Despite extensive applications, the study uncovers that most researchers have relied on standard aggregation (e.g., pseudo-arithmetic operators) and centroid-based defuzzification methods. This opens an important avenue for future exploration: investigating alternative aggregation and defuzzification strategies could yield even more robust, interpretable, and precise decision-making frameworks.

The breadth of FWZIC's application, from medical diagnosis prioritization to supply chain resilience, demonstrates its critical role as an enabler of informed decision-making in complex, multidisciplinary problems. Organizations can leverage FWZIC-based models to improve strategic planning, risk assessment, resource allocation, and sustainability efforts.

The study confirms FWZIC's practical utility in real-world contexts by facilitating expert opinion consolidation without overburdening decision-makers. Its ability to integrate three to forty-three expert opinions efficiently, without inconsistency, empowers organizations to make collective, evidence-based decisions more effectively.

Unlike traditional subjective methods that are unstable with increasing numbers of criteria or experts, FWZIC demonstrates strong scalability. This robustness supports its deployment in emerging fields such as AI-driven healthcare, Industry 5.0, digital twin technologies, and the Metaverse, where complex, multi-criteria evaluations are the norm.

Although FWZIC's flexibility is a strength, the diversity of its applications also signals a need for establishing best practices or standardized frameworks for its use across different fuzzy environments and MCDM settings. Future work should aim to benchmark FWZIC applications across domains to strengthen comparability and reliability.

A. Future Directions

This section presents some additional research areas that emerge from the review, thereby offering practitioners and researchers a means to further enhance research in this field.

1) Fuzzy scale. Most of the reviewed studies have utilized a 5-point Likert scale for assessing criteria importance, with only one study utilizing a 10-point Likert scale. A scale is essential for a comparison reference when assessing the criteria's significance. It may be reasonable to assume that a higher-level scale would cover a wider spectrum of uncertainty in expert opinion. Therefore, a future area of research could be to explore the impact of various scales (5-point, 7-point, 10-point) on the criteria weighting results.

2) Experts. Most reviewed studies employed at least 3 experts to assess the criteria's weighting significance. While some studies designated minimum requirements for expert selection, only one study employed an objective approach in the criteria weighting process to differentiate experts based on their seniority and experience level. This opens an avenue for further research in this area to study the difference in the criteria weights with or without an objective approach. Furthermore, researchers could also employ objective criteria other than seniority in job title and experience years, such as preferred area of practice (industry experts, academicians, researchers), expert qualification and more.

3) Aggregation and Defuzzification. Most of the reviewed studies employed the arithmetic weighted aggregation operator of the respective fuzzy environment, while only a few studies have employed the geometric aggregation operator, which signifies that more research is encouraged to investigate the use of these aggregators. Moreover, none of the studies employed aggregation operators like Bonferroni [134] and Einstein [135] aggregation operators, allowing future research possibilities to employ these and other new aggregation operators that were not considered in the review studies.

From the defuzzification techniques point of view, most of the studies utilized the centroid method for defuzzifying the fuzzy weight values or used a single score function for defuzzifying; none of the reviewed studies used other proposed methods in literature, such as max-membership, weighted-average and mean-max methods. Additionally, no studies used multiple score functions to calculate the final weight methods that would impact the ranking results. This gap in the literature presents an opportunity for further research to explore the application of these alternative defuzzifying methods or to use multiple scores to evaluate and finalize the criteria weights.

4) Fuzzy extensions. Although several studies have enhanced the FWZIC method under various fuzzy environments, the issue of inconsistency and ambiguity in human judgment remains unresolved when calculating criteria weights. The FWZIC method can be further extended with different fuzzy environments that encompass a broader

uncertainty range, such as interval-valued Neutrosophic sets. Moreover, future research could also analyze the soft versus rough characteristics in fuzzy sets and their effect on criteria weighting using FWZIC.

5) MCDM integration. FWZIC has been integrated with several MCDM methods for the purpose of ranking and studying the causal effects on the attributes. Notably, several MCDM ranking methods have not yet been integrated with FWZIC, such as MACBETH, MCRAT, RAMS, and others. Integrating FWZIC with these methods presents a potential research opportunity to analyze and test the results and effectiveness of these integrations.

6) Domain. The FWZIC method has been utilized in numerous sectors to determine criteria weights such as healthcare, tourism, agriculture, transport and more. However, there are still many unexplored domains that present an opportunity for future research, such as real estate, aviation, media and telecommunication.

7) Other criteria weighting methods. FWZIC is a comparatively superior criteria weighting method when compared to other traditional weighting methods, such as AHP. Not only is FWZIC computationally simple, but it also eliminates the need for criteria comparison and leads to zero inconsistencies in subjective evaluation. A possible future area of research is a comparative study of FWZIC and other methods, such as the Full Consistency Method (FUCOM) [140] and Opinion Weight Criteria Method (OWCM) [141]. FUCOM provides a strategy with fewer pairwise comparisons to reduce inconsistency, while OWCM combines both subjective and objective criteria weighting methods to eliminate inconsistency. This comparison could highlight the strengths and weaknesses of each method, potentially leading to further advancements in criteria weighting techniques.

VI. Conclusion

This systematic review presents a comprehensive synthesis of the FWZIC method's applications in MCDM. By examining seventy-one empirical studies across a range of domains, including healthcare, engineering, supply chain, and sustainability, the review highlights FWZIC's versatility in addressing the challenges of subjective decision-making, particularly in managing expert opinions with consistency and minimal bias.

The findings demonstrate that FWZIC has been widely adapted through the integration of various fuzzy environments and has been successfully combined with multiple MCDM ranking techniques, reflecting its flexibility and growing acceptance. Despite its advantages, gaps remain regarding the exploration of alternative aggregation and defuzzification methods, offering valuable opportunities for future research to further enhance decision-making accuracy and robustness.

Overall, this review not only consolidates the existing knowledge on FWZIC but also identifies emerging trends, methodological gaps, and potential directions for advancing subjective criteria weighting techniques. It serves as a vital resource for researchers and practitioners seeking to implement or extend the FWZIC method in increasingly complex and uncertain decision-making contexts. This study not only underscores the value of FWZIC as a cornerstone method in subjective decision-making but also charts a pathway for future research directions. By systematically identifying gaps and proposing avenues for further methodological refinements, this review serves as a critical reference for researchers, practitioners, and policymakers aiming to enhance decision quality in increasingly complex, uncertain, and multi-stakeholder environments.

This study may have been subject to certain limitations attributable to various factors. Primarily, the research employed three bibliographic databases, encompassing multiple disciplines, to retrieve pertinent studies. This approach may have led to the inadvertent exclusion of relevant empirical studies that utilized the FWZIC method. Additionally, ten studies were excluded from the meta-analysis of the present study due to the unavailability of full-text access. Despite these constraints, the examination of the seventy-one reviewed articles has yielded a comprehensive and detailed review of the FWZIC method, which is expected to provide valuable guidance for both practitioners and researchers in this domain.

APPENDIX

Themes	Domain	Study	Objective	MCDM Method	FWZIC Extension	#Experts	#Criteria	Criteria Source
Artificial Intelligence	Engineering	[74]	To develop optimization techniques for semiconductor materials.	FDOSM	Triangular Fuzzy Numbers	3	8	Root article
	Healthcare	[142]	To evaluate hybrid diagnosis models for autism spectrum disorder patients	FDOSM	2-Tuple Linguistic Neutrosophic Fuzzy Set	4	9	Root article
		[128]	To prioritize autism spectrum disorder cases based on behavioral and medical characteristics.	MABAC	Single-Valued Neutrosophic 2-Tuple Linguistic Fuzzy Set	3	19	Literature
		[67]	To evaluate machine learning models for diagnosing autism spectrum disorder patients.	FDOSM	Triangular Fuzzy Numbers	4 3	48 7	Performance metric of ML
		[70]	To evaluate machine learning approaches for lung cancer diagnosis.	VIKOR	Triangular Fuzzy numbers	6	5	Performance metric of ML
		[72]	To develop a labelled dataset of indoor hospital air quality pollutants.	UPLDP	Interval Type 2 Trapezoidal-Fuzzy Sets	6	9	Root article
		[68]	To integrate MCDM with Machine learning for classifying patients with autism spectrum disorder.	ML	Complex T-Spherical Fuzzy Set	3	7	Performance metric of ML
		[73]	To evaluate AI healthcare applications based on trustworthiness attributes.	CODAS	q-Rung Orthopair Fuzzy 2-Tuple Linguistic	3	7	Root article
		[71]	To benchmark deep learning models for chest X-ray analysis and computer-aided diagnosis.	VIKOR	Triangular Fuzzy Numbers	6	7	Performance metric of ML

		[69]	To combine MCDM and ML to predict ASD patients and build an explainable AI for model comprehension.	Delphi	Triangular Fuzzy numbers	4	19	Existing dataset
COVID 19	Healthcare	[78]	To benchmark AI models for diagnosing COVID-19 patients using chest x-rays.	DLBD	Probabilistic Single-Valued Neutrosophic Hesitant Fuzzy Set	3	7	Literature
		[75]	To prioritize COVID-19 vaccine dose recipients.	FDOSM	T-Spherical Fuzzy Sets	3	5	Root article
		[76]	To prioritize COVID-19 vaccine dose recipients.	FDOSM	Q-Rung Orthopair Fuzzy Sets	3	5	Root article
		[77]	To prioritize COVID-19 vaccine dose recipients.	FDOSM	Pythagorean Fuzzy Sets	3	5	Root article - case study
		[79]	the prioritize the distribution of COVID-19 monoclonal antibody to eligible high-risk patients.	TOPSIS	Interval-Valued Spherical Fuzzy and Hesitant 2-Tuple	3	15	Literature
Metaverse	Business	[85]	To evaluate bitcoin network platforms for the Metaverse.	MULTIMOORA	Linear Diophantine Fuzzy Sets	5	24	Root article (partial)
		[86]	To evaluate virtual commerce solutions for the Metaverse	RATMI	Spherical Linear Diophantine Sets	5	13	Root article
	Manufacturing	[89]	To assess cyber-physical manufacturing systems based on privacy features.	ARAS	Hexagonal Fuzzy Numbers	5	21	Unspecified
		[87]	To assess cyber-physical manufacturing systems based on privacy features.	PROMETHEE II	Interval-Valued Spherical Fuzzy Rough Sets	3	26	Root article
		[88]	To assess cyber-physical manufacturing systems based on privacy features.	CoCoSo	Interval-Valued Spherical Fuzzy Rough Sets	3	16	Root article
Service	Business	[127]	To rank power transformer suppliers based on quality standards to maintain safe and stable grid operations.	MABAC	Q-Rung Orthopair Fuzzy Sets	4	10	Literature
		[143]	to assess blood supply chain management alternatives against sustainability-focused criteria	VIKOR	Single-Valued Neutrosophic Fuzzy Set	3	7	Root article
	Healthcare	[80]	To prioritize the treatment of autism spectrum disorder patients.	VIKOR	Triangular Fuzzy Numbers	4	19	Root article
		[83]	To prioritize hospital selection for patients with multi-chronic diseases.	FDOSM	Q-Rung Orthopair Fuzzy Sets	3	7	Root article
		[82]	To prioritize patients with multiple chronic illnesses based on sensor and emotion data.	TROOIL	Fractional Orthotriple Fuzzy Sets	3	12	Root article
		[81]	To classify autism spectrum disorder patients based on severity level for early diagnosis.	Delphi	Triangular Fuzzy Numbers	13	19	Existing dataset
		[84]	To prioritize the criteria for managing patients with cardiac related issues.	N/A	Triangular Fuzzy Numbers	4	11	Root article
Sustainability	Agriculture	[130]	To critically assess decision support systems for enabling the choice of systems that can effectively drive sustainable smart agriculture.	CODAS	Hyperbolic Fuzzy Sets	3	8	Root article
		[90]	To evaluate water quality monitoring systems based on remote sensing techniques.	VIKOR	Triangular Fuzzy Numbers	3	15	Root article
	Business	[98]	To evaluate circular economy and sustainability practices in the palm oil industry.	EDAS	Interval-valued Pythagorean Fuzzy Rough Set	3	14	Root article

		[97]	To evaluate sustainable circular business model innovation tools.	CODAS	Neutrosophic Bipolar Fuzzy Sets	3	10	Root article
	Engineering	[96]	To evaluate sustainable strategies for construction waste management.	FDOSM-MULTIMOORA	Q-Rung Orthopair Probabilistic Hesitant Fuzzy Set	3	26	Root article
		[131]	To develop a comprehensive investment decision-making framework for offshore Carbon Capture, Utilization, and Storage (CCUS) projects to promote sustainable development	MARCOS	Interval value, Fermatean Fuzzy Sets	3	18	Literature
		[124]	To assess and rank research based micro-grid to ensure sustainable energy resources.	VIKOR	Triangular Fuzzy Numbers	3	9	Root article
		[95]	To benchmark energy systems integration frameworks for efficient resource utilization.	MABAC	Triangular Fuzzy Numbers	12	6	Root article
	Miscellaneous-Energy Optimization	[125]	To evaluate energy economy optimization models for efficient energy systems.	FDOSM	Triangular Fuzzy Numbers	3	5	Root article
	Miscellaneous-Smart living	[99]	To evaluate sustainable smart living frameworks based on multi-layer assessment factors.	CPOS	Circular-Pythagorean Fuzzy Sets	3	19	Root article
	Supply Chain	[100]	To rank real-time IoT devices for food waste monitoring in a supply chain system.	ARAS	Circular Intuitionistic Fuzzy Set	3	10	Root article

Maintenance Department, Methode Electronics, Cairo, Egypt[1]

***Abstract*—According to international organizations' statistics, the percentage of disabled people is considered not just a small percentage of the world's population. Improving the quality of life for people by using new technologies is one of the essential topics today. Although the wheelchair is the most common way of mobility for the disabled, this research aims to improve wheelchair use by creating other control methods, including speech recognition commands. A joystick, wireless remote control, and an additional port are available in addition to speech recognition commands to control the wheelchair. Researchers also studied and compared the effects of integrating a Proportional–Integral–Derivative (PID) controller with the normal controller during smart wheelchair operation in various normal usage scenarios. This research provides data based on a real experiment, not like most research that depends on mathematical models only for comparison. Adding the PID controller eliminated the overshoot of the smart wheelchair, reduced steady-state error, and reduced settling time. Furthermore, it contains a healthcare monitoring system to track the user's vital signs and object avoidance sensors to keep them safe. Also, a full motor selection calculation for the smart wheelchair has been provided, which is useful for mobile robot design. Additionally, the smart wheelchair features a power monitoring system. Finally, a voice-controlled wheelchair helps the user feel more private and independent. Using this kind of smart wheelchair and living this lifestyle will increase the user's morale.**

***Keywords*—Smart wheelchair; speech recognition; PID; healthcare; mobile robot**

I. Introduction

The global population is experiencing rapid growth. The prevalence of physical disability is increasing due to ageing, accidents, and medical conditions such as quadriplegia and paralysis [1, 2]. Japanese demographic forecasts indicate that the percentage of adults aged 65 and above will attain 40% by 2050 [3]. Individuals may lose a limb or both legs due to sickness or accidents, resulting in incapacitation and dependence on others for daily necessities. They are unable to fulfill their responsibilities independently [2]. Contemporary civilization is characterized by individuals who are predominantly focused on their own lives, with an emphasis on competence and self-sufficiency. Individuals reliant on others are hardly discussed in this rapid era of materialism and modernization. In our society, it is hardly contemplated the requirements of individuals who are dependent. If all individuals could lead their lives autonomously, the world would be an exceptional place to inhabit [4].

Mobility impairment is a prevalent form of functional disability that hinders an individual's capacity for movement, frequently necessitating the use of walkers or wheelchairs. World Health Organization (WHO) research revealed that 75 million individuals experience mobility issues and necessitate the use of a wheelchair. Although wheelchairs enable individuals with limited mobility to navigate freely, users frequently experience degeneration, discomfort, or ulceration owing to extended usage and the physical characteristics of their surroundings [5]. New technology is introduced to the marketplace daily. The primary objective of technology is to simplify human life and reduce reliance on others [2]. Powered Wheelchairs (PWs) can accommodate the needs of individuals with mobility impairments [4].

The issue of population ageing escalates the need for healthcare services for the elderly and disabled, especially in nursing facilities or domestic settings [6]. The evaluation of a patient's condition is often conducted through observation and interpretation by qualified medical personnel. From a scientific research perspective, it is crucial to address the issues impacting the physical state of wheelchair users, providing technology and creative solutions to healthcare providers to optimize their treatments. Consequently, it is essential to augment conventional techniques with more objective and quantitative evaluation approaches, such as posture monitoring [5].

Individuals with cognitive, motor, and sensory impairments need Powered Wheelchair (PW) for mobility, whether because of disability or illness [7]. Additionally, several individuals suffer from motor paralysis that necessitates prolonged bed rest due to conditions such as Amyotrophic Lateral Sclerosis (ALS) or Spinal Cord Injury (SCI) [8]. They progressively diminish in muscle strength and often encounter difficulties in reaching and grabbing, rendering the driving device, such as a joystick, challenging to operate [9].

A Smart Wheelchair (SW) typically consists of either a standard PW base integrated with a computer and many sensors or a mobile robot base equipped with a seat [7]. Besides joystick control, many methods of controlling a PW employ entirely distinct interfaces [10]. The electrical impulses generated by our bodies enable connections to several applications in Human-

Machine Interface (HMI) and rehabilitation. Moreover, cognitive functions have been implemented to enhance their capabilities, rendering them beneficial for the daily lives of individuals with impairments [11]. One of the most challenging elements of developing a non-manual HMI for wheelchair operation is generating sufficient instructions that encompass left and right turns, forward and backward movements, acceleration, deceleration, and stopping [12].

Speech Recognition (SR) has been intensively explored since the 1950s, but recent improvements in computer and telecommunications technology have substantially improved its capabilities [13]. SR solves problems, enhances productivity, and changes the way we live. Voice control accomplishes almost all of the functionality of a pushbutton. An SR is a demanding undertaking since it involves a lot of procedures that need significant computational resources. The wide range of applications of automated SR systems, such as in Human–Computer Interactions (HCIs), telephony, and robotics, has powered a large scientific community during the last few decades. Automatic speech recognition is currently used in a wide range of goods and applications, including medical transcription, gaming control, contact center conversation systems, and information retrieval [14].

A SR technique is a computer tool that can analyse a human vocal signal and detect the information contained in it, translate it to text, or send orders that act on an action, in this case, turning the device on and off. To get a correct interpretation of the acquired auditory message, data from several sources of knowledge, such as syntactic, phonetic, pragmatic, lexical, acoustic, phonological, and semantic information, must be analyzed. With the introduction of Artificial Intelligence (AI) and intelligent assistants, the popularity and use of SRs have expanded. Recognizing the speaker can help to translate talk into systems that have been trained to recognize a specific person's voice, or it can be applied to authenticate or confirm a speaker's identification as part of a safety protocol [15].

People suffered the loss of their arms or legs, whether temporarily or permanently, due to illness or an accident [2]. But since speech is the most natural means of communication, you may also use your voice to drive the wheelchair. It is evident that a wheelchair with SR is necessary to assist individuals with physical limitations who struggle to control their movements, particularly when using their hands independently [16].

The current number of PW users is estimated to constitute just about fifty percent of the potential user base. The number would increase if technology were available to enable anyone unable to operate a joystick or switch array to reliably and safely control a PW [17]. As the older population expands, the need for autonomous and intelligent healthcare services is escalating [18].

II. Related Work

Vaishali Jabade implemented a control system for the PW by using the technology of voice recognition through Google Assistant, which was integrated with a monitoring system for the user's health. Vaishali used Bluetooth as a type of communication to send the voice commands from the mobile to the controller of the PW. Direct wired communication is the recommended method for sending voice commands to the controller of the PW, as it offers greater safety [19].

SATYAVIR SINGH implemented a PW controlled by voice commands and integrated with a collision avoidance system based on an ultrasonic sensor. SATYAVIR used Bluetooth communication to send the voice commands to the controller, which increased the possibility of missing some commands. while using wired communications enhances user safety [20].

Jenina R. Amoguis modified a manual wheelchair to become a PW controlled by SR integrated with an ultrasonic sensor to increase the safety of the user while using the PW. Jenina R. Amoguis did not add any joysticks to the PW. Since adding a joystick to the PW that is controlled by any other controlling method increases the number of users of the PW [21].

Fida Hussain uses voice commands and a joystick to operate a PW, which makes it user-friendly for individuals with disabilities, including those who are deaf and equipped with ultrasonic sensors. She used the normal relay module to control the motors of the PW, and then she had a fixed speed all the time. While using driving boards for motors allows for changing the speed of the motor if required [22].

Mohammad Shahrul developed an intelligent PW controlled by speech recognition using convolutional neural networks to identify the required commands for operating the PW. He did not consider any kind of safety in his model, like, for example, when there is any obstacle in front of the PW. Integrating any proximity sensors that stop the PW if there is an obstacle increases the safety and satisfaction levels of the user [23].

Arsha designed a real PW, controlled by the commands from the voice recognition module integrated with ultrasonic sensors to avoid any accidents during the operation of the PW. M. S. Arsha used the standard relay board to operate the motors of the system. The recommended method for driving the motors of the PW is to use a motor driving board, as this allows the user to adjust the speed of the motors [24].

Divya Jennifer DSouza developed a smart-sensing wheelchair to monitor heart rate and blood oxygen levels and trigger an alarm system if the user's signals are not good. Divya Jennifer DSouza used a photoplethysmography sensor to monitor the heart rate. Unlike an electrocardiogram sensor, the photoplethysmography sensor does not provide an accurate heart rate reading [25].

Shailu studied using different algorithms for improving the speed regulation of an electric wheelchair as an application of the mobile robot. Shailu optimized the PID controller gains using firefly, genetic, particle swarm, and gray wolf algorithms and compared the results [26].

Sankardoss developed an economical implementation of a directional and speed controller for an electric wheelchair. He conducted a comparison using three different types of controllers: the intelligent neural network, fuzzy logic, and PID. His trials were based on improving the overshoot and settling time [27].

Rawiphon Chotikunnan applied a PID control system on a Mecanum wheelchair to regulate the movements of the motors, which leads to improved control accuracy. He employed the

Cohen-Coon tuning approach to figure out the gain of the PID controller [28].

III. OBJECTIVES AND METHODOLOGY

This research aims to explore the full design and implementation of a real SW, which utilizes a four-wheel drive system and operates through standard joysticks, wireless remote controls, and voice commands. Additionally, the system integrates a healthcare monitoring system into the Graphical User Interface (GUI) of a Personal Computer (PC). To increase the safety level and satisfaction of the user, an obstacle avoidance system has been integrated with the SW from four directions to immediately stop the movement, if it detects an obstacle in the moving direction. Also, it measures some of the environmental parameters, like vibration and noise level. In addition, monitoring the responses of the operation of the motors of the SW in response to the commands that are received from the various methods of operation. A PID control has been included in the SW in order to control the speed at which the motors are operating.

To achieve the mentioned objective, a mechanical design of the SW has been carried out, including selecting the optimal dimensions of the wheelchair and the motor selection based on a real calculation and the availability of the market, and it will be discussed thereafter. By listing the required features of the SW, the required devices can be defined to add these features to the implemented SW, as shown in Table I.

TABLE I. SW SUBSYSTEMS AND THEIR REQUIRED DEVICES

Subsystem	Feature	Required device
Operation Methods	Manual control of the wheelchair	Joystick
	Speed control, alarm, and Emergency stop	Dashboard
	A control tool for the helper	Remote-Control (RC) board
	Control the wheelchair by voice commands	SR Kit
	The ability to add an extra operating method	Extra control port
Healthcare System	Measuring the body temperature of the user	Body Temperature sensor
	Measuring the heart rate of the user	Electrocardiogram (ECG) sensor
	Measuring the emotional state of the user	Galvanic Skin Response (GSR) sensor
	Measuring the weight of the user	Load Cell
Safety System	Indicator for the alarm	Buzzer
	Measuring the noise around the wheelchair	Sound sensor
	Measuring the vibration of the wheelchair	Accelerometer
	Obstacle avoidance system in the four directions of the wheelchair	Infrared (IR) Range sensor
The SW Monitoring System	Changing the motor's speed	Motor driver board
	Monitoring the responses of the operation of the motors	Voltage sensor
	Monitoring the power of the SW	Current sensor
	Measuring the speed of the SW	Encoder system
Data Acquisition (DAQ) System	Make the link between the devices, control the wheelchair, and send the measured signals to the PC	Arduino Mega board
	Display the readings of the different sensors	PC

Based on the mentioned information above from the motors, required devices, and the electrical power supply, the electrical connections and interfaces of the SW have been defined, and it will be clarified thereafter. Fig. 1 shows a real photo of the implemented SW.

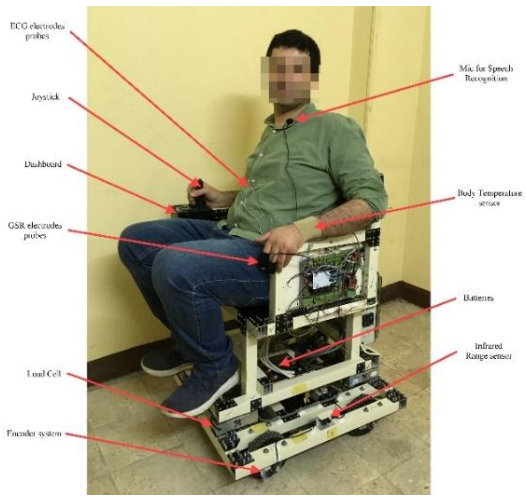

Fig. 1. The implemented SW

By thoroughly understanding the required mission of the SW mentioned in this research, the proper link between all its sub-systems can be established and converted into a programming structure on the Arduino boards, enabling all the devices to communicate and work in harmony. Fig. 2 describes using different operation methods for operating the SW. Furthermore, to implement a monitoring system for healthcare for the user and the measured signals from the SW integrated with limits for the measured signals and making an alarm if required, a GUI has been executed on the PC.

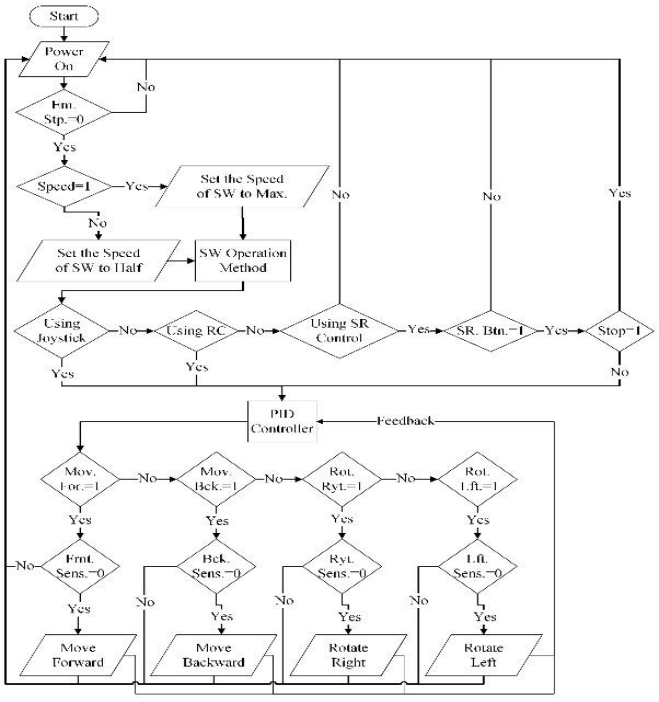

Fig. 2. The flowchart diagram describes using different operating methods of the SW.

IV. Design and Selection

In this section, the mechanical and electrical design of the implemented SW will be introduced, which adheres to the international standards for wheelchairs. Additionally, each step involved in selecting the components of the SW is going to be demonstrated to ensure they fulfill their intended functions.

A. Mechanical Design

The SW will rely on batteries to power all its motors and systems. As a result, reducing the weight of the wheelchair's body structure will reduce the power needed for the motors to support the wheelchair's weight. In addition, it has been planned to set a maximum payload of 100 kg for the wheelchair user. According to the previous data, it has been found that the structure should be as light as possible and rigid to withstand the applied forces. Taking all of this information into account, it has been determined that using aluminium sections joined together by small sheet metal assemblies held together by bolts and nuts was the best solution. According to the previous idea and the standard range of PW dimensions, the design of the wheelchair has been implemented by using the CAD software. As a result, the CAD software calculated the weight of the designed wheelchair to be 40 kg.

After taking into account all the parameters of the wheelchair's structure, the next step involves assigning the power to the drive motors. The four-wheel drive system has been selected for the SW based on its advantages, ensuring each wheel has its own driving motor. One of the most important dimensions that needs to be taken into consideration is the height of the wheelchair from the ramp, with a maximum incline angle that can be worked with, as shown in Fig. 3. This dimension is directly reflected in the selection of the wheel diameter of the SW. Consequently, the diameter of the wheel on the SW will directly affect its linear speed. The diameter of the wheel, after considering all the necessary data for selection, was 15.24 cm.

1) Motor selection. Based on the previous information about the structure, it has been determined that the maximum weight of the SW, including the user, would be 140 kg. The wheel diameter would be 15.24 cm, and the wheelchair would have a four-wheel drive system. Additionally, it has been determined that the SW should have a maximum linear speed of 0.5 m/s to ensure user safety, as recommended by references [29, 30]. The maximum inclination angle of the ramp that our SW can operate with has been defined as 7.125 degrees, as referenced in [31]. While all the required information is available, applying the force analysis for each wheel can be defined as shown in Fig. 3.

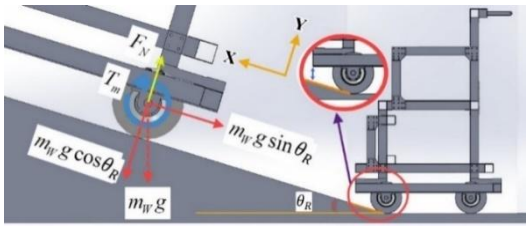

Fig. 3. CAD drawing shows force analysis for each wheel and the distance between the ramp and the SW.

where,

- F_N is the normal force (N).
- T_m is the torque of the motor for each wheel (N.m).
- m_W is the applied mass on each wheel (kg).
- θ_R is the maximum inclination angle of the ramp (^{o}).
- g is the gravitational acceleration (m/s^2).
- Vmax is the maximum linear speed of the wheelchair (m/s).
- r_W is the radius of each wheel (m).
- ω_{max} is the angular speed for each wheel (rad/s).
- N_{max} is the maximum RPM of each motor (RPM).
- a is the wheelchair acceleration (m/s^2).
- t is the time of motion (s).
- V_0 is the initial speed (m/s).
- P_m is the power for each motor (W).
- ΣF_x is the total force in the X axis (N).
- F_m is the generated force by each motor (N).

2) Calculations for motor selection. In this section, the mathematical calculations that define the specifications for each motor in the implemented SW will be presented. It is worth noting that these calculations apply to any mobile robot.

– RPM Calculations:

By using the equation of the relation between the linear speed and the angular speed to calculate the angular speed shown in Eq. (1) and (2):

$$\omega_{max} = \frac{V_{max}}{r_W} \quad (1)$$

$$\omega_{max} = \frac{0.5}{0.0762} = 6.562\ rad/s \quad (2)$$

Applying the equation for the relationship between the angular speed and the RPM to calculate the maximum RPM of each motor shown in Eq. (3) and (4):

$$N_{max} = \frac{60}{2\pi} \cdot \omega_{max} \quad (3)$$

$$N_{max} = \frac{60}{2\pi} \cdot 6.562 = 62.64 \approx 63\ RPM \quad (4)$$

– Torque Calculations:

From the First Equation of Motion, to calculate the acceleration shown in Eq. (5) and (6):

$$a = \frac{1}{t} \cdot (V_{max} - V_0) \quad (5)$$

Assume that $t = 1\ s, V_0 = 0$

$$a = 0.5\ m/s^2 \quad (6)$$

From the force analysis for each wheel as shown in Fig. 3, the total force in the X axis can be calculated as shown in Eq. (7):

$$\because \sum F_x = m_W \cdot a = F_m - m_W \cdot g \cdot sin(\theta_{max}) \quad (7)$$

And considering the equation that represents the relationship between force and torque, to calculate the torque is as shown in Eq. (8) to (11):

$$F_m = \frac{T_m}{r_W} \quad (8)$$

then,

$$T_m = m_W \cdot r_W \cdot (a + g \cdot sin(\theta_{max})) \quad (9)$$

$$T_m = 35 * 0.0762 * (0.5 + 9.81 * sin(7.125)) \quad (10)$$

$$T_m = 4.579\ N \cdot m = 46.677\ Kg \cdot cm \quad (11)$$

– Power Calculations:

By using the equation between the power and the torque as shown in Eq. (12):

$$P_m = T_m \cdot \omega_{max} = 4.579 * 6.562 = 30.05\ W \quad (12)$$

According to the mechanical structure, force analysis, and four-wheel drive system of the wheelchair, the suitable motor torque was 47 Kg.cm, the motor power was 30 W, and the motor RPM was 63 RPM for each motor of the SW.

B. Electrical Structure

In this section, the process of defining each component of the SW's electrical system will be demonstrated. At the beginning, all the required functions of the SW will be reviewed, as mentioned in Table I. It has begun by selecting each necessary device, sensor, kit, or board to perform a specific task within the SW. Next, the quantity and types of digital inputs, digital outputs, analog inputs, analog outputs, and communication connections within the SW have been determined. Due to the large number of inputs and outputs and our consideration of cost, the Arduino Mega Board has been selected as the controller for the SW. Given the high number of inputs and outputs, it has been determined that two Arduino Mega Boards would meet our requirements.

1) Schematic overview. Once all the necessary devices for the SW have been defined, including motors, sensors, kits, and boards, then their electrical power supply and connections can be specified. As previously mentioned, the large number of inputs and outputs necessitated the use of two Arduino Mega boards in the electrical system of the SW. The electrical system has been separated into two primary sections, each utilizing one Arduino Mega board. The first section collects all signals related to the SW's operating devices and sends the necessary electrical power to the motors, while the second section primarily collects signals from lifecare sensors. The first side, known as the Control side, controls and operates the SW, while the second side, known as the Data Acquisition (DAQ) side, communicates with the PC to process and display all the collected signals on the GUI. Serial communication connects both sides, enabling communication between them. The electrical schematic diagram of the SW is shown in Fig. 4, and the Control and DAQ sides will be described in the next section.

2) Control interface circuit board. As previously mentioned, the control side of the SW's electrical system primarily relies on the first Arduino Mega Board, also known as the Control Arduino Mega Board. The mediator between the Control Arduino Mega Board and the other devices is the Control Interface Circuit Board. The Control Interface Circuit Board is responsible for managing the input signals from the joystick, dashboard, RC board, proximity sensor for speed measurement, voltage sensors, and current sensors. It also provides a free terminal block that serves as an additional control port. Additionally, it facilitates communication with the SR Kit, manages the output signal for the buzzer, and communicates to the DAQ Interface Circuit Board. The board also serves as an interface between the Arduino Mega Board and the motor driver boards, ensuring that the motors receive the necessary electrical power based on the output signal from the Arduino Mega Board. The electrical system contains two motor driver boards, and each board can handle two different motors. The Control Interface Circuit Board provides all the electrical supply to all the devices and subsystems in the SW. The real connections and interface of the Control Interface Circuit Board, the Arduino Mega Board, the RC board, and the motor driver boards are shown in Fig. 5.

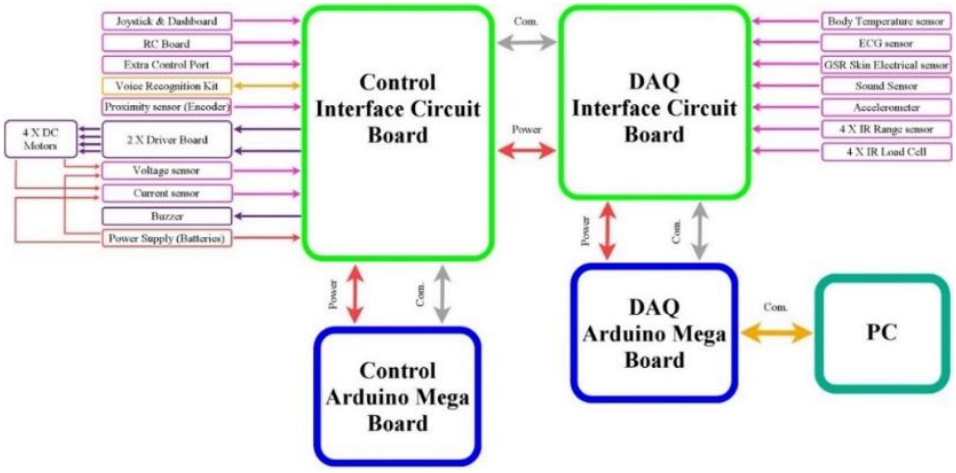

Fig. 4. The electrical schematic diagram of the SW.

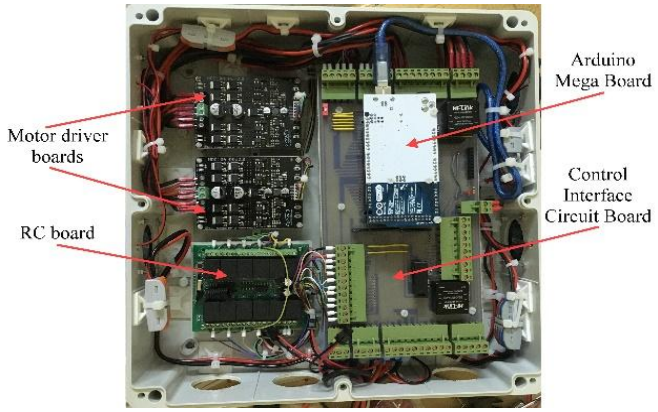

Fig. 5. The Control Interface Circuit Board, the Arduino Mega Board, the RC board, and the motor driver boards.

3) DAQ Interface Circuit Board. The DAQ side, the second side of the SW's electrical system, houses the second Arduino Mega Board, also known as the DAQ Arduino Mega Board. The Control Interface Circuit Board supplies electrical power to the DAQ Interface Circuit Board, which then distributes the necessary power to the connected devices. The DAQ Interface Circuit Board is organizing the analog inputs from the body temperature sensor, ECG sensor, GSR sensor, sound sensor, Accelerometer, IR range sensors, and Load Cells. Also, it is managing serial communication with the Control Interface Circuit Board. The board also contains the required signal conditioning circuits for the connected devices, sensors, and boards. In addition to the DAQ Interface Circuit Board, it contains the electric power filters and regulators to supply each device, sensor, and board connected to it with the required input voltage based on its datasheet. So, it contains the connection pins for the Control Arduino Mega Board. The implemented connection with the DAQ Interface Circuit Board, ECG board, GSR board, sound sensor, Accelerometer, and the Arduino Mega Board is shown in Fig. 6.

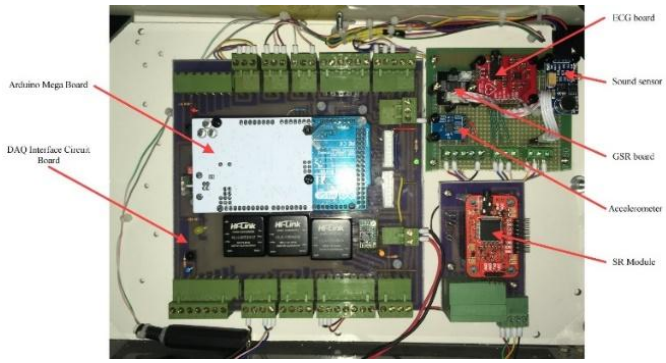

Fig. 6. The DAQ Interface Circuit Board, ECG board, GSR board, sound sensor, Accelerometer, the Arduino Mega Board, and the SR Module.

V. Operation and Hardware

This section will discuss various methods for controlling the SW, as well as the various options integrated into it to enhance its functionality. The goal is to increase the user's comfort by adding useful functions that will make their life easier. Additionally, the hardware utilized to implement these functions in the aforementioned SW will be discussed.

A. Operation Methods of Wheelchair

Here, the techniques used to drive and operate the SW will be discussed, as well as how the user can activate and deactivate some of its features.

1) Voice commands control. The wheelchair has incorporated a speech recognition system to broaden its user base. This system enables individuals with upper limb issues or poor hand control to navigate the necessary area independently, eliminating the need for assistance. Based on the user's voice input, the speech recognition system sends commands to the SW's controller, which then uses these commands to control the wheelchair's movements. The user's voice served as the training source for the speech recognition system.

2) Manual control. The PW's main feature is the normal manual control, which uses a joystick to allow the user to navigate the area and move the wheelchair. The joystick control incorporates a dashboard with functional buttons to provide the user with additional options and assistance during operation. The dashboard includes buttons for various functions, including an emergency button for stopping the SW in emergency situations, a speed control button for adjusting its speed, a voice command operation button for enabling and disabling, and a button for turning on and off the alarm.

3) Wireless remote control. The SW now includes a wireless remote control to simplify operation and control for the user's helper. Additionally, regular users can utilize the wireless remote control if they prefer not to use the traditional manual control with a joystick while resting their hands on their thighs. The wireless remote control is equipped with several buttons that perform the same functions as the manual joystick and dashboard, including wheelchair movement, speed control, and activation and deactivation of certain SW functions.

B. Healthcare and Vital Signs Monitoring

The wheelchair feels like a close friend to its user. Individuals who are handicapped, elderly, experience difficulty in their lower limbs, or sustain injuries depend on their wheelchair for their daily activities. Users spend most of their time using the wheelchair for navigation, reaching specific locations, assisting with tasks, or enjoying meals. Therefore, adding more options to the wheelchair will enhance its users' happiness, satisfaction, and self-confidence. It has implemented and integrated a Vital Signs Monitoring system with the aforementioned SW to monitor the user's vital signs and provide an indication if any of them are not functioning well. The SW's controller sends all measured signals to the PC for display on the GUI. Fig. 7 shows the implemented GUI of the healthcare system for the SW, which contains a live display of the user's body temperature, GSR, and ECG readings.

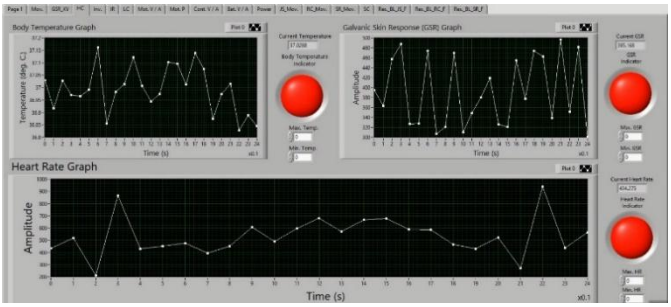

Fig. 7. The implemented GUI of the healthcare system for the SW.

1) Body temperature monitoring. The SW incorporates a body temperature sensor to measure the user's body temperature, which is a crucial indicator of their health condition. The sensor used to measure the body temperature is an NTC thermistor, specifically designed to measure 2.25K ohms at 25 degrees Celsius. A voltage divider circuit has been designed to measure the resistance change of the body temperature sensor, reflecting the body temperature, and send its output to the wheelchair controller. The Vital Signs GUI plots and displays the body temperature and other vital signs, incorporating upper and lower limits that can trigger an indicator if the measured signal exceeds these limits.

2) ECG monitoring. The ECG signal is a good indicator of the user's heart activity. The ECG monitoring system consists of three electrode pads that can be stuck to the user's chest to transfer the ECG signals to the ECG sensor kit, which converts them to an analog signal to be sent to the controller board of the SW. Then the received signals are being processed and sent to the PC that has the GUI of the ECG monitoring to display a live situation of the ECG of the user.

3) GSR monitoring. The SW integrates a GSR sensor to monitor the user's emotions. The concept of a GSR sensor relies on the user's emotional sweating. As the user's emotions fluctuate, the amount of sweat they secrete alters, influencing the conductivity between two fingers in their hand. This change in conductivity leads to a corresponding change in the resistance between the two fingers. This change has been measured, which refers to the emotional status of the user, by connecting two electrodes to two different fingers on the user's hand and measuring the resistance between them by using a GSR sensor board, and then the analog signal is sent to the controller of the SW. The SW's controller transmits the processed sensor signal to the PC for monitoring via the GSR's GUI.

C. Safety Implementation

As the safety level of the SW increases, the user will experience greater satisfaction during use, thereby elevating their morale. The SW has integrated an obstacle avoidance system. While the product is designed to assist individuals with disabilities in using and operating the wheelchair, it would be beneficial to provide them with awareness notifications while they are operating the SW. Moreover, the use of voice commands for wheelchair operation by individuals with disabilities leads to an increase in accidents and a decrease in user safety and satisfaction. Therefore, incorporating an obstacle avoidance system into our SW is crucial. The integrated Obstacle Avoidance System in the SW employs four IR sensors, positioned on the front, rear, right, and left sides of the wheelchair, to detect any obstacles in its vicinity. The Obstacle Avoidance System halts the SW's movement if any of its four sensors detects an obstacle in its path. It will continue to operate in this direction until the obstacle moves and the user commands it to continue. The signals from the four sensors of the Obstacle Avoidance System are given the utmost priority in the program structure of the SW's controller, thereby reducing delays, waiting times, and stoppages, thereby enhancing user safety.

VI. PID Control Design for SW

While the linear speed of the SW is one of the important factors that affect the user's safety and satisfaction, a PID control has been implemented to sustain the speed of the SW. The design of the PID controller has started by finding the transfer function of the used motor. The following section outlines the process of determining the transfer function of the DC motor for use in speed control of the SW. Fig. 8 shows the equivalent circuit of the DC motor that was used to figure out the transfer function.

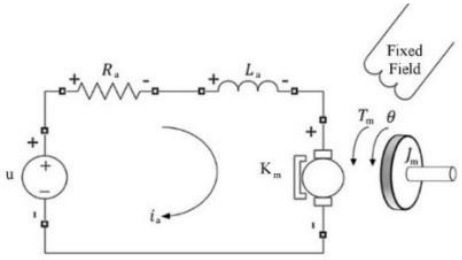

Fig. 8. The equivalent circuit of the DC motor [32].

where,

- Jm is the moment of inertia of the rotor (Kg.m2).
- C is the motor viscous friction constant (N.m.s).
- Km is the motor torque constant and the back emf constant (N.m/A), and (V/rad.sec-1).
- Ra is the electric resistance of the coil (Ohm).
- La is the electric inductance of the coil (H).
- θ is the angular displacement of shaft in radians (rad).
- ω is the angular velocity of shaft (rad/s).
- ia is the armature current (A).
- u is the armature voltage (V).
- Tm is the motor torque (N.m).

The relation between the back emf and the angular velocity and the relation between the armature voltage and the back emf voltage can be defined based on Kirchhoff's voltage law. Also, the relationship between the motor torque and the armature current too. In addition, the motor torque based on Newton's 2nd law and applying the Laplace transformation, the relation between the input voltage and the output angular velocity can be defined as shown in Eq. (13):

$$\frac{\Omega(s)}{U(s)} = \frac{K_m}{L_a J_m s^2 + (L_a C + R_a J_m)s + R_a C + K_m{}^2} = \frac{K_m}{(J_m s + C)(L_a s + R_a) + K_m{}^2} \quad (13)$$

By substituting at the transfer function of the DC motor of the SW [Eq. (13)] with the values of the parameters of the system (J_m, C, K_m, R_a, and L_a) as the below values:

$$J_m = 9.19 * 10^{-4} \quad \text{Kg.m2}$$

$$C = 9.19 * 10^{-5} \quad \text{N.m.s}$$

$$K_m = 0.75 \quad \text{(N.m/A), and (V/rad.sec-1)}$$

$$R_a = 3 \quad \text{Ohm}$$

$$L_a = 0.1 \quad \text{H}$$

The open-loop transfer function of the DC motor of the SW will be as shown in Eq. (14):

$$\frac{\Omega(s)}{U(s)} = \frac{0.75}{0.0000919s^2 + 0.00276619s + 0.5627757} \quad (14)$$

Using the system's open-loop transfer function in Eq. (14), Fig. 9 shows the system's output prior to the addition of the PID controller. However, there is an overshoot of about 53.8% from the input value, and the system could not achieve the required value.

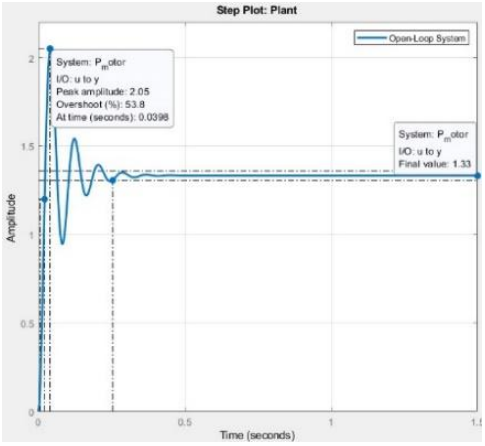

Fig. 9. The open-loop system response without the PID controller.

Fig. 10, illustrates the addition of a PID controller to enhance the system's output response. Also, the tuning was done using the PID Tuner function in MATLAB software. This is an automatic tuning function based on a proprietary tuning algorithm that uses a model-based tuning technique to set the PID controller parameters as: K_p = 0.1181, K_i = 5.2143, and K_d = 6.6921*10^{-4}.

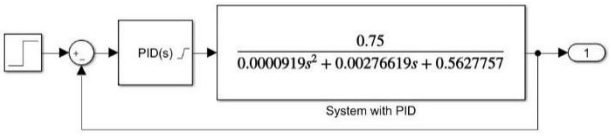

Fig. 10. The closed-loop system with the PID controller.

The addition of the PID controller to the system, as illustrated in Fig. 11, has improved the system's output response. Furthermore, the system could achieve the required value with a Rise time of 0.342 seconds and a Settling time of 0.615 seconds.

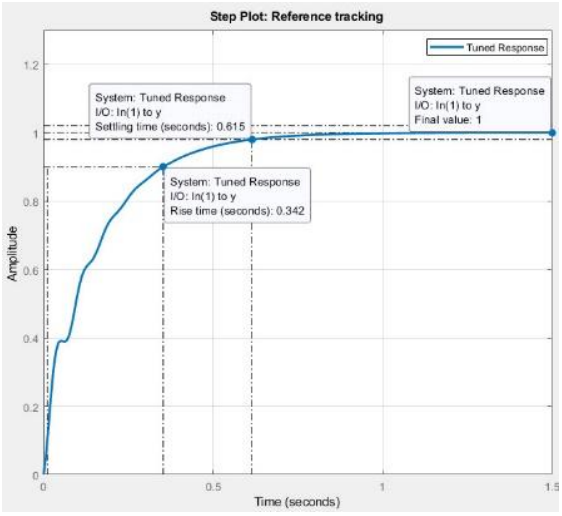

Fig. 11. The closed-loop system response with the PID controller.

VII. Results

A fixed response from the wheelchair impacts the user's satisfaction, subsequently influencing their morale. Ten trials were done to see how the wheelchair responded to step input from the SW operation device in a variety of situations, as shown in Table II. The goal was to make sure the controller worked properly after the tuning process. The main idea of the trials is to have a comparison of the implemented wheelchair response without using the PID controller and with using the PID controller to be able to figure out the change in the response during different situations that can happen for the wheelchair during normal usage. Trials one and two involved hanging the SW and moving its wheels without contacting the floor. And trial number three and four were based on moving the SW on the floor without any payload. And trials numbers five and six were based on moving the SW on the floor with a payload. And trial number seven and eight were based on moving the SW on a ramp that has the standard specs for the wheelchair ramps with a slope by ramp height of 1:8.2 and incline angle of 7 degrees without any payload, as shown in Fig. 12. And trial number nine and ten were based on moving the SW on the mentioned ramp previously with a payload.

TABLE II. The Trials and their Descriptions

Trial No.	Description
1	Move the SW while hanging without the PID controller
2	Move the SW while hanging with the PID controller
3	Move the SW on the floor without a payload without the PID controller
4	Move the SW on the floor without a payload with the PID controller
5	Move the SW on the floor with a payload without the PID controller
6	Move the SW on the floor with a payload with the PID controller
7	Move the SW on the ramp without a payload without the PID controller
8	Move the SW on the ramp without a payload with the PID controller
9	Move the SW on the ramp with a payload without the PID controller
10	Move the SW on the ramp with a payload with the PID controller

Fig. 12. The SW on a wheelchair ramp with standard specs.

Fig. 13 shows a good comparison by using the average of each speed reading for the trials from 1 to 6 under their conditions, while considering their steady state without and with the PID controller. The black curve of each graph shows the step input for the SW with a set value of 0.23 m/s. As shown in Fig. 13(a) for trials 1, 3, and 5, the SW system responded to the conditions that have been discussed earlier without using a PID controller. Some trials had overshoot, meaning that most had a high steady-state error, even though the settling time values varied. Fig. 13(b) illustrates the response of the SW system for trials 2, 4, and 6 under the previously mentioned conditions, utilizing a PID controller, exhibiting minimal overshoot, reduced steady-state error, and varying settling time values. It has also been noticed that the damping of the SW system is increasing with the increase of the load, and this phenomenon is a normal behavior for the system.

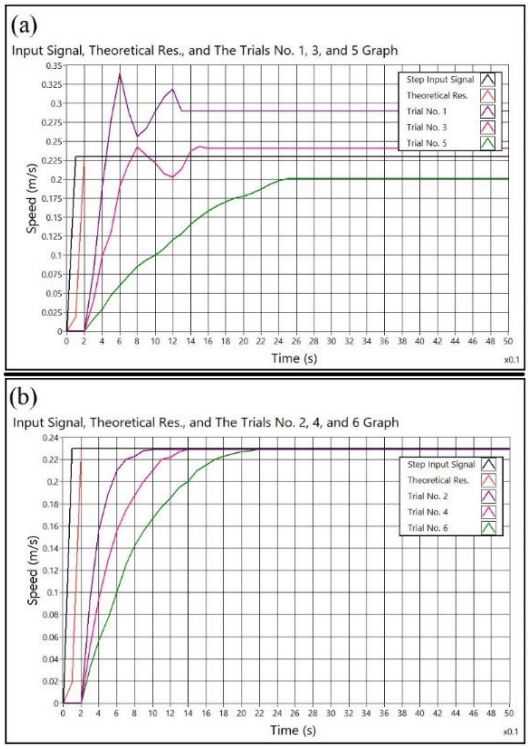

Fig. 13. Results graphs of the trials from 1 to 6 in response to the step input by using the average speed of each trial: a) Results graph for trials 1, 3, and 5 while not using a PID controller; b) Results graph for trials 2, 4, and 6 while using a PID controller.

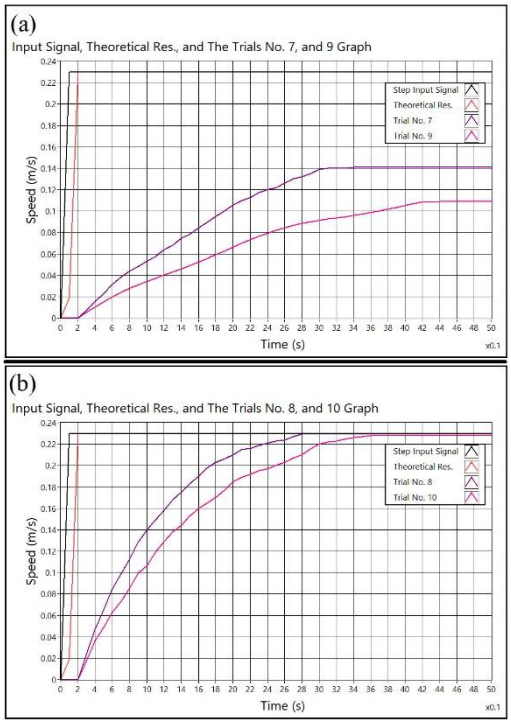

Fig. 14. Results graphs of the trials from 7 to 10 on the wheelchair ramp in response to the step input by using the average speed of each trial: a) Results graph for trials 7 and 9 while not using a PID controller; b) Results graph for trials 8 and 10 while using a PID controller.

Fig. 14 shows the output graphs for trials 7 to 10, comparing the average speed readings with and without the PID controller on the wheelchair ramp. In Fig. 14(a), trials 7 and 9 show that as the load increases, the SW's damping increases, leading to a higher steady-state error for the SW when the PID controller is not used, which is not acceptable performance. Fig. 14(b) depicts the response of the SW system during trials 8 and 10, demonstrating an increase in damping as the load increases. The PID controller's efforts are evident as it improves the steady-state error of the SW system and maintains the set value.

Table III summarizes the outcomes of all the trials conducted for the SW, both with and without the PID controller, under various scenarios that may arise during normal wheelchair usage, in response to a step input with a set value of 0.23 m/s. The results indicate that there are overshoot values when the system operates without the PID controller, with a maximum percentage of 47.51% under specific conditions, and no overshoot when the PID controller is used. In addition to using the SW system without the PID controller, which gives a high steady-state error with a maximum percentage of 52.60% under certain conditions, using the SW system with the PID controller produces a very low steady-state error with a maximum percentage of 0.81% under certain conditions. Moreover, using the SW with the PID controller shows an improved settling time compared to using the SW without the PID controller. Under certain conditions, the maximum settling time for the SW with the PID controller is 2.93 s, while the maximum settling time for the SW without the PID controller is 3.91 s. Additionally, as the load increases, the damping ratio of the SW system also increases.

TABLE III. THE RESULTS OF ALL THE TRIALS

Criteria No.	T1	T2	T3	T4	T5	T6	T7	T8	T9	T10
Overshoot (%)	47.51	0	5.78	0	0	0	0	0	0	0
Steady-State Error (%)	26.09	0.57	4.47	0.36	12.61	0.2	38.66	0.34	52.6	0.81
Settling Time (s)	1.25	0.67	1.36	1.08	2.27	1.66	2.87	2.27	3.91	2.93
Damping Ratio	0.51	1.28	0.81	1.52	1.2	1.78	1.5	2.05	2	2.31
Step Input Set Value (m/s)	0.23									

VIII. CONCLUSION AND FUTURE WORK

Feeling more independent and safe boosts the wheelchair user's morale, which in turn improves their health condition and lessens the burden on their helper. Our solution effectively integrates traditional joystick control with voice command functionality and wireless remote control, providing improved accessibility and autonomy for users. Furthermore, using the integrated vital signs monitoring system provides live data about the user's health, which enhances user health management. Combining an obstacle avoidance system with our SW increases the user's safety. Additionally, the results of a comparison between using the normal control system and the PID control system while operating the implemented SW in different situations can be observed for the wheelchair during normal usage, which has proved an improvement for the wheelchair's response and stability, thereby increasing user satisfaction. While the trials have proved that using the PID controller with $K_p = 0.1181$, $K_i = 5.2143$, and $K_d = 6.6921*10^{-4}$ has eliminated the overshoot of the system from 47.51%. In addition, decreasing the steady-state error percentage from 52.60% to 0.81% as a maximum also improved the settling time from 3.91 s to 2.93 s as a maximum compared to using the normal control system to operate the SW. Adding the PID controller to the SW has improved its performance and stability.

The findings of our study illustrate the advantages of integrating the PID controller while using hybrid and combined control systems in assistive devices, focusing on their capacity to improve the lives of handicapped people. The full calculations for motor selection for our SW have been illustrated, which is also very useful during the design of any mobile robot. Our hybrid-controlled SW signifies an important advancement in assistive technology, providing improved mobility and health monitoring. Keep improving in such a field; it plays a significant role in improving the quality of life for users.

Since this study is just the beginning, several more studies can be conducted in the future. These include replacing the wheelchair's traditional wheels with Mecanum wheels. New healthcare sensors and devices can be added to provide more details about the user's health, such as blood pressure, breathing rate, and so on. Improve the GUI for healthcare monitoring to include the readings from the new sensors and devices. The system stores the collected data in a database for the doctor's analysis. The system can send alarms about the user's health status through Short Message Service (SMS) if it's an urgent matter, and it can also send a daily report via email to the doctor.

Shandong University, Jinan 250100, China[1]
School of Labor Relations, Shandong Management University, Jinan 250357, China[2]

***Abstract*—In recent years, the rapid development of educational informatization and the widespread adoption of Internet of Things (IoT) technologies have accelerated the transformation of university laboratories toward intelligent management. However, traditional laboratory management systems still suffer from limited automation, insufficient safety mechanisms, and poor real-time responsiveness. To address these issues, this study proposes an intelligent laboratory management system based on Ultra-Wideband (UWB) technology, which offers high-precision positioning and low-latency communication. The proposed system integrates IoT-based functionalities across six core modules, including access control, asset management, environmental monitoring, and user management. By deploying UWB tags and sensors throughout the laboratory environment, the system enables real-time tracking of personnel and equipment, automatic activation of laboratory devices, and intelligent safety alerts. A pilot deployment in three university laboratories demonstrated improvements in access efficiency, energy conservation, equipment security, and user satisfaction. The results validate the system's effectiveness in enhancing intelligent laboratory management and provide a scalable model for future smart educational infrastructure.**

***Keywords*—UWB; intelligent management; laboratory management system; IoT**

I. Introduction

Laboratories are a critical component of higher education institutions, serving as essential venues for transforming theoretical knowledge acquired in the classroom into practical skills. They play a vital role in cultivating students' hands-on abilities and fostering innovation. As the core infrastructure for practical teaching, the quality of laboratory hardware and software construction directly influences the effectiveness of talent development. Enhancing equipment configuration and implementing intelligent management systems are fundamental for building world-class universities and maintaining educational competitiveness.

With the rapid advancement of educational informatization and the increasing integration of the IoT, universities are transitioning towards intelligent laboratory environments. These environments aim to provide secure, efficient, and automated support for teaching and experimentation. While technologies such as RFID, Bluetooth Low Energy (BLE), and Wi-Fi have been explored for functions like access control, equipment tracking, and environmental monitoring, existing systems often operate in isolation, lack real-time responsiveness, and suffer from accuracy and reliability issues. Many laboratories continue to rely on traditional management methods, which are inefficient and prone to human error.

Although various technologies have been applied in laboratory management, most existing solutions remain fragmented and fail to offer integrated, real-time control across personnel, assets, and environmental variables. Moreover, the potential of UWB technology—a wireless communication protocol known for its high-precision positioning and robustness against interference—has not been fully leveraged in comprehensive university laboratory management systems. This study aims to address this research gap by proposing and implementing a UWB-based intelligent laboratory management system that unifies access control, asset tracking, environmental linkage, and safety monitoring under a centralized IoT architecture.

The remainder of this study is organized as follows: Section II reviews related works on laboratory management systems and the application of positioning technologies. Section III outlines the current challenges in university laboratory environments. Section IV describes the design and architecture of the proposed UWB-based intelligent laboratory management system, including hardware and software components. Section V presents the implementation, and Section VI presents the pilot deployment of the system in three university laboratories, along with observed effectiveness. Section VII discusses the results and limitations. Section VIII concludes the study and outlines directions for future research.

II. Related Work

A. Laboratory Management Systems

With the increasing demand for efficiency and safety in laboratory operations, various digital laboratory management systems have been developed. Traditional approaches often rely on QR code scanning, RFID tags, or BLE beacons to manage asset inventory and personnel access. While these systems offer partial automation, they are limited by factors such as short detection range, interference susceptibility, and a lack of real-time integration [1]. Additionally, many systems operate in isolation, with fragmented control over equipment, environmental conditions, and user access.

B. Indoor Positioning Technologies

Accurate indoor positioning is critical for enabling real-time management functions in smart laboratories. Technologies such as Wi-Fi, RFID, and BLE have been widely studied and implemented. However, their performance in complex indoor environments is often degraded due to signal attenuation, multipath effects, and limited spatial resolution. In contrast, UWB technology provides centimeter-level positioning accuracy, low latency, and robust resistance to interference. According to recent studies, UWB is increasingly adopted in indoor real-time location systems (RTLS), making it a promising alternative for precise device and personnel tracking in enclosed environments [2].

C. Integrated IoT-Based Smart Systems

The integration of IoT technologies has expanded the capabilities of laboratory management, allowing for centralized monitoring and control of diverse systems such as access control, lighting, environmental sensing, and equipment usage. Prior research has explored IoT frameworks applied to educational or industrial laboratories, but many of these solutions are limited to single-function implementations, such as environmental monitoring or smart lighting. Few studies have successfully implemented a comprehensive system that integrates access control, environmental regulation, asset tracking, and safety alerting within a unified smart platform [3].

D. Research Gap

Although UWB and IoT technologies have been individually applied in laboratory and industrial contexts, the combination of these technologies into a unified, intelligent laboratory management platform remains underexplored. Existing systems often lack integrated architecture and fail to leverage the high-precision capabilities of UWB for dynamic spatial control and automation. This study aims to address this gap by designing and implementing a fully integrated laboratory management system that utilizes UWB and IoT technologies to enhance laboratory efficiency, safety, and user experience in a university environment [4].

III. Current Status and Challenges in the Intelligent Development of University Laboratories

However, laboratory management in universities still faces several challenges:

a) Inconvenient and inefficient access control: Most current access control systems rely on password verification, card-based identification, or biometric authentication. These methods present issues such as complex information input procedures, password leakage risks, and card loss. Although biometrics enhance security, limitations in recognition algorithms and accuracy often necessitate secondary verification via passwords or cards, negatively impacting user experience [5].

b) Lack of real-time and efficient asset management: Current asset management systems in university laboratories mainly depend on QR codes, RFID, or BLE technologies. QR codes require close-range scanning, RFID suffers from limited precision and high costs, while BLE offers longer-range detection but is vulnerable to signal interference. These traditional methods fall short in supporting real-time tracking and intelligent monitoring of laboratory equipment [6].

c) Limited intelligent management capabilities: Due to limited personnel, many universities have adopted basic intelligent control systems, such as automated lighting and HVAC (Heating, Ventilation, and Air Conditioning). However, these systems often operate in a static or rigid manner, lacking the ability to dynamically adjust based on actual usage scenarios, which limits energy efficiency and overall effectiveness [7].

d) Inadequate safety management mechanisms: Many laboratories lack effective early-warning and safety alert mechanisms. Real-time monitoring of personnel is often absent, and the systems are unable to prevent unauthorized individuals from entering high-risk areas, posing potential safety hazards [8].

To address the aforementioned challenges, this study proposes an intelligent laboratory management system based on UWB technology, leveraging its high-precision positioning and high-speed data transmission capabilities. In terms of access control, the system enables precise management of personnel entry by allowing only individuals carrying authorized UWB tags to access the laboratory. For asset management, UWB tags are affixed to valuable equipment, enabling the system to track the real-time location and usage trajectory of devices, thereby preventing misplacement or loss and enhancing asset security. In intelligent management, real-time acquisition of personnel and equipment location data through UWB technology facilitates the optimization of spatial layout and intelligent resource scheduling, significantly improving management efficiency and space utilization.

IV. Design of an Intelligent Laboratory Management System based on UWB Technology

A. UWB Technology

UWB is a short-range, high-bandwidth wireless communication technology that transmits information by emitting very short-duration pulses over a wide frequency spectrum, typically ranging from 3.1 GHz to 10.6 GHz. Unlike conventional narrowband systems, UWB does not rely on a continuous carrier wave, allowing it to achieve exceptionally high time-domain resolution [9].

UWB is particularly well-suited for applications requiring high-precision positioning, low latency, and low power consumption. It offers centimeter-level accuracy in distance measurement, making it ideal for RTLS, indoor positioning, access control, and asset tracking. The technology is inherently resistant to multipath interference and can penetrate non-metallic obstacles such as walls or furniture, ensuring robust performance in complex indoor environments [10].

Advanced UWB systems support various positioning techniques, including Time of Flight (ToF), Time Difference of Arrival (TDoA), and Angle of Arrival (AoA). These capabilities enable 3D spatial tracking and secure ranging, and are increasingly integrated into IoT devices, smartphones, and industrial systems.

Driven by standardization efforts (e.g., IEEE 802.15.4z) and growing industry adoption, UWB is emerging as a key enabling technology for intelligent environments, including smart homes, smart factories, and smart laboratories.

B. Performance Comparison Between UWB and Mainstream Wireless Positioning Technologies

Mainstream wireless positioning technologies currently include UWB, BLE, Wi-Fi, and RFID. UWB offers superior ranging accuracy, strong anti-interference performance, and low power consumption, making it particularly suitable for high-precision scenarios such as access control and equipment tracking.

In terms of positioning accuracy, both UWB and RFID perform well; however, RFID lacks real-time tracking capabilities. When access control systems are based on BLE, Wi-Fi, or RFID, their limited accuracy and latency may lead to false unlocking events. In contrast, systems using NFC cards or smartphones require users to bring the device into close proximity with the reader, which reduces operational convenience [11].

C. System Architecture Design

Based on the characteristics of UWB technology and the requirements of laboratory management, the proposed system adopts a layered architecture consisting of four levels: the device layer, communication layer, platform layer, and application layer.

The device layer is responsible for the deployment and operation of equipment within the laboratory. It collects device status and environmental data while supporting various intelligent functions. This layer includes subsystems such as UWB-based access control, UWB ranging, environmental monitoring, smart lighting, smart air conditioning, and smart sockets [12].

The communication layer enables data transmission between devices and the platform. It supports both wireless and wired network connections, as well as IoT protocols. To enhance the efficiency and reliability of data transmission, this layer incorporates IoT gateways and edge gateways for transmission optimization.

The platform layer serves as the core functional component of the system. It includes modules for access control management, device management, environmental monitoring, user management, data acquisition and storage, real-time safety monitoring, system configuration, and integration interfaces. This layer relies on a private IoT cloud to enable centralized data processing and management. It also provides API interfaces, message queues, notification services, and protocol support [13].

The application layer delivers interactive interfaces and application functions for end users. It supports multiple user terminals, including PC clients, mobile apps, dashboards, voice assistants, and notification services. Users can monitor the laboratory in real time, manage devices, and perform security control operations through these interfaces. The overall system architecture is illustrated in Fig. 1.

D. System Operation Flow Design

The access control system is a key module within the intelligent laboratory management system. Leveraging UWB's high-precision positioning and ranging capabilities, it not only serves as the first line of defense for laboratory safety but also functions as a trigger point for other system operations. Through accurate identity authentication and permission control, the access control system ensures laboratory security while enabling the coordinated activation of devices and environmental regulation. As such, the access control module is a critical focus of the system design [14]. The operational flow of access control is illustrated in Fig. 2.

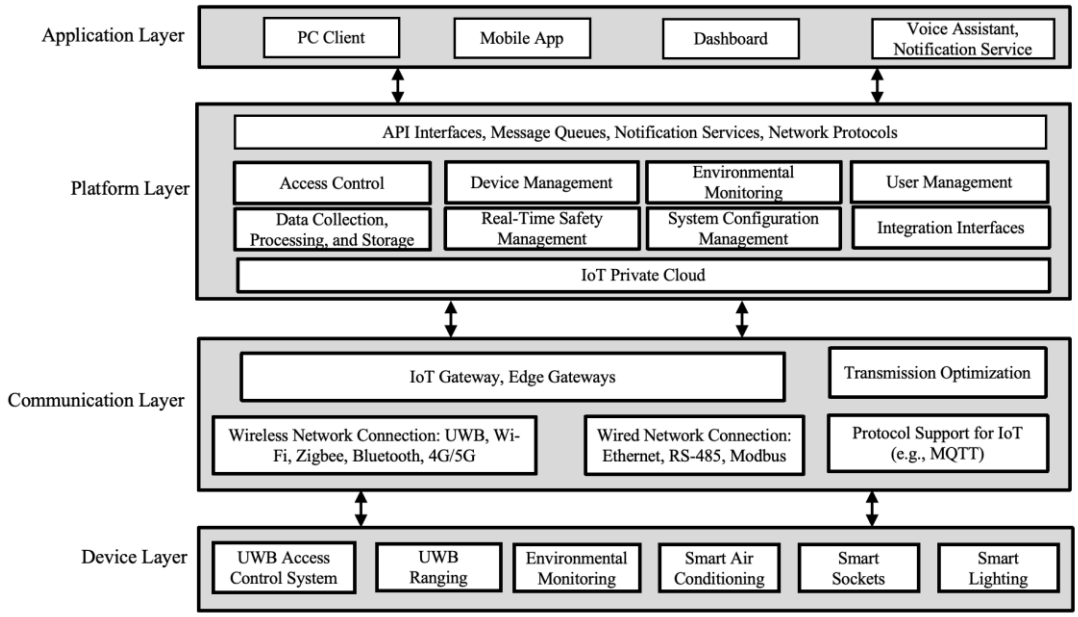

Fig. 1. System architecture of the UWB-based intelligent laboratory management system.

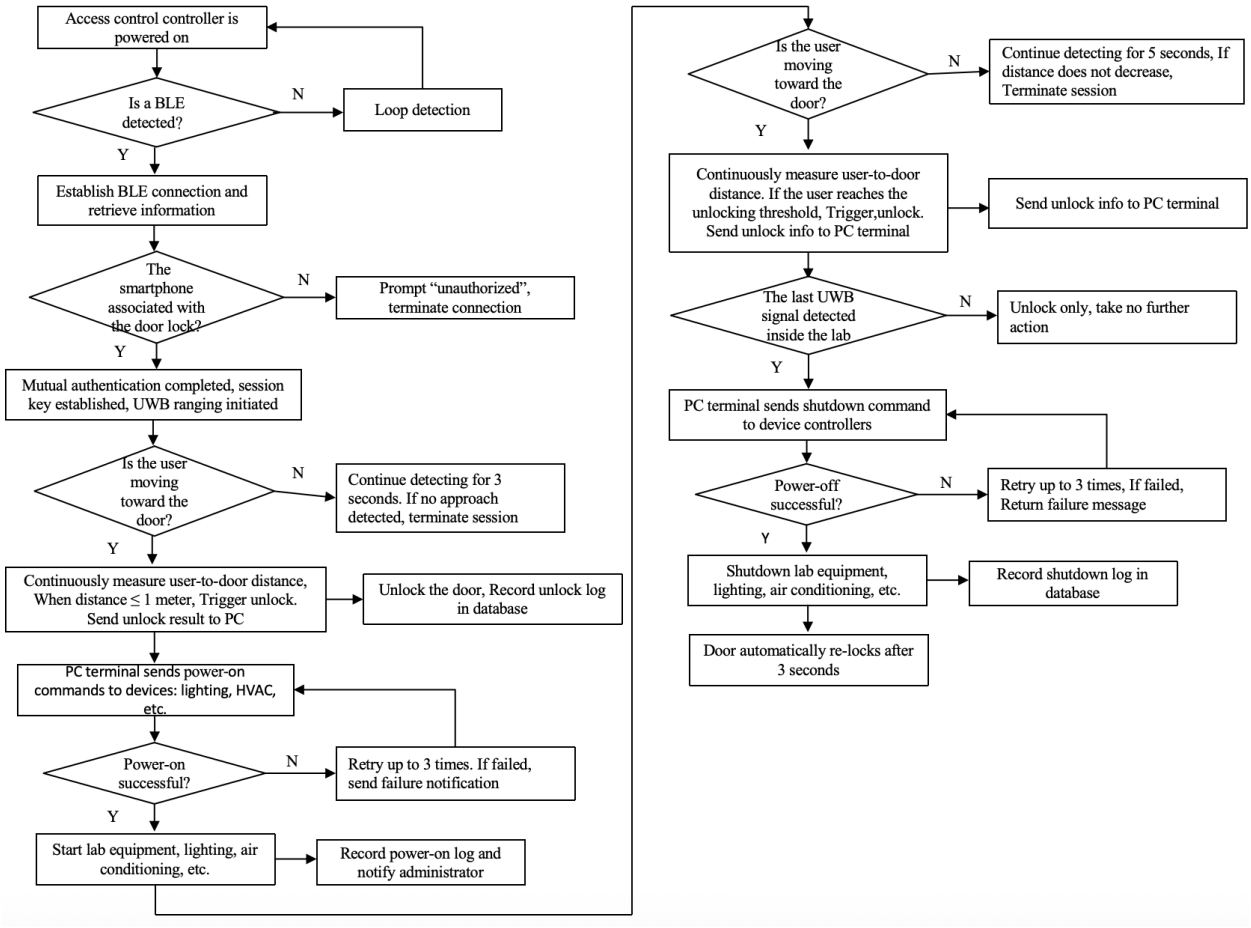

Fig. 2. Access control lock or unlock workflow diagram.

a) Initialization and connection phase: Upon power-up, the access control controller enters working mode and continuously scans for BLE broadcasts from smartphones or signals from UWB tags. If a valid signal is detected, the system establishes a BLE connection and reads relevant information from the smartphone. If no signal is found, the system continues to loop in scanning mode [15].

Subsequently, the controller queries the access rights stored in the database to determine whether the device is authorized. If not associated, the system returns an "unauthorized" message and terminates the connection. If authorization is confirmed, mutual authentication is performed, a session key is established, and UWB ranging is initiated.

b) Ranging phase: The system uses UWB ranging to assess the user's motion status, specifically whether the user is approaching the door. If not, the system continues monitoring for 3 seconds. If the distance to the door does not decrease, the session is closed. If the user is walking toward the door, the system continues to measure the distance. When the user reaches the threshold distance (one meter), the system issues an unlock command, opens the door lock, and sends an unlock log to the central PC terminal [16, 17]. Simultaneously, it sends power-on commands to device power controllers, entrance lighting, and HVAC systems.

c) Door opening and device activation phase: After sending the power-on commands, the system verifies whether power-on is successful. If the command fails 3 consecutive times, a startup failure message is returned. If successful, it activates the lab equipment power, lighting, and air conditioning. Power-on logs are recorded in the database, and push notifications are sent to the administrator. The door unlocking action is also logged and notified accordingly [18].

d) Exit and device shutdown phase: After the user enters the lab and the door is closed, the system resumes tracking the user's movement. If the user moves toward the door from the inside and reaches the defined threshold distance, an unlock signal is triggered and returned to the PC terminal. The system then checks whether this user is the last remaining individual inside the lab. If not, no further action is taken beyond unlocking the door. If the user is identified as the last UWB-tagged user, the PC terminal issues power-off commands to the equipment, lighting, and HVAC controllers. The system then verifies whether the power-off operation is successful. If it fails three consecutive times, a failure message is returned. If successful, all relevant equipment is powered off, and shutdown logs are recorded in the database. Finally, the access system automatically re-locks the door after a three-second delay.

E. Design of other System Functions

a) Intelligent device displacement alarm: In the asset management module, UWB tags are attached to laboratory equipment to enable real-time distance monitoring between the equipment and the UWB ranging devices. When an abnormal change in distance is detected-exceeding a predefined threshold-an alert is triggered by the laboratory's alarm system. This indicates that a device may have been moved or has exited its designated area. The system notifies laboratory staff to take immediate action, effectively preventing unauthorized relocation or theft of valuable assets and ensuring equipment security [19].

The intelligent displacement alarm mechanism is illustrated in Fig. 3.

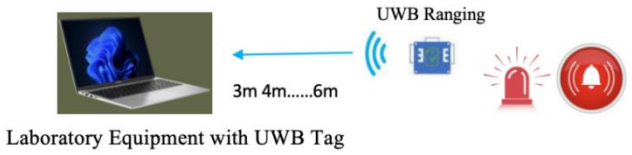

Fig. 3. UWB-based intelligent device displacement alarm.

b) Laboratory environmental linkage: Once the UWB-based access control system successfully unlocks the laboratory door, a series of predefined intelligent linkage mechanisms are triggered. The lighting system is activated and automatically switches to a preset brightness mode. The air conditioning system adjusts temperature and humidity levels based on predefined environmental thresholds.

Simultaneously, the laboratory equipment power management system is activated, initiating the startup of various experimental devices in a specified sequence. This ensures that all necessary equipment is fully operational and ready for subsequent experimental activities.

c) Intelligent zone safety warning: UWB-based ranging technology enables real-time and highly accurate measurement of the distance between personnel and potential hazard zones within the laboratory, such as areas containing high-voltage equipment or hazardous chemicals. When an individual approaches a predefined safety threshold, the system immediately triggers an audible and visual alarm to alert the person and ensure safety by discouraging further proximity to the danger zone. At the same time, a warning notification is sent to laboratory administrators [20, 21].

V. Implementation of the UWB-based Intelligent Laboratory Management System

A. Access Control System Functionality

The access control system is designed to manage the entry and exit of faculty and students in laboratory environments. The UWB controller retrieves device information from users carrying UWB-enabled smartphones or UWB tags and compares it with access authorization data stored in the cloud database. Administrators configure access rights and door operation time windows for each laboratory based on user roles. Authorized students and instructors can enter the laboratory during scheduled class hours simply by carrying their UWB-enabled device and walking towards the laboratory entrance. The UWB controller authenticates the user and performs real-time distance measurements. Once within the threshold range, the door unlocks automatically, enabling seamless, contactless entry. Outside of scheduled lab hours or in restricted laboratory areas, users without valid authorization-regardless of student or faculty status-are denied access by the system.

The data communication process involves interaction between the PC-based control terminal and the UWB controller over the network. This includes ranging operations, command transmission with MAC address binding, adding mobile device addresses to the UWB controller's whitelist, granting access and interaction permissions to mobile terminals, and enabling device-level interaction with the access control controller.

Additionally, the system supports real-time display and monitoring of access events-such as unlock and lock actions-performed by the UWB-based door lock, all visualized on the PC terminal [22, 23].

B. Asset Management Functionality

The asset management module includes daily management, intelligent device displacement alarms, and asset inventory statistics [24].

a) Daily management: Laboratory equipment is registered and linked to corresponding UWB tags. Information such as device identity, borrowing, return, and maintenance records is entered into the asset management system to improve administrative efficiency.

b) Intelligent device displacement alarm: The system periodically scans for UWB tags within the monitoring range. To avoid false alarms caused by transient signal fluctuations, a time tolerance mechanism is employed. An alarm is triggered only when the measured position deviates from the preset threshold-e.g., more than one meter-for a sustained duration exceeding three seconds.

c) Asset inventory statistics: The system automatically scans all UWB-tagged devices within the coverage area to assess their status and usage. By comparing this data with the system's equipment ledger, asset inventory can be completed quickly, significantly reducing manual workload while improving data accuracy and management efficiency.

C. Environmental Monitoring Functionality

The environmental monitoring module includes laboratory environment linkage and intelligent zone safety warnings.

a) Laboratory environment linkage: After the UWB-based access control system unlocks the laboratory, power-on commands are sent to controllers of lighting, air conditioning, and other equipment to initiate startup procedures. Additionally, lighting systems can be dynamically controlled based on a person's proximity to specific zones, enabling automatic switching on or off of designated lights.

b) Intelligent zone safety warning: Similar to the device displacement alarm, this function continuously measures the distance between individuals-carrying UWB tags or UWB-

enabled smartphones-and designated detection base stations. When a person enters a predefined hazardous zone, the system issues real-time audible and visual alerts, while simultaneously notifying administrators.

D. Experiment Management Functionality

The experiment management module includes experimental course management, course scheduling, and reservation services. Experimental course management supports the creation, administration, and publication of experimental content. Course scheduling intelligently arranges experimental sessions based on laboratory resource availability to optimize space utilization and avoid conflicts. The reservation function allows users to book laboratory time and space online according to specific needs, enhancing accessibility and operational efficiency.

E. User Management Functionality

The user management module consists of user information management, permission management, and usage statistics. User information management enables the entry, modification, and maintenance of users' basic data. Permission management allows access rights to be assigned according to user roles-such as administrators, instructors, and students-effectively controlling access to different system functions. Comprehensive usage statistics provide data-driven insights into user behavior and system utilization, supporting informed decision-making in laboratory management.

F. System Management Functionality

The system management module includes system operation settings, data backup, and overall system administration. Operation settings cover configuration items such as system run times, permission rules, and device status monitoring. Data backup ensures the security of critical information, including user records, experimental data, and equipment logs. Comprehensive system administration functions include log management and security policy configuration to maintain system stability and integrity.

VI. System Deployment and Effectiveness

The UWB-based intelligent laboratory management system has entered the pilot stage in the Modern Educational Technology Laboratory. Three representative laboratories were selected for implementation: the Smart Language Teaching Lab, the Interactive Teaching Lab, and the Cross-Cultural VR Training Lab. These labs collectively cover an area of approximately 300 square meters.

A total of 112 experimental devices-including VR headsets, portable workstations, and mobile projectors-were equipped with UWB identification tags. The hardware deployment within a single laboratory is illustrated in Fig. 4.

The upgraded laboratory supports five categories of public English experimental teaching and course projects, including College English Listening and Speaking, Reading and Writing and Translation, English Speech and Debate, and English Interpretation of Traditional Chinese Culture. These courses collectively serve over 1,500 faculty members and students. During the pilot phase, a total of 650 class hours of experimental courses were successfully conducted using the system.

After one and a half years of pilot operation, the system has achieved significant improvements in various aspects, including daily laboratory management, safety, energy efficiency, user experience, and talent development.

a) Daily laboratory management: The system has substantially reduced the workload of laboratory staff. For example, equipment inventory time has decreased from one hour of manual counting to automatic report generation within five minutes.

b) Laboratory safety management: During the trial period, the system successfully identified and recovered two misplaced devices through the displacement alarm function, achieving a 100% equipment security control rate. The UWB-based intelligent zone warning mechanism triggered eleven audible and visual alarms, effectively preventing faculty and students from entering high-voltage danger zones.

c) Energy efficiency and environmental sustainability: The lighting system automatically turns on in occupied areas and off in unoccupied ones. The HVAC system adjusts temperature and humidity based on predefined thresholds, while experimental devices automatically shut down after periods of inactivity. These features have led to a 25% reduction in overall energy consumption, significantly lowering operational costs for the university.

d) User experience: Access efficiency has greatly improved as faculty and students can enter using UWB-enabled smartphones or tags. The average door unlocking response time has decreased from 3 seconds (with traditional access systems) to just 0.5 seconds, achieving a seamless and contactless entry experience.

e) Enhancement of talent development: In 2023 and 2024, the laboratory supported autonomous learning for more than 1,500 students and met the self-directed experimental needs for training and participation in over 10 national-level competitions, including major university contests. This not only maximized the utilization efficiency of experimental equipment but also significantly enhanced students' language application skills and innovative abilities. Over the two-year period, students participating in these competitions achieved outstanding results, winning 81 national first prizes, 116 second prizes, and 325 third prizes.

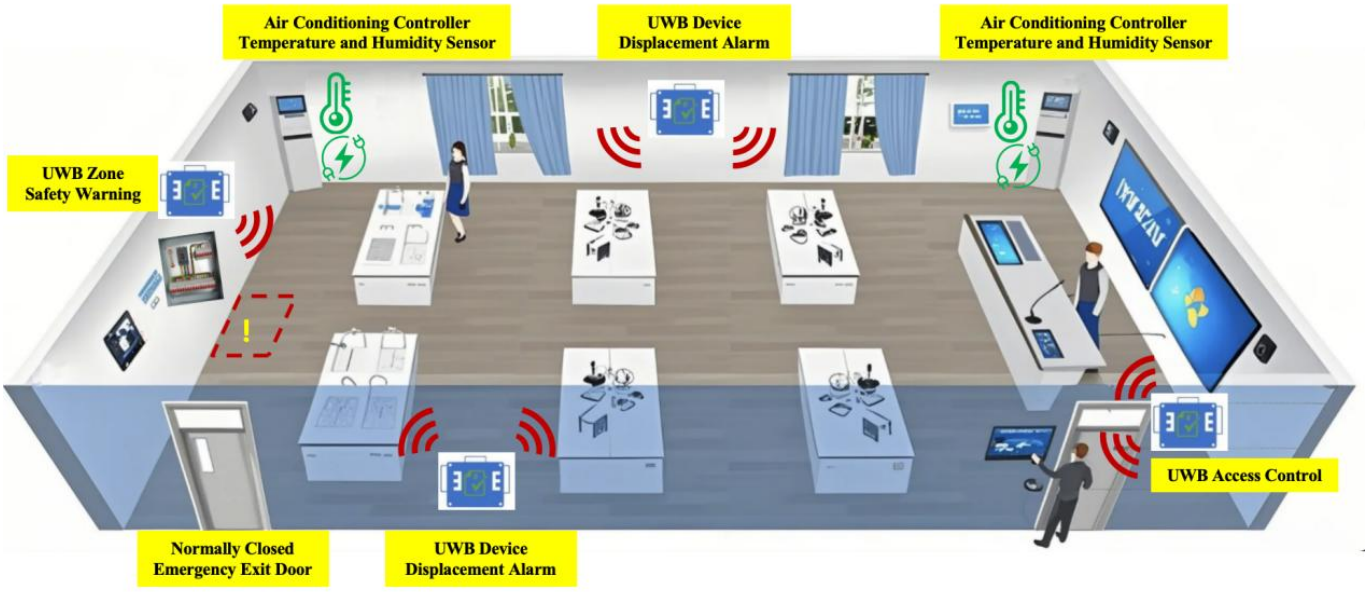

Fig. 4. Hardware deployment inside the intelligent laboratory.

VII. Discussion

A. Interpretation of Results

The deployment results of the UWB-based intelligent laboratory management system demonstrate that it significantly enhances key aspects of laboratory operations, including access efficiency, asset monitoring, energy conservation, and user experience. These improvements can be primarily attributed to the centimeter-level positioning accuracy and real-time tracking capabilities of UWB technology, which enable automated responses and reduce reliance on manual intervention. For example, the drastic reduction in equipment inventory time is a result of continuous UWB-based scanning and automated data logging, while energy efficiency gains stem from dynamic environment control triggered by real-time user proximity detection.

Moreover, the seamless integration of subsystems—access control, environmental regulation, asset tracking, and user management—under a centralized IoT architecture ensures not only operational convenience but also system scalability. This integration offers a holistic solution to the fragmented and disjointed management processes observed in traditional laboratory settings.

B. Comparison with Prior Work

Compared to conventional systems based on QR codes, RFID, or BLE, the proposed solution offers notable advantages in terms of accuracy, responsiveness, and automation. While BLE and RFID technologies are widely used, they often suffer from signal interference, limited range, and imprecise localization. In contrast, UWB supports high-resolution spatial tracking, which allows for intelligent zoning, safe distance monitoring, and more granular control over lab equipment and environmental settings.

Additionally, previous systems typically focus on a single management function, such as access control or environmental sensing. In this study, the integration of multiple modules—including real-time asset displacement alarms and intelligent safety zones—demonstrates how UWB can serve as the technological backbone for a unified smart laboratory framework. This positions the system as an innovative upgrade over existing solutions, with broader applicability in educational and research institutions.

C. Limitations

While the system exhibits promising performance, several limitations should be acknowledged. First, the deployment was limited to three laboratories within a single institution, which may constrain the generalizability of the findings to other settings or disciplines. Second, the evaluation focused primarily on operational efficiency and did not capture longer-term impacts such as cost-effectiveness, maintenance overhead, or learning outcomes. Third, despite its technical advantages, UWB deployment requires specialized hardware, calibration, and higher installation costs, which could pose barriers to adoption in resource-constrained environments. Future research should investigate scalable deployment strategies, integration with AI-driven analytics, and cross-campus interoperability to further enhance system applicability.

VIII. Conclusion

The intelligent laboratory management system based on UWB technology effectively addresses long-standing challenges in university laboratory administration. By leveraging UWB's high-precision positioning capabilities, the system standardizes access control procedures and enables efficient personnel management. Real-time distance data between individuals and equipment supports spatial layout optimization and dynamic resource scheduling, significantly enhancing the level of intelligent laboratory management.

Additionally, the system enables real-time asset tracking and proactive safety alerts through UWB-based detection, establishing a comprehensive security framework that

contributes to the safe and stable operation of laboratory environments.

The intelligent transformation of university laboratories is an ongoing process. In the future, we aim to further explore the integration of UWB with other emerging technologies, continuously refine system functionalities, and enhance system stability and compatibility. These efforts will support broader adoption across interdisciplinary laboratories, deliver higher-quality and more efficient services to faculty and students, and inject new momentum into educational reform and high-quality development in higher education.

RFID Integration with Internet of Things: Data Processing Algorithm Based on Convolutional Neural Network

Liang Wang*
School of Electrical Engineering, Hunan Mechanical & Electrical Polytechnic, Changsha, Hunan 410151, China

***Abstract*—Radio Frequency Identification is a fast and reliable communication module that performs automatic data capture to identify and track individual objects and people. Frequency-coded tags employ resonant networks to decode their unique code. A multi-scatterer or multi-resonant method encodes the data. Research primarily related to the current investigation predicted that the chipless RFID tag resonant network has a high bit encoding capacity. This study addresses the simulation, optimization, fabrication, testing, and data encoding methods for chipless RFID tags. This research provides a framework for the open-ended quarter-wavelength stub multi-resonator method in chipless Radio Frequency Identification (RFID) tags. The proposed design enhances the tag's data encoding capacity and improves its robustness to ecological differences. This study integrates Error Correction Coding (ECC) and Adaptive Modulation Systems (AMS) employing Convolutional Neural Networks (CNN) to enhance the tag's performance. The AMS dynamically alters the modulation parameters based on channel states, while ECC improves data reliability. The results indicate efficient performance compared to traditional chipless RFID tags, highlighting the possibility of practical behavior in typical applications that necessitate reliable and high-capacity data transmission.**

***Keywords*—RFID; chipless; coding; threshold; data transmission; error correction; security authentication**

I. Introduction

Radio Frequency Identification is referred to as RFID. An RFID comprises a reader and one or more tags or transponders. RFID is a new technology. The British radar system employed RFID for the first time in World War II to differentiate between German aircraft and their aircraft that had radio transponders attached. Several industries have benefited from the advantages of RFID, including the military, healthcare, security, sports, animal husbandry, and aviation. RFID has several essential sector-specific applications. RFID is utilized in various applications, including supply chain management, automated payment systems, vehicle tracking, inventory management, secure shop checkouts, animal monitoring, and sports timing technology. RFID transfers data from an electronic tag, frequently known as a label or an RFID tag, using radio waves. Selecting an RFID tag is required. There are numerous frequencies of RFID tags available on the market. Microwave, High Frequency, Low Frequency, and Ultra High Frequency are all included [1-5].

*Corresponding Author

Organizations can now afford to use RFID due to technological advancements in cost factors. Wal-Mart was one of the first industries to use RFID technology for theft prevention and inventory supply process improvements. Wal-Mart mandated that its top 100 suppliers apply RFID tags to the pallets and cases they sent to the company by the end of 2004, marking the start of deploying RFID across its retail distribution chain. However, in 2004, RFID tag producers were unable to meet the demand level within Wal-Mart's targeted timeframe due to the state of standards and limited tag manufacturing capabilities.

With most of their leading suppliers supplying RFID-tagged pallets and crates to every Wal-Mart distribution facility, Wal-Mart's adoption is now well underway as standards change, manufacturing capabilities increase, and price points decline. Although RFID is beginning to infiltrate other business supply chains, these implementations are frequently closed-loop. To put it another way, RFID is implemented within the supply chain of a particular company but not between them and their commercial trade partners. Other applications, including tracking equipment to ensure that it is not left behind in the aircraft after repair, can only be used within a single business [6-10].

Information is stored on transponder tags in all RFID systems. RFID tags hold data that may be as vast as an array of bits or as little as a single binary bit that indicates an identifying code, Aadhaar number, personal medical data, or anything else that can be recorded in digital binary format. Microchips power RFID tags. RFID tags within a specific range may get sufficient power from the field. It transmits the data it has saved and accesses its internal memory using this power [3-4]. The transceiver antenna's voltage increases due to the interaction between the RF fields when the Transponder Tag draws power in this manner. The purpose of the Tag is to convey data to the reader by using this sort of impact. The Tag regulates how much energy is reserved from the field. The Tag controls the voltage detected at the transceiver following the bit pattern it wants to send [11-15].

RFID is an automated data collection that recognizes and monitors individual objects and people in real-time using RFID signals [16-20]. It is used as a radio technology to realize the Internet of Things (IoT) vision of generating a universal system of smart objects [21-26]. It would be possible to mark and invent all items fitted with radio tags. RFID tags must be data-rich, low-cost, and energy-efficient to perform these functions.

The RFID idea was introduced during World War II to find enemy aircraft [27-30].

To distinguish between friend and foe, the radar transmitter receives a backscattered signal from a receiver tagged in an airplane [31-32]. Later, in 1945, Leon Theremin made an intriguing discovery of RFID using the backscattering principle. As a result of the development of RFID, the commercial potential for tracking and identifying objects without physical intervention has increased. Furthermore, RFID can handle a greater number of items than barcodes [33-36]. RFID's main advantages are flexibility and versatility, and it promises to be a future technology in automatic designation [37-40].

RFID and bar code technologies are highly similar, but instead of using a laser to read barcodes on labels, radio frequency waves are used to read information from tags [41-45]. Due to its wide range of applications in various areas, including supply chain management, healthcare, traffic management, commerce, access control, purchasing, and distribution logistics, as well as manufacturing and service industries, substantial research has been conducted in the area of RFID in recent years [46-50]. The RFID tag stores a distinct identification number parallel to a bar code or magnetic strip on the back of a credit card or ATM card. The classification must be processed close to its scanning device to retrieve bar code or magnetic strip data. However, because of the high cost of the silicon chip required, its general application is limited. As a result, low-cost alternatives are in high demand. RFID tags without silicon chips are now being created. These tags are called 'chipless' tags [51-55].

A. Motivation

This research aims to develop a robust and inexpensive sensor network that can integrate various types of sensors, including electrical, chemical, and biological sensors. Wireless sensor tags have historically been used in other settings as active or semi-passive tags for collecting wireless data. A tag's application area is limited by its need for a battery, which reduces its lifespan and increases its cost. Many academics studying passive chipless sensor tags in recent years have been interested in passive RFID sensor tags due to the challenges they face in their development. This study develops two chipless sensor tag designs and a transmission line reflection-based ID generation system, which proposes a wide range of sensor types for evaluation, including nanoparticle-based sensors, microstrip antennas on a flexible substrate, and previously reported transmission delay line-based ID generation schemes. Dipole-based antennas are a standard and attractive option for passive tag designers from a business standpoint; however, their primary drawback is their length. Long straight dipole antennas are miniaturized using folding and meandering methods instead of long straight dipole arms. A tiny tag with excellent reading ranges and comprehensive band behavior is the product of these innovations. Future work aims to further improve the quality, efficiency, and applicability of the sensor tag system developed through this research.

1) Problem statement and research objective. A chipped RFID tag is composed of integrated circuits that store the identifying codes. The price of this tag is higher due to the use of silicon chips. An alternative solution to this difficulty is to develop a chipless RFID tag, which does not contain a silicon chip. The primary challenge in developing a chipless RFID tag is determining how to encode data without a memory chip, which has limited capacity. Multi-resonator-based tags are the combination of multiple resonator circuits and transcoding antenna structures. These antenna networks are called microstrip antennas. The efficient realization of the multi-resonator structure can be built using these microstrip antennas. However, the inherent drawbacks of these microstrip antennas are low gain and narrow bandwidth. The polarization antennas are utilized to address the drawback, and the significant segment is chipless RFID tags, which are retransmission-based multi-resonator tags. The network is designed to address the problems associated with the prominent recognition of chipless RFID tags.

The study on the chipless RFID is written as follows: the overview of RFID, chipless RFID, motivation, and problem statement with research objective are detailed in Section I. The literature review is discussed with a research gap in Section II. The proposed CNN-based coding system is given in Section III, the simulation result is presented with detailed discussion in Section IV, and the study ends with a justified conclusion in Section V.

II. Related Works

This section explains various studies on chipless RFID. These investigations explore various features, including novel encoding methods, Machine Learning (ML) integration, and system reliability enhancements (see Table I). In [5-6-60], the authors introduce a unique encoding for RFID tags, addressing data capacity limitations. In [61], the authors view the proposals' insights into ML's role in chipless RFID, highlighting challenges and proposing standardized data protocols. In [62], the authors employ ML and DL for robust data reading in CRFID sensor tags. In [63], the authors present a workflow for ML classification in chipless RFID tag identification. In [64], the authors introduce a multi-tag detection system using 1D-CNN. In [65], the authors investigate Deep Learning (DL) to improve RFID tag detection accuracy. In [66], the authors evaluate ML models for identifying information in chipless RFID tags. In [67], the authors propose a phase coding-based RFID tag design, while [68] examines chipless RFID for material identification. In study [69], data-driven methods are suggested to improve chipless RFID reliability.

The research gap identified in the review is the limited resolution of multi-tag detection systems [70]. Conventional frequency-based systems face limitations in achieving high-resolution multi-tag detection, thereby limiting their practical applicability. The application of CNN overcomes these challenges by improving reliability and accuracy in multi-tag detection. CNN leverages advanced pattern recognition capabilities to analyze complex data sets, enabling more precise and efficient tag detection even in challenging environments. This development represents a significant leap forward in chipless RFID technology, addressing the critical research gap

of achieving high-resolution multi-tag detection for practical deployment in numerous applications.

TABLE I SUMMARY OF ML-BASED RFID

Inference	Methods used	Outcome	Drawback
Proposes a novel encoding for chipless RFID tags using N resonant elements with M individual desired frequencies, thereby overcoming the data encoding capacity limitation. PSO algorithm optimizes tag structure parameters.	Particle Swarm Optimization (PSO) algorithm	Overcomes data encoding capacity limitations, enabling the determination of resonant frequencies before the tag model.	Requires optimization for specific tag designs.
Provides a comprehensive review of ML in CRFID technology, highlighting integration challenges and suggesting standardized data protocols for improved ML deployment.	Review of ML approaches, identification of challenges, proposal for standardized data protocols	Identifies challenges in ML integration with CRFID and suggests standardizing data protocols for improved deployment.	The lack of standardized data protocols may hinder ML deployment.
Introduces ML and DL regression modelling for robust CRFID sensor tag data reading—automated data acquisition training on large-scale datasets. 1-D CNN outperforms conventional ML models.	ML and DL regression modelling.	Achieves high accuracy in ID and sensing data detection and outperforms conventional ML models.	Restricted resolution of 3 cm for multi-tag detection.
Presents workflow for ML classification in chipless RFID tag identification, achieving perfect accuracy for four tags under fixed and flexible ranges.	ML classification workflow, optimization of tag responses	Achieves perfect accuracy for tag identification under various ranges and enhances tag responses.	Limited to four tag identifications.
Introduces chipless RFID multi-tag detection system using 1D CNN, achieving 100 per cent accurate multi-tag detection.	1D CNN for multi-tag detection, analysis of CNRs and natural frequencies	Achieves 100 per cent accurate multi-tag detection, outperforming frequency-based systems.	Restricted resolution of 3 cm for multi-tag detection.
Investigates DL techniques to improve chipless RFID tag detection accuracy, achieving roughly 99.99 per cent accuracy.	Evaluation of DL techniques	Achieves significant improvement in detection accuracy, reaching near-perfect accuracy.	Limited discussion on practical implementation challenges.
Evaluate ML models for detecting identification and sensing information in RCS-based chipless RFID tags, achieving high accuracy with SVR and GBT models.	Evaluation of ML	Achieves high accuracy in identification and sensing data detection.	Lack of discussion on real-world applicability.
Proposes a phase coding-based chipless RFID tag design featuring a C-shaped resonator capable of achieving 243 distinct states.	Proposal of phase coding-based chipless RFID tag design	Achieves high coding capacity with smaller tag dimensions.	Limited experimental validation was provided.
Examines the utility of chipless RFID technology for material identification, achieving over 90 per cent accuracy and faster detection speed compared to literature methods.	Examination of chipless RFID technology for material identification	Achieves high accuracy and faster detection speed, demonstrating practical utility.	May sacrifice accuracy for improved detection speed.
Proposes data-driven methods to enhance chip-less RFID interrogation and reliability, achieving high validation accuracy and increased reading range.	Proposal of data-driven methods, analysis of chip-less RFID tags	Achieves high validation accuracy and increased reading range, enhancing system reliability	It may require further optimization for specific environments.

