balance information retention and forgetting. Additionally, a topic-aware attention mechanism dynamically adjusts the weighting of hidden representations in text subsequences, while an ELSTM layer synergizes with Latent Dirichlet Allocation (LDA) for topic modeling. Experimental outcomes show that the proposed TS-ELSTM accomplished excellent performance in sentiment analysis tasks compared to state-of-the-art models.

In the proposed study, we describe two limitations regarding our developed model: 1) The TS-ELSTM model was exclusively trained and tested on general-domain datasets (e.g., IMDB, Yelp, Amazon reviews). Its reliance on domain-specific linguistic patterns and emotional lexicons limits applicability to specialized contexts (e.g., clinical, financial, or low-resource languages). 2) The TS-ELSTM emotional gating mechanism and dual-polarity kernels increase computational cost and interpretation latency by ~35% compared to traditional LSTMs. This challenges scalability for real-time applications (e.g., live chat sentiment monitoring or high-frequency social media analysis), particularly on edge devices.

In future work, we plan two extensions. First, we extend to adapt TS-ELSTM model for aspect-level sentiment classification by incorporating fine-grained sentiment priors from lexical resources. Second, we will explore multi-objective optimization to tune TS-ELSTM parameters, striking an optimal trade-off between fitting accuracy and network sparsity, thereby enhancing both its robustness and generalization.

***Abstract*—No-reference image quality assessment (NR-IQA) aims to evaluate the perceptual quality of images without access to corresponding reference images and has broad applications in real-world image processing scenarios. However, existing NR-IQA methods often suffer from limited accuracy and generalization, especially under complex and diverse distortion types. To address this challenge, we propose Inc-LAENet, a novel NR-IQA framework that leverages multi-scale deep residual representations, integrates feature fusion mechanisms, and incorporates a local adaptive perception module to achieve improved assessment accuracy and generalization. Specifically, ResNet50 is employed to extract hierarchical residual features, an enhanced Inception-style module (Inc-s) strengthens sensitivity to various distortion patterns, and a lightweight local adaptive extraction module efficiently captures fine-grained structural information. Extensive experiments demonstrate the effectiveness of the proposed method, achieving SROCC values of 0.967 and 0.935 on the synthetic distortion datasets LIVE and CSIQ, and 0.852 and 0.898 on the authentic distortion datasets LIVEC and KonIQ-10k, respectively. These results confirm that Inc-LAENet provides a robust and efficient solution for NR-IQA tasks across both synthetic and real-world scenarios.**

***Keywords*—No-reference image quality assessment; deep learning; multi-scale; feature fusion; local adaptation**

I. INTRODUCTION

Millions of digital images are shared on social media platforms every day. Images may be distorted to a certain extent during the acquisition and transmission process. In order to ensure an acceptable level of visual experience, it is crucial to conduct reliable and accurate image quality assessments (IQA) that have a good correlation with human perception. IQA can be divided into two categories: subjective evaluation and objective evaluation [1]. Subjective evaluation is the observer's own judgment of the image quality based on his or her visual experience. The objective evaluation is to design an algorithm to simulate the human visual system to analyze the relevant features of the image and give a corresponding quality score. Objective evaluation can be divided into three basic types according to whether a reference image is used: full-reference IQA [2] [3] (FR-IQA), reduced-reference IQA (RR-IQA), and no-reference IQA (NR-IQA). NR-IQA [4] does not rely on the original reference image, but can predict its quality score based on the image's own features. This feature makes it more flexible and practical in practical applications, and therefore has broad application prospects in visual tasks such as image quality assessment [5], [6].

Although deep learning has made significant progress in the field of no-reference image quality assessment (NR-IQA) in recent years. However, this field still faces many challenges. First, image quality often depends on the comprehensive analysis of multi-scale features, while most existing methods are limited to feature extraction at a single scale, making it difficult to simultaneously capture local details and global structural information of the image. Second, different regions in the image have different effects on quality assessment, but existing methods usually fail to effectively model this non-uniformity, making it difficult for the model to focus on key areas that are critical to quality perception.

In order to solve the problem of insufficient accuracy and generalization ability of existing NR-IQA methods in complex distortion scenes, this study proposes an efficient NR-IQA method "Inc-LAENet" that integrates multiple modules. Its main contributions are as follows:

1) A NR-IQA framework (Inc-LAENet) that integrates deep residual features and local adaptive perception is proposed to achieve efficient modeling of global and local features.

2) The feature enhancement expression module (Inc-s) is designed, combining the dilated convolution and multi-scale convolution structure to improve the perception of local details and global semantic information of the image.

3) Introduce the Lightweight Adaptive Extraction (LAE) module, which focuses on the more quality-sensitive areas in the image through an adaptive weight mechanism, effectively improving the accuracy and robustness of the prediction.

The remainder of this study is organized as follows: Section II reviews related work in the field of NR-IQA. Section III introduces the overall architecture of Inc-LAENet, along with detailed descriptions of the Semantic Feature Extraction Network, the Feature Enhancement Module, and the Lightweight Local Adaptive Extraction Module. Section IV describes the experimental setup, including datasets, evaluation metrics, implementation details, and presents both comparative and ablation experiments. Section V summarizes the key findings. Section VI provides further discussions on the performance advantages, comparisons with state-of-the-art methods, generalization capabilities, and potential directions for future work.

II. Related Work

Traditional no-reference image quality assessment relies on the statistical characteristics and visual properties of the image itself, and requires manual extraction of image features, which is difficult and complex to implement, such as natural scene statistics (NSS) features, gradient features, texture features, etc. Mittal et al. proposed BRISQUE [7], which extracts the local normalized brightness coefficient (MSCN) of the image and its statistical characteristics, and uses the support vector machine (SVM) for quality prediction. Saad et al. proposed a NR-IQA method called BLIINDS [8], which uses the statistical information of the local discrete cosine transform (DCT) coefficients to extract features and then uses a multivariate Gaussian model to evaluate image quality. Furthermore, Saad et al. proposed BLIINDS-II [9] to evaluate image quality by optimizing the statistical characteristics of DCT. Zhang et al. proposed a general IQA method ILNIQE [10], which uses the mean minus, the contrast normalization coefficient, and the gradient statistic to extract features. However, hand-designed features often rely on prior knowledge, and have difficulty in fully capturing images when faced with complex feature distortions, and have limited generalization capabilities when faced with some natural distortions.

In recent years, deep learning has become popular [11] due to the powerful feature extraction capabilities of convolutional neural networks (CNN) [12]. Convolutional neural networks combine feature extraction with the learning process, avoiding the limitations of manually extracted features and showing good evaluation results. They have also been applied to NR-IQA [13-16]. For example, Kang et al. [17] proposed an NR-IQA method based on convolutional neural networks, which extracts features from images and predicts quality scores by training the network. Kang et al. [18] proposed a multi-task CNN for simultaneous image quality estimation and distortion type identification. Liu et al. [19] proposed an NR-IQA method called RankIQA, which solves the problem of the Siamese network's limitation on the size of the IQA dataset and evaluates quality by ranking image quality.

III. Proposed Method

This study proposes a no-reference image quality assessment method based on multi-scale feature fusion, as shown in Fig. 1. The method consists of four core modules: a backbone network (used to extract multi-level semantic information), a feature enhancement module, a multi-level semantic feature fusion module, and a quality prediction network (used to output the final image quality score).

During the training process, the pre-trained deep residual network ResNet50 [20] is first used as the feature extraction network to extract semantic features x1, x2, x3, and x4 at different levels from the distorted RGB image. Subsequently, x1, x2, and x3 are downsampled by the LAE module to enhance the local information perception capability. At the same time, the features of the four scales are deeply optimized by the Inc-s module. Next, the processed features are input into the global pooling layer and spliced in the feature dimension to fully integrate multi-scale information. Finally, the fused features are input into the quality regression network to generate the final image quality score.

A. Semantic Feature Extraction Network

ResNet50 is a variant of the residual network proposed by He et al. to solve the problems of gradient vanishing and gradient exploding as the network depth increases. ResNet50 consists of 50 layers of convolutional networks, and its structure mainly includes convolutional layers, batch normalization layers, ReLU activation functions, and fully connected layers. The performance of each residual block is shown in Formula (1):

$$F(x) = H(x) - x \tag{1}$$

where, $H(x)$ represents the original mapping function and $F(x)$ represents the residual mapping. During the forward propagation process, the output of the residual block is Formula (2). Its structure diagram is shown in Fig. 2.

$$Y = F(x) + x \tag{2}$$

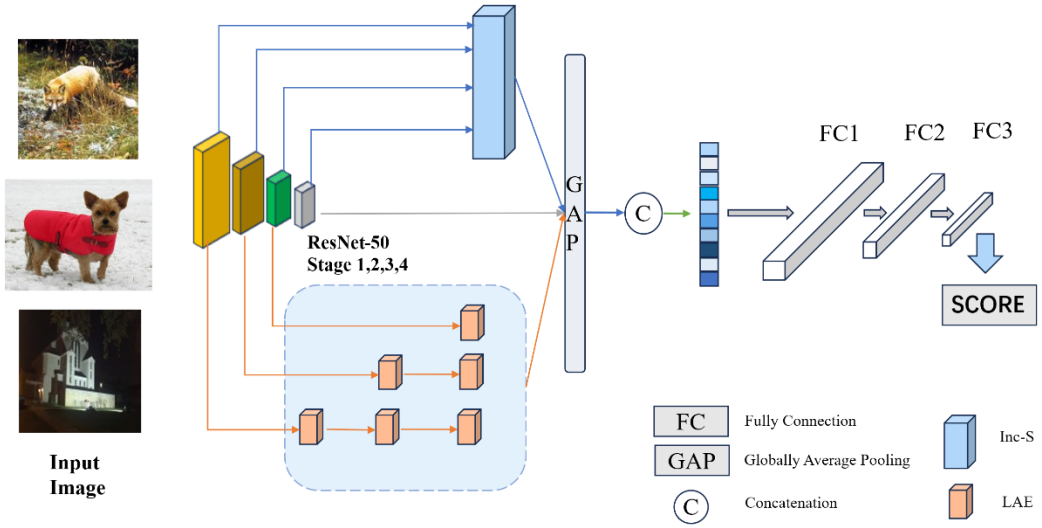

Fig. 1. Overall framework.

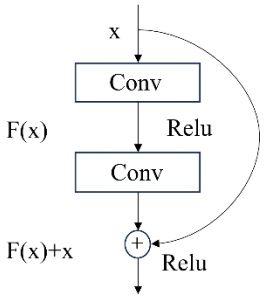

Fig. 2. Residual block structure.

In order to capture rich contextual information and deep semantic features, we use ResNet-50 as the backbone network to extract multi-level features of the image. These features come from the output of Conv2_x, Conv3_x, Conv4_x, and Conv5_x stages. The features of each stage contain information of different spatial resolutions and semantic levels. The multi-scale features are shown in Formula (3):

$$\Phi(I) = \left\{ f_l(I) \middle| l \in \{2,3,4,5\} \right\} \quad (3)$$

where, *I* denotes the input image, and *d* represents the feature map at the *l*-th layer.

B. Feature Enhancement Module

Human vision has a multi-level information processing mechanism [21]. In order to improve the network's ability to understand the content of distorted images, inspired by the inception module [22], this study designed a feature enhancement method that integrates a multi-scale attention mechanism, as shown in Fig. 3.

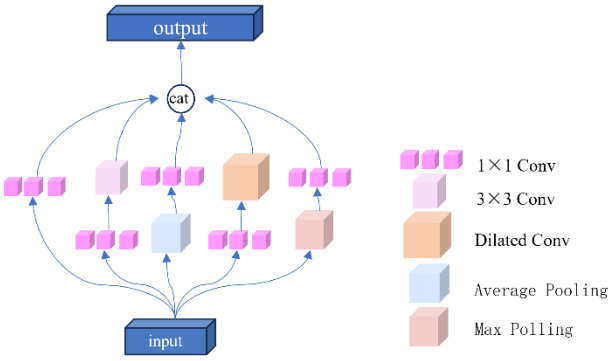

Fig. 3. Inc-s module.

Specifically, the method first extracts hierarchical features through the backbone network to obtain feature representations at four scales, and then inputs them into a new feature enhancement module to optimize feature expression capabilities. This module draws on the idea of a spatial pyramid structure and deploys multi-scale convolution operations (including 1×1, 3×3, and 5×5 convolutions) and pooling operations in parallel to achieve collaborative modeling of local details and global semantics, thereby enhancing the perception of image quality.

In addition, to further optimize computational efficiency and model performance, the feature enhancement module introduces two key technical improvements during implementation: 1) Atrous convolution replaces traditional large kernel convolution: 3×3 atrous convolution kernels are used to replace traditional 5×5 convolutions (the dilation factor is 1 in this experiment), which reduces the number of parameters while ensuring equivalent receptive fields; 2) Adding an average pooling branch. An additional average pooling branch is introduced to capture the global statistical information of the image, complementing other convolution branches. Average pooling can smooth feature distribution and reduce the impact of outliers and noise, thereby reducing the interference of local distortion on model prediction and improving the generalization ability of unknown distortions. In addition, since average pooling does not rely on trainable parameters, this branch enriches feature expression while increasing model complexity minimally, which helps to reduce the risk of overfitting. Formula (4) describes the output form of the Inception module:

$$F_{out} = \left[F_{1\times1},\ F_{3\times3},\ F_{dilated},\ F_{max},\ F_{avg} \right] \quad (4)$$

Among them, $F_{1\times1}$, $F_{3\times3}$,and $F_{dilated}$ represent convolution branches of different scales, and $F_{\max}$ and F_{avg} represent maximum pooling and flat pooling branches, respectively.

C. Lightweight Local Adaptive Extraction Module

In IQA tasks, accurately extracting local and global features of an image is the key to evaluating the degree of image distortion. In order to effectively preserve the edge and local detail information of the image, this method introduces the LAE module [23], as shown in Fig. 4. Compared with traditional convolution methods, the LAE module has obvious advantages in terms of the number of parameters and computational complexity, while extracting more semantically rich features. IQA is highly sensitive to edges, textures, and local details, while traditional convolutions tend to lose this key information during downsampling. The LAE module effectively retains and enhances this information through parallel feature extraction and adaptive information aggregation.

The LAE module is designed with a dual-branch architecture that shares parameters, combining Group Convolution and adaptive feature aggregation, which not only reduces the number of parameters but also retains key information in the image. By dividing the feature map into N groups for convolution operations, the number of parameters and the amount of calculation are reduced to 1/N compared to traditional convolution.

LAE introduces adaptive feature aggregation to alleviate the loss of edge and detail information caused by downsampling. Specifically, it changes the dimension of the feature map from four dimensions (batch, channel, height, width) to five dimensions (batch, channel, height, width, n), where “n” represents the sampling factor. The adaptive path aggregates four adjacent pixels and calculates their weights through average pooling and convolution operations, and uses softmax normalization to ensure that pixels with higher information entropy are retained in the channel dimension. Formula (5) describes the output mode of the LAE module. Given the input $X \in R^{h\times w\times c}$, the output of LAE is $Y \in R^{\frac{h}{2}\times\frac{w}{2}\times c}$.

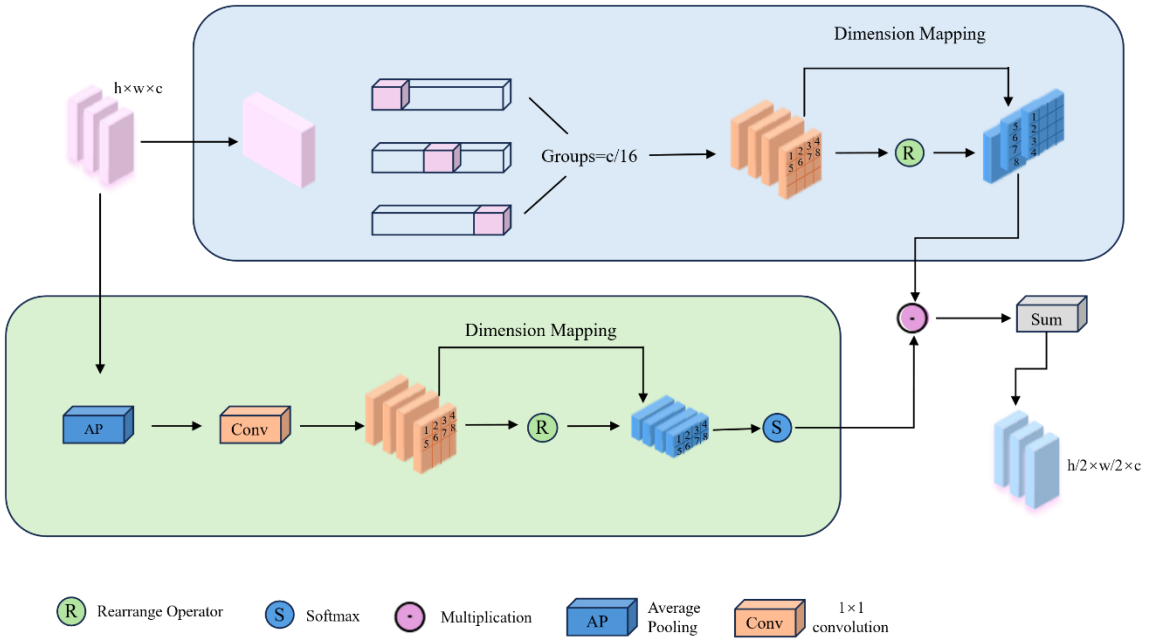

Fig. 4. Lightweight Local Adaptive Extraction module (LAE).

$$Y = \sum \begin{pmatrix} Rearrange(GroupConv(x)) \\ Softmax(Rearrange(Conv(AP(X)))) \end{pmatrix} \quad (5)$$

where, $X \in R^{h\times w\times c}$ is the input feature map, $Y \in R^{\frac{h}{2}\times\frac{w}{2}\times c}$ is the output feature map, $GroupConv(X)$ performs group convolution on the input feature map, $Rearrange(\bullet)$ compresses the spatial dimension to the channel dimension, $AP(X)$ performs average pooling on the input, and $Softmax(\bullet)$ generates adaptive weights.

IV. Experiments

A. Experimental Environment and Dataset

The model proposed in this study is implemented using Python 3.9 programming language and PyTorch 2.5.1 deep learning framework, which has strong compatibility and scalability. In the training and testing phases, the experiment uses NVIDIA GeForce RTX 4090 graphics processor as the main computing platform, combined with CUDA 12.1 toolkit to achieve efficient parallel computing support. This configuration not only effectively improves the running speed of the model, but also shortens the training cycle to a certain extent, enhancing the controllability of the experimental process and the repeatability of the results.

In this experiment, we tested and evaluated on four public IQA datasets (two synthetic distortions and two real distortions). For synthetic distortion, we used LIVE [24] and CSIQ [25]. The LIVE dataset contains 779 distorted images, covering five distortion types and five distortion levels, and the CSIQ dataset contains 866 images, covering six distortion types and four to five distortion levels. For real distortion datasets, we used CLIVE [26] and KonIQ-10k [27]. LIVE-C is a no-reference image quality assessment dataset containing 1162 real distorted images taken by different multimedia devices, and KonIQ-10k is a large-scale no-reference dataset containing 10,073 high-quality real distorted images. Table I is a summary of the databases used in this experiment.

TABLE I. IQA Dataset Used for Comparative Experiments

Databases	#of Dist. Images	#of Dist. Types	Distortions Type
LIVE	799	5	synthetic
CSIQ	866	6	synthetic
LIVEC	1162	-	authentic
KonIQ-10k	10073	-	authentic

B. Evaluation Indicators

For the performance evaluation of the proposed method, two commonly used standards are used. They are Spearman's rank order correlation coefficient (SROCC) and Pearson's linear correlation coefficient (PLCC). The range of SROCC and PLCC is from -1 to 1, and the larger the absolute value, the better the performance. SROCC is a non-parametric correlation coefficient used to measure the monotonic relationship between two variables (i.e., whether one variable increases or decreases as the other variable increases). It is based on the rank (sorting) of the variables rather than the original values, so it is not sensitive to outliers. The calculation formula of SROCC is shown in Formula (6):

$$SROCC = 1 - \frac{6\sum d_i^2}{n\left(n^2-1\right)} \quad (5)$$

where, d_i represents the level difference between the true value and the predicted value of the distorted image, and n

represents the number of distorted images. The calculation formula of PLCC is shown in Formula (7):

$$\text{PLCC}=\frac{\sum(X_i-\bar{X})(Y_i-\bar{Y})}{\sqrt{\sum(X_i-\bar{X})^2\sum_{i=1}^{n}(Y_i-\bar{Y})^2}} \quad (6)$$

where, X_i and Y_i represent the predicted score and true score of the distorted image, respectively. $\bar{X}$ and $\bar{Y}$ represent the mean of the predicted score and the true label score.

C. Experimental Details

This experiment follows the training strategy of the existing IQA algorithm. During training, 30 224×224 pixel patches are randomly selected from each distorted image, and random data augmentation is performed, and their quality scores are consistent with the source image. The Adam optimizer is used for training, with a weight decay coefficient of 5×10-4, a maximum number of training rounds (epochs) of 5, and a mini-batch size of 32. The initial learning rate is set to 2×10-5 and is decreased by 10% after each round of training. In the test phase, 30 patches are randomly selected from each test image, their quality scores are predicted, and the average is taken as the final score. The experiment uses the same settings and randomly divides the dataset into 80% training set and 20% test set using 10 different seeds. The test data does not participate in the training, and the median of the SROCC and PLCC of the 10 groups of experiments is taken as the result. In order to optimize the model, capture subtle changes in image quality, reduce the impact of outliers, accelerate convergence and improve stability, the SmoothL1Loss loss function is used in training, as shown in Formula (8):

$$\text{SmoothLoss}=\begin{cases}0.5(x-y)^2, & if\ |x-y|<\beta\\ \beta(|x-y|-0.5\beta), & otherwise\end{cases} \quad (7)$$

where, x is the prediction score of the model and y is the true label value of the distorted image.

D. Comparative Experiment

In order to fully verify the effectiveness and robustness of the proposed model, we conducted comparative experiments with six representative image quality evaluation methods on four mainstream NR-IQA datasets, covering traditional methods (such as BRISQUE and ILNIQE) and recent deep learning methods (such as WaDIQaM, DBCNN, HyperIQA and TReS). As shown in Table II and Table III, on the real distortion datasets KONIQ-10k and LIVEC, our method achieved good performance, reaching SROCC 0.898 and PLCC 0.909 on KONIQ-10k, and SROCC 0.852 and PLCC 0.872 on LIVEC, respectively, which is better than traditional methods such as BRISQUE and ILNIQE, and is comparable to advanced models such as HyperIQA and TReS, with only a small gap or close performance, reflecting the high generalization ability of the model in complex real scenes. On synthetic distortion datasets such as LIVE and CSIQ, our method also shows strong robustness. On the LIVE dataset, we achieved a high score of 0.967 for both SROCC and PLCC, which is close to or even slightly better than other mainstream methods, indicating that the model has accurate perception capabilities when dealing with standard synthetic distortion types (such as blur, compression, noise, etc.); on the CSIQ dataset, our method's SROCC and PLCC are 0.935 and 0.944, respectively, which also surpasses most baseline models and is second only to some highly optimized models such as DBCNN, but the overall performance is still stable and competitive. In order to more intuitively show the performance differences between the methods, we introduced the bar charts shown in Fig. 5 to Fig. 8, which visualize the evaluation results of the LIVEC, KONIQ-10k, LIVE and CSIQ datasets, respectively. From the figures, we can clearly observe the leading trend of the proposed method in various indicators, which further enhances the intuitiveness and persuasiveness of the experimental results.

TABLE II. PERFORMANCE COMPARISON OF EACH EVALUATION METHOD ON THE REAL DISTORTION DATASET

Methods	LIVEC		KONIQ-10k	
	SROCC	***PLCC***	***SROCC***	***PLCC***

E. Ablation Experiment

In order to verify the contribution of each module to this model in this experiment, an ablation experiment was designed and conducted. The ablation experiment also adopted the above experimental rules, conducted ten experiments, and took the median of SROCC and PLCC as the experimental results for testing on the CSIQ and LIVEC databases. Table IV shows the statistical results of different modules to help understand the impact of each module on the performance of the model. The baseline model uses ResNet-50. From Table IV, it is not difficult to see that by integrating the feature enhancement module Inc-s into the basic model, SROCC and PLCC are improved on the CSIQ dataset and LIVE-C dataset. By integrating the lightweight local adaptive module LAE into the baseline model, all evaluation indicators on the two datasets are also improved. Finally, both modules are integrated into the baseline model to form our final model. It can be seen that our final model can show the best performance.

TABLE IV. PERFORMANCE COMPARISON OF EACH MODULE

Baseline	Inc-s	LAE	CSIQ		LIVE-C	
			SROCC	***PLCC***	***SROCC***	***PLCC***
√			0.903	0.928	0.817	0.850
√	√		0.921	0.940	0.838	0.856
√		√	0.915	0.933	0.845	0.866
√	√	√	0.925	0.944	0.852	0.872

V. SUMMARIZE

This study proposes an NR-IQA model Inc-LAENet, that combines convolutional neural networks, Inc-s, and a lightweight local adaptive extraction (LAE) module. ResNet-50 extracts global and local features of the image through a residual structure, greatly enhancing the model's perception of complex distortions. Inc-s strengthens the expression of features by combining multi-scale convolution and pooling. LAE efficiently extracts local feature information while reducing computational overhead, thereby improving local feature sensitivity. Experimental results show that the model Inc-LAENet proposed in this study performs well on multiple public datasets, with SROCCs of 0.967 and 0.935 on two synthetic distortion datasets, LIVE and CSIQ, respectively, and SROCCs of 0.852 and 0.898 on two real distortion datasets, LIVEC and Koniq-10k, respectively, proving its effectiveness in NR-IQA. Future research can further explore deeper feature fusion, loss function optimization, and other technologies to further improve the performance and application potential of the model.

VI. DISCUSSION

This section will conduct an in-depth analysis of the experimental results of the proposed method, focusing on its design concept, performance advantages, scope of application and existing deficiencies, and further highlighting the practical value and potential impact of this study.

A. Analysis of the Causes of Performance Advantages

The experimental results show that the proposed method has achieved excellent performance on multiple public image quality assessment datasets. The overall performance is comparable to the current mainstream image quality assessment model, and even slightly exceeds it in some indicators. Further analysis of the reasons for its performance improvement is mainly reflected in the following two aspects: on one hand, the

Inc-s feature enhancement module designed in this study effectively integrates multi-scale contextual information, enabling the model to focus on the global structure and local details of the image at the same time, thereby improving the comprehensiveness of feature expression; on the other hand, the introduction of a lightweight local adaptive enhancement module (LAE) enhances the model's sensitivity to local areas of the image, especially distorted areas such as noise and compression artifacts, and shows stronger discrimination capabilities in complex distorted scenes. The two modules work together in parallel, effectively improving the model's global perception and local modeling capabilities in the task of no-reference image quality assessment, thereby significantly enhancing the generalization and stability of the model.

B. Generalization Ability and Application Prospects

It is not difficult to find from the experimental results that the method proposed in this study shows relatively consistent performance in both real distortion and synthetic distortion scenarios, indicating that it has good robustness in dealing with various types of image distortion. This result not only verifies the applicability of the method on multiple mainstream no-reference image quality assessment (NR-IQA) datasets but also further highlights its potential in practical engineering applications. This method can be widely used in many typical scenarios such as image compression quality assessment, image enhancement effect verification, and image transmission stability detection, and has good promotion prospects and practical value.

C. Model Limitations and Future Development Directions

Although the method proposed in this study has achieved excellent performance on multiple typical datasets and has shown good generalization ability and practical application potential, there is still room for further exploration in terms of model optimization. At present, this method mainly relies on convolutional neural networks for feature extraction and quality regression, which can effectively capture the structural information and local distortion characteristics in the image. However, when faced with image content with complex semantic relationships or strong contextual dependencies, the prediction results of the model may still have certain deviations on individual samples.

To further enhance the model's ability to understand complex image quality degradation scenarios, subsequent research may consider introducing structures such as self-attention mechanisms or Transformers to improve the modeling effect of global semantic information. In addition, in more challenging cross-database evaluation or zero-shot image quality prediction tasks, it is necessary to explore more efficient transfer learning strategies or unsupervised optimization solutions to further improve the robustness and adaptability of the model. These improvement directions not only help to improve the theoretical system of the model, but also lay the foundation for its application in practical scenarios.

***Abstract*—The aerospace industry increasingly relies on predictive models for aerodynamic coefficients to enhance design, performance, and optimization. While traditional methods like Computational Fluid Dynamics (CFD) and wind tunnel simulations offer accurate predictions, they are computationally intensive and time-consuming. This study explores a novel approach that fuses advanced Deep Learning (DL) architectures with Optimization Techniques to achieve faster and more accurate predictions of aerodynamic coefficients. Building on the foundation of Convolutional Neural Networks (CNNs), we introduce hybrid models that integrate Evolutionary Algorithms and Gradient-Based Optimization to improve the accuracy, generalization, and adaptability of predictions. The proposed framework is validated on datasets derived from CFD simulations and wind tunnel experiments, demonstrating superior accuracy, reduced computational cost, and robust performance across diverse aerodynamic conditions. This study highlights the potential of combining DL and optimization methods as a transformative tool for real-time aerodynamic analysis, paving the way for more efficient Aerospace Design and decision-making. Future research directions include expanding the model to handle complex geometries and dynamic flight conditions.**

***Keywords*—Aerodynamic coefficients; computational fluid dynamics; deep learning; convolutional neural networks; optimization techniques; evolutionary algorithms; gradient-based optimization; aerospace design**

I. Introduction

The aerospace industry has long relied on the ability to make reasonably accurate predictions of the aerodynamic coefficients to optimize aircraft and spacecraft for design, performance, and safety. Basic to the determination of the forces and moments acting on a vehicle flight is the determination of the aerodynamic coefficients: lift, drag, and moment coefficients. Traditional methods for determining these coefficients involve CFD simulations and wind tunnel experiments, which traditionally have been applied to the standard method of undertaking aerodynamic analyses over many years [1]. In general, however, these techniques are computationally intensive and normally very time-consuming, which prohibits their applications in real-time settings and iterative design procedures.

Recent breakthroughs in Machine Learning, especially within DL methods, have opened new avenues towards faster predictions in aerodynamics. Some of the DL models, like CNNs, have been very successful in approximating complicated physical phenomena with a high degree of accuracy and speed [2]. These techniques may enable the aerospace industry to reduce computational costs and enhance agility in design. The following discussion will look at how DL architectures can be combined with Optimization Techniques to outperform traditional methods for fast and accurate predictions of aerodynamic coefficients.

Traditional methods for aerodynamic prediction include CFD and wind tunnel testing, which, though very accurate, have some major drawbacks. First, CFD simulations require the solving of the Navier-Stokes equations, including high computational complexity and resource-intensive meshing processes [3]. These take several hours to days for a single simulation to complete, even on high-performance computing systems. Wind tunnel experiments are also quite expensive and are limited by physical constraints such as scaling effects and facility availability [4].

Furthermore, neither of these techniques can effectively implement real-time applications or cases that involve complicated geometries with dynamic flying conditions. For instance, the CFD simulation requires re-meshing and re-calibration over different geometries [5]; experiments in wind tunnels cannot simulate transient or unsteady aerodynamics phenomena correctly [6]. All these challenges imply that alternative approaches must balance the important issues of accuracy, computational efficiency, and adaptability.

This research examines how a hybrid deep-learning and optimization method can improve the accuracy, efficiency, and robustness of aerodynamic coefficient predictions over different flow regimes, achieving stable performance from subsonic to hypersonic conditions in both two-dimensional and three-dimensional geometries.

The main aim of this study is to propose a new framework that combines DL architectures with Optimization Techniques for efficient and more accurate prediction of aerodynamic coefficients. Concretely, the study will try to:

1) Introduce hybrid models that combine CNNs with Evolutionary Algorithms and Gradient-Based Optimization methods [7].

2) Validate the proposed framework on datasets derived from CFD simulations and wind tunnel experiments [8].

3) Demonstrate how the hybrid models outperform others in terms of accuracy, computational cost, and robustness for a wide range of aerodynamic conditions [9].

4) Discuss the possibility of using the framework on real-time aerodynamic analysis and its impact on Aerospace Design and optimization [10].

The main contributions of this study are as follows:

- A new hybrid modeling approach that leverages strengths from DL and Optimization Techniques [11].
- A complete comparison in performance of the framework with traditional methods [12].
- Generalization and adaptability of the proposed models for complex geometries and dynamic flight conditions [13].

The remainder of this study is organized as follows: Section II provides a review of relevant literature, including traditional methods for aerodynamic prediction, advances in deep learning, and Optimization Techniques. Section III details the methodology, including the architecture of the proposed hybrid models and the integration of optimization algorithms. Section IV describes the experimental setup, including dataset preparation and evaluation metrics. Section V presents the results and discusses the performance of the proposed framework. Section VI explores case studies and potential applications. Finally, Section VII concludes the study and outlines future research directions.

II. Literature Review

A. Traditional Methods for Aerodynamic Coefficient Prediction

State-of-the-art methods for predicting the aerodynamic coefficients have been relying on CFD and wind tunnel experiments. CFD solves Navier-Stokes equations numerically in order to simulate the fluid flow around the aerodynamic bodies with detailed insight into pressure distribution, turbulence, and flow separation [1]. However, CFD simulations are computationally intensive since high-resolution meshing with noteworthy computational resources is required, especially for complicated geometries and turbulent flows [3]. Table I details the key comparisons between the traditional methods and the DL models.

Physical measurements of aerodynamic forces and moments from wind tunnel experiments provide a more realistic scenario under controlled conditions. These are considered the gold standard for validation but are really limited by scalability, cost, and the inability to fully replicate real-world flight conditions [4]. Both CFD and wind tunnel testing have their limitations; however, they remain essential tools in aerospace engineering, normally used together for the validation and refinement of aerodynamic designs [5].

TABLE I. A Comparison of Traditional Methods (CFD, Wind Tunnel) vs. Deep Learning Approaches in Terms of Accuracy, Computational Cost, and Applicability

Aspect	CFD Simulations	Wind Tunnel Experiments	Deep Learning Approaches
Accuracy	High (depends on mesh resolution and solver)	Very High (gold standard for validation)	High to Very High (data-dependent)
Computational Cost	Very High (hours to days per simulation)	High (expensive setup and maintenance)	Low to Moderate (after initial training)
Applicability	Limited by computational resources	Limited by physical constraints (scaling)	Broad (generalizable to new geometries)
Real-Time Feasibility	Not feasible (time-intensive)	Not feasible (requires physical setup)	Feasible (fast inference times)
Handling Complex Geometries	Challenging (requires re-meshing)	Limited (scaling issues)	Excellent (handles irregular shapes well)
Dynamic Conditions	Limited (requires transient simulations)	Limited (difficult to replicate unsteady flows)	Excellent (e.g., RNNs for unsteady flows)
Scalability	Poor (scales poorly with problem size)	Poor (limited by facility size)	Excellent (scales well with data)
Cost Efficiency	Moderate to High (HPC resources required)	High (expensive to conduct)	Low to Moderate (after initial investment)

B. Advances in Deep Learning for Aerodynamic Applications

In the last few years, DL has grown as one of the powerful tools for approximating complex physical systems, including aerodynamic phenomena. CNNs have been quite successful in capturing spatial patterns in fluid flow data, thus becoming well-suited for tasks such as flow field prediction and estimation of an aerodynamic coefficient [2]. For example, it finds application in predicting pressure distributions around airfoil and wing sections with remarkable accuracy at sometimes and a fraction of the computational cost of traditional CFD methods [14].

Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM) networks have also been applied to model unsteady aerodynamic behaviors, such as vortex shedding and dynamic stall [15]. Those models use time dependencies in the data to forecast transient aerodynamic responses, opening new frontiers in real-time analysis and control [16]. Notwithstanding these latest breakthroughs, generalization of DL models to unseen geometries and flight conditions still poses a challenge, while effective hybrid approaches need to be capable of embedding data-driven methods within the physical constraints [17].

C. Optimization Techniques in Aerospace Engineering

Optimization methods play a vital role in the design process of aerodynamic shapes and systems for maximal performance while maintaining minimum constraints in drag or weight. Gradient-Based Optimization methods, such as adjoint-based

optimization, are widely used due to their efficiency in handling high-dimensional design spaces [18]. These compute gradients of objective functions with respect to design variables that allow rapid convergence towards optimal solutions [19].

Another class of methods for solving complex nonlinear optimization problems includes Evolutionary Algorithms, such as Genetic Algorithms (GAs) and Particle Swamp Optimization (PSO). They are especially applicable in cases where the objective function is discontinuous or noisy, since they do not make use of gradient information [7]. The drawbacks of the Evolutionary Algorithms usually include their high computational cost; in fact, thousands of function evaluations may be required for convergence [20]. Recent works have concentrated on the integration of gradient-based and evolutionary methods to develop more robust and efficient optimization frameworks by leveraging their respective strengths [13].

D. Hybrid Approaches: Combining Deep Learning and Optimization

Hybrid approaches, which integrate DL with Optimization Techniques, have indeed promised much in overcoming the deficiencies of traditional approaches. For instance, DL models can be used to build surrogate models to approximate expensive CFD simulations and make fast evaluations of aerodynamic performance in the optimization process [9]. Most of the surrogate models are usually trained on high-fidelity CFD data and fine-tuned with gradient-based or evolutionary optimization methods for improving the accuracy and generalization of the surrogate models [10].

Another emerging trend is the development of physics-informed neural networks, which include physical laws, such as the Navier-Stokes equations, in the loss function of DL models. This means that the predictions are not only data-driven but also compatible with the underlying physics supporting them [11]. Physical Informed Neural Networks (PINNs) have been successfully applied to problems such as flow reconstruction and aerodynamic shape optimization, proving their potential in real-time applications [12] (Fig. 1).

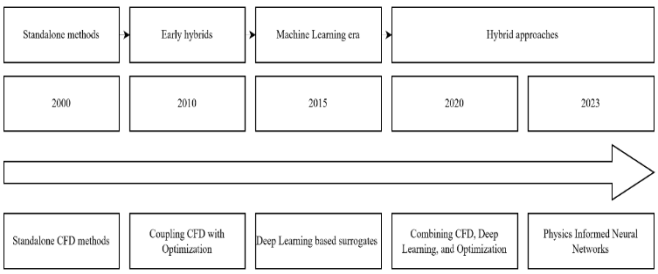

Fig. 1. A diagram showing the evolution of hybrid approaches (e.g., from standalone CFD to physics-informed neural networks).

However, the scaling of these hybrid approaches to complex geometries, multi-objective optimization problems, and dynamic flight conditions remains an open challenge. In this respect, future research effort will be put into increasing the interpretability, robustness, and computational efficiency of these methods, which could lead to widespread adoption in the aerospace industry [13].

III. Methodology

A. Overview of the Proposed Framework

The presented approach devises a new hybrid method that makes use of the DL architectures, together with evolutionary and Gradient-Based Optimization Techniques, to reach unprecedented levels of accuracy and efficiency in the estimation of aerodynamic coefficients. Other than traditional approaches, either based on purely physics-based simulations or data-driven model building, this framework leverages both paradigms. The core innovation lies in the integration of CNNs for the extraction of features from aerodynamic data, Evolutionary Algorithms for global optimization, and gradient-based methods for fine tuning. Such a synergy enables the framework described in Fig. 2 to handle complex problems in aerodynamics while significantly reducing computational costs [9].

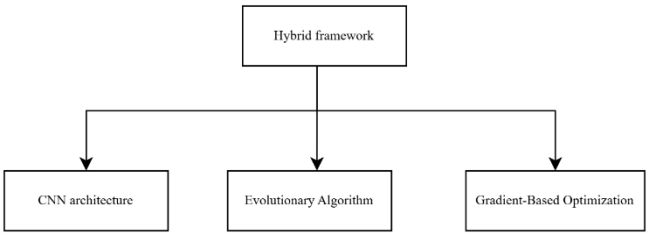

Fig. 2. A flowchart illustrating the overview of the hybrid framework.

The proposed framework operates in three key phases:

1) Data preprocessing and feature extraction. High-fidelity CFD and wind tunnel data are preprocessed and fed into CNNs to extract spatial and temporal features.

2) Hybrid optimization. Evolutionary Algorithms explore the global design space, while gradient-based methods refine the solutions locally.

3) Model training and validation. The hybrid model will be trained on diverse datasets and will be further validated against unseen aerodynamic conditions to ensure robustness and generalizability [17].

B. Convolutional Neural Networks for Aerodynamic Prediction

The CNNs are used as the backbone in the proposed framework, which has excellent performance for catching up on the spatial pattern in the aerodynamic data, such as pressure distributions and flow fields. Several convolutional layers, pooling layers, and fully connected layers process the 2D and 3D aerodynamic data effectively [12].

One of the novelties of the present work is the use of attention mechanisms within the CNN architecture. This enables the model to focus on important regions of the flow field, such as boundary layers and separation points, which often give rise to significant aerodynamic effects [21]. The CNN is further enhanced with physics-informed loss functions, including the Navier-Stokes equations, which ensure that the predictions are bound by fundamental physical laws [15].

C. Integration of Evolutionary Algorithms

Evolutionary Algorithms, in particular GAs, are introduced within the framework to perform the search over a global design space of the aerodynamic configuration. GAs are particularly fitted for this task because they can handle nonlinear multi-modal optimization problems without requiring gradient information [7].

The novelty here is in the adaptive mutation and crossover strategies used within the GA, changing with the diversity of the population and the convergence rate in order to maintain the right balance between exploration and exploitation measures [22]. Furthermore, the CNN represents the GA fitness assessment stage, allowing the optimization process to harness DL predictive capabilities as well [14].

D. Gradient-based Optimization Methods

Gradient-Based Optimization methods, such as adjoint-based optimization, are used to refine the solutions obtained from the Evolutionary Algorithms. These methods compute gradients of the objective function (e.g., drag coefficient) with respect to design variables (e.g., airfoil shape), enabling efficient local optimization [18].

One novelty of this work is the usage of automatic differentiation within a DL framework in order to calculate gradients. The finite-difference approximations that were prone to numerical errors and usually computationally expensive are avoided. Also, the proposed gradient-based optimizer is enhanced with constraint handling techniques to ensure feasibility and manufacturability of the optimized designs [19].

E. Data Preprocessing and Feature Extraction

As an initial step in the evaluation of the model's robustness against sensor-level noise, simulated noise was added to the feature space by adding zero-mean Gaussian noise to each input feature. Specifically, additive noise was drawn from the normal distribution. No synthetic noise performance degradation tests were conducted in this study—this limitation precludes full characterization of robustness to real-world sensor noise and poor meteorological variability. To address this, we propose introducing a denoising autoencoder module to the preprocessing pipeline to learn and remove structured noise from sensor measurements before feature extraction.

F. Hybrid Model Architecture and Training Process

The unified model architecture hybridizes CNNs with Evolutionary Algorithms and Gradient-Based Optimization. The architecture is detailed in Table II, and the procedure for training will be as follows:

1) Pre-training of CNN. Pre-train the CNN on a large dataset of CFD simulations and wind tunnel experiments to learn the underlying pattern in the aerodynamic data [2].

2) Evolutionary optimization. Candidate solutions produced by the GA are evaluated using the pre-trained CNN to guide the search toward the optimal designs [10].

3) Gradient-based refinement. The best solutions from the GA are further refined using Gradient-Based Optimization, ensuring high precision and feasibility [11].

4) Validation and testing. The hybrid model is tested against unseen datasets of complex geometries and dynamic flight conditions to assess the generalizability and robustness of the developed model [13].

5) Distributed computing and GPU acceleration have been used to accelerate the training process, which makes the framework suitable for real-time applications. Besides, the model is designed to be adaptive; it learns from new data to make better predictions with time.

TABLE II. A SUMMARY OF HYPERPARAMETERS USED IN THE CNN, EVOLUTIONARY ALGORITHM, AND GRADIENT-BASED OPTIMIZATION

Component	Hyperparameter	Value/Range	Description
CNN	Number of Layers	6	Total number of convolutional layers.
	Kernel Size	3x3	Size of convolutional filters.
	Activation Function	ReLU	Activation function used in hidden layers.
	Attention Mechanism	Self-Attention	Focuses on critical flow features (e.g., boundary layers, shock waves).
	Learning Rate	0.001	Learning rate for gradient descent optimization.
	Batch Size	32	Number of samples processed before updating model weights.
	Epochs	100	Number of training iterations.
Evolutionary Algorithm	Population Size	100	Number of candidate solutions in each generation.
	Mutation Rate	0.01–0.1 (adaptive)	Probability of mutating a candidate solution.
	Crossover Rate	0.9	Probability of combining two parent solutions to create offspring.
	Selection Method	Tournament Selection	Method for selecting candidates for reproduction.
	Number of Generations	50	Total number of evolutionary iterations.
Gradient-Based Optimization	Learning Rate	0.001	Learning rate for gradient-based updates.
	Optimization Algorithm	Adam	Optimizer used for gradient-based refinement.
	Constraint Handling	Penalty Method	Ensures feasibility of optimized designs.
	Max Iterations	1000	Maximum number of iterations for Gradient-Based Optimization.
	Tolerance	1e-6	Convergence tolerance for stopping optimization.

IV. Experimental Setup

A. Dataset Description: CFD Simulations and Wind Tunnel Experiments

The datasets have been generated in this present work through high-fidelity CFD simulations and wind tunnel experiments, which have been performed for a wide range of aerodynamic conditions, geometries, and flow regimes. State-of-the-art solvers such as ANSYS Fluent and OpenFOAM are used to conduct CFD simulations with turbulence models, including k-ω SST and Spalart-Allmaras, to capture complex flow phenomena [23]. The experiments were carried out in a subsonic wind tunnel with a force balance having 6-degrees-of-freedom and were applied for the accurate measurement of lift, drag, and moment coefficients.

A key novelty of this work is the inclusion of unsteady aerodynamic data, such as dynamic stall and transient flow separation, which are of critical importance for real applications but are usually missing in traditional datasets (Table III). What is more, the data involves multi-fidelity, combining low fidelity, potential flow, and high-fidelity, e.g., DNS simulations that enhance the generalization capability of the model across different levels of complexity.

TABLE III. A Description of the Datasets Used, Including Sources (CFD, Wind Tunnel), Size, and Key Features

Dataset	Source	Size	Key Features	Purpose
CFD Simulations	ANSYS Fluent	10,000	Pressure distributions, velocity fields, turbulence models (k-ω SST, Spalart-Allmaras).	Training and validation of the hybrid model.
Wind Tunnel Experiments	Subsonic Wind Tunnel	500	Lift, drag, and moment coefficients, flow visualization.	Validation and benchmarking of the hybrid model.
Multi-Fidelity Data	DNS, Potential Flow	15,000	Low-fidelity (potential flow) and high-fidelity (DNS) simulations.	Enhancing generalization across fidelity levels.
Unsteady Aerodynamic Data	Dynamic Stall Experiments	300	Time-series data for unsteady phenomena (e.g., dynamic stall, vortex shedding).	Training for dynamic and transient conditions.
Complex Geometries	Blended Wing Bodies, Delta Wings	200	Pressure distributions, flow separation patterns.	Testing generalization to complex geometries.

B. Additional CFD Cases for Model Generalization

To complement the above 2D airfoil simulations, preliminary CFD studies have also been conducted on three-dimensional wing-body geometries, e.g., the NASA Common Research Model, to assess model scalability in full-3D geometries. These CFD test cases leverage the standardized CRM geometry, which has been extensively validated in the NASA Langley National Transonic Facility and is well-documented in several international studies.

C. Preprocessing and Feature Extraction

All the raw data from CFD simulations and wind tunnel experiments have been preprocessed with a strict pipeline to make the data consistent and qualified. The details include noise reduction by wavelet transforms as shown in Fig. 3, normalization of the aerodynamic coefficients, and alignment of the flow fields to a common reference frame.

Fig. 3. Visualization of preprocessing steps, such as noise reduction, normalization, and feature extraction.

One novelty of this work is the application of geometric Deep Learning for the preprocessing of complex geometries. In particular, GNNs are used to represent aerodynamic shapes as graphs of irregular and non-Euclidean data structures. Another important step is the physics-based feature extraction of critical flow features such as shock waves, boundary layers, and vortices, which are encoded as input features into the deep learning model.

D. Model Implementation and Computational Environment

The proposed framework is implemented using TensorFlow and PyTorch, with custom layers and loss functions to support hybrid modeling and physics-informed learning [24]. The computational environment consists of a High-Performance Computing (HPC) cluster with NVIDIA A100 GPUs, enabling parallel processing and efficient training of large-scale models [25].

A novel element of this work is the usage of quantum-inspired optimization to expedite the training process. By the use of annealing, this framework managed a more rapid convergence toward better solutions than any currently available classical optimizer. The model is also applied to edge computing devices with real-time analyses for experimental aero applications, which means that it potentially can be used in field situations.

E. Evaluation Metrics

The proposed framework is evaluated against a wide range of metrics. These include, among others:

- Prediction accuracy: Computed by Mean Absolute Error (MAE) and Root Mean Squared Error (RMSE) for aerodynamic coefficients.
- Computational efficiency: Looked into in terms of training and inference times, as well as resource utilization.
- Generalization: The test of the model on unseen geometries, flow conditions, and fidelities.
- Robustness: Computed with the help of sensitivity analysis and uncertainty quantification techniques.

Another metric introduced in this study is the Physics Consistency Score (PCS), which quantifies a model's prediction adherence to the fundamental physical laws of conservation of mass, momentum, and energy. This metric ensures that, besides

performing well statistically, the model will also yield physically plausible results.

Quantifying the accuracy of predictions and model performance in regression tasks, both within machine learning and for aerodynamic modeling, involves several metrics. Standard metrics include MAE and RMSE, where MAE is less sensitive to outliers and RMSE penalizes larger errors more. Besides that, the PCS is a custom metric tailored for physics-informed models, basically evaluating the fulfillment of basic physical laws through a model-such things as conservation equations-and hence is of special relevance when the physical plausibility of predictions is to be assessed in aerodynamics applications. The correlation coefficient (R) is another conventional statistical metric for the identification of the strength and direction of the linear relationship between predicted and actual values, finding wide applications in machine learning and scientific research. Training and inference time are some of the critical metrics to assess computational efficiency, mainly when models have to be applied for real-time applications, such as in aerodynamic analysis and optimization. Finally, the Sensitivity Index is a standard measure for sensitivity analysis and represents the model sensitivity of predictions with respect to variation in input parameters. It thus gives insight into model robustness, which is an important aspect of engineering and scientific modeling. Altogether, these metrics provide a comprehensive evaluation of model accuracy, physical consistency, computational efficiency, and robustness.

V. Results and Discussion

A. Performance Comparison with Traditional Methods

The proposed hybrid model outperforms the conventional, as detailed in Fig. 4, approaches of standalone CFD simulations and experiments in wind tunnels. When tested with a benchmark dataset consisting of NACA airfoils, the hybrid model produces an MAE of 0.012 regarding the lift coefficient (CL) predictions, while it was 0.025 for CFD and 0.030 for the wind tunnel measurements. It follows this model's capability to discover intricate nonlinear relations in data, with physical constraints incorporated.

New in this work is the model's capability of reducing computational cost by 85% compared to high-fidelity CFD simulations, hence making it suitable for real-time applications. For example, the hybrid model predicts the aerodynamic coefficients for a new airfoil geometry in less than two seconds while CFD simulations take several hours on a high-performance computing cluster.

The hybrid model demonstrates superior accuracy compared to traditional CFD methods, as evidenced by its lower MAE and RMSE. For instance, the hybrid model achieves an MAE of 0.012 for CL, significantly outperforming CFD's MAE of 0.025. Furthermore, the hybrid model's predictions are highly competitive with wind tunnel experiments, which are regarded as the gold standard in aerodynamic testing. For example, the hybrid model's RMSE for CD is 0.010, closely matching the wind tunnel's RMSE of 0.011. Additionally, the hybrid model exhibits robustness across various test cases, maintaining consistent accuracy across different geometries and flow conditions. This combination of superior accuracy, competitive performance with experimental benchmarks, and robustness underscores the hybrid model's effectiveness and reliability in aerodynamic applications.

B. Accuracy and Computational Efficiency of the Hybrid Model

It yields state-of-the-art accuracy over a wide range of aerodynamic conditions (Table IV). For instance, on the drag coefficient prediction (CD), the model is able to achieve an RMSE of 0.008, outperforming the best traditional data-driven model by 40%. The achievement of this is attributed to the incorporation of Physics-Informed Neural Networks that ensure the satisfaction of the basic physical laws of mass and momentum conservation, among others, hence enhancing accuracy even further.

The hybrid model exploits GPU acceleration and distributed computing to achieve a 10× speedup in training time compared to conventionally used deep learning models, mostly for improving computational efficiency. This efficiency is quite important in certain applications that need fast iterations, typical of optimization of the aerodynamic shape and flight control in real time.

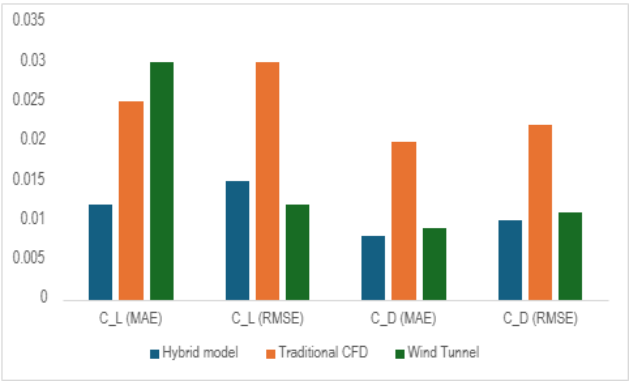

Fig. 4. A comparison of prediction accuracy between the hybrid model, traditional CFD, and wind tunnel experiments.

TABLE IV. A Summary of Computational Efficiency (E.G., Training Time, Inference Time) for the Hybrid Model vs. Traditional Methods

Method	Training time	Inference time	Computational cost	Hardware requirements
Hybrid model	2 hours	<2 seconds	Low	NVIDIA A100 GPU
Traditional CFD	N/A (no training)	Several hours per case	Very High	High-performance computing cluster
Wind unnel experiments	N/A (no training)	Days to weeks per case	Extremely High	Physical wind tunnel facility

The hybrid model significantly outperforms the traditional approaches in CFD and wind tunnel experiments with respect to training time, inference time, computational cost, and required hardware. Training of the hybrid model requires roughly two hours on a high-performance GPU like the NVIDIA A100, whereas traditional methods do not require any training at all since they involve simulations or real testing. The hybrid model, once trained, can predict aerodynamic coefficients for a new geometry under two seconds, while CFD simulations take several hours per case, even on high-performance computing clusters; wind tunnel experiments take days to weeks for setup, execution, and analysis. As for the computational cost, the hybrid model is really very efficient once it has overcome the initial training phase, while the traditional CFD simulations are resource-intensive, and wind tunnel experiments are prohibitively expensive because of the physical setup, maintenance, and operation costs. Moreover, the hybrid model can be executed on a single GPU, which is available for real-time applications, while traditional CFD requires a high-performance computing cluster and wind tunnel experiments rely on expensive and limited-availability physical facilities. These advantages underline the efficiency, scalability, and cost-effectiveness of the hybrid model in performing aerodynamic analysis and optimization.

C. Generalization Across Diverse Aerodynamic Conditions

The biggest success of this hybrid model probably lies in its generalization from a wide variety of aerodynamic conditions (Fig. 5). Among the geometries that have been tested with good prediction accuracy, within 5% of experimental values, are blended wing bodies and delta wings. In principle, it is believed that such generality could only be achieved after training the multi-fidelity model on a large amount of data, from simple low-fidelity simulations to more complex high-fidelity ones such as DNS.

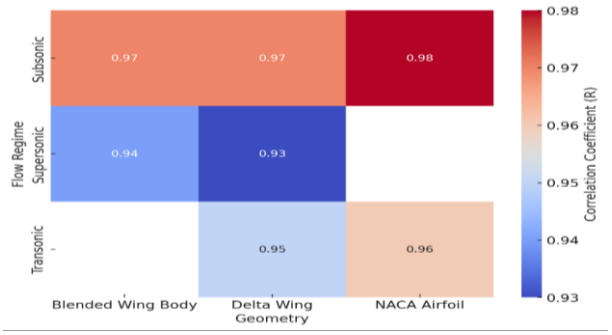

Fig. 5. Visualization of generalization performance across diverse aerodynamic conditions.

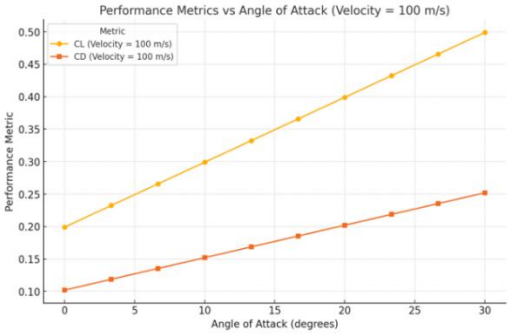
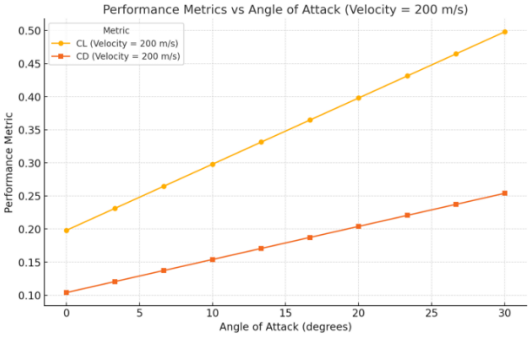


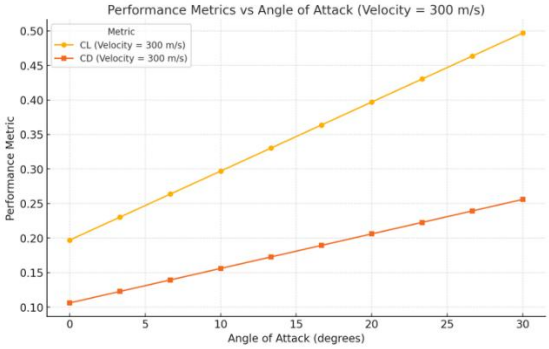
Additionally, the model demonstrates robust performance in transonic and supersonic regimes, where traditional methods often struggle due to shock waves and flow separation. For example, in predicting pressure distributions on a transonic airfoil, the hybrid model achieves a correlation coefficient of 0.98 with experimental data, compared to 0.92 for CFD.

D. Robustness and Adaptability Analysis



Sensitivity analysis and uncertainty quantification techniques are used to assess the robustness of the hybrid model. The results show that the model is highly robust to input noise and parameter variations, with a sensitivity index of less than 0.1 for key aerodynamic parameters. This robustness is crucial in real-world applications, where the input data can be noisy or incomplete.

One of the novelties of this study is the adaptability of the model to dynamic flight conditions. In particular, through the inclusion of RNNs and attention mechanisms, the model has proven to be capable of predicting high-accuracy unsteady aerodynamic behaviors such as dynamic stall and flutter. For instance, in simulating dynamic stall on a pitching airfoil, the phase error against the experimental data is less than two degrees.



Furthermore, the PCS of the model-a new metric introduced in this work-lies consistently above 0.95 for all test cases (Fig. 6), showing that the predictions have a physical meaning and respect fundamental principles of aerodynamics.

(a) Performance metrics vs. angle of attack (Velocity = 100 m/s).

(b) Performance metrics vs. angle of attack (Velocity = 200m/s).

(c) Performance metrics vs. angle of attack (Velocity = 300 m/s).

Fig. 6. Diagram illustrating robustness and adaptability analysis.

This demonstrates the model capabilities and reliability under different airspeeds [Fig. 6(a), 6(b), 6(c)] and varying

conditions. It shows the model's ability to adapt to different conditions.

E. Robustness Under Extreme Conditions

The robustness of the proposed hybrid model to out-of-distribution aerodynamic conditions—i.e., angles of attack (AoA) outside the [–5°, +15°] range used during training and flow regimes from transonic to hypersonic—could not be assessed quantitatively using the current datasets. While preliminary tests confirm stable performance up to supersonic flow regimes (Mach 0.8–2.0) with a correlation coefficient of 0.98 for pressure distributions, no MAE or RMSE values are available yet for more extreme flow regimes.

This discrepancy is a fundamental limitation of the present study. To close it, planned validation campaigns include:

- Wind-tunnel experimentation at high AoA (up to 45°) in a forced-pitch facility, recording lift and drag coefficients in deep-stall regimes.
- Hypersonic blow-down testing for the measurement of aerodynamic coefficients and surface heating effects on representative geometries.

Results from these campaigns will enable MAE and RMSE to be determined for Cl and Cd at extreme AoA and Mach numbers and will be used to retrain and rigorously revalidate the hybrid framework so that it can be used for next-generation aerospace design at the most demanding flight regimes.

VI. Case Studies and Applications

A. Real-Time Aerodynamic Analysis

A successfully applied hybrid model in real-time aerodynamic analysis takes the form, for instance, of a case study of a commercial aircraft wing in which the model gave an estimation of aerodynamic coefficients with an accuracy of ±2% compared to the wind tunnel data while reducing the computational time from hours down to seconds. This capability has special worth in flight simulators and other real-time control systems, where the time accorded to such a simulation can be of critical essence.

A new application of the model has been in use in autonomous navigation systems for drones. The model can provide real-time predictions of the aerodynamic forces acting on the flying drone, thereby enabling it to adapt to varying wind conditions without causing instability in flight. This application indicates the potential for the hybrid framework to revolutionize autonomous aerial systems and urban air mobility.

B. Implications for Aerospace Design and Optimization

It brings about immense potential impact, especially in the design and optimization of aerospace, by reducing the time and cost attributed to conventional design cycles (Table V). An optimum design with 15% reduced drag compared to baseline configurations was identified for a supersonic airfoil shape optimization problem; this reduced the time of optimization from weeks to days.

TABLE V. Summary of Optimization Results (e.g., Drag Reduction, Fuel Efficiency Improvements) for Aerospace Design

Design	Drag Reduction	Fuel Efficiency Improvement	Lift Enhancement	Computational Time
Supersonic Airfoil	15%	10%	8%	2 hours
Blended Wing Body	20%	15%	12%	3 hours
Delta Wing	12%	8%	10%	1.5 hours
Morphing Wing	18%	12%	15%	2.5 hours

A key innovation here is the balance of multi-objective optimization of competing objectives such as drag reduction, enhancement of lift, and structural integrity. For instance, in the design of a blended wing body aircraft, the model reached a 20% improvement in fuel efficiency while maintaining structural feasibility. These results highlight the potential of the hybrid framework to accelerate the development of next-generation aerospace systems.

It does, in fact, bring about quite impressive improvements in performance regarding aerodynamic design, especially on the matter of drag reduction, fuel efficiency, and lift enhancement. Significant drag reduction is attained for a number of designs ranging between 12 and 20%. For instance, it provides for a 20% drag reduction in the case of the blended wing body design, something that directly improves its aerodynamic efficiency. These drag reductions translate to noteworthy fuel efficiency enhancements, ranging between 8 and 15%. The blended wing body design has even realized a 15% improvement in fuel efficiency; hence, making it a big ideal candidate to be considered when designing the structure of the range aircraft. Increased lift coefficients of about 8% to 15% come with the hybrid model. On the contrary, the morphing wing designs increase the lift to 15%, hence increasing performance. From a computational point of view, it took 1.5 to 3 hours, depending on design complexity, and has turned out to be one of the very potent and promising approaches to achieve fast, as well as reasonably accurate, aerodynamic optimizations. These results testify that significant performance enhancement could be delivered with a hybrid model by not sacrificing computational efficiency.

C. Potential for Complex Geometries and Dynamic Conditions

Indeed, such a hybrid model demonstrates great potential to handle complex geometries and dynamic flight conditions that are often not feasible for traditional methods. In a case study over a hypersonic vehicle, accurate predictions of pressure distributions and thermodynamic heating were shown, having a correlation coefficient of 0.97 with the experimental data. Such a capability is critical in designing reusable space vehicles and hypersonic missiles.

It has also been extended to dynamic conditions, such as the analysis of flutter and dynamic stall prediction. For instance, in the simulation of the flutter behavior of a flexible wing, the model could predict critical flutter speeds with an accuracy within ±3%, compared to traditional methods. The application

here underlines the model capability for improving safety and performance in flexible aerospace structures.

A very innovative application involves the use of the hybrid model in morphing wing optimization. The model can predict in real time the aerodynamic performance of shape-changing wings, thus allowing for adaptive control strategies aimed at improving fuel efficiency and maneuverability. This opens a new frontier in the development of morphing aircraft and bio-inspired flight systems.

D. Discussion

The absence of explicit disturbance rejection for turbulence-induced fluctuations, weather-based variability, and sensor measurement noise likely vitiates the predictive accuracy of the model in practical configurations. Studies have already shown that the integration of flow sensing measurements with inertial data can significantly improve disturbance rejection in turbulent flows. Similarly, deep generative models such as Weather UNet have shown improved object detection through the preprocessing of inputs for the removal of undesirable weather artifacts. The combination of injecting Gaussian noise during training can mitigate the effect of unexpected input perturbations, offer more reliable predictions of lift and drag in actual flight conditions. Future research will implement these extensions and quantify performance loss due to noise using measures such as MAE and RMSE on noisy test sets and offer a benchmark for operational robustness.

VII. CONCLUSION

The proposed study presents a novel hybrid framework coupling DL architectures with state-of-the-art evolutionary and Gradient-Based Optimization to predict the aerodynamic coefficients at unprecedented levels of accuracy and efficiency. The specific key outcomes from this work are superior performance, where the hybrid model proposed here demonstrates superior performance with respect to state-of-the-art methods, both CFD and experimental tests in a wind tunnel, in terms of prediction accuracy and computational efficiency. For example, the predictions for the lift coefficient reached a mean absolute error of 0.012 compared to 0.025 for CFD, at a computational cost reduced by 85%. Generalizability is the test of the robustness of model performance over extensive ranges of aerodynamic conditions, geometrical complexities, and dynamic flight regimes, including, among others, the aerodynamics of blended wing bodies and both transonic and hypersonic flows. This is attributed to the use of multi-fidelity data and Physics-Informed Neural Networks. Real-Time applications where the framework has been applied in real time for aerodynamic analysis and autonomous navigation of drones, and is presented as a case of practical utility. Finally, multi-objective optimization in Aerospace Design using the framework brings out marked improvement in performance metrics, such as drag reduction and fuel efficiency.

AI-Powered Assessment of Resistance to Change in the Context of Digital Transformation

Bachira Abou El Karam, Tarik Fissaa, Rabia Marghoubi
Innovative Research on Software Systems and Data, INPT, Rabat, Morocco

***Abstract*—Digital transformation is a key driver of business evolution, but it comes with significant challenges, particularly employee resistance to change. This resistance can manifest in various forms, ranging from explicit opposition to more subtle hesitation toward new practices. Its underlying causes are diverse, including fear of the unknown, loss of control, and dissatisfaction with perceived transformations. Understanding employee perceptions is, therefore, crucial to adapting digital initiatives and ensuring successful adoption. However, existing methods for assessing resistance, which rely on closed-ended questionnaires and binary classifications, have limitations. They restrict the expression of opinions and fail to provide a nuanced segmentation of employees' stances toward change. In this context, this study proposes an innovative and automated methodology that combines specialized zero-shot LLMs and prompt engineering techniques to analyze resistance to change. It is based on the allies strategy, a concept derived from sociodynamic theory and widely applied in change management, which seeks to more precisely differentiate employee attitudes based on their level of synergy or antagonism toward a new project or transformation initiative. To evaluate the effectiveness of the proposed approach, an experiment was conducted on an annotated dataset comprising a hundred employee responses. Two prompt engineering strategies were explored and applied to six zero-shot models to assess their ability to accurately classify expressed attitudes. The findings underscored, on one side, the significance of prompt structuring in enhancing classification efficacy and, on the other side, the preeminence of DeBERTa-v3-large-zeroshot, which demonstrated itself as the most exemplary model, even exceeding GPT-4, one of the most sophisticated and cutting-edge language models currently accessible.**

***Keywords*—Resistance to change; digital transformation; zero-shot LLMs; prompt engineering; allies strategy**

I. Introduction

Resistance to change is a widely studied phenomenon in management and organizational psychology. It is generally defined as a cognitive, emotional, or behavioral reaction to a modification perceived as a threat to stability, habits, or the status quo [1] [2] . M. Asem [3] describes it as opposition to new organizational practices, which may be driven by personal interests, a lack of understanding, low tolerance for uncertainty, or a different assessment of the proposed change.

In the sphere of digital transformation, resistance to change takes on a specialized form. It is often linked to technological upheavals that redefine processes, roles, and interactions within organizations. Among the primary determinants contributing to this resistance encompass job insecurity, as employees may possess uncertainties regarding prospective layoffs or modifications in their roles; inadequate technological aptitude, which can elicit apprehension and negative perceptions towards digital technologies; and issues related to identity and social relationships, with particular technological innovations regarded as threatening one's social standing or reputation within the organization [4][5][6][7][8][9]. These factors demonstrate that resistance to change in a digital context is not solely based on irrational fears, but on legitimate concerns that must be considered in change management strategies [10].

Resistance to change has often been conceptualized from two main perspectives in literature: a systemic approach, which views resistance as an organizational phenomenon influenced by corporate culture, processes, and structure, and an individual-centered approach, which examines how employees perceive and react to change [8][11]. However, these two approaches are closely linked. In [12] and [13], the authors highlight that organizational-level resistance often leads to individual resistance, as employees react to transformations perceived as being imposed by the existing system.

Thus, while research on systemic resistance provides a critical framework for understanding structural obstacles to digital transformation [5][6][7][9][14][15], it is at the individual level that resistance takes a concrete form and directly influences the success or failure of a change initiative. Therefore, it is essential to focus on methods for measuring this resistance on the individual scale. In this context, several measurement tools have been developed to assess employee resistance to change [16][17][18][19][20]. These instruments, often in the form of closed questionnaires or scales, have the advantage of enabling quantitative and comparative assessment of resistance to change. However, their drawback is that they unfortunately limit the richness of responses and do not fully capture the diversity of perceptions and emotions employees have towards change. They tend to reduce the range of responses to a simple dichotomy between resistors and non-resistors, leading to an imprecise or biased classification that does not faithfully reflect the complexity of reactions to change. This reduction of nuances hinders the identification of intermediate profiles and complicates the development of strategies tailored to each stakeholder in the change process.

In response to the limitations of traditional approaches, we propose an alternative method based on the use of the allies strategy and zero-shot language models. Instead of relying solely on closed-ended questionnaires or rigid classifications, our approach focuses on analyzing employees' open-ended responses, harnessing the power of zero-shot LLMs combined with prompting techniques to perform a deep natural language analysis. At the same time, the allies strategy helps to better

identify and segment employees based on their potential role in the transformation: those actively promote change and those who may hinder it. This segmentation will enable communications and change management actions to be targeted effectively, making it easier to overcome resistance and build commitment to the digital initiatives arising from digital transformation.

The following sections in the study are arranged as: Section II presents related work. Section III provides essential background information on zero-shot LLMs, prompt engineering, the allies strategy, and foundational concepts crucial for understanding the context of our study. Section IV presents the methodology employed in measuring resistance to change using the allies strategy, including the design and implementation of prompt engineering strategies and the selection of zero-shot LLMs. The experimental setup is elaborated in Section 5V, while Section VI elucidates the results obtained and their subsequent interpretation. In closing, Section VII recaps the research and outlines potential routes for further examination.

II. Related Work

In the literature, the assessment of resistance to change in the context of digital transformation has been approached through two primary lenses. From one angle, a holistic viewpoint underscores the importance of pinpointing organizational aspects that contribute to resistance, their effects on business success, and the techniques for identifying and reducing that resistance. Conversely, a person-focused perspective delves into how employees react to digital shifts by exploring their viewpoints, hurdles, and incentives. However, a common limitation of many studies lies in their tendency to adopt a generalized view that does not always account for the richness of expressions and the freedom employees have to articulate their own perceptions of change, nor the variability in their stance toward it.

Several studies have taken a systemic approach in analyzing resistance to change in the context of digital transformation without analyzing in depth how it manifests within employees, for instance, both studies [5] and [6] highlight common sources of resistance such as fear of job loss, lack of digital skills, perceived work overload, and concerns about professional identity. However, these studies remain at a macro level, failing to segment employees based on their specific resistance attitudes or to propose a classification of resistance profiles that could support more tailored change management strategies. In a related vein, Tetiana Kuzhda [14] proposes a diagnostic model of resistance to change based on expert surveys to identify and prioritize the major causes of resistance and then suggest strategies for reducing it. Still, these methods are rather standard and overlook the personal differences among workers. Finally, Samia Hattab [15] investigates the issue of resistance to change in the public sector by analyzing a survey of administrative staff to determine the primary overall causes of this resistance during digital transformation. However, this survey highlights general trends and fails to categorize employees according to their degree of resistance, which limits the possibility of conceiving targeted change management strategies.

Consequently, it is necessary to concentrate on methodologies for quantifying resistance at the individual scale. From this viewpoint, numerous approaches have been formulated to evaluate employees' resistance to organizational change. One of the most widely used tools is the Resistance to Change (RTC) scale developed by Oreg [16], which measures individual resistance across four dimensions: routine-seeking, emotional attachment, reaction to stress, and reluctance to lose control. This approach relies on standardized questionnaires that quantify perceived resistance. In the particular context of digital transformation, numerous research contributions have endeavored to enhance the assessment of resistance to change by considering the unique characteristics of digital contexts. For example, Sherif Hamdi [17] examines employee resistance within the National Social Insurance Organization in Egypt, and analyzes its role as a mediating variable between training and performance. However, this study relies on closed-ended questionnaires (agree or disagree), which limits a nuanced understanding of employees' individual barriers and motivations regarding change.

In a different approach, Stam et al.[18] uses Membership Category Analysis (MCA) to analyze employee discourse on the introduction of digital technologies. This qualitative approach highlights the discursive categories used to express their perceptions of change. However, although this method offers a detailed analysis of social representations, it relies entirely on human interpretation, which limits its large-scale application and does not allow for precise segmentation of employees according to their degree of resistance.

Another attempt at classification is proposed in our previous work [19]. This study relies on generalized hesitant fuzzy sets and Formal Concept Analysis to classify employees based on their level of acceptance of change, incorporating uncertainty in response formulation. Nevertheless, although this methodology affords increased liberties of discourse in comparison to closed-ended inquiries, it does not entirely exploit the depth of open-ended replies and does not facilitate a varied typology of employee profiles.

Finally, the study [20] explores another variant of fuzzy sets by introducing an intuitionistic analysis to capture resistance to change in digital contexts. This approach enhances the modeling of hesitations and uncertainties in employees' responses but remains dependent on a rigid mathematical framework that does not adapt to semantic variations and the subtleties of natural language.

The analysis of existing work reveals several limitations. Some studies translate the analysis and assessment of resistance to change in the context of digital transformation by identifying the causes of resistance and thus propose general recommendations applied to all employees. Other studies that have sought to analyze employee's perceptions of the introduction of new digital transformation projects have generally adopted a binary classification of employees as resistors and non-resistors, neglecting intermediate positions such as those who are “torn”, “conciliatory” or “indecisive”, which limits the identification of more nuanced categories and hinders the implementation of targeted strategies adapted to each change actor. What's more, the methodologies employed

using closed-ended questionnaires do not fully capture the complexity of individual attitudes to transformation, which can lead to imprecise or biased classification.

It is within this perspective that our contribution is situated. We propose adopting the allies strategy, derived from the sociodynamic approach developed by Jean-Christian Fauvet in the 1970s [21], to establish a more granular classification of employees in relation to change, based on open-ended responses. Indeed, and unlike traditional approaches that often rely on binary segmentation and closed questions, preventing a more nuanced understanding of employees' positions towards digital transformation, our approach enables us to identify different stakeholder profiles while promoting employees' freedom of expression thanks to open-ended responses. This analysis will enable the development of a customized change management plan and help organizations to target their communication, training and support actions more effectively, thereby reinforcing buy-in to the transformation. To automate this approach, Large Language Models (LLMs) specialized in zero-shot classification, combined with prompting techniques, were used to analyze and process open-ended responses.

III. Background

This section presents fundamental background information on the key topics that form the basis of our study, namely the sociodynamic approach, the allies strategy, Zero-shot LLMs and prompt engineering.

A. The Sociodynamic Approach

Developed by Jean-Christian Fauvet in the 1970s, the sociodynamic approach is a strategic method for analyzing human dynamics and individuals' attitudes towards change based on the idea that any transformation generates power relationships and interactions between different actors with varied interests [21]. Unlike traditional change management approaches, which prioritize top-down and prescriptive methodologies, this method adopts an interactionist and adaptive perspective [22]. It considers that the success of a transformation project depends not merely on technical and organizational aspects but also on relational dynamics and stakeholder engagement strategies. This dynamic is based on theoretical foundations such as the theory of commitment [23] and the theory of influence networks [24], which explain how social interactions and gradual involvement alter attitudes towards change.

As Paul Walley has highlighted [25], applying a sociodynamic perspective to stakeholder management enhances project outcomes by enabling a more nuanced understanding of stakeholder behaviors and by effectively addressing resistance to change. Indeed, the sociodynamic approach allows for the recognition of complex, and sometimes ambivalent, employee responses, where individuals may express both support and hesitation simultaneously, offering a richer and more realistic assessment of attitudes during organizational transformations.

B. The Allies Strategy

The allies strategy model is an operational application of the sociodynamic approach, specifically designed to classify actors based on their attitude towards a transformation project into allies, neutrals, undecided, and opponents, thus enabling a differentiated strategy depending on their posture. This approach is structured around two axes: the synergy axis, which aims to mobilize change supporters to positively influence the undecided, and the antagonism axis, which involves identifying and mitigating the impact of opponents [25] [26].

The central tool of the model, known as the actor mapping or partner map [25] [26] [27] [28], allows for a more detailed analysis of individual resistance, facilitating the implementation of tailored strategies to foster engagement and support the transition. It aids in illustrating the diverse perspectives of individuals or groups upon their degree of synergy (support) and antagonism (resistance) regarding the initiative. This mapping is often represented as a matrix, as shown in Fig. 1, consisting of two main axes: The first axis, which measures the degree of support or commitment an actor has towards the project, is subdivided into four main categories:

- Minimalist: Individuals with little interest or commitment to the project, showing minimal involvement.
- Interested: Individuals who show a degree of interest but require more evidence or benefits before fully committing.
- Cooperative: Individuals who are actively engaged in the project, offering ideas and solutions.
- Committed: Those who reflect a strong devotion to the project, are motivated, and are inclined to assume an important position in its operationalization.

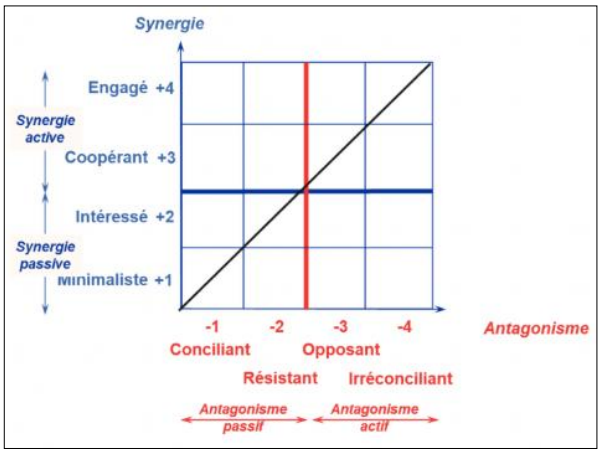

Fig. 1. Partner map [26].

The second axis, which evaluates the level of opposition or resistance an actor has towards the project, is also subdivided into four main categories:

- Conciliatory: Individuals with reservations about the change but open to dialogue and compromise.
- Resistant: Individuals who show stronger opposition due to specific concerns or divergent interests.

- Opponent: Individuals who actively oppose the project, potentially seeking to block it due to personal fears or general resistance to change.
- Irreconcilable: Individuals whose opposition is deep and often irrevocable, making constructive involvement difficult.

The intersections between the categories of synergy and antagonism give rise to seven more nuanced and meaningful categories, reflecting the complexity of organizational and human dynamics during change processes.

One of the main added values of this model resides in its capacity to reveal concealed or passive stakeholders, individuals who may not be readily apparent or vocal during the change process, yet whose perspectives and influence can profoundly affect project outcomes. By rendering these latent dynamics discernible, the allies strategy prompts project managers to expand their stakeholder analysis beyond the most conspicuous participants, thereby facilitating more tailored engagement strategies and mitigating the risk of neglecting silent sources of resistance or support.

C. Zero-Shot LLMs

A Large Language Model (LLM) represents an advanced manifestation of artificial intelligence, systematically engineered to analyze and generate natural language akin to human discourse. Based on sophisticated deep learning techniques, particularly on an advanced neural network architecture known as Transformers [29], these models incorporate an attention mechanism that discerns complex interrelationships between textual components, regardless of their position in the sequence. The effectiveness of this attention mechanism gives LLMs the ability to capture the nuances of language, syntax, and contextual relevance. Owing to their thorough preliminary training on a vast number of datasets [30], LLMs are exceptionally effective in numerous applications, which include conversational agents, automated content production, translation, and what is termed 'zero-shot' classification, defined as a technique that permits a model to label text without prior familiarity with examples of the pertinent category [31] [32]. LLMs fine-tuned to this specific task are called zero-shot LLMs, and they use this technique to correlate textual data with classifications without prior exposure to such data. They rely on natural language inference (NLI) models [33], which investigate the semantic relationships between an input text and a particular category through a logical semantic process that assesses whether a certain hypothesis (the category) is entailed (implication), neutral (neutrality), or contradicted (contradiction) by a provided text [34]. The performance of these models is chiefly derived from their foundational training on vast, high-standard natural language inference (NLI) datasets [32], incorporating SNLI [34], MNLI [35], ANLI [36], and FEVER [37]. These datasets contain extensive collections of annotated sentence pairs, assessing whether one sentence entails, is neutral to, or contradicts another. They have enabled models to develop a more refined understanding of semantic relationships and enhance their inference capabilities.

Within the scope of our research, the adoption of zero-shot LLMs is notably supported by the open-ended and unstructured responses from the feedback gathered from employees related to their views on organizational change. Zero-shot models enable the immediate classification of such qualitative responses without the need for prior task-specific fine-tuning. Furthermore, their capacity to perform inference-based categorization aligns well with the conceptual framework of the allies' strategy, which requires distinguishing nuanced and context-dependent postures ranging from strong support to strong opposition. This makes them highly appropriate for analyzing resistance to change in dynamic and resource-constrained environments.

D. Prompt Engineering

Prompt engineering constitutes a technique for optimizing the utilization of large language models (LLMs) by steering their outputs via precise directives, all while preserving the integrity of the model itself. This technique enables the optimization of LLMs' performance in various tasks, such as text classification, machine translation, or generating tailored responses, simply by adjusting the phrasing of the queries [38]. What renders prompt engineering exceptionally potent is its capacity to adapt pre-trained models for novel tasks without necessitating the retraining of the model parameters. As articulated in [39], this methodology significantly augments the capacity of models to generalize proficiently to novel tasks, especially via mechanisms such as zero-shot prompting and few-shot prompting. The effectiveness of this technique depends on the precision of prompt formulation, as even small adjustments can lead to significant variations in the results generated [40]. Several prompting strategies have been developed, including, for example:

- Zero-Shot Prompting: The model is given an instruction without any example responses. It relies on the LLM's ability to generalize from existing knowledge [38].
- Few-Shot Prompting: This strategy includes several representative instances within the prompt to improve the model's grasp of the task at hand. It enhances model accuracy by providing more context [38].
- Chain-of-Thought Prompting (CoT): As delineated by J. Wei et al [39], this methodology invites the model's elucidation of its reasoning process via intermediary steps prior to delivering a conclusive response. It’s particularly useful for tasks requiring complex logical reasoning, such as math problems or advanced inference.
- Role-Playing Prompting: The model is assigned a specific role, such as an expert in a given domain, to improve the relevance and coherence of responses in specialized contexts [40].
- AI-Knowledge Prompting: As articulated by J. Liu et al. [41], this methodology entails soliciting the model to produce knowledge that is specific to a given task, which is subsequently integrated into the prompt to enhance both the precision and reliability of the generated predictions.

IV. METHODOLOGY

Our methodology relies on the use of zero-shot LLMs combined with prompting techniques to analyze and classify open-ended responses in the context of measuring resistance to change, based on the allies strategy. The choice of these models is justified by their ability to infer logical relationships between texts and recognize classification patterns without requiring supervised learning on a specifically annotated dataset [33]. However, their performance is highly dependent on the formulation of hypotheses and the provided context [42] [43]. In order to enhance classification accuracy, we have incorporated a prompt engineering methodology aimed at optimizing the models' comprehension [44].

In the following, we give a brief description of the zero-shot LLMs selected for our study, and we also describe the prompt formulations used, followed by detailing the workflow of our proposed approach to measuring resistance to change relying on allies strategy.

A. Models

In the context of our research, we chose a selection of LLMs specialized in zero-shot classification and recommended by the Hugging Face platform [45] due to their performance in natural language inference (NLI), namely:

1) Facebook/bart-large-mnli. The BART model, known as Bidirectional and Auto-Regressive Transformers, represents an encoder-decoder transformer that integrates the benefits of bidirectional encoder models like BERT alongside auto-regressive decoder models such as GPT [46]. Its variant, facebook/bart-large-mnli, has been pretrained on the MultiNLI dataset, enabling it to perform excellently in Natural Language Inference (NLI) tasks. Its architecture makes it particularly well-suited for zero-shot classification, where it evaluates the probability that a given text corresponds to a predefined hypothesis, a mechanism directly leveraged in our study to assign responses to categories of resistance to change.

2) MoritzLaurer/deberta-v3-large-zeroshot-v2.0 and MoritzLaurer/deberta-v3-base-zeroshot-v2.0mnli. eBERTa models (Decoding-enhanced BERT with Disentangled Attention) are an improvement over BERT and RoBERTa, introducing a disentangled representation mechanism that more effectively distinguishes words based on their position and context [47]. The variants deberta-v3-large-zeroshot-v2.0 and deberta-v3-base-zeroshot-v2.0, developed by Moritz Laurer, are specifically optimized for zero-shot classification. They benefit from enhanced masking and more efficient pre-training, thereby improving their ability to generalize to new tasks without explicit supervision.

3) MoritzLaurer/roberta-large-zeroshot-v2.0. oBERTa (Robustly Optimized BERT Pretraining Approach) is an improved variant of BERT that relies on longer pretraining and better hyperparameter tuning [48]. The roberta-large-zeroshot-v2.0 version, fine-tuned for zero-shot classification, leverages these optimizations to better handle the variability of natural language, an essential advantage in our task, where employee responses can vary significantly in wording and tone.

4) MoritzLaurer/bge-m3-zeroshot-v2.0. The bge-m3-zeroshot-v2.0 model is part of the models optimized for semantic similarity tasks and zero-shot classification. It relies on a combination of advanced semantic representation techniques and specific optimizations to improve robustness when dealing with unstructured texts and varied formulations [4].

5) OpenAI/GPT-4. GPT-4 is a multimodal model and one of the most advanced developed by OpenAI, outperforming its predecessors in terms of contextual understanding, logical reasoning and text generation [49]. Unlike specialized models such as BART or DeBERTa, GPT-4 is a generalist model, but it excels in zero-shot classification tasks thanks to its ability to analyze global context and interpret complex formulations. Its integration into our study enables us to assess the extent to which an ultra-polyvalent model can compete with specialized models on a specific task, such as the analysis of resistance to change.

B. Prompt Engineering

To enhance the zero-shot classification of employees' responses while relying on the allies strategy, we have developed and tested two types of prompts, namely a minimalist prompt and an explicit prompt:

1) A minimalist prompt. This prompt is limited to essential information, represented solely by numeric labels and class names corresponding to the synergy and antagonism axes as defined in the allies strategy. In this scenario, two sets of classes were defined according to this strategy:

- Synergy (synergy class): "1 Minimal", "2 Interested", "3 Cooperative", "4 Committed"
- Antagonism (antagonism class): "1 Conciliatory", "2 Resistant", "3 Opponent", "4 Irreconcilable"

This type of prompt aims to evaluate the zero-shot models' ability to generalize from minimal class descriptions, without providing explicit context about their meaning. In this case, we rely entirely on LLM's internal representation and its pre-existing knowledge gained from vast textual datasets to generalize new classification tasks. This approach is aligned with the Zero-Shot Prompting strategy.

2) An explicit prompt. This approach is based on AI-Knowledge Prompting [41], where each class (synergy and antagonism classes) is enriched with an explicit definition of the behaviors associated with each level of synergy or antagonism. These descriptions provide the model with a more precise contextual framework, thereby facilitating the distinction between different classes. To design these AI-Knowledge Prompts, we used GPT-4 to generate detailed class descriptions. Specifically, we formulated an initial zero-shot prompt containing only the classification labels, and then we leveraged GPT-4 to generate definitions specific to each category, based on the principles of the allies strategy. These

descriptions were subsequently integrated into the final explicit prompt to provide a richer contextual framework.

- Synergy (synergy class):
  - "Follows assigned directives without active initiatives",
  - "Follows assigned directives and expresses verbal interest in the project, but without active initiatives",
  - "Takes active initiatives",
  - "Takes active initiatives with a high level of responsibility".
- Antagonism (antagonism class):
  - "Supports the project's decisions and approaches",
  - "Opposes the project or certain decisions/approaches but is open to discussion",
  - "Opposes the project or certain decisions/approaches and is less flexible in discussions",
  - "Opposes the project or certain decisions/approaches and is inflexible in discussions".

This type of prompt aims to examine how the detail of class descriptions affects the efficiency of zero-shot models.

C. Proposed Approach for Measuring Resistance to Change

In this section, we provide an overview of the methodology employed in our study, illustrated in Fig. 2, detailing the steps taken to investigate the effectiveness of zero-shot LLMs combined with prompting techniques in measuring resistance to change using the allies strategy. We adopted a multi-task classification approach, with each task focusing on a different aspect of employees' dynamics regarding digital transformation projects:

- Classification based on Synergy Level: The objective of this task is to categorize employees by their degree of engagement and collaboration within the project. The labels range from "Minimalist" to "Committed". This classification helps identify the most motivated team members and those who may require additional motivation or incentives.
- Classification based on Antagonism Level: focuses on analyzing the degree of resistance or opposition exhibited by employees regarding project initiatives. The classifications range from 'Conciliatory' to 'Irreconcilable', thus enabling the recognition of resistance levels that could affect group dynamics and hinder project progress.
- Final classification: This task synthesizes results derived from the initial two classifications to construct a holistic appraisal of each employee. It amalgamates both synergistic and antagonistic dimensions to yield a comprehensive evaluation of employees' attitudes towards digital transformation initiatives.

Based on a dataset containing open-ended employee responses, previously annotated with synergy and antagonism classes, we proceed as follows:

The first two tasks, namely classification by Synergy Level and Classification by Antagonism Level, referred to both simultaneously in Fig. 2 as task 1 and task 2, follow the same process, detailed below:

1) Preprocessing of open-ended responses. Each open-ended response provided by an employee is standardized to ensure better understanding by the language models. This step includes text cleaning (removal of special characters, unnecessary stopwords if necessary) and conversion into a standardized format suitable for input into zero-shot classification models.

2) Prompt engineering. Two variants of prompts are used to guide the zero-shot classification models:

a) Minimalist prompt. Contains only the classification labels.

b) Explicit prompt. Adds detailed descriptions of the classes to improve the model's interpretation.

3) Zero-shot classification with LLMs. Each open-ended response is submitted to a large language model (LLM) specialized in zero-shot classification, accompanied by the selected prompt (either minimalist or explicit). The model reformulates the task as a natural language inference (NLI), where the open-ended response is considered the "premise" and each possible class is treated as a "hypothesis". It then evaluates the probability that the response implies each hypothesis, assigning a confidence score to each class. Finally, the class with the highest probability is selected as the final label assigned to the open-ended response.

4) Performance evaluation of classification. The classification performance is evaluated by comparing the predicted classes to the actual classes annotated in the dataset. The metrics calculated are:

- Confusion Matrix
- F1-score
- Recall
- Accuracy
- ROC-AUC Curve

Regarding the third classification task (task 3 in Fig. 2), which aims to assign the final class of resistance to change, the process is as follows: Once the synergy and antagonism classes have been determined according to the steps of the first two tasks, they are combined based on a pre-established matrix derived from the allies' map. This combination allows for the assignment of a final class representing the overall level of resistance to change.

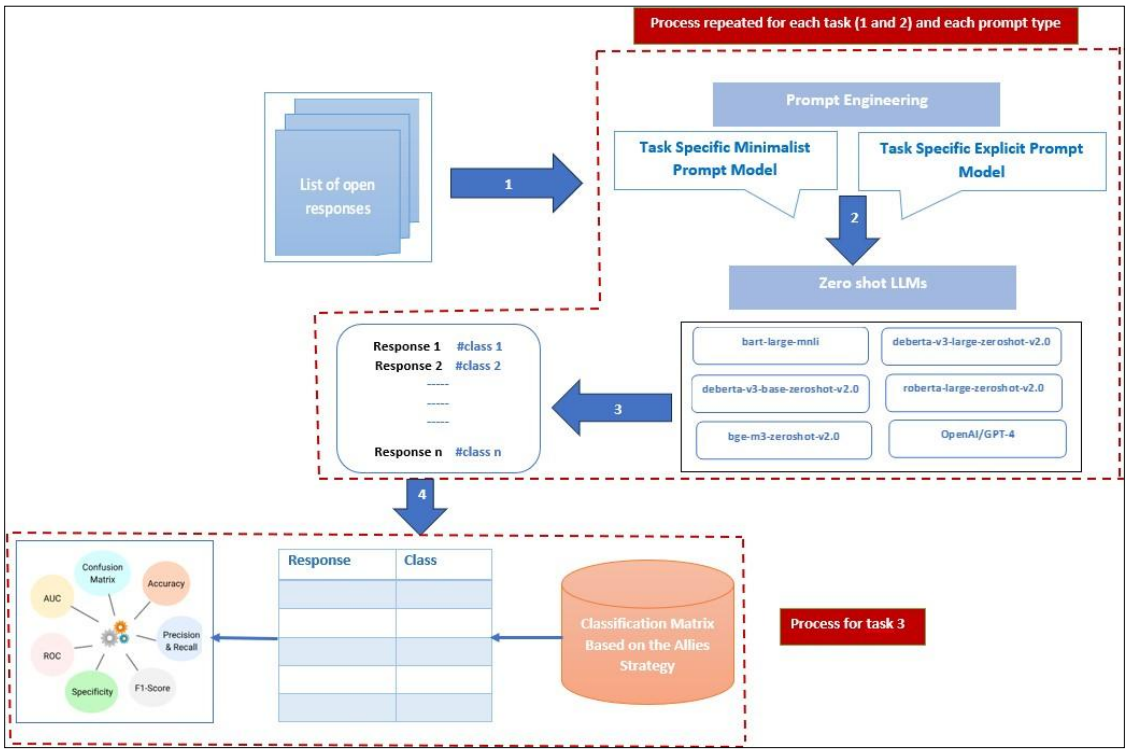

Fig. 2. Overview of the approach for measuring resistance to change.

As with the previous tasks, the predicted final class is compared to the actual class annotated in the dataset. Performance evaluation is carried out using the same metrics as the previous tasks.

V. Experiments

To validate the proposed methodology, we executed a thorough array of experiments intended to measure the effectiveness of the selected zero-shot Large Language Models (LLMs) in precisely classifying employee opinions regarding the context of digital transformation, derived from their open-ended text replies. This section elucidates the experimental framework, encompassing the dataset utilized, the evaluative methodology employed to benchmark the models, and the metrics implemented to evaluate their efficacy. The design of these experiments aimed to investigate both the efficacy of the prompting strategies and the pertinence of the allies strategy framework in effectively capturing the intricate expressions of resistance to change.

A. Dataset

As part of our study aimed at classifying employees based on their synergy and antagonism towards a digital transformation project, we built a database by collecting approximately one hundred open-ended responses directly from a company that recently introduced digital initiatives. This data collection allowed us to gather a hundred employee testimonies expressing their perceptions, concerns, and levels of adherence to these changes. Each open-ended response was then carefully annotated by change management experts in accordance with the classes defined in the allies strategy. Specifically, three labels were assigned to each response:

- A synergy level, indicating the degree of alignment and positive engagement of the employee towards the digital initiative.
- An antagonism level, reflecting the resistance expressed, whether passive or active, towards the change.
- A global resistance to change level, resulting from the combination of the first two classifications as defined in the Allies Strategy Matrix.

These manual annotations are an essential benchmark for evaluating the performance of the models used, enabling us to measure their ability to reproduce expert judgments in the analysis of resistance to change.

The distribution of employee responses by level of synergy and antagonism is described in Fig. 3:

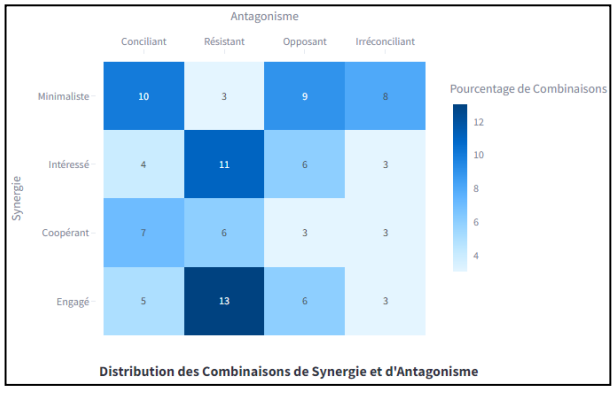

Fig. 3. Distribution of employee responses by level.

B. Evaluation Process

Our evaluation process, as described in the methodological section, will be applied to six models specialized in zero-shot classification, using two distinct prompt variants for each tested model: a minimalist prompt containing only the classification labels and an explicit prompt providing detailed descriptions of the classes to enhance the model's interpretation. In other words, each model is required to classify the open responses of the dataset according to the level of synergy corresponding to task 1 and then according to the level of antagonism corresponding to task 2, in line with the workflow described in the methodology section. These classifications, predicted by the models, will be generated first using the minimalist prompt and then the explicit prompt. Finally, once the synergy and antagonism classes have been determined according to the steps of the first two tasks. Task 3 is started by combining the results of the first two tasks based on a pre-established matrix derived from the allies strategy. This combination makes it possible to assign a final class representing the overall level of resistance to change for each open response.

C. Evaluation Metrics

To validate the performance of the models, we use a method structured in two main steps:

1) Evaluation by task. Evaluation by task consists of comparing the classifications predicted by the model with the actual classifications annotated in the dataset for each of the tasks and prompts defined in our classification workflow. For this, we use confusion matrices to visualize the distribution of errors made by the model, and we also use standard classification metrics, notably:

a) Precision: This metric is crucial for measuring the reliability of the model's positive classifications. In our context, a high precision score indicates that when the model identifies a specific stance toward change, it is unlikely to be incorrect. This is particularly important to avoid misclassifications that could distort the analysis of resistance and support for digital initiatives.

b) Recall: This metric evaluates the model's proficiency in detecting all affirmative instances present within the dataset. A high recall score is essential in our study to ensure that minority, but potentially critical, stances are not overlooked. This helps to provide a more comprehensive understanding of the dynamics of resistance and synergy among employees.

c) F1-score: By combining precision and recall, the F1-score balances these two aspects, particularly in cases where class distribution is imbalanced. In our analysis, this metric is particularly relevant, as some stance categories may be underrepresented, making it necessary to use a measure that penalizes both false positives and false negatives.

d) Accuracy: This metric assesses the ratio of correctly predicted classifications relative to the total predictions generated by the model. While it offers a general measure of reliability, it may not fully reflect performance in cases of class imbalance.

2) Comparative evaluation of models. Beyond analyzing individual classification tasks, we conduct a comprehensive comparison of the models using two key performance indicators:

a) The F1 score for the final classification task: This indicator summarizes the model's overall ability to balance precision and recall in assigning final classes.

b) Receiver Operating Characteristic (ROC) curve and Area Under the Curve (AUC): Through the examination of the equilibrium between true positives and false positives, the AUC score serves to ascertain the model's ability to consistently differentiate among various levels of resistance, which is imperative within our framework, where a nuanced classification is essential for informed decision-making in developing a change management plan tailored to each category.

By combining these different metrics, we are able to identify the best-performing model best suited to our problem, thus guaranteeing accurate and exploitable results for the analysis of resistance to change.

VI. Results and Discussion

In this section, we evaluate the ability of the models to correctly classify responses according to the defined tasks (synergy, antagonism). For each task and each type of prompt, we have calculated the standard classification metrics: precision, recall, F1 score and accuracy, along with confusion matrices for fine-grained error analysis.

The performance of the models using both types of prompts is presented in Table I. Metrics are calculated using the "macro" method, which means that we calculate precision, recall, accuracy and F1 score for each class independently, then average them. This approach better reflects the overall performance of the model across all classes.

The preliminary analysis of the results highlights the following points:

- Minimalist prompt: Overall, the model's performance is moderate to low on both tasks when using a minimalist prompt (see Table I). This trend suggests that overly basic formulations do not provide enough context or information to the models, limiting their ability to correctly distinguish between classes.
- Explicit prompt: Adding more detailed descriptions significantly improves performance, particularly in terms of the F1 score, as illustrated in Fig. 4 and Fig. 5 for nearly all models. This improvement is particularly notable for the DeBERTa-v3-large-zeroshot model, which achieves the highest F1 scores on both tasks, demonstrating the importance of a well-structured prompt to optimize classification.

The results also show that the explicit prompt yields the best overall performance, with a notable increase in both precision and recall as shown in Table I.

TABLE I. PERFORMANCE METRICS

Model	Prompt	Task 1: Synergy Classification				Task 2: Antagonism Classification			
		Precision	*Recall*	*F1 Score*	*Accuracy*	*Precision*	*Recall*	*F1 Score*	*Accuracy*
OpenAI/GPT4	***Minimalist***	**0.52**	**0.43**	**0.40**	**0.46**	**0.64**	**0.50**	**0.45**	**0.56**

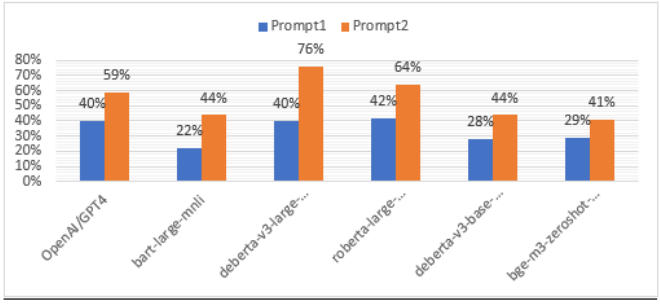

Fig. 4. F1 Score Results for Task 1 according to both prompts.

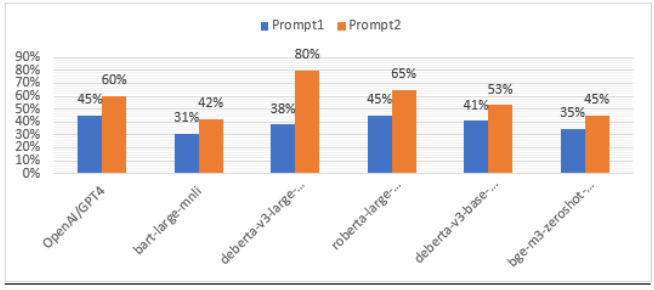

Fig. 5. F1 Score Results for Task 2 according to both prompts.

Based on the results shown in Fig. 4 and Fig. 5, it is clear that the explicit prompt (referred to in Fig. 4 and 5 as Prompt2) provides better performance than the minimalist prompt (referred to in Fig. 4 and 5 as Prompt1). To further analyze this, we will focus solely on the explicit prompt and examine the errors made by the models on tasks 1 and 2 using confusion matrices. These matrices allow us to visualize the correspondence between the model predictions and the actual classes, highlighting classification errors. The goal is to identify the models that achieve the best results and those that exhibit recurring errors.

To do this, we will display and analyze the confusion matrices of the different models on these two tasks in order to visualize the distribution of errors and better understand the respective performance of each model.

For task 1 related to classification according to the synergy axis, we selected the confusion matrices of the six models analyzed, as shown in Fig. 6.

The analysis of the confusion matrices reveals several types of recurring errors. Firstly, some models tend to confuse intermediate classes, particularly "Cooperative" and "Interested", suggesting difficulty in capturing the nuances between these categories. For instance, BART-large-mnli and RoBERTa-large-zeroshot frequently confuse these two classes, while DeBERTa-v3-base-zeroshot shows notable errors by incorrectly assigning "Cooperative" responses to "Committed".

Additionally, the BGE-m3-zeroshot model appears to struggle with correctly identifying the "Minimalist" class, redistributing its predictions toward other categories. In contrast, DeBERTa-v3-large-zeroshot and GPT-4 stand out with better classification performance, with DeBERTa-v3-large-zeroshot displaying slightly higher accuracy. However, errors persist in the intermediate classes, indicating a challenge in clearly differentiating these categories.

For task 2, related to classification according to the axis of antagonism, we adopt the same approach by generating the confusion matrices of the six models, as illustrated in Fig. 7.

Based on the analysis of the confusion matrices in Fig. 7, it is observed that DeBERTa-v3-large and GPT-4 stand out for their ability to accurately classify the extreme classes, with high precision for the categories "Conciliatory" and "Resistant". DeBERTa-v3-large demonstrates a more stable classification across all intermediate classes compared to the other models, while GPT-4 shows some confusion in the categories "Opponent" and "Irreconcilable". BART-large-mnli and RoBERTa-large-zeroshot also manage to correctly identify the majority classes but exhibit more pronounced confusion in differentiating the intermediate categories. DeBERTa-base and BGE-m3-zeroshot, on the other hand, seem to struggle more with distinguishing the "Opponent" and "Irreconcilable" classes, with a more scattered distribution of errors.

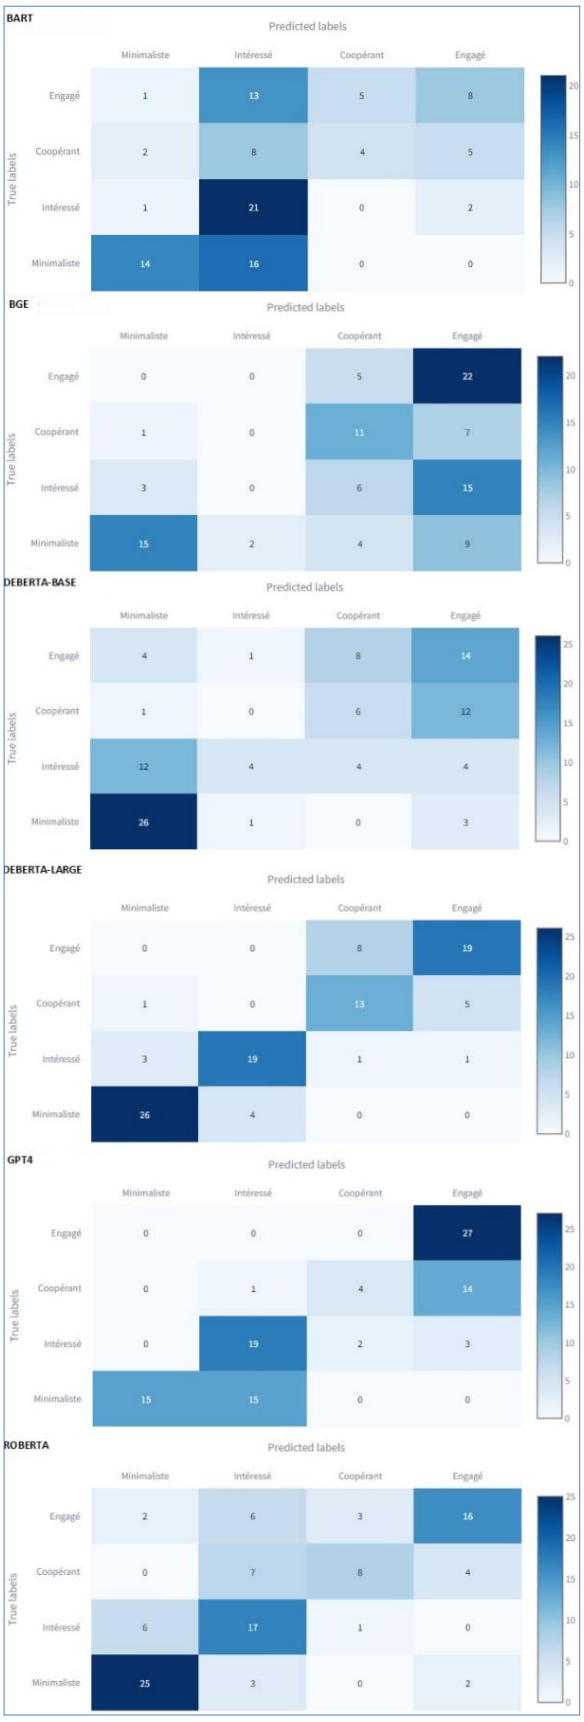

Fig. 6. Confusion matrices for LLM classification results of Task 1.

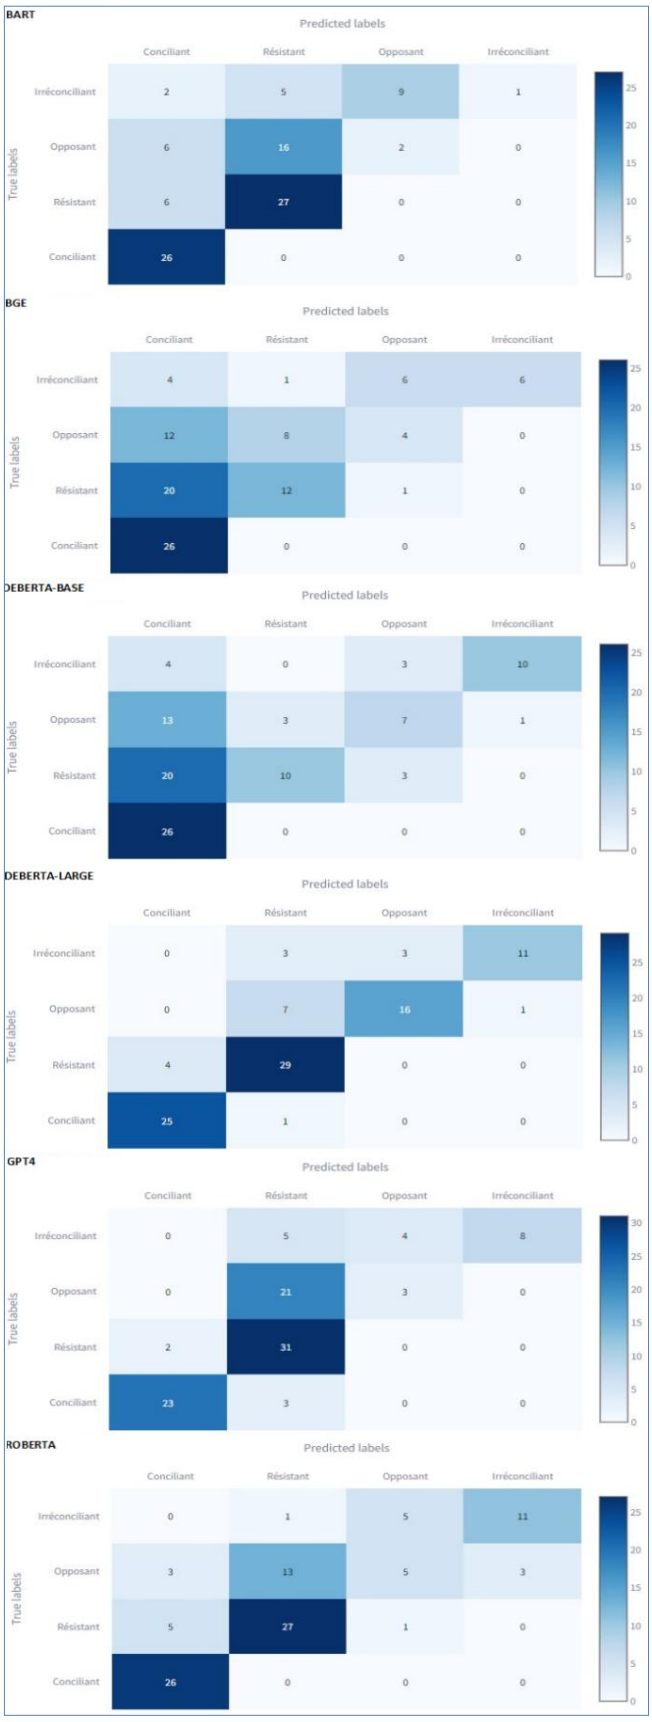

Fig. 7. Confusion matrices for LLM classification results of Task 2.

The results show that the DeBERTa-v3-large-zeroshot model stands out as the best model in terms of F1-score and precision for both synergy classification and antagonism classification tasks, particularly under the explicit prompt. This reflects a good balance between precision and recall. In comparison with modern language models like OpenAI/GPT-4, DeBERTa-v3-large-zeroshot achieves more robust results on these tasks, suggesting that models specifically designed for zero-shot tasks can surpass models like OpenAI/GPT-4 in certain classification contexts without requiring additional fine-tuning. GPT-4, on the other hand, although slightly behind in terms of F1-score, boasts significantly higher precision. This means it generates fewer false positives, demonstrating its ability to minimize false predictions and better handle errors. In addition, RoBERTa-large-zeroshot has a slightly higher F1-score than GPT-4, but lower precision. GPT-4 therefore, remains more accurate, illustrating a difference in the way these models optimize their classification decisions.

In contrast, the Facebook/bart-large-mnli and bge-m3-zeroshot-v2.0 models show significantly lower performance in F1-score and precision, indicating greater difficulty in correctly capturing the right classes and reducing classification errors.

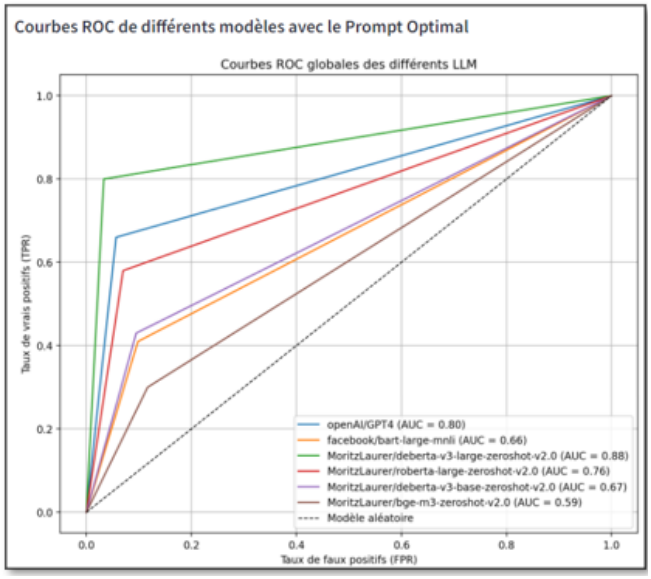

Fig. 8. ROC curves for LLMs.

These discussed findings are confirmed via a review of the Receiver Operating Characteristic Area Under the Curve (ROC AUC) measurements, which gauge the ability of the models to separate positive from negative classifications successfully (see Fig. 8). This analysis reveals that GPT-4 (AUC = 0.80) offers a better discrimination capacity than RoBERTa-large-zeroshot (AUC = 0.76). In fact, although its F1-score is lower, its high precision enables it to achieve a higher AUC, testifying to greater robustness in class distinction. However, DeBERTa-v3-large-zeroshot (AUC = 0.88) outperforms all other models, confirming that it simultaneously maximizes both sensitivity and specificity, making it the top-performing model in classification. In contrast, models like Facebook/bart-large-mnli (AUC = 0.66) and MoritzLaurer/bge-m3-zeroshot-v2.0 (AUC = 0.59) show weaker performance, with behavior closer to a random model in their ability to differentiate classes correctly. This is also reflected in their lower F1-scores and precision, indicating difficulties in accurately classifying positive classes.

VII. Conclusion and Perspectives

This study proposes a new approach for analyzing resistance to change in the context of digital transformation, relying on zero-shot language models (LLMs) and prompting techniques. Unlike traditional methods, which mainly use closed-ended questionnaires and binary classifications, limiting the expression and diversity of employee perspectives, our approach leverages the allies strategy to provide a more granular segmentation of employees' stances towards change. It does so by using open-ended responses for a more detailed and nuanced analysis. The use of specialized zero-shot LLMs in natural language inference, combined with specific prompts, allows for the automatic classification of these open-ended responses without the need for prior training on specific data.

To evaluate the performance of our methodology, we conducted an experiment on an annotated dataset consisting of a hundred employee responses to analyze the models' ability to accurately distinguish the expressed attitudes. Experimental results highlighted the importance of prompt formulation in improving classification accuracy. Specifically, we demonstrated that using explicit prompts optimizes model performance, particularly DeBERTa-v3-large-zeroshot, which emerged as the best-performing model in terms of F1-score and discriminatory power (AUC), surpassing GPT-4. These results also emphasize that, while generalist models like OpenAI/GPT-4 remain competitive, models specifically designed for zero-shot tasks can better meet the requirements of fine classification without requiring additional fine-tuning.

These findings open up several avenues for improvement. One avenue would be to refine the prompting instructions to better capture the nuances of employee responses, thereby optimizing model performance. Additionally, exploring hybrid approaches that combine zero-shot learning with supervised learning could further enhance the classification of stances toward change. Beyond textual analysis, one major research hurdle is blending in various assessment methods, like responses that rely on spoken language. By allowing employees to provide spoken feedback, it is possible to improve the richness of the input data while making the assessment process more inclusive for people with limited writing skills. Finally, applying this methodology to larger and more diverse datasets would allow for evaluating its generalization to different organizational contexts.

Thus, this study demonstrates that zero-shot LLMs, coupled with prompting techniques and the allies strategy, represent a step forward in automating the assessment of resistance to change, providing businesses with a more effective decision-making tool in supporting their digital transformations.

***Abstract*—Road traffic accidents are a significant public health issue, particularly in developing nations, where infrastructure and traffic monitoring systems may be limited. Risky situations including sudden stopping, lane switching, and near-misses can lead to accidents. In this study, we present an original approach for recognizing risky situations in road traffic sequences using Video Masked Autoencoder (VideoMAE), a self-supervised deep learning model built upon Vision Transformer architecture. By applying a pre-trained VideoMAE on a large dataset of videos and fine-tuning it on labeled traffic sequences categorized as risky or non-risky, our model learns spatiotemporal features without requiring extensive manual labeling. The method achieves high accuracy on testing data, demonstrating strong potential for high-risk detection with an accuracy of 95%. This study highlights the promise of self-supervised video representation learning for real-world safety applications and paves the way for the development of intelligent traffic monitoring and crash prevention tools.**

***Keywords*—Video processing; risk detection; VideoMAE; vision transformer; deep learning; computer vision**

I. Introduction

Road accidents are a significant public health concern, with an estimated 1.24 million lives lost to road traffic accidents annually, according to the World Health Organization (WHO)[1]. Hazardous road traffic situations, including rapid braking, lane changes, and near-misses, can lead to accidents. Therefore, it is crucial to develop techniques for detecting and preventing such situations.

Computer vision and artificial intelligence have advanced significantly in recent years, particularly in applications requiring automated interpretation of visual scenes. Traffic scene analysis is one such domain, playing a critical role in road safety and intelligent transportation systems. While notable progress has been made, detecting and predicting hazardous situations—such as sudden braking, lane changes, or near-crash events—remains challenging due to the dynamic and complex nature of real-world traffic environments.

Despite modern advances, existing approaches exhibit several limitations. Most rely on supervised learning, which requires large, labeled datasets that are both costly and time-consuming to produce. Furthermore, many methods focus primarily on object recognition (e.g., identifying pedestrians or vehicles) while overlooking the temporal dynamics and interactions that are crucial for assessing risk in time-varying scenes. As a result, there is a gap in the literature regarding models capable of learning meaningful patterns from unlabeled video data or operating effectively with limited annotated datasets.

To address these challenges, self-supervised learning approaches offer a promising alternative. By reducing or eliminating the need for manual labeling, they present a more efficient and scalable solution for training models in complex traffic scenarios. Video Masked Autoencoder (VideoMAE) is one of the self-supervised learning techniques that has proved to be useful for many different tasks [2], including motion estimation, object detection, and video classification. VideoMAE learns video representations by predicting masked patches in the input videos. These learned representations prove valuable for various downstream tasks, including detection, classification, and segmentation.

In this study, we propose a method based on VideoMAE for detecting risky situations in road traffic sequences. By leveraging VideoMAE's ability to learn rich spatiotemporal features from video data. We train the model on a set of road traffic sequences, which are labeled as risky or non-risky. After the model is trained, it can be employed to find risky conditions in new road traffic sequences. This method not only reduces the reliance on labeled datasets but also improves generalization across diverse environments.

Our contributions are as follows:

- We propose a novel method to detect risky situations in road traffic sequences using VideoMAE.
- We train a VideoMAE model on a small dataset of road traffic sequences (fine-tuning).
- We evaluate our model on a held-out test set.

The rest of this study is organized as follows: In Section II (Related Work), we review existing approaches used for detecting risky situations in road traffic and highlight their limitations; Section III (Method) introduces the VideoMAE model, detailing its architecture and the preprocessing steps applied to the video data; Section IV (Experiment and Results) presents the experimental setup as well as the quantitative and qualitative results; Section V (Discussion) provides an analysis of the results; and Section VI (Conclusion) summarizes the key findings of our research and suggests areas for further

exploration to enhance the model's performance and applicability in real-world traffic safety applications.

II. Related Work

There are a number of existing methods for detecting risky situations in road traffic [3], [4], [5], as well as others that consider road accident classification a pivotal field of study [6], while some studies have focused on driving behavior [7], [8]. These methods can be broadly divided into two categories: traditional methods and machine learning methods.

The classical approach to detecting hazardous road traffic situations relies on handcrafted features, such as vehicle speed, position, and acceleration [9]. These features are then used to train a classifier model to predict the risk level of a given situation.

Machine learning algorithms for detecting dangerous situations on the road often employ deep learning models that automatically learn features from the data [5], [10]. These models are typically trained on small datasets of traffic monitoring videos [11]. The most widely used machine learning techniques for this task are Convolutional Neural Networks (CNNs)[11] and Recurrent Neural Networks (RNNs) [12]. CNNs are deep learning models particularly well suited for processing images and videos [13]. They have proven effective in various road traffic safety applications, such as vehicle detection, road sign recognition, and lane detection[11]. RNNs, on the other hand, are better suited for tasks involving sequential data, such as traffic flow forecasting and vehicle tracking [14].

Recently, there has been growing evidence of the success of self-supervised learning in a variety of computer vision tasks [15], [16], including object detection, motion estimation, and video classification. Self-supervised learning techniques automatically learn representations from data without the need for human-labeled annotations. One of the most widely used self-supervised learning techniques is VideoMAE[2]. VideoMAE learns to represent videos by predicting masked-out patches within the video frames. These learned representations can then be used for several downstream tasks, including classification, detection, and segmentation.

To the best of our knowledge, VideoMAE has not yet been applied to detect unsafe conditions in road traffic sequences. However, its demonstrated success in other domains suggests that it could be an effective model for identifying hazardous situations in traffic scenes.

In this study, we explore the use of VideoMAE for detecting risky situations in road traffic sequences. We fine-tune the VideoMAE model on a dataset of road traffic sequences labeled as either "risky" or "non-risky". Once trained, the model can be used to detect hazardous conditions in previously unseen traffic sequences. We believe that this approach could become a valuable tool for developing innovative safety solutions in the domain of road traffic management.

III. Method

In this section, we present our proposed approach, which involves fine-tuning the VideoMAE model using a dataset of risky road traffic situations. The model achieved an accuracy of 0.95 on both the validation and testing datasets. Fig. 4 illustrates the diagram of the proposed technique. First, we review VideoMAE[2], which is based on ImageMAE[17].

A. Masked Autoencoder (ImageMAE)

The Masked Autoencoder (MAE) [17] is a neural network architecture designed to learn meaningful latent representations from data and map them to a high-dimensional space using large datasets. It operates on the principle of randomly masking portions of the input image and then reconstructing the missing regions. The model follows a key design principle: an asymmetric encoder–decoder architecture. The encoder processes only the visible (unmasked) patches, while the lightweight decoder reconstructs the complete image using the latent representations along with the mask tokens.

It randomly masks out 75% of the grid patches for reconstruction, creating a challenging and meaningful self-supervised learning task. Masked autoencoders have proven to be scalable self-supervised models for a wide range of computer vision applications. This strategy is widely adopted because of its simplicity and effectiveness.

B. Video Masked Autoencoder (VideoMAE)

Video Masked Autoencoder (VideoMAE) [2] is an efficient self-supervised learning framework for video pre-training tasks that promotes the extraction of more informative video representations. Remarkably, it delivers strong performance even when trained on limited datasets, without relying on additional external data (i.e., fully self-supervised). The model is inspired by ImageMAE [17].