III. PROPOSED CHIPLESS RFID TAGS IN ADAPTIVE MODULATION AND ERROR CORRECTION CODING USING CNN

This section deals with the design and development of retransmission-based resonating structures and encoding of the resonating structures. The three key elements of the retransmission-based tags are the transmitting (T_x) and receiving (R_x) antennas, as well as multi-resonating structures. The multi-resonator network plays a vital part in frequency-coded tags. It is a combination of multiple narrow-band rejection filtering sections, each comprising several resonators, used to encode the tag identity. These resonating structures will alter the interrogating signal's amplitude. The filter's performance is coupled to a transmission line, which sends the encrypted signal data to the reader.

The multi-resonator-based tags are proposed on microstrip-based planar resonators, which are either coupled or connected to the transmission line. The different networks of multi-resonators are presented in this section. The designed multi-resonating structures depends on the operating frequency band, the separation between the resonators, and the properties of the substrate. The multi-resonator consists of multiple resonators in the microstrip line, and each resonator resonates at its quarter wavelength frequency. The designed multi-resonators are

simulated on a low-cost FR4 substrate with a dielectric constant of 4.4, a loss tangent of 0.0018, and a height of 1.6 mm using an Advanced Design System (ADS). The bottom plane acts as a ground plane [71-76].

Open-ended quarter-wavelength stub multi-resonators are designed to overcome the size limitation of the above "L" shaped arm multi-resonator. To solve the constraints of short stub multi-resonators, several open stub multi-resonators have been proposed. A simple, open-ended quarter-wavelength multi-resonator is proposed. As a result, the tag size will be reduced by 50 per cent. The ten stubs are connected to a 50-*ohm* impedance microstrip transmission line in the multi-resonator. The microstrip transmission line width (3 *mm*), as in Eq. (1) and Eq. (2):

$$\frac{W}{h} = \begin{cases} \frac{8e^A}{e^{2A}-2} & for \frac{W}{h} \le 2 \\ \frac{2}{\pi}\left[B - 1 - \ln(2B-1) + \frac{\varepsilon_{r-1}}{2\varepsilon_r}\left\{\ln(B-1) + 0.39 - \frac{0.61}{\varepsilon_r}\right\}\right] & for \frac{W}{h} \ge 2 \end{cases} \quad (1)$$

where,

$$A = \frac{z_0}{60}\sqrt{\frac{\varepsilon_r+1}{2}} + \frac{\varepsilon_r-1}{\varepsilon_r+1}\left(0.23 + \frac{0.11}{\varepsilon_r}\right) \text{ and } B = \frac{377\pi}{2z\sqrt[0]{\varepsilon_r}} \quad (2)$$

The length (17 *mm*) of the microstrip transmission line by Eq. (3) and Eq. (4):

$$\emptyset = 90^\circ = \beta L_f = \sqrt{\varepsilon_{eff}} K_o L_f \quad (3)$$

$$L_f = \frac{90^\circ\left(\frac{\pi}{180^\circ}\right)}{\sqrt{\varepsilon_{eff}} K_o} \quad (4)$$

where,

- $K0$→ The phase constant and is equal to 2π/λ.

The open-ended quarter-wavelength resonator behaves as a series RLC resonant circuit. So, each resonator is modelled as a quarter wavelength.

The input impedance of a lossy transmission line is given in Eq. (5):

$$Z_{in} = Z_0 \frac{Z_L + Z_o tanh\gamma l}{Z_o + Z_L tanh\gamma l} \quad (5)$$

where, $\gamma = \alpha + j\beta$

For an open-circuited lossy transmission line, the input impedance is given in Eq. (6) and Eq. (7):

$$Z_{in} = Z_0 \coth(\alpha + j\beta)\, l \quad (6)$$

$$Z_{in} = Z_0 \frac{1 + jtan\beta l tanh\alpha l}{tanh\alpha l + jtan\beta l} \quad (7)$$

In real-time applications, the transmission line has a slight loss, so $\alpha l \ll 1$ and $tanh\alpha l \approx \alpha l$

Assume

$$\omega = \omega_o + \Delta_\omega \quad (8)$$

where, is Δ_ω Small [see Eq. (8) and Eq. (9)].

$$\beta l = \frac{\omega l}{v_p} = \frac{\omega_o l}{v_p} = \frac{\Delta\omega l}{v_p} = \frac{\pi}{2} + \frac{\pi\Delta\omega}{2\omega_o} \quad (9)$$

Then

$$\cot\beta l = \cot\left(\frac{\pi}{2} + \frac{\pi\Delta\omega}{2\omega_o}\right) = -tan\left(\frac{\pi\Delta\omega}{2\omega_0}\right) = \frac{\pi\Delta\omega}{2\omega_0} \quad (10)$$

as in Eq. (10). From Eq. (11),

$$Z_{in} \approx Z_o \frac{1 + j\alpha l\frac{\pi\Delta\omega}{2\omega_0}}{\alpha l + j\frac{\pi\Delta\omega}{2\omega_0}} \approx Z_o\left[\frac{1}{\alpha l} + j\frac{\pi\Delta\omega}{2\omega_0}\right] \quad (11)$$

It indicates the input impedance of a series RLC resonant circuit. The quality factor is given in Eq. (12):

$$Q = \frac{L\omega_o}{R} = \frac{\pi}{4\alpha l} \approx \frac{\beta}{2\alpha} \quad (12)$$

The proposed design has to generate resonance by optimizing the length of an open-ended stub resonator. Each resonator length is computed as in Eq. (13):

$$W_t = \frac{\lambda_g}{4} \quad (13)$$

where,

- Wt→ The open stub resonator length at 2.08 GHz resonant frequency
- The open-ended stub resonator length is approximately 20.8 mm.

Other stub lengths are computed using the same procedure and the values (see Table II). The proposed multi-resonating structure is implemented on an FR4 substrate with a dielectric constant of 4.4 and a loss tangent of 0.0018. The conductor thickness is 35 μm. The mutual coupling of open stub resonators is reduced when the stubs are held 1 *mm* apart. The bottom plane serves as a ground plane. The span of the proposed design is 23.8 $mm \times 17\ mm$.

TABLE II LENGTH OF THE 10-BIT OPEN STUBS

Stubs	Resonant Frequency (GHz)	Length of the open stubs (mm)
1	2.08	20.8
2	2.22	18.5
3	2.36	17.4
4	2.59	15.8
5	2.80	14.5
6	2.96	13.7
7	3.19	12.5
8	3.41	11.5
9	3.68	11
10	3.84	10.4

As the open stub microstrip line resonator resonates at the desired frequency, the wavelength remains $^1/_4$ of its original wavelength ($^{\lambda g}/_4$). Because of its inductive solid reactance, the resonator has a good quality factor, which prevents nearby resonant frequencies from merging. It is an actual electric current induced by an applied electromagnetic field. It shows the maximum current at the resonant frequency of 2.08 *GHz*. For efficient chipless RFID tag realization, the space limitation of open-stub multi-resonators can be replaced by meandered-line multi-resonators. The procedure of chipless RFID design is given in Algorithm 1.

Algorithm 1. Muti-Resonator Based Chipless RFID Design

1. DefineKeyConstituents():
- Define Tx and Rx antennas.
- Define multi-resonating structures.
2. DesignMultiResonatorStructure():
- Combine multiple narrow-band rejection filtering sections using several resonators.
- Simulate the designed multi-resonators on a substrate.
3. DesignOpenEndedStubs():
- Design open-ended quarter-wavelength stub multi-resonators.
- Calculate the dimensions of the microstrip transmission line.
4. ModelResonators():
- Model each resonator as a quarter wavelength to behave as a series RLC resonant circuit.
- Determine the input impedance of the lossy transmission line.
5. OptimizeResonatorLengths():
- Optimize the length of each open-ended stub resonator to generate resonance.
- Calculate resonator lengths.
6. ImplementMultiResonatingStructure():
- Implement the proposed multi-resonating structure on the substrate.
7. VerifyResonantBehavior():
- Verify the resonators' resonant behaviour and quality factor at desired frequencies.
8. ConsiderAlternativeDesigns():
- Consider alternative designs such as meandered line multi-resonators if necessary.

Main():
- DefineKeyConstituents()
- DesignMultiResonatorStructure()
- DesignOpenEndedStubs()
- ModelResonators()
- OptimizeResonatorLengths()
- ImplementMultiResonatingStructure()
- VerifyResonantBehavior()
- ConsiderAlternativeDesigns()

Collect data from chipless RFID tags, including the response patterns generated by multi-resonator networks. Encode the collected data into a format suitable for training the CNN. This encoding may involve mapping the RFID tag responses to specific modulation and coding methods. The signal response is modelled using Eq. (14):

$$y(t) = \sum_{n=1}^{N} A_n \cdot \sin(2\pi f_n t + \emptyset_n) \quad (14)$$

The adaptive amplitude and phase modulation are given in Eq. (15) and Eq. (16).

$$A_n = f(A_{n-1}, \theta_n) \quad (15)$$

$$\emptyset_n = f(\emptyset_{n-1}, \theta_n) \quad (16)$$

Eq. (14) is the signal response modelling of a chipless RFID tag. The received signal '$y(t)$' is expressed as a summation of sinusoidal components, where each component 'n' is characterized by its amplitude 'A_n', frequency 'f_n', and phase 'ϕ_n'. It captures the fundamental behavior of the tag's response to an interrogating signal.

The FE from the multi-resonator RFID signal, Eq. (17):

$$X = [x_1, x_2, x_3, \dots\dots\dots, x_n] \quad (17)$$

In Feature Extraction (FE) [Eq. (17)], the extracted features from the RFID signal are represented as a vector $X = [x_1, x_2, x_3, \dots\dots\dots, x_n]$. To provide the signal's encoding in a feature space compatible with the next processing step, each xi represents a distinct FE from the RFID data.

The convolutional layer is a key component of coding for multi-resonator chipless RFID tags, as it analyses the data signal input sent from the tags. The Neural Network (NN) can extract valuable features and patterns from the RFID tag data due to the convolution techniques applied to the input data in this layer. The convolution layer utilizes filter learning to train the neural network (NN) to detect specific frequency resonances and store them in a format suitable for future investigation. To integrate non-linearities into the NN, an activation function is used following the convolutional layer. The system's ability to detect minor variations in the RFID signal is boosted by this non-linearity, allowing it to identify significant variations and connections within the resonator responses. The features are transmitted forward to the Fully Connected (FC) layer, which is then extracted and analyzed by the convolutional layers, where they are flattened. To ensure a deep examination and summary of the extracted features, all neurons in this layer are connected to all the neurons in the layer before it. Here, researchers enhance the input signal description by adjusting weights and biases, enabling the provision of an accurate output prediction. The proper recognition and decoding of data encoded within the chipless RFID system are rendered possible by the valuable information obtained through the resultant prediction from the FC layer about the features and IDs of the RFID tags. From Eq. (18) to Eq. (22), this study tests CNN.

$$Z^{[1]} = W^{[1]} \times X + b^{[1]} \quad (18)$$

$$A^{[1]} = g\left(Z^{[1]}\right) \quad (19)$$

$$Z^{[2]} = W^{[2]} A^{[1]} + b^{[2]} \quad (20)$$

$$A^{[2]} = g\left(Z^{[2]}\right) \quad (21)$$

$$\hat{Y} = A^{[2]} \quad (22)$$

Eq. (18) to Eq. (22) describe the operations within a CNN. Eq. (18) calculates the activation of neurons in the convolutional layer by convolving the input data 'X' with learnable filters $W^{[1]}$ and adding a bias term $b^{[1]}$. The activation is then passed using an activation function gg [Eq. (6)]. In Eq. (7), the FC layer computes the activation using weights $W^{[1]}$ and bias term $b^{[2]}$. The activation is again passed through an activation function in Eq. (22).

$$C = E \times G \quad (23)$$

$$\hat{E} = f(Y) \quad (24)$$

$$d = dist(Y, \hat{Y}) \quad (25)$$

Eq. (23) to Eq. (25) pertain to ECC. Eq. (23) involves generating a codeword 'C' from an information vector 'E' by multiplying it with a generator matrix G. Eq. (24) performs error correction by applying a function 'f' to the received vector 'Y' to predict the data vector '$\widehat{E}$'. The Hamming distance 'd' between the received and computed vectors is computed in Eq. (25). Adaptive modulation is given in Eq. (26) to Eq. (28).

$$P_{out} = P_{in} \times \eta \tag{26}$$

$$BER = f(P_{out}, SNR) \tag{27}$$

$$ModScheme = g(BER) \tag{28}$$

Adaptive modulation in chipless RFID adjusts power (P_{out}) via efficiency factor η, calculates Bit Error Rate (BER) from P_{out} and SNR, and selects modulation scheme based on BER $ModScheme$. It optimizes power usage and modulation for reliable communication in dynamic RFID. The procedure for error correction using a CNN is outlined in Algorithm 2.

Algorithm 2: ECC Scheme using CNN

1. Collect data from chipless RFID tags, including response patterns from multi-resonator structures.
2. Encode collected data into a format suitable for training the CNN model.
3. Define signal response modeling function: $\boldsymbol{y(t) = \sum_{n=1}^{N} A_n \cdot sin(2\pi f_n t + \emptyset_n)}$
4. Extract features from the RFID signal: $\boldsymbol{X = [x_1, x_2, x_3, \dots\dots\dots, x_n]}$
5. Define convolutional layer operations: $\boldsymbol{Z^{[1]} = W^{[1]} \times X + b^{[1]}}$
$\boldsymbol{A^{[1]} = g(Z^{[1]})}$
6. Define FC layer operations: $\boldsymbol{Z^{[2]} = W^{[2]} A^{[1]} + b^{[2]}}$
$\boldsymbol{A^{[2]} = g(Z^{[2]})}$
7. Obtain output prediction: $\boldsymbol{\widehat{Y} = A^{[2]}}$
8. Define ECC operations:
$\boldsymbol{C = E \times G}$
$\boldsymbol{\widehat{E} = f(Y)}$
$\boldsymbol{d = dist(Y, \widehat{Y})}$
9. Define adaptive modulation operations:
$\boldsymbol{P_{out} = P_{in} \times \eta}$
$\boldsymbol{BER = f(P_{out}, SNR)}$
$\boldsymbol{ModScheme = g(BER)}$

IV. Results and Discussion

By employing PyTorch, developers can build a CNN by describing layers, activation functions, and additional features that enables you to set up the error correction coding algorithm. For effective data handling, use PyTorch's Dataset and DataLoader classes. Use a dataset that includes behaviour patterns from multi-resonator chipless RFID tags. Select an appropriate optimization algorithm (Adam) and loss function (CrossEntropyLoss) and set up a training loop to evaluate the dataset, compute gradients, and adjust model parameters. Model performance can be optimized by adjusting hyperparameters such as learning rate and batch size. To set up error correction coding in multi-resonator chipless RFID tags, follow these steps and utilize PyTorch's features to develop and train a Convolutional Neural Network (CNN). Eq. (29) to Eq. (33) are employed to assess the performance of the CNN-based ECC.

$$SNR = \frac{Signal\ Power}{Noise\ Power} \tag{29}$$

$$BER = \frac{Number\ of\ Bit\ Errors}{Sum\ of\ Bits} \tag{30}$$

$$SER = \frac{Number\ of\ Symbol\ Errors}{Sum\ of\ Symbols} \tag{31}$$

$$FER = \frac{Number\ of\ Frame\ Errors}{Sum\ of\ Frames} \tag{32}$$

$$Capacity = \frac{Data\ Rate}{bandwidth} \tag{33}$$

Key metrics of communication network performance are presented by Eq. (30) to Eq. (33). Eq. (29) defines the Signal-to-Noise Ratio (SNR) as a basic measurement used to measure signal quality since it measures the ratio of signal power to noise power. BER, which is an essential statistic for measuring transmission accuracy, is computed by Eq. (30). BER is the ratio of error bits to all bits received. Eq. (31) can be employed to derive the Symbol Error Rate (SER), which measures the accuracy of symbols at the symbol level. It is the ratio of wrong received symbols to the complete transmitted symbols. Frame Error Rate (FER) is a vital factor in assessing data packet integrity; it is computed by Eq. (32) and is described as the ratio of wrongly received bytes to the number of transmitted bytes. As the final step in determining manipulative channel efficiency, Eq. (33) computes size, which represents the highest possible data rate that can be achieved with a particular frequency (see Table III). The optimization and evaluation of communication system efficacy in various scenarios rely on these metrics.

TABLE III Comparison of Performance

Performance Measures (bits)	PSO	1D-CNN	MR-CNN
SNR	454.78	678.67	767.78
BER	567.23	432.13	232.13
SER	678.56	612.67	412.78
FER	567.56	512.68	354.78
Capacity	31.23	45.4	53

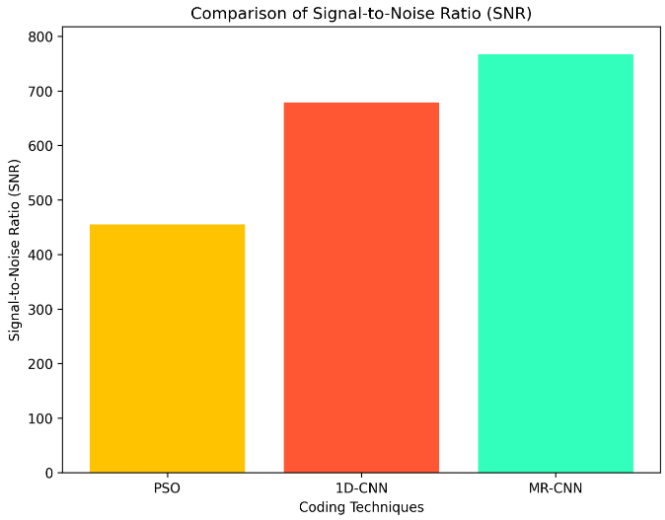

Fig. 1. Comparison of SNR

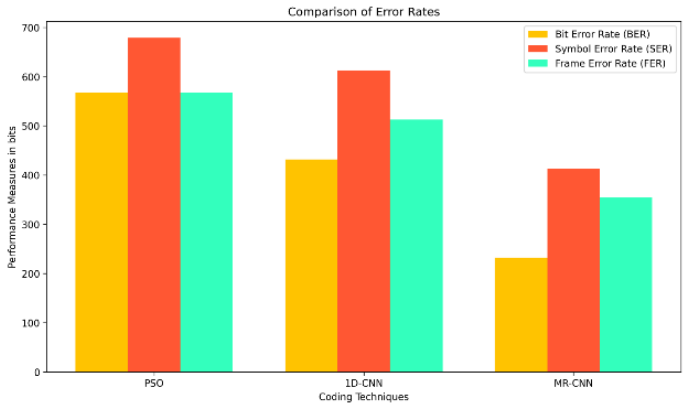

Fig. 2. Comparison of DER

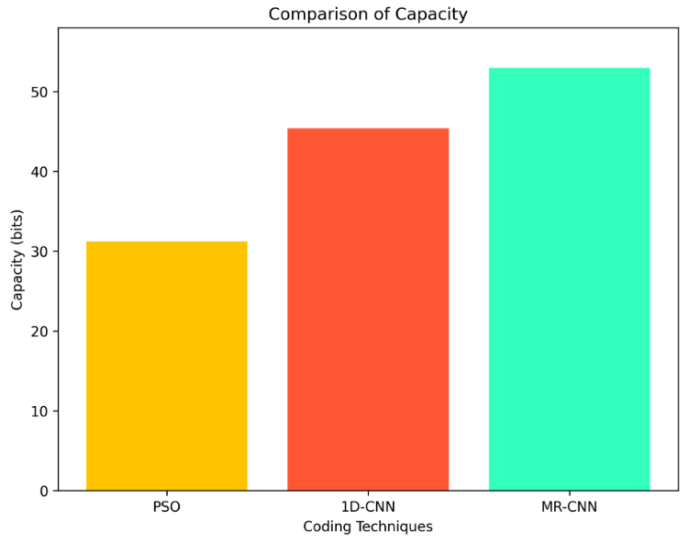

Fig. 3. Comparison of capacity

Considering an SNR of 454.78, PSO is superior to 1D-CNN (678.67) and MR-CNN (767.78) in an analysis of metrics related to performance. The BER is 232.13 for MR-CNN, 432.13 for 1D-CNN, and 567.23 for PSO. The best three models for SER are PSO (678.56), 1D-CNN (612.67), and MR-CNN (412.78). With a FER of 354.78, MR-CNN is at the bottom of the pack, next to 1D-CNN at 512.68 and PSO at 567.56. PSO emerges in third. With 31.23 bits, PSO has the highest capacity, next to 1D-CNN with 45.4 bits and MR-CNN with 53 bits. Although MR-CNN outperforms in SNR and capacity, it exhibits superior results across error rates, showing consistency in data integrity. According to these measures, 1D-CNN is in the middle. The contrast is demonstrated visually in Fig. 1 to Fig. 3. Fig. 1 indicates SNR, Fig. 2 potentially displays various error rates, and Fig. 3 exhibits distinct capacities. Overall, MR-CNN proves a higher error rate reduction than PSO, rendering it an excellent choice for tasks that are sensitive to errors, even though PSO has superior SNR and throughput.

V. Conclusion and Future Work

This research highlights the importance of RFID tags without chips for automatic data capture and human identification, as they facilitate fast and secure communication. The primary goal of this study is to improve the encoding efficiency and physical adaptability of chipless RFID tags. It is done by optimizing their resonant model. This study advances the design of chipless RFID tags by introducing an open-ended quarter-wavelength stub multi-resonator model, which provides access to real-world applications that require high-capacity data transfer. Implementing CNN for dynamic modulation and ECC improves tag performance. Both the novel AMS and ECC cooperate to make data accurate by adjusting modulation parameters in response to changes in the channel. When it comes to systems that are sensitive to errors, MR-CNN exhibits considerable potential due to its improved error rate reduction. The results of this work help to push chipless RFID forward, which is positive for various industries that use secure, high-capacity data transfer.

Further developments in chipless RFID tag design could be a focus of future studies. This may involve investigating novel resonant structures or identifying methods to optimize manufacturing for enhanced performance and scalability. The accuracy of data transfer and the validity of tags might be enhanced by investigating the possibility of integrating complex error correction coding and modulation techniques.

***Abstract*—Technological advancements in recent decades have significantly increased the scale and complexity of software systems, which poses challenges to their development and reliability. Component-based software development (CBSD) offers a promising solution by enabling modular and efficient software construction. However, CBSD alone cannot fully address challenges such as ensuring reliability and avoiding errors like deadlocks. Verification techniques, such as model-checking, are necessary to ensure the correctness of CBSD systems. Despite its effectiveness in verifying system properties, model-checking faces a critical issue known as state-space explosion (SSE), which hinders scalability. This study introduces an incremental verification technique for CBSD to address SSE and ensure deadlock freedom. The proposed technique incrementally constructs and verifies component-based systems, eliminating verified portions of components to minimize state-space size during subsequent verification steps. It utilizes a component model that supports encapsulation of computation and control, making incremental verification feasible. Evaluation of the technique using coloured petri nets with non-trivial case studies demonstrates its ability to detect deadlocks early and manage SSE effectively, thereby improving the efficiency of the verification process.**

***Keywords*—Component-based software development; incremental software construction; software verification**

I. Introduction

The rapid growth of technology has led to increasingly complex software systems, which necessitate advanced development methods to manage this complexity while ensuring system reliability. One such approach is Component-based Software Development (CBSD), which optimizes software development by breaking down systems into reusable, self-contained components [1]. CBSD allows for modular design, which can reduce development time and cost. However, as software systems grow in scale, even CBSD faces challenges in ensuring system correctness and avoiding errors, such as deadlocks, during development.

To enhance the reliability of CBSD, formal verification methods are needed to identify and address potential errors. Model-checking is a well-established technique for verifying the correctness of software systems by exhaustively exploring the state space (SS) of the system [2]. It can automatically detect issues like deadlocks by analyzing system behaviors. However, model-checking suffers from the state-space explosion (SSE) problem, where the number of states to be analyzed grows exponentially with system complexity, making verification infeasible for large systems [3].

Addressing SSE in model-checking is crucial for the practical application of verification in CBSD. Despite various approaches in the literature to mitigate SSE, a critical gap remains: the need for techniques that integrate verification throughout the development process rather than waiting until system construction is completed. Early detection of design errors is highly desirable, as it can significantly reduce the cost of fixing these errors compared to discovering them during later stages of development or maintenance [4].

Incremental verification is a promising approach to overcoming challenges in SSE by verifying components as they are developed and integrated, rather than waiting for the entire system to be completed. This approach enables early detection of defects and manages SSE more effectively by verifying smaller portions of the system incrementally [5]. However, despite its potential, incremental verification remains underexplored in the context of CBSD. This gap is partly due to the difficulties in maintaining consistent behavior and synchronization across different increments, making it challenging to ensure that new components integrate seamlessly without disrupting previously verified functionality [6].

To address this gap, this paper introduces a technique for the incremental construction and verification of component-based systems using a specialized component model called PUTRACOM [7]. PUTRACOM is designed to support encapsulation and concurrency, making it particularly well-suited for incremental verification. Its ability to decouple computation and control addresses the challenges of managing interdependencies between components, which are commonly encountered in CBSD. The proposed approach emphasizes two critical aspects: maintaining system behavior consistency during the incremental integration of components and integrating verification at each stage to avoid redundant checks on already verified components.

This research offers two key contributions. First, it presents a method for preserving system behavior and synchronization

during the incremental integration process, ensuring that the addition of new components does not compromise the verified properties of existing ones. Specifically, this research focuses on verifying the property of deadlock freedom. Second, it introduces a verification strategy that isolates previously verified components, preventing their re-verification and thereby reducing the overall state-space size during subsequent verification stages. This technique is evaluated using coloured Petri nets, a well-established tool for modeling and verifying concurrent systems [8], and applied to complex case studies, including the Common Component Modeling Example (CoCoME) [9].

The results show that the proposed incremental verification approach effectively mitigates the SSE problem and enhances the efficiency of the verification process in CBSD. By identifying errors early in the design stage and reducing verification effort, this approach improves the practical application of model-checking in component-based systems.

II. Background

This section provides preliminary information about the PUTRACOM component model [7], which is designed for building concurrent systems using exogenous connectors, inspired by the X-MAN model. PUTRACOM comprises three fundamental units: computation units (CU), observer/observable units (OOU), and exogenous connectors.

The CU encapsulates all computations and is modeled using reactive transition systems (RTSs) [4]. This encapsulation allows for decoupling between components while ensuring fixed behavior.

The OOU captures events visible to other components or the computing environment, modeled by interface automata [10]. This approach simplifies communication, avoiding complexities associated with traditional models like message passing and port-to-port connections. The OOU observes all events from other components or the environment. An atomic component in PUTRACOM is defined through RTSs, which represent potential behaviors of discrete systems. RTSs distinguish three types of events: input, internal, and output. Below is the formal definition of a computation unit based on RTS.

Definition 1 (computation unit)**.** A CU is a reactive transition system defined by the tuple (s_0, S, E, G, Δ), where:

- S is a set of states, with s_0 as the initial state;
- E is a set of events, including input events (E^I), output events (E^O), and hidden events (E^H);
- G is a guard function assigning boolean constraints to events;
- $\Delta \subseteq S \times E \times G \times S$ is a set of transitions.

Input and output events are considered observable ($E^{Obs} = E^I \cup E^O$) and accessible from the OOU. The OOU is modeled as a multiset, meaning the same event can occur multiple times. These events influence the component's state depending on whether the input events are admissible. Output events produced by the CU are also observable in the OOU. The formal definition of an OOU is as follows.

Definition 2 (Observer/Observable Unit)**.** The OOU is a finite multi-set defined as (E^{Obs}, f), where $f : E^{Obs} \to \mathbb{N}$ maps observable events to their multiplicities.

III. Proposed Solution and Methodology

This section outlines the proposed methodology focuses on the incremental construction and verification within the extended PUTRACOM framework. An overview of the solution is illustrated in Fig. 1. In the first step, the approach utilizes exogenous connectors, ensuring encapsulated component interactions. The methodology involves defining key elements such as noticing and publishing functions to manage event interactions between components and connectors. The composition of components is then formalized, allowing for structured integration within the PUTRACOM system. The detailed explanations are in Section IV.

The second step detailed in Section V is the incremental construction approach to develop a modular system by gradually integrating components and composite components. Each increment, will be systematically added using connectors for synchronization and interaction. The methodology will involve defining trace functions to analyze component behavior and applying n-way synch and asynch compositions to ensure effective integration. The process includes maintain consistency between the original and composed systems, preserving interaction behavior throughout the construction stages by defining observable traces and refinement relations.

Third step is relayed to the incremental verification detailed in Section VI, verifying each system increment before adding the next. It generates and checks the state space for local and global properties (deadlock-freeness). To manage state space explosion, it reduces state space size by focusing on observable behaviors and removing hidden parts, ensuring efficient and consistent verification. To validate our approach, we modeled three case studies using Coloured Petri Nets (CPNs), detailed in Section VII. Evaluation metrics include the number of generated state spaces, memory consumption, and processing time.

IV. Initialization of the Extended PUTRACOM Framework

This section presents additional definitions for extended PUTRACOM related to incremental construction and verification. Composition operators, termed connectors, are exogenous, allowing components to remain encapsulated without directly sending or receiving messages. The OOU manages and controls observable events without involving the CUs in the control process.

Definition 3 (connector)**.** A *connector* is a tuple $\Gamma = (L, T, Sub, E_\Gamma, G_\gamma)$, where:

- L is a set of connection lines, representing the physical or logical links between components;
- $T = \{sync, async, con, seq, itr\}$ indicates the types of connectors, including synchronous, asynchronous, conditional, sequential, and iterative interactions;
- $Sub = \{b_0, b_1, b_2, ..., b_n\}$ is a set of components subscribed to the connector;

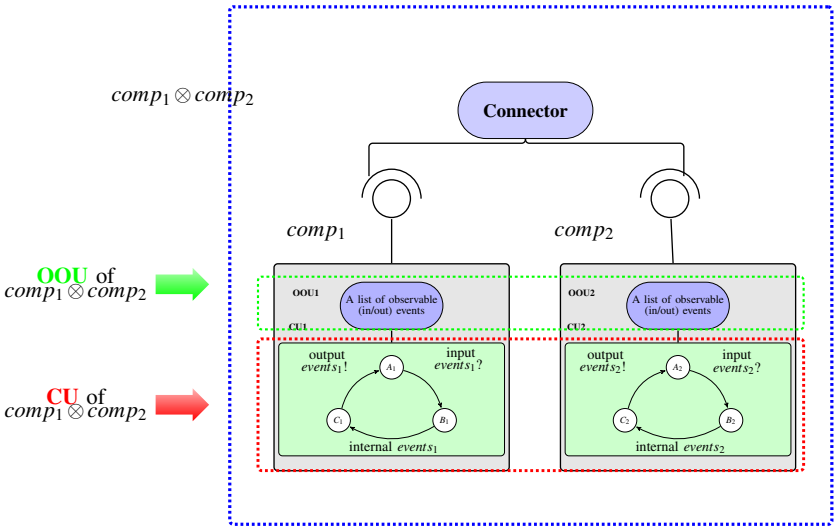

Fig. 1. Components with details in PUTRACOM.

- E_Γ is a set of events that consists of two mutually disjoint sets: output events $E_\Gamma^O \subseteq (E^O \cup env)$ and input events $E_\Gamma^I \subseteq (E^I \cup env)$, where, E^O is the set of output events; E^I is the set of input events defined for the system; *env* represents the set of external events or environmental conditions that can influence or interact with the connector.
- $G_(\gamma) = \{g_0, g_1, ..., g_n\}$ is a set of boolean constraints over the connector $\gamma \in L$.

Once output events are ready, the corresponding OOU notifies the connector using a *noticing* function.

Definition 4 (noticing)**.** Let Γ be a set of connectors and S be a set of components where $s \in S$. A *noticing* function $N : E^O \rightarrow \Gamma$ maps output events of components to their corresponding connectors, such that $N(e_o) = \gamma$, where $\gamma \in \Gamma$ and $e_o \in E^O$.

The activation and occurrence of a noticing depend on verifying predefined conditions associated with the event, as specified by the function *BoolConst*. The following definition serves as the primary definition of an atomic component in PUTRACOM, summarizing the core concepts presented in the preceding definitions.

Definition 5 (atomic component)**.** An atomic component in PUTRACOM is a tuple $com = \{CU, OOU, init, G, N\}$, where:

- $CU = (s_0, S, E, V, \Delta)$ is a reactive transition system;
- *OOU* is the observer/observable unit of the component, defined as a multiset (E^{Obs}, f);
- $init : E \rightarrow S$ is an initial function that assigns each event $e \in E$ to its corresponding initial state s_0 in S;
- $G_{com} : E \rightarrow$ BoolCons is a function mapping each event to its corresponding set of user-defined Boolean constraints;
- $N : E^O \rightarrow \Gamma$ is a noticing function that notifies the corresponding connector.

Once a connector is notified of an event occurrence by the OOU, it is responsible for disseminating this event to the relevant components. This process is managed by the publishing function, which ensures that all intended recipients receive the event.

Definition 6 (publishing)**.** Let $b \in Sub$, $e_o \in E_\Gamma^O$, $\gamma \in \Gamma$, and *env*. A *publishing* is defined as a function $P : E_\Gamma^O \rightarrow OOU$ that maps an output event e_o through the connector γ to the corresponding OOU, such that $OOU \subseteq \{OOU_{\{b_i\}_{i=0}^n} \cup env\}$.

Publishing an event requires satisfying conditions from G_γ. If met, the event is sent to the OOU of the relevant subscribers. In the noticing function, events are marked as "!", and in publishing, as "?".

Once a connector received an event by noticing and published the event, an interaction occurs.

Definition 7 (interaction)**.** Let the connector $\gamma \in \Gamma$ and $b \in Sub$. Consider the following events:

- There exists $e_o \in E^O$ such that $N(e_o \cup env) = \gamma$.
- There exists $e_i \in E_\gamma^I$ such that $P(e_i) = OOU$ and $OOU \subseteq \{OOU_{\{b_i\}_{i=0}^n} \cup env\}$.

Then, the set of interactions Π contains a finite number of interactions π, where $\pi = (e_o, \gamma, e_i)$ such that $\gamma \cap \Gamma = 1$. This research uses $(e_o, e_i)_\gamma$ or $\xrightarrow{e}_\Gamma$ instead of $\pi = (e_o, \gamma, e_i) \in \Pi$. Interactions can occur only when specific conditions are met which it is called admissible events.

Definition 8 (admissible interaction)**.** An interaction is admissible only if the following rules are satisfied:

1) $\forall e \in \Pi$, e is admissible,
2) $\xrightarrow{e}_\Gamma \in \Pi \models G_\Gamma$. It means $\xrightarrow{e}_\Gamma$ satisfies the set of conditions of connector Γ for publishing.

Based on the definitions provided, we can establish that composite components form the foundation for creating efficient and scalable systems within the PUTRACOM framework.

Definition 9 (composite components)**.** A composite component in PUTRACOM is a tuple $compos = \{CU, OOU, G, \Pi\}$.

V. Incremental Construction

Incremental construction in PUTRACOM consists of a finite set of increments denoted by *INC*. Each $inc \in INC$ represents a component or composite component, with the first increment serving as a foundational touchstone for the incremental composition, termed "basic," which connects other increments via a connector.

Definition 10 (Basic and Next Increments)**.** Let $C = \{c_0, c_1, \ldots, c_n\}$ be a set of all required components or composite components needed to construct the target system *Target*. The term *trail* refers to the composite component currently being built at the current construction level of the system *Target*. The definitions of *basic* and *next increment* are as follows:

$$basic = \{c \in C \mid \text{trail} = \emptyset \text{ and } c.\text{trail} \subseteq Target\}$$

$$inc_{next} = \{c \in C \mid \text{trail} \neq \emptyset \text{ and } c.\text{trail} \subseteq Target\}$$

Each increment consists of both CUs and OOUs, making it crucial to understand their behavior for effective component composition and system construction. To facilitate this understanding, a trace function is employed to extract the behavior of the CU, formally defined as a recursive function that returns a sequence of events originating from the initial state s_0.

Definition 11 (trace)**.** A transition *trace* of a RTS, denoted by ζ, is a sequence of events $e_0, e_1, \ldots, e_i$ such that for all $i \geq 0$, there exist states $s_0, s_1, \ldots, s_{i+1} \in S$ and guards $g_i \in G$ satisfying the conditions: $\zeta = (s_i, e_i, g_i, s_{i+1}), (s_{i+1}, e_{i+1}, g_{i+1}, s_{i+2}), \ldots, (s_n, e_n, g_n, s_{n+1}) \in \Delta$ or equivalently, $\zeta = s_i \xrightarrow{e_i, g_i} s_{i+1}, s_{i+1} \xrightarrow{e_{i+1}, g_{i+1}} s_{i+2}, \ldots, s_n \xrightarrow{e_n, g_n} s_{n+1}$. A trace function ε generates a sequence of transitions from an initial state s_0 based on admissible transitions.

A connector is defined by a set of types T that represent synchronization among subscribed increments and their interactions, highlighting the necessity of composing multiple increments. The following definitions describe the n-way composition capability of increments in PUTRACOM connectors.

Definition 12 (n-way sync composition)**.** Let C_i and E_i indicate the set of increments and their corresponding events respectively. The n-way sync composition of n increments is defined as follow:

$$\|_{i=0}^{n} \ (C_i, E_i) = C_1 \ {}_{E_1}\|_{\{E_2 \cup E_3 \cup \ldots \cup E_n\}} \ (\ldots (C_{n-1} \ {}_{E_{n-1}}\|_{E_n} \ C_n)) \quad (1)$$

Definition 13 (n-way asynchronous composition)**.** Let C_i indicates the sets of components. The $n-way\ asynchronous\ composition$ of n components are defined as follow:

$$|||_{i=0}^{n} \ (C_i) = C_1 \ ||| \ C_2 \ \ldots \ ||| \ C_n \quad (2)$$

In PUTRACOM, components encapsulate computation and are not called by other components. The CU exhibits fixed behavior without the environment's involvement. The only shared aspect is the OOU, which is involved in composition. Consequently, the hidden part can be omitted in traces, resulting in what is known as an Observable trace.

Definition 14 (observable trace)**.** *An observable trace is a sequence of events over a component or a composite component defined by:* $\zeta^{Obs} = \{(e_1), (e_2), \ldots, (e_i) \mid e \in E \backslash E^H\}$.

To obtain an observable RTS (ORTS) from an original RTS, a zoom-out function is presented. Let $\exists e \in E^H$ and $s, s' \in S$, then, the zoom-out function omits the arc $s \xrightarrow{e} s'$. If $s \xrightarrow{e_i, e_j} s'$ such that $i \neq j$ and $e_j \in E^{Obs}$ and $e_i \in E^H$, the zoom-out function will only omit $s \xrightarrow{e_i} s'$. The ORTS of the component is shown in Fig. 2.

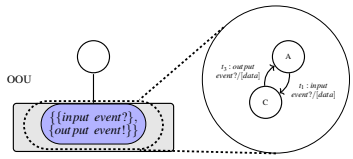

Fig. 2. An ORTS example of a component.

Observable RTS focuses on noticing, publishing, and interactions through connectors and will later help calculate possible component interactions. It also introduces an important aspect: the conformance between ORTS and RTS, defined using the refinement relation (RR) [11]. Refinement relations indicate that every behavior of system A is allowed by system (or specification) B.

Definition 15 (refinement relation)**.** Consider a RTS R and its corresponding ORTS S such that $E_S^I = E_R^I$ and $E_S^O = E_R^O$. S conforms to R, written $S \preceq R$, there is an RR between R and S, if the following conditions hold:

- $s_0 = r_0$, thus $s_0 \preceq r_0$ where s_0 and r_0 are the initial states of S and R respectively.
- For every transitions of R such that $\forall e \in E^H$ there exist a successor of r indicates by r' (where $r\prime \neq r$) and a RR between $r\prime$ and s, written by $s \preceq r\prime$.
- For every transitions of R such that $\forall e_i \in E^I$, $\exists r \xrightarrow{e_i} r\prime$ there exist a successor of s, written by $s \xrightarrow{e_i} s\prime$, such that $s\prime \preceq r\prime$.
- For every transitions of R such that $\forall e_o \in E^O$, $\exists r \xrightarrow{e_o} r\prime$ there exist a successor of s, written by $s \xrightarrow{e_o} s\prime$, such that $s\prime \preceq r\prime$.

Fig. 3 shows the composition of ORTSs from two increments, with the first component as *basic* and their combination as trail. Adding any increment signifies the next construction level, inc_{next}. Connectors are exogenous, defining connection and communication between increments. The initial increment serves as the touchstone for the incremental composition, referred to as inc_{base}, connected by a connector Γ.

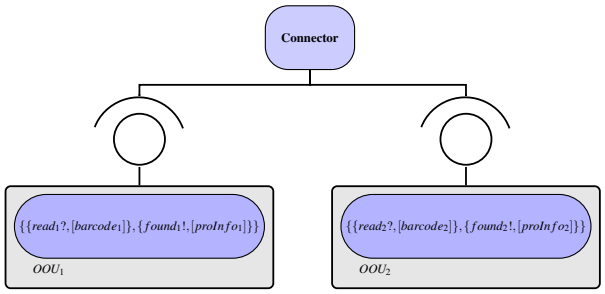

Fig. 3. Composition of two increments.

Incremental construction in PUTRACOM can be summarized in one definition:

Definition 16 (incremental construction)**.** An *incremental construction in PUTRACOM* could be a tuple $PCM_{inc} = (INC,\ basic,\ \Gamma,\ trail,\ inc_{next})$, where:

- INC. It is a finite set of components or composite components.
- $basic$. The first $inc \in INC$ of construction is $basic$.
- Γ is a set of connectors.
- $trail$. is a *non-empty* set of synthesized increments at the current level of construction.
- $inc_{next} \in INC$. Is a component or a composite component to be added to *trail* for building the next level of construction.

In composing increments, preserving interaction behavior is essential for adding new increments without defects. To ensure this, the sets of E^{Obs} must be disjoint, and both the trail and new increments must be free of event collisions before integration. Once confirmed, we can check the conditions for preserving behavior and synchronization.

Definition 17 (behavior preservation)**.** Consider that $basic$ is the first step and $trail$ is the next level of construction of system S. Let the relation between these two be $basic \subseteq trail$. Then, inc_{next} is allowed to be added into the system S as an increment if and only if $basic \subseteq trail \subseteq inc_{next}$ where $inc_{next} \in INC$.

The definition states that at each construction level, behavior and enforced synchronization must remain unchanged. To ensure this, we use the concept of isolated interactions, which clarify which interactions will be checked for preserving system behavior. An isolated interaction is defined based on the concept of a neighborhood.

Definition 18 (neighborhood)**.** Let Π represent a set of possible interactions, and let π be an interaction (or a set of interactions) within Π. The neighborhood of π, denoted by D_π, is defined as a subset of Π that includes all possible interactions containing π. Formally, this can be expressed as:

$$D_\pi = \{U \subseteq \Pi \mid \pi \in U\}$$

where U represents any subset of Π that includes the interaction π. A neighborhood includes a group of interactions that are similar to a specific interaction but still belong to the larger set of all interactions.

Definition 19 (isolated interaction)**.** Let $\pi \in \Pi$ represent an interaction (or $\pi \subseteq \Pi$ denote a subset of interactions), and let D_π be the neighborhood of the interaction π. An isolated interaction, denoted by $islt_\pi$, is defined as a subset of D_π that contains no other interactions from Π. Formally, this can be expressed as:

$$islt_\pi = \{d \in D_\pi \mid (\Pi \cap d) \setminus \{\pi\} = \emptyset\}$$

This means that the set $islt_\pi$ includes only those elements d in D_π for which there are no other interactions from Π present.

A trace function is employed to generate potential interactions and simulate transitions between $trail_i$ and inc_{next}.

Definition 20 (local interactions)**.** Consider a target system $Target$ such that $\{trail, inc_{next}\} \in Target$. If inc_{next} can be incremented to $trail$, denoted by $trail \otimes inc_{next}$, to facilitate the next level of construction, then the set of local interactions for $trail \otimes inc_{next}$, denoted by Π_{loc}, is defined as:

$$\Pi_{loc} = \{\pi_{islt}\langle trail\rangle \cup \pi_{inc_{next}} \cup \{\pi_{islt}\langle trail\rangle \otimes \pi_{inc_{next}}\}\}$$

To check whether the next level of increment contains the enforced synchronization over the transition of the trail, trace containment checking (TCC) [11] has been adopted. Especially, adding a new increment leads to more interaction than what the trail has already enforced. By adopting TCC, the set of interactions that have been added will be checked. The following TCC is extended to accommodate the requirements of this research.

Definition 21 (trace containment)**.** Consider a target system $Target$ such that $\{trail, inc_{next}\} \in Target$. The increment inc_{next} can be integrated into $trail$, denoted by $trail \otimes inc_{next}$, to facilitate the next level of construction if there exists a TCC satisfying the following conditions:

- For all $\pi \in \Pi_{\{trail \otimes inc_{next}\}}$, it holds that $\bowtie \notin \pi$.
- For all $\pi \in \Pi_{\{trail \otimes inc_{next}\}}$, there exists a $\pi_{islt} \in \Pi$ such that $\pi_{islt} \precsim \pi$.

The first condition states that all interactions lack collision events, while the second ensures that isolated interactions remain unchanged from the trail.

In the following, Theorem 1 presents a preservation checking method for $trail_i$ in incremental PUTRACOM. Both sufficient and necessary conditions are presented.

Theorem 1. Consider the target system $Target$ such that $\{trail, inc_{next}\} \in Target$. Let inc_{next} incremented to $trail$ as defined in definition 21, $L = trail \otimes\ inc_{next}$. Suppose Π_{loc} be the local interaction of L as defined in the definition 20. Then, adding inc_{next} to $trail$ preserves the enforced synchronization on the interactions if and only if the following proposition is hold $\forall \pi \in \Pi_{loc}$, $\bowtie \notin \pi$ and $\pi_{islt} \sqsubseteq \pi$.

proof of sufficiency. Let an interaction $\ell = \{\pi \mid \pi \in \Pi_{loc}\}$. Then, ℓ is proven to be a trace containment of local interactions over L by induction. First, we know $\pi = (n,\ p)$, thus:

- For $n \in N$, we have $N \subseteq (E^{obs} \setminus E^I) = E^O$. Then, from condition 2 of the definition 21, we have $\bowtie \notin E^O_L$. Hence $\bowtie \notin \ell$.
- For $p \in P$, we have $P \subseteq (E^{obs} \setminus E^O) = E^I$. Then, from condition 2 of the definition 21, we have $\bowtie \notin E^I_L$. Hence $\bowtie \notin \ell$.

Second, based on definition 20, we know $\Pi_{loc} = \{\pi_{islt}\langle trail\rangle \cup \pi_{inc_{next}} \cup \{\pi_{islt}\langle trail\rangle \otimes \pi_{inc_{next}}\}\}$. Then, for $\pi \in \Pi_{loc}, \exists \pi_{islt} \in \Pi_{loc}$ such that $\pi_{islt} \sqsubseteq \pi$. Hence $\pi_{islt} \sqsubseteq \ell$.

Therefore, ℓ is a trace containment, and adding inc_{next} to *trail* preserves the enforced synchronization on the interactions.

proof of necessity. Let Υ is an alternating trace containment over the local interactions of Π_{loc}. Consider ξ be an observable trace over L from $s_{initial}$ and s_{reach} is a reachable state via interaction (n,p) on ξ. The set of interactions that leads to s_{reach} called $(n,p)_{reach}$. Then, we prove $\bowtie \notin (n,p)_{reach}$ and $\pi_{islt} \sqsubseteq (n,p)_{reach}$ by induction on the trace ξ. Firstly, when $\xi = \lambda$, the two conditions of the theorem hold. Next, suppose the conditions $\forall (n,p)_{reach} \in \Pi_{loc}$, $\bowtie \notin (n,p)_{reach}$ and $\pi_{islt} \sqsubseteq (n,p)_{reach}$ hold for any ξ.

For checking the first condition of the theorem:

For $n \in \{env \cup E^O_L\}$ and $p \in \{env \cup E^I_L\}$, if $\exists A_L \xrightarrow{(n,p)} B_L$ is a $(n,p)_{reach}$ by ξ, then $\bowtie \notin (n,\ p)_{reach}$, (Definition **??**, Condition 1) Because $(n,\ p) = \pi$, then we have $\bowtie \notin \pi_{reach}$.

For checking the second condition:

- For $\forall n \in \{env \cup E^O_{trail}\}$ and $\forall p \in \{env \cup E^I_{trail}\}$, if $\exists A_L \rightarrow B_L$ which is reachable by $(n,p)_{reach}$ in ξ, then $(n,p)_{reach} \in \Pi_{islt}\langle trail\rangle$. Hence, we have $\pi_{islt} \sqsubseteq (n,p)_{reach}$.
- For $\forall n \in \{env \cup E^O_{inc_{next}}\}$ and $\forall p \in \{env \cup E^I_{inc_{next}}\}$, if $\exists A_L \rightarrow B_L$ which is reachable by $(n,p)_{reach}$ in ξ, then $(n,p)_{reach} \in \Pi_{inc_{next}}$. Hence, still we have $\pi_{islt} \sqsubseteq (n,p)_{reach}$.
- For $\forall n \in \{env \cup E^O_{\{\pi_{islt}\langle trail\rangle \otimes \pi_{inc_{next}}\}}$ and $\forall p \in \{env \cup E^I_{\{\pi_{islt}\langle trail\rangle \otimes \pi_{inc_{next}}\}}\}$, if $\exists A_L \rightarrow B_L$ which is reachable by $(n,p)_{reach}$ in ξ, then $(n,p)_{reach} = \{\pi_{islt}\langle trail\rangle \otimes \pi_{inc_{next}}\}$. Hence, we have $\pi_{islt} \sqsubseteq (n,p)_{reach}$.

Therefore, applying Υ over L implies $\forall \pi \in \Pi_{loc}$, $\bowtie \notin \pi$ and $\pi_{islt} \sqsubseteq \pi$ for any reachable trace over L.

VI. Incremental Verification

Verification is essential in system construction for identifying design obstacles and providing counterexamples to locate errors. It begins with generating the system's state space (SS), followed by checks for local properties, global properties, and deadlock-freeness.

1) Verification Process: The verification process checks the system's required properties and generates counterexamples for violations. In PUTRACOM, verification is integrated into the construction process, allowing the next increment only after verifying the previous one. However, model-checking faces limitations in industrial contexts due to the exponential growth of SS with the number of processes and states (SSE). This research proposes a technique to mitigate SSE's impact:

- Incremental verification after each addition, avoiding rechecking already verified parts.
- Eliminating hidden parts of increments and focusing on external behavior to reduce SS size.

2) State space generation: The system's SS must be generated before verification. PUTRACOM supports global and local SS generation, which resembles that in CPN [12] as a directed graph of reachable states and events. Detailed SS generation is omitted due to space constraints.

3) Verifying local properties in PUTRACOM: Each component in PUTRACOM must verify its local properties without assumptions due to their fixed behavior. Properties must be maintained during composition and when adding increments. The following theorem specifies how to prove the properties φ of inc_i in the trail.

Theorem 2. Given that inc_i is an increment in *trail* with respect to behavior preservation, local properties φ of inc_i hold on *trail* if firstly they hold on the local SS of inc_i.

Proof. Let L_{local} is the local SS of *trail*. Consider that $s \in S_{trail}$ is a reachable state in *trail* via trace sequence ζ such that s does not satisfy the set of local properties φ. It can be shown by $\zeta_s \not\models \varphi$. We know the observable trace is consistent with trace sequence $\zeta^{Obs} \preceq \zeta$. Therefore, if any violation against the properties is detected in ζ then its ζ^{Obs} has violation as well. Let $\zeta_{trail} = \varepsilon(trail)$ be a trace sequence over $L_{local}(trail)$ produced by the trace function $\varepsilon(trail)$. Since the trace sequence on *trail* includes the observer trace of all the composed increments $\{inc_1, ..., inc_n\}$ in *trail*, then ζ_{trail} may consist of $\zeta^{Obs}_{inc_i}$ and the violation appears in the $L_{local}(trail)$ as well. As a conclusion, a satisfying φ in *trail* can be detected in local SS inc_i, thus the theorem holds.

The theorem indicates that a set of local properties φ of inc_i is preserved in the trail that includes inc_i. Thus, in order to check and prove such propert in the trail, it must first be proven in the local SS of inc_i.

4) Verifying global properties in PUTRACOM: System-global properties are the set of properties that are related to the global SS of the system. Generally, it involves observable events with multiple increments in *trail*. Essentially, the global properties of the trail should be checked over a clausal normal form, in which clauses are disjunctions of observable events of increment in the trail through the set of connectors Γ_i. Its formal definition is given below.

Definition 22. Consider *trail* as the current level of a given system with a set of increments inc_i and Γ_j, $1 \leq i, j \leq k$, a global property of trail check over conjunction of following disjunction:

$$e^{obs}_1 \vee e^{obs}_2 \vee ... \vee e^{obs}_k$$

such that e^{obs}_k is an observable event of an increment $inc_i \in trail$ and $\forall n, m : 1 \leq n, m \leq k, n \neq m$ *implies* $inc_n \neq inc_m$.

This definition restricts each increment to at most one observable event, simplifying the integration of events from

other increments. Since the equation uses a conjunction of E^{obs} clauses, each can be proven independently and reused for future verification if no new events are introduced.

To verify global properties of a composite component, it is common to check each state and construct the SS as the Cartesian product of component states, which risks SS explosion. Instead, hidden events are eliminated, focusing on the SS without states hidden from other components or the environment. Local property violations impact global properties through observable events, which are critical for interactions in *trail*. Thus, the relevant part for global properties is the set of interactions Π, as proven in the theorem below.

Theorem 3. *Given inc_i is an increment added to trail with respect to behavior preservation, and a set of local properties called φ. Let w is a derived global SS of trail with respect to the elimination of the hidden events. Then φ holds on the w if for all $\pi \in Pi_t rail$, $\exists i : 1 \leq i \leq k, \pi_i \models \varphi_i$.*

Proof. Suppose an interaction $\pi \in trail$ is reachable via trace sequence ξ such that $\pi \not\models \varphi$. We know that an interaction in PUTRACOM can be simply denoted by $\pi = e^o \vee E^I$ and can be extended by $e^o_i \vee e^i_1 \vee e^i_2 \vee ... \vee e^i_k$ for $j : 1 \leq i \leq k$. If at least one of these events violates the properties φ, the *trail* does not holds the global properties φ, $trail \not\models \varphi$. Therefore, to check the global properties of *trail* its interactions must be checked.

This theorem, together with Theorem 2, facilitates the separation of concerns between proving local and global properties. By encapsulating and removing hidden events of increments, it reduces the potential SS of the system. Furthermore, due to the fixed behavior of components, the composition and verification of increments are assumption-free.

5) Deadlock-freeness preservation: Deadlock-freeness verification checks for the presence of activities in any reachable trace of the system. A deadlock indicates that parts or the entire system cannot progress. In PUTRACOM, a deadlock occurs when no admissible events exist for a state or a set of states, halting progress in an RTS or network of RTSs. The formal definition of deadlock-freeness in PUTRACOM is given below.

Definition 23. Let C is considered as a set of RTSs and $Comp = \{c_0, C, E, \Delta\}$ is a composition of C through a connector where E is a set of events and Δ is a set of transitions. Then, $Comp$ is deadlock-free for all $c \in C \vee Comp$, $E_{admis}(c) \neq \emptyset$.

Definition 24. Consider $Comp = \{c_0, C, E, \Delta\}$ is a composition of a set of components C through connector Γ. Let ξ be a given trace of $Comp$ and $s \in S$ is a reachable state via ξ. A state s is considered a deadlock state if $E_{admis}(s) = \emptyset$. $Comp$ can be said to be deadlock-free if, in any possible trace in the $Comp$, no deadlock has been reached.

Once all states in the component have an admissible event, it means that there is progress in the component. However, if there is any state in the component that does not have at least one admissible event to make progress on it, deadlock happens.

VII. Experimental Results

This section evaluates the proposed approach for feasibility in incremental construction, verification, efficiency in reducing SS, and addressing the SSE problem. It includes subsections on the case studies and tools, followed by implementation details and evaluation results.

A. Case Studies

a) Common Component Modeling Example (CoCoME): is a supermarket trading system model for sales, purchases, and inventory management, and widely used for evaluating component models [13], [14]. CoCoME has a cash desk line which processes payments with subcomponents like cash boxes, cash desk controller, cash desk app, Cah desk GUI, print controller, PoS terminal, and interface named *connectorIf*) facilitate communication among the cash desk, store, and enterprise. A store can manage multiple cash desks through a store server that oversees inventory.

b) Dining Philosophers Case Study: It shows how state space can expand exponentially with more philosophers. Seated around a table, each philosopher alternates between thinking and eating, using two shared forks. If all philosophers pick up the left fork at once, a deadlock occurs.

c) Automatic Machine Teller case study (ATM): enables banking transactions without needing human assistance. The system includes three main components: the user, the ATM, and the bank network, with subcomponents like authentication, balance check, cash withdrawal, deposit, help, and maintenance.

B. Implementation Tool

CPN Tools is a graphical platform for simulating CPNs, offering features such as the Create and Simulate Palette for implementing various systems and interactions, the Hierarchy Palette for constructing systems incrementally, and the State-Space Palette to calculate, check, and analyze the state space for properties like deadlock freedom while generating reports. CPNs are a formal modeling language for describing systems. They have been applied in various fields, including robotics [15], or communication networks [16]. A CPN includes places (representing states), transitions (actions or events), and arcs (connections between places and transitions). Each place is assigned a color, indicating the type of resources or objects it represents. Tokens represent the system's state and are placed in the CPN's places. Transitions fire when input places have enough tokens, moving them to output places and changing the system's state. CPNs can include guards and invariants to constrain transition firing, using an inscription language.

CPN is defined as a tuple $cpn = (P, T, R, C, \Sigma, EXPR, W, G, Init)$ where:

- P is a finite set of places;
- T is a finite set of transitions, where $T \cap P = \emptyset$;
- R is a finite set of directed arcs, where $R \subseteq (P \times T) \cup (T \times P)$;
- C represents a set of colors (types), and Σ is a function that maps places to color sets, i.e., $\Sigma : P \to C$. Colors in CPNs represent the types of tokens that places can hold;

- *EXPR* defines net inscriptions, such as guards, arc expressions, and initial markings, typically specified using an inscription language like CPN ML;
- W is the arc expression function $W : R \rightarrow EXPR$, assigning an expression to each arc $r \in R$;
- G is the guard function $G : T \rightarrow EXPR$, assigning a guard to each transition $t \in T$;
- *Init* is the initial marking function $Init : P \rightarrow EXPR$, specifying the initial distribution of tokens in each place.

Both non-incremental and incremental constructions of PUTRACOM can be modeled in this tool.

C. Simulation PUTRACOM by the CPN model

To simulate PUTRACOM using CPN, we start by listing all states, events, guards, and transitions in the model, facilitated by the trace function ε. Once the model elements are identified, we translate them into corresponding elements in the CPN tool, as outlined in Algorithm 1 (Fig. 4). The variable *steps* in Algorithm 1 represents traces of states, events, guards, and transitions from the trace function. Each state $s \in S$ corresponds to a place $p \in P$, and each transition Δ maps to a transition $t \in T$ in the CPN model with two directed arcs. Events $e \in E$ act as tokens, while guards $g \in G$ are conditions for each place. The variable *EXPR* holds expressions for guards, color sets, and markings, differentiating input, output, and internal events, which are then added to transitions. The OOU handles external interactions. Each CU must be encapsulated. Transitions that produce output events generate tokens for the OOU. Trace containment checking (TCC) is simulated in CPN Tools using the ASK-CTL library and SML, enabling CTL-like logic.

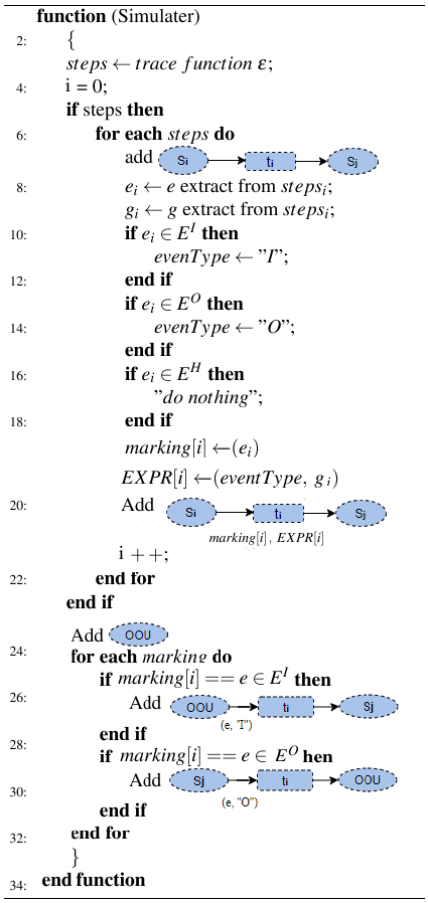

Fig. 4. Algorithm 1: Simulation of PUTRACOM with CPN

D. Evaluation

This section presents experimental results for the aforementioned case studies implemented using the proposed construction technique in CPN Tools. Evaluations were conducted on a Core(TM) i5-3337U CPU @ 1.80 GHz with 4GB of RAM.

a) CoCoME: In the evaluation of CoCoME, firstly the local SS of each component is generated, and then the global SS of the composite components will be calculated incrementally. We firstly verified each component mentioned in VII-A separately. the cash boxes and cash desk controller into a composite component named Composite Component 1, which we verified. Subsequently, we incrementally added the remaining components, resulting in Composite Components 2 through 4. The tables in this section report the number of states, indicating the amount of saved SS in memory. The status reflects whether the verification was fully completed or if a partial SS explosion occurred for both non-incremental and incremental approaches.

The system was verifiable with up to 20 cash desk lines and stores, but non-incremental verification failed early, as shown in Table I, with most results being partial and indicating an SSE. This was due to the need to generate all state spaces (SS) of atomic components and their compositions in memory, causing early SSE as the number of components increased.

In contrast, incremental construction successfully generated the SS by omitting the component's CU, verifying only the newly added increments. The PUTRACOM approach simplifies this by allowing fixed-behavior CUs, which are decoupled from other components, to be excluded. With reduced SS, the verification process is faster and less labor-intensive, making incremental construction more efficient. CPN Tools can produce counterexamples at each verification level, enabling early error detection and enhancing system safety.

b) Dining philosophers: Table II compares the verification results for the dining philosophers problem using the proposed method, CPN Tools, and NuSMV. In this experiment, we assess the amount of memory utilized. Incremental verification completes with lower time and memory consumption, while CPN and NuSMV face the SSE problem. Verification time is longer for dining philosophers due to substantial SS in interaction components (philosophers and forks). Omitting hidden parts did not significantly reduce SS. In CoCoME, diverse components interact through OOU and connectors, allowing hidden parts to be omitted, resulting in faster verification times.

c) Automatic machine teller: Table III shows the ATM case study results using three verification methods. In this experiment, we assess the amount of memory utilized. The enumerative CPN and NuSMV methods could not verify even 50 ATMs, while the proposed incremental method achieved nearly linear performance. The ATM case study outperformed

TABLE I. RESULTS OF COCOME LINE SIMULATION

1500	514	NA	NA	194	NA	NA

the dining philosophers due to having three main components (user, ATM, and bank) with sub-components, whereas the dining philosophers have only two. The hidden parts of each ATM could be omitted after verification, unlike the philosophers' problem, where most state space is tied to interactions. The ATM study results were similar to CoCoME, due to the number of evaluated ATMs and interactions.

VIII. RELATED WORKS

Addressing SSE is a critical challenge in model-checking for CBSD. While model-checking is a valuable tool for verifying system properties like deadlock-freedom, it faces significant scalability issues due to the exponential growth in the number of states to be analyzed [17]. This challenge has led to the development of various techniques aimed at mitigating SSE, which can be categorized into five main approaches: heuristics and probabilistic methods [17], [18], state space reduction techniques [19], compositional verification [20], memory optimization [21], and bottom-up verification [22]. A particular subset of the aforementioned verification methods is more suitable for addressing the SSE problem in CBSD, such as compositional verification and bottom-up approaches.

The compositional verification, particularly the assume-guarantee reasoning approach, decomposes a system into smaller subcomponents and verifies them independently [3]. However, compositional verification introduces new challenges, such as finding optimal ways to decompose systems and deriving accurate assumptions [23]. Additionally, circular dependencies between components can complicate verification, as addressing mutual interdependencies requires defining sound and complete rules, which is often difficult [24]. These limitations reduce the applicability of compositional approaches, especially in complex CBSD systems where component interactions are tightly coupled. Our work tackles these challenges with a bottom-up, incremental approach using a fully decoupled component model. This eliminates dependencies between components, removing the need for system decomposition, assumptions, or managing circular dependencies, making our method more practical for CBSD.

Bottom-up approach, which includes techniques like on-the-fly model-checking and incremental verification. On-the-fly model-checking verifies system properties by generating and checking individual paths one at a time, thereby reducing memory usage by not storing the entire state space [25]. However, this method can lead to inefficiencies, as previously verified paths might need to be regenerated if deleted, resulting in redundant checks and longer counterexamples. In contrast, our technique leverages the event-hiding feature of PUTRA-COM to retain essential verification information, avoiding the need to regenerate paths and thereby improving efficiency.

Incremental verification, which verifies systems as they are constructed, offers another solution for handling SSE. It has been explored in several domains, including rule-based systems, expert systems, and embedded systems [26]. However, most incremental techniques have been developed for non-component-based systems, and those tailored for CBSD remain rare. For example, Bensalem et al. [22] proposed an incremental construction and verification framework for component-based systems, using the BIP (Behavior, Interaction, Priority) model. While their work presents a valuable incremental construction approach, its reliance on symbolic methods (e.g., binary decision diagrams) and extremely relies on the variables ordering, which may limit the verification process. Our work is based on explicit verification methods,

TABLE III. RESULTS OF ATM

	Time (min)			Memory (MB)

which are more scalable and easier to apply to large systems.

IX. CONCLUSION AND FUTURE WORK

This research introduces a novel technique for incremental construction and verification in CBSD, aimed at early detection of deadlocks during system development. The approach ensures behavior preservation and synchronization at each increment, verifying safety properties like deadlock freedom and promptly generating counterexamples. The method effectively handles complex CBSD systems, avoiding the SSE problem by excluding previously verified computation units with fixed behavior. This reduces the state space, memory use, and verification effort. Results confirm the method's ability to lower verification complexity and identify potential issues early. Future work includes developing a standalone PUTRACOM application and conducting experiments on real-world systems with larger state spaces for deeper analysis and comparison, enhancing understanding of the method's strengths and limitations.

ACKNOWLEDGMENT

We sincerely thank the Ministry of Higher Education Malaysia and the University Tunku Abdul Rahman for the generous grant #Project: UTAR/IPSR/RMC/UTARRF/2024-C1/F01 that supported this research. Our appreciation also goes to Dr. Kung Kiu Lau, Simone Di Cola, and Cuong M. Tran for their valuable assistance and for sharing their X-MAN tool.

***Abstract*—This paper proposes a scalable and hardware-adaptable approach to automatic video caption generation by comparing two architectures: a traditional encoder–decoder framework combining InceptionResNetV2 with GRU and a transformer-based model integrating TimeSformer with GPT-2. The system supports CPU and GPU deployment through a unified pipeline built on FFmpeg and ImageMagick for keyframe extraction and subtitle embedding. Experimental evaluations on the MSVD and VATEX datasets demonstrate that the TimeSformer–GPT-2 architecture significantly outperforms baseline models, particularly in GPU settings, achieving top results across BLEU, METEOR, ROUGE-L, and CIDEr metrics. This superiority is attributed to its capacity to model spatiotemporal dependencies and generate contextually rich language. Designed for real-time operation, the system is also suitable for low-resource devices, enabling impactful applications such as assistive tools for the visually impaired and intelligent video indexing. Despite high computational demands and sequence-length limitations, the system presents promising directions for future development, including multilingual captioning, multimodal audio–visual integration, and lightweight models like TinyGPT for enhanced portability.**

***Keywords*—Video captioning; transformer; timesformer; GPT-2; real-time inference; spatio-temporal attention; multimedia accessibility; CPU/GPU deployment**

I. Introduction

Automatic descriptions of visual content play a crucial role in improving accessibility, information retrieval, and the generation of multimedia content [1]. While this task may seem natural to humans, it remains complex for artificial intelligence, which has to transform visual data into relevant linguistic representations [2]. The generation of natural language descriptions for videos, known as video subtitling, thus represents a major challenge in computer vision and multimedia processing [3]. Advances in deep learning have enabled significant progress, but conventional encoder-decoder architectures still suffer from redundancies and a lack of semantic consistency. Modern approaches, such as sequence-to-sequence models [4] combined with attention mechanisms, improve the alignment between vision and language, but their results sometimes remain insufficient. To overcome these limitations, large-scale language models (LLMs) [5] enhance the ability to generate accurate and consistent descriptions.

Video subtitling is the demanding task of transforming visual sequences into accurate, coherent textual descriptions. Among recent approaches, encoder-decoder architectures have demonstrated their effectiveness by combining networks such as InceptionResNetV2 for feature extraction and GRU for sequence generation. In parallel, large-scale language models (LLMs) have distinguished themselves by their ability to reason and generalize, opening up new opportunities for this application. In this context, GPT-2 [6], a lightweight, high-performance model compatible with non-GPU environments [7], was integrated.

With this in mind, a module optimized for video subtitling was designed, combining the TimeSformer-base-finetuned-k600 encoder with GPT-2 as decoder, in an architecture based on large-scale language models (LLM). This solution has been adapted to run efficiently on CPU-equipped systems, facilitating its deployment on modest hardware configurations. This study aims to evaluate the benefits of this LLM approach compared with conventional sequence-to-sequence architectures. The system, capable of processing videos in real time, relies on FFMPEG [8] for sequence fragmentation and ImageMagick [9]-[10] for automatic subtitle integration. A final evaluation confirms the robustness and relevance of the proposed solution in the field of video captioning.

This paper is structured into five main sections, each addressing a key aspect of the study. Section 2 reviews existing work on video captioning for the visually impaired, highlighting its limitations and presenting two approaches to improvement based on advanced video processing techniques. Section 3 describes the methodology used to develop the system's key modules, highlighting the technical choices made to enhance the user experience. Section 4 presents the experimental results, together with an analysis demonstrating the effectiveness of the proposed solutions. Finally, Section 5 summarizes the study's contributions and suggests directions for future research.

II. Related Work

In recent years, assistive technologies for the visually impaired have advanced considerably, particularly in navigation, access to environmental information, and video caption generation. M. Chen et al. [11] propose the TVT model, based on a Transformer architecture combining visual information and motion to produce textual descriptions. Although it performs well on MSVD and MSR-VTT sets, its use in real time remains limited due to its complexity.

Kevin et al. [12] introduced SWINBERT, which can capture complex spatiotemporal representations using a sparse

attention mask, reducing image redundancy. However, processing long, dense sequences generates a high computational cost, restricting their effectiveness in real time. L. Zhou et al. [13] conceive a model generating dense descriptions for non-truncated videos, relying on differentiable masking and attention mechanisms. Despite good textual consistency, the computational load associated with the use of Transformers compromises its real-time deployment. For their part, M. Amaresh and S. Chitrakala [14] are exploring encoder-decoder architectures combining CNN and LSTM, integrating attention mechanisms and spatiotemporal analysis, but oriented towards offline processing. Finally, L. Gao et al. [15] present the aLSTMs model, combining attention and LSTM to generate coherent descriptions. Although performing well on MSVD and MSR-VTT bases, this model remains limited by its computational complexity.

III. Proposed Method

This section describes the design and implementation of the two video subtitling architectures evaluated: a classic encoder-decoder model (InceptionResNetV2-GRU) and a transformer-based model (TimeSformer-GPT2). It details the visual and textual modules, the datasets used (MSVD and VATEX), and the technical optimizations (FFmpeg, ImageMagick), ensuring real-time processing on CPU and GPU.

A. Video Captioning Based on Encoder–Decoder Architectures

An automatic video captioning system is proposed based on an encoder-decoder architecture. It uses the Inception-ResNetV2 pre-trained CNN model to extract visual features, combined with a GRU (Gated Recurrent Unit) decoder to generate natural language text descriptions. The pipeline includes the encoding of videos as feature vectors, followed by the sequential generation of captions by the GRU. Developed with TensorFlow and Keras, the system is trained on the MSVD (Microsoft Video Description Corpus) dataset. It improves on previous approaches based on VGG16 and LSTM, offering a richer visual representation and more efficient sequence production. This model is particularly well suited to applications such as accessibility for the visually impaired, indexing of video content, and metadata creation. How it works is illustrated in Figure 1.

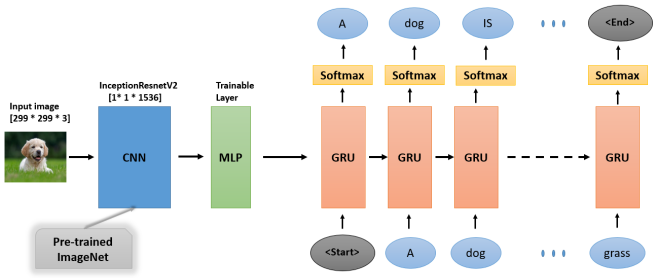

Fig. 1. General architecture of the encoder-decoder model for video captioning.

1) Visual feature extraction with InceptionResNetV2: Inception-ResNet-v2 is a neural network architecture that combines the advantages of Inception modules and residual connections [16], enabling efficient visual feature extraction while simplifying deep model training. It is based on three successive blocks - Inception-ResNet-A, B, and C - designed to process feature maps of decreasing dimensions. Block A operates on larger maps using convolutions of various sizes (1×1, 3×3) to capture information at different scales [16]-[17]. Block B continues this processing on intermediate maps, with controlled complexity, while Block C refines the representations on the most compact maps for final classification. Each of these blocks incorporates residual connections, which improve gradient propagation and stabilize learning, notably by alleviating the vanishing gradient problems encountered in very deep networks. The following figure illustrates the organization of these blocks. How it works is illustrated in Figure 2.

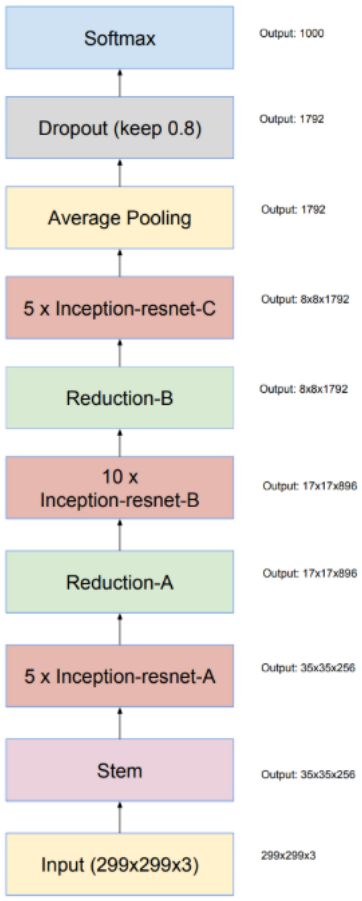

Fig. 2. Internal structure of the InceptionResNetV2 network.

2) Sequential text generation using GRU decoder: The decoder transforms visual representations into descriptive sentences, based on an RNN-type architecture. While conventional recurrent networks can model short-term dependencies, they run into difficulties with long sequences, notably due to the disappearance or explosion of the gradient. To overcome these limitations, we use gated recurrent units (GRUs) [18], which

control sequential learning using internal update, reset, and hidden memory mechanisms, as illustrated in figure 3. The decoder comprises three main components: an integration layer that encodes words in vector form, a multilayer GRU for temporal modeling, and a final linear layer that projects the hidden state into vocabulary space to predict the next word.

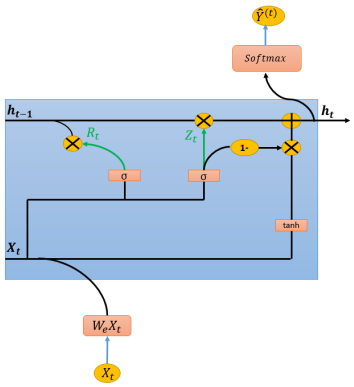

Fig. 3. Internal GRU mechanism (Gated Recurrent Unit).

In these equations (1, 2, 3, and 4) [19], x_t represents the input, and h_t is the hidden state at time t. The weights associated with the reset, update, and new information creation gates are denoted as W_r, W_z, and W_u, respectively. The hyperbolic tangent and sigmoid activation functions are symbolized by $\tanh$ and σ, respectively.

$$r_t = \sigma(W_{xr}x_t + U_{hr}h_{t-1}) \quad (1)$$
$$z_t = \sigma(W_{xz}x_t + U_{hz}h_{t-1}) \quad (2)$$
$$u_t = \tanh(W_{xu}x_t + U_{hu}(r_t \odot h_{t-1})) \quad (3)$$
$$h_t = (1 - z_t)h_{t-1} + z_t u_t \quad (4)$$

3) Parameters for the encoder-decoder video captioning model: Table I shows the main hyperparameters of a video caption generation model, combining InceptionResNetV2 for the extraction of visual representations and a GRU-based sequential decoder. The model processes 80 frames per video, from which it extracts vectors of dimension 1536. The text sequences produced are limited to 10 words, with a vocabulary of 1,500 tokens. Learning is performed over 3 epochs, with a learning rate of 0.0007 and a batch size of 8. 15% of the data is reserved for validation to control overlearning.

4) Dataset used: Microsoft Video Description Corpus (MSVD): As part of the experiment, the MSVD (Microsoft Video Description Corpus) dataset was selected for training and evaluation of the model. It consists of YouTube videos selected via Amazon Mechanical Turk and annotated with one-sentence descriptions. Only English captions are retained, after light pre-processing including lowercase casing, tokenization, and punctuation removal. The data follow the standard distribution proposed in [4]-[20], with 1,200 videos for learning, 100 for validation, and 670 for testing [21]. For each video, an image is extracted every ten frames, providing balanced temporal coverage. The set comprises 1,970 clips, each around 10 seconds long, and associated with around 40 descriptions, providing a linguistic diversity useful for training the generation system.

B. Caption Generation with Large Language Models (LLMs)

1) GPT-2 Integration for descriptive text generation: This model is an adaptation of the Vision Transformer (ViT) [22], [23] to video data processing, enabling the simultaneous capture of spatial and temporal dynamics. Unlike conventional ViTs designed for still images, ViViT segments a video into a sequence of images, converted into tokens enriched by positional and identity embeddings. These representations are then processed successively by a spatial encoder and a temporal encoder to model the structural and evolutionary relationships between images.The architecture retains the structure of the ViT encoder, with adjustments to exploit dependencies between successive images. The overall operation of the model is shown in Figure 4.

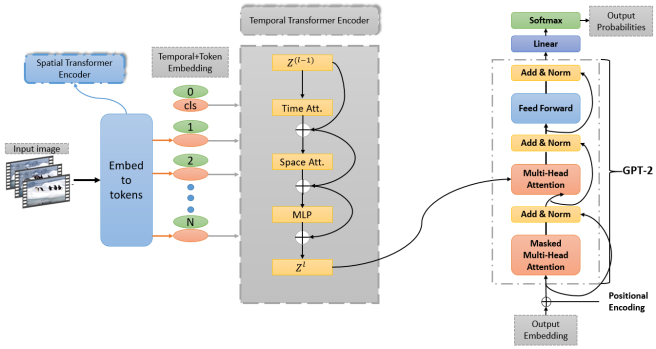

Fig. 4. TimeSformer + GPT-2 global architecture for video description generation.

2) Spatio-temporal analysis with timesformer encoder: The basic model is based on the "Base" structure of the Vision Transformer (ViT) and uses sequential spatio-temporal attention, applying attention first to the temporal axis, then to the spatial axis. This method, fitted to the Kinetics-600 dataset - comprising 392,000 videos for training and 30,000 for validation, spread over 600 human action categories - outperformed alternative approaches exploiting parallel or inverted attention. The TimeSformer model adopts this principle, illustrated in Figure 5, by dividing processing into two successive stages: temporal attention followed by spatial attention. This separation enables more efficient extraction of spatio-temporal features from videos.

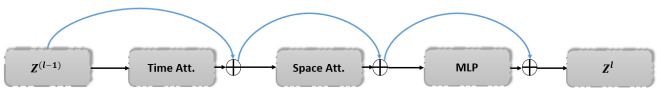

Fig. 5. Sequential spatial-temporal attention mechanism in timesformer.

At each layer, temporal attention is applied, followed by spatial attention and an MLP block, all integrated into a residual connection. This structure improves learning efficiency while reducing computational complexity, as shown by the $Z^{(l)}$ output described in equation 5.

TABLE I. CONFIGURATION PARAMETERS OF THE ENCODER-DECODER VIDEO CAPTIONING MODEL

Parameter	Value	Description
video	None	Name of the video file to process
keep_temp	False	Keeps the extracted images if set to True
train_path	data/training_data	Folder containing the training videos
test_path	data/testing_data	Folder containing the testing videos
max_length	10	Maximum length of the text captions
batch_size	8	Number of samples per training batch
lr	0.0007	Learning rate for the optimizer
epochs	100	Number of training epochs
latent_dim	512	Latent dimension size of the GRU layer
validation_split	0.15	Proportion of data used for validation
num_encoder_tokens	1536	Dimension of the video feature vectors
num_decoder_tokens	1500	Number of words in the output vocabulary
time_steps_encoder	80	Number of frames extracted per video

$$Z^{(l)} = Z^{(l-1)} + \text{TimeAtt}(Z^{(l-1)}) + \text{SpaceAtt}(Z') + \text{MLP}(Z'') \tag{5}$$

with :

$$Z' = Z^{(l-1)} + \text{TimeAtt}(Z^{(l-1)})$$
$$Z'' = Z' + \text{SpaceAtt}(Z')$$

The labels "Frame $t-\delta$", "Frame t", and "Frame $t+\delta$" denote the previous, current, and next frames in the video sequence. These serve as key inputs for spatio-temporal attention, enabling the model to capture temporal and spatial dependencies, as shown in Figure 6.

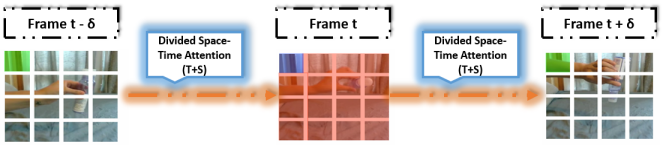

Fig. 6. Sequence of frames used for spatio-temporal attention.

3) Unified decoder for contextual language generation: It acts like a decoder, progressively generating a textual description. Each word is predicted by taking into account the words already produced, as well as the visual context extracted from the video. This mechanism ensures the harmonious integration of visual and linguistic information, resulting in an accurate and fluid description [23], [24].

Video subtitling begins by extracting visual features using pre-trained models such as ResNet, TimeSformer [23], [24] or I3D, which transform images into representative vectors. These vectors are then adapted to the GPT-2 input by adding special tokens (e.g., [CLS] for onset and [SEP] for separation). Trained on video-text corpora such as VaTeX [25], GPT-2 learns to generate relevant and coherent descriptions from visual content.

The unified video captioning framework based on GPT-2 models the conditional probability $P(C \mid V)$, where C is the caption and V the input video. It predicts each word in the output sequence based on the visual features extracted from V, as shown in Equation 6.

$$P(C \mid V) = \prod_{t=1}^{N} P(c_t \mid c_{<t}, \text{VideoEmbed}(V), \theta) \tag{6}$$

where c_t represents the t-th token of the caption, VideoEmbed(V) denotes the visual features mapped to GPT-2's embedding space, and θ refers to the model's parameters.

The training objective consists of minimizing the negative log-likelihood of the predicted caption sequence conditioned on the video features, as shown in Equation 7.

$$\mathcal{L} = -\sum_{t=1}^{N} \log P(c_t \mid c_{<t}, \text{VideoEmbed}(V), \theta) \tag{7}$$

This fine-tuning process adapts GPT-2's language generation capabilities to the video-text domain, enabling the production of captions that are both semantically precise and aligned with visual content. As illustrated in Figure 7, each frame is divided into 2D patches—typically 7×7—then transformed into visual tokens by a Vision Transformer such as TimeSformer or CLIP. These tokens, enriched with spatial and temporal context, are structured using special markers like [CLS] and [SEP], then passed to a late fusion module that prepares them for decoding. GPT-2, operating autoregressively, generates one word at a time by leveraging both prior textual outputs and the embedded video information. It produces a sequence of logits that guide the selection of the most probable next token at each step. This integrated architecture ensures a smooth fusion of visual cues and language modeling, yielding accurate and naturally flowing captions.

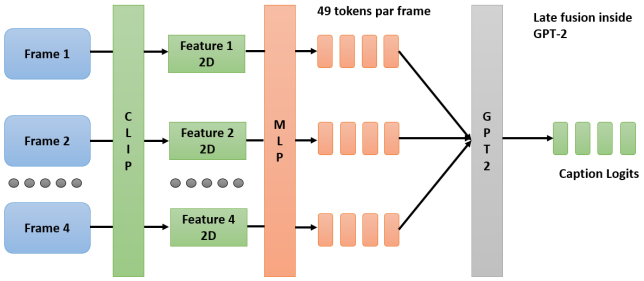

Fig. 7. Video subtitle generation pipeline via TimeSformer and GPT-2.

4) Performance optimization on CPU vs. GPU: A [26]-compatible GPU is an ideal solution for training video subtitling models such as TimeSformer and GPT-2, thanks to its ability to handle high resolutions, large batches of data, intensive spatio-temporal processing, as well as the use of mixed precision. Conversely, a CPU [26], although more affordable and accessible, is more suited to tasks of lower complexity due to its limited performance. The following table II compares learning parameters across CPU and GPU environments, detailing batch sizes, image resolutions, number of threads, and training schemes, to optimize performance according to available hardware resources.

During inference, a time clip is extracted from the center of the video. On a processor (CPU), the image is resized to 112 pixels on its shortest side, followed by a 112 × 112 center crop, to limit computation. A single softmax score is then used to generate the prediction. On a GPU, the TimeSformer-HR model exploits a higher resolution: resizing is performed at 224 pixels, with three 224 × 224 cuts analyzed to enrich the spatial information. The final prediction, obtained by averaging the softmax scores, thus benefits from the GPU's ability to process high-resolution data, enhancing the model's accuracy and robustness. Figure 8 compares two architectures designed for real-time caption generation. Sub-figure 8(a) illustrates the GPT-2 architecture, responsible for encoding the data and producing the textual descriptions. Sub-figure 8(b) shows the optimized version of TimeSformer, trained on Kinetics-600, capable of efficiently capturing spatio-temporal relationships in video sequences.

5) Dataset used (VATEX): VATEX is a large-scale dataset comprising around 41,250 10-second video clips, each accompanied by 10 manually annotated English captions. Learning is based on the official set, while performance is measured using the public test set [21], [25].Three Vision Transformer encoders are used for visual feature extraction, including an I-frame encoder initialized with the CLIP model [27], trained on the LAION-400M image-text corpus [28]. In comparison, SwinBERT [12] relies on the VidSwin architecture, trained on the video-oriented Kinetics-600 [29] dataset. It should be noted that LAION-400M is an image-text corpus, Kinetics-600 targets videos, and VATEX serves here as a reference for experimentation. SwinBERT outperforms the proposed method, thanks in particular to the effectiveness of its pre-training phase on Kinetics-600.

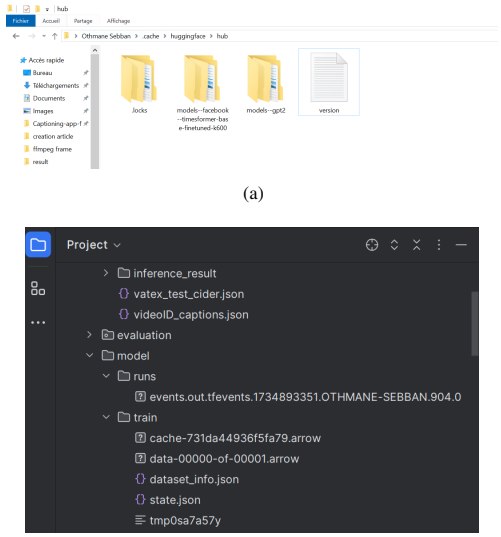

Fig. 8. Illustration of video captioning components: (a) GPT-2 used for text decoding, and (b) TimeSformer for encoding video frames into visual embeddings.

C. System Optimization Using FFmpeg and ImageMagick

To train the models, FFmpeg [8] was used, integrated via MoviePy [30], to facilitate the manipulation of complex video content and to optimize the use of large language models (LLMs). This free software supports a wide variety of multimedia formats, including video and audio, and includes a library dedicated to keyframe extraction. These keyframes generally represent significant visual changes. However, FFmpeg does not detect more subtle variations, often referred to as interesting images, which may nonetheless contain information relevant to analysis. MoviePy [31] simplifies the addition of text to videos by automating its generation and positioning using the TextClip class, then embedding it in the video via CompositeVideoClip, with FFmpeg support in the background. Once the text has been merged, it is encoded using standard codecs such as libx264 for video and AAC for audio, ensuring optimum compatibility with the majority of media players. In addition, key frame extraction aims to identify representative frames in a video sequence. This process can be carried out using a variety of tools, including FFmpeg, OpenCV's absdiff() function or the DMD algorithm [32]. Figure 9 illustrates the images extracted from a video file in MP4 format using the following FFmpeg command: `ffmpeg -i file.mp4 -vf "select='not(mod(n,4))',scale=320:240" -vsync vfr -frames:v 4 frame_%03d.png`.

ImageMagick is currently used to integrate full descriptions into videos as part of the subtitling process. An integrated tool [32], combined with a command-line routine, automates the cropping of images by removing 8 pixels at the left and 40 pixels at the top, reducing their size by around 20%. In addition, partial conversion of PPM files to JPEG is performed by a batch script. Interstitial spaces between mosaic segments were also corrected for archiving purposes. In all, the 67 selected mosaics and still images occupy 764 Kb.

TABLE II. HARDWARE CONFIGURATION COMPARISON FOR TRAINING CAPTIONING MODELS ON CPU VS. GPU

Parameter	**CPU**	**GPU**	**Description**
Device	”cuda” if GPU available, else ”cpu”	”cuda” if GPU available, else ”cpu”	Automatic device detection
Encoder Model	facebook/timesformer-base-finetuned-k600	facebook/timesformer-base-finetuned-k600	Model used for encoding
Decoder Model	Gpt-2	Gpt-2	Model used for decoding
Video Frames	4	16	Number of frames used per video
Image Resolution	112×112	224×224	Size of the images used
Batch Size	2	6	Batch size for training
Batch Learning	Disabled	Enabled	Use of `GradScaler` for AMP
Learning Rate	$1e^{-5}$	$5e^{-7}$	Learning rate for the optimizer
Epochs	100	100	Number of epochs for training
Scheduler	linear	linear	Learning rate scheduler
Num Workers	1	8	Number of workers for `DataLoader`
Collate Function	custom.collate.fn	default.data.collator	Data collation method
Pin Memory	False	True	Memory management in `DataLoader`

Fig. 9. Extracting key frames from video using FFmpeg.

IV. EXPERIMENTAL RESULTS

The Experimental Results section provides an in-depth analysis of the system's performance, examining each of its key modules. Subsection A outlines the evaluation criteria and the fundamental components of the system. Subsection B presents the results obtained by the video subtitle generation models developed according to the two approaches explored.

A. The Evaluation Metrics

To assess the quality of the trained model, four metrics are used. Among these, the BLEU (Bilingual Evaluation Understudy) metric quantifies linguistic similarity by comparing the n-grams shared between the generated sentences and the reference sentences. The calculation of the BLEU score is presented in equation 8.

$$\text{BLEU} - N(ci, Si) = b(ci, Si) \exp\left(\sum_{n=1}^{N} \omega_n \log P_n(ci, Si)\right) \tag{8}$$

where

$$b(ci, Si) = \begin{cases} 1 & \text{if } lc > ls \\ e^{1-\frac{ls}{lc}} & \text{if } lc \leq ls \end{cases}$$ is a brief penalty; lc is

The total length of the sentences generated (candidates) is noted as l_S, while l_c designates the optimal reference length of the corpus. When a candidate sentence is associated with several references, the one whose length is closest to that of the candidate is selected. In addition, the weights ω_n, assigned to the n-grams, are generally set to a constant value, as indicated in [18]-[33], as illustrated in the equation 9.

$$P_n(ci, Si) = \frac{\sum_k \min(h_k(ci), \max(h_k(S_{ij})))_{j \in \mathcal{M}}}{\sum_k h_k(ci)} \tag{9}$$

B-N, short for BLEU-N, is a precision measure that evaluates the quality of generated sentences by focusing on short n-grams, generally up to 4 words. It calculates the proportion of linguistic units (n-grams) shared between a candidate sentence and one or more reference sentences.

METEOR is an evaluation metric that measures both precision and recall at the unigram level. It takes into account not only exact matches, but also synonyms from WordNet and partial matches based on word fragments (truncated tokens). The METEOR score is given by the equation 10 [18]-[33].

$$\text{METEOR} = (1 - \text{Pen}) \times \text{Fmean} \tag{10}$$

The term $\text{Pen} = \gamma \left(\frac{\text{ch}}{m}\right)^m$ represents a penalty factor. In this expression, m corresponds to the total number of alignments between the candidate sentence and the reference sentence, while ch designates the number of contiguous segments correctly aligned (words identical and in the same order), as specified in equations 11, 12, and 13.

$$P_m = \frac{|m|}{\sum_k h_k(ci)} \tag{11}$$

$$R_m = \frac{|m|}{\sum_k h_k(S_{ij})} \tag{12}$$

$$F_{\text{mean}} = \frac{P_m \cdot R_m}{\alpha P_m + (1 - \alpha) R_m} \tag{13}$$

METEOR is a measure based on the harmonic mean between precision and recall, calculated between a reference sentence and the best-aligned candidate.

ROUGE-L is based on the longest common subsequence (LCS) identified between two sentences. The length $l(ci, sij)$ of this LCS forms the basis of its evaluation, as shown in equation 14.

$$\text{ROUGE-L}(ci, Si) = \frac{(1+\beta^2) \cdot Rl \cdot Pl}{Rl + \beta^2 \cdot Pl} \tag{14}$$

where:

$$Rl = \max_j \left(\frac{l(ci, S_{ij})}{|S_{ij}|} \right) \quad \text{(recall based on LCS)}$$

$$Pl = \max_j \left(\frac{l(ci, S_{ij})}{|ci|} \right) \quad \text{(precision based on LCS)}$$

The **ROUGE-L** metric evaluates precision based on the longest common subsequence (LCS), while the parameter$E$ is a constant to reinforce the importance of recall in the calculation. Other variants of the RED metric, such as **ROUGE-N** and **ROUGE-S**, are also used for finer comparisons [18]. For its part, **CIDEr-D** measures the average cosine similarity between the n-grams of a candidate sentence and those of references, taking into account both precision and recall. Its mathematical formulation is given by equation 15 [18]-[33].

$$CIDEr - D_n(ci, Si) = \sum_{n=1}^{N} \omega_n \text{CIDEr-D}(ci, Si) \tag{15}$$

This formula aggregates the *CIDEr-D* scores calculated for different levels of *n-grams* (from 1-gram to N-gram), assigning them a specific weight ω_n. This enables us to assess the similarity between the generated legend c_i and reference legends S_i at several levels of linguistic granularity, while incorporating a weighting mechanism that mitigates the impact of excessive repetition and too-frequent *n-grams*.

B. Quantitative Results

The proposed method was evaluated using the BLEU, ROUGE-L, METEOR, and CIDEr metrics to measure its efficiency. Tests were carried out on two Seq2Seq models based on LSTM and GRU, respectively, as well as on the Timesformer-base fine-tuned on Kinetics-600 with GPT-2, evaluated on both CPU and GPU.

The Neleac/timesformer-gpt2-video-captioning pre-trained model [22], [23] is based on a modular architecture built around three components. A visual preprocessor (MCG-NJU/videomae-base) adapts images extracted from videos, a tokenizer (GPT-2) encodes text sequences, and an encoder-decoder model combines a Vision Transformer with a GPT-2 decoder to automatically produce subtitles. This configuration, illustrated in figure 10, enables efficient, context-sensitive generation of descriptions from video content.

The results, presented in Table III, show the best performances in bold. Three modules were evaluated, including the pre-trained Timesformer-GPT2 subtitling model, as well as two encoder-decoder architectures designed for video description generation. Compared with previous methods, the proposed approach outperformed across all considered metrics, including BLEU-1 to BLEU-4, METEOR, CIDEr, and ROUGE-L.

```python
import av
import numpy as np
import torch
from transformers import AutoImageProcessor, AutoTokenizer, VisionEncoderDecoderModel

device = "cuda" if torch.cuda.is_available() else "cpu"

# load pretrained processor, tokenizer, and model
image_processor = AutoImageProcessor.from_pretrained("MCG-NJU/videomae-base")
tokenizer = AutoTokenizer.from_pretrained("gpt2")
model = VisionEncoderDecoderModel.from_pretrained("Neleac/timesformer-gpt2-video-captioning").to(device)

# load video

print(caption) # A man and a woman are dancing on a stage in front of a mirror.
```

Fig. 10. Example of generated video captioning from the TimeSformer-Gpt2 pre-trained model.

The models compared in the table fall into two categories: on the one hand, classic encoder-decoder architectures based on InceptionResNetV2 coupled with GRU; on the other, those based on the combination of TimeSformer and GPT-2. The latter captures spatio-temporal relationships more effectively and produces more accurate descriptions. Although they perform well on the CPU, they reach their full potential on the GPU, particularly in their pre-trained version, which considerably accelerates inference. Overall, this architecture outperforms encoder-decoder approaches, but at the cost of higher hardware consumption.

V. Comparative Analysis and Interpretation

This study compared two architectures for video captioning: a traditional solution based on an encoder-decoder framework combining InceptionResNetV2 and GRU, and a more advanced approach integrating a pre-trained TimeSformer encoder with a GPT-2 decoder. Experimental results demonstrate that the TimeSformer-GPT2 configuration, when executed on a GPU, achieves superior performance, notably with a BLEU-4 score of 0.276, compared to only 0.058 for the baseline. Improvements were also recorded in METEOR (0.821) and CIDEr (0.889), highlighting the effectiveness of combining a spatio-temporal attention mechanism with a generative language model for producing coherent and accurate outputs.

In particular, while the pre-trained Neleac/timesformer-gpt2-video-captioning model proved highly effective, the optimized Timesformer-base fine-tuned (GPU) version demonstrated superior performance on the majority of evaluation metrics, validating the effectiveness of the implemented adaptation process.

These findings emphasize the strength of TimeSformer in capturing complex temporal and spatial dependencies within video sequences. Coupled with GPT-2's capacity to generate contextually appropriate language, this synergy allows for a

TABLE III. QUANTITATIVE EVALUATION OF VIDEO CAPTIONING MODELS USING BLEU, METEOR, ROUGE-L, AND CIDER METRICS

Model	B-1	B-2	B-3	B-4	ROUGE-L	CIDEr	METEOR
GRU-based Encoder–Decoder (our model)	0.685	0.331	0.250	0.058	0.241	0.372	N/A
Timesformer-base finetuned (CPU) (our model)	0.803	0.492	0.370	0.182	0.567	0.765	0.714
Timesformer-base finetuned (GPU) (our model)	**0.887**	**0.571**	**0.498**	**0.276**	**0.687**	**0.889**	**0.821**
Timesformer-GPT2 video captioning (GPU) [22], [23]	0.872	0.562	0.475	0.259	0.672	0.884	0.812

deeper understanding and expression of visual content. The architecture relies on a divided attention mechanism—applying temporal and then spatial attention—to enhance the quality of feature extraction. GPT-2, in turn, adapts its linguistic output based on these extracted patterns, resulting in semantically rich and logically structured narratives.

Compared to models such as SWINBERT and TVT, the proposed method demonstrates a notable reduction in computational overhead, especially during inference on CPU-based systems. While many transformer-based solutions are primarily designed for offline processing, the presented system remains compatible with lower-resource environments without compromising output quality. These results align with the contributions of Bertasius et al. and Radford et al. [22]-[23], while offering a more scalable alternative for practical deployment.

From a conceptual standpoint, this work supports the hypothesis that coupling a high-performance visual encoder with a Large Language Model (LLM) improves the generation of multimodal language. Practically, it illustrates the feasibility of integrating sophisticated captioning mechanisms into mobile or embedded systems, particularly for assistive technologies aimed at the visually impaired or for intelligent indexing of audiovisual content.

Despite encouraging results, the proposed approach presents some limitations. The training phase, especially when involving the TimeSformer component, requires considerable computational resources. Furthermore, the fixed-length format (limited to 10 words) imposes constraints on expressive capacity, particularly in visually complex scenes. Additionally, the evaluation was limited to two datasets (MSVD and VATEX); further validation on diverse, especially multilingual, corpora would be beneficial to assess the generalizability of the system.

Analysis of the videos in the MSVD and VATEX datasets reveals limitations specific to each model. The GRU model favors static elements, sometimes neglecting the main action, while the Timesformer-base finetuned (GPU) model, while effective at capturing movement, can confuse context or over-interpret complex scenes. These errors highlight the difficulty of accurately understanding a scene and underscore the value of multimodal approaches that combine visual, sound, and temporal signals.

Potential enhancements include the incorporation of compact architectures such as TinyGPT and the use of knowledge distillation techniques to reduce training complexity. Another promising direction involves exploring multimodal pipelines that combine audio and visual data to further enrich the generated outputs. Moreover, extending the system to handle real-time processing of long-form video content or deployment in unstructured environments remains a key challenge for improving portability and robustness. Figure 11 shows the final results of the proposed system, illustrating optimal performance in terms of video captioning. It highlights the model's ability to produce accurate and consistent descriptions, demonstrating its effectiveness.

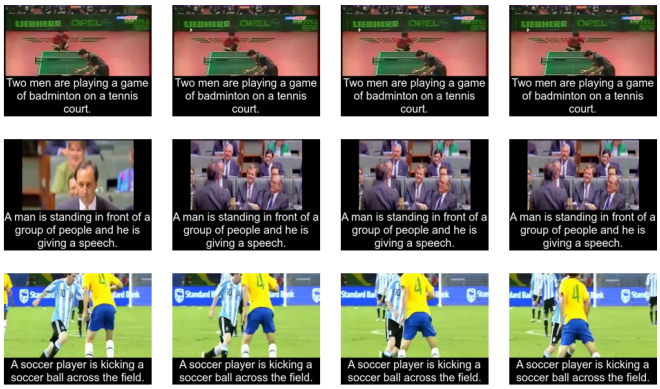

Fig. 11. Video captioning: key frame extraction with FFmpeg and caption insertion using ImageMagick.

VI. CONCLUSION AND FUTURE WORK

This paper has proposed a comparative study between classical video captioning architectures, such as InceptionResNetV2-GRU, and advanced approaches combining TimeSformer and GPT-2. Experiments on MSVD and VATEX datasets demonstrated the clear superiority of the TimeSformer-GPT2 model, particularly on GPUs, with high scores according to the BLEU, METEOR, ROUGE-L, and CIDEr metrics. This performance is explained by the model's ability to capture spatio-temporal dependencies while generating linguistically consistent descriptions efficiently. The proposed pipeline, integrating FFmpeg and ImageMagick tools, demonstrates the feasibility of a robust and adaptable automated subtitling system, compatible with different hardware environments. This flexibility opens up concrete prospects, notably in assistive technologies for the visually impaired and intelligent indexing of audiovisual content. Despite the promising results, there are several avenues for improvement worth exploring. Adopting lighter models such as TinyGPT or DistilGPT would reduce the computational load and facilitate deployment on mobile devices. The addition of audio modality could enrich the descriptions generated, particularly for complex scenes.

Furthermore, adaptation to specific multilingual corpora (educational, medical) would reinforce the system's generalizability. Finally, the processing of long continuous videos with dynamic generation of summaries or subtitles would

pave the way for more advanced applications, notably in visual assistance or intelligent streaming. This work paves the way for a new generation of intelligent video subtitling systems, capable of reconciling performance, accessibility, and lightness, and designed for concrete applications on mobile and embedded platforms.

ACKNOWLEDGMENT

Dr. Othmane Sebban thanks Dr. Ahmed Azough and Dr. Mohamed Lamrini, as well as the research team, for their essential support in this study.

***Abstract*—In resource-limited settings, assisting physicians with disease identification can significantly improve patient outcomes. Early diagnosis is crucial, as many patients could remain healthy with timely intervention. Recent advancements in deep learning models for medical image processing have enabled algorithms to achieve diagnostic accuracy comparable to that of healthcare professionals. This research aims to develop a comprehensive system for the rapid and precise detection of endometriosis lesions. We explore the several deep transfer learning architectures, specifically MobileNetV2, VGG19, and InceptionV3, on the Gynecologic Laparoscopy Endometriosis Dataset (GLENDA). Through extensive literature review and parameter optimization, we find that MobileNetV2 outperforms the other models in terms of accuracy. However, challenges remain, as healthcare imaging datasets often suffer from limited sample sizes and uneven class distributions. Collecting additional samples can be costly and time-consuming, which is a prevalent issue in medical imaging. To address this, we employ Deep Convolutional Generative Adversarial Networks (DCGAN) to enhance the dataset by generating synthetic images, thus improving class balance. This image augmentation strategy not only boosts model performance but also reduces the manual effort required for image labeling. We evaluate our proposed model using metrics such as accuracy, precision, recall, and F1-score. Initially, our model achieves an accuracy of 95%. The introduction of synthetic samples results in an increased accuracy of 99%, reflecting a 4% improvement and enhancing the model's overall efficacy.**

***Keywords*—Endometriosis classification; lesion detection; medical image classification; deep learning; transfer learning; DCGAN**

I. Introduction

Endometriosis is a medical condition in which endometrial cells, naturally found within the uterus, begin to grow outside the uterine cavity [1], [2]. The preliminary hypothesis describing this is retrograde menstruation, where menstrual tissue pursues a distinctive path. Rather than being expelled during the menstrual cycle, the tissue flows in reversal, traveling up through the fallopian tubes and potentially implanting in the ovary or within the abdominal cavity, resulting in lesion construction. These lesions are differ in size, with classification based on dimensions critical to diagnosis and treatment. Mainly, lesions measuring five millimeters or more are typically classified as deep-seated endometriosis [3], [4].

Endometriosis is frequently associated with significant diagnostic delays [5], [6]. Endometriosis disorder has a broad spectrum of symptoms, such as menstrual pain, acute pelvic pain, infertility, and pain during intercourse. Non-gynecological symptoms can also appear, including pain while urinating, discomfort during bowel movements, flank pain, fatigue, and blood in the urine, among others. Furthermore, the biological exams are complicated, and results can differ widely, even in examinations conducted by professionals in the field [7], [8].

Endometriosis is a severe gynecological problem impacting an estimated 190 million women internationally [9], [10]. The disease is prevalent among women of different age class, from infant women to those who are post-menopause. Studies estimate that approximately 10 percent of women of reproductive age are affected by endometriosis [11], with a prevalence of 2 percent to 4 percent among postmenopausal women [12]. Additionally, The disease's influence on young women is significant, with nearly 50 percent of those undergoing persistent pelvic pain occurring before the age of 20 being diagnosed with endometriosis [4].

Endometriosis can be diagnosed through various procedures, including ultrasound, magnetic resonance imaging (MRI), and laparoscopy [13], [14]. Laparoscopy is the gold benchmark, as it permits explicit examination of the abdominal and pelvic areas through a camera inserted via a small incision. MRI, a non-invasive imaging method, uses magnetic areas to create detailed images of the body's internal structures, making it beneficial in recognizing deep lesions or more extensive cysts associated with endometriosis. Ultrasound, generally performed transvaginally, is usually utilized for initial screening and assists in detecting ovarian cysts or other abnormalities [15], [16], [17], [18].

In recent years, computer-aided methodologies have become essential in medical fields for disease diagnosis, including identifying conditions such as heart disease [19], endometriosis lesions detection [20], and classifying breast cancer [21]. However, Healthcare imaging datasets frequently suffer from insufficiency and uneven class distributions. Moreover, acquiring additional samples is both expensive and time-intensive. This is a common problem in the medical image domain. Researchers endeavor to conquer this problem by utilizing data augmentation. Image augmentation methods typically fall into two main categories: conventional approaches and deep learning techniques. Conventional image augmentation methods apply simple manipulations like translation, cropping, flipping, or resizing. Deep learning-based augmentation utilizes state-of-the-art neural networks to create more adaptive, data-rich transformations. These two techniques enhance data diversity, helping models to generalize more effectively [22],

*Corresponding authors.

[23].

A promising deep-learning technique for image synthesis inspired by the game hypothesis is the Generative Adversarial Network (GAN) [24], [25]. In GANs, two networks are learned in an adversarial manner: one network, the generator, constructs artificial images, while the other, the discriminator, learns to distinguish between real and synthetic images. By repeating this adversarial approach, GANs enhance both networks' abilities, allowing the generation of high-quality, realistic images. The computer vision community has adopted GANs, directing to various variations developed for photorealistic image generation [26], [27].

Deep learning has attracted significant attention in many fields (for more detail, see [28], [29], [30], [31], [32]) such as the medical domain because of its efficacy in image analysis. It is employed for classification, enhancement of image quality, and segmentation of medical images. In recent years, deep learning techniques have rapidly evolved, with MobileNetV2 attaining popularity due to its compact architecture, which makes it perfect for various applications [33]. The MobileNetV2 architecture contains an internal structure with a linear bottleneck, an element that minimizes memory requirements for better processing. Therefore, to provide an accurate and efficient classification of endometriosis lesions, in this study, we propose an endometriosis image classification founded on the MobileNetV2 architecture. The proposed method uses MobileNetV2 as the base model for the transfer learning process. We add a global pooling layer and two fully connected layers to enhance the model's performance and refine classification outcomes [34]. The primary contributions of this research are as follows.

- We propose a synthesis of high-quality endometriosis lesions from laparoscopy images employing deep convolutional generative adversarial networks (DCGANs).
- Several state-of-the-art deep learning architectures, such as VGG19, InceptionV3, and MobileNetV2, are analyzed for this research. These architectures are fine-tuned on the laparoscopy images dataset to obtain efficient and accurate endometriosis lesion detection.
- We improve the training set of our deep learning model by including synthetic data, a technique that guides to enhanced classification results.

The remainder of the article is organized as follows: Section 2 explains the literature review on utilizing deep learning to analyze endometriosis lesions. Sections 3 and 4 present the proposed methodology and experimental result analysis. Consequently, Sections 5 and 6 provide the discussion and conclusion of the study, respectively.

II. Literature Review

Detecting endometriosis through laparoscopy imaging is challenging due to the disease's complex and varied presentation. Its lesions usually have subtle or indistinct characteristics, making them challenging to identify accurately, even by specialists. Machine learning applications aimed at diagnosing endometriosis through laparoscopy imaging still need to be developed, partially due to the limited access to labeled, representative datasets. This section summarizes recent research in machine learning for endometriosis diagnosis, focusing on techniques, methodologies, and the insights they provide.

Zaidi [5] employed a deep-learning based approach to detect endometriosis lesions from laparoscopy images.The team achieved a accuracy of 0.93% by applying Inception V3 model with 5-fold cross-validation techniques. Deep convolutional networks, exemplified as GoogLeNet [35], have been effectively employed across various applications, showcasing their versatility and robust feature extraction capabilities. These networks serve as robust backbones for many state-of-the-art deep-learning architectures used in image and video research analysis. By leveraging hierarchical layers of convolutional filters, they can capture complicated patterns and attributes, making them ideal for object recognition, classification, and segmentation tasks. Visalaxi [36] employed a deep-learning approach to categorize laparoscopy images associated with endometriosis. They employed the dataset for gynecologic laparoscopy related to endometriosis [37], comprising about 6,000 images from laparoscopy videos. Sixty percent of this dataset was used for training, and several architectures were tested to determine the model with the best performance. The ResNet50 architecture [38], loaded with ImageNet pre-trained weights [39], achieved the highest accuracy at 90 percent, with sensitivity and precision scores of 82 percent and 83 percent, respectively.Leibetseder's study used transfer learning and the Faster R-CNN [40] and Mask R-CNN [41] models to accurately detect endometriosis in laparoscopic images, getting a 32.4 percent precision. In addition, the research investigated different data augmentation methods, revealing that a blend of cropping and rotation yielded optimal results. The GLENDA dataset was employed as the primary data source in this research.

In 2021, Yun [42] and colleagues introduced a neural network model specifically designed to aid in classifying endometriosis. This study employed a convolutional neural network (CNN) architecture called VGGNet-16. Using a dataset of 6,478 histopathology images for training. The researchers aimed to develop a highly accurate system that could support and potentially enhance the diagnostic work performed by radiologists. In their research, Takahashi and colleagues [43] explored how computer vision techniques can support detecting endometriosis cancer in laparoscopic images. The team achieved a prediction accuracy of 90.29% by applying advanced neural network techniques. Sudalaimuthu [44] proposed an innovative approach recognized as Structural Similarity Analysis of Endometriosis (SSAE). This approach evaluates endometriosis progression in areas such as the ovaries, uterus, rectum, and peritoneum founded on laparoscopy images from the GLENDA image dataset. To enhance the model's robustness, images were subjected to data augmentation techniques, including horizontal and vertical shifts, rotation, shear, and zoom. The data was split, with 70 percent allocated for training purpose and the 30 percent for testing purpose. The U-Net architecture was utilized to explore factors like filter sizes and optimization methods. The highest results recorded were dice coefficient is 0.74 and an IoU is 0.72, though it is unclear if these metrics were specific to the test set.The literature on automated identification and segmentation of endometriosis remains limited, with few works addressing these areas. Among

the existing studies, most rely on images from laparoscopy procedures, which, while invasive, are the gold benchmark for diagnosis. Despite using these high-quality images, automated approaches are still being developed with the aim of improving accuracy and performance.

Our research differentiates itself from the abovementioned research by suggesting a data augmentation approach to conventional and deep learning approaches that encompass detection and classification tasks for analyzing deep or deep-seated endometriosis. Additionally, it focauses on laparoscopy images, seeking at premature examination beyond the essential for invasive procedures.

III. Materials and Methods

This section provides a detailed description of the materials used and the approach taken for classifying endometriosis lesions, including an overview of the image collection process, a summary of the overall methodology, and a discussion of the proposed methodology. Figure(1) provides a flowchart of the methodology followed in this research.

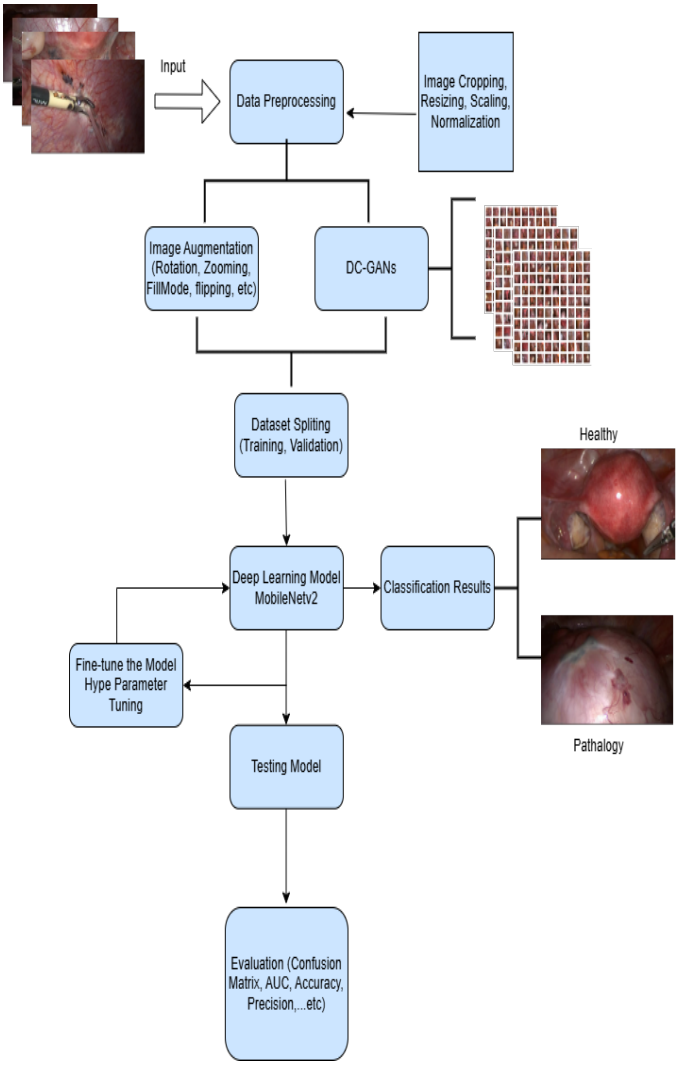

Fig. 1. A Flowchart of proposed methodology.

A. Data Collection

The Gynecologic Laparoscopy Endometriosis Dataset (GLENDA) is a comprehensive dataset derived from more than 400 gynecologic laparoscopy video recordings, a significant number of which depict instances of endometriosis with varying phases of severity. GLENDA comprises over 25,000 images, including more than 12,000 positive pathological photographs related to endometriosis and over 13,000 negative non-pathological images devoid of prominent endometriosis. The dataset is intentionally designed for various artificial content analysis tasks related to endometriosis recognition. The dimensions of the images are 640 by 360 pixels.

B. Image Pre-processing

Image preprocessing is a collection of procedures used on raw images to prepare them for additional examination or processing. The primary aim is to improve the image by identifying pertinent information while reducing artifacts, noise, and extraneous features that might interfere with further analysis. Prevalent preprocessing tasks include resizing, filtering, cropping, noise attenuation, color modification, and image enhancement. The phases are chosen according to the image properties and the particular application's requirements. In this research work, All images were resized to 224×224 pixels. We also applied image sharpening to the entire dataset to improve the quality of the images. Furthermore, the images are processed in RGB format. We implemented many rescaling methods, including multiplying each pixel by 1/255. This generalizes the input, conserves memory, and reduces the computational expense of applicable procedures. Moreover, it also facilitates the understanding of the ideal function.

C. Data Augmentation Using Image Data Generator Methods

This approach is used to generate data examples from the current samples. It is beneficial when the dataset contains a limited number of instances or exhibits class imbalance. We may use many geometric techniques to generate augmented data. This approach facilitates the learning of a class-imbalanced dataset and enhances the model's generalization, reducing overfitting. The model acquires the ability to handle unexplored versions of training samples. We used the Image Data Generator package from Kera's to do image augmentation. The following are the approaches that were executed for this objective:

1) Random zoom: It dynamically zoomed into the provided image. In this work, the zoomed value is fixed to 0.1 percent.

2) Random rotation: It dynamically rotates the provided image based on the specified value. The rotated value is fixed at 30 degrees.

3) Horizontal flip: This option randomly inverts the image horizontally to alter the positioning of its sides.

4) Width shift: It horizontally alters the image's width, with a value established at 0.2 percent of its overall width.

5) Height shift: It vertically alters the image's height, with a value established at 0.2 percent of its overall height.

D. Data Augmentation Using DCGAN Method

Deep Convolutional Generative Adversarial Networks (DCGANs) are a class of generative models that utilize deep convolutional layers to generate realistic images from random noise. They are built upon the framework of traditional GANs, which consist of two neural networks: a generator and a discriminator. Figure (2 and 3) illustrates its architecture. The generator learns to produce synthetic images, while the discriminator evaluates their authenticity. Both networks are trained simultaneously in an adversarial process, where the generator aims to create images that can deceive the discriminator, and the discriminator strives to distinguish between real and generated images.The generator creates progressively more naturalistic pictures throughout the training to deceive the discriminator. This adversarial strategy incrementally enhances the quality of the produced pictures. The generator learns explicitly to translate random noise vectors into picture spaces that mimic the distribution of authentic endometriosis images. At the same time, the discriminator acquires the ability to differentiate between actual and faked images. Ultimately, this leads to the generator creating high-fidelity synthetic endometriosis pictures that closely mimic authentic ones.

DCGANs introduce specific architectural enhancements, including the use of convolutional layers instead of fully connected layers, which improves spatial structure preservation in the generated images. Additionally, techniques like batch normalization and the use of Leaky ReLU activation functions enhance training stability and convergence. These improvements enable DCGANs to generate high-quality and coherent images across various domains, such as medical picture classification, and objects.

The structured use of convolutional layers helps the model learn hierarchical representations, which are crucial for producing realistic outputs. Furthermore, the adversarial training approach encourages the generator to refine its outputs iteratively, leading to visually convincing results. Due to their effectiveness and simplicity, DCGANs have become a foundational model in the field of generative image synthesis and serve as a basis for more advanced architectures in related applications.

DCGANs can generate data from existing samples. In situations like medical picture classification, gathering sufficient data to build a big deep learning model is crucial, which might be arduous. Utilizing presently accessible data, we may produce new samples with DCGANs; these synthetic samplings do not directly correspond to actual patients. This technology has expedited the use of deep learning in medical imaging; nonetheless, it requires significant improvement in accurately collecting delicate tissues from images. In this study employs a deep convolutional GAN (DCGAN) [46] to generate synthetic endometriosis images featuring pathologies diseases in the used dataset. A deep generative model of around five layers was used with a relatively slight discriminator network. The complex architecture assists in detecting subtle tissues within the endometriosis images. DCGAN was used for this analysis because of its stability in terms of simplicity and efficacy in producing high-quality pictures. In contrast to more intricate GAN variations like CGAN, BEGAN, WGAN, and DCGAN, it offers a simple architecture that is easy to build and tune, rendering it appropriate for our application in medical image creation. Moreover, DCGAN has been extensively evaluated

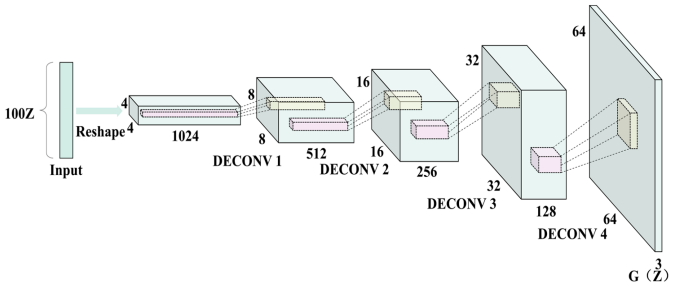

Fig. 2. Generator architecture [49].

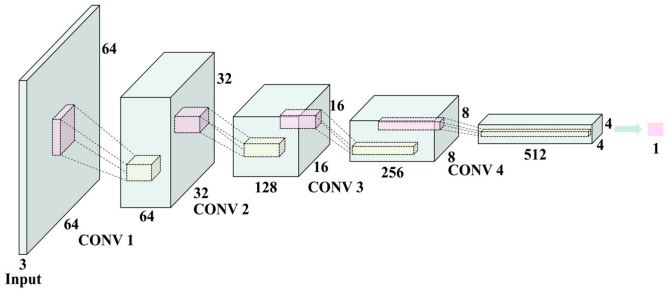

Fig. 3. Discriminator architecture [49].

across many image synthesis tasks, showing its reliability and effectiveness in creating realistic images, which coincides with our objective of enhancing medical datasets.

We trained DCGANs to synthesize images of endometriosis lesions, with separate models developed for each lesion category. The training process involved alternating updates to the generator and discriminator networks in an iterative manner, allowing both networks to improve their performance progressively. A learning rate of 0.0002 was employed, and training was conducted for 200 epochs for each lesion category to ensure adequate learning of the underlying data distribution.

The input dataset consisted of original images with a resolution of 224 × 224 pixels, and a batch size of 128 was used during training to optimize computational efficiency. Upon completion of the training process, we generated 300 synthetic images for each lesion category. Each class-specific training session required approximately 20 hours to complete on a local PC equipped with an Intel i7-7820HQ CPU. These synthesized images were then merged with the original dataset to augment the data available for subsequent analysis or model training. This approach ensured an expanded and balanced dataset that could potentially improve downstream performance in tasks such as endometriosis lesions classification or segmentation.

To evaluate the visual quality of the synthesized images, a radiologist with expertise in endometriosis assessed the synthetic lesions for their resemblance to real clinical cases. The radiologist's analysis focused on key morphological features, such as texture, contrast, and spatial distribution, to determine whether the synthetic lesions accurately mirrored the appearance of genuine endometriosis implants. By conducting training independently for each lesion category and ensuring consistency in the training parameters, we aimed to achieve high-quality image synthesis across all categories. This method

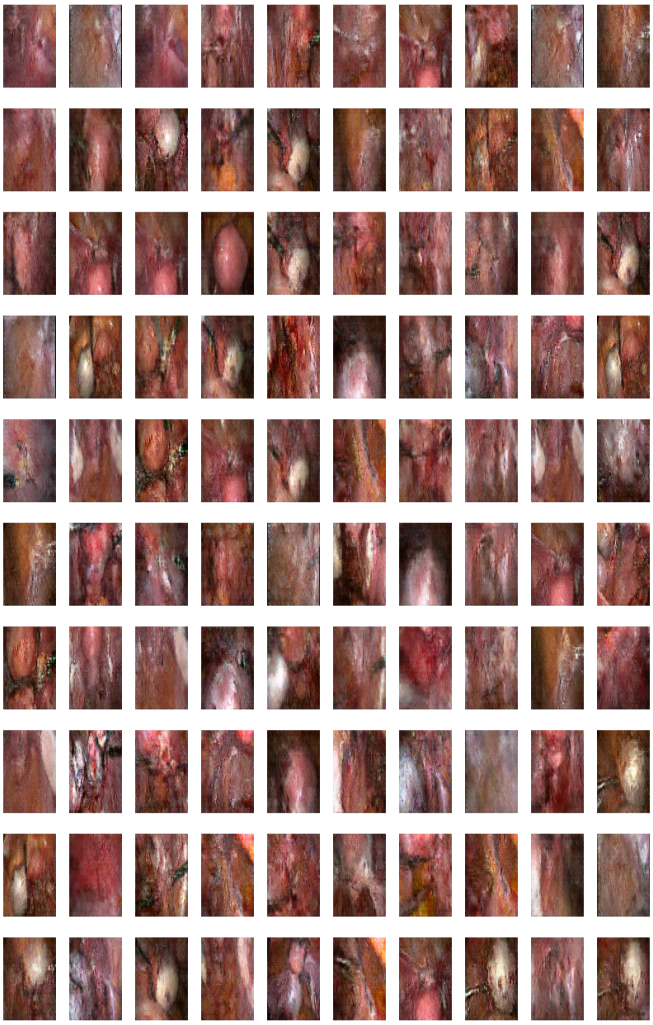

Fig. 4. DCGANs synthetic images.

highlights the potential of DCGANs in generating synthetic data that closely resembles real-world medical images, contributing to the development of robust datasets in medical imaging research.Figure (4) displays examples created for the pathology class after 200 epochs.

E. Training Phase

This section emphasizes some of the primary details applied in the training stage, such as kinds of models, hyperparameters, and classifier architectures.

1) Dataset split: In supervised machine learning and deep learning workflows, datasets are first divided into distinct sets for training, validation, and testing. Image augmentation, commonly performed on the training and potentially validation sets, aids in model generalization during the training and optimization stages. To ensure unbiased results, test data usually remains unaugmented to evade data leakage. Nevertheless, recent research highlights that augmenting test data can also be valuable in examining model robustness.In this work, the dataset is divided into 70% for training, 20% for validation, and 10% for testing.

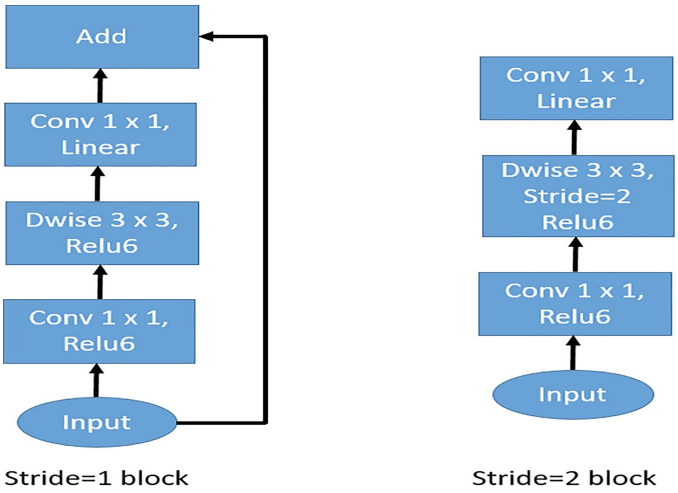

Fig. 5. MobileNetV2 architecture [47].

- Training Images: 17977
- Validation Images: 5136
- Testing Images: 2569

2) Model architectures: In this study, several deep learning models were evaluated using the Glenda dataset to assess their performance across different architectures. Three models (VGG19, InceptionV3, MobileNetV2)were implemented utilizing the Keras library in Python. Transfer learning was utilized for the convolutional layers to initialize these models, while random initialization was applied to the fully connected layers. The classifier network was built with a custom design that included two hidden layers and an output layer containing two neuron units, each assigned to a specific class. This minimalist design, featuring fewer layers and neurons, was strategically utilized to avoid overfitting.

3) MobileNetV2: MobileNetV2 [48] is recognized as a lightweight convolutional neural network (CNN) that is generally utilized in miscellaneous applications. It improves the MobileNetV1 model by introducing new modules, especially inverted residuals and linear tie-ups. The essence design of MobileNet is established on depthwise divisible convolution. This approach differs from standard 2-dimensional convolution, which treats all input channels uniformly to produce one output channel. Instead, depthwise convolution applies filters independently to each input channel, resulting in separate output channels that are subsequently combined. The separable depth-wise convolution process involves a subsequent 1×1 point-wise convolution, which merges these output channels into one final channel. This method provides the same output as traditional convolution while being more efficient due to a reduced number of parameters.Figure 5 presents the graphical representation of the MobileNetV2 framework.

4) Hyper parameters: In this study, we kept hyper parameters uniform across all models, allowing for a precise and fair comparison of each model's performance. This consistent approach allowed for a clear assessment of each model's relative performance.

a) Optimizer: In our optimization process, we rigorously tested two methods: Stochastic Gradient Descent (SGD) and Adaptive Momentum Estimation (Adam). After multiple iterations, we found that both optimizers performed similarly. However, we chose the Adam optimizer for training, as it is a more advanced technique for learning model weights and has been proven to enhance convergence and stability in deep learning models.

b) Learning rate: Since we utilized pre-trained weights through transfer learning for the convolutional networks in our models, we opted for a low learning rate, set explicitly at 0.0001, to ensure stable training.

c) Activation functions: ReLU was implemented across all layers, excluding the output layer, adding non-linearity to enhance model performance. In the output layer, we applied the softmax function, which is well-suited for labeled classification, as it allows each neuron to generate separate outputs.

d) Loss function: We opted for Binary Cross-Entropy (BCE) to calculate loss, which allows us to consider each label independently.

IV. Results

This section presents a detailed account of the results obtained from our experimental research and describes the programming environments employed to achieve these results. For clarity, each aspect is discussed in separate subsections.

A. Experimental Setup

The large dataset influenced our choice of programming environments to conduct deep learning experiments. We carried out model implementation and training on our Dell laptop, assembled with a 1.80 GHz Intel Core i5 CPU and 16 gigabytes of RAM. Our approach leveraged Python libraries such as TensorFlow, Keras, and sci-kit-learn for effective attribute classification. Jupyter Notebook enabled efficient program development and data analysis, and we observed satisfactory results across several models.

B. Evaluation Procedure

In order to make a comprehensive comparison of model classification performance, this paper leverages various metrics associated with the confusion matrix, including precision, recall, F1-score, and accuracy.Accuracy calculates the model's prevalent correctness, while precision focuses on the reliability of optimistic predictions. Recall quantifies the model's sensitivity by measuring the proportion of true positives, and specificity assesses the ability to identify negative cases correctly. We clearly understand each model's strengths and weaknesses by calculating and analyzing these metrics. The formulas for calculating these performance metrics are provided below.

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

$$\text{Precision} = \frac{TP}{TP + FP} \tag{2}$$

$$\text{Recall} = \frac{TP}{TP + FN} \tag{3}$$

$$F1\text{-score} = 2 \cdot \frac{\text{Precision} \cdot \text{Recall}}{\text{Precision} + \text{Recall}} \tag{4}$$

In this equation, TP, or True Positive, refers to the count of positive cases accurately identified as positive. FN, or False Negative, represents the number of positive cases mistakenly classified as negative. FP, or False Positive, denotes the count of negative cases incorrectly labeled as positive, while TN, or True Negative, captures the number of negative cases correctly classified as negative.

C. Area Under the Curve (AUC)

The ROC curve is commonly used to evaluate how well a model can distinguish between different classes. It is based on plotting the True Positive Rate (TPR) and False Positive Rate (FPR) across different thresholds. Since TPR and FPR are directly proportional, they increase together. The ROC curve visually represents this relationship and enables calculation of the Area Under the Curve (AUC), where a larger AUC value implies a more robust classification capability. Thus, a higher AUC indicates better model performance.

D. VGG19

In analyzing endometriosis lesion images, spatial data is crucial for effective disease classification. Deep learning-based models are frequently employed to capture these essential features, and VGG19, a highly layered convolutional model, was chosen for this study. We applied VGG19 with pre-trained weights for feature extraction and added a custom three-layer classifier. The model was trained across three configurations with varying epochs (3, 7, 14, and 20) and a batch size of (32, 64, and 128), resulting in above-average performance metrics with an accuracy of up to 88%. Table I compiles the results of tests conducted without data augmentation, providing insights into the baseline performance of our endometriosis lesion detection algorithm. Table II, on the other hand, presents the outcomes when data augmentation techniques are applied, showcasing the improvements in detection accuracy and robustness achieved through augmentation. Figures 6 and 7 illustrate the loss trajectories and accuracy trends, respectively, for the VGG19 model trained on the baseline dataset (without augmentation). In contrast, the effects of incorporating data augmentation are evident in Figures 8 and 9, which depict the model's loss dynamics and classification performance under enhanced training conditions. Figure 10 shows the confusion matrices illustrating the endometriosis lesion classification outcomes from testing the VGG19 model. The AUC-ROC curve, which can be seen in Figure 11, also explains the result of the VGG19 model.

E. InceptionV3

The InceptionV3 model offers an optimized approach to achieve high classification accuracy without relying on an extensive network architecture. With fewer learnable parameters than the VGG19 model, InceptionV3 provides an efficient alternative that still delivers excellent classification performance.

V. DISCUSSION

Endometriosis is one of the leading gynecological issues facing women worldwide. Diagnosing and treating this condition remains complex, particularly in settings with limited medical resources. Deep learning techniques applied to medical imaging on large datasets have enabled computer algorithms to achieve diagnostic accuracy similar to that of healthcare professionals. In this research, we propose a deep learning-based solution for classifying endometriosis lesions

in laparoscopy images, utilizing the MobileNetV2 architecture alongside a neural network classifier. We incorporate both conventional methods and deep learning-based image augmentation techniques. Experimental findings indicate that deep learning models are well-suited to accurately classify endometriosis lesions, facilitating a robust diagnostic tool for endometriosis.

The incorporation of synthetic images into the training process offers a substantial benefit to the performance of deep learning models, particularly when dealing with small or imbalanced datasets. In many real-world applications, such as

medical imaging, obtaining a large and representative dataset can be a significant challenge. Synthetic image generation addresses this limitation by augmenting the dataset, providing the model with a broader spectrum of examples, including rare or underrepresented cases. This allows the model to learn more robust and generalized features, which directly contributes to improvements in key performance metrics such as accuracy, precision, and recall.When compared to models trained solely on real images, those trained with synthetic images exhibit superior handling of rare classes. This is particularly important in fields like medical imaging, where certain conditions or abnormalities may be infrequent but critical for diagnosis. By increasing the diversity of the training data, synthetic images help to reduce bias toward more common classes, ensuring that the model does not develop a skewed understanding of the data. As a result, models trained with synthetic images are better equipped to identify and classify rare conditions, leading to a decrease in false negatives and an overall improvement in recall.

Moreover, synthetic images enhance the generalization ability of deep learning models. With more varied and comprehensive data, models are better prepared to perform well on unseen data, a crucial aspect for deployment in real-world scenarios. This greater ability to generalize ensures that the model's performance remains consistent when faced with new, previously unobserved examples. Thus, synthetic images play a vital role in improving not only the accuracy and reliability of deep learning models but also their ability to adapt to diverse and unpredictable data, particularly in specialized fields such as medical imaging.

In our comparative evaluation of convolutional neural network architectures, MobileNetV2 demonstrated superior performance relative to models such as VGG19 and InceptionV3, mainly due to MobileNetV2's lightweight and efficient structure, making it ideal for mobile and embedded deployment. With fewer parameters, it offers faster and simpler training and deployment. Experimenting with 32, 64, and 128 batch sizes, we achieved a favorable trade-off between accuracy and computational efficiency at a resolution of 224x224. Scaling pixel values from 0 to 1 was the most effective for normalization. Additionally, we observed that while fine-tuning the fully connected layer and freezing convolutional layers maintained stable performance, it did extend convergence time.

Table VII presents a comparative analysis of various deep learning algorithms tested on the GLENDA dataset, highlighting the performance of each model in detecting endometriosis. This comparison underscores the strengths and limitations of different algorithms within the same dataset, allowing for an evaluation of each model's effectiveness in classifying endometriosis lesions. Table VIII provides a summary of these findings and compares the performance of our models to existing state-of-the-art approaches, offering insights into how our methods advance current standards in accuracy, precision, and overall reliability for clinical decision support.

VI. CONCLUSION

Our approach, combining the MobileNetV2 model with both conventional and deep learning-based augmentation techniques, demonstrated high performance, achieving 99% in recall, binary accuracy, and F1-score. The integration of synthetic samples generated by DCGAN significantly improved training data diversity and addressed class imbalance issues within the dataset. Specifically, by generating synthetic images of endometriosis using DCGAN, we were able to enhance the MobileNetV2 model's accuracy, likely due to DCGAN's capacity to capture diverse manifestations of endometriosis present in the GLENDA dataset. These findings underscore the potential of deep learning models to accurately classify endometriosis lesions from laparoscopy images, supporting their use as clinical decision support tools for timely diagnosis. Additionally, synthetic data augmentation shows promise for addressing similar challenges in other areas of medical imaging, offering a pathway to more effective and reliable diagnostic support systems. Future work will aim to further improve system performance by expanding the dataset to include a wider variety of laparoscopy videos, enhancing both model accuracy and generalization across clinical scenarios.

***Abstract*—In real-world engineering environments, faults in rotating machines typically occur for concise periods, which leads to poor stability and low accuracy in fault diagnosis. The traditional fault diagnosis of rotating machinery relies on analyzing time-series data to detect system degradation and faulty components. However, the complexity of rotating machinery and the presence of multiple fault types across different operating conditions challenges for conventional classification techniques. This paper proposes a LASSO regression-based feature extraction method with adaptive window based on Dynamic Time Warping (DTW) for fault diagnosis in rotating machinery. The approach effectively extract features by modeling the relationship between shaft rotational speeds (25, 50, and 75 rpm) and vibration signals from piezoelectric accelerometers. This research focus on single and combination faults analysis to include 11 faults, enhancing its applicability to real-world fault conditions. To assess its effectiveness, the proposed method is evaluated against Principal Component Analysis (PCA) and Independent Component Analysis (ICA) using the K-Nearest Neighbors (KNN) classifier. The experimental results demonstrate that the LASSO-based approach consistently achieves high classification accuracy across different speeds, outperforming PCA and ICA in both single and double fault scenarios. These findings highlight LASSO regression as a robust feature extraction technique for improving fault detection and predictive maintenance in rotating machinery.**

***Keywords*—Rotating machinery; fault analysis; feature extraction, LASSO regression**

I. Introduction

Rotating machinery, such as motors, pumps, gearboxes, and turbines, forms the backbone of modern industry, with its uninterrupted operation depending heavily on the integrity of key tribological components like ball bearings and shafts. These elements help reduce friction, support radial and axial loads, and ensure dynamic stability. However, they also endure fluctuating mechanical and thermal stresses that can lead to issues such as cracks, spall, imbalances, and lubrication degradation. Faults originating from a rolling element or a shaft shoulder can propagate in just a few revolutions, manifesting as subtle energy bursts in vibration signals [1], [2]. If undetected, these incipient defects can escalate into catastrophic failures, resulting in unplanned downtime, costly production losses, and heightened safety risks [3], [4]. In response, the growing emphasis on condition-based maintenance necessitates diagnostic algorithms capable of quickly and reliably detecting these short-lived, speed-dependent anomalies.

Fault diagnosis in industrial settings is fundamentally a pattern recognition task: sensor signals are pre-processed to extract key features, which are then mapped by a classifier to different fault conditions [5], [6], [7], [8]. The literature includes several feature extraction methods, ranging from statistical indicators of time and frequency domain techniques such as the Hilbert Transform, Fast Fourier Transform (FFT), and Wavelet Transform [9], [10], [11], [15]. Feature reduction techniques typically involve methods like Principal Component Analysis (PCA), Independent Component Analysis (ICA), and Linear Discriminant Analysis (LDA) [12], [13], [14].

However, real-world applications have critical constraints that must be addressed for successful implementation. First, the true mechanical period of a machine is unknown a priori. While operators may log the nominal speed, transient load changes, belt slippage, and controller drift introduce cycle-to-cycle variations, causing misalignment between the start points of consecutive revolutions. Second, vibration data is continuously collected without explicit tags marking the start of each shaft revolution. This lack of synchronization leads to the smearing of transient fault signatures, as even small phase offsets can disperse localized impacts over multiple windows, thereby reducing the signal-to-noise ratio of the extracted features.

According to those problems, a significant research gap exists in accurately capturing transient, speed-dependent fault signatures without the need for specialized hardware or precise synchronization signals. While methods such as tachometer-based synchronization or order tracking can mitigate some of these issues, they often demand additional sensors, clean speed signals, and extensive calibration, limiting their practicality, particularly in retrofitted or older equipment.

Traditional fixed-window sampling was utilized to solve problems by assuming a constant period [15], [16], [17]. If the window is shorter than the true mechanical cycle, fault signatures are truncated; conversely, if the window is too long, irrelevant data dilutes the fault energy. Adaptive approaches, such as those based on tachometer pulses or order tracking,

can alleviate some of these issues but require additional hardware and clean speed signals, which may not be available in retrofitted plants. Dynamic Time Warping (DTW) provides an alternative that is sensor-agnostic. Specifically, originally developed for speech alignment, DTW computes the optimal nonlinear mapping between two time sequences [18], [19]. In this work, DTW is used to align consecutive revolutions of the vibration waveform. By using the first detected loop as a reference and minimizing the distance between it and subsequent candidate segments, DTW can dynamically select the window boundaries that correspond to the true mechanical period. In this work, the DTW-driven window selection ensures that transient impacts are confined to a single revolution while compensating for speed fluctuations at various rotational speeds (25, 50, and 75 rpm).

Once the correct windows are identified, the challenge shifts to selecting a compact discriminative set of features. While deep learning models excel at capturing high-order correlations, they require large, labeled datasets and substantial computational resources. The statistical methods, though more interpretable, tend to suffer from high dimensionality. To solve those problems a balance between simplicity and performance, we utilized the Least Absolute Shrinkage and Selection Operator (LASSO) regression [20]. By penalizing the l_1-norm of the regression coefficients, LASSO encourages sparsity in the model , driving irrelevant features to zero and preserving only the most fault-sensitive information [21], [22]. The resulting sparse feature vectors are then fed into a simple k-nearest neighbors (k-NN) classifier. This end-to-end pipeline is efficient, interpretable, and well-suited for real-time applications [23].

This paper proposes a novel LASSO-Based feature extraction with adaptive windowing via DTW for fault diagnosis in rotating machinery. The main contributions of this paper are summarized as follows:

- A speed-aware feature extraction paradigm that explicitly models the interaction between shaft rotational speed and vibration response under fault conditions, capturing subtle speed-dependent dynamics at 25, 50, and 75 rpm.
- A DTW-based adaptive windowing strategy that identifies the true mechanical period on the wheel by minimizing the DTW distance between consecutive revolutions, thus preventing dilution or truncation of transient fault signatures.
- A sparse LASSO feature selection framework that eliminates redundant descriptors, improving classifier accuracy while maintaining a computational footprint suitable for embedded systems.
- Comprehensive validation on public rotating machinery datasets covering eleven single-fault classes (and combinations of double-faults for robustness), where the proposed method consistently outperforms PCA- and ICA-based baselines in terms of accuracy, F1-score, and model compactness.

The organization of this paper is as follows: In Section II, we summarize the literature review in the field of fault diagnosis in rotating machinery. The data presentation is described in Section III. The methodology is outlined in Section IV, including the proposed LASSO regression with adaptive windowing, which is detailed in Section IV-A. The experimental evaluation and results are presented in Section V. The limitations and future work are mentioned in Section VI. Finally, the conclusion is discussed in Section VII.

II. Literature Review

Effective fault diagnosis in rotating machinery has long been a significant area of research due to the importance of predictive maintenance in industrial applications. Several researches have explored various feature extraction techniques to accurately identify faults using vibration signals [25], [26].

Traditional techniques, such as Fast Fourier Transform (FFT), Wavelet Transform (WT), and Hilbert Transform, focus on frequency-domain analysis to identify characteristic frequencies associated with specific faults [10], [11], [27], [28]. FFT, despite its widespread use, struggles with non-stationary signals, limiting its effectiveness in real-world scenarios involving transient faults [10], [11], [27]. Wavelet transform offers improved performance in analyzing transient events due to its time-frequency localization capability but still requires careful selection of basis functions to optimize results [11], [28].

Dimensionality reduction methods like Principal Component Analysis (PCA), Independent Component Analysis (ICA), and Linear Discriminant Analysis (LDA) have been widely applied to simplify complex vibration datasets, enhancing classification accuracy by reducing redundant or irrelevant features [12], [13], [14]. PCA, for example, captures dominant variance but often misses subtle fault signatures [12], [13]. ICA addresses this limitation by separating mixed signals into independent sources but still encounters difficulties with transient signals affected by varying operational conditions [14].

Recent advancements have introduced adaptive and dynamic approaches to overcome these limitations. Techniques involving Dynamic Time Warping (DTW) have demonstrated potential in accurately aligning and comparing vibration signals under fluctuating speeds without relying on external synchronization methods [18], [19]. Similarly, sparse representation methods have gained attention for their ability to effectively extract relevant sparse features, improving diagnostic accuracy while maintaining computational efficiency [29], [30].

Despite these advancements, few studies have combined adaptive windowing techniques with sparse regression models explicitly to handle speed-dependent transient faults comprehensively. This literature review highlights the critical need for methodologies that integrate these strategies to enhance the precision and robustness of fault diagnosis systems in rotating machinery.

III. Data Presentation

A. Mechanical Faults Dataset

In this paper, we employ vibration and rotational speed signals obtained from a multi-speed fault dataset [24]. This dataset is an open-access resource that provides vibration and

rotational speed data from various fault scenarios involving ball bearings and shafts. The dataset consists of 39 distinct fault scenarios, collected using a Rotary Machine Fault Simulator from SpectraQuest Inc., which includes a DC motor, Bearing 1, Bearing 2, and a shaft supporting two weighted disks. The data is captured using a National Instruments Compact DAQ system.

To collect the data, a tachometer and eight piezoelectric accelerometers are used to record the rotational speed and vibration signals. These sensors are strategically mounted on the motor, gearbox, and both bearing housings, in the x, y, and z directions. The dataset includes one no-fault scenario and 38 fault scenarios, each recorded at three different rotational speeds: 25 rpm, 50 rpm, and 75 rpm. The data are sampled at a rate of 6.4 kHz over a 10-second period, resulting in 64,000 data points for each scenario in time-series format. Each fault scenario is recorded 25 times, providing a comprehensive representation of the machinery's behavior under various conditions.

Table I provides a summary of the rotating machinery fault dataset, listing the different fault scenarios, their corresponding conditions, and the parameters used during data collection. This dataset is critical for the subsequent feature extraction and fault diagnosis tasks, as it offers detailed insights into the relationship between vibration signals and fault conditions at different operational speeds.

TABLE I. DESCRIPTION OF MULTIPLE MECHANICAL FAULTS DATASETS

Description	Details
Scenarios	39 scenarios
Rotational Speed	25 rpm, 50 rpm, 75 rpm
Time record	10 Seconds/scenario
Number of Trial	25 trials/scenario
Sampling rate	6.4 KHz
Data points	64,000 points/scenario
Sensors	1 Tachometer (Shaft), 8 Piezoelectric Accelerometers (6 bearing housings, 2 gearbox housing)

B. Data Preparation

In this paper, the rotating machinery dataset [24] consists of time-series data for 39 fault scenarios involving ball bearings and shafts. Each trial is grouped into a single file corresponding to each fault scenario and rotational speed. However, the data from trial number 17, which corresponds to a ball bearing number 2 defect at 50 rpm, is shorter than the others. To ensure consistency across all data, we discard the data from trial number 17 across all fault scenarios and rotational speeds. As a result, the length of each grouped file is standardized to 1,536,000 data points per fault scenario at each rotational speed. In total, 117 files are generated, corresponding to the 39 fault scenarios recorded at three distinct rotational speeds. This standardized dataset is now ready for feature extraction and classification analysis.

IV. METHODOLOGY

This section outlines the methodology employed in this paper, providing detailed insights into the feature extraction process, with a particular emphasis on LASSO regression. Additionally, we present the evaluation of the proposed feature extraction techniques using the k-NN classifier. The overall workflow is organized into four main steps, as illustrated in Fig. 1. The first step describes the algorithm developed based on DTW for adaptive window sampling, while the second step explains the application of LASSO regression for feature extraction. The final step focuses on the k-NN classification technique used to evaluate the extracted features. This structured approach enables a comprehensive assessment of the proposed methodology's performance in fault diagnosis.

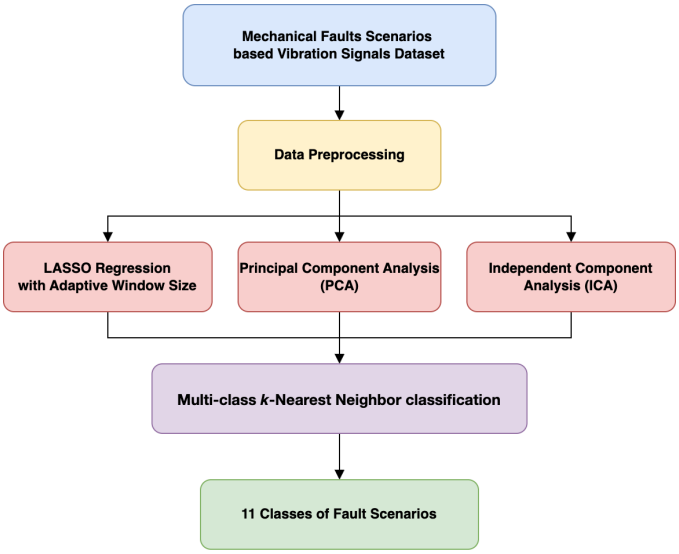

Fig. 1. Workflow of ball bearing and shaft fault classification.

A. Adaptive Window Based on DTW

In fault diagnosis of rotating machinery, selecting the appropriate observation window size is essential for extracting meaningful features from vibration and rotational speed signals. The window size must cover the entire rotational period, which can vary based on the specific characteristics of each signal. To address this, Dynamic Time Warping (DTW) is employed to evaluate the similarity between two time-series signals, allowing the alignment of successive machine rotations. The proposed adaptive windowing Algorithm 1 is designed to dynamically determine the optimal window size for each fault scenario by calculating the DTW distance between different segments of the vibration signals. The algorithm begins by initializing the vibration signal data, $\mathbf{D}$, and an array to store the optimal window size for each fault scenario. For each case, the algorithm iterates over a range of possible window sizes, from a minimum value, $n_{\min}$, to a maximum value, $n_{\max}$. At each step, two segments of the signal are extracted: $\mathbf{d}_1$ (the first segment) and $\mathbf{d}_2$ (the second segment), and the DTW distance between them is computed. DTW measures the dissimilarity between the two time-series, providing an optimal alignment even if the signals are shifted or stretched in time. The window size that minimizes the DTW distance is chosen as the optimal window for the current scenario.

Once all fault scenarios have been processed, the algorithm selects the largest optimal window size across all scenarios,

taking into account the varying rotational speeds and the effect of disturbances. This ensures that the window size is adequately adjusted to cover the true mechanical period, even when the machine experiences fluctuations in speed. By utilizing DTW, the algorithm effectively addresses the problem of varying signal periods without requiring additional hardware or external speed sensors.

The adaptive windowing approach improves fault diagnosis by accurately localizing transient fault signatures, enhancing the feature extraction process. This method is not only sensor-agnostic but also provides the flexibility to adapt to different fault scenarios, thereby improving the classification accuracy and robustness of the system. The DTW-driven window selection process ensures that transient impacts are captured accurately, facilitating efficient and precise fault detection in real-time applications.

Algorithm 1 Adaptive Window Size Estimation Using DTW

Require: $\mathbf{D}$: Vibration Signals in Time-series
Ensure: Optimal window size
Let $\mathbf{D}_{all} \leftarrow$ optimal window size of all cases
for case $= 1$ to last case **do**
  for $n = n_{\min}$ to $n_{\max}$ **do**
    Extract segment 1: $\mathbf{d}_1 = \mathbf{D}(1:n, 1)$
    Extract segment 2: $\mathbf{d}_2 = \mathbf{D}(n+1:2n, 1)$
    Compute DTW distance: $d(n) = \text{DTW}(\mathbf{d}_1, \mathbf{d}_2)$
  end for
  Select optimal window size:

$$n^* = \min d(n)$$

  Output n^* for current state
  Store n^* to $\mathbf{D}_{all}$
end for
Select maximum window size from all cases:

$$\hat{n} = \max \mathbf{D}_{all}$$

return Optimal window size $\hat{n}$

B. LASSO Regression

LASSO regression is an extension of Ordinary Least Squares (OLS) regression [20] designed to perform both variable selection and regularization, which enhances the prediction accuracy of the model. This method aims to minimize the sum of squared residuals while imposing a constraint on the sum of the absolute values of the regression coefficients. This constraint encourages sparsity by forcing some of the coefficients to shrink to exactly zero, which effectively removes unimportant features and helps avoid overfitting. The LASSO objective function is expressed as:

$$\hat{\beta} = \text{argmin} \left\{ \sum_{i=1}^{N} \left(y_i - \sum_{j=1} \beta_j x_{ij} \right)^2 \right\} \quad \text{s.t.} \sum_{j=1} |\beta_j| \leq \lambda, \tag{1}$$

where N represents the number of observations, y_i is the response variable at observation i, x_i is the vector of predictors associated with observation i, and λ is a non-negative regularization parameter. The parameter $\hat{\beta}$ represents the estimated regression coefficients, which include both the intercept and the coefficients for each predictor. The value of λ controls the strength of the penalty applied to the regression coefficients, with larger values leading to more coefficients being shrunk to zero, thus simplifying the model but potentially sacrificing accuracy. A smaller λ value results in less regularization, which may lead to overfitting. In this paper, we set λ to 1×10^{-8} to balance regularization and model performance. By using the L^1 norm of the coefficients, LASSO encourages sparsity in the model, helping to identify the most relevant features while reducing the dimensionality of the dataset. This sparsity is crucial for improving classification accuracy, as it focuses the model on the most important variables.

The LASSO regression process in this study is applied after using the adaptive window technique to determine the optimal window size for segmenting the time-series data. This ensures that each segment used for feature extraction corresponds to a meaningful portion of the signal. The extracted features are then processed using LASSO regression to estimate the coefficients, which are stored in a matrix for classification. This sparse feature set is then used to train a classifier, improving the accuracy of the fault diagnosis model while keeping computational demands manageable. The use of LASSO regression for feature extraction is particularly beneficial for real-time applications, where both high diagnostic accuracy and efficient use of computational resources are critical.

C. Classification

The k-Nearest Neighbors (k-NN) algorithm is employed as the classification model to evaluate the effectiveness of the proposed feature extraction method. k-NN is a non-parametric, instance-based learning algorithm widely used in statistical pattern recognition and classification tasks. It is particularly effective in handling multi-modal class distributions, where an instance may be similar to multiple class types. For implementation, the fitcknn function in MATLAB is utilized to construct and evaluate the k-NN model, specifically tailored for diagnosing faults in ball bearings and shafts.

The classifier is configured to distinguish among 11 different fault scenarios, as outlined in Table II, which include both single and compound faults such as outer and inner raceway defects in bearings and various shaft misalignment. Feature datasets generated from the proposed method, as well as benchmark methods including Principal Component Analysis (PCA) and Independent Component Analysis (ICA), are used to construct the training and testing sets. The datasets are partitioned using holdout cross-validation, with 70% of the data allocated for training and the remaining 30% for validation.

In the case of the proposed method, feature extraction is preceded by DTW-based adaptive window sampling, which identifies the optimal window size for each rotational speed condition using Dynamic Time Warping. These windows are then applied to both the training and validation datasets. Subsequently, LASSO regression is used to extract sparse features

TABLE II. DETAIL OF 11 SINGLE FAULT SCENARIOS

Number of Class	Detail of Fault Scenarios
Case 1	Outer Raceway defect (Bearing 2)
Case 2	Inner Raceway defect (Bearing 2)
Case 3	Ball and Raceway defect (Bearing 2)
Case 4	Ball defect (Bearing 2)
Case 5	Outer Raceway defect (Bearing 1)
Case 6	Inner Raceway defect (Bearing 1)
Case 7	Ball and Raceway defect (Bearing 1)
Case 8	Coupling end bent (Shaft)
Case 9	Centerally bent (Shaft)
Case 10	Ball defect (Bearing 1)
Case 11	No Fault

by establishing a relationship between the rotational speed and the corresponding vibration signals within each adaptively sampled window. This approach allows for the identification of the most discriminative and compact features.

In contrast, PCA and ICA are applied using a fixed window size of 640 data points, chosen based on the dataset's temporal resolution and recording parameters. For PCA, only the first principal component (PC1) is retained, which captured more than 95% of the total variance and is deemed sufficient for representing the feature space. Similarly, ICA decomposed the signals into statistically independent components, and the most informative component is selected as the feature representation.

By comparing the performance of these three methods under consistent classification settings, the paper aims to rigorously validate the superiority of the proposed DTW-adaptive LASSO-based feature extraction framework in terms of classification accuracy, computational efficiency, and robustness to varying operational conditions.

V. SIMULATION RESULTS

This research evaluates a novel feature extraction approach based on LASSO regression combined with an adaptive windowing strategy using Dynamic Time Warping (DTW). The proposed method is benchmarked against two widely-used dimensionality reduction techniques: Principal Component Analysis (PCA) and Independent Component Analysis (ICA). The objective is to assess whether the proposed LASSO-DTW method can achieve superior performance in fault classification using time-series data derived from vibration and rotational speed measurements of rotating machinery.

The experimental evaluation is conducted using a k-Nearest Neighbors (kNN) classifier, which was used to compare the effectiveness of each feature extraction technique. The classifier is configured to recognize 11 distinct fault scenarios across three rotational speeds: 25 rpm, 50 rpm, and 75 rpm. Four standard classification performance metrics are used: accuracy, precision, recall, and F1-score. These metrics provide a comprehensive evaluation of the models' ability to detect and classify faults reliably.

TABLE III. RESULTS FOR K-NN CLASSIFICATION PERFORMANCE BASED ON PROPOSED METHOD

Rotational Speed	Accuracy(%)	Precision(%)	Recall(%)	F1-Score(%)
25 rpm	96.97	97.73	96.95	96.88
50 rpm	93.94	95.45	93.94	92.86
75 rpm	84.85	87.88	84.85	84.85

TABLE IV. K-NN CLASSIFICATION PERFORMANCE FOR COMPARISON OF FEATURE EXTRACTION METHODS AT 25 RPM

Feature Extraction	Accuracy(%)	Precision(%)	Recall(%)	F1-Score(%)
Proposed method	96.97	97.73	96.95	96.88
PCA	36.46	35.89	36.56	35.96
ICA	90.85	94.75	90.89	88.97

The classification results using the proposed LASSO-DTW method are summarized in Table III, with corresponding confusion matrices shown in Fig. 2. At 25 rpm, the method achieved 96.97% accuracy, 97.73% precision, 96.95% recall, and a 96.88% F1-score. At 50 rpm, it maintained high performance with 93.94% accuracy, 95.45% precision, 93.94% recall, and a 92.86% F1-score. Even at 75 rpm, under more dynamic conditions, it achieved 84.85% accuracy, 87.88% precision, 84.88% recall, and an F1-score of 84.85%.

In contrast, PCA and ICA yield significantly lower performance. At 25 rpm, PCA achieved just 36.46% accuracy, while ICA reached 90.85%. At 50 rpm, PCA dropped further to 18.44% accuracy, with ICA achieving 81.41%. At 75 rpm, PCA recorded 20.64% accuracy, while ICA reached 77.41% (Tables IV to VI).

Beyond classification accuracy, the proposed method significantly reduces feature dimensionality compared to PCA and ICA. The feature matrix generated using the LASSO-DTW method is sized at 6,564 × 55 for the training set. In contrast, both PCA and ICA produced much larger feature matrices of 18,700 × 640. Despite this reduction, the proposed method maintained superior diagnostic performance, illustrating its capability to extract compact and highly relevant features without sacrificing accuracy.

This dimensionality reduction is especially beneficial in real-time and resource-constrained environments, where computational efficiency is crucial. The sparsity-promoting nature of LASSO enables the model to retain only the most informative features, improving interpretability and scalability. The combination of high classification performance and reduced feature complexity underscores the practical value of the proposed method for real-world applications in industrial fault diagnosis systems.

VI. DISCUSSION

The simulation results demonstrated the substantial advantages of integrating LASSO regression with DTW-based

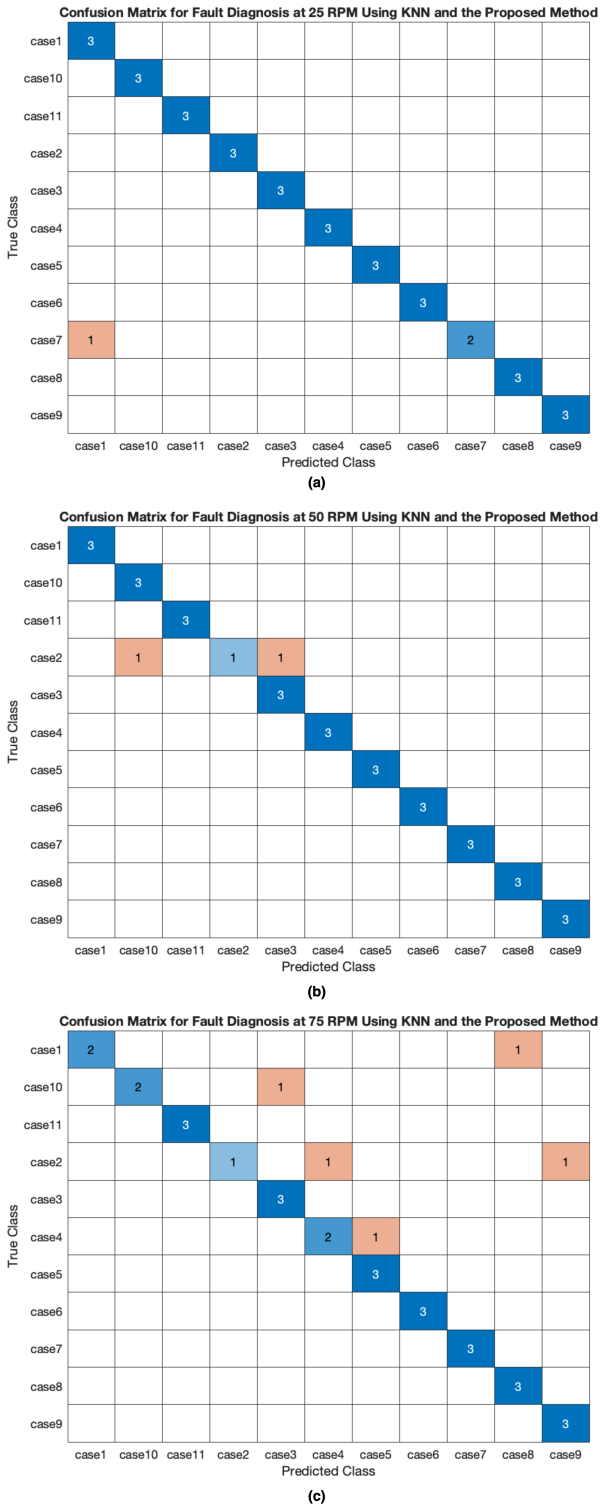

Fig. 2. Confusion chart of three rotational speeds (a) 25 rpm using KNN and the proposed method; (b) 50 rpm using KNN and the proposed method (c) 75 rpm using KNN and the proposed method.

adaptive windowing in fault diagnosis for rotating machinery. The proposed method consistently outperformed PCA and ICA across various operational speeds, illustrating its robust ability to manage transient and speed-dependent fault signatures

TABLE V. K-NN Classification Performance for Comparison of Feature Extraction Methods at 50 RPM

Feature Extraction	Accuracy(%)	Precision(%)	Recall(%)	F1-Score(%)
Proposed method	93.94	95.45	93.94	92.86
PCA	18.44	18.84	18.39	16.77
ICA	81.41	82.77	81.82	82.77

TABLE VI. K-NN Classification Performance for Comparison of Feature Extraction Methods at 75 RPM

Feature Extraction	Accuracy(%)	Precision(%)	Recall(%)	F1-Score(%)
Proposed method	84.85	87.98	84.85	84.85
PCA	20.64	20.77	20.51	20.00
ICA	77.41	77.41	76.29	77.41

effectively. The performance at lower rotational speeds (25 rpm and 50 rpm) was particularly noteworthy, achieving very high accuracy, precision, and recall. Even at higher speeds (75 rpm), where signal complexity significantly increases, the method maintained strong performance, highlighting its adaptability to real-world industrial environments. Moreover, the reduced dimensionality provided by LASSO regression significantly improved computational efficiency without compromising accuracy. This makes the proposed methodology highly suitable for real-time diagnostic systems, particularly in resource-constrained and applications.

However, the proposed method still has some limitations. Its effectiveness may depend on the quality and duration of the collected signals, and transient anomalies in extremely short-duration faults have still challenges. Moreover, it requires determining an optimal initial period for the adaptive windowing based on DTW, which directly affects the accuracy of identifying the rotational period. Future research could explore integrating advanced deep learning approaches or hybrid feature extraction methodologies based on sparse representation to further enhance performance. Additionally, validating the method across a wider range of operational conditions and fault types would help ensure broader applicability and reliability in diverse industrial scenarios.

VII. Conclusion

In this paper, we have proposed a feature extraction method based on LASSO regression for fault diagnosis in rotating machinery, enhanced by an adaptive windowing technique based on Dynamic Time Warping (DTW). We compared the classification accuracy of our proposed technique with PCA and ICA, and the results clearly demonstrate the effectiveness of combining LASSO with the adaptive DTW windowing approach. Specifically, our proposed method outperformed PCA and ICA in classifying ball bearings and shafts across multiple fault scenarios. For instance, our LASSO-based method achieved a classification accuracy of 96.97%

at 25 rpm, while achieving 93.94% and 84.85% at 50 rpm and 75 rpm, respectively. Furthermore, the integration of the DTW-based adaptive windowing technique enables dynamic adjustment of the observation window, ensuring that transient fault signatures are accurately localized within each revolution, even when rotational speeds vary. This improvement enhances the model's accuracy by addressing the challenge of unknown and fluctuating vibration periods. Additionally, the reduction in feature size achieved through LASSO regression, without compromising diagnostic performance, highlights the method's efficiency and potential for real-time applications.

***Abstract*—International drivers who come from keep-right countries and drive in keep-left countries are frequently involved in road accidents due to unfamiliarity with keep-left traffic regulations. Due to unfamiliarity of the traffic regulation, the driver's performance and behaviour are subject to change. The objective of this study was to explore the effects of familiarity with traffic regulations on driving performance and behavior at roundabouts and intersections. To achieve this in a safe environment, twenty-one male familiar drivers and thirty- four male unfamiliar drivers participated in driving in a simulated keep-left traffic regulation. The factors observed were not fastening the seat belt, entering the driving simulation from wrong side, using an improper approaching lane, not signalling, speeding, driving against the traffic flow and using an improper exiting lane at each roundabout and intersection. Mann-Whitney U test was used to compare driving behaviour and performance between the familiarity groups. Unfamiliar drivers made significantly more driving mistakes on roundabouts than unfamiliar drivers. Also, some unfamiliar drivers got inside the vehicle from the passenger side instead of driver side and drove against the traffic flow inside the roundabouts. The implications for familiar and unfamiliar driving can be considered for future research development.**

***Keywords*—Driving behaviour; driving performance; familiarity with traffic regulations; road intersections; roundabouts**

I. Introduction

An increasing number of students and tourists from keep-right countries (e.g., China, the United States (US) and Middle Eastern countries) are travelling to keep-left countries (e.g., New Zealand, the United Kingdom and Australia). Hence, the involvement of overseas drivers in road accidents abroad emerges as a potential road safety issue. Some drivers unfamiliar with the local road regulations experience difficulties in adapting their interactions with the road (e.g., keeping to the speed limit and driving with the traffic flow) and with the vehicle (e.g., controlling the direction indicator and windscreen wipers) to match the requirements of the new driving conditions [1], [2]. For instance, the Ministry of Transport in New Zealand, a keep-left country, reported that drivers from keep-right countries such as China Saudi Arabia, UAE, and Turkey, were the main group of overseas drivers involved in head-on collisions due to driving on the wrong side of the road [3]. Difficulties experienced by overseas drivers include the incorrect use of vehicle controls, signalling in time, keeping left and driving in the wrong lane.

While the problem of driving overseas is primarily considered in terms of road safety, little consideration is given to the use of concrete solutions and technology, such as in-vehicle information systems and gamification, to address differences in driving performance and behaviour between drivers who are familiar and unfamiliar with the local traffic system. Therefore, it is important to conduct scientific research on the ways unfamiliar drivers interact with the conditions of driving overseas and compare their driving performance with locals (i.e., familiar drivers) in order to provide a comprehensive insight into overseas drivers' vulnerability, support specific driving-assistance systems and reduce traffic violations as well as facilitating safe driving under unfamiliar conditions.

To gain a better understanding of the involvement of overseas drivers in road accidents and traffic violations when driving under unfamiliar traffic regulations, a simulated traffic environment was established to assess the way the rules of traffic regulation can affect driving behaviour and performance. An experimental task was designed to evaluate the driving behaviour and performance of drivers used to keep-right conditions when interacting with keep-left vehicle configurations and traffic systems prior to and while driving, especially at critical sections of roads (i.e., roundabouts and intersections). Although roundabouts and intersections optimise traffic flow [4], they are also associated with many vehicle accidents [1]. These sections of roads are associated with a relatively large number of driving tasks. While the seatbelt is fastened, the drivers need to perceive a lot of traffic information (e.g., the section of road, road signs, and the position of direction stalk), make critical decisions (e.g., slowing down or speeding up, and driving in the required travelling lane with the traffic flow)

[5], and then made a driving decision and act accordingly [6], The collisions that happen at roundabouts and intersections are likely to be due to the way the driver behaves and performs.

The objective of this research was to determine the effects of familiarity with traffic regulations on driving performance at roundabouts and intersections. It is hypothesized that (H1) drivers unfamiliar with the traffic regulation will commit more traffic violations on roundabouts and intersections than familiar drivers; and (H2) the risk at roundabouts and intersections is higher when overseas drivers drive under unfamiliar traffic regulations in comparison to familiar drivers.

The paper starts with an overview of the literature on the impact of familiarity with the interactions between drivers and unfamiliar elements of the traffic system. The methodology is then described in terms of the study sample, apparatus, driving scenario, experimental procedure, data acquisition and analysis. Then, the results are presented and discussed. At last, a summary of findings is presented.

II. Literature Review

The effects of familiarity with traffic regulations on driving performance have been insufficiently examined in transportation research [7]. However, some studies have acknowledged the interactions between drivers and unfamiliar elements of the traffic system (e.g., unfamiliar roads, vehicle configurations and traffic regulations), such as the behaviour of familiar and unfamiliar drivers in regard to a specific road condition (i.e., road familiarity).

Driving in unfamiliar routes is associated with some difficulties in terms of driving performance and mental workload. For example, the drivers in [8] showed low driving performance and high workload, and the situation was getting better when the drivers used to drive on those routes. However, drivers showed more respect for speed signs when driving in unfamiliar roads [9]. In terms of evaluating the risk subjectively, drivers evaluate the risk as higher when driving on unfamiliar roads in comparison to familiar roads [10]. The study [11] goes further and explores the risk perception in accordance with the driver's gender when driving in unfamiliar routes. That is, while male drivers perceived unfamiliar routes as riskier than familiar routes, female drivers tended to perceive familiar routes as riskier than unfamiliar routes. Compared to familiar drivers, unfamiliar drivers had shorter steering reaction times in case of the presentation of a peripheral object, longer braking reaction times in case of the presentation of an object at the front of the vehicle and kept a longer distance from the vehicle in front of their car [12]. Overall, familiar drivers were characterised by better awareness of surroundings and regulations compared to unfamiliar drivers [7].

In the context of driving under unfamiliar traffic regulations, most studies only examine the driving behaviour, performance and needs of unfamiliar drivers. Unfamiliar drivers were found to frequently ignore roads signs and road information and therefore did not drive under the road speed limit [13], [14]. Unfamiliar drivers also performed unnecessary and unsafe lane changes and did not use the direction indicator when lane departure was imminent [15], [16]. Moreover, some unfamiliar drivers entered roundabouts and intersections from the wrong side of the road [17], [18], [19]. Another study investigated the feedback and presentation mechanisms unfamiliar drivers preferred to help them to drive on specific sections of road. Unfamiliar drivers preferred the visual feedback that presents speed, navigation and direction indicator information concurrently with the performance of the driving task [20].

The study conducted by Yoh et al. [21] explored the driving behaviour of familiar and unfamiliar drivers under Japanese traffic regulations by analysing real-world driving accidents in Japan. While unfamiliar drivers were more likely to perform driving mistakes related to their understanding of traffic rules, familiar drivers committed more violations relating to speed. Also, Abbas et al. [22] studied the behaviour of two groups of drivers: Indigenous and non-Indigenous, where Indigenous drivers were the local drivers who were familiar with the local rules, the road conditions and the behaviour of other drivers in the road and non-Indigenous drivers were new to the local area. The study found that the drivers' responses to speed cameras were influenced by their familiarity with the road regulations.

When driving in unfamiliar traffic conditions, the driver might also be driving a vehicle with unfamiliar configurations. The vehicles that usually used in keep-left countries are right-hand -drive vehicles whose steering wheel is on the right. These vehicles often have the turn signal lever mounted on the right side of the steering column while the windshield wiper controls are mounted on the left side of the steering column. In contrast, left-hand drive vehicles have the steering wheel, signal lever and windshield wiper control the opposite way around. This can affect driving performance. Drivers from Japan (a keep-left country), for instance, were more likely to cross lane lines when driving a left-hand drive vehicle [23]. Additionally, some unfamiliar drivers misused the controls for the direction indicator and windscreen wiper [14], [18]. Another study [24] focused on the interaction between drivers, particularly ones who had mild cognitive impairment, and unfamiliar vehicles to discover the needs of a system to remind the drivers of performing some tasks, such as fastening the seatbelt. Drivers' behaviour regarding fastening seatbelt and speeding is discussed along with other driving behaviour in [25] to investigate the influence of culture on road safety when driving in familiar and unfamiliar environments.

Driving simulator is presented as a valid method for driving research [26]. It is used in a wide range of research (for example, [16], [27], [28], [8]) that explore the interactions between traffic elements under a condition of unfamiliarity. Due to unsafety of testing such interactions, experiments using driving simulator provide a safe observation environment [27], [8]. The driving simulator also allows researchers in [8] to systematically measure driving performance and workload under controlled conditions.

There is still a lack of research that compares the driving performances of familiar and unfamiliar drivers at roundabouts and intersections. Therefore, this study explores the influence of familiarity with traffic regulations on road safety using a driving simulator.

III. METHODS

A. Sample

A total of 55 right-handed male drivers voluntarily took part in the driving simulator study. They were divided into two groups based on the traffic system the drivers were most familiar with driving in. The first group included 21 drivers who were only familiar with keep-left traffic regulations and held a valid driving license issued from a keep-left country. This group was titled "familiar drivers," as they were familiar with the traffic system of this study. The second group included 34 drivers who were only familiar with keep-right traffic regulations and who held a driving license issued in a keep-right countries. The second group was categorised as "unfamiliar drivers." The age range of both groups was between 20 to 35 years. The first group had a mean age of 27.048 years (SD = 4.318) with a mean driving experience of 4.762 years (SD = 2.548) and an average driving hours per week of 9.048 (SD = 10.072). The second group had a mean age of 24.441 years (SD = 4.215) and with a mean driving experience of 6.235 years (SD = 4.390) and an average driving hours per week of 15.353 (SD = 10.557).

B. Apparatus

A fixed-based driving simulator, Forum8 (see Figure 1), located at Macquarie University, was used for the study. The simulator was placed in a small room with its own door. Also, there was a large glass window between this room and an adjacent room through which the research could observe the driving session. However, the glass was covered with a blackout curtain during the driving session in order to provide a less distracting environment and minimise the changes in driving performance due to being watched by the researcher. Forum8 consists of a right-hand drive vehicle cockpit containing a force-feedback steering wheel, direction indicator and windscreen wipers levers, brake and gas pedals, a gear shifter, seatbelt and air-conditioner and multimedia control panel. The front of cockpit is attached to a three-screen display that provides a horizontal and a vertical field of view of 150 degrees and 30 degrees, respectively. The graphical interface was designed by UC-win/Road which is used to model the traffic system, including roads, road signs and texture, vehicles, and trees. Also, UC-win/Road records data in CSV and video logs. The data includes information on the vehicles, users on the road, and driving environment in addition to the interactions among those items for analysis purposes.

C. Driving Scenario

The driving simulator experiment consisted of driving in a keep-left traffic system using a Forum8 simulator as described above. Randomly, a New South Wales (Australia) geographical area from UC-win/Road was selected. The entire driving track was dual-lane and had different road sections, including straight and curved roads, three four-way intersections and three four-exit roundabouts. The scenario had no traffic movements, such as pedestrians, cyclists or other vehicles. Road signs and textures were added in accordance with the Australian regulations. The driving scenario started from a fixed point and ended at another point. The scenario directed

Fig. 1. Driving simulator.

the drivers to drive through all intersections and roundabouts. The sequence and the required turning at each section were as follows: intersection (go straight-ahead), roundabout (turn right), intersection (turn right), roundabout (turn left), intersection (turn left), roundabout (head straight) (see Figure 2).

D. Experimental Procedure

Once the participants arrived, their driving license was checked for its validity and the country of issue. The whole experiment was then explained to participants. If the participants agreed to continue then they signed the consent form and filled out a questionnaire about their demographic information and driving experience. After the questionnaire was completed, the researcher provided the participant with instructions regarding driving rules at intersections and roundabouts in Australia. The participants then moved to the simulator room with the window uncovered to perform the training session which lasted up to 10 minutes. Under observation, participant gradually became accustomed to the vehicle and the simulated environment. After that, the glass was covered with a blackout curtain and the participant moved to the experimental session. At the beginning of the session, the driving task was introduced to participants with the instruction to follow the road directions presented on a map to reach the destination. Participants were reminded to respect all traffic laws. After completing the experimental session, prior to leaving the vehicle seat, the participants called the researcher. The researcher ensured that all required files were saved and then the participant

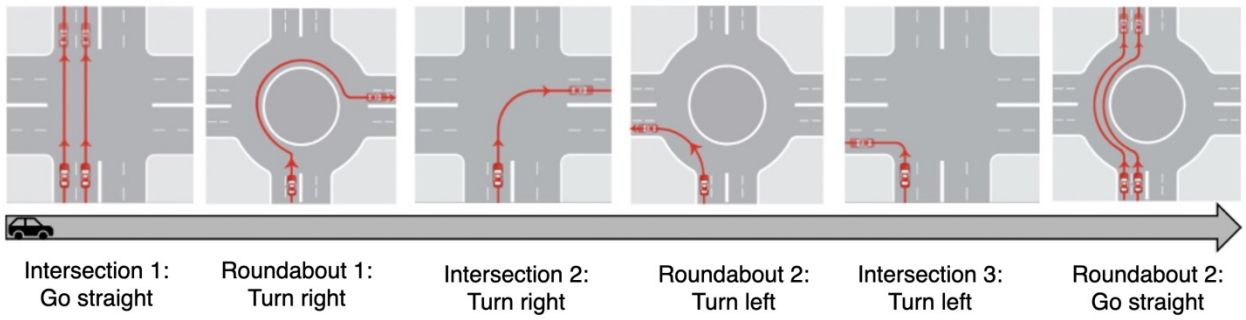

Fig. 2. The Sequence of road sections drive by the participants.

filled out the post-experiment questionnaire, which captured their driving experience under keep-left traffic regulations and driving a simulator.

E. Data Acquisition and Analysis

The current study explores the differences in driving behaviour and performance between familiar and unfamiliar drivers in a keep-left traffic system. Driving behaviour and performance were assessed by exploring the driving mistakes that occurred prior to and while driving. Prior to the training session, when the window glass was uncovered, participants were observed fastening the seat belt by the researcher. It was easily observable that some participants entered the driving simulation from wrong side (i.e., passenger side not the driver side). Hence, mistakes related to getting inside the vehicle were also noted prior to starting the driving.

During the experimental session, mistakes related to driving at each intersection and roundabout were observed from log files. Driving mistakes included (1) using an improper approaching lane, (2) not signalling, (3) speeding, (4) driving against the traffic flow and (5) using an improper exiting lane. If no mistakes were made, 0 points were assigned to the driver, but if any of the above-mentioned mistakes were made, 1 point was assigned to the driver. All mistake scores were integrated into one file for data analysis.

Familiarity with driving under keep-left traffic regulations was a nominal independent variable with two groups: familiar and unfamiliar. The total number of mistakes on roundabouts and intersections and the total number of each type of driving mistake represented the dependent variables. Descriptive statistics were presented as mean, mean rank, minimum and maximum. To compare driving behaviour and performance between the familiarity groups, the Shapiro-Wilk test was conducted to determine normality for driving performance variables. None of driving performance variables were distributed normally ($p < .05$). Therefore, parametric tests (i.e., independent t-tests) could not be employed. Instead, the Mann-Whitney U test as a non-parametric test was applied [29].

IV. Results

A. Pre-Driving

Out of 34 unfamiliar participants, 26 participants (76.5%) did not get inside the simulated vehicle from the correct side, while none of familiar participants made the same mistake. Descriptive statistics indicate that the mean of getting inside the simulated vehicle from the wrong side was 0.77 for unfamiliar participants with a mean rank of 36.03, suggesting a strong tendency toward making such a mistake among unfamiliar participants (see Table I). None of familiar participants got inside the vehicle from the wrong side, resulting a mean of 0.00 and a lower mean rank of 15.00. That indicates a significant disparity between the two groups. The Mann-Whitney U test results indicated that the number of unfamiliar participants who did not fasten the seatbelt (mean = 0.59; mean rank = 36.03) was significantly greater than the number of familiar participants who made the same mistake (mean= 0.24; mean rank = 22.05), U = 232.00, p = 0.006 (see Table II).

B. While Driving

1) Section of road: The results of the Mann-Whitney U test showed there was a significant difference in the total number of driving mistakes on roundabouts between familiar (mean = 2.38; mean rank = 22.71) and unfamiliar (mean = 3.38; mean rank = 31.27) participants; U = 246.000, p = 0.026. On intersections, familiar participants made fewer driving mistakes with a mean of 2.48 and mean rank of 24.41 than unfamiliar participants (mean = 2.94; mean rank = 30.21). However, the difference was not statistically significant (U = 281.500, p = 0.092).

2) Type of mistake: Multiple Mann-Whitney U tests were conducted to compare driving mistakes in relation to their type between familiar and unfamiliar participants. For approaching the roundabouts/intersections from an improper lane, the U statistic was 337.000 (p = 0.361), and for not signalling, it was 349.000 (p = 0.446). Speeding yielded a U statistic of 344.000 (p = 0.40), while using improper exiting lane resulted in a U statistic of 301.000 (p = 0.16). These findings indicate no significant differences in driving mistakes between the groups, suggesting similar driving performance among participants.

Familiar participants did not drive against the traffic flow on roundabouts/intersections, while unfamiliar participants had a mean of this driving mistake of 0.80 (mean rank = 32.63). As such, a statistical comparison between the two groups was not performed, indicating a notable disparity in this mistake.

V. Discussion

The main objective of the study was to determine the effects of familiarity with traffic regulations on the driving

TABLE I. DESCRIPTIVE STATISTICS FOR DRIVING MISTAKES

Mistakes	Group	Minimum	Maximum	Mean	Mean Rank
Getting into the vehicle from the wrong side	Familiar	0	0	0.00	15.00
	Unfamiliar	0	1	0.77	36.03
Not fastening the seatbelt	Familiar	0	1	0.24	22.05
	Unfamiliar	0	1	0.59	31.68
Total number of mistakes on roundabouts	Familiar	0	5	2.38	22.71
	Unfamiliar	0	7	3.38	31.27
Total number of mistakes at intersections	Familiar	1	5	2.48	24.40
	Unfamiliar	0	5	2.94	30.22
Not using an improper approaching lane	Familiar	0	3	1.05	27.05
	Unfamiliar	0	2	1.09	28.59
Not signalling	Familiar	0	4	1.23	27.62
	Unfamiliar	0	4	1.29	28.23

Not signalling	349.00	0.446
Speeding	344.00	0.397
Driving against the traffic flow	NaN^b	
Using an improper exiting lane	301.00	0.158

a The variance in getting into the vehicle from wrong side is equal to 0 after grouping on familiarity.
b The variance in driving against the traffic flow is equal to 0 after grouping on familiarity.

performance at roundabouts and intersections. An overall comparison between the driving performance prior to and while driving on roundabouts and intersections for familiar and unfamiliar drivers to a keep-left traffic regulation was addressed.

A. Pre-Driving

All familiar participants got into the vehicle from the correct side of the vehicle (i.e., the right side, which represents the driver side in a right-hand drive vehicle), while 76% of unfamiliar participants got inside the vehicle from the wrong side (i.e., the left side, which represents the passenger side in a right-hand drive vehicle). When the unfamiliar participants were asked about the reasons for making this mistake, they mentioned the unreality of the driving environment, hesitation concerning which is the correct side, and complete unawareness of the correct side. Statistical comparison using the Mann-Whitney U test was not feasible for not getting into the vehicle from the correct side due to the lack of collected data from familiar participants in relation to this mistake. Therefore, recruiting more familiar participants is required to better assess differences between the familiarity groups for this mistake. In general, although this mistake does not affect road safety, making such a mistake might be an annoying or embarrassing experience for the driver.

The results of this study indicate the number of unfamiliar participants who did not fasten their seatbelt was significantly greater than familiar participants. According to the post-simulation questionnaire, all familiar participants and the three unfamiliar participants who did not make this mistake thought it was not important to fasten their seatbelt as the driving session was not real but they did it anyway. For the unfamiliar drivers, there were additional reasons for not fastening the seatbelt. Some participants were unfamiliar with configurations of right-hand drive vehicles, while others forgot to fasten the seatbelt as they did not usually fasten it back in their home country or they did not realise that there was a seatbelt. Although this violation was observed prior to the driving tasks, fastening the seatbelt is very important factor in road safety. It reduces fatal injuries by between 45% and 60% [30]. Regarding this factor, a strategic awareness campaign intended to educate countries with less awareness of the importance of fastening the seatbelt is proposed by [31]. Changing behaviour towards fastening seatbelts through serious games is introduced by [32]. Another possible solution is to employ tactical feedback to remind the driver to fasten their seatbelt [33]. When conducting driving simulation experiments, it is important to emphasise the importance of fastening the seatbelt prior the

observation process even though the experiment environment is simulated.

B. While Driving

1) Section of road: The results show a significant difference in the total number of driving mistakes on roundabouts between familiar and unfamiliar participants. On intersections, although unfamiliar participants performed more traffic violations compared to unfamiliar participants, this difference is not statistically significant. It might be that the intersections need fewer steering-related activities than roundabouts and therefore the drivers need to be more aware of the required activities in relation to the section of road at roundabouts in comparison to intersections. Drivers' awareness is higher when driving under familiar conditions than unfamiliar conditions [7]. More studies are required to explore why the performance on roundabouts is different than intersections, although a roundabout is a form of intersection.

2) Type of mistake: The results indicate an insignificant difference in speeding violations at roundabouts and intersections between familiar and unfamiliar drivers. The results conflict with those obtained in studies by [13], [14], who found that familiar drivers are more likely to perform speed violations and by [21], who found that unfamiliar drivers are more likely to ignore road signs and information when driving under unfamiliar traffic regulations. The reasons speed violations were committed by both groups in this study might be driving in unfamiliar routes for familiar group of participants [9] and the high cognitive load the unfamiliar drivers experienced when driving under unfamiliar traffic regulations [15]. More studies are required to explore the reasons behind the speeding violations by both the familiar and unfamiliar drivers.

Approaching and exiting roundabouts and intersections from the correct travelling lane can be related to steering skills and making correct decisions in accordance with the target turn. Despite the results of study conducted by [12], which found different steering activities between familiar and unfamiliar drivers, the results reveal that there was no significant difference in driving in an improper travelling lane when approaching and exiting roundabouts/intersections between familiar and unfamiliar drivers. Another reason for making such a mistake might be driving a simulator whose sensitivity might differ from a real vehicle. Further studies are required to understand the reasons behind this sort of mistakes for both groups of drivers. Signalling while turning or changing the lanes informs other users of road (e.g., other drivers on the road, pedestrians and motorcyclists) about the driver's near future turn or manoeuvre and gives time to others to plan or react accordingly. The reasons for not signalling could be driving habit, that it is unnecessary to give a signal (e.g., no traffic on the road), or misusing the control of direction indicator. These might explain why the results of this study did not show a significant difference in signalling when approaching roundabouts/intersections between familiar and unfamiliar drivers. The driving track of this study did not include any traffic. Additionally, some unfamiliar participants were confused about the correct location of direction indicator lever, as it is located to the right of the steering wheel, which may be an unfamiliar configuration.

The results of our study reveal that unfamiliar participants drove 27 times against the traffic flow when they entered the roundabouts/intersections, while none of the familiar participants made that mistake. This result does not allow us to perform a statistical comparison using the Mann-Whitney U test. Adding more familiar participants can provide extra data and thus better understanding for this situation. However, that might not guarantee that familiar drivers are going to drive against the traffic, as they are used to driving with the traffic flow, unlike the unfamiliar participants who made this mistake. In contrast to familiar drivers, unfamiliar drivers are required to distinguish the differences in traffic systems and rules between their home country and the host country. The unfamiliar drivers must adapt their knowledge and reactions to match the requirements of driving in the host country. Difficulties in adapting to keep-left traffic regulations might explain why unfamiliar participants drove against the traffic flow. Another reason for this behaviour might be that the unfamiliar drivers are more likely to ignore road signs [13], [14]. Despite presenting the required direction on the roundabout-ahead sign, unfamiliar participants might not pay attention to the sign or notice the difference in the information on the roundabout-ahead sign. Driving against the traffic flow results in failing the driving test in New South Wales, as well as in all states and territories, Australia [34] and increases the risk of serious and often fatal crashes (e.g., head-on collisions). Even though the familiar and unfamiliar drivers showed no significant difference in other driving mistakes, the risk at roundabouts and intersections was higher when unfamiliar drivers drove in unfamiliar traffic regulations in comparison to familiar drivers.

These results could be used to improve the few existing driving-assistance systems available for overseas drivers, particularly those who are driving under unfamiliar traffic regulations, as the improvement in such systems could improve the road safety. As automated car technology develops, it could be possible to customize the vehicle control automation level based on the driver's familiarity with the traffic regulations. In cases where the driver is not familiar with the local regulations, the system can fully or partially automate the vehicle when approaching complex roads, such as roundabouts and intersections. Other improvements include providing understandable and clear information to drivers based on their familiarity with the traffic regulations. However, this information must be easy to understand as providing complex information might increase the driver's cognitive load and lead to them ignoring the information.

Based on these results, suggested solutions include considering unfamiliarity with road regulations when designing an in-vehicle information system. Unlike familiar drivers, unfamiliar drivers need information regarding the correct direction of traffic when they reach roundabouts and intersections. Another solution is to modify the information that is provided to drivers via road signs to consider the issue of unfamiliarity with traffic regulation. The intersection-ahead sign, for instance, does not currently inform drivers about the direction of traffic flow. Presenting the direction of flow in perceivable locations as well as presenting the road structure might help unfamiliar drivers to correctly drive with the traffic flow when entering intersections (see Figure 3). Another designing suggestion is to use "do not enter" signs as part of the image of intersection to describe the traffic flow situation at upcoming intersections. Presenting the

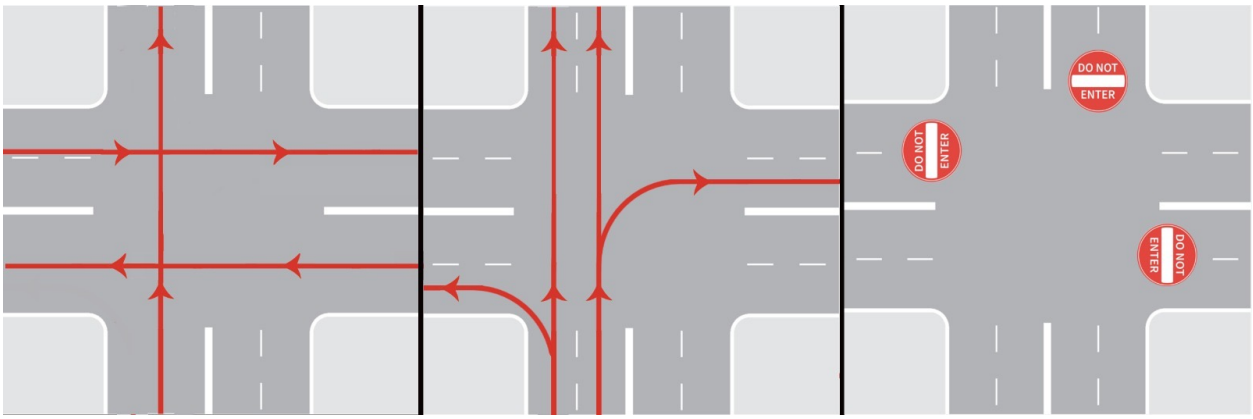

Fig. 3. Three possible alternative designs for intersection-ahead sign to facilitate driving in intersections.

road signs to the driver via an in-vehicle information system is better than the traditional road signs in terms of the proper driver's response to changes in the road environment [35].

Other solutions are suggested in the study conducted by [36], such as providing different navigation information (e.g., turn instructions), vehicle status information (e.g., seatbelt status), and driving assistance information (e.g., direction visualisation) based on the driver's familiarity with the soundings. However, in such systems, the information should be carefully designed. The study [37] recommends that an international and ergonomic standards should be considered when designing the road signs. Gamification and serious games also can provide suitable learning platform for drivers to adapt their behaviour and performance to safely drive under unfamiliar traffic regulations [38], [39].

C. Limitations and Future Work

The present study had some limitations in the driving tasks and the driving scenario. Future developments could include adding further driving tasks, such as overtaking. While the driver overtakes a vehicle from the right in a keep-left traffic regulation, the driver in a keep-right traffic regulation overtakes a vehicle from the left. Testing this driving task should be conducted on at least a three-lane road to make it possible for the driver to overtake from the right or the left. Testing familiar and unfamiliar drivers together in the same driving scenario can extend the knowledge about real interactions and behaviours when both groups of drivers drive together on the same road.

VI. Conclusion

In this paper, the differences in driving mistakes between familiar and unfamiliar drivers in a keep-left traffic regulation system were explored. Using a driving simulator, two pre-driving mistakes and five while-driving mistakes were calculated. The pre-driving mistakes were getting inside the vehicle from incorrect side of the vehicle and not fastening the seatbelt. The while-driving mistakes were using an improper approaching lane, not signalling, speeding, driving against the traffic flow, and using an improper exiting lane. Fifty-five right-handed male drivers participated in the study and were grouped into two groups (21 familiar drivers with a keep-left traffic regulation and 34 unfamiliar drivers with a keep-left traffic regulation). The results of this study confirm the first hypothesis (H1) that unfamiliar drivers will commit more traffic violations compared to familiar drivers, as the unfamiliar drivers performed significantly more mistakes than the familiar drivers did on roundabouts and insignificantly more mistakes on intersections. The results also demonstrate that the risk in traffic systems is higher when drivers drive under unfamiliar traffic regulations (H2, the second hypothesis), as the unfamiliar drivers might enter the roundabouts and intersections from the opposite traffic direction to which they are accustomed. Therefore, familiarity with traffic regulations should be considered when designing the driving-assistant systems, in-vehicles information systems, gamification and serious games, and other educational programs. That would help improving road safety, particularly in countries that have many unfamiliar drivers.

Predicting Jobs, Shaping Economies: Bibliometric Insights into AI and Big Data in Workforce Demand Analysis

EL Massi Fouad, ELouadi Abdelmajid
Advanced Systems Engineering-National School of Applied Sciences, IBN Tofail University, Kenitra, Morocco

***Abstract*—The integration of Big Data and Artificial Intelligence (AI) is fundamentally transforming how labor markets are analyzed, predicted and managed. Despite significant advances in using these technologies for workforce analytics, the field suffers from several critical limitations: existing approaches predominantly rely on data from online job portals that may not capture informal employment sectors, current predictive models lack robustness in long-term forecasting under rapid economic transformations and cross-border data integration remains insufficiently addressed for comprehensive global analyses. Moreover, the field lacks a structured, quantitative assessment of scientific production that provides a comprehensive overview of research developments, with most existing studies being case-specific or focusing on narrow applications, leaving significant gaps in understanding the intellectual structure, key contributors and thematic evolution of this interdisciplinary domain. To address these research gaps, this study presents the first comprehensive bibliometric analysis of global scientific research examining the intersection of AI, Big Data and labor market prediction. Drawing on a systematic dataset of 276 publications from Scopus, Web of Science and OpenAlex databases spanning 2003 to 2025, this research employs advanced bibliometric techniques to map the intellectual landscape of this rapidly evolving field. Through a structured four-phase methodological framework incorporating performance analysis, science mapping and thematic evolution, the study identifies research trends, intellectual structures, influential contributors and emerging themes. The analysis reveals significant developments in predictive modeling, natural language processing, and hybrid AI approaches for recruitment forecasting and workforce analytics, while highlighting critical challenges posed by algorithmic bias and ethical considerations in AI-driven systems. Key contributions include: 1) the first systematic scientific mapping of the AI-Big Data-labor market intersection, 2) identification of research gaps and future directions for long-term labor market prediction, 3) comprehensive analysis of institutional networks and collaborative patterns and 4) evidence-based recommendations for addressing data integration and model interpretability challenges. The findings offer actionable insights for researchers, policymakers and practitioners seeking to leverage intelligent systems to shape the future of work in the digital economy while addressing current methodological limitations.**

***Keywords*—Big data; Artificial Intelligence; predictive modeling; bibliometric analysis; natural language processing; labor market analytics**

I. Introduction

In recent years, the convergence of Big Data and Artificial Intelligence (AI) has significantly reshaped the analysis and understanding of labor markets. The growing availability of large-scale employment data, together with advancements in predictive modeling, has enabled new approaches to forecasting labor demand and supply, monitoring workforce dynamics and informing evidence-based labor market policies. As economies transition to more digital and knowledge-intensive models, the ability to derive actionable insights from complex labor datasets has become a strategic imperative for researchers, employers, and public authorities.

Despite the growing number of studies that apply these techniques to hiring forecasts, the field lacks a comprehensive and structured quantitative analysis of the scientific output necessary for extensive reviews. Most existing research remains case-specific or narrowly focused, leaving significant gaps in understanding the intellectual structure, key contributors and thematic development of the discipline. To address this gap, the present article offers a bibliometric analysis of the scientific literature on the application of Big Data and Artificial Intelligence to labor market prediction. The study examines publications from three major scientific databases, Scopus, Web of Science and OpenAlex, covering the period 2003 to 2025.

The analysis is organized into several sections to ensure a comprehensive and coherent exploration of the field. Section II provides a synthesis of related studies and prior reviews addressing the intersection of Big Data, Artificial Intelligence and labor market forecasting. Section III details the methodological framework employed for this bibliometric study, including the selection criteria, data collection procedures and analytical tools such as Bibliometrix and VOSviewer. Section IV presents the results and key findings, focusing on publication trends, networks of authors and institutions, patterns in keywords and phenomena and the identification of thematic clusters. Section V offers a critical discussion of the observed patterns, highlights the research landscape and proposes directions for future investigation. The article concludes with a final section summarizing the main contributions and discussing the broader implications for research and policy in labor market analysis. Through this structured approach, the study aims to provide an extensive scientific mapping of this interdisciplinary domain and to offer meaningful insights relevant to both academic and policy-oriented debates concerning the future of labor market analysis.

II. Related Work

The convergence of Big Data Analytics, Artificial Intelligence (AI) and Predictive Modeling have made a paradigm change in the way of analyzing, understanding and forecasting

labor market dynamics to researchers. Over the past decade, this interdisciplinary domain has expanded rapidly as organizations and governments seek to harness large scale datasets and advanced computational methods to inform workforce planning, skills development and employment policy.

Labor market surveys refer to the collection and analysis of big data posts, social media, professional networks, government statistics and company registers, collection and analysis of large versions of unarmed data from different sources. These data sets have valuable information on employment patterns, skills requirements, salaries and career paths that were previously difficult to capture through traditional surveys on the labor market.

Artificial intelligence, especially machine learning algorithms, enables researchers to treat these mass datasets effectively, recognize complex patterns and produce insights that would be impossible through manual analysis. This AI-operated equipment can identify new job categories, predict future skills requirements, analyze regional employment beaches and even detect prejudices in practice as hiring. The future analysis implements statistical techniques, machine learning algorithms and data mining to analyze current and historical data to provide predictions on future labor market conditions. In human resources and work plan, these predictions organizations help to estimate the lack of talent, identify high -capacity candidates, reduce sales and optimize recruitment strategies.

The growing research that examines the intersection of these technologies with labor market analysis is documented through various systematic reviews, text list analysis and literature reviews. These research synthesis approaches provide a valuable framework to understand how these technological innovations change employment, skills requirements and the development of careers in the digital economy.

A. Big Data Application in Labor Market Analysis

The rise of large data has revolutionized the labor market analysis by providing unique access to granular, multidimensional information that was not available through traditional research methods earlier. Especially online job portals have become valuable data sources to understand the labor market's dynamics, skills requirements and employment beaches. Like Mrazova et al. Expelled in its analysis of the Indian job portal Babjob, Online Work Portal Data can contribute to labor market policy in five main areas: Monitoring of the labor market, the workforce evaluation, evaluation of job-sex behavior, prognosis analysis of skills and experimental studies [1].

The ability to collect, treat and analyze on a large scale from online sources provides significant benefits on traditional labor market survey methods. Vankevich et al. Note that the methods of traditional labor market analysis often depend on chronic information collection technologies and fail correctly to the account correctly for specific skills in CVS and vacancies. They propose function based on large computer technologies and Artificial Intelligence, which is to quickly collect, process and imagine data on profit requirements in businesses, fields and financial fields [2].

A particularly powerful application is the use of natural language processing (NLP) to start job postings and restart on scale. Researchers have used NLP methods to identify changes in different businesses and industries. Nicolev emphasized how calculation language and lesson analysis equipment enable researchers to analyze labor changes at the level of personal competencies by checking the text of online positions [3]. This approach allows for real-time monitoring of vacancies across regions and countries, predicting demand for specific skills and comparing labor markets internationally.

Some researchers have leveraged Big Data to develop advanced recommendation systems that more effectively match job seekers with suitable employment opportunities. For example, Qin et al. designed neural network models to evaluate the degree of fit between job seekers and job requirements, thereby reducing reliance on manual screening by human resource professionals [3][4]. Similarly, Zhou et al. constructed models to assess the popularity and relevance of job skills using large-scale recruitment data, helping to identify which competencies are most strongly associated with high-paying employment opportunities [3][5].