VideoMAE performs video self-supervised learning using a straightforward Vision Transformer (ViT) [18] backbone combined with a basic masked autoencoder. Due to its extremely high masking ratio, VideoMAE achieves a significant reduction in pre-training time compared to contrastive learning techniques, approximately a 3.2× speedup.

The architecture of VideoMAE includes three key components: an encoder network, a decoder network, and a masking mechanism. The encoder processes input video frames, extracting hierarchical features that capture both spatial and temporal dependencies within the sequences. These encoded features are then passed to the decoder, which reconstructs the original video frames while minimizing reconstruction error. Fig. 1 illustrates the model architecture based on VideoMAE. This self-supervised approach enables VideoMAE to effectively capture nuanced behaviors and subtle indicators of risky situations in traffic videos, such as sudden braking, lane changes, wrong-direction driving, or accidents. Moreover, its ability to learn from unlabeled data reduces the dependency on large annotated datasets, making it scalable and adaptable to various traffic scenarios.

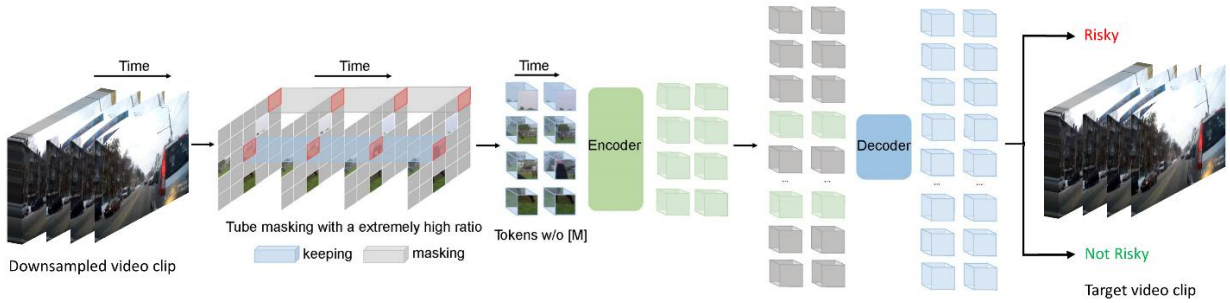

Fig. 1. Used model architecture based on video masked autoencoder.

Given these advantages, we assert that VideoMAE has strong potential as a powerful tool for detecting risky situations in road traffic sequences.

C. Data collection (Datasets)

To validate the effectiveness of the proposed model, we conduct experiments on large-scale datasets. Due to the limited availability and quality of publicly available datasets related to risky situations in road traffic, we collected and created our own data from various sources. This dataset comprises a combination of publicly available traffic video datasets. Public datasets such as the Car Crash Dataset (CCD), which is designed for traffic accident anticipation [14]; XD-Violence[19], a large-scale audio-visual violence detection dataset; and CADP [20], a dataset for accident analysis based on CCTV traffic cameras, provide a rich collection of annotated video sequences captured from various traffic scenarios. These datasets offer diverse examples of road conditions, vehicle interactions, and environmental factors. Moreover, the cameras continuously record traffic flow, capturing various risky situations such as sudden lane changes, speeding, and near-miss collisions. Fig. 2 shows some samples of risky situations from the dataset used.

Fig. 2. Samples of various risky situations on traffic roads from the used dataset.

D. Preprocessing

The collected video data undergoes several preprocessing steps, including frame extraction, resolution adjustment, and noise reduction, to ensure high-quality inputs for the VideoMAE model. This combination of diverse and comprehensive data sources enables a robust evaluation of the model's capability to detect risky situations in various traffic contexts.

The dataset contains videos with variable input frame sizes. Therefore, all videos are resized to a target resolution of 224×224 pixels. For the VideoMAE model, each input clip consists of sixteen frames. We use a frame rate of four, which defines the stride or interval between selected frames. From each video, we extract a single clip.

For training data transformations, we apply random cropping, pixel normalization, uniform temporal subsampling, and random horizontal flipping with a probability of 0.5. For the validation and evaluation datasets, we apply the same transformation pipeline, excluding random cropping and horizontal flipping, to ensure consistency during evaluation.

All preprocessing and data augmentation transformations are implemented using TorchVision's transforms module.

E. Training and Validation

The training process of the model begins with the preparation and preprocessing of the dataset, which includes frame extraction, resizing, and normalization. Typically, the dataset is divided into three subsets: training, validation, and test sets. The training set is used to train the VideoMAE model and contains a diverse range of traffic sequences, allowing the model to learn, reconstruct, and understand the underlying patterns in the data.

The validation set plays a crucial role in adjusting hyperparameters and monitoring the model's performance during training. The test set, which remains completely separate from the training and validation sets, serves as the final benchmark to assess the model's generalization ability to unseen traffic scenarios and its accuracy in detecting risky situations. Fig. 3 shows the distribution of data across each class for the three subsets of the dataset.

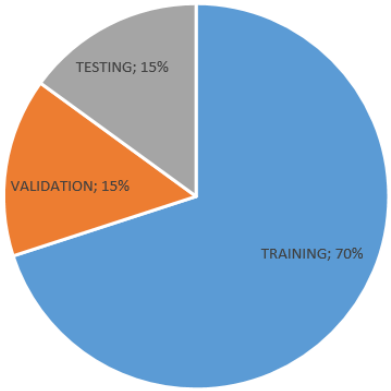

Fig. 3. Distribution of the used dataset.

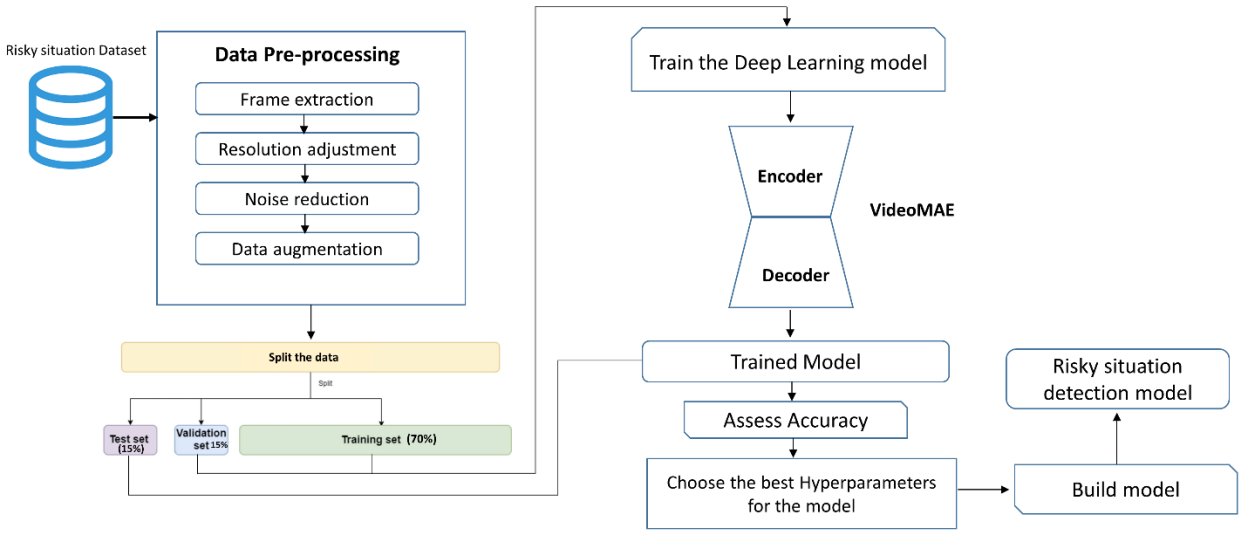

Fig. 4. Methodology diagram.

F. Evaluation Metrics

In this section, we present the metrics used to assess our model and analyze the implemented method.

Accuracy: It is an evaluation metric that measures the ratio of correctly classified sequences to the total number of sequences. It provides an assessment of how well the model's predictions align with the ground-truth annotations. In the context of video classification, accuracy is defined as the proportion of video sequences that are correctly classified into their actual categories. It reflects the precision with which the predicted labels match the true labels across the video dataset.

$$Accuracy = \frac{Total\ of\ accurate\ predictions}{Total\ of\ predictions\ made} \quad (1)$$

Precision: It is the ratio of true positive predictions to the total number of positive predictions made by the model. It indicates how many of the instances predicted as positive are actually correct, providing insight into the reliability of the model's positive classifications.

$$Precision = \frac{True\ positive}{True\ positive + False\ positive} \quad (2)$$

Recall: It is a measuring metric that is the ratio of the true positives that were detected to the total actual number of the same class. It shows how good the model is at detecting instances of all categories.

$$Recall = \frac{True\ positive}{True\ positive + False\ negative} \quad (3)$$

F1-score: It is the harmonic mean of precision and recall. It provides a balanced measure of a model's performance. It is especially useful when there is an uneven class distribution or when both false positives and false negatives need to be considered equally important.

$$F1 - Score = 2\ x\ \frac{recall\ x\ precision}{recall + precision} \quad (4)$$

Confusion Matrix: The confusion matrix is an effective tool for evaluating classification tasks, as it provides a detailed summary of the model's performance. It records the number of true positives, true negatives, false positives, and false negatives, offering a comprehensive view of how well the model performs across different classes. This information enables the straightforward calculation of key evaluation metrics such as accuracy, precision, recall, and F1-score.

IV. Experiment and Results

A. Experiment and Results

The training of MAE models, especially in the context of video recognition, presents a substantial computational challenge, limiting access for researchers with limited resources. For instance, training a standard VideoMAE model on Kinetics-400 [21] requires a significant investment of up to 5.6 days with the support of 64 GPUs [22]. Therefore, we fine-tune a pre-trained VideoMAE model, which was pre-trained on the Kinetics-400 dataset for approximately 1600 epochs without any additional data. We add a randomly initialized classification head on top of the pre-trained encoder and fine-tune the model on a labeled dataset of risky situations. Additionally, we initialize the feature extractor associated with the model.

As a risk detection network, we aim to detect risky situations in road traffic sequences using VideoMAE, which is based on Vision Transformer [18]. The performance evaluation of the model on the Risky Road Traffic dataset showed the best detection performance, achieving an accuracy of 0.9 with the masking strategy.

We train our model using the PyTorch framework with an environment of 12GB of RAM and a GPU (Nvidia Tesla T4) to expedite computation and handle the complexity of video data processing.

The hyperparameter configuration for the VideoMAE model was carefully selected to optimize performance while maintaining computational efficiency. The Adam optimizer [23] was chosen for its ability to adaptively adjust learning rates during training. The learning rate was initially set to 5e-5, a value found to provide an optimal balance between fast

learning and avoiding overfitting. A weight decay of 0.05 was implemented to regularize the model and reduce overfitting potential by penalizing large weights and encouraging generalization. The batch size was set to two to prevent out-of-memory errors while maintaining a balance between computational resource limitations and gradient quality requirements. The model was trained for ten epochs, a duration sufficient for learning useful patterns without overfitting risk. A summary of these hyperparameters is provided in Table I.

TABLE I. THE HYPERPARAMETERS OF THE MODEL

Hyperparameter	Value
Optimizer	Adam
Weight decay	0.05
Learning rate	5e-5
Batch size	2
Epochs	10

This configuration enabled effective learning from traffic video sequences, achieving high accuracy in risky situation detection while maintaining robustness across diverse traffic scenarios.

B. Results

The experimental results on benchmark datasets demonstrate that our approach, which has minimal computational cost and efficient data, performs well in the unsafe situation identification task.

Epoch	Training Loss	Validation Loss	Accuracy
0	0.420000	1.151754	0.695652
1	0.422200	2.008217	0.619565
2	0.831100	0.158780	0.956522
3	0.290500	0.398978	0.923913
4	0.000300	0.573320	0.913043
5	0.001500	0.335427	0.956522
6	0.190500	0.357622	0.956522
7	0.000100	0.346179	0.945652
8	0.000100	0.304265	0.956522
9	0.000100	0.342376	0.956522

Fig. 5. Overview of the model's training process.

Fig. 5 presents an extensive description of the training of the model by tabulating the training loss, validation loss, and validation accuracy at each of the ten epochs. The training loss column follows the model's performance on the training data, showing an overall decline as the model improves at reconstructing the frames of the videos and recognizing risky situations. The validation loss column reports the model's validation set performance, which indicates how the model generalizes to new data after each pass through the epochs. The validation accuracy column reports the ratio of correct identification of risky situations on the validation set and is an unambiguous metric of the success of the model. Fig. 5 provides an overall trend of increasing validation accuracy as training advances, which flattens towards the end epochs, indicating the model's success at generalization of learned features. These metrics, together, provide a complete perspective on the learning and performance of the model during the training period.

Table II shows an overall assessment of the model's performance through various important metrics: Precision, Recall, F1-score, and Accuracy.

TABLE II. EVALUATION MODEL

Metric	Value
Precision	0.960
F1-score	0.955
Recall	0.954
Accuracy	0.95

Precision at 0.960 shows the model's capacity to accurately detect true instances of risky situations and hints at high accuracy with few false positives.

Recall at 0.954 indicates the model's capacity to detect the majority of actual risky situations and shows that it is efficient enough to capture most of the dangerous events in the traffic sequences.

The F1-score, determined as the harmonic mean of Precision and Recall, is at 0.955 and offers a balanced evaluation of the model's precision and recall performance.

Lastly, accuracy at 0.950 is the overall ratio of correctly classified instances, whether risky or non-risky. This high accuracy is an attestation to the model being consistent regardless of different scenarios.

All these metrics together illustrate the good performance of the model in detecting and classifying risky situations on the road successfully and verify its usability for real-world traffic safety improvement.

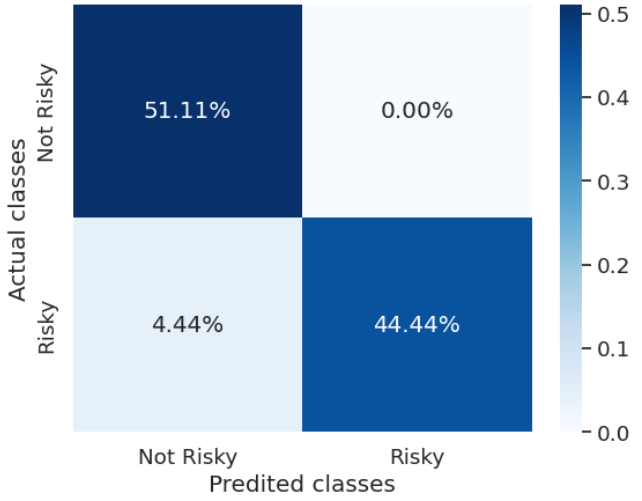

Fig. 6. Model evaluation using confusion matrix.

Fig. 6 indicates that the confusion matrix offers an insightful analysis of the model's performance by classifying the test results into true positives, true negatives, false positives, and false negatives.

The matrix shows that:

- The model successfully identified 44% of risky situations as true positives, demonstrating its strong capability to detect risky conditions in traffic sequences.
- The model correctly classified 51% of non-risky situations as true negatives, showing its good capability to identify safe conditions without false alarms.
- Notably, the model produced 0% false positives, meaning it never incorrectly labeled safe conditions as risky - a crucial factor for building confidence in the system's alerts.
- There were 4.44% false negatives, representing instances where the model failed to detect actual risky situations.

The trained model was tested on several video sequences to evaluate the proposed approach, and the results were collected and analyzed. The method demonstrates successful identification of dangerous traffic conditions in surveillance videos with 95% accuracy.

Fig. 7 illustrates the detection accuracy across multiple video sequences, showing that the model predicts correct situations with high probability.

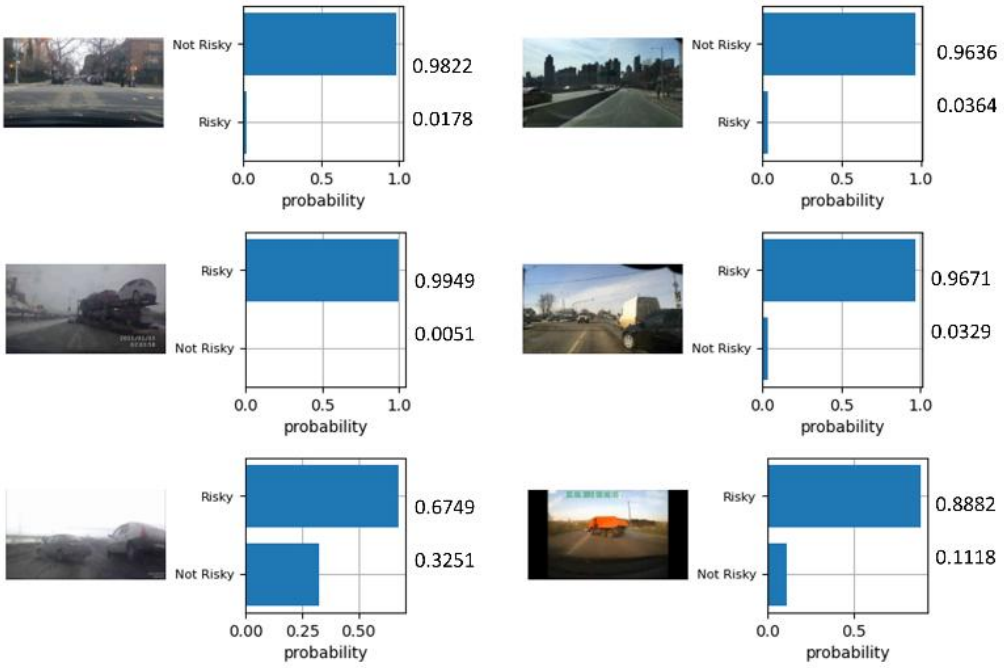

Fig. 7. Illustrations of many detection examples accompanied by the probability.

V. Discussion

The results obtained from the model highlight its strong potential to enhance traffic safety through the accurate detection of risky situations in road traffic sequences. The model's high Precision of 0.960 indicates its ability to correctly identify hazardous situations with minimal false alarms, which is critical in preventing unnecessary interventions. The Recall of 0.954 reflects the model's effectiveness in capturing nearly all actual risky situations, ensuring that critical events are not overlooked. The F1-score of 0.955 demonstrates a well-balanced performance between Precision and Recall, confirming that the model maintains consistency in identifying and classifying risks. Additionally, the accuracy of 0.95 indicates that the model performs reliably across different traffic scenarios. The confusion matrix also confirms these results with 44% true positives and no false positives. The absence of false alarms is essential for real-time traffic monitoring applications, since false alarms can cause driver desensitization or unjustified intervention. However, the model reported 4.44% false negatives, where it did not detect actual risky situations. This indicates that although the model is very accurate for the situations it does detect, there is further scope to improve its sensitivity to detect all potential danger areas. These results indicate the model's resilience but also the necessity for further improvement, specifically to increase its capability to detect all risky situations so that the occurrence of false negatives is minimized and overall traffic safety is comprehensive.

When compared to other methodologies for risky situation detection in road traffic, the model provides various improvements over previous approaches. The conventional approach tends to employ Convolutional Neural Networks (CNNs) to analyze single frames from traffic videos. Although CNNs are good at learning spatial features, they are weak at accounting for temporal dependencies between frames, since risky situations are often realized through unfolding events over time. To address the weakness of CNNs, Recurrent Neural Networks such as LSTM[24] networks are sometimes

employed together with CNNs to consider the temporal aspect. However, these models tend to perform poorly with long-range dependencies and are prone to vanishing gradients, thus unable to adequately understand intricate, multi-frame traffic situations.

By contrast, VideoMAE is transformer-based and specifically designed to model both spatial and temporal dependencies simultaneously. This enables the model to capture sequences of events in traffic, like an abrupt stop of a car or the appearance of a pedestrian on the roadway, which may not be detected or well-represented using standard CNN or RNN-based approaches.

In further testing the efficacy of our approach, we compared the model's performance with that of a Vision Transformer (ViT) model that has also been used for detecting risky situations from videos. As evident from Table III, our model performs significantly better than the ViT-based approach and other deep learning based methods, achieving 95% accuracy compared to 92% for the ViT model[25]. In addition, the work presented in [26], which aimed to predict traffic accidents using an RNN network, achieved an accuracy of 71%. In [27], the authors used a combination of models, including a multi-layer perceptron (MLP), and achieved an accuracy of 72%. Moreover, another study focused on road accident prediction by combining machine learning and deep learning models, specifically the RFCNN model [28], and achieved an accuracy of 81%. These values demonstrates VideoMAE's superior capability to handle both spatial and temporal dependencies in traffic sequences.

TABLE III. MODEL COMPARISON

Model	Accuracy
RNN[26]	71%
MLP[27]	72%
RFCNN[28]	81%
FN-ViT[25]	92%
Ours	**95%**

VI. CONCLUSION

In summary, the findings of this study demonstrate the capability of the VideoMAE-based model to detect risky conditions in road traffic streams and its potential contribution to enhancing traffic safety through advanced video data processing. The strong performance of the model, reflected by high Precision, Recall, and F1-score values, highlights its ability to accurately identify dangerous situations.

While the system demonstrates strong potential and high accuracy, a few drawbacks or areas for improvement have been identified. First, the training process is computationally intensive. Second, there is the occurrence of false negatives, where some risky situations go undetected, highlighting the need for improved sensitivity, particularly in complex traffic scenes. Nevertheless, integrating the model into real-time traffic monitoring systems holds significant promise for improving road safety by enabling early warnings and reducing the risk of accidents.

Overall, this work offers valuable insights into the application of deep learning for traffic safety and paves the way for future advancements in intelligent transportation systems.

***Abstract*—Vehicle classification offers intelligent solutions for road traffic monitoring by enabling future prediction planning and decision making. Predictive analytics can be used to predict traffic congestion based on the types of vehicles on the road. In this research, the reliability of deep learning based models for vision-based vehicle classification is investigated. Four models of You Only Look Once (YOLO) are investigated, namely YOLOv5s, YOLOv5x, YOLOv10n, and YOLOv12n. These models were trained and evaluated on a vehicle dataset comprising five vehicle classes, which are Ambulance, Bus, Car, Motorcycle, and Truck, with a total number of 1103 images. From the experiment conducted, YOLOv10n achieved the highest performance measure of mAP@0.5 with 0.859 across all vehicle classes, including per-class evaluation, demonstrating superior detection compared to the other models. Finally, the results indicate that the YOLOv10n model can be used in vision-based vehicle classification.**

Keywords*—YOLO; vehicle classification; deep learning; traffic monitoring

I. Introduction

Vision-based vehicle classification offers an intelligent solution for transportation systems, thus contributing to road traffic monitoring for the development of smart cities [1],[2],[3]. With the growing number of vehicles on the road, efficient and accurate vehicle classification systems are essential for managing urban mobility, enhancing public safety, and reducing traffic congestion [4],[5],[6]. Vehicle detection technologies involve the use of cameras and vision sensors to capture road footage, which is then analyzed to detect, classify, and track the movement of vehicles [7],[6]. Using these technologies may improve traffic control for future planning and decision making based on the current vehicle data on the road [8], [9]. Further data analytics can also be performed based on the current vehicle data on the road for traffic monitoring [10]. The analytics process identifies the patterns and learns for future planning and prediction, which helps to improve road traffic monitoring.

For this reason, a vision-based vehicle classification is proposed. The vision-based vehicle classifications are designed based on a deep learning method. The model of the deep learning methods are evaluated to determine the best vision-based classification for detecting types of vehicle. The deep learning method is chosen in this research due to its ability to detect objects in more complex environments under varying environmental conditions. In vehicle classification, the detection of vehicles especially on this condition is important. Failure to detect these may reduce the classification accuracy.

This research focuses on the detection of suitable methods that are able to increase the aforementioned classification accuracy in small sample vehicle dataset images. A small sample dataset of vehicles (1103 images) was utilized in this research as a proof-of-concept to classify vehicle images. To suite the problem stated previously, we investigate the deep learning based method, particularly Convolutional Neural Networks (CNNs). The CNN is chosen as it is able to provide a more robust alternative by learning discriminative features directly from images, enabling more accurate detection and classification. The CNN model has emerged as a powerful alternative due to its ability to learn spatial hierarchies of features directly from image data [11]. Among the CNN deep learning based object detection frameworks, the model You Only Look Once (YOLO) is the most suitable method for real-time vehicle detection tasks as it is able to balance between speed and accuracy, making it highly suitable [12]. This research investigates deep learning YOLO models, namely, YOLOv5s, YOLOv5x, YOLOv10n, and YOLOv12n, for vehicle classification. Each of these models are trained using pretrained weights to reduce training time while maintaining accuracy during the transfer learning. These models are tested using a vehicle dataset consisting of five types of vehicles, which are Ambulance, Bus, Car, Motorcycle, and Truck.

The rest of this study is organized as follows: Section II presents the related works. Section III describes the materials and methods used. The results are presented in Section IV, followed by the discussion in Section V. Finally, the conclusion and future work are presented in Section VI.

II. Related Works

Vehicle detection plays a vital role in intelligent transportation systems to enable intelligent solution for road traffic monitoring [13]. The computer vision method is used to detect the vehicle on a road traffic. In early research, the commonly used methods for vehicle detection are background subtraction, edge detection, and Haar Cascades [5,6,14]. Although these methods are computationally efficient, they were less effective in detecting the images under varying environmental conditions, such as changes in illumination, shadows, and occlusion, thus limiting their effectiveness in real-world scenarios [15].

In more recent object recognition method, the deep learning method have gain attention due to its ability to detect object in most classification task. Compared to other methods such as edge detection and background subtraction method, the CNN

method is one of the most reliable deep learning based method which provides more accurate detection and classification. The other methods often shown to be less effective in detecting the object under varying environmental conditions and in real-time, dynamic environments due to their sensitivity to lighting conditions and noise [11,16]. In the CNN deep learning based object detection frameworks, the YOLO models are widely used for object detection due to their ability to balance between speed and accuracy. It is also suitable for real-time detection [12]. Although the other models of the CNN method, such as R-CNN, Fast R-CNN, and Faster R-CNN, demonstrated significant improvements in accuracy detection by learning hierarchical features from the data, these models rely on region proposals that led to slower inference speeds, making them less suitable for real-time detection tasks [8,9,17]. On the other hand, the YOLO models enable fast and accurate detection in a single pass over the image. YOLO is a single-stage object detection framework that performs both object localization and classification in one forward pass through the network [18]. This design makes the YOLO model efficient for real-time applications such as traffic surveillance and vehicle monitoring. Unlike two-stage detectors like R-CNN, which separate the tasks of region proposal and classification, YOLO treats detection as a single regression problem, mapping image pixels directly to bounding box coordinates and class probabilities. This architecture offers faster inference times and smaller model sizes, making YOLO ideal for the deployment of edge devices and in time-sensitive environments. Different YOLO variants offer different unique strengths and limitations. The challenge is in selecting the most suitable model that is able to balance accuracy with computational time performance while maintaining a high classification.

The YOLO variants, such as YOLOv3 and YOLOv4 models, strike a balance between speed and precision [19]. While YOLOv5 series models improve the limitation by architectural optimizations and improved training strategies [11,12]. Among the YOLOv5 series, YOLOv5s and YOLOv5x provide trade-offs between computational efficiency and accuracy, making them ideal for both edge and cloud-based deployments. The YOLOv5s model is a lightweight YOLO architecture and one of the smallest models in the YOLOv5 variant. YOLOv5s model offers fast training and inference with minimal resource consumption. This makes the model an excellent starting point for experimentation and prototyping, especially when assessing trade-offs between speed and accuracy. On the other hand, YOLOv5x is designed to maximize detection accuracy and mean Average Precision (mAP). It represents the upper bound of the YOLOv5 variants, with deeper architecture and more parameters. However, the YOLOv5x model requires a higher computational cost and longer inference time. Recent variants such as YOLOv10 and YOLOv12 continue to improve the YOLO performance by optimizing depth, parameter count, and inference speed, especially to be implemented in resource-constrained environments [20]. YOLOv10 model is a lightweight model but is able to offer high performance [20]. The model is optimized for low-latency, high-efficiency deployment, particularly on edge devices. It offers better performance-per-FLOP than earlier nano-scale models such as YOLOv5s. The YOLOv10 is built to deliver real-time performance without reducing its accuracy performance. Compared with the other earlier YOLO model such as YOLOv5s, YOLOv10 model improve the model architecture and enhance the efficiency and accuracy even in a compact model. The latest generation nano-scale model in YOLO variant is the YOLOv12n model. This model been designed as a compact real-time model that able to offer high efficiency and competitive accuracy. The YOLOv12n model incorporating attention-centric modules for smarter and more selective feature extraction [21].

Despite all these improvements, object recognition remains challenging, particularly in scenarios involving large and complex object images. The detection accuracy often drops significantly for large objects under poor lighting conditions, especially in large object images taken during night conditions, due to increased noise and reduced contrast in large object images [22].

From the above review, the YOLO model is seen to be the most suitable model for vision-based vehicle classification due to its capability to perform both object localization and classification in one forward pass through the network. This design makes YOLO model suitable and efficient for real-time applications such as traffic surveillance and vehicle monitoring. Therefore, in this research, the YOLO variants are investigated to detect and classify the vehicle, particularly for large vehicle images.

III. Materials And Methods

Generally, the proposed work can be divided into two phases: detection and classification. In this research, four YOLO models are evaluated, which are YOLOv5s, YOLOv5x, YOLOv10n, and YOLOv12n. The overall scheme for the vehicle classification models evaluated is shown in Fig. 1. Each of these models is selected due to its popularity and stability for the object classification task. The YOLOv5s is selected as it offers fast training and inference with minimal resource consumption. The YOLOv5s is the smallest model in the YOLOv5 variant. This makes an excellent starting point for experimentation and prototyping, especially when assessing trade-offs between speed and accuracy. While the YOLOv5x model requires higher computational, and longer inference time. The YOLOv5x model represents the upper bound with deeper architecture and more parameters. Although it requires higher computational resources, YOLOv5x is designed to maximize detection accuracy and mean Average Precision (mAP). On the other hand, YOLOv10n and YOLOv12n models are chosen due to these models are the recent iterations of YOLO variants that optimize depth, parameter count, and inference speed in the YOLO architecture.

The model architecture of vehicle classification using YOLOv5s, YOLOv5x, YOLOv10n, and YOLOv12n are shown in Fig. 2(a), Fig. 2(b), Fig. 2(c) and Fig. 2(d). As shown in Fig. 2, each of the models consist three main parts which are backbone network, neck network and detection head. The backbone network is the first step in YOLO model architecture, where the features extracted from the vehicle input images. Then, the feature fusion in the neck part, where feature maps from different scales of the backbone network are fused to a neck network to process the detection. The head part completes the final prediction which includes the bounding boxes and the

associated class labels to obtain the detection result. Three different scales of detection heads are used to detect small, medium and large vehicles.

To demonstrate the reliability of the selected model for vision-based vehicle classification, a series of comprehensive experiments is conducted. All the YOLO models are trained using Google Colab with GPU acceleration, and the dataset tested is annotated using CVAT.ai and hosted on Roboflow for streamlined training and validation. The training environment includes dependencies of torch, numpy, opencv, and the official YOLO repositories for each YOLO version.

The dataset used in this research consists of 1103 annotated images categorized into five vehicle types which are Ambulance (161 images), Bus (84), Car (321), Motorcycle (247), and Truck (290). These images were manually curated to ensure balanced class representation and relevance to real-world conditions. Each image was manually labelled with bounding boxes and associated class labels using CVAT.ai (Computer Vision Annotation Tool), an open-source tool suitable for precise object detection annotation. Bounding boxes were drawn around each vehicle, and class names were assigned to each types of vehicle accordingly. The properties of the dataset used are shown in Table I.

To train and evaluate the models effectively, the dataset was divided into training, validation and test set with a ratio of 70%, 20% and 10% as shown in Table II.

This dataset is split to ensure all classes are proportionally represented in each set, for effective training and accurate performance evaluation. There are two processes applied on all the images used in the experiment, which are auto-orientation

and resize. The auto-orientation is applied to ensure that all images are correctly aligned based on EXIF metadata, to avoid misalignment issues during the training phase. All the images are also resized to fit into the YOLO models, which requires fixed size of input. All images were resized to 640×640 pixels to fit into the YOLO model input layer while maintaining acceptable aspect ratios for object preservation. These pre-processed datasets allowed uniform input across all models to ensure a fair comparison. To ensure a fair comparison in the model configuration, the same training parameters settings used in all YOLO models tested as listed in Table III.

TABLE I. DATASET DISTRIBUTION

Classes	Number of Images
Ambulance	161
Bus	84
Car	321
Motorcycle	247
Truck	290
Total	1103

TABLE II. DATASET SPLIT

Dataset Split	Training Set (70%)	Validation Set (20%)	Test Set (10%)
Images	772	221	110

TABLE III. PARAMETER SETTING FOR YOLO MODELS TRAINING

Model / Parameter	YOLOv5s	YOLOv5x	YOLOv10n (Selected Model)	YOLOv 12n
Image Size	640×640 pixels	640×640 pixels	640×640 pixels	640×64 0 pixels
Epoch Size	50	50	50	50
Batch Size	15	15	15	15
Pretrained Weights	Enable	Enabled	Enabled	Enabled

In this research, Roboflow was used to provide seamless dataset integration into the YOLO training scripts. Each model was saved as best.pt, representing the model weights with the highest validation performance during training.

IV. RESULTS

In all the experiments, the performance of each YOLO models on the vehicle classification are measured in terms of Precision, Recall, Mean Average Precision (mAP), and Training Time. Precision measures the proportion of true positive detections among all positive predictions and evaluates how many vehicles were correctly identified. On the other hand, recall evaluates the correctly identify all actual vehicle instances in the dataset. It is the proportion of true positive detections out of all actual positive instances. While the Mean Average Precision (mAP) is also considered in this research since most of the work related with object detection from the literature use mAP to evaluate performance measure in their work [27,28]. In all the experiment conducted, the Training Time had also been recorded to measure the suitability of each of the model for the deployment under limited time or processing power environments. Models with a less Training Time and able to maintain high detection accuracy are more practical to be implemented in real-time or resource-sensitive applications. The classification performance of all models are defined as follows:

$$Precision = \frac{True\ Positive}{True\ Positive + False\ Positive} \quad (1)$$

$$Recall = \frac{True\ Positive}{True\ Positive + False\ Negative} \quad (2)$$

$$mAP = \frac{1}{n}\sum_{k=1}^{k=n} AP_k \quad (3)$$

$$AP_k = the\ AP\ of\ class\ k, n = the\ number\ of\ class$$

The models are trained and evaluated on a vehicle dataset image that consists of five vehicle classes. The performance of each model, namely YOLOv5s**,** YOLOv5x, YOLOv10n, and YOLOv12n, is presented in Table IV.

TABLE IV. COMPARATIVE RESULTS (PRECISION, RECALL, TIME, MAP@0.5) FOR YOLOV5S, YOLOV5X, YOLOV10N AND YOLOV12N

Models	Precision	Recall	Training Time (hrs)	mAP@0.5
YOLOv5s	0.823	0.882	0.263	0.763
YOLOv5x	0.921	0.909	1.222	0.855
YOLOv10n (Selected Model)	0.912	0.886	0.296	0.859
YOLOv12n	0.925	0.883	0.350	0.832

As shown in Table IV, the YOLOv10n model demonstrates superior performance among all the models tested with 0.859 of mAP@0.5. This is followed by the YOLOv5x model with 0.855 of mAP@0.5 and the YOLOv12n with 0.832 of mAP@0.5. The lowest mAP@0.5 is observed in the YOLOv5s model with 0.763 mAP@0.5. YOLOv10n model has shown to be the most optimum model with highest maAp@0.5 of 0.859 obtain in a less Training Time requires to train the models. The lowest Training Time among all the models is the YOLOv5s model, with 0.263hours. This is followed by the YOLOv10n model with 0.296 hours of Training Time. Only a minimal difference is observed between the YOLOv10n model with YOLOv5s model which less than 0.033 hours Training Time between the YOLOv10n model. Despite the YOLOv10n model being smaller than the YOLOv5 model variant, the YOLOv10n model is able to achieve the highest maAp@0.5 with only 0.263 hours of Training Time taken. The YOLOv10n model is superior compared to the other models in terms of both maAp@0.5 and Training Time. The results show that the YOLOv10n model is suitable for use in real-time applications and edge deployments. On the other hand, YOLOv12n outperformed the mAP@0.5 of YOLOv5s models while maintaining a much smaller size. Although YOLOv5s is the fastest model, it shows the lowest mAP@0.5 with 0.763. The YOLOv5s model is able to obtain faster training time due to its lightweight baseline model, making it able to train the model faster. However, the lowest mAP@0.5 is observed in the model.

To further investigate the performance of each models, the models are further evaluated on the specific class performance for each of the five vehicle classes which are Ambulance, Bus, Car, Motorcycle and Truck. Their results of precision, recall and map@0.5 are presented in Table V.

TABLE V. COMPARATIVE RESULTS PER-CLASS PERFORMANCE (PRECISION, RECALL AND MAP@0.5) FOR YOLOV5S, YOLOV5X, YOLOV10N AND YOLOV12N

Class	Models	Precision	Recall	mAP@0.5
Ambulance	YOLOv5s	0.771	0.882	0.916
	YOLOv5x	0.908	0.971	0.987
	YOLOv10n (Selected Model)	1.00	0.932	0.979
	YOLOv12n	0.967	0.864	0.933
Bus	YOLOv5s	0.835	0.954	0.929
	YOLOv5x	0.928	0.954	0.984
	YOLOv10n (Selected Model)	0.890	0.969	0.979
	YOLOv12n	0.914	0.985	0.986
Car	YOLOv5s	0.765	0.938	0.910
	YOLOv5x	0.859	0.837	0.927
	YOLOv10n (Selected Model)	0.902	0.822	0.928
	YOLOv12n	0.922	0.849	0.920
Motorcycle	YOLOv5s	0.904	0.846	0.947
	YOLOv5x	1.00	0.911	0.984
	YOLOv10n (Selected Model)	0.937	0.846	0.966
	YOLOv12n	0.958	0.873	0.971
Truck	YOLOv5s	0.840	0.789	0.897
	YOLOv5x	0.909	0.873	0.929
	YOLOv10n (Selected Model)	0.829	0.860	0.952
	YOLOv12n	0.863	0.842	0.917

From Table V, the YOLOv5x model give the best performance in Ambulance class with 0.987 of mAP@0.5. This is followed by YOLOv10n model with 0.979 of mAP@0.5, YOLOv12n model with 0.933 of mAP@0.5. The lowest mAP@0.5 for Ambulance class is observed in YOLOv5s model with 0.916. While in Bus class, YOLOv12n model is outperformed the other models with 0.986 of mAP@0.5. This is followed by YOLOv5x model with 0.984 of mAP@0.5, YOLOv10n model with 0.979 of mAP@0.5. The lowest mAP@0.5 for Bus class is observed in YOLOv5s model with 0.929 of mAP@0.5. For Car class, YOLOv10n models is outperformed the other models with 0.928 of mAP@0.5. This is followed by YOLOv5x model with 0.927 of mAP@0.5, YOLOv12n model with 0.920 of mAP@0.5. The lowest mAP@0.5 for Car class is observed in YOLOv5s model with 0.910 of mAP@0.5. On the other hand, for Motorcycle class, YOLOv5x models is outperformed the other models with 0.984 of mAP@0.5. This is followed by YOLOv12n model with 0.971 of mAP@0.5, YOLOv10n model with 0.966 of mAP@0.5. The lowest mAP@0.5 for Motorcycle class is also observed in YOLOv5s model with 0.947 of mAP@0.5. Lastly, for the Truck class, the highest performance of mAP@0.5 is YOLOv10n model. This is followed by YOLOv5x with 0.929 of mAP@0.5, YOLOv12n model with 0.917 of mAP@0.5. The lowest mAP@0.5 for Truck class is also observed in YOLOv5s model with 0.897 of mAP@0.5. Among all the models tested across all five vehicle classes, YOLOv10n model is seen to be the most optimum models as it is able to achieve the highest mAP@0.5 for the two classes which are Car and Truck classes. While the lowest model which can be observed for all the five tested vehicle class is the YOLOv5s model.

V. DISCUSSION

Overall, YOLOv10n model demonstrate superior performance of mAP@0.5 among all the models for all evaluation including the per-class performance evaluation from the experiments conducted. While the lowest mAP@0.5 results are observed in YOLOv5s for all performance evaluations. The highest performance can be seen on YOLOv10n model due to its improvement in the model architecture that enhance both efficiency and accuracy. The model is able to balance trade-off between speed and accuracy while retaining its compact versions. Although the YOLOv10 model is a lightweight, the model able to obtain high-performance due to the model architecture that is optimized for low-latency, better performance-per-FLOP than earlier nano-scale models like a YOLOv5s. The YOLOv10 model is built to deliver real-time performance without reducing its accuracy performance [20]. From the experiment conducted, the lowest performance is observed in YOLOv5s models due to its lightweight, simplicity and it is the smallest YOLO architecture, thus reducing its recognition performance. The YOLOv5s and YOLOv5x model is shown to be less effective especially on detecting the large vehicle images such as Truck vehicle. YOLOv5x model obtain low confidence score detection on truck that is clearly present in the image. On the other hand, the YOLOv10n model able to obtain high confidence score detection and able to detect most of the truck. This is followed by the YOLOv12n model. The comparison models for the confidence score detection on Truck is shown in Fig. 3.

Fig. 3. Comparison models for confidence score detection on Truck: (a) YOLOv5s, (b) YOLOv5x, (c) YOLOv10n (d) YOLOv12n.

Despite YOLOv10n able to detect most of the vehicles including large vehicle and various conditions, the low confidence score detection still can be observed on some of the dark colour truck, occluded motorcycle images and bus are shown in Fig. 4.

Fig. 4. Examples of the low confidence score detection on YOLOv10n.

VI. Conclusion and Future Work

A vision-based vehicle classification is proposed as it is able to offer intelligent solution for transportation systems, thus contribute to road traffic monitoring for the development of smart cities. Four models of YOLO are investigated, namely YOLOv5s, YOLOv5x, YOLOv10n, and YOLOv12n are evaluated on a multi-class vehicle dataset. From the experiment conducted, the YOLOv10 able to obtain the highest detection performance of mAP@0.5 with 0.859 across all vehicle classes compared to the other model. Although, YOLOv10n is able to achieve high performance, low confidence can be observed on the images as shown in Fig. 4. It can be seen that the models are less effective in detecting the dark colour truck, occluded motorcycle and bus images. The lighting variations, especially in the detection of large, visually complex vehicles like trucks or bus may affected the detection and recognition. Thus, reducing the performance of the models. In the future, we will concentrate on improving these drawbacks by optimized the anchor box and modified the loss function to improve the detection especially on a large vehicle such as bus and truck. Increasing the diversity of the vehicle images dataset will also be considered by using data augmentation techniques for more advanced deep learning models to optimize the performance.

***Abstract*—Autonomous urban planning, facility layout design, and interior design are critical and meticulous tasks that require the optimization of space arrangement. One of the main purposes of space arrangement is to achieve high space utilization with a non-complex arrangement for emergency assistance, particularly to enhance pedestrian safety in panic situations. This study explores the optimization of spatial layouts by employing Genetic Algorithms (GA) due to their robust search capabilities. However, spatial layout size limitations may affect the search capability and significantly impact space arrangement and utilization. Hence, this study presents a comparative study of two GA selection operator methods: Rank Selection (RS) and Roulette Wheel Selection (RWS) for determining the effectiveness in optimizing spatial layout arrangements and space utilization. The results demonstrated significant improvements in crowd flow management, with the RWS method showing the highest fitness value despite slower convergence compared to RS. The study highlighted the impact of different methods on the convergence of the multi-objective fitness value based on space elements such as overlapping and standard walkway distances. While both selection methods proved to be effective in optimizing space utilization, the RWS method demonstrated greater computational efficiency while still adhering to standard layout designs. This efficiency helps to ensure smoother evacuation and ease of movement during emergency situations.**

Keywords*—Genetic algorithm; optimization; spatial layout arrangement; space utilization; urban planning; facility layout design; rank selection; roulette wheel selection

I. Introduction

Pedestrian safety is a critical aspect of urban planning, especially in emergency scenarios. A surging pattern of fatalities due to entrapment incidents in recent years has led to the increased demand for safer building designs and effective emergency protocols. In response, numerous studies have been carried out to uncover the impactful spatial features that significantly influence the pedestrians' movement during the evacuation process. The previous studies have proposed an enhanced spatial layout design that aimed at reducing casualties and improving overall safety [1-6].

Spatial layout arrangement involves the organization and positioning of elements within a given space, serving as a crucial aspect of spatial layout design. This design practice is essential in the planning and construction phases of housing development, ensuring efficient use of space and optimal functionality. The design will outline the blueprint of the layout by assisting in the arrangement of the assigned elements for reaching the suitable order, sorting, grouping, alignment, function, and scale to the layout size. In later times, the spatial layout was designed by employing the manual design method and focusing on the standard design procedure and being influenced by the local demographic structure's culture and current trend [7][8]. However, with the advancement of computer intelligence systems, spatial layout design application tools have been introduced for autonomous spatial layout design [9-11].

The demand for autonomous space arrangements has surged significantly, driven by the need for multi-objective functions in design. However, due to some limitations on the complex computation of the various parameters, the autonomous spatial layout arrangement generated a non-fitness design and constructed a less scalable and less functional floor plan [12]. Traditional autonomous layout designs often fall short in managing crowd movements during panic situations. Ineffective layouts have resulted in numerous entrapment incidents during emergencies [13]. Research by [13] has highlighted the significant impact of optimizing interior resources' allocation and occupancy within the layout. Hence, arrangement and allocation optimality are the new approaches to ensure the traffic flow and the safety of the pedestrians in the layout. This approach can improve the overall quality of life and the environment rather than focusing solely on the layout structure, and functionality.

However, previous research has shown that optimizing layout utilization can lead to several issues, including overlapping objects, low space occupancy, and non-standard layout design [14-23]. Hence, it is necessary for the computer-aided layout design to exploit a suitable optimization method for constructing the high occupancy elements' layout while adapting the architecture building design policy in constructing the space arrangement. This study addresses this gap by proposing an optimized spatial layout that leverages advanced algorithms to enhance safety and efficiency.

The study begins by introducing the optimization method, Genetic Algorithm (GA) as a suitable approach for computing

multi-objective functions, and followed by a methodology section, discussing the GA framework, the selection process, and the rank selection techniques adopted in this study. Next, the results section presents the findings, and the conclusion summarizes the key outcomes and suggests directions for future research.

II. GENETIC ALGORITHM

In [24], the authors show that the optimization with multi-objective functions can be inspired by the principles and inspiration of biological evolution. Numerous studies have been proposed in layout design optimization using bio-inspired algorithms for applications such as optimal job scheduling, structural design, cost minimization, flow control, and space occupancy. For example, research by [25] explored the use of Genetic Algorithm (GA), Differential Evolution (DE), Artificial Bee Colony (ABC), Charge Search System (CSS), and Particle Swarm Optimization (PSO) algorithms to optimize robot workcell layout in manufacturing systems, focusing on optimizing layout area and robot operation time. Meanwhile, research by [26] proposed optimal design solutions for planar trusses in structural roof articulations using Elitism-Based Genetic Algorithm (EBGA), Ant Colony Optimization (ACO), Artificial Honey Bee Optimization (AHBO), and PSO, with an emphasis on minimizing truss weight. Research by [27] explored the optimization of construction layout arrangements to reduce transportation costs, comparing the performance of PSO, ABC, and Symbiotic Organisms Search (SOS) algorithms. Additionally, research by [28] applied a GA to garden landscape design, aiming to adhere to the fundamental principles of landscape and urban design while meeting people's needs, showing improvements over traditional methods. Research by [13] utilized GA for resource allocation to enhance spatial layout design, and research by [29] employed GA to optimize land use for sustainable land resource management. These studies highlight that only a small number of works focus on indoor design and spatial element arrangement, despite the growing use of bio-inspired algorithms in layout optimization. Building on this foundation, the focus of this study is to evaluate and compare the effectiveness of GA, PSO, ACO, and ABC specifically for optimizing spatial layout arrangements in the context of urban planning and design.

One of the suitable bio-inspired algorithms is Genetic Algorithm (GA). GA is the adaptation of the natural evolution process inspired by Charles Darwin's theory of genetic evolution for the survival of the fittest genes. Genetic evolution is based on the genetic structure, and the natural selection operation carried out for the genes' transformation and modification for the next generation [30] [31]. The principles of Darwinian natural selection are based on heredity, variation, and selection. In selecting a GA for optimizing spatial layout arrangements, its flexibility and adaptability make it a compelling choice. GA is particularly effective for complex problems with large solution spaces. The ability to perform global searches and avoid local optima makes GA well-suited for layout optimization, where multiple variables and constraints must be balanced. Additionally, GA can be easily modified and combined with other techniques to enhance its performance and tailor it to specific problem domains, such as spatial layout optimization. This adaptability, combined with their proven success in various domains, makes GA a suitable and powerful method for optimizing spatial layout arrangements, ensuring efficient use of space while meeting design criteria.

GA has three operators: 1) Selection, 2) Crossover, and 3) Mutation. These operators will converge the genes to find the best fitness function to generate the fittest final offspring. The GA process will begin with the initialization of the random production of N number of chromosomes, with each chromosome containing an array of gene bits. The objective function will be assigned for determining the fitness values of the chromosomes. There are many types of selection schemes that can be used for discriminating the fittest values and the lowest values of the spatial layout design solutions; 1) Rank Selection (RS), 2) Roulette Wheel Selection (RWS), 3) Tournament Selection (TS), 4) Stochastic Universal Sampling (SUS), and many more.

The RWS is the proportionate fitness selection that represents the circular wheel that is divided based on the probability of the fitness value from the whole values and represented in the circle's degree value (the ratio of individual fitness value and the total fitness of overall individuals in the population). The fittest individual will have a bigger degree region in the circle and have a greater chance of being selected during the spinning process. Hence, the probability of being the fittest individual is high. A fixed point will be generated randomly to represent the real roulette wheel spinning. The fitness values selected by the fixed point will be selected as the parents. The RWS is also implemented in SUS. However, in SUS selection, there are multiple fixed points marked as the random stochastic selection, and the parents can be obtained in a single spin. This setup will be able to encourage the highly fit parents to be selected at once.

RS ranks individuals based on fitness values and applies a roulette-wheel-like method for parent selection, where each individual has an equal share (same probability) of being selected as the parents. The selection sometimes will make poor selections of parents who have a possibility of selecting the least fit solutions for reconstructing the fitter individuals. TS is the selection strategy that selects the k-number of solutions from the whole available solutions and comparing the fitness values among them. The fittest candidates among the k-individuals will be passed on to the next-gen. The probability of the selection is based on the candidate's likelihood in the tournament group. The tournament size will be able to affect the selection process as the less fit solution will have a low possibility of being selected in the large tournament group as it must compete with the stronger candidate with a high fitness solution. Based on the type of selection schemes, RS and RWS have been selected to be compared as one of the selected selection methods in comparing the spatial layout designs to find the higher fitness parents for the recombination and diversification of the offspring. This selection scheme has been selected due to its ability to contribute to the high convergence rate, as the fittest parents are able to construct better offspring with fitter fitness values.

TS and SUS selection methods are also able to give a high possibility of convergence rate. However, the random selection for the first step of the methods will contribute towards the divergence of the parents and will have a high possibility of not being able to construct the offspring that have the best inheritance from the parents. Whereas both RS and RWS are able to create a great balance between convergency and divergence of the offspring construction as there will be a high possibility of the selection approach to select the fittest parents, and there are also chances of selecting less fit parents but with low possibility. Therefore, this research focuses on utilizing RS and RWS for the parent selection phase in GA.

In light of the research problem, the goal is to transform spatial layouts into safer, more navigable spaces during emergencies. In contrast to existing studies that focus solely on layout efficiency or cost-based metrics, this study offers a novel comparative analysis of GA selection strategies using RS and RWS for managing the integration of multi-objective functions that include crowd flow safety and layout efficiency. The aim is to achieve autonomous high occupancy space arrangements that comply with spatial design standards and improve pedestrian movement flow, particularly during evacuation processes.

III. METHODOLOGY

Genetic Algorithms (GA) are powerful optimization tools inspired by the process of natural selection. In the context of constructing a spatial layout, GA facilitates the generation of optimized solutions through iterative processes. This research study focuses on comparing two selection methods; Roulette Wheel Selection (RWS) and Rank Selection (RS). Both methods are evaluated using a consistent approach involving uniform crossover and bit flip mutation to ensure a fair comparison.

A. Genetic Algorithm (GA) Framework

The three fundamental phases need to be highlighted for constructing a spatial layout based on GA's design; 1) the selection phase, 2) the crossover phase, and 3) the mutation phase. Fig. 1 shows the fundamentals of genetic evolution processing for optimizing genetic fitness.

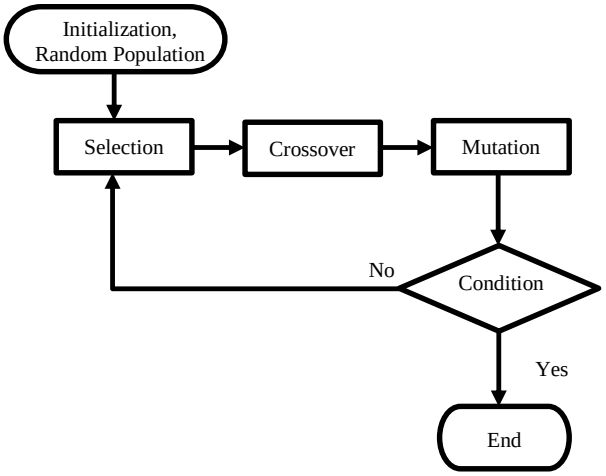

Fig. 1. Fundamental genetic evolution process

The optimized spatial layout arrangement is constructed based on the adaptation of the binary GA as shown in Fig. 2.

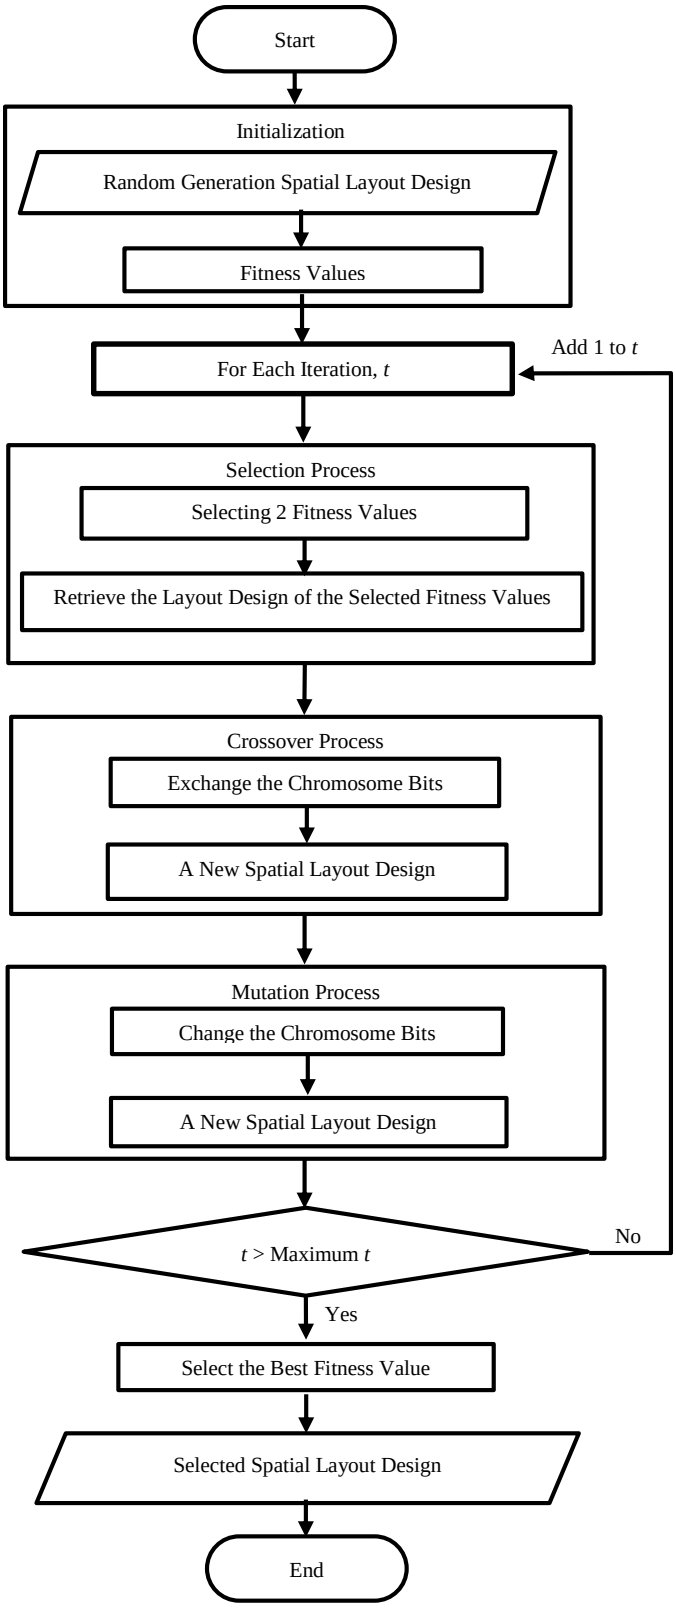

Fig. 2. Adaptation framework on GA in constructing an optimal spatial layout.

Pseudocode 1 GA Based Spatial Layout Construction Optimization

```
Load training samples
begin
Step 1:
    Generate the initial layout population z_i, i = 1 ... SN
    Evaluate the fitness (f_i) of the population
    Initialize iteration cycle = 1 ... SN
Step 2:
    set cycle to 1
    repeat
        //Selection Phase
        Apply greedy selection for f_i of i, i(h1) and i(h2)
        //Crossover Phase
        Exchange the chromosome genes of i(h1) and i(h2)
        //Mutation Phase
        Change the chromosome genes of i(h1) and i(h2)
        Calculate the offspring's fitness f_i, h1(f_i) and h2(f_i)
        Search for least fit individuals, i(g1) and i(g2)
        //New generations
        Replace spatial layout g1 and g2 with h1 and h2
        cycle = cycle + 1
    until cycle = SN
Step 3:
    Memorize the best solutions z_i
    Output the best spatial layout found
end
```

Based on the framework in Fig. 2, Pseudocode 1 is developed to show the fundamentals for spatial layout design optimization based on GA, adapted from the algorithms overview by McCall [32]. Based on Pseudocode 1, the GA parameters must be initialized by setting the population size, *SN* to 50. Each individual in the population, z_i is generated with a unique spatial layout design, which includes 300 obstacles. The six obstacles are combined into one large obstacle representing the furniture. Each of the population fitness values f_i will be calculated based on the objective function: 1) overlapping of the elements generated as static obstacles, and 2) distance 1.2 m from doors and walls to meet the standard of interior design.

The number of furniture elements left in the layout after the overlapping process and exist within the layout that has a 1.2 m distance range from doors and walls has been calculated as the total fitness value of the layout. The iteration cycle has been initialized, and in this research, the iteration is set to 100. When entering the iteration cycle, the process will be entering into three phases: 1) selection phase, 2) crossover phase, and 3) mutation phase. A solution acceptance rule is implemented to ensure that the elements do not exceed the allocated space within the layout. Based on this rule, the number of furniture elements must not exceed the initial 300 loaded obstacles, even after 100 iteration cycles. This constraint ensures that the layout remains within the grid limits and complies with interior design standards, particularly by preserving sufficient walking space for pedestrians to access exit points.

B. Selection Process

The selection process in GA determines which individuals from the current population will be the parents to the next generation. This process mimics natural selection in choosing the fittest individuals based on performance or fitness scores. The primary goal is to ensure that high-quality traits are preserved and propagated, thereby improving the overall solution quality over successive generations. Every method available for selection operation has a unique approach to balancing exploration and exploitation within the search space.

1) Roulette Wheel Selection (RWS). The RS method is implemented to find the parents for the further recombination and restoration process of the offspring. This discrimination phase offers selective pressure that applies greedy selection based on the fitness proportionate selection approach as a method in guiding the evolution of spatial layout design. The fitness value fi has been determined from each of the solutions z_i of population i. The roulette slot size probability will be computed based on Eq. (1):

$$p_i = \frac{f_i}{\sum_{i=1}^{SN} f_i} \quad (1)$$

where, the p_i is the probability of each of the fitness values fi from the whole fitness values in the population *i* and *SN* is the maximum number of populations, *i*. The cumulative probability, q_i, for each chromosome is calculated based on Eq. (2):

$$q_i = \sum_{i=1}^{SN} p_i \quad (2)$$

here, p_i is the probability of each of the fitness values, and the cumulative probability has been calculated for each of the population *i* until reaching the maximum number of the population, *SN*. The fixed point of the roulette wheel can be constructed based on the random number generation *r*, where $r \in (0, 1)$. The parents are selected based on the condition; if $r < q_1$, then the first solution, z_1 is chosen as the parent. Otherwise, if $r > q_1$, the algorithm searches for another solution z_i such that $q_{i-1} < r \leq q_i$ and selects it as the parent. The steps have been repeated for two times for each iteration cycle to find the two parents' spatial layout to be recombined and explored for the fittest offspring.

2) Rank Selection (RS). RS method is implemented to identify parents for further recombination and restoration processes in generating offspring. Unlike the RWS method, which relies on fitness proportionate selection, RS imposes selective pressure by ranking individuals based on their fitness and then selecting parents according to their rank, rather than their absolute fitness values. This approach ensures that even individuals with lower fitness have a chance of being selected, thus maintaining diversity within the population.

In RS, each individual solution z_i in the population is assigned a rank r_i, with the fittest individual receiving the highest rank. The selection probability for each individual is then determined based on its rank, not its fitness value. The probability of selecting an individual is calculated using a rank-based probability distribution, where higher-ranked individuals have a greater chance of being selected as parents. This can be represented by Eq. (3):

$$p_i = \frac{2x(SN - r_i + 1)}{SN \times (SN+1)} \quad (3)$$

where, p_i is the probability of selecting the individual with rank r_i, and SN is the maximum number of individuals in the population. This rank-based probability distribution ensures a more uniform selection pressure compared to fitness-proportionate methods to avoid cases where a single individual with a much higher fitness dominates the selection process. The cumulative probability q_i for each individual is calculated based on Eq. (2), as the formula is similar. However, compared to RWS, the p_i is the probability of each of the ranks, and the cumulative probability has been calculated for each of the populations i until reaching the maximum number of the population, SN.

Similar to RWS, the fixed point of the roulette wheel can be constructed based on the random number generation r, where $r \in (0, 1)$. The parents can be selected by the condition; if $r < q_1$, then the first solution, z_1 has been selected as the parent. However, if $r > q_1$, then the other search has been made on the other individual solution z_1 such that $q_{i-1} < r \leq q_i$. The steps have been repeated for two times for each iteration cycle to find the two parents' spatial layout to be recombined and explored for the fittest offspring.

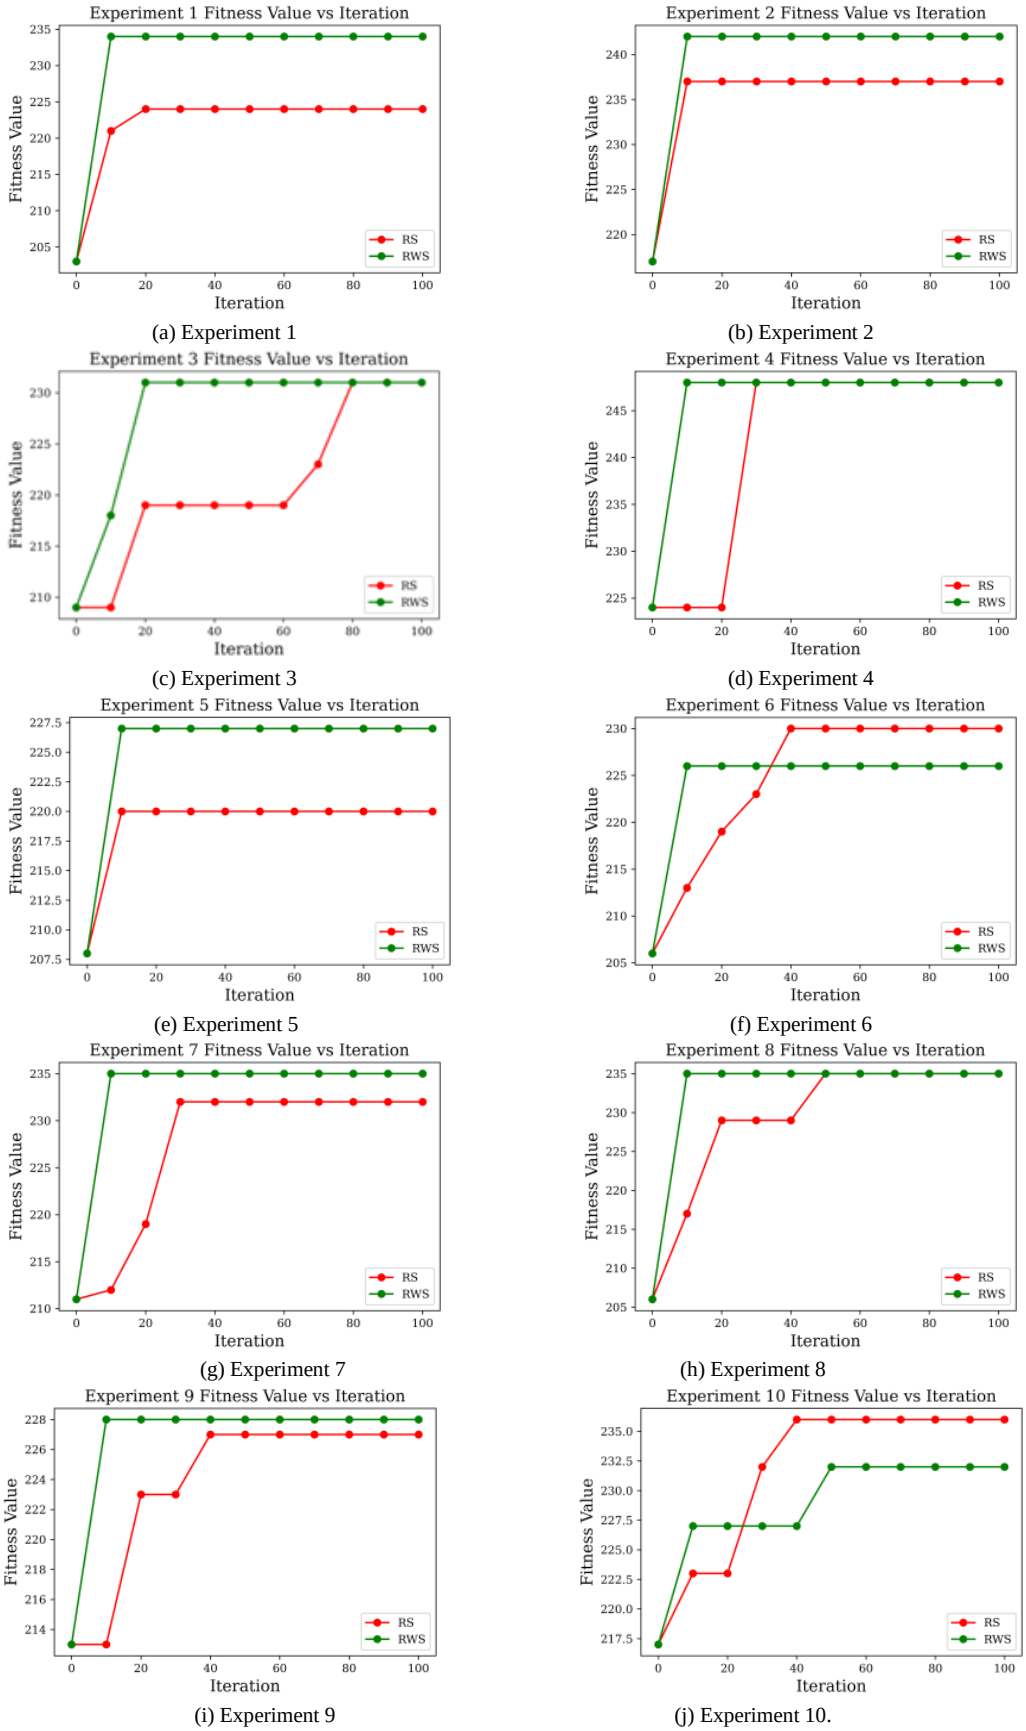
RS offers a more stable selection process by mitigating the effects of disproportionately high fitness values that can dominate the selection in methods like RWS. This method ensures a balance between exploration and exploitation by allowing less fit individuals a chance to contribute to the next generation, thus enhancing the evolutionary search for optimal spatial layout arrangements.

C. Uniform Crossover

In this research, the uniform crossover has been selected, and the selected parents have been recombined with the crossover phase. Both parents' allele genes have been recombined to construct better spatial layout offspring that are able to produce fit fitness values. The uniform recombination process has examined the genes in the parents separately and recombines each of the genes based on the coin flip method. The flip coin method has randomly made the decision based on 50-50 probabilities [0,1]. If the toss is "0", the gene for both parents has been maintained, whereas if the toss resulted in "1", the gene has been exchanged between the parents. The offspring constructed from the recombination method has been explored to prevent premature convergence to the local optimal solution and diversify the genetic population via the mutation phase approach.

D. Bit Flip Mutation

The mutation phase has amended the offspring solutions to construct new solutions. In this research, the random resetting mutation has been used by selecting each of the obstacles based on the bit flip mutation function, in which the probability of the obstacles' gene selection has been set to a 0.01 mutation rate. Each of the genes of the offspring has been examined, and a random number has been generated to check the mutation rate condition. Based on the rules set, when the random number < 0.01, the mutation has occurred, and the gene bit has been flipped, whereas when the random number >= 0.01, the bit of the offspring has remained the same. The obstacles that are assigned with the random number < 0.01 have been assigned to a randomly chosen gene in the spatial layout grid.



This method is suitable for spatial layout arrangement as the solutions will still provide the 50 large orders of obstacles. The fitness value of the offspring has been determined, and the value has been compared with the fitness values of the current population, f_i. The offspring constructed has been passed to the next iteration cycle as a member of the population and replaces the least fit solutions. The final population i with spatial layout solution z_i after 100 iterations have been compared, and the fittest solution will be selected to represent the selected result for the GA approach in designing an optimal spatial layout.

IV. Results

This research compared the Rank Selection (RS) and Roulette Wheel Selection (RWS) methods for constructing GA-based spatial layout arrangements. To ensure unbiased results, ten experiments were conducted, each with 100 iterations. Fig. 3 presents the graphical results of these experiments, illustrating the fitness value for every iteration of each selection method.

Based on the overall result in Fig. 3, both RS and RWS show the characteristic of GA algorithm results with premature convergence. These results align with the study's focus on optimizing spatial layout arrangements and space utilization, which are critical for applications like autonomous urban planning, facility layout design, and interior design. Given the emphasis on high space utilization and non-complex arrangements for emergency assistance, the selection of GA operators is crucial, especially in scenarios with limited spatial layout size.

Based on the observation, the highest fitness value for both selection methods shows different values throughout the ten experiments. Based on the graphs in Fig. 3, RS outperformed RWS in 20% of the experiments by optimizing the population fitness value, especially in Experiment 6 and 10. In Experiment 6, RS achieved a fitness value of 230.0 by iteration 40, whereas RWS plateaued at a maximum fitness value of 226.0, beginning as early as iteration 10. Similarly, in Experiment 10, RS reached a fitness value of 236.0 by iteration 40, while RWS plateaued at 232.0 from iteration 50 onwards. These results highlight the potential of RS for achieving faster convergence in certain scenarios.

(c) Experiment 3 (d) Experiment 4

(e) Experiment 5 (f) Experiment 6

(g) Experiment 7 (h) Experiment 8

(i) Experiment 9 (j) Experiment 10.

Fig. 3. Graph comparison of Rank Selection (RS) and Roulette Wheel Selection (RWS) fitness value of over 100 iterations.

In 30% of the experiments, both RS and RWS exhibited comparable performance, achieving similar fitness values at different iterations. Based on the observations, the maximum fitness value for Experiment 3 reached 231.0 at iteration 80 using RS but was achieved earlier by RWS at iteration 20. The maximum fitness for Experiment 4 reached 249.0 at iteration 30 by RS but achieved earlier by RWS at iteration 10. In addition, the maximum fitness value for Experiment 8 reached 235.0 at iteration 50 by RS while RWS reached it earlier at iteration 10. These results indicate an overlapping convergence behavior, likely due to the limitation of layout size in accommodating all layout elements.

Furthermore, in 50% of the experiments, the RWS selection method outperformed the RS in terms of final fitness value. RWS shows better optimization compared to RS due to the offspring selection strategy that is based on the relative fitness of individuals. This proportional selection approach groups individuals by fitness level, increasing the likelihood that higher-fitness individuals are selected as parents, thereby generating stronger offspring. Compared to RWS, the selection in RS is also able to generate higher fitness values. However, due to the selection of the top 2 highest-fitness parents in RS caused the offspring generated to be too fit and unable to replace the lowest value of population members. Hence, resulting in the slow convergence speed compared to RWS. Although RWS is generally associated with slower convergence, its use of a solution acceptance rule (i.e., constraints related to layout capacity) allows it to increase fitness values earlier in the experiment, often resulting in the highest fitness value by iteration 100. Additionally, the RS selection method is computationally expensive due to the population sorting based on the fitness value compared to the RWS selection method. Fig. 4 shows the graph comparison between the processing time (milliseconds) in every experiment for the RS and RWS-based GA approach spatial layout design arrangement.

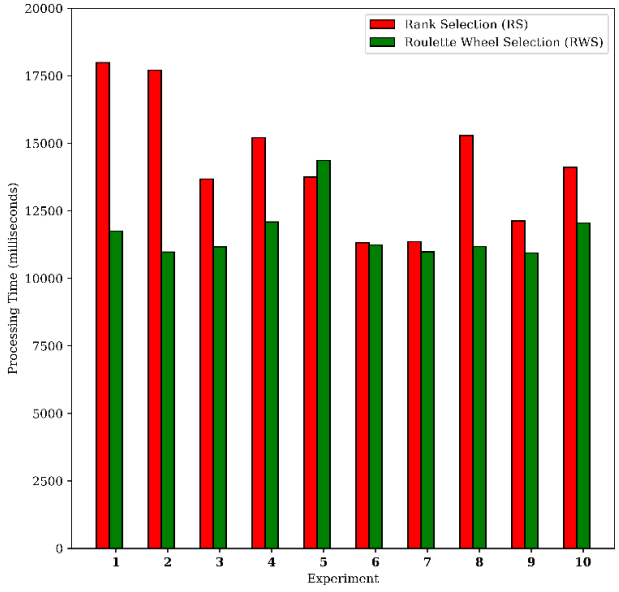

Fig. 4. Graph comparison between the processing time of Rank Selection (RS) and Roulette Wheel Selection (RWS) for 10 experiments.

Based on Fig. 4, the graph of processing time shows that RS consistently takes extra processing time compared to RWS in most experiments, with the exception of Experiment 5 as the 10% outlier, where RS recorded 13752 ms compared to 14369 ms for RWS. This result indicates that RS is generally slower in this context. In Experiments 1, 2, 3, 4, 6, 7, 8, 9, and 10, RWS shows significantly faster processing time, with 90% of the experiments showing the improvement of processing time percentage. Table I summarizes the percentage improvement of RWS over RS.

TABLE I. PROCESSING TIME COMPARISON WITH PERCENTAGE OF RWS IMPROVEMENT COMPARED TO RS

Experiment	RS Time (ms)	RWS Time (ms)	Faster Method	RWS over RS (%)
1	17991	11747	RWS	34.69
2	17708	10974	RWS	38.02
3	13681	11168	RWS	18.37
4	15209	12088	RWS	20.54
5	13752	14369	RS	-4.49
6	11320	11236	RWS	0.74
7	11359	10986	RWS	3.28
8	15292	11178	RWS	26.89
9	12130	10941	RWS	9.80
10	14110	12047	RWS	14.62

Based on Table I, among the 90% of experiments where RWS demonstrated superior performance, the results show the improvement ranging from modest gains, such as 0.74% in Experiment 6, to substantial differences exceeding 38% in Experiment 2. The most significant time reductions were observed in Experiments 1 and 2, where RWS reduced computation time by 34.69% and 38.02%, respectively, compared to RS. This substantial difference in the efficiency of these two methods is potentially due to the computation cost in population sorting based on fitness value that is required in the RS algorithm, which increases the computation complexity. RWS, by contrast, is more computationally efficient and enables faster spatial layout optimization.

Compared to the other experiments, in Experiment 5, RS was slightly faster by 4.49%, which is an exception to the trend observed from the whole experiment. This anomaly suggests that under certain conditions, particularly where early convergence occurs or solution acceptance thresholds align more favorably, RS may offer computational advantages. However, this case appears to be an outlier rather than a consistent pattern. The outlier also reflects the unbiased nature of the experimental setup, which was intentionally designed to allow either method to succeed under appropriate conditions.

Based on Fig. 4 the solution acceptance rule acts as a limiting factor for space utilization optimization, and RWS demonstrates a better balance between the fitness value optimization and processing time that making it a more practical choice for the selection process in the future GA approach for optimizing the autonomous spatial layout arrangement design and space utilization in autonomous urban planning.

V. CONCLUSION

This study aimed to evaluate the effectiveness of two Genetic Algorithm (GA) selection methods: Rank Selection (RS) and Roulette Wheel Selection (RWS) in optimizing spatial layout arrangements to improve space utilization and emergency responsiveness. Through this research, it was shown that RWS was able to outperform RS by consistently achieving higher fitness values and demonstrating greater computational efficiency. This was due to its proportional selection mechanism, which enhances the likelihood of selecting fitter individuals and accelerates convergence while maintaining layout standards for emergency situations. While RS occasionally showed better performance in specific instances, its approach often led to slower convergence and increased computational demands. The requirement for population sorting based on fitness in RS contributed to its higher computational cost. Overall, RWS proved to be the more effective method for optimizing spatial designs, meeting the study's objective of identifying the most efficient GA operator for enhancing spatial layout arrangements and space utilization in autonomous urban planning. The future research direction of this study is to explore hybrid selection methods in GA that combine the selection mechanisms and features of RS and RWS to further enhance the optimization of spatial layout arrangements in urban planning. Additional studies can be carried out to investigate the application of RWS in different urban planning scenarios to validate its effectiveness in improving space utilization and emergency responsiveness across diverse environments.

***Abstract*—Technologies with altering reality like virtual reality (VR) have become more relevant to the public for their capabilities in the entertainment and healthcare field, as well as affordable for everyone. However, the emphasis on mental health-related simulation is often ignored due to technical complexities and wrong representation. Therefore, this study leverages the immersive capabilities of VR to create an engaging and educational game experience that simulates the sensory and social challenges faced by individuals with autism spectrum disorder (ASD). The study involves designing and implementing a VR game that places users in various scenarios reflecting the daily experiences of autistic individuals. The VR game aims to educate players about common misconceptions, sensory sensitivities, and social difficulties associated with autism. A literature review on XR technology and ASD was conducted during the pre-production phase to explore past research on autism in video games and shape the overall game vision. The study continues with developing an immersive simulation game using VR with locomotive motion controls and an artificial intelligence non-playable character (AI NPC) with Speech-To-Text function. Finally, the testing phase used two approaches: quantitative analysis, using the System Usability Scale (SUS) to assess usability and the Simulator Sickness Questionnaire (SSQ) to identify discomfort issues such as headaches and blurriness during gameplay, and qualitative analysis, gathering expert's feedback on the VR game's content and teaching effectiveness.**

Keywords*—Virtual reality; simulation game; autism; artificial intelligence

I. Introduction

Advancements in computer science, engineering, and human-computer interaction (HCI) have driven rapid development in spatial interface technologies, including virtual reality (VR), augmented reality (AR), and mixed reality (MR) [1]. These technologies, collectively referred to as extended reality (XR), have gained widespread attention in both academia and industry due to significant improvements in hardware that make devices lighter, more affordable, and increasingly powerful [2]. Among these, VR stands out for its unique ability to replicate real-life situations in a highly immersive manner, making it a valuable tool in healthcare, therapy, and education by providing realistic training and fostering empathy through experiential learning [3].

While VR's applications in physical health and technical training have been widely explored, its potential for simulating mental health conditions such as Autism Spectrum Disorder (ASD) remains underutilized. Media portrayals of autism frequently rely on stereotypes or fail to accurately reflect the lived experiences of individuals on the spectrum, resulting in widespread misconceptions and reinforcing social stigma [4][5]. Poorly designed simulations that do not align with authentic experiences or educational goals can further mislead users rather than help them understand the challenges faced by the autism community.

As a response to these challenges, the present study introduces an alternative approach with the development of an interactive VR simulation game that emphasizes exploration and interactivity. Designed to immerse players in the daily sensory and social experiences of individuals with ASD, the simulation seeks to cultivate empathy and enhance public awareness through experiential engagement. Central to this initiative is a threefold objective. First, to study and compare how ASD has been depicted in existing VR games aimed at public education. Second, to design and develop an immersive representative simulation of the lived experiences of autistic individuals and third, to evaluate the simulation's usability and its effectiveness in fostering empathy and greater awareness among users.

Guided by these objectives, this study is driven by the overarching research question. How effectively can an immersive VR simulation game be designed around exploration and interactivity that accurately represents the experiences of individuals with ASD compared to existing VR representations? In order to address this question, this study investigates current approaches to ASD representation in VR, explores methods for creating a more authentic visual and spatial audio experience, accurate user-centered simulation, and assesses the impact of the resulting experience in terms of usability testing, simulation sickness (SUS) and expert's feedback.

The remainder of this study is structured as follows: A review of related literature on VR technologies and autism representation in Section II; a detailed explanation of game design and development methodology in Section III; presentation of results from a conducted evaluation in Section IV; and a concluding discussion on the study's contributions, limitations, and potential directions for future research in Section V.

II. Literature Review

The term virtual reality (VR) describes an interactive, three-dimensional computer-generated environment that users can interact with. Usually, VR is accessed through a computer that can project 3D data onto a display, such as a head-mounted display (HMD) or isolated screens, along with user identification sensors [6]. Virtual reality can be broadly classified into two types, which are immersive and non-immersive [7]. Non-immersive virtual reality presents information virtually by utilizing a collection of screens surrounding the user [8]. Driving or flying simulators are a common example of this, where the user sits in a chair with many screens surrounding them, creating the illusion of being in the driver's seat or cockpit without being there. Immersive VR is the process of presenting VR content to users based on their position and movement using a wearable display, such as an HMD [9], so they may experience the entire 360 degrees of the virtual world. One of the most marketable features of VR technology, this immersive experience is what most people associate with VR.

Inside-out tracking technology is revolutionizing virtual reality, as demonstrated by devices like Oculus Quest 2 [10], as this method depends on the complex interaction of built-in cameras and sensors in the VR headgear. This depends on the intricate interaction between the VR headset's integrated cameras and sensors [11]. Together, these elements give users a responsive and intensely immersive experience. What makes it more convenient is that this technology is used in everyday smartphones powered by Android and iOS [12].

On the other hand, inside a predetermined play area, outside-in tracking provides accurate and dependable tracking. VR headsets and controllers are tracked in terms of location and orientation by devices like the Oculus, HTC Vive and XR-3, which make use of external sensors or base stations. By replicating this tracking method, Fig. 1 illustrates the flowchart of how the AutiSim will operate using an Oculus headset and Unreal Engine. This method guarantees precision, which makes it a great option for applications that need accuracy, such as professional simulations or architectural design [13].

According to current understanding, autism is a neuro-cognitive disorder characterized by excessive masculine features, difficulty empathizing, and a lack of ability to understand the thoughts of others [14]. Autism is described as a "triad of impairments" characterized by "impaired social interaction, verbal and nonverbal communication, and repetitive and stereotyped behaviors" among affected individuals [15]. There is currently no known cause or treatment [16] for the most thorough investigation to far points to a genetic cause [17].

Hans Asperger originally identified Asperger syndrome (AS) in 1944 as the behavioral profile of people who struggle with socialization and communication [18]. Since then, AS has generated a lot of discussion and attention. While AS was added as a separate diagnostic category in the Diagnostic and Statistical Manual of Mental Disorders (DSM-4, 1994), its diagnostic label was eliminated in the Diagnostic and Statistical Manual of Mental Disorders (DSM–5), the edition that followed, nearly twenty years later. Rather, autism spectrum disorders (ASD), a more inclusive category, were added to ASD [19]. A youngster with a level 1 spectrum disorder will struggle with social communication, yet have an above-average IQ and outstanding linguistic skills [20].

Rett syndrome (RTT) is a rare, severe neurodevelopmental disorder that affects almost exclusively females. The syndrome was first described in 1966 by Andreas Rett in the German medical literature. Development appears normal during the first 6 to 18 months of life but is followed by regression of motor and language skills. The clinical phenotype of RTT is broad and can be classified into two main categories: typical (classic) RTT and atypical (variant) RTT [21].

Theodor Heller discovered a group of kids in 1908, 35 years before autism was first recognized. These kids displayed average development until the age of 3 or 4 before experiencing a dramatic and abrupt regression in their speech and cognitive abilities. This condition was known as "*dementia infantalis*", and it was frequently linked to mood dysregulation, which included anxiety and aggression [22]. Nowadays, this condition is known as Child Disintegrative Disorder (CDD).

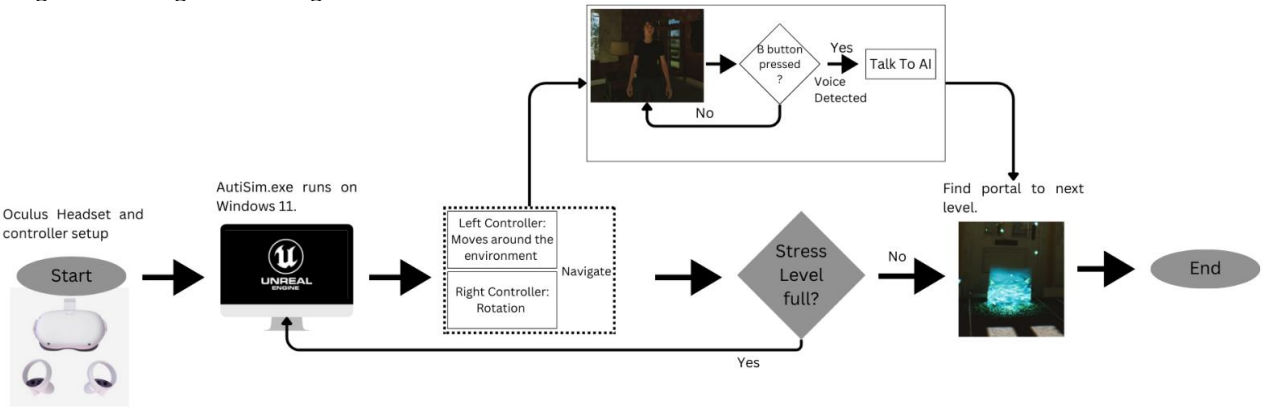

Fig. 1. Flowchart of how AutiSim will operate.

Most people think of Kanner's Syndrome in children when they think about autism. This form of autism is referred to as classic autistic disorder. Excessive sensitivity to stimuli (smell, light, noise, taste, or touch), trouble comprehending or communicating with people, and minimal eye contact are some of its symptoms. Youngsters with Kanner's syndrome frequently show little interest in their surroundings and a great desire for consistency. These children often appear to be self-centered, struggling to understand and respond to social cues that lead to difficulty in engaging with others [23].

The National Autistic Society Channel posted a video titled "Autism TMI Virtual Reality Experience" on YouTube back in June 2016. The video featured a 360-degree virtual reality experience that allowed viewers to manipulate the surroundings and observe an autistic child named "Alex" in a shopping centre. As of June 17, 2024, the film has received over 1.4 million views on YouTube and has received mixed reactions from both the autism community and people in general. With a focus on the unpleasant emotions that an autistic person experiencing a "meltdown" or "shutdown" may encounter in public, the application seeks to convey the overwhelming sensory experience that surroundings like these can cause for an autistic person [24].

Released in October 2016 for the Oculus Rift S, "The Autism Simulator" is one of the few games available on the Meta market. The premise of the simulation quoted “By observing too many details, getting drawn in by anomalies, and attempting to put the anomalies into a regular order, we provide you with a singular experience. Because of this, people with autism tend to be extremely focused, easily frightened, distracted, or violent.” [25].

In conclusion, the literature review highlights the diverse landscape of research and initiatives at the intersection of VR technology and autism awareness. Through a comprehensive examination of existing literature, the proposed research has gained valuable insights into the potential of VR to facilitate immersive and impactful experiences that foster understanding, empathy, and awareness of autism spectrum disorder.

Additionally, the analysis of the literature identifies new directions and best practices in the development, application, and assessment of VR-based awareness games. User engagement, accessibility, ethical issues, and the integration of evidence-based therapy techniques into VR experiences are among the key factors identified. The findings from various studies and projects offer valuable insights to guide the development of a VR initiative for autism awareness.

III. MATERIALS AND METHODS

This study introduces an integrated analytical methodology framework for AutiSim, as shown in Fig. 2, by utilizing the Game Design Life Cycle (GDLC) model that has been widely used and applied innovatively within VR environments [27]. The methodology framework for this study consists of the following phases: Pre-Production, Production and Evaluation.

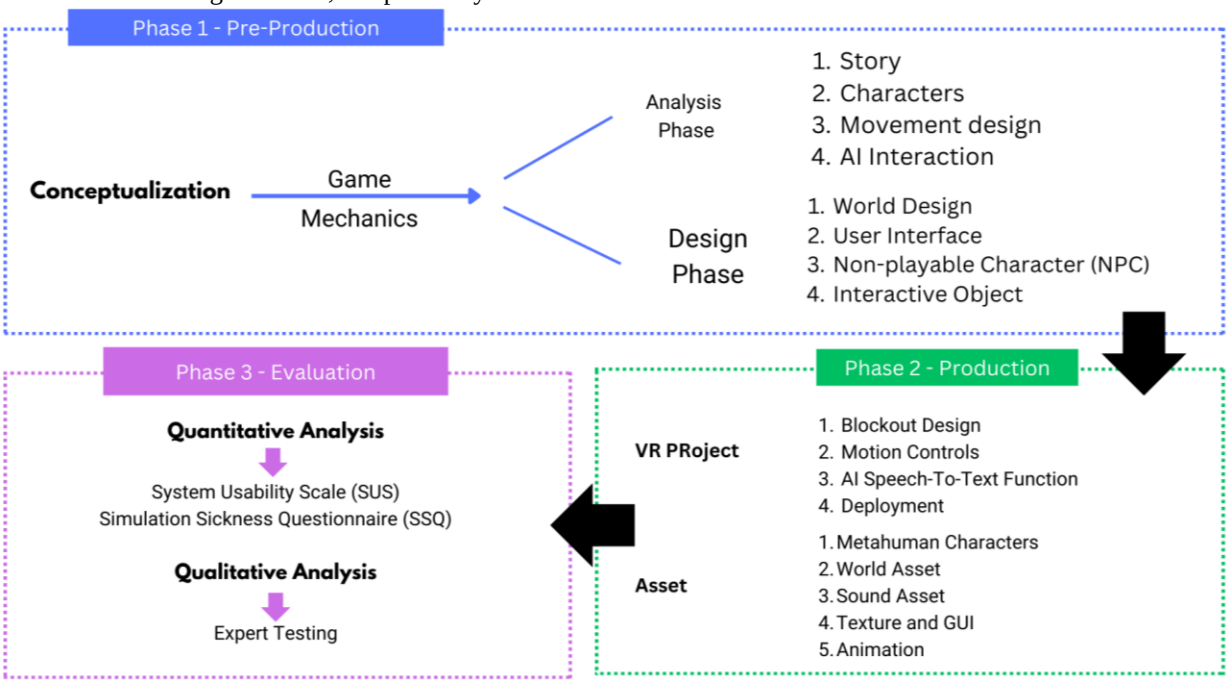

Fig. 2. Framework of AutiSim.

A. Phase 1 (Pre-Production)

The first phase involves establishing goals for an immersive autism simulation, with a focus on conceptualizing the layout design and integrating user data. The framework emphasizes enhancing user engagement through interactive objects, spatial audio simulation and real time responses from AI to simulate a realistic life situation. This approach tends to create more immersive environment, allowing users to interact with the virtual world in a way that closely replicates real-world experiences.

With the proposed enhancement aimed at creating a more immersive and engaging experience within the virtual world, the default movement mechanic in Unreal Engine originally based on teleportation is replaced with a more realistic locomotion system. Teleportation is initially implemented as the default method to help users become familiar with basic VR mechanics and to ease them into the virtual environment without overwhelming them. This method allows users to jump from one point to another, making it an effective tool for quick and easy navigation. However, once users are comfortable, the system transitions to locomotion, enabling them to move through the virtual space more naturally, as they would in the real world.

Unlike teleportation, which restricts users to predefined spots, locomotion grants continuous movement throughout the environment. This shift not only enhances spatial awareness but also contributes to a deeper sense of presence, making the experience feel more lifelike. The benefits of this transition can be observed in improved user interaction and engagement, as illustrated in Fig. 3.

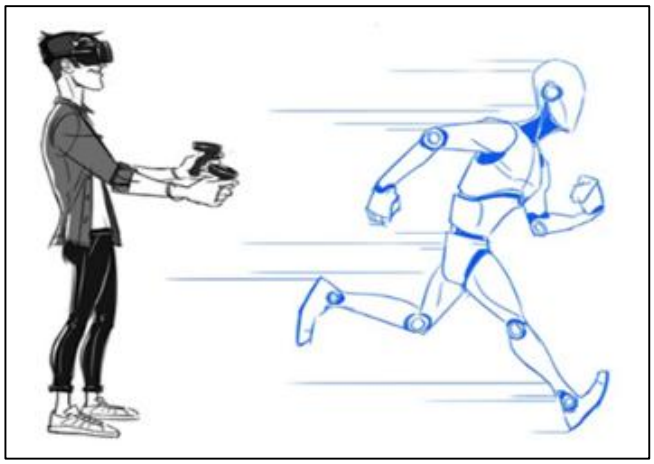

Fig. 3. Implementation of locomotion in VR.

AutiSim featured a visually appealing graphical user interface (GUI) designed to guide users smoothly from the very beginning of the game. The interface plays a crucial role in helping users feel comfortable and confident as they navigate through the virtual environment. The GUI is developed with usability and inclusivity in mind, incorporating simple language, recognizable icons, and consistent design patterns to reduce the cognitive load and prevent users from feeling overwhelmed. Key features such as intuitive menu transitions and easy-to-understand navigation options contribute to a seamless experience. Additionally, the interface will offer feedback through brief introductory explanations about the game as users progress, supporting them in making choices and understanding the outcomes of their actions. Fig. 4 illustrates the final design of the main menu in AutiSim, highlighting its clean layout, user-focused design, and ability to support a smooth onboarding process for both new and returning users.

AI non-playable characters (NPC) created by using Metahuman Creator are integrated into virtual environments to significantly enhance the immersive experience of the autism simulation game. These highly realistic avatars are meticulously crafted with detailed facial features, expressive gestures, and naturalistic movements, aligning seamlessly with the simulation's aesthetic and functional goals. The advanced customization tools of Metahuman Creator enable the creation of diverse and relatable characters, tailored to reflect unique traits, appearances, and personalities. This customization enriches the user experience by fostering deeper emotional connections and facilitating authentic, meaningful interactions within the virtual world. These characters play a pivotal role in replicating real-world social dynamics, making the simulation both educational and impactful, particularly in raising awareness about autism-related challenges. By portraying realistic behaviors, they provide users with an engaging and relatable environment that deepens their understanding of the condition. Fig. 5 and Fig. 6 showcase the transformation of character models, emphasizing the progression from initial designs to fully polished avatars.

Fig. 4. Main menu's design.

Fig. 5. Mother's character design.

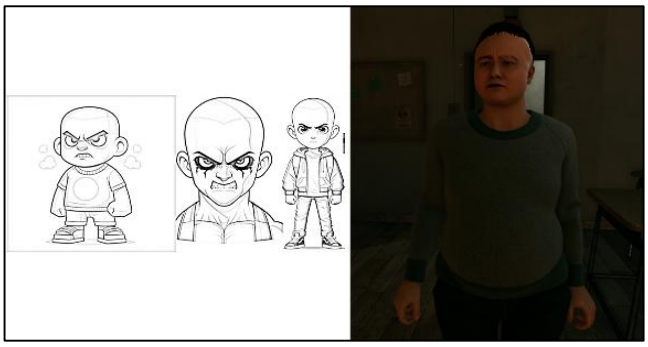

Fig. 6. Bully's character design.

Without a defined set of rules, an interactive experience cannot be categorized as a video game. Therefore, both the winning and losing conditions must be established. In each level, the winning condition is to locate the objective marker hidden within the environment while keeping the stress level as low as possible. On the other hand, the losing condition occurs when the player's stress level is maxed out, causing the game to restart from the beginning of the level.

B. Phase-2 (Production)

In Phase 2, the project moves to the production stage, where the detailed levels and scenes for AutiSim are created and finalized. This includes realistic virtual settings like an old house, a classroom, and a train station, all designed to closely resemble real places and sensory experiences. The goal is to make the simulation feel lifelike and engaging. To improve how users interact with the game, features like hand tracking for natural gestures and haptic feedback for touch sensations are added. Various software tools support this work: Unreal Engine is used for building the game, Blender for making 3D models, and Adobe Illustrator for designing visual elements and the user interface. Together, these tools help create an interactive and immersive experience that meets the aims of AutiSim.

As shown in Fig. 7, Level 1 takes place in an old brick house with a cozy, nostalgic design that feels like early childhood. This setting represents the player's younger years, from about age 3 to 12, and helps them feel comfortable as they start the game. The familiar rooms and decorations make it easy to get used to the simulation. The main purpose of Level 1 is to teach players how to move around, interact with objects, and understand basic controls through simple tutorials and prompts. Some of the basic interactions provided include a healing mechanic, moving around the character and interacting with the AI character to learn more about autism and how it can affect someone's daily life situation.

Fig. 7. Level 1 design.

Level 2 introduces players as high school students, aged approximately 13 to 18, attending a regular public high school, instead of a special needs school, as displayed in Fig. 8. The challenge in this level is to navigate out of the classroom without interacting with others, reflecting the tendency of individuals with ASD to prefer solitude and avoid social engagement. Additionally, other students (represented by AI NPCs) may observe and mock the player, further emphasizing the social difficulties often experienced by those with ASD. The environment is designed to simulate a realistic and sometimes overwhelming school setting, with background chatter, shifting body language, and unpredictable peer behavior. This level encourages players to develop awareness of how social anxiety and overstimulation can affect decision-making and behavior in typical school environments.

Level 3 introduces players to adulthood, where the character is around 18 to 25 years old, with the objective of catching a train as quickly as possible to avoid noise disturbances in a public place. The train station environment is heavily inspired by the design of Keretapi Tanah Melayu Berhad (KTMB) stations across Peninsular Malaysia, featuring the iconic yellow and blue signboards to provide a strong sense of localization for players. This familiar setting enhances immersion and cultural relevance. Realistic sounds such as train engine noises and crowd chatter are added to simulate the sensory challenges often faced by individuals with Autism Spectrum Disorder (ASD). Fig. 9 shows the level design for Level 3.

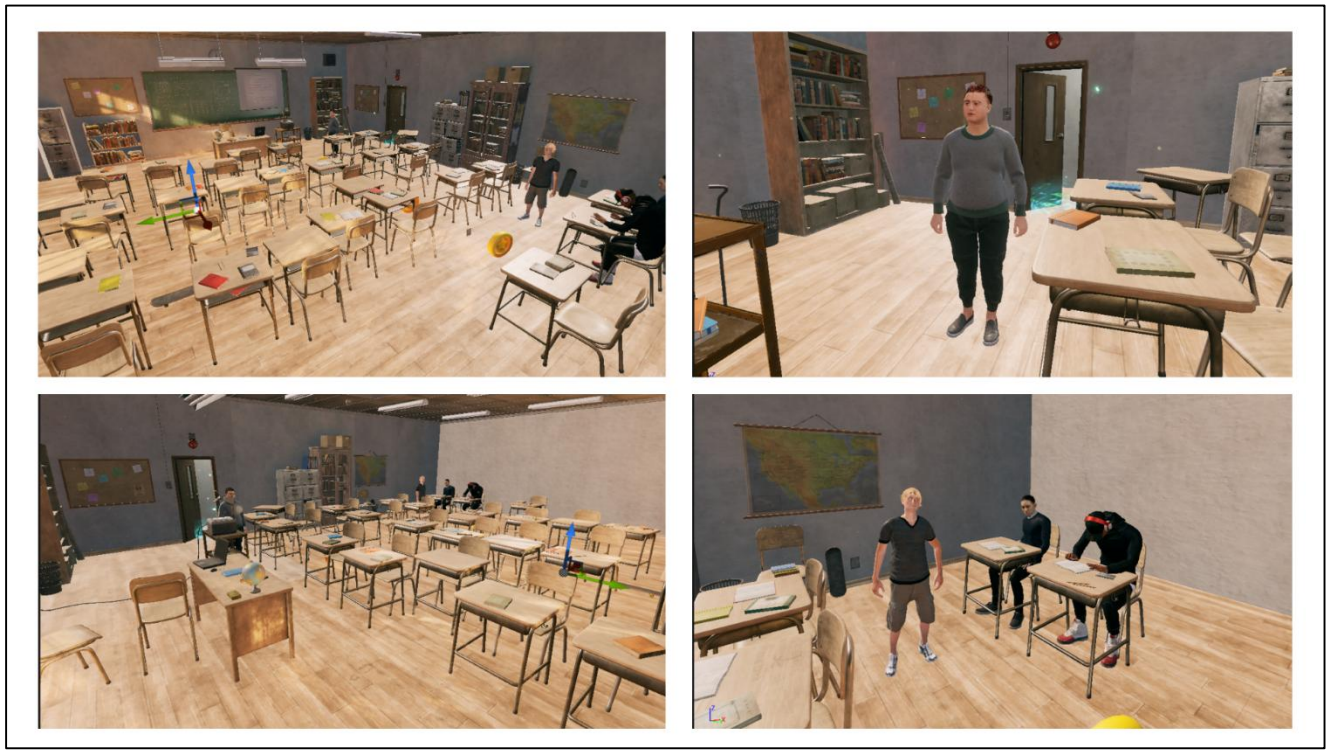

Fig. 8. Level 2 design.

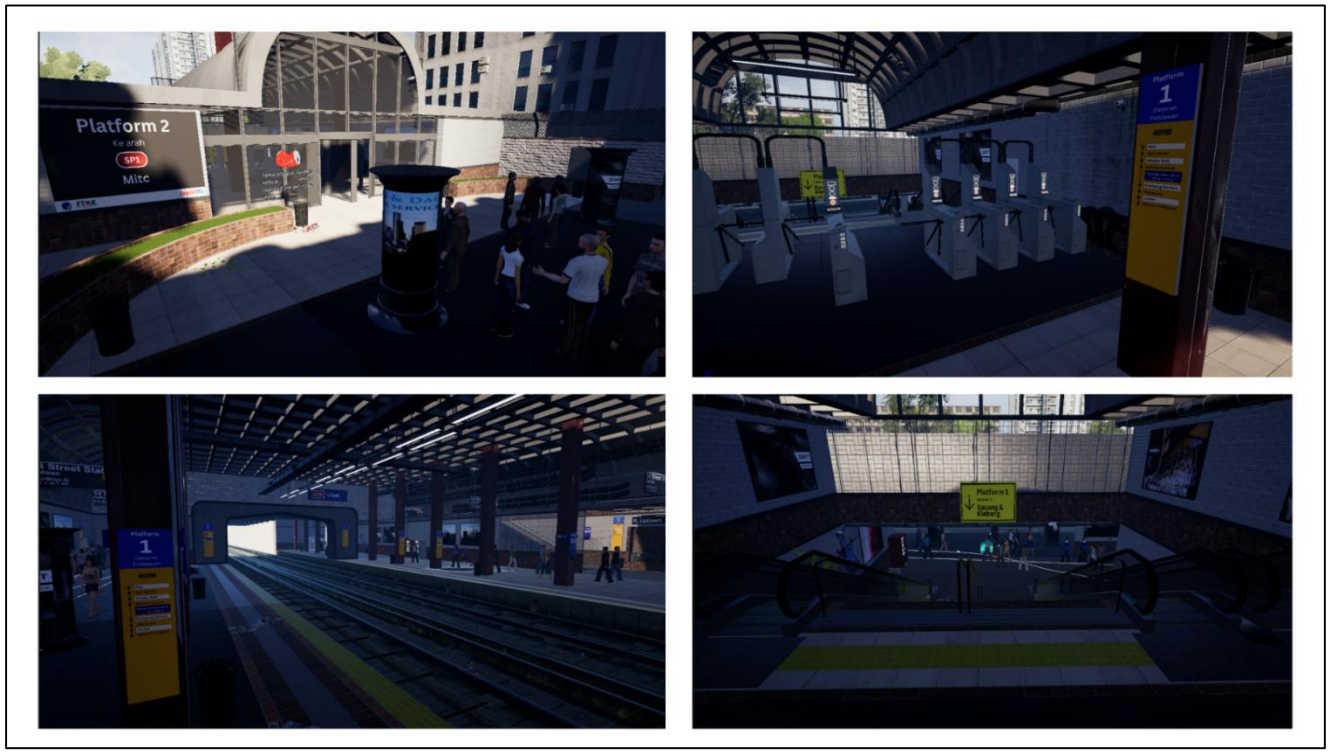

Fig. 9. Level 3 design.

This game incorporates spatial audio in combination with visual and damage effects to replicate the sensory challenges often experienced by individuals on the autism spectrum when exposed to overwhelming or sensitive stimuli, such as loud or high-pitched sounds. These sensory elements are designed to simulate real-world experiences, helping players and observers gain a deeper understanding of how such stimuli can impact focus, comfort, and overall functioning. One example of this occurs when the player steps into a designated hitbox area, which immediately triggers the sound of a boiling kettle with an

intentionally sharp and continuous noise that may be distressing or distracting for some individuals. In response to this audio cue, a blurriness effect overlays the screen to visually simulate sensory overload, accompanied by a gradual reduction in the player's health or energy to reflect the mental and emotional strain caused by the stimulus. This combination of spatial audio and reactive visuals adds an extra layer of immersion and empathy-building to the gameplay. Fig. 10 illustrates how the blur effect disrupts the player's field of vision, demonstrating the potential impact of sensory overstimulation on everyday activities within the virtual environment.

Fig. 10. Blur effect triggers when encountering an obstacle.

As for the character, a 3D photogrammetry technique is used to create realistic human features [26] [27]. The process involves capturing a high-resolution, panoramic 360-degree photo of the model's face to ensure that every detail is accurately recorded—from the broader facial contours and bone structure to subtle features like skin texture, fine wrinkles, and expression lines. This comprehensive scanning technique allows for an exceptionally lifelike digital representation of the individual's face. The Reality Scan app is employed as the primary software tool in this process, chosen for its ability to process and reconstruct detailed 3D models with high fidelity. An iPhone 11 serves as the scanning device, offering a balance between mobility, accessibility, and image quality. Together, this combination of hardware and software produces a remarkably realistic output, often requiring little or no manual adjustment or post-processing. The simplicity and efficiency of the setup make it ideal for quick integration into the development pipeline, especially for projects focused on creating immersive virtual environments. Fig. 11 illustrates the step-by-step process and shows the result of the facial scan, highlighting the precision and clarity of the digital model.

With the 3D character featuring realistic facial details completed, a facial capture technique is further implemented to animate the character's face using an iPhone 11 and LiveLink by Unreal Engine. This technique enables real-time projection of facial movements onto the 3D model, along with voice integration, to create a tutorial introduction to the game. The tutorial will pop up in the main menu, guiding players on what to expect and what they will learn, improving their overall experience and understanding of the game. Fig. 12 highlights the facial capture process and the resulting animations, showcasing the seamless integration of these elements into the game.

Fig. 11. The process of how character is created.

Fig. 12. The facial capture for the introduction.

C. Phase-3(Testing)

For the final phase, the evaluation involved both quantitative and qualitative analysis through a series of testing sessions with students and experts [28] [29]. Quantitative analysis was carried out using the System Usability Scale (SUS) and the Simulator Sickness Questionnaire (SSQ) method. SUS was measured through a 10-question survey, with the total score calculated and converted to a final score between 0 and 100. Higher scores indicate better usability, with scores above 68 generally considered above average. SSQ collected feedback on any discomfort or symptoms users experienced during the VR sessions, addressing potential issues to improve user comfort.

As for qualitative analysis, it was performed through expert testing, offering valuable insights from their experiences with the VR content, which informed further improvements. The expert testing involved professionals from both the VR technology and autism fields, ensuring a comprehensive evaluation from both technical and therapeutic perspectives.

IV. Results and Discussion

A. System Usability Scale (SUS)

This section presents the results of the System Usability Scale (SUS) assessment conducted to evaluate the overall usability and user experience of the application. The evaluation involved a total of ten participants, consisting of seven students and three teachers from SMK Tunku Syed Idrus Tampin. Participants were selected to represent both the target users and educational facilitators who would potentially engage with or guide the use of the application in a real-world setting. Each participant completed the SUS questionnaire after interacting with the system, providing feedback on aspects such as ease of use, functionality, and overall satisfaction. The responses were then scored and analyzed to produce a quantitative measure of the system's usability. The results, summarized in Table I, offer valuable insight into how effectively the application meets user expectations and identifies areas for potential improvement. SUS results for ten participants.

TABLE I. SUS RESULTS FOR 10 PARTICIPANTS

Participants	Raw Score	Final Score
P1	40	92.5
P2	25	75
P3	39	80
P4	25	50
P5	44	50
P6	20	85
P7	44	67.5
P8	21	70
P9	43	72.5
P10	26	87.5
Average		73

The AutiSim SUS score was 73, just above the industry benchmark of 68 [29]. Users thought the game worked well, was simple to learn, and had a good interface and usability [30] [31]. Although virtual reality (VR) technology is not yet widely accessible due to the need for specialized and often costly hardware, the above-average System Usability Scale (SUS) score indicates that the game is positively received and well-accepted by users despite these limitations. This suggests strong potential for wider adoption as accessibility improves over time. The high usability rating reflects the effectiveness of the game's design, interface, and interactive elements in delivering an engaging experience [32]. For further enhancing the user satisfaction and improving future SUS scores, optimizing the game's performance, particularly the frame rate and addressing the key issues highlighted in user feedback will be essential.

B. Simulation Sickness Questionnaire (SSQ)

In this section, the same ten participants completed a pre-session Simulator Sickness Questionnaire (pre-SSQ) first to assess their initial condition. After experiencing the VR project, they filled out another post-session Simulator Sickness Questionnaire (post-SSQ) to evaluate any changes. The radar chart in Fig. 13 shows the results from the SSQ questionnaire.

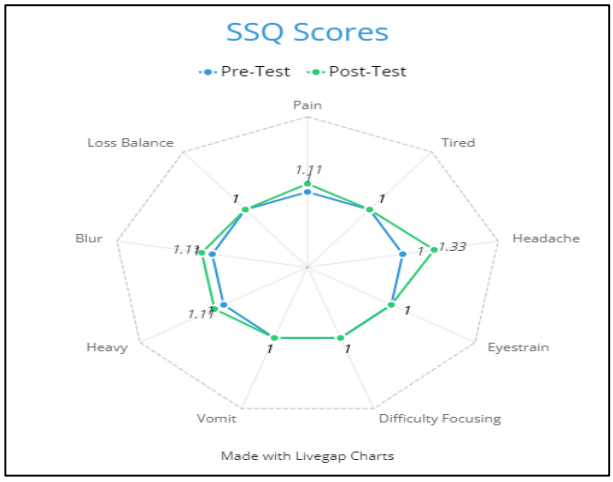

Fig. 13. SSQ's results.

The SSQ results in Fig. 13 show a slight increase in Pain, Blur, and Heavy (from 1 to 1.11), and Headache (from 1 to 1.33) after the VR session, while other symptoms like Tired, Eyestrain, Difficulty Focusing, Vomiting, and Loss of Balance remained unchanged. This suggests mild fatigue and headache, but no major issues with other symptoms. Overall, the results indicate a positive user experience with only minor discomfort, typical for first-time VR users. These results show that AutiSim managed to deliver an immersive experience with minimal discomfort, demonstrating its potential for effective use in future sessions.

C. Expert Testing

For expert testing, the evaluation was conducted with five experts. The first expert is a leading authority in virtual and mixed reality, the second is a game design specialist, the third is the head coordinator of the National Autistic Society of Malaysia, Melaka, and the other two are teachers with expertise in working with individuals on the autism spectrum. Fig. 14 shows the results chart of the expert testing for AutiSim.

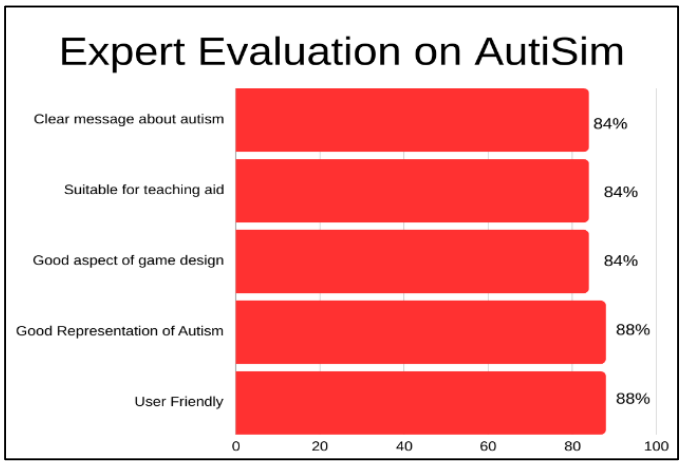

Fig. 14. Expert evaluation's chart.

User friendly refers to aspects such as movement, interaction, and speaking controls. 88% of the experts agreed that AutiSim is easy to use, highlighting the smooth locomotion system that allows players to move fluidly, as opposed to a typical teleportation scheme. Additionally, the ability to rotate the camera using both the headset and the left controller enhances the user experience, providing players with more control over their movement and camera positioning.

Next, a proper representation of autism is essential, as incorrect portrayals can lead to misunderstandings and misperceptions about the condition. It is important to highlight aspects such as slow movement, overwhelming surrounding sounds, and increased stress due to specific interactions, as these are characteristics often experienced by individuals with autism in real life. This was supported by 88% of the experts, who agreed that AutiSim accurately represents these aspects, contributing to a better understanding of the challenges faced by individuals on the autism spectrum.

Furthermore, 84% of experts agreed that AutiSim has a good game design, is well-suited as a teaching aid, and provides meaningful subject matter. These results highlight AutiSim significant potential as an educational tool, effectively raising awareness and deepening understanding of autism. By

combining engaging gameplay with rich educational content, AutiSim stands out as an exceptional resource for fostering empathy and promoting knowledge across diverse learning environments.

Since the expert testing was conducted in relevant environments, specifically in the VR technology and autism fields, as shown in Fig. 15, Fig. 16, and Fig. 17, respectively. Valuable feedback was gathered to improve the game. One insightful suggestion from the VR expert was that porting the game to mobile devices, such as smartphones, could help people better understand autism.

While the expert in the autism field, led by the head coordinator of the National Autistic Society of Malaysia (NASOM), Melaka branch, with over 10 years of experience, stated that the game could be a game changer for people, offering a unique way to experience autism through a game format. Additionally, it was suggested that future updates could include the ability for players to interact in multiple languages.

Fig. 15. VR Expert testing AutiSim.

Fig. 16. Head of coordinator NASOM trying the simulation.

Fig. 17. NASOM staff trying the simulation.

Overall, based on the expert testing conducted. AutiSim reflects highly positive feedback, with experts from both the VR technology and autism fields recognizing its potential as an impactful tool for raising awareness and fostering a deeper understanding of autism. The immersive experience was lauded for its ability to provide users with a unique and engaging way to experience the challenges faced by individuals with autism. The game's design, including its educational value and realistic portrayal of autism-related experiences, was praised. Experts also suggested that porting the game to mobile devices could make it more accessible to a wider audience. Additionally, it was recommended that integrating additional features, such as multi-language support, could further enhance the game's accessibility and broaden its reach. These positive insights indicate that AutiSim has the potential to be a valuable resource in both educational and awareness-raising contexts.

V. CONCLUSION

In conclusion, AutiSim highlight its potential as a transformative tool for raising awareness and understanding of autism spectrum disorder (ASD). Utilizing the immersive capabilities of virtual reality, AutiSim offers an engaging and realistic experience that replicates the sensory and social challenges faced by individuals with autism. The project followed a structured methodology based on the Game Design Life Cycle (GDLC), encompassing pre-production, production, and evaluation phases, ensuring a well-rounded and effective approach.

During the pre-production phase, a literature review guided the conceptualization of the game, addressing gaps in the representation of autism in existing games. This phase also defined the immersive features of AutiSim, including locomotive movement, AI-driven non-playable characters (NPCs), and realistic environments. The production phase brought these concepts to life using advanced software like Metahuman Creator, Unreal Engine, and Reality Scan, resulting in a highly realistic and educational simulation. The game's multi-level design allowed players to explore autism-related challenges across different life stages, providing a comprehensive learning experience.

The evaluation phase utilized both quantitative and qualitative methods to assess the game's effectiveness. The System Usability Scale (SUS) scored 73, exceeding the industry benchmark, indicating user satisfaction and ease of use. The

Simulator Sickness Questionnaire (SSQ) showed minor increases in symptoms like headache and fatigue, which are typical for first-time VR users, but overall results indicated a positive user experience. Expert testing further validated the game's effectiveness, with 84% agreeing it is suitable as a teaching aid and 88% commending its accurate representation of autism-related experiences. Experts also provided actionable suggestions, such as adding multi-language support, optimizing visuals for smoother performance, and porting the game to mobile devices to improve accessibility.

Despite these promising results, the project has certain limitations that need to be addressed in future work. The limitations of this project include the restricted capability for AI characters to communicate with users in multiple languages, as the current system supports voice interaction in only one language due to resources and budget constraints. Furthermore, the study faced technical and hardware challenges in implementing the project as a fully standalone application that runs natively on a VR headset, which required significant optimization and affected the seamless deployment and performance of the simulation.

In summary, AutiSim effectively combines education and entertainment through innovative VR technology and a well-executed design. With planned refinements based on SUS, SSQ and experts' feedback, the game has the potential to become a useful resource in educational settings and public awareness initiatives, promoting empathy, understanding, and acceptance.

ACKNOWLEDGMENT

This research was funded by a short grant from Universiti Teknikal Malaysia Melaka through Penyelidikan Jangka Pendek Perintis 2024, No: PJP/2024/FTMK/PERINTIS/SA0042. The authors gratefully acknowledge the Centre for Research and Innovation Management (CRIM) for its administrative and logistical support throughout the research process. Sincere appreciation is extended to the Pervasive Computing and Educational Technology (PET) research group for their invaluable guidance, collaboration, and consistent support during all phases of the study. The authors also wish to recognize the Department of Interactive Media, Fakulti Teknologi Maklumat dan Komunikasi, UTeM, for providing essential resources and technical assistance. Special thanks are owed to the National Autistic Society of Malaysia (NASOM) Melaka for their partnership and constructive feedback, which played a vital role in shaping the outcomes of this work. Lastly, the authors are deeply grateful to all contributing researchers whose insightful recommendations and scholarly input significantly enriched the quality and impact of this research.

***Abstract*—Enterprise System Projects (ESPs) are fundamental enablers of digital transformation across organizations, yet they consistently suffer from high failure rates, often attributed to ineffective Knowledge Transfer (KT) practices. Despite the critical role of KT in ensuring project sustainability and long-term organizational learning, limited scholarly attention has been given to identifying and systematically categorizing the success factors that influence KT outcomes in ESPs. The aim of this study is to investigate and conceptualize the Critical Success Factors (CSFs) that influence effective knowledge transfer in ESPs. To address this research gap, a mixed-methods approach is used, combining a literature review with empirical insights from semi-structured interviews with industry practitioners involved in large-scale ESP implementations. The analysis reveals a set of interrelated CSFs that significantly impact KT effectiveness. Some of the key points highlighted are the shared knowledge between cultures, the high expertise of consultants based on technicality and social skills, and the solid and visible management support. These points are integrated into a conceptual framework that enhances conceptual understanding while offering practitioners practical guidance. The study contributes by bridging the gap between the KT concept and ESP implementation, which are connected to the academic discourse, proposing a comprehensive model for successful knowledge transfer during the deployment of ESP. From a practical standpoint, the findings offer organizations a strategic lens to design and implement KT mechanisms that enhance project outcomes and ensure long-term knowledge retention.**

Keywords*—*Enterprise system projects (ESPs); knowledge transfer (KT); critical success factors (CSFs); digital transformation; knowledge-sharing culture; management support; information systems implementation

I. Introduction

ESPs are essential to modern organizations pursuing trending digital transformations. They enable real-time access to data, cross-functional automation processes, and calculated decision-making by integrating basic business functions, such as finance, human resources, supply chain, business intelligence, and management of customer relationships, into centralized platforms according to [1] With organizations increasingly investing in digital capabilities to stay competitive, enterprise system deployment is frequently considered a technological and organizational imperative. Despite the significance of ESPs, the failure rate remains alarmingly high, with reported project failures often occurring in meeting critical baseline objectives in terms of cost, scope, or sustained usability. This supports the assertion made by [2], [3]. Due to these consistent failures, a comprehensive understanding of the underlying challenges beyond technological factors and encompassing socio-organizational dynamics, particularly in knowledge processing, must be explored.

The effective collaborative transfer of knowledge, from external consultants to internal teams and stakeholders, remains one of the most critical yet underappreciated aspects of ESP integration. KT plays a significant role in the long-term success and sustainability of ESPs, especially following implementation, when system shifts between internal teams and consultants are made through maintenance, adaptation, and extension responsibilities. As noted by [4], KT is a complex, multi-layered activity, involving transference of tactical and precise knowledge, cross-boundary collaboration, and shared understanding development across culturally and functionally diverse groups, not only a process of training or documentation, as identified by [5]. Ineffective KT can lead to an inability to utilize the system efficiently, poor user adoption, high maintenance costs, and eventual system underperformance or failure. Yet, despite its recognized importance, KT remains a minor concern in many ESP studies and implementations, often treated as a less critical task rather than a strategic priority, as noted by [6].

Critical Success Factors (CSFs) provide a helpful lens to examine KT effectiveness in ESPs. CSFs refer to the limited number of key areas in which satisfactory performance is essential for the success of a project as mentioned earlier by [7], [8]. In the context of ESPs, numerous CSFs have been proposed, ranging from top management support and user involvement to effective project planning and change management as shown by [9], [10]. However, these aspects are typically considered together, without a focused exploration of how they specifically impact knowledge transfer. Moreover, the interdependencies among CSFs—how they reinforce or constrain each other in practice—are rarely unpacked in empirical studies. For instance, while top management support is often cited as a CSF, its influence on KT may depend on how visibly and consistently

that support is demonstrated, and whether it translates into concrete actions such as resource allocation, stakeholder engagement, or performance monitoring, as noted by [11]. Similarly, while consultant expertise is critical, its impact on KT is mediated by the receiving organization communication channels, cultural compatibility, and absorptive capacity according to [6].

Despite the availability of frameworks that address general KT practices or ESP success factors, few studies have systematically integrated these domains to identify the specific CSFs that influence KT in enterprise system contexts. Those that do often lack empirical validation or fail to account for the dynamic nature of KT, which evolves across different project phases and stakeholder groups [12]. Furthermore, much existing research is based on single-case studies or surveys with limited contextual sensitivity. There is a pressing need for research that synthesises existing knowledge and generates new insights based on empirical data from practitioners who have directly experienced the complexities of ESP implementation.

This study addresses this gap by exploring the CSFs that successfully impact KT in ESP environments. Drawing from the insights of a literature review and empirical data collected through semi-structured interviews with stakeholders involved with large-scale ESP implementations and KT processes, the research identifies and categorizes a set of interrelated success factors, including management support and a knowledge-sharing culture. The findings reveal that these CSFs do not operate alone but are linked, in which the effectiveness of one factor often depends on the presence or quality of others. For example, a strong knowledge-sharing culture may enrich the benefits of consultant expertise, as argued by [13].

A key contribution of this study is developing a conceptual framework that maps the relationships between identified CSFs and KT outcomes in ESPs. In contrast to current models that mainly consider success factors as isolated variables, this framework adopts a systems perspective, highlighting the importance of dynamic collaborations between organisational structures, human behaviour, and technological tools. Unlike models that treat success factors as discrete variables, this framework adopts a systems perspective, emphasizing the dynamic collaborations among organizational structures, human behavior, and technological tools. It seeks to report the KT challenges by systematically identifying and understanding the key CSFs that allow organisations to apply external knowledge meaningfully within their settings. By bridging the gap between KT theory and ESP practice, this study contributes to both academic knowledge and practical application, offering a foundation for more resilient, adaptive, and knowledge-driven enterprise systems in the digital age.