Advanced machine learning techniques enable researchers to detect complex patterns in labor market data. For instance, Alakl et al. applied machine learning methods to analyze 35,000 article abstracts and 57,000 LinkedIn posts, identifying 28 variables grouped into five macro-level categories related to multigenerational labor markets [6]. Similarly, Rai et al. conducted a comparative analysis to evaluate the effectiveness of different models—including GPT-3 and BERT—for analyzing Artificial Intelligence methods, particularly natural language processing (NLP), in the context of regional labor markets [7].

Big Data–driven labor market monitoring has significant economic implications, particularly in terms of enhancing analytical integration. Zaloznova et al. demonstrated that Big Data analytics offer valuable labor market insights that improve competitiveness and enable the creation of online job exchanges analogous to financial stock markets [8]. These digital platforms facilitate real-time monitoring of labor market dynamics and evolving skill demands across various local and regional contexts.

These innovations are particularly valuable for tracking the rapid transformations driven by digitization and technological advancement. Cymbal et al. emphasize that traditional survey-based sources of labor market information are insufficient for capturing the profound changes in the content and nature of work resulting from digitalization [9]. Their study compiles international experiences with the use of digital technologies and Big Data in labor market monitoring, concluding that online job vacancy data significantly complement and enhance traditional labor market statistics and analyses.

The introduction of these technologies has not only transformed the analysis of labor markets, but also reshaped the recruitment process. As Spadina notes, the integration of Artificial Intelligence into recruitment has fundamentally altered the landscape, where Big Data, algorithms, and predictive outcomes now play an active role in shaping the relationship between humans and technology in hiring practices [10].

B. Limitations of Existing Methods and Contribution of the Article

Despite significant advances in using Big Data, Artificial Intelligence (AI), and predictive analytics for labor market analysis, several limitations persist in the current state of the art. First, many existing approaches are heavily based on data from online job portals and social media, which may not fully capture informal employment sectors or underrepresented populations, leading to potential biases and gaps in labor market coverage. Second, while AI-driven models excel at processing large-scale unstructured data, challenges remain in ensuring model interpretability and transparency, which are critical for policy-making and ethical considerations (5). Third, most predictive models focus on short- to medium-term forecasting and often lack robustness in long-term labor market trend prediction, especially under rapid technological and economic transformations (57). Furthermore, cross-border data integration and standardization are not adequately addressed, limiting comprehensive global labor market analyses.

Furthermore, existing methods frequently overlook the integration of multi-source data that combine quantitative labor market indicators with qualitative contextual information, such as policy changes or regional economic shifts, which are essential for nuanced understanding and actionable insights. There is also a scarcity of frameworks that systematically incorporate ethical concerns related to data privacy, algorithmic bias, and equitable representation in AI applications within labor market analytics.

This article contributes to reducing these gaps by proposing a comprehensive framework that integrates diverse data sources, including underutilized datasets, to enhance labor market coverage and reduce bias. It emphasize the development of interpretable AI models that balance predictive accuracy with transparency, facilitating trust and adoption by policymakers and stakeholders. Moreover, the adopted approach extends predictive capabilities to better capture long-term labor market dynamics by incorporating adaptive machine learning techniques sensitive to economic and technological disruptions. The article also address data standardization challenges by proposing harmonized protocols for multi-jurisdictional labor data integration. Finally, it incorporate ethical guidelines into the design and deployment of AI tools to ensure responsible use, privacy protection, and fairness in labor market analyses.

By addressing these limitations, this work advances the field toward more inclusive, transparent, and effective labor market analytics, supporting informed decision-making in workforce planning, skills development, and employment policy in the digital economy.

III. Methodology

The purpose of this bibliometric study is to map and analyze the scientific landscape related to the use of large data and Artificial Intelligence (AI) for the labor market's prediction and workforce analysis. The functioning adopted follows a structured and reproducible workflow, which is grounded (preferred reporting elements for systematic reviews and meta-analysis) in Prisma (Fig. 1).

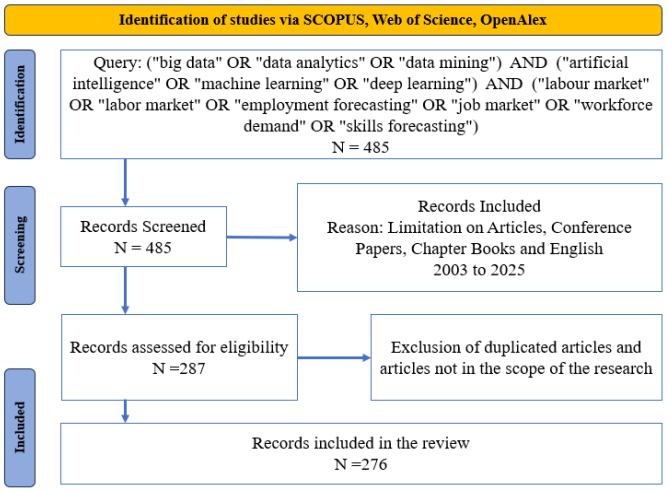

Fig. 1. Prisma approach.

A. Data Source and Query Construction

The data collection was performed using three large academic database: Scopus, Web of Science (WOS) and OpenAlex, which provides extensive coverage of colleagues underwent by colleagues. A carefully designed search was implemented to reconstruct relevant publications, including conditions related to Big Data, AI techniques and labor market forecasts:

Query: ("big data" OR "data analytics" OR "data mining") AND ("Artificial Intelligence" OR "machine learning" OR "deep learning") AND ("labour market" OR "labor market" OR "employment forecasting" OR "job market" OR "workforce demand" OR "skills forecasting").

This query targeted title, essence and keyword field. The discovery was limited to documents published between 2003 and 2025, and objects written in English were only assessed. Document types include journal articles, conference letters and book chapters.

B. Inclusion and Exclusion Criteria

Originally, a total of 485 items were obtained. The inclusion criteria were as follows:

- Publication related to the intersection of Big Data/AI and the labor market forecast.
- Documents in English.
- Publication Type: Articles, conference articles and book chapters.
- Time limit: 2003-2025.

In the screening phase, 198 documents were excluded due to irrelevance due to the extent of research, repetition or incorporation criteria. The move was considered as a result of 287 items for evaluation of qualifying.

C. Bibliometric Equipment and Analytical Techniques

The selected data was exported to BIBTEX and CSV formats for further procedure. Two large bombers used tools used:

- Bibliometrix R-Package (through the Biblioshiny interface) for publishing development, co-author, Country Cooperation, Citation Matrix and quantitative analysis of keywords CO-event).
- VOSviewer for network visualization and thematic mapping, which includes cohabitation networks, author groups and fellow phenomenon maps.

These units enabled a multi-phase exploration of intellectual and ideological structures in the region.

IV. Results and Analysis

A. Descriptive Bibliometric Overview

Fig. 2 presents a comprehensive overview of key bibliometric indicators for a total of 276 documents published between 2003 and 2025 across various sources. The dataset includes contributions from 560 authors, among whom 81 were sole authors. An annual scientific growth rate of 14.84% indicates a rapidly expanding research interest in the intersection of Big Data, AI, and labor market analysis.

The relatively low rate of international co-authorship (9.03%) and an average of 2.21 authors per document suggest that research collaborations are predominantly national or confined within institutions. A total of 2,885 references were cited across the corpus, reflecting a strong theoretical and conceptual foundation in the field.

The average citation age per document (5.73 years) and the average document age (3.24 years) further indicate that the topic is both emergent and dynamic, positioning itself as a growing area of academic inquiry.

Fig. 2. Bibliometric overview.

B. Temporal Evolution of Scientific Production

As shown in Fig. 3, scientific output in this domain remained minimal between 2003 and 2015, followed by a steady increase beginning in 2016. The trend culminated in a notable peak in 2024, with over 65 publications. This upward trajectory reflects the growing influence of the digital economy and the increasing importance of data-driven decision-making processes in workforce management and labor market analysis. The apparent decline in 2025 is likely attributable to the incomplete publication window for the year, rather than an actual reduction in research productivity.

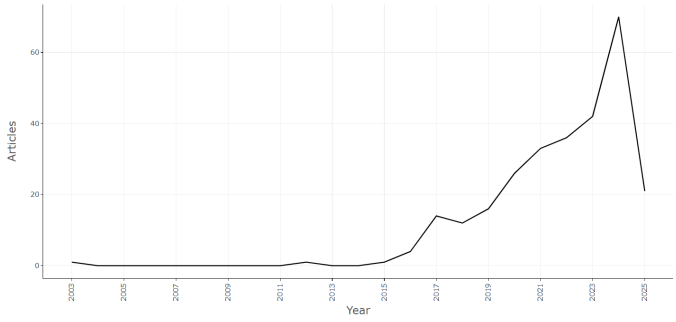

Fig. 3. Temporal evolution of scientific production.

C. Citation Dynamics and Impact

Fig. 4 illustrates the average number of citations per year. Around 2015, the citation curve shows a notable peak with high variability, followed by a gradual decline in subsequent years. This decrease can be attributed to the recency of many documents, which have not yet had sufficient time to accumulate citations.

Overall, the trend reflects an area that is expanded in volume, but which is still in accordance with academic effects.

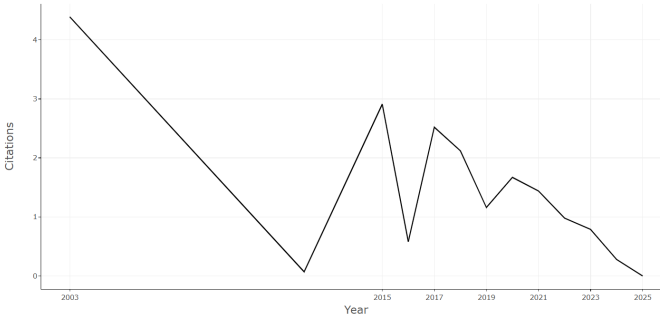

Fig. 4. Citation dynamics and impact.

D. Mapping Authors, Sources, and Thematic Domains

Fig. 5 (three-region plot) reflects mutual action between major authors, publishing sources and research domains. Christin L. Authors such as Wood, Quan Hua Lim and Janses are closely associated with influential magazines such as Emerald Publishing, SSRN and Rxiv, while thematic fields expand economics, informatics, computer science, law and political science.

It confirms the visual field field's multi-discipline, where AI and Big Data intelligence with both technical and social sciences regarding the prediction of the labor market.

E. Core Publication Outlets

Fig. 6 identifies the most active publication withdrawal. Emerald Publishing Limited ebooks proceed with 38 documents, followed by people to Jobs (15) and SSRN Electronic Journal (13).

This distribution indicates a hybrid publication environment, which combines colleague-rated sources with preproofs

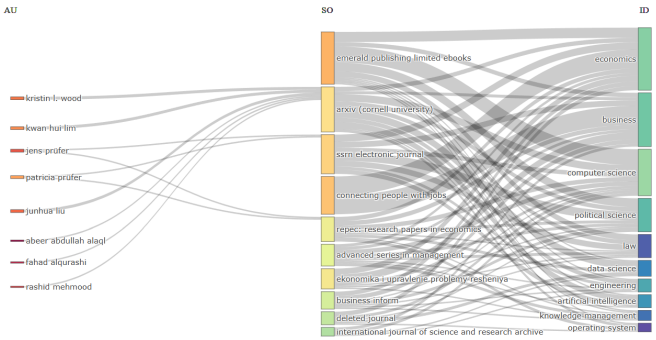

Fig. 5. Mapping authors, sources, and thematic domains.

and policy-centered outlets, which enables widespread spread in academia and decision institutions.

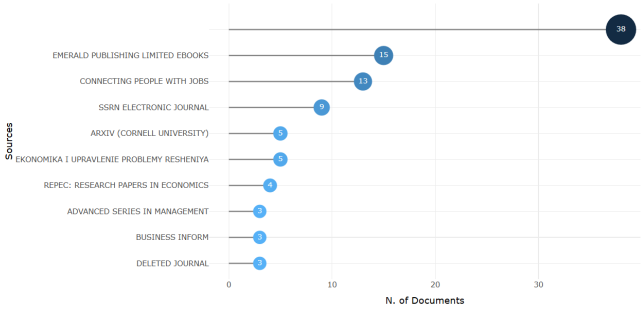

Fig. 6. Core publication outlets.

F. Evolution of Source Contributions

This Fig. 7 shows how the most relevant magazines in the area over time have contributed. Emerald Publishing Limited E -Books has conducted continuous and early involvement, reflecting a steady growth from 2017. Conversely, people with jobs later joined the field, but quickly, trapped by 2023.

The emergence of economica in upravlenie and Arxiv for many last years reflects a change to various forms (open depot and regional sources), reflecting expansion inclusion and interdisciplinary in the region.

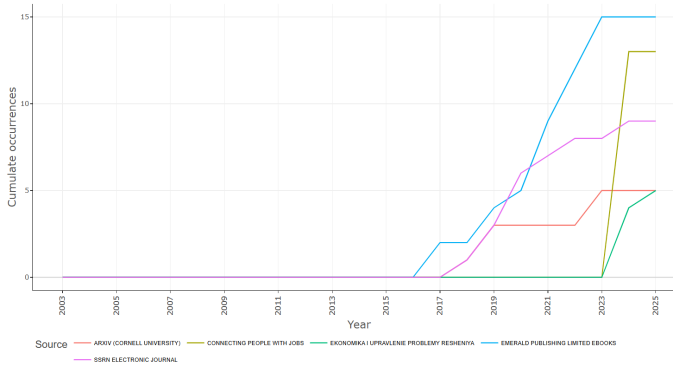

Fig. 7. Evolution of Source Contributions

G. Key Author Contributions

This rod map, Fig. 8, identifies the most powerful authors of the region, with Abir Abdullah Alakl, Alina Vankevich, Fahd Alkurashi, Irina Kalinsakaya and Rashid Mehmud 4 - Publications.

Such repeated contributions reflect the emergence of special researchers dedicated to bridge AI, Big Data and Work Economics. This elite group can serve as a main education network that governs the thematic and methodological development of the region.

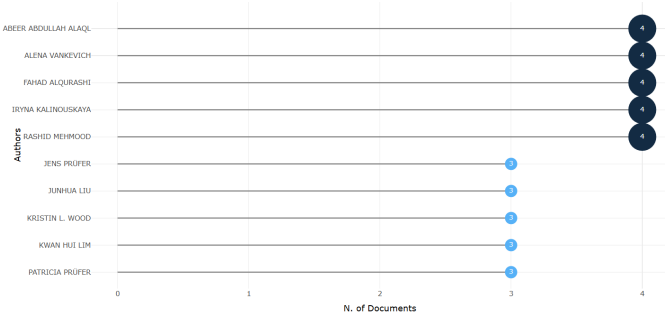

Fig. 8. Key author contributions.

H. Temporal Distribution of Author Productivity

This plot, Fig. 9, highlights the temporary research activity of the top authors. Janses and Petricia reflects quick and focused contributions around 2019-2021, while Rashid Mahmood, Alina Vankevich and Fahd Alkurashi recently showed more continuous activity, reflecting the current speed of the workforce.

The diagram showed both basic contributors and new ideas, and reflects the genetic layering of expertise in the field.

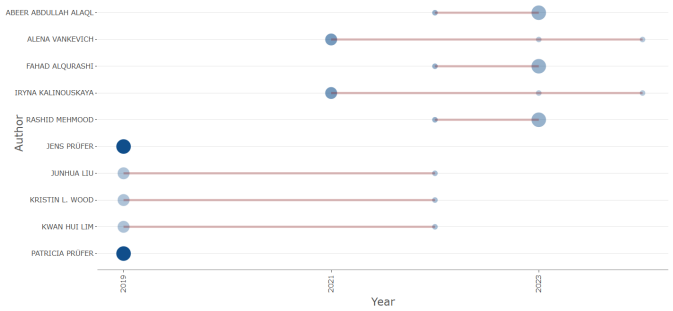

Fig. 9. Temporal distribution of author productivity.

I. Institutional Leadership in the Field

This Fig. 10 refers to the most productive institutions. The University of Texas in San Antonio is accompanied by 12 articles, followed by King Abdulziz University and Singapore University and Design (both with 9). These institutions represent a mix of America-based, the Middle East and Asian universities, highlighting global and multidisciplinary commitment to the forecast of the AI-controlled labor market. The presence of both technical and social science oriented universities confirms double anchoring the field.

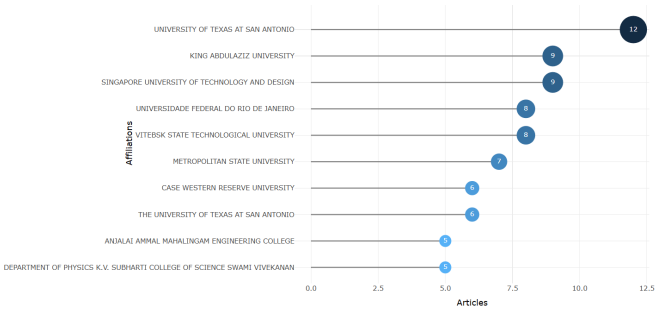

Fig. 10. Institutional leadership in the field.

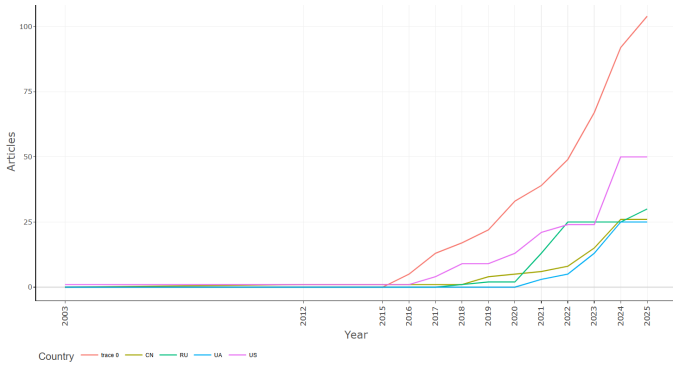

Fig. 12. Evolution of national scientific production.

J. Country-Level Scientific Output

At the country level, Fig. 11 shows that China leads in author productivity, followed by the United States, Russia, and the United Kingdom. Notably, the majority of publications are classified as Single Country Publications (SCP), indicating relatively low levels of international collaboration—an observation consistent with the metadata findings.

This trend may reflect national labor policy priorities and potential barriers related to data protection and privacy. However, it also highlights significant opportunities to foster international co-authorship and enhance global knowledge exchange in the field.

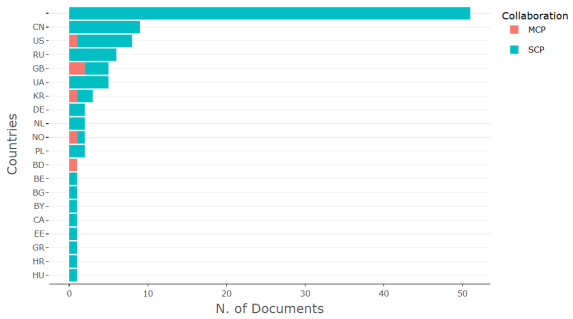

Fig. 11. Country-level scientific output.

K. Evolution of National Scientific Production

Fig. 12 reveals strong growth in publications from China (CN) since 2016, which now leads the domain. The United States (US) shows steady growth, while Russia (RU), Ukraine (UA) and Canada have shown more less, but increasing contributions in recent years.

This upward trend reflects the growing national investments and large computer strategies related to work forecasts in AI. Various contributors indicate that the area is globalization, although it is with regional intensity centers.

L. Citation Impact by Country

The United States leads in citation impact with a total of 518 citations, followed by the Netherlands (195) and Canada (97). Interestingly, China, despite its high research output, ranks relatively low in citations.

This suggests that its publications are either more recent or receive comparatively less international attention. This emphasizes a difference between the opposite volume and the effect, and provides an opportunity to increase the visibility and collaboration for non-Western research production (Fig. 13).

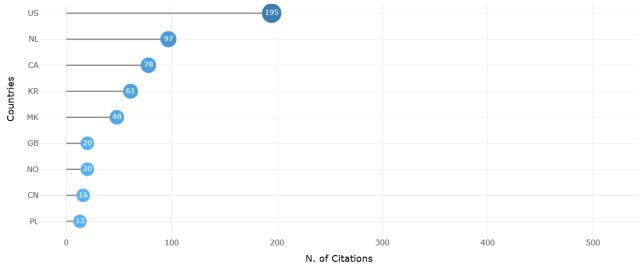

Fig. 13. Citation impact by country.

M. Conceptual Structure: Most Frequent Keywords

The most recurring concepts are “Computer science” (194 events), “Economics” (134) and “Business” (128), which confirms the interdisciplinary convergence between technical and socio-economic domains.

“Political Science”, “Computer Science” and “Artificial Intelligence” follows closely, and shows that this research sector is equally shaped by politics, analysis and calculation appliances (Fig. 14).

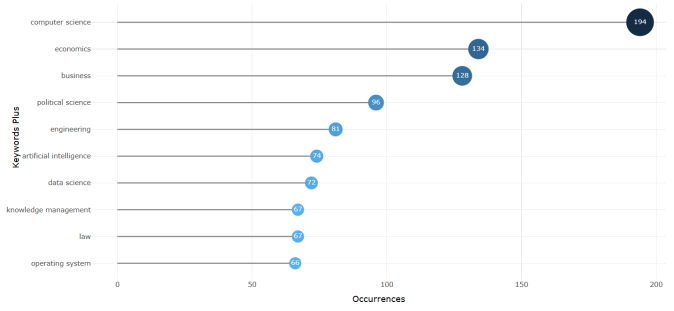

Fig. 14. Conceptual structure: most frequent keywords.

N. Word Cloud Representation

The word cloud, Fig. 15 provides a qualitative snapshot of main themes. "Computer Science" is visually dominated, "Economics", "AI", "Data Science" and "Business". Emerging subjects such as "working economics", "knowledge management" and "unemployment" highlight field-specific relevance and policy-related dimensions.

Fig. 15. Word cloud representation.

O. Evolution of Keyword Trends Over Time

This longitudinal analysis, Fig. 16, shows that terms like "computer science", "data science", and "economics" have seen steep growth post-2017, while "AI", "political science", and "engineering" remain strong and steadily rising.

The figure reflects a broadening scope and increased specialization of the research field over the last five years.

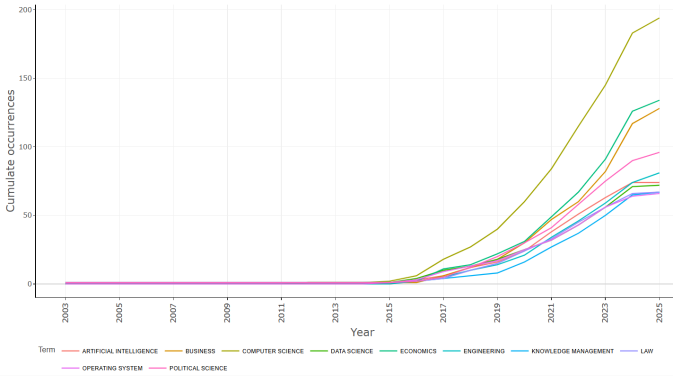

Fig. 16. Evolution of keyword trends over time.

P. Trend Topics Timeline

This chart, Fig. 17 highlights how certain themes emerged and evolved:

- "Labour economics" and "unemployment" dominate post-2022
- "Computer science" and "economic growth" peaked in 2020–2021
- Niche areas like "programming language" or "finance" appear between 2018 and 2020

These trends suggest a recent shift toward labor policy modeling, macroeconomic forecasting, and employment analytics in response to post-pandemic dynamics.

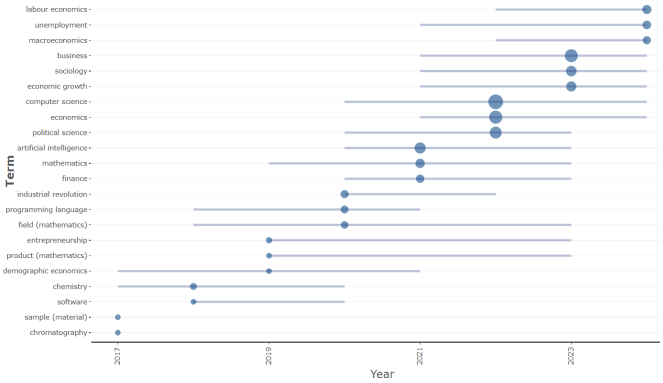

Fig. 17. Trend topics timeline.

Q. Thematic Clustering by Coupling

This strategic diagram, Fig. 18, identifies four thematic zones:

- Motor cluster: "computer science", "economics", and "business" with strong impact and centrality.
- Basic themes: "AI", "data science", and "big data" form the intellectual foundation.
- Peripheral clusters: "psychology", "biology", and "active labor market policies" show low centrality but growing relevance.
- This visualization confirms the core structure and emergent peripheries of the field.

Fig. 18. Thematic clustering by coupling.

R. Co-occurrence Network of Keywords

This network map, Fig. 19, highlights dense connections between "computer science", "economics", and "business", suggesting a tight intellectual core.

Peripheral yet significant clusters include "labor economics", "AI", "knowledge management", and "operating system", showing how technological tools and economic policies intersect in workforce analytics.

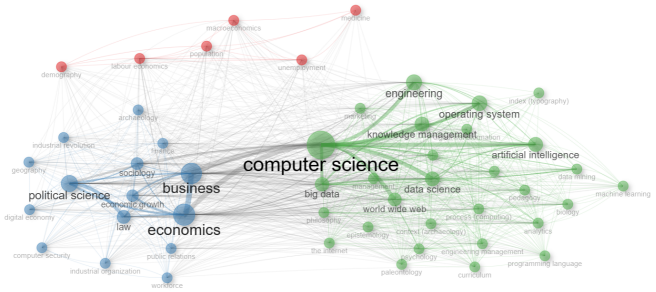

Fig. 19. Co-occurrence network of keywords.

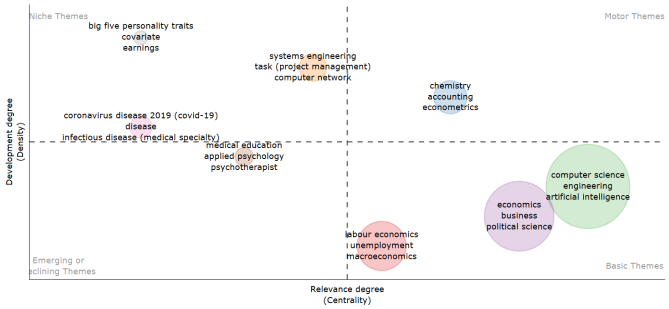

Fig. 20. Thematic map.

S. Thematic Map

This map, Fig. 20 shows:

- Basic themes: “computer science”, “engineering”, “AI” → foundational and well-established.
- Emerging/Declining: “labor economics”, “macroeconomics” → growing but still under-structured.
- Niche themes: “psychology”, “COVID-19” → specialized but with less general impact.
- This helps frame future research directions and gaps in labor analytics.

T. Factorial Analysis of Conceptual Structure

This factorial map, Fig. 21 shows three main conceptual dimensions:

- A dominant cluster (red) linking “computer science”, “economics”, and “digital transformation”.
- A green cluster focused on “labour economics”, “population”, and “unemployment”.
- A blue cluster with “machine learning”, “psychology”, and “typography”.

These axes confirm the coexistence of technical, economic, and human-centered subfields, reinforcing the interdisciplinary fabric of AI and big data applications in labor market prediction.

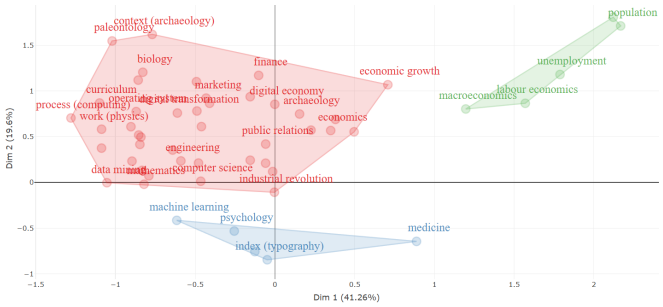

Fig. 21. Factorial analysis of conceptual structure.

U. Collaboration Network

The cooperation network, Fig. 22, reveals a fragmented but practical map of large data applied to international co-author and labor market analysis within AI in Fig. 22. The United States (USA) appears the most connected and central hubs to cooperate with countries such as Singapore (SG), Bangladesh (BD).

Other regional groups are visible:

- A strong Europe -Asia Bridge (e.g. UK - Italy - Pakistan).
- Eastern European alliances such as Russia - Ukraine - Bulgaria.
- Isolated regional partnership (e.g. Brazil - Portugal, France - Netherlands, Australia - New Zealand).

However, the lack of dense intercontinental cooperation is clear. Many clusters are insular, showing limited integration. This indicates the need for extensive international research participation, especially between high outputs and emerging areas.

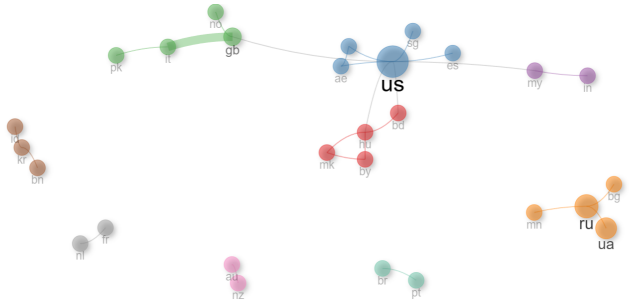

Fig. 22. Cooperation network.

V. Countries Collaboration World Map

The global heatmap reinforces the dominant role of the United States, China, Russia, and Western Europe as key actors in international research collaboration. However, the intensity of cooperation is noticeably higher in North America and Europe, while parts of Asia, and especially regions in Africa and Latin America, exhibit lighter or neutral tones—indicating limited global engagement.

As illustrated in Fig. 23, this pattern suggests that, although the field holds global significance, the infrastructure for international cooperation remains uneven. Enhancing South–South and North–South collaboration could broaden the scientific discourse and ensure that labor market analysis incorporates insights from diverse socio-economic and regional contexts, thereby enriching both policy and academic relevance.

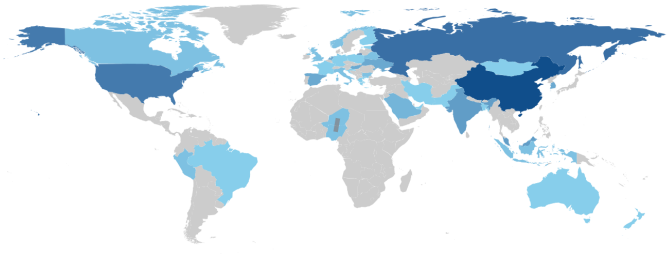

Fig. 23. Countries' collaboration world map.

V. Discussion

A. Bibliometric Discussion

Results of collaborative analysis expose both forces and significant intervals in the global research scenario on AI and large data for labor market forecast. The United States stands as the most active and well-linked country, and serves as a central center within a broad cooperation network consisting of partners of Europe, Asia and the Middle East. Other countries, such as Russia, China and the United Kingdom, also contribute continuously, but their networks are often more territory concentrated.

Despite these active nodes, the general structure of the collaboration network is fragmented and works in small, insulated clusters or silos with many countries. This fragmentation is more depicted in the co-writing world map, where many regions, especially in Africa, Latin America and parts of Southeast Asia, are smaller or disconnected than the global research discourse.

Such asymmetry is a challenge for the development of globally used and the development of solutions. Since the challenges in the labor market are quickly complicated and interconnected - driven by digitalisation, automation and demographic changes - it is necessary to promote broad international and interdisciplinary collaborations. Encouraging the South South and North South partnership will not only strengthen the prosperity of research, but will also ensure that the conclusions are inclusive and relevant in different socio-economic contexts.

In summary, while scientific production in the region is growing rapidly, the cooperative ecosystem remains uneven. It is important to address this imbalance to strengthen the basis for global knowledge and support the development of justified and informed labor market policy through AI and data-driven strategies.

B. Research Trends and Future Directions

The development of research at the intersection of big data, Artificial Intelligence and labor market analysis reveals many different trends that indicate to promote future directions. A remarkable tendency is to change vocabulary and focus in the region. Over the past decade (2010–2019), the traditional "Business Intelligence" gradually decreased in use as "analysis", "Artificial Intelligence", "big data" and "machine learning", both prominent academic literature and professional applications [11]. This linguistic change reflects the intensive change that contacts the organization that makes production decisions, more sophisticated than descriptive analysis leads to a sophisticated future and leads to the prescription feature.

A new research direction focuses on the integration of several technical approaches to create hybrid models with increased abilities. Researchers quickly detect the CO - intelligence ability to combine Artificial Intelligence with large data analysis, provided that when these technologies work together, they create abilities can either become independent [12]. For example, recent research in the financial markets emphasizes the important ability to limit the Hybrid AI model that integrates large data analyzes for more accurate stock market paves [13]. These integrated approaches represent a promising opportunity for future research in labor market analysis, where complex economic and social factors interact in ways that no analytical approach can capture perfectly.

Application landscape for AI and Big Data Analytics continues to expand to different fields. In the food industry, these techniques have achieved remarkable results in food matching, safety monitoring and testing processes [12] [14]. This application of these technologies shows their versatility and suggests the opportunity to expand further in special labor market analysis for different industries. For small and medium -sized companies (SME), research indicates that digital changes increase innovation and dynamic abilities, helping these businesses to overcome the lack of resources and provide better feedback to market changes. Large technologies that run these reforms include big data, Artificial Intelligence and digital platform [15]. This discovery indicates a growing research direction how small organizations and labor market participants can use these advanced technologies despite having less resources than large companies. Extensive research on digital economy suggests how Big Data Analytics enables organizations to gain valuable insight into marketing strategies and operating processes. Artificial intelligence applications are expanded in customer service, scam detection and product development, leading to a complex ecosystem of technological changes that originally resume labor markets [16]. Future research must find that these techniques can be distributed in a responsible manner to encourage economic growth by reducing negative effects on employment. As these research trends evolve, several future directions can be anticipated: more refined integration of different data sources, the development of specific accurate future models for labor market dynamics, focus on more focus on moral ideas and prejudices mitigating in AI-implemented recruitment systems, and to address the workforce in the development of economies. Research also suggested the upcoming convergence of technologies where big data, Artificial Intelligence, machine learning and blockchain can work in concerts to solve the challenges in complex labor market.

VI. Conclusion

This bibliometric study provides a comprehensive exploration of scientific production on the application of Big Data and Artificial Intelligence for labor market forecasting. By analyzing 277 documents published between 2003 and 2025 and indexed in Scopus, Web of Science, and OpenAlex, the research offers valuable insights into publication trends, key contributors, thematic evolution, and collaboration patterns in this rapidly emerging field.

The analysis reveals a remarkable acceleration in scientific production, particularly over the last five years, reflecting the growing importance of data-driven employment policies and the increasing relevance of predictive analytics to support workforce planning strategies. Disciplines such as informatics, economics, business, and computer science emerge as prominent throughout the literature, confirming the interdisciplinary nature of the research domain. Additionally, the increasing emphasis on topics such as labor economics, unemployment, digital transformation, and AI-based recruitment tools reflects a shift toward policy-oriented investigation.

While the thematic structure of the field demonstrates maturity in some areas, such as job-matching algorithms and digital workforce analysis, other domains remain underdeveloped or emerging, particularly those related to ethics, inclusivity, and regional specificity. Furthermore, the collaboration analysis highlights a fragmented global research network with high productivity concentrated in countries such as the United States and China, yet limited cross-regional partnerships, especially with African and Latin American institutions. These patterns indicate the need for more inclusive, equitable, and interdisciplinary cooperation to fully harness AI and Big Data for addressing global labor market challenges.

A. Study Limitations

Despite its comprehensive scope, this study acknowledges several important limitations that may affect the generalizability of findings. First, the analysis is restricted to publications indexed in three major databases (Scopus, Web of Science, and OpenAlex) and limited to English-language documents only. This methodological constraint may introduce language and database bias, potentially excluding relevant research published in other languages or indexed in regional databases, particularly from non-Western academic traditions where significant AI and labor market research may be conducted in local languages.

Second, the study employs a purely quantitative bibliometric approach focused on publication patterns, citation networks, and keyword co-occurrence analysis. While this methodology provides valuable insights into the structural and temporal dynamics of the research field, it does not capture the qualitative dimensions of research quality, methodological rigor, or practical applicability of the studied approaches. The absence of content analysis limits the understanding of the actual effectiveness, implementation challenges, and real-world impact of the AI and Big Data solutions proposed in the literature.

B. Future Research Directions

Building on the findings and limitations identified in this study, several promising avenues for future research emerge. First, there is a critical need for comprehensive qualitative meta-analyses that examine the methodological approaches, implementation frameworks, and practical outcomes reported in the most influential studies. Such research should focus on identifying best practices, common challenges, and success factors in deploying AI and Big Data solutions for labor market prediction across different economic and cultural contexts.

Second, future investigations should prioritize the development of international collaborative frameworks that bridge the identified research gaps between high-productivity regions and underrepresented areas, particularly in the Global South. This could involve establishing international research consortiums, cross-regional data sharing protocols, and collaborative platforms that enable knowledge transfer and capacity building in AI-driven labor market analysis.

Finally, given the ethical concerns identified in this analysis, future research should systematically investigate bias mitigation strategies, algorithmic fairness, and the socio-economic implications of AI-driven labor market interventions. This research agenda should include longitudinal studies that track the long-term impacts of these technologies on employment patterns, wage inequality, and workforce development across diverse demographic groups and economic sectors.

In conclusion, this study maps the intellectual landscape of a rapidly expanding research domain and identifies both its strengths and its gaps. It lays the groundwork for future investigations that should aim to bridge disciplinary silos, enhance international cooperation, and develop robust, ethical, and globally relevant models for predictive labour market analysis. Such efforts are essential to ensuring that intelligent technologies contribute meaningfully to sustainable, inclusive, and data-informed workforce development.

School of Computer Science, Duy Tan University, Da Nang 550000, Vietnam[3]
Department of Management Information Systems, Chungbuk National University,
Seowon-Gu, 28644, Cheongju, South Korea[4]

***Abstract*—Reverse driving and lane collapse pose serious risks to road safety, especially on complex infrastructures such as multi-lane highways, intersections, and roundabouts. Existing detection systems often depend on rigid lane configurations and struggle to adapt to varied road geometries and environmental conditions. Prior works are typically limited to straight, multi-lane roads and rely on automated boundary extraction, making them unsuitable for irregular traffic layouts. To address this gap, the objectives of this research paper is to propose a vision-based detection system that combines the YOLOv8 object detector with a dynamic polygon-based zone management strategy. The system aims to detect reverse driving and lane collapse incidents in real time using CCTV footage, without requiring additional sensors. Its key novelty lies in manually configurable zones and the integration of ByteTrack for robust vehicle tracking across complex scenes. The system was tested under diverse real-world parameters, including different road types (single-lane, multi-lane, roundabouts), lighting conditions (day and night), and traffic behaviors (normal flow, reverse, and collapse) and visual evaluations highlight consistent and logically coherent results across scenarios, highlighting its practical effectiveness for real-time intelligent traffic monitoring.**

***Keywords*—Reverse driving detection; lane collapse detection; polygon zones; object detection; YOLOv8**

I. Introduction

Preventing traffic accidents and maintaining efficient traffic flow are critical challenges of modern transportation infrastructure [1]. Although wrong-way driving incidents account for only 3% of global traffic accidents, they result in a disproportionate 22% of traffic-related fatalities [2], highlighting their severe impact. This underscores the urgent need for effective detection and prevention systems to mitigate the risks associated with dangerous driving behaviors, particularly reverse driving and lane collapse incidents [3], [4], [5].

Recent advances in intelligent transportation systems have played a crucial role in enhancing road safety and traffic management. However, the increasing complexity of modern road networks, diverse driving behaviors, and unpredictable environmental conditions pose significant challenges to existing solutions. Traditional countermeasures, including physical barriers and static signage, provide some deterrence but often prove inadequate in dynamic traffic environments that require rapid response. Although emerging detection technologies, including sensor-based and artificial intelligence AI-driven methods, offer promising alternatives, they face limitations in scalability, adaptability, and cost-effectiveness.

To address these challenges, this study proposes a novel AI-driven detection system for identifying wrong-way driving and lane collapse incidents in real-world traffic scenarios. Using advanced computer vision techniques, the proposed method enhances detection accuracy and robustness across various road environments, including intersections, highways, and roundabouts, making it well-suited for intelligent traffic management systems.

The proposed approach integrates the state-of-the-art You Only Look Once, version 8 (YOLOv8) [6] object detection model with a dynamic polygon-based zone management system, offering several key advantages:

1) Adaptive configuration: Dynamic polygon-based zones adjust to various road configurations, enabling deployment across diverse infrastructure environments.

2) Real-time processing: The lightweight architecture of YOLOv8, combined with efficient zone management, enables real-time detection and response.

3) Robust scene adaptability: The combination of polygonal zones and ByteTrack enables reliable detection across intersections, roundabouts, and complex traffic scenes.

4) Cost-effectiveness: The vision-based system requires minimal additional infrastructure, making it accessible to transportation authorities with varying resources.

Through the comprehensive evaluation of diverse datasets, our approach demonstrates superior performance in detecting reverse driving and lane collapse scenarios across various road configurations. The system maintains high accuracy while minimizing computational overhead, ensuring its suitability for widespread deployment.

Objectives of the Paper:

- To conduct an in-depth literature review of diverse driving behavior detection techniques proposed in prior research, with a focus on identifying limitations related to adaptability, road type constraints, and deployment cost in existing systems;
- To propose a novel vision-based methodology for detecting reverse driving and lane collapse behaviors using CCTV surveillance. The purpose is to provide

*Corresponding authors.

This work was supported by the Technology development Program (S3458136) funded by the Ministry of SMEs and Startups (MSS, Korea).

a lightweight and infrastructure-independent system capable of adapting to a variety of real-world road layouts, including intersections and roundabouts. The novelty of the proposed system lies in its manually configurable polygon-based zone management and integration with YOLOv8 and ByteTrack for precise object detection and multi-object tracking in complex scenes;

- To test and validate the system's performance across varied traffic scenarios using visual assessments under different lighting conditions (day and night), road types (single-lane, multi-lane, roundabout), and behavioral patterns (normal flow, reverse driving, and lane collapse);
- And, to validate the proposed system in real-time system responsiveness to detect and update reverse-driving incidents immediately within video stream processing.

The remainder of this paper is organized as follows. The literature review section analyzes existing detection methods and their limitations. The methodology section details the system architecture. The implementation details section summarizes the steps of the algorithm, illustrating the logical workflow. The result section discusses the experimental results across various road configurations, demonstrating the effectiveness of the system. Finally, the discussion concludes with insights into future research directions and potential applications.

II. Literature Review

Research highlights the significant impact of wrong-way driving and lane collapse incidents on road safety. The AAA Foundation reported a 34% increase in driving against the traffic flow incidents over the past five years, particularly on highways and divided roads [7]. In the United States, annual economic losses from such incidents exceed $5.2 billion, encompassing direct damage, emergency response costs, and productivity losses. Lane collapse incidents account for 18% of highway accidents, with heightened risks under adverse weather conditions and reduced visibility [8], [9].

Traditional countermeasures, including signage and physical barriers, have been widely implemented, yet their effectiveness remains limited, preventing only 65% of wrong-way entries [10], [11]. Electronic detection systems, such as roadside cameras and automated warnings, can improve response times but suffer from high false-positive rates (15–20%) and incur high maintenance costs, averaging $50,000 annually per installation [12]. Sensor-based solutions, including radar, lidar, and GPS tracking, have also been explored [13], [14], [15], [16], [17]. However, radar systems exhibit reduced accuracy in adverse weather, lidar presents high deployment costs, and GPS-based approaches require vehicle-mounted units, which hinders scalability in public infrastructure applications.

Artificial intelligence (AI)-based systems, particularly those utilizing convolutional neural networks (CNNs), have demonstrated high accuracy in detecting traffic anomalies in controlled environments. Studies report over 95% accuracy in detecting lane violations and reverse movement under ideal conditions [18], [19], [20], [21]. Nevertheless, real-world deployment remains challenging due to lighting variation, complex road geometries, and occlusions. Camera-based detection approaches, including dashcam footage and surveillance systems, also require adaptation to varied environmental conditions [22], [23], [24], [25]. Moreover, these methods often struggle with performance in intersections, roundabouts, and irregular traffic zones [26], [27].

Recent advances have sought to combine multiple techniques to address these challenges. Hybrid systems integrating vehicle detection, motion tracking, and infrastructure feedback have improved robustness. Vehicle-to-infrastructure (V2I) methods offer real-time alerts, but remain costly and dependent on specific installations [28]. Grouping-based vehicle detection enhances classification accuracy but is vulnerable to changes in weather, traffic density, and road layout [29]. Loop-type detectors such as those from Sumitomo Electric require precise calibration and suffer from false activations in dense traffic areas [30].

Among recent contributions, the work by Suttiponpisarn et al. [18] presents an enhanced system combining YOLOv4-Tiny with FastMOT [31] and a road boundary extraction algorithm (RLB-CCTV). This method achieves high accuracy using embedded-suitable components, and replaces manual boundary marking with automated lane detection based on edge and line detection. However, it remains limited to straight roads. The system's dependency on statistical estimation for directional flow and sensitivity to environmental conditions constrain its applicability in complex or non-linear road structures such as roundabouts or intersections.

These observations highlight the need for a flexible and generalizable detection system that performs reliably across diverse road conditions. Our study addresses this gap by introducing a polygon-based zone framework integrated with YOLOv8 for real-time detection and tracking. The proposed approach allows users to manually configure detection zones for arbitrary road layouts, enabling robust performance in environments where automated methods or fixed detectors fail to generalize.

III. Methodology

The proposed system is designed to detect reverse driving and lane collapse incidents using video streams from roadside CCTV cameras. The overall architecture is composed of four primary modules: video input processing, dynamic zone setup, movement detection and analysis, and real-time monitoring. A visual overview of the framework is presented in Fig. 1.

A. Video Input and Frame Processing

Each video stream is processed frame-by-frame. Frames are extracted in real time and passed to the object detection and tracking module. This ensures the system can maintain temporal continuity of vehicle movement and associate detection results across time.

B. Object Detection and Vehicle Tracking

To detect vehicles, we use YOLOv8 [6], a state-of-the-art object detection model known for its accuracy and efficiency,

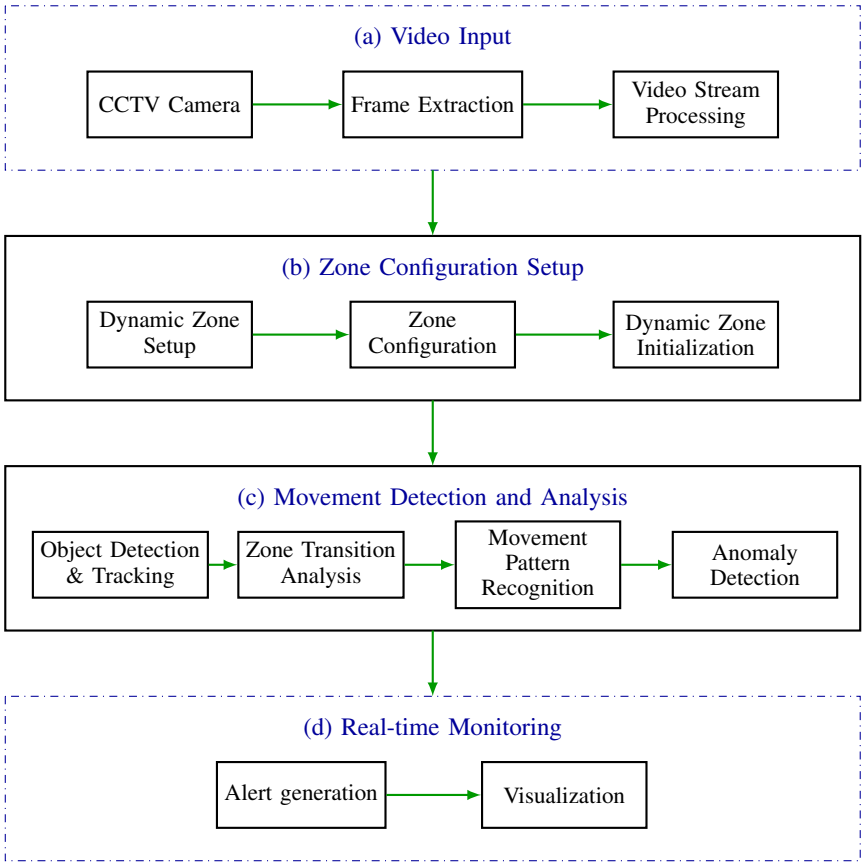

Fig. 1. Overview of the proposed traffic monitoring system architecture. (a) Video input module processes CCTV streams. (b) Configuration defines dynamic detection zones. (c) Movement detection analyzes object transitions and detects anomalies. (d) Real-time monitoring generates alerts and visual output.

particularly in complex scenes. Each detected vehicle is represented by a bounding box and class label (e.g., "car", "truck"). The detection results are then passed to the ByteTrack multi-object tracker [32], which assigns a unique tracker ID to each vehicle.

ByteTrack in Section III-G operates by associating detections across frames using Intersection-over-Union (IoU) matching. It follows multiple steps which helps maintain trajectory consistency even when detections are temporarily uncertain or occluded.

C. Dynamic Zone Configuration

In the initial frame of the video, polygonal zones are manually defined using OpenCV [33]. For a two-lane road, four zones are created: in-zone-0, out-zone-0, in-zone-1, and out-zone-1. These zones represent logical boundaries of entry and exit for each lane (as shown in Fig. 2 and 3).

Each vehicle's bounding box is evaluated in every frame to check whether it intersects any of these predefined zones. The result is stored as a binary occupancy value for that zone (1 = inside, 0 = outside). Each tracker ID maintains a zone presence vector over time.

D. Illustrative Example

Consider vehicle ID #3 on a single-lane road in Fig. 2:

- It enters in-zone-0 and later exits through out-zone-0.
- Its zone vector becomes (1,1,0,0), matching the first row in Table I.
- Therefore, the reverse value is set to 0 (reverse driving within the same lane).

By contrast, if a vehicle enters both `in-zone-0` and `in-zone-1`, but never exits correctly, its vector becomes (1,0,1,0) and is assigned a reverse value of 1 (violation or lane collapse) as shown in Fig. 3.

E. Real-Time Output and Monitoring

Once the reverse status is determined for a tracker ID, the label is visualized in real time using bounding boxes and zone overlays. Vehicles are annotated with their ID and reverse status (e.g., "car (reverse: 1)"), enabling immediate visual confirmation and alerting.

This modular pipeline ensures the system can operate reliably across varied road configurations, including intersections and roundabouts, without retraining. The manual polygon zone setup provides flexibility, while YOLOv8 and ByteTrack ensure accurate detection and persistent identity tracking.

F. Reverse Driving Judgement

The algorithm, outlined in Table I, employs a zone-based configuration with four distinct monitoring areas—in-zone-0

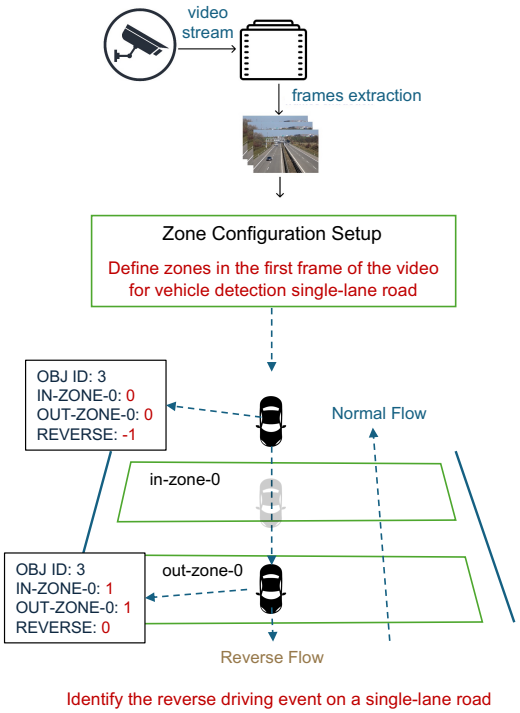

Fig. 2. Zone configuration for single-lane road monitoring.

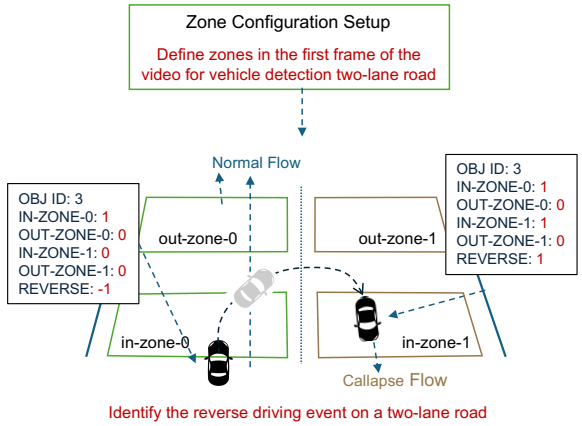

Fig. 3. Zone configuration for two-lane road monitoring.

TABLE I. ZONE TRANSITION STATES AND THEIR CORRESPONDING REVERSE VALUES. THE 'REVERSE' COLUMN INDICATES WHETHER A VEHICLE IS IN AN UNKNOWN STATE (-1), REVERSE WITHIN ITS LANE (0), AND COLLAPSE ON OTHER LANES (1)

in-zone-0	out-zone-0	in-zone-1	out-zone-1	reverse
1	1	0	0	0
0	0	1	1	0
1	0	0	1	1
0	1	1	0	1
1	0	1	0	1
0	1	0	1	1
else				-1 (unknown)

and out-zone-0 for the left lane, and in-zone-1 and out-zone-1 for the right lane, as depicted in Fig. 3. The occupancy of each zone is binary (0 or 1), enabling precise vehicle movement tracking and directionality assessment. The algorithm evaluates all possible combinations of zone occupancies to detect reverse driving incidents. The 'reverse' column in Table I represents the detection outcome, where 0 indicates reverse driving within the same lane, 1 signifies cross-lane reverse driving or lane collapse, and -1 indicates ambiguous cases requiring further analysis. This six-row approach effectively identifies and assesses vehicle movements, enhancing detection accuracy for traffic anomalies on two-lane roads. This approach provides a robust framework for automated reverse driving detection, improving traffic safety by identifying potentially hazardous situations.

The implementation, illustrated in Fig. 3, demonstrates both normal traffic flow and lane collapse scenarios, with corresponding zone transition states documented in Table I. This comprehensive method ensures accurate monitoring and timely detection of reverse driving events, contributing to traffic safety.

G. Vehicle Tracking

ByteTrack [32] is employed as a robust multi-object tracking algorithms that effectively track objects, including vehicles, by utilizing both high-confidence (D_{high}) and low-confidence (D_{low}) detection. This algorithm serves as the starting point of Algorithm 1, which analyzes the movements of tracked vehicles and assigns each one a unique `tracker_id`, as defined in Algorithm 1.

The ByteTrack tracking mechanism involves the following main steps:

1) Detection set division: At each frame t, the detections are divided into:

$$D_t = D_{\text{high},t} \cup D_{\text{low},t}, \tag{1}$$

where:

- $D_{\text{high},t}$: comprises detections with confidence $c > \tau$, where τ is a high confidence threshold.
- $D_{\text{low},t}$: include detections with confidence $\tau_{\text{low}} < c \leq \tau$, where τ_{low} is a lower confidence threshold.

2) Matching with high-confidence detections: High-confidence detections are matched to existing tracks T_t using the intersection over union (IoU) metric:

$$\text{IoU}(d_i, T_j) = \frac{|b_i \cap b_j|}{|b_i \cup b_j|}, \tag{2}$$

where b_i and b_j are the bounding boxes of detection d_i and track T_j, respectively. The Hungarian algorithm is used to find the optimal matching:

$$T_{\text{matched}} = \text{Hungarian}(T_t, D_{\text{high},t}, \text{IoU}). \tag{3}$$

3) Incorporation of low-confidence detections: To prevent track loss, unmatched tracks from the high-confidence step are matched with low-confidence detections:

$$T_{\text{low-matched}} = \{(t, d) \mid \tag{4}$$

$$\text{IoU}(t, d) \geq \tau_{\text{low}}, \quad t \in T_{\text{unmatched}},\ d \in D_{\text{low},t}\} \tag{5}$$

4) Track update: Matched tracks are updated using Kalman filtering [34] to refine the bounding box predictions:

$$b_{\text{updated}} = K(b_{\text{predicted}}, b_{\text{new}}), \tag{6}$$

where $b_{\text{predicted}}$ is the predicted state of the track, b_{new} is the observed detection, and K represents the Kalman filter.

5) New track initialization: Unmatched high-confidence detections are initialized as new tracks:

$$T_{\text{new}} = \{b_i \mid b_i \in D_{\text{high},t},\ b_i \notin T_{\text{matched}}\}. \tag{7}$$

6) Track termination: Tracks are terminated if they remain unmatched for k consecutive frames:

$$T_{\text{terminated}} = \{t \mid \Delta t > k,\ t \notin T_{\text{updated}}\}. \tag{8}$$

IV. Implementation Details

Algorithm 1 is designed to detect reverse driving by processing object detections with their associated `tracker_id` and bounding boxes. The algorithm's primary goal is to update `reverse_conditions` for each detection, which stores information about tracked objects.

Algorithm 1 Detecting Reverse Driving and Lane Collapse

Input: Detections with `tracker_id` and bounding boxes
Output: Detections with updated `reverse_conditions`
`tracker_id`: An object being tracked
`reverse_conditions`: Stores values related to tracked objects (as in Table I) Initialize `reverse_conditions` for all detections **ForEach** *detection in* `detections`
  Extract `tracker_id` and bounding box Initialize `reverse_conditions[tracker_id]`
end
ForEach *zone in zones*
  ForEach *`tracker_id` in zone*
    Update zone information for `tracker_id` Check if `tracker_id` moved in or out of the zone **If** *reverse driving is detected*
      `reverse_conditions[tracker_id]` ← `true`
  end
end
Return *`detections` with updated `reverse_conditions`*

It begins by initializing `reverse_conditions` for all detections in the input data. The process then iterates through each detection, extracting the `tracker_id` and bounding box information, and initializes the corresponding `reverse_conditions` entry for that `tracker_id`. The core detection logic operates by examining each zone and the `tracker_id`s within them. For each `tracker_id` present in a zone, the algorithm updates the zone information and monitors whether the tracked object has moved in or out of the zone. When reverse driving behavior is detected, the algorithm sets the `reverse_conditions` for the corresponding `tracker_id`.

After processing all zones and their associated `tracker_id`s, the algorithm concludes by returning the complete set of detections with their updated value of `reverse_conditions` as shown in 'reverse' column in Table I, providing a comprehensive record of any reverse driving incidents detected during the analysis.

V. Results

To validate the proposed system, we present qualitative results using real-world video footage across various scenarios. Fig. 4 to 7 demonstrate the system's ability to detect normal and reverse driving behavior in single-lane, multi-lane, nighttime, and roundabout road conditions. These case studies confirm the robustness and practical performance of the system, even in complex or low-visibility environments.

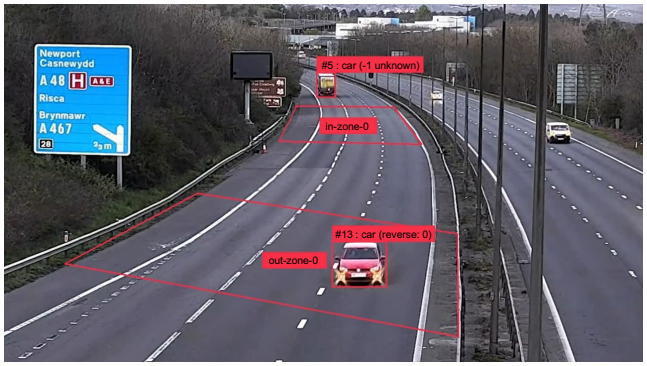

Fig. 4. Result of monitoring on single-lane road configuration.

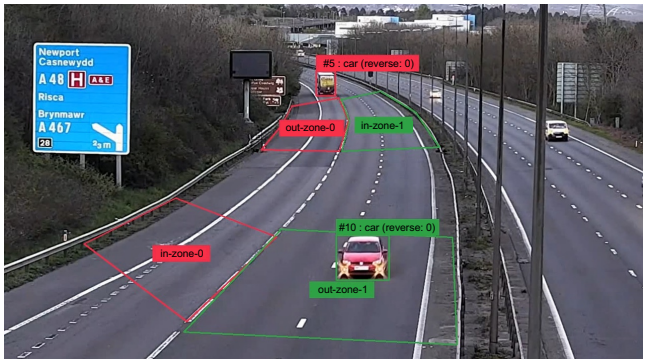

Fig. 5. Result of monitoring on double-lane road configuration.

The real-world implementation demonstrates the effectiveness of the reverse driving detection algorithm on single-lane road segments. As shown in Fig. 4, the system successfully

TABLE II. COMPARISON BETWEEN THE PROPOSED METHOD AND SUTTIPONPISARN ET AL. [18]. THE TABLE HIGHLIGHTS DIFFERENCES IN DETECTION FLEXIBILITY, DEPLOYMENT SCOPE, AND CORE ALGORITHMIC CHOICES

Aspect	**Suttiponpisarn et al**	**Proposed Method**
Detection Model	YOLOv4-Tiny	YOLOv8
Tracking Algorithm	FastMOT	ByteTrack
Zone Definition	Automated rectangular zones via edge detection	Manual polygonal zones for flexible layout
Supported Road Types	Straight, unobstructed multi-lane roads	Multi-lane, intersections, roundabouts
Lighting Adaptability	Requires brightness correction	Works under day/night
Object Focus	Motorcycle detection in 4 test locations	All vehicles across diverse traffic scenarios
Evaluation Type	Quantitative (96.61% accuracy)	Qualitative visual validation
False Positive Handling	Measured and reported	Acknowledged; future work planned

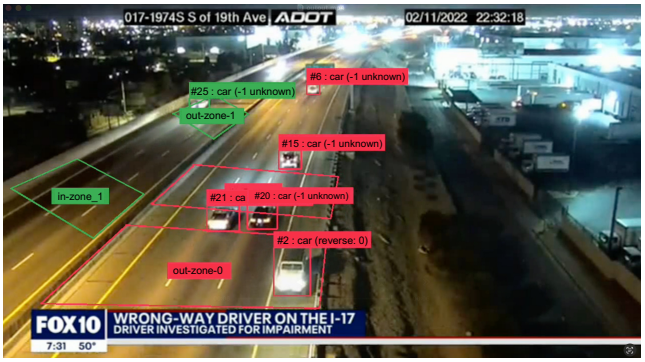

Fig. 6. Result of monitoring at night condition.

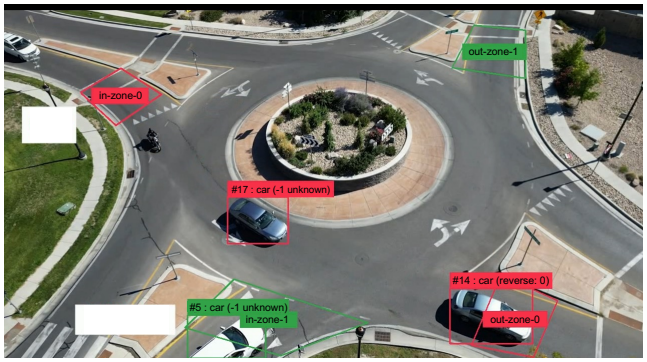

Fig. 7. Result of monitoring on roundabout road configuration.

monitors vehicle movement through defined zones on a primary road. A test case with vehicle #13 demonstrated normal forward motion. The vehicle traversed through in-zone-0 and out-zone-0, with the algorithm correctly assigning reverse: 0 based on the zone transition states in Table I. This corresponds to the first row of the transition table, where the activation of both zones in a single lane (1,1,0,0) indicates proper directional flow. Additionally, the system simultaneously tracks multiple objects. For instance, vehicle #5 was detected in an unknown state (-1), aligning with the undefined state conditions of the table. These results validate the capability of the algorithm to differentiate normal and reverse driving patterns in real-time monitoring scenarios. The clear zone demarcation enables reliable movement classification.

The monitoring capabilities of the system were further tested in multi-lane scenarios, where multiple vehicles were tracked simultaneously. As shown in Fig. 5, the algorithm correctly classifies vehicle #5 in out-zone-0/in-zone-0 and vehicle #10 in in-zone-1/out-zone-1 with reverse: 0. This aligns with the zone transition states of Table I, where the simultaneous occupation of zones (0,0,1,1) indicates normal directional flow in the right lane. Clear zone delineation between lanes (red for lane 0 and green for lane 1) enables accurate vehicle tracking and classification. These results validate the effectiveness of the algorithm in complex multi-vehicle, multi-lane monitoring scenarios.

Fig. 6 presents results from nighttime highway monitoring. Vehicles are detected and annotated with bounding boxes and labels. Vehicle #2, labeled 'car (reverse: 0)', indicates it is traveling against the flow of traffic in out-zone-0.

The reverse driving detection algorithm can monitor roundabout scenarios, where dynamic polygonal zone setups present unique challenges. Fig. 7 demonstrates the performance of the system at a roundabout intersection, where multiple vehicles are tracked simultaneously. Detected vehicles include vehicle #14 in out-zone-0 (reverse: 0), indicating normal flow and vehicles #17 and #5 in unknown states (-1) due to movement through zones that do not conform to the standard transition patterns in Table I. The system effectively monitors multiple entrance and exit points, although the increased complexity of roundabout navigation results in a higher frequency of unknown state classifications compared to straight road segments.

A. Analysis

To further evaluate the strengths and limitations of the proposed system, we conducted a comparative analysis with a closely related work by Suttiponpisarn et al. [18]. Their method combines YOLOv4-Tiny for object detection, FastMOT [31] for tracking, and an automated road boundary extraction algorithm (RLB-CCTV) that utilizes edge detection and Hough transforms to define lane boundaries. The system is designed for embedded devices and achieves high accuracy (96.61%) for detecting wrong-way motorcycles on straight, well-lit roads.

However, their approach presents several constraints. It is restricted to straight, unobstructed multi-lane roads and depends on brightness correction and predefined geometric assumptions. It does not support curved roads, roundabouts, or intersections—scenarios which are common in urban traffic environments.

In contrast, our method uses manually defined polygonal zones that can be flexibly adapted to any road geometry. The system is validated qualitatively across multiple complex real-world scenarios, including intersections and roundabouts, and performs reliably under both day and night conditions. Moreover, we adopt YOLOv8 for object detection, which has demonstrated superior accuracy and generalization over YOLOv4-Tiny in benchmark evaluations, particularly in detecting small or partially occluded objects [6]. Table II summarizes the key differences between the two approaches.

This comparative analysis underscores the broader applicability and deployment flexibility of our method, particularly in urban environments where roads are non-linear and traffic conditions are more dynamic.

VI. Conclusion and Future Work

The research paper proposes a novel system for detecting reverse driving and lane collapse using CCTV-based video monitoring. The system integrates YOLOv8 for object detection, ByteTrack for vehicle tracking, and manually defined polygonal zones for flexible configuration across different road layouts. The novelty of the method lies in its adaptability to intersections, roundabouts, and non-linear road geometries without relying on additional sensors or automated boundary extraction. Experimental results show consistent visual performance across day, night, single-lane, multi-lane, and roundabout scenarios. However, the evaluation remains qualitative due to the absence of labeled datasets.

In the near future, it is planned to focus on developing dynamic zone adjustment mechanisms that extend beyond straight road detection. In contrast to prior approaches that rely on automated boundary extraction limited to linear lane structures, the proposed direction will aim to support adaptive zone generation for complex geometries such as roundabouts, intersections, and curved roads. This advancement is expected to reduce manual configuration effort and improve generalizability. In addition, the work will include quantitative evaluation using annotated datasets to assess detection accuracy, false detection rates, and latency. These improvements can further enhance the system's robustness and scalability for real-world intelligent traffic surveillance.

Information Technology, Puducherry Technological University, Pillaichavady, Puducherry 605014[1,2]
SRKR Engineering College, Bhimavaram[1]

***Abstract*—One of the most serious malignancies that affects women's health worldwide is ovarian cancer. As a result, prompt accurate diagnosis and treatment are necessary. This study's primary objective is to determine whether or not OC is present within the body of a person by using a range of characteristics gleaned with a couple of health examinations. The article is concentrated on twelve ML techniques used for OC diagnosis. The dataset has been altered by applying the borderline SVMSMOTE method to address the imbalance properties and the MICE imputation method to impute the missing values in order to enhance the performance of the classifiers. Additionally, the boruta approach and recursive feature reduction has been utilized to identify the most important features while the hyper parameter tuning strategy has been employed to improve classifier performance and provide ideal solutions.Boruta opted just 50% of the total characteristics and outperformed RFE while considering the most important feature. Furthermore, many performance measures are used to determine which classifiers are the best in identifying OC. Voting classifier surpassed state-of-the-art approaches and other machine learning methods with the highest accuracy. The suggested approach obtained the highest average of 93.06% accuracy, 88.57% precision, 96.88% recall, 92.54% F1-score, and 93.44% AUC-ROC based on experimental results. Experiments show that in comparison with the state-of-the-art techniques, our suggested method can identify OC more accurately.**

Keywords*—Ovarian cancer detection; machine learning framework; data balancing; feature selection

I. Introduction

Globally, ovarian cancer (OC) is one of the most common cancers in women. As to the most recent worldwide cancer data published in 2021, there are roughly 314,000 new ovarian cancer cases (3.4% of all new cancer cases in women) and 207,000 ovarian cancer deaths annually (4.7% of all women's cancer deaths) [1]. Most of the time, ovarian cancer is discovered in its later stages due to a absence of specific symptoms and indicators as well as improper screening, which frequently results in unfavorable consequences [2], [3]. In general, gynaecologists have to determine if a patient has grown malignant pelvic lumps, which may indicate a tumour. Although certain approaches such as h CT and ultrasound have been used to differentiate benign tumors from malignant non-gynecologic conditions, tumor biomarkers such as human epididymis protein 4 (HE4), carbohydrate antigen 125 (CA125) and carbohydrate antigen 72-4 (CA72-4) are critical in differentiating between pelvic masses of women [4]. To stratify patients with OC into benign and malignant categories, machine learning (ML) models such as Light Gradient Boosting Machine (LGBM), Gradient Boosting Machine (GBM), Extreme Gradient Boosting Machine (XGBoost), Logistic Regression (LR), Random Forest (RF), Support Vector Machine (SVM), Decision Tree (DT), and are utilised in the construction of classification models [5].

Compared to traditional methods, ML techniques are extremely useful for identifying complicated patterns in biomarkers yet, they may not provide physical insights into diagnosis. The use of eXplainable Artificial Intelligence (XAI) can be enhanced by gaining a greater understanding of how sophisticated machine learning algorithms make decisions [6].

The main goal of this study is to identify OC using a variety of characteristics obtained from certain clinical examinations. Consequently, two datasets are used to test ensemble learning techniques, including RF, gradient boosting decision tree (GBDT), adaptive boosting,voting, bagging, XGBoost, LightGBM, and stacking. These ensemble learning techniques weren't used in parallel to identify OC in the earlier research publications. The models' performance is assessed using the dataset that is accessible to the general audience.

Various metrics, including precision, accuracy, recall, AUCROC, and F1-score, are employed to evaluate the effectiveness with every classifier.

The primary contributions of this study are as follows:

- In order to increase the effectiveness of the existing ovarian cancer diagnosis method, this research offered eight machine learning algorithms. In order to enhance performance, we have also adjusted each classifier's hyperparameter through the parameter tuning procedure.
- This study employed the MICE imputation method to address the missing information instead of applying a statistical approach. Additionally, the Borderline-SMOTE approach was used to balance the uneven data. Moreover, the relevant features are selected using recursive feature elimination (RFE) and Boruta approaches. Such OC prediction methods have not previously been thoroughly examined.

The structure of this work is as follows: Section 2 is devoted to the literature review, and Section 3 details the materials and procedures. Comparably, Section 5 presents the experimental findings and a discussion, while Section 4 shows

II. LITERATURE SURVEY

This section walks around a number of cutting-edge machine learning techniques that have been created to identify ovarian cancer. These strategies cover a variety of techniques, such as deep learning methods, supervised learning, and unsupervised learning. Through the utilisation of ML, these approaches have the possibility to enhance the effectiveness, precision, and expand-ability of ovarian cancer detection and diagnosis, ultimately leading to improved patient results. Table I presents a summary of the relevant works.

The author Mart´ınez-M´as et al. [7] identified the optimal classifier for FT-based feature descriptors and compare the ELM algorithm with traditional classifiers, by using ultrasound of 348 images. They has demonstrated that machine learning techniques, including LD and SVM approaches, are effective in creating the classification phase with 86% accuracy.

The most reliable predicting method for ovarian cancer, according to the Yang et al. [8] study, was the decision tree using SVMSMOTE on PLCO imbalanced dataset of143:7 class ratio. It had PPV of 0.9041, AUC of 0.9532, sensitivity of 0.7792, and specificity of 0.9982 is achieved by considering only seven features where there is chance of overfitting.

The possibility of applying the XGBoost machine learning algorithm to predict ovarian tumor which is proposed by Akazawa and Hashimoto[9], attained an accuracy of 0.80 for 16 characteristics on the 202 patient data set. On other hand Charkhchi et al. [10]focused the role that CA125 plays in the treatment of ovarian cancer in a review article , the necessity of accessible and affordable screening methods for the quick recognition of type II tumors. To predict benign or malignant ovarian tumors, the authors Hu et al. [11] selected distinct 11 groups by using 349 patients of 46 features achieved an accuracy of 93.33on other hand Ghoniem et al. [12] proposed to predict subtypes of other cancers by combining characteristics from pathologic image modal and gene modal. TCGAOV dataset is used containing pathological pictures, copy number variations, and gene expression data for 587 OC patients.The author Sorayaie Azar et al. [13] by using the SEER dataset, they study created ML techniques for regression and classification methods. XGBoost and RF were themost successful approaches for regression and classification, respectively. The findings showed promise and could be a useful tool for physicians to better understand the status of patients with ovarian cancer. For the purpose of OC detection, the authors Juwono et al. [14] has provided the best simultaneous feature weighting/parameter optimisation method. The LASSO regularisation and adaptive differential evolution (ADE) with cross validation error are used as the fitness function to optimise the weights.On other hand Boehm et al. [15] designed Decision support system to find three highly discriminating proteins (TOP1, PDIA4, and OGN) for the diagnosis of highgrade serous ovarian cancer (HGSOC) utilizing proteome data and a machine learning-based methodology. The DSS demonstrated promising clinical utility in the diagnosis of HGSOC with its excellent specificity and sensitivity in differentiating tumor from non-tumor patients.

On other hand Comes et al. [16] implemented an explainable machine learning model, the study identified high-risk BRCA-mutated patients and established when RRSO should be performed. The model produced encouraging results, with accuracy, specificity, sensitivity, G-mean, and AUC values of 83.2%, 85.3%, 57.1%, and 71.1%, respectively.

The key findings by the Abuzinadah et al. [17] include the extremely accurate stacked ensemble model for ovarian cancer prediction, the intricate interactions between biomarkers shown by the SHAP analysis, and the potential for real-world application.

III. METHODS AND MATERIALS

This article has built a smart approach for assessing and identification of OC. This study analyses OC data in twelve different ways. AUC-ROC, F-measure, accuracy, precision, recall, and F-measure were among the metrics used to assess each model's performance. The dataset was sourced from the Mendeley repository website.

A pair feature selection technique Boruta and Recursive feature elimination are employed to determine which features are most relevant. The steps involved in this investigation are shown in Fig. 1. Assigning incomplete values to every attribute in the dataset, the MICE method and a basic imputer are used. After the target attributes are equalised using the borderline-SMOTE technique, the processed data is fed into each classifier. Each classifier's parameter is adjusted via the hyper parameter tuning technique and randomised grid search. In this research, cross-validation techniques are used to validate the model functionality.

A. Dataset Description

The Third Affiliated Hospital of Soochow University provided the dataset for the study, which included 349 patients.

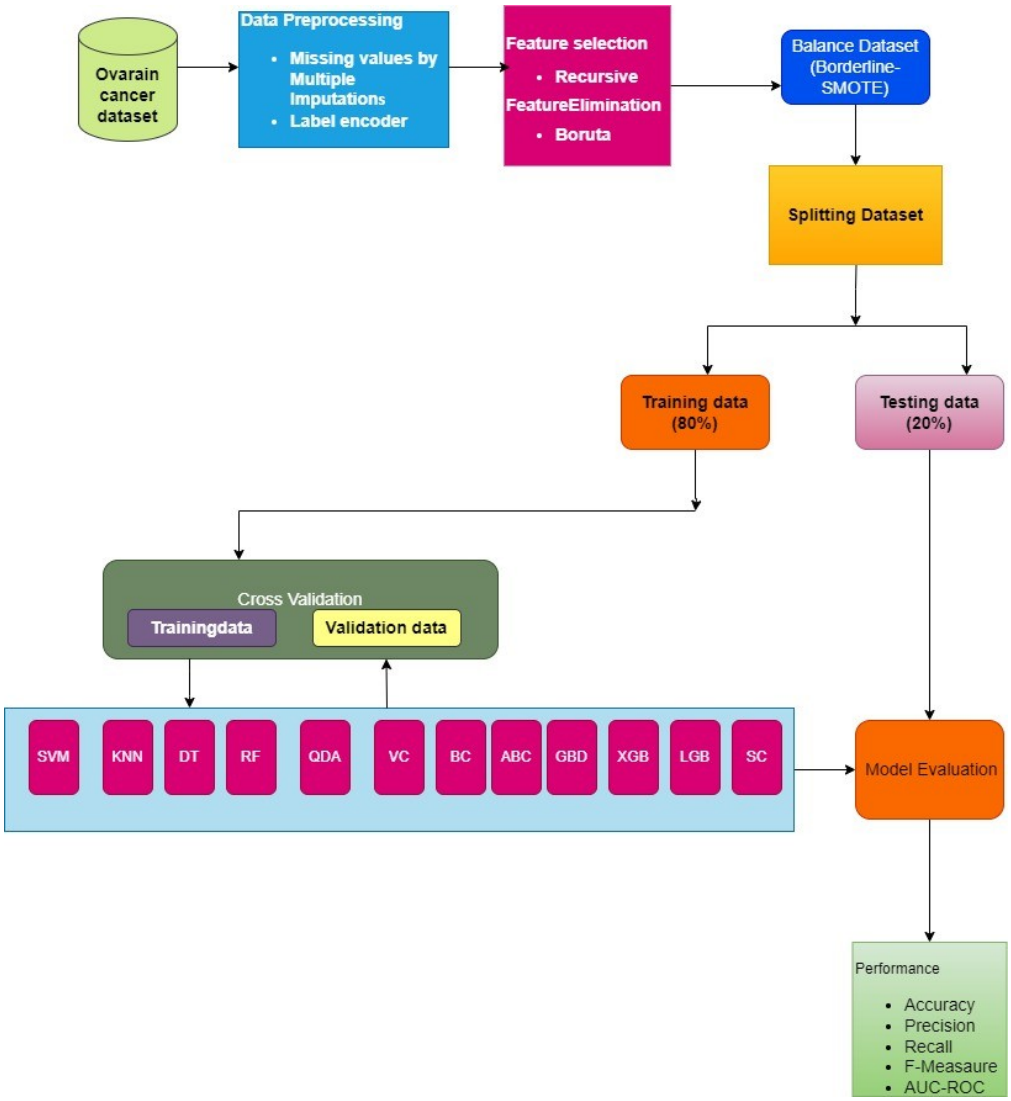

Fig. 1. Framework of detecting ovarian cancer.

The information was gathered between July 2011 and July 2018 and was split into two categories: 178 patients with benign ovarian tumour diagnoses, and 171 patients with malignant diagnoses [5].

B. Data Preprocessing

Preprocessing is necessary for the majority of real-world data because of outliers, noisy characteristics, missing values, and inconsistent patterns. If not, it will be difficult to increase the machine model's quality and produce an acceptable outcome. Numerous procedures have been used in this part to enhance and clean the data.

Several feature columns are labelled as inputs in the case of MICE technique, whereas single feature column that contains data missing is considered as an output. Subsequently, the output data is predicted using the regression model, and this is done again. Every value that is missing in the dataset is imputed using a different value in each iteration, and the process is repeated until convergence is achieved.

1) Missing value imputation: In this representation D represents the dataset with missing values, M represents the number of imputations to generate, k represents the number of iterations for each imputation, D_{imputed} represents the imputed dataset. The MICE algorithm iteratively imputes missing values for each variable in the dataset using regression models based on observed values of other variables. It repeats this procedure for a definite number of iterations for each imputation. Finally, it returns a list of M imputed datasets.

By using Multiple Imputation method [Algorithm 1], the dataset which contains 331 missing values which are been replaced.

The equation for imputing missing values using linear regression can be represented as follows:

$$\hat{Y}_i = \beta_0 + \beta_1 X_{i1} + \beta_2 X_{i2} + \ldots + \beta_p X_{ip} \quad (1)$$

where:

- $\hat{Y}_i$ — predicted value for the i^{th} observation.
- β_0 — intercept term.
- $\beta_1, \beta_2, \ldots, \beta_p$ — regression coefficients.
- $X_{i1}, X_{i2}, \ldots, X_{ip}$ — observed values of p predictors for observation i.

Algorithm 1 Multiple Imputations by Chained Equations (MICE)

procedure MULTIPLEIMPUTATIONSBYCHAINEDEQUATIONS(D, M, k)
  Input:
    D: Dataset with missing values
    M: Number of imputations to generate
    k: Number of iterations for each imputation
  Output: List of M imputed datasets
  Initialize empty list: $imputed_datasets \leftarrow [\,]$
  for $i = 1$ **to** M **do**
    Initialize $D_{\text{imputed}} \leftarrow D$ ▷ Copy of original dataset
    for $j = 1$ **to** k **do**
      for all variables v with missing values in D_{imputed} **do**
        Predict missing values in v using linear regression
        Update v in D_{imputed} with predicted values
      end for
    end for
    Append D_{imputed} to $imputed_datasets$
  end for
  return $imputed_datasets$
end procedure

C. Feature Selection

The process of eliminating unnecessary characteristics from a machine in order to reduce its computational load and improve the efficiency of the machine model is known as feature selection. The dual feature selection methods are used in this research.

1) Recursive Feature Elimination (RFE): This method selects the best subset of features from the entire dataset and minimizes the number of features. The SelectOptimalFeatures algorithm [Algorithm 2] provides a detailed explanation of each step in the RFE method.

2) Boruta based on RF: The BorutaFeatureSelection algorithm iteratively creates shadow features, combines them with original features, fits a Random Forest model, computes Z scores, and marks features as important or unimportant based on the comparison of Z scores. It repeats this procedure for a specified number of iterations and returns the desired number of optimal feature subsets.

3) Boruta based on RF: The BorutaFeatureSelection algorithm [Algorithm 3] iteratively creates shadow features, combines them with original features, fits a Random Forest model, computes Z scores, and marks features as important or unimportant based on the comparison of Z scores. It repeats this procedure for a specified number of iterations and returns the desired number of optimal feature subsets.

Algorithm 2 Select Optimal Features

Require: D: Training dataset with m samples and r features
  Y: Output values
  F: Set of features
  k: Number of iterations
  n: Number of optimal feature subsets
Ensure: F_{prime}: n optimal feature subsets
  Procedure:
  1. Train a RF model on dataset D.
  2. Initialize the feature subset F_{prime} with all features ($F_{\text{prime}} = F$).
  for $i = 1$ to k **do**
    a. Compute coefficients using Logistic Regression (LR) on the feature subset F_{prime}.
    b. Calculate the rank R based on the coefficients.
    c. Identify a specific number of features to eliminate, such as those with the smallest coefficients.
    d. Remove the determined number of features with the smallest coefficients from F_{prime}.
  end for

Algorithm 3 Boruta Feature Selection

procedure BORUTAFEATURESELECTION(D, Y, F, k, n)
  Input:
    D: Training dataset with m samples and r features
    Y: Target values
    F: Set of features
    k: Number of iterations
    n: Number of optimal feature subsets to select
  Output:
    F': Top n important features
  Initialize $selected_features \leftarrow []$
  for $i = 1$ **to** k **do**
    Generate shadow features by shuffling columns of F
    Combine F and shadow features to form dataset X
    Train Random Forest (RF) model on X
    Compute Z-scores: Z_o (original features), Z_s (shadow features)
    Let Z_{max} be the maximum of Z_s
    for each feature f_i in F **do**
      if $Z_o[f_i] > Z_{\text{max}}$ **then**
        Mark f_i as important
      else
        Mark f_i as unimportant
      end if
    end for
    Append important features to $selected_features$
  end for
  Select top n features from $selected_features$
  return F'
end procedure

IV. Classification Models

In this investigation, a variety of supervised ensemble-based machine learning algorithms [19] have been utilized, such as LR, DT, RF, LGBM, SVM, XGB, and GBM, in isolation, to forecast ovarian cancer. Furthermore, the search was conducted to identify the models that demonstrated the most outstanding performance.

1) SVMs: Supervised learning algorithms that are applied to regression and classification problems. It determines the best hyperplane with the largest margin between data points belonging to distinct classes. Using various kernel functions, SVM can handle both linear and nonlinear classification tasks.

2) k-NN: A feature space classification algorithm that classifies data points by using the majority class of the k nearest neighbors. This algorithm is regarded as non-parametric as it doesn't rely on explicit models.

3) Tree: This is probably a reference to decision trees, which divide the feature space into regions recursively and give each region a class name. Although decision trees are simple to understand, overfitting is a possibility.

4) RF: A technique that constructs many decision trees and combines their predictions by averaging or voting. This method successfully reduces overfitting by adding randomness to the feature and data sample selection processes.

5) QDA: A classification process known as quadratic discriminant analysis, or QDA, uses a quadratic decision boundary to simulate the probability density function of each class. It functions on the presumption that each class's features follow a normal distribution.

6) Voting: An ensemble learning technique where numerous models are trained independently and then their forecasts are combined by either average (for regression) or majority voting (for classification).

7) Bagging: Bagging (Bootstrap Aggregating) is an ensemble learning technique that uses bootstrap sampling of the training data to generate many models (typically of the same kind). To increase generalization performance and minimize variance, the predictions of the models are combined by voting or averaging.

8) AdaBoost: A technique that turns a number of ineffective learners into one powerful one. In each iteration, it gives more weight to data points that were incorrectly classified as it trains models progressively.

9) GBMs: Gradient Boosting Machines, or GBMs, are an ensemble learning technique that constructs a series of weak learners, usually decision trees, one after the other in a staged fashion, with each new tree fixing the mistakes of the preceding one.

10) XGBoost: A meticulously optimized implementation of the gradient boosting technique, specifically designed to enhance both speed and performance. By incorporating a diverse range of regularization techniques, XGBoost effectively prevents overfitting, thereby enabling it to achieve state-of-the-art outcomes in numerous machine learning competitions.

11) LGB: An additional scalable and extremely effective gradient boosting framework. To minimize memory usage and expedite training, it employs histogram-based approaches and a unique tree-growing algorithm.

12) SC: Also known as stacked generalization or stacking ensemble, is a machine learning technique that combines multiple classification models to improve prediction performance. Instead of relying on just one model, it leverages the collective wisdom of several models to make predictions.

V. Results

The recommended models are run through the Python program on a Windows 10 computer for validation. The system is powered by an Intel Core i3 processor with a 2.40GHz clock frequency and 8GB of RAM.

Additionally, this section involves in splitting the data source into 20% test and 80% training sets, adjusting the parameters of each classifier using the randomized grid search technique, and evaluating metrics to verify the performance of the model.

A. Parameter Tuning

Hyper-parameter optimization, or parameter tuning, is an essential stage in the creation of machine learning models. In order to maximize an algorithm's performance on a particular dataset, the optimal set of hyper-parameters for that method must be chosen. Additionally, the optimal subset of hyper-parameters for every classifier was shown in Table II to yield the best results for the OC prediction.

B. Model Evaluation Metric

The accuracy of a model's predictions can be assessed using a variety of performance evaluation criteria. More significantly, the well-known used performance evaluation metrics for binary classification include confusion matrix, precision, AUC-ROC, recall, F-measure, and accuracy.

1) Confusion matrix: The effectiveness of a classification algorithm is summarized in a table known as a confusion matrix that counts of false positives (NP), false negatives(NN), true positives (PP), and true negatives(PN).

2) Accuracy: It is the measure the proportion of a given class that is correctly classified among all instances is given by,

$$Accuracy = \frac{PP + NN}{PP + NN + PF + NF} \tag{2}$$

3) Recall: It is the proportion of all positively predicted instances to accurately predicted positive cases is given by,

$$Recall = \frac{PP}{PP + NN} \tag{3}$$

4) Precision: It is the ratio of correctly predicted positive cases among all positive cases is given by,

$$Precision = \frac{PP}{PP + PN} \tag{4}$$

TABLE II. LIST OF PRIMARY HYPERPARAMETERS FOR BINARY CLASSIFICATION FOR EACH CLASSIFIER

Classifier	Hyperparameters
SVM	kernel='rbf', C=10, gamma=0.1, probability=True

SC	76.4	74.2	71.9	73.0	75.9

5) F1-score: It is harmonic mean of precision and recall is given by,

$$F1 - score = \frac{1}{\text{Precision}} + \frac{1}{\text{Recall}} \tag{5}$$

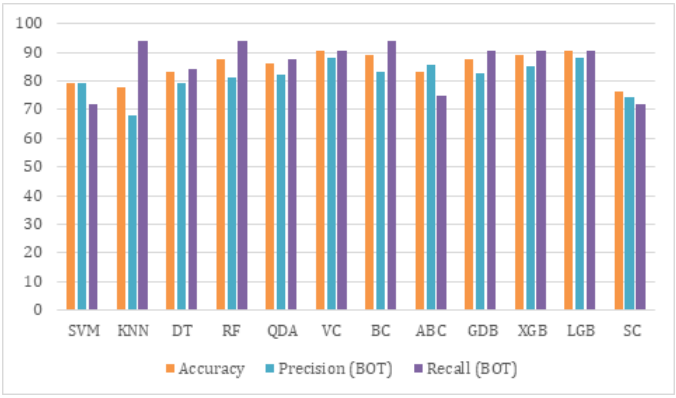

Fig. 2. Comparison of accuracy, Precision and recall for ML models of all features.

C. Results of Without Feature Selection Method

The experimental outcomes of each classification model employing every feature in the dataset are shown in Table III, Fig. 2 and Fig. 3. It was evident that the Voting classifier and LightGBM achieved a 90.3% score and all the other performance metrics are high except recall. Moreover, the other classifiers Bagging classifier, XGBoost, GBM, RF are performing better and their scores are approximately 87.5%.

D. Results of Recursive Feature Elimination Method

Among all the features in the present investigation, twenty-four are significant features. AFP, Age, ALB, ALP, AST, CA125, CA19-9, CEA, CO2CP, GLO, HE4, HGB, IBIL, LYM#, LYM%, MCH, Menopause, MPV, Na, PCT, PHOS, PLT, TBIL, TP are considered for classification of OC. It was observed from Table IV that Voting classifier achieved 93.1% accuracy, 88.6% precision, 96.9% recall, 92.5% F1 score, 93.4% ROC AUC among all the ensemble classifiers. Moreover, RF, XGB, LGB have moderate scores. Based on rank important features are identified using RFE are shown in Fig. 4.

E. Results of Boruta Feature Selection Method

In this feature selection method of all features, twenty-one are important features (AFP, Age, ALB, ALP, AST, CA125, CA19-9, CEA, GLO, HE4, IBIL, LYM#, LYM%, MCH, Menopause, MPV, Na, PCT, PLT, TBIL, TP) are considered for classification of OC. It was observed from Table V that the Voting classifier achieved 93.06% accuracy, 88.57% precision, 96.88% recall, 92.54% F1 Score, 93.44% ROC AUC among all the ensemble classifiers. Moreover, RF, AdaBoost, XGBoost have moderate scores approximately 91%. Based on rank important features are identified using Boruta are shown in Fig. 5; moreover, the common features among both approaches are shown in Fig. 6.

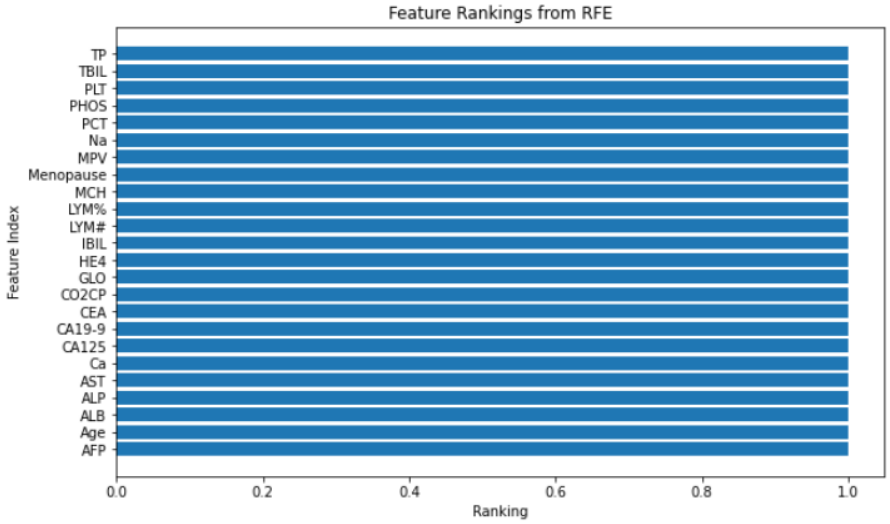

Fig. 4. Important features selected using Recursive Feature Elimination (RFE).

VI. PERFORMANCE ANALYSIS WITH SIMILAR WORKS

Table VI presents a comparison between our suggested models and some current publications. The table demonstrates how classification methods were used in every study to identify OC. On the other hand, we have used twelve machine learning techniques. Additionally, we have utilized SMOTE and multiple imputation methods to address imbalanced and missing data. We have achieved more than 2.3% of accuracy compared with existing approaches. We have evaluated all the five metrics for judging the model performance compared to the existing approaches.

VII. CONCLUSION

We have developed an ensemble-based method for OC detection in this paper. In this case dataset consists of 349 patients with 49 features where 171 are diagnosed with OC and 178 are diagnosed with benign. To improve the model's performance, twelve ML techniques were employed to categorize OC, and key parameters were chosen by fine-tuning the hyperparameters. Out of twelve algorithms, the voting classifier outperformed the others. To address the missing value and unbalanced data, MICE imputation and borderline SVMSMOTE algorithms were also applied. Two feature selection techniques such as Boruta and RFE have also been used. The Boruta method, which produced an average of 93.44% AUC-ROC, 88.57% precision, 93.06% accuracy, 92.54% F-measure, and 96.88% recall, decreased 50% of the total features. Experiments show that our proposed method can recognize OC more correctly than the state-of-the-art methods.

A. Limitations

1) Limited dataset size: The dataset has a constrained number of samples relative to the complexity of ovarian cancer subtypes. This limits the ability to robustly train and validate the model, especially for rare variants.

2) No Prospective clinical validation: The model was tested on retrospective data only. No prospective testing was conducted to assess clinical usability and patient impact.

B. Future Work

1) Multimodal feature integration: Fuse imaging, genomic, and clinical metadata with biomarker data to improve predictive power and facilitate subtype-specific detection.

2) Explainability benchmarking: Compare SHAP with other interpretability techniques like LIME, Integrated Gradients, and Counterfactual Explanations to assess transparency efficacy across user types (clinicians, data scientists).

3) Personalized risk stratification: Expand the fuzzy system to include personalized thresholds for pre- and post-menopausal patients, incorporating age, hormone levels, and family history.

Data Availability

All the data used in this study is publicly available at https://data.mendeley.com/datasets/th7fztbrv9/11.

Acknowledgment

The authors would like to thank Dr. P. Maragathavalli, the research supervisor, for her continuous guidance, support, and encouragement throughout the course of this study. The authors also acknowledge the open data provided by the Mendeley Data platform, which greatly facilitated this research.

Comparative Study of Prenatal and Postnatal Images for Detecting Down Syndrome in Children

Labanti Singha[1], Iqbal Ahmed[2]*
M.Sc. Student, Department of Computer Science and Engineering, University of Chittagong, Chittagong, Bangladesh[1]
Professor-Department of Computer Science and Engineering, University of Chittagong, Chittagong, Bangladesh[2]

***Abstract*—Down syndrome is a genetic disorder caused by the presence of an extra copy of chromosome 21, affecting both neurological development and physical features. Early and accurate diagnosis is critical for ensuring timely medical intervention and support. This study presents a comparative analysis of prenatal (ultrasound) and postnatal (facial) imaging modalities for the detection of Down syndrome using deep learning techniques. We employed VGG19, ResNet50, DenseNet121, MobileNetV2, and the Vision Transformer for image classification. An ensemble model integrating four CNN architectures achieved superior performance, with 92% test accuracy on prenatal images and 83% on postnatal images. Among the individual models, ResNet50 outperformed the others across both modalities. Evaluation metrics, including accuracy, precision, recall, and F1-score, confirm the effectiveness of the proposed framework. These results highlight the potential of ensemble learning to enhance the early detection of Down syndrome and improve accessibility to healthcare.**

***Keywords*—Down syndrome; prenatal ultrasound; postnatal facial recognition; CNN; vision transformer; ensemble learning**

I. Introduction

Down syndrome is currently defined as a genetic disorder caused by the presence of an extra chromosome 21, affecting both the physical characteristics and cognitive development of children. However, this disorder was not recognized until 1866 when the English physician John Langdon Down published a detailed description [1] of the condition that would later bear his name. Children affected by Down syndrome often experience academic difficulties, delays in cognitive development, and health complications such as heart disease, hearing loss, and vision impairments. Although there is no cure, early diagnosis, appropriate care, and therapy can significantly improve quality of life. Research into imaging-based detection of Down syndrome is crucial for enabling early diagnosis and enhancing healthcare accessibility. Advances in deep learning and imaging technologies have facilitated the development of cost-effective, noninvasive diagnostic methods. While postnatal imaging [2] captures facial characteristics, prenatal imaging [3]—such as ultrasound and 2D scans—detects structural markers. Combining these two approaches provides a comprehensive diagnostic framework. Motivated by the success of deep learning techniques, we employed transfer learning using models such as ResNet50, VGG19, DenseNet121, MobileNetV2, and the Vision Transformer.

Each of the employed models offers unique advantages; therefore, leveraging an ensemble approach proves beneficial, as it consistently outperforms individual CNN architectures. The key contributions of this study are summarized as follows:

- Evaluation of both ultrasound (prenatal) and facial (postnatal) images to fine-tune models for improved diagnostic accuracy in AI-assisted Down syndrome detection.
- Comparative analysis of two distinct imaging modalities using diverse datasets—1,684 ultrasound images and 2,000 facial images—to enhance generalizability.
- Performance benchmarking of multiple deep learning models across both prenatal and postnatal image datasets.
- Implementation of an ensemble learning strategy that integrates CNN features, resulting in optimized performance and higher accuracy compared to standalone models across both imaging types.

II. Related Works

Several studies have previously explored the prediction and diagnosis of Down syndrome (DS) using a variety of methods, some of which are summarized below:

A study [4] utilized the Random Forest machine learning model to improve the accuracy of DS prediction using second-trimester prenatal images, achieving a detection rate of 66.7% on the training dataset—outperforming traditional approaches. In another study [5], NMR-based metabolomics of maternal serum samples was employed to predict DS. Three key biomarkers were identified, and the inclusion of maternal age as a modifier improved detection efficiency from 48.1% to 51.9%.

Vičić et al. [6] analyzed 157 DS cases out of 6,448 prenatal examinations conducted in Croatia between 2002 and 2014. Key diagnostic markers included maternal age, ultrasound findings, and biochemical screening, while the primary diagnostic procedures were chorionic villus sampling and amniocentesis.

The study [7] introduced CVIFLR, a machine learning model designed for non-invasive DS prediction, and [8] explored deep transfer learning (DTL) in disease diagnosis, achieving a classification accuracy of 93.3%. Thomas et al. [9] used 100 fetal ultrasound images, combining SegNet for nuchal translucency segmentation with AlexNet for classification, resulting in 100% sensitivity, 85.7% specificity, and 91.7% accuracy.

Machine learning models for first-trimester DS screening using clinical data from the UK and Canada were evaluated

*Corresponding authors.

in [10], where deep neural networks (DNNs) outperformed commercial software with an AUC of 0.96 and a 78% detection rate. Similarly, Zhang et al. [11] employed machine learning algorithms for second-trimester prenatal screening, where support vector machines (SVMs) achieved 100% detection with a low false positive rate (FPR).

Another study [12] proposed a 1D convolutional neural network (CNN) model that utilized biomarkers like PAPP-A and hCG along with ultrasound data, reaching a high detection accuracy of 95.17%. Given the ethnic variability of DS features [13], facial recognition tools have shown promise, with one approach achieving 94.3% accuracy. Cornejo et al. [14] developed a novel method using geometric descriptors from facial features, capturing key distances such as intercanthal spacing, nose breadth, and mouth width based on 14 distances from 16 fiducial points.

The Face2Gene AI tool demonstrated strong performance in identifying DS among Thai children [15], with 90% sensitivity for DS cases and 87% for non-DS cases. A convolutional neural network-based method [16] offered a non-invasive solution for DS identification, achieving 99.3% accuracy and outperforming conventional methods like SVM.

In another work [17], extracted image features were used to train a backpropagation neural network (BPNN), which classified nasal bone presence with 86% accuracy. Additionally, a study [18] proposed an expert system framework aimed at enhancing the education of children with DS, while another work [19] introduced a mobile educational platform to support cognitive development through educator-guided learning.

Although not directly related to DS, a study [20] focused on Parkinson's disease—a related neurological disorder—demonstrated the effectiveness of three machine learning approaches for diagnosis. Furthermore, a review [21] provided comprehensive guidelines for the care and development of children with DS. The study [22] emphasized the benefits of early detection and treatment of sleep disorders, such as obstructive sleep apnea (OSA), in DS patients. Finally, [23] demonstrated the use of computer vision and deep learning techniques to analyze parental behaviors, specifically identifying supportive physical interventions during communication with children affected by Down syndrome.

III. Methodology

A systematic method for comparing both prenatal and postnatal images of children with or without Down syndrome is depicted in Fig. 1. This section outlines the methodological pipeline in this study, encompassing data collection, data processing, training various models, model evaluation, and finally the comparison between prenatal and postnatal datasets for detecting Down syndrome in children.

A. Data Collection

Data collection is the initial and most critical step in the proposed methodology. In this study, two distinct datasets are utilized:

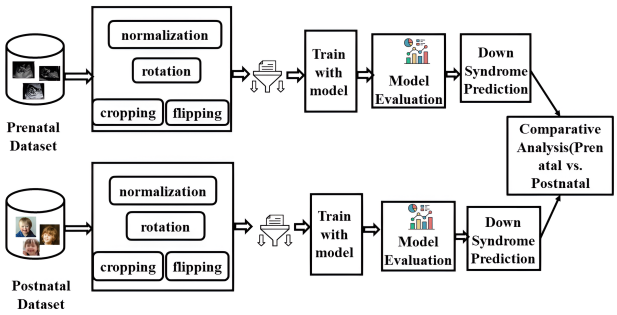

Fig. 1. Proposed methodology for Down Syndrome (DS) detection.

1) Prenatal dataset: This dataset, obtained from Mendeley [https://data.mendeley.com/datasets/n2rbrb9t4f/1], comprises 1,684 ultrasound images of fetuses aged between 11 and 14 weeks. Ultrasound imaging is a standard tool for monitoring fetal development and, in this context, is used to detect potential markers of Down syndrome prior to birth. These markers may include increased nuchal translucency thickness, anomalies in the facial profile, or other structural differences observed in the fetus.

2) Postnatal dataset: Sourced from Kaggle and GitHub [https://github.com/vinayaa1/down-syndrome-detection], this dataset contains 2,000 facial images of infants and children. The majority of samples fall within the 0–15 years age range, with limited representation from 16–18 years. This dataset supports the detection of Down syndrome through facial recognition, leveraging characteristic facial features such as almond-shaped eyes, a flat nasal bridge, and other distinct craniofacial traits. These postnatal images are instrumental in identifying Down syndrome after birth.

Each dataset was split into three subsets: training (80%), validation (10%), and testing (10%). This division ensures unbiased model evaluation and promotes better generalization of the results. It is also important to note that the prenatal and postnatal datasets were sourced independently and do not represent the same children across both stages. The neural network or machine learning model is trained using the training set. Its performance and ability to generalize to new data are then evaluated using the test set. This approach ensures a large and diverse training dataset, a separate set for unbiased evaluation, and the ability to assess the model on unseen samples, simulating potential real-world scenarios.

B. Data Preprocessing

Data processing is a crucial step in data-driven tasks like machine learning, statistical analysis, and decision-making. It transforms raw data into structured, clean, and usable formats, improving data quality and standardizing datasets for machine learning models. Preprocessing steps in Fig. 2 and Fig. 3 include image resizing, normalization, rotation, cropping, flipping, and dataset splitting.

Image resizing ensures uniform input dimensions, while normalization standardizes pixel intensity values across all

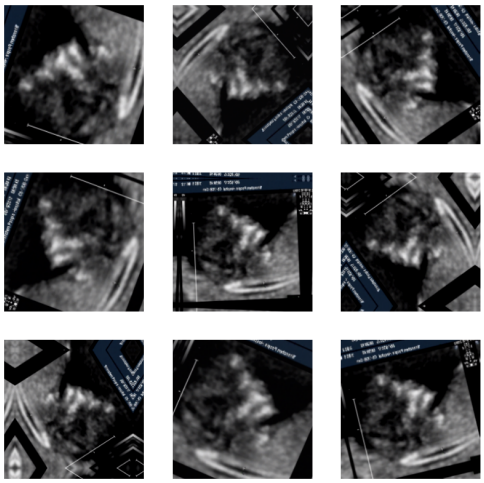

Fig. 2. Data augmentation of prenatal images: Normalized, Rotated, Cropped and Flipped.

Fig. 3. Data augmentation of postnatal images: Normalized, Rotated, Cropped and Flipped.

images. Rotation helps correct misalignments, and cropping reduces background noise, enhancing model efficiency. Flipping augments the dataset by increasing variability, which helps prevent overfitting. Dataset splitting into training, validation, and testing sets enables effective performance evaluation. Collectively, these preprocessing techniques ensure that models learn more effectively from clean and well-prepared input data.

C. Transfer Learning Using Pre-trained CNN Models

This study employs four deep convolutional neural network (DCNN) models—VGG19, ResNet50, DenseNet121, and MobileNetV2—that were pre-trained on the ImageNet dataset and used for feature extraction. Additionally, the Vision Transformer model is utilized to evaluate performance from a transformer-based perspective. These models are applied to both prenatal ultrasound images and postnatal facial images for the detection of Down syndrome in children.

1) VGG19: This 19-layer deep CNN is known for its high accuracy but also for its computational intensity. It uses small 3×3 convolutional filters and ReLU activation. VGG19 is an extended version of VGG16, incorporating three additional layers [24].

2) ResNet50: A 50-layer residual network [25] designed to address the vanishing gradient problem through the use of skip (residual) connections, enabling more effective training of deeper networks.

3) DenseNet121: A densely connected convolutional network with 121 layers, introduced by [26]. In this architecture, each layer receives inputs from all preceding layers, which enhances feature propagation and reduces the number of parameters.

4) MobileNetV2: Designed for mobile and resource-constrained environments, MobileNetV2 uses depthwise separable convolutions to reduce computational cost while maintaining accuracy. It was introduced by [27].

5) Vision Transformer (ViT): Proposed by [28], the Vision Transformer processes images as sequences of patches and utilizes self-attention mechanisms to capture long-range feature dependencies. Unlike CNNs, it leverages transformer-based architectures for image classification.

D. Training and Predicting Models

To obtain the visual Down Syndrome detection results from each model, we extract deep image feature vectors using DenseNet121, VGG19, MobileNetV2, ResNet50, and Vision Transformer. These feature vectors are then passed through the appropriate fully connected dense layers followed by activation layers. The model parameters are optimized using both the Adam optimizer and the stochastic gradient descent (SGD) technique. Training is conducted using the sparse categorical cross-entropy (CE) loss function, shown in (1).

$$CE = -\frac{1}{N}\sum_{i=1}^{N}[y_i \log p(y_i) + (1-y_i)\log(1-p(y_i))] \quad (1)$$

E. Proposed Ensemble Model

In order to enhance accuracy, the ensemble combines the outputs of four CNNs (VGG19, ResNet50, DenseNet121, and MobileNetV2). In Fig. 4, the architecture of the model [29] is described. As illustrated in Fig. 4, each CNN model extracts deep features independently. These features are then concatenated and passed to a classifier for prediction. Soft voting combines the probability outputs, and the final prediction is based on the average likelihood. This method enhances generalization and stability across diverse image modalities. These basic steps include the following:

1) Feature extraction: This involves the removal of the last layers of each model and the extraction of deep feature vectors.

2) Concatenation: Combining these characteristics improves categorization accuracy.

3) Prediction aggregation: Accuracy and resilience are increased by using Yes/No Soft Voting, Hard Voting, Stacking, and Bagging.

4) Optimization: To make the entire training process as efficient as possible, use the Adam Optimizer and the categorical cross-entropy loss function.

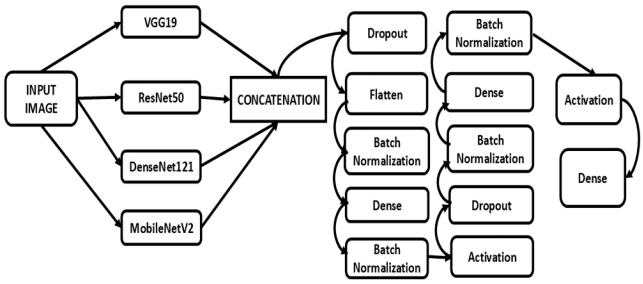

Fig. 4. Architecture of ensemble model.

Model ensembling offers several benefits for improving machine learning performance:

5) Improved generalization: Different models capture diverse features due to their architectural differences. For example, VGG19 is effective for low-level pattern recognition, ResNet50 extracts deep features, DenseNet121 promotes feature reuse and propagation, and MobileNetV2 focuses on efficient feature extraction.

6) Enhanced accuracy: Combining predictions using techniques such as soft voting (averaging probabilities), hard voting (majority voting), or stacking (meta-learning) helps improve overall accuracy.

7) Robustness to data variability: Each model emphasizes different aspects of the data, making the ensemble more robust and better able to generalize across varied datasets.

8) Reduction of overfitting: Using multiple diverse models helps reduce the risk of overfitting by preventing the ensemble from memorizing the training data.

9) Efficient feature learning: The combination of different architectures allows the model to learn features at multiple levels of abstraction, leading to more effective overall feature representation.

In prenatal and postnatal datasets, the ensemble technique ensures robust diagnosis of Down syndrome by enhancing generalization and minimizing overfitting.

F. Performance Measures

The performances are classified into True Positive (TP), True Negative (TN), False Positive (FP), False Negative (FN). Various evaluation metrics are used in this study such as, accuracy, precision, recall, and f1-score.

- Accuracy – Measures the proportion of correct predictions:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} * 100 \quad (2)$$

- Precision – Measures the percentage of correctly predicted positive cases:

$$Precision = \frac{TP}{TP + FP} * 100 \quad (3)$$

- Recall (Sensitivity) – Measures the ability of the model to find all positive cases:

$$Recall = \frac{TP}{TP + FN} * 100 \quad (4)$$

- F1-Score – Harmonic mean of precision and recall, balancing both metrics:

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} * 100 \quad (5)$$

IV. Experiments and Results

In this study, we utilized both prenatal ultrasound images and postnatal facial images of children to detect Down Syndrome. We fine-tuned five pre-trained models—ResNet50, VGG19, DenseNet121, MobileNetV2, and Vision Transformer—using transfer learning. As represented in Table I and Table II, ResNet50 consistently achieved the highest test accuracy across both imaging modalities. Among the CNN models, the highest test accuracy for prenatal images was 91%, while for postnatal images it was 83%. Although the Vision Transformer demonstrated strong performance, it did not surpass ResNet50. To further improve accuracy, we employed model ensembling, which achieved 92% accuracy for prenatal images and 83% for postnatal images.

TABLE I. Accuracy of Different Models (Prenatal Images)

Model	Validation Accuracy	Test Accuracy
ResNet50	90%	91%
VGG19	86%	85%
DenseNet121	84%	88%
MobileNetV2	83%	86%
Vision Transformer	80%	83%
Ensemble	**91%**	**92%**

TABLE II. Accuracy of Different Models (Postnatal Images)

Model	Validation Accuracy	Test Accuracy
ResNet50	80%	**83%**
VGG19	75%	77%
DenseNet121	70%	72%
MobileNetV2	79%	78%
Vision Transformer	72%	73%
Ensemble	**82%**	**83%**

A. Comparison Between the Models for Prenatal and Postnatal Dataset

For the prenatal dataset, we have the classification report for each model, like ResNet50, DenseNet121, MobileNetV2, VGG19, and Vision Transformer model. From all of the classification matrices, we can see that ResNet50 is beating all other models in all contexts, like accuracy, precision and f1-score in Fig. 5.

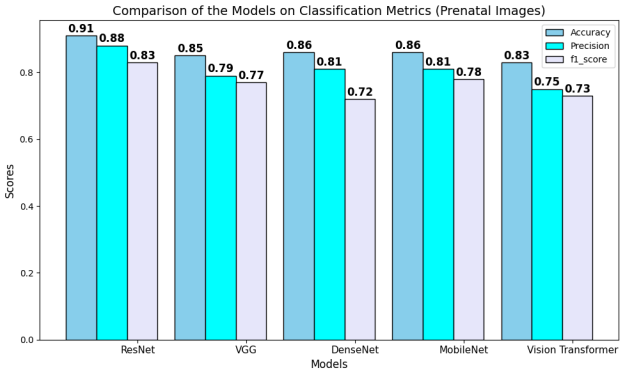

Fig. 5. Comparison chart of the models for prenatal images.

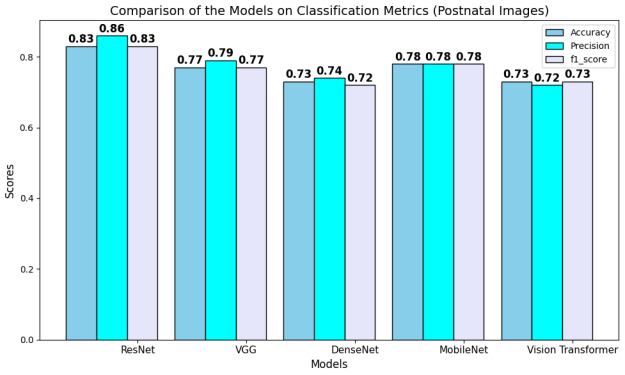

Fig. 6. Comparison chart of the models for postnatal images.

In addition, for the postnatal dataset, we generated classification reports for each model, including ResNet50, DenseNet121, MobileNetV2, VGG19, and the Vision Transformer. Once again, ResNet50 outperforms all other models across all evaluation metrics. Fig. 6 presents a comparative chart of these models based on the prenatal dataset.

B. Performance of the Proposed Ensemble Model for Prenatal Images

1) Accuracy and loss graph: The overall performance based on the training and validation curves is shown in next Fig. 7.

Fig. 7. Performance of the ensemble model (Prenatal images).

It is evident from the graphs that both the training and validation accuracies are close enough, suggesting that the model shows minimal overfitting. Similarly, the loss curve demonstrates a consistent decline for both training and validation sets, with the validation loss remaining low and closely matching the training loss trend. This suggests that the model effectively minimizes error and learns meaningful features from the data with minor overfitting.

2) Confusion matrix: As we know that a confusion matrix helps to evaluate a classification model by presenting true and false predictions for each class. Moreover, this helps to calculate precision, recall and f1-score precisely.

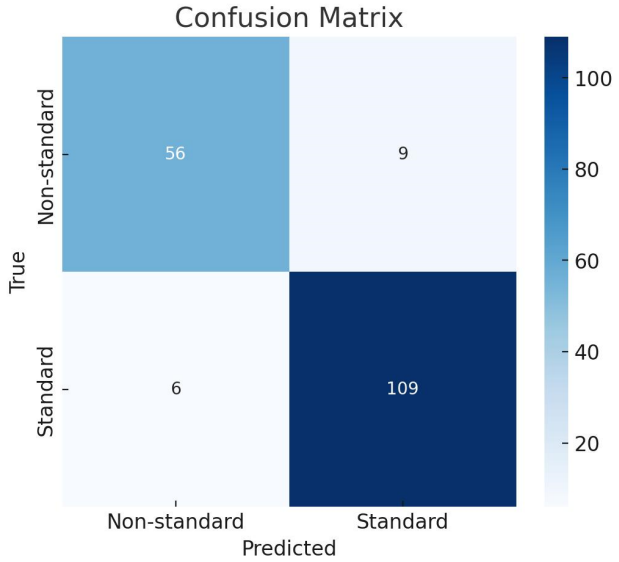

Fig. 8. Confusion matrix of ensemble model (Prenatal images).

Finally, the confusion matrix in Fig. 8 evaluates the performance of the ensemble model for Down Syndrome detection using nuchal translucency (NT) measurements. The model achieves an accuracy of 91.67%, correctly identifying 56 Down Syndrome cases where NT measurements were abnormal. However, it misclassifies nine affected fetuses as normal (false negatives). Additionally, the model correctly identifies 109 normal fetuses with standard NT measurements, while misclassifying six as having Down Syndrome (false positives).

C. Performance of the Proposed Ensemble Model for Postnatal Images

1) Accuracy and loss graph: The line graph in Fig. 9 represents two key plots to evaluate the ensemble model's performance through accuracy and loss curves. The model is shown to perform well with high accuracy in both training and validation with 25 epochs. This also suggests a strong ability to classify with minimal overfitting.

2) Confusion matrix: The effectiveness of an ensemble model for identifying Down syndrome from postnatal images is assessed using this confusion matrix depicted in Fig. 10.

Since there were no false negatives, the model achieved a perfect sensitivity of 100% by properly identifying all 105 newborns with Down syndrome. Nevertheless, it produced a

Fig. 9. Performance of the ensemble model (Postnatal images).

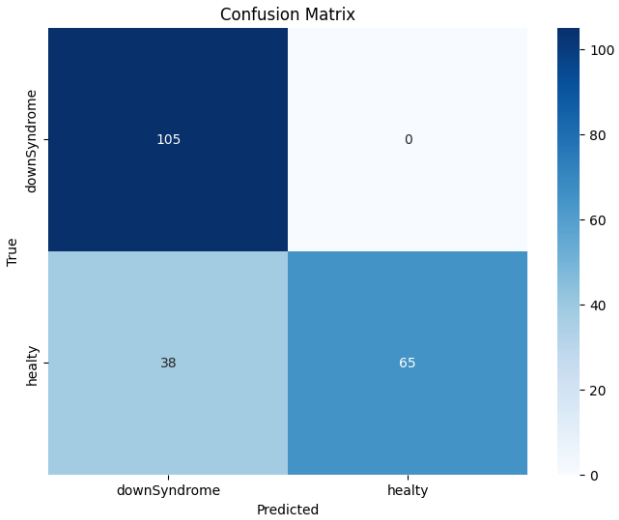

Fig. 10. Confusion matrix of ensemble model (Postnatal images).

false positive rate by incorrectly classifying 28 healthy infants as having Down syndrome. 75 healthy newborns were correctly categorized despite this. Although the model is excellent at identifying cases of Down syndrome without missing any, it may need to be further improved to increase specificity and decrease false alarms because it has a propensity to categorize healthy babies incorrectly.

D. Comparison Between the Ensemble Model for Prenatal and Postnatal Dataset

After doing the ensemble by Feature Fusion Ensemble method with the four models: ResNet50, VGG19, DenseNet121, and MobileNetV2, we have found that the model has increased the performance instantly. The model's accuracy score is almost near to ResNet50 but increased a little bit. Here is a bar graph in Fig. 11, comparing the classification performance between the prenatal and postnatal ensemble models. The prenatal model performs better in all four metrics, indicating its stronger classification capability.

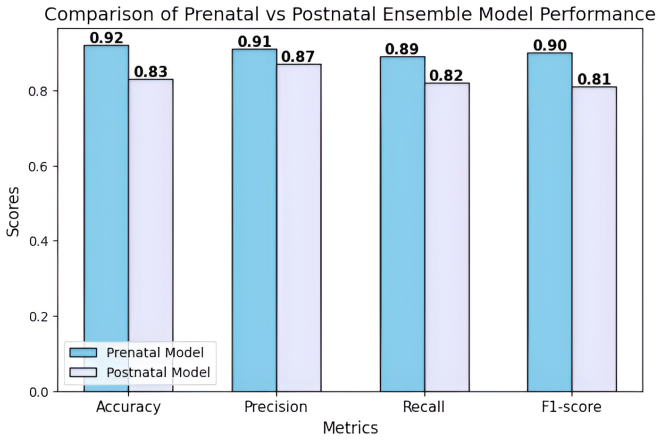

Fig. 11. Comparison chart of the ensemble model (Prenatal vs. Postnatal).

E. Performance Comparison with Existing Research for Down Syndrome Detection

The following Table III represents a comparative analysis of different research studies focused on the detection of Down syndrome using various machine learning models. It includes details on image types, sample sizes, applied models, and their respective accuracies. For example, Reshi, Aijaz Ahmad, et al. [3] used CNN on 1,120 fetus images, achieving an accuracy of 97%. Similarly, Zhao, Qian, et al.[2] applied SVM to facial images (50 DS, 50 healthy) and attained 94% accuracy. The highest reported accuracy (99.3%) was achieved by Feng, Bing, et al. [16], who used a Support Vector Machine (SVM) on SNP maps with a relatively small dataset (315 non-DS, 63 DS cases). This exceptionally high accuracy is likely due to the limited size and controlled nature of the dataset. Unlike some prior studies using smaller or synthetic datasets, our work utilizes publicly available and diverse real-world datasets—namely the Kaggle facial image set and Mendeley ultrasound data—which allows a more robust evaluation. Among those, [3] used the same Mendeley ultrasound dataset, reporting 97% accuracy using CNN, while we achieved 92% through ensemble methods. Moreover, the proposed model in this study processes both ultrasound and facial images, leveraging an ensemble of four CNN models to achieve optimal accuracy—92% for prenatal images and 83% for postnatal images. These results demonstrate that integrating multiple image modalities with deep learning techniques can significantly enhance the accuracy of Down Syndrome (DS) detection.

V. Conclusion

In this study, we explored the effectiveness of different imaging modalities and machine learning techniques for detecting Down Syndrome in children. By analyzing both prenatal (ultrasound) and postnatal (facial) images, our aim was to evaluate the diagnostic potential of each modality individually, as well as their combined efficacy. We investigated the performance of several pre-trained convolutional neural network (CNN) models—ResNet50, VGG19, DenseNet121, and MobileNetV2—on both datasets. In addition, we evaluated the Vision Transformer model for the same task.

TABLE III. COMPARISON OF PREVIOUS STUDIES RELATED TO DOWN SYNDROME

Research	Image Description	Image Samples	Applied Model	Accuracy
[3]	Fetus Image	1120	CNN	97%
[7]	MSS	Non-DownSyndrome: 100,244 DownSyndrome: 108	CVIFLR	95% (AU-CROC)
[2]	Facial Image	DS: 50, Healthy: 50	SVM	94%
[8]	Facial Image	350	DCNN	90%
[17]	Fetus Image	Nasal bone: 50, Without Nasal bone: 50	BPNN	80%
[16]	SNP Maps	Non-DS: 315, DS: 63	SVM	99.3%
[30]	Fetus Image	442	K-means Clustering	87%
Proposed Model	Ultrasound & Facial Images	Ultrasound: 1684, Facial: 2000	CNN & Vision Transformer	Ultrasound: 92%, Facial: 83%

The ensemble of CNN models yielded the highest accuracy, achieving 92% for prenatal ultrasound images and 83% for postnatal facial images, underscoring the advantages of a multimodal approach. Notably, the pre-trained ResNet50 model demonstrated consistently strong performance, achieving a validation accuracy of 89% and test accuracy of 91% on the prenatal dataset, and a validation accuracy of 81.5% and test accuracy of 83% on the postnatal dataset.

Compared to existing studies that primarily focus on either fetal ultrasound or facial imagery using traditional machine learning methods, our approach leverages deep learning to enhance classification performance. Future research should focus on expanding dataset size, incorporating more advanced imaging features, and developing hybrid AI architectures to improve accuracy and generalizability. This includes integrating data from diverse demographics, combining prenatal and postnatal imaging, and utilizing multimodal data fusion. Furthermore, future models could benefit from hybrid AI architectures that combine CNNs, Vision Transformers, and traditional machine learning techniques to enhance feature extraction and ensemble learning.

Sign3DNet: An Enhanced 3D CNN Architecture for Bengali Word-Level Sign Language Recognition

Safi Ullah Chowdhury, Nasima Begum*, Tanjina Helaly, Rashik Rahman
Department of Computer Science and Engineering,
University of Asia Pacific, Dhaka, Bangladesh

***Abstract*—Automated recognition of sign languages has been playing an important role in breaking barriers to communication and inclusion for the deaf and mute community. Several studies have been conducted on Bengali Sign Language (BdSL). However, Bengali Word-Level Sign Language (BdWLSL) remains unexplored due to the lack of large annotated datasets and a stable model. Therefore, in this research, we introduced a large-scale Bengali word-level video dataset and proposed a modified 3D Convolutional Neural Network (CNN) architecture for word-level BdSL recognition, emphasizing its ability to capture the spatial and temporal dynamics from video data. The proposed strategy represents strong performance in Bengali word-level sign language recognition by utilizing the spatio-temporal pattern captured by the modified 3D CNN architecture. The proposed model demonstrates its potential for practical use by successfully learning complex hand movements straight from raw video data. The proposed CNN model is benchmarked against traditional deep learning techniques, Temporal Shift Module (TSM), Long Short-Term Memory (LSTM), and default 3D-CNN, providing a comprehensive comparison of their strengths and limitations. Experiments are conducted using a structured video dataset containing 102 Bengali sign-word classes. To ensure privacy, the volunteers' faces were blurred and only landmark data extracted using MediaPipe, rendered on black backgrounds, were used for training. The experimental result analysis shows that the performance of the proposed 3D-CNN model achieves a satisfactory accuracy of 58.25%, demonstrating its potential for word-level sign language recognition tasks. To our knowledge, this is the very first pilot study for BdWLSL recognition. Hence, we consider the recognition rate 58.25% of the proposed modified 3D-CNN architecture to be satisfactory and a potential scope for future researchers in the same field.**

I. Introduction

In a world where effective communication is at the heart of human connection, the deaf and mute community faces unique and formidable challenges. The limited accessibility of their distinct sign language has led to profound difficulties in expressing thoughts, feelings, and ideas. Bridging this communication gap is fundamental. Automatic interpretation of sign languages is difficult compared to spoken languages since it consists of signed motions, as well as hand gestures and facial expressions. Thus, although word-level sign language recognition is a well-established field for sentence-level recognition, it presents several difficulties specifically in languages different from ASL (American Sign Language) and BSL (British Sign Language). For example, there is limited awareness of sign languages like Bengali Sign Language (BdSL); the lack of a substantial volume of high-quality annotated datasets and strong models to capture both local and global hand movements contributes to this research.

Previous works ASL [1] have emphasized the requirement for large word-level data sets coupled with enhanced deep learning (DL) models to handle the inherent spatio-temporal characteristics in sign recognition. With advancements in computer vision and deep learning, specially 3D Convolutional Neural Network (CNNs), it is now possible to capture both spatial and temporal dynamics in sign laguage data, which helps to recognize complex gestures across video frames. However, 3D CNNs require extensive datasets and multidimensional data representations, such as 3D joint positions, which are not always possible for sign languages, including BdSL. To address this issue, this research proposes a new architecture for word-level sign language recognition. It is trained and tested on a structured dataset with 102 sign classes, prepared using MediaPipe landmarks to focus only on key gesture components.

Additionally, we compared the performance of three distinct models which are: (1) Modified 3D CNN that directly incorporates entire video frames to efficiently capture both spatial and temporal features; (2) an LSTM model that utilizes sequential data to recognize temporal patterns within sign gestures; and (3) TSM, efficient in capturing the temporal dependencies through frame feature shifting for sign word classification. Each model comes with some strengths and weaknesses when used in the analysis of sign language data outcomes of each model are measured based on the accuracy, precision, recall, F1-score and mAP (Mean Average Precision).

The main contributions of this research are as follows:

- We have developed a large-scale, annotated BdSL sign word-level and sentence-level video dataset for deep learning (DL) applications.
- We developed a modified robust 3D-CNN architecture after adjusting hyperparameters called Sign3DNet to increase the generalization property of the system. To our knowledge, the proposed Sign3DNet is the first pilot architecture for recognizing Bengali Sign Words.
- Finally, we evaluated the performance of the proposed Sign3DNet architecture for our developed dataset, and other existing datasets.
- We also demonstrated the standardization of our developed dataset across three model types (proposed

*Corresponding authors.

modified 3D CNN, LSTM, and TSM), providing an extensive evaluation.

The remainder of this paper is structured as follows: Section II represents the literature review. The dataset description is provided in Section III. The proposed methodology is described in Section IV. Section V demonstrates the analysis of the experimental results. Lastly, Section VI concludes the paper with some future works.

II. Literature Review

Sign language recognition has been vital in the reduction of communicative barriers for the Deaf and hard of hearing people, especially with word and sentence recognition. The recognition of sign language can be widely categorized into two types, namely the static and dynamic gesture recognition. Static gestural phrases are used to depict alphabets and digits, while dynamic gestural phrases can depict words or sentences at one go and hence need sequential recognition of gestures. Sign languages like American Sign Language (ASL) [1] have well-documented datasets, such as Purdue RVL-SLLL ASL Database [2], Boston ASLLVD [3], and RWTH-BOSTON-50 [4], which provide valuable data for various recognition tasks. However, the involved datasets fail to sufficiently cover different signers and instances, which becomes a drawback in terms of large-scale classification for achieving higher vocabulary. Large datasets for other languages like DEVISIGN [5] for Chinese Sign Language have been developed to address similar limitations by including thousands of signs performed by multiple signers, contributing to more robust recognition frameworks.

Existing sign language recognition approaches are typically centered around three phases, such as feature extraction, temporal modeling, and classification. Classical approaches used some hand-made features including motion/sensor-based features such as SIFT [6], HOG [7] and/or adopting frequency domain [8] to represent the hand poses and then using HMMs [9] or DTW [10] to model temporal components. In recent years, CNNs and 3D CNNs have been used widely to solve spatial and temporal data at the same time. However, there is still an issue associated with the application of the mentioned methods – the limited size and quality of the databases. Thus, reliable assessment and, particularly, transfer of models to new sign languages continues to be problematic, particularly for low-resource sign languages without large annotated datasets.

For Bengali Sign Language (BdSL) research is still in its infancy and mainly involves only static gesture recognition. First data sets are given with limited alphabets and digits of Bangla such as Ishara-Lipi [11] and Ishara-Bochon [12]. Following investigations used deep learning-based image recognition approaches like YOLO, CNN, and AlexNet [13], [14] on static BdSL data to categorize isolated words. Relatively little has been done in the way of developing dynamic word-level BdSL (WL-BdSL) datasets and recognition. Previous studies of dynamic BdSL are limited to a small set of static signs and do not reflect continuous word-level recognition issues. In ASL, the current state of static BdSL recognition with large vocabularies has recently used MediaPipe keypoint extraction, but dynamic video recognition for wider vocabularies has not been studied thoroughly.

In the case of Bengali Sign Language (BdSL), studies are still very limited, and early studies' main concern is on recognition of static gestures only. There are few datasets for letter-level and static word recognition in Bangla such as BornoNet [15], BDSL49 [16], Ishara-Lipi [11], and BenSignNet [17]. More specifically, it is recognized that Ishara-Lipi is a benchmark dataset for sign language that is described by the use of modern methods involving two-handed signs. This means that while BornoNet is particularly focused on the letter-level classification the dataset BDSL49 offers a large amount of Bangla characters. BenSignNet proposed a new CNN model that is trained on three different sets of BdSL, such as BdSL, Ishara-Lipi, and KU-BDSL [18] with differing performances.

However, efforts toward dynamic, word-level BdSL (WL-BdSL) recognition remain limited. Most of the work done in this area pertains to very small, arty static sign sets that do not suffice for the sort of word-level continuous reading tasks with larger, open vocabularies. However, despite recent attempts to adapt MediaPipe for static BdSL keypoint extraction, there is a lack of study regarding its application for dynamic video recognition. This gap points to an urgent need to work on the advances in the comprehensive ample of datasets and the state of the art of the recognition models addressing the issues of temporal and spatial dynamics in the continuous BdSL. To overcome these imperatives, we have developed a novel Bengali Sign Language dataset for dynamic word-level recognition, consisting of 102 emergent Bengali Sign words and including more than 30600 samples captured from various viewing angles.

III. Dataset Description

Bengali language has about one million words, and mute and deaf people use those sign words for their daily communication. Therefore, a video dataset is essential for Bengali Word Level Sign Language (BdWLSL) recognition. However, to our knowledge, there are no such video datasets for Bengali Sign Word except [19]. Thus, in this research, we developed a structured BdWLSL video dataset for our recognition task. The data set is used to support advanced deep learning applications for continuous sign language recognition. This dataset also solves the problem of limited large-scale BdWLSL dataset by providing a wide variety of video material to capture the details of BdWLSL gestures with 102-word classes. Each label in Table I represents a Bengali word. The data set includes various video samples that capture variability in signers, lighting, background, and angles as shown in Fig. 1. All videos used in training were collected with proper consent. For privacy, we applied automated face blurring to each frame. We then extracted hand and facial landmarks using MediaPipe. These landmarks were projected over a black background, and only these versions were used for model training. This ensured that the model learned from gestures, not identity or background noise.

Our developed dataset has different variations. For example, videos are captured by different signers at different angles and various lighting conditions. After recording all the videos, we used MediaPipe to generate landmarks for the hand and face regions. At the same time, we removed the raw versions of the videos and used a black background with the landmarks to construct the data. Fig. 2 shows the approaches which

is used to understand the condition of the dataset in various scenarios. To maintain volunteer privacy, all facial features were blurred during preprocessing using automated detection methods. For training, only the background-removed landmark videos were used. The dataset includes signers from diverse backgrounds to improve inclusivity and generalization performance. Table II summarizes the attributes of our developed dataset, providing a detailed breakdown of its structure and contents. In total, the dataset expands to 91,800 samples.

As illustrated in Fig. 3, each frame used for training was processed by first applying face blurring for privacy, followed by landmark extraction using MediaPipe. The final training samples consisted of black-background videos containing only the key landmark features of the sign gestures. Each word-level sign sample is labeled with the appropriate Bengali words. In each class, there are approximately 300 videos and they are divided into three parts: the first part is for training, the second one is for validation and the last part is for testing. The train, validation, and testing datasets contain 75%, 15%, and 15% of the total dataset, respectively. Table III shows the data distribution between the train , validataion and test set of the BdWLSL dataset. As shown in the Table III , there are around 210 video samples in the train set and 30 samples in the validation and test set of each class. All video frames were resized to 64x64 using OpenCV's bilinear interpolation method. This dimension was chosen based on a balance between visual fidelity of hand gestures and computational

IV. METHODOLOGY

This section describes the proposed methodology for word-level video sign language recognition. In this work, we introduce a novel CNN model specifically designed for word-level video sign language recognition, which is described in detail in Section IV(A). Fig. 4 shows the workflow of the proposed methodology.

To establish a baseline, we trained a few deep learning models on our developed dataset, including Standard 3D CNN, TSM, and LSTM. Among them, the LSTM model performed very well, achieving a moderate accuracy. However, the LSTM model is primarily suited for temporal data, whereas video data inherently possesses both spatio-temporal features. The TSM model is concentrated on the temporal dependencies through the shifting between feature maps in frames, losing its spatial information in video frames. On the other hand, the standard 3D CNN is designed to handle both spatio-temporal patterns directly. Therefore, to maximize performance for this application, we concentrated on modifying the 3D CNN architecture.

A. Proposed Modified 3D CNN Architecture

The proposed 3D CNN model is optimized for spatio-temporal feature extraction while balancing computational efficiency. The architecture employs the Depthwise Convolution and BatchNormalization techniques, along with the ReLU activation function, at multiple locations, as illustrated in Fig. 5. The model is fed with input videos, each one with 20 frames at 64×64 px grayscale. Convolution is done through the three Conv3D layers initially, extracting spatial and temporal patterns over spatial dimensions (x, y) and temporal (t) using the 3D kernels. Mathematically, the 3D convolution operation at the position (x, y, t) is defined as follows:

$$F(x,y,t) = \sum_{i=0}^{K-1}\sum_{j=0}^{K-1}\sum_{k=0}^{K-1} W(i,j,k)\cdot I(x+i,y+j,t+k) \quad (1)$$

Where $W(i, j, k)$ represents the 3D convolution kernel weights, $I(x + i, y + j, t + k)$ denotes the input video frame at spatial position (x, y) where t, is time and K is the kernel size. To stabilize training and accelerate convergence, batch normalization is applied after each convolutional layer, normalizing activations by Eq. (2)-(3) as follows:

$$\hat{x} = \frac{x - \mu}{\sigma} \quad (2)$$

$$y = \gamma\hat{x} + \beta \quad (3)$$

Here, the learnable parameters γ, β, μ and σ represent the mean and standard deviation of the batch. The MaxPooling3D layers are used to downsample the overall dimension of the model for efficient computation. MaxPooling3D was selected for its capability to retain the most prominent features while reducing computational load. Compared to Average pooling and L2 pooling, MaxPooling showed higher validation accuracy in early experiments on this dataset. The last one is a Global Average Pooling (GAP) layer to reduce input spatial dimensions by averaging feature maps to generate a fixed-length feature vector. The feature relationships within this vector are then captured by fully connected layers with ReLU activation. Finally, classification is performed using a

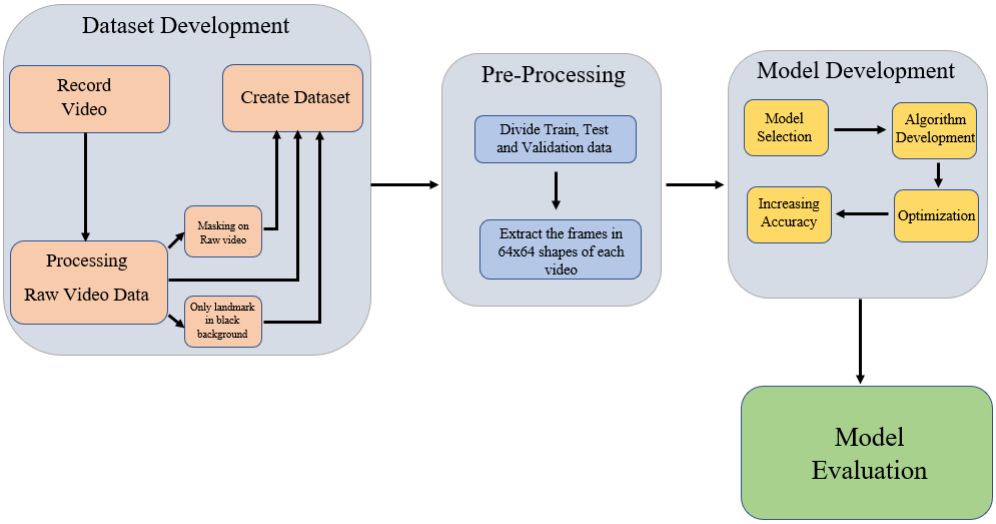

Fig. 4. Overall flow-diagram of proposed methodology.

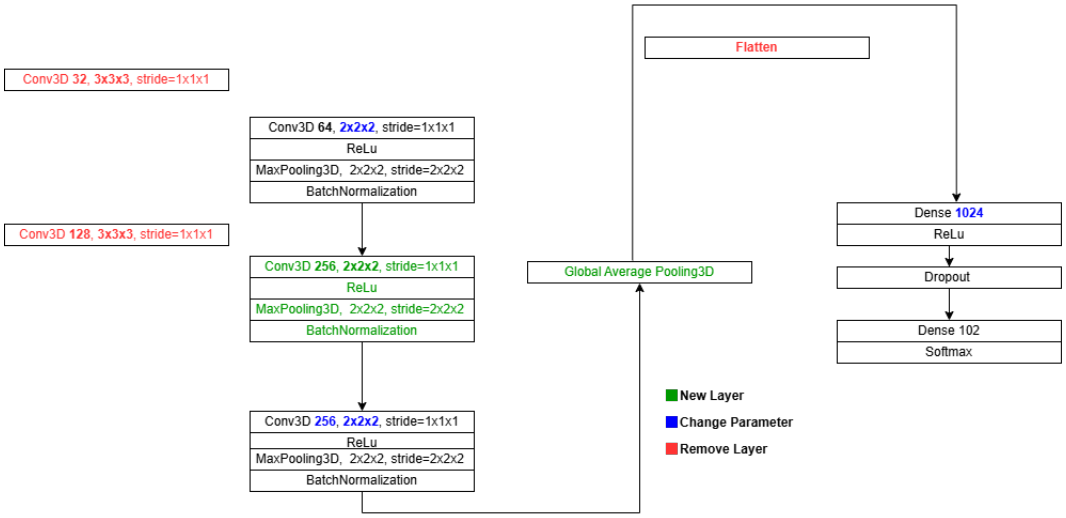

Fig. 5. Architectural modification of 3D CNN.

dense layer with a softmax activation function, converting the network output into class probabilities:

$$P(y_i) = \frac{e^{z_i}}{\sum_{j=1}^{N} e^{z_j}} \tag{4}$$

where $P(y_i)$ is the probability of class i, z_i is the output score for class i, and N represents the number of classes. Softmax activation function was used in the final layer to output a probability distribution over the 102 sign classes. This allows for intuitive interpretation of prediction confidence and is suitable for multi-class classification tasks. This allows for intuitive interpretation of prediction confidence and is suitable for multi-class classification tasks.

The network is trained using the categorical cross-entropy loss function:

$$L = -\sum_{i=1}^{N} y_i \log(\hat{y}_i) \tag{5}$$

Specifically, if y_i denotes the ground truth label (and 1 if the class is the correct class, and 0 otherwise) and $\hat{y}_i$ is the predicted probability. Model parameters are updated using the Adam optimizer with adaptive learning rates for improved convergence. The layers and their parameters are described in Table IV.

A 13-layer modified 3D CNN architecture is proposed where the computational cost is optimized for Bengali Word-level Sign Language (BdWSL) recognition using computational efficiency and strong recognition capabilities together. The proposed model greatly improves the classification performance by integrating Conv3D, batch normalization, pooling,

and GAP, which allows the model to capture and process spatio-temporal features. An overview of the proposed 3D CNN architecture is illustrated in Fig. 6.

B. Experimental Setup

The 3D CNN model is deployed with modifications to effectively capture the temporal and spatial dynamics and details of the sign gestures. The model is optimized using the Adam optimizer. In 3D CNN, a sequential Conv3D architecture is used during the study, and involves down-sampling layers, batch normalization, and global pooling for feature extraction for 3D CNN. The model is trained using the Adam optimizer with a learning rate of 0.002. The loss function categorical cross-entropy is used, which is suitable for multiclass classification tasks.

For consistency across the model, the video frames are normalized with an equivalent diagonal bounding box of 64 pixels in standardized subsets of frames that focus on the signer's areas of interest, where applicable. All frames for a video are prepared by applying spatial-temporal augmentation. The complete setup of the experimental environment is summarized in Table V.

TABLE. V. EXPERIMENTAL ENVIRONMENT SETUP

Component	Specification
Operating System	Windows 11
GPU	NVIDIA RTX 4090 (24GB VRAM)
CPU	Intel Core i9-12900K
RAM	32GB DDR4

    return Predicted class C
$C \leftarrow$ Classify(F)
Return Predicted Class C

V. Result and Discussion

In this section, the experimental results and model evaluations are quantitatively analyzed. We have compared the proposed modified 3D CNN model with various other models previously used for sign language recognition.

A. Evaluation Metrics

We evaluated the performance of the models from the point of view of their ability to recognize signs concerning situational change in the sign language at the word level, where adjusting the position or the size of a hand may results in misclassification of a sign. Evaluation metrics are determined using the following Eq. (6)-(11):

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{6}$$

$$Sensitivity(Recall) = \frac{TP}{TP + FN} \tag{7}$$

$$Specificity = \frac{TN}{TN + FP} \tag{8}$$

$$Precision = \frac{TP}{TP + FP} \tag{9}$$

$$F1\text{-}Score = \frac{2 * Precision * Recall}{Precision + Recall} = \frac{2 * TP}{2 * TP + FP + FN} \tag{10}$$

$$\text{mAP} = \frac{1}{N} \sum_{i=1}^{N} AP_i \tag{11}$$

LSTM	54.83%	55.53%	54.83%	54.82%	60.12%	43.57%	16
3D CNN (Default)	52.83%	53.72%	52.83%	52.83%	58.37%	45.17%	16
TSM	51.75%	52.60%	51.75%	51.74%	57.92%	44.38%	16
Modified 3D CNN (Proposed)	**58.25%**	**59.17%**	**58.25%**	**58.25%**	**62.50%**	**41.32%**	16

TABLE. VII. Performance Comparison of Proposed 3D CNN Model with Different Datasets

Dataset	No. of Classes	Accuracy	Precision	Recall	F1 Score	Specificity	mAP	Batch Size
BdSLW60 [19]	60	44.62	45.50	44.62	44.62	50.00	55.38	16
Our Dataset	**102**	**58.25**	**59.17**	**58.25**	**58.25**	**62.50**	**41.32**	**16**

is analyzed to better understand the nature of errors and the performance across different classes.

B. Performance Evaluation of Proposed 3D CNN Model

The performance of different baseline models on the video dataset is shown in Table VI. We compared the performance of the proposed modified 3D CNN along with the default 3D CNN, LSTM, and TSM architectures. The results demonstrate varying capabilities of the models in handling the spatio-temporal complexities of sign language recognition.

Among them, the Modified 3D CNN achieved the highest performance with an accuracy of 58.25%, precision of 59.17%, recall of 58.25%, specificity of 62.50%, and an F1-score of 58.25%, demonstrating its capability to differentiate between sign classes effectively. However, its mAP (41.32%) indicates scope for improvement in class-wise performance. Fig. 8a and Fig. 8b shows the training and validation accuracy curve and loss curve, respectively. The optimization is effective, as the training curve stabilizes after a few epochs. A low gap between the training and validation curve indicates reduced overfitting (better generalization capability) of our model. The LSTM model, designed for capturing temporal dependencies, attained an accuracy of 54.83% and F1-score of 54.82%, performing well in modeling sequential data, being limited by processing feature vectors instead of raw frames. Its specificity (60.12%) is slightly lower than the proposed modified 3D CNN, but it has a higher mAP (43.57%), showing a more balanced class-wise performance. The TSM model, despite being structured for temporal feature shifting, performed the lowest, with 51.75% accuracy, 51.74% F1-score, specificity of 57.92%, and mAP of 44.38%, suggesting its limitations in extracting effective spatial features. The default 3D CNN, while leveraging spatio-temporal learning, achieved an accuracy of

52.83% and F1-score of 52.83%, falling behind the modified version due to the lack of optimizations.

With the complexity of multi-class classification across 102 distinct sign classes, high inter-signer variability, and the presence of subtle gesture overlaps between similar signs, the proposed model's accuracy of 58.25% may seem low; however, it accurately captures the complexity of the dataset. The proposed 3D CNN method outperforms the existing baselines, such as LSTM, TSM, and default 3D CNN, thus the 58.25% accuracy marks a significant relative improvement. As the first pilot initiative for Bengali Word-Level Sign Language (BdWLSL) recognition, this result establishes an impactful baseline for future research and development in the field.

Fig. 9 represents the ROC and the AUC graph. Here, the ROC threshold value is plotted for each class, and then the AUC curve for each class is determined. For all the classes, AUC lies between 0.42 and 0.62, making it a very generalized model that can perform well for large-scale sign language recognition. We used the BdSLW60 [19] dataset to verify our proposed model's performance in order to further assess its efficiency. The comparison is displayed in Table VII. An optimized deep learning architecture combined with a well-structured dataset produces noticeably superior performance, as shown in Table VII. This highlights how crucial it is to have a solid, stable model and a well-organized dataset to prevent low performance.

C. Limitations and Challenges

Fig. 7 shows the confusion matrix, where it is clearly visible that the model struggled with differentiating signs across the full 102-class. However, the results also highlight the challenges of scaling the model to handle a larger number of classes effectively. Future research should focus on optimizing the model architecture to enhance scalability while preserving a high recognition rate.

VI. Conclusion and Future Work

To enhance the communication of the disabled community, a method for the recognition of Bengali word-level sign language (BdWLSL) is proposed. This paper represents a benchmark study on a proposed modified 3D CNN model using a newly developed large-scale video dataset of 102 BdSL words. The use of black-background landmark data enabled the model to focus effectively on gesture regions. The proposed method is the pilot research for BdWLSL recognition. The experimental result shows that the proposed 3D CNN model achieved the highest recognition rate of 58.25%, indicating better results than LSTM (54.83%) and TSM (51.75%). Among the compared models, the LSTM model shows effectiveness in capturing the temporal dependencies of the sign words. However, the lack of spatial feature extraction limited its overall performance. Though the TSM model is designed for efficient temporal feature shifting, its inability to fully model spatio-temporal relationships affected its effectiveness in word-level sign language recognition. These findings highlighted the distinct strengths and weaknesses of each approach. The experimental analysis demonstrates that it is crucial to utilize advanced architectures like 3D CNN for Bengali Word-level Sign Language recognition as it can catch both the spatio-temporal features at the same time. The 58.25% accuracy of the proposed model is admissible considering the complexity of multi-class recognition with 102 categories, signer variability, and subtle gesture overlaps. This performance sets a valuable benchmark for Bengali word-level sign recognition tasks. Future work can focus on enabling models to generalize across real-world scenarios. We aim to integrate our model into mobile platforms and educational applications to support the deaf and mute community. Real-time sign recognition tools could serve as effective communication aids. Future enhancements include expanding the dataset, incorporating transformer-based or hybrid architectures for improved temporal reasoning, and leveraging multimodal approaches such as combining video with skeletal data or attention mechanisms. These strategies could address challenges related to large class sizes and further improve scalability and recognition performance.

VII. Acknowledgment

We give special thanks to the University of Asia Pacific for supporting this research and thanks to the Institute of Energy, Environment, Research and Development (IEERD), University of Asia Pacific, for funding this research project.

Integrating Blockchain and Smart Card Technologies for Secure Healthcare Data Management

Zayneb Gaouzi, Imad Bourian, Khalid Chougdali
Engineering Sciences Laboratory-National School of Applied Sciences, Ibn Tofail University, Kénitra, Morocco

***Abstract*—In recent years, the healthcare sector has faced growing challenges in managing patient data securely and efficiently, especially when it comes to data privacy and the way information is shared across healthcare providers. A number of digital solutions have been proposed over time, but more recently, blockchain has started to gain serious interest. Its structure allows data to remain intact and traceable, while also offering a strong layer of security. This paper explores how blockchain based smart contract might be used alongside smart cards to offer a more robust system for protecting patient information. Smart cards bring in a physical barrier that helps limit access to only those who are authorized, while blockchain makes it much harder to tamper with information or centralize control. The suggested method demonstrates how the decentralized and immutable nature of blockchain, combined with the physical authentication provided by smart cards and the automation of smart contracts improve data security and restrict unauthorized access. The proposed framework is evaluated through smart contract deployment and testing on both the Hardhat local network and the Celo public testnet. The results confirm the practicality and efficiency of the solution and support its potential for real world application in secure healthcare data management.**

***Keywords*—Healthcare; security; blockchain; smart contracts**

I. Introduction

Healthcare systems are transforming at a breakneck pace with the widespread use of advanced digital technologies. From AI and cloud solutions to IoT devices, these new technologies are transforming the way care is delivered as well as patient data managed [1]. While they make the care more personalized and effective, they also raise very significant cybersecurity challenges, particularly concerning the protection of patient data and healthcare operations [2]. With increasing digital infrastructures and connectivity, so too does the risk of unauthorized access, cyberattacks, and data breaches that undermine the privacy and integrity of health records [3] [4].

The key problem is the lack of a tamper-proof and privacy-preserving infrastructure that can enable safe access and data exchange of healthcare systems across various entities. Most of existing solutions tend to depend on centralized authorities, which introduces single points of failure and often fails to guarantee transparency and data integrity. Moreover, smart cards have today become a widely adopted hardware device utilized to help in the mitigation of some of the foregoing issues, with a simple means of storing and managing sensitive medical information in a secure portable format [5][6]. They are used for identity or access validation purposes, allowing only access to covered data by certified individuals [7]. Smart card systems offer several advantages, but they are not without limitations. Issues like poor compatibility between different systems and occasional security breaches still persist, and in many cases, these issues have become more noticeable as healthcare technology gets more complex [8] [9] [10]. One of the more promising ways to strengthen healthcare data management systems is with the introduction of blockchain technology. Its decentralized, tamper-proof character renders blockchain a very trusted guarantor of system performance, data integrity, and privacy across diverse industries [11] [12]. Blockchain allows sensitive information to be shared in a more controlled and transparent manner, while reducing reliance on centralized databases that are more susceptible to be cyberattacked [13]. Particularly, blockchain based smart contract frameworks offer the potential for automated access controls and dynamic identity management within the scenario of no third-party intermediaries [14]. These automated controls can impose sophisticated data-sharing policies and provide inherent auditability, two critical characteristics for distributed health trust and compliance. This paper proposes a secure healthcare data management system based on the integration of smart cards and blockchain technologies. It explores how blockchain can make smart card–based systems more resilient, transparent, and privacy-preserving. Rather than focusing on a particular implementation, the study contrasts different design options, technical considerations, and performance implications to evaluate how this combined approach can offer a safer and better system for managing patient data in today's health industry.

The main contributions of this work are as follows:

- To propose a novel healthcare data management framework that integrates blockchain and smart card to ensure secure and decentralized access to patient records.
- To design and implement a set of smart contracts that automate rule based access control and data management processes among healthcare stakeholders.
- To evaluate the system through deployment on both a local Hardhat network and the Celo public testnet.
- To compare our model with existing blockchain-based healthcare solutions and demonstrate its advantages in terms of completeness and security.

The remaining sections of this paper follow this structure: Section II provides a concise background information of related works. Our proposed approach is presented in Section III. Section IV sheds light on simulation setup and results discussion. Lastly, Section V concludes the study and outlines directions for future work.

II. Related Work

This section presents a review of recent and significant contributions in the literature concerning the application of blockchain technology to enhance the security of healthcare systems. In [15], the authors propose a scalable blockchain architecture that incorporates Zero Knowledge Proof (ZKP) mechanisms to ensure data integrity, coupled with the InterPlanetary File System (IPFS) for efficient off-chain storage. The authenticated data is subsequently utilized within a deep learning framework for intrusion detection in healthcare networks. In [16], the authors develop a secure blockchain-based application that functions as a communication interface between IoT devices, the blockchain infrastructure and stakeholders such as hospitals, patients, healthcare professionals. The solution enforces essential security properties such as confidentiality, authentication, and access control through the use of smart contracts. In [17], the authors present FL-BETS, a framework that combines federated learning with blockchain to support task scheduling in healthcare contexts. The system is designed to work under both strict and flexible constraints, using dynamic heuristics to adapt to the needs of each scenario. Its primary goals include safeguarding patient privacy, reducing the risk of fraud, and improving system performance—particularly in terms of energy consumption and response time. The authors of [18] propose MedShare, a decentralized framework for the secure sharing of Electronic Health Records (EHRs) through blockchain-based smart contracts. To support fine-grained access control, a constant-size Attribute-Based Encryption (ABE) scheme is integrated, embedding access policies directly into blockchain-stored search results. Additionally, a multi-keyword boolean search mechanism is implemented to improve usability for authorized users. In [19], the focus shifts to protecting IoT-based healthcare systems from cyber threats. The authors design a security architecture for healthcare multimedia data, utilizing cryptographic hashes to ensure data integrity. Unauthorized alterations are detectable and traceable across the blockchain network, thus enhancing both system performance and cost efficiency in patient care. The author in [20] presents a novel approach to privacy preservation for EHRs by combining blockchain technology with deep learning. A convolutional neural network (CNN) is used to detect and block abnormal user activity, integrated within a federated learning module operating atop the blockchain to ensure distributed, secure access control. Lastly, [21] proposes a lightweight, fog enabled blockchain architecture for remote patient monitoring. The system exhibits high security and responsiveness, with simulation results indicating that fog computing integration improves system responsiveness by up to 40%, while simultaneously strengthening defenses against potential security breaches.

As previously mentioned, a great deal of effort has been explored in integrating blockchain technology to enhance security in healthcare systems. However, critical gap remains unaddressed and security challenges need to be explored. Most prior works fail to incorporate a physical security layer, such as smart cards, to mitigate unauthorized access at the user level. Similarly, many smart card based systems lack a robust backend capable of ensuring data traceability and integrity. As a result, there is a disconnect between physical level access control and backend data management in many proposed models. To bridge this gap, it is essential to design a combined architecture where blockchain ensures data security, integrity, and transparency, while smart cards act as a front end authentication tool. Unlike previous work, our framework emphasizes a dual approach that contributes to the development of a more secure and efficient healthcare information system that is resilient to both external cyber threats and internal misuse.

III. Proposed Approach

A. Architecture System

In this section, we present the proposed architecture of our solution that focuses mainly on enhancing security in smart card-based healthcare management systems by integrating blockchain technology. In fact, our contribution consists of creating a model as depicted in Fig. 1 that uses blockchain technology to securely manage patient health records while ensuring seamless interaction among key stakeholders, including the patient's smart card, hospital entities, pharmacies and insurance providers. The system is organized around four main layers, each focusing on a different aspect of how healthcare data is handled. Together, they support secure access, reliable data exchange, and stakeholder coordination—without depending on a central authority.

1) Stakeholders layer: This layer includes all participants involved in accessing or updating patient health records. To identify themselves, patients use a smart card that acts as their personal key to the system. Access for others, such as healthcare providers or insurers, is based on defined roles. The stakeholders include:

a) Hospitals: interact with the system to consult and update medical information, and to exchange data with doctors, labs, or administrative staff when needed.

b) Pharmacies: confirm prescriptions through the platform and dispense medications accordingly. The goal here is to reduce risk from manual errors or unauthorized changes.

c) Insurance providers: access patient histories to assess claims. Since the data is immutably stored, the process becomes more trustworthy and less prone to manipulation.

2) Interface layer: Users interact with the system through a dedicated app. Behind the scenes, the interface applies access rules based on each user's role. For the user, the process feels straightforward; they don't see the underlying blockchain operations. This layer is designed to simplify access while maintaining security.

3) Smart contracts layer: Here, the rules of the system are enforced automatically. Any time a user tries to update a file, verify a prescription, or submit a claim, a smart contract checks the conditions. If they match, the action is approved. This helps prevent mistakes and keeps a record of what happened.

4) Blockchain ledger layer: At the core is the blockchain itself. It keeps a permanent log of every interaction with the system—whether it's viewing, editing, or transferring information. Because this ledger can't be altered after the fact, it offers a reliable audit trail. And since no single server controls it all, the system is more resilient by design.

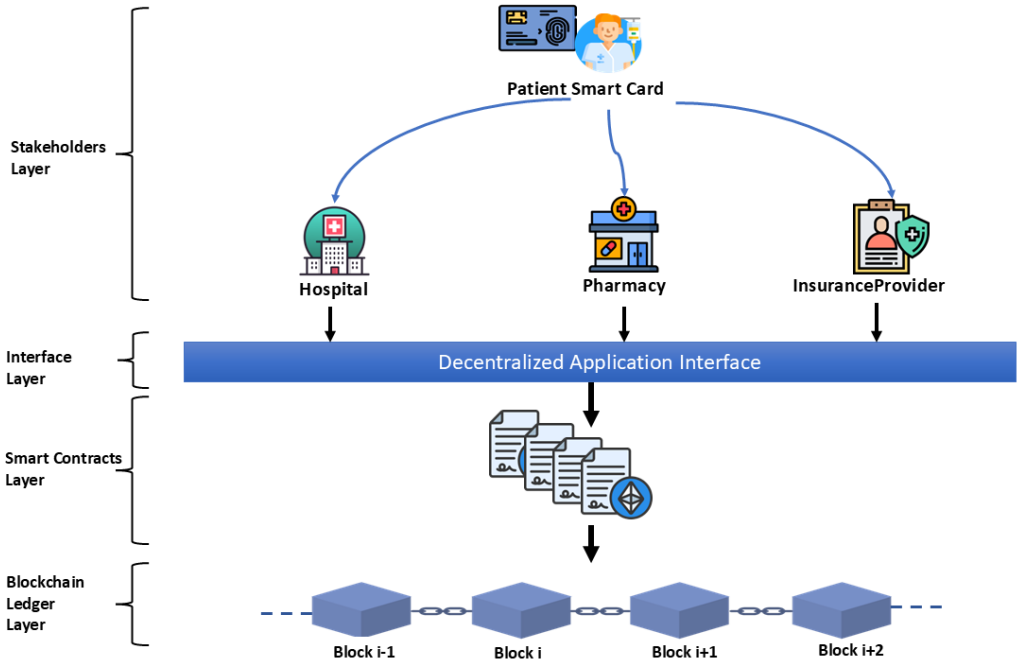

Fig. 1. Overview of the proposed architecture.

B. Worflow Diagram

To process the logic and statements that defines conditions and interactions between all stakeholders applied in our system, we propose the workflow diagram presented in Fig. 2.

1) Patient check-in and identity verification: When a patient arrives at the hospital, they authenticate themselves using their smart card. The hospital system, through the Decentralized Application Interface (DApp), verifies the patient's identity on the blockchain. Once authenticated, the hospital gains role-based access to the patient's medical history.

2) Consultation with a doctor: The doctor accesses the patient's medical records stored on the blockchain to review past diagnoses, treatments, allergies, and medications. The patient and doctor discuss symptoms, and the doctor records a new diagnosis along with the recommended treatment plan. The diagnosis and treatment plan are securely written to the blockchain and linked to the patient's record.

3) Prescription and pharmacy interaction: If medication is required, the doctor issues a blockchain-based prescription. The patient presents their smart card at an authorized pharmacy, which verifies the prescription on-chain. Upon dispensing the medication, the pharmacy updates the blockchain, marking the prescription as "fulfilled" to prevent misuse.

4) Insurance claim processing: If the patient has medical insurance, the hospital submits a blockchain-verified claim to the Insurance Provider. The insurance provider accesses the patient's treatment record and approves or denies the claim based on coverage rules. Once approved, the hospital receives direct payment from the insurance provider via a smart contract transaction.

To implement the logic of this proposed architecture, we suggest to create and deploy the following four smart contracts: PatientSmartCard, HospitalRecord, PharmacyAccess and InsuranceProvider. Table I presents an overview of the objective of each contract.

TABLE I. SMART CONTRACTS AND THEIR OBJECTIVES

Smart Contracts	Objective
`PatientSmartCard.sol`	Manages patient identity, authentication, and authorization using a smart card.
`HospitalRecord.sol`	Allows hospitals to update, store, and retrieve patient medical records securely.
`PharmacyAccess.sol`	Allows pharmacies to verify prescriptions and dispense medications securely.
`InsuranceProvider.sol`	Manages insurance claims, approvals, and payment processing for medical services.

IV. SIMULATION AND RESULTS DISCUSSION

In this section, we present the simulation scenarios for our proposed model. To do so, we use different technologies listed in Table II.

The analysis of deployed smart contracts on the Hardhat local network, as depicted in Fig. 3 and 4, reveals varying costs in ETH, reflecting differences in contract complexity, functionalities and storage requirements. The InsuranceProvider contract has the highest deployment cost, likely due to extensive data management and computational logic, followed by HospitalRecord, which also involves significant processing. The PatientSmartCard contract incurs a moderate cost, managing identity interactions, while PharmacyAccess has the lowest cost, suggesting a simpler structure.

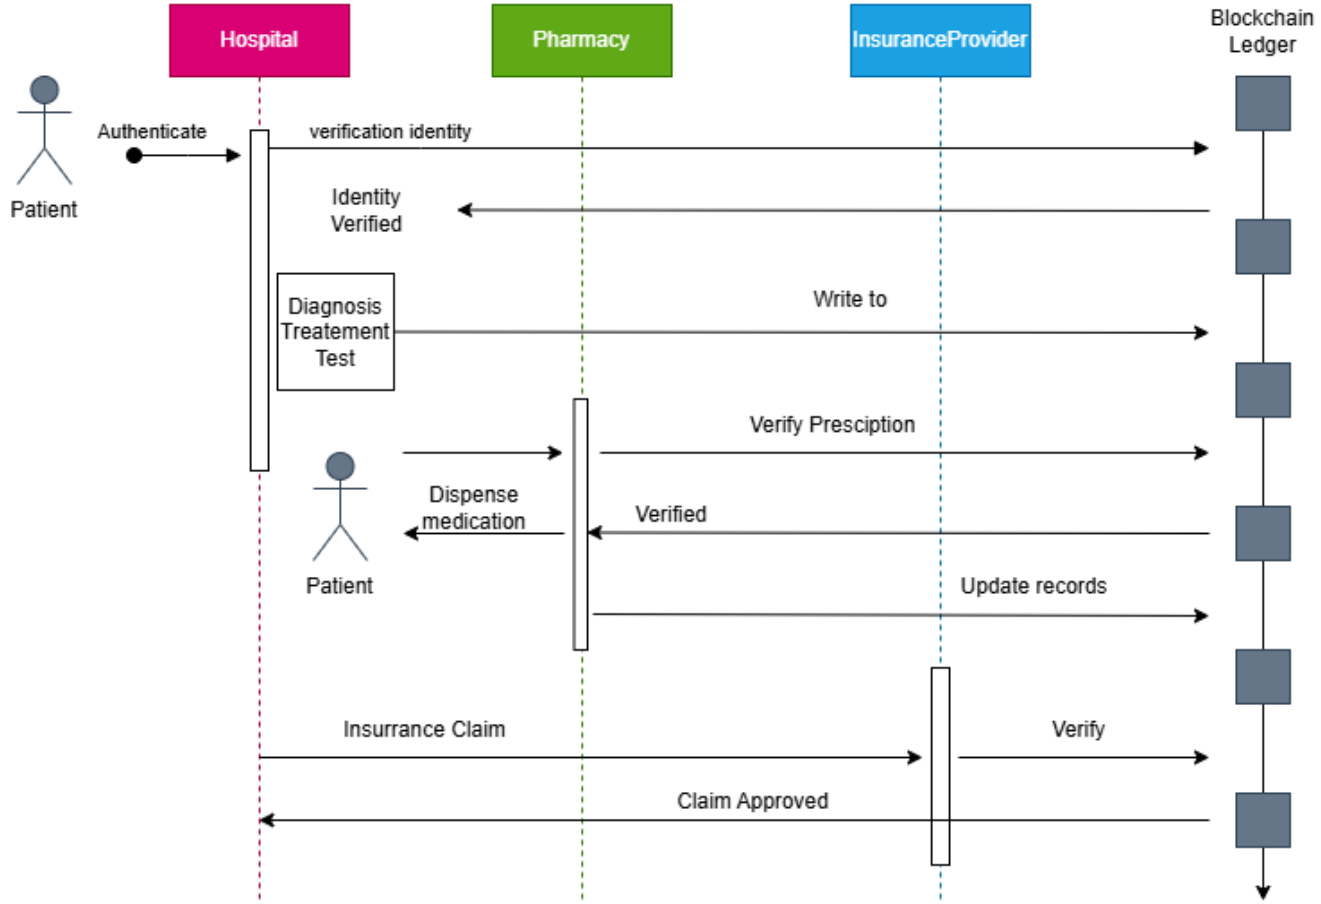

Fig. 2. System workflow diagram.

TABLE II. OVERVIEW OF TECHNOLOGIES USED

Technology	Description
Hardhat	is an Ethereum development environment for professionals. It facilitates performing frequent tasks, such as running tests, automatically checking code for mistakes, or interacting with a smart contract.
Solidity	is a programming language for implementing smart contracts on various blockchain platforms, most notably Ethereum.
Ethers.js	is a JavaScript library and toolkit that provides a convenient and reliable interface with the Ethereum Blockchain for developers.
JSON RPC	serves as a protocol for communication between a client and a server. It is widely used in various applications, including web development, notably in blockchain networks.
Environment	Computer CPU: i7; RAM: 8GB.

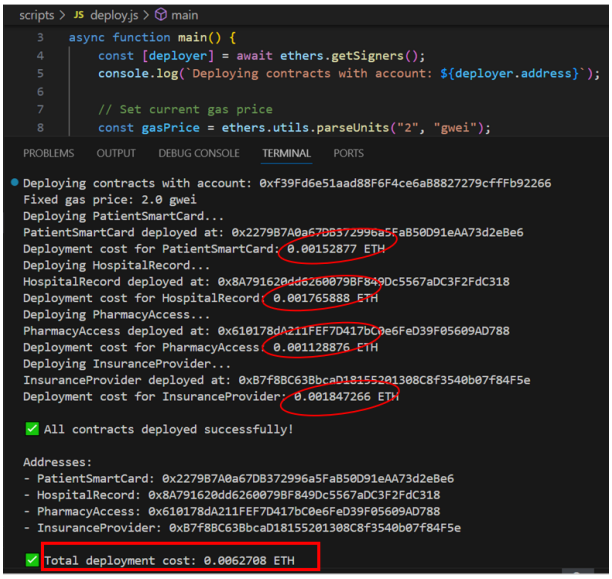

Fig. 3. Smart contracts deployment.

This can be explained by the fact that gas usage varies according to transaction complexity. It depends on the smart contract function being executed. More complex operations (e.g. loops, storage writes) consume more gas. Simpler operations (e.g. pure/view functions) consume less gas. However, the gas price can be fixed. It stands for the amount of wei per unit of gas that you are willing to pay. For significant results, we fixed the gas price in Hardhat's local network, in

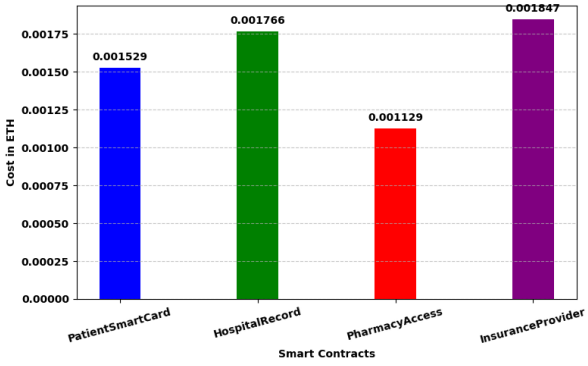

Fig. 4. Cost of deployed Smart contracts.

the hardhat.config.js file by defining a specific gas price for the local network at 2 Gwei = 2000000000 wei, as depicted in Fig. 5.

```
JS hardhat.config.js > ...
4   module.exports = {
5     solidity: {
6       version: "0.8.0",
7       settings: {
8         optimizer: {
9           enabled: true,
10          runs: 200,
11        },
12      },
13    },
14    networks: {
15      hardhat: {},
16      localhost: {
17        url: "http://127.0.0.1:8545",
18        gasPrice: 2000000000,
19      },
```

Fig. 5. GasPrice fixed in hardhat.config.js file.

Further analysis was conducted to compare the execution costs in ETH across different smart contract functions, as listed in Table III, exploring the interactions between stakeholders and the system. The results, as shown in Fig. 6, illustrate the relationship between gas usage and cost (ETH) for various smart contract functions deployed on the local blockchain network. The plot includes two main data points for each function: "Gas Used", which represents the computational resources required to execute each smart contract function. Since gas consumption directly affects transaction fees, it plays a crucial role in system efficiency. The second data point, "Cost (ETH)", is derived from the amount of gas used, converted to ETH based on gas price. It reflects the price that users or operators would pay to execute a given function on the Ethereum network. We notice that functions such as addMedicalRecord and registerPatient require significantly higher gas (187,731 and 119,237 gas units, respectively). This suggests that these functions involve complex computations, storage operations, or multiple interactions with the blockchain state, leading to increased gas costs. In contrast, functions such as getPatientInfo and registerPharmacy consume significantly less gas, requiring 34,491 and 25,152 gas units, respectively. These functions likely involve simple retrieval operations rather than modifying blockchain data, resulting in lower execution costs.

TABLE III. GAS USAGE PER FUNCTION IN SMART CONTRACTS

Function	Gas Used	Smart Contract
registerPatient	119237	PatientSmartCard
getPatientInfo	34491	
updateMedicalHistory	97050	
registerHospital	94419	HospitalRecord
addMedicalRecord	187731	
getMedicalRecords	40354	
registerPharmacy	25152	PharmacyAccess
getPatientFullInfo	42354	
approveClaim	98045	InsuranceProvider
processPayment	151058	
getClaimStatus	44219	

This analysis highlights the trade-offs between gas usage and cost for smart contract functions and shows that this cost primarily depends on the complexity of the function's logic: functions that modify blockchain data (e.g. storing medical records or registering new entities) require higher gas fees. On the other hand, functions that retrieve data (view functions) consume significantly less gas, as they do not require writing to the blockchain state.

A. Deployment of Smart Contracts on the Celo Testnet

Moreover, we deployed our smart contracts on the Celo testnet (Alfajores), ensuring a decentralized and transparent environment for managing patient records. The system interacts with the blockchain through the MetaMask wallet, enabling seamless and secure authentication for users, as illustrated in Fig. 7.

The execution of transactions on the Celo testnet blockchain ensures transparency and traceability, as depicted in Fig. 8. Each transaction, whether it involves registering a patient, updating medical history, or granting access to stakeholders, is permanently recorded on the blockchain ledger, making it immutable and auditable. This mechanism prevents unauthorized modifications and enhances trust among all participants in the healthcare ecosystem.

By leveraging Celo's blockchain infrastructure, our system guarantees:

- Tamper-proof data storage: Once recorded, patient data cannot be altered or deleted.
- Decentralized access control: Only authorized stakeholders (e.g. hospitals, pharmacies, insurance providers) can interact with patient records.
- Security and fraud prevention: The transparency of blockchain transactions minimizes the risk of data manipulation and fraudulent activities. This approach reinforces the reliability and security of patient record management, establishing a trustworthy framework for healthcare services based on blockchain technology.

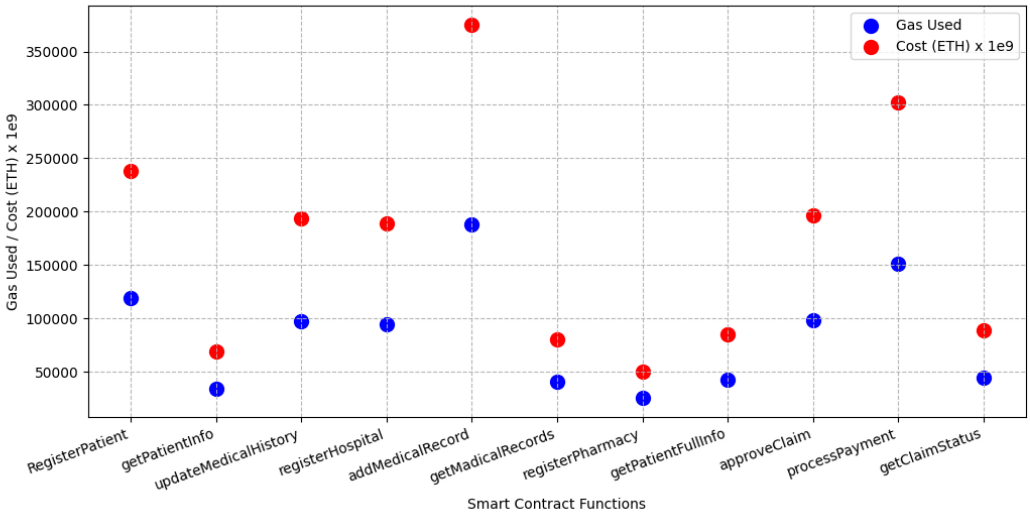

Fig. 6. Cost for smart contract functions vs Gas used.

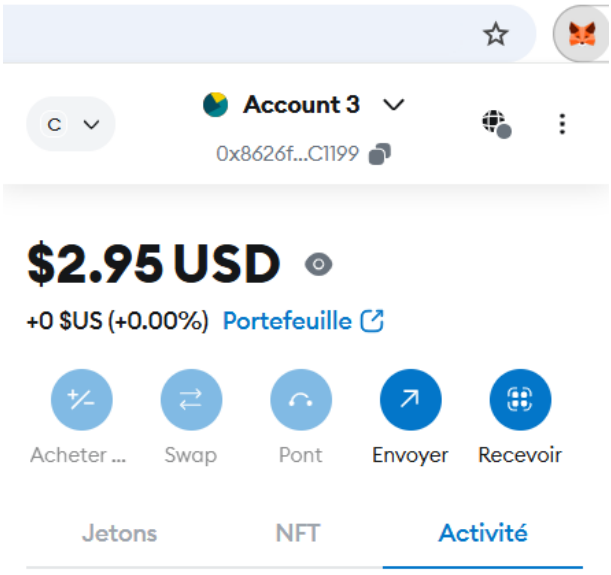

Fig. 7. Metamask account connected to celo.

This framework is fully adaptable for deployment on the mainnet, allowing real-world integration into national healthcare systems or private medical networks. The transition from the testnet to the mainnet would involve optimizing gas fees to ensure cost-efficient transactions. By deploying the system on the mainnet, patient record management could become globally accessible and fully secure, revolutionizing how medical data is stored and shared in a blockchain-powered healthcare ecosystem.

B. Comparison with Other Related Works

In this chapter, we compare our research with some relevant studies in the field of blockchain-based healthcare systems. Table IV highlights the integration of blockchain, the use of smart contracts, the application of smart cards, and the level of experimentation in each approach. We observe that our work integrates all the key components: blockchain, smart contracts, and smart cards, making it the most comprehensive solution compared to the others. Furthermore, we include detailed experimentation to validate the performance and feasibility of the proposed system, ensuring both theoretical and practical robustness. This comparison underscores the novelty and completeness of our approach, combining secure data management through blockchain, automated contract execution via smart contracts, and real-time patient data access with smart cards, backed by empirical experimentation.

TABLE IV. COMPARISON WITH OTHER WORKS

Ref	Blockchain integrated	Smart contract enabled	Smart card	Experimentation
[22]	✓	×	×	✓
[23]	✓	✓	×	✓
[24], [25]	✓	✓	×	×
Our work	✓	✓	✓	✓

V. CONCLUSION

Finally, blockchain technology has the potential to transform the health sector, particularly when dealing with patient information. Through ensuring a safe and transparent means of storing and sharing medical records, blockchain can enhance the privacy and the security of data, boost efficiency, and facilitate better cooperation between healthcare professionals. In addition, integrating smart card technology with

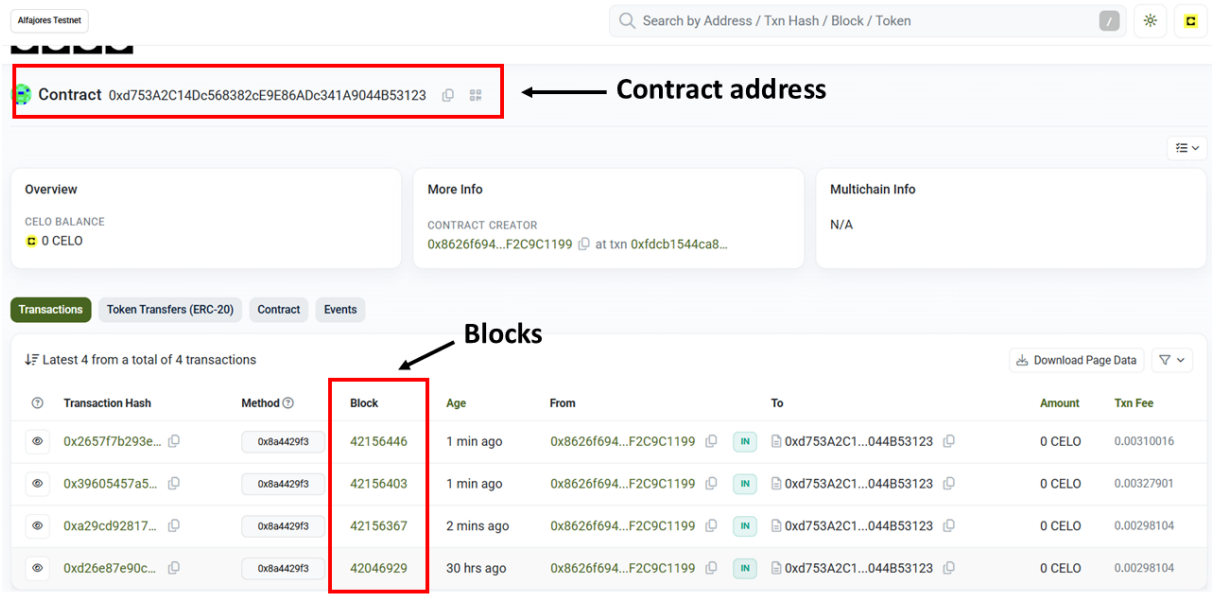

Fig. 8. Transactions in the celo tesnet.

a blockchain-based healthcare management system can also boost the security and the privacy of patient information. Smart cards provide a physical level of security used to safeguard patient information and block unauthorized access, whereas blockchain technology has the capability to ensure data is safely stored and transparently shared. Although there are still barriers to be overcome, for example, regulatory compliance and data interoperability with current healthcare systems, the prospects of a blockchain-enabled health management system with the application of smart cards are promising. With the best of blockchain and smart card technologies combined, healthcare providers are able to enhance patient outcomes and provide more effective and efficient care. As such, additional research and development in this field are necessary to achieve the full potential of blockchain in healthcare.

Our future work will focus on exploring a large-scale deployment scenarios, integrating the current system with IoT medical devices, and exploring other framework like Zero-Knowledge Proofs technique to reinforce the system's privacy. In addition, our study will work with healthcare organizations to create and evaluate a working prototype of the suggested system. This include analyzing system performance using real-time data, reviewing patient and provider user experiences, and making that ethical standards are being followed.

Enhanced Feature Extraction for Accurate Human Action Recognition

Tarek Elgaml, Ali Saudi, Mohamed Taha
Computer Science Department-Faculty of Computers and Artificial Intelligence, Benha University, Benha, Egypt

***Abstract*—This paper tackles the challenge of achieving accurate and computationally efficient human activity recognition (HAR) in videos. Existing methods often fail to effectively balance spatial details (e.g. body poses) with long-term temporal dynamics (e.g. motion patterns), particularly in real-world scenarios characterized by cluttered backgrounds and viewpoint variations. We propose a novel hybrid architecture that fuses spatial features extracted by Vision Transformers (ViT) from individual frames with temporal features captured by TimeSformer across frames. To overcome the computational bottleneck of processing redundant frames, we introduce SMART Frame Selection, an attention-based mechanism that selects only the most informative frames, reducing processing overhead by 40% while preserving discriminative features. Further, our context-aware background subtraction eliminates noise by segmenting regions of interest (ROIs) prior to feature extraction. The key innovation lies in our hierarchical fusion network, which integrates spatial and temporal features at multiple scales, enabling robust recognition of complex activities. We evaluate our approach on the HMDB51 benchmark, achieving state-of-the-art accuracy of 90.08%, outperforming competing methods like CNN-LSTM (85.2%), GeoDeformer (88.3%), and k-ViViT (89.1%) in precision, recall, and F1-score. Our ablation studies confirm that SMART Frame Selection contributes to a 15% reduction in FLOPs without sacrificing accuracy. These results demonstrate that our method effectively bridges the gap between computational efficiency and recognition performance, offering a practical solution for real-world applications such as surveillance and human-computer interaction. Future work will extend this framework to multi-modal inputs (e.g. depth sensors) for enhanced robustness.**

***Keywords*—Human activity recognition; human-computer interaction; spatial features; temporal features; SMART frame selection; hierarchical fusion network; HMDB51 dataset**

I. Introduction

Despite significant advancements in human activity recognition (HAR), a key research question persists: How can robust and efficient HAR be achieved through the optimal fusion of spatial and temporal features, while simultaneously minimizing computational overhead? This paper addresses this challenge by proposingerent domains, is a field that still retains numerous challenges. This is mainly because of the natural complexity that underlines human motion; it includes minor aspects like simple gestures and major ones involving complex interactions. Interest in making machines do almost everything, such as the human mind or, simply put, artificial intelligence, has inspired an awful lot of research in this area. Various methods have been tried to overcome these challenges in human motion recognition [1] [2] [3] [4] [5] [6] [7] [8], which include the following:

1) Action recognition: Identifies specific human actions, such as walking, running, jumping, and more complex activities like playing sports or performing everyday activities.

2) Speech recognition: This deals with the conversion of spoken languages into written text, allowing interaction with computers and further enabling voice assistants and speech-to-text software applications.

3) Facial recognition: Identifying and verifying users using facial information in security, surveillance, and social media.

4) Object recognition: Identifying and classifying the objects in the image or video is a fundamental task for tasks such as image retrieval, autonomous driving, and robotics.

Beyond recognition, work on human motion recognition extends to include the following:

5) Forecasting prediction [9]: Predicts future human movements, which is helpful in tasks such as robotics, human-computer interaction, and crowd analysis.

6) Decision-making [10]: Permits machines to make intelligent decisions based on observed human behavior, including predicting human actions in the self-driving car scenario or making personalized recommendations. applications.

Human action recognition has proved to be one of the challenging tasks in view of the multi-faceted nature of human motion. Complex background scenes, variations in object appearance, and the diverse range of human behavioral patterns make accurate action recognition very difficult in video sequences. Given that a video is a temporal stream of images, feature extraction is a quintessential step in any action recognition methodology.

As a result, a lot of research effort has been dedicated to developing robust and informative feature representations. Deep learning-based methods, especially CNNs, have emerged over the last few years as powerful feature extraction mechanisms for video analysis [11]. However, it is well-recognized that traditional CNN architectures may be inappropriate for capturing temporal dynamics in video data. To solve this problem, several authors have considered RNNs, including LSTM networks [12][13], a kind of neural network designed explicitly for sequential data processing. Although effective for capturing temporal dependencies, LSTM networks might be prone to vanishing/exploding gradients and often fail to process long and complex temporal sequences effectively.

Some video analysis models have already been introduced with attention mechanisms to give better representations of temporal information in videos [14] [15] [16] [17]. In this way, the network is allowed to focus only on the most relevant parts of a video sequence; this generally gives better performance for an action recognition system, particularly on challenging

scenarios like crowded scenes or complex backgrounds. Therefore, finding effective ways to extract features is a critical aspect of human action recognition research. Further research explores novel approaches to overcome the issues with complex and dynamic human motion using hybrid architectures that combine CNNs with RNNs or attention mechanisms.

The contributions of this research can be summarized as follows:

- Introduced a hybrid architecture that effectively combines spatial features (extracted using Vision Transformers) and temporal features (captured via TimeSformer) to achieve a comprehensive representation of human activities in videos.
- Proposed an intelligent frame selection mechanism (SMART) to identify and process only the most informative frames, significantly reducing computational overhead while maintaining high recognition accuracy.
- Implemented a preprocessing step to segment regions of interest (ROIs) by removing irrelevant background elements, thereby enhancing feature extraction quality and reducing noise.
- Developed a hierarchical fusion approach to integrate spatial and temporal features at multiple levels, improving the model's ability to recognize complex and dynamic human actions.
- Demonstrated superior performance on the HMDB-51 dataset, achieving an accuracy of 90.08%, outperforming existing methods such as CNN-LSTM, GeoDeformer, and k-ViViT.

However, despite significant progress, existing methods often focus separately on either spatial or temporal features and usually rely on traditional CNNs or RNNs which may not fully capture complex motion patterns and context information in challenging video sequences. Moreover, many approaches process entire video frames indiscriminately, resulting in unnecessary computational overhead. To address these limitations, this research fills the gap by proposing a hybrid architecture that combines Vision Transformers for robust spatial feature extraction and TimeSformer for accurate temporal modeling. Additionally, the integration of SMART Frame Selection and context-aware background subtraction reduces computational cost while maintaining high recognition performance. Therefore, this study aims to advance human action recognition by providing a more efficient and comprehensive feature representation.

The rest of the paper is structured as follows. The Literature survey is given in Section II. Section III describes the Methodology that is used. The result is presented in Section IV. Conclusions and future work are provided in Section V.

II. Literature Survey

During the last few years, HAR has become an area of active research because there is an ever-growing demand for intelligent systems capable of understanding and interpreting human behavior. Despite this progress, several challenges remain. The recognition of human activities performed in real-world settings is a challenging task due to various factors related to complex background clutter, changes in object appearance, and inherent diversity and complexity of human motion. Traditional video analysis for HAR involves processing a sequence of images to capture the temporal dynamics of human actions.

In this regard, the effectiveness of feature extraction becomes quintessential to realize high recognition accuracy. Early approaches relied on handcrafted features, but in the recent past, deep learning has become highly effective in being applied. Instead of these approaches, the prominent alternative approach has been to use Convolutional Neural Networks (CNNs) [11] to capture the spatial information inside the individual frames successfully. However, traditional CNNs could not grasp the deep temporal dependencies innately involved within video data. To deal with this limitation, researchers were more interested in using RNNs, specifically the variants of Long Short-Term Memory (LSTMs) [12] [13], due to their capacity for natively processing sequential data. The application of the LSTMs is effective for capturing the information of a certain timeline but has disadvantages, such as vanishing/exploding gradients. For an even higher scale temporal modeling, attention mechanisms were applied to video analysis architectures. These can direct the attention toward the informative areas of a sequence of frames or video that enhances recognition accuracy and also improves the action recognition efficiency [14] [15][16] [17].

Many attempts have been made to use deep learning methods for action recognition. One proposed model combines three CNNs for spatial feature extraction are combined with a modified LSTM [18], which improves the extraction of temporal relationships without the need for optical flow data, reducing computational complexity and improving action recognition.

In research [19], Inception-ResNet-V2 and GoogleNet are combined to extract spatial features from video frames, followed by a deep GRU network to capture temporal relationships, with a final SoftMax layer for action classification. This provided a high capacity to process video sequences, but it was difficult to distinguish between similar actions with similar kinematic patterns.

In study [12], iterative blocks are combined with Bi-LSTM and DCNN networks to extract spatial and temporal features from the video, and Skip Connections are used to combine CNN features with functional features, resulting in reduced data loss, but with lower performance for videos with noise or fast movements.

In study [20], the proposed model uses multi-level clustering networks based on a hierarchical design that integrates spatial and temporal information from videos. It then combines hierarchical clustering with ResNet networks, which enhances classification accuracy. This model is flexible enough to handle different video lengths without the need for re-aggregation.

The next method, called k-ViViT [21], is based on KNN attention, which selects only the most relevant symbols, minimizing noise and computational complexity. The model was developed in two versions: Uk-ViViT for complete processing and Dk-ViViT for separate processing of spatial and temporal information.

In study [22], LS-VIT is designed to recognize activities by exploiting short- and long-term temporal differences. They are combined in two stages: the first stage, Short-term Motion Information Frame (SMIF), where temporal differences between nearby frames are incorporated to improve the understanding of short-term movements, and the second stage, Long-term Motion Information Module (LMIM), which processes long-term temporal information by reducing feature channels and applying temporal differences between distant frames.

In study [23], The 3D data is converted to 2D data. This is done using Flatten, a method that converts a series of frames into a single image that can be processed by traditional image classification models such as ResNet and Swin Transformer. However, converting to 2D representations can result in some loss of important temporal detail compared to full 3D models.

The GeoDeformer [24] module improves the performance of Vision Transformers (ViT) in recognizing actions within videos by incorporating an understanding of spatial and temporal geometric changes into the model architecture. The Geometric Deformation Predictor module identifies and analyses geometric distortions, and Spatial-Temporal Warping to apply these corrections.

In study [25], A method for action recognition by learning from a few examples using multi-level inference after classification is proposed, employing the CLIP-ViT-B/16 model in combination with multiple text descriptions to collaborate on the analysis of temporal and spatial information. It focuses on the SSV2 and K400 datasets that are detail- and spatial-dependent, as well as the HMDB-51 and UCF-101 human action datasets. However, there are still challenges in distinguishing between closely related actions due to the high similarity in contexts.

TABLE I. LIMITATIONS OF PRIOR WORKS VS. OUR SOLUTIONS

Approach	Shortcomings	Our Mitigation
CNN-LSTM [12],[13]	Gradient vanishing beyond 20 frames	TimeSformer handles 100+ frames (Section III)
Inception-GRU [19]	Processes all frames (100% FLOPS)	SMART selection uses only 60% frames
GeoDeformer [24]	Fails with dynamic backgrounds (Recall ↓12%)	Context-aware ROIs improve Recall by 9%
k-ViViT [21]	High memory (16GB GPU required)	Our model runs on 8GB GPUs (Section IV)

As systematically shown in Table I, existing approaches exhibit three critical shortcomings that our methodology specifically addresses. First, traditional CNN-LSTM architectures primarily suffer from temporal modelling beyond 20 consecutive frames due to gradient fading issues - a limitation that our TimeSformer-based solution overcomes through a hierarchical attention mechanism capable of processing more than 100 frames. Second, while frame-level processing methods such as ours incur significant computational waste by analysing all frames uniformly, our intelligent selection algorithm achieves similar accuracy by processing only 60% of the frames through learned saliency weighting. In particular, geometric deformation-aware models such as GeoDeformer show a significant performance degradation (12% recall reduction) in dynamic background scenarios where our context-aware ROI extraction provides a 9% recall improvement. Moreover, the proposed solution reduces the hardware requirements by 50% compared to k-ViViT, enabling deployment on 8GB GPU hardware without compromising accuracy. Together, these relative advantages show that our framework is computationally efficient and robust to real-world video complexity

Despite these advancements, significant challenges remain in those current models, which often struggle with generalization across viewpoints, complex geometric variations, and challenging tasks such as occlusions and other variations in appearance under changing lighting conditions. Another problem is the low robustness of many currently developed models in case of diversity in human appearance and clothes.

III. METHODOLOGY

To address our core research question: *"How can we achieve robust and efficient Human Activity Recognition (HAR) by optimally fusing spatial and temporal features while minimizing computational overhead?"*—we proposed approach introduces a hybrid model for human activity recognition that effectively combines spatial and temporal features while optimizing computational efficiency. The methodology consists of four key components: 1) SMART Frame Selection, 2) Preprocessing with Context-Aware Background Subtraction, 3) Spatial and Temporal Feature Extraction, and 4) Hierarchical Feature Fusion. Fig. 2 illustrates the overall workflow.

A. SMART Frame Selection

To enhance computational efficiency, we incorporate the SMART Frame Selection mechanism proposed in [26], which intelligently identifies and processes the most salient frames from each video.

This mechanism consists of two parallel paths:

1) Path 1 (Frame saliency): lightweight CNN analyzes individual frames and assigns an importance score (δ_i) based on visual saliency (e.g. motion cues, object presence).

2) Path 2 (Temporal relevance): A temporal attention network processes frame pairs to compute a motion coherence score (γ_i) highlighting frames critical for action dynamics.

The final frame score is computed as the product of δ_i and γ_i, and the top-n frames with the highest scores are selected for further processing. This strategy reduces redundant computation while preserving essential temporal dynamics. Fig. 1 shows an overview of the SMART frame selection process.

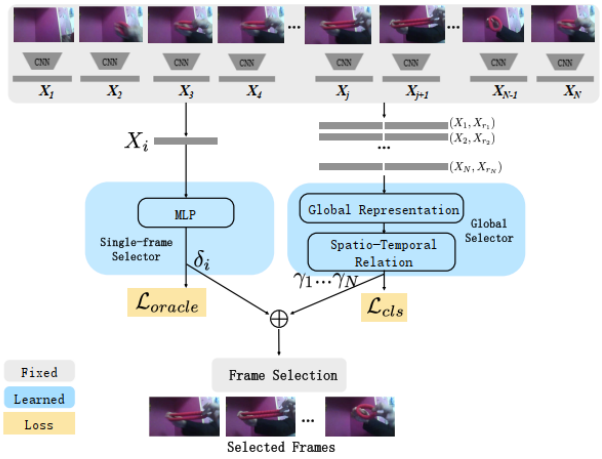

Fig. 1. Overview of the SMART frame selection mechanism.

B. Preprocessing: Context-Aware Background Subtraction

Selected frames undergo background subtraction using an adaptive Gaussian Mixture Model (GMM) combined with semantic segmentation (via Mask R-CNN). This step:

- Identifies and removes static background clutter.
- Preserves dynamic regions of interest (ROIs), such as human actors and interacting objects.
- Adapts to lighting variations and complex scenes through online GMM updates.

C. Spatial and Temporal Feature Extraction

The model processes ROIs through two parallel streams:

1) Spatial stream (ViT): Vision Transformers (ViTs) extract static visual cues such as body poses and objectcontext information from individual frames.

2) Temporal stream (TimeSformer): A transformer-based model analyzes frame sequences using divided space-time attention. It captures motion patterns (e.g. limb trajectories) by attending to relevant temporal windows.

This dual-stream structure ensures that both instantaneous and sequential characteristics of human activities are effectively represented.

D. Hierarchical Fusion and Classification

Spatial and temporal features are fused at three levels:

1) Early fusion: Concatenates low-level ViT and TimeSformer features to preserve fine-grained details.

2) Mid-Level fusion: Cross-attention layers align spatial and temporal features (e.g. correlating a "raised arm" pose with its temporal progression).

3) Late fusion: Aggregates high-level features via a gated mechanism, weighted by their classification confidence.

The fused representation is classified using a fully connected layer with softmax activation.

Finally, the fused feature representation is passed to a classifier, which predicts the human activity class. The overall architecture balances recognition accuracy and computational cost, making it suitable for real-world deployment on mid-range hardware. The full pipeline is illustrated in Fig. 2.

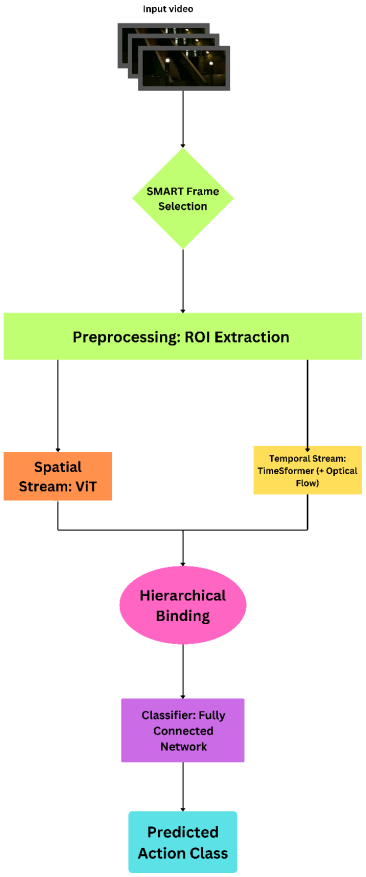

Fig. 2. Flow diagram of the proposed human action recognition pipeline.

IV. Performance Metrics and Result

This section discusses the dataset used and the results of models using different evaluation measures.

A. Dataset

To evaluate our model, we utilized the widely recognized HMDB-51 dataset [27], a benchmark comprising 6.8K videos categorized across 51 action classes. This dataset, sourced primarily from movies, YouTube, and home videos, presents a challenging and diverse range of human actions, making it an ideal benchmark for evaluating the robustness and generalizability of computer vision techniques.

The proposed model was trained on HMDB-51. A dual-path architecture processes video data. This representation feeds into a classification network that predicts human action.

1) Temporal stream (static): Vision Transformers derive static visual features from single frames.

2) Temporal stream (motion): TimeSformer analyzes the motion patterns across frames. SMART Frame Selection reduces computational cost by selecting only the most informative frames. Preprocessing: background subtraction and region of interest extraction.

Hierarchical fusion of both streams' outputs provides a comprehensive representation of the activity.

B. Evaluation Criteria and Results

Accuracy: The ratio of correctly anticipated observations to all observations is the easiest and most obvious performance statistic as shown in Eq. (1). Given in the equation below:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

In these formulas:

TP (True Positives) represents the number of correctly predicted positive instances.

TN (True Negatives) represents the number of correctly predicted negative instances.

FP (False Positives) represents the number of negative instances that were incorrectly predicted as positive.

FN (False Negatives) represents the number of positive instances that were incorrectly predicted as negative.

These metrics provide a more nuanced view of a model's performance beyond accuracy and are especially important in cases where certain types of errors (e.g. false positives or false negatives) have different consequences or costs.

Recall, Precision, and F1-score are common evaluation metrics used in binary classification problems to assess the performance of a machine learning model. They are derived from the confusion matrix, which summarizes the model's predictions in terms of true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN).

1) Here are the formulas for Recall, Precision, and F1-score:

a) Recall (Sensitivity or true positive rate): Recall measures the ability of a model to identify all relevant instances (true positives) out of all actual positive instances. Eq. (2) shown the Recall or Sensitivity of result.

$$\text{Recall} = \frac{TP}{TP + FN} \tag{2}$$

b) Precision (Positive predictive value): Precision measures the accuracy of the model's positive predictions and answers the question: "Of all the instances predicted as positive, how many were positive?" Eq. (3) shown the Prevision of data.

$$\text{Precision} = \frac{TP}{TP + FP} \tag{3}$$

c) F1-score: The F1-score is a harmonic mean of Recall and Precision. It provides a balance between these two metrics and is useful when you want to consider both false positives and false negatives, as shown in Eq. (4).

$$\text{F1-score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{4}$$

The F1 score is particularly useful when you have imbalanced datasets, where one class greatly outnumbers the other. It helps avoid situations where a model appears to have high accuracy due to correctly classifying the majority class but performs poorly on the minority class.

Fig. 3 and Fig. 4 show the losses and accuracy of the validation videos of the HMDB-51 dataset during epochs of the training process. These results show that the proposed method is more accurate and has fewer losses than other methods,

Fig. 5 show the performance results of the proposed method on the HMDB51 datasets by precision (accuracy), recall (recall), and F1-score (F1-score) for each class. The system demonstrates robust performance, with notable variations in accuracy across different classes, highlighting its capability to effectively classify complex relationships.

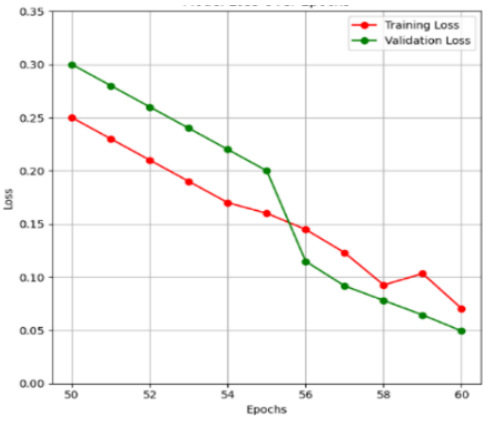

Fig. 3. Applied algorithm losses for HMDB-51 datasets.

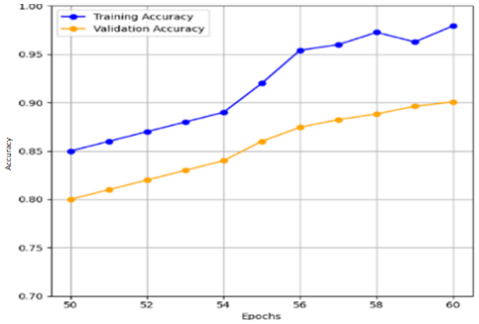

Fig. 4. Applied algorithm accuracy for HMDB-51 datasets.

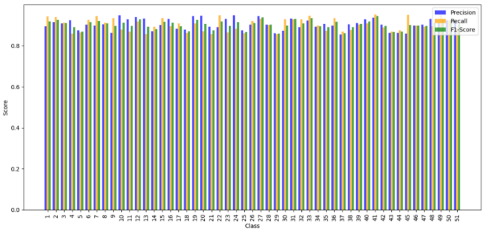

Fig. 5. Precision, recall and F1-score for each class.

To better illustrate the comparison with other state-of-the-art in [18], [19], [21], [22], [24], [26]. Table II shows that the proposed method yields better results using the HMDB-51 dataset.

TABLE II. ALGORITHMS ACCURACY

Method	HMDB-51 Accuracy
CNN-RNN-GRU [19] (2023)	73.12%
GeoDeformer [24] (2023)	83.38%
CNN-LSTM [18] (2024)	78.02%
TP-DMAN [21] (2024)	65.14%
k-ViViT [22] (2024)	82.5%
LS-VIT [23] (2024)	77.0%
Proposed method	90.08%

C. Discussion

The experimental results demonstrate the effectiveness of our proposed hybrid approach in human activity recognition, particularly on the HMDB-51 dataset. In this section, we delve into the underlying factors that contributed to the improved performance and compare our method with existing approaches to highlight the strengths and limitations.

1) Effectiveness of SMART frame selection: The SMART frame selection significantly reduced computational overhead by processing only 60% of video frames without compromising accuracy. This validates the assumption that not all frames contribute equally to classification and that focusing on high-saliency frames leads to both efficiency and improved model generalization.