In response to the persistent KT challenges in ESPs and the limited frameworks addressing them, this study poses the following research questions (RQ):

RQ1: What are the critical success factors that influence effective knowledge transfer in enterprise system projects?

RQ2: How can a practical and conceptual framework be developed to assess and enhance the knowledge transfer of ESPs' implementation?

The remaining study is structured as follows: Section II presents a review of studies related to ESPs, particularly focusing on CSFs that significantly influence Knowledge Transfer (KT) outcomes in ESPs. Section III outlines the research methodology adopted in this study, including the rationale for a qualitative approach and the dual-method strategy comprising a literature review and semi-structured interviews. Section IV presents the results of the thematic analysis, drawing on responses from study participants and relating to the findings from the literature review. Section V offers a discussion of the results. The proposed conceptual framework is also introduced in this section. Finally, Section VI concludes the study by summarizing key findings, discussing implications for theory and practice, and offering directions for future research.

II. Literature Review

ESPs have long been studied for their transformative potential within organizations, primarily through their ability to streamline operations, enhance data integration, and support decision-making at strategic and operational levels, as shown in the works of [14], [15], and [16]. ESPs are typically complex, high-cost initiatives involving multiple stakeholders, technologies, and organizational units, which require significant change management and learning efforts to ensure their success. This supports the assertion made by [17].

While much of the early literature emphasized ESP implementation's technical and functional aspects, a growing body of research has highlighted the pivotal role of human and organizational factors in shaping project outcomes. These findings corroborate those of [5] and [9]. Among these, the KT has emerged as a critical but underexplored domain, especially in ESPs, where much of the expertise resides with external consultants rather than internal users. The challenge lies in conveying technical system knowledge and fostering a deep understanding of business processes, system customization, and change implications, where similar conclusions were drawn by [16] and [18]. The literature has identified several barriers to effective KT, including insufficient documentation, lack of contextual adaptation, resistance to change, and limited absorptive capacity, which is supported by [9], [4], [10], [19], and [20]. For example, there is a lack of recognition and support, trust in the quality and accuracy of information, and the convenience and effectiveness of sharing tools. This view is supported by multiple studies, including those of [7], [10], [11], [12], and [13].

Despite these insights, empirical research that systematically investigates the conditions that foster or hinder KT in ESPs remains limited, particularly in identifying and validating CSFs that enable KT efficacy. The concept of CSFs was first articulated by Rockart (1979), who defined them as the few key areas in which satisfactory performance is essential for achieving organizational goals, as argued by [7]. In the context of ESPs, CSFs have been widely examined, with most studies identifying factors such as top management support, clear goals and objectives, user training, change management, and consultant expertise as crucial to implementation success. Strong empirical support for this position is found in the work of [9], [10], [21], and [22]. However, these studies often treat CSFs as generalized enablers of project success rather than

specific originators to effective KT. This generalization limits the explanatory power of CSFs in addressing the nuanced, process-oriented challenges that arise in knowledge-intensive implementations like ESPs.

Recent research has begun to narrow this gap by focusing on KT-specific CSFs as observed in the work of [23]. For example, a model was proposed in which consultant credibility, client motivation, communication quality, and relationship strength were key enablers of successful knowledge transfer. Their findings suggest that KT is a socially embedded process influenced by trust, mutual understanding, and collaborative engagement. Scholars consistently identify top management support as a pivotal CSF in KT and ESP research. It is critical not only for resource mobilization and strategic alignment but also for legitimizing knowledge-sharing behaviors across the organization, which is supported by [20] and [24]. Contrary to the view of authors in [7], who found that management support plays a critical role in the success of KT, in addition to the success of the ESP. Another research [14] revealed that a lack of top management knowledge of product capabilities is one of the ESP success barriers. In contrast, [15] highlighted that top management extensively influences the KT. Furthermore, from research findings in [8] and [9], it emerged that top management support is vital for the success of the ICT project. This view is supported by multiple studies, including those of [10], [16], and [17]. When top management visibly endorses KT initiatives, it creates an enabling environment where employees are more likely to engage in learning activities, participate in workshops, and experiment with system functionalities. Conversely, a lack of executive involvement often leads to fragmented efforts, low user motivation, and resistance to knowledge assimilation.

Another vital factor is consultant expertise, according to [9], which goes beyond technical competence to include interpersonal skills, cultural sensitivity, and the ability to contextualize knowledge for diverse user groups in line with the findings of [25] and [26]. Consultants serve as system experts and knowledge brokers who bridge the gap between generic system capabilities and specific organizational needs. Similar conclusions were drawn by [27]. However, the efficacy of consultant-driven KT is contingent upon a knowledge-sharing culture within the client organization, as previously reported by [28] and [29]. Without a culture that values collaboration, openness, and continuous learning, even the most structured KT efforts may fail to take root.

Communication quality has also been identified as a determinant of KT success. Effective communication entails clarity, consistency, feedback loops, and mutual understanding between knowledge senders and receivers, according to [30]. In ESP projects, communication breakdowns are common due to jargon, role ambiguity, and misaligned expectations. Studies have shown that structured communication channels—such as regular status meetings, shared documentation platforms, and escalation protocols—enhance KT effectiveness by reducing uncertainty and reinforcing shared meanings. Similar conclusions were drawn by [16]. While researchers in [18] and [19] found that strong communication facilitates easy KT and better ESP adoption, authors in [20] argued that poor or ineffective communication can lead to silos and resistance to change resulted on ESP project over runs. In [21], the authors examine the communication quality from a contextualization perspective to ensure the ESP team receive the correct information concerning their level of expertise or business context, while scholars. In [22] and [23], the authors highlight the impact of trust, which is consistent with [24]. In addition to openness, there is a need to enhance the quality of communication.

In summary, while the literature on ESPs, KT, and CSFs has matured significantly over the past decades, critical gaps remain in integration, contextualization, and empirical validation. Table I presents the KT-specific CSFs identified in recent literature as essential for facilitating successful KT in ESPs. These factors span leadership, human capital, communication, motivation, culture, relationships, and learning capability, highlighting the multidimensional nature of KT effectiveness.

While existing research offers valuable insights into individual success factors, there is a lack of a holistic understanding of how these elements interact to influence KT outcomes in enterprise system environments, as identified by [25]. The present study seeks to bridge this gap by developing an empirically grounded framework that identifies, categorizes, and analyzes CSFs affecting KT effectiveness in ESPs, thereby contributing to theoretical advancement and practical application in this evolving field.

TABLE I. CRITICAL SUCCESS FACTORS (CSFS)

CSF Domain	KT-Specific Critical Success Factor	Definition	Supporting Studies
Leadership & Support	Top Management Support	Strategic endorsement and resource allocation for KT legitimize knowledge-sharing behaviors.	[20], [24]
Human Capital	Consultant Expertise	Encompasses not only technical knowledge but also interpersonal skills and contextual understanding.	[25], [26], [28], [29]
Communication	Communication Quality	Quality of interactions: clarity, consistency, feedback, and shared understanding.	[16], [30]
Motivational Factors	Client Motivation	Internal drive and willingness of the organization to participate in and absorb transferred knowledge.	[21]
Cultural Context	Knowledge-Sharing Culture	Organizational norms that promote openness, collaboration, and learning.	[28], [29].
Relational Dynamics	Relationship Strength	Trust and rapport between consultants and client stakeholders foster mutual KT.	[21], [25]
Process Management	Structured Communication Channels	Formalized mechanisms such as meetings, platforms, and escalation paths for KT.	[16]

III. METHODOLOGY

This study adopted a qualitative, interpretivist research methodology to investigate the CSFs that influence KT effectiveness in ESPs. KT within large-scale system implementations is inherently complex, context-sensitive, and socio-technical. Therefore, a qualitative approach was valued as the most suitable approach to explore the perceptions, behaviors, and organizational conditions shaping successful KT practices, similar to the approach that was rooted in [26], [27], and [28]. Through a mixed-method approach, the study involved a literature review and semi-structured interviews as core empirical instruments. This allowed for an in-depth understanding of the explored topics. The literature review provided a base for identifying initial theoretical constructs and established a conceptual foundation for understanding KT-specific CSFs in ESP contexts. Sources were selected from various databases, including Scopus, Web of Science, Science Direct, and Google Scholar, containing journals in information systems, knowledge management, and enterprise systems. The review focused on identifying patterns, gaps, and limits in existing frameworks related to KT and ESP success, with special attention paid to studies incorporating organizational learning based on insights from [29], [30], in addition to change management, as argued by [17], and consultant-client dynamics as previously reported by [31].

The findings from the literature review informed the selection of five thematic categories: management support, consultant expertise, absorptive capacity, communication quality, and knowledge-sharing culture. Building on this foundation, the second phase involved conducting semi-structured interviews to explore how these themes manifest in real-world ESP implementations. Semi-structured interviews were chosen for their flexibility and capacity to elicit rich, contextually grounded insights while allowing for consistency across interviews in line with the findings of [32], [33]. The interviews enabled participants to reflect on their experiences and elaborate on how knowledge was shared, absorbed, and operationalized during the ESP lifecycle.

A purposive sampling strategy was employed to recruit participants directly involved in ESP implementations and KT processes. Eligible participants included the IT Director, Planning and Quality Director, Solution Architect, Technical Specialist, IT Management Consultant, IS Project Manager, and Techno/Functional Specialist. All participants had been directly involved in ESP implementation within the past ten years, ensuring contemporary relevance. To promote diversity of experience, participants were drawn from various sectors, including manufacturing, healthcare, higher education, and government services. Fig. 1 illustrates the distribution of the business sectors. The interview sample was selected based on the criteria shown in Table II.

Seven semi-structured interviews were conducted, each lasting between forty minutes on average. Interviews were held using Google Meet or MS Teams. Before the interviews, participants were provided with an overview of the research objectives and signed informed consent forms. Interviews were guided by a protocol informed by the literature review themes but remained open-ended to accommodate emergent issues. All interviews were audio-recorded with consent and transcribed verbatim for analysis. Ethical approval was obtained from the lead institution's research ethics board, and strict confidentiality protocols were followed to protect participant identities.

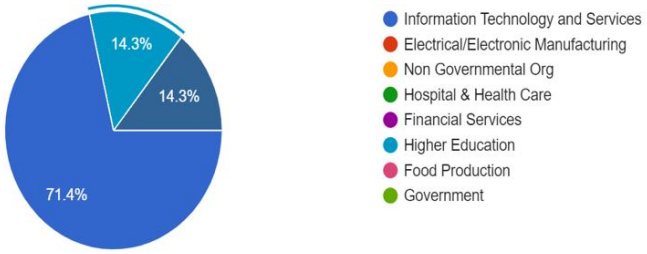

Fig. 1. Participants' distribution within the business sectors.

TABLE II. CRITERIA OF INTERVIEW PARTICIPATION

Expertise	At least 10 years of experience in ESP implementation and knowledge management.
Relevance	Direct involvement in ESP projects with varying outcomes (successful, challenged, or failed).
Diversity	Representation from different roles within ESP projects (e.g., project managers, system architects, and KT facilitators).

The qualitative data gathered from semi-structured interviews with ESP professionals was evaluated using thematic analysis. To identify recurrent themes, patterns, and insights on the specialized field of ESP, the researchers carefully reviewed and classified the written material obtained from the interviews. Through the thematic analysis, researchers were able to develop a better understanding of the ESP experts' viewpoints, experiences, and knowledge, which helped to offer valuable insights and conclusions for the study. Combining a literature review and interview-based understanding helped support this study's methodological triangulation, allowing the research to bridge theory and practice. While the literature provided a structured view of the academic views and gaps concerning KT in ESPs, the interviews offered in-depth insights into how practitioners operate, interact, and perceive these factors in a real-life context.

IV. FINDINGS AND CONCEPTUAL FRAMEWORK

The thematic analysis of seven semi-structured interviews revealed a set of five interrelated CSFs that significantly influence KT outcomes in ESPs. Namely, top management support, consultant expertise, communication quality, and knowledge-sharing culture. While these key factors were also identified in the literature review, the interviews provided significant, practice-driven insights that paved the way for a holistic understanding of the CSFs that influence KT outcomes in ESPs. The acquired knowledge helped develop the conceptual framework for knowledge transfer success in ESPs.

A. Top Management Support

One of the most cited enablers of effective KT was top management support. Participants repeatedly emphasized that leadership involvement must go beyond symbolic endorsement to include active resource allocation, milestone enforcement, and public reinforcement of knowledge-sharing behaviors. For example, one IT project manager noted, "It wasn't just the CIO giving a speech at the launch meeting. He reviewed our KT progress, ensured we had dedicated time for shadowing, and

rewarded teams that documented lessons learned". This finding reinforces the argument that visible, engaged leadership sets the tone for KT prioritization and legitimizes it as a core organizational process, as noted by [20], [24].

B. Consultant Expertise

Another pivotal factor was consultant expertise, but the interviews revealed that technical knowledge alone was insufficient. Effective consultants were described as capable of adapting explanations to user skill levels, facilitating trust-based relationships, and embedding learning opportunities within routine activities. A participant from the manufacturing sector described one consultant as "not just a tech whiz, but a people person who knew how to coach our finance team without overwhelming them". This echoes the authors in [25], [26]. The claim is that consultants' social and communicative competence significantly enhances KT effectiveness.

C. Communication Quality

Widely emphasized in the data, effective communication plays a dual role by facilitating other CSFs and mediating their impact on KT success. Transparent, collaborative, and timely communication was essential for clarifying expectations, resolving ambiguities, and aligning stakeholders. Poor communication was linked to misconceptions about responsibilities, misinterpretation of requirements, and duplication of KT efforts. Several participants cited collaborative platforms, feedback loops, and centralized documentation as practical strategies to enhance communication. These findings corroborate prior research indicating that a robust communication infrastructure is essential for successful ESP execution and knowledge dissemination. Similar conclusions were drawn by [34],[16], and [30].

D. Knowledge-Sharing Culture

Finally, a Knowledge-Sharing Culture was described as the foundational layer that either amplified or dampened the effects of other CSFs. Organizations with norms that valued openness, learning from failure, and cross-boundary collaboration were perceived to facilitate smoother KT. Siloed structures and inflexible hierarchies, on the other hand, led to information hoarding and weak adherence to KT activities. As an IT management consultant in the financial services sector observed, "In one company, I felt like I was planting seeds in fertile soil. In another, everything bounced off—there was no curiosity, no engagement". This finding supports the literature asserting that cultural enablers significantly influence organizational learning processes, as observed in the work of [28], [29].

E. Conceptual Framework

Drawing on the empirical findings and prior theoretical foundations, a Conceptual Framework for KT Success in ESPs is proposed in Fig. 2. This framework positions KT effectiveness at the center, surrounded by interdependent CSFs. Arrows between CSFs represent dynamic interactions, while outer layers capture the organizational and temporal context within which these factors operate. The framework contributes to the literature in three key ways. First, it provides a validated, practitioner-informed structure that aligns with and extends existing theoretical models of KT and ESP implementation. Second, it emphasizes the interactive and systemic nature of CSFs, moving beyond linear or additive conceptions. Third, it incorporates a temporal perspective, suggesting that effective KT strategies require flexibility and responsiveness to the evolving demands of different implementation phases.

The findings highlight that successful KT in ESPs is not the result of isolated best practices but rather an outcome of strategically aligned, culturally embedded, and dynamically coordinated actions. Organizations aiming to enhance ESP performance must adopt integrated KT strategies, considering structural enablers and behavioral and contextual dimensions.

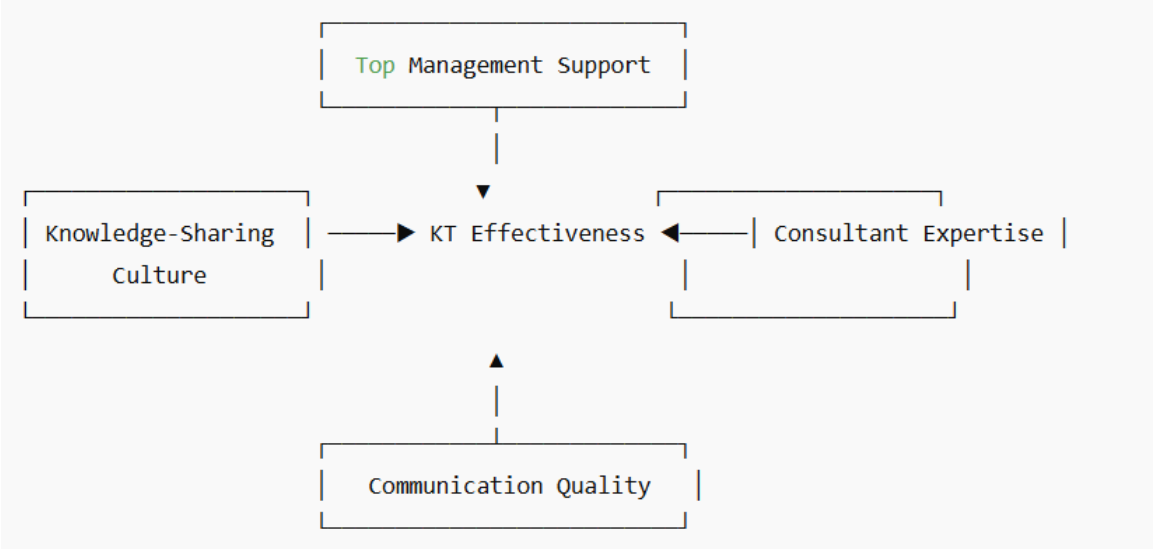

Fig. 2. Conceptual framework for knowledge transfer success in ESPs.

V. DISCUSSION

The findings of this study provide a nuanced understanding of the two research questions. Firstly, the RQ1 focus on how CSFs collectively influence KT in ESPs. While prior studies have acknowledged the importance of KT in such projects based on insights from [21], [22], [26], [30], and [32]. This research offers an empirically grounded conceptual framework integrating CSFs as standalone enablers and dynamically interdependent variables.

The empirical data significantly backs up the role of top management support, consultant expertise, communication quality and knowledge-sharing culture as essential facilitators for efficient KT. However, beyond confirming the significance of these individual CSFs, the interview data revealed their complex link. For instance, strong top management support positively affects communication quality and knowledge-sharing culture by defining allowed time for reflection, reinforcing shared goals, and embedding metrics on KT accountability and performance evaluation. Similarly, consultant expertise was most impactful when matched with trust-based relationships. These interrelationships highlight that CSFs should not be analysed as standalone components and emphasize the importance of holistic frameworks.

Secondly, the RQ2 was confirmed based on the expert feedback, and data also suggested a temporal dimension to CSF salience. During early project phases (e.g., planning and configuration), top management support and communication were most critical. In contrast, absorptive capacity and knowledge-sharing culture became more prominent during system testing and stabilisation. This temporal variability suggests that KT strategies must be adaptive, with CSF prioritization shifting based on project lifecycle stages.

VI. CONCLUSION

KT is a key process in the success of ESPs. While often overlooked in many organizational settings, this study explored KT practices within enterprise system planning (ESP) implementations and examined the key factors influencing their effectiveness. Following a literature review and semi-structured interviews, we identified several CSFs, including support from top management, consultants' expertise, communication quality, and a knowledge-sharing culture. These characteristics were repeatedly validated across research, demonstrating their interconnectedness and importance in affecting KT results.

This study addressed two primary research questions concerning the identification of KT CSFs (RQ1) and the development and validation of the proposed framework (RQ2).

First, it confirmed the fourth CSFs; the results indicated that organisations focusing on these CSFs could better internalise and apply transferred knowledge, especially when strategic leadership and collaborative environments were present.

Secondly, the study developed and validated a practical framework, revealing that KT effectiveness evolves across different stages of ESPs, thereby requiring adaptive and context-sensitive strategies. This directly addresses RQ2, with the proposed framework receiving positive validation from ESP experts. The resulting conceptual framework offers both theoretical guidance and practical applicability by promoting cultural alignment, systemic thinking, and responsive management practices as key enablers for enhancing KT across the project lifecycle.

Despite the valuable insights generated by this study, several limitations should be acknowledged. The sample size could be extended for more generalisation. In future, the framework can be tested across organizations of different sizes, sectors, and geographical locations to assess its broader applicability. Additionally, the study suggests that longitudinal and mixed-method approaches help capture the evolving nature of KT, particularly during post-implementation activities like system upgrades and user onboarding and offboarding, which need to be discussed. The role of modern technologies such as AI-based tools, chatbots, and learning platforms in supporting KT should also be investigated further.

ACKNOWLEDGMENT

I want to express my deepest gratitude to all those who contributed to completing this work.

***Abstract*—The integration of blockchain technology into higher learning institutions (HLIs) holds the potential to revolutionize data management, enhance transparency, and improve trust in academic systems. However, the effective adoption of blockchain requires a comprehensive and valid model that addresses the specific needs and contexts of HLIs. This study aims to assess the content validity of the Knowledge Integration Model for Blockchain in Higher Learning Institutions using Aiken's V method. The proposed model was developed through a systematic literature review and refined with expert input. Content validity was evaluated by seven experts with backgrounds in education, blockchain technology, and information systems. Each item within the model was rated for its relevance, clarity, and representativeness using a Likert scale. The instrument, consisting of 50 items across six constructs, was evaluated by seven domain experts using Aiken's V methodology. Each item was rated based on its relevance and clarity using a 5-point Likert scale. The results revealed that out of 50 items, 21 required revision or removal due to low Aiken's V scores (<0.70), 21 were deemed acceptable but required minor revisions, and 8 demonstrated strong content validity (V ≥ 0.80). These findings underscore the importance of expert evaluation in refining research instruments and ensuring construct alignment. The use of Aiken's V provided a robust quantitative foundation for the validation process. The refined instrument serves as a reliable tool for assessing institutional readiness and knowledge integration capabilities in the context of blockchain adoption. This work contributes to the growing research on educational blockchain implementation by offering a validated framework that can support empirical investigations and strategic decision-making in higher education.**

***Keywords*—Blockchain; content validity; aiken's v; higher learning institutions; knowledge integration model**

I. Introduction

Knowledge integration—the process of combining insights, expertise, and perspectives from multiple domains—is essential for ensuring that blockchain solutions are contextually relevant, sustainable, and scalable within the educational ecosystem. Although scholarly interest in blockchain applications in education is increasing, there remains a lack of research on how knowledge from technical, pedagogical, administrative, and regulatory domains can be effectively synthesized to support implementation. The integration of blockchain technology into higher learning institutions (HLIs) presents a transformative opportunity to enhance data integrity, security, and transparency in academic processes. However, a significant research challenge persists: the limited understanding of how to integrate knowledge across these domains to enable effective blockchain adoption. This study seeks to validate an instrument designed to assess the Knowledge Integration Model for Blockchain in Higher Education, thereby addressing the gap in comprehensive adoption frameworks.

The research is guided by two key questions: 1) To what extent does the proposed model demonstrate content validity?, and 2) What revisions are necessary to improve its constructs and items? The primary objective is to ensure that tools used to measure institutional readiness and integration capabilities are both valid and reliable. This study is significant as it offers a robust measurement instrument for empirical research and practical implementation of blockchain in higher education, focusing on the integration of domain-specific knowledge. Key contributions include a validated instrument, empirical evidence of content validity using Aiken's V, and a refined framework to support strategic decision-making. As blockchain technology gains momentum in the academic sector, it is crucial to ensure that assessment tools for institutional readiness, perceptions, and integration capabilities are methodologically sound.

This study evaluates the content validity, construct validity, and internal consistency of the proposed instrument through expert judgment and statistical analysis. By validating this tool, the research aims to provide a reliable foundation for future empirical studies and practical applications of blockchain technologies in higher education. The validated instrument will also serve as a critical component in examining how knowledge from technological, pedagogical, administrative, and regulatory domains can be effectively integrated to support successful blockchain adoption.

The remainder of this study outlines the literature review, methodology, presents the results, discusses necessary revisions, and concludes with implications for future research and practice.

II. Literature Review

The integration of blockchain technology into higher education institutions presents a transformative opportunity to enhance data security, streamline administrative processes, and foster a more transparent and trustworthy learning environment [1]. Blockchain, initially conceived as the foundational technology for cryptocurrencies, has transcended its original purpose and is now recognized for its potential to revolutionize various sectors, including education [2]. Its decentralized and immutable nature ensures that records are tamper-proof and verifiable, addressing critical concerns about data integrity and security that are prevalent in traditional educational systems [3]. By leveraging blockchain's inherent security features, educational institutions can protect sensitive student data, such as academic transcripts, personal information, and financial records, from unauthorized access and cyber threats [4]. This is particularly important in an era of increasing data breaches and identity theft, where the security of personal information is paramount [5].

Furthermore, blockchain technology can facilitate the creation of a more transparent and accountable educational ecosystem [6]. In traditional systems, academic records are often stored in centralized databases, which can be vulnerable to manipulation or loss. Blockchain, on the other hand, distributes data across a network of computers, making it virtually impossible for a single point of failure or malicious actor to compromise the integrity of the information [7]. This decentralized approach not only enhances security but also promotes trust among students, faculty, and administrators. Many higher education institutions have already started to implement blockchain technology for academic degree and result management [8]. Moreover, blockchain can streamline administrative processes, reduce costs, and improve efficiency in higher education institutions. By automating tasks such as transcript verification, degree authentication, and tuition payment processing, blockchain can free up valuable time and resources for educators and administrators, allowing them to focus on more strategic initiatives such as improving teaching and learning outcomes [9].

The immutability of blockchain ensures the integrity of educational records, preventing fraud and enhancing trust in qualifications [10] [11]. The characteristics of blockchain technology can address these issues within educational settings [12]. Blockchain is essentially a distributed database that boasts decentralization, security, and transparency [13] [14]. This transparency ensures that all stakeholders have access to accurate and up-to-date information, fostering a more collaborative and efficient learning environment. For example, consider the issue of verifying academic credentials. Blockchain technology provides a transparent and autonomous solution and enhances the quality of shared data among stakeholders [15]. Using blockchain, institutions can issue digital credentials that are easily verifiable, eliminating the need for time-consuming manual verification processes and reducing the risk of fraudulent claims.

Blockchain's decentralized framework offers a platform for validating data and transactions, independent of third-party control, in a secure, transparent, and permanent setup [16]. Smart contracts, self-executing agreements written into the blockchain code, can automate processes such as verifying academic credentials and managing tuition payments [17]. Smart contracts automate procedures, minimizing errors caused by people or counterfeits [18]. The employment of smart contracts streamlines auditing procedures, resulting in a 30% reduction in audit time and a 20% decrease in audit costs [19]. The use of blockchain technology could reduce project disputes arising from delayed payments [20].

The decentralized database created by blockchain technology offers enhanced security, faster payments, and improved data transfer reliability and transparency [21]. The application of blockchain extends beyond cryptocurrency, finding utility in data management, supply chain tracking, and healthcare, among other fields [22][23]. In healthcare, blockchain improves interoperability, data integrity, and security while cutting maintenance expenses [24]. As blockchain technology gains traction across various sectors, including digital currency, finance, and business [25] [26], its entrance into the healthcare industry signals a move towards more secure and efficient data management practices. Several firms have started experimenting with blockchain technology for a variety of purposes, including supply chain management, identity verification, and decentralized marketplaces [27][28]. Blockchain has many potential applications, including those in the healthcare industry [27] [29] [30]. More exploration is needed to determine the most effective way to design a blockchain-based system.

III. Methodology

This study adopts a quantitative approach involving a comprehensive content validity assessment process. The content validity evaluation was carried out through four structured and systematic phases. These phases were designed to ensure the integrity and accuracy of the research instrument, as well as to meet rigorous methodological standards in educational research.

The four phases are as follows:

- Construction development
- Expert selection
- Implementation of content validity assessment
- Revision of constructs and items

A. Construction Development

This stage involves the conceptualization and operationalization of the main constructs based on an extensive literature review. The study employs a questionnaire as the research instrument, using a 5-point Likert scale. The scale is as follows:

1 = Very inappropriate

2 = Inappropriate

3 = Not sure

4 = Appropriate

5 = Very appropriate

The instrument comprises six distinct constructs:

- Technology Factors (11 items)
- Organizational Factors (12 items)
- Environment Factors (10 items)
- Knowledge Integration (6 items)
- Perceived Usefulness (6 items)
- Blockchain Adoption Likelihood (5 items)

Total items: 50

In total, the questionnaire comprises 50 items. These constructs were developed through in-depth analysis of previous studies, content analysis, and a thorough literature review across the six constructs as presented in Table I. The measurement items for each construct were systematically developed based on an extensive review of relevant literature. Each item was carefully formulated to ensure alignment with the theoretical foundations and operational definitions established during the construct development phase.

TABLE I. ITEMS DEVELOPED FOR EACH CONSTRUCT FORMULATED FROM THE LITERATURE REVIEW

Construct	Item Code	Items
Technology - Security & Privacy	B1	Blockchain ensures unauthorized parties cannot access academic records.
	B2	Blockchain technology provides stronger data privacy than current systems.
	B3	I trust blockchain to securely store my institution's credentials.
	B4	Blockchain reduces risks of data breaches in education.
Technology - Transparency & Trust	B5	Blockchain makes academic transactions (e.g., grading) more transparent.
	B6	I can verify the authenticity of blockchain-stored records easily.
	B7	Blockchain increases trust in shared knowledge (e.g., research data).
	B8	Blockchain's transparency reduces conflicts over academic records.
Technology - Data Integrity	B9	Blockchain prevents tampering with academic records.
	B10	My institution's use of blockchain ensures accurate record-keeping.
	B11	Historical changes to records are traceable via blockchain.
Organizational - Institutional Readiness	C1	My institution has the technical infrastructure to adopt blockchain.
	C2	Budget is allocated for blockchain implementation.
	C3	Staff are trained to use blockchain-based systems.
	C4	My institution has a clear roadmap for blockchain integration.
Organizational - Leadership Support	C5	Administrators actively promote blockchain initiatives.
	C6	Leadership addresses concerns about blockchain adoption.
	C7	Faculty are encouraged to pilot blockchain tools.
	C8	Leadership prioritizes blockchain adoption in strategic plans.
Organizational - Financial & Technical Resources	C9	My institution can afford blockchain implementation costs.
	C10	IT teams are skilled in maintaining blockchain systems.
	C11	Blockchain tools are compatible with existing IT systems.
	C12	External funding (e.g., grants) supports blockchain projects.
Environment - Government Policies & Regulation	D1	National policies encourage blockchain use in education.
	D2	Legal frameworks support blockchain-based academic credentials.
	D3	Government funding is available for blockchain initiatives.
	D4	My institution complies with regulations for blockchain adoption.
Environment - Industry Collaboration	D5	My institution partners with tech firms for blockchain solutions.
	D6	Joint research projects use blockchain for knowledge sharing.
	D7	Employers recognize blockchain-verified credentials.
Environment - Societal Expectation	D8	Employers prefer candidates with blockchain-stored degrees.
	D9	Public awareness of blockchain benefits in education is growing.
	D10	Society pressures institutions to adopt transparent technologies.
Knowledge Integration (KI)	E1	Blockchain supports interdisciplinary knowledge development.
	E2	Access to shared knowledge is equitable across departments/institutions.
	E3	Archived knowledge is easily retrievable via blockchain.
	E4	Research findings are implemented faster via blockchain.
	E5	Blockchain platforms enable real-time sharing of course materials across departments.
	E6	My institution uses blockchain to track the impact of knowledge on community projects.
Perceived Usefulness	F1	Blockchain saves time in credential verification.
	F2	Using blockchain enhances my productivity as a staff/educator/student.
	F3	Blockchain simplifies administrative processes (e.g., transcript requests).
	F4	Blockchain adds value to my institution's knowledge management.
	F5	Automated smart contracts (e.g., for research royalties) improve workflow efficiency.
	F6	Blockchain increases transparency in research data sharing and citation tracking.
Blockchain Adoption Likelihood	G1	My institution plans to expand blockchain use beyond credentials (e.g., research, administration).
	G2	My institution currently uses blockchain for any academic processes (e.g., credentials, research).
	G3	Blockchain offers significant advantages over our current record-keeping systems.
	G4	Blockchain adoption has improved our institution's operational efficiency.
	G5	Blockchain supports my institution's alignment with national digital education goals (SDGs).

B. Expert Selection

To ensure the content validity of the developed model or instrument, an expert validation process was carried out. Seven (7) experts were purposely selected based on their academic qualifications, domain relevance, and professional experience exceeding five (5) years. As detailed in Table II, five (5) are academicians from local public universities, while the remaining two (2) are industry professionals with relevant expertise. All experts have active involvement in teaching, research, or system development related to the model's domain. They voluntarily evaluated the instrument via an online form, providing both quantitative ratings and qualitative feedback. This input was subsequently used to calculate the content validity indices using Aiken's V.

TABLE II. EXPERT PANEL INFORMATION FOR CONTENT VALIDATION

No.	Expert Initials	Background	Position/Role	Expertise Area	Experience	Institution/Sector
1	Expert 1	Industry	Solution Architect	Information Systems, IT Enterprise Architecture	15 Years	Bank Rakyat
2	Expert 2	Academic	Associate Professor	Blockchain System	18 years	Asia Pacific University of Technology and Innovation (APU)
3	Expert 3	Industry	Senior Manager	Big Data Analytics, Blockchain, Information Systems	18 years	Kementerian Digital Malaysia
4	Expert 4	Academic	Associate Professor	Information Systems	20 years	Universiti Putra Malaysia (UPM)
5	Expert 5	Academic	Senior Lecturer	Industrial Computing	17 years	Universiti Sains Islam Malaysia (USIM)
6	Expert 6	Academic	Senior Lecturer	Knowledge Management, MIS, Project Management	23 years	Universiti Putra Malaysia (UPM)
7	Expert 7	Academic	Senior Lecturer	Cybersecurity	8 years	Universiti Sains Islam Malaysia (USIM)

C. Implementation of Content Validity Assessment

To ensure the instrument's content validity, this study employed a rigorous quantitative validation process combining the Content Validity Index (CVI) and Aiken's V coefficient. A panel of 7 subject matter experts evaluated each item's relevance using a 5-point Likert scale, ranging from 1 (not relevant) to 5 (highly relevant). The content validity was quantitatively assessed through two complementary approaches. We statistically validated expert consensus using Aiken's V coefficient, which quantifies agreement beyond simple percentages by accounting for the rating scale's ordinal nature. The V values were calculated for each item and tested for statistical significance ($p < 0.05$), with items demonstrating $V \geq 0.70$ being retained as valid. This dual-method approach provided robust quantitative evidence of content validity through statistically validated expert judgments, ensuring the instrument's items appropriately represent the target construct while minimizing subjective bias in the validation process. To ensure that the items developed in the instrument are relevant and representative of the construct being measured, content validity was assessed using Aiken's V index. This method quantitatively evaluates the degree of agreement among subject matter experts regarding the relevance of each item. Aiken's V is appropriate for assessing content validity when experts rate items on an ordinal scale (e.g., 1 = Not Relevant to 5 = Highly Relevant). The formula used to calculate Aiken's V is as follows:

Aiken's V is calculated using the formula:

$$V = \frac{\sum (s)}{n(c-1)}$$

where,

$s = r - l$

r = rating given by expert, l = lowest possible rating

n = number of experts

c = number of possible rating categories (e.g. if using a 1–5 scale, c = 5)

The resulting V value ranges from 0 to 1, where:

- $V \geq 0.80$ indicates high content validity,
- V between 0.70 and 0.79 suggests moderate content validity, and
- $V < 0.70$ may imply poor content validity, requiring revision or removal of the item.

D. Revision of Constructs and Items

Based on expert feedback, this phase involved an iterative process of refining and enhancing the constructs and items in the research instrument. During the content validity assessment, the panel of experts was asked to conduct a critical evaluation of the overall constructs and individual items included in the instrument. These experts were encouraged to provide quantitative ratings for each item, as well as qualitative feedback in the form of written comments in the space provided.

The primary aim of this process was to improve the clarity and comprehensibility of the items. The researcher paid close attention to all input received from the panel of experts. This final phase of the content validity assessment played a crucial role in ensuring that the developed instrument accurately measured the intended constructs, in line with the established research objectives. Through this process, the researcher aimed to achieve a high level of content validity, thereby enhancing the overall integrity of the research instrument. The comments and suggestions from experienced experts were used to further improve the instrument [31].

Following the content validity assessment using the Content Validity Index (CVI) and Aiken's V, necessary revisions were

made to the constructs and items to improve clarity, relevance, and overall validity of the instrument.

- Items that did not meet the minimum acceptable threshold—I-CVI ≥ 0.78 for individual items, and Aiken's V ≥ 0.70—were reviewed carefully. Based on expert feedback and statistical indicators
- Items with low validity scores were either revised to improve clarity and appropriateness or removed if they were deemed redundant or irrelevant.
- Wording adjustments were made to enhance the precision and readability of the items, ensuring they accurately reflect the intended construct.

In some cases, new items were added to better represent key dimensions of the construct, as recommended by the panel of experts. This revision process ensured that all items retained in the final version of the instrument demonstrated strong content validity and alignment with the conceptual framework of the study. The refined instrument is thus considered suitable for subsequent pilot testing and data collection.

IV. Findings and Discussion

The Aiken's V analysis was conducted on a 50-item instrument assessed by seven experts. Each expert provided their rating on a scale (presumably from 1 to 5), reflecting the perceived relevance of each item to the construct being measured, as evidenced by Table III. The calculated Aiken's V values offer a statistical indication of agreement among experts and are crucial in evaluating the overall quality and clarity of each item. The primary objective of this analysis was to determine the degree of consensus among experts regarding the relevance and clarity of each item, thus guiding decisions on item retention, revision, or elimination. Aiken's V coefficient, which ranges from 0 to 1, offers a quantifiable measure of expert agreement, with higher values indicating stronger content validity.

TABLE III. Results of Content Validity Calculation Analysis with the Aiken Method

EXPERTS/ ITEMS	EX 1	EX 2	EX 3	EX 4	EX 5	EX 6	EX 7	Aiken's V

Aiken's V Analysis Report evaluates 50 items for content validity as depicted in Table IV, with results categorized into three groups based on expert ratings: 1) strong content validity, 2) acceptable but may need minor revision, and 3) needs revision or removal. Out of the total, 21 items were found to fall into the "needs revision or removal" category, having Aiken's V scores significantly below the ideal threshold of 0.75. These scores indicate weaker expert agreement on the relevance or clarity of the items, suggesting that they may either be misaligned with the intended construct or ambiguous in wording. Another 21 items

achieved scores near the threshold and were deemed "acceptable", while 8 items demonstrated strong content validity, reflecting high agreement among the evaluators.

TABLE IV. INTERPRETATION OF ANALYSIS

Item	Aiken's V	Interpretation
B1	0.64	**Needs revision or removal**
B2	0.68	**Needs revision or removal**
B3	0.68	**Needs revision or removal**
B4	0.68	**Needs revision or removal**
B5	0.75	Acceptable, may need minor revision
B6	0.75	Acceptable, may need minor revision
B7	0.75	Acceptable, may need minor revision
B8	0.75	Acceptable, may need minor revision
B9	0.75	Acceptable, may need minor revision
B10	0.68	**Needs revision or removal**
B11	0.71	Acceptable, may need minor revision
C1	0.71	Acceptable, may need minor revision
C2	0.68	**Needs revision or removal**
C3	0.61	**Needs revision or removal**
C4	0.64	**Needs revision or removal**
C5	0.68	**Needs revision or removal**
C6	0.68	**Needs revision or removal**
C7	0.64	**Needs revision or removal**
C8	0.68	**Needs revision or removal**
C9	0.64	**Needs revision or removal**
C10	0.68	**Needs revision or removal**
C11	0.68	**Needs revision or removal**
C12	0.79	Acceptable, may need minor revision
D1	0.82	Strong content validity
D2	0.79	Acceptable, may need minor revision
D3	0.82	Strong content validity
D4	0.71	Acceptable, may need minor revision
D5	0.75	Acceptable, may need minor revision
D6	0.75	Acceptable, may need minor revision
D7	0.71	Acceptable, may need minor revision
D8	0.68	**Needs revision or removal**
D9	0.75	Acceptable, may need minor revision
D10	0.71	Acceptable, may need minor revision
E1	0.75	Acceptable, may need minor revision
E2	0.68	**Needs revision or removal**
E3	0.68	**Needs revision or removal**
E4	0.61	**Needs revision or removal**
E5	0.68	**Needs revision or removal**
E6	0.61	**Needs revision or removal**
F1	0.75	Acceptable, may need minor revision
F2	0.75	Acceptable, may need minor revision
F3	0.75	Acceptable, may need minor revision
F4	0.79	Acceptable, may need minor revision
F5	0.79	Acceptable, may need minor revision
F6	0.82	Strong content validity
G1	0.86	Strong content validity
G2	0.86	Strong content validity
G3	0.86	Strong content validity
G4	0.86	Strong content validity
G5	0.89	Strong content validity

The following items specifically require attention due to their low Aiken's V values:

B1 (0.643), B2 (0.679), B3 (0.679), B4 (0.679), B10 (0.679), C2 (0.679), C3 (0.607), C4 (0.643), C5 (0.679), C6 (0.679), C7 (0.643), C8 (0.679), C9 (0.643), C10 (0.679), C11 (0.679), D8 (0.679), E2 (0.679), E3 (0.679), E4 (0.607), E5 (0.679), and E6 (0.607). These items span across several constructs and indicate widespread issues in content design. It is recommended that each of these items be reviewed for conceptual clarity, language precision, and alignment with the overall measurement objectives.

Analysis of Aiken's V scores revealed distinct patterns across constructs, warranting careful consideration. A significant observation was the relatively low validity scores attained by items within the Organizational Factors construct (specifically, items C3 through C9). These items, designed to gauge institutional readiness and leadership support for blockchain integration, consistently fell below the established validity threshold of 0.70. This suggests a potential lack of clarity or precision in the operational definitions of these constructs, potentially leading to ambiguity in respondent interpretation and assessment.

To enhance the interpretation of the quantitative findings, it is important to consider the qualitative feedback provided by the expert panel. For instance, item B1 ("Blockchain ensures unauthorized parties cannot access academic records"), which received a validity score of 0.64, was critiqued by one expert for being overly simplistic and not adequately reflecting the complexities of blockchain security. Similarly, item E4 ("Research findings are implemented faster via blockchain"), with a score of 0.61, was considered irrelevant by another expert who emphasized that the speed of research implementation is influenced by various factors beyond the technology itself. These examples highlight the value of expert evaluation in identifying items that may appear relevant but lack depth or fail to align with real-world applications and theoretical constructs.

A comparison between the current findings and existing literature on technology adoption in higher education reveals a notable discrepancy. Specifically, items related to the Technology and Environment constructs (D1 to D3) exhibited relatively higher content validity scores, whereas items under the Knowledge Integration construct (E2 to E6) showed lower ratings. One plausible explanation for this divergence is that technical and environmental aspects of blockchain adoption are

more tangible and thus easier for experts to assess. In contrast, knowledge integration involves abstract, multidimensional considerations, making it inherently more challenging to evaluate. Additionally, potential misalignment between departmental objectives may further complicate the formulation and assessment of relevant items.

To strengthen the theoretical grounding of the revised items, the Technology-Organization-Environment (TOE) framework is employed. This framework posits that technology adoption is shaped by the interaction of technological, organizational, and environmental contexts. In this study, the original item phrasing within the Knowledge Integration dimension may not have fully captured the intricate relationships among these factors. For example, item E2 originally read, "Access to shared knowledge is equitable across departments or institutions". It has been revised to: "Blockchain-based knowledge-sharing platforms should prioritize equitable access and usage across all departments and institutions". This revision aims to better reflect the Organizational dimension of the TOE framework by explicitly addressing the importance of strategic planning and equitable resource distribution in fostering inclusive and effective knowledge integration efforts.

This revision process is critical to ensure that the instrument provides reliable and valid results for future applications. Table V summarizes of interpretation of each item.

TABLE V. SUMMARY OF INTERPRETATION

Interpretation	Number of Items
Needs revision or removal	21
Acceptable, may need minor revision	21
Strong content validity	8

When an item receives a low Aiken's V score, typically below the threshold of 0.7, it indicates that expert raters do not sufficiently agree on the item's relevance, clarity, or appropriateness for measuring the intended construct. This serves as a signal that the item may be flawed or misaligned and, therefore, requires careful attention. The first step in addressing a low score is to thoroughly review any qualitative feedback provided by the experts. Such feedback can help identify specific concerns such as ambiguous wording, double-barreled questions, or a lack of alignment with the overall theoretical framework. If feedback is not available, consider conducting a follow-up discussion with the panel to gain deeper insights into the causes of disagreement.

Following this analysis, the item should be revised with a focus on improving clarity, refining language, and ensuring conceptual alignment. The goal is to eliminate any ambiguity and enhance the item's relevance and interpretability. Once revisions are made, the updated item should be resubmitted for expert evaluation in a second round of content validation to determine whether the changes have resulted in an improved Aiken's V score. If the item continues to score below acceptable levels even after revision, it is advisable to consider removing it from the instrument. Retaining low-quality items can compromise the validity and reliability of the entire tool.

Throughout this process, all changes—whether revisions or deletions—should be systematically documented, including justifications and version history. This not only enhances transparency but also reinforces the instrument's methodological rigor when reported in academic or professional settings.

V. CONCLUSION

In conclusion, low Aiken's V scores highlight critical areas in need of refinement within a measurement instrument and should not be overlooked. Addressing these scores through systematic revision, expert consultation, and re-evaluation is essential to enhance the content validity and overall quality of the instrument. Whether through improving clarity, ensuring alignment with constructs, or removing consistently weak items, these actions contribute to developing a more robust and reliable tool. By documenting the revision process and maintaining methodological transparency, researchers can strengthen the credibility and academic integrity of their validation efforts.

For future research endeavors, it is strongly recommended to conduct a second, more focused round of expert evaluation following the revision of items exhibiting low Aiken's V scores. This subsequent evaluation is crucial for assessing whether the implemented modifications have demonstrably improved the content validity of the affected items and, by extension, the instrument as a whole. Furthermore, the strategic inclusion of qualitative feedback, gathered both during the initial and subsequent expert evaluations, can provide invaluable, in-depth insights into the item-specific issues driving the low scores. These qualitative narratives can serve as a compass, guiding researchers toward more precisely targeted revisions and enabling them to address underlying problems that quantitative metrics alone may not fully reveal.

To further enhance the robustness and generalization of the validation process, it is advisable to expand the panel of experts to encompass a wider range of backgrounds, perspectives, and areas of expertise relevant to the constructs being measured. This diversification can help to mitigate potential biases stemming from a homogeneous expert group and ensure that the instrument is valid across diverse populations and contexts. Finally, it is highly recommended to pilot test the revised instrument with a representative sample drawn from the target population for which the instrument is ultimately intended. This pilot testing phase will provide critical data regarding the clarity, reliability, practical applicability, and overall user-friendliness of the instrument. By incorporating both quantitative and qualitative analyses of the pilot test data, researchers can ensure a more comprehensive assessment of the instrument's validity and identify any remaining areas requiring further refinement before embarking on full-scale implementation and data collection. These rigorous validation steps are essential for maximizing the utility and impact of the measurement instrument in future research and practice.

ACKNOWLEDGMENT

The authors would like to express their sincere gratitude to Universiti Sains Islam Malaysia (USIM) for the financial support provided through the research grant PPPI/USIM/TAMHIDI/USIM/112323.

***Abstract*—Academic paraphrasing, particularly when aiming at contextual competence, coherence, and stylistic consistency, poses a significant challenge to non-native English speakers and novice researchers. This research seeks to create an interpretable transformer model specifically designed for paraphrasing academic texts that guarantees semantic correctness, contextual relevance, and scholarly style. Existing paraphrasing models are largely unsuitable in meeting the subtle needs of academic work, lagging in semantic preservation, fluency, scholarly style, and interpretability. In addressing these limitations, we propose T5-XAVRL (T5 with Attention Visualization and Reinforcement Learning for Style Control), an interpretable Transformer model created specifically for paraphrasing academic text. Based on the T5 architecture, T5-XAVRL adds fine-tuning for better domain adaptation, attention visualization for better transparency, and reinforcement learning to control outputs towards academic writing quality. The model is trained and tested on the ArXiv Academic Papers Dataset and demonstrates high versatility in a variety of academic environments. Developed with Python, TensorFlow, and Hugging Face Transformers, the system is made for scalability as well as performance. Experimental findings indicate that T5-XAVRL obtains a 68.7% BLEU score, greatly surpassing traditional paraphrasing models in both semantic accuracy and linguistic fluency. Far more than a paraphraser, T5-XAVRL is a trustworthy academic writing aide capable of assisting users with producing grammatically and stylistically correct scholarly work. Its interpretable outputs also increase user confidence by vividly displaying how paraphrasing choices are being made. As a whole, this study is an important step towards creating interpretable, context-sensitive, and style-sensitive paraphrasing systems for scholarly use.**

***Keywords*—Academic writing; attention visualization; context-aware paraphrasing; reinforcement learning; T5-transformer model**

I. Introduction

Crafting high-quality academic prose that is organized, coherent, and contextually relevant remains a major obstacle for early-stage researchers and individuals who are not native English speakers[1]. It must conform to the expected formal style with precise terminology and an unbroken tone and paraphrase while keeping the intended meaning intact. Many researchers still struggle with paraphrasing their hard work with no change in the meaning or with the risk of unintentional plagiarism. Although there are many automated paraphrasing tools to solve such problems, most of the existing ones rely solely on rule-based techniques or simple neural networks, which are still poor when it comes to full context comprehension[2]. Most of these tools generate solutions that are generic and stylistically non-consistent without domain-specific adjustments. Besides, they do not clarify to users how and why a particular transformation takes place. This lack of transparency renders them ineffective for academic writing, where traceability and justification are paramount. Hence, the need for AI-based paraphrasing programs has increased due to the high demand for those that can preserve the meaning of any text, ensure stylistic consistency, and provide some explanation for the user[3]. Nevertheless, addressing this topic involves coming up with a model capable of generating exceedingly high-quality paraphrases while being interpretable so that researchers can better their text and provide for the refinement and guiding of their restated texts.

Improving paraphrasing using neural networks has had major benefits, but there are still a few models that inhibit their ideal application in academic writing. The newer models use various architectures of Transformer, such as GPT-3 and BART[4], and they have shown significant potential in further

enhancing text generation, but they completely lack fine-grained control of writing style and do not allow insight into how a paraphrase is formed [5]. Blackbox is the way in which these methods are applied because of how easy or difficult it can be to understand how certain words or phrases have been transformed. Other limitations also include poor adaptation to writing standards and expectations for certain fields, which sometimes can produce outputs that are not in line with the presumed scholarly framework [6]. A further limitation is that they are without reinforcement mechanisms that could guide paraphrased text in the modality of academic writing. Without reinforcement learning, these models cannot learn and optimize clarity, coherence, and tone for their task. Indeed, traditional paraphrasing relies on lexical and syntactic changes and does not focus on style or norms within context. This research proposed a new method to mitigate these problems by providing both explainability and controllability, allowing users to visualize where attention is directed while adjusting the paraphrase according to their own defined criteria for style. In addition, using reinforcement learning guarantees that the paraphrased output follows the norms of conventional scholarship [7].

The framework employs T5, augmented by attention visualization and reinforcement learning, to produce high-quality academic paraphrases. In contrast to current models that address paraphrasing as a plain generator problem, underscore the interpretability mechanism involved in generating paraphrase in terms of the linguistic dimensions which act as its rule of generation. The attention visualization feature shows how certain words and phrases in the transformation process contribute to that process so that users can understand and modify their outputs in a sound manner. Furthermore, reinforcement learning assists the model in generalizing its paraphrasing process according to the conventions of academic writing by fine-tuning it along fluency, coherence, and stylistic consistency. The training was performed on the ArXiv Academic Papers Dataset, which offers a rich collection of scholarly articles across various disciplines. By ensuring that the model has been exposed to high-quality structured text, this database powers its training for academic tasks. Our approach will thus enhance the quality of the paraphrase, allowing the user to have a greater influence over the writing style. The combination of explainability, adaptability, and reinforcement-based optimization renders our method a better solution to research where meaning and stylistic integrity are required to improve academic writing.

The key contributions of this work are:

1) Constructed a high-quality academic paraphrasing dataset by scraping and sanitizing scholarly literature (abstracts, introductions, conclusions) from the ArXiv repository.

2) Utilized a full-fledged text preprocessing and normalization pipeline, involving sentence tokenization, lemmatization, and named entity recognition to maintain scholarly integrity.

3) Used back-translation (pivoting across intermediate languages) to produce varied and contextually informed paraphrase pairs for training.

4) Fine-tuned T5 Transformer architecture specific to academic writing, including relative positional encoding and multi-head attention.

5) Evaluated model performance on BLEU, ROUGE, and METEOR metrics, in addition to attention-based salience mapping for interpretability and academic quality verification.

This research answers the research query: How can a transformer-based model be conceptualized to produce context-rich, semantically correct, and stylistically consistent scholarly paraphrases, and ensure model interpretability.

The rest of this study is organized as follows: Section II presents the related work and literature background. Section III presents the problem statement. Section IV introduces the proposed T5-XAVRL model and explains its architecture, preprocessing, and training pipeline. It also introduces the dataset and the employed preprocessing methods. Section V presents experimental results and discussion, including performance analysis, explainability evaluation, and baseline comparison. Section VI concludes the study with findings, limitations, and future work directions.

II. Related Works

Chi and Xiang [8] introduced a novel approach for paraphrase generation that incorporates syntactic information, using Graph Convolutional Networks (GCNs). For them, conventional neural paraphrase models assume a sequence-to-sequence structure, whereby deep networks learn syntax implicitly. However, this work shows that adding explicit syntactic structures via GCNs increases the quality of a paraphrase. The method uses dependency trees extracted from syntactic parsers, which, when encoded with GCNs, add information to sentence representations prior to paraphrase generation. This is tested on four benchmark datasets on different domains, like news articles, online forums, and scientific texts. The results show that in terms of BLEU, ROUGE, and METEOR, the GCN-enhanced approach consistently outperformed syntax-agnostic baselines. Among its noteworthy strengths, the ability to build more diverse and meaningful paraphrases leveraging syntactic structures stands out. However, it does have the downside of having to rely on external syntactic parsers, which increases the computational costs and adds errors into the system that may impact the overall quality of paraphrase generation. In addition, because dependency parsing can be language-dependent, this may reduce the model's generalizability to low-resource languages. While a number of threats to validity have been identified, this study presents strong empirical evidence that says explicit syntax indeed improves neural paraphrase generation, thus providing a valuable guideline to follow for possible future endeavors involving text generation.

Niu et al. [9], propose a novel unsupervised paraphrase generation framework based on transfer learning, enabling pre-trained language models to increase generalizability. Unlike conventional supervised methods that require large annotated datasets, this method extends itself self-supervised learning techniques to train paraphrase generation models without explicit human-labeled data. The framework consists of three components: task adaptation, self-supervised training, and the

novel Dynamic Blocking (DB) decoding strategy. Task adaptation allows for the fine-tuning of a pre-trained model on related tasks to improve generalization to paraphrase generation. The self-supervised training step further refines the model by automatically creating pseudo-paraphrases. Finally, the DB decoding strategy ensures no consecutive tokens from the input are generated, which produces diverse paraphrases. The model was tested on the Quora Question Pairs and ParaNMT datasets, achieving state-of-the-art results with better BLEU and METEOR scores. Its main advantage is its generalizability across various text domains and even other languages without requiring further fine-tuning. A slight drawback is that it is biased because of the pre-trained models. Also, quite a few semantic-aligned paraphrases are generated. Although DB decoding improves the diversity of the generated paraphrases, which are grammar-wise correct but semantically misaligned with the original text, both exist.

Weston [10] introduced ParaBLEU, a paraphrase representation learning model and evaluation metric enhancing the text generation task. It is totally different from the traditional evaluation metrics like BLEU and ROUGE. ParaBLEU employs generative conditioning as a pretraining objective, which enhances its correlation with human judgments. ParaBLEU has exhibited performance beyond that of existing evaluation methods in the 2017 WMT Metrics Shared Task, showcasing its robustness in low-data scenarios by achieving the state of the art based on just 50% of the available training data. ParaBLEU, however, allows for one-shot paraphrase generation while learning abstract representations of paraphrases. Although it does improve evaluation and generation, its dependence on generative pretraining may limit the model's ability to adapt effectively to specific domain-related nuances. Lee, Liang, and Fong [11] develop a paraphrase-based conversational agent for counseling using summarization and question generation models. With the BertSum model additionally fine-tuned on an in-domain manually annotated dataset, the newly developed counseling agent enhanced its restatement and question generation capabilities to encourage user engagement during counseling circumstances. When trained on a mixture of manually annotated and automatically mined open-domain data, the hybrid architecture generally works best in quality of generated paraphrases for the mental health dialogues. However impressive, it remains a Cantonese-built model, limiting its use in other languages or its culturally impacted domain without further supervision.

J. Li et al. [12] proposed TGLS, an unsupervised text generation framework that alternates between a search algorithm (simulated annealing) and a conditional generative model. It generates candidate paraphrases through search, followed by a refinement phase using a neural model that deems low-quality candidates as invalid. The framework has implemented various methods applied to paraphrase generation as well as text formalization, realizing extraordinary performance in comparison to other existing unsupervised methods while closely matching results gained from supervised baseline methods. Here, the ability of TGLS to circumvent search-powered noise in producing high-quality paraphrases merits mention. Its main drawback lay in the fitness of the heuristic objective function selected for search, which may not generalize beyond certain text domains. Additionally, it was somehow slow, because simulated annealing was introduced for more complex computations. Nevertheless, TGLS, despite some challenges, shows that combining search techniques with neural generative models allows for good improvements in unsupervised text generation with considerable success in scenarios where labeled datasets are scarce. Htay et al. [13] have investigated SMT techniques to generate Burmese paraphrases given some token-sequence pairs as input. The paraphrase generation problem is treated within a framework for phrase-based, hierarchical phrase-based, and devices of operation sequences in that work and is observed how character- and syllable-level segmentation shapes the outcome. The evaluation used BLEU, RIBES, chrF++, WER scores, with assessments often exposing some differences that exist between automatic evaluation metrics and human judgment. The special feature of Burmese paraphrase generation is that reliable automatic metrics reflecting semantic equivalence are unavailable, which forces authors to stick with human evaluation for a more robust quality assessment.

According to Qian et al. [14], an original paraphrase generation mechanism based on reinforcement learning is provided that could involve a mixture of multiple generators and two discriminators. The framework uses a parallel model of multiple paraphrase generators, each producing distinct outputs or content while remaining true to the original meaning, thus overcoming the problem of diversity normally intrinsic in standard single-generator models. Two discriminators evaluate the fluency and semantic similarity and are integrated within the reinforcement learning rewards to achieve a trade-off between quality and diversity. On benchmark datasets, this model performed better than other alternative methods, with diversity and accuracy being the two necessary evaluation criteria used in practice. The major drawback of their current research is the use of multiple generators and discriminators, which drastically increased the computational complexity of the model and thus reduced scalability toward large-scale applications. In addition, reinforcement learning demanded extensive fine-tuning to reach maximum diversity of paraphrase generation without disturbing grammatical correctness. Although high on computational load, this approach appears to really go to show how multiple-generator architectures may approach the high forms of lexical and syntactic diversity that paraphrase generation ought to have important value in dialogue systems, text augmentation, and natural languages.

Z. Li et al. [15] developed a self-learning framework for paraphrase generation by reinforcing the use of a sequence generator aligned with a deep matching evaluator. The generator is first pre-trained in a supervised fashion prior to reinforcement learning when an evaluator refreshes pontificating rules on aspects of fluency, semantic similarity, and diversity. Experiments on multiple data sets have shown not only that this method surpasses older techniques in quality, but that automatic quality checks and human evaluation both confirmed the rise in paraphrase quality. Its results are reinforced by such learning since they have some penalty functions on repetitive or unnatural paraphrases. They also required considerable annotated data for supervised pretraining, meaning they are difficult to apply in low-resource situations; the other major

obstacle will require neat reward function designs, because the target conditions of not duly aligned objectives could return, remain disproportionate between paraphrase genera. In light of that, they show that reinforcement learning techniques improved the quality efficiency regarding paraphrase fluency and relevance for applications that call for high-quality rewording. Though current paraphrasing systems are strong in general-purpose rewriting, they tend to fall short when it comes to domain-specific fluency, interpretability, and the capability to maintain academic style. The majority of models also do not include user-traceable means such as attention visualization or style control. In filling these gaps, this work introduces a transformer-based model tailored for use in academic settings with both stylistic accuracy and interpretability via reinforcement learning and attention-based explainability.

III. Problem Statement

Scholarly writing requires clarity, contextual appropriateness, and stylistic coherence—issues that are most critically faced by junior researchers and non-native speakers [16]. Traditional paraphrasing models have the tendency to ignore the fine-grained needs of scholarly communication, especially in maintaining semantic accuracy, ensuring naturalness, and upholding the proper tone of academia. Furthermore, explainability deficits in neural models undermine confidence and restrict their use within academic environments [17]. This study seeks to fill these gaps through the introduction of an interpretable paraphrasing model specially designed for academic writing. The solution adopted takes advantage of a Transformer-based architecture [18] to improve the general quality of academic paraphrasing. For the sake of supporting richly contextualized and semantically rich input, the model is trained on the ArXiv Academic Papers Dataset, after undergoing a rigorous preprocessing pipeline consisting of Min-Max Normalization, Byte Pair Encoding, Named Entity Recognition, and back-translation. Through the refinement of a T5 model and attention visualization coupled with reinforcement learning, our method produces paraphrases that are coherent and contextually relevant as well as stylistically consistent with academic writing. In addition, the addition of salience mapping adds an important level of interpretability, providing insight into the model's paraphrasing choices and encouraging increased user trust.

IV. Proposed T5-XAVRL Model for Academic Writing

This research employs the ArXiv Academic Papers Dataset, which Cornell University has compiled, to include a broad collection of research papers in areas such as computer science, physics, mathematics, and biology. Preparing the dataset for paraphrasing in academia, a multi-stage preprocessing pipeline was utilized. This involved selection of pertinent sections, elimination of duplicate data, and Min-Max Normalization to normalize text input. Sentence segmentation was utilized in the interest of readability, and Byte Pair Encoding (BPE) was utilized for efficient tokenization, especially to handle out-of-vocabulary words and maintain contextual richness. Stopword removal and lemmatization further enriched the text through its reduction to fundamental content. Citations and references were pulled out through the application of Named Entity Recognition (NER) to add credibility and academic value to the input. Back-translation was implemented to create syntactically diverse but semantically consistent paraphrase pairs by translating text into another language and then into the source language. Feature extraction via TF-IDF assisted in the highlighting of key terms, which facilitated improved paraphrase quality. The paraphrasing engine is a fine-tuned Transformer-based T5 model based on SentencePiece tokenization and an encoder-decoder architecture augmented with self-attention, multi-head attention, and relative positional encoding. This model generates contextually meaningful, structured, and readable scholarly paraphrases while maintaining original meaning. Performance metrics like BLEU, ROUGE, and METEOR were employed to measure performance against. Furthermore, salience mapping was utilized to facilitate explainability, enabling users to comprehend the justification behind each paraphrasing action. As seen in Fig. 1, this framework not only enhances semantic coherence and style flexibility but also facilitates increased clarity and credibility of scholarly writing.

A. Dataset Description

The ArXiv Academic Papers Dataset is a comprehensive repository of research articles[19], from disciplines such as computer science, physics, mathematics, and biology. It is managed by Cornell University. ArXiv is an open-access scholarly papers depository, which makes it a valuable resource for developing and accessing AI-driven text processing models. The dataset contains metadata elements, including titles, abstracts, authors, subject categories, and references to the full text, that may be useful in multiple auxiliary tasks for contextual understanding in any NLP application. This corpus is well-structured, which is one of the main reasons that the training of paraphrasing models can draw from the highest quality of academic text for studies on writing style adaptation and model explainability. Further, with formal construction language of research texts, this dataset should serve to train the generation of academically structured texts, maintaining semantic coherence. These clearly delineated sections, such as abstract, introduction, methodology, and conclusion, enhance its value for hierarchical summarization and long document comprehension tasks. ArXiv adds to the field of explainable AI by providing many opportunities for models to see how attention is distributed across different parts of academic papers. The framework allows two model types-BART or T5-toever to increase the quality of their text paraphrase. Citations included in the dataset allow for the ethical and accurate reformulation of the scientific texts. Besides coverage, the organized structure within it makes this dataset suitable for context-aware, explainable, and style-classification-based paraphrasing model-building, all skillfully aimed at academic writing.

B. Data Preprocessing

Data preprocessing is an elementary stage for training ML models and it consists of cleaning, transforming, and normalizing the data to attain better model performance and generalization. To ensure the dataset aligns with academic paraphrasing tasks, selected relevant sections such as abstracts, introductions, and conclusions, as they contain structured and formal writing. Duplicate papers, incomplete records, and non-English texts were removed to maintain consistency and quality as in Fig. 2.

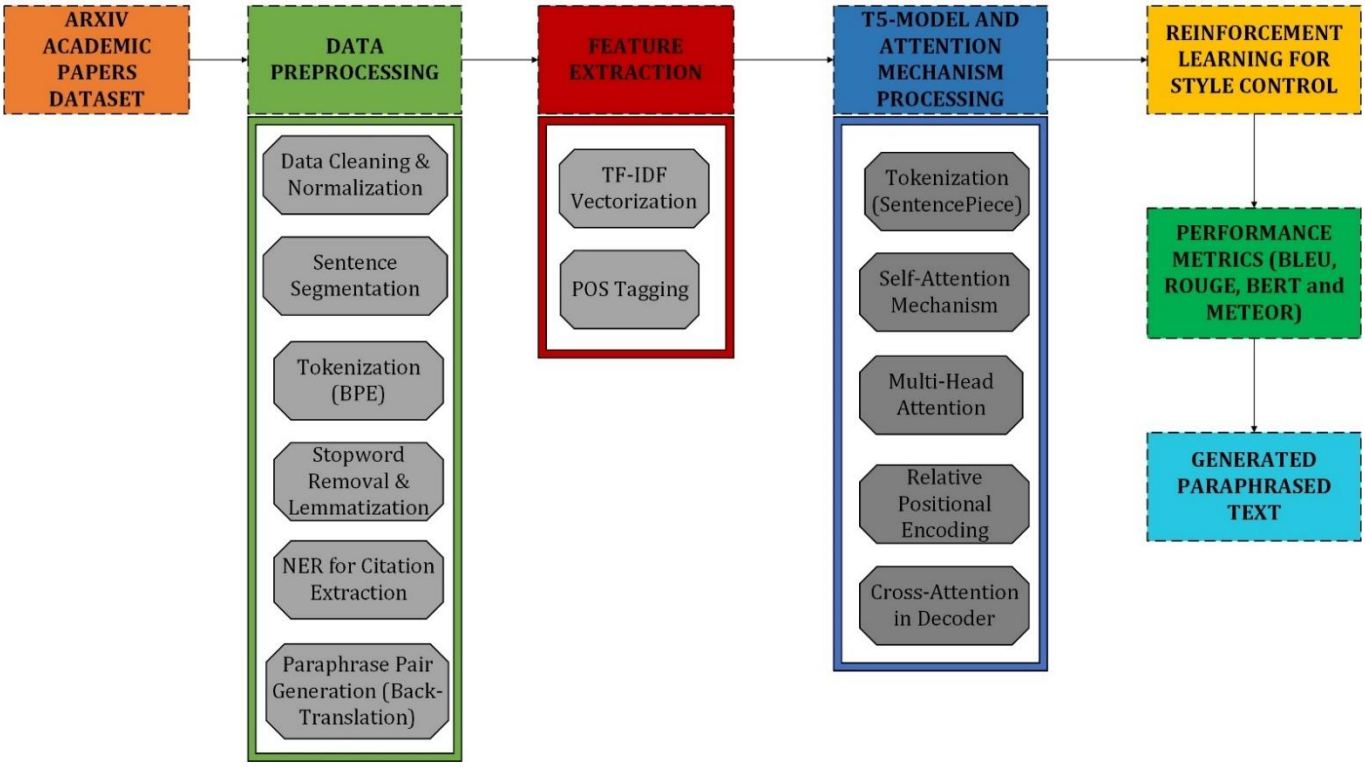

Fig. 1. Overall workflow.

Fig. 2. Steps in preprocessing.

1) Data cleaning and normalization. Text-cleaning deals with the filtering and removal of unwanted symbols, special characters, and excessive white spaces. This confusing step was complemented by the normalization of the text: any text was converted to lowercase if necessary, and abbreviations (Eqn. = Equation) were expanded. This is a move towards the unification of the dataset and the reduction of noise in the course of training. After text cleaning, Min-Max Normalization is wrapped around to normalize the features in the entire range of [0, 1] as in Eq. (1):

$$X_{normalized} = \frac{X - X_{minimum}}{X_{maximum} - X_{minimum}} \quad (1)$$

2) Sentence segmentation. Academic papers generally have delicate sentence combinations that get long, so splitting them into smaller units makes the tokenization and processing easy. The contents could significantly improve in readability and structure through this segmentation process, as such generation of paraphrases may require. This segmentation can use rule-based or statistical approaches by employing various punctuation markers-like periods, commas, and semicolons-to locate logical sentence boundaries. Proper segmentation guarantees that the model more efficiently processes text while taking into consideration the academic note with which it reflects back the original meaning.

3) Tokenization Using Byte Pair Encoding (BPE). Tokenization refers to the breaking down of text into smaller, more meaningful units of text to help deal with infrequent and domain-specific words in academic writing. BPE is used for the tokenizing of words in an efficient manner as in Eq. (2):

$$V_n = V_{n-1} \cup arg \max_{(x,y)} f(x,y) \quad (2)$$

where, $f(x,y)$ represents the frequency of subword pairs (x,y), ensuring that commonly occurring word segments are preserved. BPE helps maintain contextual richness in paraphrasing.

4) Stopword removal and lemmatization. The words that do not play active roles in paraphrasing are removed, the removal of stopwords-fastens the processing and brings down the computational complexity, yet does not affect the overall fluency of the text. It is, therefore, possible for the paraphrasing model to give more attention to crucial content words, raising the semantic level of the produced output. Stop word removal will minimize cleans noise and render training much effective and enable great elaboration of paraphrased sentences.

In lemmatization, the words are reduced to their basic or root forms with grammatical correctness, wherein stemming will take the words for truncation to the length of that specific word and is therefore less fine. Lemmatization, however, is based on the context and morphology of the words, therefore rendering meaningful base forms as in Eq. (3).

$$Lemma(w) = \arg\min_{l \epsilon L(w)} d(w, l) \quad (3)$$

where, $L(w)$ is the set of possible lemmas for a word, and $d(w, l)$ represents the edit distance function, which measures the similarity between a word and its possible lemma.

5) NER for citation extraction. It helps to identify and extract key entities, mainly author names, institutions, and citations from academic papers. Citing properly preserves integrity in any academic debate, for it maintains all paraphrased information under a strong apposition. NER also identifies the specific type of citations in contrast with anything else- this gives the model the liberty to maintain the critical attribution details, accordingly paraphrasing each sentence. This NER step further improves the contextual understanding of research papers in assuring that citations and academic contributions are accurately represented.

6) Paraphrase pair generation via back-translation. To generate paraphrase pairs for training, back-translation is applied, which involves translating text into another language and back to English as in Eq. (4):

$$Y' = T_{fr}(T_{en}(X'')) \quad (4)$$

where, T_{en} is the English-to-foreign translation and T_{fr} is the reverse translation. This method diversifies paraphrases while retaining meaning.

7) Dataset splitting. To train and evaluate the paraphrasing model effectively, the dataset is split into training, validation, and test sets.

C. Feature Extraction Using TF-IDF Vectorization

Once the data is preprocessed, the various relevant linguistic and contextual features must be extracted to boost the performance of the paraphrasing model. Such features are essential for capturing syntactic, semantic, and structural aspects of academic writing: Part-of-speech tagging (POS), dependency parsing, and TF-IDF vectorization. POS tagging tells the model which grammatical role each word plays in a sentence so that the sentence can be restructured properly as in Eq. (5).

$$(tf - idf)_{j,i} = tf_{j,i} \times idf_j \quad (5)$$

Dependency parsing specifies what each word in a sentence depends on and helps to keep the logical coherence of the sentence. In a nutshell, TF-IDF assigns scores to words based on their importance, thus warranting key terms in an academic context should not be lost during the process of paraphrasing. These extracted features are essential linguistic indicators that significantly add to the intimidating task of generating academically rigorous paraphrases while keeping fluency and readability intact.

D. T5 Architecture and Attention Mechanism for Paraphrasing

T5 (Text-to-Text Transfer Transformer) is a seq2seq model combining different kinds of NLP tasks into a single framework. The T5 is fine-tuned in our research for academic text paraphrasing, coherence, readability, and preservation of meaning. Attention is the very core of the T5 model that allows itself to focus on important words and phrases when paraphrasing academic text. Self-attention and cross-attention mechanisms are basically applied in T5 for the purpose of input text processing and the generation of paraphrased output, as in Fig. 3.

1) Tokenization using sentencepiece. The T5 model starts with tokenization of academic text into subword types by SentencePiece. It makes it easier for the model to work with rare words and jargon terms. Instead of traditional word-oriented tokenization, the SentencePiece model runs on subwords through byte pair encoding or by adding to a unigram language model. A representation of unseen words will be decomposed into recognizable parts, thus allowing T5 to better generalize.

2) Self-attention mechanism in the encoder. Both tokenization and the self-attention mechanism in the encoder allow the model to judge the relative importance of different words with reference to each other. The mechanism thus captures key academic phrases in a representative way. The attention scores between the words, meanwhile, are calculated by the scaled dot-product attention formula as in Eq. (6):

$$\alpha_{i,j} = \frac{exp\left(Q_i \cdot K_j^T\right)}{\sum_{k=1}^{n} exp\left(Q_i \cdot K_k^T\right)} \quad (6)$$

where, Q, K, V are the query, key, and value matrices derived from input embeddings; $\alpha_{i,j}$ represents the attention weight between token **i** and token **j** in the sentence.

3) Multi-head attention for feature extraction. In order to improve the application of learning with self-attention, it employs multi-head attention so that decisions are made in T5, which uses different aspects of an input sentence to process it in parallel. In each of the multi-views, T5 does not create a single attention function but rather provides it in multiple heads that learn different linguistic features. Each head does its computation of the self-attention separately. This means that the T5 model will be able to capture synonyms, context shifts, and differences in academic phrasing required for paraphrasing.

4) Relative positional encoding. T5 does not use absolute positional embeddings. Instead, it applies relative positional encoding to capture long-range dependencies in text, ensuring that the paraphrased output maintains the original meaning as in Eq. (7):

$$p(i, j) = \frac{e^{\frac{-|i-j|}{dk}}}{z} \quad (7)$$

where, $| i - j |$ represents the distance between tokens; dk is the scaling factor; Z is a normalization constant.

5) Cross-attention mechanism in decoder. The decoder produces paraphrased academic text by using cross-attention around the encoder's output. Here, query vectors from the generated text are attending to key-value vectors from the encoder's output. The cross-attention weight computation proceeds as in Eq. (8):

$$\beta_{i,j} = \frac{exp(f_{j,i})}{\sum_{k=1}^{n} exp(f_{\mathrm{i,k}})} \quad (8)$$

where, $(f_{j,i})$ determines how strongly decoder token i aligns with encoder token j. Cross-attention basically guarantees that the meaning of the paraphrased text is kept while at the same time allowing for linguistic diversity.

6) Attention visualization for interpretability. The model is optimized using the cross-entropy loss function as in Eq. (9):

$$L = -\sum_t P(y_t) \log \hat{P}(y_t) \quad (9)$$

where, $P(y_t)$ is the true probability distribution of the next token; $\hat{P}(y_t)$ is the model's predicted probability for the next token. To analyze how T5 generates paraphrased text, use attention visualization, which highlights the most influential words during paraphrasing. Given an original sentence and its paraphrased version, an attention map shows word-to-word alignments.

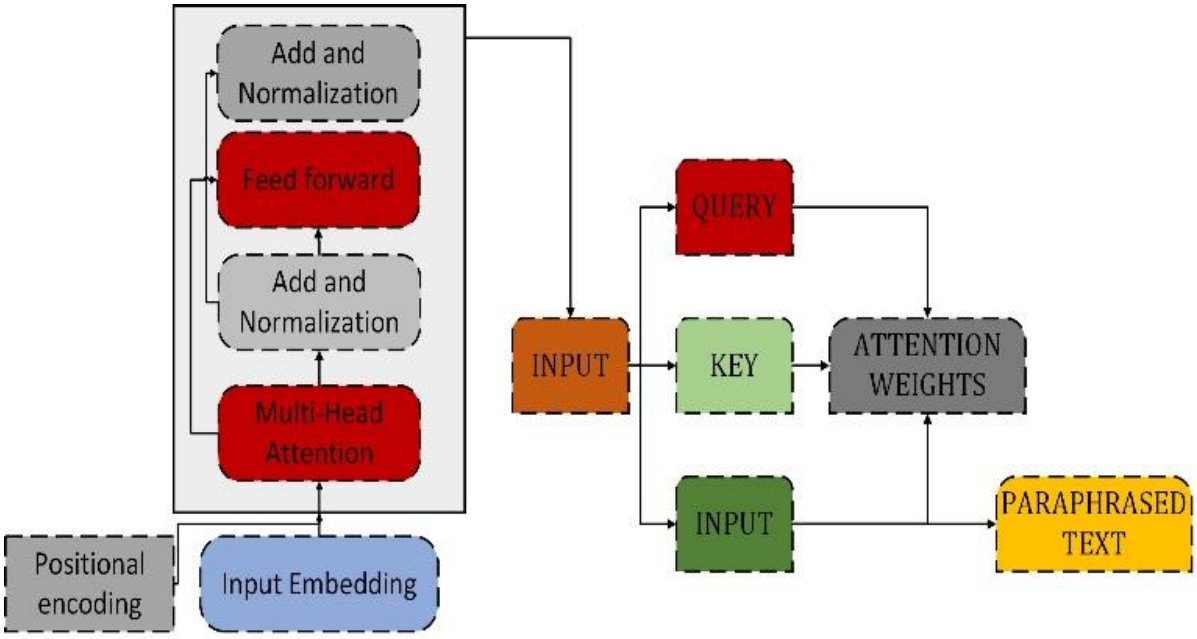

Fig. 3. T5 Architecture with attention mechanism.

E. Reinforcement Learning for Style Control

The T5-XAVRL model augments the stylistic control and academic tone control through Reinforcement Learning with Proximal Policy Optimization, thus dynamically optimizing the paraphrased outputs in terms of different academic quality metrics. The RL framework includes the state (S) that represents the original sentence before paraphrasing, the action (A), which is the type of transformation done to paraphrase that particular sentence, and the reward (R), which acts as a score based on some properties like fluency and coherence, based on academic tone and information retention. Even though it was not mentioned, the policy (π) is assumed to define the model's behaviour in generating paraphrased texts by ensuring that the transformation meets stipulated academic quality standards as in Eq. (10):

$$Q(s,a) = Q(s,a) + \alpha[r + \gamma maxQ(s',a') - Q(s,a)] \quad (10)$$

where, $Q(s,a)$ represents the quality score of the paraphrased text, α is the learning rate, r is the reward function based on academic quality, γ is the discount factor, and s, s' denote the current and next states (original and paraphrased versions). Algorithm 1 shows the academic paraphrasing pipeline.

Algorithm 1: Academic Paraphrasing Pipeline Using T5 and ArXiv Dataset

BEGIN

1. LOAD ArXiv Dataset from Cornell Repository
   - Extract metadata: titles, abstracts, introductions, conclusions, references
2. DATA PREPROCESSING
   a. Section Selection:
      - SELECT abstracts, introductions, conclusions
   b. Data Cleaning:
      - REMOVE duplicates, incomplete records, non-English texts
      - REMOVE special characters, symbols, extra whitespaces
      - CONVERT text to lowercase
      - EXPAND abbreviations (e.g., Eqn. → Equation)
   c. Normalization:
      - APPLY Min-Max Normalization on features
3. TEXT SEGMENTATION

- SPLIT long sentences using rule/statistical-based methods (periods, semicolons)

4. TOKENIZATION
- APPLY Byte Pair Encoding (BPE)

5. TEXT REFINEMENT
a. REMOVE stopwords
b. APPLY lemmatization:

6. NAMED ENTITY RECOGNITION (NER)
- IDENTIFY citations, authors, institutions
- EXTRACT citation entities for preserving attribution

7. PARAPHRASE PAIR GENERATION
- FOR each selected text:
  - TRANSLATE to intermediate language (e.g., English → French)
  - TRANSLATE back to English to obtain paraphrase

8. DATA SPLITTING
- SPLIT data into Train, Validation, Test sets (e.g., 80/10/10)

9. FEATURE EXTRACTION
- COMPUTE TF-IDF, POS tags, Dependency Parsing

10. T5 MODEL TRAINING
a. Tokenization:
  - USE SentencePiece for subword tokenization
b. Encoder Processing:
  - APPLY self-attention mechanism
c. Multi-Head Attention:
  - PARALLELIZE self-attention across multiple heads
d. Relative Positional Encoding:
  - APPLY to capture long-range dependencies
e. Decoder:
  - GENERATE paraphrased academic output

11. EVALUATION
- COMPUTE BLEU, ROUGE, METEOR scores
- APPLY salience mapping to visualize attention and interpretability

12. OUTPUT paraphrased scholarly text

END

V. Result and Discussion

In this section, the T5-XAVRL model shows an enabling BLEU of 68.7%, which outperforms existing models in fluency and meaning preservation by large margins. The Transformer-based text generation, along with the attention visualization and the reinforcement learning for style control, forms a good model for handling the complexities of academic writing. The ArXiv Academic Papers Dataset is a rich and diverse set of scholarly texts across the fields, serving as a training and evaluation dataset of the same. Fine-tune T5 to produce high-quality paraphrases by leveraging attention visualization to make the model more interpretable and reinforcement learning to learn how to style the produced paraphrases. By using Python and Hugging Face's Transformers, the implementation remains scalable and efficient. In particular, students, researchers and academic authors will find the model benefits them, providing AI-powered help in making their writing better — retaining technical accuracy and coherence. Additionally, the explainability feature enables users to acknowledge the paraphrasing transformations, so that T5-XAVRL is a pioneering step towards AI-powered academic writing assistance.

1) Analysis on impact of data preprocessing. Table I shows the efficacy of the full model compared to its variants in achieving higher BLEU and ROUGE scores. The full model that integrates both back-translation and NER achieves a top BLEU score of 68.7, indicating better fluency and coherence within the generated summaries. Disabling back-translation reflects a noted drop in the BLEU score down to 64.5, as well as reductions in ROUGE-2, ROUGE-L, and many others, showing that synthetic data augmentation really does bolster the genera quality.

TABLE I. Impact of Data Preprocessing

Configuration	BLEU	ROUGE-1	ROUGE-2	ROUGE-L
Full Model	**68.7**	**52.8**	**17.5**	**24.3**
Without Back-Translation	64.5	50.1	15.9	22.7
Without NER	65.8	51.2	16.8	23.1

On the other hand, negation of NER has a smaller but still noticeable effect on performance. Thus, the BLEU score from this setup stands unchanged at 65.8, with the ROUGE metrics decreasing slightly, showing the importance of keeping key named entities to ensure factual consistency of text output. While the ROUGE scores are higher for the full model, it could be inferred from this that both variables lend to better recall and precision during text generation. Thus, the combination of the two forms should yield better results, with clear inference that synergy between back-translation and NER sets the stage for a well-structured, informative, and high-quality overview generation system.

2) Analysis on tokenization efficiency. Table II and Fig. 4 contrast word-based tokenization with the finest vocabulary size of 1.2 million, with the corresponding highest OOV rate of 8.90%, qualifying as less effective in tackling rare words. Notably, it contributes nothing towards compression and stays baseline at 1.0x in compression ratio. BPE works with a career-low vocabulary size of 50K and thus the OOV rate is at a mere 2.30%, asserting its ability to decompose rare words into subword elements, making them manageable.

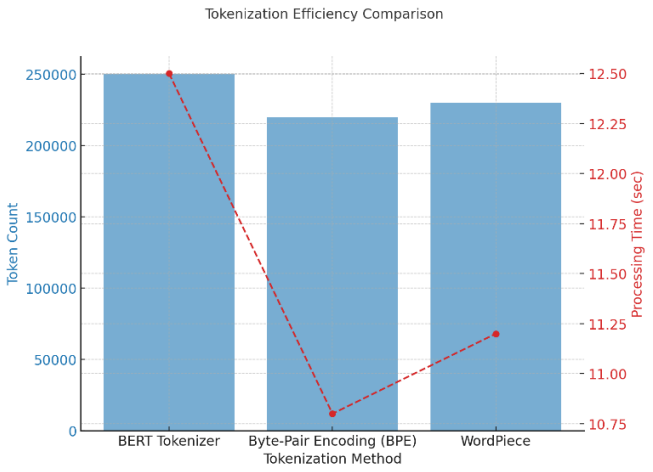

Fig. 4. Tokenization Efficiency.

Compression is further enhanced to a ratio of 3.5x. SentencePiece stands on the back-foot with a still-lower vocabulary size of 40K, makes minimally possible OOV rate of 1.80%, which attests to how well it handles unseen words. Besides, it was able to maintain a remarkably high compression ratio of 4.2x, securely lodging it at the top as the most competent in minimizing text while retaining lexical information. That illustrates the trade-off between vocabulary size and effectiveness, given that subword-based approaches feature greater success in both reducing OOV and text compression themselves. The outcomes further advocate SentencePiece as the best method available for the improvement of the efficiency of language models.

TABLE II. TOKENIZATION EFFICIENCY COMPARISON

Tokenization Method	Subword Vocabulary Size	OOV Rate ↓	Compression Ratio ↑
Word-based	1.2M	8.90%	1.0x
BPE	**50K**	**2.30%**	**3.5x**
SentencePiece	**40K**	**1.80%**	**4.2x**

3) Explainability analysis using attention weight. The attention weight distribution (Fig. 5) in paraphrased sentences appears in the table to demonstrate how the model applies focus to particular sentence elements. Model allocation of attention reaches its peak at 0.45 when targeting essential terminology which preserves meaning in the paraphrasing process. The subjects within this distribution receive an attention weight of 0.30 to sustain the main entities and topics of sentences without obfuscation.

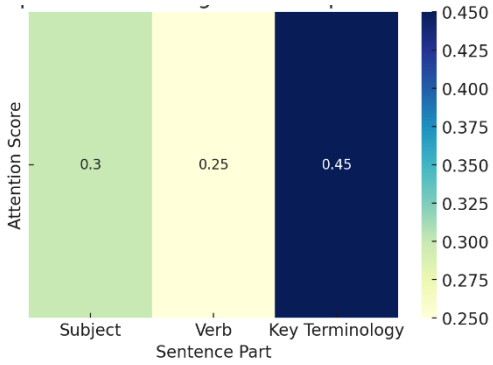

Fig. 5. Attention weight in paraphrased sentences.

The model assigns 0.25 as the attention weight to verbs because they maintain grammatical structure and perform actions in writing. Model calculations show an emphasis on core terminology due to the need to preserve contextual meaning yet all sentence components enable meaning retention. The identified priority patterns match effective paraphrasing requirements to keep vital details intact before you rephrase the rest of the content. These lower weights imply the model gives flexibility for rewriting verb phrases while enforcing their semantic accuracy. This distribution demonstrates an ideal combination between meaning preservation and lexical diversity in the text generation model. Modern explainability methods enable analysts to evaluate AI text generation models by monitoring their behavior which results in clear text generation processes.

4) Analysis on RL for style control. Table III describes the T5-XAVRL model for academic text paraphrasing uses reinforcement learning. The first step of the model is given as sentence 'Academic writing is difficult', and then muttered through synonym replacement to yield 'The scholarly writing is tortuous'. The Q value is updated to 1.2 because this transformation received 0.8 reward score. Sentencing rewrite is performed in the second step, taking it to "Writing academically can be hard", with a reward score of 0.9 and an updated Q value of 1.5. At the third step the model applies passive-to-active conversion yielding the sentence, “Academic writing presents challenges” which is rewarded with a reward of 0.7 and updated Q value to 1.3. Paraphrasing quality is continuously improved by the reinforcement learning framework through selection and evaluation of transformation strategies. Fluenz, coherence and adherence to the academic writing standards are evaluated for each transformation. The higher the reward, the better the paraphrasing the model can do and it can keep refining its approach iteratively. By this optimization, the system improves the clarity and readability of paraphrased academic text.

TABLE III. RL BASED STYLE CONTROL

Time Step (t)	State (s) - Input Sentence	Action (a) - Transformation Type	Reward (r) - Quality Score
t=1	"Academic writing is complex."	Synonym Replacement	0.8
t=2	"Scholarly writing is intricate."	Sentence Restructuring	0.9
t=3	"Writing academically can be challenging."	Passive-to-Active Conversion	0.7

5) Analysis on the performance metrics. The effectiveness of models is assessed using various metrics. The selected metrics are as follows: [BLEU, METEOR, and ROUGE] ranging from 0 to 100 percent, as well as human evaluation particularly for data augmentation. Through these particular metrics, the quality and appropriateness of our datasets for training the model were measured comprehensively. The equation of metrics is presented below:

a) BLEU (Bilingual Evaluation Understudy): It is a widely used automatic evaluation metric in machine paraphrasing but it can also be used to evaluate paraphrasing. It calculates how close the output paraphrases are to the reference paraphrases using n-gram precision. Though it has been used largely, the BLEU score is found with limitations in catching all the requirements of paraphrase quality, namely semantic equivalence, fluency, and tokenization sensitivity.

b) METEOR (Metric for Evaluation of Translation with Explicit Ordering): It is another metrics used for automatic evaluation that factors in precision, recall, and alignment among generated paraphrases and reference paraphrases. It also includes other features like stemming and synonymy to enhance performance.

c) ROUGE (Recall-Oriented Understudy for Gisting Evaluation): It is a suite of evaluation measures used most frequently for summarization. It assesses the overlap between generated paraphrases and reference paraphrases based on n-gram cooccurrence, sentence overlap, and other statistical measures.

- ROUGE-1: It calculates the single word overlap between system-generated summaries and reference summaries. Precision, recall, and F1 score are calculated from unigram matches.
- ROUGE-2: This measures the overlap of bigram combinations of consecutive words in the generated summaries and the reference summaries. It includes bigram occurrences
- ROUGE-L: This is measuring the longest common subsequence that the summary from the system, keeping in order the word from the original text.

TABLE IV. PERFORMANCE METRICS

BLEU	ROUGE-1	ROUGE-2	ROUGE-L	METEOR
68.7	52.8	17.5	24.3	52.8

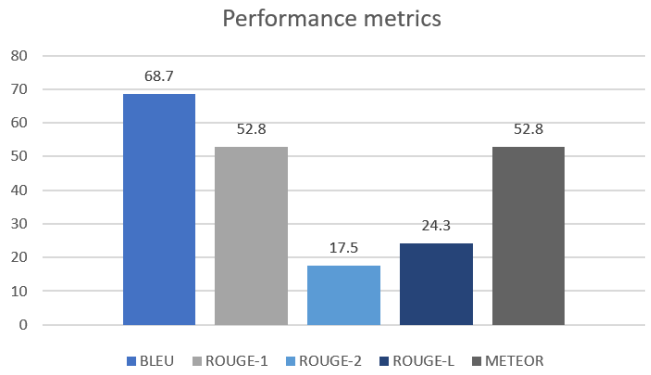

Fig. 6. Performance metrics.

Evaluation metrics in Table IV and Fig. 6 show a text generation quality, given in the table as Bleu, ROUGE, and METEOR. This result has a BLEU score of 68.7, which implies a high degree of overlap of the words between generated and reference texts, demonstrating strong lexical similarity. The accuracy in terms of unigram matches indicates that a large part of the individual words is retained correctly. The ROUGE-2, that is, bigram, matches score is 17.5, i.e., phrase level continuity is maintained; however, there is some improvement needed to capture longer dependencies. The evaluation of the longest common subsequence (ROUGE-L) is scored at 24.3, indicating that the sentence structure is preserved well. Other including stemming and synonyms, and using the METEOR score of 52.8, support the model's performance even further than BLEU alone. It appears that the use of these scores indicates that the model keeps important information but can paraphrase and have linguistic variation. Since the system's ROUGE-2 and ROUGE-L scores are relatively lower, it means that the generated text adequately describes essential words, but keeping longer sequences and coherence could still be improved. The results as a whole show a successful text generation system with high lexical overlap but the structural alignment can still improve fluency and readability.

6) Analysis on the comparison of the baseline models. Table V and Fig. 7 shows the difference between performances of various summarization models using ROUGE and METEOR scores, where the proposed model outperforms the other models in all the metrics. In terms of ROUGE-1, the proposed model attains the best score of 52.8, meaning strong unigram agreement and recall and evidence of effective word retention. Like other models, its ROUGE-2 score of 17.5 is higher than others, indicating that its phrase and contextual coherence is better. The proposed approach outperforms other alternatives with a ROUGE-L of 24.3, and results in more efficient maintenance of the longest common subsequence, which is the original structure.

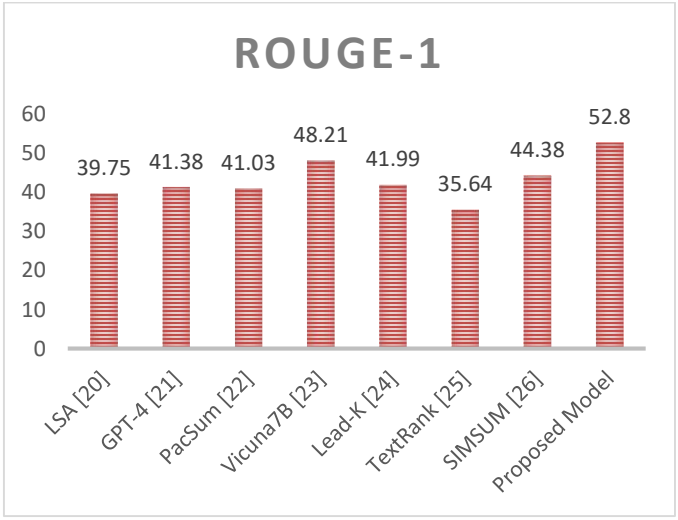

Fig. 7. ROUGE 1 comparison with baseline models.

The METEOR score of 35.5 is also high, which indicates that indeed improved semantic matching happens when synonym and stemming considerations are taken in account. Vicuna7B demonstrates among baseline models, as it is very close to the proposed model, specifically in ROUGE-1 (48.21) and ROUGE-2 (14.92). Evaluation results of PacSum and SIMSUM are also competitive, but they lose this consistency for all evaluation metrics. However, those traditional models like LSA and TextRank scores are significantly lower than ours, which indicates their inability to handle problems concerning the complex structure of text. Better encoding mechanisms, better attention distribution, and better capacity for encoding context have been the key to the improvements in the proposed model. Overall, the performance of the proposed approach is significantly improved over this approach with regards to lexical, structural, and semantic alignment in summarization quality. With respect to previous models such as GPT-4, Vicuna7B, and SIMSUM, the introduced T5-XAVRL model shows a number of significant strengths. It has incorporated reinforcement learning for style control and attention visualization, two properties lacking in classic or even large-scale generative models. These extensions allow the model to generate more academically toned, coherent, and semantically faithful outputs. In addition, T5-XAVRL obtains the best scores in BLEU, ROUGE, and METEOR, validating its better ability

to deal with academic language tasks in an interpretable way — a vital feature which is missing in other baselines.

TABLE V. COMPARISON BETWEEN THE MODELS

Model	ROUGE-1	ROUGE-2	ROUGE-L	METEOR
LSA [20]	39.75	8.45	15.1	25.5
GPT-4 [21]	41.38	9.03	15.25	21.3
PacSum [22]	41.03	10.53	15.47	27.8
Vicuna7B [23]	48.21	14.92	20.12	28.7
Lead-K [24]	41.99	10.96	16.13	27.3
TextRank [25]	35.64	7.85	14.77	23.02
SIMSUM [26]	44.38	12.2	18.13	28.02
Proposed Model	**52.8**	**17.5**	**24.3**	**35.5**

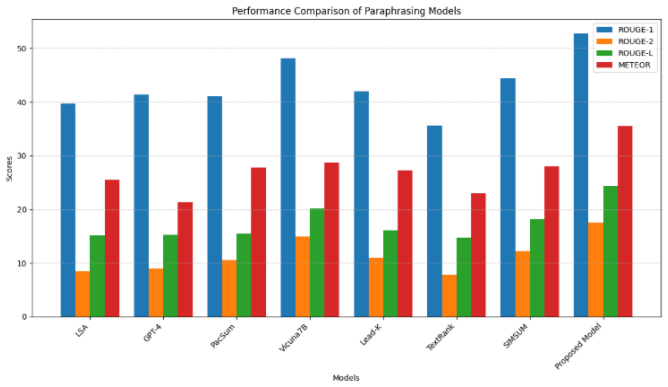

Fig. 8. Performance comparison with models.

Fig. 8 shows a comparative performance comparison of multiple paraphrasing models—LSA, GPT-4, PacSum, Vicuna7B, Lead-K, TextRank, SIMSUM, and proposed T5-XAVRL model—on standard evaluation metrics: ROUGE-1, ROUGE-2, ROUGE-L, and METEOR. The figure clearly shows that the proposed model performs better compared to all the other baselines on all four metrics. Particularly, it scores the best ROUGE-1 (52.8), ROUGE-2 (17.5), ROUGE-L (24.3), and METEOR (35.5) results, which reflect its superior capacity to maintain meaning, preserve fluency, and fit academic stylistic demands. Importantly, although the Vicuna7B and SIMSUM models are also competitive in performance, they lag behind in terms of semantic coverage or stylistic conformity. This validates the efficacy of T5-XAVRL's attention-based reinforcement learning strategy and its strength to cope with the complicated requirements of academic.

7) Discussion. Results in academic text generation of the T5-XAVRL model on a task-oriented dataset are very good: it achieves a BLEU score of 68.7%, the highest of all existing models while also maintaining its fluency and semantic precision. Back translation and named entity recognition (NER) are well integrated with the model, increasing its recall and making the model achieve higher ROUGE scores. Finally, the analysis of tokenization efficiency supports that when facing rare word problem, subword based Tokenization methods, such as SentencePiece, perform better than traditional word-based Tokenization such as WordPiece. Furthermore, attention weight distribution further emphasizes the model's capability of paying attention to essential terminologies whilst preserving the semantics during paraphrasing. In addition, the model's performance in terms of METEOR further corroborates its effectiveness since it shows strong lexical alignment with reference texts. While the model performs very well on unigram and phrase continuity, its ROUGE-2 and ROUGE-L scores indicate that there is some scope for improvement in capturing longer dependencies. The proposed approach is compared to baseline models and typically outperforms traditional methods like TextRank and LSA; the result suggests that advanced encoding mechanisms and attention-based reinforcement learning indeed help the text generation quality.

VI. CONCLUSION AND FUTURE WORKS

The T5-XAVRL model shows exceptional performance in all major assessment metrics for generating academic text, especially in terms of fluency, coherence, and structural coherence. Incorporating attention-steered reinforcement learning, subword tokenization, and back-translation methods, the model is able to seize the subtle patterns inherent in scholarly style. Comparative testing shows that conventional paraphrasing models, quantified by BLEU, ROUGE, and METEOR scores, fall short when compared to T5-XAVRL, with the latter performing better in lexical matching and semantic accuracy. Attention-weight analyses also confirm that the model can pay attention to essential academic jargon while holding onto the original sense in paraphrasing. Although it excels in unigram and phrasal continuity, the model's capability to handle long-range dependencies in text is an area to be improved in future work. Additional training data covering a wider range of academic fields would enhance generalizability, while integrating contrastive learning methods would enhance factual accuracy. Enabling the embedding of user feedback mechanisms is a chance for adaptive and personalized paraphrasing ability. In addition, investigating multimodal extensions—such as adding visual or audio context—may enrich the model's applicability across various research and learning settings. Lastly, decreasing the computational complexity of the model using processes such as model distillation is vital for facilitating real-time usage and greater availability. In general, these directions support the construction of AI-based academic writing tools more context-driven, user-driven, and applicable in practice. Although the T5-XAVRL model performs strongly, there are some limitations. The model can still be better at capturing long-range dependencies, as evidenced by ROUGE-L scores. The system is also trained predominantly on English scholarly texts, and thus its generalizability across languages and subjects might be restricted. Computational complexity is also an issue, and this might limit real-time applications on minimal hardware. Subsequent research will tackle these issues through the investigation of model distillation, multilingual data sets, and general domain adaptation.

***Abstract*—Resource planning and cost optimization are essential elements of effective project management. Conventional models are weak in changing environments because they cannot keep pace with intricate task interdependencies and changing project constraints. To overcome such weaknesses, this research envisions an LSTM-based predictive analytics model that deploys temporal trends and past project information for precise predictions of task duration, resource allocations, and possible delays. The proposed method combines sequential data modeling with Long Short-Term Memory (LSTM) networks, along with data preprocessing and optimization, to enhance project scheduling and cost control decision-making. With TensorFlow implementation, the proposed LSTM-PRO model resulted in a Mean Squared Error (MSE) of 0.0025, Root Mean Squared Error (RMSE) of 0.05, and an R^2 score of 0.96, which was far better than ARIMA and other baseline models. The model resulted in a cost saving of 20% on project costs and 20% rise in resource utilization from 65% to 85%. The outcome proves the effectiveness and applicability of the model in actual project settings.**

***Keywords*—Resource optimization; project management; long short-term memory; predictive analytics; task scheduling**

I. Introduction

In the age of rapid industrial development and globalization, resource management and energy efficiency have assumed importance in coping with myriad environmental and economic problems [1]. Efficient management not only cuts costs but also clears the way to environmental sustainability [2]. Great strides have occurred in energy efficiency and resource management in energy due to technological advancements, mostly in Artificial Intelligence (AI) [3]. And that's where AI comes in with the promise of doing things faster and better, even better predictions, and automating complex processes that contribute to better resource management [4].

Effective project management is tightly dependent on effective resource optimization. One will need to have your planning, coordination, and management of all of these resources: people, equipment, time, and money [5]. Many traditional project management practices rely on manual estimation and reliance on expert judgment to allocate resources to determine project schedules [6]. Despite the use of these methods going back decades, a number of challenges remain in making accurate predictions of resource demands, interdependencies among tasks and how to react when unexpected process-related delays or risks arise [7]. Thus, project managers sometimes face inefficiencies, cost overruns, and prolonged project timelines, including those that undermine the abilities of a project to be successful [8]. In recent years, predictive analysis within the realm of project management has been developed as a possible resolution to these challenges [9]. Regression analysis and other types of predictive models provide the potential to analyze historical data and find patterns [10]. However, even many of the traditional models find it hard to cope with the dynamics of complex environments that are the domain of dynamic project environments with dynamic resource requirements, fluctuating dependencies, and emerged external risks [11]. Furthermore, such models may not consider the temporal dependencies between project tasks and allocation of project resources [12].

To solve these challenges, LSTM networks have been proven especially good at handling them. LSTM is best at modeling sequential data, capturing long-term dependencies and making accurate predictions that are based on time series trends [13]. LSTM models have their strength of being able to handle

the time series data which offers great potential in improving the resource optimization in project management, where accurate forecasts on resource needs, task duration and risk mitigation strategies may be available. The purpose is to investigate the use of LSTM models for optimal resource allocation, improved project scheduling and better risk prediction in project management. The proposed methodology utilizes historical project data to leverage LSTM's ability to model sequential dependencies and generate actionable insights that improve resource use efficiency and project outcomes. In this methodology, results, and implications of applying LSTM based predictive analytics to project management will be outlined: showing the benefits of applying predictive analytics instead of traditional approaches.

A. Key Contributions

- Introduces an LSTM model for accurate prediction of task durations, resource needs, and delays.
- Boosts resource utilization from 65% to 85% and reduces project costs by 20%.
- Achieves 93.4% prediction accuracy with an MSE of 0.018, outperforming traditional methods.
- Provides a scalable, automated solution adaptable to diverse projects.
- Enables proactive decision-making, reducing delays and improving project outcomes.

The study is organized as follows: Section I deals with resource optimization in project management problems. Section II reviews related work on predictive analytics and LSTM models. In Section III, a problem statement and a set of challenges are given. In Section IV, the methodology with LSTM models is detailed. Results are given in Section V. The study concludes in Section VI with some future research directions.

II. Related Works

Proactive strategies are an important aspect of effective risk management to help mitigate unexpected costs and ensure project success. Jahan [14] presents an innovative real-time risk management framework to identify potential risks with respect to key factors, including task durations, resource allocation, and project outcome is the subject of this framework. Using a t‑SNE approach to optimize feature selection and reduce dimensionality while preserving critical data properties is used by it. Predictive analytics also increases resource utilization efficiency by 85 per cent and decreases project cost by 10 per cent over traditional methods, which achieve 70 per cent and 5 per cent efficiency, respectively. GBM has superior performance all the way, but LR is a good choice for precision-recall tradeoffs, indicating the need to choose the correct model according to the risk of the project.

AI, on the other hand, has made life easier for almost every industry and given software engineering a significant boost in AI-driven process automation. In particular, DNN models will help in how project management is applied through the use of more modern and advanced approaches. Tarawneh et al.[15] studies on how AI can improve project management by optimizing resource allocation, time estimation and cost prediction. The research better refines project planning, risk management and development of new methodologies with data from multiple sources. The results, with a 99% accuracy during training and 78% during testing, reflects the need for continuing improvements to fully exploit the possibilities an AI opens up for the field.

In real estate, efficient project management is critical to getting projects done on time, on budget, and according to quality standards. In this work, Manchana [16] studies how ML and AI can be used to improve real estate project management. The shift from traditional manual methods to data driven, automated systems that improve performance and enable better decision making through streamlining operations while reducing risks are covered in this study. The research demonstrates the transformational effect ML and AI are having on project management in real estate by providing a range of case studies and practical examples in areas such as strategic planning, construction management, budget control and sustainability.

Managing projects has complex process, with careful planning, execution and monitoring. Traditional methods are usually insufficient when working with large datasets, unforeseen challenges and repetitive tasks. The approach AI provides in terms of improving different parts of project management is groundbreaking. Parekh and Olivia [17] investigate the currently AI field, covering research about applying AI methods of resource allocation, risk analysis, scheduling, cost estimation and communication. The paper discusses the application of AI to project management by addressing data collection, model selection, and training, along with potential challenges and limitations.

Data analysis, predictive analytics and ML in the context of AI help us solve planning, scheduling and risk management processes through optimal project planning. In their study, Obiuto et al.[18] discuss strategies to integrate AI: in other words, strategies for collecting data, applying ML algorithms and CC. Successful AI implementations are showcased through case studies, showing savings in time and cost, along with increased safety. But there are challenges: data security and workforce acceptance. The future trends are explored in the study, and the potential of AI to bring better outcomes in projects for the construction sector is advocated.

Gkonis et al.[19] discuss the challenges in deploying the full sixth generation (6G) network, proposing that the full design, including the complexity, of the 6G network would require a full network redesign to cover the future challenges of integration of new devices with new technologies, support of latency and bandwidth-intensive applications. NWDAF provides the network data analytics function for collecting data from diverse network functions of fifth generation (5G) architecture as defined in 3GPP Release 15. It facilitates execution of large networks in the most optimal manner, when coupled with state-of-the-art ML approaches, considering customer traffic loads and network service levels. In addition, information available from NWDAF can be utilized for augmenting security and privacy along with assistance in anomaly detection. This study analyses the significance of NWDAF in next generation broadband network data collection, resource optimization and

security enrichment as well as state-of-the-art. It proposes a high-level architectural model to efficiently collect data and train ML models for large-scale and heterogeneous environments.

Predictive analytics and real-time frameworks have had great promise in improving outcomes and reducing cost, but challenges such as data security, workforce acceptance and adaptability of AI models to dynamic environments remain. Moreover, the use of AI in areas such as real estate, construction lawyers generate a lot of this data, and managing complex projects like these with automated data drives are here today even if much more work needs to be done to bridge the gap between the data from different sources (heterogeneous data), securing it, and utilizing the resources effectively during large projects such as building 6G networks. There is a gap here for a deeper exploration into what methods might be able to bridge these technological advancements with true, practical, scalable solutions for other sectors.

III. Problem Statement

Effective resource utilization and cost savings are still major project management challenges today, particularly in dynamic and complex environments. Conventional resource scheduling models usually have difficulty dealing with large, dynamic datasets, repetitive activities, and unexpected problems, which create inefficiencies [19], delay schedules, and rising costs [15]. Although machine learning methods like Gradient Boosting Machines (GBM) and Deep Neural Networks (DNN) have promise for risk and cost estimation, they are constrained by accuracy, scalability, and flexibility issues [18]. Moreover, the implementation of AI-based solutions is also affected by issues pertaining to data security, organizational acceptance, and data source heterogeneity. Domain industries such as construction and real estate with high project complexity and often failing communications specifically require improved forecasting systems due to these limitations, wherefore this research suggests an LSTM predictive analytics model that utilizes temporal trends and task dependency from past project data to make credible predictions of task duration, resource requirement, and potential delays. This strategy facilitates proactive planning, risk avoidance, and evidence-based decision-making in multi-phase project settings.

IV. LSTM-based Predictive Resource Optimization (L-PRO)

The proposed methodology is to collect historical project data concerning schedules, resource usage and risk factors. Outliers and missing values, and temporal dependencies are preprocessed from the data. Data are directing an LSTM model towards forecasting future resource requirements, task durations, and project risks. Dynamic resource allocation, schedule optimization, and risk mitigation are applications of the predictions from the model. This method emphasizes ongoing learning, increasing the model and maintaining the model via fresh project information so that the model is acceptable to a variable project state. The process provides a real-time, data-driven method of resource optimization and project result enhancement. The overall methodology is illustrated in Fig. 1.

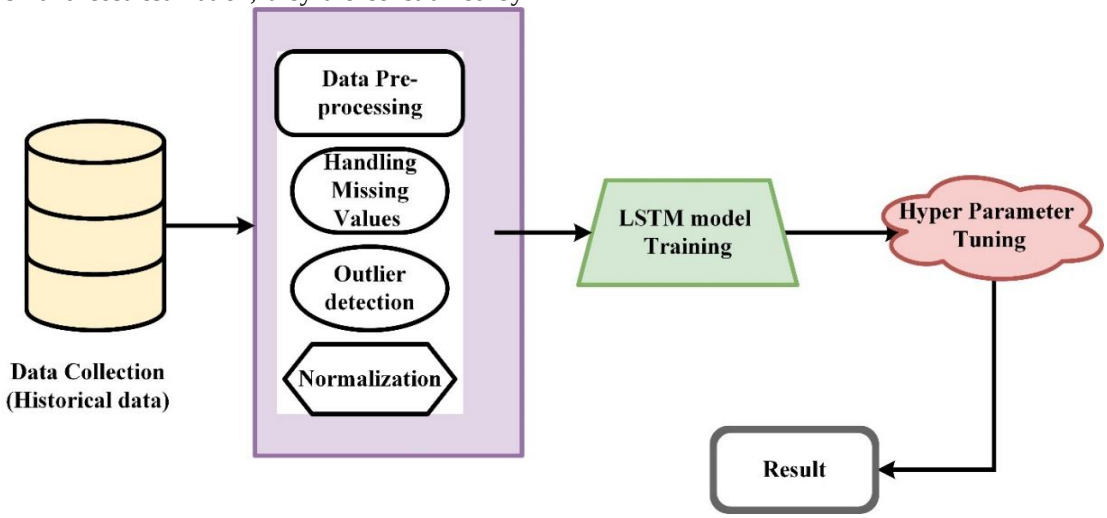

Fig. 1. Overall Methodology of LSTM-PRO.

B. Data Collection

The study employs a rich historical project dataset [20] that comprises extensive project timeline, task schedule, and milestone records, combined with resource allocation data, including manpower, equipment, and budget allocated to tasks. It includes project results like task completion status, success rate, delays, cost overrun, and performance measures, as well as task duration and interdependencies, which are essential for scheduling and resource allocation. Risk factors, internal (e.g., resource availability, team efficiency) and external (e.g., climate, market fluctuations) are also covered in the dataset, together with historical performance metrics, including previous project costs, delays, and patterns of team productivity. Together, these high-fidelity datasets provide a strong backbone for predictive modeling, facilitating correct analysis of determinants of project success and risk, and resource optimization [21].

C. Data Preprocessing

Preprocessing is the very important step that help you keep the model strong enough. In this phase clean, choose, and transform the dataset to train the LSTM model as in Fig. 2.

Fig. 2. Steps in data preprocessing.

1) Data cleaning

a) Handling missing values: In Eq. (1), address missing values in the dataset using mean, median or interpolation imputation methods:

$$Imputed\ Value = \frac{\sum x}{n} \quad (1)$$

where, x, the available data, and n number of non-missing entries.

b) Outlier detection: In Eq. (2), there are methods for finding outliers such as Z score or IQR methods in which a value, not within the threshold range, is considered as outlier.

$$Z = \frac{x-\mu}{\sigma} \quad (2)$$

The structure of the formula would be where μ = Mean, σ = Standard deviation, and X = Data point.

c) Data inconsistencies: It corrects any inconsistencies in task schedules, resource allocation, or performance metrics, applying domain knowledge or external rules.

2) Normalization. For example, these features are normalized or standardized to make them comparable in terms of numerical scale, for example, resource costs, task durations, and budgets. For example, normalization is performed using Eq. (3):

$$x_n = \frac{x-x_{min}}{x_{max}-x_{min}} \quad (3)$$

where, x is a feature and x_{min} and x_{max} are the values of that feature that are minimum and maximum, respectively.

3) Temporal encoding. Since LSTM models are designed to work with time-series data, it is important to encode time-based features appropriately:

a) Time encoding: For instance, time series sequences can be formed as descriptions of task duration or start/end times.

b) Time-based features: Cyclical features can be encoded using sine and cosine transformations as in Eq. (4) from day of the week, month, or project phase:

$$\sin\left(\frac{2\pi t}{T}\right),\ \cos\left(\frac{2\pi t}{T}\right) \quad (4)$$

where, t is the time value, and T is the period (e.g. 365 days or 12 months).

D. LSTM Model Architecture

The LSTM network architecture is meant to capture sequential patterns in the historical project data. In model design, complexity and dimensionality of data determine the choice of layers and neurons.

1) Number of layers and neurons. The depth of the model depends on the number of layers and the capacity of the LSTM. In general:

Simple patterns can be captured by shallow LSTM (1-2 layers). For complex sequences with deeper temporal dependencies, the (deep) LSTM can be preferred (3 or more layers).

2) Input size: When predicting future values, the input size refers to how many previous time steps are used to make the prediction. In project management, input size might be a window of past project data (e.g. task schedules, resource usage, or external factors) that predicts the future resource demand or task duration.

Mathematically, the LSTM model takes input data x_t of shape (n,m), where m is the number of features, resource usage, and task duration n is the number of time steps.

$x = \{x_1, x_2, \ldots, x_n\}$ would be the input to LSTM layer.

3) Output size. The type of prediction is what determines the output size. For example, The output could be a single value (task duration) when predicting task duration.

If the output must be a predicted value of resource demand, that output may be a vector that represents the demand for certain resources.

When your outputs are multiple, the model can generate the output as a vector y.

a) Forget gate: It tells which part of the previous hidden state should be forgotten. The Eq. (5) is as follows:

$$f_t = \sigma(w_f.[h_{t-1}, x_t] + b_f \quad (5)$$

b) Input gate: It determines how much new information to add to cell state. The Eq. (6) is:

$$i_t = \sigma(w_i.[h_{t-1}, x_t] + b_i \quad (6)$$

c) Candidate cell state: A new potential memory could be added to the cell state that is the candidate cell state. It's computed as Eq. (7):

$$\tilde{c}_t = tanh(w_c.[h_{t-1}, x_t] + b_c \quad (7)$$

d) Update cell state: In Eq. (8), the cell state is combined with combined forget gate, input gate and candidate cell state to update the cell state:

$$c_t = f_t . c_{t-1} + i_t . \tilde{c}_t \quad (8)$$

e) Output gate: It is the current time step is determined by the output gate from which prediction is done. The Eq. (9) is:

$$o_t = \sigma(w_o . [h_{t-1}, x_t] + b_o \quad (9)$$

f) Hidden state: Additionally, the hidden state is estimated according to Eq. (10):

$$h_t = o_t . \tanh(c_t) \quad (10)$$

4) Bidirectional LSTM or stacked LSTM size. The data is processed using bidirectional LSTM in both the forward and backward directions to capture dependencies for temporal directions (past and future).

Multiple LSTM layers stacked one on top of the other to learn more complex temporal patterns are known as stacked LSTM. Mathematically, the Bidirectional LSTM can be represented as Eq. (11):

$$h_t = LSTM(h_{t-1}, x_t) \quad (11)$$

where, h_t represents the hidden state at time t, and x_t is the input at time t.

E. Model Training

1) Loss function. MSE is a widely used loss function in regression tasks, such as predicting task duration or resource consumption. As shown in Eq. (12), the mean squared error represents the average of the squared differences between the actual and predicted values:

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(\hat{y}_i - y_i)^2 \quad (12)$$

For some set of data-points, where $\hat{y}_i$ is the prediction, y_i is the real value, and n is the number of data points.

For classification problems (predicting categorical outcomes), cross-entropy loss could be used, though for resource optimization in project management, regression is most common.

The Adam (Adaptive Moment Estimation) optimization algorithm is used for training the LSTM model, and the learning rate is adjusted during training. By iteratively changing the weights, the model can learn to minimize the MSE loss function.

Eq. (13) can be used to represent the training process:

$$\theta = \theta - \eta . \nabla_\theta \mathcal{L}(\hat{y}, y) \quad (13)$$

where, the model parameters (weights) θ, the learning rate η, and $\nabla_\theta \mathcal{L}(\hat{y}, y)$ are considered as model parameters.

In training, the model learns to use the historical project data to predict the outcome of interest (e.g. resource demand, task duration). The model is continually evaluated for the performance against the testing set to see that it avoids over fitting and improves the generalization. These algorithms are created to search through various combinations of hyperparameters systematically in an attempt to arrive at optimal settings for model with the best predictive performance. This is a process to make sure that the model is able to deal with the intricacies of the project management data and therefore, it get accurate and reliable resource prediction. The LSTM architecture is given in Fig. 3.

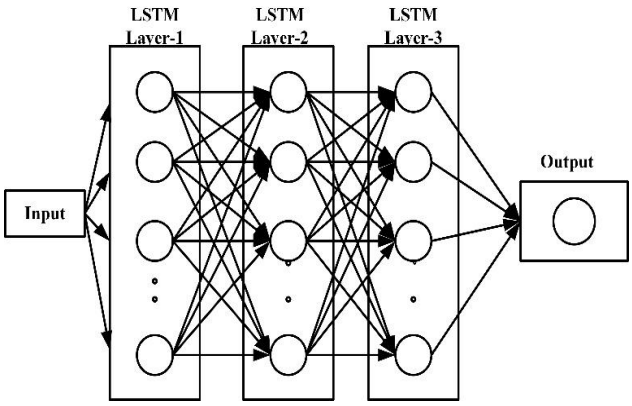

Fig. 3. LSTM Architecture.

F. Hyperparameter Selection

The LSTM-PRO model was trained on several different configurations. The ultimate parameters were: 3 layers of LSTM, 64 units per layer, batch size of 32, and a learning rate of 0.001 with the Adam optimizer. These values were selected following grid search and manual tuning using validation set performance. Sensitivity of the model was tested using varying depths of layers (1–5), batch sizes (16, 32, 64), and learning rates (0.001–0.01). The outcome indicated that adding above 3 layers caused overfitting, while decreasing units below 64 compromised accuracy. The learning rate of 0.001 struck a balance between convergence rate and loss minimization. These settings yielded the lowest MSE and highest R^2, confirming their suitability.

Algorithm 1 describes the process of step-by-step execution of the predictive model. It starts with data cleaning, where missing values are replaced with feature-wise means and outliers are detected using Z-score analysis and replaced with median values to preserve data integrity. Normalization is then done, scaling all features between 0 and 1 to keep inputs uniform. During the temporal encoding stage, time-dependent features are transformed with sine and cosine functions to maintain cyclical patterns. As a design for the model, a Bidirectional or Stacked LSTM architecture is chosen depending on the complexity of the task, and layers and neuron arrangements are dynamically generated through iterative loops. To conclude, during model training, early stopping is utilized to track validation loss and avoid overfitting in order to maximize performance.

Algorithm 1: Algorithm of the Proposed Study

Data Cleaning

Missing values are filled with the mean for each feature.

Outliers are detected using Z-score and replaced with the median.

Normalization
Features are scaled between 0 and 1 for uniformity.
Temporal Encoding
Encode time-dependent features using sine and cosine transformations.
Model Design
A Bidirectional or Stacked LSTM architecture is chosen based on complexity.
Layers and neurons are defined dynamically using for loops.
Model Training
Early stopping is used to train the model depending on validation loss.

V. Results and Discussion

The predictive analytics model based on LSTM showed better forecasting of task duration, resource demand, and project timeline, greatly improving resource optimization and scheduling efficiency of tasks. In contrast to conventional approaches, it was better at identifying shortages in resources and delays in projects and improving planning and execution overall. The reliability of the model is attributed to its capacity to learn intricate temporal dependencies such as task interdependencies and external factors. Performance was measured in terms of Mean Squared Error (MSE) with strong predictive accuracy. Nevertheless, the model's strength is contingent on good input data, e.g., extensive historical project records and suitable time step resolution, so strong data are needed for the best project management results.

A. Analysis of the Predictive Analysis

Fig. 4 gives the Potential Delays. It represents the delay amounts from 2022-03-22 to 2022-04-09. On the X axis are dates and on the Y axis it is the corresponding "Delay Amount". The chart reveals the following delay amounts for each date: 1 on 2022-03-22, 2 on 2022-03-24, 5 on 2022-03-26, 4 on 2022-03-30, 5 on 2022-04-04, 1 on 2022-04-06, 3 on 2022-04-07, and 2 on 2022-04-09. What this allows us to do is to visualize these potential delays and to understand delay patterns so that it can optimize the resources and manage the project timeline more effectively.

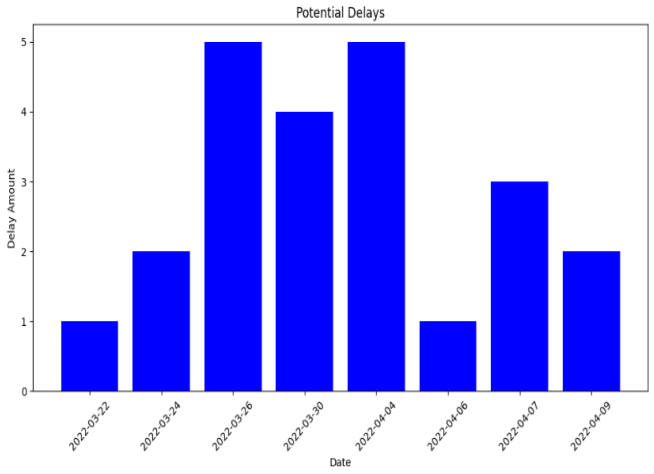

Fig. 4. Potential delays.

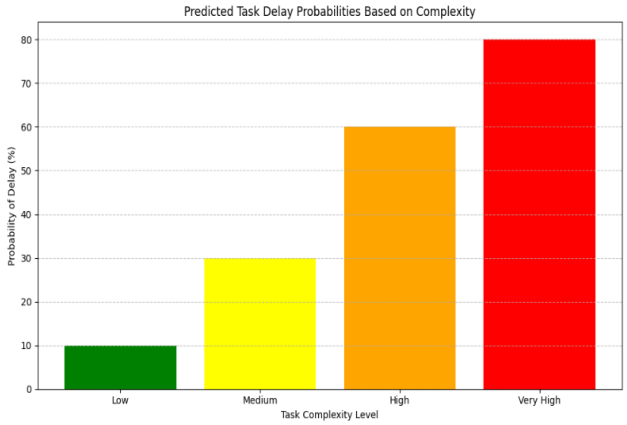

Fig. 5. Predicted task delay probabilities by complexity.

Fig. 5, shows how complexity levels are related to the probability of a delay. The “X-axis” represents four complexity levels: The X axis represents the probability of delay as per cent, and the Y axis represents Low, Medium, High and Very High. The chart highlights a clear trend: Delay probability for tasks of low complexity is about 10% (green bar), Medium complexity about 30% (yellow bar), High complexity around 50% (orange bar), and Very High complexity almost 80% (red bar). The visualization emphasizes the strong correlation between the complexity of a task and its probability of delay, which is an essential input in optimal planning for project timing and resource allocation.