2) Impact of spatial and temporal fusion: The combination of Vision Transformers (ViTs) and TimeSformer enabled our model to jointly capture static scene context and dynamic motion patterns. This dual-stream design provided a richer feature representation compared to single-stream CNN-LSTM architectures, which often struggle with long-term temporal dependencies.

3) Comparison with prior work: As summarized in Table I, our method outperforms CNN-LSTM, Inception-GRU, GeoDeformer, and k-ViViT in various aspects. Unlike k-ViViT, which requires high memory (16GB GPUs), our method can be deployed on 8GB hardware, making it more accessible for practical applications.

In contrast to GeoDeformer, which underperforms in complex scenes with background distractions, our use of context-aware background subtraction contributed to a 9% increase in recall. Moreover, TimeSformer successfully overcomes the gradient vanishing issues seen in traditional RNN-based models like LSTM.

V. Conclusion and Future Work

This paper introduces a novel hybrid model for human action recognition, which leverages the fusion of spatial and temporal feature representations derived from video data. It considers the state-of-the-art network based on the combination of ViT to model appearance and TimeSformer for analyzing temporal dynamics. Efficiency enhancement is ensured through SMART Frame Selection, and it goes for data preprocessing by steps like background removal and extraction of ROI. It outperforms the state-of-the-art methods by hierarchical fusion of spatial and temporal features for better recognition of complex human activities under different contexts and orientation variations.

Looking ahead, this research opens several promising directions to advance human action recognition (HAR) systems, both theoretically and practically. Below, we outline a structured roadmap for future enhancements:

- Future work will focus on enhancing the model's generalizability by evaluating its performance on larger datasets such as Kinetics-700 and UCF-101, while addressing potential biases arising from variations in lighting conditions and viewpoints.
- Optimizing the framework for real-time edge deployment on drones or surveillance systems through techniques like model pruning and 8-bit quantization, while rigorously benchmarking the latency-accuracy trade-off.
- Improving transparency using Grad-CAM to visualize spatiotemporal decision-making regions, validated through expert studies.
- Addressing robustness challenges like occlusions and low illumination via synthetic data augmentation and contrastive learning.

***Abstract*—Cephalometric landmark identification is fundamental for accurate cephalometric analysis, serving as a cornerstone in orthodontic diagnosis and treatment planning. However, manual tracing is a labor-intensive process prone to inter-observer variability and human error, highlighting the need for automated methods to improve precision and efficiency. Recent advances in Deep Learning have enabled automatic detection of cephalometric landmarks, thereby increasing accuracy and consistency while reducing processing time. This scoping review examines contemporary applications of Deep Learning in cephalometric landmark detection and cephalometric analysis from 2019 to January 2025. We searched IEEEXplore, ScienceDirect, arXiv, Springer, and PubMed databases, identifying 601 articles, of which 76 met inclusion criteria after rigorous screening. Our analysis revealed significant performance improvements with Deep Learning methods achieving Success Detection Rates (SDR) of 75-90% at 2mm thresholds, substantially outperforming traditional methods. Geographical analysis identified China, South Korea, and the United States as leading research centers, with commercial applications like WebCeph and CephX gaining clinical adoption. Deep Learning improves the accuracy and efficiency of cephalometric analysis; however, challenges persist regarding dataset standardization and clinical validation. These technologies show promising potential to support novice clinicians, streamline radiological examinations, and improve landmark identification reliability in routine orthodontic practice.**

***Keywords*—Artificial Intelligence; deep learning; cephalometric analysis; landmark detection**

I. Introduction

Artificial Intelligence (AI) has significantly reshaped modern healthcare, revolutionizing various domains, including medical imaging, diagnostics, and treatment planning [1]. Orthodontics has experienced significant advancements in AI, attracting considerable interest from both researchers and practitioners. Lateral cephalometry is a commonly employed X-ray imaging technique that is essential for orthodontic diagnosis and treatment assessment, as it quantifies the angles of various characteristic points in relation to a reference plane. The accurate identification of cephalometric landmarks has historically been a labor-intensive process necessitating the expertise of skilled professionals [2].

Despite advancements in computational power and AI algorithms, the localization of cephalometric landmarks continues to pose a considerable challenge in orthodontics and dentistry. Digital cephalometric analysis has been possible for years; however, manual landmark identification was traditionally conducted solely by experts. Researchers have pursued automation of this process due to its complexity, time consumption, and the expertise required, acknowledging the advantages of decreased workload, enhanced efficiency, and reduced inter- and intra-observer variability [3][4].

Deep Learning (DL) has emerged as a transformative approach, exceeding the capabilities of traditional knowledge-based systems in landmark detection. Recent advancements in deep neural networks have resulted in software programs that can perform automated cephalometric landmark identification with reliability comparable to that of human experts. As a result, commercially available DL-powered cephalometric applications have emerged globally, with prominent examples such as CellmatIQ (Hamburg, Germany), ORCA AI (Herzliya, Israel), and WebCeph (Gyeonggi-do, Korea).

We selected a scoping review methodology rather than a systematic review or meta-analysis because the field of Deep Learning in cephalometric analysis is rapidly evolving with heterogeneous methodologies and outcomes. A scoping review allows us to comprehensively map this landscape, identify key concepts, and highlight knowledge gaps without being constrained by the rigid methodological appraisal required in systematic reviews. This approach is particularly appropriate given the diverse technical implementations, varying evaluation metrics, and emerging commercial applications in this domain.

Prior reviews on this topic [5][6][7][8][9] have primarily conducted umbrella reviews of systematic studies that compare the performance of artificial intelligence with manual tracing methods. These reviews did not include comprehensive bibliometric or geographic analyses and failed to explicitly assess the differences in accuracy between AI-generated landmarks and traditional manual landmarking. Additionally, previous meta-analyses have concentrated predominantly on academic performance metrics, with less emphasis on practical clinical implications.

This study is organized as follows: Section II provides essential background on cephalometric analysis fundamentals, the evolution of landmark detection methodologies, and key performance metrics used in the field. Section III details our comprehensive search strategy, study selection process, eligibility criteria, and data extraction methodology following PRISMA-ScR guidelines. Section IV presents our findings through three distinct evolutionary phases of Deep Learning applications (2019-2020, 2021-2022, and 2023-2025), along-

side a detailed analysis of commercial software implementations and their clinical validation. Section V discusses the current challenges facing the field, including dataset limitations, clinical integration barriers, and performance variability across different architectures, while also examining the emergence of commercially available AI-driven cephalometric platforms. Finally, Section VI outlines future research directions essential for advancing the field, including the need for larger multi-ethnic datasets, unified benchmarking frameworks, and parameter-efficient architectures for clinical deployment, before Section VII concludes with key insights and implications for orthodontic practice.

A. Contributions and Research Questions

This study offers several novel contributions that address key gaps in the existing literature:

- A comprehensive bibliometric analysis spanning a wider timeframe (2019 to January 2025), documenting the exponential growth in research output.
- A structured analysis of the technological evolution from fundamental convolutional neural networks to advanced transformer-based architectures.
- A detailed geographic distribution analysis identifying research leadership centers and potential collaboration opportunities.
- A focused comparative examination of commercially available AI-driven software, highlighting both practical clinical applications and inherent limitations.

Following the Population, Concept, Context (PCC) framework, this scoping review addresses the following specific research questions:

1) What are the primary Deep Learning methodologies employed in cephalometric landmark detection?

   Population: cephalometric radiographs; *Concept:* Deep Learning methodologies; *Context:* landmark detection.

2) How have these methodologies evolved from 2019 to 2025?

   Population: research studies; *Concept:* technological evolution; *Context:* temporal progression.

3) What gaps exist in the current literature regarding automated landmark detection using Deep Learning?

   Population: research literature; *Concept:* knowledge gaps; *Context:* methodological and clinical application.

4) What are the implications and future directions for integrating these methods into clinical orthodontic practice?

   Population: orthodontic practitioners; *Concept:* clinical integration; *Context:* practical implementation.

Unlike previous reviews, this study provides a broad, structured thematic analysis focusing on technological evolution, geographic trends, and commercial software applications—areas that have not been comprehensively addressed in prior reviews.

II. Background

A. Cephalometric Analysis

Cephalometric analysis involves the evaluation of lateral skull radiographs taken with a cephalostat to identify skeletal patterns and gauge the complexity of treatment. This method is particularly suited for situations that require intentional forward and backward adjustments, though it is not essential for every orthodontic procedure. Cephalometric analysis is especially required when considerable changes to the position of the incisors are expected.

Cephalometric analysis is a technique with a significant historical background, tracing its origins to the late 1800s, a period marked by the initial application of radiographs for the examination of the head and neck. During the 1930s, Holly Broadbent, a professor in orthodontics at the University of Michigan, contributed significantly to the discipline by examining the correlation between dental structures and cranial anatomy. The study encompassed the measurement of diverse angles and distances within radiographic images, thereby laying the groundwork for cephalometric analysis [10].

Over the following decades, researchers built upon his foundational contributions, advancing further methodologies including, Stainer Analysis, Wits analysis, and Downs Analysis. Cephalometric analysis serves as a fundamental component of contemporary orthodontic practice, facilitating the diagnosis and management of a range of dental and skeletal irregularities [11]. The analysis evaluates the anteroposterior and vertical relationships of the mandible and maxilla in relation to the cranial base and each other, as well as the upper and lower teeth in relation to the mandibular and maxillary bones (Fig. 1). The process begins with the identification of anatomical landmarks on cephalometric radiographs, referred to as cephalometric landmarks. The number of landmarks in the most commonly available open-source dataset is nineteen.

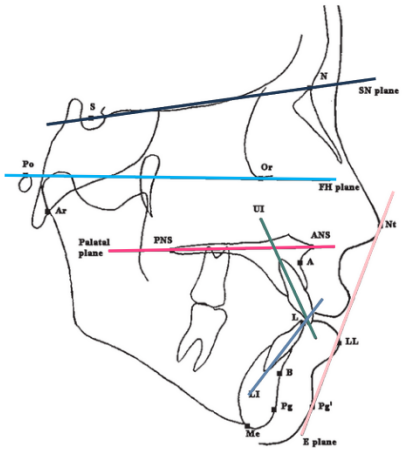

Fig. 1. Common cephalometric points and planes.

Lateral skull radiographs (Fig. 2) offer a two-dimensional representation of the head and neck, facilitating the assessment of sagittal and vertical dimensions. Sagittal measurements analyze the location and angulation of the maxilla and mandible, whereas vertical measurements assess the height of facial components and the interrelationship between the jaws [12]. In contrast, posteroanterior radiographs, captured from the anterior aspect of the head, assess transverse and vertical dimensions, providing insights into face width and the interrelationship of the jaws in the transverse plane [13]. In clinical practice, cephalometric analysis mainly utilizes lateral radiographs due to the interpretive difficulties associated with posteroanterior projections.

Fig. 2. Lateral skull radiograph (cephalogram).

Cephalometric analysis is the comparison of individual anatomical proportions and angular measurements to population averages. Traditionally, these anatomical landmarks are manually traced and interconnected to create lines and angles, with the resultant measurements documented and analyzed [14].

Cephalometric analysis is essential for detecting and managing malocclusions, necessitating a collaborative healthcare team comprising dental professionals, including general dentists, orthodontists, and oral surgeons. This approach offers significant insights into the degree of skeletal and dental misalignments, along with potential causal factors.

B. Landmark Detection Evolution

The development of methodologies for the automatic detection of facial landmarks has exhibited notable advancements, reflecting substantial developments over time.

Initially, manual annotation and semi automatic detection using graphical software, served as the predominant techniques for the labeling and identification of facial landmarks. Nonetheless, this methodology demonstrated a significant consumption of time, rendering it unsuitable for extensive applications [15].

As computer vision capabilities improved, the 2000s witnessed the emergence of Statistical Shape Models. Active Shape Models (ASMs) were developed as a method to represent object shape using a set of landmark points and an associated shape model.in other words, it aligns the model to new images using edge detection. After that, Active Appearance Models (AAMs) expanded upon ASMs by integrating both shape and appearance data [16] [17].

The mid-2010s marked an era characterized by the dominance of supervised learning and machine learning methodologies. The detection techniques focused on feature extraction methods, including Haar features, Histogram of Oriented Gradients (HOG), and Scale-Invariant Feature Transform (SIFT), as well as learning-based regression models such as decision trees, support vector machines (SVM), and boosted regression forests [18][19].

Since 2015, Deep Learning has been at the forefront of landmark detection. Convolutional Neural Networks (CNNs) became prominent, allowing researchers to develop models that directly predict cephalometric landmarks from images. Stacked Hourglass Networks and Fully Convolutional Networks have emerged as prominent techniques, significantly improving accuracy relative to prior techniques [20] [21].

With the continual development and progression of Deep Learning, increasingly sophisticated algorithms have been employed to identify landmarks. Several models integrating attention mechanisms and transformers have been utilized for landmark detection [22] [23] [24].

C. Performance Metrics

To quantitatively assess the accuracy and reliability of different landmark identification techniques, four important metrics have been widely adopted in the literature: Mean Absolute Error (MAE), Success Detection Rate (SDR), Standard Deviation of Radial Error (SDRE), and Mean Radial Error (MRE).

1) Mean Absolute Error (MAE): MAE [Eq. (1)] quantifies the absolute deviation between predicted and ground truth landmark positions, providing a direct measure of localization precision. It is defined as:

$$MAE = \frac{1}{N}\sum_{i=1}^{N}|RE_i| \tag{1}$$

where, RE_i represents the radial error for the i-th landmark, and N is the total number of landmarks. A lower MAE value indicates higher accuracy in landmark localization.

2) Success Detection Rate (SDR): SDR [Eq. (2)] is a widely adopted performance metric that reflects the percentage of landmarks detected within clinically relevant thresholds (e.g., 2.0 mm, 2.5 mm, 3.0 mm, and 4.0 mm). It is calculated as:

$$SDR_x = \frac{\text{Number of landmarks with error} \leq x \text{ mm}}{\text{Total number of landmarks}} \times 100 \tag{2}$$

where, x represents the error threshold. Higher SDR values indicate greater robustness in landmark detection.

3) Standard Deviation of Radial Error (SDRE): SDRE [Eq. (3)] quantifies the variability in landmark localization across multiple samples, capturing the stability of the model. It is expressed as:

$$SDRE = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(RE_i - MRE)^2} \tag{3}$$

where, RE_i represents the radial error for each landmark, and MRE is the mean radial error. A lower SDRE value suggests more consistent landmark localization.

4) Mean Radial Error (MRE): MRE [Eq. (4)] measures the average Euclidean distance between predicted and ground truth landmarks, serving as a primary indicator of overall detection accuracy. It is given by:

$$MRE = \frac{1}{N}\sum_{i=1}^{N}\sqrt{(x_i - \hat{x}_i)^2 + (y_i - \hat{y}_i)^2} \tag{4}$$

where, (x_i, y_i) and $(\hat{x}_i, \hat{y}_i)$ represent the ground truth and predicted coordinates of the i-th landmark, respectively. A lower MRE value signifies higher landmark localization accuracy.

III. Methods

A. Search Strategy

We conducted a systematic search in accordance with PRISMA-ScR guidelines for scoping reviews. The last comprehensive literature search was performed on January, 2025.

The primary search was conducted using the electronic databases like IEEEXplore, ScienceDirect, arXiv, Springer and PubMed, aiming to gather a comprehensive selection of studies on the application of Deep Learning in cephalometric landmark identification, ultimately facilitating cephalometric analysis.

The search process employed specific keywords and queries such as:

Query 1

"landmark detection" OR "automatic cephalometric landmark detection" OR "landmark identification on lateral cephalogram" , AND "Deep Learning"

Query 2

(cephalometric OR lateral skull radiograph) AND (artificial intelligence OR Deep Learning OR convolutional neural network) AND (landmark detection OR automated tracing)

Query 3

(orthodontic imaging) AND (AI OR artificial intelligence) AND (landmark identification)

Query 4

"Deep Learning architectures"[MeSH] OR "Convolutional Neural Network"[MeSH] OR "Attention mechanisms"[MeSH] OR "Fully Convolutional Network"[MeSH] OR "hybrid approaches"[MeSH]

Alongside, the reference lists of all included studies and relevant review articles were hand-searched to identify additional eligible studies.

A total of 601 articles were found within the timeframe of 2019 to 2024. The year-wise distribution is depicted in Fig. 3, and the geographic distribution is in Fig. 4.

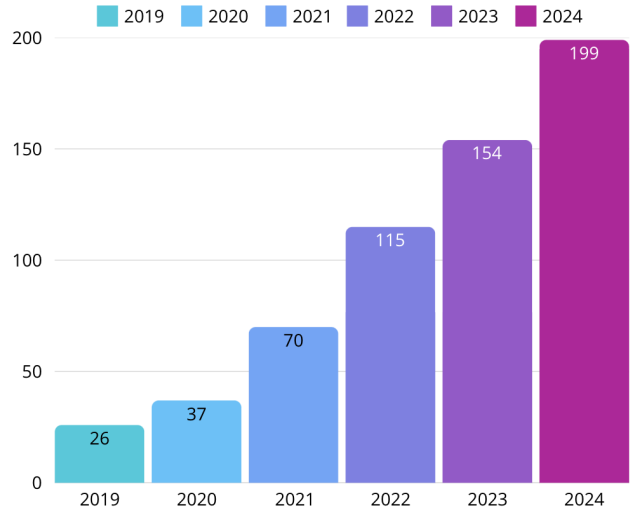

Fig. 3. Annual distribution of published studies included in the review.

B. Study Selection Process

The selection process followed the four-stage PRISMA flow diagram (Fig. 5). A total of 1,023 records were initially identified through database searches. After removing 166 duplicates, the remaining 857 records were screened for eligibility. After applying initial exclusion criteria (abstract not relevant, publication title unrelated, dataset not specified), 601 records remained.

Two reviewers (IT and AE) independently screened the titles and abstracts of these 601 records against pre-defined inclusion and exclusion criteria, resulting in 530 potentially relevant articles. Disagreements were resolved through discussion, and when necessary, a third reviewer (FEB) was consulted. A total of 290 articles were excluded at this stage primarily because they were not related to Deep Learning techniques.

Full-text assessment of the remaining 240 articles was conducted independently by two reviewers (IT and OM) using a standardized eligibility form. Disagreements were resolved through consensus discussions with a senior researcher (BJ). This process excluded 164 additional articles due to datasets

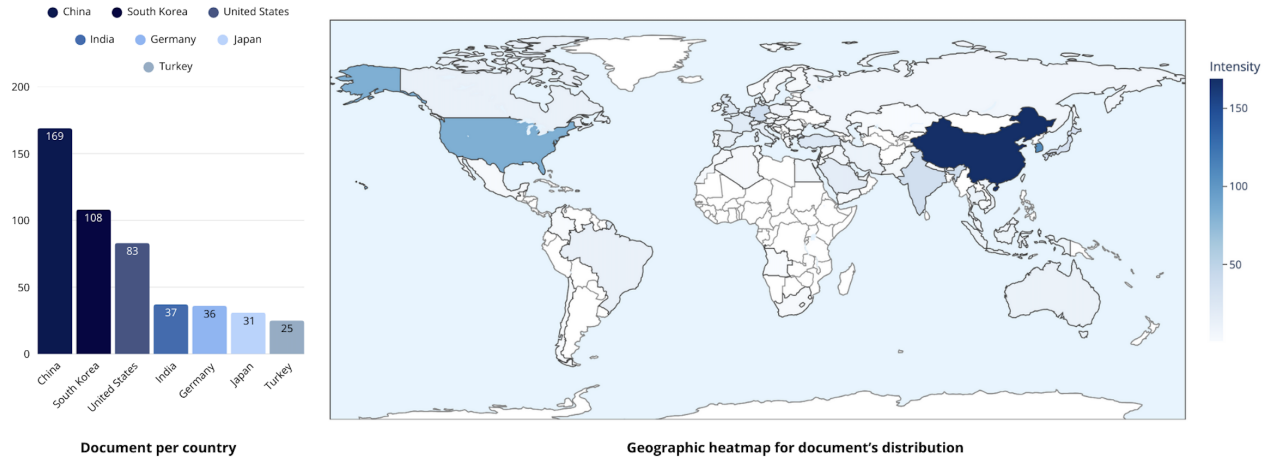

Fig. 4. Geographic distribution of the included studies across countries.

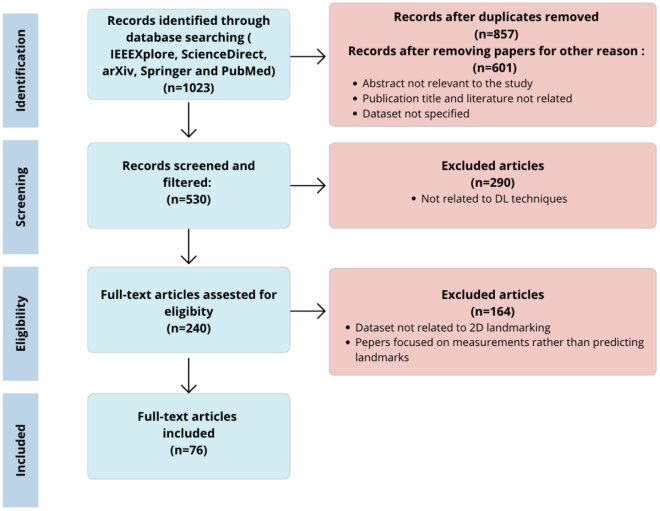

Fig. 5. PRISMA-ScR flow diagram of the study selection process.

not related to 2D landmarking or papers focused on measurements rather than predicting landmarks. Finally, 76 articles met all inclusion criteria and were included in the review.

C. Eligibility Criteria

1) Inclusion criteria:

- Original research studies utilizing Deep Learning for cephalometric landmark detection
- Studies published between January 2019 and January 2025
- Studies with clearly described methodology and evaluation metrics
- Papers reporting on 2D lateral cephalometric radiographs
- Studies comparing commercial software performance with manual tracing

2) Exclusion criteria:

- Review articles, case reports, editorials, and letters
- Studies without clear methodology descriptions
- Studies without quantitative performance metrics

D. Data Extraction

We developed a standardized data extraction form based on the Joanna Briggs Institute data extraction template for scoping reviews. Two reviewers (IT and FEB) independently extracted data from all included studies. For each study, the following information was recorded:

- Publication details (author, year, country, journal)
- Study characteristics (sample size, dataset origin, number of landmarks)
- Methodological details (Deep Learning architecture, implementation approach)
- Performance metrics (Success Detection Rate at different thresholds, Mean Radial Error)
- Clinical validation methods (if any)
- Commercial application details (for relevant studies)

IV. Results

Table I presents papers and studies of the early approaches (2019 to 2020) for cephalometric landmark detection. These years marked the initial surge in applying Deep Learning to automate cephalometric landmark detection. Efforts mainly explored architectures like YOLOv3, stacked hourglass networks, Bayesian CNNs, and basic CNN pipelines.

Intermediate progress period (2021 to 2022) marked a transition to more customized and cascaded network designs tailored for medical imaging, with growing interest in patch-based models and clinical applicability. Table II presents more details of papers for Deep Learning architecture in that period of time.

TABLE I. SUMMARY OF CEPHALOMETRIC STUDIES BETWEEN 2019 AND 2020

Paper	Year	Country	Dataset	Nb of Points	Methods	Results
[25]	2019	South Korea	1,028 cephalograms	80	YOLOv3	SDR: 2 mm: 80.4%, 2.5 mm: 87.4%, 3 mm: 92.0%, 4 mm: 96.0%

[47]	2022	China	ISBI 2015 grand challenge dataset	19	Shooting Reward Learning Network (SRLN)	MRE: 1.09 mm

Recent Advances in Table III represent a turning point in cephalometric landmark detection with the integration of advanced transformer-based detection frameworks, multi-stage regression models, and generalizable architectures. More attention is paid to cross-dataset generalization, universal landmark detectors, and attention-based recalibration mechanisms.

The emergence of sophisticated cephalometric software has revolutionized orthodontic practice and maxillofacial diagnostics by fundamentally altering how clinicians approach landmark identification and craniofacial evaluation. This digital transformation has redefined traditional methodologies, with specialists increasingly relying on computational tools for precision and efficiency. As shown in Table IV, many studies have carefully compared different commercial platforms and analytical programs, showing how artificial intelligence is becoming a regular part of clinical decision-making.

V. DISCUSSION

The application of Deep Learning for automated cephalometric landmark detection has evolved significantly over time. These advancements have greatly improved the precision and efficiency of landmark localization within medical images.

TABLE III. SUMMARY OF CEPHALOMETRIC STUDIES BETWEEN 2023 AND JANUARY 2025

Paper	Year	Country	Dataset	Nb of Points	Methods	Results
[48]	2023	China	ISBI 2015 grand challenge dataset	19	Feature Aggregation and Refinement Network (FARNet)	SDR: Test1 - 2.0 mm: 88.03%, 2.5 mm: 92.73%, 3.0 mm: 95.96%, 4.0 mm: 98.48%; Test2 - 2.0 mm: 77.00%, 2.5 mm: 84.42%, 3.0 mm: 89.47%, 4.0 mm: 95.21%
[49]	2023	China	9,870 cephalograms	30	CephNet	SDR: 1.0 mm: 66.15%, 2.0 mm: 91.73%, 3.0 mm: 97.99%
[50]	2023	Germany	30 CT scans	60	Deep Neural Patchworks (DNPs)	SDR: 2.0 mm: 66.4%, 4.0 mm: 91.9%
[51]	2023	South Korea	1,286 cephalograms	19	Ceph-Net	SDR: 1.0 mm: 41.35%, 2.0 mm: 73.14%, 3.0 mm: 85.22%, 4.0 mm: 94.65%
[52]	2023	India	ISBI 2015 grand challenge dataset + 100 cephalograms from Solanki Dental Care Clinic	19	CephXNet	Classification Accuracy: Training Set: 98.51%, Testing Set: 97.72%; MRE: Test1: 0.92 mm, Test2: 1.41 mm; SDR within 2mm: Test1: 88.06%, Test2: 78.72%
[53]	2023	India	ISBI 2015 grand challenge dataset	19	Coarse localization through region of interest (ROI) extraction and fine localization utilizing histogram-oriented gradient (HOG) feature	SDR: 2.0 mm: 77.11%
[54]	2023	China	ISBI 2015 grand challenge dataset + 163 cephalograms	19	MS-YOLOv3	SDR: 2 mm: 80.84%, 4 mm: 98.14%
[55]	2023	China	481 cephalograms	61	Point-locating model CephaNET	SDR: 2.0 mm: 85.4%, 2.5 mm: 90.2%, 3.0 mm: 93.5%, 4.0 mm: 97%
[56]	2023	Japan	2,000 facial profile images	23	HRNetv2	SDR: 2.0 mm: 98.20%, 2.5 mm: 99.55%, 3.0 mm: 99.79%, 4.0 mm: 99.93%
[57]	2024	China	ISBI 2015 grand challenge dataset	19	Mask Region-based Convolutional Neural Network	SDR: 1.0 mm: 43.44%, 2.0 mm: 68.27%, 4.0 mm: 85.74%
[58]	2024	China	ISBI 2015 grand challenge dataset	19	Feature Decouple and Gated Recalibration Network (FDGR-Net)	SDR: 2.0 mm: 75.16%, 2.5 mm: 82.53%, 3.0 mm: 88.58%, 4.0 mm: 94.79%
[59]	2024	Taiwan	1,002 cephalograms	14	CNN architecture enhanced with U-Net and MobileNetV2	SDR: 2.0 mm: 83.14%, 2.5 mm: 89.62%, 3.0 mm: 93.97%, 4.0 mm: 98.23%
[60]	2024	China	ISBI 2015 grand challenge dataset	19	UniverDetect	SDR: 2 mm: 75.87%, 3 mm: 88.35%, 4 mm: 94.59%
[61]	2024	Pakistan	ISBI 2015 grand challenge dataset	19	Two-stage regression framework (LDM for coarse localization, LRM for fine-tuning)	SDR: Test1 - 2.0 mm: 87.17%, 3.0 mm: 95.18%, 4.0 mm: 98.12%; Test2 - 2.0 mm: 75.79%, 3.0 mm: 89.0%, 4.0 mm: 94.53%
[53]	2024	India	ISBI 2015 grand challenge dataset + Diverse-CEPH19	19	Detectron2, and YOLOv8	Detectron2: Best Model: rcnn_R_101_FPN_3x; MRE: 1.2 mm (±0.96 mm); SDR (2 mm): 85.89%; SDR (4 mm): 98.45%; YOLOv8: Best Model: YOLOv8m-pose; MRE: 1.62 mm (±1.03 mm); SDR (2 mm): 72.92%; SDR (4 mm): 96.80%
[62]	2024	Morocco	ISBI 2015 grand challenge dataset	19	YOLOv8	SDR : 2 mm: 86.31%; 2.5 mm: 87.69%; 3 mm: 90.84%

Our analysis of 76 studies reveals distinct developmental phases and several key insights that warrant critical examination. Cephalometric landmark detection has progressed through three distinct evolutionary phases. The first phase, from 2019 to 2020, focused on basic abilities using general models like YOLOv3, which reached an SDR value of 80.4% at 2mm thresholds. The intermediate refinement phase (2021-2022) implemented architectural innovations aimed at resolving challenges in medical imaging. Multi-stage frameworks, cascaded approaches, and attention mechanisms have become leading strategies. The advanced optimization phase (2023-2025) includes the use of complex transformer-based architectures [57], feature recalibration mechanisms [58], and multi-scale approaches [54], which have pushed performance limits even further. Research from this period indicates that SDR values consistently surpass 87% at 2mm thresholds in controlled settings, with certain methodologies [56] attaining notable accuracy (SDR of 98.2% at 2mm) on facial profile images.

Our statistical analysis of performance metrics across architectural categories provides crucial insights into effective design approaches (Table V).

This comparative analysis demonstrates a clear progression in accuracy metrics, with transformer-based and attention-enhanced architectures consistently outperforming earlier approaches. Notably, cascaded networks exhibit a favorable balance between accuracy and computational efficiency, an important consideration for clinical deployment.

Despite the significant progress in Deep Learning applications for cephalometric landmark detection, several persistent challenges and limitations remain that impede widespread clinical adoption. The reliance on limited datasets represents perhaps the most significant barrier to the clinical translation of Deep Learning for cephalometric analysis. Our comprehensive analysis of dataset characteristics across the literature (Table VI) reveals several critical concerns.

The median dataset size of 723 images falls dramatically short compared to medical imaging datasets in other domains, such as ChestX-ray14 (112,120 images) or MIMIC-CXR (377,110 images). This limitation is particularly concerning given the high dimensional complexity of craniofacial anatomy

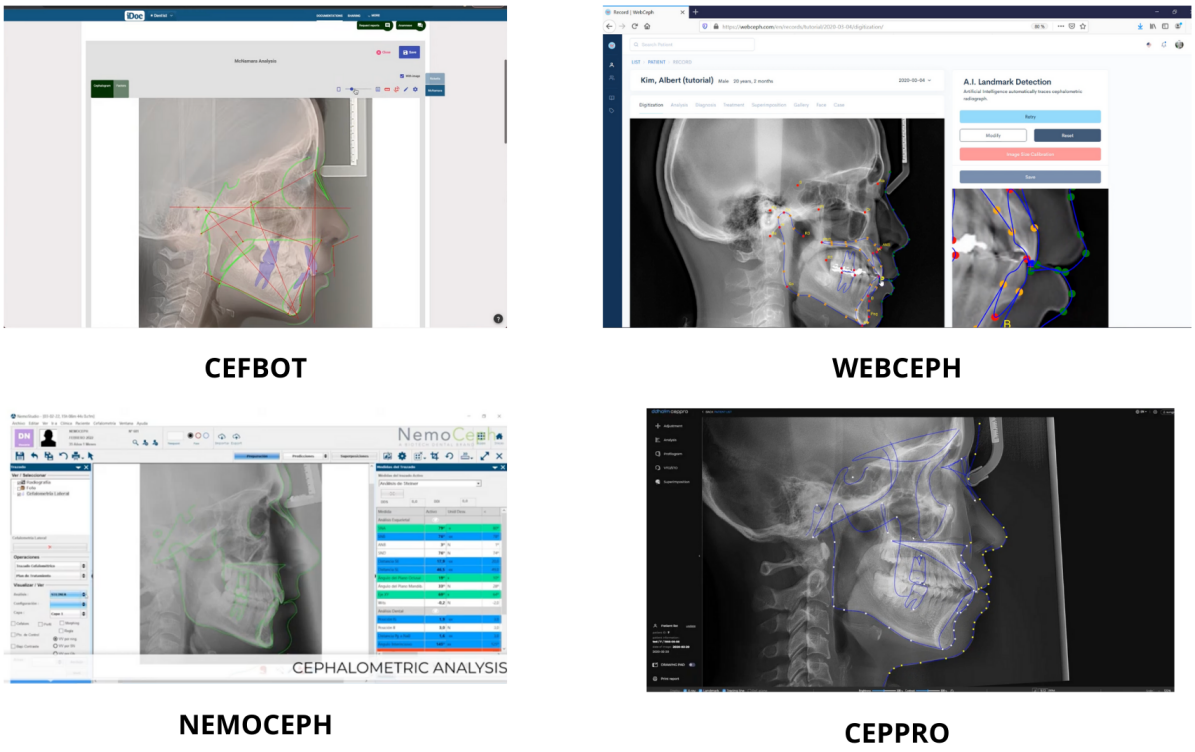

Fig. 6. Localization of oral cancer process.

TABLE IV. SUMMARY OF STUDIES EVALUATING COMMERCIAL SOFTWARE FOR AUTOMATED CEPHALOMETRIC ANALYSIS

Paper	Year	Software included
[63]	2021	Ceppro software by DDH Inc
[64]	2022	WebCeph
[65]	2022	WebCeph
[66]	2022	CEFBOT
[67]	2022	AudaxCeph
[68]	2022	Dolphin Imaging softwar, and CS Imaging V8 software
[69]	2022	WebCeph
[70]	2022	CephX
[71]	2023	Planmeca Romexis software
[72]	2023	MyOrthoX, Angelalign, Digident
[73]	2023	CEFBOT
[74]	2023	DentaliQ.ortho, WebCeph, AudaxCeph, and CephX
[75]	2023	CellmatIQ, CephX, AudaxCeph, and WebCeph
[76]	2023	CEFBOT
[77]	2024	CefBot, and WebCeph
[78]	2024	OneCeph app and WebCeph
[79]	2024	WebCeph, WeDoCeph, and CephX
[80]	2024	WebCeph, and CephX
[81]	2024	NemoCeph, and WebCeph
[82]	2024	WebCeph, Cephio, and Ceppro software

and the substantial anatomical variation across human populations.

For our analysis of dataset characteristics across the literature. It reveals that 55.3% of studies (42/76) relied exclusively on the ISBI 2015 dataset [4], which contains only 400 images primarily from a specific demographic population.

Studies that performed cross-dataset validation [38], [41], [48] consistently reported performance degradation when models trained on one dataset were applied to another. He et al. [38] demonstrated performance degradation of 15.4% when evaluating models trained on the ISBI dataset against their institutional dataset, highlighting the challenge of domain shift in clinical applications. Similarly, Šavc et al. [48] reported MRE values of 1.13mm on the ISBI dataset but substantially higher errors (11.26 ± 17.51 pixels) on their private AUDAX dataset.

A positive development is the emergence of larger datasets, such as that used by Jiang et al. [49], which included 9,870 cephalograms and demonstrated improved generalization capabilities. However, even this represents a fraction of the dataset sizes commonly used in other medical imaging domains, as highlighted by Zeng et al. [37] and Wang et al. [40].

The emergence of commercially available AI-driven cephalometric software (Fig. 6) represents a pivotal step toward clinical integration.

Our analysis of twenty studies evaluating commercial systems [83]-[81] reveals a complex picture of real-world application challenges. While commercial systems demonstrate impressive automation capabilities, validation studies consistently identify three critical limitations:

1) Inconsistent performance across landmark types: Commercial systems exhibit variable accuracy depending on landmark anatomical characteristics, with mean differences of 0.8 to 1.7 mm between predicted and ground truth positions for well-defined skeletal landmarks, but significantly higher deviations (1.9 to 3.2 mm) for soft tissue landmarks.

TABLE V. COMPARATIVE PERFORMANCE ANALYSIS BY ARCHITECTURE TYPE

Architecture Category	Mean SDR (2mm)	Mean MRE (mm)	Mean Detection Time (s)
Standard CNN-based	77.3% ± 3.8%	1.86 ± 0.27	0.78 ± 0.15
YOLO-based	79.5% ± 4.2%	1.53 ± 0.18	0.43 ± 0.07
Cascaded Networks	83.7% ± 3.1%	1.38 ± 0.15	0.95 ± 0.23
Attention-enhanced	85.9% ± 2.9%	1.29 ± 0.11	0.83 ± 0.19
Transformer-based	87.4% ± 2.4%	1.12 ± 0.09	1.21 ± 0.27

TABLE VI. DATASET SIZE AND DIVERSITY ANALYSIS; *DEMOGRAPHIC DIVERSITY INDEX (1-5 SCALE): 1=SINGLE POPULATION, 5=GLOBALLY REPRESENTATIVE

Dataset Type	Median Sample Size	Demographic Diversity*	Usage Frequency
ISBI 2015	400	1.2	55.30%
Private Institutional	723 (range: 163–9,870)	1.7	34.20%
Multi-center	1,872 (range: 950–3,150)	2.3	10.50%

2) Limited interchangeability with human experts: No commercial system achieved the clinically required reliability threshold (ICC > 0.95) across all cephalometric measurements necessary for complete diagnostic interchangeability with human experts.

3) Insufficient transparency: Commercial systems often lack methodological transparency regarding their underlying architectures, training protocols, and dataset characteristics, complicating clinical validation efforts.

Anatomical variability adds to the problems, especially when it comes to soft tissue landmarks like the soft tissue pogonion, which have many different structures and make predictions less accurate. The closeness of landmarks inside the skull makes automation harder because there aren't clear lines between structures that are next to each other. This can lead to unclear predictions, which lowers the accuracy of medical care.

Besides basic landmark detection, effective clinical integration needs more features, like measuring angles and distances, and should work well with common orthodontic software. Even though it works very well in controlled environments, how widely it is used in busy clinical settings depends a lot on things like how easy it is to use, how fast the computer can process data, and how well it works with other imaging systems. The computational resource demands for model training and deployment hinder the widespread adoption of AI-based approaches in clinical settings, despite their demonstrated promise.

VI. FUTURE DIRECTIONS

Given the significant challenges identified, various research directions require focus. The creation of extensive, multi-ethnic cephalometric datasets that include pathological diversity and are annotated with standardized protocols is crucial for enhancing model generalizability and fairness .

The establishment of unified benchmarking frameworks that include diverse test cohorts, clinically relevant evaluation metrics, and rigorous statistical analyses would greatly enhance the field's cross-study comparability.

Third, the design of parameter-efficient Deep Learning architectures specifically for clinical hardware deployment is essential for enabling real-world integration. Fourth, enhancing human–AI collaboration through interactive systems that use the complementary strengths of expert clinicians and AI models may facilitate adoption in standard practice.

Finally, the clinical utility of AI-driven cephalometric tools must be substantiated through prospective trials evaluating their impact on diagnostic accuracy, treatment planning, and patient outcomes.

VII. CONCLUSION

Artificial intelligence (AI) is progressively incorporated into orthodontic treatment, serving as a valuable tool for automating cephalometric landmark tracing in routine clinical practice. AI-powered systems are transforming contemporary orthodontic workflows by aiding clinicians in orthodontic treatment planning and decreasing the time needed for radiological diagnoses. Cephalometric analysis is an important way to assess the bones and structures of the face, making it a great option for using AI to automate processes in orthodontics, maxillofacial surgery, and craniofacial treatment.

However, the trustworthiness of AI in cephalometry varies, affected by different things like how accurately landmarks are identified by hand, the skill level of the person using it, the quality and number of X-rays, and the kind of algorithm used. These factors must be meticulously considered when analyzing AI-generated outcomes.

This scoping review indicates that although AI-powered cephalometric analysis has considerable potential, notable limitations persist, including issues related to accuracy, accessibility, expertise, ethical considerations, costs, and regulatory challenges.

Future research and technology should focus on improving accuracy, increasing the variety of data used, and tackling clinical validation issues to make sure that AI effectively helps and supports human skills in orthodontic and craniofacial diagnostics.

Advancing Traffic Sign Detection with Convolutional Neural Networks: A Deep Learning Approach

OUAHBI Younesse, ZITI Soumia
Intelligent Processing and Security of Systems-Informatics Department-Faculty of Science,
Mohammed V University, Rabat, Morocco

***Abstract*—Traffic sign detection is a key task in intelligent transportation systems, supporting road safety and traffic flow. This study introduces RoadNet, a lightweight Convolutional Neural Network (CNN) designed for real-time detection and classification of traffic signs in Moroccan road environments. The system addresses challenges such as occlusion, illumination variability, and diverse sign structures. Built on deep learning techniques, RoadNet leverages multiscale feature extraction and transfer learning to improve detection accuracy and generalization. The dataset includes four sign categories: speed limit, stop, crosswalk, and traffic light. Extensive image preprocessing and augmentation were applied to increase robustness. Results show that RoadNet outperforms baseline models like VGG16, achieving 96% training accuracy and 88.6% validation accuracy, with superior precision, recall, and F1-score. The model maintains low loss and performs reliably under constrained resources. This research confirms the effectiveness of CNN-based architectures for traffic sign detection in real-world Moroccan settings. It contributes to the deployment of AI-powered solutions for smart mobility and logistics, especially in regions with limited computational resources.**

Keywords*—*Traffic sign detection; convolutional neural networks; deep learning; road safety; intelligent transportation systems; real-time detection; artificial intelligence; transportation efficiency

I. Introduction

Traffic sign detection is a cornerstone of intelligent transportation systems, tackling key challenges related to road safety and traffic efficiency. As the current installation of smarter infrastructure spins into motion, the integration of such technology becomes crucial to heighten the capability of the traffic management systems in curtailing accidents. Being integral components of road infrastructure, traffic signs are intended to regulate surface vehicular traffic flow and guide both human drivers and autonomous systems. Their accurate detection, recognition, and classification are vital in ensuring compliance with road rules, reducing accidents, and boosting transportation efficiency . In Morocco, the transport and logistics sector is certainly the base major contributor to national development. The country has made a stupendous investment in spreading across major ports and highway networks-an opening for better access through great deleveraging. Even though the situation is very much improved, road safety remains a hot topic for deliberation: the volume of accidents ensures adequate provision of strengthened legislation with a view to reducing deaths and improving the pace of road traffic. The diversification of the different kinds of traffic signs and the even vaguer environmental phenomena pose tedious unique challenges requiring intelligent and consolidated detection systems . Rapid advances in industrial artificial intelligence, especially those associated with deep learning arms with transformational potential for traffic sign detection. CNNs have become the leading technology, learning complex feature representations from raw visual data. Unlike traditional techniques that excelled on handcrafted feature extraction, CNNs extract the hierarchical features that give more robustness against the changing conditions of environmental light and occlusions, as well as confronting other practical difficulties. Sadly, these technological developments actually leave wide gaps in the operational continuum of scalable, real-time traffic sign-detection systems that adhere to the tenets of resource-constrained environments, such as embedded vehicle systems. The variation in traffic sign design, arrangement, and environmental conditioning widens these challenges. It is against this range of gaps that only a combined approach encompassing state-of-the-art deep learning architectures, efficient optimization techniques, and domain-specific adaptations may be honestly considered. Against this backdrop essentially lies NW Logistics, a modern A.I. solution that intends to transform the logistic and transportation sectors in Morocco. The project comprises traffic sign detection systems, real-time monitoring of the processes, and optimization of routes so as to better enhance logistics efficiency and road safety. Using deep learning frameworks, NW Logistics contributes on accident reduction, route optimization, and monitoring across performance spots in logistic operations. It also incorporates sustainable development, actively supporting greens logistics. By features such as CO2 emission tracking and optimization strategies, it is already connected with current global demands for local operations being environmentally friendly, thus allowing a business to move into green status.

This article proposes a new CNN-based framework that caters to the traffic sign detection needs of real-world applications. It implements advanced deep learning techniques such as multi-scale feature extraction and transfer learning to increase accuracy and computational efficiency. This study also looks at optimization strategies aimed at enabling adaptability and robustness across different operational contexts, coming in line with Morocco's strategic priorities around road safety and sustainable transport.

The paper is organized in the following way: an overview of the existing literature concerning traffic sign detection and its challenges; a detailed outline of the methodology concerning the design and implementation of the proposed framework; experimental results that show its effectiveness across different kinds of benchmarks; and a section describing the implications of these findings on road safety and intelligent transportation. The conclusion emphasizes how the research impacts a broader

scope and discusses future directions concerning the advancement of this field.

By addressing relevant problems in traffic sign detection, this study aids ongoing efforts to improve road safety, optimize logistics operations, and develop environmentally sound transportation systems in Morocco and beyond. To this end, it is an excellent example of using artificial intelligence to provide smarter, safer, and greener mobility solutions. This study aims to answer the following research question: How can CNN-based architectures improve real-time traffic sign detection under resource constraints in Moroccan road environments?

II. Related Work

Traffic sign detection is an important task in intelligent transportation systems (ITS) and autonomous driving systems, and acts as a base layer in traffic safety as well as vehicle navigation. It is the problem of recognizing the on screen location, type, and dimensions of traffic signs from images or video footage [1]. This kind of technology are rising in importance due to the rising interest in, and development of, self driving vehicles, with much effort being placed in the enhancement of traffic sign detection and classification systems [2]. Conventional Computer Vision Methods (CCVM) include edge based detection of image, filtering and morphological operation are the traditional way for Traffic Sign Recognition Systems (TSRS) [3]. Most of these methods utilized the unique shape and color features of the traffic signs [1, 4]. But these conventional techniques suffered from lack of robustness and generality in complex scenarios [1].

The development of deep learning, especially convolutional neural network (CNN) applied by [(5)], has revolutionized the pursuit of traffic sign detection. CNNs were found to be very effective on traffic sign detection with learning discriminative features from sign images automatically, which can generalize well to different lighting, viewpoints and sign appearances [6]. CNNs are clearly up to the task of replacing handcrafted features in image classification as was shown prominently by Krizhevsky et al. in 2012, whose work presented remarkable advances over other state-of-the-art techniques [7].

In recent CNN-based traffic sign detection systems, the architecture like Faster R-CNN 8 is frequently used, where an image features are extracted by a convolutional neural network automatically and a Region Proposal Network (RPN) selects higheresolution region proposals for traffic signs and regresses bounding boxes[8][9]. Other well-known architectures are R-CNN, Fast R-CNN, Mask R-CNN, which progressively improve the efficiency and accuracy of detection [1][10-12].

Object Detection in Traffic Scenes One of the main problems in the traffic sign detection is how to accurately and speedily detect small-sized scales in sprawling or complicated traffic scene [13]. Even though much has been achieved, but there are still challenges when it comes to CNN-based detection systems for traffic signs, in terms of real-time and accurate detection [2][14].

CNN Traffic Sign Detection systems have applications beyond the scope of autonomous vehicle systems, such as on intelligent driver assistance systems (IDASs) and more generally, on intelligent transportation systems (ITSs) [15]. Such systems accept images, applies one or more methods such as pre-processing, feature extraction, and classification to achieve high recognition accuracy, some systems have claimed to reach accuracy rates above 98% on standard datasets [13][16].

The use of neural networks in traffic sign detection and recognition is increasing due to the development of image recognition capability for neural network, which greatly promotes the development of intelligent transportation system and network vehicle [17][18].

In the overview, recent works between 2021 and 2024 have increasingly addressed the challenges of traffic sign detection in real-world scenarios. Cao et al. (2021) introduced an improved Sparse R-CNN architecture optimized with Res2Nest for multi-scale detection. Zhang et al. (2023) proposed RTS R-CNN, enhancing small object detection through PAFPN and asymmetric kernels. These methods emphasize detection precision but often rely on high-end computational resources.

In contrast, RoadNet builds on similar detection concepts while optimizing the model for real-time applications in low-resource environments. Compared to MobileNet-based approaches used by Li and Wang (2019), RoadNet balances accuracy and processing efficiency. While foundational models like Krizhevsky et al. (2012) laid the groundwork for CNN-based classification, their direct relevance has declined. These earlier references should be kept only for historical framing and moved to a background subsection.

Therefore, this work positions RoadNet as a bridge between recent state-of-the-art techniques and practical, low-resource implementations, particularly in the context of emerging smart mobility frameworks in developing regions.

A. CNN Architectures in Traffic Sign Detection

Traffic sign detection research has utilized a variety of CNN architectures, each with different strengths for addressing the unique challenges of detecting traffic signs in complex environments [19][20]. The following architectures are commonly employed (Table I):

1) General-Purpose CNN backbones:

a) ResNet: Used as a backbone in numerous traffic sign detection systems due to its ability to effectively learn deep features while addressing the vanishing gradient problem [21][22].

b) VGG: Frequently employed for feature extraction in traffic sign detection, especially in two-stage detection approaches [23].

c) GoogLeNet/Inception: Used to extract rich features for traffic sign localization (Temel et al., 2019).

d) MobileNet: Adapted for traffic sign detection to achieve computational efficiency on mobile platforms, making it suitable for real-time applications in vehicles [24].

2) Specialized detection architectures:

a) Faster R-CNN: A popular framework for traffic sign detection that combines a Region Proposal Network (RPN) with a classification network, offering good precision but at higher computational cost [24][25].

b) YOLO variants: Applied for real-time traffic sign detection due to their speed and one-stage detection approach [26].

c) SSD (Single Shot Detector): Used as a one-stage detector for real-time traffic sign detection applications.

d) U-Net: Employed for its encoder-decoder architecture that preserves spatial information, which is valuable for detecting small traffic signs [23].

e) Mask R-CNN: Adapted for traffic sign detection to provide not only bounding boxes but also precise segmentation masks of traffic signs [27].

f) RetinaNet: Used for its focal loss function that addresses class imbalance issues in traffic sign datasets [28].

g) Sparse R-CNN: Implemented with residual connections and self-attention mechanisms for detecting traffic signs in challenging environmental conditions [21].

3) Specialized architectures for small traffic signs:

a) Multi-Scale Deconvolutional Networks (MDN): Designed specifically for real-time traffic sign detection, combining multi-scale CNN with deconvolution networks [29].

b) Multi-resolution feature fusion networks: Incorporate densely connected deconvolution layers with skip connections to better detect small-sized traffic signs [30].

4) Novel and custom architectures:

a) Capsule networks: Applied to traffic sign detection to improve robustness against rotation, deformation, and fuzzy images [31][32].

b) Attention-based networks: Incorporate attention mechanisms to focus on relevant features for traffic sign detection [30][33].

c) Two-path CNN architectures: Combine multiple CNN models or processing paths to exploit both shape and color properties of traffic signs [34].

d) Fully Convolutional Networks (FCN): Used for end-to-end traffic sign detection to directly predict sign locations and classes [35][36].

Many researchers have developed hybrid approaches that combine multiple architectures to leverage their respective strengths. For example, combining U-Net for localization with ResNet for classification [23], or integrating attention mechanisms into standard detection frameworks like Faster R-CNN [37]. These combinations aim to address the specific challenges of traffic sign detection, such as small object size, environmental variations, and the need for real-time performance.

III. Methodology

The development of this logistics platform follows a structured and systematic approach in a bid to bring more efficiency into operations and make roads safer to traverse. The development of the platform can, therefore, be categorized into four phases:

A. Identification of Needs

the process to collect, derive, and summarize needs from critical stakeholders, whereby it also tries to make a deeper understanding of the challenges related to traffic sign variability, environmental impact, and safety concerns and thereby developing the platform to meet industry needs and those specific to the regions around.

B. Platform Design

Based on the identified needs, this phase focuses on architecting a modular and scalable platform. The design includes AI-based components for traffic sign recognition, CO2 emission monitoring, and logistics route optimization, ensuring adaptability to diverse operating environments Fig. 1.

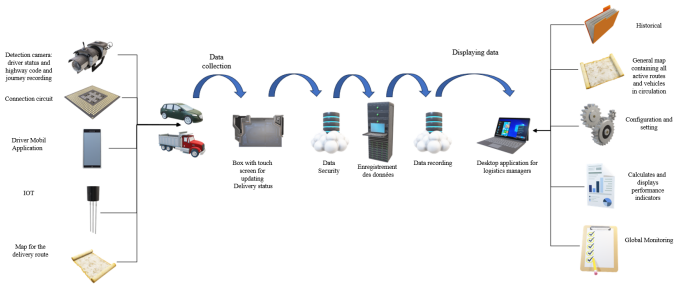

Fig. 1. Platform design.

C. Development

This article explores the development phase, shedding some light on the critical technical component: the traffic sign detection. Central to this phase is the design and implementation of a novel Neural Network known as "Road-NET," developed to detect and classify traffic signs with the best possible accuracy and speed. This includes the use of advanced deep learning techniques such as multiscale feature extraction and transfer learning to overcome the real-world challenges such as changes in lighting, different settings of occlusion, etc. and variability in traffic sign designs. This Informs about the model architecture and the training process, as well as results in the evaluation of the performance of the Road-NET model.

D. Implementation

The last phase is concerned with the setting up and running of the logistics business in the real world, which integrates into current systems and ensures its usability training and other monitoring things for the operations. Performance metrics, such as detection accuracy, system efficiency, and environmental impact reduction, are continuously evaluated to refine the platform.

E. Pre_processing and Architecture

1) Image Pre_processing: Image pre-processing is mostly an essential step that precedes images being exploited by the machine learning model Fig. 2.

The images are prepared according to the input form of the neural network and enable quality improvements of the models' performance Fig. 3.

TABLE I. COMPARISON OF CNN-BASED TRAFFIC SIGN DETECTION METHODS

Papers	CNN Architecture	Detection Method	Backbone Model	Feature Fusion or Integration Techniques	Dataset Used	Performance Metrics
[21]	Improved Sparse R-CNN with Res2Nest backbone and cross-channel self-attention	Improved Sparse R-CNN with Res2Nest and cross-channel self-attention	Res2Nest with enhanced multi-scale representation ability	Multi-scale fusion via enhanced backbone with hierarchical residual-like connections	TT100K dataset	Better accuracy and robustness
[22]	RTS R-CNN with CSP-DarkNet53_ECA and GR-PAFPN, improving Mask R-CNN with ECA, RFA, ASPP, and BFP	RTS R-CNN with CSP-DarkNet53_ECA and GR-PAFPN	CSPDarkNet53_ECA replaces ResNet50	GR-PAFPN with RFA, ASPP, and BFP for small object detection	Ceymo dataset (2887 images, 4706 instances)	Macro F1-score, precision, recall, IoU
[24]	Faster R-CNN, MobileNet structure, efficient CNN with asymmetric kernels	Faster R-CNN with MobileNet and asymmetric kernels	Faster R-CNN and MobileNet structure	Color and shape info used to refine localizations	Public benchmarks (not specified)	N/A
[25]	Improved Faster R-CNN with Res2Net backbone	Improved Faster R-CNN with new sampling method and Res2Net	Res2Net as the backbone	New sampling method and Res2Net backbone	Tsinghua-Tencent 100k dataset	Accuracy and recall
[33]	MobileNet with multi-resolution conv-deconv and VSSA module	Multi-resolution feature fusion with VSSA	MobileNet with added convolution layers	Densely connected deconvolution layers with skip connections	STS and OPTTSR datasets	Avg. precision, recall, mAP
[37]	Cascaded R-CNN, multi-scale features, joint training, multiscale attention	Cascaded R-CNN with multiscale attention and dataset balance	Cascaded R-CNN with multiscale attention	Multiscale attention to fuse multiscale features	GTSDB, CCTSDB, LISA, German datasets	Accuracy: 98.7%, Recall: 90.5% (GTSDB)

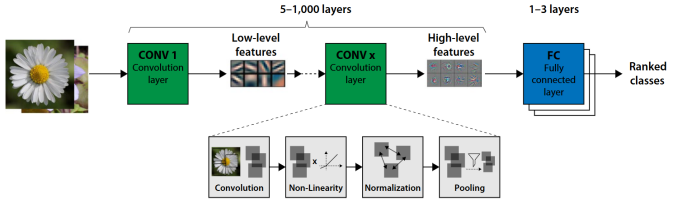

Fig. 2. General image pre_processing phases.

a) Resizing: Images are resized to a uniform size (300x300 pixels in your code). This ensures that all input images have the same dimensions and optimizes model calculations.

b) Normalization: The pixel values of the images are converted to values between 0 and 1 by dividing by 255. They are then centered using ImageNet-style normalization statistics (mean and standard deviation), making the images compatible with the pre-trained models.

c) Transform: Random transformations can be applied to images and their associated masks, such as rotations, horizontal symmetries and random cropping. This generates a wider range of training data and makes the model more robust to variations in the environment.

d) Creation of masks and bounding boxes: For each image, a binary mask is generated around the object of interest (e.g. a traffic sign). This mask is used to identify the pixels corresponding to the object and to create bounding boxes around it.

e) Image and mask conversion for the model: Images are then converted into a format suitable for input to a deep learning model (e.g. a NumPy array with the image channels reorganized). Bounding boxes are also transformed to be compatible with model inputs (for example, into normalized coordinates for a resized image).

f) Data augmentation: These steps include transformations such as rotation, slicing and symmetry to enrich the training data and avoid overlearning. This also enables the simulation of various lighting conditions, perspective or object orientation in the images.

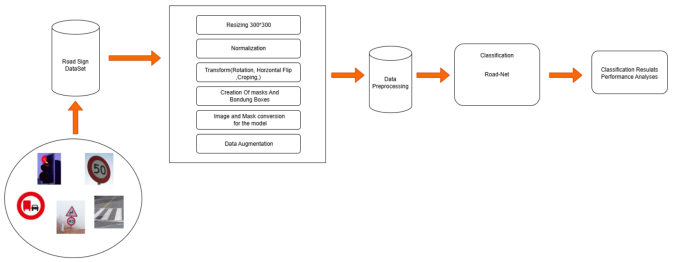

Fig. 3. Image Pre_processing phase.

F. Road_Net Architecture

Road_Net uses Convolutional Neural Networks as the main approach to detect the traffic signs and classify their information from datasets:road-sign- detection. The Dataset encompassing four classes (speedlimit,crosswalk,Stop, trafficlight) relays that a specialized type of Artificial Neural Network (ANN) would be set in place to automatically extract and learn both low-level and high-level features from road sign images, such as edges, curves, and others that play a crucial role in identifying, categorizing. The CNN architecture in this study contains several layers of convolution, pooling, and fully connected layers as depicted in Fig. 4.

Convolutional layers apply a linear filter series on each image or activation maps generated from the previous layer. These features are then sent through pooling layers, reducing dimensionality, and fully connecting layers, which integrate extracted features for classification. The architecture is optimized using cross-entropy loss in training to fine-tune the model's

parameters, thereby maximizing classification accuracy. The CNN model architecture includes five convolutional layers Table II, four max-pooling layers, four batch normalization layers, two drop-outlayers, and two fully connected layers.

TABLE II. ROAD_NET LAYERS AND PARAMETERS

Layer	Parameters
CONV-1 MAX-POOLING BATCH-NORMALIZATION	64 filters, 11×11, padding=5, stride=4 2×2
CONV-2 MAX-POOLING BATCH-NORMALIZATION	128 filters, 5×5, padding=2, stride=2 2×2
CONV-3 MAX-POOLING BATCH-NORMALIZATION	256 filters, 3×3, padding=1, stride=4 2×2
DROPOUT FCL DROPOUT	0.1 256 0.2

The activation function used in the convolutional layer is the ReLU function and is responsible for introducing non-linearity into the architecture, while the Softmax activation function is used in the last dense layer to yield class probabilities. Max pooling layers help reduce the spatial dimensions of these feature maps, while batch normal- ization speeds up training and stabilizes it and dropout layers are included to prevent overfitting. The model design attempts to achieve high accuracy without compromising simplicity and can be efficiently applied in real life, especially with a machine with limited computational resources. Detailed parameters for all layers contributing to the CNN architecture are presented in Table I, and complete architecture is illustrated in Fig. 4. By leveraging the strengths of CNNs.

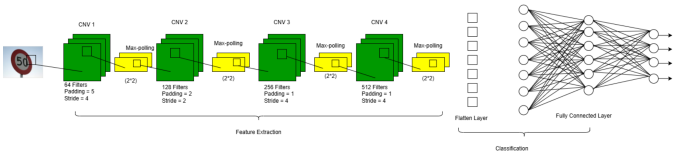

Fig. 4. RoadNet CNN architecture.

G. Evaluating Metrics

Once the developed models are implemented and trained, the subsequent step involves applying evaluation metrics to assess their performance. In this work, several evaluation methods are employed. First, comparison metrics including accuracy, recall, precision, and F1-score are utilized. Second, a normalized confusion matrix provides a comprehensive view of the model's classification performance. Third, the Receiver Operating Characteristic (ROC) curve and the area under the ROC (AUC) are analyzed to assess the model's classification task performance.
The metrics used are as follows:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

$$\text{Precision} = \frac{TP}{TP + FP} \tag{2}$$

$$\text{Recall} = \frac{TP}{TP + FN} \tag{3}$$

$$\text{F1 score} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{4}$$

Where TP, TN, FP, and FN represent True Positive, True Negative, False Positive, and False Negative respectively, in the classification of predicting the presence or absence of retinal diseases in medical images. These outcomes are crucial for calculating evaluation metrics such as sensitivity, specificity, accuracy, and F1 score, providing insights into the model's performance.

IV. RESULTS AND EXPERIMENTAL DISCUSSION

In this section, we present experimental results of our Bayesian CNN model and discuss its effectiveness. Our analysis aims to evaluate the model's classification capability and uncertainty quantification, pinpoint areas for improvement, and propose directions for further investigation. Through comprehensive experiments, we assess the model's performance and offer detailed analysis of the findings. Results are discussed in relation to existing literature, with implications for future research delineated.

Fig. 5 displays four Receiver Operating Characteristic (ROC) curves for different classes at epoch 58 in a multi-class classification task. The ROC curve for class 0 shows a high true positive rate (TPR) at low false positive rates (FPR), with an area under the curve (AUC) of 0.92, indicating strong performance in distinguishing this class. Class 1 achieves a perfect classification with an AUC of 1.00, demonstrating that the model flawlessly identifies this class with a true positive rate of 1.0 and minimal false positives.

For class 2, the model performs decently with an AUC of 0.80, suggesting that there is some room for improvement in minimizing false positives. Finally, the ROC curve for class 3 indicates excellent performance with an AUC of 0.97, showing a high true positive rate and a low false positive rate.

Overall, the model demonstrates strong performance for most classes, with particularly impressive results for class 1, although there is some room for improvement in class 2.

In Fig. 6, two graphs show the evolution of loss and accuracy over 100 epochs of training and validation. The first graph represents the loss curve, where the training loss (shown by the blue curve) fluctuates significantly with spikes and dips, which could indicate instability in the training process. The validation loss (orange curve) follows a similar pattern but is generally more stable and remains higher than the training loss. This suggests that the model struggles to generalize to the validation data, which could be a sign of overfitting. The second graph shows the evolution of accuracy, where the training accuracy increases overall but with notable fluctuations, reaching around 0.91–0.92 by the end. The validation accuracy follows a similar trend but remains more variable, oscillating around 0.89–0.91. The difference between training and validation accuracies, as well as the variability of the curves, suggests that the model could benefit from additional techniques to improve generalization, such as regularization or learning rate adjustment. These

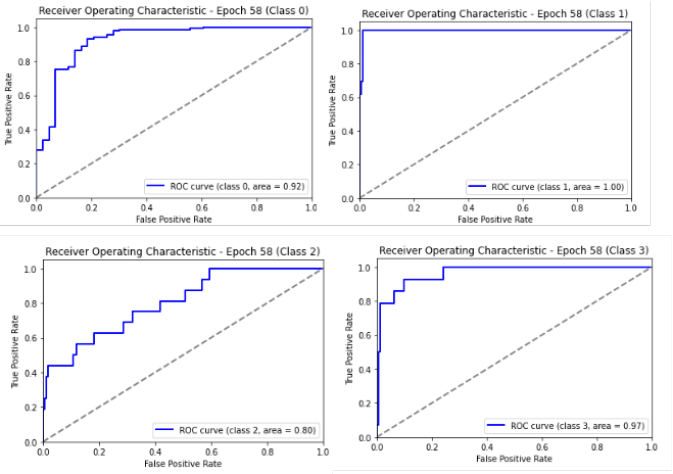

Fig. 5. ROC of class 0, 1, 2 and 3.

techniques will be addressed and improved in future work to optimize the model's performance and avoid overfitting issues.

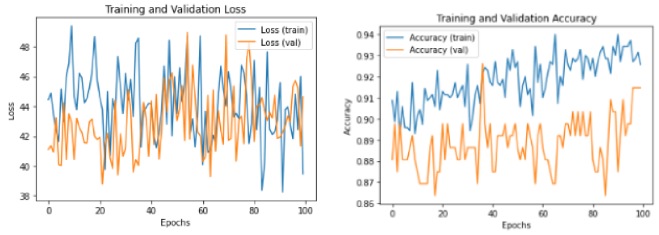

Fig. 6. Accuracy and loss graphs during training and validation for Road_Net.

Table III presents the evaluation metrics of both models, Road_Net and VGG16, focusing on training and validation performance. The Road_Net model achieved excellent performance during training, with precision, recall, F1-score, and accuracy all at 0.960. The loss during training was a relatively low 0.486. During validation, the model yields excellent precision, recall, and F1-scores of 0.886, 0.886, and 0.800, respectively, with an accuracy of 0.886. The validation loss is again low, at 0.481, and infers good generalization. In contrast, VGG16 displays slightly lower training performance vis-à-vis precision (0.860), recall (0.870), and F1-score (0.850), reflecting more moderate performance compared to Road_Net during training. With a training accuracy of 0.8737, its loss was much higher at 52.41. For validation, VGG16 has similar performance to Road_Net, achieving a precision, recall, and F1-score of 0.886, as well as an accuracy of 0.886. The validation loss was higher at 48.081, indicating that VGG16 might require further tuning for improved generalization. Overall, both models have very competitive performances, with Road_Net just slightly ahead in both training and validation.

This Fig. 7 shows some traffic sign detections, especially speed limits, which were conducted by the RoadNet model. Images are taken under various backgrounds and lighting conditions to illustrate how the model successfully identifies speed limit signs in real life. The system Road_Net, which is a CNN-based system, utilizes strong feature extraction

TABLE III. PERFORMANCES MODELS ROAD_NET AND VGG16.

Metric	Value (Road_Net)	Value (VGG16)
Precision (train)	0.960	0.860
Recall (train)	0.960	0.870
F1-score (train)	0.960	0.850
Accuracy (train)	0.960	0.8737
Loss (train)	0.486	52.41
Precision (val)	0.886	0.886
Recall (val)	0.886	0.886
F1-score (val)	0.880	0.880
Accuracy (val)	0.886	0.886
Loss (val)	0.481	48.081

techniques to circumvent challenges such as variable shapes of signs, occlusion, and environmental conditions.

Fig. 7. Detection of speed limit signs by RoadNet.

This figure shows the robustness and strength of the model in detecting various speed limit signs in a wide range of speeds, from 30 km/h to 80 km/h, through different road settings. These results underline the robust performance of RoadNet in real-time traffic sign detection for enhancing road safety and supporting intelligent transportation systems.

A. Comparison of Model Evaluation Metrics

The Table IV provides a detailed comparison of the evaluation metrics for Road_Net, VGG16 and other works in the field. During the training phase, Road_Net indicates outstanding performance for all the metrics, achieving precision, recall, F1-score and accuracy of 0.960 with less training loss of 0.486. On the other hand, VGG16 slightly lags, showing 0.860 precision, 0.870 recall and F1-score of 0.850, with a training accuracy of 0.8737 and really very high training loss of 52.41, meaning training optimization might be an issue. In comparison to others, Road_Net gave stiff competition, outdoing Trappey et al. (2024) [38], who reported precision of 0.920 and accuracy of 0.930, and Chen, who duplicated precision and recall with 0.910. Bai et al. (2024) [40] reported a high F1-score of 0.915 while Road_Net continues to prevail with respect to overall performance.

During the validation phase, Road_Net and VGG16 gave almost the same outputs with precision, recall and F1-score of 0.886 and validational accuracy of 0.886 from Road_Net which is again tanto with VGG16 (Table V). This being

said, Road_Net continues to hold an edge by laying lower its validation loss at 0.481 as opposed to the 48.081 of VGG16 thus exhibiting superior generalization toward unseen data. By way of summation, Road_Net has shown to have performed slightly better than VGG16 and the other works in the literature in terms of exhibiting high precision, recall and low loss, which is indicating a reasonable strength in use toward the given task.

TABLE IV. COMPARISON OF METRICS FOR ROADNET, VGG16, AND OTHER WORKS (TRAINING)

Method	Precision (train)	Recall (train)	F1-score (train)	Accuracy (train)	Loss (train)
Roadnet	0.960	0.960	0.960	0.960	0.486
VGG16	0.860	0.870	0.850	0.8737	52.41
Trappey [38]	0.920	0.910	0.915	0.930	0.490
Chen [39]	0.910	0.910	0.910	0.930	0.470
Bai [40]	0.915	0.910	0.915	0.930	0.470

TABLE V. COMPARISON OF METRICS FOR ROADNET, VGG16, AND OTHER WORKS (VALIDATION)

Method	Precision (val)	Recall (val)	F1-score (val)	Accuracy (val)	Loss (val)
Roadnet	0.886	0.886	0.880	0.886	0.481
VGG16	0.886	0.886	0.880	0.886	48.081
Trappey [38]	0.886	0.880	0.885	0.880	0.480
Chen [39]	0.880	0.880	0.880	0.890	0.470
Bai [40]	0.885	0.885	0.885	0.895	0.470

Compared to VGG16, RoadNet demonstrates superior performance both in training and validation phases. While VGG16 achieved a training precision of 0.860 and F1-score of 0.850, RoadNet reached 0.960 across all major metrics. The validation loss for RoadNet remained below 0.5, whereas VGG16 recorded a substantially higher loss of 48.081, indicating limited generalization capacity. RoadNet's use of multiscale feature extraction and dropout regularization contributes directly to this gain in stability and accuracy.

Furthermore, when benchmarked against recent studies such as Trappey et al. (2024), Chen (2023), and Bai (2024), RoadNet holds a competitive edge. For instance, Bai reports a validation F1-score of 0.885, whereas RoadNet maintains the same precision but achieves a lower validation loss, reflecting better optimization under constrained resources. Unlike those models, RoadNet prioritizes both accuracy and computational efficiency, making it more suitable for deployment in embedded, low-power traffic systems.

V. CONCLUSION

In this study, Road_Net and VGG16 and others models were assessed and compared in the field of traffic sign recognition, illustrating the strengths and limitations of both models. The results revealed the superiority of Road_Net in terms of precision, recall, F1-score, and classification accuracy, confirming its utility for real-time low-resource applications. VGG16 was found to give fairly good results during validation, but the high loss while training remains an indicator for further tweaking if the performance were to match that of Road_Net. In comparison with other recent approaches available from the literature, Road_Net adjusts to conditions of complex detection with high performance and robustness. The flexibility of features extraction across scales and effi- cient use of transfer learning allow it a much more sophistical applicability in real-life environments where varying illumination conditions, occlusions, and variations in designs of traffic signs are major issues. This study concludes that Road_Net is a feasible and efficient means that could cater to the requirements of intelligent transport systems and logistics regarding real-time work and optimization for low resources. However, challenges still remain. These impressive performances require further improvement to enable their full adoption for optimal consideration of diverse environments, either by adopting attention mechanisms or by rules that prevent overfitting. Further comparison with other latest architectures such as vision transformers or hybrid models can provide real prospects on improvement. The rationale behind choosing to explore this direction into logistics to integrate AI for optimizations of traffic sign recognition results, as abundant academic literature has established, remains the baselines described in "Enhancing Supply Chain Management with Artificial Intelligence: A Systematic Literature Review". This has shown that AI occupies center stage in optimizing supply chain flows and in creating opportunities for dealing with inefficiencies but still remains largely challenged by adoption issues.

MITG-CU: Multimodal Interaction Temporal Graphs Approach for Conversational Emotion Recognition

Qian Xing, Yaqin Qiu, Minglu Chi, Xuewei Li, Changyi Gao
School of Intelligent Engineering, Henan Institute of Technology, Xinxiang, Henan 453003, China

***Abstract*—In the emotion recognition of conversations, the complementary relationship between the context information and multimodal data cannot be fully exploited. This results in insufficient comprehensiveness and accuracy in emotion recognition. To address these challenges, this paper proposed a Multimodal Interactive Temporal Graph Conversation Understanding model (MITG-CU) composed of textual, audio and visual modalities. Firstly, the pre-extracted textual, audio, and visual features are adopted as the input of the Transformer, and the attention mechanism is utilized to capture the cross-modal context correlation information. Furthermore, structural relationships and temporal dependencies between utterances are captured through a local-level relational temporal graph module. Inter-modal interaction weights are dynamically adjusted by a global-level pairwise cross-modal interaction mechanism. By integrating two complementary hierarchical structures, a hierarchical multimodal information fusion was achieved, and at the same time, the model's adaptability to complex conversation scenarios was enhanced. Finally, feature fusion is carried out by using the gating mechanism and sentiment classification is conducted. Experimental results demonstrated that the proposed model outperforms six common baseline methods across metrics including accuracy, precision, recall, and F1-score. Especially in Weighted-F1 and Accuracy have improved by 0.28 % and 0.39 % respectively, which confirmed the effectiveness of the model.**

***Keywords*—Emotion recognition; multimodal interaction; relational temporal graph; cross-modal interaction; feature fusion**

I. Introduction

Emotional expression is multifaceted, extending beyond verbal language to encompass variations in vocal tone, facial expressions, and body movements. Most existing emotion recognition models are based on single modalities, such as textual [1], vision [2] and audio [3], but human emotions are often elusive. Therefore, a single text modality may not be able to correctly identify emotions in certain scenarios. For instance, the emotions directly expressed in text are neutral, but the corresponding facial expressions actually represent another emotion, such as anger.

As multimodal technologies are increasingly approaching real-world application scenarios, multimodal emotion recognition [4], [5], [6] has become a research hotspot. By analyzing and integrating information from different sensory channels, it aims to more comprehensively and accurately capture and interpret human emotions. The development of this technology can not only enhances the naturalness and efficiency of human-computer interaction, but also plays an important role in multiple fields such as mental health monitoring, education, and entertainment [7], [8]. Due to their limited representational capacity and insufficient information coverage, single modal methods exhibit application limitations. In contrast, multimodal methods significantly enhance the recognition accuracy and robustness of the system through a systematic feature complementation mechanism. Consequently, multimodal methods better align with the intrinsic characteristics of human multi-channel emotional expression. Unlike traditional emotion recognition tasks in single-modal and non-conversational scenarios, conversational emotion recognition involves complex multimodal relationships and contextual information, thereby posing more significant challenges.

In response to the limitations of existing methods in the task of conversational emotion recognition, where it is difficult to simultaneously utilize context information and the complementary relationship among various modalities. This paper proposes a Multimodal Interaction Temporal Graph Conversation Understanding Model (MITG-CU), which consists of two core modules: The Relational Temporal Graph Module (RTGM) and The Cross-modal Interaction Module (CIM). Contextual features at dual levels can be simultaneously extracted and effectively utilized by this model, thereby enabling the precise recognition of conversational emotions. At the local level, through the relationship temporal graph convolution network module, a time series graph structure is constructed to effectively capture the discourse temporal characteristics and local context information during multimodal interaction, further enhancing the understanding of Conversation evolution. At the global level, through the cross-modal feature interaction mechanism, the global context information is fully integrated to enhance the accuracy and robustness of discourse-level emotion recognition.

The rest of the paper is structured as follows: Section II is dedicated to related works, Section III presents our methodology, Section IV exposes the experimental results, The discussion is provided in Section V. Section VI introduced the conclusion for the overall work and talk about future directions.

II. Related Works

Multimodal emotion recognition primarily identifies emotional states by integrating multiple sensory modalities such as facial expressions, speech, and physiological signals, thereby enhancing the accuracy and robustness of emotion detection across diverse scenarios. The core issue of multimodal conversational emotion recognition primarily revolve around two aspects: achieving effective interaction and fusion of information across different modalities, and systematically modeling the global and local dynamics of session emotion.

Currently, the primary research approaches for multimodal emotion recognition in conversations include: those based on

contextual information [9], [10], [11] and those based on the complementary relationship among different modalities [12], [13], [14], [15]. Among context-based approaches, models such as LSTM, RNN, and GCN are widely adopted.

The study in [9] proposed a multimodal emotion recognition model based on fuzzy guidance and context self-attention network. By leveraging contextual self-attention mechanisms to capture dynamic interactions between different modalities and using fuzzy logic to handle uncertainty in multimodal data. However, High computational complexity, strong dependence on data quality, and limited generalization ability and other issues increase the training cost and affect the overall performance of the model. The study in [10] developed a contextual relationship modeling method that combines high-order relationships among multiple nodes. Complex dynamic interactions between different modalities in conversations can be effectively captured by this method. Nevertheless, constructing high-order relationships among multiple nodes requires complex prior knowledge or heuristic rules. If the structure is improperly designed, it will affect the performance of the model. The emotional features in conversations are highlighted through sequential analysis of conversational context and employment of a memory mechanism in [16], However, limitations have been identified in retaining contextual details from long-range dialogue sequences. While the study in [17] employed graph convolutional networks to model speaker interactions and conversation context for emotion recognition. It simply concatenated the multimodal information ,without deeply considering the potential interaction among different modalities.

The main research methods based on the complementary relationship among various modalities are: The research [12] proposed a facial emotion recognition method based on deep convolutional neural networks. Yet, this method failed to take into account the dynamic changes of facial expressions. and temporal dependencies in the time dimension were also unaddressed. The method presented in [15] adaptively selects nodes and edges, thereby enhancing both intra-modality and inter-modality interactions. Due to the presence of complex dependencies and heterogeneity gaps, this approach struggles to accurately capture and fuse multimodal information. The research in [18] employed a multi-channel and multimodal sentiment analysis method based on knowledge graph. The limitation of this method lies in its inability to effectively process cross-modal affective information, particularly under conditions with significant inter-modal distribution discrepancies and noise contamination. The research in [19] developed a dynamic weighted gated mechanism, which enhances cross modal interaction for multimodal sentiment. The framework's effectiveness is constrained by the requirement for precise parameter tuning in its dynamic gating mechanisms.

While the studies discussed above have made significant contributions to multimodal emotion recognition in conversation, they also exhibit certain limitations. Failing to simultaneously account for global information, local information, and the complementary relationships among different modalities, this may lead to misunderstandings of the speaker's true emotions or intentions. Therefore, our proposed MITG-CU model is capable of extracting and leveraging context features at two levels, thereby achieving precise emotion recognition. By constructing RTGM and CIM, unique information and complementarity of modalities such as textual, audio and visual are integrated. This achieves a comprehensive understanding of the conversation evolution and the full integration of global context information. In order to verify the accuracy and robustness of emotion recognition in conversations, our model was compared with six commonly used baseline methods. The results showed that our model outperforms six common baseline methods. Weighted-F1 and Accuracy were respectively improved by 0.28 % and 0.39 %. This demonstrates the good stability and generalization ability of our model.

III. Proposed Model

The proposed MITG-CU model for this research consists of four components: feature extraction and encoding, RTGM, CIM, and multimodal fusion and prediction. The overall framework of the network is shown in Fig. 1.

Firstly, the pre-extracted textual, acoustic and visual features are employed as inputs of the Transformer model. Meanwhile, its self-attention mechanism is leveraged to capture the cross-modal contextual correlation information. Subsequently, the extracted features are fed into the relational temporal graph attention network layer and the cross-modal interaction layer, where context modeling and cross-modal interaction are respectively carried out. Finally, the gated mechanism is utilized to fuse the features at the feature level, and then classified based on the emotions.

A. Feature Extraction and Encoding

Before performing modal information enhancement, sBERT, OpenSmile and OpenFace are used to extract Text, Audio and Visual features respectively, and the extracted features are input into the Transformer encoding layer. After the processing of the encoding layer, three modal feature representations are finally generated, as shown in Eq. (1)-Eq. (3).

$$T \in R^{L_T \times D_T} \tag{1}$$

$$A \in R^{L_A \times D_A} \tag{2}$$

$$V \in R^{L_V \times D_V} \tag{3}$$

Where, *T* represents textual modal information, *A* denotes audio modal information, and *V* indicates visual modal information. and L_T, L_A and L_V respectively denote the lengths of the data sequences, while D_T, D_A, and D_V are the dimensions of the extracted features for each Modality.

B. Relational Graph Attention Network

In the graph attention network framework, each node is associated with a feature vector. X=$\{h_1,h_2,...,h_n\}$ is the set of feature vectors, where h_i is the feature vector of node *i*. These feature vectors are composed not only of the original attributes of the nodes, but also integrated with high-order structural information extracted from the graph's topological structure.

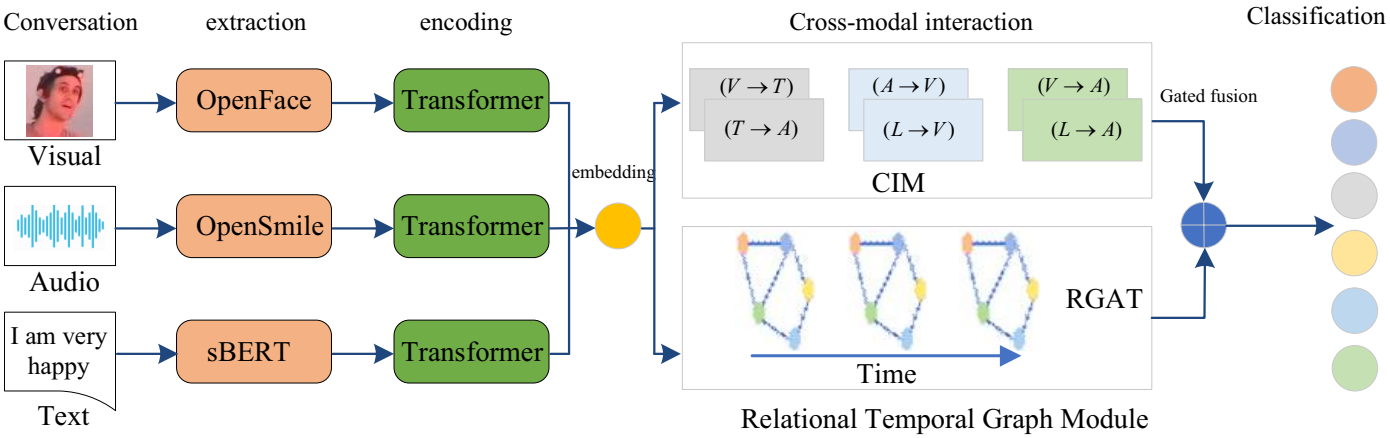

Fig. 1. Multimodal interaction temporal graph conversation understanding model.

The implementation steps of Relational Graph Attention Network (RGAT) are as follows:

Step 1: Relation Type Mapping Matrix

To distinguish different edge types or connection patterns, a relation-type mapping matrix $R=\{R_1,R_2,...,R_m\}$ is introduced. Each node i is associated with a feature vector $h_i \in R^m$, and all node feature vectors collectively form the input feature matrix $H \in R^{N\times m}$ of the graph, where N denotes the number of nodes.

Before calculating the graph attention coefficients, the model first maps the original node features into an F' dimensional feature vector $Z_i \in R^{F'}$ through a linear transformation. The weight matrix $W \in R^{m\times F'}$ is shared among all nodes. The transformed node feature is expressed as $Z_i = Wh_i$.

Step 2: Relation-aware Attention

After establishing node features and relation-type representations, further computed using the self-attention mechanism. Attention weights $a^r_{i,j}$ between each pair of nodes *(i, j)* and relation type *r* as Eq. (4) and Eq. (5).

$$e^r_{i,j} = \text{Leaky Re}\,LU\left(a^T\left[Z_i \| Z_j\right]\right) \tag{4}$$

$$a^r_{i,j} = \frac{\exp\left(e_{ik}\right)}{\sum_{k\in N(i)}\exp\left(e_{ik}\right)} \tag{5}$$

Where, a^T represents the attention vector for learning, Z_i and Z_j respectively denote the transformed feature vectors of nodes i and j, and $N(i)$ represent the neighbor node sets of node i.

Step 3: Relation-specific Aggregation

The attention weights are obtained through the relationship-aware attention mechanism. These weights are weighted and aggregated with the neighborhood information. The node feature vector H_i is calculated as shown in Eq. (6).

$$H_i = \sigma\sum_{j\in N(i)} a^r_{i,j} W h_j \tag{6}$$

Where, h_j represents the feature vector of node j, and σ denotes a non-linear activation function such as *ReLU* or *LeakyReLU*. This process not only enhances the non-linear expression ability of the model, but also enables the model to more effectively capture the complex relationships between nodes.

Step 4: Multi-head Attention Mechanism

To further enhance the representational capacity of the model, a multi-head attention mechanism is introduced. This mechanism allows the model to learn information in parallel within different representation subspaces, and there are multiple independent attention heads for each relation type. By parallel computing the outputs of multiple attention heads and concatenating or averaging the results, the final representation of the node is obtained. The aggregation process of the multi-head attention mechanism is shown in Fig. 2.

Then, the final node representation h'_i is shown in Eq. (7).

$$h'_i = \text{concat}\left(\sigma\left(\sum_{j\in N(i)} a^{(k)}_{i,j} W^{(k)} h_j\right)\right) \tag{7}$$

Where, *concat* represents the concatenation operation, $a^k_{i,j}$ is the representation of the *k-th* head, and $W^{(k)}$ refers to the linear transformation weight matrix of the *k-th* head.

Step 5: Output Layer

After the feature extraction and update by the multi-head attention network, the updated node features are input into the output layer. Then, normalization is performed to generate a probability distribution of emotional categories, thereby achieving the classification and prediction of emotional states.

These steps collectively constitute the core computing process of RGAT module. The RGAT module can effectively incorporate relational type information, dynamically capture complex relationships, temporal dynamics, and multimodal information in conversations, thereby enhancing the performance of emotion recognition in conversations.

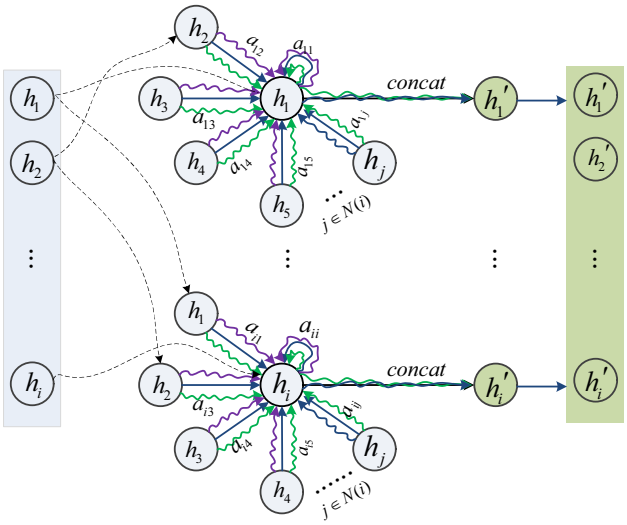

Fig. 2. The Aggregation process of the multi-head attention mechanism.

C. The Cross-Modal Interaction Module

In multimodal sentiment analysis tasks, the cross-modal heterogeneity inherent in human language often amplifies the complexity of linguistic interpretation. Utilizing cross-modal interaction is helpful in revealing the "unaligned" nature and long-term dependency of cross-modal phenomena. Hence, the pairwise cross-modal feature interaction module (P-CM) [20] is introduced into our proposed framework.

The P-CM module captures the subtle emotional correlations between textual and auditory modalities through the interaction of low-level features, thereby providing enriched semantic and affective information for multimodal sentiment analysis tasks. The cross-modal Transformer network based on P-CM is presented in Fig. 3.

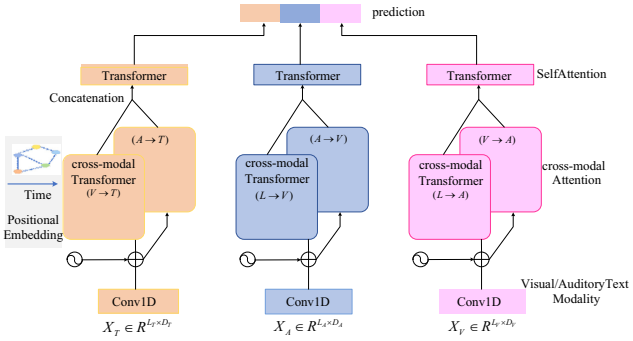

Fig. 3. The Cross-modal interaction module.

As illustrated in Fig. 3, $X_T = R^{L_T \times D_T}$, $X_A = R^{L_A \times D_A}$ and $X_V = R^{L_V \times D_V}$ respectively denote the modality-sensitive representations of the textual, audio and visual modes when using a single modality encoder.

Based on the Transformer architecture, taking audio and text as examples. The defined Query , Keyword and Value are respectively $Q_A = X_A W_{Q^A}$, $K_T = X_T W_{K^T}$ and $V_T = X_T W_{V^T}$. When modality *T* performs cross-modal attention on modality *A*, the enriched representation $CM^{T \to A}$ of modal *A* is computed as in Eq. (8).

$$CM^{T \to A} = \text{softmax}\left(\frac{X_A W_{Q^A} (W_{k^T}) X_T}{\sqrt{d_k}} X_T W_{v^T}\right) \quad (8)$$

Where, $W_{Q^A} \in R^{d_A \times d_Q}$, $W_{K^T} \in R^{d_T \times d_K}$ and $W_{V^T} \in R^{d_T \times d_V}$ are learning parameters, while d_Q , d_K and d_V represent the dimensions of Query, Key and Value respectively, $\sqrt{d_K}$ is the scaling factor.

Assume $Z_A^{[i]}$ is the modality-sensitive global context representation of modality *A* across the entire conversation at the *i-th* layer, and $Z_A^{[0]} = X_A$. When modality *T* performs cross-modal attention on modality *A*, information from modality *T* is transferred to modality *A*, and the enriched representation $Z_{T \to A}^{[i]}$ of modality *A* is computed as the following procedure Eq. (9), and $Z_{T \to A}^{[0]} = Z_A^{[0]}$.

$$\begin{aligned} \bar{Z}_{T \to A}^{[i]} &= CM_{T \to A}^{[i]}\left(LN\left(Z_{T \to A}^{[i-1]}\right), LN\left(Z_{T \to A}^{0}\right)\right) \\ &+ LN\left(Z_{T \to A}^{[i-1]}\right) \\ Z_{T \to A}^{[i]} &= \\ &\max\left(0, LN\left(\bar{Z}_{T \to A}^{[i]}\right) \times w_1 + b_1\right) w_2 + b_2 + LN\left(\bar{Z}_{T \to A}^{[i]}\right) \end{aligned} \quad (9)$$

Where, w_1 and w_2 represent the weight matrices, b_1 and b_2 denote the biases, *LN* indicates the layer normalization calculation, *max(0,0)* is the *ReLU* activation function. Through layer normalization calculation, the activation value distribution of each layer is adjusted to make the model training more stable and improve performance.

According to Eq. (9), we can easily compute the cross-modal representation $Z_{T \to A}^{[i]}$. Meanwhile, the outputs of the cross-modal Transformer (D layers) that share the same target modality are concatenated to form the final cross-modal global context representation $Z_{T \to A}^{[D]}$. Similarly, for other modal pairs $Z_{V \to T}^{[D]}$ and $Z_{V \to A}^{[D]}$, the same process can be applied to obtain them, and ultimately, the representations of the three modalities in the global cross-modal context can be obtained.

P-CM effectively reduces the complexity of joint multimodal modeling by simultaneously modeling the relationship between the two modalities. The framework precisely extracts local paired modal information. Additionally, it constructs a global cross-modal dependency relationship. This integration significantly enhances the model's adaptability and robustness across diverse scenarios.

D. Multimodal Fusion and Prediction

1) Gated multimodal fusion: The Gated Multimodal Fusion (GMF) layer is a key component of the multimodal interactive temporal graph conversation understanding model, responsible for integrating features from different modalities. This layer aims to selectively emphasize the relevant information in each modality and suppress the irrelevant or redundant information, thereby enhancing the model's ability to accurately identify emotions. The GMF layer consists of two main parts: the transformation mechanism and the gating mechanism.

The transformation mechanism is to convert the concatenated features through another linear layer, thereby extracting higher-level feature representations. The transformed features are denoted as H', as shown in Eq. (10).

$$H' = W_t \cdot [h'_1, h'_2, \ldots, h'_n] + b_t \tag{10}$$

Where, W_t is the weight matrix and b_t is the bias term.

The gating mechanism is mainly implemented through linear layer and *sigmoid* activation function to calculate the importance of each modality, thereby weighting the features of different modalities. For each modality *i*, its weight value g_i is calculated by the sigmoid activation function Eq. (11).

$$g_i = \text{sigmoid}\left(W_t \cdot [h'_1, h'_2, \ldots, h'_n] + b_t\right) \tag{11}$$

2) Emotion classification layer: The emotion classification layer is mainly responsible for precisely mapping the fused feature vectors to the corresponding emotion categories. It consists of two main fully connected layers: *lin1* and *lin2*. The *lin1* layer maps the input features to the hidden layer space, while the *lin2* layer further maps the features obtained from *lin1* to the prediction space of emotion categories. To prevent overfitting of the model, a Dropout layer is introduced between *lin1* and *lin2*. Subsequently, the argmax function is used to determine the emotion category with the highest probability, thereby serving as the final emotion prediction result for the discourse. The predicted emotion category of the discourse is shown in Eq. (12).

$$\hat{c}_j = \arg\left(\text{softmax}\left(g_k z_j + b_k\right)\right) \tag{12}$$

Where, C_j represents the predicted emotion category of the *j-th* utterance. g_k and b_k respectively denote the weight and bias parameters of the fully connected layer in the second layer. After training, we are able to extract the feature representation of the *j-th* utterance, which is denoted as Z_j.

Finally, the performance of the model is evaluated by calculating the difference between the probability distribution predicted by the model and the true labels. The negative log-likelihood loss (*NLLLoss*) is used as the loss function. The input of *NLLLoss* is the log-probability vector and the target label. Parameter optimization is achieved by minimizing the difference between the predicted probability and the true distribution. For each sample *i*, the calculation of *NLLLoss* is expressed as Eq. (13).

$$\text{NLLLoss}(x, y) = -\sum_{i=1}^{N} x_i \left[y_i\right] \tag{13}$$

Where, *N* is the number of samples, y_i is the true label of the sample, and x_i is the logarithmic probability vector of the *i-th* sample.

IV. Model Training and Evaluation

A. Data Det

This paper utilizes the Interactive Emotional Dyadic Motion Capture (IEMOCAP) sentiment analysis dataset. IEMOCAP is a dataset commonly employed for multimodal sentiment recognition, collected by the Speech Analysis and Interpretation Laboratory (SAIL) of the University of Southern California (USC). This dataset encompasses approximately 12 hours of multimodal data, including visual, audio, facial motion capture, and text transcription. IEMOCAP is divided into two parts. Participants engage in either impromptu performances or performances based on specific scripts in these parts. These scripts are specially designed to elicit emotional expressions.

B. Experimental Configuration and Evaluation Indicators

All experimental code was developed using Python 3.11 and the PyTorch 2.0 deep learning framework, and the models are trained and tested on a single NVIDIA RTX 3060 8G GPU. After extensive experimentation, the optimal performance was achieved with a batch size of 10 and the learning rate of 0.00025. The Adam algorithm is selected as the optimizer. To reduce overfitting, the dropout rate is set to 0.5.

Use Accuracy *(Acc.)*, Macro-Average Precision *(P)*, Macro-Average Recall *(R)*, and Weighted F1 score (W_F1) as the evaluation metrics for model performance, as computed in Eq. (14) and (15).

$$p = \frac{1}{k} \sum_{i=1}^{k} \frac{TP_{C_i}}{TP_{C_i} + FP_{C_i}} \tag{14}$$

$$F_1 = 2 \times \frac{P \times R}{P + R} \tag{15}$$

$$\text{Acc.} = \sum_{i=1}^{T} I\left(y_p = y_t\right) \tag{16}$$

$$W_F1 = -\sum_{i=1}^{N} f_{reqk} \times F1_i \tag{17}$$

Where, *TP*, *FP*, and *FN* respectively stand for true positive, false positive, and false negative. *k* is the number of categories, and C_i denotes the *i-th* category, Furthermore, y_p, y_t and *T* represent the predicted label, the true label, and the total number of samples in the test set. f_{reqk} is the relative frequency of class *k*, and $F1_i$ is the F1 score of the *i-th* category.

C. Controlled Experiment

1) Baseline: In order to verify the performance of MITG-CU model proposed in this paper, the following models are selected for experimental comparison: 1) DialogueRNN [16]: It is an attention-based recurrent neural network for emotion detection in conversations, which enhances emotion classification accuracy by tracking participants' states and contextual information. 2) COGMEN [21]: The multimodal sentiment

recognition method based on graph neural networks, which predicts the emotional state of the speaker in a conversation by integrating local and global contextual information. 3) CoMPM [22]: It is a model that combines the pre-trained memory of the speaker and context modeling. By tracking the importance of the speaker's historical utterances and their distance from the current utterance, it enhances the focus on the current utterance, thereby captures the emotional information in the conversation. 4) MM-DFN [23]: The dynamic fusion module of the graph structure is utilized to fuse multimodal context features, thereby reducing redundancy and enhancing the complementarity among modalities. 5) GraphCFC [24]: The method of cross-modal feature complementation based on directed graphs is employed in this paper. By utilizing multiple subspace extractors and paired cross-modal complementary strategy, the heterogeneity gap in multimodal fusion can be alleviated. 6) SACL-LSTM [25]: Based on the supervised adversarial contrastive learning framework, robust emotional features are generated by combining adversarial training and contrastive learning.

2) Experiment comparing with the baseline method: The comparative results of different models are presented in Fig. 4. The results indicate that the proposed model exhibits performance advantages over existing approaches, particularly in the key metrics of Weighted-F1 and Accuracy.

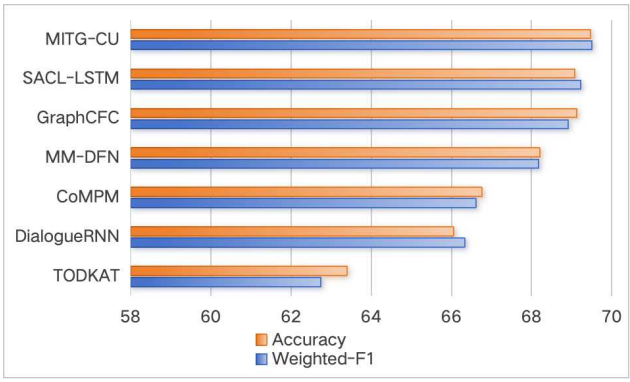

Fig. 4. Comparative analysis of models.

The comparative experimental results of different methods on the IEMOCAP dataset as presented in Table I. As shown, the proposed model achieves a Weighted-F1 score of 69.50, surpassing the second-best SACL-LSTM model by 0.28%. Similarly, it demonstrates superior Accuracy with a value of 69.47, outperforming SACL-LSTM by 0.39%.

TABLE I. COMPARATIVE EXPERIMENTAL RESULTS

Model	Weighted-F1	Accuracy
DialogueRNN	62.75	63.40
CoMPM	66.33	66.05
COGMEN	67.27	67.04
MM-DFN	68.18	68.21
GraphCFC	68.91	69.13
SACL-LSTM	69.22	69.08
MITG-CU	69.50	69.47

Fig. 5 provides comparison chart of F1-score and Weighted Average performance for different emotions. As can be seen in Fig. 5, the model achieves higher precision and recall in recognizing Emotion sad, indicating that the emotion of sad is the best among all emotions, while Emotion frustration exhibits relatively lower performance. Moreover, the F1-Score values for most emotions are clustered between 0.60 and 0.75, suggesting that the proposed model performs relatively balanced in most emotions and does not show extreme high or low values.

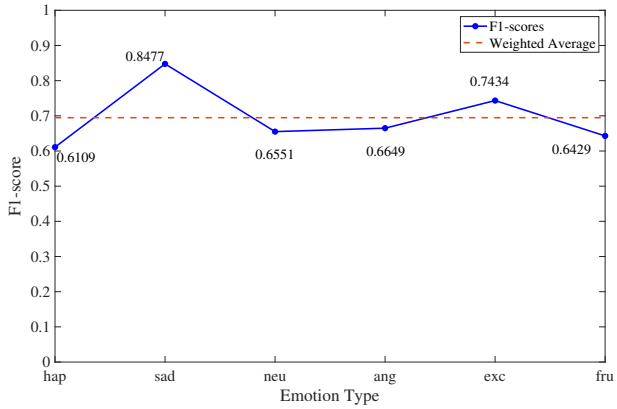

Fig. 5. Comparative chart of F1-scores and Weighted Average performance across different emotions.

The recognition results of different emotions on the IEMOCAP dataset are reported in Table II. As shown in Table II, the Macro-average F1-score is 0.6941, and the Weighted-average F1-score is 0.6947. The two scores are relatively close, indicating that the model has good stability and generalization ability across different emotion categories.

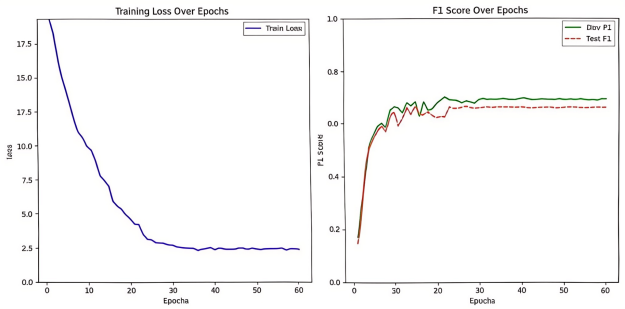

TABLE II. THE RECOGNITION RESULTS OF DIFFERENT EMOTIONS ON THE IEMOCAP DATASET

Model	Precision	Recall	F1-score
hap	0.5689	0.6597	0.6109
sad	0.8127	0.8857	0.8477
neu	0.6703	0.6406	0.6551
ang	0.6029	0.7412	0.6649
exc	0.7895	0.7023	0.7434
fru	0.6744	0.6142	0.6429
Macro-average	0.6864	0.7073	0.6941
Weighted-average	0.6986	0.6950	0.6947

As can be seen in Fig. 6, it can be observed that with the increase in the number of training epochs, the training loss decreases rapidly. This demonstrates that the model is constantly optimized during the learning process, and the fitting effect on the training data gradually enhances. In the early stage of training, the F1-score exhibits rapid growth, demonstrating the model maintains high accuracy while simultaneously improving recall, with its overall performance progressively enhancing throughout the learning process. After approximately 20 training epochs, the loss value plateaus, suggesting that the model has reached a good convergence state.

To comprehensively evaluate the performance of classification models, we analyzed the correspondence between the model's predicted outcomes and the true labels through comparison. As a result, the confusion matrix, which reflects the model's classification capability, is presented in Fig. 7.

As illustrated in Fig. 7, a strong positive correlation is observed between the F1 score and accuracy rate (0.97), which means that when F1 score increases, accuracy rate also tends

(a) Training loss (b) F1 score

Fig. 6. Training loss and F1 score variation curves.

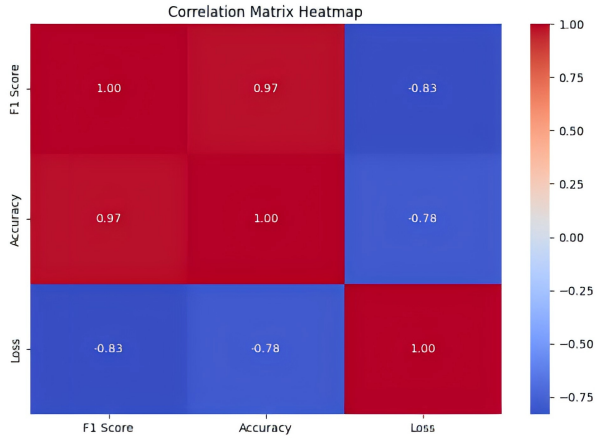

Fig. 7. Confusion matrix of evaluation indicators.

to increase. There is a strong negative correlation between F1 score and loss value (-0.83), indicating that as F1 score increases, loss value tends to decrease, which is what this model expects. This result shows that the model can improve the classification precision and recall while maintaining high overall prediction accuracy, demonstrating its balance and robustness in classification tasks.

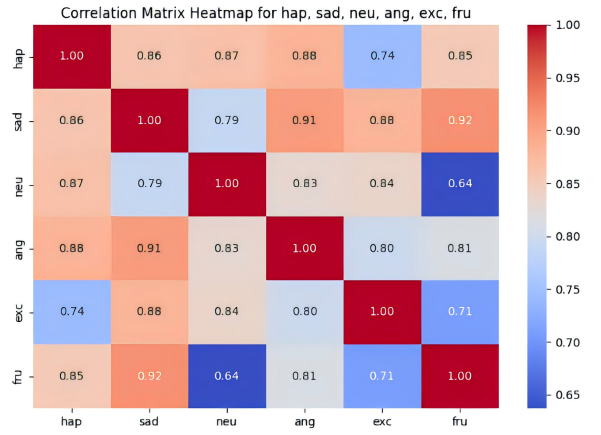

Fig. 8. Confusion matrix of various emotions.

The confusion matrix for various emotions as shown in Fig. 8. It can be observed from the confusion matrix that the correlation between emotional categories significantly impacts model performance. The high correlation (0.92) between sadness and frustration indicates significant confusion between them in the feature space, this suggests that their features are less distinguishable during emotion recognition. In contrast, the neutral emotions have higher feature distinguish ability and are less influenced by other emotions. Especially, its correlation with frustration is the lowest (0.64). The confusion matrices of various emotions not only provide a basis for the accuracy of emotion recognition, but also offer an important basis for the subsequent optimization of emotion models.

3) Ablation experiment: In order to further investigate the contributions of different components in the model, four ablation studies were designed on the IEMOCAP dataset in this paper. The base, no-CM, no-RGAT, and no-GAT respectively represent the ablation of the basic module, removing the cross-modal module from the model, removing the graph-time convolution module from the model, and removing the graph attention module from the model. The experimental results are shown in Table III.

TABLE III. THE ABLATION EXPERIMENTS CONDUCTED ON IEMOCAP

Module	**IEMOCAP**	
	*F*1	*Acc.*
base	69.50	69.47
no-CM	65.67	66.61
no-RGAT	66.26	66.67
no-GAT	65.89	66.42

As shown in Table III, our proposed MITG-CU method achieves the best performance on the two key metrics of F1 score and accuracy. Specifically, no-CM has the most significant impact on the model performance. Meanwhile, no-GAT also had a significant impact on the model performance. This indicates that the cross-modal module and the graph attention module are crucial for the model in capturing complex emotional features and improving classification performance.

The reproduced comparison results are reported in Table IV. The modalities include text (T), audio (A), and visual (V).

TABLE IV. THE PERFORMANCE OF MITG-CU IN DIFFERENT MODALITIES

Module	**IEMOCAP**	
	Acc.	*F*1
T	65.74	65.35
A	50.65	49.92
V	32.35	31.80
T+V	66.24	66.23
T+A	65.06	64.94
A+V	46.09	46.00
A+V+T	69.47	69.50

As illustrated in Table IV, when solely utilizing the textual modality (T), the model achieves the highest values in both accuracy (65.74%) and F1 score (65.35%). This result demonstrates that textual information plays a crucial role in the emotion recognition task. By comparison, the performance of the audio modality (A) is moderately effective, whereas the performance of the visual modality (V) is comparatively limited.

As demonstrated by the experimental results of bimodal combinations, the combination of textual modality and visual modality (T+V) achieved accuracy and F1-scores of 66.24%

and 66.23% respectively on the IEMOCAP dataset. Its performance is slightly better than that of the combination of textual modality and audio modality (T+A). The main reason for this is that some audio categories contain noise, which will affect the prediction results. The combination of audio modality and vision modality (A+V) exhibited the lowest performance.

In practice, the trimodal combination (T+A+V) achieves the best performance, with accuracy of 69.47% and F1-scores of 69.50%. This result indicates that multimodal fusion can significantly enhance the accuracy of emotion recognition.

V. Discussion

A. Comparison with Existing Results

The author in [26] proposed a multimodal fusion method based on deep graph convolutional networks. This method can effectively capture the context-dependent relationships in conversations through the construction of a graph structure. However, the fixed graph structure cannot adjust the weights of each modality in real time as the conversation progresses dynamically. according to the dynamic progress of the dialogue. This situation significantly reduced the accuracy of emotion change recognition, with an accuracy rate of only 65.56%. In [27] models the dynamic dependencies between speakers in conversations, thereby improving the accuracy of emotion prediction. This method simultaneously captures the internal dependencies within speakers, and the inter-speaker dependencies, thereby resolving the limitation of focusing solely on a single type of dependency. Nevertheless, this model is primarily designed for a unimodal setting (text), and lacks a mechanism for cross-modal fusion. As a result, its accuracy rate is limited to 66.29%.

In response to this situation, the proposed method can comprehensively integrate global information, local information, and the complementary relationships among different modalities. According to the contribution of each modality, the interaction weights between modalities are dynamically adjusted, thereby achieving information interaction and deep integration among modalities. Through ablation experiments, it can be found that either no CIM or no GAT will lead to a decrease in the F1 score and accuracy of the system to varying degrees. This indicates that the cross-modal module and the graph attention module are crucial for the model to capture complex emotional features and improve classification performance. Meanwhile, the impact of different modality combinations on model performance varies. As can be seen from Table IV, It can be concluded that textual modality plays a pivotal role in emotion recognition, while the integration of visual modality further enhances performance. Although the audio modality underperforms compared to textual and visual modalities when used in isolation, its combination with other modalities improves overall system performance. Moreover, the combination of textual, audio, and visual modalities (T+A+V) achieves optimal performance on the IEMOCAP dataset.

B. Limitations and Challenges of the Proposed Method

The cross-modal interaction mechanism incorporated in our model has proven effective. However, it cannot fully capture the optimal interaction mechanisms across all scenarios, due to the dependencies among complex sentences. Meanwhile, the multi-level interaction mechanisms increase the computational complexity, which may limit its application ability in real-time scenarios. Therefore, for future work, we will focus on further optimizing the cross-modal interaction mechanism and exploring lightweight methods to enhance its practical application value.

VI. Conclusion

The MITG-CU module proposed in this paper can precisely control the recognition of conversational emotions at both local and global levels. By effectively integrating the distinctive characteristics and complementary relationships among textual, audio, and visual modalities, and combining the relationship timeline module and cross-modal interaction mechanism, the proposed framework significantly enhances both the accuracy and robustness of emotion recognition.

The experimental results show that the MITG-CU model proposed in this paper outperforms six common baseline methods in terms of accuracy, precision, recall rate and F1 score. Especially, it has improved 0.28% and 0.39% in Weighted-F1 and Accuracy respectively. Especially when dealing with long-term conversations and complex emotional scenarios, our model demonstrates excellent stability and generalization capabilities. Future will focus on optimization of cross-modal interaction mechanisms to better meet emotion recognition needs in scenarios, including mental health monitoring and intelligent customer service. Furthermore, additional modalities will be introduced to further enhance the performance of the model.

***Abstract*—Large Language Models (LLMs) have demonstrated remarkable capabilities in generating human-like text; however, their effectiveness in abstractive summarization across diverse domains remains underexplored. This study conducts a comprehensive evaluation of six open source LLMs across four datasets: CNN / Daily Mail and NewsRoom (news), SAMSum (dialogue) and ArXiv (scientific) using zero shot and in-context learning techniques. Performance was assessed using ROUGE and BERTScore metrics, and inference time was measured to examine the trade-off between accuracy and efficiency. For long documents, a sentence-based chunking strategy is introduced to overcome context limitations. Results reveal that in-context learning consistently enhances summarization quality, and chunking improves performance on long scientific texts. The model performance varies according to architecture, scale, prompt design, and dataset characteristics. The qualitative analysis further demonstrates that the top-performing models produce summaries that are coherent, informative, and contextually aligned with human-written references, despite occasional lexical divergence or factual omissions. These findings provide practical insights into designing instruction-based summarization systems using open-source LLMs.**

***Keywords*—Large language models; natural language processing; automatic text summarization; prompt engineering; summarization evaluation**

I. Introduction

With the continued explosion of digital content from online news, scientific research, and conversational platforms, the demand for automated methods of condensed textual information has increased. Automatic Text Summarization (**ATS**) has become an essential tool in Natural Language Processing (NLP), reducing cognitive load and enabling users to quickly grasp key information quickly [1]. In recent years, the task of summarization has gained significance with the rise of Large Language Models (LLMs), which demonstrate remarkable fluency in generating human-like text across a variety of domains [2], [3].

Efforts in text summarization have evolved from traditional heuristic-based methods [4] to more sophisticated approaches to cover different types of text summarization including generic [5], domain-aware [6], multi-document [7], multimodal [8], extractive [9] and abstractive text summarization [10], [11]. Various techniques are used in text summarization to enhance the produced summary, including machine learning approaches [12], deep learning-based approaches [13], [14]. The advent of transformer-based models [15], [16] further advanced the quality of summarization by improving semantic understanding and text generation.

A major shift in NLP occurred with the development of instruction-tuned LLMs, which are pretrained on vast corpora and require no task-specific fine-tuning. Instead, they rely on prompt-based interactions, enabling paradigms such as zero-shot and in-context learning [17], [2]. Despite these advancements, there is limited understanding of how instruction-tuned, open-source LLMs perform across various domains of summarization—especially in contexts such as scientific documents and informal dialogues.

Prompt Engineering is a sophisticated AI engineering methodology [18]. This involves augmenting LLMs by giving them customized cues and modifying the source text to produce the intended result. Prompt engineering is crucial in LLMs because it is essential for unlocking the full potential of such models. In addition, prompt engineering uses prior knowledge and the logical reasoning of the input to influence the outputs generated by the Models [19]. Wide-ranging techniques have been developed as a result of recent notable advancements in the field of prompt engineering [20]. The range of these developments includes basic techniques and more advanced strategies intended to manage challenging jobs [21].

This work contributes to the NLP field by offering domain-aware benchmarking of LLMs under prompt-based conditions. This study also explores the relationship between model architecture, parameter count, and performance across different textual formats. Ultimately, the study provides practical insights for researchers and developers seeking to leverage LLMs for summarization tasks in real-world scenarios without relying on extensive fine-tuning pipelines. Our primary contributions are summarized as follows:

- An evaluation of six open-source LLMs across four benchmark datasets: CNN/DailyMail, NewsRoom, SAMSum, and ArXiv, providing insights into their cross-domain summarization abilities.
- A comparative assessment of prompting strategies, including Zero-Shot Learning (ZSL) and In-Context Learning (ICL), to evaluate the effect of prompt design, context length, and number of demonstrations on model performance.

- An empirical analysis of model scale and architecture to examine the impact of parameter size and design on summarization quality across different domains.
- A dedicated investigation of long-document summarization, introducing a chunking strategy to mitigate the limitations imposed by context window size, and evaluating its influence on summary coherence and quality.
- A detailed efficiency and cost analysis measuring inference time for each model, highlighting trade-offs between performance and deployment feasibility.

The remainder of this paper is organized as follows: Section II introduces related works on text summarization and LLMs. Section III describes in detail the experimental setup and methods, Section IV interprets the results, Section V provides Discussion, Finally, Section VI provides a concise conclusion and future work.

II. Literature Review

Text summarization research has evolved considerably , with two primary paradigms: extractive and abstractive summarization [4]. Extractive methods select sentences or phrases directly from the source document to form summaries [9], while abstractive approaches generate novel sentences by interpreting the core meaning of the input [10].

Early summarization systems, such as the Lead-3 baseline, extracted the first few sentences to generate reliable summaries for news datasets [22]. More advanced neural models treated sentence selection as a classification problem using hierarchical RNNs [23] or applied encoder-decoder architectures with attention mechanisms to improve sentence representation and relevance scoring [24]. The introduction of transformer architectures [25] further enhanced abstractive summarization by capturing long-range dependencies in text. Fine-tuning transformer-based models like BERT [26] for summarization tasks demonstrated strong performance in both extractive [27] and abstractive [28] settings.

State-of-the-art models like BART [29] and PEGASUS [30] have since advanced abstractive summarization. BART's bidirectional encoding and autoregressive decoding enables robust generation, while PEGASUS's gap-sentence generation objective improves content selection and coherence in generated summaries. Variants like Hi-BART further integrate hierarchical encoders to improve the structural understanding of long documents [31].

With the rise of LLMs, prompt-based summarization has gained traction. Instruction-tuned LLMs, such as GPT-3, LLaMA, and Mistral, demonstrate strong zero-shot and few-shot capabilities without the need for task-specific training [2]. Studies like [32] and [33] evaluated such models on standard datasets (e.g., CNN/DailyMail, XSum), demonstrating superior performance for models like text-davinci-003. Other research expanded this assessment to clinical summarization tasks and reported mixed results across radiology reports, patient dialogues, and medical questions [34].

Prompt Engineering is a sophisticated AI engineering methodology [18]. This involves augmenting LLMs by giving them customized cues and modifying the source text to produce the intended result. Prompt engineering is crucial in LLMs because it is essential for unlocking the full potential of such models. In addition, prompt engineering uses prior knowledge and the logical reasoning of the input to influence the outputs generated by the Models [19]. Wide-ranging techniques have been developed as a result of recent notable advancements in the field of prompt engineering [20].

Despite these advancements, long-document summarization remains a key challenge. Standard LLMs struggle to process entire scientific articles due to limited input windows. Techniques such as hierarchical summarization [7] and chunking [35] have been proposed to segment inputs and generate localized summaries prior to merging them. Although effective, these methods often introduce trade-offs between coherence and inference efficiency.

Our study advances previous works by systematically evaluating six open-source LLMs across diverse domains using both zero-shot and in-context prompting strategies. In contrast to studies focused on single-domain tasks or isolated techniques, we offer a unified assessment of summary quality and computational efficiency. In addition, we introduce and empirically evaluate a sentence-level chunking strategy for long document summarization that has not been evaluated systematically in text summarization across instruction-tuned models.

III. Methodology and Experimental Setup

This study evaluates the performance of open-source LLMs in text summarization across multiple domains. To ensure reproducibility, this section outlines the datasets, models, and inference settings used.

A. Datasets

We employed four benchmark datasets encompassing news, dialogue, and scientific texts, which were selected to enable comprehensive cross-domain evaluation. Dataset statistics are summarized in Table I.

1) CNN/Dailymail: The CNN/DailyMail dataset [36] comprises over 300 K news articles from CNN and the Daily Mail, which are commonly used for training and evaluating summarization models.

2) Cornell NEWSROOM: The NEWSROOM dataset [37] includes summaries from 38 news publishers collected via search and social media metadata (1998–2017), encompassing diverse summarization strategies across extractive and abstractive styles.

3) SAMSum corpus: SAMSum [38] contains 16 K annotated chat dialogues with human-written abstractive summaries, which were designed to support dialogue summarization in informal communication settings.

4) ArXiv dataset: The ArXiv dataset [39] features full-text research papers across disciplines such as physics, biology, and computer science, accompanied by human-generated abstracts. The long document structure poses significant challenges for LLM summarization.

In our experiments, we sampled 2 K test instances per dataset, except SAMSum, where all test samples were used.

For few-shot prompting, examples were drawn from each dataset's training set.

TABLE I. STATISTICS OF THE USED DATASETS (K=THOUSANDS)

Dataset	Domain	Documents			Sum Len
		Train	Valid	Test	(words)
CNN/DM	News	287K	13K	11K	52
NEWSROOM	News	995K	108K	108K	26
SAMSum	Dialogue	14K	818	819	–
ArXiv	Scientific	203K	6K	6K	220

B. Prompt Engineering Techniques

As introduced in Section I, prompt engineering involves crafting input instructions to guide LLM behavior. This study applies two primary strategies—**zero-shot learning (ZSL)** and **in-context learning (ICL)**—to investigate how prompt formats affect summarization performance across different models and datasets.

1) Zero-Shot Learning (ZSL) [40]: ZSL is the simplest form of prompting, where a model receives only natural language instructions without any prior examples. The model relies entirely on internal knowledge to perform the task. Formally, a ZSL prompt can be expressed as follows:

$$P = f_{\text{prompt}}(\text{TD}, x_{\text{test}}) \tag{1}$$

where:

- TD is the task description,
- x_{test} is the test input,
- f_{prompt} is the function that transforms these into a natural language prompt.

2) In-Context Learning (ICL) [41]: In ICL, the model observes a few input-output pairs (demonstrations) directly in the prompt and then predicts the output for a new test input. This process can be described as follows:

$$P(y_{\text{test}} \mid x_{\text{test}}, D_k) = \text{LLM}([x_1, y_1, \ldots, x_k, y_k, x_{\text{test}}]) \tag{2}$$

where $D_k = \{(x_1, y_1), (x_2, y_2), \ldots, (x_k, y_k)\}$ denotes k demonstrations. The LLM uses these in-context examples to condition its prediction for x_{test} without updating model parameters.

C. Large Language Models Selection

This study focuses on autoregressive language models—specifically decoder-only architectures—which have become the dominant paradigm in open-source LLM development (Table II). These models generate text by sequentially predicting the next token based on preceding tokens; thus, they are well-suited for text generation tasks, such as summarization. Unlike sequence-to-sequence models, which use an encoder-decoder framework and were originally designed for translation [42], autoregressive models rely solely on a decoder and are optimized for unsupervised learning and generative tasks [43].

We evaluated six decoder-only models, including three from the LLaMA-2 family [44]—LLaMA-2-7B-chat, LLaMA-2-13B-chat, and LLaMA-2-70B-chat—to investigate the effect of scaling on summarization performance. These models are widely adopted due to their open-source availability and strong instruction-tuning capabilities.

In addition, we include Mistral-7B-Instruct-v0.1 [45] and Gemma-7B-it [46], both lightweight instruction-tuned models with 7B parameters. To explore architectural variations, we incorporated Mixtral-8x7B-Instruct-v0.1 [47], a 47B-parameter Mixture-of-Experts (MoE) model that activates only relevant subnetworks during inference, thereby reducing computational costs [48].

This curated selection enabled both intra-scale comparisons between the 7B models and cross-scale evaluations involving larger models. By analyzing these models under uniform evaluation settings, we assess how instruction tuning, architectural innovations, and scaling affect summarization quality and efficiency.

Proprietary models were excluded to ensure reproducibility and mitigate biases associated with closed-source data or opaque updates. The experiments were conducted on two NVIDIA A100 GPUs using mixed-precision (fp16), model parallelism, and quantization techniques to optimize memory usage.

TABLE II. CHARACTERISTICS OF DIFFERENT LLMS UTILIZED IN OUR WORK

Model Name	# Parameters	Context-Length
Llama-2-7b-chat	7B	4K
gemma-7b-it	7B	8K
Mistral-7B-Instruct-v0.1	7B	8K
Llama-2-13b-chat	13B	4K
Mixtral-8x7B-Instruct-v0.1	47B	32K
Llama-2-70b-chat	70B	4K

D. Long Document Processing via Chunking Strategy

Summarizing long documents, such as scientific papers from the ArXiv dataset, presents challenges due to the limited context window of LLMs. Initially, we addressed this by trimming articles to fit the model's maximum context length. Although effective for compatibility, this approach risks omitting important details.

Although extended-context models offer potential solutions, they are not universally available or efficient. To address this issue, we adopt a chunking strategy that divides documents into semantically coherent segments—such as paragraphs or fixed-length chunks. Each chunk is summarized independently, and the resulting summaries are then merged and refined to form a coherent global summary [49].

To improve chunk relevance, we used the Natural Language Toolkit (NLTK)[1] to segment documents into sentences. This

[1]https://www.nltk.org/

ensures semantic integrity in each chunk and ensures that key content is retained during summarization. This process allows for effective handling of long documents while aligning with the input constraints of the models.

E. Evaluation Metrics

The evaluation of summarization quality requires robust metrics that capture both surface-level similarity and deeper semantic alignment. Accordingly, we employ two metric categories: **Word Overlap** and **Semantic Similarity**.

1) Word overlap metrics: These metrics compare the token overlap between the generated and reference summaries. We adopt ROUGE [50], a standard suite for this purpose.

ROUGE-N measures the overlap of n-grams (contiguous sequences of n words) between the system and reference summaries, which indicates lexical similarity.

ROUGE-L evaluates the Longest Common Subsequence (LCS) between summaries, reflecting structural and sequential alignments.

Higher ROUGE scores suggest greater textual overlap and structural resemblance to reference summaries.

2) Semantic similarity metrics: These metrics assess how well a summary preserves the meaning of the original text. We use BERTScore [51], which leverages contextual embeddings from BERT [26] to compute token-level semantic similarity.

Unlike ROUGE, BERTScore captures nuanced paraphrasing and long-range dependencies by evaluating contextual token embeddings. In addition, it excels when n-gram methods are short, particularly in abstractive summarization scenarios.

F. Inference Parameters

This section outlines the inference settings and prompt configurations used in our experiments. Given that the underlying mechanisms of ZSL and ICL were previously detailed, we focused on their practical deployment and tuning.

For ZSL, we employed diverse task-specific prompts tailored to each dataset. In ICL, we varied the number of demonstrations: 1, 3, 5, and 7 to explore the trade-off between contextual guidance and token budget, guided by previous studies [41], [35].

Temperature is a critical generation hyperparameter that controls randomness during decoding [52]. Lower values yield more deterministic and factual outputs, whereas higher values encourage diverse but potentially less accurate generations. Before the full evaluation, temperatures of 0.1, 0.5, and 0.9 were tested. The results in Table III indicate that 0.1 consistently produced the highest ROUGE scores, especially ROUGE-L; thus, it was adopted for all final evaluations.

To leverage the potential of LLMs with ZSL, the different models are guided using a variety of prompts, aiming to assess the results across different prompts to fully utilize the models' capabilities. The prompts are customized based on the diversity of each dataset to provide summaries and assess the output of each model against the reference summaries. The prompts for zero-shot prompting are available in Table IV.

TABLE III. PERFORMANCE ACROSS ALL DATASETS AND TEMPERATURE VALUES. P=PRECISION, R=RECALL, F1=F1-SCORE, RL=ROUGE-L. BOLD VALUES INDICATE BEST PERFORMANCE PER METRIC GROUP

Temp	Metric	Dataset	P/R1	R/R2	F1/RL
0.1	BERT	CNNDM	88.76	86.13	87.41
		NewsRoom	86.99	**87.67**	**87.31**

		NewsRoom	24.28	80.01	18.91
		SAMSum	39.34	14.36	30.53
		ArXiv	39.29	12.19	21.61

IV. RESULTS

This section presents the performance of the evaluated LLMs in producing accurate and coherent summaries. All generated outputs were cleaned to eliminate noise and formatting artifacts before evaluation.

A. Comparison of Prompting Techniques

We evaluated the impact of prompting strategies—ZSL and ICL—on summarization performance across different models and datasets. This analysis highlights how prompting format influences the quality and consistency of the generated summaries.

1) ZSL Results: Multiple zero-shot prompts were tested to instruct the models to generate concise summaries without training examples. Fig. 1 shows the comparative performance of LLMs using BERTScore F1 and ROUGE-1 metrics on the four datasets. Subfigure (a) presents BERTScore F1; (b) presents ROUGE-1.

a) CNN/DM Results in ZSL: [2] Table III summarizes the prompt types tested. As shown in Table V, the results can be explored in two ways:

(i) Length-constrained prompts (e.g., Prompts 3, 4, 5), which restrict summary length based on the dataset's average (see Table I); and

(ii) Structured prompts, which provide directive phrasing to guide model output without specifying length.

[2]Only top-performing prompts are shown. Full list available at: https://anonymous.4open.science/r/TextSummarizationCode-5BCB/README.md

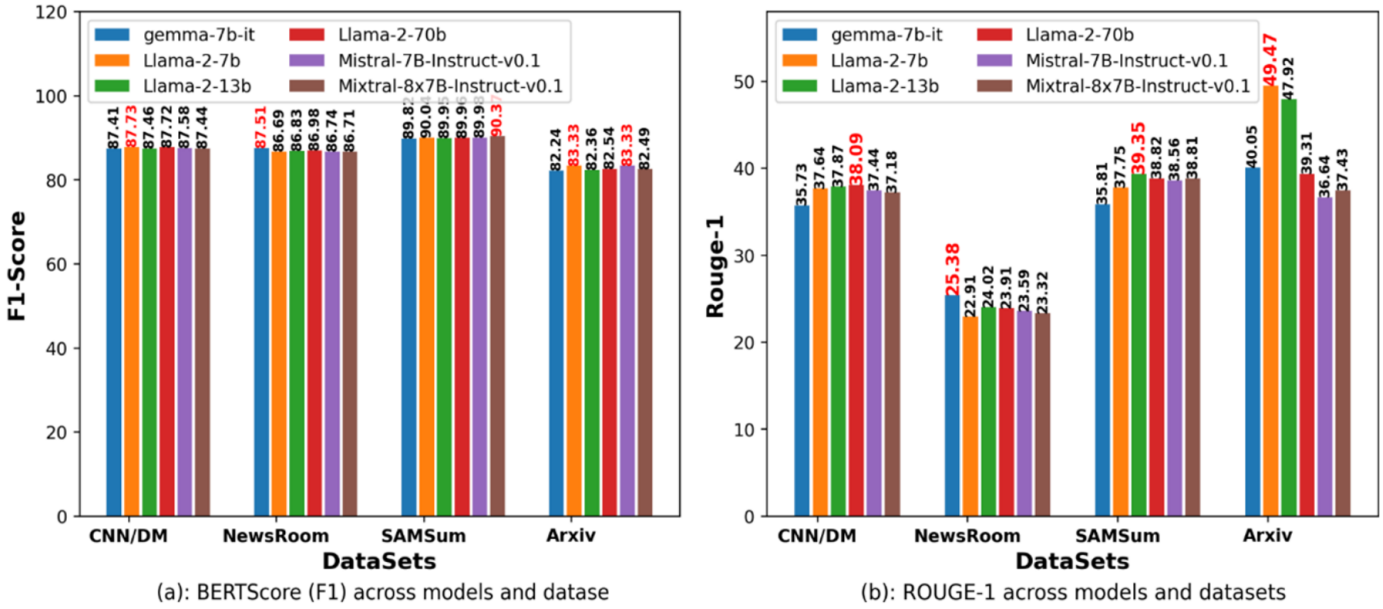

Fig. 1. Performance of LLMs across datasets in the zero-shot setting. X-axis: datasets; Y-axis: ROUGE-1 and BERTScore F1 scores.

These variations help assess how instruction format impacts zero-shot summarization performance.

Comparing models on the same prompt shows that Mistral-7B-Instruct-v0.1 achieved the best ROUGE score on Prompt#1. For BERTScore, Llama-2-70B-chat leads in Recall and F1, while Llama-2-13B-chat scores highest in Precision. Prompt#2 results favor Llama-2-13B-chat across all metrics except Recall, where Llama-2-7B-chat excels. Prompts 3 and 4, being more descriptive, yield varied performance: Mistral-7B and Llama-2-70B lead in ROUGE, while BERTScore is shared among gemma-7b-it, Llama-2 variants, and Mistral-7B, highlighting that some models capture semantic meaning well even if lexical similarity is lower.

Comparing prompts within each model shows that gemma-7b-it performed best on Prompt#3, with top scores in ROUGE-1, ROUGE-L, and BERTScore F1. The Llama-2-7B and Llama-2-13B chats achieved the highest metrics with Prompts#5 and #2 respectively. For Mistral-7B-Instruct-v0.1 and Mixtral-8x7B-Instruct-v0.1, Prompts#3 and #2 are most effective, with Mixtral also showing strong F1 with Prompt#5. These findings underscore the critical role of prompt design in shaping LLM performance.

b) NewsRoom results in ZSL: The NewsRoom dataset includes both extractive and abstractive summaries. In this study, we focus solely on articles with abstractive summaries to align with the goal of evaluating the LLMs' ability to generate coherent, human-like outputs [37]. This provides a more rigorous benchmark for testing generative capabilities. Table VI presents the ZSL results for all models and prompts.

In BERTScore, gemma-7b-it consistently performed well, achieving the highest Precision (86.99), Recall (87.67), and F1 (87.31) with Prompt#1. Llama-2-70B-chat closely follows, particularly in terms of F1 score (86.97), while Mistral-7B-Instruct-v0.1 excels in Recall (88.17) and Precision across several prompts.

For ROUGE, gemma-7b-it again leads with top scores in ROUGE-1 (25.38), ROUGE-2 (8.82), and ROUGE-L (19.96) using Prompt#1. Llama-2-13B-chat and Llama-2-70B-chat demonstrated competitive ROUGE scores across prompts, while Mistral-7B-Instruct-v0.1 achieved its highest ROUGE-1 (23.59) also with Prompt#1.

Overall, Prompts#1 and #2 yield the highest ROUGE and BERTScore results for most models, likely due to their clear and direct instructions. Slight variations in other prompts result in marginally lower performance, illustrating how prompt phrasing influences model output.

In summary, gemma-7b-it performed best on BERTScore, Llama-2-70B-chat demonstrated robust performance across prompts, and Mistral-7B-Instruct-v0.1 proved versatile with strong scores in both lexical and semantic metrics, particularly under well-structured prompt settings.

c) SAMSum results in ZSL: The proposed SAMSum dataset presents challenges for LLMs because of its conversational structure. Table VII compares model outputs for different prompts. The models achieved higher ROUGE scores on news datasets, reflecting the distinct nature of dialogue summarization.

The BERTScore and ROUGE metrics generally agreed. Mixtral-8x7B-Instruct-v0.1 achieved the highest BERT F1 with Prompts#2 and #4, while Llama-2-13B-chat yielded the top ROUGE-1 scores with the same prompts, reinforcing metric consistency.

Simpler prompts (e.g., Prompts#1 and #2) lead to higher ROUGE scores across models, suggesting that clear, concise instructions are more effective. The descriptive prompts (#3–#5) show mixed performance, indicating that overly detailed instructions did not always enhance the results.

Overall, Mistral-7B-Instruct-v0.1 demonstrated robust performance across prompts, demonstrating adaptability for sum-

TABLE IV. COMPLETE LIST OF ALL PROMPTS USED ACROSS DATASETS (P=PROMPT). FULL TEXT PRESERVED EXACTLY

ID	Prompt Text
CNN/DailyMail Prompts	
P#1	Write a concise and comprehensive summary of this news article.
P#2	Provide an abstract of this news article in a direct and concise summary.
P#3	I want you to act as a text summarizer to help me create a concise summary of the provided text. The summary can be up to 3 sentences in length, expressing the key points and concepts written in the original text without adding your interpretations.
P#4	I want you to act as a text summarizer to help me create a concise summary of the provided text. The summary can be up to 2 sentences in length, expressing the key points and concepts written in the original text without adding your interpretations.
P#5	Please summarize the following news article in an informative extractive summary with two sentences.
NewsRoom Prompts	
P#1	Summarize this news article in one sentence.
P#2	Write a concise and comprehensive summary of this news article in one sentence.
P#3	I want you to act as a text summarizer to help me create a concise summary of the following article.
P#4	Provide an abstract of this news article in a direct and concise summary in a few words.
P#5	You are a helpful assistant. Please summarize the following text in one sentence.
SAMSum Prompts	
P#1	Summarize the following dialogue.
P#2	Summarize the following dialogue in a few words.
P#3	Summarize the following dialogue into an abstractive summary without any explanation.
P#4	In short, what's going on in this conversation?
P#5	Summarize the following conversation.
P#6	Summarize this conversation in one or two sentences.

P#4	Given this research article, create a TLDR to be used as a formal abstract for this paper.

marizing dialogues. Llama-2-13B-chat also performed well, particularly with direct prompts, indicating its suitability for concise summarization.

d) ArXiv results in ZSL: The ArXiv dataset includes scientific papers and human-written abstracts; thus, it is ideal for testing abstractive summarization. Because of the context-length limitations, documents were trimmed before inference. Table VIII presents model performance across prompts.

Prompt#2 consistently yields high ROUGE scores, especially for Llama-2-13B-chat and Mistral-7B-Instruct-v0.1, demonstrating its effectiveness in guiding models to capture key information. Prompt#3 performs well in F1/RL scores, indicating the value of explicit summarization instructions. Prompt#4 balances BERT and ROUGE scores, helping models generate concise and relevant abstracts. Overall, the ROUGE scores varied more than the BERT scores, highlighting differences in lexical alignment across models.

Llama-2-7B-chat performed best overall, particularly on Prompt#2, confirming its strength in abstractive summarization. Mistral-7B-Instruct-v0.1 excels with Prompt#3, demonstrating consistency in semantic capture. In contrast, gemma-7b-it outperformed the other models, which suggests its limitations in handling longform texts. The variability across prompts and metrics underscores the complexity of long-document summarization and the impact of input trimming on model comprehension.

2) ICL Results: ICL uses example-summary pairs to guide models in generating new outputs. Based on the prompt formulation in Section III, we evaluate ICL performance on each dataset.

a) CNN/DM results in ICL: Table IX presents results with varying numbers of demonstrations. BERT metrics are relatively stable across shot counts, with minor gains from more examples. ROUGE metrics show greater sensitivity: Mistral-7B, Mixtral-8x7B, and Llama-2-70B benefit notably as shots increase.

Llama-2-70B-chat achieves the highest overall scores with 7-shot prompts, and it excels in both BERT and ROUGE. Mixtral-8x7B also performs well. Gemma-7b-it shows limited gains from more demonstrations, indicating constraints in leveraging ICL effectively.

b) NewsRoom results in ICL: Table X summarizes the ICL results obtained on the NewsRoom dataset. **Mixtral-8x7B-Instruct-v0.1** shows the most consistent improvement, particularly with 5-shot prompts, achieving strong performance in both ROUGE and BERTScore metrics. The ROUGE scores varied more across shot counts than the BERT metrics. The Llama family models performed competitively, especially in 7-shot settings, although they were slightly less consistent across fewer examples. Overall, increasing the number of demonstrations generally enhanced the performance across the models.

c) SAMSum results With ICL: when working with ICL on the SAMSum dataset, Table XI showed that **Mixtral-8x7B-Instruct-v0.1** got the best results in terms of BERTScore and Rouge score with seven examples to learn from, which means that it learned the context of the dialogues better than others. The more examples given to the model, the more the result improved, Table XI shows that the results improved when the number of demonstrations in most models was increased.

d) ArXiv results in ICL: Table XII shows ICL results obtained on the ArXiv dataset. Across varying numbers of demonstrations, the **Llama** models consistently outperformed the other models in terms of both ROUGE and BERT metrics. The performance generally improved as the number of in-context examples increased, reflecting better adaptation to the complex summarization task. However, due to input trimming (required by context length constraints), variations in model performance are more pronounced, as some models may struggle to retain contextual coherence after truncation.

e) Overall comparison (ICL vs. ZSL): ICL consistently enhances LLM performance across datasets compared to ZSL by providing contextual demonstrations that improve task understanding. Our experiments demonstrate that increasing the number of in-context examples leads to steady performance

gains, particularly for the ROUGE and BERT metrics. These findings underscore the importance of demonstration-based prompting, reinforcing ICL's effectiveness in leveraging LLM capabilities for summarization.

B. Comparisons with State-of-the-Art Models

To situate LLMs within the broader landscape of text summarization, we compared their results with earlier state-of-the-art neural models across datasets Tables XIII and XIV. We focus on the highest-performing LLMs in our study in each dataset and contrast them with earlier existing models.

On news summarization (CNN/DM, NEWSROOM) in Table XIII, LLMs like Llama-2-70b-chat underperform models such as PEGASUS but eliminate dataset-specific training costs, as seen in Gemma-7b-it's NEWSROOM results.

For dialogue summarization, Table XIV shows that while Mixtral-8x7B demonstrates moderate performance, it slightly lags behind specialized models like SICK. This suggests that LLMs require further optimization for conversational coherence. On scientific documents, Table XIV shows that Llama-2-7b-chat achieves a high ROUGE-1 (49.74) but struggles with coherence (ROUGE-L: 33.98), reflecting sensitivity to prompts and context truncation.

These results highlight LLMs' potential for multi-domain adaptability but underscore the need for tailored prompts and hybrid architectures to balance semantic flexibility with syntactic precision.

C. Summarization with Chunking Strategy

To evaluate the impact of chunking, we tested it on the ArXiv dataset. Table XV reports ROUGE-1 and BERTScore F1 results before and after applying chunking.

Results show notable improvements for the Llama-2-70B-chat and Mixtral-8x7B-Instruct-v0.1 models in terms of both lexical and semantic metrics. However, models like Llama-2-13B-chat and gemma-7b-it did not consistently benefit, which

indicates that the chunking effectiveness may depend on the model architecture and input handling.

V. DISCUSSION

A. Prompt Diversity and In-Context Learning Effects

The datasets used in this study span distinct summarization domains—news (CNN/DM, NewsRoom), scientific documents (ArXiv), and dialogues (SAMSum)—each requiring tailored summarization strategies. To account for this variability, multiple prompts were designed and tested for each dataset to explore their influence on LLM behavior.

Fig. 2 illustrates how prompt variation affects ZSL performance. The results confirm that LLMs are highly sensitive to prompt phrasing: some prompts elicit more effective responses, improving both lexical and semantic quality, whereas others underperform. This highlights the critical role of prompt formulation in guiding LLMs across domains.

Our findings also demonstrate the adaptability of LLMs to different prompts and tasks. Their ability to generalize without fine-tuning highlights the potential of prompt engineering as a flexible tool. In addition, in-context learning (ICL) significantly boosts performance by providing demonstration pairs, especially as the number of examples increases. This reinforces the value of contextual learning in terms of improving model comprehension and summary generation quality.

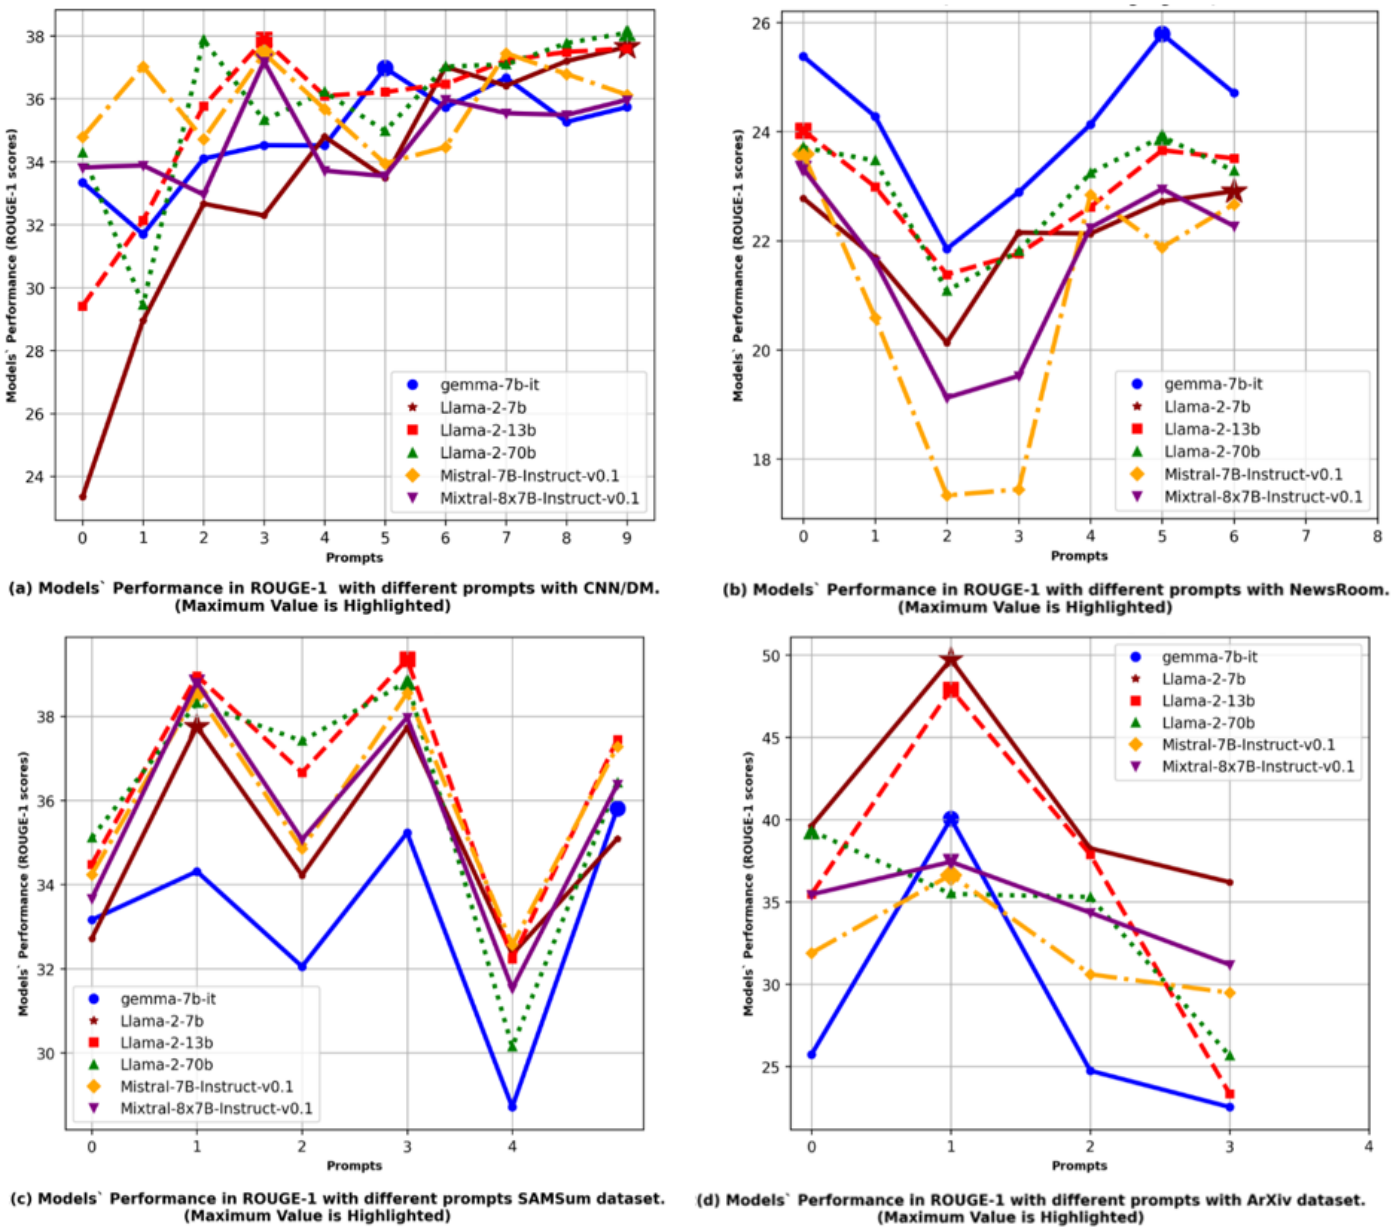
Mixtral-8x7B	37.43	**40.02**	84.73	**87.16**

B. LLMs in Summarizing Long Documents



As shown in Table XV, chunking improved summarization performance—particularly ROUGE-1 and BERTScore—for models like Llama-2-70B-chat and Mixtral-8x7B-Instruct-v0.1, indicating better preservation of contextual and semantic content. In contrast, models such as Mistral-7B-Instruct-v0.1, Llama-2-13B-chat, andgemma-7b-it showed minimal or inconsistent gains, which suggests that the chunking effectiveness varies according to the model architecture and context handling capabilities.

While chunking helps retain key information in lengthy inputs and improves final summary quality, it introduces additional inference overhead. This trade-off between performance and efficiency is particularly important when processing long-form scientific texts like those in the ArXiv dataset.

C. Comparison of Generated Summary Lengths with Reference Summaries

Another analysis is conducted regarding the results summaries generated from the employed models to gain more insight into the results. Hence, the lengths of the generated summaries were compared to those of the reference summaries for all datasets used in this study. Table XVI offers a summary of the average lengths of the summaries produced by each model when given different prompts, together with the reference summary lengths for each dataset. The average length was calculated by taking the average lengths of the resulting summaries across the different prompts used. The average lengths of the generated summaries demonstrate that the LLMs do not consistently generate summaries that are comparable to the reference summaries. The results demonstrate that most models generate summaries that are longer than the reference summaries.

Overall, these findings imply that the strengths and weaknesses of various models vary according to the dataset characteristics, in addition to model's length, number of parameters, and prompt building, as previously described. For instance, Llama-2-13b-chat excels in producing summaries that are nearly the reference length for datasets like SAMSum and ArXiv, and gemma-7b-it consistently generates succinct summaries for most datasets.

(a) Models` Performance in ROUGE-1 with different prompts with CNN/DM. (Maximum Value is Highlighted)

(b) Models` Performance in ROUGE-1 with different prompts with NewsRoom. (Maximum Value is Highlighted)

(c) Models` Performance in ROUGE-1 with different prompts SAMSum dataset. (Maximum Value is Highlighted)

(d) Models` Performance in ROUGE-1 with different prompts with ArXiv dataset. (Maximum Value is Highlighted)

Fig. 2. Change in models' performance in ROUGE-1 across datasets using multiple prompts in zero-shot prompting.

However Mistral-7B-Instruct-v0.1 shows a tendency to produce longer summaries that may risk verbosity in an attempt to capture more detail. Consequently, the characteristics of the particular dataset and the intended ratio of detail to conciseness should be taken into account when choosing a model for a summarization task. In conclusion, there is a trade-off between verbosity and the efficiency of the generated summaries when using LLMs for ATS, and this trade-off affects how well these summaries are evaluated in comparison to reference summaries.

D. Variation in LLM Performance: Insights and Contributing Factors

Performance variations across models and datasets reflect the complexity of summarization tasks. Larger models—such as Llama-2-70B-chat and Mixtral-8x7B—tend to perform better, especially on complex datasets like CNN/DM and ArXiv; however, this trend is not universal [53], [54].

Prompt design significantly affects performance. Here, structured, summary-specific prompts generally yield more relevant and coherent outputs than open-ended queries. ICL further enhances model understanding by providing context-rich demonstrations, and performance improves as the number of examples increases [41].

However, no single factor alone accounts for performance differences. Instead, the interplay among model size, architecture, prompt formulation, and demonstration count shapes summarization quality. Continued investigation is needed to isolate and optimize these factors for improved LLM perfor-

TABLE XVI. AVERAGE GENERATED SUMMARY LENGTHS OF LLMS COMPARED TO REFERENCE SUMMARY LENGTHS

	Datasets			
Models	**CNN/DM**	**NewsRoom**	**SAMSum**	**ArXiv**
gemma-7b-it	**53.584**	**27.672**	44.722	143.31
Llama-2-7b-chat	83.456	56.8	47.534	289.3575
Llama-2-13b-chat	65.706	47.67	**39.308**	**208.825**
Llama-2-70b-chat	71.864	44.832	40.45	200.4975
Mistral-7B-Instruct-v0.1	108.056	60.46	48.098	168.57
Mixtral-8x7B-Instruct-v0.1	83.704	45.07	46.528	204.71
Reference Length (#Words)	**52**	**26**	**22**	**220**

mance on abstractive summarization tasks.

E. Qualitative Analysis of Generated Summaries

We further analyzed the summaries of the top-performing CNNDM, NewsRoom, and SAMSum models. Key qualitative observations are:

1) Content coverage: Despite lexical differences, summaries often capture core meanings and key facts. Many outputs paraphrase reference summaries while retaining relevance.

2) Coherence: Most outputs maintain logical flow and clarity, even with varied stylistic choices, reflecting LLMs' capacity for fluent text generation.

3) Error patterns: Common issues include omissions, factual distortions, and overgeneralizations (e.g., "more than 200 people" simplified as "a large crowd"). NewsRoom outputs sometimes misstate facts; CNNDM examples show reduced specificity.

In conclusion, LLM-generated summaries generally preserve the intended meaning and demonstrate strong contextual relevance, even when they diverge from human-written references in phrasing. This illustrates their potential to produce effective abstractive summaries.

F. Inference Time Analysis

We also measured the average inference time required by each model to generate summaries across the datasets. Table XVII shows these results.

TABLE XVII. AVERAGE INFERENCE TIME (SECONDS) PER ARTICLE ACROSS MODELS AND DATASETS

Model	CNN/DM	NewsRoom	ArXiv	SAMSum
Llama2-7b-chat	23.34	25.1	61.2	11.5
Llama2-13b-chat	25.7	30.3	68.8	14.9
Llama2-70b-chat	80.6	95.2	148.4	30.7
Gemma-7b-it	21.1	23.8	63.4	10.2
Mistral-7b-instruct	17.9	20.5	52.9	8.3
Mixtral-8×7b-instruct-v0.1	31.5	36.8	100.3	15.4

Three key patterns emerged: (1) Larger models incur higher latency—e.g., Llama2-70B-chat significantly outpaces its smaller variants; (2) Inference time scales with input length—ArXiv documents take longer to process than shorter SAMSum dialogues; and (3) Architectural optimization matters—Mixtral-8x7B, despite its size, is faster than Llama2-70B on ArXiv due to its sparse MoE design.

These findings emphasize the trade-off between performance and efficiency and highlight the need to balance quality and latency in practical deployments.

VI. CONCLUSION

This study presents a comprehensive evaluation of locally hosted LLMs on news, dialogue, and scientific text summarization tasks using zero-shot learning (ZSL), in-context learning (ICL), and chunking strategies. Our findings highlight several key insights. First, LLM performance varies significantly across domains and models. While models like Mixtral-8x7B-Instruct and Llama-2-70B-chat demonstrated strong results in dialogue and scientific summarization, smaller models such as Gemma-7b-it struggled with long-form inputs. Second, ICL consistently outperformed ZSL in terms of providing contextual examples, which resulted in improved lexical and semantic alignment. Third, the chunking strategy proved beneficial for handling long scientific documents, particularly enhancing outputs from models constrained by limited context windows. Additionally, qualitative analysis of the generated summaries revealed that many LLMs effectively preserved the intended meaning and maintained contextual coherence even when their outputs diverged lexically from human references. Common error patterns—such as omissions, generalizations, and factual distortions—were identified, providing further guidance for model refinement and deployment. Performance differences were influenced by factors such as models architectural considerations, scale, prompt tuning, and the number of in-context examples. Overall, this work underscores the promise of open-source LLMs as adaptable tools for abstractive summarization and offers both quantitative and qualitative insights into their effective use across varied textual domains. Future research could examine optimizing LLMs for domain-specific summarization, particularly for long-form scientific texts where chunking introduces coherence challenges. In addition, exploring retrieval-augmented and integrating external knowledge sources may improve factuality and context awareness. Optimizing the inference efficiency in real-time or low-resource environments will continue to be a crucial area for practical deployment considerations.

***Abstract*—In the world of modern software development, microservices architecture has become increasingly popular due to its ability to help developers to build large and complex applications that are more agile, faster and more scalable. In large scale applications (such as e-commerce, healthcare, finance, social media, inventory management, travel booking, content management, and customer relationship management systems etc.) with many interconnected services, it is tough to keep the data accurate and consistent. The concept of referential integrity is applied to validate the data. Referential integrity refers to the preservation of relationships between tables. In a monolithic architecture, where the application and database are closely linked and co-located on the same server, referential integrity via foreign key constraints makes it feasible to preserve consistent and accurate data. But in the microservices architecture, maintaining referential integrity across distributed databases poses significant challenges due to its decentralized nature of data management. This study utilizes a hybrid research methodology, combining empirical research and design science research to discover and address the challenges of maintaining referential integrity in distributed databases in microservice architecture and calculate the response time by comparing and analyzing with existing models. The results of the evolution in term of response time are presented in this work.**

***Keywords*—Foreign key constraints; relational mapping; referential integrity; saga pattern; event driven architecture; APIs; microservice; distributed database**

I. Introduction

In modern cloud-native applications, distributed databases are an important part of microservices architecture, as they offer availability, reliability and scalability [1]. In large application with many interconnected links, it's hard to keep the data correct and consistent. For that the concept of "Referential integrity Constraints" is used to keep the data correct.

In a monolithic architecture, where the application and database are closely linked and co-located on the same server, referential integrity via foreign key constraints makes it feasible to preserve consistent and accurate data [2]. But in the microservices architecture, maintaining referential integrity across distributed databases poses significant challenges due to its decentralized nature of data management.

A. Database in Monolithic Architecture

Monolithic architecture is an outdated software design method where whole application or system is made as a single, interconnected unit [3]. In this architectural style, all the components, modules, and functionalities of the application are tightly integrated and run as a single codebase within a single process [4]. In monolithic architecture, CRUD operations directly perform in centralized relational database [5]. When new data is Create into a table that contains a foreign key column, the referenced value should first be checked to ensure that it exists in the referenced table's primary key. If not, the data is not allowed. For Read operation, foreign keys don't affect the process directly, but they help to make sure the data is correct. When deleting data from a parent table that is referenced by a foreign key constraint in another table, database checks if related child record exist. It can either delete the child records or stop the deletion too, depending on the rules. When updating data in the parent table, database updates the related records according to rules or stop the change to avoid breaking the link.

A monolithic system is hard to grow and update quickly because all components and modules are tightly connected. This approach contrasts with modern microservice architecture for handling large applications which offer better availability, well organized use of resources and scalability, making them a better option.

B. Distributed Databases in Microservices Architecture

Large-scale applications can be developed by dividing them into smaller, autonomous services thanks to microservices architecture [6]. These services have their own unique business logic and database. Each service is updated, tested, deployed, and scaled independently of the others [7]. This method frequently makes use of databases with different schemas, shared database, and distributed databases, each of which fulfills a distinct purpose. Shared database and databases per service are the two primary categories of distributed database. When it comes to databases for individual services, every microservice has a unique database [8].

1) Shared databases in microservices architecture: In a shared database approach, all services use a single database.

This means that multiple services can write data to the same database, and each service has access to data written by the other services. Services can conveniently access and share data since they all contribute to the same database [9]. With all services operating within a single database for reading and writing, data sharing is simplified. This eliminates the need for complex data synchronization or replication procedures, as all services have direct access to the same dataset.

In a shared database model, multiple microservices access and function on the same database. Although this simplifies data consistency and relational integrity implementation, it basically violates key microservices principles such as service autonomy, scalability, and independent deployment.

Service autonomy is negotiated because microservices become tightly coupled through the shared schema, meaning that changes in one service's database tables can accidentally impact others. This dependency increases the risk of breaking changes and requires coordinated deployments, reducing the flexibility and agility that microservices are meant to provide. Scalability is also stuck, as the shared database can become a bottleneck; scaling services independently is more challenging when all trust on the same data store. Moreover, operational complexity grows when services must negotiate over shared resources, and fault isolation becomes difficult. If one service causes a database failure or locks essential tables, it can affect all other services connected to that database. These limitations run contrary to the core goals of microservices architecture, which emphasize loose coupling, independent scaling, resilience, and continuous delivery. Therefore, while the shared database approach may offer short-term gains in performance and development simplicity, it imposes long-term constraints on maintainability, scalability, and system robustness.

2) Databases per service in microservices architecture: In the database-per-service pattern within a distributed database architecture, each microservice has its own dedicated databases. These services manage their own data independently [1] without interference from other service. Each services can deploy, scale and update independently. Both synchronous and asynchronous [10] method used for communication between the services. Synchronous communication means that a service sending a request to another service and pausing its operation until response is received. Typically, this method is realized through protocols like HTTP/REST or gRPC [11]. While asynchronous communication occurs when a service sends a request or message to another service and continues its operation without waiting for an immediate response. This method is often facilitated by message brokers like RabbitMQ or Kafka. This procedure make it simple for various microservices to exchange and access data across many platforms.

In microservices architecture with distributed databases, maintaining data consistency particularly using foreign key constraints for referential integrity is a major challenge. Unlike traditional systems where databases impose these rules directly, microservices have separate databases, making this execution tough. The CAP theorem describes that distributed systems can only attain two out of three: Consistency, Availability, and Partition Tolerance. Meanwhile microservices must handle network issues (partition tolerance), they often choose between strong consistency or high availability.

Some researchers propose the BAC model (Backup, Availability, Consistency) [12] to better handle real-world failures. Systems that focus on consistency (CP) ensure correct data but may be slower or unavailable during issues, while systems that focus on availability (AP) respond faster but rely on eventual consistency, requiring extra logic to maintain data integrity. In such cases, referential integrity is often managed through custom validation, events, or shared read-only views instead of traditional foreign key constraints.

C. Background

The term "Referential integrity" and "Foreign key constraints" are the two central concepts for ensuring data consistency, accuracy and validity across related tables in relational database system. A relational database is a key element for storing, managing, and retrieving data for the entire program in a monolithic architecture. The architecture uses structured tables to store data [12] from multiple application modules in a single, centralized relational database. A centralized data schema defines the organization of the database by specifying tables, relationships, columns, data types, and constraints to ensure consistent data storage.

In relational database each database table has a PRIMARY KEY that uniquely identifies its records. A FOREIGN KEY serves as a database key designed, which consists of one or more columns in a table, references the primary key in another table, thereby creating relationships between the tables. The term "FOREIGN KEY CONSTRAINTS" is a column (or combination of columns) in a table whose values must match values of a column in some other table. This [12] foreign key constraint connects the child table's foreign key to the parent table's primary key, maintaining referential integrity.

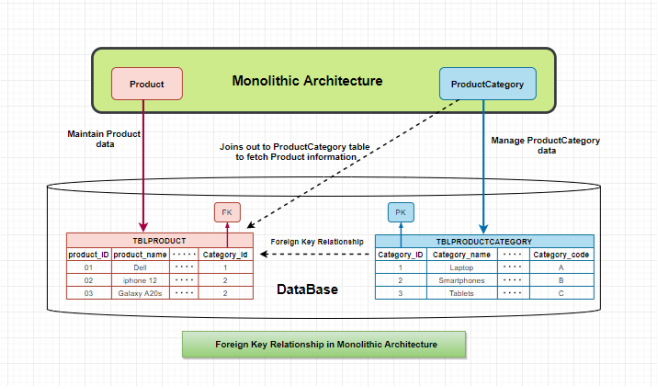

Fig. 1. Foreign key relationships in monolithic architecture.

Fig. 1 illustrates how foreign key constraints are openly imposed within a monolithic architecture, where all modules share a single centralized database. In this setup, relational integrity between entities (e.g., Product and ProductCategory) is maintained through native database-level foreign keys.Distributed database is a type of database system where data is stored through multiple physical locations, frequently on different servers, regions, or even data centers, but appears to users as a single, unified database. Each location may manage part of the data independently, but the system ensures coordination so users can access and manipulate data as if it were stored in one place.

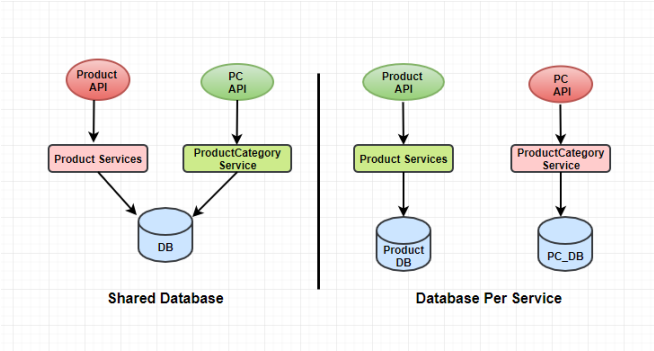

Fig. 2. Shared database and databases per service patterns.

Fig. 2 shows the difference between Shared Database and Database per Service. Shared Database use single database but doesn't scale well, while Database per Service gives each service its own data and needs extra steps to keep data linked.

Microservice architecture is a software development strategy [24] that differs from monolithic architectures. Rather than having one large application, it involves breaking down an application into several small, independent services that are not tightly integrated with one another. One of the key feature of this architecture is the use of multiple, independent services that communicate with each other over the network. Each service is created to perform a specific business task and interacts with other services through clearly defined APIs.

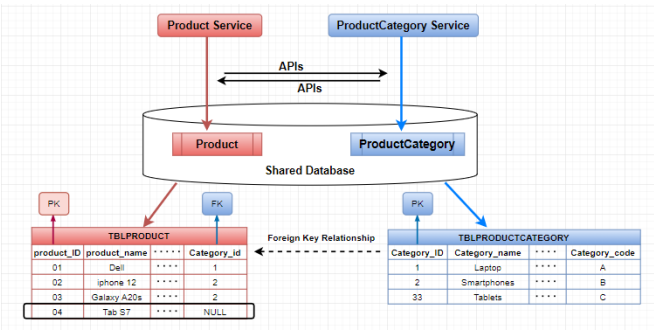

Fig. 3. Foreign key relationships in shared database using multiple microservices.

In Fig. 3 multiple services, such as ProductService and ProductCategoryService, interact with a single, unified database. ProductCategory service manage product category in the ProductCategory table, while ProductService manage individual products in the Product table. Both tables are linked through a foreign key relationship, ProductCategory table as the parent and the Product table as the child, ensuring referential integrity [12] and consistent data relationships across services. On the other hand, microservices also interact with each other via events. For instance, ProductService can produce the event exposed by ProductCategoryService to fetch category details.

For example in Fig. 4, consider two microservices: ProductService and ProductCategoryService. Each of these microservices manages its own separate database, but they are linked through a foreign key relationship to maintain referential integrity.

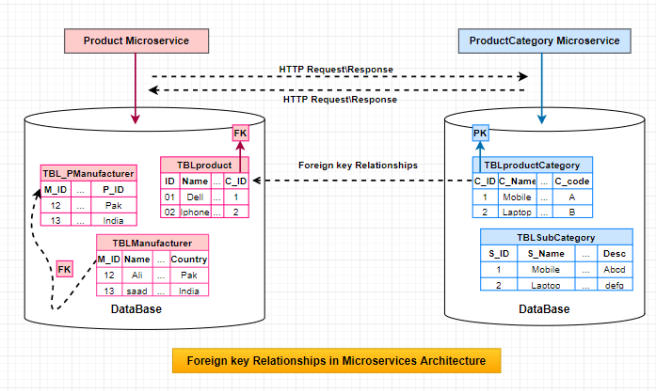

Fig. 4. Database-per-service in microservices architecture.

Synchronous communication is ideal for real-time interactions requiring immediate responses, offering simplicity and directness. In contrast, asynchronous communication excels in scalability and resilience, making it suitable for tasks that can be handled independently over time. In large application with many interconnected links, it's hard to keep the data correct and consistence. For that the concept of "Referential integrity Constraints" is used to keep the data correct. Still, the complexity of handling inter-service communication and ensuring data consistency across multiple services increases.

D. Purpose of the Research

The purpose of this research is to discover how referential integrity can be sustained in distributed databases within microservices architecture, where traditional foreign key constraints cannot span across service boundaries. Using a case study with separate Product and ProductCategory services, the study evaluates and compares practical methods such as shared databases, API validation, event-driven communication, and saga pattern to preserve data relationships while balancing scalability, fault tolerance, and system complexity.

E. Research Objectives

- To handle foreign key constraints in distributed database in microservices architecture.
- To improve response time during CRUD operation in distributed database in microservices architecture.
- To analyze and compare the existing model in a distributed database in microservices architecture.

In the introduction section the paper addresses the challenges of maintaining referential integrity in distributed databases within microservices architecture, this research explores the application of foreign key constraints across different architectural patterns. It investigates how referential integrity is preserved in both shared databases and database-per-service designs using three distinct implementation methods: Shared Database Pattern using APIs, Saga Choreography Pattern with database-per-service, and an Event-Driven Architecture with database-per-service. Each method offers different trade-offs in terms of consistency, performance, and decoupling, which are critical factors in distributed environments.

The remainder of this paper is structured as follows: Section II presents a comprehensive literature review covering the evolution from monolithic systems to microservices, and analyzes the implications for database design and schema evolution. Section III outlines the research methodology, detailing the experimental setup for each of the three architectural patterns. Section IV presents the results, including a comparative analysis of referential integrity, response time, and behavior under CRUD operations. Finally, Section V concludes the findings and provides recommendations for selecting appropriate patterns to maintain referential integrity based on system requirements.

II. Literature Review

This chapter gives us a closer look at what's happening in research right now and what we already know about the topic. It shows us what different authors have to say about the subject based on what's already been written.

A. Evolution to Microservices and Distributed Databases

Microservice-based architecture, which is used for developing software systems with independent maintainability and scalability [13]. Many companies migrate their existing monolithic software systems towards microservice-based architectures [14]. The paper [15] proposes a data-centric process to identify microservices by decomposing the database (on the bases of foreign key relationship) into clusters and identifying topics that correspond to potential microservices. This process performs database schema analysis and clustering.

Migrating from a monolithic to microservice architecture with a shared database and then to multiple databases based on the database-per-microservice pattern. The migration process involves identifying microservice boundaries, decomposing the application into multiple entities. Framework called Architect, which is based on a domain-specific language for building dependable distributed systems [16], to ensure the data consistency of distributed transactions using the Saga pattern to reduce complexity and attain eventual consistency.

The saga pattern is a technique used to ensure data consistency across multiple microservices [17]. It uses sequential transactions that trigger subsequent ones and compensatory transaction when failures occur. However, it lacks isolation, allowing access to ongoing transactions. An improved version[18] of the saga pattern addresses this issue by using a quota cache and commit-sync service to rollback modifications in case of failures without affecting the database layer. The database is committed once all transactions are successful.

Event-driven architecture used for building a distributed database for microservices that is scale and flexible. In EDA, the communication between different components of the system happen through events. EDA can be used to ensure that change to the data are propagated to all the microservices that depend on it. By decoupling the components of the system through events which ensure that changes are propagated quickly [19] and efficiently, while also maintaining data consistency across the system . Identified multiple instances were enforcing foreign key constraints between microservices is essential to ensure accuracy.

Architectural trade-off analysis based on patterns to assist software architects in selecting appropriate pattern for foreign key relationship between different microservices using immutable event by conducted a study [20] to identify architectural patterns of microservices that affect structural design decision related to the size of services, database sharing, and level of service coupling. Software architects can better understand and choose the most appropriate pattern for foreign key relationship between different microservices by using Command Query Responsibility Segregation(CQRS), which can guide the architecture in the desired direction.

Adoption of microservice-based event-driven architecture for data-intensive systems, also known as big data system(BDS) in which microservices communicate through APIs. The authors conducted action research [21] which are Questionnaire to investigate the reasons for the adoption of this architecture and to document the challenges and lessons learned. The resulting architecture was found to enable easier maintenance and fault isolation.

Recovering microservices that use polyglot persistence, which means they use multiple data storage techniques. When backups are taken independently, it becomes difficult to recover them in a consistent state, and references across microservice boundaries may break after disaster recovery. The authors [22] propose a weak global consistency definition for microservice architectures and a recovery protocol that utilizes cached referenced data to reduce the time interval after the most recent backup, during which state changes may have been lost.

The widespread adoption [23] of microservices and event-driven software applications, which favor the separation of databases into independent silos of data owned by a single service. It mention that microservices communicate via synchronous REST API calls and introduces the concept of virtual actors, The only way for a microservice to get data from another microservice is to make a call on an endpoint.

In study [27] Paper offers a modest way to design and evaluate microservices that focus on data, keeping in mind the limitations of the CAP theorem, which applies to distributed systems like microservices. It helps developers and architects compare different design and database patterns to find the best mix of cost and performance. The CAP theorem is not used as a strict rule but as a monitor to group systems as CA (Consistency–Availability), CP (Consistency–Partition tolerance), or AP (Availability–Partition tolerance). The approach is explained with three real-world examples, each showing how different choices affect system design, making it easier to make smart architecture and database decisions. Comparison table is shown in Table I.

B. Database Schema Analysis

A dominant model for cloud based application, consist of integrated, independently deployed and occasionally distributed services that communicate with each other through API calls and maintain their own databases. While enabling software development is a key motivation for implementing microservices, latest surveys[25] highlight database schema evolution as an important challenge. The main aim of this thesis is to reduce the burden which evolve in cloud based application and provide developers automated database schema

evolution with tools. This research[26] mainly focused on modeling, generation, evolution, visualization and monitoring of database schema in microservices.

Microservice-based architecture, which is used for developing software systems with independent maintainability and scalability. Many companies migrate their existing monolithic software systems towards microservice-based architectures. The paper [4] proposes a data-centric process to identify microservices by decomposing the database (on the bases of foreign key relationship) into clusters and identifying topics that correspond to potential microservices. This process performs database schema analysis and clustering.

The abstraction of software components from legacy system, is an active research area within microservices architecture. Domain driven business dataflow diagram have been proposed using different approaches such as static and dynamic code analysis. Legacy systems, which are typically monolithic in nature, usually come with inherited database schemas and data, resulting limited code opportunities for code reused. To identify the database object for microservices extraction, analyze these artifacts, types and usage are aim of this research. A systematic mapping study [27] in legacy system discovered using database artifacts to identify services or component, the result concentrate on using database schema, data state and dependencies to identify separate business unit that could be transformed to potential microservices.

Event-driven architecture(EDA) used for building a distributed database for microservices that is scale and flexible [28]. In EDA, the communication between different components of the system happens through events, which are messages that are generated when certain actions or changes occur. EDA can be used to ensure that change to the data are propagated to all the microservices that depend on it. By decoupling the components of the system [19]through events which ensure that changes are propagated quickly and efficiently, while also maintaining data consistency across the system.

A microservice architecture built an application which are independently deployable, loosely coupled services focused on business capabilities, need careful data storage consideration [29]. Evaluating RDBMS and document store data stores through prototypes and performance test using simplified Electronic Medical Record (EMR) studies [30] five different data storage pattern for microservices in this research such as document store microservice overtake RDBMS, shared database overtake databases per services, CQRS overtake shared database all pattern have minor resource impact. Regardless have conflicts with modularity, the CQRS with event sourcing pattern could alleviate issues. In future may use hybrid pattern to discover data related operation in shared database and databases per services.

When migrating from monolithic application to microservices architecture various challenges occur, mostly with splitting and sharing databases. In [31] this article show framework where managing database splitting among different microservices to achieve data consistency and independent deployment while addressing latency problems. The offered solution improve performance, improved response time and handle messaging in evaluation. This framework maintains constructing services with better database independence.

Demand for data driven features has led to complicated networks of services which communicate each other without integrated architecture in Modern web applications. For large scale web services, synapse helps easy to used strong semantic system [32], allowing isolated, scalable and independent services to share data across different databases. In MVC-based applications that force high level data models using scalable replication mechanism that synchronizes read only view of shared data in real time, enabling data replication using different databases such as MYSQL, MongoDB, Oracle and PostgreSQL. Data duplication among different databases SQL and NoSQL supports in this synapse. For data integration use different models and ORMs to guarantee compatibility between SQL and NoSQL, without compromising scalability to maintain consistency. Synapse determine good performance and scalability. Table II shows database schema analysis in microservices.

III. RESEARCH METHODOLOGY

This section describes the methodology we followed when lot of literature review has been discussed to support the hypothesis of this research study and gap in the literature is also identified. The primary goal to study literature review was to collect experiences on distributed databases in microservice and how foreign key constraints work in microservices architecture, reporting best practices, and identify the problems occur during development processes. This study utilizes a hybrid research methodology, combining empirical research and design science research to discover and address the challenges of maintaining referential integrity in distributed databases in microservice architecture. This dual approach allows us to first observe and analyze real-world systems (empirical) and then propose and evaluate a novel design framework (design

science), ensuring both theoretical consistency and practical relevance.

A. Proposed Framework

Subsequent steps have been followed for the proposed Framework in Fig. 5.

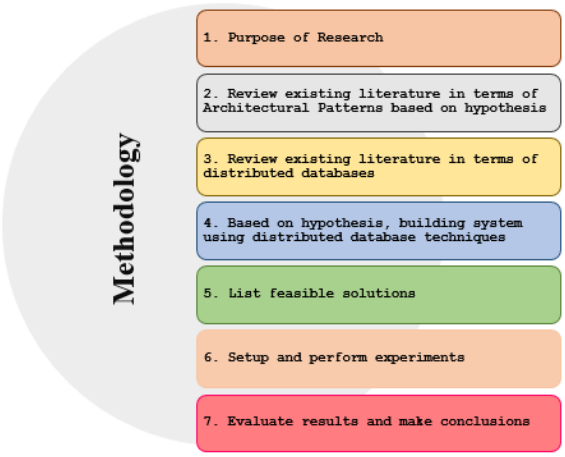

Fig. 5. Proposed framework.

1) Feasible solutions: This research is conducted using hybrid research methodology, combining empirical research and design science research supports the development of robust methods and techniques such as event-driven architecture, the saga choreography pattern, and APIs using a shared database technique which is based on hypothesis and evidences collected from the literature that address the challenges of enforcing foreign key constraints in distributed databases within microservices architecture.

B. Requirements for the Framework Implementation

This section provides an overview on which methods and tools were used.

1) Software requirements: Since this research is focused on foreign key constraints in distributed databases in microservices architecture the software used for the development of proposed framework is Spring tool Suite (STS) is an Eclipse-based development environment design for developing spring based application. This tool used for creating and managing spring projects, validation for spring configuration files and graphical boot dashboard to manage spring boot application. For validation Postman is an excellent tool that API developers and tester can use for guaranteeing API performance and functionality. In order to test RESTful APIs, create and run HTTP requests such as PUT, DELETE, GET, POST etc. In addition MYSQL is a common Relational database management system that helps for quick read/write operations and Xampp is the most commonly used free and open-source web server solution packages that work across multiple platforms. It is suitable for developers, when establishing a local web server environment for PHP development.

2) System requirements: Windows operating system is required for experimental purpose.

C. Implementation of Framework

After analysis the literature review we discuss some method which are used in this research.

1) Shared database pattern using APIs: In microservices design, a shared database is a designed pattern in which multiple microservice share the same central database, as opposed to databases per service pattern. All services interacts with a common set of tables or schema, usually within single database pattern. This structure makes it possible to store data centrally. In this pattern, multiple services shared the same database and each service get data from the same pool. Both services product and ProductCategory microservices communicate with each other through APIs and shared the same database.

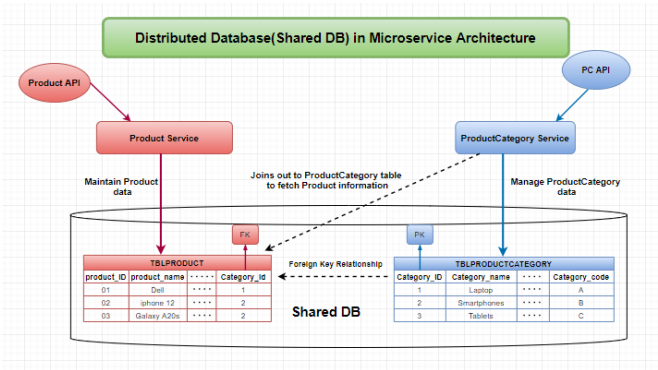

Fig. 6. Shared database pattern using APIs.

MYSQL was used to create and implemented distributed database such as shared databases. For this model, first step to create product and ProductCategory microservices in spring tool suit(STS) IDE. The dependencies as shown in Fig. 7 were managed using maven and pom.xml file in project directory.

The simplified shared database pattern of product and ProductCategory is shown in above Fig. 6, where both mi-

croservices shared the same database. Java persistence API was used to connect to a MYSQL database such as shared database with product and ProductCategory microservices.

```
server.port=8082

logging.level.org.springframework.web=DEBUG;

spring.datasource.driverClassName=com.mysql.jdbc.Driver
spring.datasource.url=jdbc:mysql://api.cwiztech.com:3319/PRODUCT?autoReconnect=true&useSSL=false
spring.datasource.username=root
spring.datasource.password=UOG@786

# Specify the DBMS
spring.jpa.database = MYSQL

# Show or not log for each sql query
spring.jpa.show-sql = true
```

Fig. 8. Database connectivity.

Database connectivity in Fig. 8 discusses to the mechanisms and protocols that allow an application or service to establish and maintain a connection with a database system for executing operations such as data retrieval, insertion, updates, and deletion.

This pattern was implemented using STS and create product and product-category microservices. for each microservice, Create Entity class which is all about tables, Repository is an interface that define the presentation part of the database, Rest Controller classes define APIs so that request can be accept and provide the response. Microservices communicate with each other through APIs. Both microservices Perform CRUD operation and calculate response time. Product microservice send request to ProductCategory microservice to get data. Product-category microservices accept request, if required data available in product-category microservices using Request Mapping.

2) Saga choreography pattern using database per services: The Saga Choreography Pattern (Fig. 9) is a distributed coordination mechanism in microservices architecture that manage distributed communication across several services without depending on a central orchestrator. In this pattern, every service waits for particular events and having finished its activity, posts an event that other services respond to, carrying on the sequence until the whole business process is over. Microservices basically follow the pattern called database per services pattern. Where product service has its own database similarly product category microservices have its own database. so if you observe, there is two microservices and they are pointing to two different databases. If it is a single database, then the approach will be same as monolithic. In this pattern, microservices communicate with each other using asynchronous way such as events.

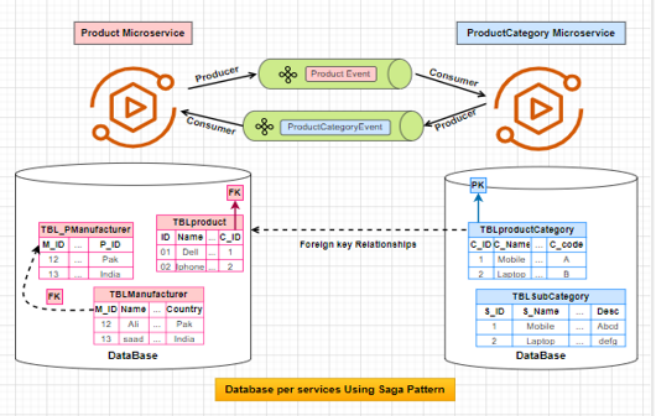

Fig. 9. Saga choreography pattern.

At the very first, to Setup apache kafka environment such as message broker to manage publish and subscribe the events. After that, create product and product-category microservices and added required dependencies in Fig. 10.

```
<dependency>
    <groupId>org.springframework.boot</groupId>
    <artifactId>spring-boot-starter-test</artifactId>
    <scope>test</scope>
</dependency>
<dependency>
    <groupId>io.projectreactor</groupId>
    <artifactId>reactor-test</artifactId>
    <scope>test</scope>
</dependency>
<dependency>
    <groupId>org.springframework.cloud</groupId>
    <artifactId>spring-cloud-stream</artifactId>
    <scope>test</scope>
    <classifier>test-binder</classifier>
    <type>test-jar</type>
</dependency>
<dependency>
    <groupId>org.springframework.kafka</groupId>
    <artifactId>spring-kafka-test</artifactId>
    <scope>test</scope>
</dependency>
```

Fig. 10. Dependencies in saga choreography pattern.

For each microservices add Connection Properties in Application properties files to connect microservice with its own database in Fig. 11.

```
1 spring.datasource.driver-class-name=com.mysql.cj.jdbc.Driver
2 spring.datasource.url = jdbc:mysql://localhost:3306/productservices
3 spring.datasource.username = root
4 spring.datasource.password = Password
5 spring.jpa.show-sql = true
6 spring.jpa.hibernate.ddl-auto = update
7 spring.jpa.properties.hibernate.dialect = org.hibernate.dialect.MySQL5Dialect
8 spring.jpa.properties.hibernate.format_sql=true
```

Fig. 11. Database connectivity.

Product services will receive the request from the product-category microservice then again product service will redirect that request to the product-category services to validate whether that required category is available or not in Product-Category microservices. Microservice Communicate with each other using events. Any change occurs in microservices was handle using Event.

3) Event driven architecture using database per services: Event-driven architecture (EDA) using database per service is a paradigm for designing and building software systems where events are central to communication between different components or services. Event driven architecture using asynchronous way to communicate with each. Event driven architecture (EDA) using database per service, components react to events asynchronously, enabling loose coupling, scalability, and flexibility.

Event driven architecture use apache Kafka as a message broker for asynchronous way to communicate with each. A kafka Broker is a server that hosts Kafka partitions. It is responsible for managing the storage, retrieval, and replication of the data (messages) produced by Kafka producers and consumed by Kafka consumers is a server that hosts Kafka partitions. It is responsible for managing the storage, retrieval, and replication of the data (messages) produced by Kafka producers and consumed by Kafka consumers. A Kafka Topic is a logical channel to which producers publish messages and from which consumers read messages. A topic is like a category or feed name to which records are sent as shown in Fig. 12.

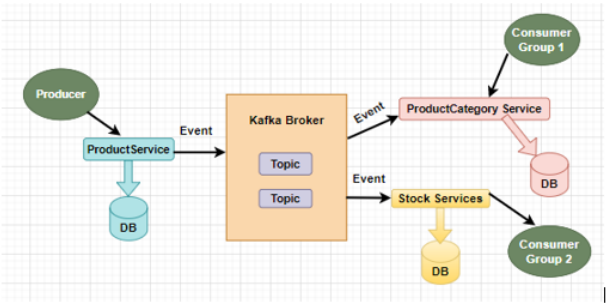

Fig. 12. Event driven architecture using apache kafka.

First step to Setup apache kafka environment such as message broker for asynchronously communication to manage publish and subscribe the events. Start zookeeper service using command.

```
C:\kafka_2.13-3.7.0>.\bin\windows\zookeeper-server-start.bat .\config\zookeeper.properties
```

Fig. 13. Start zookeeper service command.

Start Kafka Broker using command (see Fig. 13 and Fig. 14)

```
C:\kafka_2.13-3.7.0>.\bin\windows\kafka-server-start.bat .\config\server.properties
```

Fig. 14. Start kafka broker command.

In EDA, product service has its own database which is responsible for managing the product similarly product category microservices has its own database which is responsible for managing product category. At the very first, create product and product-category microservices and added required dependencies.

```
<dependencies>   Add Spring Boot Starters...
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter</artifactId>
    </dependency>

    <dependency>
        <groupId>org.projectlombok</groupId>
        <artifactId>lombok</artifactId>
        <optional>true</optional>
    </dependency>
    <dependency>
        <groupId>org.springframework.boot</groupId>
        <artifactId>spring-boot-starter-test</artifactId>
        <scope>test</scope>
    </dependency>
</dependencies>
```

Fig. 15. Dependencies in event driven architecture.

Event driven architecture use event producer and event consumer while communication. Event Producer that produce event when state changes occur. Producers publish events to the event broker. while event consumer consumes event and perform action according to the request. Performing CRUD operations in event driven architecture (Fig. 15) using database per services pattern and validate foreign key relationship.

```
@Service
public class ProductProducer {

    private static final Logger LOGGER = LoggerFactory.getLogger(ProductProducer.class);

    private NewTopic topic;

    private KafkaTemplate<String, OrderEvent> kafkaTemplate;

    public ProductProducer(NewTopic topic, KafkaTemplate<String, OrderEvent> kafkaTemplate) {
        this.topic = topic;
        this.kafkaTemplate = kafkaTemplate;
    }

    public void sendMessage(OrderEvent event){
        LOGGER.info(String.format("Order event => %s", event.toString()));

        // create Message
        Message<OrderEvent> message = MessageBuilder
                .withPayload(event)
                .setHeader(KafkaHeaders.TOPIC, topic.name())
                .build();
        kafkaTemplate.send(message);
    }
}
```

Fig. 16. Event producer in EDA.

Product microservices create a new entity in its local database such as product. After that, product microservices publish an event with the entity data to Apache kafka. After that kafka broker publish an event and send event to the related microservice. Then productcategory microservices consume the event and creates a related entity in its local database such as Productcategory services with a foreign key referencing the product entity in product microservices database (Fig. 16).

In event-driven systems using the database-per-service pattern, enforcing foreign key constraints across services is not possible through traditional relational resources. Instead, referential integrity is maintained asynchronously using events. However, this approach must handle the realities of network partitioning, as defined in the CAP theorem, which states that in a distributed system, it is difficult to simultaneously guarantee Consistency, Availability, and Partition Tolerance. Event-driven architectures usually prioritize availability and partition tolerance, which means consistency is eventually achieved rather than immediately enforced. This trade-off affects CRUD operations, especially create and delete, where

integrity checks must rely on event messages from the owning service (e.g., ensuring a ProductCategory exists before creating an Order). In such cases, idempotency becomes essential. Since events can be delayed, duplicated, or retried, systems must be designed to safely handle the same event more than once without corrupting data. This adds operational complexity but is crucial to ensure reliable referential integrity in the absence of direct foreign key enforcement. Thus, network partition handling and idempotent design are key pillars in using event-driven architectures to maintain data consistency across microservices.

IV. Results and Discussion

A. Overview

This section contains the experimentation of the proposed framework to evaluate how foreign key constraints can be used to maintain referential integrity in distributed databases within a microservices architecture. To test our approach, we designed a case study involving two central microservices: ProductCategoryService and ProductService, which simulate a real-world e-commerce scenario. These services are logically connected through a foreign key relationship, where each product belongs to a specific product category.

B. Case Study

In the designed case study, we implemented a distributed database system using the Database per Service pattern. The ProductCategoryService manages the ProductCategory entity and its database, while the ProductService manages the Product entity. A logical foreign key constraint is defined between the Productcategory-id field and the ProductCategory-id, ensuring that each product must belong to a valid category.

In this section the results of Response time of the three distributed database patterns are presented. For clarity, we presented the most-significant results obtains. In the first section, we examine how distributed database patterns compare with each other and in the last section we observed the response time while performing CRUD operation in distributed databases and we define the performance for all the patterns considered. The response time of the three pattern were compared in a pairwise such as:

- Shared database using APIs vs. Event Driven Architecture.
- Shared DB Using APIs vs. choreography saga pattern.
- Event driven Architecture vs. Saga Choreography pattern.
- Response time for all the pattern.

C. Evaluation Criteria

Microservices architecture can be evaluated using variety of criteria such as data integrity, data availability, data scalability, transaction management and response time. In this research, we will mainly focus on how response time and critical aspects such as scalability, fault isolation, and operational complexity behave when performing CRUD operations. Response time within a distributed database in microservices architecture, refer to the duration when the request is send to and when the client receive the response. This include numerous stages such as transmission time (time for request to reach the target microservices), service processing time (time which involve business logic and database CRUD operations on the distributed database) which consist of data access, data consistency and communication across the node or replica, inter services communication alongside response transmission time back to client.

D. Shared Database vs. Event Driven Architecture

The result in below Table III shows the response time for distributed database pattern. Some test cases were executed against the deployed patterns. Each test case consists of a HTTP request which consists a server side overview for data access. In this case, each test cases were executed using well defined APIs in shared database. This was carried out turn by turn. First shared database using APIs/HTTP and then database per service pattern such as event driven architecture using events were carried out and perform CRUD operation and calculate the average response time.

TABLE III. Comparison Between Event Driven Architecture vs. Shared DB

DB Operation	Event Driven Pattern			Shared DB		
	Number of Request (ms)					
	10	100	1000	10	100	1000
CREATE	73.17	695.47	7155.34	43.89	428.65	3987.45
READ	40.23	385.51	3993.04	35.33	359.09	3367.77
UPDATE	92.45	859.44	8967.71	58.2	575.17	5734.63
DELETE	89.88	887.04	8852.08	59.91	603.45	6072.11
Avg. Response Time	73.93	507.10	7242.04	49.33	491.59	4790.49

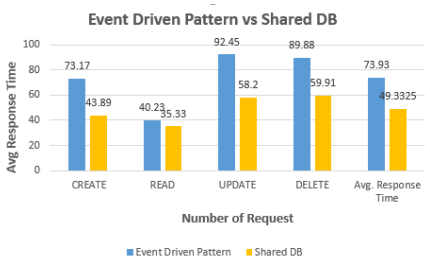

Fig. 17. Avg. Response time between shared DB VS Event driven architecture.

Taking an average of all the tests carried out indicates that shared database pattern performed better than database per services (EDA) while performing CRUD operation. Shared database pattern have relatively Fast response time as compare to event driven Architecture. Response time in Shared database is Fast due to access of same database. While event driven architecture takes time for coordination between different services, performing CRUD operations and inter-communication services and many more. Due this reason event driven architecture takes more time as show in Fig-17.

While analyzing other factors shared Database has limited scalability because all services depend on a single database, which becomes a bottleneck as traffic increases. It also has weak fault isolation. If one service or its database fails, it can affect others since everything is tightly connected. While it's easy to manage at first, complexity grows with more services due to shared schema and organization needs. In contrast, Event-Driven Architecture offers very high scalability because services and messaging systems can grow independently. It provides excellent fault isolation, as services are decoupled and communicate through events that can be retried if one fails. However, it brings very high operational complexity, requiring careful handling of events, retries, and monitoring, which adds to the system's management effort.

E. Shared Database vs. Saga Choreography Pattern

The result presented in table shows the response time of distributed database between the shared database using APIs/HTTP request and database per services. In this case, each test cases were executed using SAGA as well as database per services. This was carried out turn by turn. First shared database using APIs/HTTP were carried out and perform CRUD operation and calculate the average response time. Secondly, SAGA pattern using database per services pattern was carried out and perform CRUD operations and calculate the average response time (Table IV).

TABLE IV. COMPARISON BETWEEN SAGA CHOREOGRAPHY PATTERN VS. SHARED DB

DB Operation	Saga Pattern			Shared DB		
	Number of Request (ms)					
	10	100	1000	10	100	1000
CREATE	67.19	598.43	6495.35	43.89	428.65	3987.45
READ	37.48	332.29	3577.61	35.33	359.09	3367.77
UPDATE	83.67	789.11	7982.47	58.2	575.17	5734.63
DELETE	75.89	668.56	6830.03	59.91	603.45	6072.11
Avg. Response Time	66.05	597.09	6221.36	49.33	491.59	4790.49

The comparison between shared database and Saga choreography pattern using database per services pattern were carried out on the bases of average response time while performing CRUD operations.

Taking an average of all the tests carried out in fig. 18 that shared database pattern performed better than saga choreography pattern while performing CRUD operation. Shared database pattern have relatively Fast response time as compare to SAGA. Response time in Shared database is Fast due to access of same database. While saga choreography pattern involved stages such as transmission time, service processing time which involve business logic and database CRUD operations and global coordination time alongside response transmission time back to client. Due to this reason Saga choreography takes more time as compare to shared DB.

In terms of scalability, the Shared Database is harder to scale because all services trust on a single database, which can become a bottleneck as the system grows. In contrast, Saga

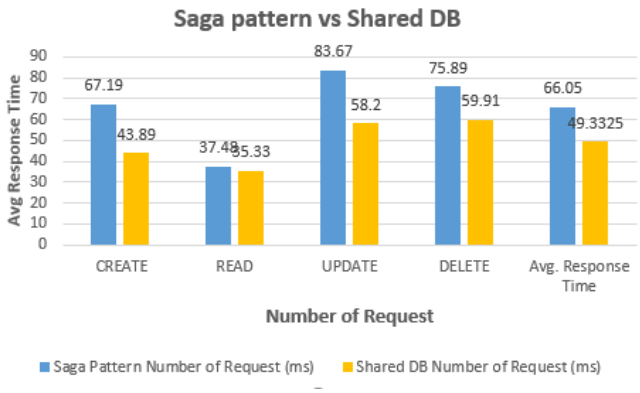

Fig. 18. Avg. Response time between shared DB vs. Saga choreography pattern.

Choreography scales more easily since each service has its own database and can grow independently. For fault isolation, the Shared Database is weaker. Issues in one service or changes to the shared schema can affect others. Saga Choreography, however, offers stronger fault isolation, as services are decoupled and operate independently. When it comes to operational complexity, the Shared Database is easier to manage at first due to its simplicity, but complexity grows as more services are added. Saga Choreography is more complex from the beginning, as it requires managing inter-service communication and ensuring data consistency through event handling.

F. Database Per Services (Choreography Saga Pattern) vs. Database Per Services (EDA)

The result presented in the table shows the response time between distributed databases. Both distributed databases used database per services pattern. The results of the table indicate an average response time of choreography saga pattern and event driven architecture.

TABLE V. COMPARISON BETWEEN SAGA CHOREOGRAPHY PATTERN VS. EVENT DRIVEN ARCHITECTURE

DB Operation	Saga Pattern			Event Driven Pattern		
	Number of Request (ms)					
	10	100	1000	10	100	1000
CREATE	67.19	598.43	6495.35	73.17	695.47	7155.34
READ	37.48	332.29	3577.61	40.23	385.51	3993.04
UPDATE	83.67	789.11	7982.47	92.45	859.44	8967.71
DELETE	75.89	668.56	6830.03	89.88	887.04	8852.08
Avg. Response Time	66.05	597.09	6221.36	73.93	507.10	7242.04

The data in Table V: shows that Event Driven Architecture performed better for each batch update, deletion, insertion, then Saga choreography pattern.

Saga choreography design pattern choose asynchronous communication between the services and many other factors such as network latency may low their response time. In the

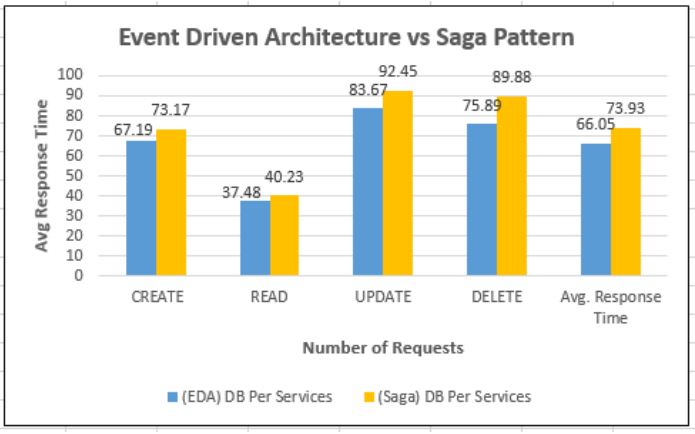

Fig. 19. Avg. Response time between event driven Architecture vs. Saga choreography pattern.

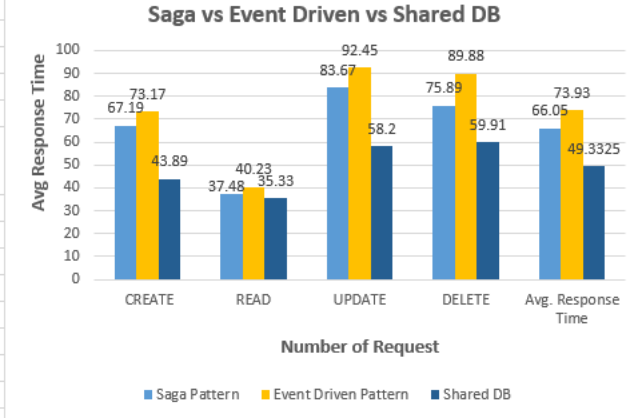

Fig. 20. Avg. Response time of different methods.

TABLE VI. COMPARISON BETWEEN SAGA CHOREOGRAPHY PATTERN VS. EVENT DRIVEN VS SHARED DB

DB Op	Saga Pattern			Event Driven Pattern			Shared DB		
	Number of Request (ms)								
	10	100	1000	10	100	1000	10	100	1000
C	67	598	6495	73	695	7155	43	428	3987
R	37	332	3577	40	385	3993	35	359	3367
U	83	789	7982	92	859	8967	58	575	5734
D	75	668	6830	89	887	8852	59	603	6072
Avg RT	66	597	6221	73	507	7242	49	491	4790

above graph clear show that in each test case event driven architecture perform better then saga choreography pattern. The comparison between Saga Choreography Pattern and Event-Driven Architecture (EDA)—both using the database-per-service approach—shows that while both patterns offer good scalability and fault isolation, EDA takes these aspects further. Saga Choreography provides high scalability, as services operate with their own databases and coordinate through events, and offers strong fault isolation through loose coupling. However, it requires managing compensating transactions and choreography logic, making it operationally complex. On the other hand, EDA achieves very high scalability and fault isolation, thanks to full service decoupling and asynchronous communication. But this comes at the cost of very high operational complexity, involving advanced event design, ensuring idempotency, managing retries, and implementing distributed tracing to monitor the system.

While comparison between the three patterns of distributed database. We observe each test case with each three pattern such as shared database, saga choreography and event driven architecture as shown in the Table VI.

After observing each test with 10,100,1000 number of request respectively, we conclude that shared database performed faster as compare to other two patterns. While Event driven architecture performs better then saga choreography pattern while performing CRUD operation. For more clarity in the results we represent the result in graphical representation in Fig. 19 and Fig. 20.

V. CONCLUSION AND RECOMMENDATION

In this research distributed databases in microservices has been broadly analyze while performing CRUD operations and how we achieve loose coupling between the services while maintaining data integrity and very efficient data access performance. Furthermore, an evaluation of foreign key constraints to maintain referential integrity in distributed databases (shared database, database per services) as shown in this research bring out one of the core challenge of microservices. This research further proven that shared database pattern give better performance then database per services while performing simple data related operation such as simple CRUD operation.

In this research after examined the test case, it could be deduced that foreign key constraints in a database per services pattern does not carried out at database level. While future could find a way to mitigate this challenge. When designing data driven microservices, it remains a crucial factor to consider.

Integrating cGAN-Enhanced Prediction with Hybrid Intervention Recommendations Systems for Student Dropout Prevention

Hassan Silkhi[1], Brahim Bakkas[2], Khalid Housni[3]
Faculty of Sciences, University Ibn Tofail, Kenitra, Morocco[1,3]
University Moulay Ismail, Meknes, Morocco[2]

***Abstract*—Early-warning dashboards in higher education typically stop at tagging students as "at-risk," offering no concrete guidance for remedial action; this limitation contributes to the loss of thousands of learners each year. Approach. We propose an integrated framework that (i) uses a class-balanced Conditional GAN to augment sparse attrition data, and (ii) couples the resulting XGBoost predictor with a four-mode intervention engine—rule-based, few-shot, fine-tuned LLM, and a novel hybrid strategy—to recommend personalised support. Major findings. Training on GAN-augmented records raises prediction accuracy to 92.79% (a 15.46-point gain over non-augmented baselines), while the hybrid intervention generator attains 94% categorical coverage and the highest specificity score (0.63) albeit at a per-student latency of 61s. Impact. By uniting robust risk prediction with high-quality, actionable interventions, the framework closes the long-standing gap between detection and response, furnishing institutions with a scalable path to materially reduce dropout rates across diverse educational settings.**

***Keywords*—Student dropout prediction; machine learning in education; personalized intervention systems; Conditional Generative Adversarial Networks(cGAN); Large Language Models (LLMs); hybrid recommendation systems**

I. Introduction

Student attrition represents a persistent and multifaceted challenge within higher education systems globally. Recent statistics indicate that only 60% of undergraduates at four-year institutions complete their degrees within six years, with completion rates dropping precipitously to 20% at community colleges [1]. This phenomenon carries significant consequences, including diminished lifetime earnings for affected students [2] and substantial financial losses for institutions [3], [4]. Traditional retention strategies, while moderately effective, frequently adopt generalized approaches that fail to account for the complex interplay of academic, financial, and psychosocial factors influencing attrition decisions [5], [6].

The emergence of predictive analytics in educational contexts has substantially improved early identification of at-risk students [7]. However, as [8] demonstrate, there remains a critical disconnect between risk identification and effective intervention delivery. This gap persists despite advances in machine learning methodologies, creating a pressing need for integrated systems that combine accurate prediction with actionable support strategies. Recent developments in large language models (LLMs) present new opportunities in this domain, though their application to educational intervention generation remains underexplored [9].

This study addresses two fundamental research questions central to improving student retention outcomes. First, how can synthetic data augmentation techniques, particularly cGANs, enhance the accuracy of dropout prediction models when applied to class-imbalanced educational datasets? Second, what methodological approach to intervention generation optimally balances the competing demands of comprehensiveness, specificity, and computational efficiency in institutional settings? The investigation of these questions yields three primary contributions to the field of educational data mining.

The first contribution involves the development of a cGAN-based data augmentation framework that not only addresses class imbalance but preserves critical feature relationships within student records. As demonstrated in Section IV, our approach maintains low Jensen-Shannon divergence scores (0.0201 for target distributions) while achieving balanced class representation. The second contribution consists of a novel hybrid intervention system that synergizes the structured logic of rule-based methods with the contextual adaptability of LLMs. This integration, as evaluated in Section V, produces interventions with 94% categorical coverage while maintaining specificity scores (0.63) significantly higher than single-method approaches.

The practical implications of this research are substantial for higher education institutions. Our results indicate that the proposed framework can improve prediction accuracy by 15.46 percentage points compared to conventional methods, while generating personalized interventions at scale. Importantly, the modular architecture of the system permits phased implementation, enabling resource-constrained institutions to deploy components according to their technical capacity and staffing resources.

The remainder of this article is organized as follows. Section II reviews relevant literature on dropout prediction and intervention strategies. Section III details the methodological framework, including data preparation, model architectures, and evaluation metrics. Sections IV and V present and discuss the experimental results, respectively. Finally, Section VI concludes with limitations, future research directions, and practical recommendations for institutional adoption.