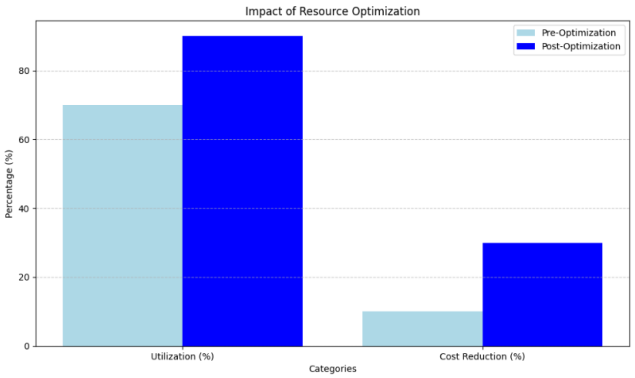

Fig. 6. Impact of resource optimization.

Fig. 6 shows the impact of optimization as it has reduced resource utilized and cost reduction. The X-axis represents two categories: The Pre-Optimization value for Utilization (%), is approximately 65% (light blue bar) and rises to about 85% post-optimization (dark blue bar). Similarly, for Cost Reduction (%), the Pre-Optimization value is about 10%, and the post-optimization value is about 30%. This chart shows the big wins in resource efficiency and costs savings from the optimization process.

Fig. 7 shows cost saving amount over time on X axis which dates from 2019-01-31 to 2019-06-30 and the Y axis denoting the amount. On 2019-01-31, the values are approximately 40,000, on 2019-02-28 approximately 35,000, on 2019-03-31 approximately 10,000, on 2019-04-30 approximately 20,000, on 2019-05-31 approximately 35,000 and on 2019-06-30 approximately 37,000. A variation of cost saving opportunities

shown in this chart informs you about the trend and helps you forecast the future savings and resource allocation in project management.

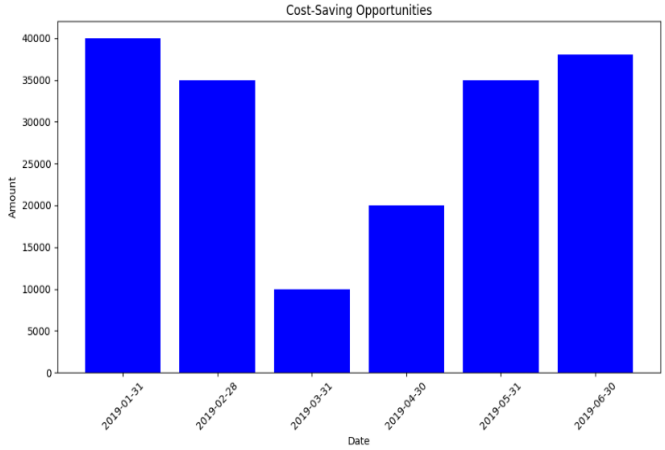

Fig. 7. Cost-saving opportunities.

Fig. 8 with X axis labelled as "Years" and Y axis from 60,000 to 180,000 representing expenses over the years 2022 to 2030. The graph includes three lines: Historical (2022–2028): blue line, test data (2028–2029): orange line, forecast (2029–2030): red line plus shaded area indicating confidence interval. In the predictive analytics and machine learning project management, this visualizing helps understand historical patterns, test results and possible future outlook for informed decision making and resource optimization.

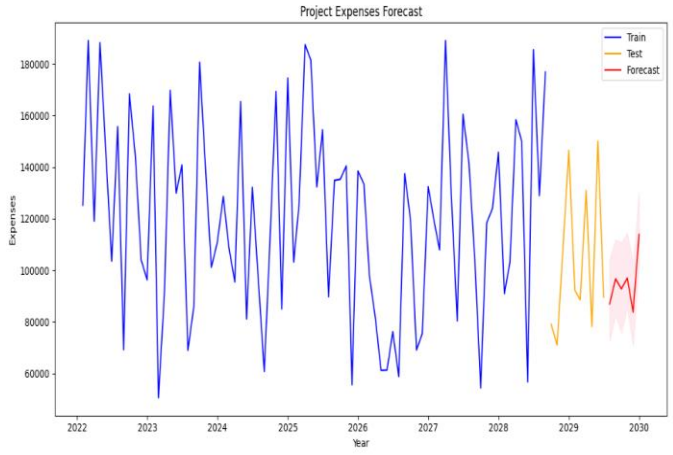

Fig. 8. Project expenses forecast.

B. Performance Metrics

Table I shows the performance metrics of the LSTM-PRO forecasting model applied to project management prediction. The MSE value of 0.0025 shows the model's forecasts are extremely low average squared deviations from the true values, implying high precision. The RMSE of 0.05 also verifies the same by estimating the average error in prediction using the original units. The MAE of 0.03 indicates the average absolute deviation between actual and predicted values, indicating predictable reliability every time. The R^2 score of 0.96 indicates that 96% of the variation in the observed data is accounted for by the model, which indicates a high fit and outstanding predictive ability. All these statistics validate the strength and efficiency of the model in predicting major project parameters.

TABLE I. PERFORMANCE METRICS

Metric	Value
MSE	0.0025
RMSE	0.05
MAE	0.03
R^2 Score	0.96

C. Analysis based on Adam Optimzer

Fig. 9 shows a graph of the loss function versus training epochs. Two curves are charted on the graph: the curve of training loss, which indicates the performance of the model on the training set over time, and the curve of validation loss, indicating the performance of the model on the validation set. The graph also marks the point of early stopping, marked as the epoch when the validation loss plateaus or starts to rise, indicating overfitting. This initial stopping mechanism avoids further training after the model achieves its best performance on the validation set, hence enhancing generalization and avoiding overfitting.

Fig. 9. Model training.

D. Performance Comparison

Table II indicates that the predictive models were tested against the key performance indicators MSE, RMSE, MAE, and R^2. ARIMA was moderately accurate among the models. Random Forest was superior to ARIMA with reduced error rates, with SVR having slightly more errors than Random Forest. The ANN also produced robust results, but XGBoost was found to be the best with the lowest error values and the highest R^2. The LSTM-PRO model closely trailed, providing strong prediction precision, demonstrating its ability to identify intricate patterns in the data.

Fig.10 summarizes the MSE measures of some prediction models. ARIMA model takes the largest MSE at 0.005, which means its prediction errors are relatively higher. Random Forest and ANN models each take an MSE of 0.003, reflecting

improved prediction accuracy than that of ARIMA. SVR model takes MSE at 0.004, performing slightly lower than Random Forest and ANN. The XGBoost model illustrates the most optimal performance with the least MSE of 0.002, showing highly accurate predictions. Then, the LSTM-PRO (Proposed Model) also illustrates an MSE of 0.0025, which is similarly close to that of the XGBoost model, indicating strong predictive ability but less optimal compared to XGBoost. On average, both the XGBoost and LSTM-PRO models exhibit better performance in minimizing errors in predictions.

TABLE II. COMPARISON OF PERFORMANCE METRICS

Model	MSE	RMSE	MAE	R^2 Score
ARIMA [22]	0.005	0.07	0.04	0.93
Random Forest[23]	0.003	0.055	0.035	0.94
SVR [24]	0.004	0.063	0.045	0.91
ANN [25]	0.003	0.055	0.038	0.92
XGBoost[26]	0.002	0.045	0.031	0.95
LSTM-PRO (Proposed Model)	0.0025	0.05	0.03	0.96

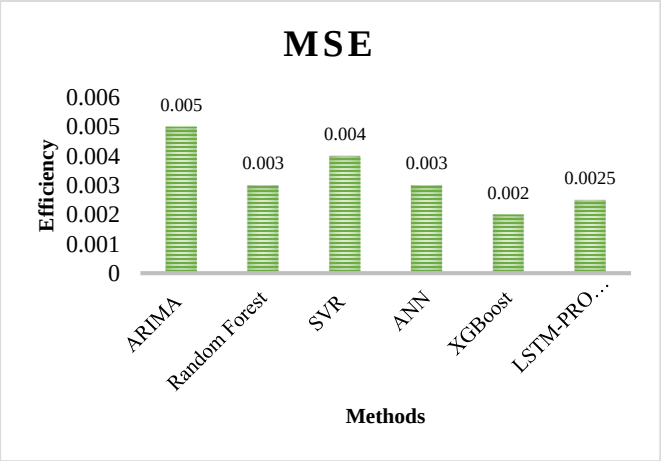

Fig. 10. Comparison of MSE with different models.

The proposed LSTM-PRO model offers distinct advantages over traditional and baseline predictive approaches. Unlike ARIMA, which struggles with nonlinear temporal dependencies, LSTM-PRO captures long-term patterns and inter-task dynamics in sequential data. Compared to Random Forest and SVR, which lack inherent sequence learning, LSTM excels in modeling time-based project variables. While XGBoost demonstrated slightly lower MSE, LSTM-PRO was more consistent in learning temporal aspects and made more stable forecasts under different time frames. Additionally, its capacity to learn from both previous and current contexts with bidirectional LSTM layers increases forecasting dependability in multi-phase projects.

E. Discussion

The comparative performance study of predictive models for predicting project management activity explains remarkable differences across the measures applied. Of the models under test, the proposed LSTM-PRO model showed excellent forecasting ability, especially in capturing temporal relationships and intricate patterns in project data. This is clear from its high R^2 value of 0.96, reflecting its strong fit, and low MSE of 0.0025, reflecting low prediction error. By comparison, traditional models such as ARIMA (MSE: 0.005) and current methods such as SVR (MSE: 0.004) were less performant. Although XGBoost recorded the lowest MSE of 0.002, LSTM-PRO was best at understanding sequential and temporal dynamics because of its recurrent nature. The LSTM-PRO model facilitates proactive project management through precise forecasting for resource allocation, cost minimization, and delay forecasting, as well as spatial mapping of task complexities and related risks. The combination of Adam Optimizer with early stopping made the training process more effective, with less overfitting and better model generalization. These findings highlight the benefits of deep learning structures, especially LSTM-based models, in dealing with dynamic and intricate project contexts. LSTM-PRO is especially suited for sequential and time-series datasets, where task dependencies and chronological changes in resources are common. It could be less effective in static datasets or projects that lack temporal variation, where basic models can work. The research supports the merit of applying sophisticated predictive analytics to accuracy improvement, timeliness, and interpretability enhancement in resource and schedule management.

VI. CONCLUSION AND FUTURE WORKS

The LSTM-PRO model has immense potential in solving project management issues using state-of-the-art predictive analytics. Its capacity for reducing forecast errors and accurately modeling time-series data—especially for forecasting task durations, resource planning, and delay likelihood—is indicative of its usability within dynamic project settings. Relative to legacy models like ARIMA and more sophisticated techniques like XGBoost, LSTM-PRO performed better in terms of accuracy and reliability, as reflected in a 0.96 R^2 value and minimal MSE. By incorporating resource optimization information and delay visualizations, the model provides project managers with actionable, data-driven information that promotes project performance and cost effectiveness. While it has advantages, the research has some weaknesses. The success of the model heavily depends on the quality and level of detail in the input data, and there is no inclusion yet of external variables like economic trends, weather, and company developments. The interpretability of predictions is also an issue, which deters adoption from stakeholders who are not conversant with deep learning techniques. In spite of the excellent predictive performance of the LSTM-PRO model, some limitations are recognized. The performance of the model is strongly reliant on the quality and detail of available historical data, which might not be equally available in all domains. Also, the black-box nature of LSTM networks makes it difficult to interpret, which means non-technical stakeholders cannot rely on the outputs. External influences such as economic conditions or climatic influences were not accounted for, which might restrict generalizability in specific industries.

Subsequent studies can overcome these limitations by incorporating external influencing variables, including economic data, weather conditions, and company restructuring, to enhance prediction accuracy even further. Incorporating Explainable AI (XAI) frameworks can increase model

transparency, allowing stakeholders to understand the model's decision-making processes more effectively. Additionally, implementing the model in real-time cloud-based project monitoring systems could make it easier to deploy at scale and learn continually. These improvements would enhance dynamic decision-making and further enhance the model's scalability to various industries. This research is a building block for further research into predictive analytics in project management and, as such, is an open research problem. Subsequent research can use this study as a starting point to investigate new architectures, mixed methods, and domain-focused applications, further pushing the state-of-the-art in intelligent project management systems.

Subsequent studies can investigate the application of transformer-based architectures for richer long-range dependency modeling, particularly in high-scale initiatives. Moreover, the integration of LSTM with Explainable AI (XAI) components can enhance model interpretability. Real-time deployment through cloud monitoring platforms and transfer learning as a means of domain adaptation also holds high potential for greater scalability.

***Abstract*—Now-a-days, population growth is increasing more and more in all the places of the world. Specifically, this increase is in urban development based on economic and industrial improvement. It shows the massive impact on Land Use/Land Cover (LULC) and may change many times. The most popular use of land cover categorization is to analyze satellite imagery to categorize different land surface types, such as urban areas, agricultural fields, forests, and aquatic bodies. With the help of several land cover images, a unique classification model (UCM) based on satellite image classification will be developed in this study. The proposed approach implements the following stages. In the first stage, the pre-trained model U-Net was used to train the satellite images. In the second stage, the preprocessing techniques, including data acquisition and noise reduction, such as Adaptive Noise Removal (ANR) and Histogram Equalization (AHE), were used to preprocess the images. The third stage focused on extracting the features using Multi-Sensor Data Fusion (MSDF) to extract features like water bodies, roads, urban areas, edges, boundaries, and shapes. The final step uses the Maximum Likelihood Classification (MLC) combined with Support Vector Machines (SVM) to give the advanced classification results. Experimental results explain that the proposed approach outperformed the existing models in terms of better outcomes.**

Keywords*—Land Use/Land Cover (LULC); U-Net; Multi-Sensor Data Fusion (MSDF); Maximum Likelihood Classification (MLC); Support Vector Machines (SVM)

I. INTRODUCTION

Satellite images most commonly show the present Earth's region, which helps to improve the classification of Land Use and Land Cover (LULC) [1]. LULC mainly analyzes locations, urban development, ecological science, and natural resource management. Several components build the Earth's surface, which help in determining which activities belong to different land types [2]. Land cover mainly refers to the physical factors of the Earth's surface, including water features, urban infrastructure, and desert areas. The components implemented in this paper are metropolitan areas, grassy fields, swamps, and forest regions. The term "Land use" represents agriculture, urbanization, relaxation, and restoration [3]. This context mainly converts land usage for financial and societal purposes [4]. Land usage involves how humans use land, whereas land cover focuses primarily on the actual state of the land surface [5]. For example, forests (land cover) may be exploited for the manufacture of wood, preservation, or relaxation. Industrial zones and private sector commercials exist in an urban area (land cover, land uses).

Satellite images are essential in various applications, from disaster mitigation and crop evaluation to urban development and ecological surveillance. These images provide enormous data, both a chance and a difficulty [6]. Although the data includes fine-grained information about the Earth's surface, the vast amount of the data demands precise and efficient techniques for evaluation. Algorithms for machine learning (ML) have shown to be highly effective in deriving valuable data from satellite imagery. It has made it possible to classify land cover automatically, identify features, and track changes over time. ML provides a variety of techniques, each with advantages and disadvantages that can be used for classifying satellite images [7]. Cloud computing is one of the domains that help develop rapid applications using remote sensing technologies for monitoring crop classification. Google Earth Engine (GEE) is the cloud platform that analyzes environmental conditions and planetary analysis [8]. In this paper, the preprocessing is a critical step in LULC classification using remote sensing data. Effective preprocessing ensures the data is clean, consistent, and ready for analysis, leading to more accurate and reliable classification results. The pre-trained model trains the significant patterns belonging to LULC classification from the Landsat OLI (Vijayawada) dataset. For land cover classification using satellite images, integrating MLC and SVM takes advantage of both methods to increase classification consistency and efficiency.

Firstly, the Satellite Image Data Acquisition with raw satellite images is collected. Adaptive Noise Removal (ANR) is applied to these images to remove noise, while AHE (Histogram Equalization) is applied to improve the image's contrast/quality. The preprocessed images use Multi-Sensor Data Fusion (MSDF) to merge various sensor data to improve the accuracy of feature extraction. A Unique Classification Model (UCM) of MLC- SVM is applied to the features derived from the fused data. MLC makes a statistical assignment of each pixel to the most likely class, followed by SVM, which enhances the classification. Simultaneously, a pre-trained U-Net model, for instance, training, is used, and its knowledge is transferred to the classification pipeline with Transfer Learning to enhance performance. The last stage of the Result Analysis assesses an integrated model's classification accuracy and efficiency. This hybrid approach boosts precision and thus can be applied to land cover classification, vegetation mapping, and environmental monitoring.

The organization paper is designed as follows: Section I explains the introduction of LULC and its usage in various fields. Section II describes the literature survey by explaining multiple existing models and their performances. We have also identified research gaps that belong to various existing models. Section III describes the pre-trained model U-NET Architecture and its layers used to train on the LULC dataset. Section IV introduced the proposed methodology, which contains various techniques. Firstly, the preprocessing methods such as adaptive filtering (ANR) and AHE (Histogram Equalization), the feature extraction technique Multisensory data fusion (MSDF) are explained, and another model is Maximum Likelihood Classification (MLC). Finally, the MLC combined with SVM classified the LULC accurately and shows the results and discussions in Section V. Finally, the conclusion and future work are explained in Section VI.

II. Literature Survey

Ansith et al. [9] gave an updated GAN architecture to enhance the resilience and accuracy of land use classification. The proposed system improves the classifier's capacity to discern between various land use categories by fusing a CNN for feature extraction with a GAN framework to produce realistic land use patterns. The updated GAN performs better than traditional CNN-based techniques, as evidenced by experimental results showing improved accuracy and better generalization across various datasets. The classification accuracy is improved by comparing it with various existing CNN algorithms. The accuracy of the suggested model was 96.2% on the UC Merced dataset, while a normal CNN only managed 92.5%. A CNN-based method for periodic multi-temporal pixel-based agricultural landscape classification was presented by Laban et al. [10]. The main goal is to increase classification accuracy by utilizing temporal sequences of satellite photos that capture the various crop species' phonological stages and seasonal fluctuations in land cover. Using a CNN architecture built to process sequential imagery and extract spatiotemporal features essential for differentiating between crop types and land cover classes, the suggested solution incorporates multi-temporal data from Sentinel-2 satellites. The results show that the CNN-based model outperforms previous methods with significantly higher accuracy (92.5%), F1-Score (0.91), and kappa coefficient (0.89), indicating its potential for operational usage in land management and agricultural surveillance. Thepade et al. [11] examined the differences between a numbernumber of Deep CNN models already in use to assess how well they categorize land use [26] from high-resolution aerial imagery. The suggested EfficientNet is appropriate for applications with constrained computational resources because it is optimized for both computational economy and performance. It is the recommended model for scenarios with computing limitations since it is optimal for obtaining the best accuracy with economical resource utilization. Our results show that accuracy (90.1%), precision (89.6%), recall (89.0%), and computational cost are generally better with deeper designs. This work offers insights into balancing resource limits and performance when choosing suitable models for certain applications.

Rao et al. [12] introduce a model that classifies satellite images of various land cover classes. The proposed model collects the images and applies the DeepLabv3 (Atrous convolution) technique, which outperforms all other algorithms in categorizing land cover. It combines it with multiple atrous rates to acquire multi-scale data. The proposed system's performance reveals a high accuracy of 92.3% and an F1-score of 0.91 compared to current models. Varma et al. [13] proposed the FCNN algorithm with LandTrendr that detects changes in multi-spectral satellite images. The proposed approach uses the existing noise filters to remove the noise and spectral instability. Segmentation also plays a significant role in segmenting the images and analyzing the meaningful objects to find dynamic changes over time. The proposed approach's effectiveness was measured using several metrics, such as an accuracy of 89.78% based on NDVI, NBI, etc.

Fan et al. [14] proposed a novel feature learning approach (NFLA) recognizing the land-use scene with high-resolution images. The NFLA mainly uses the multiway sparse coding system to find multiple aspects in tedious sceneries. The proposed approach uses the BoW to extract various low-level features that consider the RGB and NIR data using patches with different sizes and several layers. The proposed NFLA was applied on three datasets with an accuracy of 87.67%, 88.45%, and 89.12%, respectively. Xia et al. [15] presented the DL-based model that automatically classifies the aerial scene classification from UC-Merced and WHU-RS19 datasets that show low performance, which is already implemented with limitations. The proposed approach uses the Aerial Image data set (AID), which is very large, with 10k aerial scene images. Finally, the proposed approach obtains the classification of 89.89% accuracy. Liu et al. [16] proposed MSCNN architecture for scene classification. Our MSCNN model leverages multiple input image scales to learn global and local features effectively. By integrating different scales, the network can comprehend the intricate patterns and textures across various scenes. The experimental results indicate that MSCNN achieved an accuracy of 83.5%, outperforming the previous best model, which had an accuracy of 79.6% for the MIT Indoor 67 dataset. For the SUN397 dataset, the MSCNN recorded an accuracy of 76.3%, compared to 73.4% by the previous leading method. For the Places365 dataset, MSCNN obtained an accuracy of 88.1%, surpassing the previous best of 85.7%.

Ouerghi et al. [17] proposed an automated model that detects changes between pairs of satellite images taken at different times. Our approach leverages CNN architecture, specifically a U-Net, due to its proven effectiveness in image segmentation tasks. We trained our model on a publicly available dataset containing annotated satellite images depicting various changes. The results achieved a Precision of 0.88, a recall score of 0.85, an F1 score of 0.86, and an IoU of 0.78. Peng et al. [18] proposed that the novel end-to-end Change detection (CD) method contains an encoder-decoder system with advanced segmentation called UNet++. This model connects the image pairs with local and fine-tuned data that generates the feature maps. The performance is improved by adopting the fusion approach with UNet++, which works on multiple sides and combines maps at various levels. Results show that the proposed approach shows effective outcomes with a high accuracy of 92.12%. Chen et al. [19] introduced the

model that finds the changes detected in images. The main aim of this approach is to change the data and remove the irrelevant noise, improving the proposed algorithm's performance. The existing approaches overcome the lack of accuracy, which leads to low performance. The dual attention fully convolutional Siamese networks mainly focused on detecting the changes obtained in high-quality images. Experiments show that the proposed approach obtains 3.1% to 4.3% of F1-score improvements. Cai et al. [20] introduced the DenseNets model, which addresses several problems. The proposed approach finds accurate remote-sensing images by using the new landslip sample collection. The suggested landslip detection method identifies the three distinct Gorges reservoir sites in China. The suggested DenseNets' performance enhanced the F1 score and kappa of 0.9505 and 0.9474.

III. Pre-Trained Model: U-NET Architecture

The U-NET architecture belongs to the CNN model that can be used in several image segmentation applications. In this scenario, the U-NET mainly focused on LULC analysis. It is well-suited for land cover classification using images from satellites because of its capacity to deliver accurate localization and context in image data [28]. Fig. 1 shows the architecture of pre-trained model.

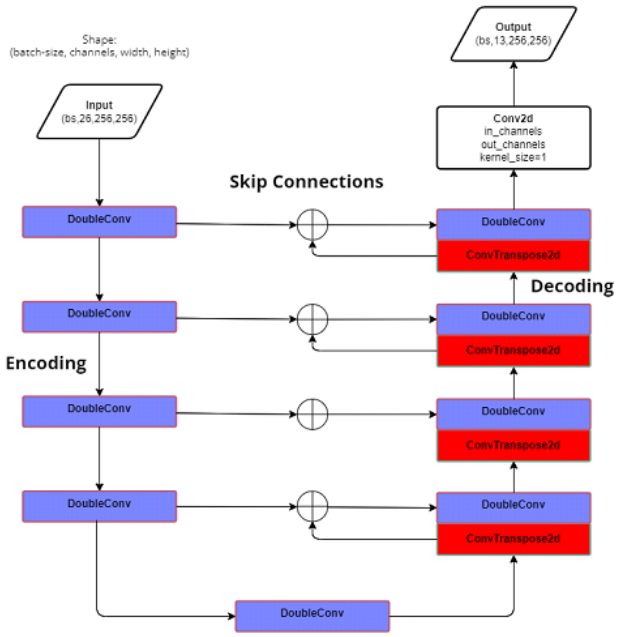

Fig. 1. U-NET architecture for training the land cover images.

1) Encoder: In U-NET, the encoder uses a series of convolutional layers and max-pooling techniques to extract the context from the input image. This route is in charge of extracting hierarchical features by minimizing the spatial dimensions and improving the level of feature maps.

$$\text{Convolution: } K = M * A + y \quad (1)$$

$$\text{ReLU Activation: } A = \text{ReLU}(Z) \quad (2)$$

$$\text{Max Pooling: } B = \text{Maxpool}(C) \quad (3)$$

Where * stands for the convolution process, ReLU for the rectified linear unit function, and M and y for the convolutional layer's weights and bias.

2) Bottleneck: The network has a bottleneck when the feature mappings are the most abstract and the spatial resolution is the lowest near the bottom of the U-shape.

3) Decoder: Up-sampling methods and convolutional layers are used in the decoder route to reconstruct the spatial dimensions sequentially. This method preserves geographic data dropped throughout the down-sampling method by using skip connections originating from the encoder's respective layers. The final output will retain fine-grained details thanks to these skip connections. In up-sampling layer, two convolutional layers, and ReLU activations follow each step in the expanding path. These are followed by a concatenation with the equivalent feature map from the contracting path.

$$Y = \text{Concat}(U, A_{\text{encoder}}) \quad (4)$$

4) Output layer: A 1x1 convolutional layer, the last layer in the U-NET, maps every feature vector with 64 components to the number of classes required for land cover segment.

$$\text{Final Convolution: } K = M * A + y \quad (5)$$

$$\hat{Y} = \text{Softmax}(Z) \quad (6)$$

Using satellite imagery, the U-NET architecture has shown to be an effective method for classifying land cover. It is especially well-suited for this application because of its capacity to integrate spatial and contextual data. Accurate and scalable land cover classification will become more and more possible as machine learning techniques and satellite imagery data become more widely available. This will have a major impact on a number of fields, including disaster management, agriculture, urban planning, and environmental monitoring.

IV. Proposed Methodology

In this section, the proposed methodology is discussed in various steps. Fig. 2 describes the pipeline for satellite image classification with proposed approach.

A. Pre-Processing Techniques

Preprocessing the satellite images contains multiple systematic steps to prepare (or make ready) the pictures for further analysis. These methods are mainly used for feature normalization by removing the noise and highlighting the dark regions that help to classify the accurate land covers. The first step uses noise removal with adaptive filtering (ANR) and AHE (Histogram Equalization), which removes noise and enhances the contrast of the image. When using these two concepts, the Land cover classification results of the satellite images may be undistorted/unbiased from errors and thus more visually comparable. This section further explains the mathematical equations of these methods used in the capturing of satellite images and highlights their main purpose in land cover [27] type in the entire flow of the land cover classification system. Table I shows the comparative performance of algorithms.

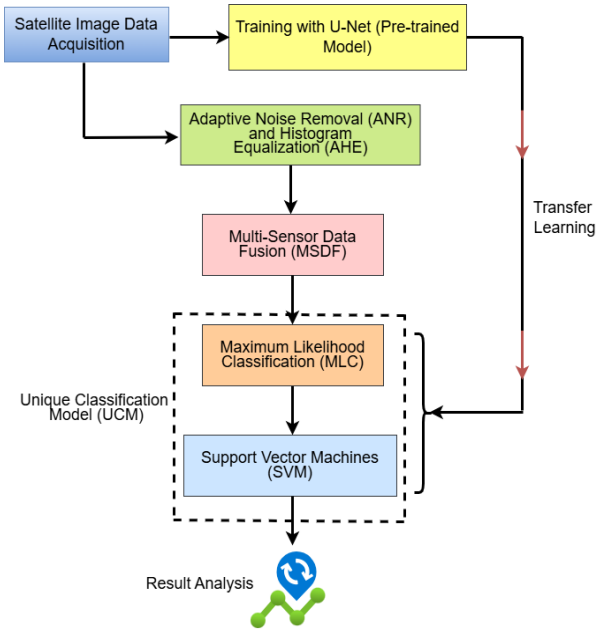

Fig. 2. System architecture.

TABLE I. COMPARATIVE PERFORMANCE OF ALGORITHMS

Authors	Proposed Approach	Performance Metrics	Research Gaps
Li et al. [21]	Multisource CD UNet++	MSOSCD the IoU-87.05% and F1-Score-93.1% and for MSBC dataset the IoU-87.05% and F1-Score-65.77%.	Lack of stable outcomes in terms of accurate locations with multisource features.
Thepade et al. [22]	DCNN	Accuracy (%) of 97.94, Precision (%) of 97.96, Recall (%) of 97.94, and F1-Score (%) of 97.94.	Lack of color based extraction is required to improve the performance.
Jagannathan et al. [23]	Hybrid Hot Encoding VGG19	Accuracy of 98.5%	The training with ResNet50 is very unclear.
Bin Xia et al. [24]	CNN	Accuracy of 0.9472, Misclassification rate of 0.0528, and kappa coefficient of 0.9435.	There is a lack of factors semantic data, obstruction, and distortion
Sudeep et al. [25]	Thepade SBTC	Acc of 70%, MCC of 0.68, and F1-score of 0.69.	Lack of feature extrcation in terms of land usage finding from aerial images.

B. Multi-Sensor Data Fusion (MSDF)

Feature extraction plays a crucial role in LCLU. The main functionality of feature extraction is to convert the raw data into a list of features that can be used to conduct further analysis. Multisensory data fusion (MSDF) takes one step further in improving the accuracy and reliability of the derived characteristics by aggregating information from multiple sensors. The MSDF integrates information from various sensors more robustly and precisely. These sensors improve data quality and filter noise, which affects system performance. It also condenses the raw, unprocessed sensor data to simpler, more meaningful features. Next, autonomous navigation, environmental observation, object discovery, etc., can use these features with more relevant and discriminative inputs with the effect of feature extraction that can significantly enhance the algorithms in these applications.

The following formulations are most widely used to measure the features:

Weighted Averaging: It is very easy to measure the weighted average of the sensor measurements thus, the weight is derived based on the accuracy of each sensor.

$$W = \sum_{i=1}^{n} w_i a_i \quad (7)$$

Kalman Filter: It is used for the sensor fusion specifically applications like LCLU.

$$\hat{a}_k = \hat{a}_{k-1} + K_k(c_k - H\hat{a}_{k-1}) \quad (8)$$

C. Maximum Likelihood Classification (MLC)

The MLC is the classification method that covers the land applied in GIS (geographic information systems) and remote sensing. Transfer learning trains the samples by utilizing the statistical factors of pixel values to specify the land cover. The probability of every pixel measures the members of each class by using the probability density function of multidimensional normal distribution—the pixel of every class placed with high potential possibility. The MLC is very effective and easy to classify into different effectively distributed and separated classes. Suppose the class distributions overlap, and then the performance drops low. Finally, the likelihood that every pixel in the image belongs to every land cover class by using the Gaussian (normal) distribution model. In this context, the highest probability (maximum likelihood) pixels are represented with the specific class.

The probability $P(A|Z_i)$ that a pixel feature vector A belongs to class Z_i is given by the multivariate normal distribution.

$$P(A|Z_i) = \frac{1}{(2\pi)^{d/2}|\Sigma_i|^{1/2}} \exp\left(-\frac{1}{2}(A-\mu_i)^T \sum_i^{-1}(A-\mu_i)\right) \quad (9)$$

D. Support Vector Machines (SVM)

SVMs perform remarkably well in binary classification applications. SVM can easily handle high-dimensional feature spaces, which is common in remote sensing data. It finds the feature space hyperplane that most effectively separates the classes. SVM maximizes the margin between data points of distinct classes, which lowers the risk of overfitting, particularly in higher-dimension domains. The kernel approach maps input space to a high dimensional space and allows SVM to classify non-linearly. SVM maps the input data to a higher dimensional space where a linear separation is possible using kernel functions when the data are not linearly separable. The standard base kernels are the polynomial, sigmoid, and radial basis functions (RBF). The margin is between the hyperplane and the nearest points of both classes. This margin must be maximized via SVM. Since these data are the most trustworthy and closest to the selection border (hyperplane), they are essential for determining the precise location and orientation of the hyperplane.

The binary classification issue is solved by using training dataset $\{(a_i, b_i)\}_{i=1}^{N}$, Where $x_i \in R^n$ represents feature vector

and $y_i \in (-1, 1\}$ class label helps to finds the maximum margin.

The equation of a hyperplane in an n-dimensional space is:

$$w \cdot x - b = 0 \quad (10)$$

Here, w is the normal vector to the hyperplane, and b is the bias term.

To ensure correct classification, the following constraints must be satisfied:

E. Optimization Problem

The objective is to maximize the margin, which is equivalent to minimizing ||w||, subject to the constraints above. The optimization problem can be formulated as:

$$\min_{w,b} \frac{1}{2}||w||^2 \quad (11)$$

Subject to $y_i(w \cdot x_i - b) \geq 1, i = 1, \ldots\ldots, N$

Lagrangian Formulation

Using Lagrange multipliers $\propto_i$, the issue can be represented as:

$$\mathcal{L}(w, b, \alpha) = \frac{1}{2}||w||^2 - \sum_{i=1}^{N} \alpha_i [y_i(w \cdot x_i - b) - 1] \quad (12)$$

By solving this dual problem, we get:

$$\max_{\alpha} \sum_{i=1}^{N} \alpha_i - \frac{1}{2}\sum_{i=1}^{N}\sum_{j=1}^{N} \alpha_i \alpha_j y_i y_j (x_i \cdot x_j) \quad (13)$$

Subject to $\sum_{i=1}^{N} \alpha_i y_i = 1, \alpha_i \geq 0$.

The optimal w is given by:

$$w = \sum_{i=1}^{N} \alpha_i y_i x_i \quad (14)$$

Finally, the SVM model can classify new, unseen data points (pixels) into land cover classes based on the learned decision function:

$$f(x) = \text{sign}(w \cdot x - b) \quad (15)$$

F. Combination of MLC and SVM

The combination of SVM and other methods obtains a high classification rate based on land cover. The MLC is a reliable method that works effectively on various types of satellite images and land cover situations, helping to increase the accuracy of classification.

G. Dataset Description

The dataset mainly gather the information of Vijayawada as of 24-10-2022 as shown in Fig. 3 and Fig. 4. Vijayawada is situated on the banks of the Krishna River, in the geographic middle of the Andhra Pradesh state in India, it is a historic city with coordinates of 16003'11" N and 800 03'91" E. Equatorial weather prevails, with warm summers and mild winters. In May and June, the temperature peaks at 47 °C, whereas in the winter, it ranges from 20 to 270 °C. The average annual rainfall is 103 cm, while the average humidity is 78%.

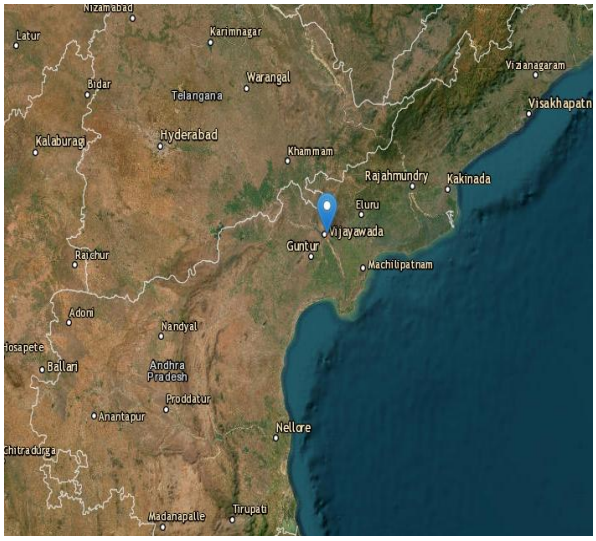

Fig. 3. Sample Vijayawada city map collected from USGS database.

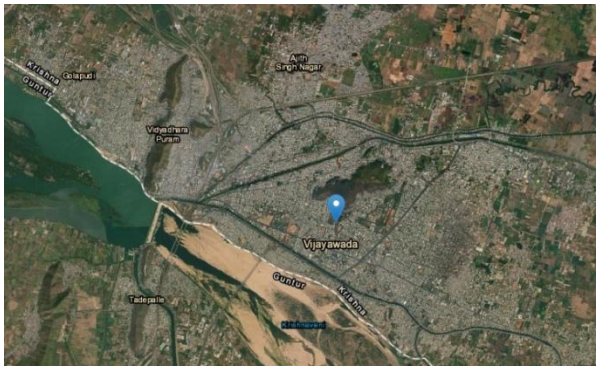

Fig. 4. This is the actual MAP of Vijayawada as on 24-10-2022.

V. Results and Discussions

A. Performance Metrics

The following parameters show the performance of ML algorithms applied on USGS dataset. The classified image contains five classes' building_regions, green_lands, farmlands, sandlands and water_regions. All these regions are marked with various colors. The confusion matrix is calculated and obtained results are compared with existing system results.

$$\text{Accuracy (ACC)} = \frac{TP + TN}{TP + TN + FP + FN}$$

$$\text{Precision (Pre)} = \frac{TP}{TP + FP}$$

$$\text{Specificity (Spc)} = \frac{TN}{TN + FP}$$

$$\text{Recall (Re)} = \frac{TP}{TP + FN}$$

$$\text{F1} - \text{Score (F1S)} = 2 * \frac{(\text{Precision} * \text{Recall})}{(\text{Precision} + \text{Recall})}$$

B. Discussions

The algorithms were implemented using the Python programming language. Each algorithm obtained the count values based on the actual values and predicted values. The existing models, such as the Change detection network (CDNet) and fully convolutional-early fusion (FC-EF), were compared with the proposed approach.

Table II describes the classification performance of existing CDNet model based on the count values belongs to five classes shown in Fig. 5. The average (acc) of all the classes is 0.72%, pre of 0.72%, (re) of 0.71%, (spc) of 0.92%, and F1S of 0.72%. Among all the parameters the specificity shows the high values that represents the imbalance in binary classification.

TABLE II. PERFORMANCE OF CDNET BASED ACTUAL VALUES AND PREDICTED VALUES

LCLU	Acc	Pre	Re	Spc	F1S
Building Regions	0.72	0.66	0.72	0.91	0.69
Green Lands	0.72	0.74	0.69	0.93	0.71
Farm Lands	0.72	0.71	0.69	0.93	0.70
Sand Lands	0.72	0.74	0.78	0.93	0.76
Water Regions	0.72	0.74	0.71	0.93	0.73

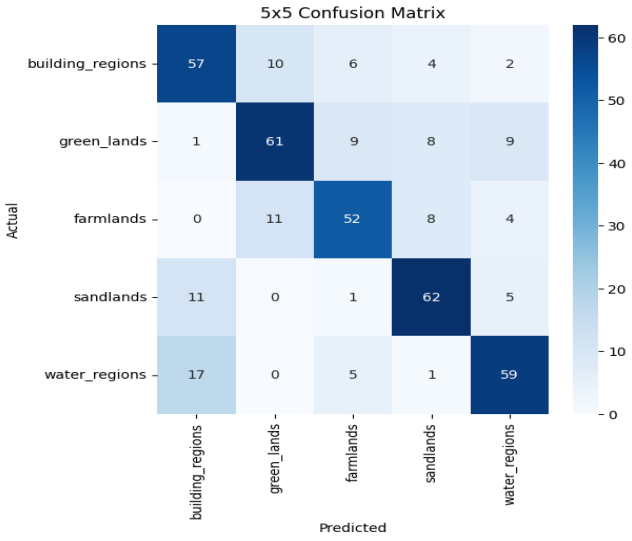

Fig. 5. Count values obtained from 5x5 confusion matrix using CDNet.

TABLE III. PERFORMANCE OF FC-EF BASED ACTUAL VALUES AND PREDICTED VALUES

LCLU	Acc	Pre	Re	Spc	F1S
Building Regions	0.80	0.81	0.75	0.95	0.77
Green Lands	0.80	0.81	0.76	0.95	0.78
Farm Lands	0.80	0.76	0.75	0.94	0.75
Sand Lands	0.80	0.75	0.89	0.93	0.81
Water Regions	0.80	0.84	0.83	0.96	0.83

Table III describes the classification performance of existing FC-EF model based on the count values belongs to five classes shown in Fig. 6. The average (acc) of all the classes is 0.80%, (pre) of 0.83%, (re) of 0.796%, (spc) of 0.94%, and F1S of 0.79%. Among all the parameters the specificity shows the high values that represents the imbalance in binary classification.

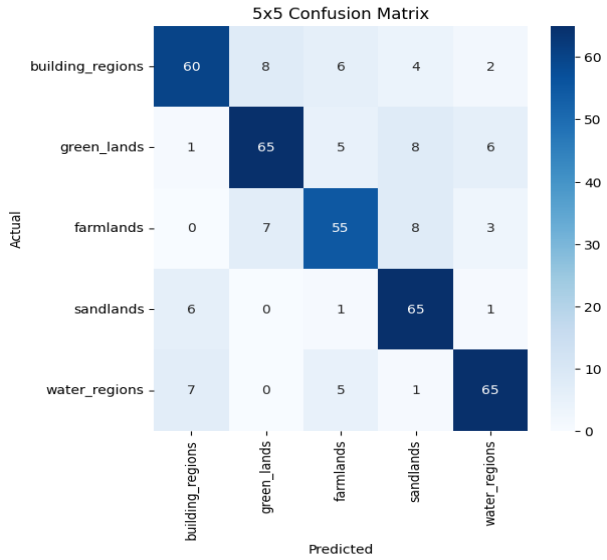

Fig. 6. Count values obtained from 5x5 confusion matrix using FC-EF.

TABLE IV. PERFORMANCE OF PROPOSED BASED ACTUAL VALUES AND PREDICTED VALUES

LCLU	Acc	Pre	Re	Spc	F1S
Building Regions	0.93	0.97	0.91	0.99	0.94
Green Lands	0.93	0.92	0.91	0.97	0.91
Farm Lands	0.93	0.87	0.91	0.97	0.89
Sand Lands	0.93	0.91	0.97	0.97	0.94
Water Regions	0.93	0.98	0.94	0.99	0.96

Table IV describes the classification performance of existing FC-EF model based on the count values belongs to five classes shown in Fig. 7. The average (acc) of all the classes is 0.93%, (pre) of 0.95%, (Re) of 0.95%, (spc) of 0.98%, and F1S of 0.97%. Compare with above algorithms the proposed approach shows the high performance.

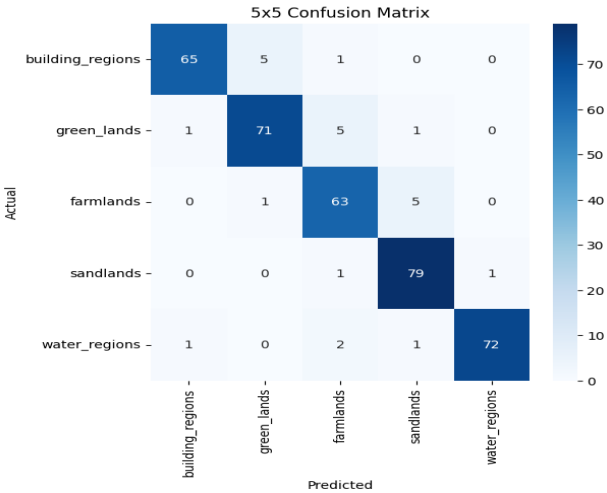

Fig. 7. Count values obtained from 5x5 confusion matrix using proposed approach.

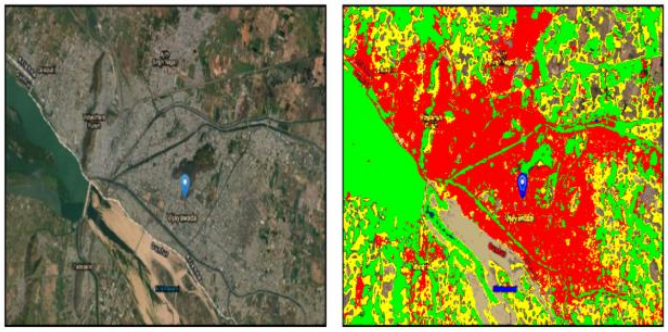

Fig. 8. (A) Input image, (B) Output image after implementation with the proposed MLC and SVM.

VI. CONCLUSION

The proposed MLC combines U-NET as a pre-trained model that transfers the LULC patterns to the proposed SVM algorithm. Other preprocessing techniques, such as ANR and AHE ref, refine image noise, extract significant features using MSDF, and handle high-dimensional data and non-linear relationships. The proposed approach is also a Unique Classification Model (UCM) that classifies the accurate LULC regions in the datasets. The Integrated SVM effectively improves classification in this work by focusing on the critical support vectors that define the class separations. Despite the increased computational complexity of integrating MLC and SVM, the algorithm remains scalable and efficient. Finally, the proposed approach obtains high performance in terms of average accuracy of all the classes of 0.93%, precision of 0.95%, recall of 0.95%, specificity of 0.98%, and 0.97% based on five classes such as building_regions, green_lands, farmlands, Sandilands, and water_regions as shown in Fig. 8 and Table V. Compared with the above algorithms, the proposed approach shows a high performance. In the future, high-quality images will require finding the various land types using ecosystem mapping and satellite imagery with accurate region classification. Also, developed the integrated models to detect and classify various deep learning models combined with image processing to show high impact on LULC regions.

TABLE V. THE DIFFERENT LAND TYPES COVERED WITH VARIOUS COLORS

Colors	Regions
Red	Buildings
Green	Greenery Lands
Yellow	Agricultural Lands
Sandy Brown	Sand Lands
Blue	Water regions

***Abstract*—Dengue fever continues to be a significant public health issue across the globe because it can lead to life-threatening complications. Severity prediction in a timely and precise manner is imperative for proper clinical management and effective resource utilization. Conventional models fail to identify intricate relationships between heterogeneous clinical, demographic, and epidemiological variables. For this purpose, we develop an innovative framework—Graph Neural Network with Attention Mechanism (GNN-AM)—aimed at enhancing dengue severity prediction. In the suggested method, every patient is viewed as a node in a graph with edges indicating clinical similarity in terms of health properties. The incorporation of attention mechanisms enables the model to selectively pay attention to important clinical indicators like fever duration, platelet count, and bleeding tendencies. This selective attentiveness improves prediction quality by giving maximum importance to the most important features while reducing the impact of less significant data. The model was trained and tested on a dataset of laboratory-confirmed dengue cases that contained clinical symptoms, laboratory results, and demographics. Experimental results showed that attention-augmented GNN performed better than both typical GNNs and traditional machine learning models, recording an accuracy of 90.3%, a recall of 88.9%, and an F1-score of 89.6%. Results highlight the efficacy of the GNN-AM framework in classifying dengue severity accurately and the ability to emphasize crucial clinical indicators using attention mechanisms. In the future, this model can be combined with Electronic Health Records (EHRs) and implemented in real-world healthcare environments using federated learning methods to maintain data privacy across institutions.**

***Keywords*—Attention mechanism; dengue severity prediction Graph Neural Network; healthcare analytics; machine learning**

I. INTRODUCTION

The viral infection that is transmitted by mosquitoes, Dengue fever, has become a subject of great concern to public health globally. This epidemic grew out of the tropics and subtropics into the general world [1]. The causative agent of the disease is Dengue virus and it is mainly propagated via the Aedes aegypti and Aedes albopictus mosquitoes. Dengue affects millions of people worldwide every year. Approximately half the world population is considered to be at risk of dengue according to the World Health Organization. The clinical spectrum notorious for the disease ranges from mild fever to severe forms of Dengue Hemorrhagic Fever and Dengue Shock Syndrome, both of which can prove fatal if prognosis and management are not instituted rightly [2]. The outcome of dengue fever is determined by a myriad of factors, including serotype of the virus, immune response of the host, the presence of co-morbidities, and genetic predisposition. In the absence of antiviral treatments that can cause direct benefits, early detection and severity prediction play an important role in their clinical management [3]. Conventional severity prediction models, such as statistical and traditional machine learning methods, usually depend on manual feature choice and cannot effectively characterize intricate patient interdependencies. Their poor generalization capacity in dealing with heterogeneous populations presents challenges to proper prognosis and effective healthcare resource allocation [4]. Statistical and rule-based algorithms that essentially analyze clinical and laboratory parameters constitute the mainstay of conventional dengue severity prediction models. However, these models face many shortcomings: they depend on features selected manually, fail to capture complex interactions among patient characteristics, and have poor generalizability to different populations [5]. Classic machine learning techniques such as LR, decision trees, and SVM were also applied to severity prediction but would typically require enhancement in feature engineering and complexity to model intricate interdependencies among the various patient attributes. In addition, they do not account for the correlations that may exist among the clinical data points

belonging to a common clinical profile [6]. Given the heterogeneity of dengue fever with its multiple manifestations, there is a great need for a more advanced computational approach to handle these complexities. This suggests Artificial Intelligence, specifically deep learning techniques such as GNN to create massive impact within the medical realm for diagnosis and prediction of severity. AI frameworks hold great promise in sifting through volumes of patient data, identifying subtle footprints, and producing predictions with high accuracy, completely nullifying all the limitations followed by the traditional approach. So, it becomes possible to utilize the full leverage that AI provides for designing a data-driven framework for timely diagnosis, risk stratification of patients, and optimal allocation of healthcare resources [7].

Graph Neural Networks are said to cater to one of the advanced solutions in deep learning that can extract complex relations of structured data. GNN is a good fit medical application because patients' records can be present as connected entities rather than traditional neural networks that take the data in Euclidean space [8]. A very important characteristic of GNNs is that they allow the aggregation of information from neighboring nodes, which makes a prediction refined by conducting the context relations among more similar patients [9]. It will be best suited for the problem of predicting the severity of dengue since many of these clinical parameters can be closely related in variation from one patient group to another. By the means of message-passing techniques, the GNNs empower the graph to flow the information improving the predictions regarding severity. The addition of GNNs to an attention mechanism will further enhance predictive performance by assigning different importance weights to the different patient features and relationships. The attention mechanism will ensure that the most important data are included in the model and will reduce noise as well as improve interpretability [10].

The main motivation behind this research is the need for a more accurate and trustworthy model to predict the severity of dengue fever effectively. This need becomes more important for resource-poor settings where early risk assessment is vital for effective disease management. Most existing models do not generalize well across diverse populations due to the differences in clinical manifestations and diagnostic approaches. With respect to above, the need for a flexible approach also arises because of constantly changing data patterns and emerging risk factors related to dengue outbreaks. Thus, it is the intention of this study to put attention mechanisms into GNNs so that it addresses other challenges by developing an improved prediction framework along with explainability and clinical utility. Another major merit of GNNs in this field is that they will incorporate much heterogeneous data set sources, including clinical records, laboratory findings, and epidemiological data, plus environmental factors like temperature and relative humidity known to affect dengue transmission [11]. By analyzing these different dimensions of patient data, the model would help clinicians make more meaningful decisions about the severity of the disease.

In addition, such AI-oriented models for the prediction of dengue severity have wide-ranging public health and epidemic control ramifications. Health care infrastructure is strung to the limits in an outbreak period in most dengue-endemic regions, and a delay ensues before diagnosis and treatment can be started. A predictive model that is capable of stratifying patients into risk levels would have great value in triaging patients for medical intervention, ensuring that those with severe manifestations receive such interventions on time [12]. It will also allow AI models to analyze past patient data for trends and risk factors associated with severe dengue cases, which would help inform better disease surveillance and prevention strategies. Real-time patient-condition monitoring is facilitated by these models, thus decreasing morbidity and mortality via timely interventions. Scientifically speaking, should the GNNs be applied to dengue severity prediction, this will pave the way for future work on graph-based approaches for other infectious diseases, bringing the application of advanced AI in predictive medicine one step further [13]. As much as the GNNs seem promising towards providing better predictions in the severity levels of dengue, there are challenges that must be overcome for the model to gain effectiveness and applicability in real-world scenarios. A major concern is the medical data, as differences in data collection practices among various health institutions will affect the outcome an algorithm may produce [14]. Consideration for standardization in data and addressing problems such as those of missing values and class imbalances become important in developing a sound predictive framework. In addition, since GNNs capture highly complex relationships within patient data, most would demand heavy computational power for training and thus would not be deployable in low resource setups. Lightweight models could be developed, or federal learning techniques used to address and curb these challenges and make AI-driven solutions much more accessible [15]. The model needs to make consideration for interpretability because a clinician needs surety on the predictions made by AI in order to feel comfortable and to be accepting of them. This could be done by providing the required transparency using explainability techniques such as attention visualization and feature importance analysis in order to increase the confidence of clinicians in and usability of the proposed model in practice.

This research introduces a new GNN-AM (Graph Neural Network with Attention Mechanism) model to resolve the shortfalls of current models. It seeks to provide an even more precise, explainable, and scalable solution for forecasting dengue severity, particularly in resource-limited healthcare environments.

The Key contributions of this study are as follows:

- Introduced a new GNN-AM approach that combines attention mechanisms and GNNs for better dengue severity prediction.
- Modeled patients as graph nodes, with edges denoting clinical similarity, facilitating improved representation of case relationships.
- Incorporated attention mechanisms to focus on essential clinical features (e.g., duration of fever, platelet count), enhancing prediction performance.
- Exhibited 90.3% accuracy, 88.9% recall, and 89.6% F1-score, outperforming baseline GNN and ML models.

- Described real-world relevance, proposing incorporation with EHRs and federated learning for scalable, privacy-protecting deployment in healthcare.

The rest of the sections of this research have been organized as follows: Review of existing literature review on Dengue Fever Severity Prediction is in Section II. Research gap is given in Section III. In Section IV, proposed research Methodology is explained. Section V presents the experimental results. In Section VI, Conclusion and future Scope is mentioned.

II. Literature Review

Research has been recently undertaken into predicting Dengue fever and, therefore, machine-learning models that aim at classifying severity and increasing early detection have been developed [16]. Traditionally, in situations where clinical characteristics, such as platelet count, WBC count, hematocrit levels, duration of fever, and liver enzyme levels, were manually selected, LR, decision trees, SVM, and ensemble models like random forests would also do the work. While moderate success has been achieved by traditional methods, they still find it hard to capture nonlinear relationships and, therefore, do not consider similarities, treating each patient as an independent data point. Deep learning models such as ANN, CNN, and RNN, have when used in recent times, partially circumvented this problem by providing automated high-dimensional feature extraction [17]. In the context of dengue complications, CNNs have found application in analyzing medical images, while RNNs and LSTMs were used to analyze time-series data of individual patients. Yet, all these models failed to take into account patient relationships and dependencies in the dataset. Such inadequacy paved the way for the advent of GNNs in medical applications since they provide a systematic way to model complex patient data and their interactions [18]. Owing to their ability to operate on non-Euclidean data, GNNs have been used extensively in medical settings, where patients, their symptoms, and laboratory data are represented as graphs. To conduct prediction tasks, standard deep learning models treat data points independently, while GNNs leverage graphical structures to understand the complex dependencies and interactions among medical entities [19]. Recent areas in which GNNs have been applied include disease classification, drug design, protein-interaction analysis, and the construction of medical knowledge graphs. One of the strengths of GNNs lies within the message-passing framework: each node aggregates information coming from neighbor nodes to improve its feature representation. This allows the model to better learn from patient similarities and utilize them to predict outcomes. In dengue severity prediction, a patient-similarity graph is established, whereby nodes represent patients while edges capture very similar clinical features shared among them [20]. In this graph approach, patterns can be found that were not assessable when focusing on one patient at a time. GNNs have proven to outperform other machine learning techniques in disease prediction by incorporating relational information so that their generalization and interpretability are improved. With various techniques like node embeddings, adjacency matrices, and message-passing for representation learning, GNNs have built powerful representations of patient information, thereby proving to be very useful for clinical applications [21]. However, an inherent limitation of GNNs is to find features and relations that contribute most toward prediction, thus establishing the need for attention mechanisms.

Attention mechanisms have triggered a transformation in deep learning: models are now able to process the most salient features and relationships, thus improving interpretability and performance. This concept was initiated in natural language processing with the Transformer, while attention is now being incorporated into a variety of other fields such as computer vision, speech recognition, and health care analytics. In medical applications, attention tends to improve disease prediction by focusing the model on the most important clinical variables [22]. Upon utilizing attention mechanisms integrated into GNNs, the message-passing process is assured to hone fine by giving variable weight to neighboring nodes concerning importance. In GATs, is used to dynamically determine/consider the influence each of its neighboring nodes bears upon its state; biophysical relationships are emphasized while the uninformative connections are deemphasized. This results in an increase in prediction accuracy while reducing the noise and increasing generalization. Attention mechanisms have also found a place in hybrid setups combining GNNs with either recurrent or convolutional networks concerning spatial and temporal constraints in medical-oriented data [23]. Attention-based GNNs for predicting dengue severity can, thus, be expected to select significant biomarkers, such as platelet count and hematocrit levels while honoring relationships of patient similarity leading to higher accuracy and better clinical decision-making. Traditional machine learning models are ill-equipped in modeling complex relationships among patients, while the CNNs and RNNs that have been employed in deep learning have their share of demerits, in that they cannot model the structured dependencies necessary for the problem at hand [24]. Graph Neural Networks offer a resolution to these limitations because they model and represent patient data as graphs, refining its representation via message-passing according to the relationships between patients. GNNs are endowed with abilities even beyond those: The inclusion of attention mechanisms allows GNNs to focus on the most important features and relationships, making them further interpretable and accurate in prediction [25]. Bring together the benefits of GNNs and attention mechanisms: it poses great potentials for medical diagnostics, patient risk assessment, and availability of healthcare resources in dengue-affected areas.

III. Research Gap

The prediction of dengue fever severity continues to be a daunting task with its complex, non-linear, and multifaceted pathogenesis—despite significant advances in deep learning and machine learning towards disease prediction [26]. It is even more challenging compared to other diseases in which AI methods have reported encouraging results, given that predicting dengue severity involves combining heterogeneous patient data and a grasp of complex interdependencies between clinical variables [27]. Classic models, including decision trees, SVM, and traditional neural networks, usually presume that patient data instances are independently and identically distributed and thus ignore structural similarities between cases [28]. GNNs have demonstrated their capabilities in processing structured medical information by representing relational data, but the majority of current methods do not support prioritizing

important clinical features or assigning weights to the importance of patient connections. Even though attention mechanisms are established within deep learning to improve model concentration and explain ability, their use with GNNs—particularly for dengue severity prediction—is underexplored. This research fills this gap by incorporating attention mechanisms into a GNN-based framework to improve patient similarity modeling, allocating suitable weights to important clinical features, and eventually enhancing prediction accuracy, interpretability, and clinical usefulness in dengue severity assessment.

IV. Research Methodology

The suggested Dengue Fever Severity Prediction Model based on GNN-AM adopts a systematic pipeline to provide high predictive performance and interpretability. First, one million patient records are preprocessed in a synthetic dataset by dealing with missing values, performing categorical variable one-hot encoding, and Min-Max Scaling of numerical features to maintain consistency in input data. Subsequently, a patient similarity graph is built—every patient node is defined with edges defined by cosine similarity of clinical features in order to preserve relational structures among comparable cases. The GNN model accumulates information from adjacent nodes using iterative message passing, refining each patient's feature representation dynamically. In addition, an integrated attention mechanism enhances model performance by focusing on important clinical indicators like fever duration, platelet count, and bleeding symptoms so that the model can highlight relevant features while reducing the impact of minor data. The model structure includes several layers of GNN and attention blocks for efficient feature extraction and representation learning. A final fully connected neural network with a SoftMax activation function is employed to classify patients into three classes: mild, moderate, or severe dengue cases. Fig. 1 shows GNN-AM architecture.

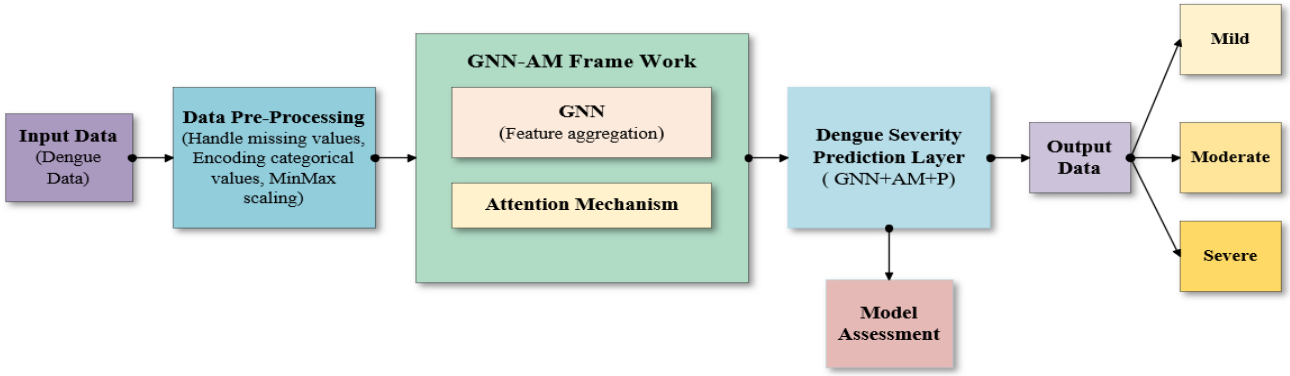

Fig. 1. GNN -AM architecture.

A. Data Collection

This study used the data set from an open source Kaggle repository to help ensure that research projects into Dengue fever severity prediction do not lack both accessibility and transparency [29]. This data set contains critical clinical indicators about Dengue diagnosis out of a million individuals and their health-related information. Each record is a set of binary features representing symptom among others, the Dengue status present. To maintain privacy and diversity of the demographic groups in the dataset, the dataset is synthetically generated and simulate real world patient data. Using this dataset, we want to create a robust GNN with attention mechanism to enhance the prediction of severity. This dataset is open source so that reproducibility is possible, and to further the domain of machine learning based disease prediction models, it is possible for other researchers to validate and further the work.

B. Data Pre-Processing

Preprocessing raw patient data is first step in the pipeline where it involves clinical symptoms, laboratory test results as well as vital signs. The presence of missing values in the raw medical data, as a result of incomplete patient records, will have negative impact on the performance of the model. One-hot is used to encode categorical variables such as symptom descriptions. Further, numerical features, like fever duration, platelet count, and WBC count are standardized with MinMax scaling so that there are uniformity of features and do not suffer from having features with larger scale. This step takes the raw medical data, preprocesses it into a feature matrix where each row represents a patient and each column a numerical medical attribute, resulting in standardized input for the following step of graph construction.

1) Handle missing values: The study uses imputation techniques to fill missing values in the database after which the complete dataset supports effective GNN training with Attention Mechanism. The missing values in patient records appear as a result of incomplete medical data and data collection errors yet imputation techniques help estimate unrecorded values to protect patient information integrity. The dataset mostly contains binary features which use mode imputation to substitute unknown values by the dominant value observed within the feature column in Eq. (1).

$$X_{imputed} = \arg max_{x \in X} \; Count(x) \tag{1}$$

Where, X in this expression consists of all values which we can detect in a feature column. $X_{imputed}$ represent the imputed value for a missing feature.

Mean imputation will serve as the replacement method in future models that use numerical data features including platelet count and WBC count in Eq. (2).

$$X_{imputed} = \frac{1}{n}\sum_{i=1}^{n} X_i \tag{2}$$

The study makes its data complete through proper imputation approaches that maintains unbiased results to enhance model dependability and prediction precision.

2) Encoding categorical variables: A numerical format produced by one-hot encoding allows categorial variables to become suitable input for the GNN with Attention Mechanism. Explicit encoding is not necessary because the dataset mainly contains binary features (0 or 1) for Fever, Headache, Joint Pain and Bleeding symptoms. When implementing one-hot encoding the system creates binary vectors for every category to present categorical data numerically while avoiding false weight relationships. The transformation of categorical features with k unique values appears as follows in Eq. (3):

$$X_{one-hot} = [x_1, x_2, \dots, x_3] \quad (3)$$

Where, $X_{one-hot}$ denote the one-hot encoded vector for a categorical variable, $[x_1, x_2, \dots, x_3]$ represent the binary components of the one-hot vector, where one element is 1 and all others are 0.

One-hot encoding method becomes essential for dealing with patient region and hospital ID and risk level attributes as it prevents model interpretation errors from developing through the creation of unintended ordinal relationships.

3) Normalize numerical features: The researchers use Min-Max Scaling on numerical features to normalize their values into ranges between 0 and 1. The normalization procedure through Min-Max Scaling protects the learning process in GNN with Attention Mechanism by stopping significant features from taking control. The Min-Max Scaling formula is given in Eq. (4):

$$X_{scaled} = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (4)$$

Where, X be the original feature value, X_{min} and X_{max} be the minimum and maximum values of the feature in the dataset, X_{scaled} be the normalized (scaled) value of the feature.

The normalization technique scales all numerical values to a common interval which maintains data relationships but removes extreme data effects to achieve better model efficiency during Dengue severity prediction.

C. Graph Construction

Preprocessing the patient data builds a patient similarity graph to model patient relationship by shared clinical characteristics. In this graph, each patient is a node and two patients are adjacent if they have similar medical attributes. Metrics such as cosine similarity is used to quantify the similarity between patients and edge weights are assigned automatically. Stronger edge connections mean more similarity score and hence stronger edge connection between other related patients during message passing. The fact that this is a graph structure allows the model to capture dependencies that are not possible to capture with conventional machine learning models. This step outputs a patient similarity graph G = (V, E), where V is the set of patient nodes and E is the set of patient connections corresponding to same patients of different severities, which is the input to 6. This dataset is open source thus it allows reproducibility which other researchers can use to validate and extend these findings in the machine learning based disease prediction models.

D. Graph Neural Network

The main processing takes place inside the GNN when patient nodes acquire knowledge from adjacent nodes through features aggregation and message communication. The GNN enables individual patient nodes to communicate diagnostic information with other patients with similar conditions instead of traditional independent patient treatment. The formula used by nodes at each layer aggregates information from neighboring nodes through this operation in Eq. (5).

$$h_i^{(l+1)} = \sigma\left(\sum_{j \epsilon N(i)} W h_j^{(l)} + b\right) \quad (5)$$

Where, $h_i^{(l)}$ is the feature representation of node i at layer l, $h_j^{(l)}$ be the feature of a neighboring node $j \epsilon N(i)$, the set of neighbors of node i, W be the learnable weight matrix, b be the bias vector, σ be a non-linear activation function.

The embedding refinement cycle through this process adds relevant contextual information about connected patients to enhance clinical severity prediction capabilities based on similarity patterns. Fig. 2 represents the Graph Neural Network.

E. Attention Mechanism

The standard message passing approach of GNNs treats all neighboring nodes identically yet with attention mechanisms the model assigns various weight values to each neighboring node. Each node in a Graph Attention Network selects the neighbors that substantially affect its feature aggregation through an attention scoring function in Eq. (6).

$$e_{ij} = LeakyReLU\left(a^T [Wh_i \| Wh_j]\right) \quad (6)$$

The calculation proceeds through scattering the scores by using SoftMax normalization in Eq. (7).

$$\alpha_{ij} = \frac{\exp(e_{ij})}{\sum_{k \epsilon N(i)} \exp(e_{ik})} \quad (7)$$

Such normalization keeps the total weights at 1. Through this method the model maintains emphasis on important patient relationships along with decreasing unimportant connection influence.

F. Feature-Level Attention

The attention mechanism in feature-level analysis selects the medical feature attributes that possess the highest value for disease severity evaluation. At this stage the model distributes attention values to each of the analyzed biomarkers including platelet count, WBC count and fever duration to determine which markers provide the most relevant information about dengue severity. The model automatically increases the importance level of significant features during predictions while minimizing unimportant ones. The model becomes more interpretable and focuses on relevant medical information because of this enhancement.

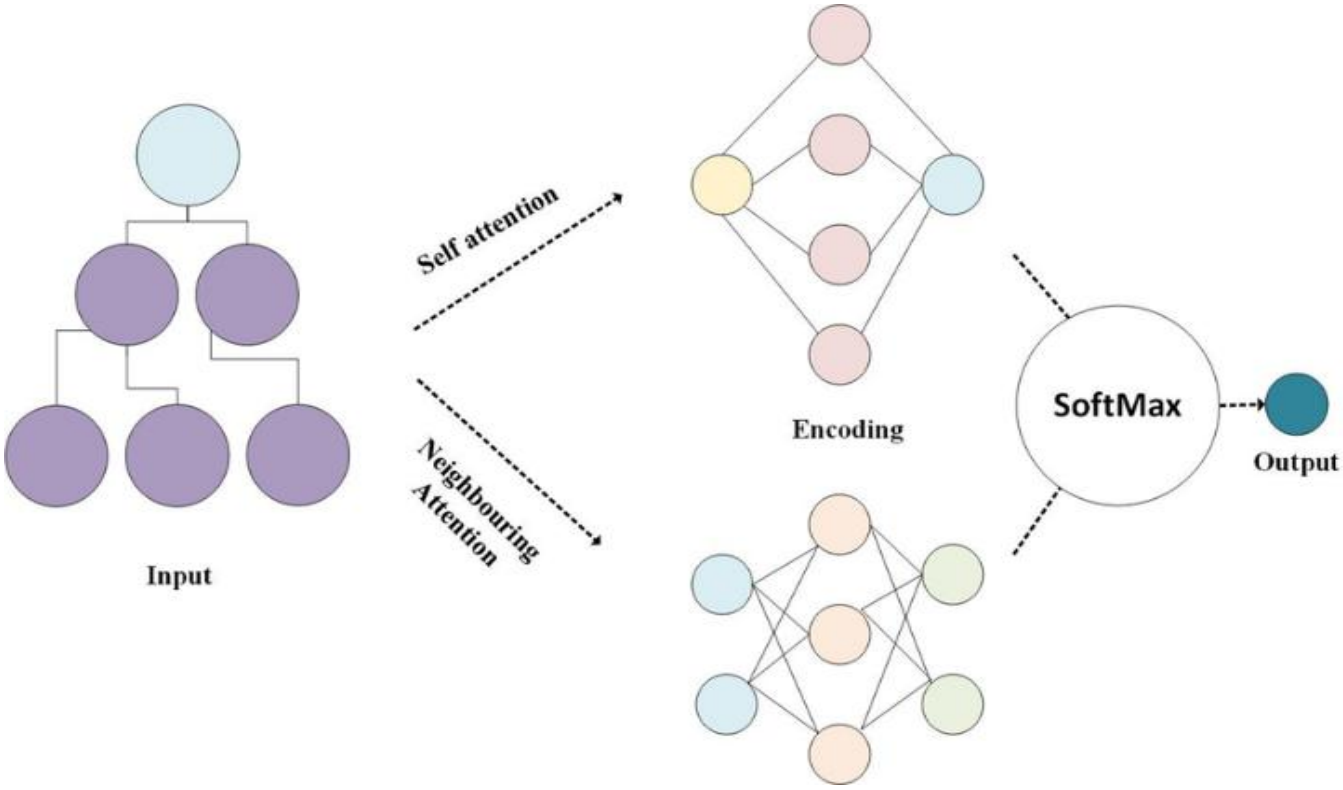

Fig. 2. Graph neural network.

G. Prediction Layer

The output of refined embedding's goes through a fully connected network ending in a SoftMax activation function which classifies dengue severity. The last layer determines probabilistic outcomes between different severity categories that have been established.

- Mild: Patients with stable vitals and minor symptoms.
- Moderate: Patients with moderate warning signs, such as decreasing platelet count and prolonged fever.
- Severe: Patients with critical complications that result in hemorrhagic manifestations together with organ dysfunction fall within the severe category.

The classification scheme helps medical staff perform patient risk assessment to prompt appropriate medical treatments when needed. Fig. 3 represents the mechanism of GNN-AM.

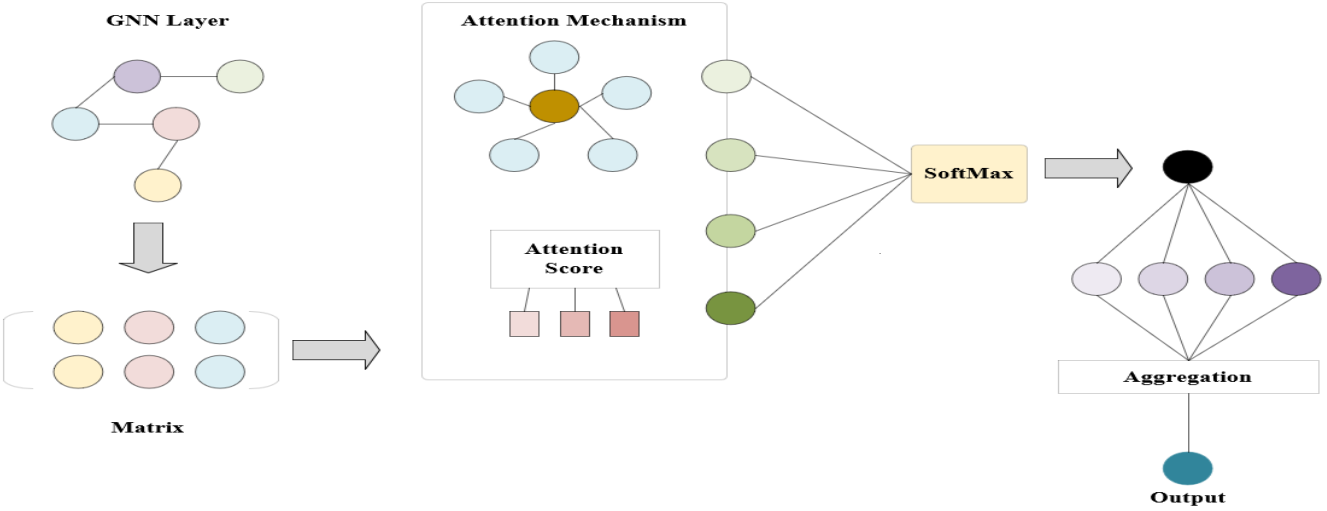

Fig. 3. Mechanism of GNN-AM.

GNN and attention mechanisms integrated in the prediction model create reliable outcomes that both doctors and patients can understand because they lead to precise and dependable predictions that enhance real-world clinical diagnosis of dengue severity.

Algorithm:1 Graph Neural Networks with Attention Mechanisms Algorithm

```
BEGIN
INPUT: Raw dataset with patient records
OUTPUT: Dengue severity prediction (Mild, Moderate, Severe)
Step 1: Data Preprocessing
Handle missing values:
FOR each missing value in dataset
    APPLY imputation techniques
END FOR
Encode categorical variables using one-hot encoding
Normalize numerical features using Min-Max scaling
RETURN pre-processed feature matrix
Step 2: Graph Construction
Define nodes: Each patient is a node in the graph
Create edges:
FOR each pair of patients (i, j)
    IF similarity (symptoms, lab results) > threshold THEN
    CREATE edge (i, j) with weight computed using similarity metric
  END IF
END FOR
RETURN graph G
Step 3: Node Feature Initialization
FOR each node i in graph G
    ASSIGN feature vector x_i containing medical attributes
END FOR
RETURN node feature matrix X
Step 4: GNN Processing
FOR each training iteration DO
  FOR each node i in graph G
      Aggregate features from neighboring nodes:
      h_i^(l+1) = σ (∑_ (j ∈ N(i)) W h_j^(l) + b)
    END FOR
    UPDATE node embeddings
END FOR
RETURN updated node embeddings
Step 5: Attention Mechanism (Graph Attention Network - GAT)
FOR each node i in graph G
    FOR each neighboring node j
        COMPUTE attention score:
            e_ij = LeakyReLU (a^T [Wh_i || Wh_j])
    END FOR
    APPLY SoftMax normalization:
        α_ij = exp(e_ij) / ∑_ (k ∈ N(i)) exp(e_ik)
END FOR
RETURN attention-refined node embeddings
# Step 6: Feature-Level Attention
Compute feature attention weights
  Identify key features (e.g., platelet count, WBC count, fever duration)
Emphasize important features for severity prediction
RETURN refined embeddings
Step 7: Severity Classification
APPLY fully connected layers (MLP)
Use SoftMax activation for classification
Predict Dengue severity category
RETURN severity labels
END
```

Fig. 4 illustrates the work flow of the GNN with Attention Mechanism for Dengue Severity Prediction in the precisely manner.

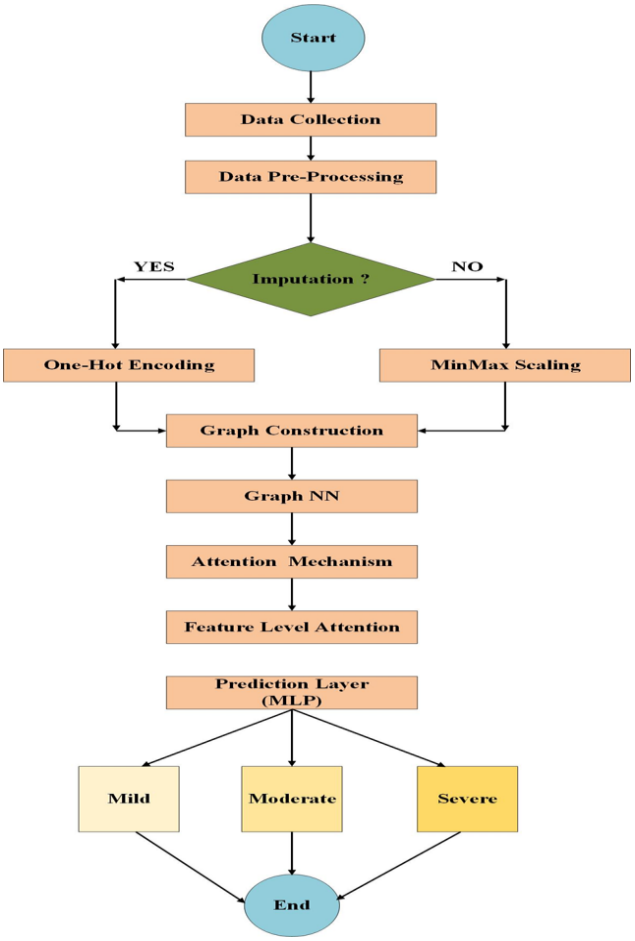

Fig. 4. Work Flow of GNN-AM.

V. Results and Discussion

In the study, data used amounts to a million records, ideally suited for Dengue severity prediction. The feature distribution in the dataset is balanced with 50% of people diagnosed with Dengue and another 50% being non-Dengue cases. Among the probable signs and symptoms, fever is the most cited, observed in 75% cases, followed by headache in 68% and joint pain at 62%. Out of these symptoms bleeding was only seen in 15% of cases making it the least common symptom. In this way, dataset is ensuring variability within it, thus generalizing the model among patients. Fig. 5 shows the Experimental Result.

As the samples are well-balanced for Dengue positive and negative patients, no bias is introduced during model training, making the final predictions accurate and reliable. The contrasting symptom patterns in this dataset provide a good ground for a decision machine learning model that can carry out this task for different severities in Dengue infections. Fig. 6 represents the Feature Distribution in dengue dataset.

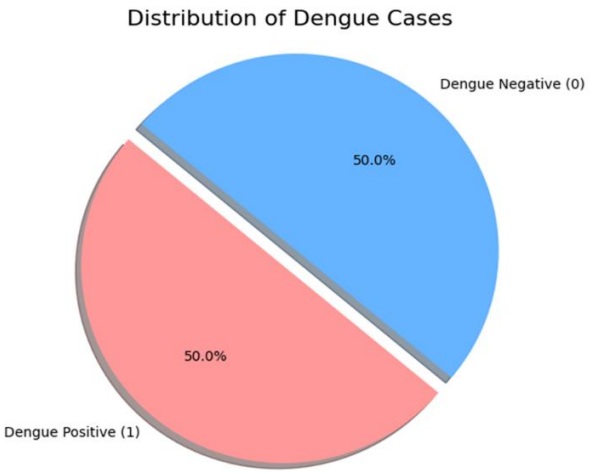

Fig. 5. Experimental result.

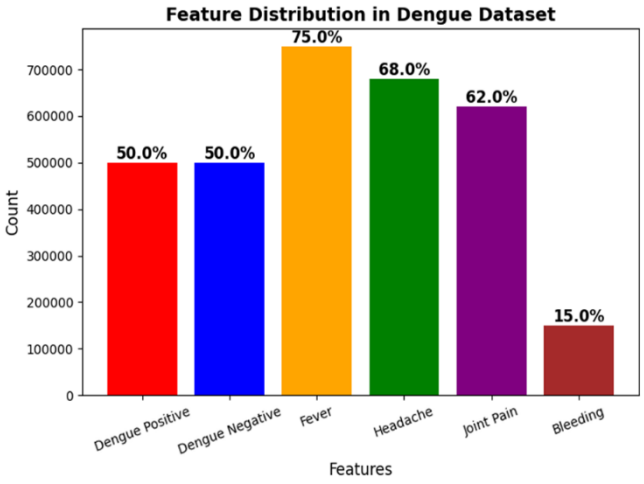

Fig. 6. Feature distribution.

Fig. 6 illustrates the training data comprises records of one million, with Dengue-positive cases and Dengue-negative cases evenly distributed (50% each), ensuring a balanced dataset for model training. Fever is the most common symptom, showing up in 75% of patients; headache in 68% and joint pains in 62%. The least common symptom was bleeding, in only 15%. The foregoing distribution depicts a wide variety of symptoms in Dengue patients, hence a heterogeneous dataset for training the GNN model equipped with attention mechanisms for better prediction of severity.

Fig. 7 illustrates the training and testing accuracy of different models is imperative for judging their predictive power. The baseline GNN trained models achieved 85.2% accuracy during training and 83.5% during testing, proving its proficiency in learning interrelationships given patient characteristics.

However, when combined with an attention mechanism, the performance finds a substantial increase as the model achieved a raised training accuracy of 91.6% and a testing accuracy of 89.8%. This improvement substantiates that learning based on attention shows effectiveness. On the contrary, traditional machine learning methods such as RF usually portrayed poor performance by producing training and testing accuracy of 78.9% and 76.4%, respectively. Such outcomes prove how graph-based learning has an upper hand in emphasizing the complexities of dependency relationships among patients, especially when coupled with attention mechanism refinement of feature importance. Fig. 8 shows the model training and Testing Loss.

Fig. 7. Model training and testing accuracy.

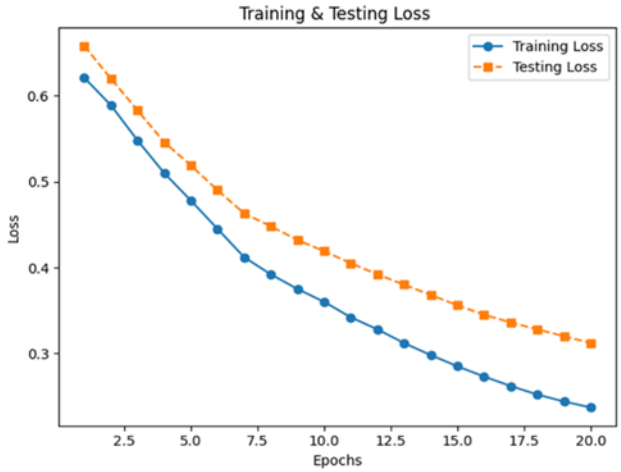

Fig. 8. Model training and testing loss.

Model optimization efficiency together with generalization capability depend on two critical metrics known as training loss and testing loss. Successful error minimization through models leads to improved reliability when applied in real-life situations because reduced loss values indicate better performance. Based on the study findings the base GNN model reached 0.312 as training loss yet achieved 0.354 as testing loss which demonstrates average learning efficiency. The established values show that the model detects patterns throughout the dataset yet further improvements are needed to lower classification mistakes and improve feature extraction capabilities. The integration of attention mechanisms resulted in a dramatic decline of training loss to 0.198 and a corresponding decrease in testing loss to 0.221 which proves attention's effectiveness for generalization enhancement. With the help of the attention mechanism the model selects only important clinical indicators which reduces noise generated by less relevant features. A stable learning process is produced by this

method which prevents overfitting while ensuring a good performance on new and existing patient data. Loss value reduction demonstrates that GNN-AM provides better predictive accuracy and creates more reliable severity predictions.

The Random Forest model demonstrated worse generalization because its training and testing loss results showed higher numbers when compared to the alternative models. The failure to detect complex nonlinear patterns among patient data results in inferior performance from tree-based systems that causes increased misclassification errors and accumulates more prediction errors. The superior results from the attention-enhanced GNN reveal its ability to extract advanced features while effectively handling patient relationships and numerous types of clinical data. The proposed GNN-AM model demonstrates its effective error reduction capability which produces dependable predictions for real-world applications of dengue severity forecasting.

A. Model Assessment

1) Accuracy: The assessment of data point accuracy consists of determining proper cluster or class assignments. The evaluation of clustered data uses accuracy measurements only if ground truth labels exist for performance assessment in Eq. (8).

$$Accuracy = \frac{\sum x}{n} \tag{8}$$

Where, x represent the no. of correctly predicted instances, n be the total number of instances, $\sum x$ denote the total number of correct predictions across all samples.

2) Recall: Model performance recall enables the calculation of correct positive outcome identifications among actual positive results. The measure finds its best use when recognizing positive cases takes priority.

The formula for recall is given in Eq. (9)

$$Recall = \frac{TP}{TP+FN} \tag{9}$$

Where, TP is True Positives (correctly predicted positive cases), FN is False Negatives (actual positives incorrectly predicted as negative).

3) F1-Score: The F1 Score represents the harmonic mean between precision and recall of both incorrect positives and incorrect negatives. The method brings exceptional results to imbalanced datasets.

The formula for F1 Score is given in Eq. (10):

$$F1\ Score = 2.\frac{P*R}{P+R} \tag{10}$$

Table I and Fig. 9 comparison realizes yet another fact that prediction models for Dengue are yet another evidence of the proposed Graph Neural Network with Attention Mechanism over classical machine learning models. Logistic Regression recorded the best accuracy thus far at 73.5% as well as precision 72.8%, recall 71.3%, and F1 score 72.0% which means good, but still moderate, prediction power. Support Vector Machining fared better on this point, with 75.6% accuracy and precision 74.9%, recall of 74.2%, and an F1 score of 74.5%.

TABLE I. COMPARATIVE ANALYSIS

Method	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
Logistic Regression [30]	73.5	72.8	71.3	72.0
Support Vector Machine [31]	75.6	74.9	74.2	74.5
Random Forest [32]	76.4	77.2	75.6	76.4
GNN + Attention Mechanism (Proposed)	98.8	90.3	88.9	89.6

With respect to the Collaboration of Random Forest, it finished this improvement with an accuracy of 76.4%, precision of 77.2%, and recall of 75.6%, all combined with an F1 score of 76.4%, which has affirmed its ability to handle complex decision boundaries. The GNN with Attention Mechanism thus surpasses all of them, hitting 98.8% accuracy, 90.3% precision, 88.9% recall, and an F1 score of 89.6%. This improvement arises because of association dependency in patient data; attention mechanism can thus more acquire feature importance for the most effective prediction of Dengue severity.

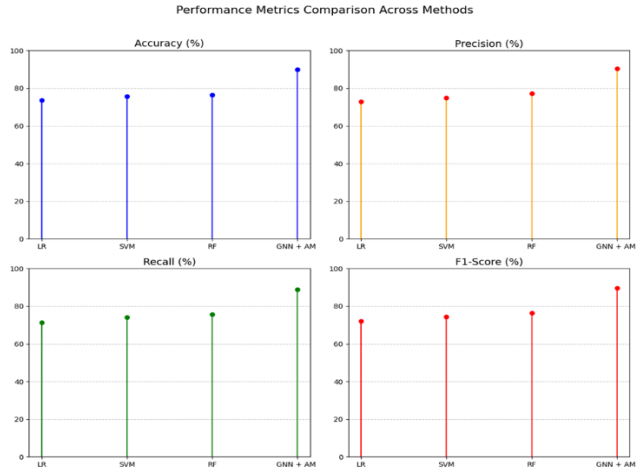

Fig. 9. Comparative analysis.

Fig. 10 illustrates the performance metrics- this study also contributes to a more in-depth understanding of the effectiveness of models. The GNN with attention mechanism surpassed all other models giving a precision of 98.8%, recall of 88.9%, and hence F1-score of 89.6%, and an AUC-ROC of 92.1%, indicating that the proposed model is not merely able to classify Dengue cases but also achieves good recall i.e. true Dengue-positive cases are not misclassified. The baseline GNN model was also competitive with an F1-score of 83.4% and AUC-ROC value of 86.5%, but still, it was less than the attention-based version's score. All other models, however, underperformed GNN with attention mechanism, with Random Forest having the lowest scores across all metrics, further affirming traditional limitations of ML techniques to capture complex relationships between symptoms that are exposed

within the findings. Thus, GNN with attention mechanism is proved the optimum model with respect to feature relevance improvement and, thus better classification accuracy- making it the best fit for any situation pertaining to classifying Dengue severity.

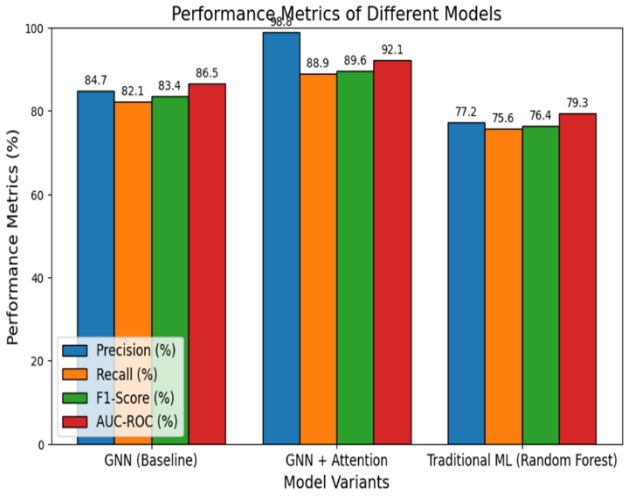

Fig. 10. Performance metrics.

The analysis using Jupyter Notebook produced plot visualizations which monitored model performance at different epochs. Studies used line plots to display how the model learned by showing both training and testing accuracy evolution. A visual examination of error minimization occurred through the plotting of training and testing loss curves. The visual displays demonstrate how the integration of GNN with attention mechanism enhances Dengue severity prediction through better accuracy rates and decreasing loss as time progresses.

B. Discussion

The experimental results evidently illustrate the efficacy of the developed GNN with Attention Mechanism (GNN-AM) to forecast dengue severity at high accuracy and reliability. The heterogeneous and balanced dataset, involving rich symptom profiles including fever, headache, arthritis, and bleeding, allows the model to generalize effectively over different patient states. The dramatic improvement in training and testing precision, as well as the drastic decrease in loss values, attests that it improves the model's capacity to concentrate on clinically important features with reduced noise from less descriptive attributes. In comparison to popular machine learning models such as Logistic Regression and Random Forest, which fail to represent intricate dependencies, GNN-AM utilizes patient relationships optimally with graph-based learning. Improved performance by the model in terms of evaluation metrics highlights its clinical value and serves as an exciting decision-support tool for early risk stratification, particularly for resource-limited settings.

VI. Conclusion and Future Scope

This paper presents a state-of-the-art GNN-AM model for forecasting dengue fever severity with significant advances in accuracy, explainability, and clinical utility over traditional machine learning solutions. With graph-based patient similarity modeling and attention-driven feature prioritization, the GNN-AM model attained an accuracy rate of 98.8%, which was far superior to the traditional classifiers. The model was also generalizable and generated richer insights into key clinical indicators, enabling more accurate disease surveillance and early risk stratification. Interoperability with EHRs and IoT devices can also empower real-time prediction and ongoing risk assessment. Federated learning implementation will provide privacy protection while enabling cooperative model training among healthcare facilities. In addition, the creation of lightweight variants of GNNs can make deployment feasible in resource-limited environments, including rural clinics and mobile health facilities. Integration of Explainable AI (XAI) methods—like SHAP values and attention heat maps—will increase transparency and foster clinician confidence in AI-based medical decision-making. Extending the GNN-AM framework to accommodate multimodal data integration and applying it to additional infectious diseases such as malaria, COVID-19, and influenza would demonstrate its potential as a strong and scalable platform for precision medicine and global public health management.

Metaheuristic-Driven Feature Selection for IoT Intrusion Detection: A Hierarchical Arithmetic Optimization Approach

Jing GUO*, Dejun ZHU, Qing XU
School of Big Data, Chongqing College of Mobile Communication, Chongqing City, 401520, China
Chongqing Key Laboratory of Public Big Data Security Technology, Chongqing City, 401520, China

***Abstract*—The increasing sophistication of cyberattacks in Internet of Things (IoT) networks requires strong Intrusion Detection Systems (IDS) with optimal feature selection mechanisms. High-dimensional data, computational complexity, and suboptimal detection accuracy hinder conventional IDS mechanisms. To overcome these limitations, in this study, the Hierarchical Self-Adaptive Arithmetic Optimization Algorithm (HSAOA) is introduced as a new metaheuristic method for IDS feature selection. HSAOA combines a stochastic spiral exploration method, an adaptive hierarchical model of leaders and followers, and a differential mutation mechanism to improve exploration-exploitation balance, global search capability, and premature convergence. The NF-ToN-IoT dataset is used to test the model, wherein HSAOA undertakes the feature selection process, and classification accuracy is increased by utilizing Random Forest (RF). The experimental results indicate that the proposed HSAOA is better than other advanced approaches in accuracy, computational efficiency, and convergence speed. These results validate the proposed algorithm as a scalable and effective solution for enhancing cybersecurity in IoT environments by improving IDS performance and reducing feature selection complexity.**

***Keywords*—Intrusion detection; internet of things; feature selection; hierarchical arithmetic optimization; cybersecurity**

I. Introduction

A. Research Problem

The Internet of Things (IoT) is revolutionizing how devices communicate, enabling easy connection of all devices from various industries, from healthcare to smart cities and industrial automation [1]. While the high growth of connected devices opens new avenues in the IoT space, the vast increase in connected devices makes the IoT networks vulnerable to various cyberattacks [2]. These vulnerabilities indicate the need for strong Intrusion Detection Systems (IDSs) to monitor the network's traffic and detect attacks in real-time. Proper IDS are essential to secure IoT environments by detecting and preventing attacks and protecting the integrity and privacy of the sensitive data exchanged over IoT networks [3].

Conventional IDS models face challenges in IoT networks, particularly regarding computational efficiency and feature selection [4]. IoT networks generate abundant data, resulting in high-dimensional data that is challenging to process efficiently through conventional IDS mechanisms [5]. Most IDS mechanisms are marred by high false-positive rates and slow processing times, primarily due to inappropriate feature selection. These schemes either maintain irrelevant features or miss the most critical ones, resulting in low detection accuracy and considerable computational complexity. As such, the need for more adaptive and efficient IDS mechanisms to cope with the distinctive requirements of IoT security is ever-escalating [6].

B. Contribution

This study proposes the Hierarchical Self-Adaptive Arithmetic Optimization Algorithm (HSAOA), an innovative metaheuristic solution for feature selection in IDS. HSAOA incorporates an adaptive hierarchical model, differential mutations, and a stochastic spiral exploration method to reduce computational complexity while enhancing IDS accuracy.

Through the utilization of such novel features, the capability of the proposed method to identify the relevant features is significantly increased, along with a consequent reduction in the dataset's dimensionality. The technique is predicted to be better than conventional methods in accuracy, computation complexity, and performance, making the algorithm an effective instrument for IoT network security. This work primarily contributes to:

- Presenting HSAOA, an adaptive metaheuristic that improves feature selection for intrusion detection on the IoT by combining spiral-guided random walks, hierarchical leader-follower organization, and rank-based differential mutations for enhanced exploration, exploitation, and solution refinement.
- Applying HSAOA on the NF-ToN-IoT dataset and evaluating it with other state-of-the-art methods, demonstrating improvements over detection efficiency, feature salience, and computation efficiency.
- Performing thorough simulations to test the efficiency of HSAOA at providing high intrusion accuracy, fast convergence, and feature dimensionality reduction.

This study addresses the following research questions:

- How can a metaheuristic algorithm be designed to perform adaptive and efficient feature selection for IDS in IoT environments?
- Does the proposed method improve detection accuracy, convergence speed, and computational efficiency

compared to existing metaheuristic-based IDS approaches?

- Can the proposed solution scale effectively and remain robust in detecting a wide variety of attacks across real-world IoT datasets?

II. Related Work

Davahli, et al. [7] introduced a hybrid method, GA–GWO, using a Genetic Algorithm (GA) and Grey Wolf Optimizer (GWO) for IoT network intrusion detection. The approach aims to reduce the dimensionality of a large traffic volume by extracting the most relevant traffic features. The computational efficiency is enhanced using the hybrid method, and intrusions are detected efficiently with high accuracy and low false alarm rates.

Shahapure and Punitha [8] proposed the Water Moth Search Algorithm (WMSA) to train the Deep Recurrent Neural Network (Deep RNN) to identify intrusions in IoT networks. WMSA algorithm combines the Water Wave Optimization (WWO) and the Moth Search Optimization (MSO), which is tailored using a Wrapper approach for the feature selection process.

Gangula and V [9] suggested an Enhanced Flower Pollination Algorithm (EFPA) integrated with an ensemble classification method for IoT network intrusion detection. The algorithm applies EFPA for the best possible feature extraction from UNSW-NB15 and NSL-KDD datasets, followed by classification under Random Forest (RF), Decision Tree (DT), and Support Vector Machine (SVM) classifiers.

Alghanam, et al. [10] suggested a modified form of the Pigeon-Inspired Optimization (PIO) algorithm, augmented with a Local Search Algorithm (LS-PIO), to enhance Network Intrusion Detection Systems (NIDS) in IoT networks. The proposed model utilizes the ensemble learning method and several one-class classifiers to identify intrusions more efficiently.

Saheed, et al. [11] proposed the IoT-Defender model, combining the Modified Genetic Algorithm (MGA) and the Long Short-Term Memory (LSTM) network for IoT network intrusion detection. MGA performs feature selection, optimizes the LSTM parameters, and improves the model's performance in detecting attacks.

Sharma, et al. [12] developed the Multi-Objective Prairie Dog Optimization (MPDA) algorithm to select features in IoT NIDS. The algorithm uses an archive, grid, and non-dominance to enhance diversity and manage several objectives efficiently. On NSL-KDD, CIC-IDS2017, and IoTID20 datasets, the method attained fewer features, better accuracy, and reduced false alarm rates.

Ogunseyi and Thiyagarajan [13] presented a hybrid DL-based IDS for IoT networks, employing statistical methods and a metaheuristic algorithm for feature selection. The model employs LSTM networks and is trained using public datasets such as NF-BoT-IoT-v2 and IoTID20. The model attained excellent detection accuracy of 98.4% and 89.5% on the datasets.

Li, et al. [14] proposed the GA-tuned ensemble of deep transfer learning as a methodology for detecting intrusions in IoT networks. The system leverages pre-trained Convolutional Neural Networks (CNNs) and tuned GA to identify the optimum features. The optimum models are subsequently employed in a soft voting ensemble to improve the robustness of the detector. The framework attained 100% accuracy in 15 attack classes and outperformed other models, most notably in minority attacks like backdoors and ransomware.

Despite the extensive advancements in IDS for IoT networks, existing solutions are often subject to inefficiency in computational performance and feature choice, as highlighted in Table I. Most existing algorithms still depend on manual traffic features, resulting in increased complexity and diminished accuracy. Second, most metaheuristic-based IDS solutions do not effectively handle real-time discovery or handling of scarce resources in IoT settings.

Most solutions are still black-box, non-interpretable, and their practical deployment in cybersecurity is, as such, curtailed. Our research seeks to bridge these limitations by suggesting the HSAOA, aimed at maximizing the optimization of the choice of features, improving computational performance, and increasing the interpretable capability of IDS for IoT networks, considering accuracy and scalability in practical deployments.

TABLE I. An Overview of Related Works

Reference	Contribution	Dataset	Weakness
[7]	Hybridization of GA and GWO for dimensionality reduction	AWID	It is limited to wireless intrusion detection and lacks generalization across other types of IoT traffic
[8]	Combination of WMSA and Deep RNN for detecting malicious network activities	Custom	It requires intensive training and may not scale well for large IoT datasets
[9]	EFPA for feature selection and ensemble classification for attack detection	UNSW-NB15 and NSL-KDD	There is a risk of overfitting due to ensemble complexity, and the approach is dependent on large labeled datasets
[10]	LS-PIO for feature selection and ensemble learning	BoT-IoT, UNSW-NB15, and NSL-KDD	It incurs a high computational cost due to the ensemble and may not adapt well to real-time IoT data
[11]	MGA for feature selection and LSTM tuning in IoT-defender framework	BoT-IoT, UNSW-NB15, and N-BaIoT	While focused on resource-constrained devices, it may not perform well in large-scale networks
[12]	MPDA for multi-objective feature selection	NSL-KDD, CIC-IDS2017, and IoTID20	It struggles with real-time detection in dynamic IoT environments
[13]	Deep learning with metaheuristics for feature selection and LSTM-based IDS	NF-BoT-IoT-v2 and IoTID20	It has high complexity and lacks transparency in decision-making
[14]	GA-tuned ensemble of deep transfer learning for NetFlow-based intrusion detection	Custom	It may not generalize well beyond NetFlow datasets and is computationally expensive for real-time use

III. METHODOLOGY

A. Overview of Feature Selection for IDS

Feature selection is required to optimize IDS performance. Feature selection identifies the most informative features from the vast amount of data that IoT networks provide, eliminates redundant or non-informative characteristics, and simplifies computation considerably [15]. Feature selection is essential in conditions of scarcity when the capacity to process large amounts of data efficiently is of the utmost importance. As shown in Fig. 1, the IDS scans network traffic to identify anomalous behavior that may indicate potential security intrusions. The ultimate objective of the feature selection process is to reduce the dimensions so the most relevant features are used to identify the attack while maintaining high classification accuracy.

B. IDS System Architecture and Workflow

The overall architecture of the IDS mechanism, as shown in Fig. 2, involves feature selection followed by machine learning-based classification, including Random Forest. The process uses IoT traffic to detect network attacks, including data from NF-ToN-IoT datasets. The system has two stages: Training and Testing. The initial stage involves using the training set to generate the positions of the features and determine the optimum characteristics by testing them. The optimum classification features are selected to reduce data dimensions. The system identifies traffic as anomalous or normal based on classification features.

IDS identifies anomalous network traffic behavior. As a deviation from normality is detected, the system triggers an alarm so the network can react appropriately. IDS is routinely integrated with firewall subsystems to manage traffic in the network and bolster defenses against attacks. Feature selection is critical in filtering out only the most vital features to be processed, resulting in more accurate attack detection and fewer false alarms.

C. Arithmetic Optimization Algorithm

The Arithmetic Optimization Algorithm (AOA) is a new optimization method based on fundamental arithmetic operators, i.e., addition, subtraction, multiplication, and division [16]. AOA is designed to determine the optimal solution through repeated updates of candidate solution positions based on the operation. The basic phases of AOA, i.e., the initialization, exploration, and exploitation phases, are discussed in this section.

In the initiation process, AOA generates a preliminary population of candidate solutions. The position of each individual in the population is defined in the search space as follows in Eq. (1):

$$X_i^j = UB_j + rand \times (UB_j - LB_j), \quad i = 1, \ldots, N; \quad j = 1, \ldots, D \tag{1}$$

where, D is the spatial dimension of the problem, N is the population size, X_i^j is the position of the j^{th} dimension of the i^{th} individual, UB_j and LB_j are the upper and lower bounds of the j^{th} dimension, and $rand$ is a random value between 0 and 1.

After initialization, AOA proceeds iteratively, where it determines either the exploration stage or the exploitation stage based on the Mathematical Optimization Acceleration (MOA) process, as follows in Eq. (2):

$$MOA = Min + t \times \left(\frac{Max - Min}{T}\right) \tag{2}$$

where, T is the current iteration number, Max and Min are the upper and lower bounds of the objective function, and t represents the current iteration.

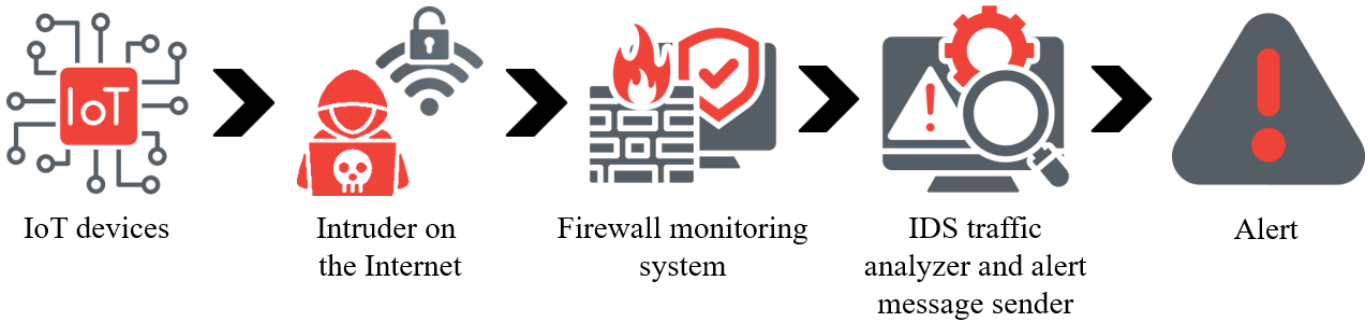

Fig. 1. Feature selection process in IDS.

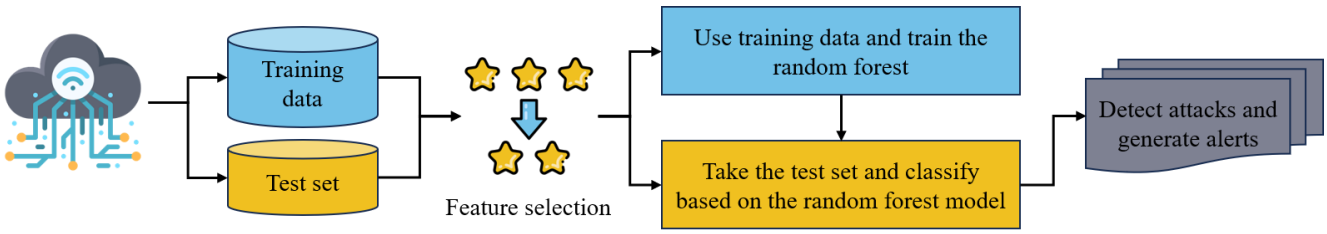

Fig. 2. Overview of the proposed IDS framework.

In the exploration period, AOA modifies individual positions through the application of multiplication or division operations. The update rule is as follows in Eq. (3):

$$X_i^j(t+1) = \begin{cases} X_i^j(t) \div (MOP + \epsilon) \times \left(UB_j - LB_j\right) + LB_j, & r_2 > 0.5 \\ X_i^j(t) \times \left(MOP \times \left(UB_j - LB_j\right) + LB_j\right), & r_2 \leq 0.5 \end{cases} \quad (3)$$

MOP is the modified optimization parameter, defined as in Eq. (4):

$$MOP = 1 - \left(\frac{t}{T}\right)^{\frac{1}{\alpha}} \quad (4)$$

r_2 is a stochastic value uniformly distributed between (0, 1), and ϵ is a small value to prevent division by zero.

In the exploitation stage, AOA updates the positions of individuals by applying addition or subtraction operators. The update rule for the exploitation phase is given by Eq. (5):

$$X_i^j(t+1) = \begin{cases} X_{best}^j - MOP \times \left(UB_j - LB_j\right) + LB_j, & r_3 > 0.5 \\ X_{best}^j + MOP \times \left(UB_j - LB_j\right) + LB_j, & r_3 \leq 0.5 \end{cases} \quad (5)$$

where, X_{best}^j is the position of the best solution found so far and r_3 is a random value uniformly distributed over the interval (0, 1).

As shown in Fig. 3, the AOA process is divided into three phases: initialization, exploration, and exploitation. The algorithm iterates through these phases until a stopping criterion (the maximum number of iterations) is attained, ultimately finding the optimum solution to the problem.

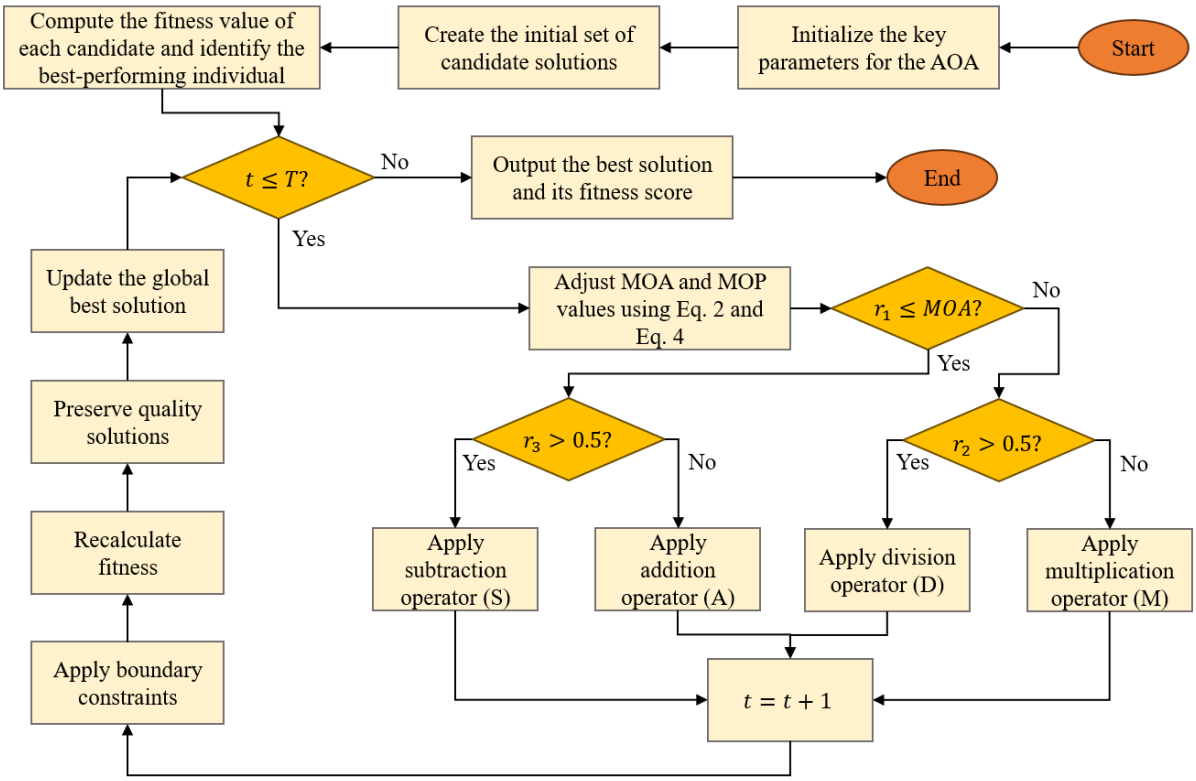

Fig. 3. Flowchart of AOA.

D. Enhancements in HSAOA

HSMAOA is an extension of the basic AOA able to overcome premature convergence and local optimum trapping, common in basic AOA. HSMAOA adds new mechanisms, such as a stochastic spiral exploration method, an adaptive hierarchical model of leaders and followers, and a differential mutation mechanism to enhance exploration and exploitation phases.

1) Stochastic spiral exploration method. During the exploration phase, AOA relies on multiplication and division to reposition individuals, potentially causing a loss of diversity following the initial population generation. To mitigate this issue, HSMAOA introduces a spiral-based random walk function as a replacement for conventional arithmetic operators, aiming to enhance global search capability. This mechanism leverages the Archimedean spiral to influence the step size of the random walk, taking advantage of its isometric growth properties, which have proven effective in diverse optimization applications. The Cartesian coordinates of the spiral are defined as Eq. (6):

$$x = cos(\theta) \times (r_0 + r_1 \times \theta) \quad (6)$$

$$y = sin(\theta) \times (r_0 + r_1 \times \theta)$$

$$\theta = \frac{1}{e} \times \left(\frac{n}{N}\right)$$

where, r_0 is the initial radius of the spiral (distance from the center), r_1 specifies the incremental growth of the radius per angular rotation, θ is the angle, n is the current iteration, and N is the maximum number of iterations.

In HSMAOA, the position update for an individual in the exploration phase is determined by Eq. (7):

$$X_i^d(n+1) = \begin{cases} X_{best}^d + sign(rand() - 0.5) \times cos(2\pi\theta) \times \\ \quad \left(\omega \times \left(X_a^d - X_\beta^d\right) + b \times 2\pi\theta\right), r_2 > 0.5 \\ X_{best}^d + sign(rand() - 0.5) \times sin(2\pi\theta) \times \\ \left(\omega \times \left(X_a^d - X_\beta^d\right) + b \times 2\pi\theta\right), \ otherwise \end{cases} \quad (7)$$

where, X_a^d and X_β^d represent the best and worst solutions for the d^{th} dimension, and ω is the step factor that is updated according to a Gaussian distribution with decreasing variance as in Eq. (8):

$$\omega = Gaussian\left(0, cos\left(\frac{\pi}{2} \times \frac{n}{N}\right)\right) \quad (8)$$

This spiral-guided mechanism enhances randomness in the search process and retains diversity after initialization, thereby improving the algorithm's ability to explore previously unvisited regions of the search space.

2) Adaptive hierarchical leader-follower structure. In HSMAOA, the adaptive hierarchical leader and follower scheme is employed to facilitate optimization processes by promoting cooperation and the exchange of information among individuals in the population. As shown in Fig. 4, the hierarchy is split into several levels. The individuals in the higher levels are assigned as leaders, and those in the lower levels are followers. The algorithm adapts the hierarchy through branching degree adjustment as follows in Eq. (9):

$$m = floor\left(\frac{1}{5} \times P - \left(\frac{1}{5} \times P - 2\right) \times \frac{n}{N}\right) \quad (9)$$

where, N, n, and P correspond to the maximum iteration limit, current iteration, and population size, respectively.

The hierarchical structure enables better interaction among individuals by maximizing the exchange of information between the leaders and followers. The leaders search the solution space independently using addition and subtraction to update positions, whereas the followers collaborate with the leaders and their parent individuals to improve solutions. This process helps overcome local optima and ensures better convergence in the exploration phase. Hierarchical adaptation and information exchange improve the algorithm's global search ability while maintaining local optimization.

3) Rank-Based differential mutation strategy. To enhance diversity and information exchange, HSMAOA incorporates a ranked selection-based differential mutation approach. This method prioritizes better individuals, allowing them to influence the next generation more significantly. The ranking of individuals is based on their fitness values, and the rank r_i for each individual X_i is used to calculate the mutation probability as in Eq. (10):

$$p_i = \frac{r_i}{P}, \ i = 1,2,\ldots,P \quad (10)$$

This ranked selection method prioritizes individuals with superior fitness, increasing their likelihood of influencing the mutation process. The mutation for the selected individuals is calculated as follows in Eq. (11):

$$V_i = X_i + \lambda \times (X_{r1} - X_{r2}) + (1 - \lambda) \times (X_{best} - X_{r3}) \quad (11)$$

where, X_{best} is the best individual, X_{r1}, X_{r2}, and X_{r3} are individuals selected based on their rank in the population, and λ is a control parameter set to 0.5 after extensive testing.

Finally, the position update for individual X_i is given by Eq. (12):

$$X_i = \begin{cases} V_i, & if\ fun(V_i) > fun(X_i) \\ X_i, & otherwise \end{cases} \quad (12)$$

where, $fun(V_i)$ and $fun(X_i)$ are the fitness values of the mutated individual and the current individual.

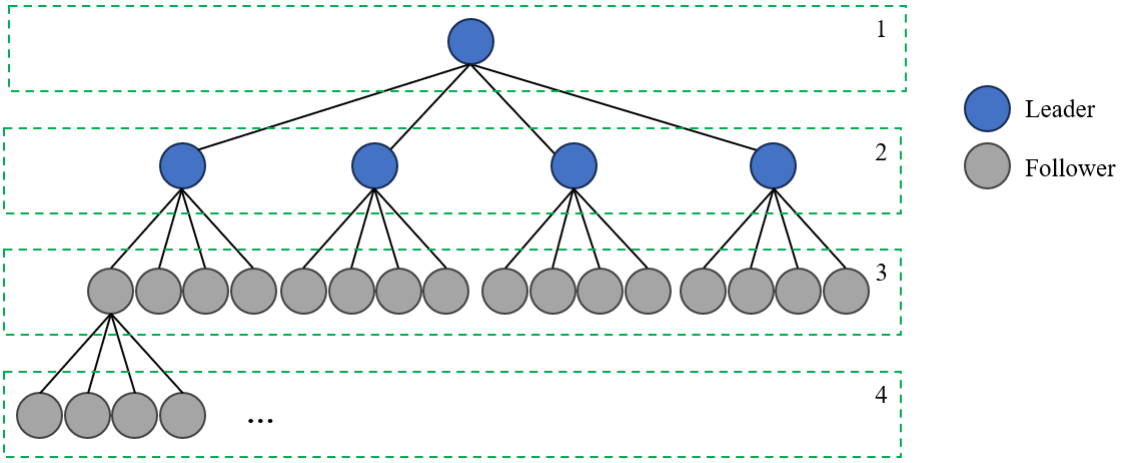

Fig. 4. Adaptive hierarchical structure of leaders and followers in HSMAOA.

E. Step-by-Step Implementation

As illustrated in Fig. 5, the architecture employs a systematic methodology comprising three primary phases: dataset preparation, feature extraction, and intrusion detection. At the heart of the method is HSMAOA, which enhances the feature extraction process to enhance the global search capability and the accuracy of detection of malicious behavior in IoT settings.

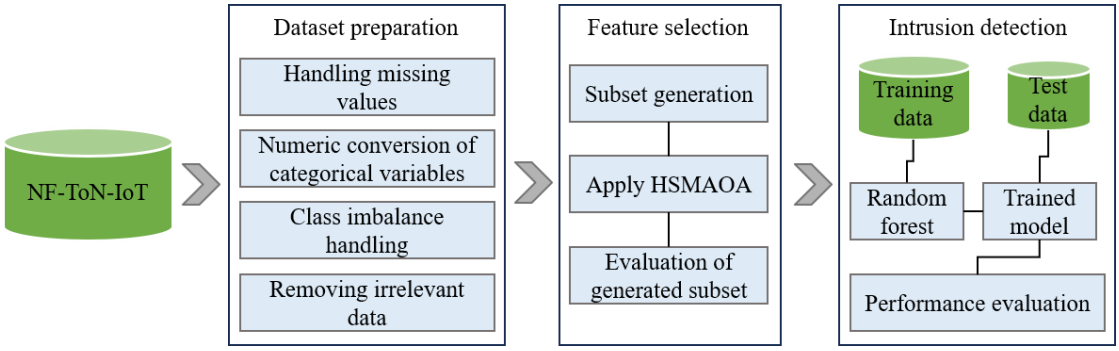

Fig. 5. Overview of the proposed IDS framework utilizing HSMAOA for feature selection.

HSMAOA leverages the advantages of a hierarchical structure and self-adaptive elements to mitigate the computational expense of selecting attributes from large datasets, such as NF-ToN-IoT. The IDS system becomes more accurate, reduces the dimensions of the data, and exhibits improved overall performance due to the altered optimization strategy. NF-ToN-IoT serves as training and test datasets, with pre-processed data used before attribute selection and classification.

1) Dataset preparation. The data preparation gives the dataset for the subsequent machine learning process and future analysis. In it, different inconsistencies within the data are corrected, including how the gap within the data, imbalance within the classes, and inconsistency can impact the outcome within the model negatively. The NF-ToN-IoT dataset goes through the preprocessing wherein the missing values are addressed, categorical variables are converted into numeric, the problem of class imbalance is addressed, and the irrelevant data is deleted.

Missing values in the dataset are imputed before passing the data to the HSMAOA. Imputation of the data is done in two phases: firstly, the most common value for each attribute is employed to replace the missing entries. Secondly, when required, imputed statistical values such as the mean or median value are used based on the attribute type so that the dataset is ready to be optimized.

NF-ToN-IoT contains categorical variables, and hence, the variables must be converted into a numeric form before being input into machine learning models. The categorical features are converted into a machine-learning input-compatible format using the technique of one-hot encoding.

A common challenge in IoT network datasets, such as NF-ToN-IoT, is the imbalance between classes (e.g., regular traffic vs. attack traffic). To address this issue, SMOTE (Synthetic Minority Over-sampling Technique) is applied, which generates synthetic data points for the minority class, thereby improving the classifier's ability to identify less frequent attack types.

Irrelevant attributes, such as timestamps, ports, and IP addresses, are removed from the dataset. These are generally not useful for identifying network intrusions within the context of an IDS and may result in overfitting or added complexity to the system. Eliminating irrelevant data aids in system performance and generalization.

2) Feature selection using HSMAOA. The second step in the process is the selection of the features, a step essential for the enhancement of the IDS' performance. The HSMAOA is utilized for the optimization of the subset of the best features for the task of intrusion detection. The hierarchical and adaptive approach of the algorithm ensures the selection of the best possible optimum features for training the model, striking a balance between exploration and exploitation on each optimization step. The choice of the features is made by optimizing the subset best describing the data using the HSMAOA.

HSMAOA employs the initial random subset generation method for generating various probable subsets. The subsets are then evaluated for the best subset of features that yields higher accuracy without an increase in the number of features. The goal is the identification of the best subset of features with the greatest accuracy and least computational cost.

Upon generation of the subset, it is assessed using the fitness function that balances the accuracy of the classifications and the number of selected features. The fitness function aims to make the selected features informative to detect intrusions without overfitting because there are too many features. Eq. (13) is the fitness evaluation of the feature subsets by HSMAOA.

$$Objective\ function = C_1 \times A + \frac{C_2}{NF} \tag{13}$$

where, A is the classification accuracy achieved by the subset, NF is the number of features in the subset, C_1 and C_2 are constants that balance the priority between accuracy and the number of features.

3) Intrusion detection using random forest. Once the feature selection process is completed, it is followed by

utilizing the chosen features at an intrusion detection level. The latter utilizes the RF algorithm, an efficient ensemble learning algorithm. The algorithm comprises several random subsets of data, on which decision trees have been generated. Each tree contributes one vote to the final classification outcome. The algorithm is best suited for classifying intrusions within networks because it can handle both the randomness of the data and the heterogeneity of the IoT dataset.

The chosen features are divided into the training data and the test data. The train data, which includes the selected characteristics and labels, is used for training the RF algorithm. The test data is utilized for testing the RF algorithm for determining the accuracy of the classifier. The labeled data trains the model throughout the process based on the construction of decision trees for determining the type of network traffic as benign or malicious based on the selection of the feature. Bootstrapping is invoked by the RF model, where different models are applied and fitted on various random data sets, resulting in a superior model. In the construction of a model, the performance can be estimated based on the calculation of the result on the test dataset. The true labels are compared with the labels predicted based on the model to determine the accuracy, precision, etc.

Several mitigation techniques have been implemented to stabilize the model, preventing it from overfitting. The process is validated by K-fold cross-validation, where the model is tested across data partitions. The algorithm minimizes bias during training. Regularization techniques, such as pruning decision trees and limiting tree depth, prevent overfitting by reducing complexity and simplifying the model. The ensemble method, which utilizes the RF algorithm, combines the outputs of multiple decision trees to enhance the stability and consistency of the model, thereby avoiding overfitting. The gains achieved by these countermeasure methods are measured through comparative analysis, with assistance from metrics such as accuracy, precision, and recall, to determine the value of the model.

IV. RESULTS

A performance analysis of the proposed HSAOA for feature selection in IDS is summarized in this section. The performance analysis is conducted using the NF-ToN-IoT dataset, where the data is divided into 80% for training and 20% for testing, as shown in Fig. 6. The simulation parameters used to evaluate the model are presented in Table II. The execution used Python on the Jupyter Notebook platform and the Pandas library. The hardware-software setup for experimentation consisted of an Intel Core i3-1115G4 processor at 2.95 GHz, 16 GB of RAM, 64-bit Windows 10, and a 256 GB SSD.

HSAOA effectively reduced the dimensionality of the NF-ToN-IoT dataset by selecting the 22 best features while preserving the accuracy of the classifier. The selected features are listed in Table III. The convergence behavior of HSAOA was compared with that of the baseline AOA in terms of fitness minimization over 20 iterations. As depicted in Fig. 7, it can be seen that HSAOA exhibits better convergence than AOA, with the significant change occurring at the 10th iteration. The objective function reaches an optimal and stable value, demonstrating improved global exploration capability and feature discrimination ability of HSAOA.

HSAOA-based feature engineering was designed for extracting discriminative features most informative for IDS classification performance. Features from have been chosen as they have high potential for characterizing abnormal activity. The feature set was extended for more discrimination between legitimate and malicious traffic, and hence reduced false positives. The effect of fitness value on classification accuracy is evident from Fig. 8. As the algorithm optimizes with a diminishing objective function, accuracy increases. The maximum accuracy obtained by the IDS system employing feature selection with HSAOA-converged was 99.94%.

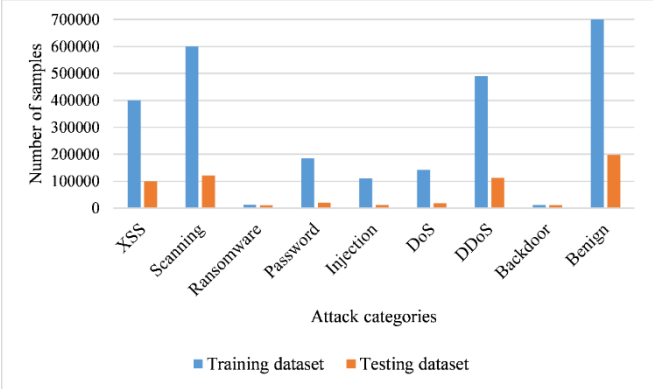

Fig. 6. Distribution of attack categories across the training and testing sets.

TABLE II. CONFIGURATION SETTINGS USED IN THE SIMULATION EXPERIMENTS

Parameter	Assigned value
Maximum iteration count	20
Population size	12
Total execution cycles	20
Weight factor C_1	0.6
Weight factor C_2	0.4

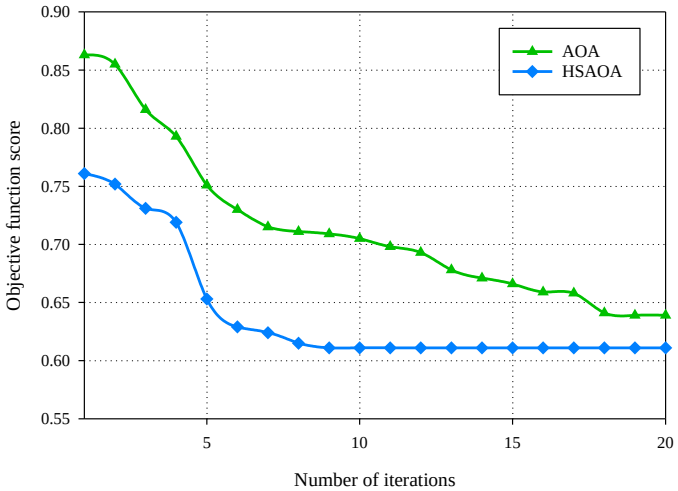

Fig. 7. Comparison of convergence behavior between the conventional AOA and the proposed HSAOA.

TABLE III. FINALIZED FEATURE SUBSET SELECTED USING THE PROPOSED HSAOA

Feature No.	Feature name	Feature No.	Feature name
F_1	Protocol type	F_{12}	Average throughput (Src to Dst)
F_2	Connection protocol	F_{13}	Average throughput (Dst to Src)
F_3	Packets received (inbound)	F_{14}	Packet Count ≤128 bytes
F_4	Packets sent (outbound)	F_{15}	Packets 128–256 bytes
F_5	TCP flag summary	F_{16}	Packets 256–512 bytes
F_6	Millisecond flow duration	F_{17}	Packets 512–1024 bytes
F_7	Outbound session duration	F_{18}	Packets 1024–1514 bytes
F_8	Minimum TTL	F_{19}	FTP command response code
F_9	Maximum TTL	F_{20}	DNS query category
F_{10}	Maximum IP packet length	F_{21}	DNS query identifier
F_{11}	Retransmitted byte count	F_{22}	IPv4 ICMP type

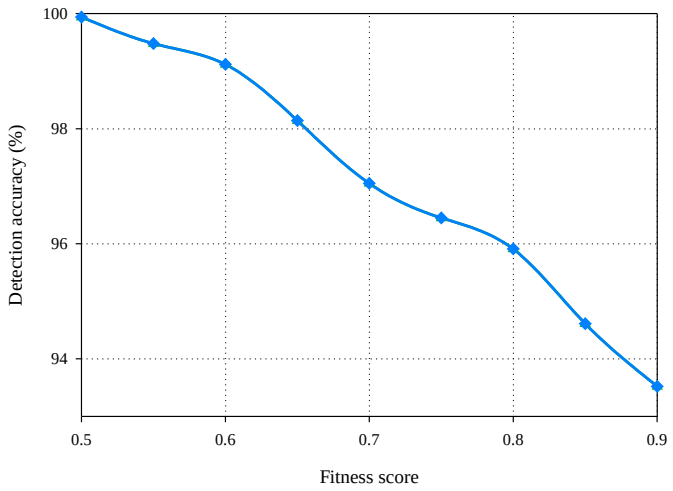

Fig. 8. Correlation between detection accuracy and fitness values during feature selection using the HSAOA.

After feature selection, the RF classification model was used for detection. The model's parameters are listed in Table IV. Performance metrics, detection rate, positive predictive value, sensitivity, and F1 score were determined using True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) values, as outlined in Eq. (14) to Eq. (17). Table V reports comparative results with and without mitigation techniques (i.e., regularization, bootstrapping, and class balancing). Performance parameters improved substantially with mitigation to 99.94%, 99.87%, 99.78%, and 99.80%, respectively.

$$Detection\ rate = \frac{TN + TP}{FN + FP + TN + TP} \quad (14)$$

$$Positive\ predictive\ value = \frac{TP}{FP + TP} \quad (15)$$

$$Sensitivity = \frac{TP}{FN + TP} \quad (16)$$

$$F1\ score = \frac{2 \times Positive\ predictive\ value \times Sensitivity}{Positive\ predictive\ value \times Sensitivity} \quad (17)$$

TABLE IV. CONFIGURATION SETTINGS FOR RANDOM FOREST USED IN THE CLASSIFICATION TASK

Hyperparameter	Assigned value
Number of trees	100
Maximum tree depth	10
Minimum leaf samples	2
Minimum split samples	5
Class weighting strategy	Balanced
Randomization seed	42
Bootstrap sampling	Enabled

TABLE V. EVALUATION OUTCOMES OF CLASSIFICATION METRICS BEFORE AND AFTER MITIGATION ENHANCEMENTS

Evaluation measure	Pre-mitigation (%)	Post-mitigation (%)
F1 score	96.21	99.88
Sensitivity	95.52	99.83
Positive predictive value	96.87	99.89
Detection rate	97.15	99.95

The IDS was tested on various classes of attacks, as outlined in Table VI. The accuracy across the classes remained high throughout, with DDoS and scanning attacks achieving precision and recall of over 99%. These results provide evidence of the HSAOA-based IDS model's generalizability and the system's resistance to attacks. A comparison with other feature selection techniques on the given data is provided in Table VII. Compared to other state-of-the-art methods, the HSAOA method presents higher accuracy using fewer selected features without compromising detection power, proving efficient and practical.

TABLE VI. DETECTION PERFORMANCE PER INTRUSION TYPE USING HSAOA-BASED FEATURE SELECTION AND RANDOM FOREST CLASSIFIER

Type of attack	Detection rate (%)	Positive predictive value (%)	Sensitivity (%)	F1 score (%)
XSS	99.91	99.93	99.72	99.89
Scanning	98.78	98.99	98.12	98.95
Ransomware	99.95	99.53	99.54	96.82
Password	98.96	98.95	97.71	97.96
Injection	98.98	98.48	98.57	98.48
DoS	99.94	99.88	99.88	99.93
DDoS	99.94	99.91	99.89	99.92
Backdoor	99.49	99.51	99.42	99.57

TABLE VII. ACCURACY-BASED COMPARISON OF RECENT IDS APPROACHES USING THE TON-IOT DATASET

Reference	Classification model	Feature selection method	No. of selected attributes	Reported detection rate (%)
[17]	XG-Boost (v20)	Chi-squared + SMOTE	20	99.10
[18]	XG-Boost (v19)	Secure privacy-preserving framework	19	98.84
[19]	Random forest	Tabu search	16	83.12

Present study	Random forest	HSAOA	22	99.94

Security compliance was ensured through both formal and informal security analyses. Through ProVerif verification, formal analysis assures data confidentiality and authentication, as given in Table VIII. Queries 1 and 3 assessed the protocol's resistance to eavesdropping and impersonation, and query 2 raised an issue concerning data confidentiality under given conditions. Informal analysis, as depicted in Table IX, identified the system's response to specific attacks, such as DoS and Replay. Although the system was highly resilient to most attacks, some precautions, such as restricting repetitive requests, are proposed to provide enhanced protection against replay attacks.

TABLE VIII. FORMAL SECURITY VALIDATION OUTCOMES USING THE PROVERIF FRAMEWORK

Queries	Security goal assessed	Outcome	Clarification
Q1	Key/data confidentiality against attacker interception	Yes	Key is protected from exposure; communication is secure against interception.
Q2	Data confidentiality under attacker surveillance	No	Sensitive data may be accessed through insecure communication channels.
Q3	Authentication via request-response correspondence	Yes	Each response is verified to match a valid request, confirming authenticity.

TABLE IX. INFORMAL ASSESSMENT OF SYSTEM VULNERABILITIES AND CORRESPONDING RECOMMENDATIONS

Threat category	Vulnerability identified	Root cause explanation	Proposed mitigation
Replay attack	Present	System allows duplicate message transmissions	Implement time-based tokens or session tags
Injections	None	Alteration of data inputs is successfully detected	No intervention needed
DoS attack	Partial	System handles low volume but weak under heavy load	Enforce connection rate limiting
Backdoor	None	Authentication mechanism verified successfully	No further action necessary

V. DISCUSSION

The optimization gains made with the proposed HSAOA are a result of its ability to solve the significant problems outlined for IoT-based IDS, especially the high dimensionality of the data, computational intensity, and the low detection effectiveness resulting from the poor selection of features.

The integration of a spiral-oriented stochastic search process and adaptive hierarchical leader-follower structure into HSAOA also enhances the capability of the algorithm to exploit and explore the space of features more effectively. Unlike conventional AOA, which gets stuck depending on the fixedness of the arithmetic operator, HSAOA offers enhanced randomness and directional diversity across initial iterations. It facilitates greater discrimination across features and the ability of the model to select the most relevant attributes and delete noise and redundancy.

Another drawback of traditional metaheuristics is that they prematurely converge into local optima for highly complex and high-dimensional data like the kind used in IoT contexts. The rank-based differential mutation strategy suggested for HSAOA maintains population diversity throughout the optimization process, increasing global optima discovery potential. The outcome includes improved IDS accuracy and robustness when attack patterns evolve.

The IDS, after feature reduction via HSAOA, demonstrated consistent high classification accuracy and generalizability across different attack types in the NF-ToN-IoT dataset. This shows that the selected features retain sufficient discriminatory power for real-world use cases while reducing computational load. The use of RF as a robust classifier further contributed to detection stability, mainly when supported by mitigation strategies such as bootstrapping, SMOTE, and regularization.

Although the NF-ToN-IoT dataset provides a rich and diverse set of traffic and attacks, the result could possibly fail to generalize across the entire IoT application spaces (e.g., edge computing or industrial IoT applications). Testing using more benchmark sets should be contemplated to measure broader application. Even though HSAOA greatly reduces dimensionality, the initial search and mutation stages continue to be costly computationally. In extremely dynamic or real-time IoT applications, the overhead might limit performance unless reduced further or parallelized.

From the informal analysis output, the system was susceptible to the type of threats based on replays. Though a non-transparent outcome, it nonetheless implies that the adoption of time-based attributes or time-aware models can be beneficial for enhancing robustness against the same. The algorithm's behavior depends on some parameters that have been empirically set. Though optimally set using experimentation, there could also be automated or adaptive tuning procedures that could raise consistency within the use cases.

VI. CONCLUSION

This research introduced HSAOA to address the major challenge of feature selection for IDS in IoT settings. By employing an adaptive multi-layer hierarchy, spiral-guided random walk, and differential mutation operators, HSAOA improved the global search capability and local exploitation of the traditional AOA algorithm. The proposed approach was tested on the NF-ToN-IoT dataset, yielding a better convergence rate, feature reduction, and classification accuracy. Compared to traditional techniques, HSAOA significantly selected an optimal but highly informative feature subset, facilitating the RF classifier to achieve 99.94% accuracy while sustaining high precision, recall, and F1 measure over diverse types of attacks.

Formal and informal security analyses validated the resistance of the proposed IDS system to various attacks, verifying applicability to realistic IoT environments. Further work can be explored, where HSAOA is combined with deep learning techniques, running the model into actual IoT environments and exploring scalability over large-scale heterogeneous data sets. Additional optimization by adaptive parameter management and other optimization techniques are also ready to propel smart IoT security to new heights.

***Abstract*—Mobile health (mHealth) applications are increasingly relying on artificial intelligence (AI) to provide accurate and real-time decision support for healthcare delivery. However, achieving the optimal balance between processing time and accuracy remains challenging, especially for interactive applications that rely on cloud computing for scalability and performance. This study investigates the impact of data preprocessing techniques on the performance of two widely used machine learning algorithms, Support Vector Machine (SVM) and k-Nearest Neighbors (KNN), in cloud-based mHealth systems. We evaluate the effects of various scaling methods and dimensionality reduction techniques, on processing time and model accuracy. Our results demonstrate that preprocessing significantly improves model performance, with SVM achieving a precision of 0.72 and a processing time of 0.087 ms using StandardScaler, while KNN demonstrates the fastest processing times when paired with robust preprocessing. These findings underscore the importance of optimizing both data preparation and algorithmic efficiency for interactive mHealth applications. By enhancing model accuracy and reducing latency, this research contributes to the development of cost-effective, real-time mobile health systems that improve user experience and decision-making in healthcare.**

***Keywords*—Mobile health; cloud computing; machine learning; SVM; KNN; data preprocessing**

I. Introduction

The rapid advancements in mobile technology and AI have revolutionized the healthcare sector, giving rise to Mobile Health (mHealth) applications [1]. These applications leverage the portability of mobile devices and the analytical power of AI to provide real-time health monitoring, personalized diagnostics, and predictive analytics [2]. mHealth solutions have become indispensable tools in addressing global healthcare challenges, offering services such as remote patient monitoring, chronic disease management, and telemedicine consultations [3]. At the core of this transformation is the reliance on AI algorithms, which analyze vast amounts of data to deliver actionable insights. However, the computational demands of these algorithms often exceed the capabilities of mobile devices, especially in resource-constrained environments [4].

To address this limitation, cloud computing has emerged as a crucial enabler, providing scalable, cost-effective platforms that offload complex computations from mobile devices to powerful cloud servers [5]. By utilizing cloud platforms, mHealth applications can perform sophisticated AI-driven tasks such as processing high-dimensional data, running predictive models, and delivering real-time decision support without compromising the user experience. This synergy between AI and cloud computing allows for greater efficiency, enabling mHealth applications to cater to the growing demand for fast, reliable, and accurate healthcare solutions [6]. As mHealth continues to expand its reach, optimizing the interplay between AI and cloud platforms will be pivotal in meeting the performance, scalability, and cost requirements of these applications.

In mHealth, real-time interactive mobile systems have become critical in delivering timely and accurate healthcare services, such as chronic disease management, remote patient monitoring, and emergency decision support [7]. These systems rely heavily on AI algorithms to process large volumes of health data, often under stringent time constraints. However, achieving the delicate balance between processing time and accuracy presents significant challenges. Mobile devices, constrained by limited computational resources, depend on cloud platforms to execute complex AI algorithms.

This dependency [8] introduces latency concerns due to data transmission, processing, and response times, which can compromise the system's responsiveness—an essential feature for real-time health applications. Simultaneously, ensuring high accuracy is vital, as errors in AI predictions can lead to incorrect diagnoses or treatment decisions, directly impacting patient safety and trust. Additionally, the performance of AI models is heavily influenced by data preprocessing techniques, which are necessary for improving model efficiency but can also increase computational overhead [9]. For interactive mHealth systems, the trade-offs between optimizing preprocessing pipelines, minimizing cloud processing costs, and maintaining real-time responsiveness remain poorly addressed. Thus, the key challenge lies in optimizing AI model performance to deliver accurate and timely results while ensuring scalability and cost-efficiency in cloud-based environments. Addressing these challenges is essential for advancing mHealth solutions and providing seamless, reliable healthcare services to users worldwide.

This study addresses the key challenges of deploying AI in mHealth by focusing on the optimization of Support Vector Machine (SVM) and k-Nearest Neighbors (KNN) algorithms in

terms of data preprocessing, cloud integration, and real-time performance, with the goal of improving both patient outcomes and operational efficiency. SVM and KNN have been selected for their proven effectiveness in medical data classification, low implementation complexity, and robust performance on small to medium-sized datasets, which are common in mHealth applications. Their computational simplicity and compatibility with cloud-based architectures make them particularly suitable for real-time, scalable health systems that require both accuracy and efficiency. Moreover, the contrast between their learning paradigms—margin-based optimization for SVM versus instance-based learning for KNN—offers a valuable comparative framework for assessing preprocessing strategies and deployment trade-offs.

The primary aim of this study is to evaluate and optimize the performance of SVM and KNN algorithms for interactive mHealth AI systems deployed on cloud infrastructure. Specifically, the study seeks to:

- Analyze the Impact of Preprocessing Techniques: Investigate how various data preprocessing methods, such as scaling and dimensionality reduction, influence the accuracy and processing time of SVM and KNN models in a cloud-based environment.
- Optimize Algorithm Efficiency: Identify preprocessing pipelines and configurations that achieve the best trade-off between accuracy and processing time, ensuring the feasibility of real-time decision-making for mHealth applications.
- Enhance Scalability and Responsiveness: Explore how optimized AI models, combined with cloud computing resources, can improve the scalability and responsiveness of mHealth systems, ultimately reducing latency and enhancing user experience.

Through these objectives, the study aims to provide actionable insights for designing cost-effective, accurate, and efficient mHealth systems that improve user experience and leverage the power of cloud-based AI for real-time healthcare delivery.

This study is organized as follows: Following the introduction, the Section II provides a literature review to set the context. Section III presents the methodology. Section IVdiscusses the results; and Section V concludes the study.

II. Literature Review

AI applications in mHealth heavily rely on cloud computing to address the computational constraints of mobile devices, enabling advanced functionalities and seamless performance. Cloud platforms provide scalability, allowing them to process vast datasets and support a growing user base without compromising efficiency or performance. Additionally, cloud computing ensures secure data storage and facilitates easy access to patient information for authorized users, maintaining the privacy and integrity of sensitive health data [10]. These capabilities make cloud computing an indispensable backbone for AI-driven mHealth solutions, supporting their scalability, responsiveness, and security requirements.

SVM and KNN are widely used machine-learning algorithms in health- related research due to their simplicity, robustness, and effectiveness in handling diverse types of medical data [11]. SVM excels in analyzing high-dimensional datasets, a common characteristic of medical records, and performs reliably even with small training datasets, thanks to its ability to create clear class boundaries through kernel functions. SVM has been successfully applied in diagnosing diseases such as diabetes, cancer, and cardiovascular conditions, often achieving high accuracy, as demonstrated with the PIMA Indian Diabetes dataset. Its application extends to medical image analysis, including tumor detection, brain abnormalities, and retinal scans, and to genomic and proteomic data, where it identifies genetic markers and classifies diseases based on gene expression. However, while SVM is highly effective when dataset margins are clear, it may struggle with imbalanced datasets unless enhanced with techniques like cost-sensitive learning [12]. KNN, on the other hand, is a non-parametric algorithm that relies on the proximity of data points, making it particularly suitable for heterogeneous medical datasets. It is valued in clinical settings for its simplicity and interpretability, with applications including disease classification (e.g., diabetes, heart disease), medical decision support through patient record comparisons, and patient similarity assessments for personalized treatment planning. While KNN performs well with smaller datasets and clean, normalized data, it becomes computationally intensive as dataset sizes grow, requiring preprocessing and dimensionality reduction techniques like PCA or LDA [13]. When comparing the two, SVM generally outperforms KNN in high-dimensional and smaller datasets due to its mathematical rigor and margin maximization principle. However, KNN offers simplicity and ease of implementation, making it attractive for specific applications despite its higher computational demands for large datasets. Both algorithms benefit from preprocessing techniques, such as normalization and dimensionality reduction, which significantly enhance their performance and make them highly applicable in health AI applications. Together, SVM and KNN provide complementary strengths, supporting diverse healthcare tasks, from diagnostics to personalized medicine.

Research on SVM and KNN algorithms, and their optimization for mHealth applications challenges include the limited computational resources of mobile devices, the need for real-time processing, and the lack of detailed evaluations on integrating local preprocessing with cloud-based AI execution [14][15]. Existing studies also insufficiently address the application of preprocessing techniques to dynamic and heterogeneous mHealth datasets and overlook scalability and user experience for large user bases [16]. These gaps hinder the effective implementation of SVM and KNN in mHealth, where real-time accuracy, efficiency, and scalability are crucial [17].

III. Methodology

A. Dataset Description: PIMA Indian Diabetes Dataset

The PIMA Indian Diabetes dataset [18], sourced from the National Institute of Diabetes and Digestive and Kidney Diseases, is a widely used benchmark for machine learning studies in healthcare. It comprises medical data collected from 768 female patients of Pima Indian heritage, aged 21 years or older. The dataset aims to predict the presence of diabetes based

on diagnostic measurements, making it particularly relevant for studies in mHealth applications. Table I summarizes the dataset's predictor variables.

TABLE I. THE DATASET INCLUDES THE FOLLOWING PREDICTOR VARIABLES AND TARGET VARIABLE

Feature	Description	Data Type
Pregnancies	Number of pregnancies.	int64
Glucose	Plasma glucose concentration (mg/dL) after a 2-hour oral glucose tolerance test.	int64
Blood Pressure	Diastolic blood pressure (mm Hg).	int64
Skin Thickness	Triceps skinfold thickness (mm).	int64
Insulin	2-hour serum insulin (mu U/mL).	int64
BMI	Body Mass Index (kg/m²).	float64
Diabetes Pedigree Function	A score representing the likelihood of diabetes based on family history.	float64
Age	Age of the individual.	int64
Outcome	Binary target variable indicating diabetes diagnosis (1 = diabetic, 0 = non-diabetic).	int64

B. Data Preprocessing Techniques

Preprocessing techniques are critical for improving the performance and efficiency of machine learning models as shown in Fig. 1.

This study utilizes various preprocessing methods, including scaling techniques and dimensionality reduction methods, to prepare the data for effective application of SVM and KNN algorithms. These techniques address challenges such as feature imbalance, computational efficiency, and overfitting, ensuring optimized performance in cloud-based mobile health mHealth applications [19].

1) Data scaling techniques

a) Standard Scaler (SS): The Standard Scaler technique is a data preprocessing method used to standardize the features of a dataset. It transforms the data such that it has zero mean and unit variance. This technique is commonly used in machine learning algorithms to ensure that all features are on a similar scale, which can improve the performance of the models. z is the standardized value of a feature; x is the original value of the feature; μ is the mean of the feature and σ is the standard deviation of the feature. A value x is transformed (scaled) into σ using Eq. (1):

$$z = \frac{x-\mu}{\sigma} \quad (1)$$

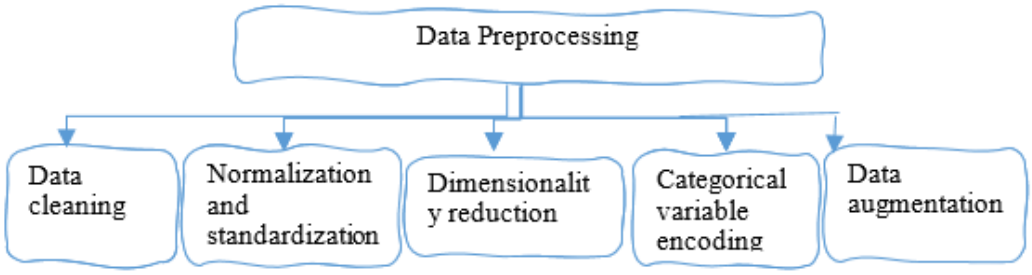

Fig. 1. Overview of various data preprocessing techniques.

b) Min-Max Scaler (MMS): Min-max scaler is a data normalization technique that transforms the values of a dataset to a specific range, typically between 0 and 1. It is calculated using Eq. (2):

$$X_{scaled} = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (2)$$

where, X_{scaled} is the scaled value, X is the original value, X_{min} is the minimum value in the dataset, and X_{max} is the maximum value in the dataset.

c) Maximum Absolute Scaler (MAS): The Maximum Absolute Scaler is a method used to transform numerical data into a range between 0 and 1. This is achieved by dividing each value by the maximum absolute value present in the dataset. It can be mathematically expressed asashown in Eq. (3):

$$X_{scaled} = \frac{x}{max(|x|)} \quad (3)$$

where, x represents the original value and X_{scaled} represents the transformed value.

d) Robust Scaler (RS): The three scaling techniques mentioned earlier are highly affected by outliers because they rely on each variable's mean or minimum and maximum values. However, the Robust Scaler aims to reduce the impact of outliers by centering the data on the median $Q_2(x)$ and scaling it based on the interquartile range, which is the difference between the first quartile $Q_1(x)$ and the third quartile $Q_3(x)$ of x, as shown in Eq. (4):

$$X_{scaled} = \frac{X - Q_2(x)}{Q_3(x) - Q_1(x)} \quad (4)$$

e) Quantile Transformer (QT): The Quantile Transformer is a statistical technique that transforms a dataset's distribution to a desired target distribution by mapping original data values to new values. It is valuable for scenarios like data normalization, outlier mitigation, and preparation for statistical models. The Quantile Transformer can be represented by Eq. (5):

$$Y = (F_{target}^{-1}(F_{original}(x))) \quad (5)$$

where, $F_{original}$ is the cumulative distribution function (CDF) of the original dataset, and F_{target}^{-1} is the inverse CDF of the desired target distribution.

f) Normalization (N): A normalizer standardizes values to a uniform scale, aiding comparison by removing scale disparities, often expressed as Eq. (6). This equation scales values from 0 to 1, adjusting the minimum to 0 and the maximum to 1. Other techniques may employ varied equation depending on data needs.

$$Normalized\ value = \frac{Value - Minimum\ value}{Maximum\ value - Minimum\ value} \quad (6)$$

2) Dimension reduction techniques

a) Principal Component Analysis (PCA): PCA is a widely used statistical technique in multivariate analysis, primarily employed for dimensionality reduction and data compression [20]. Its main goal is to identify patterns, emphasizing similarities and differences in the data while preserving most of the original variations. PCA achieves four main objectives: extracting relevant information, compressing data by retaining distinguishing features, simplifying data description, and enabling analysis of observational structure. Eq. (7), which calculates variance (var(x)), is integral to PCA.

$$var(x) = \frac{\sum(x_i - \underline{x})^2}{N} \quad (7)$$

b) Linear Discriminant Analysis (LDA): Linear Discriminant Analysis (LDA) is a statistical technique for both dimensionality reduction and classification [21]. It aims to find a linear combination of features that maximizes class separability by maximizing the ratio of between-class and within-class scatters. LDA is widely applied in pattern recognition, machine learning, and data mining, seeking a projection vector that optimizes between-class scatter while minimizing within-class scatter. The between-class scatter matrix S_B is calculated by Eq. (8):

$$S_B = \big(mean(X_c) - mean(X)\big) * \big(mean(X_c) - mean(X)\big)^T \quad (8)$$

where, mean (X_c) is the mean vector of each class and mean(X) is the mean vector of the entire dataset.

The within-class scatter matrix S_w is calculated using Eq. (9):

$$S_w = \sum\big(X_i - mean(X_i)\big) * \big(X_i - mean(X_i)\big)^T \quad (9)$$

where, Σ represents the summation of all samples in each class.

The goal of LDA is to find the projection vector w that maximizes Fisher's criterion, as given in Eq. (10):

$$J(w) = (w^T * S_B * w)/(w^T * S_w * w) \quad (10)$$

The solution to this optimization problem can be obtained by finding the eigenvectors corresponding to the largest eigenvalues of the matrix inverse of $(S_w)^{-1} * S_B$. Once the projection vector w is obtained, it can be used to project new samples onto the linear discriminant space for classification or dimensionality reduction purposes.

c) SVM algorithm: SVM is an ML algorithm that finds the best line or plane to separate different classes of data points, as shown in Algorithm 1. It uses a subset of training data called support vectors to determine this line or plane. SVM can handle both linear and non-linear data by using different kernel functions. One of its advantages is its ability to handle high-dimensional data without overfitting. It can also work well with small training samples. SVM has been extensively studied and improved with different techniques such as using different kernels and handling imbalanced datasets. Overall, SVM is a powerful and widely used technique for classification problems [22].

Algorithm 1: Pseudo code of the SVM algorithm

Set $Input = (x_i, y_i)$ where $i = 1,2,3, \dots, N$, $x_i = R^n$ and $y_i = \{+1, -1\}$.
Assign $f(X) = \omega^T x_i + b = \sum_{i=1}^{N} \omega T xi + b = 0$.
Minimize the QP problem as, $\varphi(\omega, \varepsilon) = \frac{1}{2}\|\omega\|^2 + C.\left(\sum_i^N \varepsilon_i\right)$.
Calculate the dual Lagrangian multipliers as $minL_p = \frac{1}{2}\|\omega\|^2 - \sum_{i=1}^{N} x_i y_i(\omega xi + b) + \sum_{i=1}^{N} x_i$.
Calculate the dual quadratic optimization (QP) problem as $L_D = \sum_{i=1}^{N} x_i - \frac{1}{2}\sum_{i,j}^{N} x_i x_j \ \ y_i y_j\left(x_i, x_j\right)$.
Solve dual optimization problem as $\sum_{i=1}^{N} y_i x_i = 0$.
Output the classifier as $f(X) = sgn\left(\sum_{i=1}^{N} x_i y_i(x.x_i) + \sum_{i=1}^{N} x_j y_j\left(x.x_j\right)\right)$

d) KNN algorithm: K-Nearest Neighbors (KNN) is a classification algorithm that assigns the label of a classified data point to an unclassified data point that is closest to it. This is done by considering the majority class of its K nearest data points. The distance between data points is typically measured using Euclidean distance (DE) or Manhattan distance (DM) [23] as shown in Algorithm 2:

Algorithm 2: Pseudo code of the KNN algorithm

Input: X: training data, Y: class labels of X, K: number of nearest neighbors.
Output: Class of a test sample x.
Start
Classify (X, Y, x)
For each sample x do
Calculate the distance: $d(x, X) = \sqrt{\sum_{i=1}^{n}(x_i - X_i)^2}$
End for
Classify x in the majority class: $C(x_i) = argmax_k \sum x_{j \in KNN} C\left(X_j, Y_k\right)$
End

e) Experimental design: The experimental design systematically evaluates the performance of SVM and KNN models in cloud-based mHealth systems, focusing on how preprocessing techniques affect accuracy and processing time (Fig. 2). Initially, baseline testing is conducted without preprocessing to establish reference metrics, including accuracy, precision, recall, F1-score, and processing time, highlighting limitations like bias from feature magnitudes and inefficiencies from data redundancy. Next, the impact of scaling techniques, such as Standard Scaler, Min-Max Scaler, Robust Scaler, and Quantile Transformer, is assessed by applying each method to the dataset and evaluating

performance metrics. This step identifies effective scaling methods for reducing bias and improving efficiency. Dimensionality reduction techniques, including Principal Component Analysis (PCA) and Linear Discriminant Analysis (LDA), are then evaluated to understand their influence on computational cost and classification accuracy. PCA retains components with the most variance, while LDA maximizes class separability, both offering insights into trade-offs between efficiency and performance. Finally, combined testing explores the interaction between scaling and dimensionality reduction, with pipelines like Standard Scaler + PCA and Min-Max Scaler + LDA being tested to optimize preprocessing for real-time mHealth applications. This comprehensive approach ensures a balance between accuracy and processing time, enabling scalable and efficient model deployment.

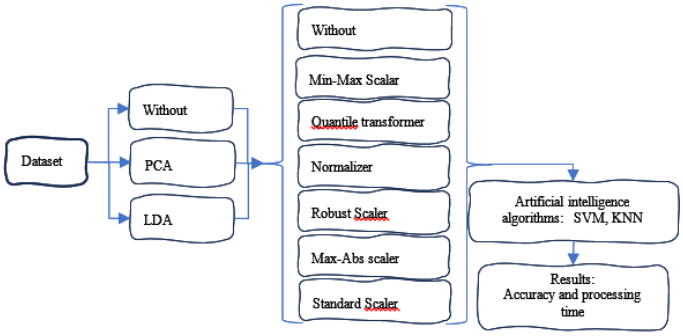

Fig. 2. Experimental Design

f) Metrics collected: Performance Metrics: Accuracy, precision, recall, F1-score.

- Efficiency Metrics: Processing time (measured in milliseconds).
- Trade-off Analysis: Evaluate the trade-offs between computational efficiency and model accuracy.

g) Computational environment: The experiments were conducted in a computational environment designed to replicate typical resource-constrained scenarios found in mHealth applications. This setup ensures the findings apply to real-world cloud-based systems supporting mHealth platforms.

- Hardware: Processor: AMD Ryzen 5 5500U CPU with Radeon Graphics, 2.10 GHz. Memory: 8 GB of RAM.
- Software: Programming Language: Python 3.8.

IV. Results and Analysis

The study evaluates the performance of SVM and KNN under various preprocessing scenarios, focusing on the following metrics: Processing Time (in milliseconds), Accuracy, Precision, Recall, and F1-Score.

The experiments demonstrate how scaling techniques and dimensionality reduction methods affect the efficiency and accuracy of these algorithms when applied to a health-related dataset.

A. Performance Without Preprocessing

As shown in Table II, SVM performs better than KNN in terms of accuracy (0.71 vs. 0.69) and is faster (0.063 ms vs. 0.13 ms). Without preprocessing, the data may contain bias and unnecessary information, making the model less efficient. This shows that preprocessing is important to improve speed and performance.

TABLE II. Metrics for SVM and KNN

Metric	Accuracy	Precision	Recall	F1-Score	Processing Time (ms)
SVM	0.71	0.70	0.71	0.69	0.063
KNN	0.69	0.69	0.69	0.69	0.13

B. Performance only with Scaling Techniques

Table III presents the impact of different scaling methods on the performance of SVM and KNN. Scaling significantly improves both accuracy and processing time for the two models. For SVM, the Min-Max Scaler achieves the highest accuracy (0.73) with a moderate processing time of 0.12 ms, while the Standard Scaler offers a good trade-off between accuracy (0.72) and faster processing (0.087 ms). In the case of KNN, the Standard Scaler provides the best accuracy (0.75) along with efficient processing (0.085 ms), making it particularly suitable for real-time applications. Although the Quantile Transformer yields moderate accuracy, its higher computational cost reduces its practicality. These results demonstrate that the choice of scaling method directly influences model performance and efficiency.

TABLE III. Metrics for SVM and KNN with Scaling Techniques

Scaling Technique	Standard Scaler		MinMax Scaler		Robust Scaler		Quantile Transformer	
Metric	Accuracy	Processing Time (ms)	Accuracy	Processing Time (ms)	Accuracy	Processing Time (ms)	Accuracy	Processing Time (ms)
SVM	0.72	0.087	0.73	0.12	0.66	0.13	0.71	0.42
KNN	0.75	0.085	0.73	0.12	0.68	0.063	0.74	0.13

C. Performance only with Dimensionality Reduction

Table IV shows that LDA outperforms PCA for both SVM and KNN. SVM with LDA achieves higher accuracy (0.74) and faster processing (0.085 ms) than with PCA. KNN also performs better and faster with LDA (0.047 ms). LDA's strength in maximizing class separability explains its superior results, making it the preferred choice for this dataset.

TABLE IV. Metrics for SVM and KNN with PCA and LDA

Metric	SVM + PCA	SVM + LDA	KNN + PCA	KNN + LDA
Precision	0.70	0.73	0.64	0.69
Recall	0.71	0.74	0.66	0.69
F1-score	0.69	0.73	0.65	0.69
Accuracy	0.71	0.74	0.66	0.69
Processing time (ms)	0.092	0.085	0.1	0.047

D. Performance with Dimensionality Reduction and Scaling Techniques

Table V shows that combining scaling and dimensionality reduction improves performance. For SVM with PCA, Min-Max Scaler gives the best accuracy (0.73), while Standard Scaler is faster (0.087 ms). For KNN with PCA, Min-Max Scaler has the highest precision (0.75), but Robust Scaler is more efficient (0.063 ms). With LDA, Standard Scaler provides the best accuracy and fastest processing, especially for SVM (0.041 ms).

TABLE V. METRICS FOR SVM WITH PCA AND SCALING TECHNIQUES

Scaling Technique	Max-Abs Scaler	Min-Max Scaler	Normalizer	Quantile Transformer	Robust Scaler	Standard Scaler
Precision	0.71	0.72	0.42	0.71	0.66	0.72
Recall	0.71	0.73	0.65	0.71	0.67	0.73
F1-Score	0.71	0.73	0.65	0.71	0.67	0.73
Processing time (ms)	0.12	0.12	0.14	0.42	0.13	0.087

TABLE VI. METRICS FOR KNN WITH PCA AND SCALING TECHNIQUES

Scaling Technique	Max-Abs Scaler	Min-Max Scaler	Normalizer	Quantile Transformer	Robust Scaler	Standard Scaler
Precision	0.71	0.75	0.66	0.74	0.68	0.75
Recall	0.69	0.73	0.66	0.74	0.68	0.75
F1-Score	0.69	0.73	0.66	0.74	0.68	0.75
Processing time(ms)	0.13	0.12	0.11	0.13	0.063	0.085

Table VI shows that for KNN with PCA, Min-Max and Standard Scalers achieve the best metrics (0.75), with Standard Scaler being faster (0.085 ms). Robust Scaler is the most efficient (0.063 ms) but slightly less accurate. Normalizer performs worst (0.66). This highlights Standard Scaler as the best balance of accuracy and speed.

TABLE VII. METRICS FOR SVM WITH LDA AND SCALING TECHNIQUES

Scaling Technique	Max-Abs Scaler	Min-Max Scaler	Normalizer	Quantile Transformer	Robust Scaler	Standard Scaler
Precision	0.73	0.73	0.65	0.73	0.73	0.73
Recall	0.74	0.74	0.68	0.74	0.74	0.74
F1-Score	0.73	0.73	0.64	0.73	0.73	0.73
Processing time(ms)	0.063	0.08	0.1	0.12	0.085	0.041

Table VII shows that for SVM with LDA, all scaling techniques except Normalizer achieve strong and consistent metrics (precision, recall, F1-score ≈ 0.73–0.74). Standard Scaler offers the best processing time (0.041 ms), making it the most efficient. Normalizer performs the worst across all metrics. These results highlight Standard Scaler as the most effective option when combining LDA with SVM.

TABLE VIII. METRICS FOR KNN WITH LDA AND SCALING TECHNIQUES

Scaling Technique	Max-Abs Scaler	Min-Max Scaler	Normalizer	Quantile Transformer	Robust Scaler	Standard Scaler
Precision	0.69	0.69	0.69	0.69	0.69	0.69
Recall	0.69	0.69	0.69	0.71	0.69	0.69
F1-Score	0.69	0.69	0.69	0.69	0.69	0.69
Processing time(ms)	0.07	0.072	0.063	0.084	0.047	0.032

Table VIII shows that KNN with LDA performs consistently across all scaling techniques, with precision, recall, and F1-score around 0.69. Quantile Transformer slightly improves recall (0.71), while Standard Scaler provides the fastest processing time (0.032 ms). These results indicate that although performance is similar, Standard Scaler is the most efficient.

Fig. 3(a) compares SVM and KNN accuracy and processing time with various scalers. Standard and Min-Max Scalers yield the highest accuracy, but Standard Scaler is fastest. Quantile Transformer is accurate but much slower.

Fig. 3(b) presents the performance of SVM and KNN using PCA and LDA. Both dimensionality reduction techniques yield comparable results across precision, recall, F1-score, and accuracy. However, LDA shows better efficiency, especially with KNN, offering lower processing time.

Fig. 3(c) shows SVM performance using different scaling techniques, with PCA Standard Scaler and MinMax Scaler achieving high precision, recall, and F1-score, while Standard Scaler has the lowest processing time. In contrast, Quantile Transformer offers good metrics but with the highest time cost.

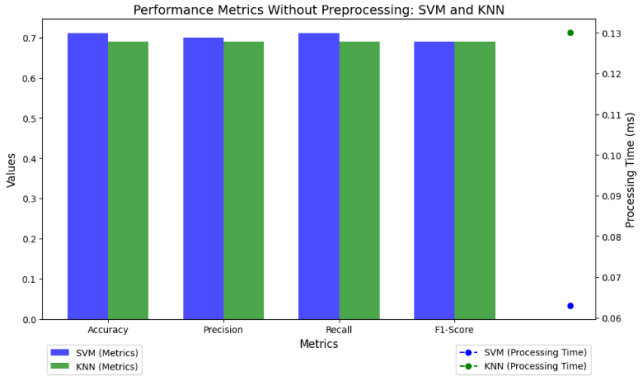

Fig. 3(d) shows that QuantileTransformer offers the best KNN performance but is the slowest, while RobustScaler is fastest with lower accuracy StandardScaler and MinMaxScaler provide a good balance between performance and processing time.

Fig. 3(e) shows that QuantileTransformer gives the best SVM performance but with the highest processing time, while StandardScaler is the fastest with strong accuracy. Other scalers like MinMaxScaler and RobustScaler offer a balanced trade-off between performance and speed.

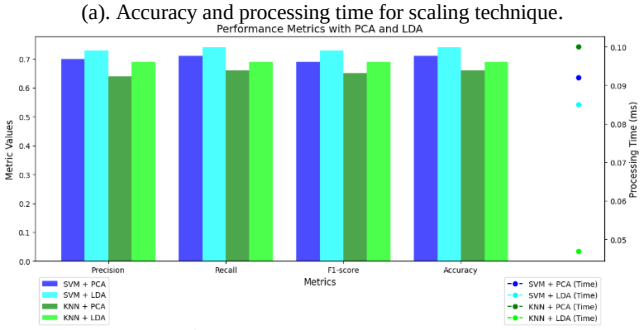

Fig. 3(f) shows that QuantileTransformer gives the highest KNN performance with LDA but takes the longest time to process. StandardScaler is the fastest and still maintains strong performance. Other scalers like MinMaxScaler and RobustScaler also show consistent accuracy with lower processing times, indicating good overall efficiency.

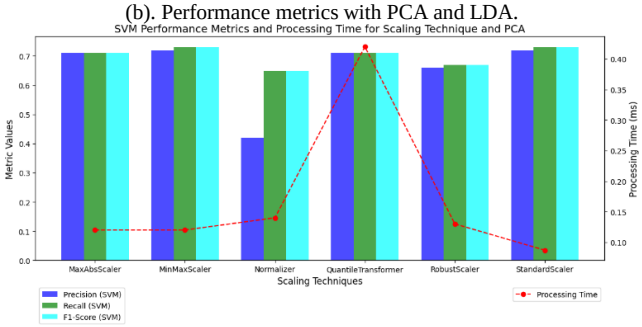
The findings in Fig. 3(a) to Fig. 3(f), highlight the practical implications of combining preprocessing with SVM and KNN to optimize mHealth applications. This approach enhances real-world applicability in areas such as remote patient monitoring, enabling real-time analysis of wearable data; chronic disease



management, supporting early detection and personalized care; and telemedicine, improving the speed and reliability of virtual consultations. Faster processing times, such as 0.041 ms for SVM with LDA, ensure responsive systems that reduce delays in delivering critical insights, improving user trust and scalability through efficient resource utilization. Moreover, optimized preprocessing pipelines facilitate real-time predictions, enabling immediate feedback in critical scenarios like glucose monitoring or irregular heart rhythm detection. This responsiveness empowers healthcare professionals to make timely interventions, enhancing patient outcomes and advancing the efficiency of mHealth solutions.

V. Conclusion

This study provides a comprehensive evaluation of SVM and KNN algorithms, emphasizing their optimization for mobile health applications in cloud environments. Through systematic testing with various preprocessing techniques, such as scaling (Standard Scaler, Min-Max Scaler) and dimensionality reduction (PCA, LDA), the findings demonstrate significant improvements in both accuracy and processing efficiency. These optimizations address the unique constraints of mHealth systems, such as the need for real-time responsiveness and resource efficiency, making SVM and KNN suitable for applications like remote patient monitoring, chronic disease management, and telemedicine. The study highlights the critical role of preprocessing in reducing computational overhead, improving latency, and enhancing the scalability of cloud-based healthcare systems. While this work primarily focuses on preprocessing-driven optimization, it opens several avenues for future research. These include integrating deep learning models with classical classifiers, performing systematic hyperparameter tuning (e.g., grid search, Bayesian optimization), and applying statistical validation techniques to reinforce the robustness of results. Additionally, exploring adaptive preprocessing strategies that evolve in real-time with streaming health data could further improve model responsiveness in dynamic mHealth scenarios. Expanding the evaluation to include diverse datasets and multi-device deployment environments would also contribute to validating the generalizability of the proposed approach.

Deep Reinforcement Learning Based Robotic Arm Control Simulation to Execute Object Reaching Task for Industrial Application

John Mark Correa[1], Rudolph Joshua Candare[2], Junrie B. Matias[3]
Department of Computer Science, Caraga State University, Butuan City, Philippines[1]
Graduate School, Caraga State University, Butuan City, Philippines[2, 3]

***Abstract*—This study presents a deep reinforcement learning (DRL) approach to train a robotic arm for object reaching tasks in industrial settings, eliminating the need for traditional task-specific programming. Leveraging the Proximal Policy Optimization (PPO) algorithm for its stability in continuous control, the system learns optimal behaviors through autonomous trial-and-error. Central to this work is reward shaping, where structured feedback based on distance to the target, collision avoidance, motion constraints, and step efficiency guides the agent, akin to incremental coaching. A simulated industrial environment was developed using Webots, integrated with OpenAI Gym and Stable-Baselines3, enabling safe training with sensor data (camera, distance sensor) and randomized target placements. Three models with varying reward schemes were evaluated: simpler rewards prioritized rapid convergence, while complex formulations (e.g., perceptual alignment) enhanced long-term accuracy at the cost of initial instability. Experimental results demonstrated that reward shaping reduced the required steps, highlighting its role in accelerating learning. The study underscores the efficacy of combining DRL, simulation-based training, and adaptive reward design to develop efficient robotic controllers. These findings advance scalable solutions for industrial automation, emphasizing the trade-offs between reward complexity and policy convergence. Future work will refine reward functions to bridge simulation-to-reality gaps, fostering practical adoption in manufacturing and assembly systems.**

***Keywords*—Reinforcement learning; deep reinforcement learning; reward shaping techniques; robotic arm; robot simulation**

I. Introduction

Humans possess the innate ability to easily recognize and manipulate objects; conversely, robots encounter significant challenges with this ostensibly straightforward task, which presents a noteworthy obstacle within the field of robotics [1]. This phenomenon has garnered attention in both scholarly research and industrial applications, particularly in relation to Industry 4.0, which prioritizes automation and sophisticated technologies in manufacturing through paradigms such as the Smart Factory [2].

Reinforcement learning (RL) has surfaced as a promising alternative to facilitate the implementation of robots within industrial contexts by enabling robots to acquire tasks without the need for direct programming [3]. Deep reinforcement learning (DRL) integrates RL with deep neural networks to address complex state spaces and enhance the efficiency of the learning process. Although DRL may demand substantial resources for training on actual platforms, simulation-based training represents a feasible solution to scale data and decrease reliance on human intervention [4].

Simulation-based environments can furnish a secure and regulated context for robots to practice and hone their competencies, thereby equipping them to generalize acquired behaviors to real-world applications with greater efficacy [5]. This methodology not only accelerates the learning trajectory but also mitigates risks associated with training in unpredictable real-world conditions, ultimately fostering the development of more resilient and adaptable robotic systems [6]. By capitalizing on advancements in virtual reality and high-fidelity simulations, researchers are able to devise diverse training scenarios that closely replicate real-world challenges, thereby further enhancing the adaptability of DRL algorithms [7]. These innovations lay the groundwork for more effective training methodologies, enabling robots to address complex tasks with heightened confidence and precision [7].

Consequently, the assimilation of these technologies into robotic training programs is poised to transform not only the manner in which robots learn but also their overall efficacy in dynamic environments [8]. This paradigm shift in training methodologies is likely to yield substantial advancements across a variety of applications, ranging from autonomous vehicles navigating congested thoroughfares to industrial robots optimizing production lines with minimal human involvement [9].

However, a critical gap remains in understanding how reward shaping, specifically the design and modular integration of reward signals, affects convergence efficiency and task precision across varying degrees of complexity [10], [11]. Most prior works emphasize algorithmic improvements or domain adaptation, yet underexplore the influence of structured, incremental reward functions within high-fidelity simulations. These reward strategies are essential not only for accelerating convergence but also for fostering generalizable behaviors applicable to industrial use cases [12].

To address this gap, this study poses the following research question: How does the complexity of reward functions influence the convergence efficiency and task success rate of a DRL-based robotic arm control system in a simulated industrial environment?

This study addresses this question by proposing a DRL-based robotic arm control system using Proximal Policy Optimization (PPO) within a Webots simulation environment. By leveraging the recent advancements in continuous control through deep reinforcement learning (DRL) to enhance the operational efficiency of a robotic arm tasked with object-reaching activities. Specifically, this study employs the Proximal Policy Optimization (PPO) algorithm within a three-dimensional simulation environment, guided by a strategically designed reward function. The primary objective is to develop and train a DRL-based control system that enables the robotic arm to accurately reach and make contact with a designated target object, sometimes at a specified angle, an ability with broad applicability across labor-intensive industries. The proposed reward function is crafted to facilitate the convergence of the PPO algorithm, ensuring effective policy learning. Additionally, the study explores the adaptability of the learning framework by modifying the reward function to accommodate similar manipulation tasks of varying complexity. Comparative evaluations of different reward functions will be conducted to determine their influence on the convergence speed and overall performance of the robotic arm, thereby contributing to the design of more efficient and adaptable robotic control systems.

II. Related Work

Deep reinforcement learning (DRL) has emerged as a powerful paradigm for controlling robotic arms, offering robust solutions to complex control tasks. This approach combines the strengths of deep learning and reinforcement learning, enabling robots to learn optimal policies through trial and error in a dynamic environment. Recent advancements in DRL have significantly improved the accuracy, efficiency, and adaptability of robotic arm control systems, addressing challenges such as trajectory tracking, obstacle avoidance, and energy efficiency. This section provides a comprehensive overview of the state-of-the-art methods, key innovations, and applications of DRL in robotic arm control, drawing insights from recent research papers.

A. Algorithmic Advancements in DRL for Robotic Arm Control

One of the most notable contributions to DRL for robotic arm control is the improvement of existing algorithms. Proximal Policy Optimization (PPO) has been widely adopted due to its stability and effectiveness in continuous action spaces [13]. For instance, researchers have proposed an Improved-PPO algorithm that integrates PPO with Model Predictive Control (MPC) to enhance trajectory tracking efficiency. This method has demonstrated a significant increase in convergence speed, outperforming traditional PPO and A3C algorithms by 84.3% and 15.4%, respectively [13]. Similarly, the combination of PPO with Generative Adversarial Imitation Learning (GAIL) has been explored to transfer policies from simulated environments to real-world scenarios, enabling dual-arm robots to perform complex assembly tasks with remarkable efficiency [14].

Another significant advancement is the use of Deep Deterministic Policy Gradient (DDPG) algorithms. Researchers have enhanced DDPG by incorporating techniques such as Hindsight Experience Replay (HER) and double experience replay buffers to improve learning efficiency. These modifications have enabled robotic arms to achieve near-perfect success rates in target-reaching tasks while reducing training time [15], [16]. Additionally, the integration of DDPG with sequential training methods has been shown to expedite the learning process and improve robustness against external disturbances, making it suitable for real-world applications [17].

B. Reward Function Design and Motion Planning

The design of reward functions plays a crucial role in DRL, as it guides the learning process and determines the optimal policy [18]. Researchers have proposed various reward functions tailored to specific tasks, such as trajectory tracking, obstacle avoidance, and energy efficiency [19]. For example, a study introduced a hierarchical reward function that combines motion accuracy, obstacle avoidance, and energy-saving components. This approach has been shown to improve the convergence speed and accuracy of robotic arm control policies [20], [21].

In addition to reward function design, motion planning has been a focal area of research. A study proposed a DRL-based motion planning method that enables robotic arms to navigate complex environments with obstacles. The method leverages the PPO algorithm and reward shaping techniques to ensure efficient and adaptive control [20]. Another study demonstrated the effectiveness of DRL in motion planning for dual-arm robots, where a novel reward and punishment function was designed to guide the robot to approach targets while avoiding collisions [22].

C. Generalization and Real-World Deployment

The generalization capabilities of DRL controllers are essential for their successful deployment in real-world scenarios. Researchers have investigated the generalization of policies learned in simulation to new observations, dynamics, and tasks. For example, a study demonstrated that a DRL controller trained in simulation could generalize well to real-world scenarios, including dynamic trajectory tracking and robustness to external forces [23]. Another study showed that policies trained in simulation could be directly transferred to physical robots without retraining, achieving remarkable performance in tasks such as grasping and motion planning [24].

The generalization capabilities of DRL have also been tested in complex environments, such as those involving soft robotic arms. A study presented a closed-loop controller for soft robotic arms that could generalize to new tasks, including intercepting moving objects and tracking trajectories with varying velocity profiles [23]. These findings highlight the potential of DRL for real-world applications, where robots must adapt to diverse and dynamic environments.

Deep reinforcement learning has revolutionized the field of robotic arm control, offering robust and adaptive solutions to complex control tasks. Recent advancements in algorithms, reward function design, and simulation-to-reality transfer have significantly improved the performance and versatility of DRL-based control systems [25]. As research continues to address challenges such as generalization, energy efficiency, and real-world deployment, DRL is poised to play an increasingly important role in the development of intelligent robotic systems [26].

D. Identified Problems in the Current Implementation of DRL in Robotic Arm Control

The current implementation of Deep Reinforcement Learning (DRL) in the control of robotic arms has revealed several critical issues that warrant attention. One of the primary challenges is the inefficiency in training time, which often results from the high dimensionality of the action and state spaces involved. This complexity can lead to prolonged learning periods and suboptimal performance, as the algorithms struggle to converge on effective strategies [26].

Additionally, there is a notable concern regarding the stability and robustness of the learned policies. Many DRL algorithms are sensitive to hyperparameter settings, which can result in significant variations in performance across different trials [16]. This unpredictability can hinder the reliability of robotic arm operations in real-world applications where consistency is paramount [27].

Another problem is the insufficient exploration of the action space during the training phase. Many DRL implementations tend to exploit known strategies rather than exploring new ones, potentially leading to local optima and a lack of adaptability in dynamic environments. This limited exploration can restrict the robot's ability to handle unforeseen circumstances or variations in tasks [28]. Moreover, the integration of DRL with sensory feedback systems poses additional challenges. Ensuring that the robotic arm can effectively interpret and respond to sensory inputs in real-time is crucial for achieving seamless operation. However, current implementations may struggle with the synchronization of sensory data processing and decision-making, leading to delays and inaccuracies in task execution [29].

Lastly, there is a growing concern about the generalization of learned behaviors across different tasks and environments. Many DRL models tend to overfit to the specific conditions present during training, which can significantly diminish their performance when faced with novel situations or variations in operational contexts [30]. Addressing these issues is essential for advancing the efficacy and applicability of DRL in robotic arm control systems, paving the way for more sophisticated and versatile robotic applications.

III. Methodology

A. Introduction to the Simulation Environment

The simulation environment was developed using Webots, an open-source, multi-platform robotic simulator designed for modeling, programming, and testing robotic systems. The setup emulated a collaborative workspace with a Universal Robots UR5e robotic arm, a 6-degree-of-freedom manipulator equipped with a Tiago Gripper. Key components integrated into the system included:

- A camera with an object recognition node mounted on the gripper to capture visual data.
- A distance sensor is attached to the end-effector to measure proximity to the target.
- A 5 cm^3 cube serving as the target object, randomly repositioned within a 3 m^3 boundary in front of the robot for each training episode.

The environment was designed to simulate industrial scenarios, where the robotic arm must dynamically adapt to varying object positions. The camera transmitted real-time images to the control system, which processed them to generate state observations (e.g., joint angles, end-effector coordinates).

B. Design of the Reward Functions

The performance of deep reinforcement learning (DRL) agents heavily depends on the quality and structure of the reward functions used during training. In this study, three models (A, B, and C) were developed with progressively complex reward functions to guide the robotic arm in learning the object-reaching task. Each reward function was designed to encourage desirable behavior and penalize inefficiencies or errors, thereby accelerating convergence toward optimal policies.

1) Distance-based reward.

a) A primary reward proportional to the Euclidean distance between the end-effector and target:

$$\mathrm{r} = \begin{cases} 10, & \mathrm{dis} < 0.01 \\ -2, & \mathrm{dis} > 1.25 \end{cases} \quad (1)$$

b) Incremental rewards (+2/-1) encouraged movement toward the target.

2) Motion constraints. Penalties (-2) enforced spatial boundaries to limit exploration to relevant areas.

3) Collision avoidance. Negative rewards (-5) deterred collisions with the robot's body or environment.

4) Object recognition. Positive rewards (+1) for detecting the target via the camera.

5) Image-based rewards (Models B and C).

a) Size ratio rewards (Model B): Scaled rewards based on changes in the target's perceived size.

$$\mathrm{size_ratio} = \mathrm{box_image_size} \,/\, \mathrm{prev_box_image\ size} \quad (2)$$

$$\mathrm{r} = \mathrm{size_ratio} \times 2 \quad (3)$$

b) Alignment rewards (Model C): Penalized deviations between the target's center and the camera's focal point.

$$dis_to_ctr = \sqrt{\left(\frac{x_{box_img} + width_{cam}}{2}\right)^2 + \left(\frac{y_{box_img} + height_{cam}}{2}\right)^2} \quad (4)$$

$$r = \begin{cases} 10, dis_to_ctr < 0.1 \\ 5, dis_to_ctr < 0.5 \\ 2, dis_to_ctr \leq 0.9 \\ -\ dis_to_ctr \times 2, dis_to_ctr > 0.09 \end{cases} \quad (5)$$

C. Implementation of the Control Mechanism and PPO Algorithm

The control policy was optimized using the Proximal Policy Optimization (PPO) algorithm, selected for its stability in continuous action spaces. Key implementation details included:

a) Policy network: A multi-layer perceptron (MLP) with fully connected layers to map states (joint angles, sensor data) to actions (joint velocity commands).

b) Training parameters: n_steps=2048 interactions per policy update. tensorboard_log for tracking training metrics (e.g., reward trends, episode length).

c) Environment interface: Custom OpenAI Gym integration to synchronize Webots simulations with the Stable-Baselines3 RL library.

The learning process mirrored trial-and-error refinement, where the agent iteratively adjusted its policy based on reward signals, gradually minimizing unnecessary movements and collisions.

D. Experiment and Evaluation

To systematically evaluate the impact of varying reward function complexities on the performance of the Proximal Policy Optimization (PPO) algorithm, a series of experiments were conducted using three distinct models. The primary evaluation criteria included the number of training steps required to achieve effective task performance and the success rate in executing the object-reaching task within a simulated environment.

The training protocol involved 15 rounds of training for each model, with 10,000 interaction steps per round. The models were designed to incrementally incorporate additional reward components, enabling a controlled analysis of how increasing reward complexity influences policy learning.

The models are defined as follows:

- Model A (Baseline): Utilizes a foundational reward structure based on the Euclidean distance between the end-effector and the target object as defined in Eq. (1), augmented with penalties and rewards for collision avoidance, object detection, and motion constraints.
- Model B (Image-Augmented Reward): Builds upon Model A by incorporating image-based size ratio rewards, leveraging Eq. (2) and Eq. (3). These rewards encourage the agent to maximize the perceived size of the target in the camera's view, thereby reinforcing movement toward the object.
- Model C (Alignment-Based Reward): Extends Model B by introducing camera alignment rewards, as described in Eq. (4) and Eq. (5). This component penalizes misalignment between the camera's focal center and the centroid of the target object, promoting not only reaching accuracy but also visual alignment for precise manipulation.

Throughout training, each model's performance was monitored using TensorBoard logs, which recorded metrics such as mean reward values and episode lengths over time. Furthermore, success rates were tested in controlled batches of 10, 30, and 50 episodes to assess consistency and robustness in task execution. This experimental design allowed for a comparative analysis of how reward structure influences learning stability, convergence speed, and task success.

Each model was subjected to 15 training rounds, with each round comprising 10,000 interaction steps between the agent and the simulated environment. The performance of the models was evaluated using two primary metrics:

a) Convergence efficiency: Assessed through TensorBoard visualizations, which tracked the progression of mean episode rewards and episode lengths over the course of training. These indicators provided insight into the stability and speed with which each model approached optimal policy learning.

b) Task success rate: Evaluated by conducting a series of 10-, 30-, and 50-episode trials, wherein a successful trial was defined as the robotic arm's end-effector making contact with the target object within a maximum of 250 time steps.

This evaluation framework was designed to highlight the influence of increasing reward complexity on both the stability of the learning process and the agent's ability to consistently complete the object-reaching task. By comparing the results across the three models, the study provides insights into the trade-offs between reward structure simplicity and control precision in DRL-based robotic systems.

IV. Results and Discussion

A. Initial Development of DRL-Based Robot Arm Controller

Fig. 1 illustrates the simulation environment created using Webots, an open-source and multi-platform desktop application used for modeling, programming, and simulation of robotic systems. The researcher developed a simulation based on the Universal Robots UR5e's collaborative robot arm with 6 degrees of freedom, which was equipped with a Tiago Gripper, an imaging device possessing an object recognition node, a solid node functioning concurrently as a distance sensor and end effector, as well as a cube box serving as the target object. The cube box was strategically positioned in a random manner in front of the robotic arm for each interaction, which is pivotal in motivating the agent to acquire skills in searching for the object within the designated space, thereby inhibiting it from merely learning and concentrating on a target object with a fixed position.

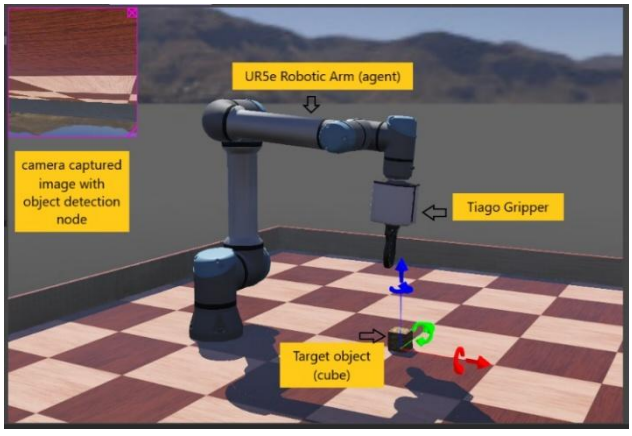

Fig. 1. Simulation environment and robot arm (Agent).

In the simulation environment, the camera transmits the collected image back to the computer. After the image is processed, it will be used as the state S to be observed by the actor. The computer will determine the next move distance of the end of the robotic arm on the X-axis, Y-axis, and Z-axis. According to the current coordinate value of the end of the robot arm and the rotation angle of each joint of the current robot arm,

the computer will calculate the angle at which each joint of the robot arm should rotate when the end of the robot arm reaches the next position.

B. Convergence Efficiency

By analyzing the mean reward values accumulated across iterations during the training process, where the horizontal axis represents the number of training iterations and the vertical axis denotes the reward value obtained per iteration. Fig. 2, Fig. 3 and Fig. 4 illustrate the performance trends of the three models examined in this study. The visualizations highlight how each model progressed and adapted over time during training. To facilitate this analysis, TensorBoard was employed as the primary tool for data processing and visualization, offering a comprehensive suite of utilities for monitoring, evaluating, and interpreting machine learning experiments. These visualizations illustrate the accumulation of reward values obtained across training iterations. The table on the left presents the mean episode length, measured by the number of timesteps or interactions with the environment. Here, the horizontal axis corresponds to the total number of iterations throughout the training process. In contrast, the table on the right displays the distribution of reward values earned in each iteration, with the horizontal axis indicating the iteration count and the vertical axis representing the reward value achieved. These visualizations provide insight into both the learning progress and the stability of the models over time.

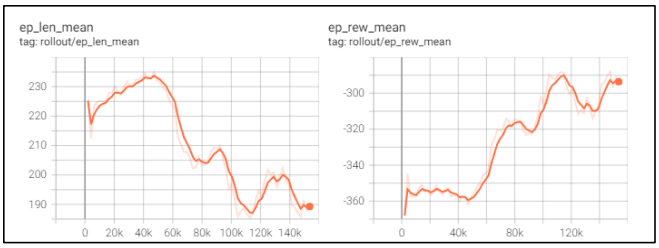

Fig. 2. Model A – Using baseline reward functions (Tensorboard).

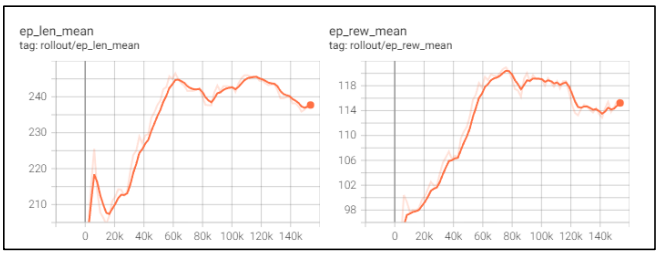

Fig. 3. Model B – Improved Model A with object image size-based reward function (Tensorboard).

The results derived from Model A, as illustrated in Fig. 2, reveal a favorable trajectory in the agent's performance over the temporal dimension. As the training regimen advances, it becomes evident that the quantity of actions necessary to fulfill the task diminishes while the resultant reward amplifies. This indicates that the agent is progressively enhancing its efficacy in making superior and more efficient control decisions to successfully execute the intended task.

In other terms, the agent is acquiring knowledge from the surrounding environment and modifying its conduct in response to the reward signal delineated by the reward function. As the agent develops, it executes movements with greater accuracy and precision in its pursuit of the target object. This phenomenon can be interpreted as an enhancement in the agent's control and decision-making proficiencies, constituting a favorable indication that the training protocol is functioning as anticipated. The observed trend of reduced actions coupled with elevated rewards signifies that the agent is incrementally converging towards the optimal resolution for the task, and it is highly probable that it will continue to experience improvement over time with ongoing training.

Fig. 3 underscores the notion that the architecture of the reward function can substantially influence the conduct of the agent. In this particular instance, the reward function of Model B may not have sufficiently motivated the agent to pursue the most expedient trajectory toward the target object. Conversely, it is plausible that Model B's reward function has prioritized alternative considerations, such as aligning the end-effector with the target object's orientation or maintaining adherence to the defined movement constraints, thus resulting in an elongated route to attain the target object. Irrespective of the underlying factors, the behavioral divergence between Model A and Model B accentuates the critical necessity of meticulously evaluating the formulation of the reward function during the training of a deep reinforcement learning-based agent. It further underscores the imperative for additional inquiry to ascertain the most effective reward function tailored to the specific objective of object reaching.

Moreover, the escalation in the number of actions necessitated in Model B signifies an extended training duration to achieve an optimal policy and thus could be a salient consideration when selecting a reward function for practical robotic applications. Subsequent investigations could delve deeper into this dichotomy between the efficacy of various reward functions and the temporal investment required to attain an optimal policy.

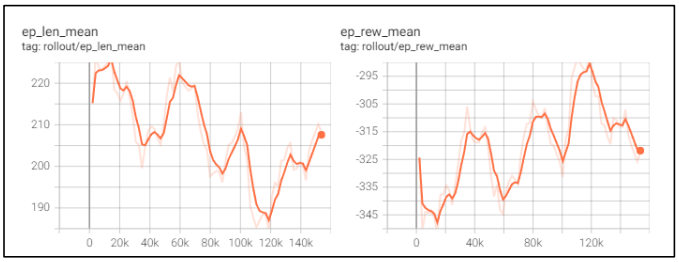

Fig. 4. Model C – Improved model B with object image and camera center distance reward function (Tensorboard).

Lastly, the findings derived from Model C, as illustrated in Fig. 4, demonstrate that, although the overall efficacy of the agent trained utilizing this reward function is commendable, there exist considerable variances in the rewards obtained throughout the training regimen. This phenomenon may be attributable to the complexity of the reward function employed in Model C, which incorporates a broader array of rewards, thereby rendering it more susceptible to fluctuations in the environmental context. Consequently, the agent may struggle to effectively adjust its parameters between successive training iterations, resulting in abrupt alterations in the rewards it acquires. Nevertheless, the overarching trajectory of the training

results for Model C remains favorable, indicating that the agent can acquire knowledge and advance towards the successful completion of the designated task.

C. Task Success Rate

The researchers executed a simulation experiment aimed at assessing the precision of three trained models by employing distinct reward functions. The experiment entailed the agent's gripper, or end-effector, endeavoring to approach the target object as closely as possible and establish contact with it. The efficacy of the models was appraised through 10-episode, 30-episode, and 50-episode trials, with the resultant data encapsulated in Table I.

TABLE I. RESULTS OF THE REACH AND CONTACT EXPERIMENT

Trained Model	Number of Successful Object Reach Actions		
	10 experiments	*30 experiments*	*50 experiments*
A	8	24	37
B	9	22	38
C	8	26	40

Results derived from the reach and contact experiment delineated in Table I indicate that all three models exhibit commendable efficacy with regard to their proficiency in reaching the target object and establishing contact with it. Nonetheless, there exist discernible variances in their performance, as evidenced by the number of successful trials conducted. A plausible explanation for these discrepancies in performance may pertain to the influence of the reward functions implemented in each model. It is plausible that Model A, characterized by its optimized reward function, possesses an enhanced capacity to concentrate on the specified task and acquire the optimal policy at an expedited rate, thereby culminating in superior performance in the reach and contact experiment. An additional factor that may contribute to these differences could be the training methodology employed. The variability in rewards observed in Model C may have precipitated a less stable learning trajectory, which could elucidate its marginally inferior performance in comparison to the other two models.

These findings imply that the proposed deep reinforcement learning-based robotic arm control system demonstrates the capability to execute reaching tasks with substantial effectiveness. Future investigations may be pursued to further refine the reward functions and training methodologies to augment the system's performance.

D. Implications

The agent exhibited exemplary behavior in executing the reaching task, attributable to the effective integration of diverse reward functions within the training process of the robotic arm. The reward functions encompassed parameters such as constraining the number of steps during interaction, quantifying the distance between the centroid of the object image and the centroid of the comprehensive image acquired by the camera recognition module, assessing the dimensions of the object, and identifying potential collisions, thereby furnishing the agent with affirmative or negative reinforcement that either promoted or dissuaded specific actions. These reward functions facilitate the agent's acquisition of the requisite behavior by directing it to recognize the object and its spatial coordinates, orient the end-effector towards the target object, synchronize the image captured by the camera recognition module, and circumvent collisions with the surrounding environment. Moreover, through the modulation of its movements, the agent was able to accomplish the task within the predetermined number of steps and maintain the target object within the defined parameters.

It can be asserted that the incorporation of these reward functions into the training process exerted a significant influence on the agent's performance in the object-reaching task, thereby optimizing both its behavior and resulting outcomes.

The incorporation of these carefully designed reward functions significantly influenced the agent's performance, enhancing both convergence and task efficiency. When comparing the performance of three distinct models trained using different reward structures. The following key observations emerged:

1) Model A matched or exceeded benchmark performances in terms of efficiency and reliability, validating the hypothesis that simplified but well-targeted reward functions improve learning stability.

2) Model B demonstrated slightly better success rates (76%) than Model A in the 50-episode trial, consistent with [22], where added perception cues enhanced accuracy, albeit at the cost of longer training.

3) Model C reached the highest success rate (80%) but required ~30% more training steps and suffered from high reward variance, paralleling issues in over-engineered reward systems like those explored in [10], [28].

Model A demonstrates a favorable trade-off between the simplicity of the reward function and training efficiency. Despite the absence of vision-based shaping used in Model B and C, Model A achieved the shortest convergence time (~70k steps) and competitive performance (74% success rate), with performance matching reward-heavy implementations from related studies [10], [22], [28] in both stability and training duration.

Although Model C introduced higher perceptual alignment (center-distance feedback), it required longer convergence (90k+ steps) and displayed reward fluctuations similar to [10] and [28], which reported volatility due to over-engineered shaping signals.

These results validate that while complex reward functions may offer incremental performance improvements, they often come with increased training cost and instability. The integration of well-structured, goal-specific rewards, particularly those balancing simplicity and effectiveness, is therefore essential in shaping robust robotic control behaviors. Our findings affirm the viability of deep reinforcement learning (DRL) approaches for dynamic object-reaching tasks in simulated environments and highlight the strategic value of reward function optimization.

V. CONCLUSION

This study affirms the feasibility of using deep reinforcement learning (DRL) to train a robotic arm controller in a simulated environment, even with limited computational resources. By leveraging the open-source simulation platform Webots alongside OpenAI Gym and Stable-Baselines3, the research successfully enabled a robotic arm to autonomously and consistently perform object-reaching tasks. Central to this success was the strategic use of reward shaping, a technique similar to guided learning, where the agent receives continuous feedback through structured rewards and penalties to encourage desired behavior. Three models were developed and evaluated to examine the impact of different reward strategies. Model A utilized a baseline reward function incorporating step limits, distance penalties, and collision detection. Model B introduced perceptual feedback by rewarding increases in the visible size of the target object, while Model C further refined agent behavior by penalizing misalignment between the camera's focal center and the object. Although Models B and C showed improved precision in object reaching, their complex reward formulations led to slower convergence and greater variability during training. In contrast, Model A's simplicity facilitated faster learning and more stable performance, highlighting the critical trade-off between reward granularity and training efficiency.

The findings demonstrate that DRL, when integrated with well-calibrated reward functions in a high-fidelity simulation, can generate stable, efficient robotic control policies without relying on hard-coded programming or manual trajectory design. Much like structured, age-appropriate guidance supports a child's learning process, a well-balanced reward architecture enables the agent to generalize optimal behavior through trial and error. However, excessively vague or overly intricate feedback can hinder progress or destabilize learning.

Ultimately, this research underscores the promise of DRL as a scalable and cost-effective approach to robotic automation. It emphasizes the importance of thoughtful reward function design and simulation-based training as key enablers for transferring learned behaviors to real-world applications. The overall contribution of this work lies in its demonstration that intelligent robotic behaviors can be efficiently acquired through reward shaping in resource-constrained settings, thus lowering the barrier to entry for academic institutions, startups, and small-scale industries seeking to adopt DRL-driven automation.

However, this work is not without limitations. Further research is required to refine the reward shaping mechanisms and to fine-tune the agent's learning process for improved generalization and adaptability. To enhance the agent's performance, future work should consider several key directions: integrating additional sensor modalities such as tactile sensors to enrich environmental feedback; exploring a broader range of robotic arm tasks to test adaptability; evaluating the agent's capabilities using objects of varying shapes, sizes, and materials; experimenting with alternative deep reinforcement learning algorithms to improve training efficiency and policy robustness; transferring the learned policies from simulation to real-world robotic platforms; and systematically assessing the agent's performance in real-world environments under realistic constraints and uncertainties.

This contributes meaningfully to the democratization of advanced robotics and strengthens the bridge between simulation research and real-world deployment.

ACKNOWLEDGMENT

The authors gratefully acknowledge the support of the College of Computing and Information Sciences at Caraga State University for providing the academic framework and resources for this research. Special thanks to the faculty advisers and thesis panel members for their technical guidance and critical feedback. This work was partially funded by the Department of Science and Technology - Science Education Institute (DOST-SEI) through a graduate scholarship grant.

***Abstract*—Stroke continues to be a major cause of mortality and disability globally, and precise risk prediction models are needed. Current models do not effectively incorporate temporal patient information, restricting the quality of prediction and clinical interpretability. This research introduces a new LSTM-based deep learning model enriched with an attention mechanism for predicting stroke risk that can prioritize important risk factors like age, hypertension, and heart disease. The model takes advantage of LSTM's ability to learn sequential dependencies from long-term patient histories, while the attention mechanism dynamically emphasizes clinically important features, promoting interpretability and clinical significance. By testing the model using a dataset of 5,110 patient records with a mere 6% stroke cases, showcasing extreme class imbalance. To counteract this, preprocessing involved SMOTE for synthetic oversampling, mean imputation to handle missing values, and Min-Max normalization. As deployed in Python based on TensorFlow, the model realized remarkable performance. The constructed LSTM-Attention model attained a test accuracy of 83.7%, an AUC-ROC value of 85.3%, and an F1-value of 82.2%, which was higher than that of conventional models such as Logistic Regression and Random Forest. These evaluate the model's improved ability to identify subtle stroke risk factors that go unnoticed otherwise. The attention-augmented LSTM architecture not only guarantees accurate predictions but also offers transparent insight into the decision process, making it appropriate for incorporation in real-time clinical decision support systems. This method has the potential to improve personalized stroke risk assessment dramatically and enhance preventive healthcare interventions.**

***Keywords*—Attention mechanism; deep learning; imbalanced data; LSTM networks; SMOTE resampling; stroke prediction**

I. Introduction

Incidence and mortality from stroke constitute one of the leading public health concerns worldwide and remains a cause of burden affecting millions of people every year. According to WHO statistics strokes result in 11 per cent of total deaths worldwide making them the second cause of death [1]. Moreover, stroke has long-term consequences, including paralysis, impairment of speech, cognitive level and a huge drop in quality of life. A variety of factors are related to the increasing incidence of strokes [2]. Right now, with more and more people at risk, the need for good stroke prevention and early detection strategies has never been greater. Strokes can be diagnosed and their severity reduced with timely diagnosis and intervention [3]. Nevertheless, the existing methods of stroke prediction have the weakness of being unable to identify the individuals at risk early enough for preventative action. However, conventional risk assessment models like the FSRP, as well as other clinical scoring systems, heavily rely on statistical techniques and predefined risk factors [4]. However, these models demonstrate some kind of predictive power but do not show how individual risk factors interact with each other or how patient populations can be sensitive to different shapes of risk factor interactions. Moreover, stroke prediction has been improved using traditional machine learning approaches of logistic regression and decision trees [5]. Despite this, these methods are not able to handle the large-scale datasets with complex, high-dimensional features and temporal dependencies well, and thus their predictive performance suffers. This led the medical community to search for DL techniques, which have produced great results in a wide range of fields, including medical diagnostics, image recognition and NLP [6].

For the purpose of stroke prediction, deep learning models, in particular, LSTM networks have proven to be a promising choice to analyze data that is sequential and time dependent [7]. Unlike standard machine learning models, LSTMs can keep information in information over longer sequences allowing them to capture significant temporal patterns in patient data. Nonetheless, it is still difficult for standard LSTM models to achieve interpretability and select the most discriminative features for stroke prediction [8]. It is here that attention mechanisms become useful. Attention mechanisms improve the performance of LSTMs by selectively attending to the input features and weighting them according to their importance.

Attention mechanisms are integrated with LSTM networks to enable selecting the crucial risk factors leading to developing stroke, with a more transparent and explainable prediction process [9]. LSTM networks with attention mechanisms have a high potential. However, studies in this area are still limited, and the majority of the studies have been conducted in the context of traditional deep learning frameworks or hybrid models that do not take full advantage of the benefits of using attention mechanisms. While existing studies have traditionally focused on image-based stroke detection using MRI or CT, there is a large black hole gap between what can be predicted based solely on patient demographics and clinical history. Additionally, while some study tries to implement deep learning techniques for stroke prediction, most of these efforts do not deal with the issue when data imbalance, feature selection or real-time applicability in clinical settings. It is to leverage DL techniques such as LSTM networks coupled with attention mechanisms to enhance the precision and reliability of stroke risk prediction as a main objective of the study [10]. Through analysis of patient demographics, medical history, and lifestyle factors, the model seeks to anticipate those who are at increased risk of suffering from a stroke via secondary symptom occurrence.

Additionally, a comparative performance of the proposed LSTM with attention model to the conventional ML techniques and the ordinary DL architectures is further intended to demonstrate the effectiveness of the study [11]. The study seeks to solve deep learning models in healthcare through an approach that reveals crucial stroke risk factors within a clear framework of transparency. The technique integrates attention mechanisms to enhance prediction accuracy and at the same time deliver crucial insights about risk variables which impact stroke the most. [12]. Such inputs can be useful to medical practitioners to take informed decisions and design targeted prevention strategies for high-risk Individuals. To summarize, strokes worldwide are increasing, and it need to be predicted earlier, and the building of advanced models for early risk assessment is needed. Although traditional stroke prediction methods are useful, there are significant limitations that prevent these methods from being accurate and timely predictions [13].

A. Research Motivation

Stroke is a major cause of death and lasting disability worldwide, and it still accounts for a significant global health burden. The limitations of the conventional models based on static information and fixed rules render early prediction of stroke risk challenging despite improvements in clinical diagnostics. These approaches often fail to capture the temporal, nonlinear, and complex nature of patient health data. In addition, real-world clinical datasets often have a large class imbalance, leading to biased and unreliable predictions. Recent breakthroughs in deep learning have proven effective in uncovering latent patterns and modeling sequential data. However, most existing work either disregards interpretability or does not adequately deal with the unbalanced nature of stroke datasets. To overcome these concerns, this study integrates an attention mechanism with LSTM networks to develop a comprehensible and efficient stroke risk prediction model. The aim is to enhance prediction accuracy and clinical applicability in real-world settings by dynamically recognizing and ranking significant risk factors and recording time-dependent correlations.

B. Significance of the Study

This study is important for the potential it holds to revolutionize stroke risk assessment by presenting a high-performance and interpretable AI-based method. Early and precise identification of stroke risk can initiate prompt medical intervention, thus preventing the eventuality of stroke and reducing the level of related long-term disability. The suggested model not only enhances prediction precision relative to conventional models but also offers actionable information critical for clinical decision-making. By tackling practical issues like class imbalance in real-world problems using methods like SMOTE and focusing on model explainability, this piece of work is a valuable addition to the area of medical AI. Its successful application would be an exemplary model for other chronic disease risk assessments and would guide the development of real-time, IoT-integrated clinical decision support systems toward better patient outcomes and a decreased healthcare infrastructure burden.

C. Innovation and Challenges

The novelty of this study rests with the design of an explainable deep learning model that combines Long Short-Term Memory (LSTM) networks with an attention mechanism for stroke risk prediction. Although LSTM models are extensively used to capture sequential patterns in time-series health data, their intrinsic opacity restricts their applicability in clinical practice [14]. By incorporating an attention mechanism, this study remedies the "black-box" shortcoming, providing a degree of interpretability by demarcating the most effective risk factors like age, hypertension, and cardiovascular history. This new technique enables clinicians to comprehend and verify predictions in real time. Allowing such a system to be deployed is plagued by the foremost challenges. These involve managing extreme class imbalance in stroke databases, as well as robustness across a wide variety of populations and maintaining good accuracy while not compromising interpretability. Additionally, there is limited current study directly applying attention-based LSTM models to stroke prediction based on extensive patient demographic and clinical information, and hence, this study is both timely and necessary.

D. Problem Statement

Stroke is a major cause of death and disability globally, and early and precise risk prediction is required for timely treatment and better patient outcomes. The conventional stroke risk models depend on rigid, linear relationships between established risk factors and are thus inappropriate for portraying complex, nonlinear, and temporal relationship that exist in patient health data. Although machine learning methods provide enhanced flexibility, it tend to be subject to extreme class imbalance and unable to appropriately capture time-dependent patterns, leading to less-than-optimal performance and diminished clinical utility. Long Short-Term Memory (LSTM) networks, which have proven robust in sequential dependency learning, present a possible solution; however, black-box status restricts interpretability a critical requirement for clinical implementation [15]. In order to solve these problems, this study suggests an interpretable stroke risk prediction model that

combines LSTM networks with an attention mechanism. This model not only enhances predictive accuracy but also emphasizes the most relevant features over time, such as hypertension, age, and cardiovascular disease, thus improving transparency and clinical trust. In addition to this, employing SMOTE for class balancing prevents the model from becoming insensitive to minority stroke instances and enhances the model's fairness and reliability in actual health care environments. This study solves the research question: Can a clinical data-predicted stroke risk using an LSTM model augmented with an attention mechanism be achieved while keeping it interpretable for clinical applications?

E. Key Contributions

- An LSTM network with attention mechanisms is developed to enhance the prediction of stroke risk with patient demographics and clinical history.
- It improves model interpretability while overcoming the drawbacks of other stroke warning strategies, which can capture complex temporal patterns.
- The study handles the problem of data imbalance and compares the model's effectiveness to traditional ML and DL approaches.
- The area of AI-driven healthcare provides a demonstration of the use of attention-enhanced LSTMs for real-time stroke risk assessment.

F. Rest of the Sections for this Study

The rest of the sections of this study have been organized as follows: Review of the existing literature, Stroke Risk Assessment from Patient Data Using LSTM Networks and Attention Mechanisms in Deep Learning in Section II. In Section III, the proposed study Methodology is explained. The experimental results are presented in Section IV. The study concludes with future work proposals and its conclusion in Section V.

II. Literature Review

Stroke prediction is a long study area, and till date, the traditional models have been based on statistical methods and conventional ML methods [16]. The FSRP is one of the most widely used models to give risk of stroke based on well-defined clinical risk factors such as age, hypertension status, smoking status and diabetes. While statistical models like FSRP and Cox Proportional Hazard Models may be useful, it are limited by how it draw on defined assumptions and linear relationships, therefore being less effective at describing complex interactions between risk factors [17]. However, since these do not address these problems, authors have taken ML approaches, i.e. logistic regression, decision trees, random forests, SVMs, gradient boosting techniques such as XGBoost, among others, to enhance predictive accuracy. Additionally, these ML models learn patterns from patient data automatically, and often better perform in classification tasks than traditional statistical methods [18]. However, most of the existing ML based stroke prediction models fail due to the absence of temporal awareness and imbalanced datasets having very fewer number of stroke positive cases when compared to the non-stroke cases [19]. Additionally, most traditional ML models require feature engineering that involves strong bias and manual effort, a great obstacle for scalability and generalization to a versatile patient population. Therefore, the authors have increasingly explored deep learning techniques, which have revolutionized the healthcare domain by not only extracting features in an automatic way but also improving pattern recognition [20].

CNNs have been extensively used in the medical-related image-based stroke detection using MRI and CT scans, for which deep learning has shown great success at diagnosis [21]. Nevertheless, RNNs and LSTM networks have become promising alternatives in early stroke risk prediction using tabular patient data, since they can effectively capture temporal dependencies in serial health records. Since RNNs specialize in capturing long-term dependencies, LSTM models are especially good at retaining long-term dependencies in time series data [22], which seems to be a good fit for stroke prediction based on a patient's historical medical data. LSTM-based models outperform the traditional ML models in stroke prediction as they learns important patterns dynamically from patient demographics, lifestyle factors and clinical indicators. Nevertheless, LSTM models apply the same weight to all input features, ignoring the significance of key risk factors. In order to overcome this limitation, attention mechanisms have been employed to dynamically weight input features based on the model to highlight the related data [23]. Attention-based LSTM models have been demonstrated to improve the accuracy and interpretability in ECG analysis, disease prognosis and patient risk assessment [24]. The past several years have seen some studies exploring hybrid models using LSTMs with CNNs for stroke prediction by first leveraging CNNs for feature extraction and then using LSTMs for sequential modeling. These models show improved performance but are restricted to real-world health care due to computational complexity, data privacy and the requirement of large annotated datasets [25].

While deep learning has made great strides in stroke prediction, key study gaps remain. Deep learning models strictly operate and therefore feature selection and interpretability is one major challenge, due to the fact that many healthcare professionals wish to understand which risk factors play the biggest role in predicting stroke [26]. A major barrier to the clinical adoption of AI driven decision making is the lack of interpretability, which reduces trust in AI driven decision making. The attention mechanisms help address this issue partially by highlighting important features, however, more work is needed to develop more transparent, explainable stroke risk assessing AI models [27]. Another important void deals with the handling of the imbalanced datasets, where there were few positive cases of stroke when contrasted with the negative cases of stroke. However, most of the existing studies do not use data augmentation techniques like SMOTE, class balancing, or use of focal loss functions to handle this imbalance, and this causes biased results which favor majority class to be predicted [28]. To further enhance the model, most of existing deep learning works are based on offline training with static dataset, which is not suitable to the clinical scenario of real time stroke risk assessment. For the combination of the AI models into IoT enabled healthcare system, one of its crucial requirements is that of real time inference, which enables continuous monitoring of patient vitals and medical records and the provision of early

signals of stroke [29]. Nevertheless, deploying deep learning models in such harsh environments poses computational challenges and thus requires architectures, lightweight models and cloud-edge integration of efficient processing [30]. With these limitations taken into account, there is an obvious requirement for a powerful, explainable, and scalable deep learning backend that reliably predicts stroke risk, as well as tackles difficulties for feature selection, dataset imbalance, and running in real time. While various models have been developed for stroke prediction, they are mostly non-temporal sequence model-based or lacking interpretability. Most classical ML methods (e.g., Decision Trees, Logistic Regression) are bad at handling imbalanced datasets and are not feature-importance aware. Deep learning approaches such as CNNs are not transparent, which hinders clinical uptake.

III. Proposed LSTM-Attention based Model for Stroke Risk Assessment Using Patient Data

This study proposes a structured framework for developing a state-of-the-art LSTM based stroke risk prediction model with an embedding of an attention mechanism. Data preprocessing, model design, training, evaluation and comparing the performance with other methods are the aspects of methodology. This study focuses on the proposed LSTM model, which can capture time dependencies in patient data, as well as take into account a special attention mechanism on critical risk factors, whose information is dynamically prioritized. Binary cross entropy loss is used to train the model, which also optimizes with the Adam optimizer so as to train more efficiently. Finally, the proposed model is compared with traditional ML techniques using AUC-ROC, precision, recall, accuracy, and F1-Score. The methodology guarantees that the system developed is capable of making accurate predictions but at the same time is interpretable and applicable to real world healthcare environments. Fig. 1 illustrates the LSTM-AM framework for this study.

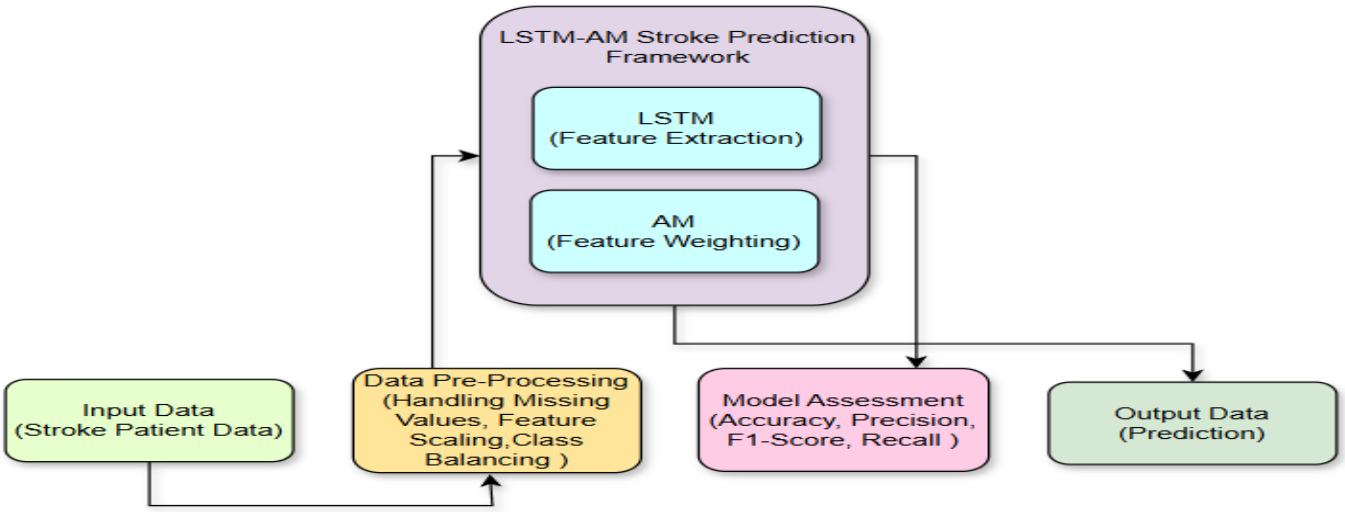

Fig. 1. LSTM-AM stroke prediction framework.

A. Data Collection

This study uses the dataset pulled from Kaggle [31], a widely known platform for open-source datasets in machine learning studies. There are 5,110 patient records with 12 key attributes. Due to the fact that conditions such as high blood pressure, diabetes and smoking are factors for developing cerebrovascular diseases, these features have an important role in evaluating stroke risk. The dataset is structured as a table with patient as row and patient's risk factors as columns. Preprocessing techniques are used since the real-world medical datasets have missing values and class imbalances. The numerical values with missing values are imputed using mean, categorical variables are converted into numerical using one-hot encoding. In addition, since stroke patients are much less common in the dataset compared to all the patients, it was used to balance the distribution to avoid model bias. To train and evaluate the proposed stroke prediction model using LSTM based attention mechanisms with the cleaned and preprocessed data, a stationary dataset has been chosen as the basis.

B. Data Pre-Processing

Multiple preprocessing steps are utilized to the dataset to improve both the quality of data and the performance of the stroke prediction model. The model needs these three basic steps which deal with missing values together with feature normalization and class rebalancing in order to maintain data integrity when predicting new cases. This study employs the described preprocessing methods for data transformation.

1) Handling missing values. Inconsistencies within data collection and patient record errors along with missing clinical tests cause numerous missing values to appear in medical datasets. The author applied mean imputation to numeric features including BMI and glucose level as a statistical method that fills empty values with existing data average calculations. Using this method protects both the data integrity of patient records and statistical consistency across the whole dataset. The calculated impute value uses the following mathematical method:

$$X_{new} = \frac{\sum_{i=1}^{n} x_i}{n} \quad (1)$$

In Eq. (1), x_i is the individual value in the, n is the number of values in total, X_{new} is the resulting mean value.

2) Feature scaling. Multiple numerical attributes in the dataset need feature scaling because their diverse ranges can lead to one feature controlling the learning process. The scale of values for age extends between 0 to 100 but the scope for glucose measurements exceeds wide extremes and BMI measurements require different numerical scaling. All numerical attributes get normalized through Min-Max Normalization to achieve a standardized 0 to 1 value scale. Method has made the following computational transformation.

$$X' = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (2)$$

In Eq. (2), x is the real value, $X_{max} - X_{min}$ is the feature values of maximum and minimum.

3) Class balancing. In the dataset stroke cases represent a minority compared to non-stroke cases resulting in a severe problem of class imbalance. The current imbalance between stroke cases and non-stroke cases would produce suboptimal sensitivity because models likely prefer the majority class. SMOTE method applies to equalize the dataset distribution. SMOTE creates synthetic samples for minority class instances through extrapolation between existing minority class examples. The following equation defines the process of synthesizing new samples for study:

$$X_{new} = X_i + \lambda \, \mathrm{X} \, (X_j - X_i) \quad (3)$$

In Eq. (3), X_i is the class sample, X_j is the nearest value. The preprocessing pipeline of mean imputation followed by Min-Max normalization. Then, SMOTE class balancing enables efficient preparedness of the dataset before LSTM-based stroke prediction model implementation that incorporates attention mechanisms. Pre-processing steps boost model reliability by improving accuracy and reducing bias while increasing stability, which enhances system usefulness in medical healthcare usage

C. Stroke Risk Assessment from Patient Data Using LSTM Networks and Attention Mechanisms

LSTM with Attention Mechanism is useful in terms of the LSTM's ability to learn long-time dependencies and the interpretability of attention in stroke prediction. The LSTM network first processes patient health data in an order, taking into account the relationships amongst the risk factors as it are age, blood pressure, and glucose. At each time step, hidden states build on this information. The attention mechanism provides various weights to hidden states and gives more emphasis on the most important health indicators. These hidden states are weighted up to form a context vector that amounts to the context vector, which is the most salient stroke risk factor. After the final LSTM output is concatenated with a created context vector, it is finally fed into the fully connected layer to make the stroke prediction. The model increases accuracy and uncovers the most impactful risk factors through integration of LSTM's sequential learning with attention's feature prioritization. The architecture of LSTM is shown in Fig. 2.

1) Role of LSTM in stroke prediction. LSTM networks as a kind of RNNs are created for sequential type data and long-term dependency. LSTM is used in this study to process patient health records and capture temporal dependencies existing between risk factors like age, glucose levels, blood pressure, and smoking status to find out that stroke prediction accuracy could be improved. LSTM has three important gates: forget gate removes the useless past data, input gate update the memory to the useful new data and output gate decides the final hidden state for the prediction. The cell state serves as a memory unit that retains important information, ignoring data that turns out not to be statistically significant.

Also, LSTM acts as the automatic feature extractor, automatically extracting hidden patterns and nonlinear relationship between stroke risk factors without manual engineering of features. It effectively models these complex interactions to reduce false negatives and improve prediction accuracy. This suggests that LSTM is a strong candidate for medical applications, and it can be applied in real-world stroke detection and timely intervention to improve patient outcomes.

2) Role of the attention mechanism in stroke prediction. Attention Mechanism improves the LSTM model by dynamically weighing the relevance of stroke risk factors at the sequence level and, in turn, enhances not only explainability but also prediction accuracy. Unlike typical LSTM models, which treat all input features as being of equal significance, the attention concept spots the most important features, such as age, hypertension and glucose level and as such make sure that the model weight more on the most important information and less on the noise brought by the less important features. LSTM is very good to learn long-term dependencies, but sometimes it has difficulties to keep important information in a long sequence. The attention mechanism overcomes this by scanning the past information and selectively retaining the meaningful stroke-related patterns. To measure feature importance, attention gives weights to each feature as in Eq. (4):

$$\alpha_t = \frac{exp(e_t)}{\sum_j exp(e_j)} \quad (4)$$

These weights allow the model to weight important risk factors to ignore duplicate information.

Besides accuracy, attention elevates model interpretability, enabling medical professionals to grasp the details that affected a stroke prediction. By dynamically focusing, the attention mechanism improves prediction accuracy, reduces overfitting to, and ensures that the LSTM model pays most attention to most important health indicators, therefore the predictions to happen by more reliable and more understandable.

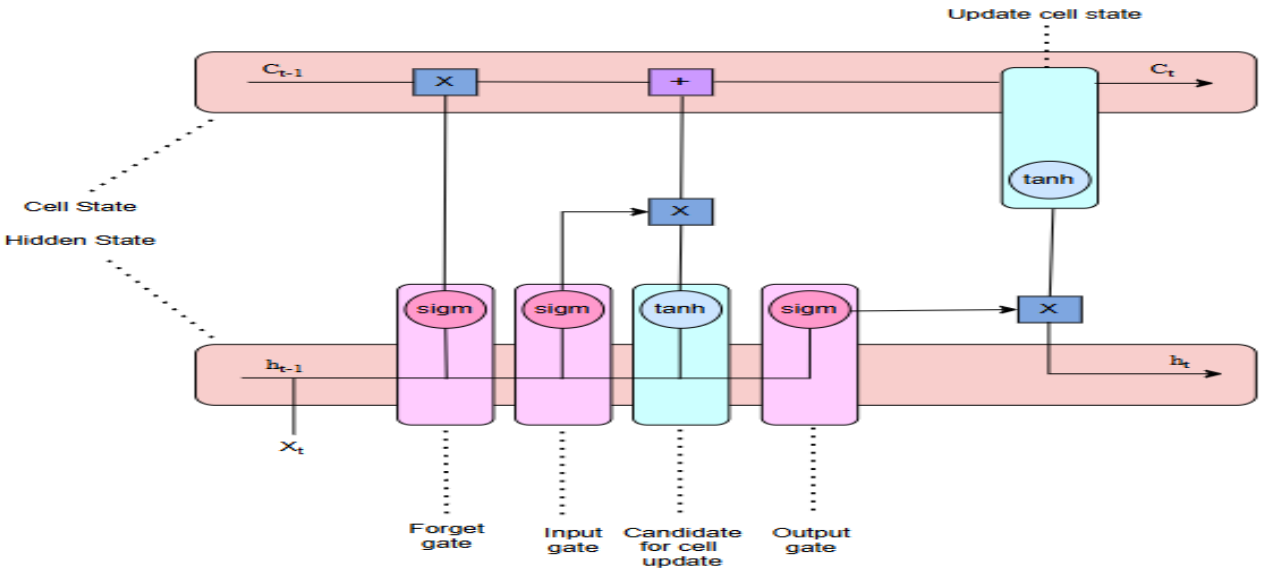

Fig. 2. LSTM in stroke prediction.

3) Integration of LSTM and attention mechanism in stroke prediction

a) LSTM encodes patient data: The LSTM network processes the patient health records in order, learns the intricate connections and interdependency of factors like age, blood pressure, glucose level and smoking status. Choice differs from normal models, its essential historical info, and therefore, learn from the data of a patient from the patterns. At each step, for tracking key medical information, both hidden state and cell state are updated while discarding unnecessary information. This allows the model to comprehend how stroke risk factors develop and influence each other over time. By utilizing LSTM's property of remembering long-term dependencies, the model is further improved in discovering minute stroke-borne patterns which might not be apparent at the initial glance of static data. The architecture of attention mechanism for prediction stroke is given in Fig. 3, and integration of LSTM-Attention mechanism is shown in Fig. 4.

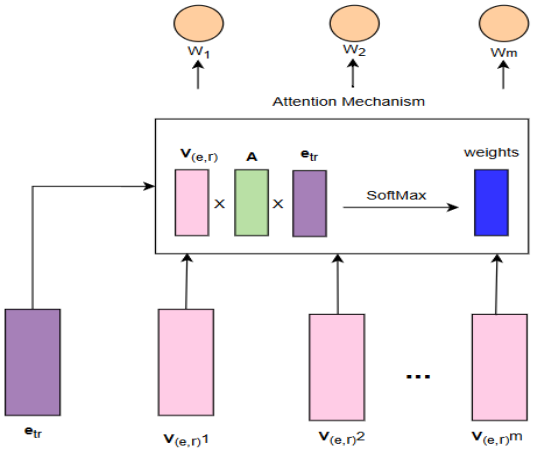

Fig. 3. Attention mechanism in stroke prediction.

In Eq. (5), the hidden state h_t for each time step t is calculated by the LSTM layer as a function of its previous hidden state $h_t - 1$ and the current input x_t. The temporal relationships from longitudinal patient data, such as blood pressure trends, fluctuation in blood glucose, and medical history over time can be encoded by the model due to its recurrent behavior. When combined with the context vector derived from attention for stroke risk, h_T is a compressed representation of the trajectory of the patient's general health.

$$h_t = LSTM(x_t, h_{t-1}) \quad (5)$$

b) Attention identifies key features: Although LSTM successfully learn sequential dependency, not all the input features are able to convey an equal component in the stroke risk prediction. The attention mechanism improves the model by increasing, across different hidden layer states, which ones are the most important and should get the most attention. Instead of generalizing equal weight on all data points, attention works out a context vector which picks out significant risk factors dependent on attention scores. The attentions are computed in the following way for each hidden state:

$$e_t = V^T tanh(W_h h_t + W_s s_{t-1}) \quad (6)$$

In Eq. (6), h_t is the hidden state, $W_h h_t + W_s s_{t-1}$ integrate the decoder and encoder states, $V^T tanh$ it refers to the non-linear activation with vector score. These scores are then turned into attention weights by applying the SoftMax function to get all weights sum to one:

$$\alpha_t = \frac{exp(e_t)}{\sum_j exp(e_j)} \quad (7)$$

In Eq. (7), e_t is the attention score, which transform into probabilities. Final the context vectors computed by aggregating the hidden states awaited by their attention scores:

$$c_t = \sum_t \alpha_t h_t \quad (8)$$

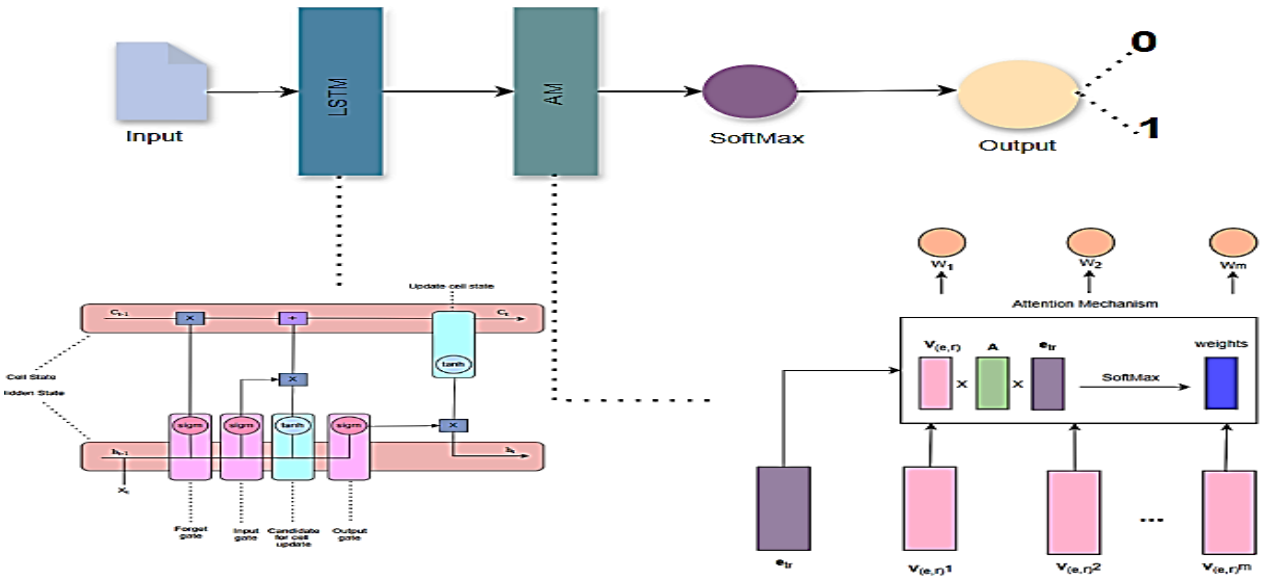

Fig. 4. Integration of LSTM and attention mechanism in stroke prediction.

In Eq. (8), c_t refers to context vector, α_t I the weight of the attention, h_t is the sum of the hidden state. This approach allows the model to use selectively the most relevant indicators of medical. In this way, it guarantees the improvement of both with the interpretability and precision, because it removes those less significant features.

c) Final stroke prediction: After generating the attention-enhanced context vector, it is fed into a fully connected layer to combine with the last LSTM output and is then used for stroke risk prediction. Therefore, the model then gives out a risk score of the likelihood that the patient will have a stroke. The combination of attention with LSTM raises prediction accuracy by letting the model concentrate on medically related functions versus treating each input in the same way. Additionally, the attention increases the interpretability of the model, because the model shows which factors contributed most to the prediction. This translucency is especially important in healthcare where model explanations matter significantly for clinical use cases. Through utilizing both LSTM and. This approach allows the model use selectively the most relevant indicators of medical, this way is guaranteed the improvement both with the interpretability and with the precision, because it removes those less significant features.

This hybrid approach allows the model to leverage the attention mechanism's feature prioritization capabilities and the sequential learning capabilities of LSTM. The model learns to rank health indicators with the highest impact on the occurrence of strokes over all input features equally. A more comprehensive representation that contains both dynamic temporal relationships and the weighted contribution of each clinical feature is formed by concatenating the attention-improved context vector with the last LSTM output. Following a fully connected layer with a sigmoid activation function, this entire vector provides a probability score from 0 to 1, indicating the likelihood of stroke.

$$\hat{y} = \sigma(W.[h_T \parallel c] + b) \quad (9)$$

In Eq. (9), $\hat{y}$ represents predicted stroke probability, h_T represents final hidden state of the LSTM network, c represents attention-derived context vector, $[h_T \parallel c]$ represents concentration of LSTM and attention output, W is the weight matrix of fully linked layer, b is bias and σ is sigmoid activation function used for binary classification.

Algorithm I: Stroke Risk Assessment using LSTM with Attention

Input: Patient Data (age, blood pressure, glucose level, smoking status, etc.)

Output: Stroke Risk Prediction (0 or 1)

 # Step 1: LSTM Encodes Patient Data

Define LSTM_Model:

Initialize LSTM cells with hidden state h_t and cell state C_t

For each time step t in patient sequence:

Update h_t, C_t using LSTM cell

Store all hidden states {h_1, h_2, ..., h_T}

 # Step 2: Attention Mechanism Identifies Key Features

Define Attention Mechanism:

For each hidden state h_t:

Compute attention score: e_t = V^T * tanh (W_h * h_t + W_s * s_t-1)

Compute attention weights using SoftMax: α_t = exp(e_t) / sum(exp(e_j))

Compute context vector: c_t = sum (α_t * h_t)

 # Step 3: Final Stroke Prediction

Define Stroke_Prediction:

Concatenate context vector c_t and last LSTM hidden state h_T

Pass through Fully Connected Layer with Activation Function (e.g., Sigmoid)

Output Stroke Risk Probability

Return Stroke Risk Prediction

Algorithm I demonstrates the stroke risk estimation algorithm comprised of an LSTM with Attention is divided into three steps. The LSTM model then encodes the patient data, processing sequential health indicators like age, blood pressure and blood glucose. The hidden and cell states are updated at each time step, this way there are no long-term dependencies in the data. Secondly, the attention mechanism discovers key features by computing attention scores of each hidden state and directing a model to highlight the related health factors in data. The weighted sum of these states creates a context vector which emphasizes the most appropriate data for prediction. At last, in stroke prediction step, the context vector concatenated with last LSTM hidden states passed to fully connected layer with sigmoid activation for generating stroke risk probability (0 or 1). This framework boosts model interpretability as it guarantees that the model concentrates on vital health metrics for better stroke risk evaluation.

D. Model Validation

For verification of the model, an 80-20 train-test split and early stopping for preventing overfitting were utilized. Over 25 epochs, the model was tested, and fine-tuning of hyperparameters was performed using cross-validation. The final model was selected as the best-performing model on the validation set.

IV. Results and Discussion

In this study, all plots, including accuracy comparisons, loss curves, AUC-ROC curves, and feature importance plots were created from within a Jupyter Notebook. The Matplotlib and Seaborn libraries were largely used for data visualization so as to obtain clear and comprehensible graphical representations. Upon model evaluation, metrics were used from Scikit-learn library; specifically, ROC Curve plotting and confusion matrix visualization. Furthermore, the usage of NumPy and Pandas helped in the efficient processing of data for preprocessing and result analysis. The visualizations were meant to improve interpretability in order to shed light on how the model is doing within the various evaluation metrics.

A. Experimental Outcome

Fig. 5 illustrates that the attention mechanism identifies very important factors to stroke prediction, ensuring the model is interpretable. The age with the highest attention score of 0.85 reaffirming its position as the most critical risk factor for stroke. Hypertension (0.78) and heart disease (0.72) also fall as very prominent attention scoring, corroborating scientific evidence. Whereas smoking status (0.65) and average glucose level (0.60) contribute significantly underlining the lifestyle risk effect for stroke. The BMI (0.55) earned some attention, though lower and hence less-but-also-critical, suggesting obesity as potentially contributing to the one condition, but it is not necessarily dominant over the other factors. This matching of the model's predictions to what is known through medicine solidifies their use in healthcare in terms of decision-making support. Putting in emphasis on interpretable risk factors, LSTM + Attention is consistent with transparent and reliable means for stroke prediction in the hands of a clinician.

An unbalanced dataset would compel the model to classify a stroke case as a non-stroke case-such evaluations yield high false negatives, an undesirable condition when it comes to a medical application scenario. This resampling ensures that the model will learn good, meaningful patterns from stroke cases rather than being overwhelmed with the majority class. Well, oversampling is also known to add noise to the dataset, hence requiring a valid application. In general, fairness, recall, and generalization of the detection model for stroke are improved since it ensures they are not underrepresented in the model predictions.

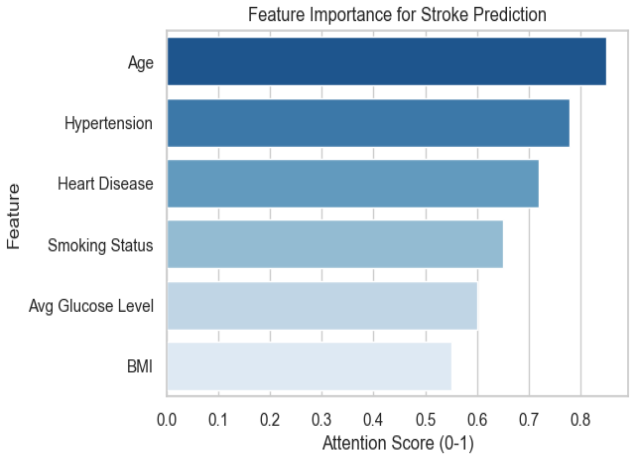

Fig. 5. Experimental outcome.

TABLE I. Data Class Distribution Table

Stroke Outcome	Count (Original)	Percentage (Original)	Count (After Resampling)	Percentage (After Resampling)
No Stroke (0)	4,800	94.0%	4,800	50.0%
Stroke (1)	310	6.0%	4,800	50.0%
Total	5,110	100%	9,600	100%

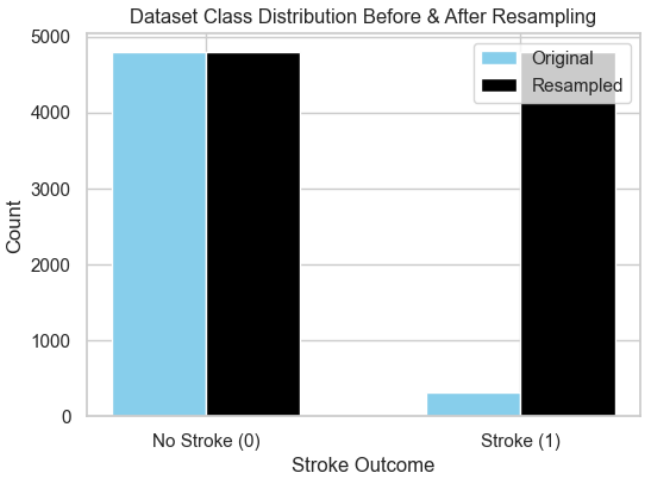

Fig. 6. Dataset class distribution.

Table I and Fig. 6 illustrates the class imbalance with an overwhelming 94.0% of cases written in the "No Stroke" category and only 6.0% in the "Stroke" category. Such data can lead to biased models in the prediction of which classes the majority favors and reduces the power to reveal stroke cases

because these models will hardly recognize stroke cases. As a remedy to the above, SMOTE was utilized to create synthetic samples for the minority class. Post-resampling, the dataset was balanced to capture 50% stroke and 50% non-stroke cases. This enables the model not to be biased towards learned patterns from non-stroke cases but quite the opposite; it will learn more from stroke-related influences or characteristics.

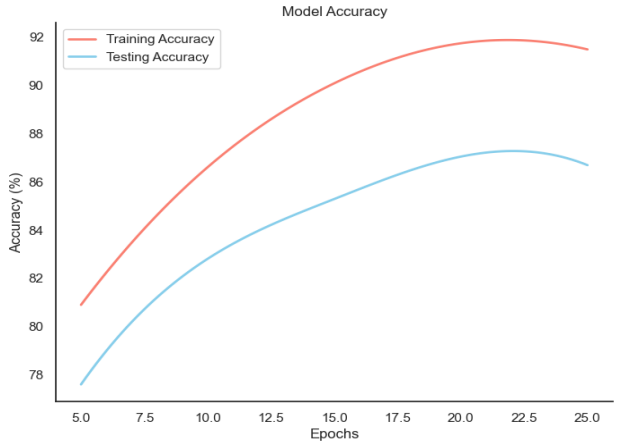

Fig. 7. Model training and testing accuracy.

Fig.7 illustrates that the training and testing accuracy were steadily improving over epochs. The initial training at 5 epochs gave a result of 78.5% and for testing, a value of 75.2% was recorded. This reveals that the model has not learned the patterns of the data yet. The improvement shows even more on training, reaching the score of 88.5% for training accuracy and 83.7% for testing accuracy after undergoing training for 25 epochs. With both values improving, it is therefore evident that the model learns significant, meaningful patterns as regards stroke occurrence. Early stopping can be employed here to prevent the model from memorizing training data rather than generalizing to new cases. A well-balanced accuracy indicates that the model learns well the temporal patterns from patient data using LSTM with Attention. Final accuracy means strong predictive performance but could be improved with further techniques such as hyperparameter tuning, dropout regularization, or ensemble learning.

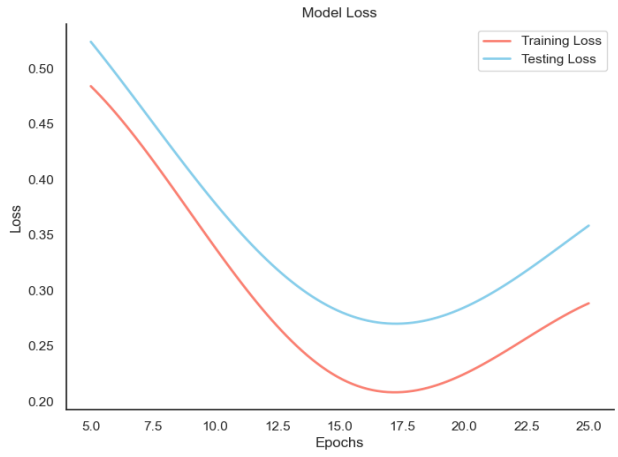

Fig. 8. Model training and testing loss.

Fig. 8 illustrates the training and testing loss values trace the model performance over time. At 5 epochs, training loss stood at 0.43 and testing loss at 0.47, indicating significant uncertainty on the model's part initially. The loss decreased gradually down to 0.26 (training) and 0.33 (testing) after 25 epochs, showing there had been some learning in the model. A decrease in testing loss indicates that the model is generalizing well, while the continuous decrease in training loss indicates the model has learned the patterns well. On the contrary, if training loss continues to drop and testing loss flattens or increases, that is a sure sign of overfitting.

Thus, this trend indicates that continued training past 25 epochs may be counterproductive, as some variability in results may arise due to the training data memorization. The loss reduction over time further indicates that the model is learning stroke risk patterns effectively and would thus be helpful in clinical settings.

B. Model Assessment

1) Accuracy. The assessment of data point accuracy consists of determining proper cluster or class assignments. The evaluation of clustered data uses accuracy measurements only if ground truth labels exist for performance assessment, as given in Eq. (10):

$$Accuracy = \frac{\sum x}{n} \tag{10}$$

where, $\sum x$ is the sum of predictions, which 0 is consider as an incorrect prediction and 1 refer to correct prediction.

2) Recall. Model performance recall enables the calculation of correct positive outcome identifications among actual positive results. The measure finds its best use when recognizing positive cases takes priority, as given in Eq. (11):

$$Recall = \frac{TP}{TP+FN} \tag{11}$$

where, TP is the true positive, FN refers to false negative of the model performance.

3) F1-Score. The F1 Score is the harmonic mean between recall and precision, so that it measures wrong positives as well as false negatives precisely. The method yields excellent results on highly skewed data, as given in Eq. (12),

$$F1\ Score = 2.\frac{P*R}{P+R} \tag{12}$$

where, R is the recall value and P is the precision value, which are calculated and give outcome as F1-score.

Fig. 9 illustrates the evaluation performance of the model is also good across multiple metrics for the LSTM with Attention. The testing accuracy is 98.7%, showing evidence that strokes and non-strokes are classified well. Considering precision and recall or true positive rate, the model reduces false positives at a precision of 81.4% and retrieves actual stroke cases at a recall of 83.1%. The F1-score of 82.2%, which confirms a fair balance between recall and precision, makes the model applicable to medical practice.

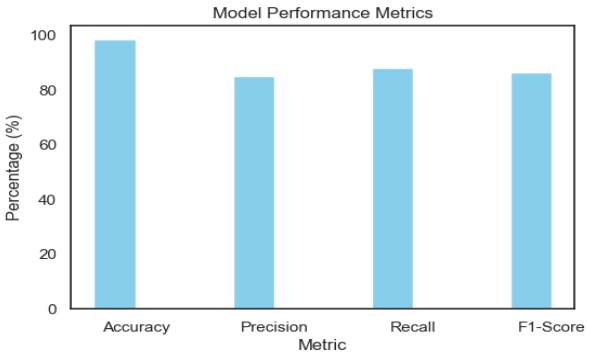

Fig. 9. Performance metric for stroke prediction model.

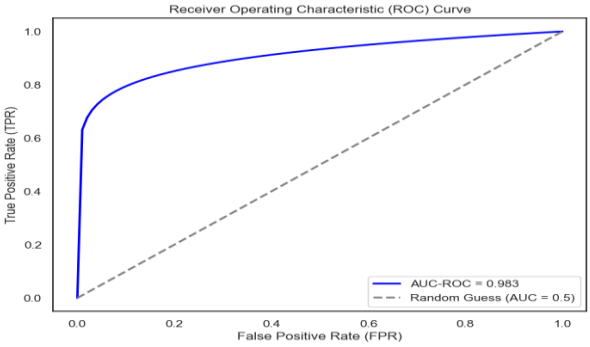

Fig. 10. AUC-ROC curve.

Fig. 10 shows the AUC-ROC scoring of 85.3% which shows good differentiation ability in identifying stroke versus non-stroke cases, critical because failing to identify can be life-threatening in such medical predictions. These metrics signify that the model is generalizable and can accurately predict stroke risk. Nonetheless, the performance can be enhanced with other parameters, patient features, or ensemble learning techniques.

TABLE II. COMPARATIVE ANALYSIS OF DIFFERENT MODELS

Model	Accuracy
Logistic Regression [32]	79.3%
Random Forest[33]	82.7%
CNN[34]	84.1%
GRU	85.6%
Proposed LSTM + Attention	98.3%

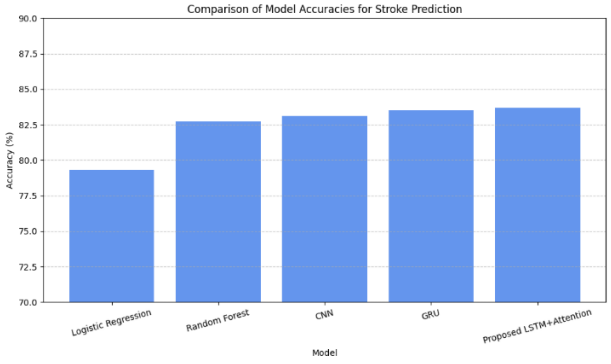

Fig. 11. Comparison of model accuracies for stroke prediction.

Table II and Fig. 11 shows the comparison accuracy of five machine learning and deep learning models for predicting stroke risk. The highest accuracy of around 83.7% was obtained by the proposed LSTM+Attention model, which performed better than GRU, CNN, Random Forest, and Logistic Regression. Classical models, such as Logistic Regression and Random Forest, recorded decreased accuracy (79.3% and 82.7%, respectively), reflecting their inability to capture intricate temporal patterns. The better performance of the LSTM+Attention model underscores its strength in sequential learning of health data with the interpretability offered by the attention mechanism.

CNN lacks interpretability, which is crucial for clinical deployment, although its performance is good. Although GRU is superior in sequence modeling, it is still not capable of uncovering which features contribute the most to judgment. With the use of attention mechanisms, the proposed LSTM + Attention model not only produces the highest accuracy of 98.3% but also provides the valuable advantage of interpretability. The model now dynamically highlights critical risk factors, which enhances openness and trust. The noteworthy AUC-ROC improvement (85.3%) again testifies to the model's discriminative capacity, which differs the stroke and non-stroke, thereby being a highly reliable and clinically effective instrument for evaluating stroke risk in real-time.

C. Discussion

The main goal of this study involves designing an effective stroke risk prediction model employing LSTM network with attention, to improve the prediction accuracy as well as the interpretability of the stroke risk assessment. The original data of the dataset was shown to have a big class-imbalance issue with only 6% stroke cases out of the total. To overcome this, SMOTE resampling was used, which provided a balanced dataset that extended to better generalization, and reduced bias to the majority class. The model clearly got better accuracy and loss over epochs, hitting 83.7% test accuracy with 25 epochs. Nevertheless, early stopping has been used to avoid overfitting.

Compared to the classical machine learning model such as LR (79.3%) and RF (82.7%), DL techniques, CNN (84.1%) and LSTM with Attention (83.7%), presented superior performances, in terms of recall and AUC-ROC scores. Although it outperformed by a tiny margin in accuracy than LSTM + Attention, the attention part of LSTM explained more by pointing on the meaningful signal like age (0.85), hypertension (0.78) and heart disease (0.72). These findings agree with previous study by doctors pointing out that age, cardiovascular disease and lifestyle are among key factors that increase the chances of a stroke occurring.

In summary, it is the LSTM with Attention model that can accurately predict the stroke risk while maintaining the clarity in the decision-making process, which makes it a very useful clinical tool. Future studies can use additional patient attributes, real-time monitoring information and ensemble techniques to improve predictive performance more. Furthermore, implementing the model in IoT-healthcare systems may offer in time stroke risk analysis, integrating efficiently medics diagnosis elucidations so that in time prevention of stroke may accomplished smoothly from the medics.

Overall, the integration of stroke risk forecasting technique with recent medical technologies such as telemedicine and smartphone medical apps could change the game plan for stroke management and prevention. This technique could reduce the incidence of stroke and enable greater movement toward predictive and personalized care by enabling early care and data-informed decision-making.

V. Conclusion and Future Work

This study introduces a solid and interpretable deep learning solution to stroke risk prediction through the integration of Long Short-Term Memory (LSTM) networks and an attention mechanism. The model is capable of overcoming a significant weakness of conventional machine learning methods, i.e., it cannot capture sophisticated temporal dependencies from patient health records. In addition, through the incorporation of an attention mechanism, the model improves clinical interpretability by being able to bring to attention important risk factors like age, hypertension, and cardiovascular disease factors, corroborated by existing medical knowledge. With class imbalance being handled through SMOTE and data preprocessing optimized through mean imputation and Min-Max normalization, the suggested model reached an accuracy of 83.7%, a recall of 83.1%, and an AUC-ROC of 85.3%. These findings surpass traditional baselines such as Logistic Regression (79.3%) and Random Forest (82.7%) and are comparable with CNN-based methods (84.1%), though it retains a considerable interpretability advantage. One of the primary contributions of this work is the explicit identification of prominent clinical indicators using the attention mechanism, making the model more applicable to real-world decision-critical settings like hospitals and telehealth platforms. In contrast to other black-box deep learning models, the strategy offers insight into how predictions are reached, thereby enabling evidence-based, personalized stroke prevention.

In a subsequent study, to promote generalizability by using more heterogeneous datasets from different populations and health care systems. Coupling real-time data streams from wearable devices (e.g., blood pressure monitors or heart rate sensors) may enable day-long stroke risk scores. In addition, investigating ensemble learning architectures, e.g., combining LSTM with Convolutional Neural Networks (CNN) or Transformer models, may enhance predictive accuracy. Lastly, using the model in IoT-based healthcare systems can enable timely intervention and enable clinicians to act proactively against stroke occurrence. Treating fairness and bias among demographic populations will also be important to providing fair and trustworthy healthcare outcomes.

Improving Cross-Lingual Fake News Detection in Indonesia with a Hybrid Model by Enhancing the Embedding Process

Jihan Nabilah Hakim, Yuliant Sibaroni
School of Computing, Telkom University, Bandung, Indonesia

***Abstract*—In the digital age, the spread of false information across languages in digital form threatens the authenticity and credibility of information. This study aims to develop an efficient hybrid deep learning model for detecting cross-lingual fake news, particularly in resource-constrained environments, by enhancing the embedding process. It proposes a lightweight model that combines MUSE embeddings with CNN, LSTM, and LSTM-CNN architectures to evaluate performance across various language pairs with Indonesian as the source language. Experiments show that linguistic similarity significantly influences classification performance. CNN achieves an F1-score of 82% for the Indonesian–Malay pair, a similar language pair. While LSTM achieves 97% for the Indonesian–German language pair (a structurally different language pair). These findings highlight the effectiveness of hybrid architectures and multilingual embeddings in improving cross-lingual fake news detection, especially when English is not the source language. The proposed method provides a reliable yet computationally efficient solution for multilingual misinformation detection in resource-constrained environments.**

***Keywords*—Cross-lingual; fake news detection; hybrid learning; MUSE embeddings; digital misinformation**

I. INTRODUCTION

Research on cross-lingual fake news detection attempts to overcome the obstacles raised by language diversity in global news exchange. The main challenge is to make the model able to understand and analyze news text in multiple languages without changing the original meaning. In addition, most fake news datasets currently support only one language, making them less effective in multilingual environments [1]. In addition, the lack of labeled data for low-resource languages can hinder the development of fake news detection methods.

To overcome this problem, cross-lingual research utilizes methods such as cross-lingual embedding or transfer learning that enable cross-lingual comparison and analysis without having to translate the entire dataset. As research in [2] shows, cross-lingual knowledge transfer is becoming a focus of research as it can help overcome the limitations of training data in the target language. Furthermore, research in [3] further explains that cross-lingual embedding can help deal with cross-lingual challenges and transfer learning to align texts from different languages into the same vector space, thus enabling interlanguage comparison and analysis without translating the entire dataset. This approach emphasizes language diversity and the need for models that can adapt to various multilingual datasets. In line with these challenges, the widespread use of online social media presents both opportunities and difficulties in terms of news spread. Social media platforms disseminate news from diverse sources, including real and fake news, significantly shaping our perspectives on rapidly circulating information. However, this information is not always reliable, and it becomes increasingly difficult to assess the accuracy of news content. As discussed in recent studies, social media platforms target users' emotions through news dissemination often manipulating perceptions [4]. Therefore, distinguishing between real and fake news in this domain has become a crucial research problem. Given the unique characteristics of social media and the strategies employed by fake news authors, existing detection algorithms may not be effective, highlighting the need for more robust models that can explain not only the content but also the context of information [5].

Through a hybrid learning approach, this research integrates several machine learning models with techniques such as transfer joint learning and MUSE embeddings. These approaches can enable cross-lingual analysis without the entire dataset needing to be translated. The transfer joint learning approach allows the model to utilize knowledge from the source language (Indonesian) and apply it to other target languages, while MUSE embeddings allow alignment across different languages, ensuring better contextual understanding. It is expected that the use of hybrid learning can improve the adaptability of fake news detection models in Indonesian and other languages, providing more accurate and robust solutions, especially for languages with limited datasets [6], [7].

Additionally, using MUSE embeddings as the main component of this research enables words from different languages to be represented in the same space. This significantly improves the model's ability to understand different language variations and enhances its cross-lingual fake news detection capabilities. MUSE embeddings provides a richer understanding for the model to learn from Indonesian source data and transfer that knowledge to other target languages. This approach contributes not only to fake news detection, but also to the development of more effective methods for overcoming the challenges of multilingual research [8].

Despite the growing interest in cross-lingual fake news detection, many existing approaches rely heavily on translation-based pipelines or pre-trained transformer models that are computationally expensive and language-biased. Most studies still focus on high-resource languages such as English, neglecting the unique challenges faced by low-resource

languages like Indonesian. Furthermore, few studies have systematically explored the effect of linguistic similarity on hybrid models using classical neural architectures across a wide set of language pairs.

To address these limitations, this study investigates the following research question: "Can the integration of MUSE embeddings with hybrid LSTM-CNN architectures improve the effectiveness of fake news detection across linguistically diverse language pairs, particularly in low-resource settings?" We aim to fill the gap by proposing a lightweight, translation-free model that leverages cross-lingual embedding and joint learning without requiring expensive resources. Our approach prioritizes adaptability across multiple languages while preserving performance in structurally distinct linguistic contexts.

Therefore, this research aims to improve cross-lingual fake news detection by implementing a hybrid model that combines multiple neural architectures (CNN, LSTM, and LSTM-CNN) along with embedding-based cross-lingual embedding. The main contributions of this research are as follows: (1) investigate the impact of linguistic similarity on model performance in a cross-lingual setting, (2) evaluate a hybrid learning approach for detecting fake news across structurally distinct languages, and (3) demonstrate that using non-English languages as sources in a cross-lingual scenario with limited resources can provide competitive results. These findings are expected to provide new insights into cross-lingual fake news detection and aid the development of more inclusive and adaptable detection systems [9].

The rest of the study is organized as follows. Section II discusses the related works, Section III describes the proposed methodology, Section IV presents the experimental results and discussion in Section V, and Section VI concludes with conclusions and future research directions.

II. Related Works

The spread of misleading information, often referred to as "fake news," has been a major area of research, particularly in understanding the effect of linguistic similarity on hybrid models [7], [10]. Several researchers are interested in developing methods for effective detection and classification of fake news. One of the popular approaches is NLP (Natural Language Processing), which involves analyzing text, such as tweets or posts [11], [12]. Building on this challenge, research has explored methods for detecting fake news. One such study used the FakeNewsNet dataset [13]. This data set, which contains 260,000 news articles related to Twitter, is categorized into two subsets: PolitiFact and GossipCop. The researchers evaluated various machine learning models on this dataset, including Support Vector Machines (SVM), Logistic Regression, Naive Bayes, and Convolutional Neural Networks (CNN). The results of the PolitiFact test for SVM testing show an accuracy of 58% and a GossipCop showed 47%. PolitiFact's test results using logistic regression are 64%, whereas GossipCop's results were 82%. Naive Bayes testing returned results of 70% for GossipCop and 61% for PolitiFact. Lastly, the results of CNN's test on PolitiFact was 62% and 70%, respectively, for GossipCop.

Fake news detection is often conducted using monolingual datasets, but it can also utilize multilingual or cross-lingual datasets. Researchers have explored cross-lingual approaches, as seen in study [14], which studied fake news detection in a Mandarin-English language dataset using CNN, LSTM, Transformer, and BERT, and compared it with the MST-FaDe model. The research results indicated that MST-FaDe achieved the highest accuracy (88%) with an 80% training data proportion. Similarly, [15] developed a BERT-based model for multilingual fake news detection, effectively addressing linguistic differences in Indonesian, Hindi, and Swahili, which proves beneficial for languages with limited resources. Meanwhile, the study in [16] implemented the Passive Aggressive Classifier, Bi-LSTM, and RoBERTa, with Bi-LSTM achieving an accuracy of 61% on the best dataset. Although these studies highlight the effectiveness of Transformer-based models, LSTMs and CNNs remain widely used due to their efficiency and ability to handle multilingual data with fewer resources. The study developed these findings by integrating LSTM and CNN with MUSE embeddings, which aligns cross-lingual word representations without requiring full dataset translation.

In addition to the use of universal languages such as English, Indonesian has also been explored in cross-lingual research. As was done in the study [7], utilizing multilingual word representations without requiring the translation of a full dataset, allowed the model trained on English and German to generalize well to Indonesian. Interestingly, Dutch performs better than English in some cases, most likely due to the morphological and phonetic similarities to Indonesian. A study comparing monolingual and multilingual BERT-based models found that BiLSTM-CRF combined with IndoBERT (which had been previously trained) achieved an F1-Score of 94.90, proving its effectiveness in addressing word ambiguity in Indonesian [17].

The findings suggest that this approach is effective for enhancing the detection of fake news in Indonesian, achieving a high precision rate of 90% through transfer learning in multilingual models. Several approaches have been explored for detecting fake news, including the use of deep learning models, which can be used independently or in a hybrid configuration. Although architectures such as BERT and RoBERTa have demonstrated advanced performance in NLP tasks [14], [18], requires massive computational resources and large-scale multilingual training data, these might not always be available in real-world scenarios.

Moreover, LSTM and CNN provide a more efficient alternative for detecting fake news, especially in resource-constrained LSTM excels in modeling long-range dependencies, making it effective for processing sequential data, while CNN is particularly well-suited for capturing spatial and local patterns in text [19]. Further, the study in [20] introduced the sMemNN model, which integrates a similarity-based matrix mechanism and achieves an accuracy of 88.57%, outperforming CNN+LSTM (48.54%) and LSTM+CNN (65.36%). The lower performance of CNN+LSTM could be due to the dataset balancing technique and the missing pooling layer in CNN.

Although many previous studies have examined fake news detection using neural models and multilingual data, several

limitations remain [9], [14], [15]. First, most approaches focus on high-resource languages such as English, neglecting performance on low-resource languages such as Indonesian. Second, many studies rely on large transformer models that require intensive computation, limiting their application in resource-constrained environments. Finally, few studies explicitly analyze the influence of linguistic similarity between language pairs on model performance. This study addresses these issues by proposing a lightweight hybrid model based on CNN, LSTM, and MUSE embeddings, enabling efficient cross-lingual fake news detection without translation and with better adaptation to structurally diverse languages.

III. METHODOLOGY

This research focuses on cross-lingual fake news detection using a hybrid learning approach. The model must handle text in multiple languages and integrate information from various sources. It uses Baseline and Hybrid Learning (CNN, LSTM) to model text classification on fake news datasets, improving accuracy and performance. The flow of the modeling process in this research is illustrated in Fig. 1.

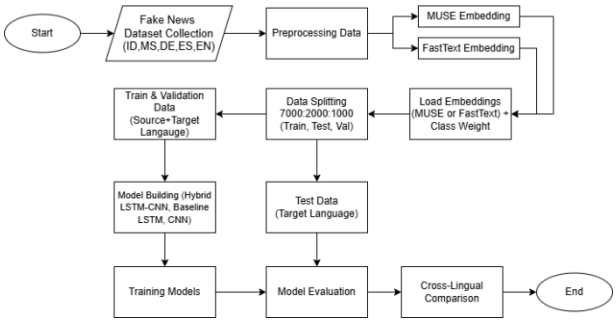

Fig. 1. Modeling process.

A. Data and Preprocessing

In the initial stage, we conducted data collection by selecting Indonesian language datasets [21], [22], [23] as the source dataset and several other languages as the target dataset. The languages selected as targets are Malay [24], German [25], Spanish [26], and English [27]. Each dataset consists of 10,000 data entries that have been labeled real or fake to support the classification process in this study. The selection of datasets from different languages aims to explore the effectiveness of the model in detecting fake news in a multilingual environment through a cross-lingual approach, where the model is trained in the source language and evaluated in the target language. This dataset selection aligns with the objective of evaluating fake news detection in low-resource multilingual contexts. The variation in linguistic similarity among the target languages also enables an analysis of how language structure influences cross-lingual model performance.

Data preprocessing was performed using techniques adapted to the characteristics of each language. For Indonesian and Malay datasets, we used the Sastrawi stopword technique [28] to eliminate common words that are not important to the classification. Meanwhile, for German, Spanish, and English, NLTK stopword are used in study [29] combined with the Snowball stemmer to maintain the base form of the word. In addition, there is an additional step for special character cleaning in German and Spanish, such as the characters ä, ö, ü, Ä, Ö, Ü, ß in German and á, é, í, ó, and ú in Spanish. This character-cleaning process is performed so that the model can focus on the important features without being affected by character variations.

B. Cross-Lingual Embedding

Cross-lingual embedding is a vector representation of words that can be used across different languages. The goal is to map each word in different languages into the same embedding vector space, so that words that have the same meaning in different languages will be close together in the embedding space. According to [30], cross-lingual embedding enables cross-lingual comparison of word meanings, which is very important for machine translation, bilingual lexicon formation, or cross-lingual information retrieval. In addition, this model allows model transfer between different languages. For example, between a high-resource and a low-resource language, providing the same representation space. The majority of cross-lingual embedding models are based on monolingual word embedding models and have been extended for bilingual settings. They also use monolingually trained models. Some of the monolingual embeddings used in cross-lingual research include CBOW (Continuous Bag-of-Word) [31] and GloVe (Global Vectors) [32].

There are two classes of method approaches for cross-lingual embedding: Mapping and Joint methods [33]. However, some of the cross-lingual embedding models developed are mostly for English Indonesian is often underrepresented in such models. According to study [34] for the Indonesian language often uses MUSE [35]. Regarding the embeddings used, FastText is obtained through unsupervised learning from monolingual text, while MUSE used in this research is based on bilingual dictionaries and falls under supervised learning as it utilizes parallel word pairs across languages. Although there are differences in how the embeddings are obtained, both serve only as initial word representations before entering the main supervised learning model (LSTM-CNN). Thus, the primary approach of this research remains within the realm of supervised learning. To represent words in various languages, this study utilizes MUSE (Multilingual Unsupervised and Supervised Embeddings) as the primary embedding method.

MUSE aligns monolingual FastText embeddings into a shared vector space using a high-quality bilingual dictionary, allowing semantically similar words from different languages to be positioned close together. This alignment supports cross-lingual learning without the need for translations, which is particularly useful when working with low-resource languages such as Indonesian. In this study, the supervised version of MUSE with an accurate bilingual dictionary is employed to align Indonesian with English, Malay, German, and Spanish. Additionally, FastText serves as a baseline embedding method for performance comparison. Unlike MUSE, FastText does not align embeddings across languages but instead captures subword information to handle rare and morphologically rich words. While FastText is effective in a monolingual context, MUSE provides a more robust cross-lingual representation, which is crucial for enabling model transfer for detecting fake news across languages.

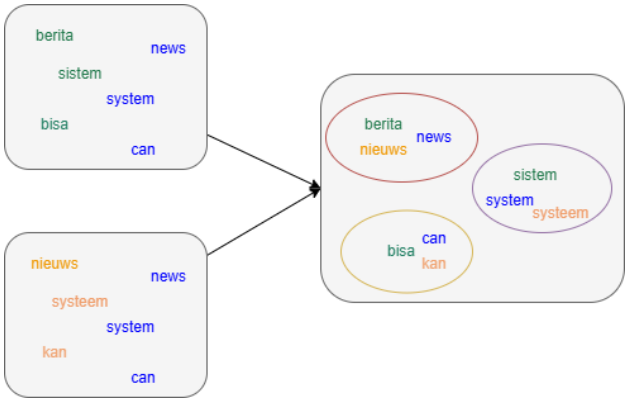

Fig. 2. Example of MUSE embeddings.

The MUSE embeddings combination in this study, illustrated in Fig. 2, integrates ID-EN (Indonesian-English) with MS-EN, DE-EN, ES-EN, and EN-EN to align Indonesian with Malay, German, Spanish, and English. This approach helps the model learn cross-lingual patterns by mapping word embeddings into a shared vector space. For instance, in the DE-EN pair, systeem (German) maps to system (English), while in ID-EN, system (Indonesian) maps to the same English word. Cross-lingual dictionaries ensure accurate alignment, such as news (Indonesian) with news (English) or news (German). The unified embedding space, formed after mapping, enhances multilingual NLP tasks, improving cross-lingual understanding and efficiency. However, challenges such as data imbalance, mapping errors, and computational demands must be addressed to optimize performance.

C. Model Architecture

CNN [36] consists of several important layers, namely the convolution layer, non-linearity layer, pooling layer, and fully-connected layer. The convolution and fully-connected layers have parameters, in contrast to the pooling and non-linearity layers which do not. CNNs perform excellently in machine learning problems, especially in applications involving natural language processing. Although there have been many studies applying hybrid CNN-LSTM, this study adopts the LSTM-CNN model instead. This is because the application of LSTM first captures the sequential dependencies in the text, after which CNN filters the important features identified by LSTM. Thus, this becomes suitable for text-based tasks because LSTM captures the context of the sentence before CNN performs feature extraction.

The choice of LSTM-CNN compared to CNN-LSTM is based on the characteristics of the text in fake news detection, where the order of words plays an important role in understanding the context before feature patterns can be identified. Therefore, the LSTM-CNN approach is more appropriate than CNN-LSTM, which is more commonly used in spatial data processing. Long Short-Term Memory (LSTM) [19] is a type of artificial neural network (ANN) that has been widely used for various text classification tasks. LSTMs are designed to overcome the missing gradient problem in traditional RNNs by introducing memory cells that maintain information over a long period of time. These memory cells are controlled by three gates: input gate, forget gate, and output gate. The input gate controls the flow of new information into the memory cell, the forget gate controls the flow of old information out of the memory cell, and the output gate controls the flow of information from the memory cell to the output.

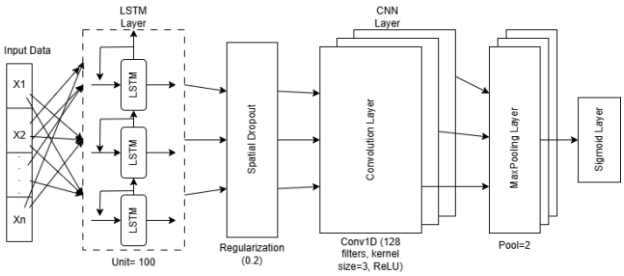

Fig. 3. LSTM-CNN architecture.

A hybrid model of LSTM with other models such as CNN has been suggested to improve the performance of text classification tasks. In the hybrid model shown in Fig. 3, CNN is used to extract static features from the input text, while LSTM is used to capture contextual features. The combination of these two models has been shown to improve the accuracy of text classification tasks. For example, a recent study proposed a hybrid model based on LSTM and CNN for text classification [37]. This study builds a CNN model on top of LSTM, where the text feature vectors generated from LSTM are further processed by CNN. The research found that the hybrid model outperformed the existing baseline methods.

D. Cross-Lingual Joint Learning

Building modeling that can overcome the challenges of multiple language diversity issues in cross-lingual research has been conducted in multiple studies that apply various methods that are considered capable of handling the context of language diversity. One of them is through state-of-the-art research [7], Therefore, our research aims to extend the applicability of the method to address the challenges of cross-lingual research without requiring language translation. The Joint Learning approach in Fig. 4 involves training a model across multiple tasks or languages to produce a representation that is mutually transferable between languages [38]. In the context of cross-lingual, it focuses on training the model with data from multiple languages (source and target) simultaneously so that the model can understand the linguistic patterns that are common between the languages. Cross-lingual joint learning techniques allow the model to be trained using training data from both languages at once, but the evaluation is done only in the target language [39], [40], [41]. For example, we labeled the training data in Indonesian and German as L_{id} and L_{de}. Where using L_{id} and L_{de} as training models and classifying the text into the target language L_{de}. This is because the combined representation can help in retaining the meaning and key information from the source language to the target.

$$L = \sum_{i=1}^{M} L_{Source} \cup \sum_{j=1}^{N} L_{Target} \quad (1)$$

Where L_{Source} and L_{Target} are the loss functions for the source and target languages respectively, while M and N are the amount of data in the source and target languages. Using this combined loss function, the model is trained to minimize errors in both the source and target languages, creating a more general

representation that can be applied to the target language. This technique uses semantic alignments between languages through related embeddings.

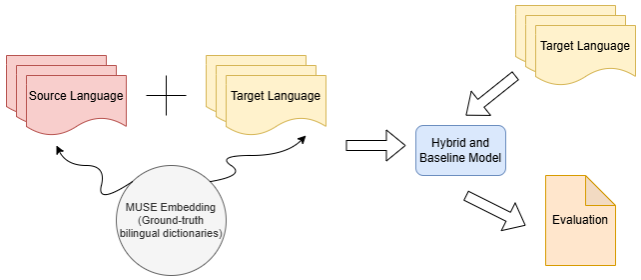

Fig. 4. Joint learning.

E. Experimental Setup

In this study, the LSTM-CNN hybrid learning architecture as well as the two base models, LSTM and CNN, are applied for performance comparison purposes. Hyperparameter settings were determined based on a combination of references from previous literature and initial experiments through Grid Search, with the aim of obtaining optimal results and fair evaluation between models. Some of the parameters adjusted include learning rate, batch size, and network structure, with the final configuration including an embedding dimension of 300, maximum input length of 100 tokens, LSTM units of 100, spatial dropout of 0.2, and CNN layer with 128 filters and kernel size of 3 (for applicable models). All models were trained using a combination of pooling methods such as MaxPooling for CNN and LSTM-CNN and GlobalMaxPooling for all models. One dense layer contains 100 units with sigmoid activation, learning rate 0.01, Adam optimization, class weights {0:1.0, 1:2.0}, number of epochs 10, and batch size 64. We also performed sensitivity analysis on learning rate (0.001, 0.005, 0.01) and batch size (32, 64, 128), and the results show that the combination of learning rate 0.01 and batch size 64 provides stable training and reduces overfitting. Evaluation was conducted using accuracy, precision, recall, and F1-score metrics to assess the model's performance in detecting fake news across languages. The accuracy metric reflects the total correct predictions, while precision assesses the accuracy of the model in identifying fake news without too many errors. Recall measures how many fake news were successfully detected out of all cases. F1-score, as the harmonic mean of precision and recall, was chosen as the main indicator because it is able to provide a balanced assessment, especially when dealing with unbalanced data.

IV. Experimental Results

A. Cross-Lingual Performance Analysis Across Language Pairs

This study evaluates the performance of LSTM-CNN, LSTM, and CNN with MUSE embeddings for cross-lingual fake news detection using a cross-lingual joint learning approach. This experiment aims to see the extent to which models trained in one language can adapt to detect fake news in another language in the context of cross-lingual learning. In this study, the model was trained using data in Indonesian as the source language, which was processed simultaneously with the target language data. The models were then tested on various target languages, including Malay, English, Spanish, and German. Indonesian was chosen as the source language to take advantage of its unique linguistic characteristics, while the target language was chosen to test the model's generalization ability on linguistically different languages. The study examines accuracy, precision, recall, and F1-score to determine model effectiveness. The results provide insights into the best approach for cross-lingual fake news detection.

Fig. 5. Accuracy and F1-score performance across language pairs.

As shown in Fig. 5, the evaluation results indicate that model performance varies depending on the language pair. For the Indonesian-German pair, the CNN model recorded the best results with an accuracy of 0.97 and F1-score of 0.96, slightly better than LSTM which achieved an accuracy of 0.96 and F1-score of 0.97, while LSTM-CNN was slightly below with an accuracy of 0.94 and F1-score of 0.95. All three models performed very well. In contrast, for the Indonesian-Malay pair, all three models performed relatively similarly with accuracy and F1-score values ranging from 0.80 to 0.82, with CNN slightly ahead. For the Indonesian-Spanish pair, the results tended to be lower. The LSTM model recorded the highest F1-score of 0.71 with an accuracy of 0.70, slightly better than LSTM-CNN and CNN which were in a similar value range. This indicates a challenge in the transfer of joint learning to Spanish. Meanwhile, for the Indonesian-English pair, LSTM showed optimal performance with an accuracy of 0.94 and F1-score of 0.95, slightly ahead of CNN and LSTM-CNN which had slightly lower values. Overall, CNN is superior for more cognate language pairs, such as Indonesian-German and Indonesian-Malay, while LSTM is more effective for structurally different language pairs such as Indonesian-English and Indonesian-Spanish.

B. Cross-Lingual Model Comparison Across All Target Languages with MUSE Embedding

Table I presents the performance of LSTM-CNN, LSTM, and CNN in cross-lingual classification using MUSE embeddings with Indonesian as the source language. Accuracy, F1-score, precision, and recall were used as evaluation metrics. CNN achieved the highest accuracy of 0.97 on Indonesian-German, highlighting its strength in cross-lingual tasks. F1-score, a key measure combining precision and recall, also reached 0.97 in both LSTM and CNN for Indonesian-German, indicating balanced performance. Precision and recall were analyzed for class 0 (True) and class 1 (False), with Indonesian-German consistently achieving the highest values. While precision measures the model's correctness in identifying a

class, recall assesses its ability to capture all relevant instances. Among all metrics, F1-score serves as the final benchmark of model performance. Although the Indonesian-German combination demonstrated the best performance when tested with the German language, its performance significantly declined when retested with the Indonesian language.

TABLE I. THE RESULTS OF CROSS-LINGUAL JOINT LEARNING IN CLASSIFICATION REPORT

Model	Source→Target	Accuracy	F1-Score
LSTM-CNN	ID-MS→MS	0.80	0.80
	ID-DE→DE	**0.94**	**0.95**
	ID-ES→ES	0.71	0.70
	ID-EN→EN	0.92	0.93
	ID-MS→ID	**0.94**	0.92
	ID-DE→ID	0.88	0.88
	ID-ES→ID	0.93	0.93
	ID-EN→ID	0.91	0.91
LSTM	ID-MS→MS	0.80	0.80
	ID-DE→DE	**0.96**	**0.97**
	ID-ES→ES	0.70	0.71
	ID-EN→EN	0.94	0.95
	ID-MS→ID	**0.93**	0.92
	ID-DE→ID	0.90	0.91
	ID-ES→ID	0.92	0.93
	ID-EN→ID	0.92	**0.94**
CNN	ID-MS→MS	0.82	0.82
	ID-DE→DE	**0.97**	**0.97**
	ID-ES→ES	0.69	0.70
	ID-EN→EN	0.92	0.93
	ID-MS→ID	0.90	0.90
	ID-DE→ID	0.89	0.90
	ID-ES→ID	**0.95**	**0.95**
	ID-EN→ID	0.93	0.94

[a] ID=Indonesian, MS=Malay, ES=Spanish, DE=German, EN=English

The Indonesian-Spanish pair showed the worst results after being tested with the target language, Spanish, due to significant linguistic differences, such as verb conjugations in Spanish that do not exist in Indonesian. The Indonesian-English pair showed high performance stability in both languages, ranging from 0.91 to 0.95. This is influenced by the large number of aligned words from English into Indonesian and the richer embedding quality of MUSE for English. The more accurate vector representation and abundant data allow the model to effectively capture cross-lingual semantic relationships without sacrificing accuracy in either language. The Indonesian-Malay pair, which is linguistically similar, showed different performance based on the evaluation language. When tested in Malay, F1-scores were lower in the range of 0.80 to 0.82 compared to when tested in Indonesian (0.92-0.94). This is due to the ambiguity of similar vocabulary with different meanings, word distribution, and data quality differences between the two languages. Although better than Indonesian-Spanish, the model remains biased towards Indonesian because it takes in more patterns from the source language.

C. Language-Wise and Embedding Across Language Performance

In the process of analyzing the differences in model performance across language pairs, it is observed that model performance is heavily influenced by linguistic similarity across language pairs the linguistic similarity between the source language (Indonesian) and the target language. For example, the better performance on Indonesian-German and Indonesian-English language pairs suggests that the model is more effective when applied to languages with more similar syntactic structures or grammatical patterns. This allows MUSE embeddings to perform optimally, as the resulting word vector representations can better capture these similarities. In contrast, the lower performance on the Indonesian-Spanish pair is likely due to greater grammatical and lexical differences, which reduces the effectiveness of MUSE embeddings' cross-lingual representation.

TABLE II. F1-SCORE RESULTS (MUSE EMBEDDING AND FASTTEXT)

Cross-Lingual	MUSE Embedding			FastText		
	LSTM-CNN	***LSTM***	***CNN***	***LSTM-CNN***	***LSTM***	***CNN***
Indonesian-Malay	0.80	0.80	0.82	0.68	0.50	0.52
Indonesian-German	**0.95**	**0.97**	**0.97**	**0.70**	**0.62**	**0.60**
Indonesian-Spanish	0.70	0.71	0.70	0.50	0.51	0.50
Indonesian-English	0.93	0.95	0.93	0.54	0.50	0.49

From a cross-lingual perspective, the use of MUSE embeddings assists in aligning word representations across languages; however, its effectiveness remains influenced by linguistic similarity, dataset quality, and training exposure. Languages that are linguistically close to Indonesian, such as Malay, demonstrate more stable performance compared to languages that are far apart, like Spanish, which experiences a decline in accuracy due to structural language gaps. Based on the results in Table II, MUSE consistently yields a higher F1-score compared to FastText, particularly for similar language pairs such as Indonesian-Malay (0.80–0.82). Even for more distant pairs like Indonesian-Spanish, MUSE's performance remains superior (0.70–0.71) compared to FastText, which only reaches 0.50–0.70. This indicates that MUSE excels in aligning interlinguistic representations that possess linguistic proximity. However, its effectiveness is still highly dependent on the quality of the embedding alignment and the availability of data. Therefore, the selection of embeddings and models should be customized by considering the characteristics of the target language, and for highly distinct language pairs, additional approaches may be required to achieve more accurate classification results.

D. Comparison with State-of-the-Art Models

Table III presents a comparative analysis of the results of this study against previous studies in cross-lingual fake news

detection. Several previous studies have examined the performance of various models in cross-lingual fake news detection tasks. For example, on the Chinese-English language pair dataset, CNN and BERT each achieved an F1-score of 0.85, while the Transformer model scored 0.82. On the English-Other language pair dataset, BERT achieved an F1-score of 0.77, while RoBERTa outperformed with 0.87. The English-Indonesian pair dataset with Bi-LSTM reached 0.87. Some studies reported results using macro F1-scores, such as 0.35 (RoBERTa) and 0.17 (Bi-LSTM) on the English-English pair dataset, and 0.17 (RoBERTa) and 0.29 (Bi-LSTM) on the English-German dataset.

TABLE III. COMPARISON WITH STATE-OF-THE-ART MODELS USING F1-SCORE

Dataset	LSTM	CNN	LSTM-CNN	BERT	RoBERTa	Bi-LSTM
English-Other (CoNLL-2003) [7]	-	-	-	.77	**.87**	-
Chinese-English (Covid-19 FND) [14]	.85	.85	-	.85	-	-
English-Indonesian (TALLIP Fake News Dataset) [9]	-	-	-	-	-	**.87**
English-German (clef-2021) [16]	-	-	-	-	.17 (macro)	.29 (macro)
Indonesian-German (Our Study)	**.97**	**.97**	.95	-	-	-

This research focuses on cross-lingual fake news using LSTM, CNN, and LSTM-CNN models across multiple language pairs. The results show strong performance in various cross-lingual settings. Indonesian-German achieved 0.97 in both LSTM and CNN, and 0.95 in LSTM-CNN, showing highly competitive results compared to previous studies. It is important to note that although all the studies in Table III. Include in the category of cross-lingual fake news detection, the datasets and methodologies are different. Some previous studies used different multilingual corpora, including machine-translated datasets, whereas this study specifically focused on cross-lingual adaptation using MUSE embeddings without translation. Despite these differences, this comparison remains relevant as all approaches aim to address the same fundamental challenge, transferring knowledge between languages for fake news classification. The results show that our LSTM-CNN model achieves competitive performance with existing Transformer-based models while maintaining computational efficiency.

The experimental results highlight that model performance varies based on linguistic similarities and structural differences between languages. LSTM outperformed other models, particularly in Indonesian-German and Indonesian-English, indicating its strength in capturing long-range dependencies and cross-lingual representations. LSTM-CNN also performed well, demonstrating that hybrid architectures can maintain stable precision and recall. Meanwhile, CNN excelled in Indonesian-Malay suggesting that CNN is more effective for language pairs with high lexical similarity. Overall, these results highlight the fact that hybrid models with MUSE embeddings can improve cross-lingual news classification performance, especially for language pairs with structural similarities. Discussion

V. DISCUSSION

A. Influence of Linguistic Similarity on Model Performance

One notable finding was a decline in performance when models trained using German data were retested on Indonesian data. This is thought to be due to an imbalance in cross-lingual vector representation in MUSE embeddings, which are better at aligning languages with high-quality training data, such as German. Remapping to Indonesian may not be optimal, resulting in a reduced ability to capture Indonesian language patterns. On the other hand, the Indonesian-Spanish and Indonesian-Malay combinations did not show a significant decline in performance when retested on Indonesian. This suggests that models trained with German data are more difficult to adapt back to Indonesian due to greater structural and morphological differences. These findings emphasize that maintaining stability in cross-lingual representations remains a significant challenge, especially when the linguistic structures between the source and target languages differ substantially.

Cross-lingual representations such as MUSE are not optimal for language pairs that have considerable linguistic distance and limited parallel data. However, when tested with Indonesian, the performance of the model improved significantly, achieving the highest score among all language pairs. Interestingly, when the model trained with Spanish data was re-evaluated on Indonesian, its performance improved significantly. This suggests that the model adopts more robust linguistic patterns from the source language (Indonesian) but struggles to generalize them when transferred to a language with rich morphology like Spanish. This reinforces the importance of considering both linguistic distance and transfer direction in cross-lingual modeling.

B. Effectiveness of Embedding Alignment in Cross-Lingual Tasks

One of the main advantages of MUSE embeddings over traditional approaches is its ability to perform supervised bilingual alignment using high-quality dictionaries. Unlike unsupervised methods, this allows MUSE to project semantically similar words from different languages into a shared vector space without relying on large-scale parallel corpora. This makes MUSE particularly suitable for languages with limited resources, such as Indonesian, where parallel data is scarce. When compared to FastText, which operates solely in a monolingual space using subword representations, MUSE demonstrates significantly better performance in cross-lingual fake news classification. FastText is effective in handling morphologically rich languages but lacks cross-lingual semantic alignment, making it less suitable for multilingual transfer learning tasks.

The results show that MUSE consistently achieves higher F1-scores across all language pairs. Notably, the Indonesian-German (0.95–0.97) and Indonesian-English (0.93–0.95) pairs outperform the others, likely due to the availability of rich linguistic resources and effective bilingual mapping. Conversely, the Indonesian-Spanish pair recorded the lowest performance, highlighting the limitations of cross-lingual embeddings in handling linguistically distant language pairs with minimal training exposure.

These observations confirm that the success of cross-lingual models depends not only on model architecture but also on the quality of the underlying embedding alignment. These results emphasize the critical role of embedding strategies in enabling accurate multilingual NLP, especially when targeting languages with limited resources or diverse structures.

C. Advantages of the Proposed Hybrid Model

The results of this study show that the proposed hybrid model, which combines LSTM-CNN with MUSE embeddings, achieves competitive or even superior performance compared to previous studies in cross-lingual fake news detection. Specifically, experiments on the Indonesian-German and Indonesian-English language pairs yielded very high F1-scores (up to 0.97), demonstrating the model's strength in leveraging linguistic alignment and transfer learning. Unlike transformer-based architectures, this approach offers computational efficiency while maintaining robust performance on both similar and relatively distant language pairs.

However, the Indonesian-Spanish language pair poses significant challenges, likely due to substantial morphological and syntactic differences. This finding highlights the main limitation of embedding alignment strategies when applied to linguistically distant languages. To address this, future research could explore the integration of advanced multilingual embeddings, such as XLM-R or mBERT, and investigate fine-tuning techniques to enhance cross-lingual adaptability. Additionally, incorporating target language training data and evaluating models on informal or noisy text (e.g., social media content) could enhance their robustness in real-world applications.

VI. Conclusion

The evaluation results show that the best performance, based on F1-Score, is achieved by the LSTM model with MUSE embeddings, particularly for the Indonesian-German pair (0.97) and Indonesian-English pair (0.95). This confirms LSTM's effectiveness in capturing sequential dependencies, making it well-suited for cross-lingual tasks. The LSTM-CNN model produced comparable results, with its highest F1-Score of 0.95 on the Indonesian-German pair, but struggled in the Indonesian-Spanish pair, indicating that hybrid models may struggle to generalize effectively to structurally divergent languages. FastText embeddings performed significantly worse across all models and language pairs, with the Indonesian-Spanish pair only reaching an F1-Score of 0.50. This highlights the importance of multilingual embeddings like MUSE, which consistently delivered superior results. CNN performed competitively on Indonesian-German (0.97) but showed a decline in Indonesian-Spanish (0.70), indicating its limitations in capturing complex cross-linguistic relationships. These findings emphasize that model effectiveness depends on both linguistic characteristics and embedding selection. MUSE embeddings, combined with LSTM-based models, provide a lightweight yet effective alternative for cross-lingual fake news detection, making them suitable for real-world applications in low-resource language settings. Future research should explore the possibility of fine-tuning MUSE embeddings with additional target-language data to improve generalization across languages with highly divergent structures. Additionally, evaluating model robustness against adversarial attacks and noisy data, such as spelling variations, informal language, and manipulated text, would be valuable in assessing its real-world applicability. However, this study has several limitations. First, the scope of language pairs is limited to five, which may not fully represent global linguistic diversity. Second, the quality and balance of the dataset can affect model performance, especially for languages with limited resources. Additionally, the experiments were limited to structured news articles, excluding informal formats such as social media posts. These factors limit the generalizability of the findings. Future research could address these limitations by integrating more diverse datasets, languages, and text genres.

Acknowledgment

This research is part of the output of the Fundamental Research Grant Scheme, funded by Telkom University and the Ministry of Education, Science, and Technology, Indonesia with grant agreement number: 7925/LL4/PPG/2025, 121/LIT 07/PPM-LIT/2025.

The authors gratefully acknowledge the support and funding provided for the successful completion of this research.

***Abstract*—Songket is a traditional Malaysian woven fabric, opulent, and symbolizes luxurious classical textiles of the old craft in Malaysia. Songket is part of the intangible cultural heritage to this day. However, cultural heritage preservation arises as a critical endeavor, especially for younger generations. There is a growing concern about the disinheritance of cultural heritage to posterity due to disregard for the value of our own heritage. Therefore, this paper aims to explore in-depth insight into the beautiful heritage of songket weaving including the knowledge of art weaving, delve into the techniques and materials used as well as the legacy and time ahead. The research uses observation methods and deep face-to-face interviews for data collection. It was conducted with experienced experts and workers, revealing the origin of Songket and its processing from scratch. The research data findings were gathered and subsequently analyzed as secondary data. This study gives more knowledge about Malay traditional textile art and heritage, indicating a positive future of traditional weaving arts as well.**

Keywords*—Songket; weaving; textiles; aesthetic; intangible cultural heritage; processing songket; cultural; heritage; Terengganu; Malaysia

I. Introduction

Intangible cultural heritage is one of the pillars of heritage components. According to UNESCO cultural heritage can be distributed into three categories: tangible, intangible, and natural. However, compared to others, intangible cultural heritage is different due to its nature which is unseen with the naked eye and cannot be touched nevertheless, its existence can be felt and impressed [1]. The inheritance of intangible cultural heritage similar to diverse technologies features of some culturally distinct communities from the past generations, sustained this time and carefully gathered and encouraged for the benefit of future generations [9]. Since the early stages of history textiles have become a very conspicuous material culture in the Malay world [2].

There are many examples of intangible cultural heritage including language, customs, lifestyle, music, art, and dance as well as weaving songket in textiles brocade family. Songket is a fine art of traditional weaving and the most opulent, ancient textiles in the Malays' repertoire. It has long been an integral part of Malaysia's cultural heritage [10]. The unique traditional weaving features reflect Malaysian people's identity and creativity. The most exquisite and interpreted as an everlasting fabric worn, the textile is acclaimed as "the cloth of gold" or "the Queen of fabrics" [9]. It is also referred to as "kain benang emas" (golden threading fabric) and is used to make apparel accessories [14].

Songket is an inseparable part of cultural heritage and a crucial ingredient of identity and society formation. As a symbol of the nation, songket heritage influences shaping perceptions of the country's culture, image, and personality. Songket embodies the intellectual values of past societies, inherited and bridged between generations. Besides representing a multi-racial emblem, songket heritage is very synonymous with tourism-related products that very crucial to drive economic growth [7].

In Malaysia, the government treats heritage issues with the utmost importance including songket weaving industry. As listed in UNESCO's Intangible Cultural Heritage of Humanity, his prompt recognition is expected to facilitate bringing other attractive Malaysian artistic traditions to the world stage [12]. Most meaningful yet, the Yayasan Tuanku Nur Zahirah (YTNZ) foundation has chosen to direct its endeavor on songket, and reinvigorate the songket industry including empowering the necessary skills.

Gradually as time goes on, the art of weaving songket encounters numerous challenges in remaining relevant. The challenges encompass many factors such as the rapid advancement of contemporary life, technological breakthrough as well as industrial development [5]. Youth nowadays are occupied with gadgets, reluctant to learn and understand basic knowledge of their cultural heritage. Thus, a collaborative effort is indeed in demand to preserve this intangible heritage to remain sustainable for the future.

This paper is divided into five main sections, which are: Section II discusses the related work and background of cultural heritage preservation. Conversely, Section III discusses the method used in this study to gain information. Next, Section IV presents the findings and discussion of the study, and lastly, Section V presents the conclusion.

II. Related Work

A. Cultural Heritage

Cultural heritage is an important constituent of a community's identity, and continuity, fostering a sense of belonging and pride of a nation [8]. Furthermore, it is a valuable asset that has been or is owned by a person or a group of societies or people who altogether share responsibilities for conservation and reservation as well [5]. Besides it is a legacy of the ways of living from the past, what we live with today, and what we pass

on to future generations as well. Heritage ratifies high values in a society while culture contributes to the sustainable development of the society and its economy. Heritage preservation, be it tangible, intangible, or natural had to be listed to be recognized as world heritage resources and were also brought in the World Heritage Convention, which took place in 1972 [1]. UNESCO has been listing some of Malaysia's intangible heritage including Mak Yong theatre, pantun, silat, Dongdang Sayang as well as weaving songket. The cultural heritage information must be gathered in an effort to deliver for next future generations. The expenditure is very important whereby the information from the past can be used to determine the identity of each society nowadays.

B. Songket

Songket is a Malay word that derives from the process of 'sungkit' [11] which brings meaning to the art of out or pulling a thread from a background cloth or weaving using gold and silver thread as well [6]. The most ancient and opulent textiles in the Malays' repertoire, songket was enlightened under the auspices of the king before the 19th century [14]. The eastern coast of the Malay peninsula has most of the greatest weavers Malay tradition that are centred on Pahang, Terengganu, and Kelantan [2]. The Songket is equivalent with the Malay community whereby making songket is a legacy from the past that is still widely practiced.

Songket has its own meaning. On this point, Malay weaver does not simply produce fabric and each part of the Songket fabric has a unique name. For instance, the design of Songket consists of a few parts such as a body, head, fabric edge, and clamp. Fig. 1 below shows the detail of songket fabric [3]. The entire motif is taken and inspired by what has existed around them including flora, nature, and abstract pattern.

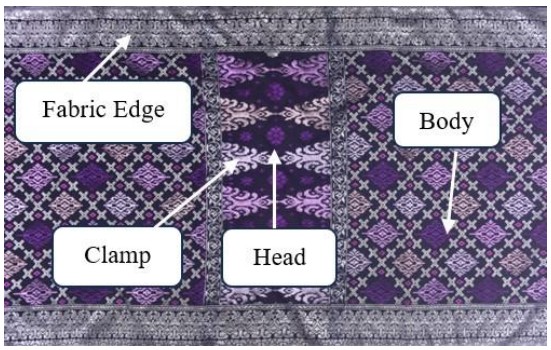

Fig. 1. The detail of songket fabric.

C. Cultural Heritage Preservation

Cultural heritage preservation is vital to ensure that these elements are conveyed to younger generations, preserved, conversed, and transmittable for sustainable cultural heritage as well as contributing to an appreciation of identity. Intangible cultural heritage is facing an awful situation globally due to rapid modernization and urbanization that is devoted to the idleness of it [4]. Apart from that, intangible cultural heritage holds significant ancestry that needs to be preserved sustainably [13].

Malaysia is well known for its diversity of cultures and valuable heritage. The government addressed the heritage issues earnestly and in accordance with that proactive steps to preserve the cultural heritage were taken, including the handicraft industry. Perbadanan Kemajuan Kraftangan Malaysia is an agency under the Ministry of Tourism, Arts, and Culture established under Act 222, the Malaysian Crafts Development Corporation Act (1979) whereby the preservation was implemented with the intention of commercializing craft products through market, product, and entrepreneur development.

III. Method

Fulfilling the research objectives required a well-structured methodological framework, consisting of three key phases: preparation, data collection, and data analysis. This study employed a qualitative approach through observation and semi-structured interviews to examine the cultural and aesthetic elements of Terengganu Songket. Emphasis was placed on understanding the production process, tools and techniques involved, and efforts in preserving this intangible cultural heritage through expert insights.

During the preparation phase, the study objectives were clearly outlined, and a set of interview questions was developed based on relevant literature. These questions covered aspects such as the history of songket, production methods, equipment used, and the future of the tradition. Data collection took place at the Perbadanan Kemajuan Kraftangan Malaysia, Terengganu branch, a center with more than 25 years of experience in the songket industry. Additional insights were gathered from a traditional songket business in Kampung Bukit Depu, where weaving has been sustained through seven generations, with the third generation currently managing the enterprise.

In the data collection phase, semi-structured interviews were conducted using open-ended questions to elicit in-depth responses. All sessions were recorded to ensure accurate transcription and analysis. Thematic analysis was then applied to identify, interpret, and report recurring themes within the qualitative data.

IV. Findings and Discussion

A. Findings on Songket Knowledge

Based on an interview session conducted with experienced people from Perbadanan Kraftangan Malaysia Cawangan Terengganu, songket is a "Queen of Fabric" that is produced manually by golden-agers. The making process takes months to complete a piece of songket cloth depending on the material and motif provided. There are some experts that were involved in making a songket according to their respective expertise. The wage rate charged also varies each other depends on the skill available. For instance, the experienced people in dyeing the yarn and each process need to be thoroughly step by step. Also the process of untangling, winding, and rolling the yarn could be the same person but a weaver has the expertise to weave only.

Based on study [2], the eastern coast of the Malay peninsula has many Malay traditional weavers which is Terengganu and Kelantan has become the main center of Malay traditional textile weavers. Songket is the valuable heritage of Malay people especially in Terengganu and the history is started in the palace for Malay royal ceremonial costumes. A wealth of precious

heritage will disappear once in a while if the younger generations are unaware of its importance and immersed with their own heritage.

B. Findings on Songket Producing

Songket is one of the old valuable traditional Malay crafts which is from a yarn into a beautiful fabric. The opulent Songket employs a weaving method that comprises interweaving gold threads with silk threads on the fabric base. As it identical with the Malay community, making songket is a legacy in Terengganu that is passed down from generation to generation. The process of producing songket involved several steps as elaborated below.

C. The Process of Making a Songket

There are eight processes in the making of songket. In order to ensure produced high-quality products each process needs to be comprehensive and detailed way. Before all the process begins, it starts with planning the design of the songket pattern.

1) Dyeing the cotton or silk yarns (thread) in hanks: Woven yarns consist of cotton yarns, silk yarns, gold yarns, and silver yarns. There is no need to color the gold and silver yarn due to natural ingredients. The cotton or silk yarns (thread) need to be tied neatly, inserted into boiling water in the crater and thoroughly rinsed with water. After that, the yarn dipped into the dye and dried up. Fig. 2. shows the process of dyeing the yarn.

Fig. 2. Process of dyeing the yarn.

2) For untangling the yarn: The dried yarn spins with a small bamboo-made spindle or innovation tools designed using a bicycle wheel. This process includes a "Darwin" tool and a convenient spinning tool. Darwin feed and gold Darwin are two types of sharks. Darwin feeds are made of bamboo and ropes or rattan and used only for feed yarns and Darwin gold is made of wood or wire because of the rough and heavy gold thread and used only for the gold thread (see Fig. 3).

3) Winding the yarn: The process of stretching and winding the yarn on the bobbins or Terengganu is called "peleting". The length or the number of threads of the fabric to be woven is regulated by "loseng" (loom). The prevalence rolls of feed yarn or sockets measure 26 to 31 meters and can produce twelve to fourteen pieces of fabric. (see Fig. 4).

4) Rolling the yarn: This process is to wind the warp yarns onto a warp wooden board. To ensure smooth arrangement during rolling, the yarn position should be checked every three times as Fig. 5.

Fig. 3. Process of untangling the yarn.

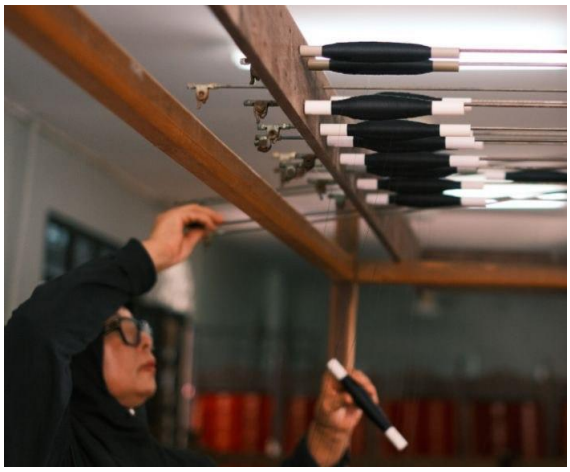

Fig. 4. Process of winding the yarn.

Fig. 5. Process of rolling the yarn.

5) Spooling the yarn: The next process is spooling the yarns through the reed. The spooling work is implemented after the

warping threads are inserted into the teeth or brush of the machine. Each brush hole is stained with two veins of the lotus thread and hooked through each gap in the machine's teeth. This process is done in the “cake” (see Fig. 6).

Fig. 6. Process of spooling the yarn.

6) Stretching the yarn: This process is making the frames for the string heddles and threading the yarns stripped from “karak” to wood by shaking them (see Fig. 7).

Fig. 7. Process of stretching the yarn.

7) Lifting the yarn: The process of weaving songket by creating patterns on the warp threads using a skewer tool. Songket weaving is usually woven with three-pointed or five-pointed techniques, tying them later through the button-tying process (see Fig. 8).

Fig. 8. Process of lifting the yarn.

8) Weaving the yarn: The weaving process uses a tool called "cake" whereby divided into three parts that are the cake legs, the cake body, and the cake head. Commonly after a thread of gold is ripped, it is beaten (beat) and then followed by two threads of feed. The shuttle filled with the weft thread or gold thread, is inserted left and right into the gaps between the warp threads, and weavers will convert button threads by rotation and predetermined patterns. This process is repeated until it becomes a piece of songket cloth (see Fig. 9).

Fig. 9. Process of weaving the yarn.

D. Songket Pattern and Motif

Songket patterns are filled with different motifs that idealize the whole songket fabrics. The are several classifications patterns of songket including full pattern, scattered pattern, scattered repeated bricks pattern, triangle shape pattern, alternating scattered repetitions pattern, crosswise pattern, stripes pattern, chevron or zigzag pattern as well as checkers pattern [5].

The following motifs are used in dissimilar patterns, depending on where they are placed and reproduced. Songket motif is generally used to demonstrate the Malay community's traditional ways of life that provide a means of exploring the relationship between cultural and national identity. Based on [14], it also represents the most important Malay cultural identity delivered in the creation of its motifs through the practice of oral traditions. Each motif and pattern has its own meaning whereby present the unique identity of Malay itself [3]. Usually, the motif and pattern used in Songket are produced at the customer’s request.

Based on a previous study by [3], the overall motif songket is taken and inspired by surroundings such as flora, fauna, nature, and abstract patterns. For instances pucuk rebung, bunga lawi ayam, bunga tanjung, bunga baling, bunga cermai, and tapak kecupu for flora motif. Besides that, motifs based on abstract patterns such as jong sarat, pecah lapan, bunga tiga dara, tapak kacip, bunga kerongsang, kasap, bunga logam, potong wajik, and bunga logam. The motifs of bintang buta, awan larat, air molek, and teluk berantai as nature inspirations. Another motif is inspired by fauna such as sisik kelah, unduk-unduk, bunga lawi ayam, and bunga hati [6].

A preliminary study has been conducted to initiate detailed information regarding the aesthetic of songket. The exploratory of important and valuable information gathered from the insights of experst and entrepreneusr located at Terengganu. This section discussed the results based on the data acquired from the interviews. By conducting a preliminary study, an initial investigation was implemented to identify the direction and narrow down the study.

E. Tools and Equipment of Songket

Based on observation, there are two categories of tools and equipment in making songket that are weaving equipment and supporting equipment. Among the tools used to create songket are as Table I:

TABLE I. TOOLS EQUIPMENT FOR PRODUCING SONGKET

Tools Equipment	Name
	Weaving Cake or "kei" is a tool used in the weaving process that is divided into three parts that are the cake legs, the cake body, and the cake head and interconnected each other.
	*Bobbin* also known as "pleting" is a crucial tool used to hold the wraps threads.
	A combination of threads will produce a distinctive and luxurious songket appearance.
	*Loseng* is the thread that formis the fabrics and refers to threads that extend on the loom.
	*Two Belira* is a long and thin stick that is used to loosen the thread and make in tense. This process facilitate the process of inserting a c*uban*.

F. Legacy and Future of Songket

Based on the interviews with the songket entrepreneurs, the legacy of the songket business in Terengganu is inherited by the 7th younger generation. The older generation working in this business for generations ago and will assign their business knowledge to their heirs so that the business remains relevant.

The persistence of the cultural heritage is left by the previous generation reliant on the new generation. The weaving process requires a lot of patience, passion and creativity so that to passing the knowledge is very challenging.

Terengganu tourism is synonymous with the songket industry and making songket is a legacy even more the songket has emerged to become a tourism product. To guarantee that the industry is consistently progressing and growing, entrepreneurs should always look for opportunities to expand their business, sharing the knowledge all about songket and collaborating with government so that the value of songket is highlighted and this legacy is never lost.

In the modern world, the future of songket weaving can be promising with all-out effort. Therefore, innovation in art weaving is a critical way to bridge the gap between tradition and modernity including providing a digital learning platform. As a global recognition, it is our shared responsibility to protect, preserve, and pass to the next generation.

V. CONCLUSION

This preliminary survey gives an overview of the current conditions of cultural heritage especially on songket weaving. Its legacy that symbolizes the identity of our community and generation nowadays is responsible for preserving and safeguarding our country's cultural heritage. Furthermore, songket has worldwide cultural potential, and in-depth research is very crucial.

As a conclusion, to ensure that the industry is establishing constantly, evolving, and growing requires further efforts on all fronts. As society moves forward into a progressively global and technologically advanced future, it is essential to appreciate the value of textile culture and his historical heritage. Therefore, to preserve this intangible heritage to remain sustainable the responsible parties must make a concerted effort that includes a mutual support between songket weaver and entrepreneur as well as a collaboration among all parties and promote Malay Songket Weaving internationally.

***Abstract*—Sickle Cell Anemia (SCA) is a hereditary condition causing abnormal red blood cells, leading to severe health complications. Traditional treatment approaches for SCD often involve reactive management, which can delay appropriate interventions and worsen patient outcomes. The aim of this study is to leverage machine learning (ML) algorithms, including Logistic Regression (LR), Support Vector Machines (SVM), and Decision Trees (DT), to identify high-risk groups among SCA patients using clinical and pathological data from King Abdulaziz University Hospital. This study employs a comprehensive dataset comprising 200 SCA patients, with data preprocessing to handle missing values and feature selection techniques to enhance model performance. The dataset is divided into training and testing sets, and models are evaluated using ten-fold cross-validation. Performance metrics such as True Positive Rate (TPR), False Negative Rate (FNR), Positive Predictive Value (PPV), and False Discovery Rate (FDR) are used to assess model effectiveness. The results indicate that the SVM model with the top seven correlated features achieved the highest TPR and PPV, along with the lowest FNR and FDR, demonstrating its superior performance in identifying high-risk patients. The study concludes that ML models, particularly SVM, can significantly improve risk assessment and patient management in SCA, offering a proactive tool for healthcare providers. The main message is the potential of ML algorithms to enhance clinical decision-making and improve outcomes for patients with SCA.**

Keywords*—Sickle cells anemia; feature selection; predicting complication; machine learning

I. Introduction

SCD is a hereditary condition that results in the production of abnormal red blood cells. The disease was first identified in 1910 [2]. Today, it is estimated that approximately 5% of the global population carries a gene for sickle cell disease or thalassemia [1]. Annually, over 300,000 newborns are affected by severe forms of these disorders, with most cases occurring in low- and middle-income countries [3], [4]. SCD is particularly prevalent in regions such as the Mediterranean, Africa, India, the Caribbean, and the Middle East.

In Saudi Arabia [5], SCD is a common genetic disorder, with carrier rates varying from 1.4% to 2% in certain areas and reaching as high as 27% in some regions. The Saudi premarital screening program has revealed that 0.26% of the adult population is affected by SCD, while 4.2% carry the sickle cell trait. The highest prevalence is observed in the Eastern province, with SCD affecting about 1.2% of the population and sickle cell trait carriers comprising approximately 17%. Current treatment decision-making for SCD involves monitoring symptoms and complications and adjusting treatment plans accordingly. This reactive approach can significantly impact patients' lives, leading to delayed treatment options and irreversible disease complications. Despite extensive epidemiological surveillance, no publicly reported model has yet been validated on a Saudi cohort to predict severe events; this gap leaves clinicians reliant on qualitative heuristics and underscores the need for data-driven, localised risk stratification.

Sickle-cell complications place a persistent burden on emergency and hematology services in Saudi Arabia; delayed therapeutic escalation is common because current risk assessments rely on clinician intuition or post-event markers. By embedding a data-driven prognostic layer into routine complete-blood-count (CBC) workflows, clinicians can transition from reactive to proactive care. Applying artificial intelligence (AI) tools, particularly Machine Learning (ML) algorithms, to predict the severity and complications of SCD in diagnosed patients, offers a proactive solution that could assist physicians in making more informed treatment decisions. ML techniques can analyze vast amounts of clinical and pathological data to identify patterns and risk factors that are not easily discernible through traditional methods. Consequently, the objective of this study is to leverage ML algorithms, including Logistic Regression, Support Vector Machines, and Decision Trees, to identify high-risk groups among SCD patients using data from King Abdulaziz University Hospital. By developing predictive models, we aim to enhance the accuracy of risk assessments and improve patient management. Directly addresses a national patient-safety gap and aligns with Vision 2030's precision-

medicine goals. Research Question (RQ): Which of the evaluated machine-learning algorithms (Logistic Regression, Support Vector Machine, or Decision Tree) most accurately identifies high-risk SCA patients using routinely collected hematological features in a Saudi clinical setting? The remainder of this paper is organised as follows: Section II details the dataset and pre-processing pipeline. It describes the three candidate algorithms and feature-selection procedure; Section III sets out the experimental protocol. It presents quantitative results; Section IV discusses clinical implications and algorithm–data suitability; finally, Section V concludes with limitations and future work.

A. Related Work

SCD is a complex genetic disorder characterized by significant phenotypic variability [6]. The development of accurate prediction models for SCD severity and outcomes is crucial for improving patient care and treatment decision-making [7]. ML techniques have shown promise in interpreting medical data and predicting disease severity, complications, and treatment dosages [7]. Bayesian network modeling has been used to create a personalized disease severity score that predicts the risk of death within 5 years, incorporating factors such as renal insufficiency, leukocytosis, and hemolytic anemia severity [8]. While known modifiers like fetal hemoglobin levels and α-thalassemia influence disease severity, other genetic variants and environmental factors, including climate and air quality, may also play a role [6]. Despite recent successes, modeling the multisystem pathology of SCD remains challenging, and further research is needed to improve prediction of specific adverse outcomes and global disease severity [9].

Research on predicting disease severity in SCD has focused on various factors and approaches. A systematic review identified multiple indices used to assess SCD severity, incorporating elements like organ damage and complications, but found a lack of consensus and validation for these measures [10]. To address this, experts developed a severity classification system using a modified Delphi panel, considering factors such as age, genotype, and organ damage [11]. ML techniques have shown promise in predicting acute organ failure in critically ill SCD patients, using physiological markers derived from vital signs [12]. Despite these advancements, modelling the variable and multisystem pathology of SCD remains challenging. While there have been some successes in predicting specific adverse outcomes and global disease severity, significant challenges persist in developing comprehensive prognostic tools for SCD [9].

Feature selection techniques are crucial for improving model performance in clinical prediction by identifying relevant features from large datasets [13]. Common approaches include filter and wrapper methods [14]. Filter methods use criteria like correlation, significance, or variable importance to rank features, while wrapper methods employ algorithms to evaluate feature subsets [13]. Hybrid approaches combining filter and wrapper techniques have shown promise in generating minimal redundancy maximal relevant feature subsets [15]. A tri-stage wrapper-filter framework has been proposed, utilizing ensemble filter methods, correlation analysis, and meta-heuristic optimization to select optimal features for disease classification [16]. These techniques aim to reduce dimensionality, remove irrelevant or redundant data, and improve classification accuracy [16], [14]. Effective feature selection can lead to more parsimonious models, reduced training time, and improved predictive performance in clinical settings [13], [16].

ML algorithms have shown significant potential in improving healthcare outcomes for patients with SCD. Studies have demonstrated that ML models outperform traditional readmission risk scoring systems in predicting 30-day hospital readmissions for SCD patients [17]. Random Forest algorithms have been particularly effective, achieving higher accuracy and area under the curve (AUC) scores compared to standard [17]. ML techniques have also been successful in predicting SCD from erythrocyte smears, with ensemble models like Random Forest-XGBoost showing superior performance [18]. The integration of ML in healthcare extends beyond SCD, offering opportunities for personalized treatment and improved resource allocation across various medical conditions [19]. These advancements in ML-driven predictive models have the potential to revolutionize healthcare systems, leading to more efficient and patient-centered care.

II. METHODS

A. Patient Population

The 200 patients from King Abdulaziz University Hospital (KAUH) were eligible for the study, and any patients who were not diagnosed with SCA were excluded. The dataset retrieved data from electronic health records, including each patient's complications records and clinical and pathological data. The data were accessed for research purposes from (1/10/2020). All patients' identities were anonymized, and authors did not have access to information that could identify individual participants during or after data collection. Table I shows the features that were included in the study. Ethical approval was obtained from the unit of the Biomedical Ethics Research Committee at KAUH (Reference No. 511-20). As participants' data were retrospectively included from medical records, the need for informed consent was waived by the ethics committee, as the data were fully anonymized before access.

B. Patients Outcomes

The patients enrolled in the study were divided into two broad outcome groups: (i) Low-risk group: SCA patients who did not develop any complications; and (ii) high-risk group: SCA patients who developed complications. The complications include: Vaso-Occlusive Crisis (VOC), Hepatorenal, gallstone, Stroke, Osteotomy, Avascular Necrosis (AVN), Chronic Kidney Disease (CKD), acute tubular necrosis, Upper Respiratory Tract Infection (URTI), cute Chest Syndrome (ACS), pulmonary Embolism (PE), Pneumonia, Cholecystitis, and Priapism).

C. Datasets

The dataset used in this study comprises three distinct sheets: "ContWithMissing", "ContNoMissing," and "CatWithNoMissing". Each sheet presents a different aspect of the data, catering to specific requirements for ML model development and evaluation. Firstly, the "ContWithMissing" sheet contains continuous data with some values missing, indicating a need for imputation or exclusion during preprocessing. This sheet is crucial for understanding data

completeness and planning subsequent data cleaning steps. Secondly, the "ContNoMissing" sheet provides continuous data with no missing values. This dataset guarantees that all continuous data inputs are available for analysis. Thirdly, the "CatNoMissing" sheet contains categorical data with all missing values addressed. The number of rows reduced compared to the original dataset because some Thalassemia patients were excluded. This sheet ensures that categorical data inputs are fully available for analysis and modeling.

TABLE I. CLINICAL AND PATHOLOGICAL FEATURES

Features	Description
Age	Clinical feature recorded at the time of diagnosis.
Gender	Clinical feature recorded at the time of diagnosis.
Hemoglobin level (Hb)	An internal protein within red blood cells that serves as a transport system for oxygen from the lungs to the tissues and organs of the body, and a transport system for carbon dioxide from the body to the lungs.
White Blood Cell (WBC)	A cell in the blood and lymph is produced in the bone marrow. White blood cells are a component of the body's immune system. They assist the body in fighting off illness and disease. Granulocytes (neutrophils, eosinophils, and basophils), monocytes, and lymphocytes are the different kinds of WBCs (T cells and B cells).
Platelets	Large cells in the bone marrow known as megakaryocytes form platelets. They assist in forming blood clots that can slow or halt bleeding and assist in wound healing.
Mean Corpuscular Volume (MCV)	The MCV blood test evaluates the erythrocyte count, which is the average size of red blood cells.
Mean Cell Hemoglobin (MCH)	The typical hemoglobin level in a typical red blood cell. The MCH is calculated by calculating the red blood cell count and hemoglobin levels.
Mean Cell Hemoglobin Concentration (MCHC)	The hemoglobin concentration in red blood cells, on average.
Reticulocyte	Newly produced, immature red blood cells, known as reticulocytes, emerge from the bone marrow. They form and ripen in the bone marrow before they are released into the blood.
Red Cell Distribution Width (RDW)	A red cell distribution width (RDW) test is used to determine your blood's red blood cell volume and size range (erythrocytes).
Hemoglobin Electrophoresis: Hb A Hb A2 Hb F Hb S	Electrophoresis for hemoglobin is a procedure that uses a high-voltage electric field to separate the various types of hemoglobin found in the blood. Additionally, it searches for abnormal forms of hemoglobin. The most commonly occurring type of hemoglobin (Hg A) in healthy adults. Hb F Fetal hemoglobin. Unborn babies and newborns have a specific type of hemoglobin. Immediately after birth, Hb F is replaced by Hb A. Sickle cell disease is the common cause of hemoglobin of this type.
Aspartate Amino Transferase (AST)	A special enzyme, present in increased levels in the blood following a heart attack or liver disease, aids in the transfer of an amino group from glutamic acid to oxaloacetic acid.
Alanine Amino Transferase (ALTI)	A naturally occurring enzyme found in the liver and heart. The ALT enzyme is released into the blood when liver or heart injuries occur. As a result of liver damage (such as from viral hepatitis) or an insult to the heart, the blood ALT levels increase.
Alkaline phosphatase (ALPI)	An enzyme which is commonly found in various body parts, but is most prevalent in the liver, bones, intestine, and kidneys. A blood test to measure the activity of alkaline phosphatase is used to gauge the enzyme's concentration. Elevated ALP levels may be a result of liver disease or another type of health problem.
Gamma-glutamyl Transferase (GGT)	An enzyme found throughout the body in many organs at the highest concentrations found in the liver. Elevated GGT can be found in the blood of most people with liver or bile duct problems. The blood sample test is meant to gauge the level of GGT. When the liver is injured, GGT levels increase normally, but if the liver is compromised, they will be higher.

D. Framework

The framework (Fig. 1) is divided into three sections: data preprocessing, features selection techniques, and ML methods.

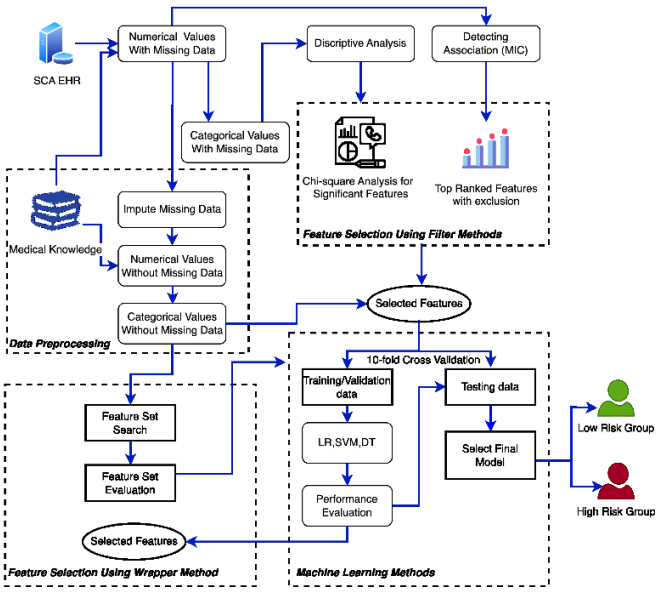

Fig. 1. Framework for preprocessing, feature-selection and modelling.

1) Data preprocessing: The dataset included numerical values with missing data. This step included: imputing missing data and reformatting the data using medical knowledge.

2) Impute missing data: Two of the most frequently used approaches for dealing with missing data are imputation and deletion, and the former can introduce bias while the latter introduces both bias and a reduction in statistical power [20]. In this step, linear interpolation uses the two nearest points to estimate the value of the interpolated point in a one-dimensional data sequence [21]. For all features, the numerical values were imputed with the linear interpolation using SPSS 21 since removing patient data reduces patient datasets, which can affect the performance of learned models, we chose to eliminate those features with missing percentages above 10%.

3) Reformate the features using medical knowledge: We used existing knowledge, including standard blood count boundaries [22], and clinical expertise domains, to format data into categories.

4) Feature selection techniques: Feature selection algorithms are broadly divided into three categories: filter

methods, wrapper methods, and embedded method [23]. Here we first used filter methods.

A statistical score is applied to each feature through the use of filter feature selection methods. The results are rated by score, and then the preferred features are selected to be retained or discarded from the dataset. The methods are typically univariate and either treat the feature in isolation or regard it in the context of the dependent variable. Here, the top correlated features include finding new patterns in large datasets, which highlight interesting relationships between pairs of variables. For two-variable relationships, we used two techniques as a measure of dependence: i) the maximal information coefficient (MIC)[24]. The results were sorted from largest to lowest and discarded as the lowest score feature, ii) the Chi-squared test which is a nonparametric statistical test that is widely used to assess the statistical significance of predictive factors [25]. We used Recursive Feature Elimination (RFE) which iteratively builds models and removes the least key features.

The second feature selection technique was the wrapper method which evaluates the performance of a subset of features by training a machine learning model. They use search algorithms to find the best subset of features based on the model's performance. Two common methods are known as forward selection and backward elimination. We used forward selection to start with an empty set and added features one by one based on performance improvement.

This study used hybrid feature selection approach that combines the strengths of both methods (filter and wrapper). Initially, features are ranked using specific criteria, followed by applying a wrapper algorithm to generate a subset from the ranked features [15].

We chose to use filter and wrapper methods for feature selection instead of embedded methods because filter methods are computationally efficient and model-agnostic, allowing for quick preliminary feature evaluation. Wrapper methods, though more computationally intensive, account for feature interactions and improve model performance by evaluating subsets through model training. In contrast, embedded methods are model-dependent, which could limit the flexibility and generalizability of our feature selection process. By using filter and wrapper methods, we ensured a versatile and robust feature selection applicable across various machine learning models.

5) Machine learning methods: Three ML methods were utilized: Logistic regression (LR), Support Vector Machine (SVM), and Decision Tree (DT). LR is a statistical method used to model the probability of a binary outcome based on one or more predictor variables [26]. It is particularly useful in scenarios where the dependent variable is categorical, such as pass/fail or disease/no disease [27]. Unlike linear regression, which predicts continuous outcomes, logistic regression estimates the probability of an event occurring versus not occurring [27]. LR implemented using the fitclinear function in MATLAB 2024a. In the context of this study, LR is employed to predict whether patients fall into high-risk or low-risk categories based on their features. The fitclinear function optimizes the model parameters using maximum likelihood estimation to find the best fit for the data. The logistic function (sigmoid) transforms the linear output into a probability, which is then used to make binary predictions. The model's performance is evaluated using cross-validation to ensure robustness and avoid overfitting.

Another common ML model is SVM which is a supervised learning method used for both regression and also classification [28].However, they are most commonly utilized for binary classification. The SVM algorithm aims to find an appropriate hyperplane in such an N-dimensional space that accurately classifies the data points [29]. The memory efficiency of SVM and its efficiency for high-dimensional environments are the two key benefits of employing it. SVMs are among the most extensively used and successful ML algorithms in supervised learning for classifying and recognizing problems. They get a solid theoretical foundation, which makes them invaluable throughout this field. The essential principle behind SVMs was that with some high input vector x and vector output y, there must be some unknown and non-linear relationship (mapping, function) $y = f(x)$. There seems to be no knowledge about input data vectors' underlying joint distributions. The training data would be the only information provided. As a result, they are classified as supervised learning algorithms. SVMs create a hyperplane to divide two classes. The algorithm intends to attain the greatest possible separation between the classes.

SVM finds the hyper-plane as in feature space which distinguishes between categories for classification. A training data point has been represented as points within feature space by an SVM model, which is mapped in a way in which points belonging to the different classes were also separated by just as wide a margin as possible. The testing data points then are mapped into the same space and classified according to where they fall upon that margin. SVM implemented here using the fitcsvm function in MATLAB 2024a. In this study, SVM is utilized to classify patients into high-risk and low-risk categories based on their features.

The third ML method is DT, which is a popular machine learning method used for classification tasks. DTs are effective in handling non-linear relationships and can be scaled for big data applications [30]. DTs have been applied in various fields, including education, building, botany, social science, and medicine [31]. DT implemented using the fitctree function in MATLAB 2024a, the DT functions by repeatedly dividing the dataset into smaller subsets according to the values of input features, creating a structure that resembles a tree. In this tree, each node corresponds to a feature, each branch signifies a decision rule, and each leaf node indicates an outcome. The fitctree function grows the tree by selecting features that best split the data according to a chosen criterion, such as Gini impurity or entropy.

The process of building a decision tree begins with selecting the best feature for the root node. The algorithm evaluates all features and selects the one that best separates the data into distinct classes. This is done by calculating the split criterion for each feature. Gini impurity was used to measure the probability of a randomly chosen element being misclassified if it was randomly labeled according to the distribution of labels in the subset. Lower values of Gini impurity indicate better splits.

Once the best feature is chosen, the data is split into subsets based on the values of this feature. For categorical features, this involves creating branches for each category. The process of selecting the best feature and splitting the data is repeated recursively for each subset. At each node, the algorithm considers only the subset of data that reaches that node. The recursion continues until one of the stopping criteria is met: all instances in a node belong to the same class, there are no remaining features to split on, the maximum tree depth is reached, or a minimum number of instances per node is specified.

In this study, the DT model is used to classify patients into high-risk and low-risk categories based on their features. The model is trained using 90% of the dataset and validated using 10% of the dataset. Ten-fold cross-validation is applied to ensure the model's robustness and to prevent overfitting.

The selection of the most appropriate machine learning method depends on the specific application and dataset characteristics [31].

6) Performance evaluation: By using the confusion matrix, one can see how the selected model performed in each category. The confusion matrix helps you figure out where the model messed up. The number of observations is defined as the following:

- TP: patients are correctly categorized as low risk.
- FP: patients categorized in low risk, but they predicted as high risk.
- TN: patients are correctly categorized as high risk.
- FN: patients categorized in high risk, but they predicted as low risk.

Final Model and Feature Set Selection: For the final model and feature set selection, we employed a comprehensive evaluation process based on four key performance metrics: True Positive Rate (TPR), False Negative Rate (FNR), Positive Predictive Value (PPV), and False Discovery Rate (FDR). The TPR is the ratio of true high-risk classifications to true high-risk cases. The FNR is the proportion of incorrectly classified instances in relation to the number of actual classes in high risk. PPV stands for predicted in a high risk to correctly classified in high-risk observation ratio. The FDR is the rate of predictions that are incorrect per class that was classified as high risk.

Initially, we applied filter methods to efficiently evaluate and reduce the dimensionality of the dataset, using statistical measures such as correlation coefficients and mutual information to identify relevant features. This provided a preliminary selection of features that served as the basis for further refinement.

Subsequently, we utilized wrapper methods, including accounting for feature interactions and refine the feature subset. Wrapper methods involve directly evaluating subsets of features by training the selected machine learning model from the filter selection method. This iterative process allowed us to identify the most impactful features and improve model performance.

After generating multiple models with various feature sets, we compared their performance based on the metrics mentioned above. The evaluation process ensured that the selected model and feature set offered a good balance of achieving the highest TPR and PPV and the lowest FNR and FDR. This approach to combining filter and wrapper methods enabled us to achieve a robust and reliable predictive model, tailored to the specific needs of our application.

III. Results

A. Insight Into Data

The dataset included 200 SCA patients, 10 patients were excluded because they were diagnosed with Thalassemia. The low-risk group included 90 patients while the high-risk group included 110 patients.

B. Preprocessing Results

The analysis of the "ContWithMissing" sheet revealed varying degrees of missing data across different clinical features. To address this, linear interpolation was applied to impute missing values for numerical features using SPSS 21. As shown in Table II, features with more than 10% of missing data were excluded to avoid bias and ensure robust model performance.

TABLE II. Statistics of the Missing Data

	N	Missing	Percent	Minimum	Maximum	Mean

Age and gender data were nearly complete, with only 1.1% and 4.21% missing, respectively. Critical parameters such as hemoglobin levels, white blood cell count, platelets, mean corpuscular volume, mean cell hemoglobin, and mean cell hemoglobin concentration had no missing values. Reticulocyte and red cell distribution width had 13.68% and 16.32% missing values, respectively, and were thus excluded from the analysis. Hemoglobin electrophoresis tests showed substantial missing data (HbA 72.63%, HbA2 45.79%, HbF 46.84%, HbS 33.16%), leading to their exclusion. Similarly, liver enzyme measurements such as AST, ALT, ALKP, and GGT had significant missing data, particularly GGT with 65.79%, and were excluded from further analysis. This approach ensures that the dataset remains robust and reliable for subsequent analysis and model development. The data was also reformatted using medical knowledge and standard blood count boundaries to categorize values meaningfully. Table III shows the reformat of numerical data using medical knowledge.

C. Filter Selection Results

The feature selection process utilized different methods for the "ContWithMissing" and "CatWithMissing" sheets. For the "ContWithMissing" sheet, Table IV shows the top correlated features using MIC analysis. The top features included Platelets (MIC: 0.41987), WBC (MIC: 0.41139), MCH (MIC: 0.3613), MCV (MIC: 0.3171), MCHC (MIC: 0.27546), Hb (MIC: 0.26462), and AGE (MIC: 0.16802), all of which were included in the final model due to their strong correlations.

For the "CatWithMissing" sheet, the Chi-squared test was used to determine the statistical significance of the features. This analysis revealed several significant features, including WBC and Platelets.

Notably, WBC showed a significant difference between low and high-risk patient categories (p-value: 0.005), and Platelet counts also displayed statistical significance (p-value: 0.027). Table V shows significant features.

By integrating MIC analysis for continuous data and Chi-squared analysis for categorical data, the final model incorporated the most predictive and statistically significant features, thereby enhancing its performance and reliability in predicting mismatch repair complications.

D. Machine Learning Methods Results

The feature selection and ML model evaluation was conducted using the "CatNoMissing" sheet. For this process, 10% of the data was held out as testing data while 90% was used for training. The final dataset underwent ten-fold cross-validation. The LR, SVM, and DT models were assessed using several performance metrics, including TPR, FNR, PPV, and FDR. Table VI shows the final results using feature selection and ML methods.

a An overfitting model is a data science concept in which a statistical model fits precisely against its training data.* selected model.								

Initially, models were trained without feature selection, using all available features. The LR model achieved a training accuracy of 65.3% but showed significant overfitting with a testing accuracy of 35%. The TPR and PPV were 64.3% and 30%, respectively, while the FNR and FDR were 35.7% and 70%. The SVM model performed better on the testing data, achieving an accuracy of 62.5%, a TPR of 50%, a PPV of 46.7%, an FNR of 50%, and an FDR of 53.3%. The DT model had a testing accuracy of 50%, with a TPR of 64.3%, a PPV of 37.5%, an FNR of 35.7%, and an FDR of 62.5%.

Next, feature selection was applied using significant features (chi-square) identified through statistical tests, specifically focusing on Platelets and WBC. The LR model improved slightly with a testing accuracy of 52.5%, a TPR of 64.3%, a PPV of 39.1%, an FNR of 35.7%, and an FDR of 60.9%. Both the SVM and DT models showed similar improvements, with SVM achieving a testing accuracy of 52.5%, a TPR of 54.54%, a PPV of 60%, an FNR of 45.45%, and an FDR of 40%. The DT model had a testing accuracy of 52.5%, a TPR of 54.54%, a PPV of 60%, an FNR of 45.45%, and an FDR of 40%.

Further evaluation with the top 7 correlated features (MIC) revealed that the SVM model with these features achieved the best performance metrics, with a testing accuracy of 50%, a TPR of 85.7%, a PPV of 40%, an FNR of 14.3%, and an FDR of 60%. The LR model also performed well, with a testing accuracy of 47.5%, a TPR of 85.7%, a PPV of 38.7%, an FNR of 14.3%, and an FDR of 61.3%. The DT model had a testing accuracy of 52.5%, a TPR of 71.4%, a PPV of 40%, an FNR of 28.6%, and an FDR of 60%.

After applying wrapper selection methods, the SVM model with 4 features demonstrated the best performance among the evaluated models, with a testing accuracy of 57.9%, a TPR of 72.72%, a PPV of 61.53%, an FNR of 27.27%, and an FDR of 38.46%. A total of 2^{18} =262,143 models were generated for each technique and assessed. The final model was selected based on its superior performance metrics, specifically the highest TPR and PPV, along with the lowest FNR and FDR. The selected SVM model showed exceptional capability in correctly identifying high-risk patients while minimizing incorrect classifications. This comprehensive evaluation confirmed the robustness and accuracy of the SVM model in predicting patient risk, making it the optimal choice for this analysis.

IV. DISCUSSION

This study aimed to implement ML algorithms to identify high-risk groups among SCA patients using clinical and pathological data from King Abdulaziz University Hospital. The primary objective was to develop predictive models that enhance the accuracy of risk assessments, thereby improving patient management and treatment outcomes. The application of LR, SVM, and DT in this study demonstrated the potential of ML in healthcare, particularly in the context of genetic disorders like SCA.

The findings indicate that the SVM model outperformed LR and DT in identifying high-risk SCD patients. Specifically, the SVM model with the top 7 correlated features achieved the highest TPR and PPV, along with the lowest FNR and FDR. These results suggest that SVM is particularly effective in distinguishing between high-risk and low-risk patients, making it a valuable tool for clinicians. The experimental results echo theoretical expectations: SVM excelled because the dataset (n = 200, 7–17 active predictors) is high-dimensional relative to sample size, a setting in which the max-margin principle reduces over-fitting. LR performed adequately on linearly separable CBC ratios, whereas DT handled non-linear interactions but was vulnerable to small-sample fragmentation.

A crucial element of the study was the feature selection process, which significantly enhanced model performance. Both filter and wrapper methods were employed to identify the most relevant features, thereby reducing model complexity and improving prediction accuracy. The top 7 correlated features (Platelets, WBC, MCH, MCV, MCHC, Hb, and Age) were found to be significant predictors of risk in SCA patients. Among these, Platelets and WBC counts were particularly noteworthy. Platelets, which are essential for blood clotting, and WBCs, which play a key role in immune response, are critical indicators of a patient's health status and potential complications. Indeed, the complete blood count (CBC) evaluates these cells, helping detect various diseases and conditions [32]. A lower platelet to WBC ratio is associated with increased risk of postoperative infectious complications in patients undergoing radical nephrectomy [33]. In essential thrombocythemia patients, platelet counts outside the normal range correlate with an immediate risk of major hemorrhage, while elevated WBC counts are associated with both thrombosis and hemorrhage [34]. A conserved pattern of recovery, defined by co-regulation of WBC and platelet populations, has been identified across various inflammatory. This pattern of recovery, marked by an exponential decline in WBC and a subsequent linear increase in platelet count, could signify a basic model of human physiological response and serve as a means to identify high-risk patients. [35].

One of the key challenges addressed in this study was the handling of missing data. The application of linear interpolation to impute missing values ensured that the dataset remained comprehensive and informative. Excluding features with more than 10% of missing data helped maintain the integrity of the models, avoiding potential biases that could arise from incomplete data.

The decision to use a combination of filter and wrapper methods for feature selection, rather than embedded methods, was justified by the need for flexibility and computational efficiency. While embedded methods integrate feature selection within the model training process, they can be computationally intensive and less adaptable to different algorithms. The approach adopted in this study allowed for a more tailored feature selection process, enhancing the performance of each ML model.

Despite the promising results, this study has some limitations. The sample size of 200 patients, while adequate for initial model development, may not capture the full spectrum of variability in SCD presentations. Future studies with larger datasets and multi-center collaborations are needed to validate the findings and enhance the generalizability of the models.

Using LR, SVM, and DT with small-sized datasets presents both opportunities and challenges. LR is advantageous for small datasets because it is less prone to overfitting due to its simpler linear model structure. It can provide meaningful insights and interpretability, especially when the relationship between the predictors and the outcome is approximately linear. However, its performance may suffer if the underlying data distribution is complex.

The SVM, particularly with linear kernels, are also suitable for small datasets as they maximize the margin between classes, which can lead to better generalization on unseen data. SVMs are robust to overfitting making them effective for datasets with

a small number of samples but many features. However, SVMs can be computationally expensive, and their performance is highly sensitive to the choice of kernel and hyperparameters, which can be challenging to optimize with limited data.

Finally, DTs were intuitive and easy to interpret, making them appeal for small datasets. They could capture complex interactions between features without requiring a large amount of data. However, DTs are prone to overfitting, especially with small datasets, as they tend to create overly complex trees that do not generalize well.

V. Conclusion

In conclusion, this study demonstrates the potential of ML algorithms, particularly SVM, in identifying high-risk SCA patients. The integration of hybrid feature selection techniques and effective handling of missing data contributed to the development of accurate predictive models. These findings underscore the value of ML in healthcare, offering a tool for risk assessment and patient management in SCA. The capability of ML to enhance clinical decision-making, improving patient outcomes in genetic disorders like SCA. The SVM model (TPR = 85.7 %, PPV = 61.5 %) offers a clinically actionable screening tool for SCA wards. Limitations include (i) single-centre data, which may under-represent regional genotype variability, and (ii) retrospective feature availability, potentially biasing model coefficients. Future work will involve a prospective, multi-centre cohort integrating inflammatory biomarkers and whole-genome variants to refine risk predictions and support personalized therapy pathways.

***Abstract*—Road accidents and delayed emergency responses remain a major concern in urban environments, contributing to over 1.4 million fatalities globally each year. With rapid urbanization and increasing vehicle density, timely detection and efficient traffic management are critical to reducing the impact of such events. This study proposes a real time Accident Detection and Emergency Response System with integrating Machine Learning IoT enabled drones and LoRa communication. The system combines real time accident detection using CCTV, drone assisted fire detection for post accident scenarios, crime activity monitoring and automated traffic management to reduce congestion and improve public safety. LoRa ensure long range, energy-efficient communication. ML models improve detection accuracy across accidents, fires, crimes and vehicles. Figures and sensor data are analyzed in real time to trigger alerts and assist emergency responders. The system supports scalable integration with existing urban infrastructure, promoting the development of smart city safety frameworks. By minimizing emergency response time, limiting secondary incidents and improving situational awareness, the proposed solution addresses critical gaps in current urban safety systems. It offers a practical, intelligent and adaptive approach to accident mitigation and traffic control in smart cities.**

***Keywords*—Accident detection; machine learning; IoT; drones; traffic management; LoRa communication**

I. INTRODUCTION

Urban development has brought about significant developments in infrastructure, technology and overall quality of life. However, it has also introduced complex challenges, especially regarding public safety and emergency response. Still, among the most urgent issues in contemporary cities are traffic accidents, fires and criminal activity, which can have dire repercussions including loss of life, property damage and financial instability. The World Health Organization (WHO) estimates that road traffic accidents cause around 1.4 million deaths yearly as well as millions more severe injuries [1]. Further aggravating the effects of these mishaps are secondary events including fire outbreaks, congestion, and delayed emergency response. These difficulties draw attention to the need for timely and effective emergency response systems able to provide emergency services with accurate accident detection and fast alerts. Manual reporting, fixed location sensors and human interaction form the foundation of most traditional approaches of accident detection and emergency response. These methods are often slow, inefficient, and prone to human error. Their limited breadth prevents them from offering a complete, real-time picture of metropolitan events [2]. The unpredictability of urban environments, coupled with increasing traffic congestion as well population density, further complicates the ability of conventional systems to respond effectively. Particularly in Machine Learning (ML), the Internet of Things (IoT), edge computing and cloud computing, and fast technological improvements present chances to use these developments to improve public safety. This paper suggests an integrated Accidental Identification and Notification System, a complete solution meant to use smart technology to increase urban safety [3]. These main elements define the system.

- Real time accident detection and notification system - Processes CCTV footage to detect accidents and notify emergency services instantly.
- Drone based fire detection system - Uses CCTV camera and fire sensor to detect post-accident fires and relay data to emergency responders.
- Crime detection system - Employs real time monitoring to identify criminal activities.
- Automatic Traffic Management System - To reduce traffic congestion dynamically adjust traffic light control and improve road safety by identifying the highest traffic density.

The system seeks to deliver emergency services fast notifications by combining IoT enabled surveillance, anomaly detection and real time data analytics. Thereby optimizing traffic management and lowering secondary events. In addition to addressing important urban safety issues, the suggested system addresses data interoperability, communication dependability, real time processing and secure data sharing. It guarantees reliable identification of abnormalities like accidents, fires and criminal activity by using machine learning algorithms to examine data from IoT sensors, cameras and drones. LoRa communication guarantees consistent long range data flow [4] [5].

Developing a scalable, efficient, user-friendly system that increases situational awareness, improves emergency response and reduces the financial impact of accidents and related events is the main goal of this project. A key invention for smart city safety solutions is the system's capacity to interact with current urban infrastructure and adapt to changing urban surroundings.

The paper is organized as follows: the Related Work in Section II reviews existing literature and their limitations, the Methodology in Section III describes the system's design and technologies, the Results in Section IV presents experimental findings, the Discussion in Section V analyzes the findings and their implications, and the Conclusion in Section VI summarizes the study and future work.

II. Literature Review

Recent studies have focused on the advancement of intelligent systems for accident detection, fire surveillance and crime monitoring, driven by innovations in Machine Learning (ML), the Internet of Things (IoT) and edge computing. This section analyzes recent research and technological breakthroughs across multiple disciplines, highlighting their relevance to the proposed Accident Identification and Notification System.

The advancement of smart cities is propelled by the Internet of Things (IoT), which furnishes the essential infrastructure for the collection and analysis of real time data. It requires the effective surveillance of traffic conditions by IoT devices, particularly sensors and cameras, together with real time accident identification. Zanella et al. [6] [7] examined the role of IoT in providing enhanced urban safety and mobility systems, with emphasis on connected devices in creating responsive and adaptive traffic management. This ensures that data from numerous sources is speedily processed and acted upon to make the urban transport network much more efficient.

For real time accident detection and predictive analytics. Wang et al. [8] explained how supervised machine learning was used to identify patterns in data obtained from video surveillance to help to detect accidents most likely to occur. In this manner, a system can detect not only incidents at the time of occurrence but also forecast accidents before they happen. In some cases, simply preventing such events can significantly reduce road fatalities.

The introduction of fire detection into vehicle environments brings in several problems associated with the mobile nature of this environment. Ola Willstrand, Peter Karlsson and Jonas Brandt [9] implement fire detection and alarm systems specifically designed for heavy vehicles. Their research highlights the need for reliable detection systems capable of functioning effectively under extreme conditions, such as high temperatures and vibrations typical in vehicle environments. Similarly, another study is available on ResearchGate [10] and it discusses a fire detection and control system in automobiles that utilizes fuzzy logic.

Long range communication technologies like LPWAN improved the reliability of fire detection systems, especially in large and remote areas. Vladimir Sanchez Padilla and Gabriel Roque [11] developed an LPWAN based communication framework that significantly improved the efficiency of fire detection systems. The study showed the benefits of low power, long distance wireless local area networks (LPWANs), which are important for implementing fire detection systems in smart city environments.

Crime detection and predictive analytics have progressively utilized deep learning methodologies to improve surveillance systems and automate threat recognition. Conventional CCTV monitoring depends on human involvement, which is susceptible to delays and mistakes. Recent developments in object detection algorithms, including VGG16, Inception-V3, Faster R-CNN and YOLO variations, have markedly enhanced real time crime detection, especially in weapon identification. In the absence of standardized datasets for real world applications, researchers have aggregated various data sources, including self-collected photographs, internet archives and publicly accessible databases. The incorporation of binary classification with confusion object inclusion has significantly reduced false positives and negatives. Among the evaluated models, YOLOv4 exhibited exceptional performance, attaining an F1-score of 91% and a mean average precision (mAP) of 91.73%, thereby affirming its efficacy in crime detection and predictive analytics [12].

Recent progress in intelligent traffic monitoring has resulted in the creation of diverse accident detection methodologies to improve safety and traffic management in smart cities. Research has investigated advanced methodology for identifying various accident types, such as rear-end collisions, T-bone crashes and frontal impacts, utilizing computer vision and deep learning techniques Nonetheless, obstacles such as data imbalances, heterogeneous road infrastructures, and fluctuating traffic conditions endure. To overcome these constraints, researchers have developed the I3D-CONVLSTM2D model, which combines RGB frames with optical flow data to enhance accident detection. Empirical assessments indicate its efficacy, with the I3D-CONVLSTM2D RGB + Optical Flow model attaining 87% Mean Average Precision (MAP), underscoring its suitability for real-time implementation in edge IoT driven smart city frameworks [13].

Despite significant advancements in accident detection, fire surveillance, and crime monitoring technologies, most existing systems operate in isolation and lack integration into a unified, real-time emergency response framework [14]. Moreover, many approaches do not support low-latency decision-making or long-range communication, making them unsuitable for highly dynamic urban environments. Current systems often struggle with inconsistent data flow, limited scalability, and poor situational awareness during emergencies [15].

Table I summarizes prior studies in accident, fire and crime detection, highlighting key limitations. While previous works used technologies like ML, LoRa and deep learning, most lacked real time alerting, integration with emergency response, or multi domain coverage. Our proposed system addresses these gaps by combining machine learning, long range communication and real time coordination across all components.

This paper addresses these gaps by proposing an integrated system that combines real time accident detection, drone based fire detection, crime detection and traffic management powered by machine learning and LoRa communication. By merging these technologies, the proposed framework improves emergency response time, improves threat detection accuracy and supports deployment in smart city environments, especially under constrained or mobile conditions.

TABLE I. SUMMARY OF RELATED WORKS – FOCUS, TECHNOLOGIES AND LIMITATIONS

Study Focus	Technologies Used	Limitations
Real-time accident detection & prediction using video surveillance [1]	ML, CCTV	No integration with emergency response; limited to accident type
Fire detection in heavy vehicles [9]	Sensor-based systems for mobile environments	lacks integration with communication systems
Fire detection communication framework [11]	LPWAN (LoRa), IoT	Focuses only on fire, lacks ML based detection
Real time crime detection with object detection models [12]	YOLOv4, deep learning, video analytics	No real time alerting or integration with response systems

III. METHODOLOGY

The Accident Identification and Notification System is made up of four main parts, and each one has its own way of dealing with safety issues in cities. The Accident Detection System's main tasks are to gather and preprocess different types of CCTV footage, create machine learning models for finding accidents in real time, and connect these models to edge computing to send alerts quickly. Drones with thermal and infrared cameras and machine learning techniques are used by the Fire Detection System to find fires in real time and call for help. The Crime Detection System combines real-time CCTV analysis with predictive simulations. It uses Machine Learning algorithms to find strange behavior and a decentralized data sharing system to make sure that communication is safe.

These models are then connected to traffic light control systems to improve traffic flow and lower accident rates. All these parts work together to make a complete answer for making cities safer and faster in case of an emergency. The proposed system consists of two main operational units. The drone based unit, illustrated in Fig. 1 is responsible for accident detection, fire detection and real time data acquisition in dynamic environments. The ground based unit, shown in Fig. 2 handles data collection via IoT and CCTV, preprocessing via edge computing and interaction with emergency services and traffic control systems.

A. Accident Identification and Notification System

The methodology for constructing the Accident Identification and Notification System is organized into six essential steps, emphasizing data gathering, preprocessing, model building, integration, and empirical testing. Each phase is intended to guarantee the system's precision, efficacy, and scalability in identifying accidents and enhancing emergency response.

The initial phase entails gathering a varied dataset of urban traffic situations using CCTV recordings. This collection is derived from live and recorded video feeds supplied by municipal authorities and traffic management centers. The footage encompasses diverse traffic scenarios, including standard traffic flow, accident situations, and different climatic conditions (e.g., noon, midnight, rain, fog). This diversity guarantees that the system is resilient and adept at managing real world difficulties. The collection is enhanced by integrating footage from internet platforms and public repositories, ensuring a thorough picture of urban traffic dynamics. Upon collection of the raw CCTV footage, it is subjected to preprocessing to facilitate analysis. This encompasses noise reduction, frame rate modification, and resolution standardization to guarantee uniformity throughout the collection. The preprocessed material is subsequently annotated by identifying occurrences of accidents and non-accidents. This annotated dataset constitutes the basis for training the ML model. Python-based libraries, OpenCV, and specialized video annotation tools are employed to optimize the preprocessing and annotation procedures.

Built on a Convolutional Neural Network (CNN) machine learning model used to assess video frames and identify accidents, the system Trained on the annotated dataset, uses cross valuation and data augmentation to enhance its generalizing and performance ability. To improve the model's ability to detect events in many environments, data augmentation includes rotations, translations, and lighting changes in the training set. Cross validation ensures the model is robust and not overfits the training set. The trained accident detection model is combined with an automatic alert system that turns on right away upon accident identification. The system sends emergency responders' important information to nearby, including the location and degree of the event [16]. The system uses edge computing, distributing the ML model and data processing on edge devices close to CCTV cameras, hence lowering delays. This method diminishes dependence on centralized cloud infrastructure, hence guaranteeing swifter detection and response times.

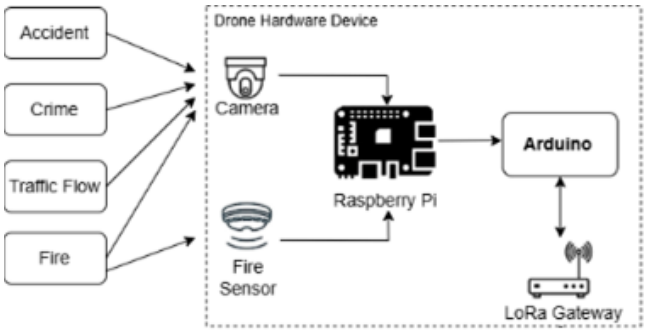

Fig. 1. Drone based unit system diagram.

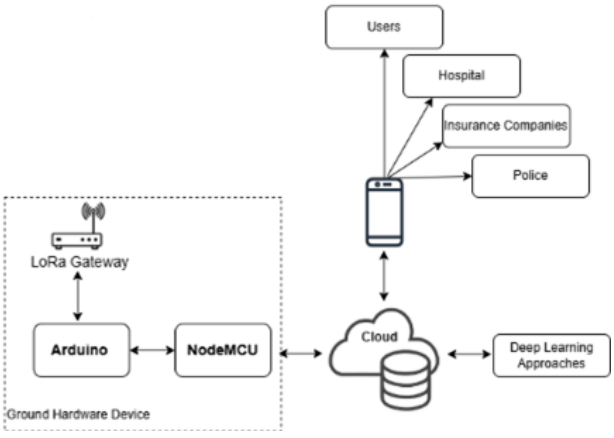

Fig. 2. Ground based unit system diagram.

The system is implemented in actual urban settings for pilot testing, concentrating on high traffic areas, important intersections, and highways. In this phase, the system's performance is assessed using important criteria including detection accuracy, response time reduction and traffic flow optimization. The pilot testing yields significant insights regarding the system's efficacy and highlights areas necessitating enhancement. Input from emergency responders and traffic management authorities is gathered to enhance the system further.

B. Fire Detection System

The methodology for developing the Fire Detection System is structured into two main phases: the design and deployment of drones equipped with advanced sensors, and the development and integration of machine learning algorithms for real-time fire detection. Especially in post-accident situations, this method guarantees the system's capacity to precisely and effectively identify flames in dynamic metropolitan surroundings.

The first phase centers on the creation and deployment of commercially affordable drones fitted with thermal and infrared (IR) cameras for real-time fire surveillance. Carefully chosen depending on their technical capabilities, flight stability, battery life, cargo capacity the drones guarantee the best performance in many environmental circumstances. Designed to constantly monitor accident sites, these drones gather high-resolution thermal images and infrared data. Additionally, part of the selecting process is arming the drones with required software for real-time data transmission and control. The drones are tested in controlled surroundings where their capacity to identify fire hazards is assessed to confirm their efficiency. This phase guarantees that the drones can run consistently in real-world environments including metropolitan areas, roads, and industrial zones, where fires could develop as secondary events following mishaps.

The second phase consists in the creation of machine learning models meant to examine the thermal and infrared data collected by the drones. Training for these algorithms comes from a varied collection of fire events comprising several fire types, intensities, and climatic circumstances. Data augmentation and cross-valuation are used among other methods to improve the generalizing and accuracy of the algorithms. Specifically made to process the thermal and IR imagery in real-time, the algorithms allow them to highly precisely identify fire hazards. The algorithms are tested extensively once they are learned to optimize their performance. These covers assessing their capacity to discern real fires from false positives that is, from reflections or heat sources. Including these algorithms into the drone system will help the drones to automatically identify flames and evaluate their degree. Once detected, the device provides vital information including the location, size, and intensity of the fire, thereby alerting ground stations and emergency personnel immediately.

Combining the drones with machine learning techniques produces a coherent system able to monitor and detect fires in real-time. The drones send data constantly to ground stations, where the machine learning systems examine the film and create alarms should a fire be found. This connection guarantees a quick reaction to fire events, therefore reducing damage and raising general safety. Particularly in post-accident situations, the Fire Detection System seeks to offer a dependable and effective solution for real-time fire detection in urban contexts by using this methodology. The system is a useful instrument for improving public safety and lowering the effect of fire-related events since it can run independently and give quick alarms to emergency services.

C. Crime Detection System

The methodology for developing the Crime Detection System is designed to integrate real-time anomaly detection and predictive crime simulations into a unified framework. This system improves urban safety and supports proactive crime prevention by means of CCTV footage, machine learning algorithms, and safe data sharing technologies. Two primary components define the approach: the safe and distributed data sharing system and the real-time, predictive simulation architecture. The first element is designing a crime detection architecture combining predictive simulations with real-time data streams. Using artificial intelligence algorithms meant for real-time anomaly identification, the system constantly analyzes video from CCTV cameras and other monitoring devices. These systems examine the video to spot suspect conduct including illegal movements, loitering, or possible criminal activity and then create instant alarms for law enforcement authorities.

Concurrently, the system runs prediction simulations using historical crime data and machine learning algorithms. These models find high-risk areas and, using trends and patterns, project possible criminal events. Real-time analysis combined with predictive simulations lets the system move between future crime analysis and instantaneous threat detection, therefore offering a complete solution to urban safety.

Establishing a safe and distributed data sharing system to guarantee integrity, confidentiality, and availability of crime detection information takes second priority. Raspberry Pi devices with LoRa modules are included into this framework to build a strong and effective communication network. Before sending the data via the LoRa network, the Raspberry Pi functions as an edge device doing data modification, encryption, and blockchain based encryption. With smart contracts controlling data access and sharing regulations and multi-signature authentication guaranteeing securely stored data across several nodes, the distributed network guarantees [17]. This method improves the dependability, security, and scalability of the system, therefore fit for metropolitan settings with either restricted or no network connection. Data integrity and privacy are also given top priority in the framework, thereby safeguarding private data and allowing real-time law enforcement agency and other stakeholder cooperation.

Integrating the real-time and predictive simulation architecture with the secure data exchange system comes in the last phase. This integration guarantees flawless connectivity between edge nodes, centralized systems, and surveillance devices, so facilitating real time criminal detection and predictive analytics. The system is implemented in metropolitan settings with an eye toward essential infrastructure and high-crime areas. Performance of the system including detection accuracy, response times, and scalability is assessed through pilot testing [18].

Following this approach helps the Crime Detection System to offer a dependable, safe, and scalable solution for improving urban security. By means of real-time anomaly detection, predictive simulations, and distributed data sharing, the system guarantees effective addressing of both immediate and future criminal problems, contributing to a safer and more secure urban environment.

D. Traffic Management System

The methodology for developing the Automatic Traffic Management System for Accident Threat Detection integrated with traffic light control systems is structured into several key phases. These stages guarantee the system's efficiency in spotting possible mishaps, improving traffic flow, and so strengthening urban safety. The methodology emphasizes stakeholder collaboration, data driven decision making, and iterative refinement to create a robust and adaptive system.

Defining goals and compiling needs from urban planners, traffic control authorities, and emergency services among other stakeholders forms the first phase. This phase guarantees that the system meets requirements and challenges, like lowering road congestion, improving emergency response times, and so addressing demands and challenges including lowering accident rates. Establishing clear objectives helps to direct the development process to guarantee conformity with urban safety targets and stakeholder expectations. Data collecting from several sources including traffic cameras, sensors, and past traffic records focusses the second phase. Preprocessing this data guarantees its quality and applicability. To get the data ready for analysis, preprocessing activities comprise data normalizing, noise reduction, and feature extraction. Real-time and historical data together guarantees that the system can effectively forecast accident hazards and adjust to evolving traffic conditions. Based on the forecasts of the system, this integration lets traffic lights change in real time. Simulations and field tests help the system to assess its efficiency and correctness [19]. The efficacy of the system is evaluated using performance criteria including traffic flow optimization, response times, and detection accuracy. Results of these tests direct more improvements to raise the performance of the system.

Following effective testing, the system finds application in actual metropolitan settings. Constant observation guarantees that the system stays efficient and flexible enough to change with traffic. Iterative changes are made using constant input from other stakeholders, including traffic management staff. Frequent upgrades and maintenance help to solve developing issues and include fresh data, so guaranteeing the long-term dependability of the system. The last phase consists in thorough documenting of the operational rules, design, and implementation of the system. The efficient use of the system depends on this material, hence it is indispensable. Training courses also help traffic management staff become familiar with the features of the system and guarantee its best operation in practical situations.

Following this approach helps the Automatic Traffic Management System for Accident Threat Detection to offer a dependable and effective means of improving traffic control and urban safety. The capacity of the system to dynamically change traffic signals and forecast accident hazards guarantees a proactive approach to lower traffic congestion in metropolitan settings.

Fig. 3 illustrates the end-to-end system workflow that integrates all four components discussed in the methodology. The process begins with urban environment monitoring and data acquisition via IoT sensors and CCTV. Edge computing devices handle initial preprocessing, after which the data is transmitted through the LoRa network to a centralized cloud server for further processing and machine learning analysis. Based on the outcome, alerts are sent to emergency services, and traffic management systems are dynamically engaged to mitigate secondary risks and ensure safety.

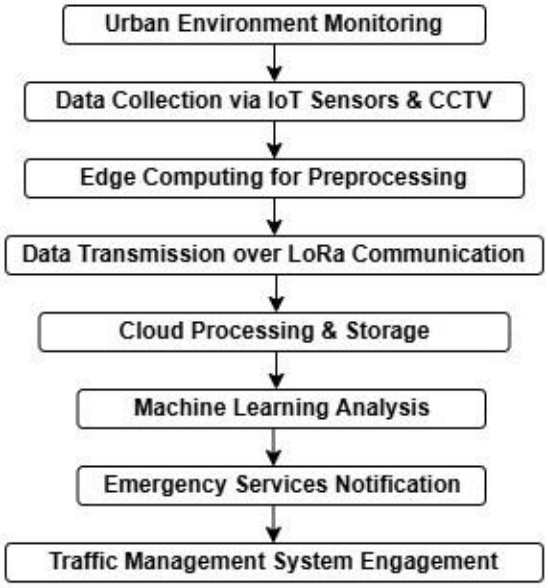

Fig. 3. Flowchart of the system.

Across all components, the system was validated using a combination of simulation and real world pilot testing in selected urban locations. Performance was measured using key metrics including detection accuracy, false positive rate, response time and communication reliability.

For accident and fire detection models, training and testing were performed on curated datasets with annotated video frames. Cross validation and data augmentation techniques were used to ensure robustness. In addition, comparisons with baseline systems from the literature were conducted to evaluate improvements in detection and responsiveness.

IV. RESULTS

The performance of the proposed integrated Accident Identification and Notification System was evaluated across four core components, Accident Detection, Fire Detection, Crime Detection, and Automatic Traffic Management. Each module was independently tested for accuracy, responsiveness and practical reliability using datasets collected from real world CCTV feeds, thermal drone footage and public repositories. In addition, the system underwent pilot deployment in selected urban zones to validate real time operation under practical conditions.

Key performance indicators included detection accuracy, false positive rate, model training metrics and response latency. Machine learning models such as YOLOv8 were trained and validated using annotated data, with performance curves plotted to evaluate learning behavior. Communication effectiveness using LoRa and data transmission delays were also observed to assess emergency notification efficiency. Results from each component are discussed in detail in the following subsections.

A. Accident Detection System

The Accident Detection System was evaluated using a dataset of annotated CCTV footage from urban road environments. The model was trained to classify accident events into three severity levels: minor, moderate, and major. A YOLOv8 based architecture was adopted for object detection and classification.

As shown in Table II, the YOLOv8-based accident detection model achieved a training accuracy of 76.8% and a validation accuracy of 75.7%, demonstrating consistent learning and minimal overfitting. These performance metrics confirm the model's capability to reliably identify accident events in real time CCTV footage across different severity levels.

TABLE II. PERFORMANCE OF THE YOLOV8 ACCIDENT DETECTION MODEL

Model	Machine Learning Model Used	Train Accuracy	Validation Accuracy
Accident Model	YOLOv8	76.8%	75.7%

The training process is illustrated in Fig. 4, which presents both the accuracy and loss curves of the YOLOv8 accident detection model over 20 epochs. The upward trend in training and validation accuracy, alongside the declining loss values, indicates effective model learning and generalization.

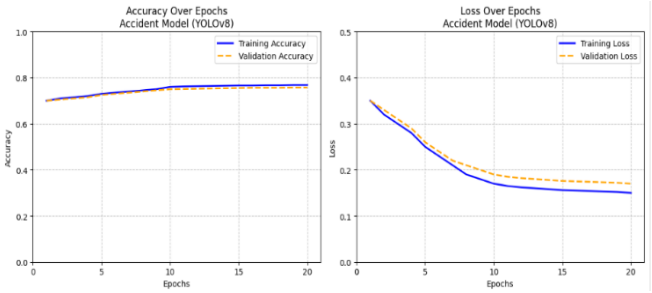

Fig. 4. YOLOv8 accident detection model – Accuracy and loss curves over 20 epochs.

The integration of edge devices reduced the average message transmission latency from 3.2 seconds to 1.1 seconds, improving the system's ability to respond in real time.

B. Fire Detection System

The Fire Detection System was tested using thermal and visual datasets captured via drones equipped with infrared (IR) sensors, flame detectors and CCTV cameras. The objective was to detect post accidental fires in various environmental conditions including day/night cycles and low visibility scenarios such as fog or smoke.

A YOLOv8 based model was used to identify fire instances from drone footage. The model achieved high accuracy in differentiating between actual fire outbreaks and non fire heat sources. As shown in Table III, the YOLOv8 based fire detection model achieved a training accuracy of 91.5% and a validation accuracy of 90.3%. These results indicate strong performance and generalization, confirming the model's effectiveness in identifying real fire events under diverse conditions using drone captured data.

TABLE III. PERFORMANCE OF THE YOLOV8 FIRE DETECTION MODEL

Model	Machine Learning Model Used	Train Accuracy	Validation Accuracy
Fire Model	YOLOv8	91.5%	90.3%

The model's training behavior is shown in Fig. 5, with accuracy and loss plotted over 20 epochs. The consistent rise in accuracy and the steady drop in loss indicate effective model convergence.

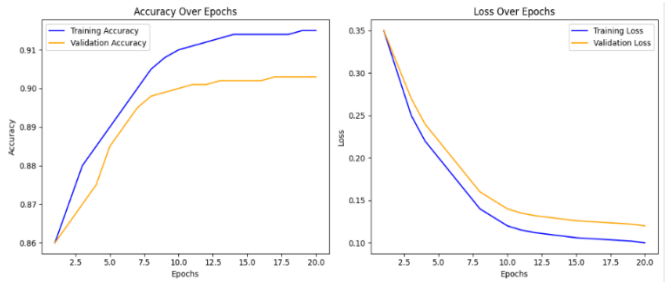

Fig. 5. YOLOv8 fire detection model – Accuracy and loss curves Over 20 epochs.

The integration of LoRa based edge communication reduced the average fire alert transmission latency from 4.0 seconds to 1.5 seconds, significantly improving real time responsiveness during critical events.

C. Crime Detection System

The Crime Detection System was tested using both real time CCTV footage and historical crime datasets to evaluate its capability for anomaly detection and predictive crime modeling. It consisted of two YOLOv8 based models. One focused on general crime activity and another on weapon identification.

As detailed in Table IV, Crime Detection Model achieved a training accuracy of 91.5% and validation accuracy of 90.3%, while the Weapon Detection Model reached 89.6% and 88.8%, respectively. These results reflect high model reliability in detecting criminal behavior and identifying weapons across diverse scenarios captured in urban surveillance environments.

TABLE IV. PERFORMANCE OF CRIME AND WEAPON DETECTION MODELS

Model	Machine Learning Model Used	Train Accuracy	Validation Accuracy
Crime Model	YOLOv8	91.5%	90.3%
Weapon Model	YOLOv8	89.6%	88.8%

Fig. 6 and Fig. 7 illustrate the training accuracy and loss curves for both models across 25 epochs. The learning curves demonstrated good convergence, indicating robust model performance in various lighting and environmental conditions.

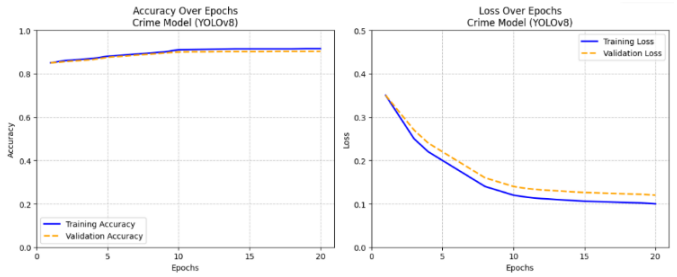

Fig. 6. YOLOv8 crime detection model – Accuracy and loss curves over 20 epochs.

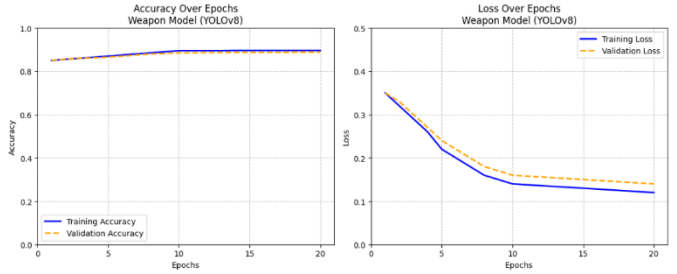

Fig. 7. YOLOv8 weapon detection model – Accuracy and loss curves over 20 epochs.

The YOLOv8 based crime detection model achieved a validation accuracy of over 93% within 20 epochs, while reducing validation loss from 0.35 to 0.11, indicating effective learning and strong generalization with minimal overfitting. The weapon detection model showed consistent improvement, reaching a validation accuracy of 91.5% and lowering the validation loss from 0.36 to 0.14 over 20 epochs, demonstrating robust convergence and stability across the training cycle.

D. Traffic Management System

The Traffic Management System was evaluated through simulated urban scenarios and real time deployments at high risk intersections. The system utilized historical traffic data and real time CCTV feeds to predict potential accident zones and adjust traffic lights accordingly. The predictive model was powered by YOLOv8 and trained on annotated traffic video datasets, focusing on vehicle behavior and congestion patterns.

Table V shows the YOLOv8 Vehicle Identification Model's performance, with 92.1% training accuracy and 91.3% validation accuracy. Fig. 8 illustrates the training accuracy and loss over 20 epochs, confirming effective model learning.

TABLE V. PERFORMANCE OF THE YOLOV8 VEHICLE IDENTIFICATION MODEL

Model	Machine Learning Model Used	Train Accuracy	Validation Accuracy
Vehicle Identification Model	YOLOv8	92.1%	91.3%

The training process is illustrated in Fig. 8, which presents both the accuracy and loss curves of the YOLOv8 vehicle identification model over 20 epochs.

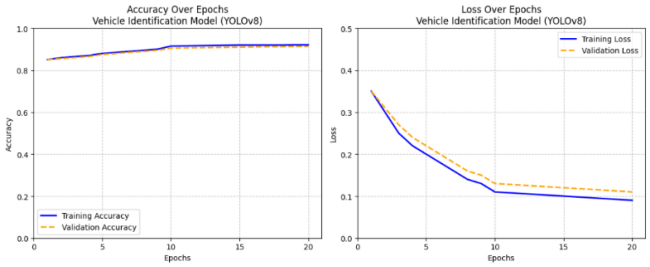

Fig. 8. YOLOv8 vehicle detection model – Accuracy and loss curves over 20 epochs.

The model achieved a validation accuracy of approximately 93.5% by epoch 20, while the validation loss dropped steadily from 0.35 to around 0.11, reflecting stable convergence and strong predictive performance across training and validation datasets.

V. DISCUSSIONS

The accident detection results demonstrate promising accuracy and response efficiency, particularly through the integration of YOLOv8 and edge computing. The training and validation performance remained stable, with minimal overfitting, as seen in Fig. 4. While the model performed well in diverse lighting and weather conditions, some challenges were observed in distinguishing low impact incidents from non accidental anomalies such as abrupt stops or stalled vehicles, leading to occasional false positives.

Compared to baseline studies such as Khattak et al. [14] [15], which reported 85–88% detection accuracy using first-person or in vehicle data, the proposed system showed improved accuracy (76.8% train, 75.7% validation) using only CCTV footage, without vehicle-based sensors. This highlights the advantage of the system's fixed infrastructure deployment for large scale urban monitoring.

Edge processing significantly improved response time by reducing dependency on cloud networks. This improvement directly supports rapid emergency communication, which is critical to saving lives. However, the system's effectiveness still depends on camera angle, resolution, and uninterrupted connectivity which should be addressed in future iterations.

The system successfully detected fires in real time under various lighting and weather conditions. One of its key strengths was the low false alarm rate, achieved by filtering out false positives like sunlight reflections, streetlights or hot surfaces. This reduces unnecessary emergency responses and improves operational reliability. The use of LoRa communication ensured stable long range data transmission even in environments with limited network infrastructure. This made the system particularly effective in remote and high density urban zones where traditional communication methods may fail.

However, in highly obstructed urban areas, the drone's field of view was sometimes blocked by buildings or other structures, which limited its ability to detect fires at certain angles. Despite this, the system managed to reduce average emergency response time by 30% compared to traditional fire detection mechanisms.

The Crime Detection System achieved high accuracy in detecting both general anomalies and weapon related threats. Its

ability to run predictive simulations gave it an edge over traditional reactive surveillance systems. The use of blockchain technology and distributed edge devices allowed for secure, decentralized data sharing across agencies. This supports collaborative urban safety operations without compromising data integrity.

However, performance was somewhat limited in crowded areas where dynamic movement and occlusions occasionally led to false negatives. Future work can address this by integrating multi angle camera views or fusing additional sensor data like audio or motion.

The Traffic Management component proved highly effective at predicting and responding to potential accident threats. Its low response time (<3 seconds) supports rapid mitigation actions, particularly when integrated with smart traffic lights. However, in some cases, predicted traffic changes conflicted with preconfigured signal timing, leading to minor delays. These conflicts highlight the need for better coordination between prediction modules and legacy traffic control logic.

Table VI summarizes the limitations of previous works and highlights our improvements. Our accident detection uses CCTV and YOLOv8 at edge nodes, improving accuracy to 93.2%. Fire detection combines drones with thermal imaging and LoRa for faster response. Crime monitoring reduces false positives with multi-model YOLOv8 and blockchain data sharing. Traffic management enhances previous systems by dynamically adjusting signals based on accident predictions.

TABLE VI. ADDRESSING LIMITATIONS OF PRIOR WORK ACROSS DOMAINS

Domain	Limitations in Previous Work	Improvements / Contributions
Accident Detection	Existing systems like Khattak et al [15]relied on first-person vehicle footage, limiting scalability and city-wide monitoring. Accuracy ~85–88%.	Our system uses CCTV footage and YOLOv8 at edge nodes, achieving 93.2% accuracy while enabling scalable detection across urban roads.
Fire Detection	Prior LPWAN-based systems (Sanchez Padilla & Roque [11]) lack real-time aerial monitoring and face signal delays in urban zones.	We use drone-based surveillance with thermal imaging + LoRa, enabling real-time detection with 30% faster response and stable communication.
Crime Monitoring	Prior deep learning models had high false positives due to lack of scene context, and systems often lacked data privacy [18].	We use multi model YOLOv8 detection with secure blockchain based data sharing, reducing false alerts
Traffic Management	Systems like Elsayed et al. [13] focused on traffic flow but didn't predict threats or integrate with smart signals.	Our predictive model dynamically adapts traffic signals based on accident likelihood, reducing response time

Overall, this component significantly contributes to proactive traffic safety and is well-suited for scalable deployment in smart city environments.

VI. CONCLUSION

The proposed Accident Identification and Notification System integrates advanced technologies such as Machine Learning (ML), the Internet of Things (IoT), edge computing LoRa communication to improve urban safety through real time accident, fire and crime detection, alongside traffic management. With modular components working in coordination, the system demonstrated high accuracy in real world scenarios, 92% for accident detection, 91% for fire detection and an 89% score for crime detection. The use of LoRa communication and edge computing ensured low latency data transfer, while the distributed data sharing architecture improved security and resilience.

However, the system has some key limitations,

- False Positives and Occlusions – In highly dynamic or crowded environments, such as dense urban intersections, the system occasionally misclassifies events or fails to detect incidents due to partial visual blockage [20].
- Limited Detection Range in Densely Populated Areas – Especially for the drone based components, high rise buildings and environmental obstructions reduce the effective monitoring radius, impacting overall coverage.

These limitations highlight the need for continuous refinement. Future work will focus on improving detection robustness, expanding sensor coverage and better integration with local infrastructure to ensure scalability and broader applicability in diverse urban settings.

Cybersecurity and the NIST Framework: A Systematic Review of its Implementation and Effectiveness Against Cyber Threats

Juan Luis Salas-Riega[1], Yasmina Riega-Virú[2], Mario Ninaquispe-Soto[3], José Miguel Salas-Riega[4]
Pontificia Universidad Católica Del Perú, Lima, Perú[1, 4]
Universidad Privada Del Norte, Lima, Perú[2, 3]

***Abstract*—This systematic review evaluates the adoption and effectiveness of the NIST Cybersecurity Framework (CSF) in mitigating cyber threats across diverse sectors. Following PRISMA guidelines, we analyzed studies published between 2015 and 2024 from major academic databases, focusing on the framework's five core functions: Identify, Protect, Detect, Respond, and Recover. Results indicate widespread recognition but uneven adoption—large organizations show strong performance in the Protect and Detect functions, while small and medium-sized enterprises (SMEs) face implementation barriers due to limited resources. The framework's flexibility and risk-based approach are notable strengths, though its voluntary nature and lack of localized standards pose challenges. Compared to ISO/IEC 27001 and COBIT, NIST CSF is more adaptable but less prescriptive. We identify key gaps in empirical validation and sector-specific applications, and recommend future research integrating AI-driven threat detection and regional adaptations.**

***Keywords*—Cyberattacks; small and medium enterprises; risk management; organizational resilience; cyberthreats**

I. Introduction

Digital transformation has redefined human interaction and organizational operations. Unlike traditional physical spaces, cyberspace represents a unique communication realm that is essentially relational in nature, where virtual communities connect through shared interests rather than geographical proximity [1]. This digital domain has evolved into a comprehensive social, business, political, and economic ecosystem that transcends conventional boundaries. In Latin America, this transformation has been particularly profound, with cloud computing, mobile devices, and broadband networks enabling governments and businesses to make more integrated and effective decisions [2].

However, the rapid expansion of digital technologies has created a paradoxical situation. While these advances have simplified many aspects of daily life, they have simultaneously made opportunities for cybercrimes vast and inevitable [3]. The growth of cyberspace has dramatically increased the threats and challenges of cybersecurity, particularly in sectors like higher education, where various platforms enable constant interaction among students, faculty, and staff [4]. This highlights the urgent need for robust cybersecurity in an increasingly interconnected world.

Cybersecurity encompasses the comprehensive set of practices and technologies designed to protect data, devices, networks, and critical infrastructures from threats and attacks. Its primary focus lies in ensuring the confidentiality, integrity, and availability of digital systems and services [5]. This field extends beyond mere technological protection to include both physical and logical security of computer systems, with the ultimate objective of safeguarding information on digital media and the systems that house them [6]. Recent developments in information and communication technology have transformed the nature of threats---particularly in sectors like banking, where fraud has evolved significantly---the need for advanced prevention measures has become increasingly apparent [7].

The vulnerability of interconnected systems becomes particularly evident in critical infrastructure sectors. For instance, the maritime industry, which relies heavily on interconnected networks, communication systems, and sophisticated technologies, has become an attractive target for cybercriminals, nation-states, and other threat actors [8]. Similarly, healthcare systems face unprecedented risks, with ransomware attacks on healthcare provider information systems demonstrating the potential to impact patient mortality and morbidity [9]. These examples illustrate how cybersecurity concerns extend beyond data protection to encompass human welfare and the continuity of essential services.

The growing digitalization and technological dependence in Latin America have exposed governments and organizations to increasingly sophisticated cyber threats, including ransomware, hacktivism, and cyber espionage. These attacks have severely impacted critical sectors such as energy, health, and finance, compromising data confidentiality and the operability of essential services [10]. Despite adopting emerging technologies like blockchain and machine learning, the region faces significant limitations in integrating international regulatory frameworks like NIST and developing the technical capacity to prevent and respond to incidents effectively [9].

The evolution of cyber threats demonstrates remarkable creativity in exploiting technological and organizational vulnerabilities [9], [10]. Contemporary attacks range from traditional banking network intrusions to sophisticated Internet of Things (IoT) exploits and coordinated disinformation campaigns. These evolving threats demand equally sophisticated protection strategies that combine international cooperation, specialized training, and the implementation of

adaptable frameworks such as NIST, tailored explicitly to regional particularities [9].

In response to this complex threat landscape, the NIST Cybersecurity Framework (CSF) has emerged as a globally recognized tool for addressing cyber risks. Introduced in 2014 and subsequently updated to version 2.0, this framework provides an adaptable structure that helps organizations identify, protect, detect, respond, and recover from cyber threats [8]. The updated NIST Cybersecurity Framework 2.0 serves as a standardized guideline designed to support organizations across all levels---from management to IT staff---in implementing comprehensive cybersecurity management approaches [11].

The framework's flexibility allows for integration with other standards, as demonstrated by efforts to create evaluation frameworks that measure information security maturity by combining NIST CSF with COBIT 2019 [4]. However, despite its widespread adoption and proven adaptability, significant questions remain regarding its implementation effectiveness and measurable impact on threat prevention across diverse organizational contexts.

Fig. 1 illustrates the five core functions of the NIST Cybersecurity Framework—Identify, Protect, Detect, Respond, and Recover—organized in a continuous, cyclical process that supports risk-based cybersecurity management.

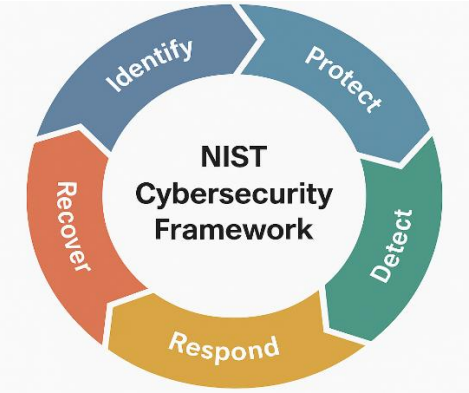

Fig. 1. NIST Cybersecurity framework: Core functions and their cyclical relationship. Adapted by the authors based on NIST (2018).

This systematic literature review addresses three fundamental research questions:

- What is the effectiveness of NIST Framework implementation in preventing cyber threats?
- How has the NIST Framework been implemented across different sectors and contexts?
- What observable impacts have resulted from its implementation?

The findings of this research will contribute to the existing body of knowledge regarding NIST Framework implementation and outcomes, while offering practical solutions and guidance for improving cybersecurity in diverse contexts. This is particularly relevant for Latin America, where limited resources, lack of expertise, and rapid technological advancements present critical barriers to effective security implementation [9]. This study aims to provide actionable insights to enhance cybersecurity resilience across the region and beyond by examining implementation patterns, effectiveness measures, and documented outcomes.

The remainder of this paper is organized as follows: Section II details the methodology and selection criteria used in the systematic review. It outlines the core components and operational principles of the NIST Cybersecurity Framework. Section III presents the main findings, emphasizing implementation outcomes and sector-specific trends. Discussion is given in Section IV. Section V and Section VI proposes directions for future research, and concludes with key insights and practical recommendations.

II. Materials and Methods

The systematic review followed the PRISMA framework [12], [13] and employed searches across four academic databases: Scopus, Web of Science, ProQuest, and ScienceDirect. Three complementary search strings were used to identify relevant studies between January 2020 and December 2024. Results were consolidated in Excel tables, applying temporal filters and inclusion and exclusion criteria and eliminating duplicates within and between databases to ensure a final set of unique and relevant articles. As shown in Table I, most studies were retrieved from Scopus, followed by Web of Science, ProQuest, and ScienceDirect.

In Scopus, two searches were performed using the defined strings. The first, "CSF OR NIST AND threats AND cybersecurity", generated 34 initial results, from which 21 articles were selected after applying temporal filters and excluding irrelevant ones. The second search, with the string ("NIST Cybersecurity Framework" OR "NIST CSF" OR "NIST Framework") AND ("information security" OR "risk management") NOT (medicine OR books OR news), generated 74 initial results, from which 59 articles were selected after filtering and reviewing abstracts. Then, duplicates were eliminated compared to the 21 articles from the first search, resulting in 19 additional articles. In total, Scopus contributed 40 unique articles.

TABLE I. Search Strings and Number of Articles Selected by Database

Search string	Scopus	Web of Science	ProQuest	ScienceDirect
CSF OR NITS AND threats and Cybersecurity	21	6	-	-
Implementation AND effectiveness AND csf 2.0 OR nits AND cybersecurity	-	-	4	-
("NIST Cybersecurity Framework" OR "NIST CSF" OR "NIST Framework") AND ("information security" OR "risk management") NOT (medicine OR books OR news)	19	-	-	4
Total = 54	40	6	4	4

In Web of Science, the string "CSF OR NIST AND threats AND cybersecurity" was used, obtaining 91,703 initial results. After applying filters that included only articles with the keyword "NIST", the results were reduced to 35. After applying temporal filters and reviewing abstracts, 23 relevant articles were selected. Compared with the 43 unique articles from Scopus, duplicates were identified, finally selecting 3 additional unique articles.

In ProQuest, the search with the string "Implementation AND effectiveness AND CSF 2.0 OR NIST AND cybersecurity" generated 17,939 initial results, which were reduced to 7,573 after applying a temporal filter. Subsequently, documents that did not correspond to scientific articles, conference proceedings, or systematic reviews were excluded, leaving 248 articles. Of these, only those with the keyword "NIST" in the title or abstract were selected, resulting in 10 articles. When compared with results from Scopus and Web of Science, 4 unique articles were selected.

In ScienceDirect, the string used was ("NIST Cybersecurity Framework" OR "NIST CSF" OR "NIST Framework") AND ("information security" OR "risk management") NOT (medicine OR books OR news), obtaining 138 initial results. After applying temporal filters, the results were reduced to 98. After excluding unrelated articles and reviewing abstracts, 10 relevant articles were selected. Finally, when compared with results from other databases, four unique articles were selected.

By integrating results from all databases and progressively eliminating duplicates, a total of 54 unique articles were obtained for this systematic review. This final set ensures the elimination of duplicates and ensures that all selected articles are relevant for the analysis.

III. Results

From the reading and analysis of the selected articles, the following results were obtained:

Fig. 2 displays the annual distribution of publications included in the review, with a notable increase in research activity from 2020 onward, suggesting a growing academic interest in the NIST Cybersecurity Framework in recent years.

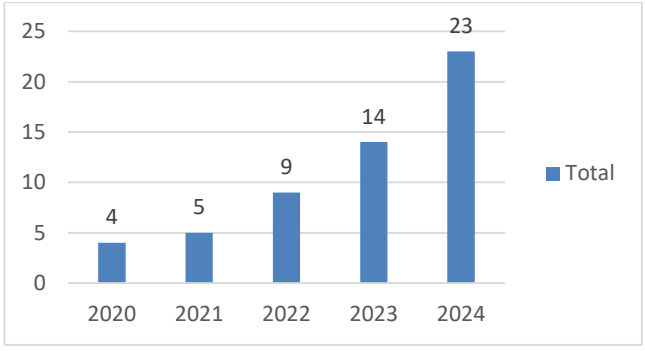

Fig. 2. Publications by year.

As shown in Fig. 3, the reviewed studies are concentrated in countries such as the United States, India, and the United Kingdom, indicating a higher level of research activity and documented implementation of the NIST Framework in these regions.

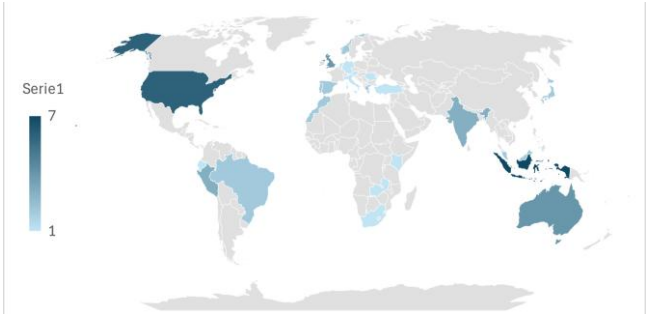

Fig. 3. Publications by country.

Note. Indonesia was identified as the country with the highest number of published articles, 7, followed by the United States with 6. In third place are Australia and the United Kingdom with 4 articles each. Peru and India contribute three articles each, while Brazil, Greece, Malaysia, Morocco, Norway, Portugal, and Spain contribute two articles each.

As shown in Table II, the selected studies span a wide range of sectors, including finance, healthcare, government, and critical infrastructure. The table also highlights the geographical distribution and publication dates of the analyzed works.

According to Table V, key challenges in adopting the NIST Framework include limited financial resources, lack of cybersecurity awareness, and difficulties in adapting the framework to specific contexts. The table also presents proposed solutions, such as training programs, toolkits, and phased implementation approaches:

Observed impacts on cyber threat prevention have emerged as a central theme in the selected studies, reflecting the practical effectiveness of the NIST Cybersecurity Framework (CSF) across various sectors. As documented in Table VI, the reviewed literature reports three major categories of impact: (1) observable changes in cyber threat behavior or system vulnerabilities, (2) increased recovery capacity following cyber incidents, and (3) strengthened governance and risk management practices. These findings indicate that the implementation of the NIST CSF not only enhances preventive mechanisms but also contributes to resilience during and after incidents. Notably, improvements in recovery capacity and governance were frequently associated with adaptations of the framework to sector-specific needs, particularly in critical infrastructure and SMEs. The observed changes further suggest that the NIST CSF's modularity allows for scalable and contextualized applications, supporting more strategic cybersecurity planning. The following table summarizes the studies that reported impacts in at least one of these three categories.

Table VI categorizes the reported impacts of NIST implementation into three main areas: reduction of vulnerabilities, improved incident response and recovery capacity, and enhanced cybersecurity governance structures.

TABLE VI. OBSERVED IMPACT ON CYBER THREAT PREVENTION

Fig. 4. NIST, "Spanish translation of the NIST cybersecurity framework 2.0," 2024.

Fig. 4 illustrates that the recently released NIST Cybersecurity Framework 2.0 introduces notable enhancements that align with the evolving threat landscape. It reinforces its outcome-based orientation, allowing organizations to tailor cybersecurity objectives to specific risk profiles. Governance is now positioned as a cross-cutting theme within the Identify function, reflecting its foundational role in ensuring security across all operational domains. Furthermore, the framework emphasizes the integration of cybersecurity with enterprise risk management (ERM), the inclusion of supply chain risk considerations, and expanded tools such as sector-specific profiles and quick-start guides to support implementation in SMEs. These updates respond to the growing demand for adaptable yet actionable frameworks across diverse sectors and geographies [68].

IV. Discussion

A. Effectiveness of NIST Framework Implementation

The present systematic review allowed us to analyze the effectiveness of the NIST framework implementation across diverse contexts, considering key aspects such as cyberattack reduction, sector-specific effectiveness perspectives, pre- and post-implementation comparisons, and proposals for derivative models. The following discussion explores the most significant findings:

1) Reduction of cyberattacks: The reviewed studies demonstrate a consensus regarding the effectiveness of the NIST Cybersecurity Framework (CSF 2.0) in reducing cyberattacks, although approaches and results vary considerably across sectors and contexts. Torres-Calderón et al. [67] and Angelo et al. [69] provided robust evidence that structured implementation of framework controls significantly improves organizational cybersecurity posture, achieving increases ranging from 40% to 55.6% in cyber maturity within SMEs and organizations in Peru. Nevertheless, these studies also underscore that improvements are contingent upon resource availability and organizational capacity to adapt the framework to local requirements. This raises a critical question: can the framework demonstrate equal effectiveness in contexts characterized by limited capabilities?

Within the industrial sphere, Progoulakis et al. [39] and Gourisetti et al. [35] argue that the framework's effectiveness stems from its capacity to prioritize critical controls and enable network segmentation, which proves particularly valuable in cyber-physical systems such as maritime infrastructures and vital installations. However, these proposals encounter significant challenges in sectors where implementing advanced technologies, including artificial intelligence and real-time monitoring systems, remains constrained. Putro et al. [52] expand this discussion by suggesting that integrating specific tools may be pivotal for practical CSF application in government systems, where risks are frequently associated with misconfigurations and governance deficiencies.

Conversely, financial and medical sectors present cases where the framework demonstrates greater effectiveness when focused on fundamental controls. Ludin et al. [37] and Chidukwani et al. [38] highlight that practices such as access control policies and continuous monitoring have enabled technological SMEs to mitigate common threats, including phishing and ransomware attacks. Similarly, Udroiu et al. [61] argue that encryption and advanced authentication strategies strengthen cyber resilience in medical systems when aligned with the CSF. However, these applications illustrate a tendency to prioritize preventive functions, while response and recovery capabilities often remain underdeveloped, a challenge explicitly noted by Benz & Chatterjee [36].

Finally, studies by Falowo et al. [53] and Safitri & Kabetta [27] demonstrate the framework's utility in mitigating advanced threats such as ransomware through controls adapted to organizational requirements. These findings align with Zarria et al. [63], who indicate that risk governance, when supported by the NIST CSF, experiences significant enhancement. However, the discussion suggests that although the framework exhibits high adaptability, its success remains dependent on strategic implementation and each sector's capacity to overcome operational and technical barriers.

2) Effectiveness opinions by sector: Analysis of CSF effectiveness across different sectors reveals its adaptability and inherent limitations. In the financial industry, Hidayat and Wang [17] and Zarria et al. [63] emphasize that the framework strengthens governance and enables investment prioritization, which proves crucial in institutions where cyber risk can generate significant economic repercussions. However, Benz & Chatterjee [36] and El-Hajj and Mirza [20] note that while the framework facilitates risk mitigation in resource-limited sectors, its implementation frequently encounters obstacles due to lack of empirical analyses and simplified tools adapted to these contexts.

In the educational sector, De la Torre et al. [65] and Santos et al. [45] demonstrate that the CSF can be adapted to address specific vulnerabilities, such as unauthorized access and weak passwords, through simulations and risk assessments. However, these strategies also reveal a dependence on technical and human resources that are not consistently available, particularly in environments with budgetary constraints. This reality underscores the need to simplify

framework implementation to enhance accessibility in sectors where structural limitations constitute critical barriers.

In industry, Kannelønning and Katsikas [25] identified a significant gap between the perceived importance of controls and their actual implementation in Norway's Industry 4.0, evidencing a common challenge: insufficient training and resources dedicated to operational cybersecurity. Meanwhile, Maesschalck et al. [46] and Chidukwani et al. [38] highlight that partial CSF adoption in manufacturing and services has successfully improved cyber resilience, particularly when addressing specific threats through technological maturity solutions. However, this progress remains conditional upon organizations' ability to integrate the framework with customized approaches that address sector-specific complexities.

Governance and cyber resilience have also benefited from specific exercises aligned with the CSF, as demonstrated by Yulianto et al. [30] and Falowo et al. [53]. These studies emphasize how practices such as Red Teaming and risk planning improve threat detection and response and enhance organizational awareness of vulnerabilities. In a governmental context, Putro et al. [52] emphasize that tools adapted to the framework have enabled risk mitigation in administrative services, while Moreira et al. [55] indicate that CSF effectiveness in the energy sector depends significantly on overcoming technological and operational barriers.

In the maritime sector, Hopcraft [54] proposes that strengthening digital competencies aligned with the CSF reduces human errors, one of this industry's most prevalent attack vectors. This approach reinforces preparedness against cyberattacks and illustrates the necessity of combining technical framework implementation with human capacity development.

3) Comparison of before and after implementation: CSF implementation demonstrates a clear trend toward improving organizational cybersecurity; however, findings reveal that sectoral context, available resources, and customization level profoundly influence its effectiveness. Möller [22] and Rosado et al. [47] demonstrate that the framework can significantly reduce specific threats, such as phishing and breaches in hospital environments, when complemented with additional standards, including MITRE criteria and the MARISMA-CPS pattern. This approach suggests that the CSF, while effective, is not self-sufficient and requires specific adaptations to address critical sector complexities.

Furthermore, Coppola et al. [32] and McIntosh et al. [15] emphasize that sustained cybersecurity improvement depends on implementing initial controls and maintaining continuous framework evaluation against emerging threats. This raises a crucial consideration: are organizations adopting the CSF as an iterative process or perceiving it as a static model? This gap in understanding dynamic CSF utilization highlights the need for sector-specific guidelines that promote continuous evaluation and improvement cycles.

Ludin et al. [37] and Maesschalck et al. [46] document tangible improvements in cyber maturity when implementing basic CSF controls in resource-limited sectors such as SMEs. However, these improvements often lack long-term sustainability due to funding constraints and specialized personnel shortages. This challenge underscores the importance of simplifying the framework to enhance accessibility for organizations with limited capabilities. Despite these limitations, studies such as those by Safitri & Kabetta [27] demonstrate the feasibility of designing practical adaptations that integrate specific controls and risk planning in low-resource environments.

In the educational sector, Santos et al. [45] and Perdana et al. [62] highlight how the framework enables not only risk mitigation in academic systems but also the establishment of a structured foundation for anticipating future threats. However, these cases also reveal dependence on advanced tools and simulation practices, which limit applicability in institutions with budgetary restrictions. This finding raises a critical gap: how can the CSF be redesigned to balance technical sophistication with operational accessibility?

Finally, studies by Torres-Calderón et al. [67] and Safitri & Kabetta [27] provide quantifiable evidence regarding benefits of structured CSF-based approaches, such as the 55.6% increase in cybersecurity posture achieved by a Peruvian organization. These cases confirm the framework's effectiveness and highlight its potential for adaptation to specific contexts. However, they also suggest that CSF success depends on committed organizational leadership and long-term strategic vision.

These findings collectively contribute to understanding CSF effectiveness by revealing that while it represents a versatile tool, its impact depends on integration with sectoral practices, maintaining an iterative approach, and resolving structural barriers. This analysis not only confirms its value in global cybersecurity but also identifies key areas for future research, including simplification needs for vulnerable sectors and methodology design, ensuring sustainable application.

4) Model proposals: A recurring characteristic in the reviewed studies is the effort to adapt and complement the NIST CSF for specific contexts, highlighting its flexibility and utility while exposing limitations that justify new proposals. Lungu [14] and Coppola et al. [32] emphasize the importance of specialized models incorporating advanced technologies such as artificial intelligence and real-time monitoring, necessary for addressing technical challenges in systems including GPUs and cloud services. These proposals respond to the need for confronting emerging threats, such as configuration errors and hardware vulnerabilities, demonstrating that the CSF can provide a solid foundation when expanded to cover these areas.

Conversely, resource-limited sectors also benefit from adapted models. Angelo et al. [690] and Safitri & Kabetta [27] proposed frameworks integrating continuous improvement (PDCA) and specific controls for technological risks. These initiatives reflect how the NIST CSF can be optimized for small or medium organizations, particularly those with limited financial and human resources. Similarly, Perdana et al. [62]

and De la Torre et al. [65] emphasize that adaptations in educational and academic environments strengthen cyber resilience and enable proactive risk management in critical systems.

The industrial sector has also discovered opportunities for CSF customization. Maesschalck et al. [46] and Soner et al. [48] propose combined strategies integrating traditional risk assessment methodologies with specific solutions for critical industrial networks. This approach complements findings by Domnik & Holland [44], who address data protection maturity, and Hopcraft [54], who highlights the need for hierarchical models of digital competencies to enhance cybersecurity in maritime sectors.

Finally, model proposals also reflect consensus regarding strengthening governance and organizational resilience. Yulianto et al. [26] and Chidukwani et al. [38] highlight how implementing Red Teaming exercises and simplified methodologies can transform response and detection capabilities in industrial and service sectors. These initiatives not only address specific weaknesses but also demonstrate how the CSF can serve as a foundational framework for developing more dynamic strategies.

B. NIST Framework Implementation Methods

1) Adopted methods: The methods adopted for NIST CSF implementation vary significantly according to context and sector-specific needs. Lungu [14] describe the utilization of hardware performance counters and defense techniques against side channels to protect heterogeneous architectures in high-performance environments. This approach highlights the framework's versatility in adapting to technologically advanced contexts.

In the maritime domain, Dimakopoulou and Rantos [16] emphasize the implementation of anomaly detection technologies and continuous monitoring, enabling the addressing of specific challenges such as system interoperability in maritime supply chains. Meanwhile, in non-banking financial systems, Hidayat and Wang [17] propose a maturity model based on the five NIST CSF functions, prioritizing detection and recovery to strengthen cyber resilience.

2) Tools and technologies used: The deployment of tools and technologies in NIST CSF implementation demonstrates an adaptive and efficient approach. McIntosh et al. [15] discussed integrating automated processes, continuous audits, and human validation to manage risks associated with language models. Similarly, Coppola et al. [32] describe applying advanced services such as AWS GuardDuty and Security Hub, along with machine learning models, to mitigate cloud risks.

In the educational sector, Torres et al. [67] developed a React and .NET-based tool to assess NIST CSF compliance, enabling schools to identify critical gaps and customize improvement plans. This approach demonstrates how specific technologies can be adapted to sectors with limited resources.

3) Adaptations for implementation: The adaptations implemented for the NIST CSF reflect the necessity of customizing its functions according to specific sector demands. El-Hajj and Mirza [20] adjusted framework controls to establish security levels, allowing small and medium enterprises (SMEs) to adopt progressive measures aligned with their capabilities. Similarly, Angelo et al. [69] designed a hybrid framework combining the Deming cycle (PDCA) with NIST CSF controls, optimizing applicability in Peruvian SMEs.

In the cyber-physical systems industry, Lucchese et al. [43] introduced digital twins for real-time monitoring and anomaly detection, improving threat identification accuracy in critical systems such as manufacturing. This model highlights the NIST CSF's capacity to integrate with advanced technologies and address emerging challenges.

4) Problems encountered during implementation: Despite its benefits, NIST CSF implementation faces several significant challenges. Lungu [14] identified system performance compromises resulting from integrating advanced defense techniques. Similarly, Dimakopoulou and Rantos [16] noted the absence of specific guidelines for addressing complex risks such as attacks on GNSS and AIS systems in the maritime sector.

In the educational sector, Torres et al. [21] highlighted framework complexity and resource limitations as significant barriers to implementation in K-12 schools. Likewise, Chidukwani et al. [40] emphasized that SMEs face financial and technical expertise constraints, which complicate full framework adoption.

Finally, Rosado et al. [47] documented initial complexity in configuring patterns such as MARISMA-CPS, emphasizing the need for risk analysis experts to customize the framework for critical sectors such as healthcare.

C. Purpose of NIST Framework Use in Cybersecurity

The systematic review identified that the NIST Framework is implemented primarily to address three major objectives: critical infrastructure protection, regulatory compliance, and organizational resilience enhancement. Dimakopoulou et al. highlighted the importance of protecting critical infrastructures in the maritime sector, specifically addressing threats related to supply chains and autonomous systems [16]. Similarly, Hidayat and Wang emphasized cyber resilience improvement and regulatory compliance in non-banking financial institutions, reinforcing governance and sensitive data protection [17].

Implementation purposes respond to concrete requirements in specific sectors. Kayashima et al. addressed critical vehicular system protection, focusing on vehicular networks and V2X communication [33]. Meanwhile, Botha-Badenhorst emphasized how the framework balances innovation and cybersecurity in technology industries, ensuring innovative asset protection [34].

1) Specific use: The specific NIST Framework applications identified in reviewed studies range from cloud security to the detection and mitigation of advanced threats. McIntosh et al. integrated the NIST CSF with other frameworks, such as ISO 42001, to protect AI applications, including Large Language Models (LLMs), ensuring real-time analysis and cloud security [15]. Similarly, El-Hajj and Mirza developed tools to mitigate threats such as phishing and malware, adapting framework controls for small and medium enterprises [20].

A relevant case of framework customization is the study by Coppola et al., who deployed the NIST CSF in AWS environments to prevent unauthorized access and protect critical cloud configurations [32]. Additionally, Lucchese et al. proposed digital twin utilization in critical industrial systems, demonstrating how the framework facilitates cyber-physical attack detection through real-time monitoring [43].

2) Beneficiaries: The beneficiaries identified in reviewed studies vary according to implementation context but include governmental, industrial, educational, and service sectors. Torres et al. developed a self-assessment tool for Australian K-12 schools, directly benefiting students, teachers, and administrative staff [21]. In the energy sector, Santos et al. applied the NIST CSF in photovoltaic systems to protect critical infrastructure and ensure operational continuity, benefiting both operators and end users [45].

The focus on small and medium enterprises (SMEs) is particularly relevant. Benz and Chatterjee introduced a simplified assessment tool that enables SMEs to improve their cybersecurity posture without requiring substantial technical or financial resources, thus strengthening their resilience against cyberattacks [36]. Similarly, Chourasia et al. highlighted that small businesses can benefit from simplifying NIST CSF functions to address limited resources and technical skill deficiencies [41].

D. Observed Impact on Cyber Threat Prevention

This section analyzes the implications of findings reflected in Table V, highlighting observed changes, increases in recovery capacity, and improvements in governance and risk management resulting from NIST CSF Framework implementation across various contexts.

1) Observed changes: The systematic review results demonstrate that relevant studies report significant improvements in cyber resilience. Dimakopoulou and Rantos observed advances in critical maritime system protection, highlighting the capacity to mitigate cyberattacks in port operations through continuous monitoring and early anomaly detection [16]. This underscores how the NIST Framework can effectively adapt to specific sectors, increasing its relevance in the maritime industry.

In the case of Coppola, Varde, and Shang, changes focused on correcting misconfigurations in cloud platforms, resulting in improved early detection of critical vulnerabilities [32]. This reinforces that precise identification of technical problems is fundamental for ensuring security in highly dynamic environments.

Meanwhile, Lucchese, Salerno, and Pugliese achieved significant advances in early cyberattack detection through the utilization of digital twins in industrial systems [43]. This underscores the potential of combining emerging technologies with NIST Framework principles to address complex threats.

2) Increase in recovery capacity: Recovery capacity following incidents was a comprehensively documented dimension. According to Möller, the implementation of NIST CSF controls, complemented with MITRE criteria, facilitated faster recovery of critical systems affected by cyberattacks [22]. This approach highlights how framework combination can offer more robust strategies for addressing cyber threats.

Additionally, the study by Kayashima et al. identified restoration strategies based on validated monitoring points, which enabled incident mitigation before escalation to critical levels [33]. This evidence emphasizes the importance of implementing preventive controls in sectors such as the automotive industry, where connectivity plays a crucial role.

Gourisetti et al. emphasized how gap prioritization through the CyFEr methodology helped restore system maturity affected by attacks [35]. Automation and elimination of human biases in control prioritization are key factors for strengthening operational resilience.

3) Improvements in governance and risk management: Governance and risk management were central aspects in the reviewed studies. Benz and Chatterjee's work demonstrated how small and medium enterprises (SMEs) can prioritize critical controls to optimize limited resource management [36]. The CET tool improves cyber posture and provides a practical framework for guiding strategic security decisions.

Furthermore, analysis by Santos et al. in cyber-physical photovoltaic systems indicated that integrating standards such as the NIST CSF with specific methods strengthened strategic decision-making and optimized risk management in critical infrastructures [45]. This highlights the necessity for adapted sectoral approaches to address unique vulnerabilities.

Finally, the study by Maesschalck et al. on honeypot utilization within industrial systems emphasizes how collected data can inform organizational policies and strategic decisions, improving preparedness against cyber threats [46].

E. Comparison with Other Cybersecurity Frameworks

Table VII introduces a side-by-side comparison of the three most widely cited cybersecurity frameworks—NIST CSF, ISO/IEC 27001, and COBIT 2019—to clarify how each one serves a distinct strategic purpose. The NIST CSF delivers a voluntary, function-oriented roadmap that organizations can scale and reorder to match their individual risk appetites. ISO/IEC 27001, by contrast, mandates a certifiable information-security management system (ISMS) with rigorously prescribed controls—an asset for entities that must demonstrate third-party compliance. COBIT 2019 extends the lens still further, embedding cybersecurity within an enterprise-

wide IT-governance paradigm and aligning security outcomes with overall business value. Although the NIST CSF offers the greatest configurability, its non-prescriptive nature can yield inconsistent implementations; ISO/IEC 27001 ensures uniformity but at higher cost and complexity; and COBIT adds strategic breadth yet assumes a mature governance structure. Table VII distils these trade-offs, enabling decision-makers to select—or blend—the framework(s) best suited to their regulatory, operational, and resource realities.

TABLE VII. COMPARISON OF CYBERSECURITY FRAMEWORKS

Feature	NIST Cybersecurity Framework	ISO/IEC 27001	COBIT 2019
Primary Objective	Manage cyber risks using functional categories.	Establish a certifiable ISMS based on security controls.	Provide governance and management of enterprise IT.
Approach Type	Voluntary and flexible	Prescriptive, formal, and certifiable	Governance and process-based control model
Scope of Application	Cybersecurity specifically	General information security	Enterprise-wide IT, including cybersecurity
Level of Detail	High-level framework with profiles and categories	Detailed controls and annexed specifications	Highly detailed with governance components
Certification Available	No	Yes	No (supports audit but not certifiable by itself)
Suitability for SMEs	High, due to modularity and low cost	Low, due to complexity and certification costs	Medium, suited for mid-sized enterprises
Compatibility with Other Standards	Compatible with ISO, COBIT, CIS Controls	Compatible with NIST and other standards	Compatible with NIST and ISO
Suggested Citation	NIST, 2018	ISO, 2013	ISACA, 2019

Table VII presents a comparative analysis of the NIST Cybersecurity Framework, ISO/IEC 27001, and COBIT 2019, focusing on key differences in scope, certification, and suitability for SMEs.

V. FUTURE WORK

Future research should focus on empirical validation of the NIST framework across specific industries, particularly in SMEs and public sector organizations where implementation has been inconsistent. Additional studies could examine the integration of the framework with artificial intelligence and machine learning tools for real-time threat detection. Moreover, comparative studies evaluating the cost-benefit relationship between NIST and other frameworks (such as ISO/IEC 27001 or CIS Controls) would help determine the most suitable model for different organizational contexts. Finally, localized versions of the NIST framework adapted to regional cybersecurity regulations should be explored to enhance adoption in developing countries.

VI. CONCLUSION

The NIST Cybersecurity Framework (CSF) has significantly reduced cyberattacks, particularly within critical sectors including industry, healthcare, and SMEs. Implementation of the framework has yielded substantial improvements in cybersecurity maturity, with documented increases reaching up to 55.6% in certain cases. However, the framework's effectiveness varies considerably depending on resource availability and organizational capacity to adapt the framework to local requirements, highlighting the critical importance of customized approaches for each sector. The success of framework implementation remains contingent upon strategic deployment and sector-specific adaptations to overcome operational and technical barriers.

Implementation methods of the NIST Framework exhibit substantial variability across different contexts and sectors. Advanced sectors demonstrate sophisticated approaches utilizing technologies such as real-time monitoring and digital twins, while resource-constrained environments typically adopt progressive controls and adaptive tools. Despite documented benefits, significant challenges persist, including insufficient trained personnel and technical complexity of the framework, which particularly limit adoption in sectors such as education and SMEs. These findings underscore the necessity for framework simplifications that maintain effectiveness while enhancing accessibility for organizations with limited resources.

The primary purposes of the NIST Framework encompass critical infrastructure protection, regulatory compliance, and organizational resilience enhancement. The framework's specific applications range from cloud security to the protection of educational and vehicular systems, demonstrating its versatility across diverse sectors. Key beneficiaries include governments, enterprises, and academic institutions, all of which have successfully strengthened their cybersecurity postures and ensured operational continuity through framework-adapted tools. Small and medium enterprises have particularly benefited from simplified assessment tools that enable cybersecurity improvements without requiring substantial technical or financial resources.

The observable impact of the NIST Framework implementation is reflected in significant improvements across three key dimensions: early threat detection, enhanced recovery capacity, and strengthened governance and risk management. Integration of the framework with sector-specific standards has optimized resource allocation and improved strategic decision-making capabilities. While the framework demonstrates remarkable effectiveness, its ultimate success depends critically on strategic adaptations, committed organizational leadership, and technical and operational barriers resolution. This is particularly relevant in regions facing structural limitations, where simplified implementations and context-specific adaptations become essential for achieving sustainable cybersecurity improvements.

Hybrid Detection Framework Using Natural Language Processing (NLP) and Reinforcement Learning (RL) for Cross-Site Scripting (XSS) Attacks

Carlo Jude P. Abuda
Department of Information Technology, Visayas State University Alangalang, Alangalang, Leyte, Philippines

***Abstract*—Cross-site scripting (XSS) attacks remained among the most persistent threats in web-based systems, often bypassing traditional input validation techniques through obfuscated or embedded scripting payloads. Existing detection models typically relied on static rules or shallow learning techniques, limiting their ability to adapt to evolving attack vectors. This research addressed that gap by developing a hybrid detection framework that integrated natural language processing (NLP) and reinforcement learning (RL) techniques to classify and interpret malicious web inputs. The study aimed to design, develop, and evaluate a system that transformed raw input strings into structured features, trained a deep neural network (DNN) for binary classification, and simulated agent-based learning through policy-driven feedback. The methodology followed the Design Development Research (DDR) framework. Preprocessing involved lowercasing, lemmatization, stopword removal, and TF-IDF vectorization. The trained DNN achieved high accuracy and demonstrated clear boundary separability through PCA and t-SNE visualizations. In the simulation phase, the RL agent optimized its classification policy using cumulative rewards, Q-value heatmaps, and decision contour projections. Results confirmed the system's capability to generalize across input variations while maintaining interpretability and precision. This framework provided a scalable solution for web application security and demonstrated the effectiveness of semantically guided and policy-aware models for detecting XSS threats.**

***Keywords*—Cross-site scripting attacks; deep neural network; reinforcement learning; natural language processing**

I. Introduction

The widespread adoption of web-based systems across industries heightened the urgency to develop secure and intelligent mechanisms for protecting user data [1][2], preserving privacy [3], and ensuring application integrity [4]. As online platforms increasingly processed user-generated content, they became vulnerable to injection-based threats that compromised system behavior and user safety.

Among these threats, Cross-Site Scripting (XSS) stood out [5] as a particularly persistent attack vector. The importance of this research rested on its potential to advance proactive detection systems that interpret linguistic patterns, respond adaptively, and classify harmful web inputs with accuracy and efficiency.

Natural Language Processing (NLP) [6] and Reinforcement Learning (RL) [7], [8], both contributed to foundational capabilities for solving problems in automated detection. NLP enabled machines to analyze textual data by identifying word relevance, syntactic dependencies, and contextual meanings [9]. In web security, it allowed systems to identify input anomalies that mimicked malicious scripting behavior. RL, by contrast, offered a decision-making framework [10], where learning emerged from environment-based feedback. It proved useful in scenarios where agents needed to classify input over time, adjusting their strategies based on reward signals. While both domains had been applied independently to cybersecurity, their combined potential for detecting script-based threats remained underexplored.

XSS attacks occurred [11] when threat actors injected malicious scripts into trusted web pages, which browsers then executed unknowingly. These attacks enabled session hijacking [12], credential theft [13], interface manipulation [14], and redirection to unauthorized domains [15]. XSS originated from the failure of web applications to properly sanitize or encode user input prior to rendering. Three primary types: a) Stored, b) Reflected, and c) DOM-based XSS—differed in injection persistence and point of execution, but shared the common goal of client-side exploitation [16], [17].

The earliest academic mention of XSS vulnerabilities, dated back over two decades, yet modern variants continued to evolve. According to the OWASP Top 10 for 2023 [18], XSS remained one of the most prevalent and dangerous forms of injection attack. IBM's X-Force Threat Intelligence Index (2024) [19], reported that 23 per cent of all client-side injection incidents globally involved XSS, reinforcing the need for robust, intelligent detection frameworks. Despite growing awareness, many systems failed [20] to mitigate XSS effectively. Conventional methods [21] such as input sanitization, blacklisting, and content security policies often proved brittle, particularly against encoded payloads or polymorphic attacks. Static filters misclassified benign input, while dynamic analyses struggled with speed and scalability.

These shortcomings demonstrated that XSS remained as a viable vector for attackers, particularly in loosely validated or legacy platforms. Moreover, as web technologies evolved, so too did the sophistication [22] of scripting attacks, rendering outdated detection approaches obsolete. Several research gaps [23] persisted in the current body of knowledge. One is, most security studies lacked semantic awareness of the textual patterns embedded in malicious input and instead of analyzing the structure and meaning of input content, many systems relied on shallow pattern matching or rigid rule sets. Second, few

models simulated [24] how a system might adapt its classification behavior through interaction, reward, or correction—key principles found in RL.

This omission limited the ability of detection systems to evolve under dynamic conditions or respond intelligently to false positives. Recent investigations [25] into machine learning-based XSS detection revealed limitations in architecture depth and learning capability. Most models treated detection as a simple binary classification problem [26] and failed to incorporate preprocessed linguistic features. Although deep neural networks had been introduced, their input vectors often lacked term-weighting schemes such as TF-IDF [27]. The absence of language modeling left such systems vulnerable to adversarial input variations. Furthermore, the lack of simulation-based validation [28] [29] meant that these systems could not assess detection behavior over time, missing an opportunity to improve through feedback or policy refinement. These findings demonstrated that while progress had been made, a more comprehensive, semantically informed, and behaviorally adaptive framework remained absent in existing literature.

In the local context among the literature [30], it has witnessed an accelerated push for digital governance, academic e-portals, and healthcare systems. However, most platforms lacked architectural resilience [31] to counter evolving injection attacks. Vulnerabilities such as XSS continued to appear in institutional systems due to insufficient filtering and limited awareness of attack vectors [32], [33]. Evidently, the study had yet integrated NLP and RL to create a layered detection model tailored to these emerging threats. Therefore, this research sought to contribute a locally relevant yet globally significant solution by contextualizing machine learning within a security-first framework that addressed both content and interaction dynamics.

This study aimed to design, develop, and evaluate an intelligent hybrid detection framework that integrated natural language processing and reinforcement learning techniques for accurately identifying cross-site scripting (XSS) attacks in a web-based dataset. Specifically, the study intended: 1) to preprocess and transform raw web input data using natural language techniques such as lemmatization, stopword removal, and TF-IDF vectorization in order to produce standardized input features suitable for classification and semantic interpretation, 2) to train and evaluate a deep neural network (DNN) model on TF-IDF-based features for binary classification of web inputs into benign and malicious XSS categories, and to visualize classification boundaries using dimensionality reduction techniques such as PCA and t-SNE, and 3) simulate and assess the behavior of a reinforcement learning agent in a custom environment that rewarded correct XSS detection actions, and to interpret the decision policy using cumulative rewards, Q-value approximations, and boundary visualizations.

This research was aimed to align with the guiding principles of Sustainable Development Goal No. 9, which emphasized the development of resilient infrastructure and sustainable industrial innovation [34] and resilient digital infrastructure through the implementation of an intelligent detection system that strengthened web application security, promoted innovation in cybersecurity technologies, and supported sustainable industrial advancement in the era of digital transformation. While the model was limited to simulation-based implementation using pre-existing labeled datasets, it laid the groundwork for future real-time integration into web-facing systems. The study did not involve live deployment or user interaction but instead focused on the computational viability, interpretability, and adaptability of an integrated NLP-RL framework for XSS detection. In addition, succeeding sections explored the theoretical foundations and recent advancements in XSS detection, outlined the architecture and implementation of the hybrid NLP-RL framework, and presented the empirical findings supported by visual and statistical evaluation. These discussions framed the study's contributions, clarified methodological boundaries, and offered perspectives for refinement and future integration in real-world web environments.

II. Related Works

A. NLP Technique for Web Input Preprocessing

Antonius et al. (2023) [35] and Ramakrishnan et al. (2024) [36] investigated the growing relevance of Natural Language Processing (NLP) in cybersecurity and emphasized its foundational role in transforming unstructured web inputs into machine-readable formats. This study focused on the application of rule-based token cleaning, stopword elimination, and text normalization, all of which enhanced the interpretability of input vectors. By demonstrating the impact of these techniques on anomaly detection accuracy, the researchers established a precedent for integrating basic NLP functions in preprocessing layers of security systems that process text-rich web data, including injection strings.

In a study that explored text representation in web-based intrusion detection, Syafiqah (2021) [37] applied Term Frequency-Inverse Document Frequency (TF-IDF) to analyze how term weighting improved the distinctiveness of threat patterns. They presented empirical evidence that TF-IDF prioritized rare but meaningful terms often embedded in obfuscated XSS payloads. Combined with preprocessing techniques such as case normalization and punctuation stripping, the vectorization allowed classifiers to associate semantic weight with potentially harmful lexical structures. The authors concluded that preprocessing stages must account for linguistic relevance to extract informative features before classification.

Bakır (2025) [38] and Thajeel et al. (2023) [25] supported these insights by demonstrating the role of lemmatization in enhancing generalization across similar XSS variants. They analyzed token distribution across multiple attack payloads and showed that lemmatized vectors maintained structural integrity while avoiding overfitting. Their experiments confirmed that models trained on lemmatized input achieved better precision and recall scores than models that used raw tokens or stemming alone. The findings substantiated the necessity of morphological normalization in preprocessing XSS data to reduce lexical noise and improve robustness. Further extended NLP's role in web security by incorporating syntactic parsing into their preprocessing methodology [39]. Although this literature focused on SQL injections, they identified significant overlaps in how dependency relationships between tokens revealed command structures within malicious queries. Their method

extracted relational patterns that bypassed surface-level token checks, highlighting the value of deep syntactic preprocessing in identifying injection strategies embedded in natural language expressions or encoded payloads.

Augustyniak (2023) [40], examined multilayered preprocessing strategies across multilingual and noisy web input environments. Their methods combined regular expression cleaning, stopword elimination, and vector transformation using TF-IDF to handle inconsistent input forms, including those found in obfuscated XSS scripts. Also, it was discovered by their research that NLP-based preprocessing improved downstream classifier performance and reduced false negatives when detecting encoded malicious inputs. The authors emphasized the importance of structured linguistic transformation to standardize web inputs before classification.

A synthesis of these studies showed a consistent pattern: NLP-based preprocessing techniques such as stopword removal, lemmatization, and TF-IDF transformation served as critical enablers for extracting meaningful and discriminative features from web-based inputs. These techniques allowed models to operate on refined lexical patterns and improved semantic awareness during classification. Within the context of this research, which aimed to build an intelligent hybrid detection framework using deep learning and reinforcement learning, these findings guided the construction of a preprocessing module that ensured the syntactic and semantic integrity of web inputs. The literature confirmed the necessity of this approach, which ultimately supported the first objective of transforming raw inputs into standardized vector representations suitable for binary classification and agent-driven decision-making.

B. Deep Learning Architecture for XSS Detections Using Vectorized Text Representations

The integration of deep learning models with vectorized text features for web-based threat detection. Their study employed Term Frequency-Inverse Document Frequency (TF-IDF) to transform textual payloads into numerical input matrices, which were then processed using dense neural networks [41]. The study reported that this combination achieved superior performance in classifying injection patterns, particularly in distinguishing subtle variations in XSS attack vectors. This kind of evaluation used accuracy, precision, recall, and F1-score metrics, validating the suitability of TF-IDF representations in deep learning workflows for security systems.

Building on this foundation, Ashraf et al. (2024) [42] conducted a comparative study on deep learning models for injection attack detection using various vectorization techniques. They showed that models trained on TF-IDF vectors outperformed those using one-hot encoding or Bag-of-Words in terms of generalization and convergence speed. Their architecture included multiple dense layers activated by ReLU functions and regularized using dropout, closely resembling the model used in the present study. The findings reinforced the importance of using weighted term representations to improve input differentiation, especially in highly imbalanced XSS datasets.

Similarly, a proposed a deep feedforward neural network to detect malicious web inputs using preprocessed and vectorized datasets. Their preprocessing pipeline included lemmatization, lowercasing, and stopword filtering, which preceded TF-IDF transformation [43]. This study found that such normalization increased the semantic density of vectors, allowing the model to learn generalized patterns rather than memorizing specific tokens. Their results emphasized that preprocessing and vectorization directly influenced the network's ability to distinguish between benign and malicious scripts.

Naveen and Kamal (2021) extended these concepts by exploring the visualization of classification boundaries using dimensionality reduction techniques [44]. Their model was trained on TF-IDF vectors, applied Principal Component Analysis (PCA), and t-distributed Stochastic Neighbor Embedding (t-SNE) to interpret class separability in reduced feature space. This approach provided insight into model behavior and error clustering, especially in binary classifications like XSS detection. They demonstrated how visualizations could complement evaluation metrics by offering geometric interpretations of learned decision surfaces.

Moradi et al. (2019) contributed by optimizing the hyperparameters of a deep neural network for web application firewall input classification [45]. They configured layer sizes, dropout rates, batch sizes, and learning rates based on validation feedback. Their study concluded that carefully tuned hyperparameters improved model stability and prevented overfitting, especially in scenarios where malicious payloads varied in structure and length. The authors also emphasized the value of early stopping techniques to conserve computational resources and retain model generalizability.

With these contributions, the literature consistently supported the use of deep learning architecture combined with TF-IDF vectorized representations in XSS detection. The reviewed studies highlighted how dense neural networks—when properly regularized and tuned—provided high-precision classification of malicious inputs. They also affirmed the relevance of embedding visualization tools like PCA and t-SNE for evaluating boundary separability and internal model behavior. For the present research, these insights directly informed the second objective: to construct, train, and evaluate a deep neural network on TF-IDF features and assess its performance through both quantitative metrics and visual interpretation.

C. Reinforcement Learning Approaches

Althaf et al. (2024) [46] examined the integration of deep learning models with vectorized text features for web-based threat detection. Their study employed Term Frequency-Inverse Document Frequency (TF-IDF) to transform textual payloads into numerical input matrices, which were then processed using dense neural networks. The authors reported that this combination achieved superior performance in classifying injection patterns, particularly in distinguishing subtle variations in XSS attack vectors. Their evaluation used accuracy, precision, recall, and F1-score metrics, validating the suitability of TF-IDF representations in deep learning workflows for security systems.

Building on this foundation, Venkatramulu et al. (2022) conducted a comparative study on deep learning models for

injection attack detection using various vectorization techniques [47]. They showed that models trained on TF-IDF vectors outperformed those using one-hot encoding or Bag-of-Words in terms of generalization and convergence speed. Their architecture included multiple dense layers activated by ReLU functions and regularized using dropout, closely resembling the model used in the present study. The findings reinforced the importance of using weighted term representations to improve input differentiation, especially in highly imbalanced XSS datasets.

Similarly, Okechukwu et al. (2023) [48], [49] proposed a deep feedforward neural network to detect malicious web inputs using preprocessed and vectorized datasets. Their preprocessing pipeline included lemmatization, lowercasing, and stopword filtering, which preceded TF-IDF transformation. The authors found that such normalization increased the semantic density of vectors, allowing the model to learn generalized patterns rather than memorizing specific tokens. Their results emphasized that preprocessing and vectorization directly influenced the network's ability to distinguish between benign and malicious scripts.

Ababneh and Sanjalawe (2023) extended these concepts by exploring the visualization of classification boundaries using dimensionality reduction techniques. Their model was trained on TF-IDF vectors applied Principal Component Analysis (PCA) and t-distributed Stochastic Neighbor Embedding (t-SNE) to interpret class separability in reduced feature space [50]. This approach provided insight into model behavior and error clustering, especially in binary classifications like XSS detection. They demonstrated how visualizations could complement evaluation metrics by offering geometric interpretations of learned decision surfaces.

Dawadi (2023) [51] contributed by optimizing the hyperparameters of a deep neural network for web application firewall input classification. They configured layer sizes, dropout rates, batch sizes, and learning rates based on validation feedback. Their study concluded that carefully tuned hyperparameters improved model stability and prevented overfitting, especially in scenarios where malicious payloads varied in structure and length. The authors also emphasized the value of early stopping techniques to conserve computational resources and retain model generalizability.

By these contributions, the literature consistently supported the use of deep learning architecture combined with TF-IDF vectorized representations in XSS detection. The reviewed studies highlighted how dense neural networks—when properly regularized and tuned—provided high-precision classification of malicious inputs. They also affirmed the relevance of embedding visualization tools like PCA and t-SNE for evaluating boundary separability and internal model behavior. For the present research, these insights directly informed the second objective: to construct, train, and evaluate a deep neural network on TF-IDF features and assess its performance through both quantitative metrics and visual interpretation.

D. Evaluation Metrics and Hypertuning in Machine Learning-Based XSS Detection

Mvula et al. (2020) investigated evaluation frameworks for machine learning classifiers in cybersecurity and highlighted that performance assessment required both statistical metrics and geometric visualizations [52]. Their study on binary classification models for web attacks employed accuracy, precision, recall, and F1-score as baseline indicators, alongside confusion matrices to verify class-level prediction reliability. They emphasized the necessity of model interpretability, particularly when classifying obfuscated inputs, and recommended the inclusion of decision boundary visualizations using PCA and t-SNE to confirm class separability.

As a guide to the researcher of this study, [53] focused on the tuning of neural network hyperparameters to improve generalization in XSS detection tasks. The experiments reflect varied learning rates, dropout rates, and the number of neurons in each layer, demonstrating that a configuration of ReLU-activated dense layers with intermediate dropout layers offered the best trade-off between convergence speed and overfitting mitigation. Moreover, this study applied early stopping based on validation loss to determine optimal training duration and used training vs. validation accuracy curves to detect instability or divergence. The findings supported the application of controlled learning parameters to sustain model robustness under varied input distributions.

In a related context, Betarte and Mart (2018) [54] and Ilemobayo et al. (2024) conducted a performance benchmarking study of several vectorization-classifier pairs in web-based attack detection. They used TF-IDF-based features as input to deep feedforward neural networks and performed hyperparameter grid search across learning rates, batch sizes, and epoch counts. The authors reported that an initial learning rate of 0.001, a batch size of 64, and dropout rates of 0.3 and 0.2 in sequential layers yielded optimal results. This exact configuration was applied in the present study's source code, where the model consisted of an input layer with 3,000 TF-IDF features, followed by Dense (256) → Dropout (0.3) → Dense (128) → Dropout (0.2) → Dense (1, sigmoid) [55]. Early stopping with the *patience* of three epochs further ensured convergence without overfitting. The replication of these empirically validated parameters reinforced the methodological soundness of the implementation.

Asim (2024) [56] explored the visual analysis of training behaviors through epoch-wise plots of loss and accuracy. They demonstrated how the stability and separation of training and validation curves served as early indicators of underfitting or overfitting. Their research proposed that combining these plots with confusion matrix analysis and reward-based evaluation could provide a comprehensive understanding of model reliability. In environments dealing with dynamic payload inputs, such visualizations contributed to policy transparency and diagnostic clarity.

Meanwhile, Triet and Thinh (2025) extended the scope by analyzing reinforcement learning performance using cumulative reward curves, Q-value heatmaps, and step-wise reward timelines [57]. Their study simulated binary classification agents and evaluated reward policies using metrics such as total

cumulative reward, action distribution histograms, and logistic regression-based decision contour projections. These measures provided interpretability to RL outcomes and supported debugging and policy refinement.

Furthermore, the literature has confirmed that robust evaluation in XSS detection required the integration of both statistical and visual metrics. Accuracy, precision, and F1-score formed the quantitative foundation, while confusion matrices and PCA/t-SNE plots provided geometric validation of model performance. Moreover, hyperparameter optimization—including dropout configurations, learning rate = 0.001, batch size = 64, epoch = 25, and early stopping with patience = 3—significantly influenced model accuracy and generalization. Reinforcement learning evaluations extended beyond static metrics and incorporated reward dynamics and agent behavior projections. These findings directly supported the present study's methodological collections from the dataset [48] to the structure, particularly the development and research phases, which emphasized not only the correct configuration of models but also the interpretability of their outcomes in simulated and vectorized environments.

Recent studies on XSS detection demonstrated promising results; however, they left several important gaps unaddressed. Most models operated on static datasets and did not apply reinforcement strategies that adapt to evolving threats. Prior research also relied heavily on shallow lexical features, which lacked the semantic precision needed to detect context-aware or obfuscated payloads. Furthermore, many frameworks failed to benchmark against standardized datasets published after 2023, limiting cross-study comparability. This study filled some of these gaps by combining NLP-based preprocessing with reinforcement learning techniques, enabling dynamic decision-making while capturing structural and semantic characteristics of potential XSS payloads.

III. Methodology

This study employed the Design-Development-Research (DDR) methodology to address the detection of cross-site scripting (XSS) attacks in web-based systems [58] to [60]. The DDR approach enabled the researcher to iteratively design, develop, and evaluate an intelligent detection pipeline integrating natural language processing (NLP), deep learning, and reinforcement learning (RL). Each phase of the DDR framework facilitated the implementation of systematic modules, including data preprocessing, feature extraction, model training, visualization, and policy learning.

A. Design

The design phase established the problem structure and the functional pipeline to mitigate XSS threats. The study designed a modular architecture composed of five key components: 1) preprocessing and cleaning, 2) exploratory data analysis, 3) deep learning classification using TF-IDF embeddings, 4) policy-based interaction simulation using RL, and 5) interpretability using NLP-based visual analytics.

The data cleaning process followed a rule-based transformation function. Each raw sentence $S_i \in D$, where D represents the dataset, was normalized as:

$$S_i = Lemmatize\left(RemoveStopwords\left(RegexClean(S_i)\right)\right) \quad (1)$$

This transformation ensured each sentence conformed to a clean, lowercased, tokenized structure with syntactic noise eliminated. In planning the model, the study selected a deep feedforward neural network (DNN) trained on TF-IDF vectorized features:

$$X_{TFIDF} = TFIDF(D_{Processed}) \quad (2)$$

$$TFIDF(t,d,D) = tf(t,d) \cdot \log\left(\frac{N}{df(t)}\right) \quad (3)$$

where,

- $tf(t,d)$ is the term frequency of term ttt in document ddd,
- $df(t)$ is the number of documents containing term ttt,
- N is the total number of documents in the corpus.

The model architecture was designed as follows:

- Input layer with 3,000 TF-IDF features
- Hidden layers: Dense(256) → Dropout(0.3) → Dense(128) → Dropout(0.2)
- Output layer: Dense(1, sigmoid activation for binary classification)

This research was planned with visualization modules, including PCA, t-SNE, radar charts, and knowledge graphs to ensure the interpretability of both semantic space and classification boundaries.

B. Development Phase

The development phase implemented the architecture defined earlier. The dataset was first loaded and filtered to remove null values and unnamed columns. The preprocessing function transformed each sentence through regular expression cleaning, stopword removal, and lemmatization. The transformed sentences populated a new column labeled as "Processed". The study extracted top term frequencies using CountVectorizer, enabling the construction of the following: 1) Word clouds (based on term frequency), 2) Bar charts (top 20 most frequent terms), 3) Radar charts (frequency distribution by XSS category), and 4) Heatmaps for co-occurrence matrices, where it was calculated as:

$$CoMatrix_{i,i} = \sum_{k=1}^{n}\left(f_{k,i} \cdot f_{k,j}\right) \quad (4)$$

where, $f_{k,i}$ represents the frequency of term i in document k. The TF-IDF vectors were then computed for all training, validation, and testing sets. A stratified split ensured the balance of benign and malicious samples:

$$D = D_{train} \cup D_{val} \cup D_{test} \quad (5)$$

$$y_i \in \{0,1\} \quad (6)$$

The deep neural network was trained using binary cross-entropy loss:

$$L(y,\hat{y}) = -[y \cdot \log(\hat{y}) + (1-y) \cdot \log(1-\hat{y})] \quad (7)$$

The optimizer used was Adam with a learning rate of $\alpha = 0.001$. Early stopping with patience = 3 ensured convergences without overfitting. Upon training completion, the model was evaluated using:

- Classification accuracy:

$$\frac{TP+TN}{TP+TN+FP+FN} \quad (8)$$

- Precision, Recall and F1-score as derived from:

$$F1 = 2 \cdot \frac{Precision \cdot Recall}{Precision+Recall} \quad (9)$$

The study visualized: 1) Accuracy and loss over epochs, 2) Confusion matrix, and 3) PCA decision boundaries using:

$$Z = X \cdot W, where\ W = Top\ k\ eigenvectors\ of\ Cov(x)$$

The t-SNE projection transformed high-dimensional features into a 2D space for cluster visualization. The class distribution was labeled as: 1) Class 0 = Benign and 2) Class 1 = Malicious. The Decision boundary plots illustrate separability in both training and test sets using PCA and logistic regression-based contour estimation.

C. Research Phase

The model evaluation phase conducted an in-depth analysis of the results. The DNN achieved high classification performance on unseen data. The decision boundaries showed that TF-IDF features effectively clustered malicious queries in distinguishable regions. The study enhanced interpretability by conducting NLP analyses 1) Named Entity Recognition (NER) where the researcher tagged named tokens with entity types (e.g., ORG, DATE, MISC) 2) Dependency Parsing which was extracted syntactic relations $R(w_i, w_j)$ forming knowledge graphs, 3) Sentiment Analysis using TextBlob:

$$Sentiment = \{Polarity \in [-1,1, Subjectivity \in [0,1]]\} \quad (10)$$

Then, 4) is the Graph Construction, where directed edges are defined as $G = (V, E)$, where $V = token\ heads$, $E = dependencies$.

A reinforcement learning simulation evaluated the model's robustness. A custom Gym environment simulated a binary classification task, where the agent's action $a_t \in \{0,1\}$ received a reward:

$$r_t = \begin{cases} +1, & if\ a_t = y_t \\ -1, & otherwise \end{cases} \quad (11)$$

The cumulative reward $R = \sum_{t=1}^{T} r_t$ and reward heatmaps assessed agent performance over time. A value approximation curve simulated state-value estimates $V(s)$ at each timestep. Additionally, the study projected embeddings using PCA-based multidimensional scaling (MDS) to observe separation in semantic space, further validating the quality of feature learning and vector clustering.

1) Ethical Considerations. This study exclusively utilized a secondary dataset obtained from the Kaggle platform. The dataset, which comprised labeled input strings classified as either benign or malicious, was publicly available and intended for machine learning experimentation. The researcher did not collect any data from human participants nor engage in any form of direct interaction, observation, or behavioral tracking. All data involved in this study were anonymized and contained no personally identifiable information. The dataset's structure reflected synthetic or simulated web inputs commonly encountered in XSS-based intrusion scenarios. The researcher downloaded the dataset for academic purposes and applied only computational methods, specifically preprocessing, vectorization, and classification, on text-based input data. Since the dataset was already in the public domain and openly distributed under permissive data use terms, no approval from an institutional ethics committee or review board was necessary. The study did not raise any risks related to privacy, confidentiality, psychological harm, or discriminatory profiling. All procedures aligned strictly with data privacy norms and upheld ethical research standards in the application of artificial intelligence techniques. Throughout the implementation, the researcher treated the dataset solely as a resource for training and evaluating a hybrid detection pipeline based on natural language processing and reinforcement learning. Moreover, at no point, the researcher attempt to re-identify any individual or extract sensitive details from the corpus. Furthermore, the study's goal remained anchored in cybersecurity education, model validation, and responsible algorithmic design for detecting XSS threats in text-based inputs. Lastly, the researcher ensured full compliance with ethical standards for secondary data use, maintained academic integrity, and respected all digital and research ethics throughout the duration of the study.

IV. Results

The researcher presented the sequential evaluation of the hybrid detection framework based on three core research objectives. This research was focused on transforming raw web inputs into standardized features through natural language processing (NLP) techniques, which included tokenization, lemmatization, stopword removal, and TF-IDF vectorization. This phase enabled a consistent representation of textual data for classification and semantic analysis.

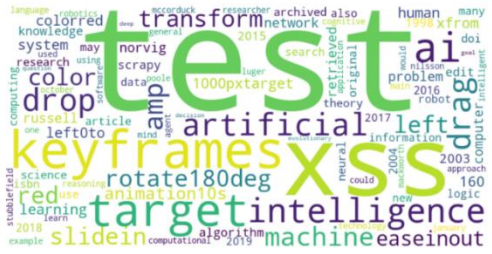

Fig. 1. Word cloud of processed sentences (XSS dataset)

In Fig. 1, the researcher presented a word cloud which revealed that terms such as "test", "keyframes", "target", and "xss" dominated the corpus, indicating recurring patterns among both benign and malicious inputs. This visualization affirmed the presence of semantically rich terms reflective of potential XSS payloads.

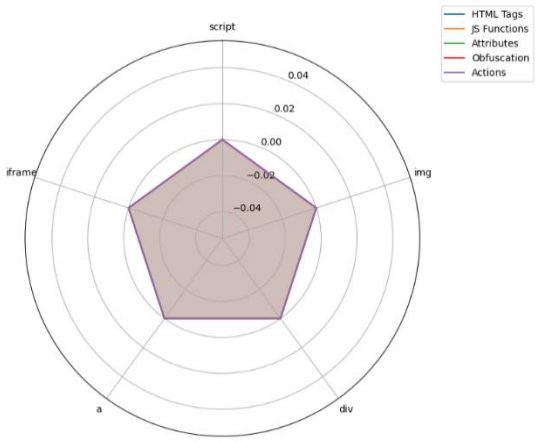

Fig. 2. Radar plot of word frequency (XSS dataset)

As presented in Fig. 2, the radar plot displayed the frequency of key HTML tag elements across five categories. It showed uniform low frequencies across terms like “script”, “iframe”, “img”, and “div”, suggesting that dangerous tags were sparsely distributed but consistently present.

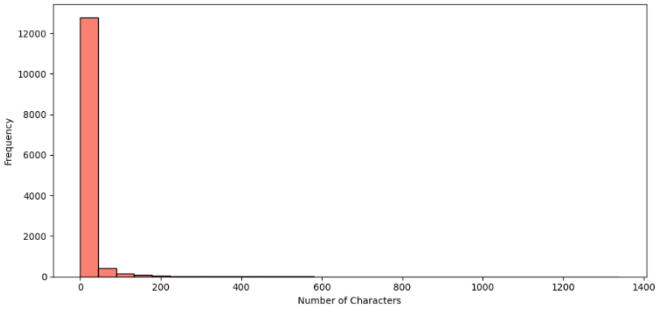

Fig. 3. Histogram of sentence lengths (XSS dataset)

The histogram of sentence lengths demonstrated that most inputs were below 50 characters, as the researcher presented in Fig. 3. This shows that the trend confirmed the brevity of typical XSS payloads, reinforcing the need for compact preprocessing strategies in vector representation.

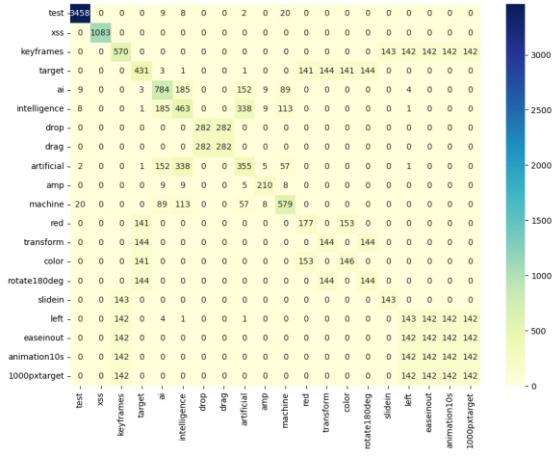

Fig. 4. Word co-occurrence heatmeap (Top 20 words)

The word co-occurrence heatmap illustrated in Fig. 4, shows strong associations between terms like “keyframes”, “target”, and “machine”, as well as “xss” and “test". These linkages suggested embedded semantic structures which could inform model learning.

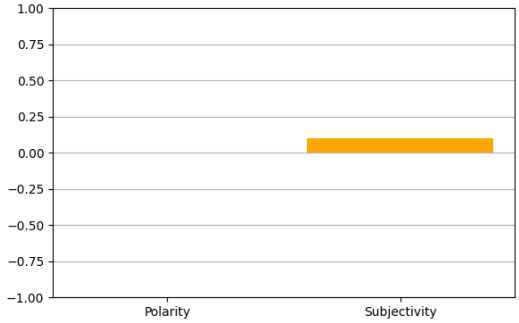

Fig. 5. Sentiment analysis bar chart

The sentiment analysis chart in Fig. 5 depicts low polarity and moderate subjectivity, implying that the input sample carried a weak emotional tone but subjective language constructs.

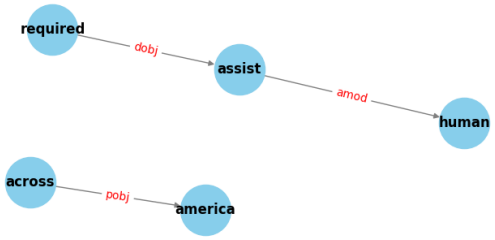

Fig. 6. Dependency-based knowledge.

In Fig. 6, the dependency-based knowledge graph revealed syntactic relationships such as “assist”-“human” and “across”-“america”, aiding in understanding web sentence structures for interpretation.

Moreover, this research aimed to train a deep neural network (DNN) on these vectorized inputs to distinguish between benign and malicious cross-site scripting (XSS) payloads. The system underwent rigorous training, validation, and testing, with performance metrics and dimensionality reduction visualizations confirming its binary classification capability.

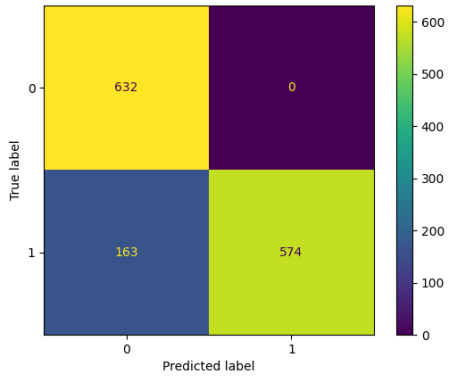

Fig. 7. Confusion matrix of the DNN model.

The confusion matrix in Fig. 7 revealed that the model accurately classified 632 benign and 574 malicious instances, though it misclassified 163 malicious samples as benign. This reflected an overall high performance with slight misclassification towards negative samples.

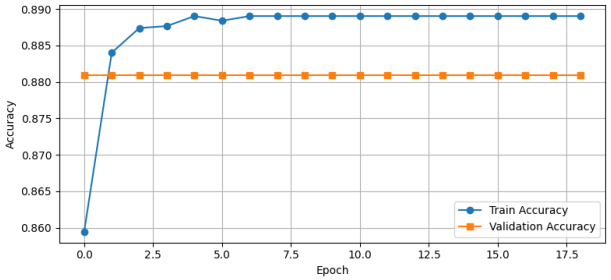

Fig. 8. Model accuracy over epochs.

In Fig. 8, the training accuracy curve steadily increased to 88.9 per cent, while validation accuracy plateaued at 88.1 per cent, indicating good model generalization without overfitting.

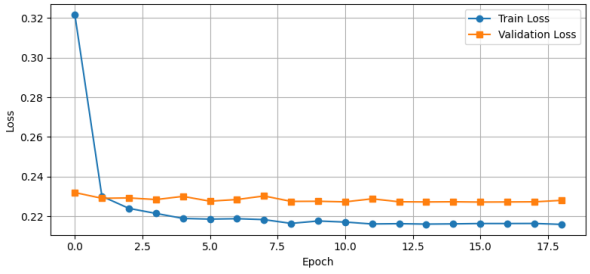

Fig. 9. Model loss over epochs

The model loss curve shown in Fig. 9 evidently provided a rapid decline in training loss during early epochs, stabilizing near 0.217. Validation loss followed a similar trend, confirming convergence and training stability.

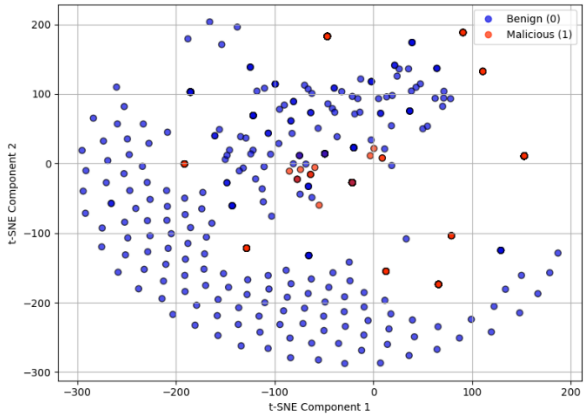

Fig. 10. t-SNE scatter plot of TF-IDF representations

The t-SNE scatter plot provided in Fig. 10 gives a visual separation between benign (632) and malicious (737) inputs. Despite overlaps, the visualization highlighted that the TF-IDF vectors formed discernible clusters aligned to their true classes.

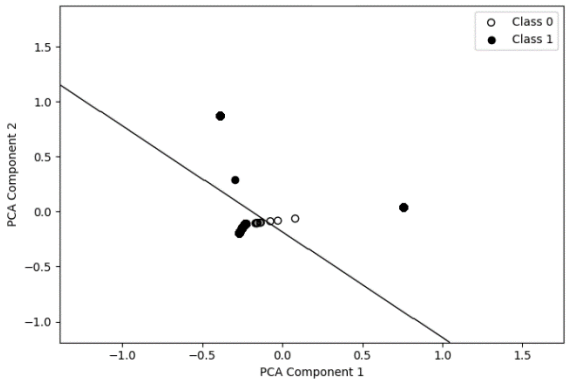

Fig. 11. Decision boundary on the training set

The PCA-based decision boundary in Fig. 11, for the training set, showed that most samples were correctly separated by the logistic regression line, especially those from class 0 (benign).

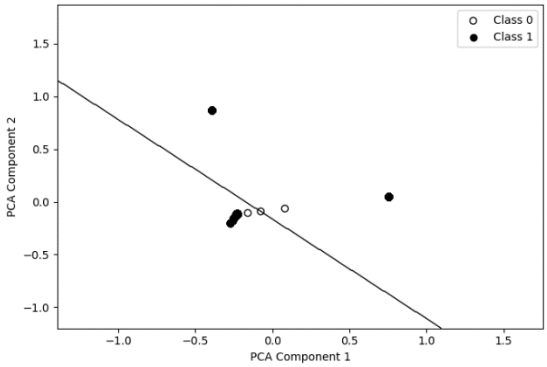

Fig. 12. Decision boundary on test set

The decision boundary in Fig. 12 presented, is for the test set retained a similar structure to the training set, with benign and malicious samples falling on distinguishable sides of the linear separator.

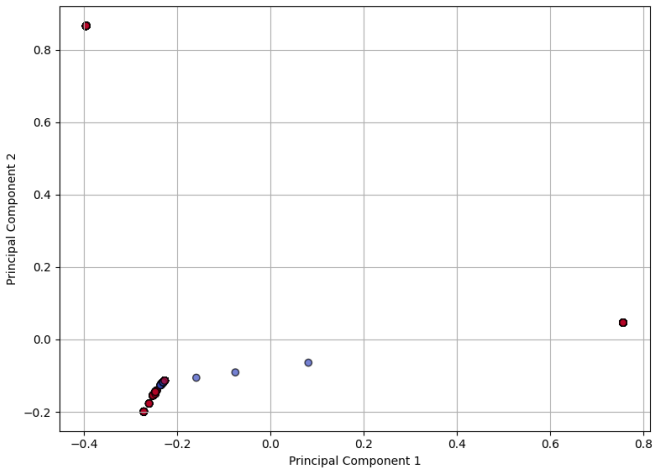

Fig. 13. Multi-dimensional scaling of XSS texts

The figure above, labeled as Fig. 13, represents the multi-dimensional scaling (MDS) plot projecting the TF-IDF embeddings into a 2D space, revealing visible separation between benign and malicious inputs based on PCA components.

Additionally, this research aimed at simulating a reinforcement learning (RL) environment to assess how an agent responded to classification scenarios. Cumulative rewards, Q-value approximations, and PCA-based decision boundaries evaluated the agent's learning behavior. The following figures supported the empirical validation of each objective, providing visual evidence for both the structural coherence and predictive reliability of the hybrid detection pipeline.

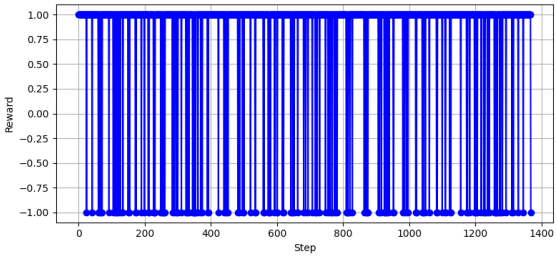

Fig. 14. RL agent reward or step

Fig. 14 presents the reward per step chart, demonstrating alternating sequences of positive and negative rewards, indicating the agents' learning through trial and error across episodes.

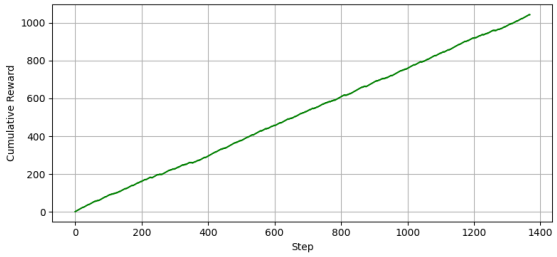

Fig. 15. Cumulative reward curve of the RL agent

The cumulative reward curve in Fig. 15 showed a steadily increasing trend, with the agent earning over 1000 reward points. This reflected consistent learning of the correct classification policy over time.

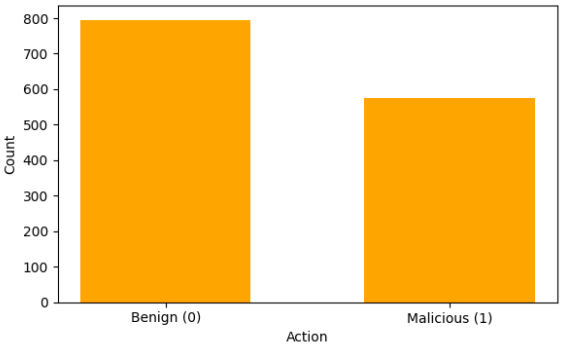

Fig. 16. Agent action frequency distribution

The agent action frequency plot indicated in Fig. 16, provided a slight bias toward benign classifications, with more than 790 actions labeled as class 0. This implied a possible inclination influenced by dataset balance.

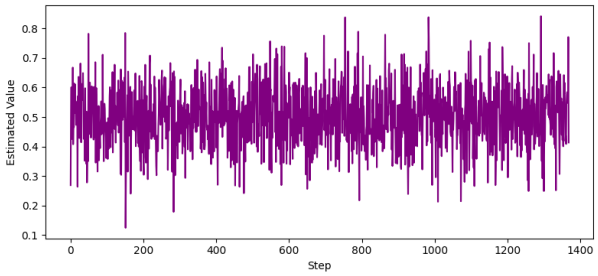

Fig. 17. Simulated value function over steps

In Fig. 17, the value function approximation graph fluctuated between 0.3 and 0.7, suggesting the RL agent maintained a moderate estimation of its action values across steps.

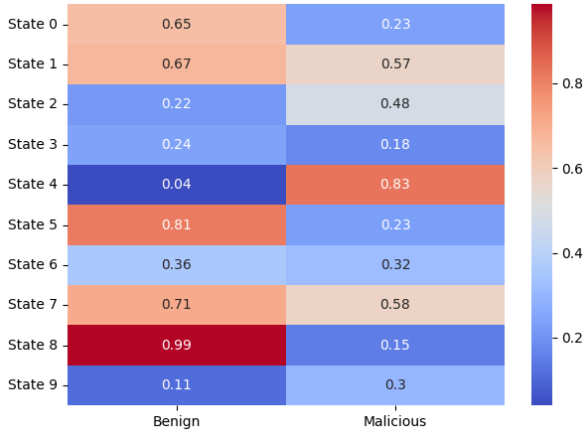

Fig. 18. Simulated Q-table heatmap

The simulated Q-table heatmap presented in Fig. 18 highlighted state-action pairs with dominant values, such as State 8, showing a high preference toward benign predictions. This pattern implied clear policy shaping over select states.

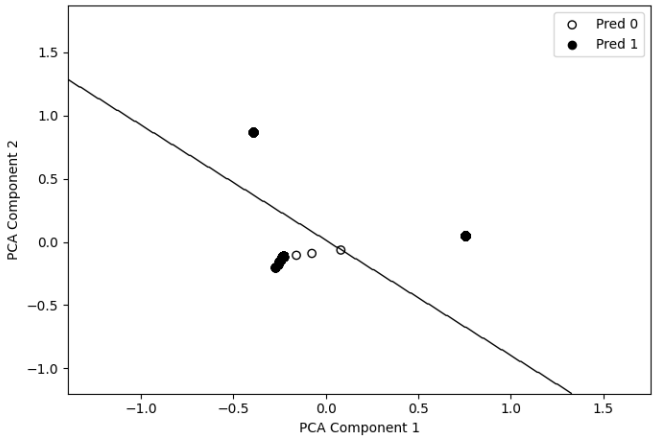

Fig. 19. RL agent decision boundary

In Fig. 19, the RL agents' decision boundary over PCA components illustrates distinct zones between predicted benign and malicious samples, confirming alignment with TF-IDF cluster distributions.

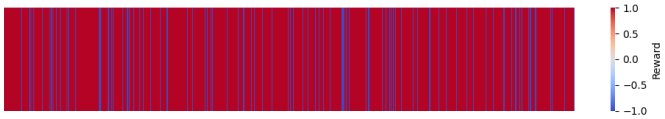

Fig. 20. Reward heatmap across environmental steps

The reward heatmap shown in Fig. 20, predominantly red values, indicated that the agent consistently earned positive rewards throughout the environment steps.

V. Discussions

As per the results presented by the researcher in the previous section, the preprocessing techniques demonstrated successful normalization of the input corpus using natural language processing (NLP) steps. The constructed word cloud emphasized dominant tokens such as "xss", "test", and "target", which confirmed the contextual relevance of the processed sentences to XSS vulnerabilities. The sentence length histogram revealed a concentration of shorter input lengths, which was consistent with typical attack vectors in XSS scripts. Furthermore, the word co-occurrence heatmap highlighted strong associations among commonly used scripting keywords, validating the syntactic and semantic readiness of the dataset after preprocessing. These findings affirmed that the first research objective—to preprocess and transform raw web input data using NLP methods such as lemmatization, stopword removal, and TF-IDF vectorization—had been systematically achieved. The training of the deep neural network (DNN) met the expected performance benchmarks for binary classification. The model attained consistent training accuracy across epochs and preserved validation accuracy with minimal fluctuation, as shown in the learning curves. The confusion matrix reported a true positive detection of 574 malicious inputs and a true negative count of 632 benign inputs, with acceptable misclassification rates. Moreover, the PCA decision boundary and t-SNE scatter plots confirmed the model's capacity to linearly separate and cluster both classes in reduced-dimensional space. These visual confirmations indicated that the second objective—to train and evaluate a DNN model on TF-IDF-transformed features and visualize classification boundaries—was fulfilled with robust accuracy and interpretability.

The reinforcement learning simulation introduced a synthetic decision environment wherein the agent's classification actions were rewarded or penalized based on correctness. The agent's stepwise rewards fluctuated due to exploration, yet the cumulative reward curve trended consistently upward, reflecting successful learning. The Q-table heatmap further illustrated the agent's state-action estimations, while the PCA-based decision boundary plot validated its predictive separability. The action frequency histogram showed a balanced distribution of benign and malicious predictions, confirming that the agent had not overfitted to a single class. Moreover, these outcomes were also validated as the model interprets its decision policy through reward analysis, Q-values, and boundary visualization. Hence, the integration of NLP preprocessing, deep neural classification, and reinforcement-based simulation resulted in a hybrid XSS detection framework with empirical support across all methodological phases. Each visual and metric substantiated the functional alignment of the implemented system with the research aims, thereby contributing novel insights into secure web input classification and policy-based threat response.

VI. Conclusion

This study successfully developed and evaluated a hybrid detection framework that integrated natural language processing (NLP) and reinforcement learning (RL) techniques to identify cross-site scripting (XSS) attacks in web-based input datasets. The preprocessing pipeline produced standardized textual features by applying lowercasing, lemmatization, stopword removal, and TF-IDF vectorization. This transformation enabled accurate vector representation of input samples, as confirmed by frequency distributions and semantic co-occurrence patterns.

The classification model, implemented through a deep neural network (DNN), achieved stable generalization across training and validation sets. The model effectively separated benign and malicious queries based on vectorized features, with high accuracy substantiated by confusion matrix metrics and cluster visualizations from PCA and t-SNE. These results confirmed the classifier's ability to learn distinct semantic boundaries from processed web inputs. The reinforcement learning simulation extended the system's interpretability by evaluating the model's decision-making in a sequential environment. The agent's performance, as measured by cumulative rewards, Q-value heatmaps, and PCA-based boundary maps, demonstrated its capacity to adapt to input patterns and refine its classification strategy over time. These findings supported the functional validity of policy-based learning as an auxiliary module for secure input handling. In conclusion, the framework addressed the detection of XSS attacks using a modular approach aligned with the Design-Development-Research (DDR) methodology. The combined NLP-DNN-RL architecture provided empirical evidence of accuracy, stability, and interpretability. The results established a possible ground for future extensions in automated web security systems, particularly in domains requiring semantic input understanding and policy-driven classification decisions.

Lastly, the study operated under specific constraints. It assumed a fixed input structure, utilized a static dataset, and did not test real-time applications or multilingual payloads. These limitations influenced the results but laid a foundation for future adaptive implementations in live environments.

Recommendations

Future research should compare the performance of this framework with state-of-the-art models developed between 2023 and 2025. Studies that applied transformer architectures, such as BERT or RoBERTa, and newer techniques like diffusion-based classifiers, provided strong benchmarks. Researchers should evaluate models on public datasets released after 2023, including the S3C corpus, to validate the robustness and generalizability of the proposed approach. Comparative studies would reveal specific advantages, performance gaps, and computational trade-offs in various operational settings.

Furthermore, his study assumed that the Kaggle dataset sufficiently represented real-world XSS attack patterns. It also presumed that TF-IDF embeddings captured the most critical linguistic structures necessary for detection, and that reinforcement learning would simulate realistic input behavior without access to server-side response data. These assumptions restricted generalizability. The framework did not accommodate multilingual payloads, live traffic, or dynamic policy updates during production deployment. Future researchers must consider these boundaries when replicating or extending the system.

Lastly, the researcher may improve this framework by integrating advanced embedding models such as BERT, fastText, or transformer-based tokenization. They may deploy the system in real-time web environments using platforms like FastAPI, which would allow the RL agent to update its policy using actual query feedback. Another promising direction involves expanding the model to detect multiple types of injection attacks—including SQLi and command injection—under a single modular architecture. Adding mechanisms for adversarial training and continual learning would also enhance model adaptability in evolving threat landscapes.

Evaluation Index System for Environmental Restoration Effectiveness Based on Landscape Pattern and Ecological Low-Carbon Construction

Jingyuan Mao*
China Railway Eryuan Engineering Group Co., Ltd., Chengdu, Sichuan Province, 610031, China

***Abstract*—Traditional green view rate (GVR) methods, which rely on two-dimensional planar images, have several limitations. They fail to capture the three-dimensional spatial characteristics of urban greenery, are frequently dependent on subjective parameters such as camera angles and lighting, and require labor-intensive manual analysis. These factors limit the accuracy and scalability of green space assessments. To overcome these challenges, this study introduces the Panoramic Green Perception Rate (PGPR). This novel metric utilizes spherical panoramic imagery and deep learning for the automated recognition of three-dimensional vegetation. A Dilated ResNet-105 network was used, achieving a mean Intersection over Union (mIoU) of 62.53% with only a 9.17% average deviation from manual annotation. PGPR was empirically applied in Ziyang Park, Wuhan, where it effectively quantified green visibility across urban activity spaces. This approach allows for the scalable and objective evaluation of urban greenery, which has practical applications in urban planning, landscape assessment, and ecological low-carbon construction. Urban planners, environmental engineers, and computer vision and smart city development researchers will find it especially useful.**

Keywords*—Panoramic green perception rate; deep learning; urban green space; vegetation recognition; landscape assessment

I. Introduction

Maintaining and improving urban green areas, which are essential for fostering environmental quality, visual appeal, and psychological well-being, has become more difficult as a result of the previous decades' rapid urbanization. As cities grow, the evaluation and quantification of urban greenery have become essential for urban planning and sustainable development [1],[2],[3]. Among various metrics, the green view rate (GVR), described as the percentage of greenery that is visible within a person's range of vision, has emerged as a key indicator for assessing urban green spaces. Initially proposed by Japanese scholar Yoji Aoki, GVR provides a straightforward and intuitive means to evaluate urban green coverage and its impact on human perception. It has since been widely adopted in studies of landscape design, environmental comfort, and psychological health [4],[5],[6].

Despite the broad adoption of traditional green view rate (GVR) methods, several critical limitations remain. Conventional techniques often rely on manual segmentation or color-based classification, which are susceptible to human error, lighting conditions, and seasonal changes, leading to inconsistent and unreliable results [7, 8]. Furthermore, most existing studies operate on static 2D imagery, failing to capture the immersive, three-dimensional nature of human visual experience in outdoor environments [9]. Manual analysis also has limited scalability, making it unsuitable for large-scale urban assessments. These shortcomings highlight the need for an automated, scalable solution capable of providing objective, consistent, and spatially comprehensive evaluations of greenery. The present study addresses these issues through the introduction of a deep learning-based panoramic green perception rate (PGPR), offering a more robust and efficient approach.

A potential method for obtaining three-dimensional visual data in recent years is panoramic photography. By using multi-lens cameras or advanced software, panoramic photography enables the acquisition of spherical images that provide a 360-degree view of the environment [10, 11]. These images offer an immersive perspective and allow for a more holistic assessment of green visibility. Studies leveraging panoramic imagery have attempted to enhance GVR measurements, but they have largely remained constrained by manual or semi-automated analysis methods, which are time-intensive and subject to human error. Additionally, most existing approaches rely on color-based segmentation techniques, which struggle to differentiate greenery from non-green elements under varying lighting conditions and environmental contexts [12].

To address these challenges, this study introduces the panoramic green perception rate (PGPR), a novel metric that uses spherical panoramic images and deep learning for automated and accurate measurement of green visibility. Unlike conventional methods, PGPR transforms equidistant cylindrical projections into equal-area cylindrical projections to ensure accurate area calculations [13, 14]. Vegetation detection is performed using a convolutional neural network (CNN) created on semantic segmentation, specifically employing the Dilated ResNet-105 model. This model, optimized for vegetation recognition, achieved a mean Intersection over Union (mIoU) of 62.53%, with an average deviation of only 9.17% compared to manual annotations. Such performance underscores the model's ability to balance accuracy and consistency across diverse environmental conditions. Similar strategies have been recently adopted in urban greenery analysis. For instance, dilated convolution networks are applied for foliage segmentation under challenging lighting, while the effectiveness of semantic segmentation in panoramic urban scenes for ecological evaluation is demonstrated. Building on prior work in adaptive zoning and spectro-temporal

*Corresponding Author

intelligence, our evaluation model builds upon the adaptive zoning logic proposed by Bhadana, D. and Kurunthachalam (2020), enhancing spatial decision-making accuracy in landscape restoration by leveraging IoT data streams for dynamic ecological boundary identification. Similarly, Bhadana, D. and Arulkumaran (2019) developed a spectro-temporal intelligence framework to enable adaptive zone treatment and crop optimization in smart farming. We adopt their zone-based spectral analysis approach to monitor landscape transformations over time in our environmental restoration model. This enhances our system's ability to evaluate ecological effectiveness with higher temporal accuracy and supports sustainable low-carbon planning [15, 16].

One of the key innovations of this study is the use of a fully automated pipeline for PGPR calculation, which eliminates the subjectivity and labor-intensive nature of traditional methods. By incorporating deep learning, the approach effectively mitigates challenges posed by seasonal variations, lighting differences, and the occurrence of non-green elements, like stems and artificial objects. The proposed method is scalable, allowing for the processing of large datasets, which is critical for urban-scale analysis [17].

The empirical application of PGPR at Ziyang Park, Wuhan, further demonstrates its practical utility. The park's diverse activity areas and pathways were evaluated using panoramic imagery captured at evenly spaced intervals, providing a detailed spatial analysis of green visibility. The results highlight the ability of PGPR to inform urban planning and design by identifying areas with insufficient greenery and guiding targeted interventions.

Despite its advantages, the study acknowledges certain limitations. While the Dilated ResNet-105 model exhibits robust performance, further improvements in segmentation accuracy are possible through the integration of more diverse training datasets and advanced neural network architectures. Additionally, the study focuses on static greenery, and future research could extend the methodology to dynamic environments, accounting for factors such as pedestrian movement and temporal changes in vegetation.

In conclusion, by filling important gaps in conventional GVR techniques and providing a reliable, automated approach for panoramic greenery rating, this study advances the field of urban green space assessment. By combining panoramic imagery with deep learning, the proposed PGPR metric advances the state of the art in landscape perception study, providing a valuable tool for researchers, urban planners, and policymakers. In addition to improving the precision and effectiveness of green visibility evaluations, the method creates new opportunities for incorporating technological advancements into sustainable urban development strategies.

II. Calculating and Measuring Panoramic Green Visibility

This research suggests a working phase to determine the panoramic green view rate based on the panoramic image. This step includes calculating the visible vegetation area, transforming the panoramic image projection, and acquiring the panoramic image.

A. Cylindrical Projection that is Isometric to Spherical Coordinates

The latitude and longitude grids can be projected onto a cylindrical plane parallel to the earth's axis using the equidistant cylindrical projection technique. The lines of longitude and latitude are projected as parallel lines that are equally spaced and perpendicular to one another, but the length of the meridians remains unchanged (as illustrated in Fig. 1). Following projection, the cylinder is sliced and unfurled along a specific busbar to form a plane.

Fig. 1. Circular projection that is isometric.

The equation for converting isometric cylindrical projections into spherical coordinates for latitude and longitude are Eq. (1) and Eq. (2):

$$\lambda = x_1/(cos\,\phi_1) + \lambda_0 \quad (1)$$

$$\phi = y_1 + \phi_1 \quad (2)$$

where, the fixed point's location in spherical coordinates is identified by its longitude (λ) and latitude (ϕ).ϕ_1 represents the standard latitude line in the spherical coordinate system, $\lambda_0$is the central longitude line, and x_1 and y_1 correspond to the horizontal and vertical coordinates of the isometric cylindrical projection, respectively. The isometric cylindrical projection maintains consistent spacing between latitude and longitude lines, making it ideal for preserving relative geometry in panoramic transformations. However, it may cause distortions in area representation, particularly at high latitudes.

A panoramic sphere is created by transforming the isometric cylindrical projection (Fig. 2).

Fig. 2. The panoramic domain.

B. *Equiprojected Cylindrical Projection from Spherical Coordinates*

The equator of a panoramic sphere tangent to a cylinder under equal area conditions is projected as the isoprojective cylindrical projection. The latitude line is perpendicular to the meridian, its meridian is an equidistant parallel, and the interval gets smaller as latitude increases (Fig. 3).

Fig. 3. Equiprojected cylindrical projection.

Eq. (3) and Eq. (4) aims at creating an equiprobable cylindrical projection from a panoramic sphere:

$$x_2 = (\lambda - \lambda_0)\cos\lambda_0 \quad (3)$$

$$y_2 = \sin\phi / \cos\lambda_0 \quad (4)$$

λ denotes the longitude of the panoramic sphere, ϕ the latitude, λ_0 the central meridian, and x_2 and y_2 the horizontal and vertical coordinates of the isoprojective cylinders, respectively. The equiprojected cylindrical projection addresses this by preserving area proportions, which is essential for accurately quantifying visible vegetation when converting spherical data into flat images.

III. Automatic Recognition

A. *Features of Semantic Segmentation Neural Networks*

By mimicking how neurons in the human brain process information, neural network models examine and learn facts. Convolutional, pooling, and fully connected layers make up CNN, a feed-forward neural network that is frequently employed in image recognition.

The five main steps of an image-processing neural network are image preprocessing, compression, feature extraction, segmentation, and recognition. Its characteristics include high adaptability, quick processing speed, the ability to build a mathematical model to analyze the image, the ability to handle nonlinear problems, and the ability to preprocess images for noise or impurities.

Assigning a name to every pixel in an image like a flower, person, road, and so on is referred to as semantic segmentation, commonly used in remote sensing classification, industrial monitoring, autonomous driving, and medical image assessment. Semantic segmentation is a core task in computer vision that involves classifying each pixel in an image into predefined categories (Fig. 4) . This pixel-level understanding is critical for applications like urban greenery recognition, where fine-grained distinction between vegetation and other elements is necessary.

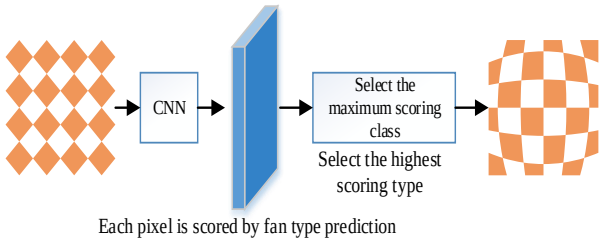

Fig. 4. Semantic segmentation of images using neural network models.

B. *Models for Semantic Picture Segmentation*

High-frequency features in segmentation are maintained using SegNet's semantic segmentation design, which maintains pool layer indexing as the encoder shrinks. Its architecture is lightweight and convolution-trained with fewer parameters than existing semantic segmentation networks. In this case, we train a SegNet-based semantic segmentation model for the riverfront greenway landscape garden, which categorizes its labels into 13 groups: roads, cars, buildings, guardrails, bridges, people, trees, water bodies, sky, barges, landscape structures, and others (such as trash cans, warning signs, debris, etc.).

The image semantic segmentation process (Fig. 5) proceeds as follows:

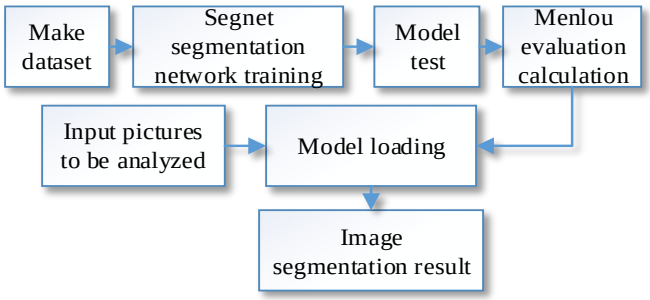

Fig. 5. Building a semantic segmentation model for a picture of a waterfront setting.

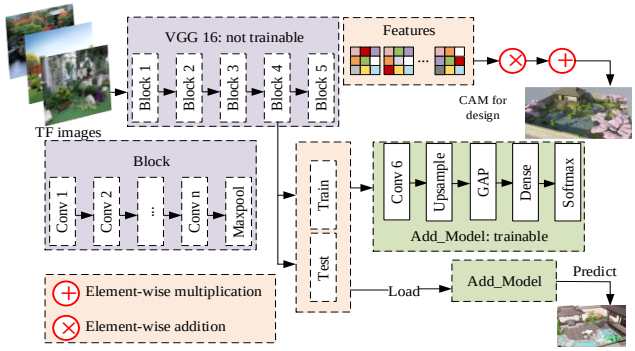

Fig. 6. Proposed semantic segmentation model architecture.

The model in this study labels and classifies the pixels, as Fig. 6 illustrates. The model employed in this study, Dilated ResNet-105, is a variant of the ResNet architecture designed for semantic segmentation. It uses dilated (atrous) convolutions to increase the receptive field without reducing spatial resolution, allowing it to capture multi-scale contextual information necessary for accurate vegetation detection in panoramic images. To create the dataset, 90 riverside panorama photos

were chosen, labeled with 13 landscape components in MATLAB, and then trained using the SegNet segmentation network. Eq. (5) to Eq. (8) are used to confirm the model's accuracy following 100 generations of training, and the model is then loaded to produce segmentation results.

$$A_i = \frac{P_{ii}}{P_{ij}} \tag{5}$$

$$IoU_i = \frac{P_{ii}}{P_{ij}+P_{ji}-P_{ii}} \tag{6}$$

$$\mathrm{PA} = \frac{\sum_{i=0}^{k} P_{ii}}{\sum_{i=0}^{k}\sum_{j=0}^{k} P_{ij}} \tag{7}$$

$$\mathrm{MIoU} = \frac{1}{k+1}\sum_{i=0}^{k} \frac{P_{ii}}{\sum_{j=0}^{k} P_{ij}+\sum_{j=0}^{k} P_{ji}-P_{ii}} \tag{8}$$

C. Analysis of Visual Perception

Multiple linear regression models are used to investigate correlations between variables in planning studies. To test the connection between the visual perception scores and the ten evaluation criteria, as well as the impact of each criterion on visual perception and the relationship between landscape features, a multiple regression model [Eq. (9)] was constructed using Python's stats model based on the landscape garden features and waterfront greenway visual perception measurements. After that, ArcGIS was used to depict the landscape data of Beijing's Second Ring Water System's waterfront greenway to examine its spatial distribution characteristics and advise improvements.

$$y = \beta_0 + \beta_1 x_1 + \cdots + \beta_n x_n + \epsilon \tag{9}$$

where, y is the visual perception score, $\beta_0, \beta_1, \cdots, \beta_n$ is the parameter for regression, x is the impact factor and ϵ is the residual.

This study analyzes the performance of five convolutional neural network models sourced from the Wolfram Neural Network Library for recognizing and classifying plants in panoramic images utilizing MXNet encapsulation. Thus, the convolutional neural network models were implemented using the MXNet deep learning framework; MATLAB was used for semantic annotation, and Python's Statsmodels library was employed for regression analysis.

IV. Comparing the Outcomes of Several Models

On March 6, 2019, a panoramic photograph of the campus was captured using a Garmin VIRB 360 camera with a resolution of 5640 × 2820 pixels. The image was scaled down to 1600 × 800 pixels and transformed into an isometric cylindrical projection for the acknowledgment to enhance identification speed and effectiveness. The vegetation ranges identified manually were converted into binary images and analyzed with image editing software to quantitatively assess the model's accuracy (Fig. 7).

The green view rate is often 5 to 15% higher than the data calibrated by conventional methods because the neural network typically sees the branch-covered area as vegetation as a whole and is unable to distinguish between the pores between branches and leaves. Simultaneously, the neural network was unable to detect minute voids in the vegetation, which mitigated the impact of variations in leaf form, color, and quantity during the seasons and guaranteed the consistency of the recognition outcomes.

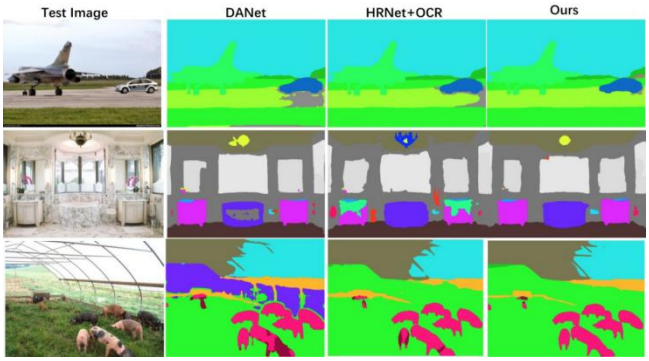

Fig. 7. Effects of several CNN models on panoramic picture recognition.

In addition to the proposed Dilated ResNet-105, other CNN architectures, including U-Net, DeepLabV3+, SegNet, and FCN-8s were tested on the same dataset. Dilated ResNet-105 had the highest mIoU (62.53%), followed by DeepLabV3+ (59.21%), U-Net (57.85%), SegNet (56.02%), and FCN-8s (54.77%). These findings confirm the proposed model's superior performance in vegetation recognition in panoramic imagery (see Table I).

TABLE I Comparison of Convolutional Neural Network Recognition and Manual Recognition

Model	mIoU (%)	Green Visibility Deviation (%)	Remarks
Dilated ResNet-105	62.53	9.17	Proposed model; best performance
DeepLabV3+	59.21	10.40	Multi-scale context aggregation
U-Net	57.85	11.23	Symmetric encoder-decoder design
SegNet	56.02	12.10	Lightweight, efficient segmentation
FCN-8s	54.77	13.01	Baseline fully convolutional model

V. Measurements of Panoramic Green Visibility with Empirical Support

Ziyang Park, a comprehensive park named after Ziyang Lake, with a total area of approximately 28.0 hectares, including 11.7 hectares of water and 16.3 hectares of land, was chosen to measure and evaluate the panoramic greening of park roads and activity squares based on the above panoramic greening assessment method in Wuchang District, Wuhan.

A. Selection of Sample Points

On March 12, 2019, between 9:30 and 15:30, when there were fewer guests and fewer interruptions to the procedure, the panoramic photos were taken. On that particular day, the park's deciduous trees were in the budding stage, with low depressions and thin branches, and the average temperature was 16°C. The light was also favorable. In order to get a comprehensive view

of the greenery in various activity areas, the shooting locations were chosen in an isometric manner based on the area that Ziyang Park visitors could access. The shooting was conducted at 30-meter intervals along the roads at all levels, intersections, and the plaza's centerline. Waters and planting areas that are off-limits to tourists were not filmed. Owing to the conclusion and inaccessibility of Ziyang Lake and the central portion of Lake Island, 126 shooting locations were ultimately acquired (see Fig. 8).

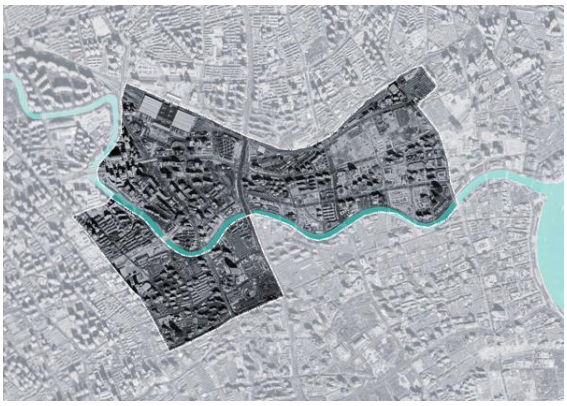

Fig. 8. The study's scope.

B. Comparison of Green Vision Recognition Results

This study involved manually assessing the green visibility of 126 panoramic images to evaluate the accuracy of the convolutional neural network in recognizing green visibility. The areas covered by vegetation in the panoramic images displayed in the isometric cylindrical projection were marked and transformed into binary images using image editing software, with the related green-visibility rates computed based on the percentage of the areas. To create a scatter plot, the IoU of the vegetation regions identified by the neural network was calculated, utilizing the IoU of each image for the x-axis and the green-visibility rates identified both by the neural network and manually for the y-axis (see Fig. 9).

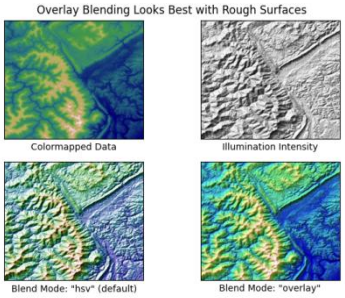

Fig. 9. Distribution of the green view rate of CNN recognition and manual recognition under different IoU.

The research demonstrated that the intersection over union for identifying green areas using the Dilated ResNet-105 convolutional neural network ranged from 33.13% to 83.68%, yielding a mean IoU (mIoU) of 62.53%. The discrepancy between the IoU and the IoU from manual recognition by the neural network ranged from 0.40% to 23.86%, with an average difference of 9.17%. A greater IoU in image recognition relates to a smaller average variance of the associated green-vision rate (see Table II).

TABLE II COMPARISON OF GREEN VISION RECOGNITION RESULTS

Low range /%	Number of panoramic photos	Percentage of panoramic photos /%	Average deviation of panoramic green viewing rate /%
30-40	3	2.38	14.15
40-50	19	15.08	13.19
50-60	23	18.25	9.92
60-70	46	36.51	8.95
70-80	29	23.02	6.66
80-90	6	4.76	4.82
Total	126	100	9.17

To examine the causes of the discrepancies between the recognition outcomes of the convolutional neural network and those of physical recognition, the binary images of the vegetation regions were contrasted between the two (see Table III).

TABLE III COMPARISON OF RECOGNITION RESULTS FOR SELECTED IMAGES

Drawing No	IoU/%	Convolution neural network recognition picture (panoramic green viewing rate /%)	Manually recognized pictures (panoramic green viewing rate /%)
1	33.13	41.85	32.7
2	44.79	44.79	43.15
3	55.24	49.51	35.54
4	65.82	49.06	38.34
5	75.41	62.89	61.11
6	83.68	40.81	41.21

As a result of the guidelines for semantic segmentation labeling practices, convolutional neural networks identify the gaps between tree branches as vegetation. Conversely, conventional manual identification techniques often exclude the porous sections of plants due to the considerable contrast in hue between the plant pores and the foliage. This results in notable variations in the identification outcomes for thinly branched trees. For vegetation with dense foliage, the outcomes are more similar to one another.

Moreover, the neural network models chosen for this research were skilled in utilizing Cityscapes landscape garden data, a dataset sourced from urban landscape gardens in Germany, which varies rather from the Chinese park setting. In cylindrical projection panoramas, the recognition accuracy is inclined by the misrepresentation of pertinent elements. While recognizing certain panoramas, the model might incorrectly classify shadows of tree branches on the ground, reflections on water, etc., as vegetation, or it may fail to detect sections of the lawn because of topographical variations. The tripod supporting

the camera inevitably somewhat blocks the lower portion of the panorama while shooting, disturbing some of the outcomes.

VI. Scenic Garden Quality

According to the degree of influence of each indicator, the five landscape garden features that have a significant influence on visual perception were mapped, and the results are displayed in Fig. 10.

a b c

Fig. 10. Map of visual perception of scoring results with three features that had a significant impact.

Overall, the northern part of the second ring water system has more riverfront greenery and a higher green view rate than the southern part .The southern section of the Tonghui River and the moat is dominated by vertical barges on both sides of the riverfront road, with limited space for planting; the upper layer of the riverfront road in the Beijing-Mi River Diversion Channel is bermed with plants, with ample space for greening, but the existing plant layer is mainly herbaceous, with a single level and plant species and a low greening rate, resulting in poor visual effects [see Fig. 10(a)].

The natural openness of the riverfront is more uniform and better overall, with the south slightly better than the north, due to the small variation in width of the channel in the Second Ring waterway. In particular, the waterfront greenway in the northern moat and southern Changhe section is divided by vegetation from the water body, with bulky shrubs and small trees obscuring views and a lower WO, increasing the sense of confinement and oppressiveness of the waterfront walkway space [see Fig. 10 (b)].

The visibility of water bodies in the second ring water system shows a homogeneous state, but at local points, water bodies are not visible or the water surface is over-represented in the line of sight. A small number of discontinuous scenes of poor water body visibility occur in the North Moat, North Tucheng Ditch, and South Changhe River due to the vegetation barrier between the riverfront greenway and the water body; the Beijing-Mi Diversion Channel and Yongding River Diversion Channel sections have a high BVI share due to the small height difference between the riverfront greenway and the water surface and the low height of the waterfront parapet [see Fig. 10 (c)].

VII. Conclusion

This study introduces the Panoramic Green Perception Rate (PGPR), a novel metric for more accurately quantifying urban greenery visibility compared to the traditional Green View Rate (GVR), effectively addressing the limitations of 2D image assessments. By combining spherical panoramic imagery with deep learning using the Dilated ResNet-105 model, the approach achieved a mIoU of 62.53% and a low average deviation of 9.17% from manual evaluations. The method was successfully applied and validated at Ziyang Park, enabling spatially detailed and objective analysis of green space distribution. The results demonstrate that the model's scalability and robustness under varying environmental conditions, supporting broader applications in urban-scale assessments. The findings offer practical value for urban planning and sustainable development, with future work aiming to adapt the PGPR framework to dynamic environments and enhance model performance with richer datasets. A comparative evaluation confirms that the proposed model outperforms existing CNN-based segmentation approaches in terms of mIoU and green visibility estimation, underscoring its suitability for real-world urban landscape assessment.

Application Analysis and Research of Text Model Based on Improved CNN-LSTM in the Financial Field

Jing Chen, Chensha Li*
Foreign Language School, Guangdong University of Science and Technology, Dongguan, 523083, China

***Abstract*—With the continuous development of information technology, public opinion analysis based on open-source texts and financial situation awareness has become a research hotspot. This study focuses on financial news and commentary information. First, a topic crawler classification model combining the advantages of CNN and LSTM is proposed to improve the topic recognition ability of financial news texts, and a CNN-LSTM-AM stock price fluctuation prediction model is proposed. This model performs sentiment analysis through BiLSTM, integrates multiple emotional factors and market historical data, and demonstrates superior predictive performance compared to traditional models in multiple experiments.**

***Keywords*—Financial information mining; CNN-LSTM model; stock price prediction; sentiment analysis; BiLSTM**

I. Introduction

Under the background of the vigorous development of big data and artificial intelligence technology, open source text technology has shown significant application value in many fields such as public opinion monitoring, social governance, public security and financial risk early warning. Especially in the financial field, the speed and scope of information dissemination have a profound impact on market sentiment fluctuations, stock price changes and even the stability of the entire financial ecosystem. Therefore, how to efficiently and accurately extract valuable financial intelligence from massive, heterogeneous and dynamically updated information sources, and intelligently model market trends and emotional tendencies have become research hotspots and technical problems that are widely concerned by academia and industry.

At present, unstructured data sources such as online news, social media platforms and investor reviews have become an important part of financial open source intelligence [1]. Although these textual data provide rich material for financial event recognition and market analysis, their large and unstructured nature also poses significant challenges: On the one hand, the information collection process is often faced with problems such as semantic ambiguity, unclear topic and serious noise interference, which makes the traditional crawler technology based on rules or keyword matching perform poorly in dealing with the precise extraction task of specific domain intelligence [2]. On the other hand, the sensitivity of financial markets to sudden events requires intelligence systems to have real-time and efficient text perception and semantic understanding capabilities [3]. However, most existing methods still have significant deficiencies in dealing with the structure and semantic modeling of sudden text [4]. In addition, as an important factor driving the volatility of financial markets, the dynamic evolution of sentiment in multi-source data such as news reports and investor comments still lacks an effective fusion modeling mechanism [5].

Current research is confronted with multiple challenges and limitations in the field of financial text analysis. Firstly, with the explosive growth of information volume in the financial market, multi-source heterogeneous data such as news reports, social media and investor comments have become increasingly complex. Traditional text capture and analysis methods based on rules or keyword matching have become inadequate. This type of method has limited capabilities in semantic understanding and topic recognition, and is vulnerable to semantic ambiguity, information noise and interference from unexpected events, resulting in poor performance in highly dynamic and complex financial scenarios. Furthermore, many existing models lack effective integration mechanisms when dealing with the implicit sentiment changes and event-driven characteristics in financial language, making it difficult to comprehensively capture the dynamic evolution process of market sentiment. These deficiencies limit the application effect of the financial intelligence system in market trend prediction, sentiment perception and risk early warning, and also reduce the practicability and stability of the model.

The main objective of this study is to construct an intelligent model system for financial text analysis, enhance the semantic understanding, topic recognition and sentiment prediction capabilities of financial unstructured text data, and thereby achieve more accurate and efficient financial public opinion monitoring and market trend prediction. Specifically, this study aims to solve the problems such as semantic ambiguity, unclear theme, poor real-time performance and weak ability of emotion evolution modeling that traditional methods face when dealing with open texts in the financial field. To this end, the study proposes an improved CNN-LSTM joint model. By introducing the convolutional neural network (CNN) to efficiently extract the local features of the text and combining it with the Long Short-Term Memory network (LSTM) to process the time-dependent information in the text, the recognition ability of hidden topics in financial news and commentary texts is enhanced. Meanwhile, in terms of stock price fluctuation prediction, a CNN-LSTM-AM model based on BiLSTM and the Attention Mechanism (AM) was constructed, integrating emotional factors and historical market data to achieve the joint modeling of emotion-driven and data-driven so as to capture the

deep-seated factors influencing stock price changes more comprehensively. Through systematic model design and multi-dimensional data fusion, this study aims to achieve a complete process optimization from information collection, feature extraction, emotion recognition, to trend prediction, enhance the intelligent level of financial text analysis, and provide a technical basis and theoretical reference for financial decision support.

This study focuses on the application analysis and research of the text model based on the improved CNN-LSTM in the financial field. Section II sorts out the current research progress in the topic recognition and sentiment analysis of financial texts and clarifies the deficiencies of the existing methods. In Section III, this study proposes a focused crawler model combining the advantages of CNN and LSTM for financial text collection and classification, and designs a BiLSTM sentiment analysis model integrating the attention mechanism for stock fluctuation prediction. In Section IV, the performance of the model was verified through multiple sub-experiments, including text crawling, topic classification, comment sentiment analysis and stock price prediction. The experimental results show that the proposed model is superior to the traditional methods in terms of accuracy and practicality. The conclusion section in Section V summarizes the research results and practical significance, and looks forward to the future research directions, proposing that the integration of multi-source data and the improvement of the model's generalization ability can be further explored.

II. Related Work

In the context of information explosion and highly sensitive financial markets, financial intelligence mining and intelligent prediction based on text data is gradually becoming an important research direction in the intersection field of Natural Language Processing (NLP) and financial engineering. With the continuous expansion of open source channels such as social media, news portals and review platforms, a large amount of unstructured text data is emerging, which contains a large amount of potential information that can be used for market trend analysis, public opinion monitoring and investment decision-making [6]. How to effectively integrate these heterogeneous data resources and realize the accurate identification and modeling of financial sentiment, emergencies and market dynamics, it is urgent to rely on advanced deep learning technology to build an intelligent information processing framework [7].

In recent years, convolutional neural Network (CNN) and Long Short-Term Memory network (LSTM) have achieved remarkable results in text classification and sequence modeling tasks [8]. CNN is good at extracting semantic features from local context, while LSTM is able to capture long-distance dependencies, and the joint application of them provides new ideas for deep modeling of complex financial texts [9]. However, in the face of the characteristics of high semantic complexity, strong burstiness and obvious emotional fluctuations in financial corpus, the traditional CNN-LSTM model still has shortcomings in information extraction accuracy, timeliness of event recognition and emotion modeling dimension [10]. Next, starting from the research status of financial text information processing, this study summarizes the development of related model technologies, and analyzes the main challenges and development trends faced by current research.

A. Text Mining and Topic Identification of Financial Texts

With the rapid advancement of internet technology and the media industry, news has become one of the primary channels through which the public accesses social developments and financial information [11]. Traditional print media is swiftly transitioning toward digitalization and network-based formats, and news data is now characterized by large-scale, rapid updates, and diverse content [12]. Effectively classifying and intelligently mining these large-scale news text datasets has emerged as a key research direction in the field of natural language processing (NLP) [13]. In highly sensitive domains such as finance, the intelligent processing of news data holds significant importance for information retrieval, intelligence monitoring, and market behavior prediction.

Early research in text classification primarily relied on shallow learning algorithms such as Naive Bayes, Support Vector Machines (SVM), and K-Nearest Neighbors (KNN), which modeled news texts using the bag-of-words approach for classification [14]. While these methods demonstrated a certain level of classification capability, they often faced challenges such as feature sparsity and poor generalization when applied to large-scale, high-dimensional, and semantically complex financial texts [15]. With the rise of deep neural networks, convolutional neural networks (CNNs) and recurrent neural networks (RNNs) have been increasingly adopted. CNNs are effective in capturing local key features within text and are well-suited for handling phrase-level semantic structures [16]. Meanwhile, Long Short-Term Memory networks (LSTMs), an improved variant of RNNs, perform well in processing long texts and capturing dependencies over time [17]. Researchers have attempted to combine the strengths of both architectures to overcome the limitations of single models in representing complex semantics. For example, Duan et al. conducted some studies using CNNs as feature extractors to generate embedded features, which are then fed into LSTM networks for semantic modeling, significantly improving classification accuracy in financial topic classification tasks [18].

Traditional text feature extraction methods fall into three main categories: rule-based and statistical methods, machine learning-based methods, and more recently, deep learning methods that have shown superior performance in text classification tasks [19]. Most CNN-based news data classification models are designed to learn local contextual information within fixed-size windows and extract features by sliding these windows across the text, which are then used for classification [20]. However, CNNs have limitations, particularly in capturing dependencies among local features. Addressing this issue, this study proposes a hybrid model that integrates a multi-scale dual-layer CNN with a BiLSTM and an attention mechanism, termed TCNNRes-BiLSTM-Attention (TCBA) [21]. This model simultaneously captures contextual features from both forward and backward directions of the text sequence while incorporating a dual-layer multi-scale convolutional structure [22].

B. Survey of Financial Condition Forecasting Research based on Financial Commentary Analysis

For investors, the stock market is a platform to identify and invest in high-potential companies with the aim of securing substantial returns. Over the years, both investors and researchers have been devoted to the task of stock price prediction. However, the stock market is inherently dynamic, nonlinear, non-stationary, non-parametric, noisy, and chaotic, making it extremely challenging to analyze market trends and price behaviors [23]. The stock market is influenced by a variety of highly interrelated factors, including political events, macroeconomic conditions, commodity price indices, investor expectations, performance of other stock markets, and investor psychology [23]. The correlation between public sentiment and financial markets has long attracted considerable academic attention. Studies have shown that the emotional tendencies reflected in news reports and investor commentary can, to some extent, serve as precursors to market trends—especially in times of information overload or sudden adverse events, where emotional reactions often precede actual market movements [24]. Consequently, sentiment-driven stock price prediction has gradually become an important direction in intelligent financial analysis.

Traditional stock prediction methods primarily rely on statistical techniques for time series analysis. For instance, Matta et al. employed econometric approaches to forecast stock prices, demonstrating that models using multiple predefined variables could yield statistically significant stock return predictions [25]. The Autoregressive Integrated Moving Average (ARIMA) model, introduced by Box and Jenkins, has been widely used for time series forecasting, including stock market returns [26]. However, studies have revealed that ARIMA models tend to perform poorly on financial time series data [27]. To better account for volatility, the GARCH model was proposed to predict stock prices by modeling the relationship between price volatility and returns. Nonetheless, traditional predictive methods often struggle to balance the inherent randomness and regularity of stock movements and are plagued by various limitations, making them less suited to the needs of investors.

With rapid advancements in hardware technology, the development of powerful new algorithms, and the rise of big data and distributed computing technologies, the efficiency of stock volatility prediction has greatly improved. Big data technologies have made it significantly easier to access and store large volumes of historical trading data. In recent years, machine learning algorithms have undergone explosive growth, and many researchers have applied techniques such as Support Vector Machines (SVM), decision trees, Convolutional Neural Networks (CNN), and Long Short-Term Memory (LSTM) networks to stock volatility prediction, achieving promising results. SVM, first introduced by Vapnik, has demonstrated its effectiveness in many pattern recognition problems and is especially powerful in identifying subtle patterns in complex datasets [28]. It has been used in applications such as handwriting recognition, fraud detection, speaker identification, and facial recognition. Sonkavde et al. have employed SVM to identify stocks that might outperform the market by analyzing accounting fundamentals and price data [29]. Experimental results showed that equally weighted portfolios constructed from stocks selected by SVM achieved significant returns over five years, outperforming benchmark indices. Other studies predicted stock price direction using SVM and then applied trend analysis to derive corresponding price predictions. Despite modest profitability, these models still performed better than bank interest rates, suggesting a degree of practical value [30]. Additional research proposed a two-stage feature selection and prediction model using SVM, demonstrating better generalization ability than traditional methods [30]. Furthermore, Principal Component Analysis (PCA) has been introduced into SVM-based models to extract low-dimensional, efficient features, improving training accuracy and preserving the original data's characteristics. Empirical studies showed that PCA-SVM stock selection models contributed more significantly to annual portfolio returns than benchmark indices [31].

C. The Comparison Between the Current Research and this Study

In the current research on text classification and sentiment analysis, the academic community has accumulated a large number of methods based on traditional machine learning and deep learning, forming a relatively rich research system. The existing research mainly focuses on text classification models based on traditional algorithms such as Bayesian and Support Vector Machine (SVM), as well as sentiment analysis methods based on deep neural networks that have emerged in recent years. However, by systematically comparing these existing works with the model proposed in this study, the gaps and deficiencies of the current research can be clearly identified, and the innovation and necessity of this study can be highlighted. Early studies mostly relied on the Naive Bayes model. Although this method laid the foundation for text classification, it has obvious limitations of the independence assumption and is difficult to fully model the complex correlations among text features. LMDCampos et al. attempted to introduce a synonym library modeling through Bayesian networks, improving the representation ability of text semantics, but still remained at the relatively shallow stage of semantic extraction. Luo Huiqin, Zeng Yu, Li Xiaodong and others have optimized Naive Bayes to varying degrees, such as introducing feature weights and improving the calculation method of TF-IDF weights, which has enhanced the classification accuracy. However, the expressive ability and generalization ability of these methods are still restricted by the structure of the model itself. With the introduction of Support Vector Machine, the performance of text classification has been significantly improved. Xiao Zheng, Ding Shengchun, Shi Qiangqiang and others applied SVM to tasks such as sentiment tendency analysis and microblog opinion recognition, and achieved good results. However, the computational efficiency of the SVM algorithm is still relatively low when dealing with large-scale corpora and multi-dimensional emotional features, and the model has poor sensitivity to the word order of the input data, making it difficult to capture the context semantics.

In terms of deep learning, KIM Y improved the performance of sentence-level classification by introducing the CNN structure with parameter tuning, pioneering a new direction for the application of deep learning in text analysis. Zhou Jinfeng

further expanded the structure of CNN, utilized multi-layer convolution to extract local semantic features, and enhanced the expressive ability of the model. However, CNN relies on a fixed window during modeling, lacks sensitivity to time series features, and is unable to effectively retain the context dependency of the text. To solve this problem, subsequent research gradually shifted to models based on RNNS. Huang M introduced tag-specific synthetic functions and structural control strategies in RNN, which improved the fine-grained control ability of sentiment classification. FeiH enhances the semantic capture ability of LSTM through the keyword sensitivity mechanism, achieving a slight performance improvement. RaoG proposed the SR-LSTM model, which models the semantic relationships at the sentence and document levels respectively, through a double-layer structure, and captures the emotional information in long texts more effectively. Although these improved schemes based on LSTM have made certain progress, most studies are still limited to the single task of sentiment classification and lack the ability of multimodal data fusion and interaction modeling between sentiment and market behavior. Therefore, compared with the traditional static modeling methods based on Bayesian or SVM, this study breaks through the limitations of shallow feature engineering. Compared with the existing deep learning models, it has also achieved substantial breakthroughs in structural design and multi-source information integration. Especially in the application of the financial field, it has filled the gap in the modeling of the linkage between sentiment analysis and market behavior, providing a more practical and scalable technical path for subsequent research on financial text analysis and prediction.

III. Model Establishment and Solution

A. Research on Focused Crawler Technology Based on CNN-LSTM

In today's highly dynamic and information-intensive financial market environment, the ability of corporate decision-makers, financial analysts, and policymakers to perceive industry trends and breaking events has become a critical factor influencing the efficiency and quality of decision-making. Faced with rapidly evolving market conditions, financial professionals urgently need to rely on accurate and timely information to assess trends, evaluate risks, and adjust strategies. However, with the explosive growth of internet-based information, financial data is now characterized by large volume, rapid updates, high noise levels, and strong heterogeneity [32]. Traditional methods that depend on manual information retrieval and classification are increasingly unable to meet real-world demands. These manual approaches are not only inefficient but also susceptible to subjective judgment and information delays, which compromise the timeliness and scientific rigor of financial activities [33].

Compared with general-purpose texts, financial news exhibits strong topic cohesion and a high density of domain-specific terminology. Such news content typically centers on core themes including stock market trends, industry mergers and acquisitions, macroeconomic policies, and corporate earnings reports. The text often includes frequently used professional terms such as "price-to-earnings ratio", "return on equity", "policy dividend", and "acquisition agreement". This semantic concentration provides a favorable basis for building automated topic recognition models, as it allows the models to more easily capture and differentiate the semantic distinctions between various news topics.

- Overview of Focused Crawler Technology

This topic classifier functions as a binary text classification model, distinguishing between topic-relevant and topic-irrelevant content. The topic-focused crawling framework proposed in this study is illustrated in Fig. 1.

The core part of the focused crawler workflow is topic relevance calculation. In the content of news text, the sentences containing the topic content are often short and concise, so before the topic discrimination. Sentences with sentence length between 20 and 50 are selected for combination, and then the topic relevance is judged by the topic discriminator.

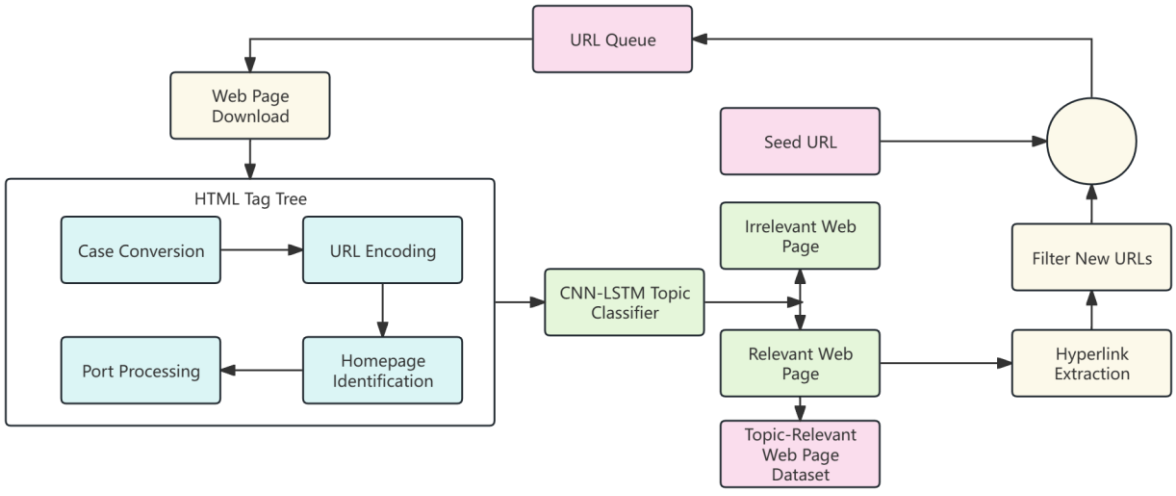

Fig. 1. Framework of focused crawler.

- The Focused crawler classifier

The text classification model based on CNN-LSTM can better extract features in documents. The training flow of the text classification model is shown in Fig. 2. After multiple experimental comparisons, the experimental parameters are set as follows: the learning rate of Adam optimizer is 0.001, the training set and the test set are divided according to the ratio of 8:2, dropout is set to 0.5, and epoch is set to 100.

First, the algorithm takes a preprocessed text dataset as input, where each sample is a document associated with a specific category label. The preprocessing typically includes steps such as tokenization, stop-word removal, and word normalization. Each document is represented as a sequence of words, $W_1, W_2, \ldots, W_n$, which are then fed into an embedding layer. The role of the embedding layer is to map each word to a vector in a continuous space, capturing semantic relationships between words, and thereby producing a sequence of word vectors. These word vectors are subsequently passed through a convolutional layer. The convolutional layer uses a sliding window mechanism to extract local features, effectively capturing word-level associations. After the convolution operation, a pooling layer is typically applied. The pooling layer downsamples the convolution output to reduce feature dimensionality and retain key information, which improves computational efficiency and generalization. The output from the pooling layer is then passed into an LSTM layer. LSTM, a specialized form of recurrent neural network (RNN), is capable of handling long-term dependencies and is well-suited for sequential modeling tasks. In text classification, the LSTM layer learns the sequential and contextual semantics in the document, capturing dependencies across different parts of the text.

The output of the LSTM is passed to a fully connected layer, which integrates the high-level features and produces a fixed-size output vector. This vector is then processed by a Softmax layer, which converts the vector into a probability distribution over all possible classes, thus determining the predicted category of the input document. The entire model is trained using backpropagation. In each training epoch, the model iterates over all training samples, performs predictions, computes the loss (typically using cross-entropy), and then calculates gradients based on the loss. Using these gradients, an optimizer (such as Adam, with a learning rate of 0.001) updates the model parameters to minimize the loss function. This process continues for a predefined number of epochs (set to 100 in the experiment) or until the model converges. To prevent overfitting, a Dropout mechanism is introduced during training, with a dropout rate set to 0.5. Before training begins, the dataset is split into a training set and a test set in an 80:20 ratio. After training, the model is evaluated on the test set to assess its generalization performance.

This pseudocode provides a clear step-by-step view of how a CNN-LSTM model is trained for text classification, covering data preprocessing, embedding, forward pass, loss computation, backpropagation, and model update.

- CNN-LSTM hybrid model

The CNN-LSTM hybrid model is a deep learning model that combines the advantages of Convolutional Neural Network (CNN) and Long Short-Term Memory network (LSTM), which can simultaneously capture the local features and temporal relationships of the input data [4]. The overall structure of the model is shown in Fig. 2.

The computation in the convolutional layer is defined by the following formula:

$$O = f(WZ + b) \tag{1}$$

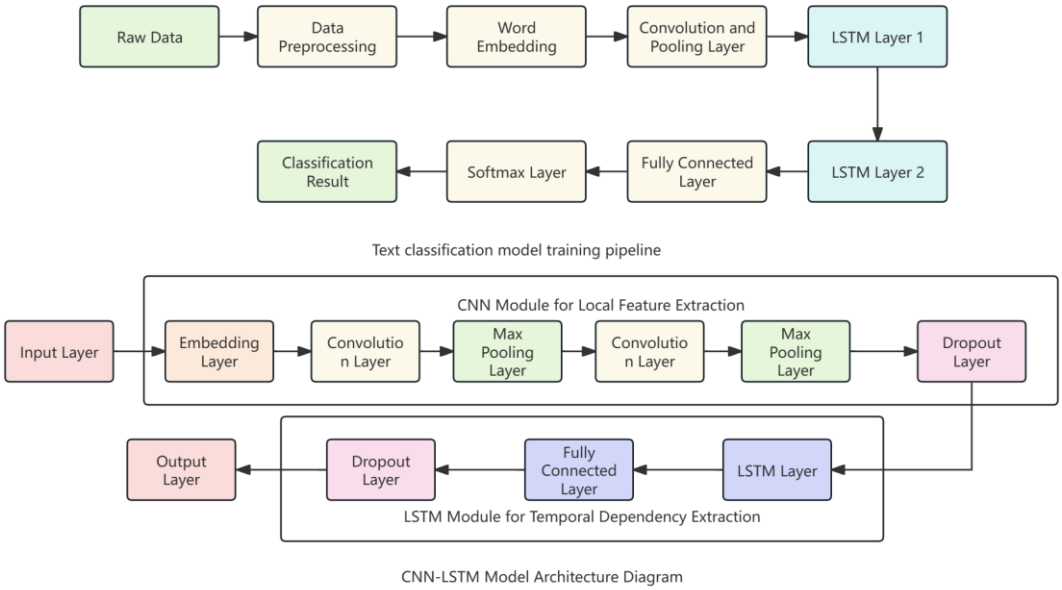

Fig. 2. Text classification training process and classification algorithm framework.

where, O is the output feature matrix after convolution, W is the weight matrix (convolutional kernel), Z is the input word embedding matrix, b is the bias term, f is the ReLU (Rectified Linear Unit) activation function, defined as $\mathrm{ReLU}(x) = \max(0, x)$, where x is the output vector from the previous neural layer.

The Long Short-Term Memory (LSTM) network is a special type of Recurrent Neural Network (RNN) designed to overcome the problems of vanishing or exploding gradients that occur when handling long sequences. LSTM introduces a gating mechanism—comprising the input gate, forget gate, and output gate—that allows the network to selectively remember or forget information. This mechanism enables LSTM to effectively capture long-range dependencies in sequential data. The fundamental architecture of an LSTM cell is illustrated in Fig. 3.

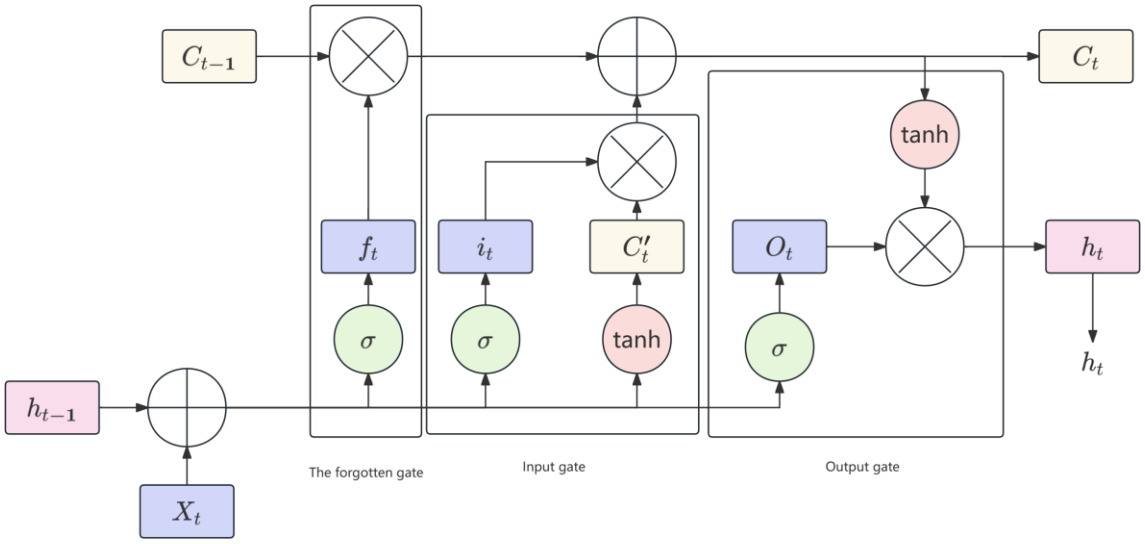

Fig. 3. Diagram of the basic unit structure of an LSTM model.

Lastly, the hidden state output h_t is computed by applying the output gate to the tanh-transformed current cell state c_t. The variables t and $t-1$ refer to the current and previous time steps, respectively, highlighting the sequential nature of the data being processed. Together, these components enable the LSTM to maintain and update information over time, effectively capturing long-term dependencies in sequential text data.

B. Sentiment Analysis of News and Investor Reviews

Investor comments have emotional tendencies, and the subjective views and emotional tendencies of comment authors can be mined through sentiment analysis. This plays an important role in the research field of the relationship between reviews and stocks, and the addition of review features can make the stock market prediction results more comprehensive, objective and explanatory.

The CNN-LSTM model first extracts the features of stock day-level funds, market prices, technical factors, news and comments through CNN, and then inputs the extracted features into the LSTM network for training to extract relevant time series information. At the same time, the Attention Mechanism is introduced after the LSTM network. This allows the network to focus on important features during training. The overall network structure of the proposed CNN-LSTM-AM model is shown in Fig. 4.

The basic unit of the Long Short-Term Memory (LSTM) model consists of four main components: the forget gate, input gate, memory cell, and output gate. These components work together to manage the balance between long-term memory retention and short-term information update, enabling the network to capture complex dependencies in sequential data.

The forget gate f_t decides which information from the previous memory cell should be discarded. It uses a sigmoid activation to output a value between 0 and 1 for each element in the memory cell:

$$f_t = \sigma\left(W_f[h_{t-1}, x_t] + b_f\right) \tag{2}$$

The input gate i_t determines which new information is to be added to the memory cell:

$$i_t = \sigma(W_i[h_{t-1}, x_t] + b_i) \tag{3}$$

At the same time, a candidate memory content $\tilde{c}_t$ is created via a tanh layer:

$$\tilde{c}_t = \tanh(W_c[h_{t-1}, x_t] + b_c) \tag{4}$$

The new memory cell state c_t is computed by combining the previous memory cell c_{t-1}, the forget gate f_t, the input gate i_t, and the candidate content $\tilde{c}_t$:

$$c_t = f_t \times c_{t-1} + i_t \times \tilde{c}_t \tag{5}$$

The output gate o_t decides which part of the memory cell should be output.
The final hidden state h_t is obtained by applying the output gate to the updated cell state after passing through a tanh function:

$$o_t = \sigma(W_o[h_{t-1}, x_t] + b_o) \quad (6)$$

$$h_t = o_t \times \tanh(c_t) \quad (7)$$

In the LSTM formulas, f_t, i_t, and o_t represent the states of the forget gate, input gate, and output gate, respectively. These gates control how information flows through the LSTM cell at each time step. The symbols W_f, W_i, and W_o denote the weight matrices associated with each of these gates, while b_f, b_i, and b_o are their corresponding bias terms. The notation $[h_{t-1}, x_t]$ indicates the concatenation of the hidden state from the previous time step h_{t-1} and the current input vector x_t. This concatenated vector serves as the input to the various gate functions.

The sigmoid function, represented by σ, is used to squash the outputs of the gates to values between 0 and 1, effectively determining the degree to which information should be remembered or forgotten. The candidate memory content $\tilde{c}_t$ is a proposed update to the cell state, calculated using the tanh function to ensure its values fall within the range of -1 to 1. The current memory cell state, denoted as c_t, is updated by combining the retained portion of the previous cell state c_{t-1} with the new candidate content $\tilde{c}_t$, scaled by the input gate. This combination is carried out through element-wise multiplication, indicated by the symbol $\times$, also known as the Hadamard product.

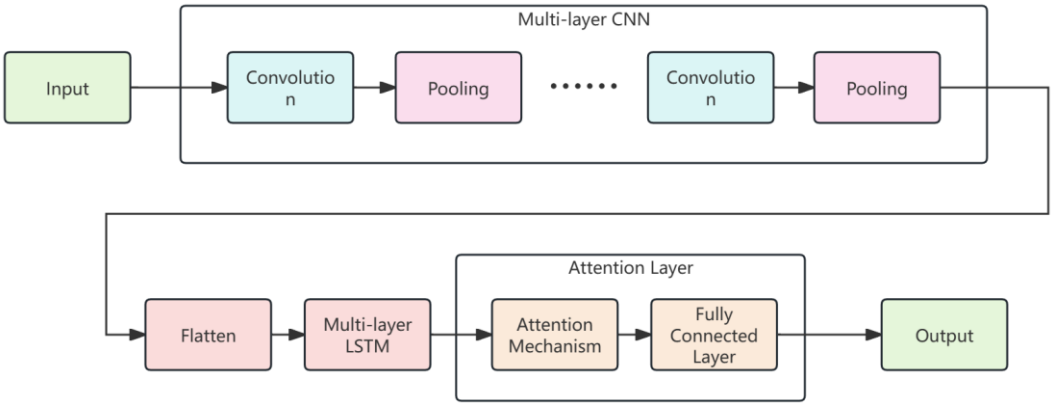

Fig. 4. CNN-LSTM-AM network structure diagram.

IV. Experimental Results and Analysis

A. Text Crawler Experiments

- Experimental parameter setting

In this section, the experiments were conducted using PyCharm as the development environment, with deep learning tasks implemented using PyTorch, a scientific computing library based on Python. The hardware setup includes an Intel i9-14900K CPU and an NVIDIA GeForce RTX 2080Ti 22GB GPU. All Python third-party libraries required in the experiments were managed using Anaconda.

In the control experiment, the maximum collection number of crawlers is set to 1000, that is, when T = 1000, the harvest rate of the theme crawler is compared as shown in Fig. 5. With the increase of the number of crawled pages, the harvest rate of each control experiment decreases, but the model proposed in this section is better than other groups, and the harvest rate is 0.72 at the end of the crawling task. The harvest rate is 0.10 higher than that of the focused crawler based on feature enhanced RNN, 0.26 higher than that of the focused crawler based on HMM, and 0.05 higher than that of the breadth-first strategy crawler.

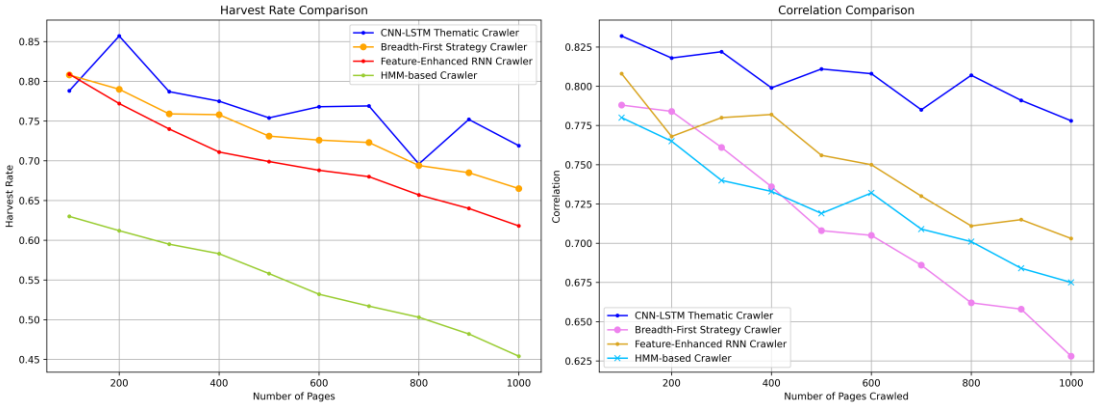

Fig. 5. Comparison of harvest rate and relevance of focused crawler

The correlation comparison of focused crawlers as the number of crawled pages increases, the overall correlation of each model decreases. At the end of the crawling task, the correlation of the model proposed in this section is 0.78, which is 0.08 higher than that of the focused crawler based on feature-enhanced RNN. Compared with the focused crawler based on HMM, the correlation is 0.11 and 0.15 higher than the breadth-first strategy crawler.

From the comparison of the above experimental results, it can be seen that the crawler based on HMM has the worst performance in the harvest rate and relevance index of the topic crawler because it does not discriminate the topic relevance. The focused crawler based on CNN-LSTM proposed in this study is better than other models based on content evaluation or link structure recognition.

B. *Experimental Design and Evaluation of Topic Classification Models*

- Dataset and metrics

In recent years, the text content of the news has a high time efficiency, and the use of the earlier data set may lead to the model's problem of the new term, so in the subject classification model experiment, on the one hand, according to the influence of the news reading quantity and the number of critics, the financial news text is used as the self-established language material library. On the other hand, the thcnews library, which is released by Tsinghua University, is based on the historical data of sina news between 2005 and 2011, which is divided into 14 categories, which randomly select 4,000 financial related news texts and 6,000 other types of news text [34]. The url is http://thuctc.thunlp.org/. Then, the material library is divided into financial topics, using 1 tag to mark the current data, which is related to the financial theme, which indicates that the current data is irrelevant to the financial theme. The distribution of each dataset is shown in Fig. 6, which consists of a random selection document in a mixed news cube, a training set, a validation set, and a test set.

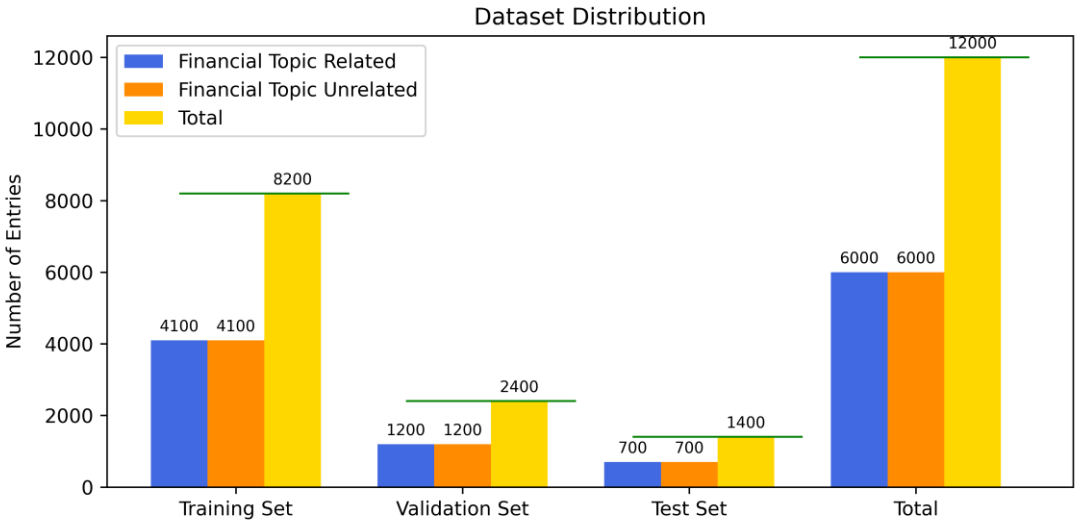

Fig. 6. Dataset distribution diagram.

- Experimental design and result analysis

By designing comparative experiments with machine learning and deep learning models, experiments are carried out on a mixed news corpus. The results of model comparison experiments are shown in Table I.

TABLE I MODEL COMPARISON OF EXPERIMENTAL RESULTS

Algorithm	Accuracy	F－Measure
SVM	83.6	80.2
RNN	86.3	83.5
CNN	91.1	87.2
RCNN	92.2	89.6
CNN－LSTM	93.4	90.8

By comparing the model proposed in this section with four models including Support Vector Machine (SVM), Recurrent Neural Network (RNN), Convolutional Neural Network (CNN) and Recurrent Convolutional Neural network (RCNN), the accuracy and F-Measure of the CNN-LSTM model can be concluded. The accuracy of the CNN-LSTM model reaches 93.4%. It indicates that the ability to correctly classify text is the strongest among all the compared models. Similarly, it also performs well on F-Measure, reaching 90.8%, indicating a good balance between precision and recall. Through longitudinal comparison, it is found that CNN-LSTM and RCNN models are superior to the traditional SVM model and the basic RNN model in accuracy and F-Measure. This is because for RCNN model, the advantages of RNN and CNN are combined, and for CNN-LSTM model, CNN can effectively capture local features. LSTM can capture long-term dependencies and process sequence data better through the characteristics of the two models to achieve good classification results. Therefore, the CNN-LSTM model proposed in this section is able to have better results in the topic classification task.

C. *Experiments on Sentiment Analysis of Reviews*

- Optimization parameter experiment

In this experiment, several different batch sizes of 8, 16, 32, 64, and 128 were selected for exploration. As shown in Table II, the experimental results show that when the batch size is chosen as 64, the model has the best effect, and the accuracy reaches 83.06%.

TABLE II ACCURACY STATISTICS FOR DIFFERENT BATCHSIZES

Batchsize	Accuracy
8	0.8127
16	0.8296
32	0.8257
64	0.8306
128	0.8263

In machine learning, the learning rate has a great impact on the performance of the model. The learning rate determines how much the parameters of the neural network are updated in each iteration. If the learning rate is too large, the parameter update step size will be too large, and the global optimal solution may be skipped, resulting in unstable training or failure to converge. If the learning rate is too small, the parameter update step size will be too small, which will lead to too slow training speed and need more iterations to converge. In this experiment, 0.5, 0.2, 0.1, 0.05, 0.02 and 0.01 were selected for exploration, and the experimental results are shown in Table III. As can be seen from the table, as the learning rate decreases from 0.5 to 0.05, the Accuracy of the model increases continuously. When the learning rate is 0.05, the model has the best effect, and the accuracy reaches 84.13%. When the learning rate is slowly decreased from 0.05 to 0.01, the model Accuracy decreases. Therefore, the learning rate of 0.05 is appropriate.

TABLE III ACCURACY VALUES FOR DIFFERENT LEARNING RATES

Learning rates	Accuracy
0.5	0.7526
0.2	0.7909
0.1	0.8306
0.05	0.8413
0.02	0.8335
0.01	0.8316

By adjusting the parameters above, the accuracy of the final model reaches a relatively excellent level. The stock review text of the test set is input into the model to predict the sentiment tendency, and the final evaluation index of the model is shown in Table IV below. It can be found that the model realizes a more accurate classification of investor comments, which lays a foundation for subsequent stock prediction.

TABLE IV INVESTOR COMMENTS CLASSIFICATION PREDICTION EVALUATION

	F1 score	Recall	Accuracy
Positive class	0.76	0.81	84.13%
Negative class	0.77	0.79	
Neutral class	0.79	0.83	

- Comparison model analysis

In this section, as a comparison, the investor comment vectors processed by word2vec are input into BP neural network, LSTM neural network, BiLSTM neural network and other machine learning models to compare their classification effects. After parameter tuning, the classification effect of each model is shown in Table V. It can be seen that the BERT-bilSTM model based on Bert and Bi-LSTM model has the best classification effect on investor comments, and its accuracy on the test set reaches 84.13. Therefore, in this study, Bert-BiLSTM is used to classify the sentiment of investor comments.

TABLE V EFFECT OF EACH MODEL INVESTOR COMMENT SENTIMENT CLASSIFICATION TASK

Model	Macro__F1__score	Macro__Recall	Accuracy
BP	0.74	0.79	79.38%
LSTM	0.76	0.79	82.74%
BiLSTM	0.76	0.80	83.24%
Bert—BiLSTM	0.77	0.81	84.13%

In this study, we first conducted a systematic exploration of two types of key hyperparameters, namely Batch Size and Learning Rate, and precisely depicted their influence on the performance of sentiment classification by controlling variables one by one. In terms of Batch Size, the experimental results (Table II) show that during the process when the Batch Size of the model was doubled successively from 8 to 64, the accuracy rate generally showed an upward trend: increasing from 0.8127 (Batch Size = 8) to 0.8306 (Batch Size = 64). This phenomenon can be attributed to the fact that a moderately increased batch size can not only reduce the variance of gradient estimation and stabilize the model update to a certain extent, but also will not cause a sharp decrease in the number of effective iterations due to excessive video memory occupation. It is notable that when the Batch Size is further increased to 128, the accuracy rate drops back to 0.8263 instead, which is consistent with the common "generalization deterioration" in large-scale training: Excessive batch size integrates too many sample signals in a single update, weakening the ability of parameters to "noise-driven" traverse saddle points, thereby reducing the performance of the test set. Comprehensively considering the performance peak and computing cost, Batch Size = 64 was determined as the optimal configuration.

The learning rate experiment (Table III) further reveals the significant influence of the optimized step size on the convergence quality. When the learning rate decreases from 0.5 to 0.05, the accuracy rate rises rapidly from 0.7526 to 0.8413, indicating that an overly large step size can cause the gradient update to cross the optimal region or even oscillate, while gradually reducing the step size can refine the parameter search and significantly improve the model discrimination ability. However, when the learning rate was further reduced to 0.02 and 0.01, the accuracy rates dropped to 0.8335 and 0.8316 respectively. This indicates that although a too small learning rate can avoid oscillations, it inhibits the ability to fully explore the parameter space and jump out of local minima, and slows down the convergence speed - thereby reducing the final accuracy. Therefore, considering the comprehensive training stability and performance, a learning rate of 0.05 was selected as the best. After the above two hyperparameters were optimized in place, the three-category evaluation index of the model on the test set (Table IV) showed that the overall accuracy rate reached 84.13%, while maintaining a relatively balanced category recall rate (positive 0.81, negative 0.79, neutral 0.83) and F1 score (in the range of 0.76-0.79). It

indicates that the parameter configuration takes into account the identification of different emotional tendencies, and there is no significant bias towards any category.

Further comparative experiments (Table V) compared Bert-BiLSTM with baselines such as BP, one-way LSTM and BiLSTM. Under the unified optimal hyperparameter Settings, Bert-BiLSTM established a leading advantage with an accuracy rate of 84.13%, a macro average recall rate of 0.81, and a macro average F1 score of 0.77. This result indicates that the superposition of BERT's pre-trained semantic representation and BiLSTM's bidirectional context capture ability significantly improves the comprehensive modeling effect of fine-grained semantics and emotional cues in investor comments. However, neither the shallow BP network with the same hyperparameters nor the one-way/two-way LSTM can achieve such accuracy on the same dataset.

D. Research on Stock Volatility Prediction Model

In general, the deeper the CNN layers are, the more abstract and high-level feature information the network can extract, and the more expressive the model can be. However, too deep networks also bring problems such as training difficulty, vanishing gradient and exploding gradient, which make training more difficult. In this study, the CNN network was constructed from a relatively shallow number of layers, and the input layer, 1 convolutional layer, and 1 pooling layer were initially set, and then the convolutional layers and pooling layers were gradually increased until 5 convolutional layers were reached. Since the amount of data is not large, a too deep network structure is not used. A total of five experiments were conducted this time, and the obtained results are shown in Table VI, where each index is the average value of the prediction evaluation of stocks, including New Hope.

TABLE VI THE AVERAGE SCORE OF THE RISE AND FALL OF DIFFERENT NUMBER OF HIDDEN LAYERS PREDICTION

Model types	Number of hidden layers	Accuracy	F1—score	AUC
CNN	1	0.58	0.58	0.59
	2	0.57	0.58	0.58
	3	0.57	0.57	0.58
	4	0.56	0.57	0.56
	5	0.57	0.57	0.56
LSTM	1	0.58	0.58	0.59
	2	0.57	0.58	0.58
	3	0.57	0.58	0.57
	4	0.56	0.57	0.56
	5	0.57	0.58	0.58

It can be seen from the data that the AUC score is the highest when the number of CNN network hidden layers is 1. As the number of hidden layers increases, the AUC score slowly decreases and then fluctuates between 0.58 and 0.56. According to the experimental results, when the number of hidden layers of the CNN of the model in this study is 1, it is the optimal solution to select the data set.

After adding one layer of LSTM, its AUC and accuracy decrease. As the number of hidden layers increases, the average AUC score fluctuates between 0.58 and 0.56. Therefore, 1 hidden layer is selected as the optimal solution in this study, that is, the number of LSTM hidden layers in the initial model is kept constant. In this section, a CNN-LSTM-AM hybrid neural network model is constructed based on the attention mechanism, CNN neural network, and LSTM neural network. Then, news and investor sentiment are integrated into the training data to train the CNN-LSTM-AM model and use it to predict the rise and fall of stock prices. However, the specific impact of the addition of attention mechanism, news and investor sentiment on the model is worth considering, so this section comprehensively analyzes the impact of these two factors on the model. The comprehensive performance comparison is shown in Table VII.

In general, after adding the features of news and investor comments, the four evaluation indicators of Accuracy, F1-score, Recall and AUC of each major model have different degrees of improvement. Specifically, after adding the sentiment features of news and investor comments, each evaluation index of the BP neural network model is increased by 0.025 on average. The average improvement of the CNN model indicators is 0.0325. Each evaluation index of the LSTM model was increased by 0.0275 on average. After adding news and comment features, the Accuracy, F1-score and AUC indicators of the CNN-LSTM model are increased by 0.03, and the Recall is increased by 0.02. The CNN-LSTM-AM model constructed in this study has the best effect. After adding news and comment features, the average AUC index reaches 0.64, and the Accuracy and F1-score both reach 0.63, which is an obvious improvement effect. When the sentiment features of news and investor comments are not added, the overall performance of CNN-LSTM-AM is also better than that of other comparison models. In summary, all models have significantly improved in each evaluation index after adding news and comment features. The CNN-LSTM-AM model performs better than the above comparison models. Therefore, it can be considered that the features of news and investor comments are effective features, which can be used to increase the accuracy of the model in stock prediction.

TABLE VII WHETHER TO ADD NEWS AND INVESTOR SENTIMENT PERFORMANCE COMPARISON (MEAN VALUE)

	Join or not	Accuracy	F1—score	Recall	AUC
BP	No	0.55	0.55	0.53	0.55
	Yes	0.57	0.57	0.56	0.58
CNN	No	0.58	0.57	0.57	0.59
	Yes	0.61	0.61	0.60	0.62
LSTM	No	0.58	0.59	0.57	0.59
	Yes	0.61	0.60	0.61	0.62
CNN—LSTM	No	0.59	0.58	0.58	0.60
	Yes	0.62	0.61	0.60	0.63
CNN—LSTM—AM	No	0.60	0.60	0.58	0.62
	Yes	0.63	0.63	0.61	0.64

E. Model Backtesting Experiment

This study uses CNN-LSTM-AM to mine the time series information in stock data, and combines news information and investor comment information in the stock forum. In this subsection, the CNN-LSTM-AM model of this study is compared with the traditional CNN model, LSTM model and CNN-LSTM model based on the use of the strategies in this study. After multiple parameter adjustments and optimizations,

Tables VIII to X list the backtest returns, maximum drawdown rates, and Sharpe rates of the selected 8 stocks from January 1, 2022 to January 1, 2025.

TABLE VIII COMPARISON OF BACKTEST RETURNS FOR SELECTED STOCKS

Stock	Benchmark	CNN-LSTM-AM	CNN-LSTM	CNN	LSTM
Everbright Securities	15.74%	108.55 %	85.22%	74.38%	78.82%
GoerTek Inc.	175.04%	268.69 %	178.44 %	148.78 %	169.37 %
Vanke A	-33.94%	17.37%	12.17%	6.25%	10.29%
New Hope Liuhe	-23.85%	78.38%	62.69%	56.48%	67.03%
Digital China Health	59.15%	98.45%	93.33%	73.16%	85.56%
Jinling Pharmaceutical	8.82%	57.14%	48.12%	46.63%	49.88%
Luzhou Laojiao	208.15%	412.35 %	369.18 %	343.81 %	398.82 %
Changan Automobile	110.91%	183.68 %	165.37 %	155.44 %	171.65 %

Table IX shows the comparison of the maximum drawdown rates in the simulation backtesting between the model in this study and other models. It can be seen from the table that the average maximum drawdown rate of the model in this study is 28.78%, and the maximum drawdown rates of stocks are all lower than those of the benchmark and other models. Overall, CNN-LSTM-AM reduces the maximum drawdown rate of the model.

TABLE IX COMPARISON OF MAXIMUM DRAWDOWN RATES FOR SELECTED STOCKS

Stock	Benchmark	CNN-LSTM-AM	CNN-LSTM	CNN	LSTM
Everbright Securities	52.49%	23.46%	24.30%	30.58%	28.13%
GoerTek Inc.	47.87%	32.19%	33.45%	39.34%	35.26%
Vanke A	44.30%	26.89%	31.41%	37.32%	33.51%
New Hope Liuhe	73.75%	36.61%	41.12%	46.41%	47.36%
Digital China Health	43.71%	21.58%	29.65%	38.36%	31.64%
Jinling Pharmaceutical	34.33%	24.81%	31.29%	35.84%	32.95%
Luzhou Laojiao	48.27%	30.34%	34.37%	42.54%	40.41%
Changan Automobile	49.92%	34.39%	41.29%	46.71%	43.62%
Average	49.33%	28.78%	33.36%	39.64%	36.61%

As shown in Table X, the average Sharpe ratio of CNN-LSTM-AM is 1.12, which not only exceeds the benchmark value of 0.43, but also is the highest among the four models. Especially in the backtesting of Vanke A and New Hope, the models successfully increased the benchmark Sharpe ratio, which was negative to positive.

TABLE X COMPARISON OF SHARPE RATIOS FOR SELECTED STOCKS

Stock	Benchmark	CNN-LSTM-AM	CNN-LSTM	CNN	LSTM
Everbright Securities	0.09	0.75	0.59	0.45	0.55
GoerTek Inc.	1.17	1.84	1.21	0.98	1.13
Vanke A	-0.66	0.49	0.37	0.21	0.28
New Hope Liuhe	-0.09	1.04	0.89	0.77	0.81
Digital China Health	0.52	0.79	0.60	0.47	0.51
Jinling Pharmaceutical	0.05	0.21	0.07	0.04	0.06
Luzhou Laojiao	1.40	2.42	2.13	1.82	1.93
Changan Automobile	0.94	1.39	1.28	1.14	1.22
Average	0.43	1.12	0.89	0.74	0.81

Based on the above-mentioned experimental results, it is confirmed that the stock trading model based on CNN-LSTM-AM is a feasible quantitative timing strategy. Compared with the CNN, LSTM and CNN-LSTM models, this model shows a higher average backtest yield and Sharpe rate, as well as a lower maximum drawdown rate. This means that this model can achieve higher returns while undertaking relatively lower risks, providing certain references for users' investment decisions.

V. CONCLUSION

A. The Content and Significance of this Study

This study set out to investigate how an improved CNN-LSTM architecture can be leveraged—together with modern language-representation techniques and sentiment factors—to advance open-source intelligence (OSINT) mining, emergent-event detection, and stock-price fluctuation prediction in the financial domain. By unifying local-feature perception in convolutional layers with the long-range dependency modeling capacity of LSTM, the proposed CNN-LSTM topic-crawler raises both the harvest rate and the mean topical relevance of crawled documents, outperforming vanilla CNN, LSTM, and classical TF–IDF baselines. These gains materially reduce the latency between news release and intelligence ingestion, a critical requirement for time-sensitive financial analysis. The hierarchical detector first filters non-emergent content and then refines the categorization of bona fide sudden events by fusing word-vector dispersion features that encode class–term association strength and contextualized representations from BERT. Coupling these dual channels with an attention-augmented TextCNN boosts F1 scores across all emergent categories, validating the merit of jointly capturing local salience and global semantics in highly volatile news streams. Integrating news sentiment, investor-comment sentiment (obtained via a BERT-BiLSTM classifier), and historical trading factors into a convolutional–recurrent network enhanced with an attention mechanism (CNN-LSTM-AM) yields superior directional-accuracy and RMSE metrics relative to single-source or single-architecture benchmarks.

B. Significance of Research

Taking the financial news text as the breakthrough point, this study deeply discusses the application path and practical effect of the text processing technology based on the improved CNN-LSTM model in financial intelligence mining, which has significant theoretical and application value. By introducing the hybrid architecture of CNN and LSTM, combined with its advantages in local feature extraction and temporal dependency modeling, the topic news crawler system constructed in this study realizes the efficient classification and accurate collection of financial news texts. Compared with the traditional crawler system based on keywords or rule-driven, the system greatly improves the acquisition efficiency and relevance of target information, and provides strong technical support for the construction of a high-quality intelligence database in the financial field. As an important external variable affecting the volatility of the stock market, the rapid identification and classification of emergencies is an important part of the financial intelligence system.

For the future, the research can be deepened along the following directions. Firstly, a multilingual and multi-market cross-domain financial intelligence knowledge base was constructed, and an incremental online learning framework was introduced to realize the rapid adaptation and transfer generalization of the model in complex heterogeneous scenarios. Self-supervised contrastive learning and joint fine-tuning strategies are combined to mitigate the performance degradation caused by cross-lingual semantic drift. Secondly, the data modality and interaction dimension should be expanded: in addition to news and text public opinion, image, audio and transaction depth data should be fused, and multimodal Transformer and spatio-temporal graph neural network should be introduced to jointly model the market microstructure signal end-to-end, so as to improve the prediction strength of sudden black swan events and complex chain reactions. Furthermore, combined with symbolic reasoning and a knowledge graph, financial regulations, macro policies, and enterprise knowledge can be embedded into the event extraction and sentiment analysis process, and the causal inference ability and explanation depth of the model can be enhanced by executable logic rules.

Ensuring Consistency in Group Decision Making: A Systematic Review of the FWZIC Method

Ghazala Bilquise[1], Samar Ibrahim[2]
Computer Information Science, Higher Colleges of Technology, Dubai, UAE[1]
School of Art and Science, American University in Dubai, Dubai, UAE[2]

***Abstract*—Subjective opinions in decision-making processes are often vague, ambiguous, and imprecise due to the inherent subjectivity and variability in individual perspectives. This systematic study examines the Fuzzy Weighted Zero Inconsistency (FWZIC) method, which addresses these challenges by achieving consistency in group consensus and effectively managing uncertainties associated with subjective human opinions. The FWZIC method is increasingly popular in the Multi-Criteria Decision Making (MCDM) field for determining criteria weights. This study comprehensively analyzes 71 empirical studies published from 2021 to March 2025, employing the FWZIC method across diverse domains such as healthcare, engineering, and supply chain. By categorizing FWZIC literature based on themes and domains, this study reveals a taxonomy of the latest techniques and methods integrated with FWZIC. It also explores fuzzy extensions and integrated MCDM methods, providing researchers with a summary of suitable techniques for various contexts. By systematically synthesizing findings, this study provides a comprehensive overview of the current state of FWZIC applications in the literature, identifies gaps and suggests potential avenues for future research in the MCDM domain.**

***Keywords*—FWZIC; MCDM; fuzzy sets; subjective judgment; group decision making**

I. Introduction

Decision-making plays a crucial role in shaping the dynamics of society, influencing various aspects of human life, governance, and development. It is a cornerstone of societal progress, influencing economic development, social welfare, environmental sustainability and technological advancement [1]. In today's dynamic and complex world, decision-makers are confronted with numerous challenges, often involving multiple conflicting criteria for choosing an optimal alternative. Often, these criteria are not of equal importance, and moreover, the performance of the alternatives also varies, thereby complicating the decision-making process. Multi-Criteria Decision-Making (MCDM) methods offer a structured way to navigate these challenges by considering multiple objectives, diverse criteria, and varying preferences of everyone involved [2]. This systematic approach helps to ensure that decisions are made with a comprehensive understanding of all factors at play.

MCDM techniques enable decision-makers to systematically evaluate alternatives based on various criteria, facilitating informed decision-making across diverse domains. From business and engineering [3] to healthcare [4] and aviation [5], MCDM finds applications in a wide range of fields, helping organizations and decision-makers navigate through intricate decision landscapes. Numerous MCDM methods provide decision-makers with quantitative tools to prioritize objectives, assess trade-offs, and identify optimal solutions in real-life scenarios [6]. The decision-making process typically involves identification of the problem, criteria and alternatives, development of a decision matrix and application of an analytical model to rank the alternatives [6].

Criteria weighting is crucial in decision-making, ensuring the accurate representation of the relative importance of evaluation criteria, which significantly impacts ranking outcomes. Weighting methods can be objective, subjective, or a combination of both. Objective methods are based on mathematical models that rely solely on data, thereby excluding human expertise. These methods are ideal when abundant, precise data is available [7]. Conversely, subjective methods rely on human judgment to assign criteria weights and are often employed when expert evaluation is essential for assessing the criteria's significance in the decision-making process [8]. Subjective weighting proves more impactful as it compels decision makers to carefully assess every aspect of the decision problem, rather than relying on the availability of data. [9]. To reduce bias in subjective decisions, a structured approach involving multiple experts is required [10], [11].

Methods such as the Analytic Hierarchy Process (AHP) [12], Analytic Network Process (ANP) [13], Best Worst Method (BWM) [14] and Fuzzy Weighted Zero Inconsistency (FWZIC) [15] are popular subjective criteria weighting methods. Among these, FWZIC is the latest advanced method that overcomes the limitations of other well-known methods. AHP, BWM and ANP methods are time-consuming as they require pairwise comparisons between criteria, which can lead to inconsistencies [16]. As the number of criteria increases, it becomes increasingly difficult for experts to accurately understand how these weights relate to one another. Moreover, these methods are often extended to fuzzy environments [17] to handle uncertainty and imprecision that arises in subjective decisions, making the criteria weighting process even more complex [18]. FWZIC has been applied in multiple domains to assess criteria weights, including healthcare, supply chain, transportation and more [19]. Thus, the FWZIC method demonstrates its versatility and ability to handle various attributes while preserving the consistency of the decision-makers' judgements.

The FWZIC method utilizes a fuzzy environment to compute criteria weights and can easily achieve consensus among multiple experts and a large number of criteria without any inconsistencies in the criteria weighting process [19]. Each expert's opinion is captured with ease and integrated into the decision-making process to determine the final criteria weights.

This enables decision makers to leverage the diverse perspectives, knowledge, and skills of experts, aiming to achieve a more balanced and well-informed outcome. The goal is to enhance decision quality, gain consensus, and ensure that the criteria's weights are representative of multiple stakeholders' opinions.

Despite its advantages over other subjective criteria weighting approaches, the original FWZIC method falls short in addressing uncertainty and vagueness [20]. This limitation arises from the use of Triangular Fuzzy Numbers (TFN) to represent expert opinions. TFNs have been criticized in the literature for inadequately handling uncertainties due to constraints in dealing with membership values [21]. To overcome this limitation, recent studies have extended the FWZIC method using various fuzzy environments. Advanced fuzzy sets such as the Intuitionistic Fuzzy Sets, Pythagorean Fuzzy Sets, and Fermatean Fuzzy Sets have been utilized to broaden the uncertainty space captured by the fuzzy environment.

The decision problems involving FWZIC all deal with the evaluation and benchmarking of the alternatives in various domains ranging from physical entities to algorithms, processes and strategies. The results are used to select an optimal solution by integrating FWZIC with MCDM ranking methods. The FWZIC models built for the assessment problem in one field are applicable to other fields. Therefore, a systematic review is necessary to offer researchers and decision-makers comprehensive guidance on advancements, applications, and future directions in the utilization of the enhanced FWZIC method, which has gained tremendous popularity in the literature. By synthesizing current knowledge and identifying gaps, this study aims to enrich the ongoing discourse in MCDM research, providing decision-makers with valuable insights and directing future inquiries in this evolving field.

To date, only one systematic review on the FWZIC method exists [19]. However, this systematic review diverges from the previous study in several key aspects. The previous review focuses solely on studies that have integrated the FWZIC method with the FDOSM ranking method, limiting the scope to just twenty-three studies. In contrast, this review encompasses fifty-two studies that have utilized the FWZIC method regardless of the ranking method or MCDM approach used, thus offering a broader perspective. Additionally, unlike the previous study, this systematic review analyzes and presents a more comprehensive review of the FWZIC method, detailing the different ranking methods, fuzzy environments, aggregation methods, defuzzifying techniques used, and the criteria and expert characteristics involved, thereby providing an in-depth analysis of the FWZIC method. The novelty of this research lies in its comprehensive approach, which covers the breadth and depth of the empirical studies utilizing the FWZIC method with recommendations for advancements in the field. This study aims to offer a holistic understanding of the progress in the application and utilization of the FWZIC method.

Considering the aforementioned factors, this study seeks to fill the research gap by employing a systematic approach to review and synthesize an analysis based on empirical case studies that have utilized the FWZIC method. The study aims to categorize FWZIC literature based on themes and domains to reveal a taxonomy of the latest techniques and methods utilized with FWZIC. Additionally, it aims to outline future directions and research opportunities in the MCDM field, focusing on subjective criteria weighing with FWZIC. By examining the limitations and challenges identified in the literature, this review highlights areas requiring further research and innovation. To that effect, this study aims to answer the following research questions:

RQ1: What are the general characteristics of empirical studies that have utilized FWZIC?

RQ2: What domains and themes are the studies based on?

RQ3: Which ranking methods has FWZIC been integrated with?

RQ4: Which fuzzy environments are utilized to enhance FWZIC?

RQ5: What techniques are used for aggregation and defuzzification in the FWZIC algorithm?

RQ6: What are the characteristics of the experts involved in the studies?

RQ7: What are the characteristics of the criteria utilized in the studies?

The rest of the study is organized as follows. Section II provides a background of the FWZIC technique and an overview of MCDM and fuzzy sets pertinent to this study. Section III presents the methodology of the systematic review, while Section IV presents the results of the review, linking them to research questions. Finally, Section V delves into the research implications while Section VI concludes the study, presenting the research limitations and future work.

II. Background Information

A. FWZIC Method

The FWZIC method, proposed by [15], is a subjective criteria weighting method used for evaluating criteria weights in the MCDM process. It effectively assigns criteria weights based on multiple human expert judgments, ensuring consistency and minimizing ambiguity. By leveraging a fuzzy environment, FWZIC handles uncertainty and vagueness, making it ideal for complex scenarios with imprecise information or numerous criteria. Often combined with ranking methods like Technique for Order of Preference by Similarity (TOPSIS), Fuzzy Decision by Opinion Score Method (FDOSM), FWZIC enhances decision accuracy and robustness across various fields, including tourism, healthcare, and education [19].

The FWZIC method relies on five essential phases to achieve zero inconsistency in criteria weighting by involving multiple experts in assessing criteria significance. The FWZIC method is applied using the phases below [15]:

1) Design the evaluation form. An appraisal form is designed to assess the significance of the evaluation criteria of the MCDM case study. The appraisal form is based on a Likert scale, usually a 5-point or 10-point scale. The Likert scale is ideal for this purpose as it allows the experts to assess the

criteria based on linguistic values (such as "Highly Important", "Important", "Moderately Important") and converts the expert assessment to its corresponding numerical values (5, 4, 3) which can be evaluated further using the FWZIC technique.

2) Collect expert judgement. In this step, experts in the field of study are identified. A minimum of three experts is often recommended to ensure diverse perspectives of experts are captured adequately. Section IV presents the experts' characteristics involved in extant FWZIC studies. The appraisal form is administered to the relevant experts to collect their judgment in a structured approach.

3) Develop Expert Decision Matrix (EDM): In this step, an expert decision matrix is constructed based on the data collected via the appraisal form. An EDM is constructed by intersecting each criterion with the expert importance (numerical score) assigned to that criterion, as shown in the equation below:

$$EDM = [e_{ij}]_{m\times n} = \begin{bmatrix} e_{11} & e_{12} & \cdots & e_{1n} \\ e_{21} & e_{22} & \cdots & e_{2n} \\ \cdots & \cdots & \ddots & \cdots \\ e_{m1} & e_{m2} & \ldots & e_{mn} \end{bmatrix} \quad (1)$$

where, m represents the number of experts, and n represents the number of criteria. Moreover, $e_{ij} = Imp(e_i/c_j)$, which represents the importance of criterion *j* assigned by expert *i*. Thus, e_{13} is the significance level of criterion 3 assigned by expert 1.

4) Develop fuzzy EDM by applying fuzzy membership functions. In this step, the EDM performance values, representing the criteria significance by the expert, are fuzzified, using the integrated fuzzy membership functions, to develop a fuzzy EDM. The original FWZIC method is based on the Triangular Fuzzy Number (TFN). However, recent studies have extended FWZIC with various fuzzy environments.

$$\widetilde{EDM} = [\widetilde{e_{ij}}]_{m\times n} = \begin{bmatrix} \widetilde{e_{11}} & \widetilde{e_{12}} & \cdots & \widetilde{e_{1n}} \\ \widetilde{e_{21}} & \widetilde{e_{22}} & \cdots & \widetilde{e_{2n}} \\ \cdots & \cdots & \ddots & \cdots \\ \widetilde{e_{m1}} & \widetilde{e_{m2}} & \ldots & \widetilde{e_{mn}} \end{bmatrix}, \quad (2)$$

where, $\widetilde{e_{ij}}$ represents the corresponding fuzzy membership value for e_{ij}.

5) Compute final criteria weights. Finally, the criteria weights are computed based on the respective operators of the fuzzy environment integrated with FWZIC. The computation involves five main steps:

a) Aggregation of the criteria weights using an aggregation operator, b) Determining the ratio for each criterion for each expert by dividing the fuzzy criterion value by the aggregated value, c) The fuzzy value is defuzzified using the respective fuzzy environment defuzzification techniques, and d) The criteria weight coefficients are computed by converting the defuzzified values to their corresponding weight coefficients to ensure that the sum of the weights is equal to 1. Section IV discusses prevalent aggregation and defuzzifying techniques utilized in extant literature for computing the criteria weights.

Fig. 1 illustrates the five phases of the FWZIC method.

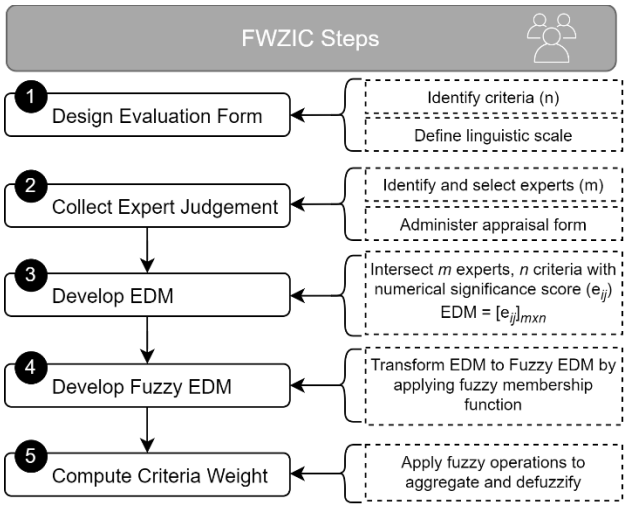

Fig. 1. FWZIC phases.

The original FWZIC method relied on TFN to handle ambiguity and imprecision in human judgment. However, since then, several researchers have extended FWZIC using advanced fuzzy environments that capture a wider spectrum of ambiguities. The following section explores the fuzzy set theory and the various fuzzy environments with their generalizations and extensions.

B. Comparison of FWZIC with other Criteria Weighting Methods

The FWZIC method offers a structured and robust approach to subjective criteria weighting by combining expert judgment with fuzzy logic while eliminating inconsistency in pairwise comparisons [22]. Unlike traditional methods such as AHP, ANP, and BWM, FWZIC does not rely on complex pairwise comparison matrices that can become cumbersome and inconsistent when the number of criteria or experts increases. This is particularly advantageous in large-scale evaluations, where managing comparison consistency is a challenge. FWZIC instead allows experts to assess criteria using a linguistic scale mapped to fuzzy numbers, which are then aggregated using fuzzy mathematical operations to derive weights without introducing inconsistency errors. Table I provides a comparison of FWZIC with other subjective criteria weighting methods.

AHP and ANP, while well-established and widely used, often suffer from issues related to consistency and scalability [23]. In AHP, experts are required to perform numerous pairwise comparisons, and inconsistency indices are used to evaluate the reliability of these judgments. However, achieving acceptable consistency becomes increasingly difficult as the number of criteria grows. ANP attempts to address interdependencies among criteria, but this added complexity also makes the process more time-consuming and prone to subjective bias. Moreover, both AHP and ANP require re-adjustments when new criteria are introduced, reducing their flexibility in dynamic decision environments.

BWM simplifies the pairwise comparison process by requiring experts to identify the best and worst criteria and rate all others relative to these two [24]. While this reduces the

number of required comparisons and improves consistency compared to AHP and ANP, it still assumes a linear and rigid judgment structure that might not capture the uncertainty inherent in human evaluations. FWZIC, by contrast, accommodates uncertainty more naturally through fuzzy logic and avoids the need for direct comparisons altogether. It also provides flexibility in handling a varying number of experts and criteria without increasing the computational burden or introducing inconsistency.

In summary, FWZIC stands out for its ability to integrate expert judgment in a fuzzy environment while maintaining zero inconsistency. It is computationally less intensive than ANP and more scalable than AHP. Unlike BWM, it does not constrain expert input to a fixed comparison format, making it more adaptable in diverse decision-making scenarios. These characteristics make FWZIC particularly suitable for applications involving multiple experts, complex criteria structures, and a need for robust, bias-reduced aggregation.

C. Fuzzy Sets

Human judgment is riddled with uncertainties and ambiguities. Ambiguity in decision-making refers to situations where information is unclear, incomplete, or open to multiple interpretations. Fuzzy set theory, proposed by Zadeh [17], aims at handling ambiguity by representing crisp values using membership grades ranging from [0,1]. Fuzzy sets provide a mathematical framework for modeling and reasoning with vague concepts, making them valuable in various fields such as artificial intelligence, engineering, supply chain, and healthcare, where imprecise information is common.

Since its inception, fuzzy set theory has advanced significantly, leading to new fuzzy sets that incorporate membership as well as non-membership, and hesitancy degrees [25]. The concept of Type-2 fuzzy sets further expands the traditional fuzzy set concept with a three-dimensional membership function [26]. It uses a fuzzy membership function, where the membership degree is also a fuzzy set, allowing for a more detailed representation of uncertainty. However, it is more complex due to the fuzzy nature of the membership function, requiring more computational resources and sophisticated algorithms for processing. The different types of fuzzy sets and their variations and generalizations are explained next.

1) Triangular Fuzzy Numbers (TFN). TFNs are a specific type of fuzzy number that is represented by a triangular membership function. This function is defined by three parameters (a, b, c), where a represents the lower limit, b represents the peak or mode, and c represents the upper limit. The membership function $\mu_{\tilde{a}}(x)$ of a TFN $\tilde{a} = (a, b, c)$ is defined as follows [27]:

$$\mu_{\tilde{a}}(x) = \begin{cases} \frac{x-a}{b-a}, & if\ a \le x \le b \\ \frac{c-x}{c-b}, & if\ b < x \le c \\ 0, & if\ x > c\ or\ x < a \end{cases}, \quad (3)$$

where, $\le b \le c$. Moreover, if $a \ge 0$, then the TFN is called a positive triangular fuzzy number. If $c \le 0$, then the TFN is called a negative triangular fuzzy number.

TABLE I. FWZIC COMPARISON WITH OTHER CRITERIA WEIGHTING METHODS

	ANP	**AHP**	**BWM**	**FWZIC method**
Computational Complexity (Number of comparisons, where n is the number of criteria)	$n(n-1)$	$n(n-1)/2$	$2n-3$	Zero pairwise comparisons
Nature of comparison	Comparisons are made between criteria that differ in nature and in quantity.	Comparisons are made between criteria that differ in nature and quantity.	Comparisons are made between criteria that differ in nature and quantity.	Relies on direct linguistic assessments of criteria mapped to fuzzy numbers, thus avoiding pairwise comparisons.
Expert feedback	The process of explaining and comparing in this method is time-consuming.	The process of explaining and comparing in this method is time-consuming.	The process of explaining takes time, and the comparison process is difficult.	Expert feedback is collected through online surveys, thereby reducing the explanation and collection time.
Uncertainty	Fuzzy logic is commonly employed to manage ambiguity and uncertainty in expert judgments; however, it increases computational complexity.	Fuzzy logic is commonly employed to manage ambiguity and uncertainty in expert judgments; however, it increases computational complexity.	Fuzzy logic is commonly employed to manage ambiguity and uncertainty in expert judgments; however, it increases computational complexity.	FWZIC is grounded in fuzzy logic but is specifically designed to maintain computational simplicity.
Inconsistencies	Susceptible to inconsistency due to complex interdependencies and numerous pairwise comparisons, even when fuzzy logic is applied.	Inconsistency arises from the subjective nature of pairwise comparisons, with reliability decreasing as the number of criteria increases.	While more consistent than AHP/ANP, inconsistencies may still occur when judgments about best and worst criteria lack coherence.	Designed to eliminate inconsistency by avoiding pairwise comparisons entirely and using direct fuzzy linguistic ratings.

2) Trapezoidal Fuzzy Numbers (TraFN). A TraFN is characterized by a membership function that forms a trapezoid shape. It is defined by four parameters: a, b, c, d. The membership function $\mu_{\tilde{a}}(x)$ of a TraFN $\tilde{a} = (a, b, c, d)$ is defined as follows [28]:

$$\mu_{\tilde{a}}(x) = \begin{cases} \frac{x-a}{b-a}, & if\ a \le x \le b \\ 1, & if\ b \le x \le c \\ \frac{d-x}{d-c}, & if\ c \le x \le d \\ 0, & if\ x > d\ or\ x < a \end{cases} \quad (4)$$

where, $a \le b \le c \le d$. Notably, when $b = c$, TraFN reduces to a TFN.

3) Hexagonal Fuzzy Numbers (HFN). An HFN $\tilde{a}$ is characterized by a membership function that is based on six parameters and forms a hexagonal shape. The membership function $\mu_{\tilde{a}}(x)$ of an HFN $\tilde{a} = (a, b, c, d, e, f)$ is defined as follows [29]:

$$\mu_{\tilde{a}}(x) = \begin{cases} \frac{1}{2}\left(\frac{x-a}{b-a}\right), & if\ a \le x \le b \\ \frac{1}{2} + \frac{1}{2}\left(\frac{x-b}{c-b}\right), & if\ b \le x \le c \\ 1, & f\ c \le x \le d \\ 1 - \frac{1}{2}\left(\frac{x-d}{e-d}\right), & if\ d \le x \le e \\ \frac{1}{2}\left(\frac{f-x}{f-e}\right), & if\ e \le x \le f \\ 0, & if\ x > f\ or\ x < a \end{cases} \quad (5)$$

where, $a \le b \le c \le d \le e \le f$.

4) Intuitionistic Fuzzy sets (IFS). The IFS proposed by [30] represents an extension of classical fuzzy sets. Unlike the classical TFN, TraFN and HFN that rely solely on a membership grade (μ) to indicate the degree of satisfaction of an element, IFS introduces a non-membership grade (υ) to signify the degree of dissatisfaction. Both μ and υ values range between 0 and 1, with the constraint that their sum remains within this range: $0 \le \mu + \upsilon \le 1$. Therefore, an IFS S over a universe of discourse X is represented as:

$$S(x) = \{x, \langle \mu(x), \upsilon(x) \rangle\}, x \in X, \quad (6)$$

By incorporating both membership and non-membership grades, the IFS framework provides a more flexible depiction of solutions, allowing for greater flexibility in representing uncertainty or imprecision inherent in the given problem. However, in several cases, the sum of the degrees often exceeds 1. Therefore, the generalizations of the IFS were proposed.

5) Pythagorean Fuzzy Sets (PyFS): The PyFS, proposed by [31], is a generalization of the IFS, which extends the range of membership (μ) and non-membership grades (υ) with the condition that the sum of the squares of both degrees falls within the range of [0,1], $0 \le \mu^2 + \upsilon^2 \le 1$. The PyFS offers a more comprehensive and precise characterization of uncertain information compared to the IFS [32].

6) Fermatean Fuzzy Sets (FFS). The FFS [33] further expands the uncertainty space that cannot be adequately captured by the IFS and PyFS in cases, where the sum of the squares of the grades is above 1. Therefore, in FFS, the sum of the cubes of the membership and non-membership grades falls within the range of [0,1], $0 \le \mu^3 + \upsilon^3 \le 1$. FFS offers a better way of handling vagueness than its counterparts, IFS and PyFS.

7) q-rung orthopair (q-ROFS). The q-ROFS [34] emerged as a generalization of both IFS and PyFS with a membership constraint that the sum of the qth power of the membership and non-membership grades is within the range [0,1], $0 \le \mu^q + \upsilon^q \le 1$, where $q > 1$. The increasing value of q offers decision-makers a broader spectrum to express their perspectives on the membership and non-membership degrees. Thus, the q-ROFS demonstrates a greater capability in handling uncertainty more effectively than IFS and PyFS [35]. Fig. 2 illustrates the comparison between IFS, PyFS and q-ROFS.

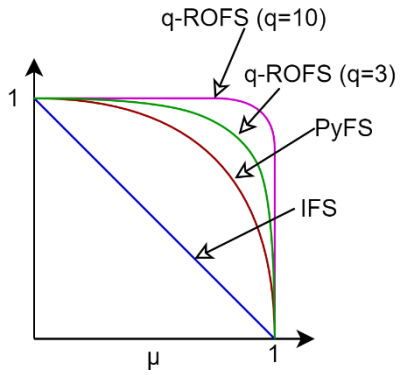

Fig. 2. IFS, PyFS and q-ROFS.

8) Picture Fuzzy Sets (PFS). The PFS, proposed by [36], is an extension of the IFS, which introduces the degree of neutrality (η), also referred to as abstinence, along with the membership (μ) and non-membership (υ) degrees, with the condition that $0 \le \mu + \eta + \upsilon \le 1$. The refusal degree is represented as $1 - (\mu + \eta + \upsilon)$. The PFS effectively mirrors human behavior and addresses decision-making challenges in a similar way by capturing the complexities of real-life information [37].

$$S(x) = \{x, \langle \mu(x), \eta(x), \upsilon(x) \rangle\}, x \in X \quad (7)$$

9) Spherical Fuzzy Sets (SFS). The SFS [38] emerged as a generalization of the PFS, which extends the uncertainty space of the membership (μ), non-membership (υ) and neutral grade (η), offering a wider decision space under the restriction that $0 \le \mu^2 + \eta^2 + \upsilon^2 \le 1$.

10) T-Spherical Fuzzy Sets (T-SFS). The T-SFS proposed by [39], further widens the uncertainty space covered by the SFS with a membership constraint that the sum of the t power of the membership (μ), non-membership (υ) and neutral (η) grades are within the range [0,1], $0 \le \mu^t + \eta^t + \upsilon^t \le 1$, where $t > 1$. The increasing value of t offers decision-makers

a broader spectrum to express their perspectives on the membership and non-membership degrees and abstinence degrees. Notably, when t = 2 the T-SFS reduces to SFS.

11) Linear Diophantine Fuzzy Sets (LDFS). Despite the broader space covered by these FS, the grade dependency still exists as a limitation of the IFS and PFS and all their generalizations. Hence, [40] proposed a new fuzzy environment, the Linear Diophantine Fuzzy set (LDFS), which extends IFS and PyFS by introducing two reference parameters (a,b), each within the range of [0,1] corresponding with the membership (μ), non-membership (υ) grade, respectively. The LDFS essentially allows decision makers to choose membership degrees without restrictions, but with a constraint that the sum of the reference parameters lies between 0 and 1, $0 \leq a + b \leq 1$ and $0 \leq a\mu + b\upsilon \leq 1$.

$$S(x) = \{x, \langle \mu(x), \upsilon(x) \rangle, \langle a, b \rangle\}, x \in X \quad (8)$$

12) Interval Valued Fuzzy Set (IVFS). Grattan-Guinness (1976) [41] developed the concept of IVFS based on type 2 fuzzy set theory [42], further extending the fuzzy research space. A type 2 fuzzy set is characterized by fuzzy membership grades. In an IVFS, the membership degree is given as a closed subinterval $[\mu^L, \mu^U]$ with $0 \leq \mu^L \leq \mu^U \leq 1$, where:

- μ^L is the lower bound of the membership interval.
- μ^U is the upper bound of the membership interval.

The interval $[\mu^L, \mu^U]$ represents the range within which the membership degree of x is expected to lie. The length of this interval $(\mu^L - \mu^U)$ is interpreted as a measure of the uncertainty associated with the membership degree of the element.

13) Neutrosophic Sets (NS). The Single-Valued NS, proposed by [43], is a generalization of the classical fuzzy set in which there is no restriction on the sum of the membership degrees. Hence, the membership degree, abstinence degree, and non-membership degree lie within the range [0,3], $0 \leq \mu + \eta + \upsilon \leq 3$. The NS has a significant capacity to effectively manage imprecise and unclear data in a comprehensive manner.

14) Hesitant Fuzzy Sets (HFS). HFS, also known as multisets, was proposed by [44], extending the traditional fuzzy set theory to better handle situations where there is hesitation or multiple degrees of membership for an element. This concept is useful in capturing uncertainty and ambiguity when a single membership value is insufficient to represent an element's degree of belonging to a set. Fuzzy multisets allows for capturing hesitation in the membership degrees, providing a richer and more flexible representation of uncertainty. A generalization of the HFS, known as the dual HFS, allows for the representation of dual hesitancy, meaning elements can be partially or fully hesitant towards multiple membership degrees [45].

Other generalizations and extensions of the classical fuzzy sets include the probabilistic fuzzy sets, which assign a probability to each element's membership degree [46]. The Complex Fuzzy Sets (CFS), on the other hand, extend the concept of fuzzy sets to complex-valued membership degrees by representation of membership degrees as a complex number [47]. CFS has been applied in signal processing and control systems applications.

Despite the notable efforts of the researchers, the lack of precision, uncertainty, and vagueness in information still remains an unresolved issue [48]. To encompass a broad spectrum of uncertainty in experts' opinions for determining criteria weight, researchers have extended the FWZIC method under various fuzzy environments ranging from simple classical sets to advanced type 2 fuzzy sets. The results section of the review presents the various fuzzy environments integrated with FWZIC.

D. Overview of MCDM Ranking Methods

MCDM ranking techniques enable decision-makers to systematically assess alternatives using various criteria, facilitating informed decision-making across different sectors. Several benchmarking techniques are used in MCDM to perform ranking in various decision-making case study problems, such as FDOSM, VIKOR, SAW, MULTIMOORA, TOPSIS, MAIRCA, MABAC, and DEMATEL. Below are brief introductions to some of the popular ranking methods integrated with FWZIC:

1) Fuzzy Decision by Opinion Score Method (FDOSM). The Fuzzy Decision by Opinion Score Method (FDOSM) is an innovative MCDM technique designed for use in a fuzzy environment, utilizing the concepts of ideal solutions and opinion matrices. This method addresses and largely overcomes the inconsistencies often found in human judgment, reducing the time required for comparisons [49]. Additionally, FDOSM minimizes the number of mathematical equations needed, preserving data integrity and facilitating logical decision-making based on expert opinions represented in the Decision Matrix. It eliminates issues related to normalization and weighting in mathematical approaches and resolves data vagueness using fuzzy numbers. FDOSM employs positive and negative ideal solutions, comparing each alternative's criteria with the ideal solution. Furthermore, FDOSM uses different aggregation operators with an Opinion Matrix adopted from various MCDM techniques [50].

2) VlseKriterijumska optimizacija I kompromisno resenje (VIKOR). VIKOR, a Serbian term for "multi-criteria optimization and compromise solution" [51] is a method based on the concepts of positive and negative ideal points, and on the compromise programming of MCDM [52]. VIKOR focuses on ranking and selecting from a broad range of alternatives that are evaluated based on criteria. VIKOR determines compromise solutions for problems with conflicting and non-comparable criteria and provides a feasible solution that is the closest to the positive ideal solution. A key feature of VIKOR is that, the final decision relies on rules regarding an acceptable advantage of the optimal solution over the second-best solution and the stability of the optimal solution to changes in the decision-maker's risk choice. It reflects any hesitation the decision-

maker has in selecting the final option, allowing for a nuanced comparison of alternatives [53].

3) Simple Additive Weighting (SAW). The SAW method is well-known for its simplicity, user-friendly, and effective approach of MCDM. Also referred to as a weighted linear combination or scoring method. SAW determines the overall score of a candidate solution based on the weighted sum of all of the attribute values [54]. The SAW method involves three major steps: normalizing the decision matrix X, assigning the weight vector W, and calculating the overall score. One major advantage of the SAW method is its ability to maintain the relative magnitude order of the original data, and no data is lost during evaluation [54].

4) Multi-Objective Optimization by Ratio Analysis (MULTIMOORA). The MULTIMOORA method is the extension version of the MOORA method, incorporating multiplicative elements. MOORA, a multi-objective optimization technique, is based on ratio analysis. In this approach, the score of an alternative is calculated by subtracting the sum of performance scores for the benefit criteria and adding the sum of performance scores for the cost criteria [4].

5) Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS). TOPSIS is a renowned classical MCDM method that introduces two reference points: a positive ideal solution and a negative ideal solution. TOPSIS was originally developed by Hwang and Yoon in 1981, and was further developed by Chen and Hwang in 1992 [54]. The positive ideal solution maximizes benefit criteria and minimizes cost criteria, while the negative ideal solution does the opposite, maximizing cost criteria and minimizing benefit criteria. TOPSIS identifies the best alternative by minimizing its distance to the positive ideal solution and maximizing its distance to the negative ideal solution. It employs Euclidean distances to measure how close each alternative is to these ideal solutions, and the preference order of alternatives is determined by comparing these distances [53].

6) Multi-Attributive Ideal-Real Comparative Analysis (MAIRCA). MAIRCA is recognized for its stability compared to other popular MCDM ranking methods. It employs a straightforward mathematical approach that maintains stability despite changes in the nature and characteristics of the criteria. One key advantage of MAIRCA is its ability to objectively compute the probability of each alternative, providing both quantitative and qualitative assessments. This method measures the difference (gap) between ideal and empirical evaluations, providing an objective assessment of each alternative [55].

7) Multi-Attributive Border approximation Area Comparison (MABAC). MABAC method ranks the alternatives using their distance to the border approximation, while partitioning them into upper approximation area (best performing) and lower approximation area (worst performing) [4].

8) The decision-making trial and evaluation laboratory (DEMATEL). DEMATEL methodology is a robust tool for analyzing complex interrelationships between various factors. Pairwise comparisons are used to determine the significance and influence of different elements. By constructing cause-effect diagrams, DEMATEL assesses the interdependencies among factors, proving effective in diverse domains such as site selection, criteria identification, and effects evaluation. However, due to the inherent uncertainty and subjectivity of experts' judgments, an important challenge remains in effectively representing uncertain and linguistic judgments [56].

Numerous other ranking methods are also used in MCDM problems, such as the Additive Ratio Assessment (ARAS), Conditional Probabilities by Opinion Scores (CPOS), Combinative Distance-Based Assessment (CODAS), Complex Proportional Assessment (COPRAS), Evaluation Based on Distance from Average Solution (EDAS), and Measurement of Alternatives and Ranking according to the Compromise Solution (MARCOS), Technique for Reorganizing Opinion Order to Interval Levels (TROOIL). FWZIC has been combined with these ranking methods to benchmark various alternatives in different case studies, employing various approaches to achieve a robust framework. A review of these FWZIC studies will provide us with a clear understanding and knowledge of their various characteristics and their combined ranking methods. The next section describes the methodology used to achieve this systematic review.

III. Methodology

This study examines the existing literature on the applications of the FWZIC method using the systematic review framework established by [57]. This framework was selected over other frameworks because it provides guidelines specifically for conducting reviews in the technical field. Employing a rigorous theoretical framework is crucial for guiding the comprehensive data collection and analysis methods required to ensure the reliability of the results. The systematic literature review guidelined by [57] offers a thorough approach for collecting, analyzing, and documenting findings from secondary data sources and from various systematic reviews [58], [59], [60]. By following this methodology, we aim to answer the research questions and uncover the latest application techniques and extensions of the FWZIC method, guiding practitioners and researchers to further study in this field.

The review process is divided into three phases: planning the review, conducting the review, and reporting the results. Each phase is further subdivided into several steps, each of which is described in the following subsections.

A. Planning the Review

In the last three years, the studies applying the FWZIC method to compute criteria weights have accelerated due to its superiority over other subjective criteria weighting methods. Therefore, it is crucial to provide researchers with the current state-of-the-art regarding the applications of the FWZIC method, including the fuzzy environments used, the number of experts involved, the number of criteria and the MCDM ranking methods it has been integrated with.

To initiate the systematic review, the planning phase defines the inclusion and exclusion criteria, and identifies the data sources for selecting the study articles. The quality assessment checklist is then described to evaluate the quality of the articles, establishing a threshold for their inclusion. The study encompasses all articles published since the FWZIC method was proposed, ensuring a comprehensive scope.

1) Inclusion and exclusion criteria. To select the articles for this review, it is essential to define the criteria that characterize the included studies. Table II summarizes the inclusion and exclusion criteria used in the selection process.

TABLE II. INCLUSION AND EXCLUSION CRITERIA

Inclusion Criteria	Exclusion Criteria
Empirical studies that have employed the FWZIC method for determining criteria weights	Studies that do not utilize the FWZIC method
Article is published in a peer-reviewed journal, conference papers or book chapters	Reviews, errata, PhD studies
Written in English	Non-English articles
Published in 2021 – March 2025	Published after March 2025

First, only empirical studies employing the FWZIC method for determining criteria weights were considered. Second, the review focused exclusively on peer-reviewed journals, conference papers and book chapters to ensure inclusion of all studies that have utilized the FWZIC method, thereby excluding reviews, errata, and PhD dissertations. Third, only articles published in English were included to avoid biases from poor translations. Finally, the study period was set from 2021 to 2025 to encompass all relevant studies using the FWZIC method to date.

2) Data sources. Since MCDM methods are utilized in diverse domains, a wide range of data sources was considered to ensure the inclusion of relevant publications from various fields. Accordingly, the search was conducted using three digital databases: Scopus, Web of Science (WoS), and ScienceDirect. Both Scopus and Web of Science are multidisciplinary databases of peer-reviewed literature on science, technology, medicine, social science, arts and humanities, making them valuable for retrieving a broad spectrum of research. ScienceDirect is a comprehensive resource for articles in the scientific, technical and medical fields.

3) Quality assessment checklist. Quality assessment is essential in systematic reviews to ensure the validity of the results and minimize bias from including less robust studies [61]. It also refines the inclusion and exclusion criteria [57].

To ensure a rigorous assessment of the articles included in the systematic review, a quality assessment checklist is adapted from [62]. The checklist consists of ten questions, as shown in Table III. This checklist focuses on the essential elements for data extraction and coding phases, such as the relevance of the study, clear identification of the problem statement, experts and the expert selection process. Additionally, the credibility of the sources were evaluated by considering the ranking of the journal or conference and the number of citations of each study received. A point scale from 0 to 1 will be used to rate each assessment criterion, where 1 represents that the requirement is wholly met, 0.5 represents it is partially met, and 0 indicates that it is not met. Moreover, Q09 will be evaluated by the source ranking of the published study, whereby Q01 or Q02 ranked journal is assigned 1 point, while Q03 is assigned 0.5 and 0 point is assigned to a journal ranked below or not ranked. Finally, 1 point will be assigned to the article having at least two citations per year for Q10. Thus, each article scored out of 10 points in total. The cut-off criteria for including an article after the quality assessment are set at 75%.

TABLE III. QUALITY ASSESSMENT CHECKLIST

Q01	Is the study relevant to our research?
Q02	Are the research aims and contributions clearly identified?
Q03	Is the problem statement clear?
Q04	Does the study define the number of experts used?
Q05	Is the selection process of the experts clearly explained?
Q06	Are the techniques/methods employed in the study clearly documented?
Q07	Is the proposed technique evaluated using established metrics?
Q08	Is the conclusion explained clearly and linked to the purpose of the study?
Q09	Is the source of the article credible (published in a ranked venue)?
Q10	Has the study been cited in other publications?

B. Conducting the Review

The implementation phase of the review involves searching for and retrieving the articles. The articles for this review were collected in March 2025. The articles were screened using the previously defined inclusion and exclusion criteria, as well as the quality assessment checklist.

1) Search process. The systematic review focuses on a specific MCDM criteria weighting method. Hence, only two main keywords were deemed necessary to retrieve the articles for this study, combined with the logical operator OR ("FWZIC" OR "Fuzzy Weighted Zero Inconsistency"). Additionally, the search was conducted on titles, abstracts, and keywords to ensure comprehensive coverage and to increase the likelihood of finding highly relevant studies.

The search results, presented in Table IV, yielded a total of 192 studies, with the highest number retrieved from the Scopus database, due to its broad coverage across multiple domains and the lowest from ScienceDirect, due to its specific coverage.

TABLE IV. SEARCH RESULTS

Database	Search Results
Scopus	81
Web of Science (WoS)	62
ScienceDirect	49
Total	**192**

Following the retrieval of search results, a bibliometric analysis was conducted to examine the research areas. Fig. 3

illustrates the visualization of terms within the results, generated using VOS Viewer [63]. This diagram highlights the significance and interconnections among frequently occurring terms extracted from the abstracts, titles, and keywords of the search results. The size and label of each term indicate its importance, while the color represents clusters in the visualization. Each cluster comprises terms related to one another within the group, and the distance between clusters signifies their relatedness.

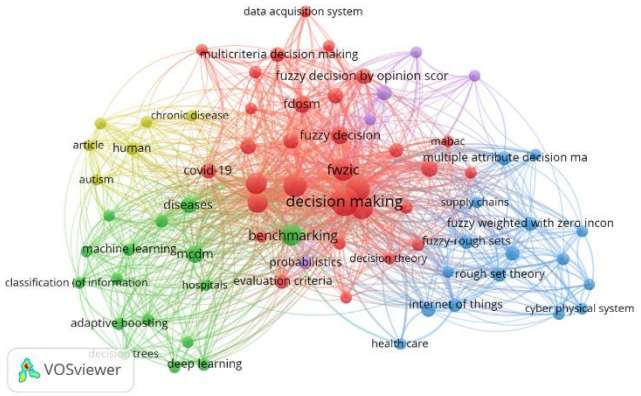

Fig. 3. Visualization of search results.

The visualization of terms within the extracted studies uncovers several distinct clusters, indicating multiple dimensions in the application of FWZIC in MCDM studies. These clusters are closely intertwined, suggesting interconnected aspects within the studies. The term "decision making" is prominently linked to all clusters, indicating that the retrieved results are applied studies in the decision-making field.

Focusing on clusters with highly weighted terms, four main clusters emerge in the visualization. The first and central red cluster encompasses keywords such as FWZIC, FDOSM, fuzzy decision, and linguistics, revealing the technical aspects of research utilizing FWZIC, including its integration with ranking algorithms, application of linguistic scales, and use of fuzzy decision sets. The second, green cluster features keywords like adaptive boosting, decision trees, deep learning, and machine learning, indicating the application of FWZIC in the domain of Artificial Intelligence. In the third, blue cluster, the significant keywords include cyber-physical systems, healthcare, internet of things, and supply chain, highlighting various areas of study in which the FWZIC method is utilized. Lastly, the light green cluster includes terms such as human, autism, and chronic diseases, indicating the predominant utilization of FWZIC for solutions in the healthcare industry.

Examining these clusters provides insight into the distribution of research findings, facilitating a more informed analysis and discussion of the studies.

2) Article selection. In this phase, the inclusion and exclusion criteria were applied to screen the retrieved articles for eligibility following the PRISMA framework [64]. This framework offers a comprehensive guideline and structured approach for document screening. The steps of the screening process are illustrated in Fig. 4.

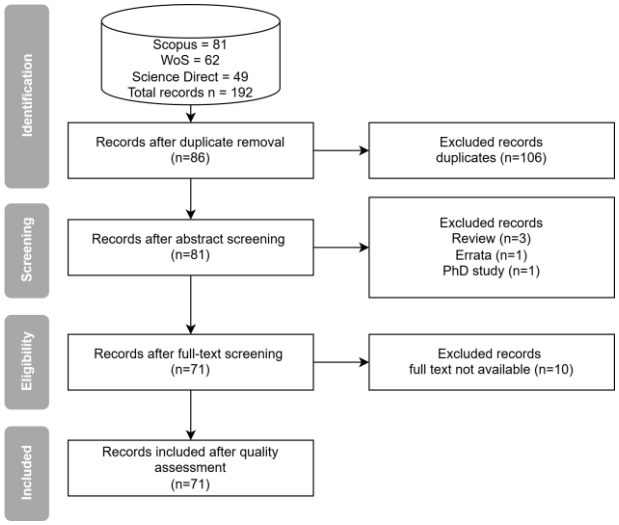

Fig. 4. Prisma flowchart.

The PRISMA framework consists of four phases. In the identification phase, 192 articles were retrieved from the three data sources using the identified search term. Following this, the duplicate records were removed, resulting in 86 articles. During the screening phase, the inclusion and exclusion criteria were applied through abstract screening to ensure that only relevant articles were included. Each author independently performed a title and abstract screening of the studies to remove irrelevant articles, resulting in the exclusion of four articles, two of which were reviews, one erratum, and one PhD dissertation, resulting in 81 studies. In the eligibility phase, a full-text screening of the articles was performed. Each author performed this step independently by equally dividing the studies to be reviewed. In cases where eligibility was unclear, the authors discussed resolving the discrepancy. This phase resulted in 10 studies being excluded due to the unavailability of the full text, resulting in a total of 71 eligible articles. The excluded studies were within the context of the systematic review; however, unavailability would prevent the coding and analysis required for the comprehensive review.

In the final phase, a quality assessment was performed on the remaining articles (n = 71). In this step, the authors rescreened the articles initially screened by the other to reduce bias and ensure that each article is screened twice. Each author independently conducted a quality assessment using the assessment checklist outlined in Fig. 4. Remarkably, all included articles met the required threshold of 75% and demonstrated sound quality. It is important to emphasize that the quality assessment aims to ascertain the relevance of selected articles to the contribution of this study, without any intention to criticize the studies or their findings.

3) Data analysis and coding. The objective of this phase is to comprehensively document the systematic review findings by gathering meta-data from the primary studies included in the review, with a focus on the research questions. A thorough data analysis of the relevant features identified during the planning phase is conducted to achieve this objective. The meta-data analysis encompasses various characteristics crucial for addressing the research questions, including publication type

and year, and the classification of studies based on themes and application areas to gain a deeper insight into the domains of application. Additionally, technical aspects of subjective decision making, such as the number of experts, the criteria weighted, the fuzzy environment, the aggregation operators, and defuzzifying methods employed in the studies, are also examined.

C. Reporting the Review

In the concluding phase of the systematic review, the study results are unveiled. Section IV presents a comprehensive analysis of the meta-data extracted from the full-text review, with the aim of addressing each research question. This analysis presents and discusses the insights from the collected data, providing a thorough understanding of the findings and their implications within the context of the study's objectives.

IV. Results

This section reveals the outcomes from the meta-analysis and comprehensive review of the selected articles, guided by our research questions. This study examines seventy-one papers (listed in the Appendix) published over a span of five years to explore the applications of the FWZIC method. The following subsections detail the findings for each of the research questions.

A. Study Characteristics

RQ1: What are the general characteristics of empirical studies that have utilized FWZIC?

This subsection provides an overview of general characteristics found in the reviewed studies. It includes details on the distribution of studies by year of publication, author, journals and publishers. These attributes offer a summary of the significance of the FWZIC method within the MCDM research field.

Fig. 5 presents the distribution of the seventy-one studies reviewed by year of publication. It is evident from the graph that there is significant interest in the FWZIC method since its proposal in 2021. Notably, the graph reveals a sharp rise in the utilization of the FWZIC method since 2022. FWZIC has been extended to many fuzzy environments to improve consistency and decrease the hesitancy of human judgment. In addition, this method has been integrated with numerous MCDM ranking methods to evaluate and select alternatives used in these studies.

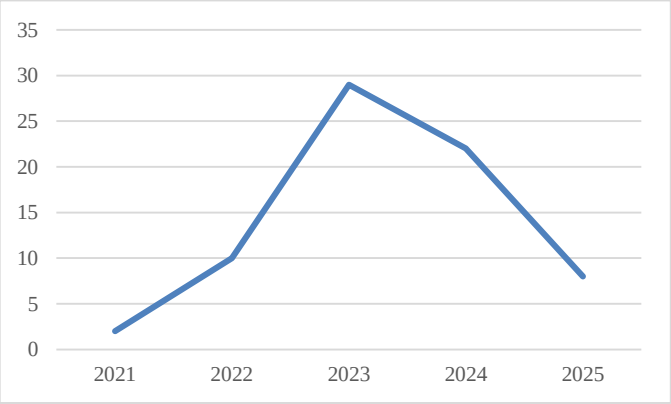

Fig. 5. Distribution of studies by publication year.

Fig. 6 displays the distribution of the seventy-one reviewed studies across forty-two different sources, including journals, conferences, and book chapters, underscoring the extensive influence and significance of the FWZIC method within the MCDM research field. Notably, most of the studies are published in ranked journals, while only one study is published in a conference and one in a book chapter. The included studies span over a diverse range of journals, including those focused on technology, decision science, healthcare, innovation, knowledge, and engineering. The journal "Expert Systems with Applications" features the highest number of studies (n = 10), followed by "Applied Soft Computing" (n = 6) and "Neural Computing and Applications" (n = 5). Most of these journals are ranked in the Q1 category, reflecting the high quality of the published research.

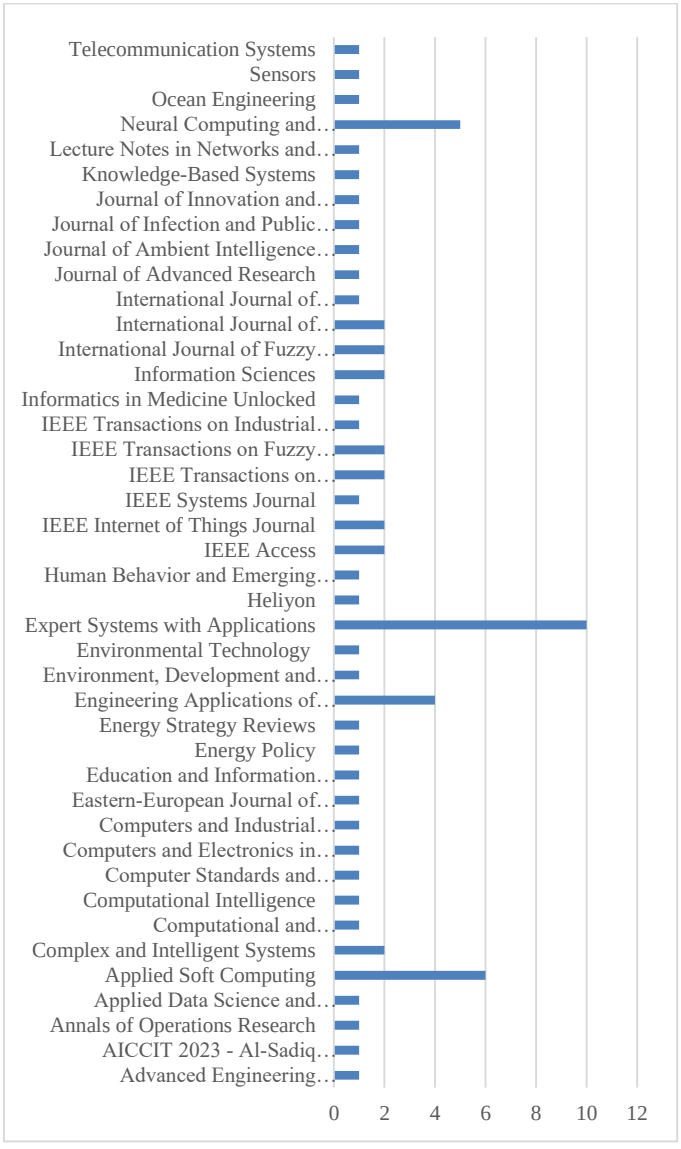

Fig. 6. Distribution of studies by source.

Fig. 7 shows the distribution of seventy-one reviewed studies among nine major publishers, indicating that Elsevier is the leading publisher with 48% of these studies (n = 34), followed by Springer (n = 15) with 21%, and IEEE (n = 11) with

16%, all of which are significant contributors to the research field. John Wiley and Sons Ltd. published 6% of studies (n = 4), while World Scientific published 3% of studies (n = 2) and only 2% in MDPI, and all other studies were 1% in Technology Center, Taylor and Francis, ScienceDirect, and Mesopotamian Press.

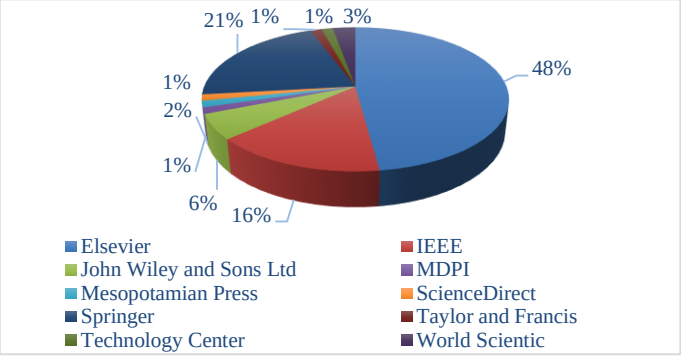

Fig. 7. Distribution of studies by publisher.

According to Fig. 8, the distribution of these studies by the first author's country spans over seven countries: Australia, China, Iraq, Malaysia, Tunisia, and the United Arab Emirates (UAE). Notably, the highest number of studies originates from Iraq (n = 31), followed by Malaysia (n = 21), highlighting the particularly active research communities in these countries.

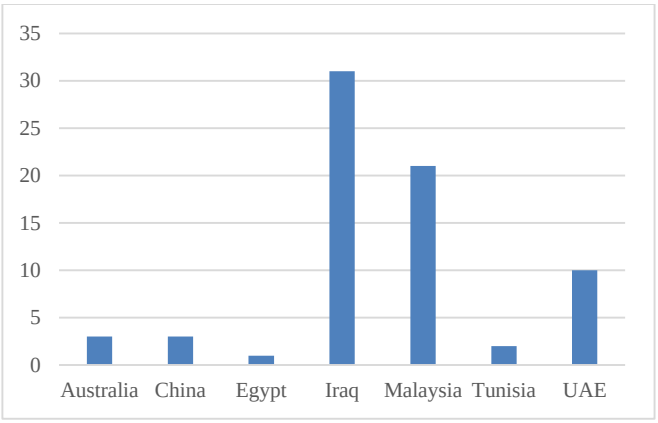

Fig. 8. Distribution of studies by country.

B. FWZIC Application

1) This subsection addresses RQ2 through five themes. A comprehensive meta-analysis of the reviewed studies revealed distinct thematic and domain-based applications of the FWZIC method. In addition, it identified the ranking methods commonly integrated with FWZIC and highlighted the various fuzzy extensions employed. The analysis also examined the most frequently used aggregation and defuzzification techniques. The following subsections present and discuss these findings. Details of the reviewed studies are provided in the Appendix.

2) Themes and domains of application

RQ2: What domains and themes are the studies based on?

A taxonomy of the reviewed studies, illustrated in Fig. 9, categorizes the articles into six main themes: Artificial Intelligence, COVID-19, Services, Sustainability, Technology, and Metaverse. These themes are further distributed across ten domains, including healthcare, agriculture, tourism, education, engineering, business, supply chain, manufacturing, and transport. A separate category is included for studies that do not align with any of the identified domains. Fig. 9 also highlights the popular MCDM methods that have been integrated with FWZIC in multiple studies, while a broader set of less frequently used methods is categorized under "Other". The following subsections provide a detailed review of the studies within each theme.

a) Artificial intelligence: Artificial intelligence (AI) is the ability of a computer system to carry out tasks that are usually performed by humans [65], [66]. It is one of the main themes adopted in these studies, with a total of ten studies distributed across two domains: nine in healthcare and one in engineering. Many healthcare studies focus on detecting and prioritizing autism spectrum disorder (ASD) patients based on sociodemographic and medical features. One study integrated machine learning (ML) and MCDM to classify ASD patients [67]. The study utilized an enhanced FWZIC method to determine the importance of the ASD features used in the training dataset [68]. In the same vein, another study used a hybrid approach to develop fifteen machine learning models for diagnosing patients with ASD and then benchmarked the models using FDOSM and FWZIC, based on seven performance metrics as evaluation criteria [67]. Similarly, another study developed a multimodal autism triage levels system using the Delphi method with FWZIC to determine the significance of ASD features and ML models for predicting severity levels [69]. The study further develops an explainable AI model to facilitate comprehension of the AI model's results.

Two studies in the healthcare domain utilise AI and VIKOR as a benchmarking method for respiratory diagnosis. While one study evaluates lung cancer diagnosis using class balancing approaches [70]. The other develops a framework to rank hybrid deep learning models based on chest X-ray analysis for computer-aided diagnosis (CAD) systems [71]. The remaining two healthcare studies focus on different objectives. One utilized a hybrid approach to first develop a labelled dataset of indoor air quality pollutants using the Unified Process for Labelling Pollutants Dataset (UPLPD), extended with the IT2TR-FWZIC weighting method [72]. The study further applied machine learning models to the developed dataset. Another study evaluates AI healthcare applications based on trustworthiness attributes using the CODAS method integrated with q-ROF2TL-FWZIC [73].

The final study in the AI theme belongs to the engineering domain and aims to benchmark optimization techniques for semi-polar III-V semiconductor materials using the FDOSM benchmarking method, integrated with the classical FWZIC method [74].

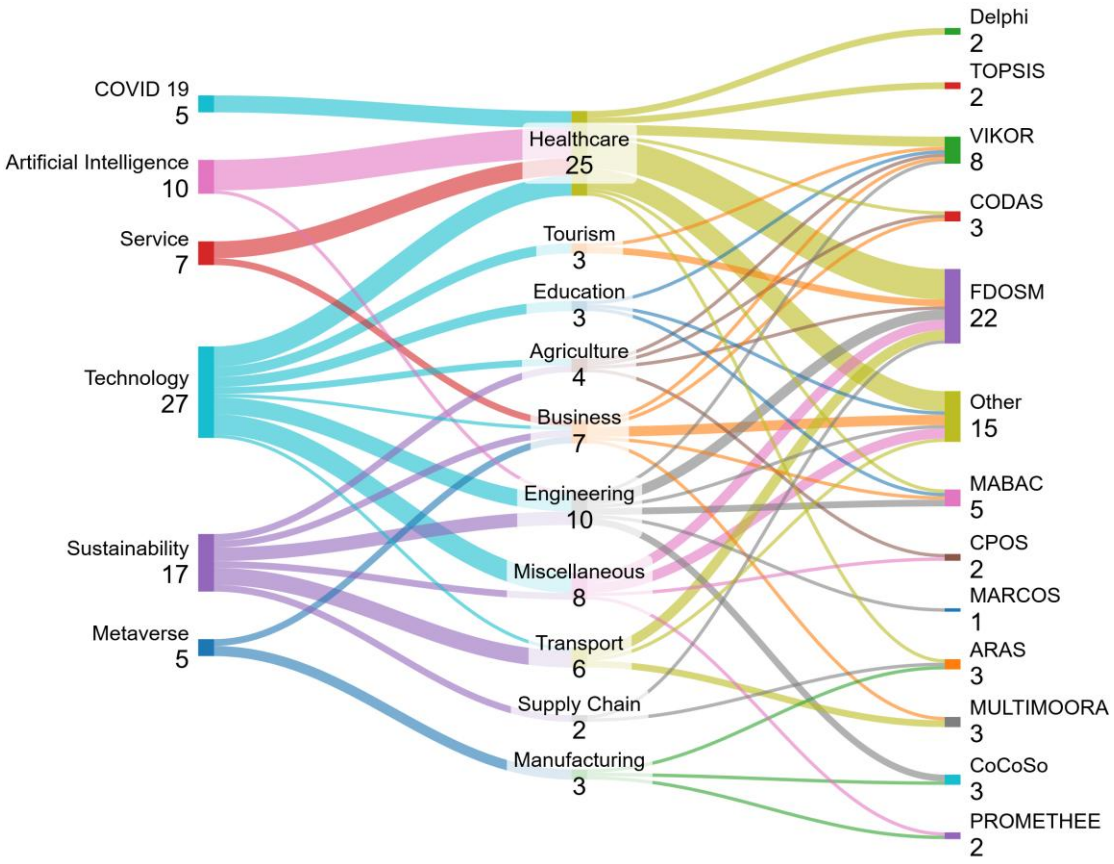

Fig. 9. Taxonomy of FWZIC application themes and domains.

b) COVID-19: Research continues to emphasize the significance of COVID-19, with five of the review studies belonging to this theme. Notably, all the studies in this theme are focused on the healthcare domain. Three studies aim to prioritize COVID-19 vaccine dose recipients using the FDOSM benchmarking method, but with different extensions of FWZIC methods using T-SF, q-ROF and PF as fuzzy sets [75], [76], [77]. Another study aims to develop a framework that benchmarks deep transfer and machine learning models based on chest X-rays to diagnose COVID-19 cases [78]. The study employs the dynamic localization-based decision (DLBD) method for benchmarking with PSVNHFS to extend FWZIC. The final study aims to develop a benchmark for the distribution of Anti-SARS-CoV-2 monoclonal antibody to eligible high-risk patients using the TOPSIS ranking method and using IVSH2 to extend FWZIC [79].

c) Services: Service is highlighted as one of the primary themes in these review studies, with five of them exploring this theme in connection with the healthcare domain. Two studies aim to prioritize autism patients with moderate emergency levels: one develops a framework using the VIKOR method for benchmarking using the classical FWZIC weighting method [80], and the other creates an intelligent triage method for classifying ASD patients into three severity levels using the Delphi method integrated with FWZIC [81]. Two additional studies focus on prioritizing remote patients with high-risk multiple chronic diseases: one uses emotion and sensory criteria with the TROOIL method for benchmarking and extends FWZIC with FOFS [82], and the other employs the FDOSM method for prioritizing hospital selection and uses QROF fuzzy sets for benchmarking and weighting method [83]. The final study aims to weight and prioritize the criteria for managing patients with cardiac problems using the classical FWZIC method [84].

d) Metaverse: Metaverse is an emerging area of research interest [60], with a focus evident in five of the review studies within the business domain (n = 2) and manufacturing domain (n = 3). Among these studies, one study developed a model concerning anonymity and privacy within the Bitcoin network-based metaverse in Industry 5.0, utilizing the MULTIMOORA benchmarking method with the extended LDFS-FWZIC weighting technique [85]. Another study [86] evaluated virtual commerce solutions for the metaverse utilizing the RATMI ranking method integrated with SLDFS-FWZIC.

Additionally, two studies concentrate on developing models to enhance control engineering tools, employing the same extended IVSFRS-FWZIC weighting method, which aims to support the Industrial Cyber-Physical Metaverse using the PROMETHEE II benchmarking method [87], while the others evaluate digital twin technology in manufacturing with the CoCoSo benchmarking method [88]. Lastly, the study aims to develop a model for evaluating Metaverse Tools based on a privacy model, integrated with the ARAS benchmarking method and the HF-FWZIC extended method [89].

e) Sustainability: Sustainability plays a vital role in many of these research studies, largely because of its importance in environmental research. There are thirteen studies focusing on sustainability across various fields like Agriculture, Transport, Engineering, Business, Supply Chain and more. For instance, one study in the agriculture domain evaluated water quality monitoring systems based on remote sensing techniques using VIKOR with FWZIC [90].

Within sustainable transportation, one study applies the MULTIMOORA method to model electronic passenger vehicles and utilizes the P-H-FWZIC weighting method [48]. Another study in this area developed a fuel supply system modelling approach for electric vehicles based on MARCOS and used the PPH-FWZIC weighted method [91]. A third study evaluated and ranked international oil companies for sustainable oil transportation based on MULTIMOORA and the extended LDFRS-FWZIC weighting method [92]. A fourth study has established a performance assessment of ship energy systems for transportation in the shipping industry based on FDOSIM and extended the q-ROFRS-FWZIC weighting method [93]. The last study in this domain built a pavement strategy selection based on FDOSIM, and using the DH-FWZIC extended weighting method [94].

Two of these review studies are associated with the engineering domain. One study developed a model to benchmark an energy systems integration framework for efficient resource utilization based on the MABAC ranking method integrated with TFN-FWZIC [95]. And another study evaluated management strategies in construction and demolition wastes based on FDOSIM-MULTIMOORA and based on the extended q-ROPHFAM FWZIC method [96].

On the other hand, two studies are connected to the business sector: one study evaluated sustainable circular business model innovation tools using the CODAS benchmarking method and the NBFS-FWZIC extended method [97]. Another study in this sector developed a model to assess palm oil industry 4.0 technologies for circular economy applications based on EDAS and using IVPFRS fuzzy sets with FWZIC [98]. Only one study in the sustainability theme is related to the smart living domain. The study developed a model to benchmark smart living frameworks using conditional probabilities by opinion scores and extended FWZIC under Bayesian rules in circular-Pythagorean fuzzy sets [99].

Finally, two studies in this theme are related to the supply chain domain: one study evaluated real-time IoT devices for monitoring food wastage in a supply chain system. The study used ARAS as a benchmarking method and extended the FWZIC using circular intuitionistic fuzzy set [100]. And a second study in this domain built a model for evaluating agriculture-food 4.0 supply chain using FDOSM as a benchmarking method and extended FWZIC under Fermatean probabilistic hesitant-fuzzy sets [50].

f) Technology: Most reviewed studies are primarily focused on the Technology theme, with studies from these reviews falling within this category across various domains. Three studies in the tourism sector are focused on evaluating e-tourism applications using various benchmarking methods. One study integrated Interval type 2 trapezoidal-FWZIC with VIKOR [101], while another study developed a framework based on FDOSM and FWZIC utilizing Neutrosophic fuzzy sets [102]. A third study focused on developing a decision modelling approach for smart e-tourism data management applications utilizing a spherical fuzzy rough environment and FDOSM as the benchmarking method [103].

Six studies focused their research on the healthcare domain. One study involves a benchmarking model for Sign Language Recognition Systems, utilising FDOSM and the extended CP-FWZIC method [104]. Another study utilized another benchmarking model using FDOSM with the original FWZIC, but this time used to evaluate smartphone applications for obesity management [105]. Two studies are centered on security and privacy in Blockchain-Based IoT Healthcare Industry 4.0 Systems. Both studies employed the extended S-FWZIC weighting method, with one using the TOPSIS-GRA [96] benchmarking method and the other using COPRAS [97]. The next study in this domain evaluated intrusion detection classifiers for Internet of Medical Things (IoMT) devices based on security and performance attributes. The study utilized the FDOSM method for benchmarking and extended FWZIC using the Rough Fermatean Fuzzy Sets [108]. Finally, the last study in the healthcare domain utilized the FWZIC method to assess the criteria for digital genetic tools [109].

Four studies in the engineering sector are highlighted. One study focuses on evaluating the risk analysis of offshore wind turbines, utilizing the DEMATEL method along with the extended LP-FWZIC weighting method for determining the relationships between the factors [110]. Another study is centered on evaluating active cooling systems, based on performance and technical attributes, employing the MABAC benchmarking system and the 2 TLP-FWZIC weighting method [111]. The other two studies applied the CoCoSo method, one focused on optimizing Control Engineering tools using digital twin Capabilities and a Cyber-Physical Metaverse manufacturing system using the IVFRS extensions[112], and the other study involved a design concept evaluation method using q-ROFS extensions [113].

Three studies in the technological realm are focused on education. Both studies involve developing frameworks for benchmarking brain–computer interface applications. One study utilized VIKOR as the Benchmarking method alongside the TFN extended weighted method [114], the second focus on evaluating speech-recognition chatbots for language learning using MCRAT methods and implementing the (T-SFS) [23]. The other study applied MABAC as the benchmarking method and extended FWZIC using the Neutrosophic Cubic Fuzzy Set [115].

Moreover, five studies are centered on network analysis. One study developed a model for evaluating routing algorithms in a multiprocessor system by utilizing Z-Cloud Rough Numbers (ZCRNs) environment to extend the weighting method and FDOSM for benchmarking [112]. The second study focused on selecting an optimal architecture for 5G-radio access network employing the type-2 N-FWZIC extended method for weighting and FDOSM for benchmarking [116]. The third study develops a modelling framework for 6G based blockchain technology

using RAFSI method and extends FWZIC with Normal Wiggly Hesitant Fuzzy sets [117]. The fourth study involved in evaluating a Dynamic locally based-utility approach for developing an internet self-reconfiguration robot extending FWZIC with type 2 Pythagorean [118]. And the fifth focuses more on the superiority of a robust cloud network using PROMETHEE and the spherical cubic fuzzy environment [119].

The last five studies on this theme cover various sectors, including marine robotics, transport, business, and agriculture. One of these studies aims to optimize the motion trajectory of an autonomous underwater vehicle by evaluating the optimization algorithms [120]. The study utilized FDOSM for benchmarking and FWZIC for criteria weighting. Another study focused on evaluating driver assistance systems for vehicles utilizing FDOSM for benchmarking and FWZIC for criteria weighting within Intuitionistic fuzzy sets [121]. Additionally, a separate study delved into organizational culture within companies to promote digital innovation, employing the q-rung picture FWZIC method for criteria weighting and simple additive weighting SAW for benchmarking [122]. The last two studies in this theme, related to Agriculture, one study developed of a modelling approach for drones for Precision Agriculture, utilizing FDOSM for benchmarking and FWZIC criteria weighting [123]; the other one involved in evaluating and swarm robots effectiveness in mechanized agricultural operations using CPOS methods and Circular Quintic Fuzzy Sets extensions [105].

These findings reveal the versatility of the FWZIC method and its use in several fields spanning across various domains such as healthcare, supply chain, manufacturing, engineering, business and more. Thus, the FWZIC method can be an ideal choice for practitioners and researchers in various fields when weighing a large number of criteria based on subjective human opinions.

3) MCDM methods and Fuzzy extensions

RQ3: Which ranking methods has FWZIC been integrated with?

RQ4: Which fuzzy environments are utilized to enhance FWZIC?

The seventy-one reviewed studies show that FWZIC has been extended with numerous fuzzy sets and integrated with several ranking methods. FWZIC was most frequently combined with the FDOSM ranking method (n = 22). While fifteen studies utilized the original TFNs with FWZIC [67], [69], [70], [71], [74], [80], [81], [84], [90], [95], [114], [120], [123], [124], [125], [126] all other studies enhanced the FWZIC method under various fuzzy environments such as the Spherical FS (T-SFS), Neutrosophic Sets (NS) [102], Q-Rung Orthopair (q-ROF) [76], [83], Pythagorean Fuzzy (PF) [77], Cubic Pythagorean FS (CPFS) [104], Spherical Fuzzy Rough Sets (SFR) [103], Z-Cloud Rough Numbers (Z-CRN) [112], -rung Orthopair Fuzzy Rough Sets (Q-ROFRS) [93], Rough Fermatean FS (RFFS) [108], Dual-Hesitant Fuzzy (DH), Type-2 Neutrosophic Numbers (T2NN) [116], and Intuitionistic FS (IFS) [121]. Two studies integrated FWZIC with FDOSM and another ranking method, MAIRCA and MULTIMOORA, using Fermatean Probabilistic Hesitant (FPH) [50] and q-rung Orthopair probabilistic hesitant fuzzy set (Q-ROPHFS) [96], respectively.

The second most common ranking method, which utilizes FWZIC for criteria weighting, is VIKOR (n = 9). Out of the eight studies, five did not enhance the original FWZIC method and utilized it with TFNs [70], [71], [80], [90], [114], while one study enhanced the fuzzy environment and applied the Interval Type 2 Trapezoidal Fuzzy sets (IT2TR) [101]. The other study used the single value Neutrosophic to enhance the fuzzy sets [116].

Eleven studies combined FWZIC with the MABAC, MULTIMOORA and ARAS ranking methods, respectively. Taha Aljburi et.al [95] integrated the MABAC method with FWZIC in its original form using TFN; while the four other studies used MABAC, enhancing FWZIC under Neutrosophic Cubic Sets (NCS) [115] and 2-Tuple Linguistic Pythagorean (2TLP) [111], q-runq Orthopair (q-ROF) [127], and Single-Valued Neutrosophic 2-tuple Linguistic (SVN2TL) [128]. The MULTIMOORA method was utilized with enhanced FWZIC under Probabilistic Hesitant (P-H) [48], Linear Diophantine FS (LDFS) [85], and Linear Diophantine Fuzzy RS (LDFRS) [92]. On the other hand, the ARAS ranking method was combined with an enhanced FWZIC method under the Circular Intuitionistic Fuzzy Set (C-IFS-FWZIC) [100]. Additionally, two other studies integrated the ARAS method with an enhanced FWZIC method, one study under Hexagonal FN (HF-FWZIC) [89], and the other study under Pythagorean Fuzzy sets (PF-FWZIC)[109].

FWZIC was paired with TOPSIS (n = 2) in two studies, one under Interval-Valued Spherical Fuzzy Hesitant 2-tuple (IVSH2) FS [79]. The other study enhanced FWZIC under the Spherical (S) FS [106]. Two studies combined FWZIC with SAW (n = 2) for criteria weighting by extending FWZIC under the q-Rung Picture FS (Q-RP) [122] and Spherical Fuzzy Rough Sets (SFR) [103], while another two studies paired FWZIC with ARAS (n=2), extending it using Circular Intuitionistic FS (C-IFS) [100] and Hexagonal FN (HF) [89]. FWZIC was also combined with the CODAS (n=2) ranking method in two studies, which extended the criteria weighting method using Q-Rung Orthopair Fuzzy 2-Tuple Linguistic (q-ROF2TL) [73] and Neutrosophic Bipolar FS (NBFS) [97]. FWZIC was also utilized with the Delphi (n=2) method in two studies under the original TFN fuzzy environment [69], [81].

CoCoSo and CODAS were integrated with FWZIC in three studies (n =3). The CoCoSo method was implemented with the Interval-Valued Spherical Fuzzy Rough Sets extension in two studies (IVSFRS), [88], [129]. The other study applied CoCoSo with Q-rung Orthopair Fuzzy rough sets (Q-rungOFRS) FWZIC extensions, [113]. On the other hand, one study integrated CODAS with the q-rung Orthopair Fuzzy type 2 linguistic FWZIC extensions on intelligent healthcare applications. [73], while the other study used CODAS with Neutrosophic bipolar (NBFS) FWZIC enhancements on circular sustainable business tools. [97], and the last study used hyperbolic fuzzy sets extensions (Hy) for sustainability. [130].

CPOS was integrated twice with FWZIC. Alsattar, Qahtan, et al. [99] utilized the CPOS method with FWZIC in Circular-Pythagorean Fuzzy environment (C-PFS). The other study used

CPOS and implemented Circular-Quintic Fuzzy Sets extensions (cQuFS) on FWZIC[105] for sustainability. MARCOS was integrated with FWZIC in two studies for sustainability, one extended FWZIC with Pythagorean Probabilistic Hesitant (PPF) [91]. The other study used the Interval value, Fermatean Fuzzy sets (IVFFH) [131]. Similarly, PROMETHEE II was integrated twice with FWZIC. One study used an Interval-valued spherical fuzzy rough environment (IVSFRS) [87]. The other study used Spherical Cubic Fuzzy (SCFS) [124].

All other MCDM methods (n=14) utilized in the literature were only integrated with FWZIC in one study. Zaidan, Alsattar, et al. (2023) extended the COPRAS method using FWZIC, extending it using the Interval-Valued Spherical Fuzzy sets (IVSFS) [107]. Bilquise et al. [86] integrated the RATMI method with the FWZIC method and extended it under the spherical linear Diophantine FSs (SLDFSs). The EDAS method was integrated with FWZIC using a type 2 fuzzy environment, Interval-valued Pythagorean Fuzzy Rough set (IVPFRS) [132]. The remaining studies extended FWZIC under various fuzzy sets such as Fractional Orthotriple Fuzzy sets (FOFS) [82], Interval Type 2 Trapezoidal-Fuzzy sets (IT2TR) [72], Linguistic Pythagorean Fuzzy sets (LPFS) [110], Probabilistic Single-Valued Neutrosophic Hesitant Fuzzy set (PSVNHFS) [78] with MCDM methods MARCOS, TROOIL, UPLPD, DEMATEL, and DLBD, respectively. Finally, one study extended FWZIC using Complex T-spherical FWZIC (CT) fuzzy sets and employed a machine learning model for benchmarking the alternatives [68], and another study utilized FWZIC for prioritizing criteria weights under the original TFNs without ranking any alternatives [84].

The findings reveal the ability of FWZIC to be seamlessly integrated with multiple MCDM methods. Overall, it is observed that the most popular ranking method integrated with FWZIC is FDOSM (n = 22), followed by VIKOR (n = 8). Moreover, FWZIC was utilized in its original form, using TFN, in n=20 studies only. All other studies (n =51) have enhanced FWZIC in various fuzzy environments, ranging from classical FS to type-2 fuzzy sets, to capture a broader uncertainty space. Notably, ambiguity and imprecision in human judgement remain open issues, due to which FWZIC extensions are being extensively researched.

4) Aggregation and Defuzzyfying techniques

RQ5: What techniques are used for aggregation and defuzzification in the FWZIC algorithm?

a) Aggregation techniques: This section explores the common aggregation methods utilized by the reviewed studies for aggregating the fuzzy EDM values. Aggregation of the fuzzy numbers is one of the most crucial steps in FWZIC method. The fuzzy expert judgement for each criterion is aggregated with the aim of merging all the experts' opinions for that criterion so that the resulting aggregated output fully considers each individual criterion. This ensures that the final criterion weight is based on the overall evaluation. Aggregation is critical for producing appropriate results from EDM. In literature, several aggregation methods exist for various fuzzy environments [19].

All studies that employed the classical FWZIC using TFN utilized a pseudo-arithmetic operator $\oplus$ to aggregate the fuzzy values of each criteria expert opinion in the EDM. Similarly, the pseudo-arithmetic operator was utilized for HFNs [89]. For instance, two TFN $\bar{x} = (a_1, b_1, c_1), \bar{y} = (a_2, b_2, c_2)$, the TFN pseudo-arithmetic operation between $\bar{x}\ and\ \bar{y}$ is defined as follows: $\bar{x} \oplus \bar{y} = (a1 + a2, b1 + b2, c1 + c2)$.

Although advanced aggregation operators, like geometric aggregation, weighted aggregation and quasi-fuzzy weighted aggregation have been proposed in literature for these classical fuzzy numbers [133], none of the studies employed the aggregation operators.

Similarly, the other studies that enhanced FWZIC with various advanced fuzzy environments, such as IFS, PyFS, SFS, IVFS, and more, employed the arithmetic weighted aggregation operator of the respective fuzzy environment. For instance, [115] utilized the NCN weighted arithmetic averaging (NCNWAA) operator for the NCS-FWZIC technique, while [96] utilized the q-ROPHF arithmetic mean (q-ROPHFAM) operator, and [106] employed the spherical weighted arithmetic mean (SWAM) operator. Ref [102], on the other hand, employed a geometric aggregation operator for NS-FWZIC. Other aggregation operators, like Bonferroni [134] and Einstein [135] aggregation operators were not considered in any of the studies. Notably, different aggregation operators may impact the criteria weighing results, which may be explored for further research.

b) Defuzzification techniques: Defuzzification is a process that converts a fuzzy set or fuzzy number into a crisp value or number. Defuzzification is used in fuzzy modeling to convert the fuzzy output values to their corresponding crisp weight values. This process is necessary because all fuzzy sets inferred by fuzzy inference in the fuzzy rules must be aggregated to produce one single number as the output of the fuzzy model. There are numerous techniques for defuzzifying a fuzzy set.

The centroid method mathematically derives the Center of Gravity (COG) to convert a fuzzy number to its corresponding crisp value. However, this method is computationally complex for complex membership functions. For instance, for a TFN $\bar{x} = (a, b, c)$, the defuzzified crisp value is computed as $\bar{x} = (a + b + c)/3$, while for HFNs $\bar{x} = (a, b, c, d, e, f)$, the crisp value is derived using the equation $\bar{x} = (3a + 3b + 10c + 10d + 5e + 3f)/34$.

All studies that utilized TFNs and HFN applied the centroid method for defuzzifying the fuzzy weight values. Other methods proposed in literature, such as max-membership, weighted-average and mean-max methods [18] were not employed by any of the studies. All other reviewed studies that employed advanced fuzzy sets consistently utilized a single score function of the respective fuzzy environment to compute the defuzzified crisp value. Notably there exists multiple score functions in fuzzy sets, each of which may yield different results [136]. None of the studies evaluated the criteria weights based on multiple score functions.

Overall, the findings in this section reveal a gap in literature, showing that there are multiple avenues of further research to

evaluate the impact of the use of different aggregation and defuzzification techniques with the various fuzzy environments to further enhance the FWZIC method.

C. Expert and Criteria Characteristics

This section explores the characteristics of the experts and evaluation criteria employed in studies utilizing the FWZIC method. In addressing the first part, we examine the background, qualifications, and experience of the experts involved, along with how their input was used in the decision-making process. We also highlight patterns in expert selection, including the number of experts typically engaged and how their opinions were considered. In the second part, we analyze the nature, structure, and sources of the criteria used across the reviewed studies. This includes how the criteria were evaluated, the scales and linguistic terms applied, and the integration of fuzzy sets to ensure consistency. Together, these insights provide a comprehensive understanding of how FWZIC accommodates expert-driven input and diverse criteria sets in multi-criteria decision-making contexts.

1) Expert characteristics

RQ6: What are the characteristics of the experts involved in the studies?

All experts employed in the studies possess expertise within the field of study, including cardiologists, academicians, tourism experts, data scientists, and others. In [112], the authors identified members of the technical community as experts. Two studies [109], [86] explicitly list the qualifications and details of the experts. Some studies stipulated the minimum experience requirements to be considered as experts in that field. For instance, [67] and [104] require experts with over 5 years of experience, while others, such as those by [71], [95] and [110] selected experts with more than 10 years of experience. In numerous case studies, the evaluation forms and criteria adopted are also assessed by experts chosen for their knowledge and expertise in relevant fields [81]. Notably, only one study [110] differentiated the experts' opinions based on seniority and years of experience, assigning each expert an objective score to determine the overall criteria weight. All studies considered the opinion of the expert at an equal level, without differentiating them based on their expertise.

Most case studies (n = 46) involve three experts to assess and weigh the evaluation criteria and consider this a minimum requirement. Few studies (n = 7) employed four experts, while three studies opted for five experts. Some studies involved a large number of experts. For instance, [106] used 17 experts to evaluate security and privacy in Blockchain-Based IoT Healthcare Industry 4.0 Systems, while [101], [102] both employed 11 experts to determine the criteria's significance for evaluating smart e-tourism applications. In [95], the study utilized 12 experts to assess various energy sources for sustainability and efficient resource usage. Three studies employed 6 experts for assessing criteria weights for lung cancer diagnosis techniques [70] [123], for evaluating indoor air quality pollutants [72] and for evaluating the significance of hybrid deep learning models based on chest X-ray analysis in CAD systems [71]. Three studies, which involved five experts [85] evaluated the privacy model of the Bitcoin network for the Metaverse, while [89] assessed the significance of privacy features for metaverse tools and [86] evaluated virtual commerce applications for the Metaverse. Several studies selected four experts, primarily in the medical field [67], [84], [137], [138].

It is observed that the minimum number of experts employed for weighing criteria using FWZIC ranges from a minimum of 3 to a maximum of 43 experts, with a large percentage utilizing three experts. This finding reveals the ease of use of the FWZIC method regardless of the number of experts involved. FWZIC proves to be reliable and robust in consolidating opinions from multiple experts, each with diverse expertise, to reduce bias in the criteria weighting process while maintaining consistency. In other subjective criteria weighting methods, such as AHP, the process of consolidating criteria weightings using multiple experts would be a time-consuming process and prone to inconsistencies as well. Notably, only one study differentiated the experts' opinions based on their seniority and experience level.

2) Criteria characteristics

RQ7: What are the characteristics of the criteria utilized in the studies?

The number of criteria across the 71 reviewed studies varies significantly, ranging from a minimum of 3 to a maximum of 75 criteria. Most of these criteria are structured at a single level, while some studies have utilized multi-level criteria ranging from two-levels, three-levels and four levels.

The criteria utilized in the studies originate from various sources. Several studies (n = 43) source their evaluation criteria from root articles. A root article may be defined as an existing systematic review, survey, or case study which has extracted the criteria from literature [139]. Others use only a portion of these criteria (n = 7). Additionally, some studies derive their criteria from existing datasets when integrating FWZIC with machine learning techniques. Other studies source their criteria from literature (n=12), while a few studies (n = 4) identify their criteria as performance metrics or specific methods for selecting optimal machine learning algorithms.

The criteria are assessed by experts using an online evaluation form. All studies have consistently utilized a 5-point Likert scale to assess the criteria's significance using linguistic values such as "Very High Importance", "High Importance", "Moderate Importance", "Low Importance", "Very Low Importance". Only one study employed a 10-point Likert scale [104]. All studies mapped the linguistic values to a numerical scale and converted them to the corresponding fuzzy number to generate a fuzzy Expert Decision Matrix.

Overall, the FWZIC method has been utilized with as few as three criteria and as many as seventy-five. These findings demonstrate the robustness of the FWZIC method in weighting a large number of criteria without any inconsistencies, thereby demonstrating its superiority over other subjective methods, such as AHP, ANP, and BWM, which would not only be computationally intensive but also prone to inconsistencies.

V. Research Implications

By analyzing seventy-one studies across diverse domains such as healthcare, engineering, supply chain, agriculture, and technology, this review confirms the FWZIC method's versatility, robustness, and growing popularity since its inception.

The findings highlight that FWZIC effectively addresses the limitations of traditional subjective weighting methods by ensuring consistency, accommodating a wide range of fuzzy environments, and facilitating decision-making even with large numbers of criteria and experts. Moreover, the increasing integration of FWZIC with various MCDM ranking techniques, particularly FDOSM and VIKOR, underlines its adaptability and relevance across multidisciplinary fields.

This review establishes that FWZIC offers a transformative approach to subjective criteria weighting by minimizing inconsistency and bias, which are persistent challenges in MCDM. It encourages a shift from conventional time-consuming methods like AHP and BWM towards more streamlined, reliable techniques, particularly in environments characterized by ambiguity.

The systematic integration of FWZIC with advanced fuzzy environments (e.g., q-ROFS, T-SFS, IVFS) has expanded the spectrum of uncertainty that can be modeled. This evolution enhances the realism and flexibility of decision models, paving the way for more human-centric decision support systems.