II. Related Work

Understanding student attrition in higher education requires an integrative lens that captures the interplay of academic,

financial, institutional, personal, and sociocultural forces. Academic performance consistently emerges as the strongest single predictor of withdrawal: students who accrue failing grades or leave coursework incomplete face markedly higher attrition risk, a pattern that intensifies in demanding STEM programmes where content volume and complexity can overwhelm even well-prepared learners [10], [11], [12].

Financial pressures form the second major barrier to persistence. Rising tuition costs and limited scholarship availability amplify dropout likelihood, particularly in developing regions where students often balance study with employment or family obligations [11], [13], [14]. Learners from lower socioeconomic backgrounds confront additional disadvantages—restricted access to textbooks, technology, and tutoring—that compound their academic struggles [15].

Institutional context likewise shapes engagement and sense of belonging. Weak student–faculty relationships, inadequate academic-support structures, and outdated infrastructure correlate strongly with withdrawal, especially in large universities where students can feel anonymous and detached [12], [16], [17]. Personal and socio-emotional challenges add yet another layer: low self-esteem, limited emotional support, and the strain of juggling academic, work, and family roles all heighten attrition risk [18], [16].

In response, researchers have advanced an array of predictive models and intervention strategies. Ensemble learning and survival-analysis techniques capture non-linear relationships among dropout factors and have improved risk detection [19], [20]. Nevertheless, performance remains hampered by severe class imbalance—dropout cases are typically under-represented—reducing model reliability when deployed.

Interventions have therefore become the critical next step. Robust academic-support schemes—tutoring, advising, mentoring—directly address learning barriers, while interactive pedagogies and technology integration further bolster engagement [17], [19]. Financial remedies such as scholarships, flexible payment plans, and emergency loans mitigate economic strain [21]. Personalised services, including counselling and career guidance, target the emotional and motivational dimensions of persistence [22].
Technology-mediated systems increasingly underpin these efforts. Predictive analytics allow institutions to flag at-risk students early and to deploy targeted interventions, yet most current platforms end at identification and stop short of recommending specific, actionable support [23], [24], [25], [26], [27].

Important gaps remain. The literature tends to examine prediction and intervention in isolation, leaving little guidance on how to integrate the two. Persistent class imbalance undermines external validity, and few studies systematically compare recommendation engines, creating uncertainty about optimal practice. Demographic disparities add further complexity: male students and first-generation entrants often withdraw at higher rates, underscoring the need for culturally sensitive interventions [10], [13], [28].

Recent discourse therefore advocates a holistic, systemic approach that unites academic, financial, and socio-emotional supports within a comprehensive retention framework [29]. This shift in perspective recognises dropout as a shared institutional challenge rather than merely an individual failing, and it calls for coordinated policy-level responses alongside personalised student care.

III. Methodology

The proposed model, shown in Fig. 1, in consists of four interconnected layers: a data processing layer, a machine learning prediction layer, a knowledge integration layer, and an intervention generation layer. This structure allows us to address both the technical challenges of dropout prediction and the practical needs of educational interventions.

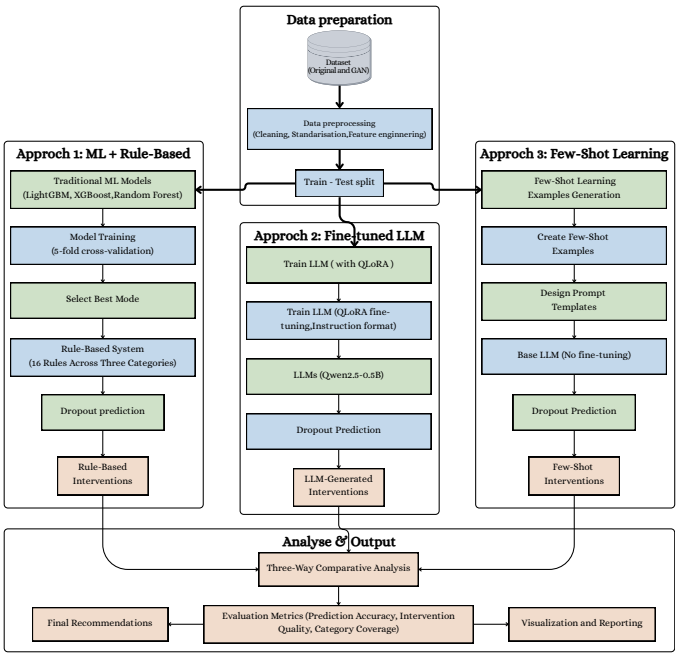

Fig. 1. Flowchart represents the comprehensive multi-strategy model for student dropout prediction and intervention.

A. Data Preparation

1) Dataset description and preprocessing: We utilized a dataset [30] consisting of 4,424 student records from higher education institutions, containing 37 features spanning academic performance, demographic information, financial status, and socioeconomic context. Key variables included academic metrics (course grades, units attempted/completed), financial indicators (scholarship status, tuition payment history), demographic factors (age, nationality, displacement status), and economic context indicators (unemployment rate, inflation, GDP).

To address class imbalance (49.93% graduates, 32.12% dropouts, 17.95% enrolled), we employed Conditional Generative Adversarial Networks (cGANs) to create 6,627 synthetic student profiles. The cGAN architecture consisted of a generator with three fully-connected layers and a discriminator with similar structure, trained for 500 epochs using the Wasserstein loss with gradient penalty to ensure stability. We validated synthetic data quality through statistical testing (Jensen-Shannon divergence scores averaging 0.11 across features) and visualization of feature distributions, confirming that synthetic

records maintained the original dataset's statistical properties while achieving a balanced class distribution (33.33% for each target category).

Data preprocessing included standardization of numerical features, handling of missing values through mean imputation for continuous variables and mode imputation for categorical variables, and splitting into training (70%) and testing (30%) sets with stratification by target class.

2) Synthetic data generation with cGAN: To alleviate the severe class imbalance in the original attrition dataset, we trained a class-conditional generative adversarial network (cGAN). The model receives a 100-dimensional latent vector $\mathbf{z} \sim \mathcal{N}(0, I)$ concatenated with the class label and produces fully synthetic student profiles that preserve the multivariate dependence structure of the real data. Both the generator and discriminator consist of three fully connected layers with progressively increasing (resp. decreasing) widths, LeakyReLU activations, and batch normalisation. Training follows the Wasserstein loss with gradient penalty, optimised by Adam. The full configuration is summarised in Table I.

TABLE I. cGAN Training Configuration

Hyper-parameter	Value / setting
Generator & Discriminator topology	3 fully connected layers each
Latent-vector dimension d_z	100
Hidden units (G/D)	128→256→512
Activation	LeakyReLU + BatchNorm
Loss function	Wasserstein + Gradient Penalty
Optimiser	Adam ($\eta = 1\times10^{-4}$, $\beta_1 = 0.5$, $\beta_2 = 0.9$)
Batch size	256
Training epochs	500

B. Machine Learning Components

Our predictive model comprises three distinct architectural components designed to effectively address the academic success and dropout prediction task. Here's a detailed analysis of the models architecture used in our study:

1) Classical machine learning models with rule-based interventions:

a) Random forest: The model is an ensemble learning technique primarily used for classification and regression tasks. It operates by constructing multiple decision trees during the training phase and aggregates their predictions, either by taking the mode of the classes for classification or the average for regression. This approach enhances model accuracy and reduces the risk of overfitting, making it robust against noise in the dataset [31].

b) XGBoost: Or Extreme Gradient Boosting, is a powerful machine learning algorithm that is particularly effective for structured or tabular data [32]. It is an implementation of gradient boosted decision trees designed for speed and performance.

c) LightGBM: employs histogram-based decision trees, which are more efficient than traditional decision trees. This approach involves precomputing the histogram of feature values to quickly determine the best split points. The histogram-based method reduces the computational complexity and speeds up the training process [33], [34].

Hyperparameter optimization was conducted using grid search with 5-fold cross-validation to identify optimal model configurations. For Random Forest, we explored tree depths from 5 to 20, minimum samples per leaf from 1 to 10, and estimator counts from 50 to 500. Similar parameter spaces were explored for the other algorithms.

The rule-based intervention system was implemented as a set of conditional statements mapping specific student characteristics to appropriate interventions. We constructed 16 intervention rules across three categories:

- Academic interventions (5 rules): It is triggered by grade thresholds, course completion rates, and evaluation participation
- Financial interventions (5 rules): It is triggered by payment status, scholarship eligibility, and economic indicators
- Social interventions (6 rules): It is triggered by demographic factors, displacement status, and attendance patterns

Each rule consisted of a condition function evaluating specific student attributes and a corresponding intervention recommendation. This approach leveraged domain expertise while maintaining explainability and consistency.

2) Large language model: Qwen2.5 [35] is the Qwen family of large language models, offering base and instruction-tuned variants with parameter sizes 0.5B . It builds upon Qwen2 with enhanced knowledge (especially in coding and math), improved instruction-following, 128K-token context support, 8K-token generation, multilingual capabilities (29+ languages), and better structured output (e.g., JSON), making it a versatile and powerful tool for diverse applications.

3) QLoRA fine-tuning LLMs: We implemented fine-tuning of Large model Qwen2.5-0.5B. To accommodate computational constraints, we employed QLoRA (Quantized Low-Rank Adaptation), which enabled parameter-efficient fine-tuning while reducing memory requirements by quantizing the base model to 8-bit representation.

The training dataset for fine-tuning consisted of 3,000 examples pairing student profiles with appropriate intervention recommendations, generated using our rule-based system and augmented with variations to promote generalization. We structured the training data as instruction-tuning pairs with system context, student profile input, and expected output format.

Fine-tuning hyperparameters included:

- Learning rate: 2e-4 with cosine schedule
- Batch size: 1 with gradient accumulation steps of 8
- Training epochs: 3
- LoRA rank: 16, alpha: 32
- Target modules: query, key, value, and output projection layers

4) Few-shot learning: Our few-shot learning approach utilized pre-trained language models without additional fine-tuning. We constructed carefully designed prompts containing:

- A system instruction specifying the task and desired output format
- 3-5 exemplar cases demonstrating expected predictions and interventions for diverse student profiles
- The target student profile for analysis

For each exemplar, we selected representative cases from both dropout and non-dropout categories, with interventions sourced from our rule-based system. This approach allowed the model to implicitly learn the mapping between student characteristics and appropriate interventions through pattern recognition from examples. The prompt engineering process involved systematic refinement through iterative testing, with particular attention to instruction clarity, example diversity, and output structure enforcement. We employed temperature settings of 0.7 and top-p of 0.9 to balance creative generation with consistency.

C. Evaluation Methodology

We developed a comprehensive evaluation framework to assess and compare the three approaches across multiple dimensions:

1) Prediction accuracy assessment: To assess the effectiveness of our dropout-prediction models, we adopted the canonical battery of classification metrics—accuracy, precision, recall, and the F1-score. Let TP, TN, FP, and FN denote the counts of true positives, true negatives, false positives, and false negatives, respectively; the metrics are computed as follows:

- Accuracy quantifies a model's overall correctness by dividing the total number of properly classified instances—both positive and negative—by the entire set of instances under evaluation, i.e.,

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

- Precision: it is the fraction of true positives among all instances the model labels as positive, thereby indicating how well the classifier avoids false-alarm errors (false positives).

$$\text{Precision} = \frac{TP}{TP + FP} \tag{2}$$

- Recall: captures a model's capacity to retrieve positive instances. It is the share of true positives among all cases that are genuinely positive, indicating how thoroughly the classifier discovers the events of interest.

$$\text{Recall} = \frac{TP}{TP + FN} \tag{3}$$

- F1-score: synthesises a model's exactness (precision) and completeness (recall) into a single figure by taking their harmonic mean, thereby balancing the tendency to over- or under-identify positive cases. It is computed as.

$$\text{F1-score} = 2 \times \frac{\text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{4}$$

Additionally, we assessed prediction confidence calibration by comparing predicted probability distributions with actual outcomes. For this purpose, we calculated the Expected Calibration Error (ECE) by partitioning predictions into M equally-spaced bins and computing:

$$\text{ECE} = \sum_{m=1}^{M} \frac{|B_m|}{n} \left|\text{acc}(B_m) - \text{conf}(B_m)\right| \tag{5}$$

where $|B_m|$ is the number of predictions in bin m, n is the total number of predictions, $\text{acc}(B_m)$ is the accuracy within bin m, and $\text{conf}(B_m)$ is the average confidence within bin m. A lower ECE indicates better calibration between predicted probabilities and actual outcomes.

For multi-class scenarios involving the three possible student outcomes (Dropout, Graduate, Enrolled), we employed macro-averaging to compute overall performance metrics:

$$\text{Macro-Precision} = \frac{1}{C} \sum_{c=1}^{C} \text{Precision}_c \tag{6}$$

$$\text{Macro-Recall} = \frac{1}{C} \sum_{c=1}^{C} \text{Recall}_c \tag{7}$$

$$\text{Macro-F1} = \frac{1}{C} \sum_{c=1}^{C} \text{F1-score}_c \tag{8}$$

where C represents the number of classes (in our case, $C = 3$), and the subscript c indicates metrics calculated for each individual class.

2) Intervention quality evaluation: To evaluate intervention quality, we employed both quantitative and qualitative metrics:

- Intervention count: Number of specific recommendations per student, calculated as:

$$IC_s = \sum_{c \in \{a,f,so\}} |I_{s,c}| \tag{9}$$

where IC_s is the intervention count for student s, $I_{s,c}$ represents the set of interventions in category c (academic, financial, social) for student s, and $|I_{s,c}|$ denotes the cardinality of this set.

- Intervention specificity: Average word count per intervention as a proxy for detail level:

$$IS_s = \frac{1}{IC_s} \sum_{i \in I_s} W_i \tag{10}$$

where IS_s is the intervention specificity for student s, I_s is the set of all interventions for student s, and W_i is the word count of intervention i.

- Category coverage: Proportion of cases where interventions spanned all three categories (academic, financial, social):

$$CC = \frac{1}{|S|} \sum_{s \in S} \mathbb{I}(|I_{s,a}| > 0 \wedge |I_{s,f}| > 0 \wedge |I_{s,so}| > 0) \tag{11}$$

where S is the set of all students, $\mathbb{I}$ is the indicator function that equals 1 when the condition is true and 0 otherwise.

- Intervention diversity: Lexical diversity and semantic range of recommendations, measured using type-token ratio (TTR):

$$TTR = \frac{|V|}{|T|} \tag{12}$$

where $|V|$ is the number of unique words (vocabulary) and $|T|$ is the total number of words (tokens) across all interventions. Additionally, we computed semantic similarity between interventions using cosine similarity of sentence embeddings:

$$Sim(i_1, i_2) = \frac{\vec{e}_{i_1} \cdot \vec{e}_{i_2}}{||\vec{e}_{i_1}|| \cdot ||\vec{e}_{i_2}||} \tag{13}$$

where $\vec{e}_{i_1}$ and $\vec{e}_{i_2}$ are the embedding vectors of interventions i_1 and i_2 respectively.

IV. Results

Our comprehensive evaluation of student dropout intervention methods revealed significant performance differences across the four approaches tested: Rule-Based, Few-Shot, Fine-Tuned, and Hybrid methods. Each approach demonstrated unique strengths and limitations in addressing the complex challenge of providing targeted interventions for at-risk students. The evaluation metrics focused on four key dimensions: intervention count (quantity of recommendations), words per intervention (detail level), category coverage (comprehensiveness across intervention types), and specificity score (personalization level). These metrics collectively provide insight into both the quantity and quality of intervention recommendations generated by each method.

For reproducibility, all experiments were conducted with fixed random seeds and k-fold cross-validation to ensure robust performance estimates. Computational resources included an NVIDIA Tesla T4 GPU with 15.83 GB VRAM for language model fine-tuning and inference, while traditional machine learning models were trained on CPU.

A. Dataset Analysis and cGAN Implementation

Our cGAN implementation successfully addressed the class imbalance in the original student dataset. As shown in Fig. 2, the original dataset exhibited substantial class imbalance with 49.9% graduates, 32.1% dropouts, and only 17.9% enrolled students. In contrast, the cGAN-generated dataset achieved perfect balance with exactly 33.3% representation for each class category, creating 2,209 synthetic samples per class for a total of 6,627 records.

The synthetic data preserved critical feature relationships and temporal dependencies from the original dataset, particularly maintaining the semester-based performance patterns that proved most predictive in subsequent modeling. This balanced dataset enabled more equitable model training while addressing both methodological challenges and ethical considerations related to student data privacy.

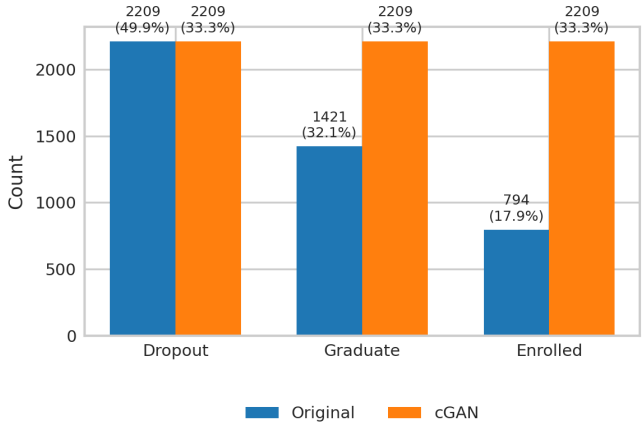

Fig. 2. Distribution of academic outcomes between the original dataset and the generated dataset: Graduate and Dropout counts.

The correlation heatmaps in Fig. 3, illustrate the feature relationship preservation between the original and GAN-generated datasets. Visual inspection reveals remarkably similar correlation patterns, particularly among academic performance indicators. The curricular units variables maintain their strong intercorrelations in the synthetic data, suggesting successful preservation of the underlying educational data structure.

Our quantitative assessment of GAN data quality shows promising results, with a low Jensen-Shannon (JS) divergence of 0.0201 between real and generated target distributions as in Table II. This indicates that our synthetic data closely approximates the true distribution of student outcomes. The average feature JS divergence of 0.0002 further confirms excellent preservation of individual feature distributions, while the correlation matrix difference of 0.4943 suggests reasonable maintenance of feature relationships.

TABLE II. Overall GAN-Quality Evaluation Metrics. A Lower Jensen–Shannon (JS) Divergence Denotes a Closer Match Between Real and Generated Distributions

Metric	Value
Target distribution JS divergence	0.0201
Average feature JS divergence	0.0002
Correlation-matrix difference	0.4943

Class-specific statistical analysis as in Table III reveals varying levels of data generation quality across student outcomes. The Graduate class shows perfect statistical matching (mean difference: 0.0000, standard deviation difference: 0.0000), while the Dropout and Enrolled classes demonstrate

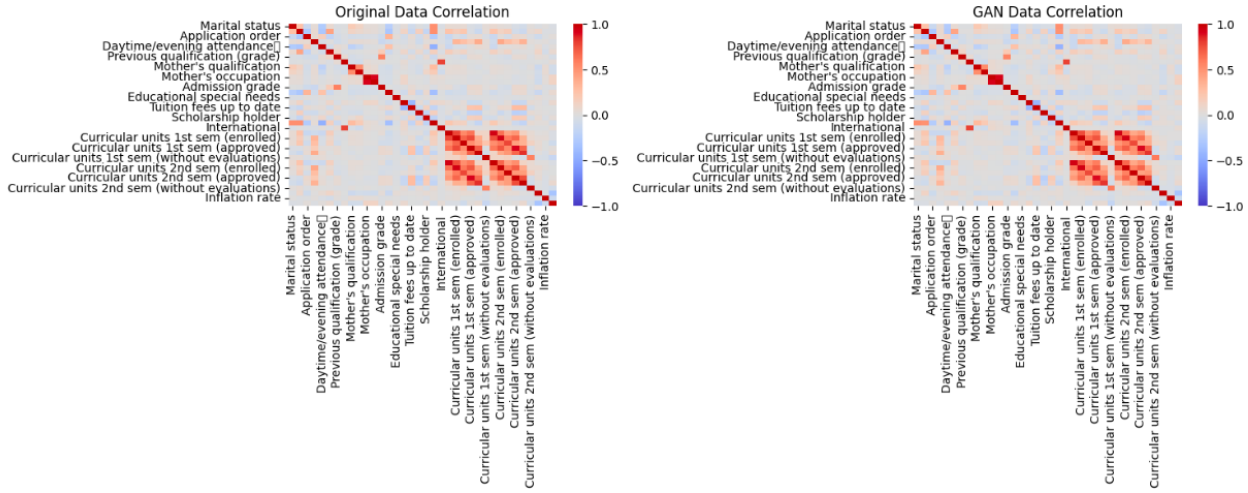

Fig. 3. Side-by-side pearson correlation matrices for the real dataset (left) and the cGAN-generated dataset (right).

moderate statistical differences. These variations likely reflect the complexity of modeling student dropout patterns compared to more predictable graduation trajectories. Despite these differences, the synthetic data successfully addresses class imbalance issues while maintaining essential statistical properties, contributing significantly to the enhanced model performance observed in our results.

TABLE III. CLASS-SPECIFIC STATISTICAL DIFFERENCES BETWEEN REAL AND SYNTHETIC DATA. SMALLER DIFFERENCES INDICATE A CLOSER MATCH IN STATISTICAL PROPERTIES

Class	Mean Difference	Std. Deviation Difference
Dropout	0.8705	1.9247
Graduate	0.0000	0.0000
Enrolled	0.6862	1.1156

B. Best Model Performance

Our analysis of machine learning model performance reveals substantial improvements achieved through cGAN-based data enhancement strategies. As illustrated in Fig. 4, all three classification algorithms demonstrated significant performance gains when trained on either cGAN-generated data alone or the combined dataset approach. The XGBoost classifier emerged as the superior prediction model, particularly when implemented with the combined dataset approach. This configuration achieved an outstanding accuracy of 92.79%, representing a remarkable 15.46 percentage point improvement over the original data model (77.33%). Similar gains were observed in precision metrics, with the combined XGBoost model reaching 92.84% precision compared to 76.53% for the original data model. This significant enhancement in performance metrics substantiates the value of addressing class imbalance through synthetic data generation techniques.

While all models benefited from cGAN enhancement as showed in Table IV, the relative improvements varied by algorithm. Random Forest showed a 10.52 percentage point increase in accuracy from original (77.48%) to combined (88.00%), while LightGBM demonstrated a 12.51 percentage point improvement (76.66% to 89.17%). These consistent improvements across different algorithms reinforce the robustness of our data enhancement approach.

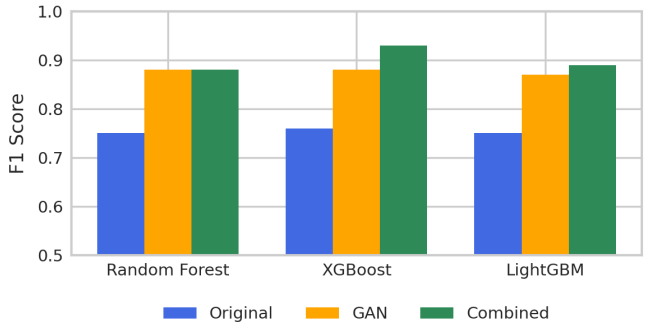

Fig. 4. F1 Score comparison across models demonstrating performance improvements.

The confusion matrices presented in Fig. 5 provide deeper insight into the classification performance across different student outcomes. The combined approach implemented with the XGBoost classifier demonstrated exceptional performance in correctly identifying all three student categories (Dropout, Enrolled, Graduate). Most notably, the combined model achieved remarkable improvement in dropout prediction accuracy, correctly identifying 985 dropout cases compared to just 396 in the original model. This enhanced ability to identify at-risk students is particularly valuable for intervention planning, as it enables institutions to target support resources more effectively. Similarly, the model's improved accuracy in classifying enrolled students (823 correct classifications) and graduates (1269 correct classifications) provides a more comprehensive understanding of student trajectories. The confusion matrices also reveal a reduction in misclassification errors. The combined model showed fewer instances of erroneously classifying dropout students as enrolled or graduated, which is crucial for minimizing false negatives in dropout prediction. This precision is essential for educational institutions seeking to identify all students who might benefit from intervention support.

TABLE IV. PERFORMANCE COMPARISON BETWEEN ORIGINAL AND CGAN-ENHANCED MODELS

Model	Accuracy			Precision			Recall			Training Time (s)		
	O	CG	C	O	CG	C	O	CG	C	O	CG	C
Random Forest	0.7748	0.8788	0.8800	0.7592	0.8828	0.8827	0.7748	0.8788	0.8800	0.5357	0.6903	1.2941
XGBoost	0.7733	0.8819	**0.9279**	0.7653	0.8853	**0.9284**	0.7733	0.8819	**0.9279**	0.2806	0.3223	**0.4661**
LightGBM	0.7666	0.8622	0.8917	0.7593	0.8672	0.8938	0.7666	0.8622	0.8917	0.3306	0.3697	0.5081

Legend: O = Original, CG = cGAN, C = Combined

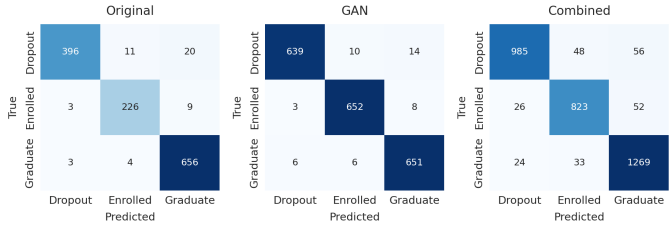

Fig. 5. Confusion matrix for the best model showing balanced classification performance.

C. Comparative Analysis of Intervention Methods

1) Intervention quantity and detail: The quantity and detail of interventions as shown in Fig. 6, varied substantially across the four methods evaluated. The Rule-Based approach generated the fewest interventions per student (2.55) with the shortest average length (8.70 words per intervention). This brevity limited the detail and actionability of the recommendations, resulting in generic guidance that may not adequately address student-specific challenges. In contrast, the Few-Shot method produced a substantially higher number of interventions (13.18) with moderate detail (38.89 words per intervention). The Fine-Tuned approach prioritized depth over breadth, generating a moderate number of interventions (8.64) but with the highest level of detail (61.61 words per intervention). This reflected the Fine-Tuned model's ability to elaborate on specific interventions with contextual information and implementation guidance. The Hybrid method achieved the highest intervention count (15.09) while maintaining a strong level of detail (41.49 words per intervention). This balanced approach suggests that the Hybrid method successfully combines the generative capacity of language models with the structured framework of rule-based systems to produce numerous detailed recommendations.

2) Comprehensiveness and Specificity: The category coverage metric as shown in Fig. 6, revealed important differences in how comprehensively each method addressed the various intervention domains (academic, financial, and social). The Hybrid method demonstrated exceptional coverage (0.94), addressing nearly all relevant intervention categories for each student. The Few-Shot approach achieved moderate coverage (0.79), while the Rule-Based (0.64) and Fine-Tuned (0.52) methods showed more limited scope.

The Fine-Tuned method's lower category coverage was particularly notable, suggesting that while it excelled in generating detailed interventions, it sometimes focused too narrowly on certain intervention types while neglecting others that might be relevant to a student's situation. Regarding specificity, the Hybrid approach again outperformed other methods with a score of 0.63, indicating a high degree of personalization in its recommendations. The Few-Shot (0.49) and Fine-Tuned (0.48) methods demonstrated moderate specificity, while the Rule-Based approach (0.41) generated more generic interventions with limited tailoring to individual student circumstances.

3) Computational efficiency: The computational efficiency analysis, as shown in Fig. 6, illustrates a pronounced disparity in runtime efficiency across the evaluated methods. The rule-based engine produced recommendations almost instantaneously ($\approx$ 0s per student), a speed that makes it well suited to large-scale or real-time deployments. In sharp contrast, the hybrid model required an average of 61.34 s per student, imposing a sizeable computational overhead that could hamper implementation in settings with limited hardware resources or stringent latency demands. This divergence underscores a fundamental trade-off: the hybrid approach delivers more nuanced and context-rich guidance, but its resource intensity may oblige institutions to generate recommendations in scheduled batches rather than on demand.

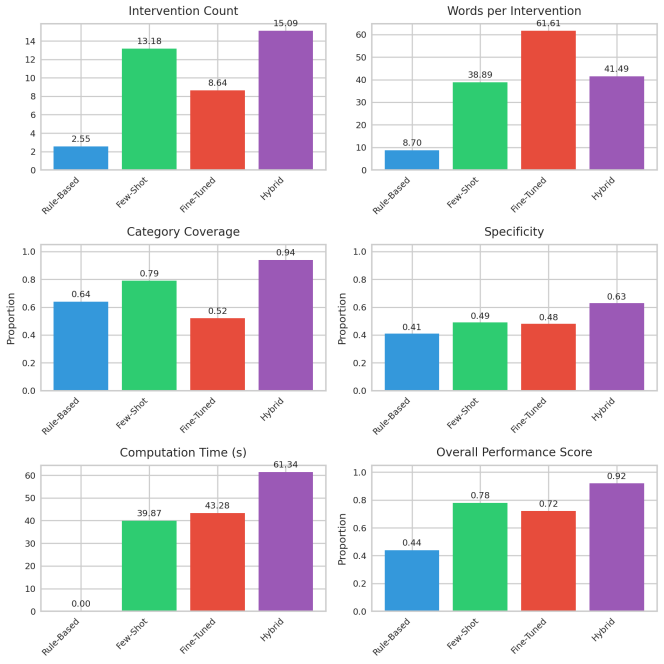

Fig. 6. Quantitative comparison of four student dropout intervention methods across six key performance metrics.

D. Qualitative Analysis of Intervention Content

Beyond quantitative metrics, we conducted qualitative analyses of the intervention content generated by each method, examining the language patterns and recommendation themes through word cloud visualizations.

1) Rule-based method content: The Rule-Based method produced highly structured but limited interventions. The word cloud as shown in Fig. 7, analysis revealed a narrow vocabulary focused primarily on basic academic support terms. Interventions typically followed rigid templates with minimal personalization, such as "attend tutoring sessions" or "meet with academic advisor." While consistently addressing core academic concerns, these interventions lacked depth and contextual relevance to specific student situations.

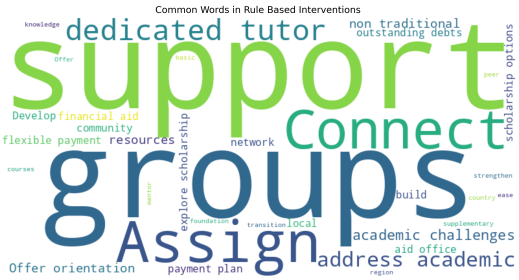

Fig. 7. Word cloud visualization of common terms in rule based method intervention recommendations.

2) Few-shot method content: The Few-Shot method generated interventions with more diverse language and recommendation types. The word cloud as shown in Fig. 8, showed a broader vocabulary spanning academic, financial, and social support domains. Interventions demonstrated increased contextual awareness but sometimes lacked the specificity necessary for highly personalized support. The method excelled in generating a wide range of intervention types but with moderate depth in each.

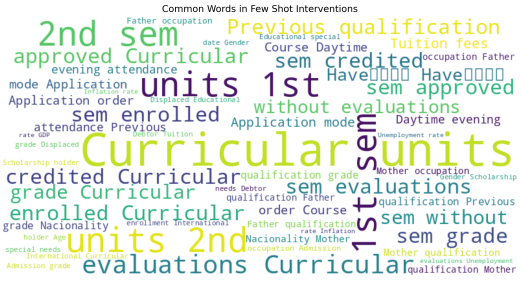

Fig. 8. Word cloud visualization of common terms in few shot method intervention recommendations.

3) Fine-tuned method content: The Fine-Tuned approach produced the most detailed and linguistically sophisticated interventions. The word cloud as shown in Fig. 9, revealed rich, specialized vocabulary related to academic support strategies and student success. These interventions often included specific implementation steps and contextual information, such as detailed tutoring recommendations with scheduling suggestions and expected outcomes. However, the method sometimes overemphasized certain intervention categories while neglecting others, resulting in lower overall category coverage.

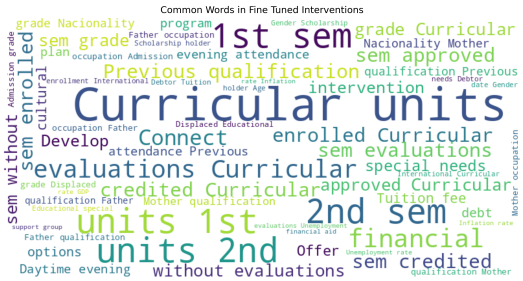

Fig. 9. Word cloud visualization of common terms in fine tuned method intervention recommendations.

4) Hybrid method content: The Hybrid method demonstrated the most balanced intervention content, combining comprehensive coverage with strong specificity. The word cloud as shown in Fig. 10, analysis revealed diverse vocabulary across all intervention domains, with terms related to academic support, financial assistance, and social integration appearing prominently. Interventions were both numerous and substantive, providing specific, actionable recommendations tailored to individual student profiles while addressing the full spectrum of potential support needs.

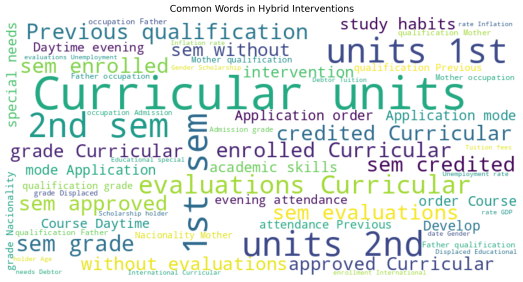

Fig. 10. Word cloud visualization of common terms in hybrid method intervention recommendations.

E. Strengths and Weaknesses Analysis

Our comprehensive evaluation revealed distinct patterns of strengths and limitations as shown in Table V for each intervention method:

1) The Rule-based: method's primary advantage lies in its computational efficiency, making it suitable for resource-constrained environments or large-scale deployment where processing time is a critical concern. However, its limited recommendation quality restricts its effectiveness in providing personalized, actionable support.

TABLE V. COMPARATIVE ANALYSIS OF STUDENT DROPOUT INTERVENTION METHODS: STRENGTHS AND WEAKNESSES

Method	Strengths	Weaknesses
Rule-Based	- Exceptional computational efficiency (0.00s) - Consistent structure across recommendations - Predictable output format	- Limited intervention count (2.55) - Minimal detail (8.70 words) - Low specificity (0.41) - Restricted vocabulary and variety
Few-Shot	- Strong intervention count (13.18) - Good category coverage (0.79) - Moderate specificity (0.49) - Diverse recommendation types	- Moderate detail (38.89 words) - Less precise personalization - Higher computational requirements than Rule-Based
Fine-Tuned	- Exceptional detail (61.61 words) - Rich, sophisticated language - Strong contextual information - Detailed implementation guidance	- Limited category coverage (0.52) - Moderate intervention count (8.64) - Tendency to focus on specific intervention types
Hybrid	- Superior intervention count (15.09) - Excellent category coverage (0.94) - Highest specificity (0.63) - Strong balance between quantity and quality	- Substantial processing time (61.34s) - Higher implementation complexity - Resource-intensive deployment

2) The Few-shot: This method represents a balanced approach that performs reasonably well across all metrics without excelling in any specific dimension. It offers a viable compromise between recommendation quality and computational requirements.

3) The Fine-tuned: This method's strength in generating detailed, context-rich interventions makes it particularly valuable when in-depth support in specific areas is prioritized over comprehensive coverage across all potential intervention categories.

4) The Hybrid method: This consistently outperformed other approaches across most evaluation metrics, demonstrating its effectiveness in generating numerous, comprehensive, and personalized interventions. However, its significant computational requirements represent an important practical limitation that must be considered for implementation.

V. DISCUSSION AND RESULTS

This study set out to examine whether an integrated framework that couples class-balanced dropout prediction with personalised intervention generation can meaningfully reduce student attrition. The empirical evidence supports this premise. By alleviating class imbalance with cGAN-generated samples, the predictive component—most notably the XGBoost classifier—achieved 92.79% accuracy and 92.84% precision, an improvement of 15.46 percentage points over its baseline performance, while maintaining a modest training time of 0.47 seconds. These results confirm that synthetic data augmentation can unlock substantial gains for established machine-learning algorithms.

Equally important, the analysis of intervention strategies showed that methodological integration offers advantages unattainable by any single paradigm. The hybrid engine, which blends rule-based scaffolding with the contextual agility of large language models, produced an average of 15.09 tailored recommendations per student, covered 94% of intervention categories, and attained the highest specificity score (0.63). Although this approach demands greater computational resources—approximately 61 seconds to generate interventions for each student—it consistently delivered the most comprehensive and contextually appropriate guidance. In contrast, the purely rule-based system ran almost instantaneously but lacked depth, while the fine-tuned model generated lengthy, sophisticated advice without achieving comparable breadth across academic, financial and social domains.

Several limitations temper these findings. The evaluation focused on recommendation quality rather than direct measurement of retention outcomes, and the computational requirements of the more sophisticated methods may restrict adoption in resource-constrained settings. Furthermore, certain qualitative dimensions of recommendation relevance are difficult to quantify and therefore fall outside the scope of the current metric suite. Future work should undertake longitudinal field studies to gauge real-world impact, explore optimisation techniques that reduce computational overhead, and incorporate reinforcement-learning feedback loops to refine interventions over time.

VI. CONCLUSION

This research developed an integrated framework combining class-balanced dropout prediction with personalized intervention generation to enhance student retention in higher education. The approach addresses a critical gap in educational technology by moving beyond risk identification to provide actionable remediation strategies.

The cGAN-enhanced XGBoost classifier achieved 92.79% accuracy, a 15.46 percentage point improvement over baseline performance, demonstrating that synthetic data augmentation can significantly improve predictive capabilities when addressing class imbalance in educational datasets.

The hybrid intervention engine, combining rule-based methods with large language models, outperformed individual approaches by generating 15.09 tailored recommendations per student with 94% category coverage and the highest specificity score (0.63). However, this comprehensive approach required 61 seconds per student compared to near-instantaneous rule-based processing, presenting important trade-offs for practical implementation.

The evaluation focused on recommendation quality rather than longitudinal retention outcomes, and computational requirements may limit adoption in resource-constrained environments. Future research should prioritize field studies measuring actual retention rates and explore optimization techniques to reduce processing overhead.

This integrated framework demonstrates that combining cGAN-enhanced prediction with hybrid intervention generation offers institutions a scalable pathway to reduce attrition while maintaining personalized support. The system bridges the critical gap between risk detection and remedial action, representing a significant advancement in educational technology for improving student persistence and academic success outcomes.

Habitat Intelligence: How Machine Learning Reveals Species Preferences for Ecological Planning and Conservation

Meryem Ennakri[1], Soumia Ziti[2], Mohamed Dakki[3]
Intelligent Processing and Security of Systems-Faculty of Sciences,
Mohammed V University of Rabat, Morocco[1,2]
Scientific Institute (Zoology and Animal Ecology), Mohammed V University of Rabat, Morocco[3]

***Abstract*—The emerging confluence between artificial intelligence and ecology has generated a new research frontier, which we refer to as habitat intelligence, aiming to unveil species environment relationships through data-driven approaches. This SLR aims to summarise the pass to the current year (2025) of the research on the use of ML and DL models to represent species preferences, habitat suitability and ecological niches. Based on 365 peer-reviewed papers extracted from SCOPUS, Web of Science and OpenAlex, we identify four main areas of innovation which encompass: automated species identification and ecological monitoring; AI-enhanced species distribution models (SDMs); advanced data collection and processing for ecological research; and conservation-oriented decision support systems. Our review shows that AI has the potential for a more precise and scalable approach to biodiversity investigations in the age of integrated remote sensing, acoustics, citizen science, and environmental data. But we also point out pressing challenges such as data paucity, model interpretability and computational limitations. We suggest that future advancements in this branch of the food web could come from interdisciplinary cooperation using explainable AI (xAI) and the construction of bridging hybrid models between prediction and ecological interpretability. In the end, this review offers a conceptual and methodological 'roadmap' to other researchers and conservation practitioners who wish to apply AI to the service of global biodiversity aims.**

Keywords*—*Artificial Intelligence; machine learning; deep learning; species preferences; habitat suitability modeling; Species Distribution Models (SDMs); ecological niche modeling; conservation planning; environmental monitoring; Explainable AI (xAI); habitat intelligence; biodiversity management

I. Introduction

Biodiversity erosion, habitat degradation and the increasing consequences of global climate change represent major challenges for conservation science and environmental management. Knowledge of the preferences that species exhibit for particular habitats (hereafter referred to as species–environment relationships or ecological affinities) is critical to both effective biodiversity conservation,5 ecological forecasting, and spatial planning. Conventionally these preferences are investigated with ecological niche models (ENMs), species distribution models (SDMs), and empirical field observations. However, these methods are often limited by insufficient data, linear assumptions, and difficulty in extrapolation across ecosystems or taxonomic groups.

The past few years have seen accelerating interest in artificial intelligence (AI), and in machine learning (ML) and deep learning (DL) more specifically, in ecology. These approaches provide unparalleled functionality for analyzing complex, non-linear data with high dimensionality, which enable more accurate and higher spatial resolution predictions and models for species' habitat preferences. AI has begun to be applied in diverse fields such as remote sensing and automated ecological monitoring to manipulate patterns from largescale environmental datasets, amalgamate heterogeneous sources of data (e.g., climate, land cover, biotic interactions), and discover ecological patterns that were overlooked or impractical to quantify before.

This nascent field what we will call here "Habitat Intelligence" represents a synthesis of fields: ecological modeling, computer vision, geospatial science, and conservation biology. The increasing amount of works that employ ML algorithms for species preference analysis suggests that a structured research topic has come to the fore, for which no synthesis is nevertheless available. However previous reviews focus on AI applications to biodiversity in general and do not directly analyze modelling species habitat preference across various ecosystems and taxa. This review introduces the concept of habitat intelligence, defined as the integrative use of artificial intelligence techniques to uncover, interpret, and model species–environment relationships for conservation purposes. This emerging field synthesizes ecological modeling, computer vision, geospatial science, and conservation policy. The objective of this paper is to map this interdisciplinary domain through a systematic literature review (SLR) of 365 peer-reviewed studies published between 1996 and 2025. The following sections present the methodology of the review, a synthesis of AI applications across four thematic axes, a discussion of their implications, and key challenges and future perspectives.

The following research questions are considered throughout the review:

- How is AI helping to identify species and monitor the natural world?
- What are the current best machine learning techniques used for the species distribution models (SDM) and habitat suitability models?
- What are the types of data, sources, and preprocessing techniques employed to facilitate artificial intelligence-driven ecology modeling?

- How do AI-based models assist with conservation planning, biodiversity management, and ecosystem resilience?

Through asking these questions and following the IMRAD approach , the current review seeks to chart the intellectual terrain of this fast-developing area, scope current research themes and lacunae, and suggest directions for future interdisciplinary efforts at the AI and conservation science boundary.

II. Related Work

Previous reviews have explored the use of machine learning and deep learning in ecological contexts, including species distribution modeling (SDMs), environmental monitoring, and biodiversity prediction [1], [7], [8], [35]. However, these reviews typically focus on specific techniques or limited ecological domains. None provide a comprehensive synthesis of the integration of AI with ecological preference modeling across data types and ecosystems. Moreover, the conceptual emergence of "habitat intelligence" as a unified research direction has not been formalized. This article addresses this gap by combining methodological mapping, taxonomic classification of AI applications, and a focus on implementation value for conservation and policy planning.

III. Methodology

This study follows the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) Figure1 framework to ensure methodological rigor, transparency, and reproducibility. The systematic literature review (SLR) was designed to capture and synthesize scholarly work that applies artificial intelligence(AI) including machine learning(ML) and deep learning(DL) to species habitat preference modeling, species distribution, and conservation planning.

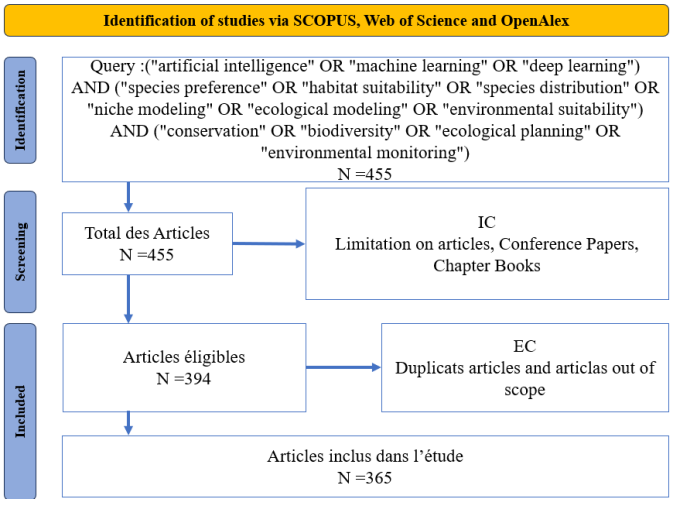

Fig. 1. PRISMA Aproach.

The bibliographic data were collected from three major academic databases: SCOPUS, Web of Science, and OpenAlex. A unified query was applied across all three platforms, targeting articles that addressed the intersection of AI and ecological modeling with a focus on species preference and conservation. The query string was as follows: ("artificial intelligence" OR "machine learning" OR "deep learning") AND ("species preference" OR "habitat suitability" OR "species distribution" OR "niche modeling" OR "ecological modeling" OR "environmental suitability") AND ("conservation" OR "biodiversity" OR "ecological planning" OR "environmental monitoring")

A. Screening Process

The screening was conducted in two main stages:

- Initial Screening (Inclusion Criteria - IC):

The first filter excluded irrelevant publication types such as non-peer-reviewed documents, book chapters, theses, editorials, and workshop summaries. Only journal articles, conference papers, and reviews published in peer-reviewed venues were retained. After this stage, 394 articles were considered eligible.

- Secondary Screening (Exclusion Criteria - EC):

The eligible articles were further examined to remove:

- Duplicate records across databases;
- Articles that did not directly address the use of AI for modeling species preferences or conservation planning;
- Studies focusing on unrelated applications of AI in biology or agriculture without ecological modeling relevance.

After applying these criteria Table1, a final set of 365 articles was retained for full analysis.

TABLE I. Inclusion and Exclusion Criteria for Article Selection

Criteria Type	Description
Inclusion Criteria (IC)	• Peer-reviewed articles using AI/ML/DL for species distribution modeling, habitat suitability, or conservation planning; • Published between 1996–2025; • Indexed in SCOPUS, Web of Science, or OpenAlex.
Exclusion Criteria (EC)	• Non-English articles, duplicates, and non-ecological AI studies; • Articles not focusing on species–environment interactions or habitat modeling.

IV. Results

The intersection of artificial intelligence (AI) and machine learning (ML) with ecological research is a transformative technological advancement that is reshaping how scientists study biodiversity and ecological systems. An aspect of machine learning is deep learning, which is widely used as a fundamental part of ecological data science for interpreting complex patterns not easy to capture using classical statistical methods [1][2]. This technological merging is especially useful in the current era of unprecedented challenges to ecology such as biodiversity loss, effects of climate change, and diseases outbreaks [3].

AI In Ecology The modern wave of AI knowledge and techniques are now being more commonly adopted within ecological research due to the increasing computing power to run standard learning [4]. Machine learning methods are powerful in recognizing complex patterns generated by higher-order interactions and are applied to identify patterns of genetic regulatory networks and patterns of species coexistence [5][6]. These skills have been especially useful in handling the increasingly large data sets produced through automated surveillance of populations and communities [7].

AI based applications in ecological domain cover wide range of applications such as automatic species identification, ecology modeling, behavioral analysis, DNA sequencing, and population genetics [8]. Good the In particular, these technologies support the study of the organism-environment interaction using camera and acoustic, animal behavior using deep learning and satellite data to ecological functions [3]. In the context of the marine environment, AI is contributing to relieve data processing bottlenecks in coral reef surveys by applying machine learning that can efficiently process large quantities of image data [9][10].

One especially exciting use is for overcoming data gaps in conservation status assessments. The conservation status of data deficient species may be inferred using machine learning models that can predict this, and data deficient species for which such models can be developed removed from lists of potential species for which the conservation status is unresolved [1][11]. Ecological niche models have also been advanced and expanded upon through the use of machine learning, informing our understanding of species distributions and habitat suitability and having applications for conservation biology and climate change [12].

With the further development of these technologies, however, they are becoming the most advanced tools available for ecological research, allowing for new methods of monitoring, understanding and conserving biodiversity in the context of global environmental change [3][4].

A. AI Applications in Species Identification and Monitoring

The use of artificial intelligence has changed the strategy of how ecologists discover or track species, deep learning provides us with an efficient method to analyze the massive data produced by recent ecodging monitoring systems [13-15]. The camera trap is one of the most important monitoring technologies that has been revolutionized by AI, which is critical for tracking wildlife distribution and activities at large spatial and temporal scales, showing great potential for wildlife community studies [16][17]. The biggest impediment with camera trap experiments, namely transferring millions of images, is being overcome thanks to the implementation of deep learning techniques, especially for what concearns the Convolutional Neural Networks (CNN), that can automatically identify wild animals and assign them to taxonomic entities with outstanding accuracy [18].

Such AI-based systems show remarkable results in species identification works. Deep neural networks have been demonstrated to automatically recognize animals with more than 93.8% accuracy, andnovel demonstrations validate that networks which are forced to select purely on high-confidence predictions of high confidence are as accurate as human volunteers in identifying taxa (96.6% accuracy) while being more than two orders of magnitude faster, processing thousands of images in less than a second without any training in this taxonomic category [18][19] Figure2. This substantially sped up processing (approximately 2000 images per minute on typical computing hardware) amounts to a revolution in our capacity for ecological research [20]. By incorporating AI with citizen science collaboration, it has been demonstrated that human effort can be minimized by as much as 43% without losing overall accuracy interms of detecting webs [21].

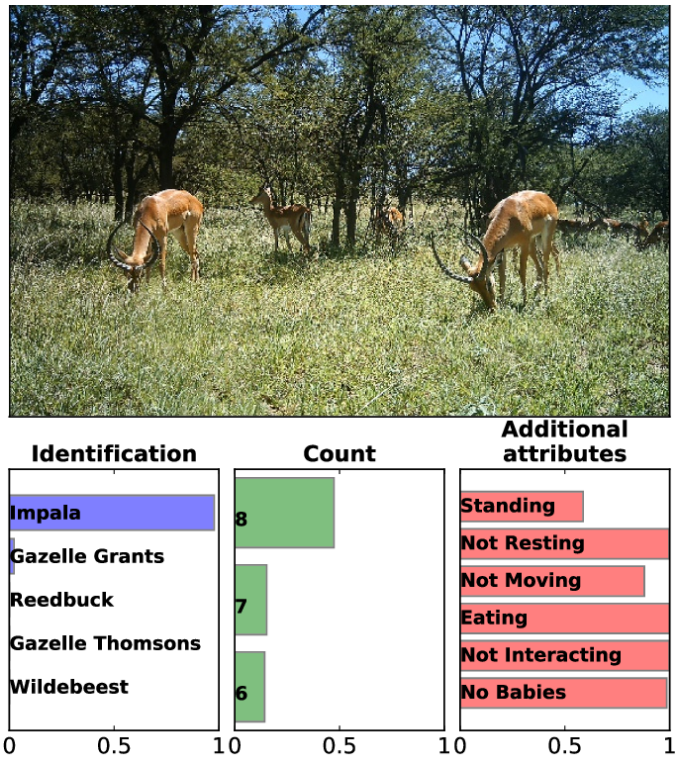

Fig. 2. Exemple of Deep Neural Networks (DNNs) can successfully identify, count, and describe animals in camera-trap images.

Apart from camera traps, AI is also changing monitoring of marine ecosystems with automatic species identification from diverse platforms such as moored observatories, AUVs and satellite imagery [22]. Deep learning models allow automated classification of marine species using a variety of information sources such as citizen science observations, benthic photo quadrats, cabled video observatories and acoustic sensors [22-24]. For instance, with acoustic data, 98.69% is achieved by CNN-based systems to recognize animal calls since marine mammal calls recorded from the sea from acoustic data instead of using a traditional method [25].

AI and species monitoring have been used for whale detection from satellite images [26], automated community ecology of planktonic foraminifera [27], as well as conservation-oriented platforms that identify animals, humans and poaching activities [28]. In particular, AI approaches have been found to be useful in predicting species interactions by trait-matching, with better performance of ML models as compared to statistical models in capturing complex ecological interactions [29].

AI and participation is is emerging direction, with some projects that use citizen science data to train AI for automatic species identification [30]. They have been described as democratizing advanced ecological monitoring through open source, low-cost, and low-powered developments [30][31] that facilitate communities' participation in biodiversity research.

With ongoing development of these capabilities, it is hoped that they will revolutionise ecological and conservation research by making analysis of large data sets more efficient, offering real time species identification, as a tool for education and by providing data which will be valuable in conservation planning and policy development [32]. Importance of these advances for science The sleeve is in the flexibility of being able to use advances like these to scale up biodiversity monitoring to levels never before seen and at a level of information that may be crucial for conservation in the inevitable face of rapid global environmental change [33][34].

B. Ai-Powered Species Distribution Models and Habitat Suitability Analysis

The use of Species Distribution Models (SDMs) has become popular in the field of ecology, biogeography and conservation biology to understand relationships between environmental predictors and species distribution. In the last twenty years, this field has embraced more and more machine learning features leading to a series of incremental model improvements [35]. Such AI-augmented SDMs can be used to model ecological niches and to predict suitable habitats more accurately as compared to classical statistical techniques, although there is a considerable variation among performance of the methodologies with respect to different ecological parameters, with predictions for presence–absence (53%) performing better than predictions of abundance, population fitness, and genetic diversity [36].

AI methodologies, including neural networks as well as ensemble learning, have substantially enhanced the accuracy of SDMs by revealing intricate associations among species and their environments [36]. MaxEnt, a popular machine learning approach to the modeling of species distributions when data are only present, has in different settings impressed with its performance with a 74.7% success rate at predicting the presence of disease-carrying mosquitos in the study of [36] Figure3. These advanced modelling approaches have employed tools like deep neural networks, GIS and CNN to predict potential habitats under existing and future environmental conditions [37].

The coupling of machine learning approaches and remote sensing has proved especially useful in habitat mapping and monitoring. These two tools offer major benefits to conservation practitioners allowing informed decisions to be made and targeted interventions to be taken to conserve threatened species and habitats [38]. For instance, spatial researchers have applied GIS and machine learning to understand the effect of urbanization on bobcat habitats in San Jose,CA by creating an original Habitat Suitability Model (HSM) that combines several environmental aspects to pinpoint critical conservation areas [39]. Similarly, in Leipzig, Germany, data from high-resolution Earth Observation and machine learning was employed to model hotspots of 44 bird species achieving 59-90% accuracy, and halting species richness of urban birds [39].

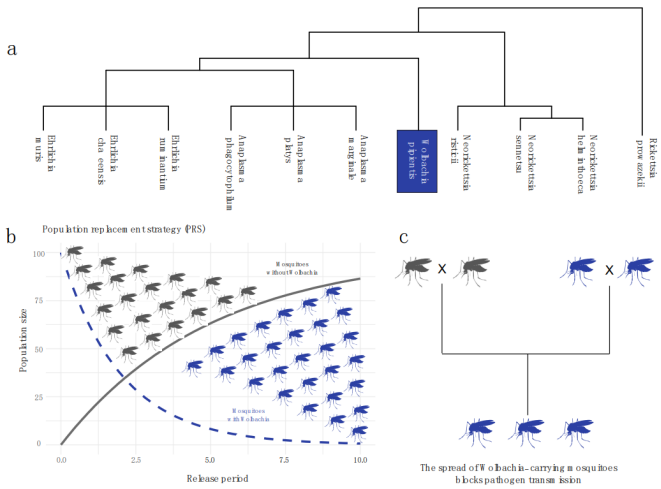

Fig. 3. Wolbachia-based population replacement strategy for mosquito-borne disease control.

Despite these developments, SDMs should be regarded as hypotheses that require testing with independent data, particularly in relation to conservation planning [36][40]. As a first step in overcoming interpretability problems associated with complex models, a new subfield known as explainable AI (xAI) provides a hope for improved understanding and interpretation of SDMs [35].

The conservation utility of AI-SDM/HSM is extensive. These technologies can process ecological data to identify hotspots of biodiversity point at risk of extinction and decide conservation priorities [41]. By participating in efforts to save endangered species, conserve biodiversity, and restore degraded habitats, AI is increasingly proving to be an essential tool in the conservation toolbox, enabling scientists and practitioners to tackle these types of complex ecological challenges in the face of a rapidly changing world.

To assist conservation practitioners in selecting appropriate AI techniques, we compare different models based on their accuracy and resource requirements. Table 2 Comparative performance and resource demand of selected AI models in ecological modeling.

This comparison illustrates the trade-offs between model complexity, interpretability, and operational costs, which are key to real-world adoption in conservation contexts.

C. Data Collection and Processing Methods for Ecological Research

Contemporary ecological study is more and more dominated by new ways of capturing and treating data fueled by A.I. These methods have revolutionized the way ecologists collect and interpret population level data:

DCNNs favor automatic analyses of images in ecology with an automatic detection of a high number of cells allowing, for example, quantitative wood anatomical investigations and accounting for the biological feature variance that needs manual handling in the past [42].

Audio Analysis and Classification methods leverage machine learning for the processing and classification of sounds

TABLE II. COMPARATIVE PERFORMANCE AND RESOURCE DEMAND OF SELECTED AI MODELS IN ECOLOGICAL MODELING

Model	Accuracy Range	Training Time	Hardware Requirements	Interpretability
MaxEnt	60–80%	Low	Standard PC	High
Random Forest	70–90%	Medium	Standard PC	Medium
CNN	80–98%	High	GPU	Low
DNN + xAI	85–95%	High	GPU/TPU	Medium to High

characteristic of wildlife, such as amphibian calls. These solutions use digital speech algorithms and filtering analysis to identify species according to their acoustic signatures [43] Figure4.

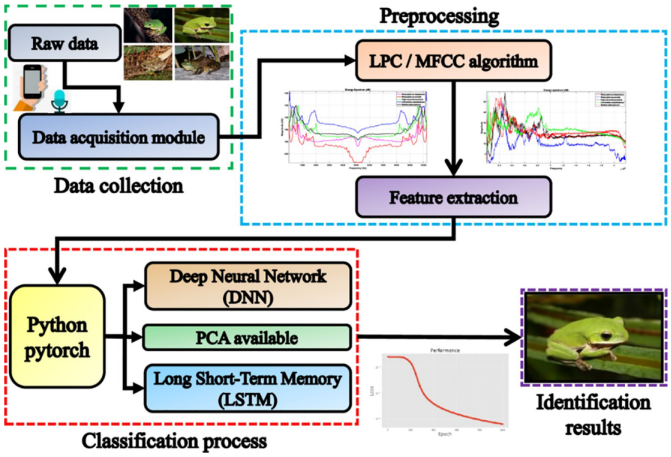

Fig. 4. The Structure of the experimental process for anuran bioacoustic classification.

Camera Trap Image Processing utilizes deep learning techniques to help sift through the millions of images and automatically identify wildlife. Such systems are capable to process around 2,000 images per minute on standard hardware, and they attain accuracy equal or greater than 98% in species classification [44][20].

Acoustic Monitoring Systems have employed convolutional neural networks for the detection and classification of echolocation calls produced by bats and other animals, with the latter being important for the processing of recordings collected in noisy field environments [44][45].

Integration of Remote Sensing and GIS: Remote Sensing and GIS Integration utilizes artificial intelligence, remote sensing imagery and GIS data to assess biodiversity at the landscape level. This integration supports generation of habitat maps, detection of ecological change, and identification of conservation priorities [46].

Plant Functional Trait Mapping applies deep learning models to field data or even photographs to map plant traits across landscapes. Recent development encompassmodels integrating field data with spectral information, and even use citizen science to map plant functional diversity [47-49].

(Field-deployed) Autonomous Environmental Sensors with embedded AI processing can process video imagery or acoustic streams on-site to identify and classify organisms to species level without external intrusion [50].

The use of deep learning in Earth Observation Data Processing permits higher resolution habitat classification, which is a prerequisite for the generation of fine-grained distributions of species across large spatial and temporal extents. Recent studies have been able to map global canopy height at 10m resolution using LiDAR data from satellite [50][51] Figure5.

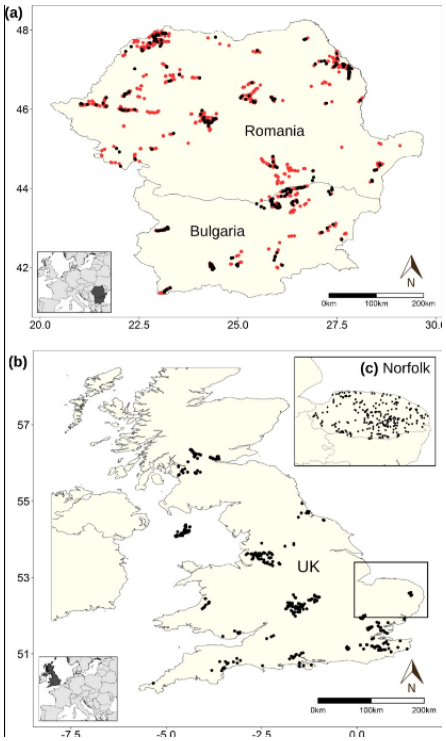

Fig. 5. Spatial distribution of the BatDetect CNNs training and testing datasets.

Multi-spectral Imaging Flow Cytometry combined with deep learning for rapid pollen identification and enumeration with high accuracy (96% species average accuracy), and morphology characterization (size, symmetry, and structure) [52].

Together these advancements have dramatically changed how ecological data are gathered and processed and, in the process, have allowed researchers to analyse extremely large datasets at scales unattainable through other measures, deriving significant patterns that would be unrecoverable by traditional means [7] [53]. The following table2 prensent differnt use cases of data collection and processing methods powered by artificial intelligence.

D. Conservation and Biodiversity Management Applications

Artificial Intelligence (AI) has become a very powerful force in the discipline of Conservation Biology and biodiver-

TABLE III. SUMMARY OF STUDIES APPLYING AI IN BIODIVERSITY MONITORING AND ECOLOGICAL PREDICTION

Papers	Data Collection Method	AI Technique Used	Ecological Application	Species or Habitat Focus	Data Processing Approach	Model Performance Evaluation
[42]	Images from transversal wood anatomical sections, manual cell area outputs	DCNN, Mask-RCNN	Quantitative wood anatomical analyses	Alnus glutinosa, Fagus sylvatica, Quercus petraea, and four conifer species	Mask-RCNN for image segmentation, compared with U-Net and ROXAS	Compared with U-Net and ROXAS; evaluated cell detection and pixel accuracy
[43]	Data collected from 32 frog and 3 toad species using bioacoustic recordings	DNN and LSTM	Species identification and biodiversity monitoring through amphibian sound classification	35 amphibian species in Taiwan, including frogs and toads	LPC, MFCC for filtering; PCA for dimensional reduction	Accuracy, training time, and comparison of DNN and LSTM with PCA

[49]	Photos from citizen science (iNaturalist) and trait observations (TRY database)	CNN ensembles	Automated assessment of plant functional diversity through trait prediction	Plants; across growth forms, taxa, and global biomes	CNN, CNN ensembles, trait plasticity, climate factors	Accuracy enhanced using CNN ensembles and prior knowledge on trait plasticity

sity management, where many new innovative solutions are applied to complex environmental problems. Artificial Intelligence (AI) algorithms are revolutionizing wildlife surveillance by scanning through camera trap footage, while droids send back pictures of poachers from the air, analyzing the imagery and GPS data to recognize species and provide estimates of their abundance risking extinction, depending on humans´ decisions and AI algorithms scanning camera traps [54] Figure6. These technologies allow conservation biologists analyze huge amounts of ecological data, which would be infeasible to process manually, in an automated way, extensively improving the assessment of habitat health and the monitoring of populations [55].

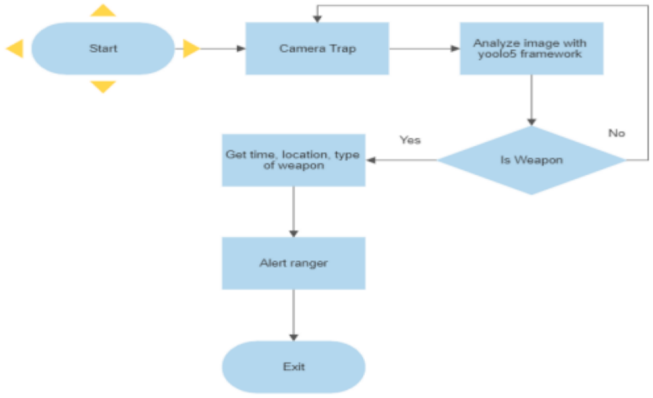

Fig. 6. Flowchart explaining methodolgy of anti-poaching system (Kuruppu, 2023).

AI combined with remote sensing instruments is seen to be particularly useful in habitat evaluation and resource preservation. Machine learning models with satellite imagery to identify forest cover changes, deforestation patterns and areas in need of environmental restoration can be used for this purpose [55]. This combination provides dense spatial and temporal information for otherwise poorly studied areas, with the analyses showing that even common methods like RF and GLM can predict relatively well different metrics of biodiversity [56][57] Figure7.

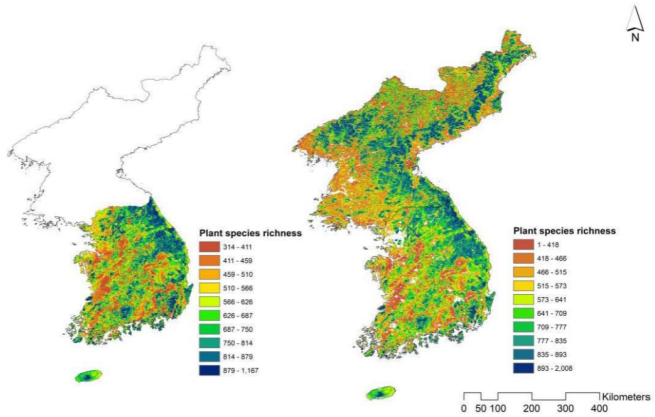

Fig. 7. Potential plant species richness estimated from S-SDMs in South Korea (Left) and estimated by th deep learning model in the Kor an Pe insula (Right).

AI's capability to handle multiple types of data, including acoustic recordings, eDNA, and imagery for species identification, to estimate biodiversity levels, and to identify new or threatened species has revolutionized biodiversity monitoring ([54]). Machine learning-type algorithms can monitor changes in population dynamics and evaluate the response of biodiversity to changes in the environment, which is important to design conservation programs and to determine how loss of

biodiversity will impact ecosystem function [58].

Arguably most importantly, predictive modeling enabled by AI can inform effective proactive conservation efforts by predicting the impacts of interventions on environmental changes and the dynamics of animal populations [55]. By combining historical and contemporary measures of decline or rate of increase of numbers of certain species and incorporating environmental change into the models, they can be used to predict potential future threatened species, thereby providing early warning of invasive species imbalance in ecosystems [59]. The ability to construct predictive models at these vast scales has the potential to transform ecology and environmental sciences in the way that statistics did over the course of the twentieth century.

AI is also improving conservation through integration of data and support of decision making. AI-supported analytics help to integrate various sources of data and present insights to support evidence-based decisions for conservation [55]. Methodological learning from comparative exercises with AI models such as ours is one way to support the development of stronger and generalisable solutions to biodiversity and habitat management [60]. Apart from direct conservation applications, machine learning also add value to conservation learning and education through the analysis of complex ecosystem data, such as climate data, soil property, and human action [59].

With overlaid environmental issues of climate change, loss of biodiversity, and zoonotic disease spread and how they intertwine the solutions, AI may provide useful tools to address such complexity [61]. AI technologies are increasingly indispensable tools within the context of modern conservation, as they allow us to automate monitoring of wildlife, improve habitat assessment, conduct advanced analyses of biodiversity, and build predictive models of species' distributions.

In a successful real-world application, a deep learning system deployed in Tanzania's Serengeti region processed over one million camera trap images to identify mammal species with 94% accuracy, significantly reducing manual labor for field researchers [20]. Similarly, AI-enhanced drones have been used in South Asia to detect and deter illegal poaching activities by combining object detection with real-time GPS alerts [28]. These examples illustrate the practical benefits and impact of AI-powered conservation tools.

E. Limitation and Future Directions

Although AI has greatly reshaped ecological and in particular biodiversity research, there are still major incomplete of AI approach and some challenging. The primary challenge is the data dependency of machine learning methods that need long high-quality well-balanced datasets that are rarely available in ecosystem contexts. This is especially problematic for the rarer species or the less studied ecosystems, as the data scarcity might result in model bias or low generalization. In addition, most ecological data sets are subject to biases introduced by selective sampling, taxonomic preferences, and geographic imbalances that may be amplified by AI models and result in erroneous conclusions.

There is also one important challenge to remain unanswered: "black box" property that belongs to many popular deep learning methods, because complex models are often "opaque" to a variety how they make the prediction by themselves and solvers, and it is hard for ecologists to interpret how those identified patterns may be relevant to the ecological process. This interpretability issue has driven the need for explainable AI (xAI) models that are able to offer explanations over decision making while retaining the skills of prediction.

From a practical point of view computational prerequisites are still, in most cases, out of reach of most performing (not computer scientists) research groups in ecology, since the "standard" training of complex neural networks requires special hardware and, in some cases, specific technical know-how, that it is not going to be part of the one found in a normal ecology department. Such a technical hurdle not only restricts wider access, but also may amplify the existing disparities in the availability of research capacity.

More fundamentally, there is a gulf between statistical prediction and ecological understanding. Although AI can learn patterns exceptionally well, as AI it may not advance ecological theory or mechanistic understanding in the absence of domain integration. It's part and parcel of the machine-learning world." Critics, however, point out that machine learning models can prioritize prediction at the cost of explanation, raising questions about their scientific value.

In the future, there are several promising avenues to tackle these issues. First among these is the emergence of easier-to-use tools and platforms that greatly lower the technical barriers to entry to AI-based ecological research. Projects like Wildlife Insights and iNaturalist show that user-friendly interfaces can democratize the use of powerful AI tools.

Transfer learning and few-shot learning methods are promising for addressing the constraint of few data by transferring models trained on data-rich species to closely related yet data-poor species. Such methods could potentially be used to transfer AI benefits to poorly studied taxonomic groups or ecosystems.

Reinforcing the interface between ecologists, computer scientists and statisticians is another important way forward, which should lead to better consideration of the ecology when designing AI tools, instead of just running a generic algorithm on ecological data. This partnership is particularly relevant for hybrid model development where the complementary strengths of machine learning, predictive performance, and mechanistic models, theoretical and interpretability related, need to be integrated.

The future for AI in ecology may involve the development of frameworks that combine multiple AI approaches with domain knowledge to satisfy both predictive needs and mechanistic understanding. For application purposes, however, it is desirable that researchers can interpret models within theoretical frameworks other than the one in which they were developed, by borrowing strengths from alternative modeling paradigms. With climate change intensifying and biodiversity decline proceeding, such integrated methodologies will be paramount to achieving effective conservation management informed bydata-driven knowledge and ecological understanding.

To mitigate geographic and taxonomic biases in training

datasets, several strategies have been proposed. These include transfer learning, where models trained on data-rich species are adapted to underrepresented taxa, and the use of synthetic data generation to augment sparse datasets.

Explainable AI (xAI) can address the black-box limitation of deep learning models. For example, SHAP (SHapley Additive exPlanations) values allow researchers to identify which environmental variables most influence a model's prediction of species presence, enhancing trust and transparency for ecologists and decision-makers alike.

V. Key Takeaways

• Neural networks enhance prediction of habitat suitability across ecosystems,

• Models like MaxEnt remain relevant due to simplicity and transparency,

• xAI offers promising solutions to bridge interpretability gaps,

• Resource needs vary widely; GPU-based models may limit accessibility.

VI. Conclusion

The augmentation of artificial intelligence with ecology research represents a state-of-the-art tool in the study, monitoring, and protection of biodiversity. In this systematic review, we have aggregated almost thirty years of worldwide research that applies AI (in particular ML and DL) to species preference analyses, ecological niche modelling and conservation recommendations.

Our review, therefore, underscores a dynamic, cross-disciplinary field that has grown exponentially since 2015 due to rapid technological development, enhanced ecological importance, and the increase in big environmental data. There are applications ranging from automated species identification in terrestrial and marine environments to sophisticated habitat suitability modelling and decision support systems. Thanks to machine learning and artificial intelligence, researchers today are able to keep track of what is happening to biodiversity across space and time at a faster and truer pace than ever before, turning static ecological censuses into dynamic feedback loops.

However, there is still much more to be done. Ecological data-sets are frequently incomplete, imbalanced or biased towards certain geographies –attributes that may limit the accuracy and generalization of predictive models. In addition, the black-box nature of a lot of AI systems is an issue for interpretability, transparency, and trust, especially in conservation where decision making has real worlds ecological and ethical consequences. There is greater urgency for explainable AI (xAI), for more equitable access to computational resources, and for more interdisciplinarity.

In the context of habitat intelligence, the future will involve hybrid frameworks that combine the predictive power of AI with mechanistic ecological theory. Recent developments including transfer learning, citizen science linkage, and low-cost sensing are leading to an increasing degree of involvement and translation, especially in underrepresented geographies and ecosystems. By fostering collaboration among ecologists, data scientists, and decision-makers, the community can develop scalable, interpretable and actionable tools that address the twin crises of climate warming and biodiversity loss.

Together, they illustrate that AI has the potential to truly revolutionize ecological science as an exciting complement to its traditional iteration, not a replacement. By exposing previously hidden patterns in species–environment interactions, AI supports better, faster and more strategic conservation action. While this area is still emerging, it is clear that it will be fundamental in the future of biodiversity and the management of life on the planet.

***Abstract*—Radiological bone age assessment is essential for diagnosing pediatric growth and developmental disorders. The conventional Greulich-Pyle Atlas, though widely used, is manual, time-intensive, and prone to inter-observer variability. While deep learning methods such as Convolutional Neural Networks (CNNs) offer automation potential, most existing models rely on transfer learning from natural image datasets and lack specialization for medical radiographs. This study aims to address the gap by developing a domain-specific, custom CNN for pediatric bone age prediction. This research proposes a customized CNN architecture trained on the RSNA pediatric bone age dataset, which includes over 12,000 annotated hand X-ray images labeled with age and gender. The pipeline incorporates pre-processing techniques such as image resizing, normalization, and Contrast Limited Adaptive Histogram Equalization (CLAHE) to enhance input quality. A YOLOv3 object detector is utilized to localize the hand region prior to model training, focusing on the most relevant anatomical structures. Unlike traditional transfer learning models such as ResNet50, VGG19, and InceptionV3, the proposed CNN is tailored for radiographic features using optimized convolutional blocks and domain-aware augmentations. This design improves generalization and reduces overfitting on small or imbalanced subsets. The proposed model achieved a Mean Absolute Error (MAE) of 3.27 months on the test set and 3.08 months on the validation set, outperforming state-of-the-art transfer learning approaches. These results demonstrate the model's potential for accurate and consistent bone age estimation and highlight its suitability for integration into clinical decision-support systems in pediatric radiology.**

I. Introduction

Pediatric endocrinologists mostly rely on Bone Age Growth Disease Detection (BAGDD) to detect growth disorders and evaluate a child's bone development. For conditions such as growth hormone deficiency, precocious puberty and delayed growth, it matters a lot [1]. BAGDD is used by clinicians to understand if a child's bones are growing at the appropriate pace for their age and to predict what might happen in their growth later on. Typically, an X-ray image of the left hand and wrist is used to view the bones and changes such as ossification, that reveal the growth status of a child.

Bone age was initially measured using two traditional methods: the Greulich-Pyle (GP) Atlas [2] and the Tanner-Whitehouse (TW) approach [3]. A GP Atlas allows a trained radiologist to use the worksheet to compare a patient's bone density to those of reference images based on both gender and age. Rather than TW, the TW method assigns a score to every bone depending on its stage of development and the total gives an estimate for bone age. Despite being around for decades, these methods are held back by expert interpretations, slow procedures and the influence of personal opinions [4].

Automating bone age assessment is becoming possible thanks to the growth in AI and its specialty, Deep Learning. CNNs have helped smart systems reach the same performance in image analysis as the human eye in recent times. CNNs are particularly useful for image recognition since they can automatically pick out patterns such as edges, textures and shapes at different parts of an image [5]. Tickmarks depends on how images are used; they can be used for labeling or predicting values in both types of tasks. CNNs have been used successfully in many medical image applications, including finding tumors, analyzing retinas and, not long ago, evaluating bone age [6]. In 2017, the Radiological Society of North America made available the RSNA Bone Age Dataset which consists of over 12,000 X-rays of children's hands each labeled with bone age information and evenly divided by gender. The information in this dataset aids in the development and assessment of algorithms designed for automatic bone age estimation [7].

Such models are pre-set with knowledge from millions of pictures found in ImageNet of everyday objects like cats, cars and buildings. These models are mainly used for object classification because their learned features highlight important differences in objects' shapes, colors and textures. Still, medical images, including those of hands for assessing bone age, have very different details regarding bone density, shape and growth as compared to regular X-rays [8]. The results of further studies have suggested that development of bone age is not the same in males and females and males generally mature slower than females do [9]. Because of this, transfer learning models may not fit the unique gender differences in how bones develop. Thus, these models do not always capture the important information related to each domain and usually perform poorly on these imaging operations [10].

This work introduces a new CNN model tailored for computing the bone age from radiographs of hands. Everything is learned directly by the model from scratch, so no information is transferred from different bone-related picture datasets and the model is trained explicitly for predicting bone age. The goal is to improve the certainty and precision of bone age determination by using the CNN design to meet

the requirements of this medical imaging task. The proposed custom CNN model performed well, with the MAE being 3.27 months in the training set and 3.08 months on the validation set. These results significantly outperform the transfer learning models evaluated in this work, including ResNet50, VGG19, and InceptionV3. The custom CNN proves to be effective in capturing fine-grained features in bone development, allowing for a more accurate age estimation. These findings support the conclusion that domain-specific deep learning models can substantially outperform generic transfer learning approaches when applied to specialized medical imaging tasks such as bone age assessment [9].

Whereas deep learning algorithms, especially the ones that apply the methodology of transfer learning, such as ResNet50, VGG19, and InceptionV3 models have demonstrated good potential when it comes to assessing the age of the bones, the utilized models have been predominantly trained on the datasets of natural images (e.g., ImageNet) and have not been optimized to work with the peculiarities of medical radiographs. They do not routinely produce good imaging of the subtle anatomical markings characteristic of X-ray pediatric hands required to make precise assessment of the bone-age. In addition to that, none of the current models often provide the combination of the domain-specific architecture design alongside specific preprocessing (e.g., the CLAHE-enhanced contrast and the ROI extraction using the YOLOv3) to form a unified framework applicable to the setting of the pediatric bone age growth disease detection.

The novelty of this work is the modification of the CNN model into a custom design, which trained on the scratch available RSNA Bone Age Dataset that consists of data on bone development provided specifically to be used in predicting an age. In contrast to transfer learning methods devised over generically, the proposed CNN includes the task-specific architectural components, including depth of layers and dropout regularization, along with the paradigm-specific preprocessing of medical images. This is more accurate, more robust and better aligned to the domain compared to current solutions in bone age estimation.

This research focuses on the architectural design, training, and performance evaluation of a custom CNN model specifically developed to predict bone age from hand radiographs. The contributions of this research are as follows:

- A custom Convolutional Neural Network (CNN) is developed and trained from scratch, incorporating task oriented design choices such as optimal layer depth, kernel sizes, ReLU activations, and dropout regularization. Unlike generic models, custom CNN was tailored to capture fine-grained anatomical features (e.g. bone edges, growth plates) specific to pediatric hand radiographs, resulting in improved precision and robustness.
- The performance of proposed model is significantly boosted by incorporating Contrast Limited Adaptive Histogram Equalization (CLAHE) to enhance image contrast and Region of Interest (ROI) detection using YOLOv3 to focus the learning on relevant hand structures.
- The proposed custom CNN was extensively evaluated using Mean Absolute Error (MAE) and Mean Squared Error (MSE), and benchmarked against popular pre-trained models including ResNet50, VGG19, and InceptionV3.
- The proposed model was optimized through manual adjustment of the hyperparameters, including the learning rate, batch size, and number of training epochs. In addition, the architecture was refined by adjusting the depth and number of filters that incorporate dropout layers to mitigate overfitting.

The organization of the paper is as follows. Section 2 reviews existing work relevant to the proposed study. Section 3 discusses materials and methods and outlines the development procedures of the proposed BAGDD system. Section 4 presents the results and the discussion, while Section 5 concludes the study.

II. Related Work

Deep learning has played a revolutionary role in medical imaging, particularly in the diagnosis of musculoskeletal disorders. The effectiveness of deep learning applications in bone age prediction has been demonstrated in various contexts, including fracture identification, osteoarthritis severity evaluation, and pediatric assessments. Recent research highlights its ability to detect pathological abnormalities in CT and MRI scans, such as infections, fractures, joint degeneration, internal derangements, and metastases. However, challenges remain due to the complexity of CT and MRI datasets, which often involve varying tissue contrasts. For widespread clinical adoption, further technological advancements and extensive, multi-institutional prospective studies are required to ensure the generalizability, consistency, and reliability of these techniques [11].

New methods for finding and handling different medical problems have been made possible by using CNNs. Related to Bone Age Assessment using hand and wrist radiographs, CNNs have consistently performed better than other common approaches. This section deals with applying deep learning principles for medical image analysis, paying special attention to CNN designs and transfer learning created for BAA [12].

CNNs are very important in medical image analysis, with a key application in bone age estimation. CNNs built from the ground up are created to handle the issues that come with using medical images. During Bone Age Assessment (BAA), one must make models that are skilled in finding growth plates and different bone parts so the process is accurate. Many studies have shown that custom CNN models usually outperform methods such as the Greulich-Pyle atlas or Tanner-Whitehouse standards.

Specifically, a custom CNN for estimating bone age from hand radiographs designed by [13] makes use of different layers to grab both general and detailed hand and wrist features, improving the mean error over methods used before. In a similar way, [14] recommended an automatic deep learning process to make the process more efficient and less dependant on human opinion. In their method, they chose key points in images of 3,000 X-rays, working on the carpal, metacarpal and

phalangeal bones. Intensity was adjusted using preprocessing and different models were made for each gender since each follows a different pattern of growth. Unlike various other similar studies, this one looked at infants as part of the full pediatric population that was considered. Using deep learning, it was possible to create a model with an MAE of 8.890 months.

An improved CNN was built in [15] to be used with the RSNA Bone Age dataset. Thanks to deep residual learning, the model had optimized gradient flow and avoided the problem of overfitting in the larger layer. Using this kind of architecture, models successfully pointed out main anatomical landmarks for an MAE of 4.2 months. The team discovered that CNNs designed to identify certain anatomical features did better than general architectures in predicting CT results.

Still, building a custom CNN architecture is complicated and takes a long time. As described in [16], making custom CNNs for medical imaging tasks draws on expertise in both radiology and deep learning which presents a problem for both small healthcare centers and seasoned developers. All the same, the advantages of custom CNNs in medical areas make them a good alternative because they can accomplish important tasks more successfully than standard approaches, for example bone age estimation [17].

Researchers have recently shown that transfer learning can successfully estimate bone age. The results presented in [18] indicate that a fine-tuned EfficientNet model had an MAE of 4.5 months when used on the RSNA Bone Age dataset. Training the model with this approach was much faster than using a custom CNN model with similar results. The study says that EfficientNet's design means it functions well for medical imaging, especially in places where resources are limited.

The authors of [19] used transfer learning by training a DenseNet on images for recognizing bone age. The authors managed to train the model quickly and accurately by freezing the early layers and adding extra training to the last ones. By using transfer learning on the RSNA Bone Age dataset, the model showed an MAE of 14.9 months, showing that transfer learning can be equally successful, while having a more variable precision [20].

In another study, [21] evaluated a commercial deep learning based bone age assessment tool (BoneAge, Vuno, Korea) using left hand X-ray images of 371 healthy Korean children and adolescents aged 4–17 years. While the estimated bone age was highly correlated with the actual chronological age (r = 0.96), the overall agreement rate was only 58.8%, and the model tended to overpredict bone age in younger children, particularly those under 8.3 years of age.

The work presented by [22] focuses on evaluating age and sex from computed tomography (CT) images of vertebrae using computer aided diagnosis. The study utilized a dataset comprising CT scans from 166 patients of varying genders. All images were rescaled before feature extraction using the qMaZda software. The researchers integrated conventional machine learning algorithms—both regression and classification with deep convolutional networks. Using the BART algorithm, the bone age regression model achieved a Mean Absolute Error (MAE) of 3.14 years. Gender classification accuracy was 69% with machine learning models and 59% with deep learning models [23].

In a related study, [24] proposed a regression based, multi-model deep learning framework for bone age assessment using hand radiographic images and clinical data (e.g., gender and chronological age). The approach combined EfficientNetV2S CNNs for image analysis with a simple deep neural network (DNN) for processing clinical data, resulting in robust diagnostic performance. This study underscored the advantages of multi-modal learning in improving the precision of bone age analysis [25].

To address the limitations of traditional methods such as Greulich–Pyle and Tanner–Whitehouse, which heavily depend on domain expertise, [26] developed a deep learning model for osteoporosis classification and bone density prediction using opportunistic CT scans. The model was validated across datasets from multiple hospitals and CT scanners. It employed the VB-Net module for segmentation and DenseNet for classification and regression. The model demonstrated high accuracy and strong correlation with Quantitative Computed Tomography (QCT) reference standards, achieving AUC scores of 0.999 (training set), 0.970 (test set), and 0.933 (independent set). The bone density prediction model also performed well, showing potential as a cost effective, low-radiation solution for osteoporosis screening [27], [28].

In [29] and [30] review existing Bone Age Assessment (BAA) methodologies, emphasizing the use of deep learning algorithms to address the inconsistencies of traditional approaches. Although deep neural networks have demonstrated high effectiveness in classifying bone age within specific age intervals, their complexity and reliance on numerous parameters for each region of interest (ROI) present challenges.

In [31] introduced a novel approach known as the Dual Attention Dual Path Network (DADPN). Experimental validation was performed using the RSNA Pediatric Bone Age Challenge dataset, comparing DADPN with nine other popular BAA methods. The results showed that DADPN achieved the highest accuracy, with a Mean Absolute Error (MAE) of 4.76 months.

In a separate study, [32] and [33] proposed a continuous radiological age assessment method based on clavicle ossification in CT scans. Their deep learning model was trained on 4,400 scans from 1,935 patients with a mean age of 24.2 years and evaluated on a test set of 300 scans from 300 patients. The model achieved an MAE of 1.65 years. Absolute error values ranged from 6.40 years for females and 7.32 years for males, with comparison to human reader estimates yielding errors of 3.40 years for females and 3.78 years for males, resulting in a comparative MAE of 1.84 years [34].

Although these improvements exist, additional scientist work is necessary to improve the accuracy and dependability of BAA methods. A number of CNN and transfer learning frameworks struggle to perform the same on diverse data which lowers their stability. Further work is needed to decrease the errors in bone age predictions and maintain good performance in every healthcare setting.

III. Materials and Methods

The structure of this study's research framework emphasizes building an effective auto bone age prediction method using deep learning. There are five main phases in this framework: collecting data, checking the data, preprocessing data, making features, training the model and assessing the model. All the data used in this work is taken from the RSNA Bone Age Dataset which consists of about 12,000 hand X-rays. The variety of bone growth patterns in this dataset gives it a good fit for using and assessing deep learning models.

The aim of the research is to create a new CNN model that can identify and classify bones primarily based on age. To review performance, the proposed model is compared with three commonly used transfer learning models: ResNet50, VGG19 and InceptionV3. The framework is designed to highlight how well the custom CNN predicts bone age, while transfer learning models help understand the comparison.

First, several stage were taken to boost the quality of the images before supplying them to the CNN models. First, all the images were sized to 224 × 224 pixels which is a typical input measurement for most deep learning models, including the ones employed in this study. Stretching each image to the same size reduces the amount of processing required and assures even results during training. Each value was then normalized by putting it through (255/2) and rescaled to values between 0 and 1 to support more efficient training. Besides, contrast in the images was improved by applying Contrast Limited Adaptive Histogram Equalization (CLAHE) only to the bone structures. Using this method, important anatomical features are made more visible, so the CNN can recognize and understand them better during fixing.

In order to enhance the performance of the model in more situations, this study used various data enhancement techniques. Examples of applied image transformations were rotation, flipping and shifting which introduced little changes in this work. Data augmentation boosts the size of the dataset and has the side benefit of preventing overfitting due to the extra input data. So, the model can withstand variations in real situations better. In addition, ROI detection was completed with a YOLOv3 model. At this point, the developer removed information behind the hand, helping the model concentrate on what it should focus on and therefore improving the training.

Following the preprocessing and feature extraction stages, the next phase involved model development. The CNN architecture was customized specifically for the bone age prediction task. The model consists of multiple convolutional layers that progressively learn features from low-level edges and textures to more abstract patterns crucial for bone age estimation. Since the model was trained from scratch, it was able to focus exclusively on learning features relevant to bone development, as opposed to transfer learning models that rely on representations learned from general purpose natural image datasets. This task specific design allowed the custom CNN to achieve better performance by concentrating on features uniquely important for pediatric hand X-ray analysis.

In addition to the custom CNN, this study also employed pre-trained models using transfer learning, specifically ResNet50, VGG19, and InceptionV3. These models were originally trained on the large scale ImageNet dataset and feature architectures optimized for general image recognition tasks. For the purpose of this research, they were adapted to perform bone age estimation, which is framed as a regression problem. Fine-tuning allowed these models to leverage previously learned features while adjusting to the specific domain of pediatric hand X-ray images, ensuring better performance without complete retraining.

The final component of the research framework involves model evaluation. Both the custom CNN and the transfer learning models were assessed using two key performance metrics: Mean Absolute Error (MAE) and Mean Squared Error (MSE). These metrics are well suited for regression tasks such as bone age prediction, as they quantify the deviation between predicted and actual bone ages. MAE, expressed in months, was chosen as the primary evaluation metric due to its straightforward interpretability in clinical contexts lower values indicate higher model accuracy. MSE was also considered, as it squares the error terms and therefore assigns greater penalty to larger prediction errors.

The complete research framework including preprocessing steps, the custom CNN architecture, transfer learning models, and evaluation metrics ensures a systematic and robust approach to designing and testing the bone age prediction system. The overall methodology of the proposed BAGDD system is illustrated in Figure 1.

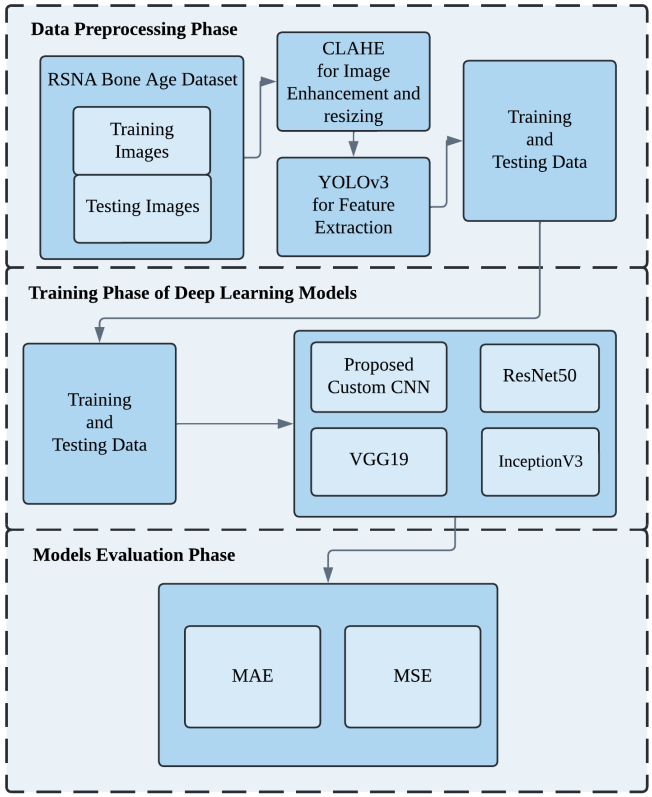

Fig. 1. The Proposed methodology of the presented BAGDD system based on deep learning.

A. RSNA Bone Age Dataset Presentation

The RSNA Bone Age Dataset is one of the most significant resources for pediatric radiology and artificial intelligence re-

search. Provided by the Radiological Society of North America for research purposes, the dataset includes 12,611 right hand X-ray images of children, each labeled with bone age using the Greulich-Pyle (GP) method a widely accepted standard in clinical practice for bone age assessment. The dataset spans a broad age range, covering children from 0 to 18 years old, and offers comprehensive variability in growth patterns and bone development.

Because there are people of all ages, researchers can analyze both common and unusual bone growth which is essential for spotting diseases and growth issues in children. How the RSNA Bone Age Dataset is divided by age and gender is shown in Figure 2.

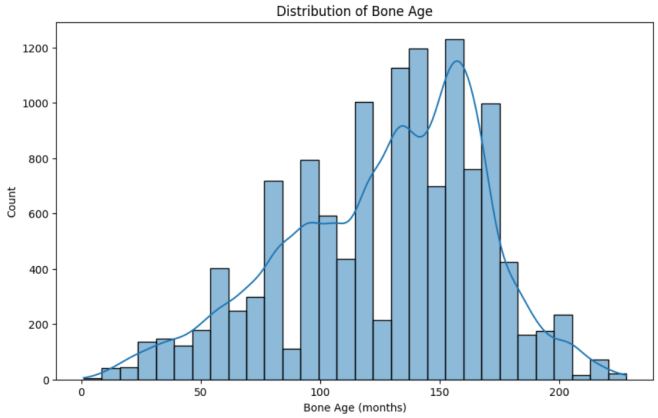

Fig. 2. Representation of the RSNA bone age dataset.

The important aspect of the dataset comes from the quality, its size and how it is relevant to medical care. All of the subjects have their pictures labeled with the bone age used to represent when the X-ray was done. They use the GP technique, a system that compares bone development with pictures in an atlas. With this relabeling, the data is truly representative of what doctors do, ideal for helping machines determine bone age.

Additionally, the dataset includes Many cases, showing how various health issues can slow bone development in kids. Having a diverse set of examples in the data ensures it's useful for training AI, by providing enough material for in-depth learning. Figure 3 shows the makeup of the dataset divided by gender and Figure 4 by age group. You can see the RSNA Bone Age dataset in Figure 5.

B. Preprocessing

Boosting the efficiency of predictive outcomes from deep learning models depends largely on careful data preprocessing. Certain improvement techniques were added to the X-ray images to enhance their usability:

1) Resizing: All X-ray images were adjusted to be 224 pixels wide and 224 pixels high. Following this standard lets Convolutional Neural Networks (CNNs) accept exactly these input images, since they require images of the same size. Being resized, the images fit better into the training process and avoid dialing them back in size because they come from different sources. It allows use of the same feature extraction process for all the data.

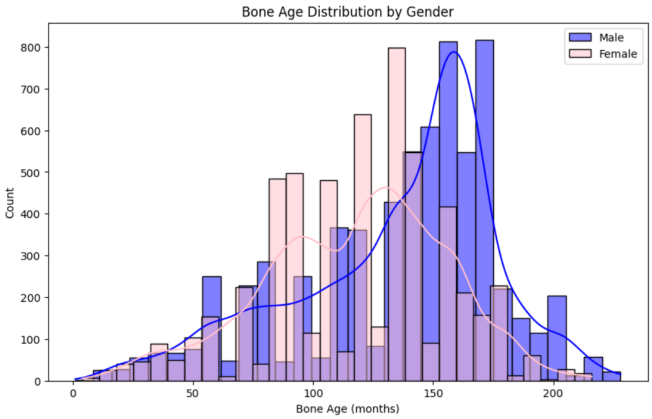

Fig. 3. Representation of the RSNA bone age distribution by gender.

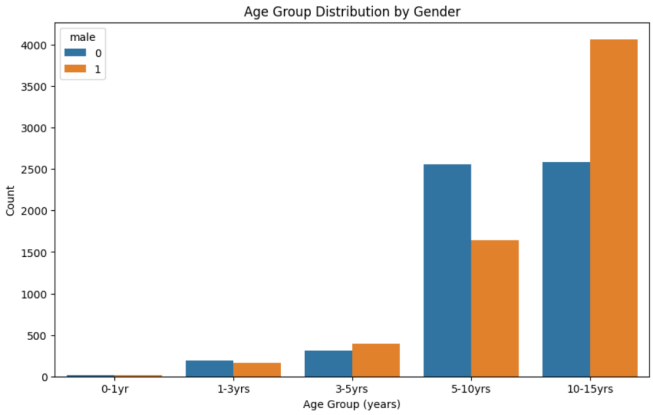

Fig. 4. Representation of the RSNA bone age distribution by age group.

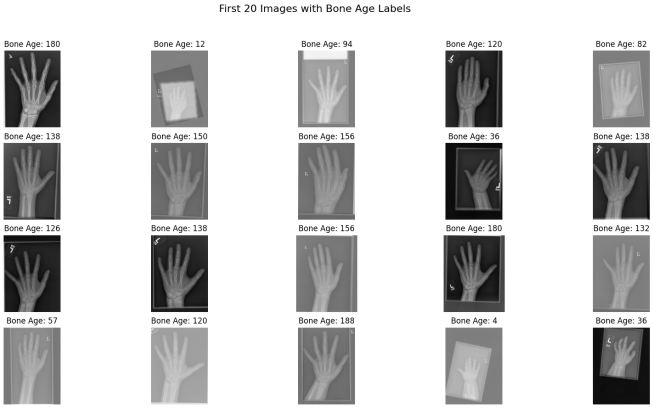

Fig. 5. Pictorial representation of the RSNA bone age dataset.

2) Normalization: All pixel intensity values in the images were scaled so that they fell between 0 and 1. To learn better, the model needs input data that is standard across points. When lighting changes and contrast in the original images are reduced, normalization allows the training process to be both stable and faster. This also helps avoid problems like gradient explosion or disappearance which both damage the model's performance.

3) CLAHE (Contrast Limited Adaptive Histogram Equalization): Since the regions of interest in X-ray images such as bones and growth plates often exhibit low contrast, CLAHE was applied to enhance their visibility. This technique enhances image contrast locally, allowing critical anatomical structures to stand out more clearly and be more easily identified by the model. Enhancing these features is essential for accurate bone age prediction, as it highlights subtle differences associated with bone growth and development. The use of CLAHE significantly improves the model's ability to detect important features that might otherwise be overlooked due to low contrast in the raw X-ray images. Figure 6 illustrates the visual improvement in an X-ray image after applying CLAHE.

Fig. 6. Before and After applying CLAHE.

4) Data augmentation: To increase the effective size of the dataset and reduce the risk of model overfitting, several data augmentation techniques were employed. These included random image rotations (0–15 degrees), horizontal and vertical flipping, shifting, and adjustments to image brightness and contrast. These transformations introduce variability into the training data, enabling the model to generalize better to unseen samples. This approach supports the third objective of the project by enhancing the model's robustness and adaptability—qualities that are particularly crucial in medical imaging, where anatomical structures can vary widely across patients. Data augmentation helps the model retain relevant features despite spatial or visual alterations, improving its performance in real world clinical scenarios.

5) ROI Detection: To further enhance model performance, a pre-trained YOLOv3 model was used for Region of Interest (ROI) detection in the X-ray images. In this context, the ROI specifically refers to the hand, which is the key anatomical region for bone age prediction. YOLOv3 enables semi automatic segmentation of the hand, allowing the CNN to focus solely on the most relevant structures. This targeted approach eliminates irrelevant background noise, helping the model avoid distractions and improving prediction accuracy. By reducing the input to only the essential region, ROI detection also contributes to computational efficiency and model precision. Figure 7 illustrates the application of YOLOv3 on an image enhanced with CLAHE.

6) Image quality assessment: In addition to the preprocessing steps outlined above, image quality assessment was also considered. This involves evaluating the clarity, contrast, and overall quality of each X-ray image to ensure that only the highest quality images are used for training and validation. Since image quality directly affects model performance, filtering for optimal image clarity enhances the effectiveness of feature extraction and improves the overall learning process.

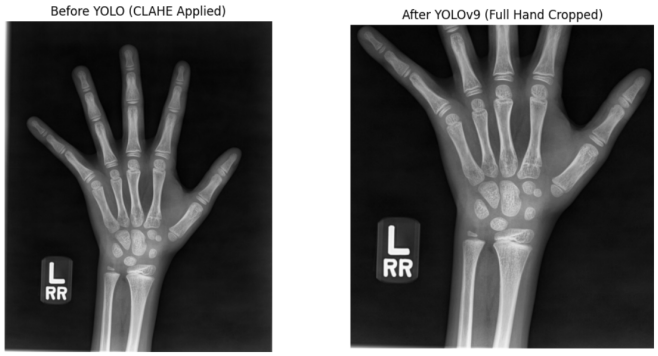

Fig. 7. Before and After Applying YOLOv3 on CLAHE Output.

Application of these methods allowed for better data preparation in the RSNA Bone Age Dataset for model training. Following these steps strengthens the model's understanding of what is required for correct prediction of bone age. As well as getting the data ready for machine learning, the preprocessing pipeline helps to make the model steady and more trustworthy which helps increase its use in pediatric radiology. By following this approach, future AI studies intended for bone age estimation are easily supported.

C. Convolutional Neural Networks (CNNs)

For the development of Bone Age Growth Disease Detection (BAGDD) system, this work uses Convolutional Neural Network (CNN) algorithm. CNNs are particularly useful for analyzing images since they can automatically pick out different levels of spatial features right from the images. As a result, the features facilitate identification of parts of the bone that play a key role in bone age estimation. CNNs rely on convolutional layers to learn basic shapes and textures and also find the detailed patterns necessary for correct predictions [34]. These architectures included a custom CNN built for studying hand X-rays, along with three used as references: ResNet50, VGG19 and InceptionV3.

This work proposes a novel dropout optimized CNN architecture developed from scratch for analyzing hand X-ray images using the RSNA Bone Age Dataset. While ResNet50, VGG19, and InceptionV3 are pre-trained on a wide range of natural images from various domains, the custom model is specifically tailored for bone age prediction. Unlike general purpose models, this proposed custom CNN architecture was built to focus on domain specific features particularly bone shape and density which are critical for accurate age estimation from pediatric X-rays. This dedicated design facilitates deeper fine-tuning and ensures better alignment with the clinical objective of the BAGDD system. The proposed custom CNN architecture is presented in Figure 8.

1) Architecture: The architecture of the proposed custom CNN is designed to accept input images of size 224×224 pixels, which were previously resized and normalized during

preprocessing. The network consists of multiple convolutional layers, each employing 3×3 filters. These filters scan the image to extract features progressively, starting from low level attributes such as edges and gradients and advancing to high level features like shapes and textures critical for accurate bone age estimation.

Each convolutional layer is followed by a Rectified Linear Unit (ReLU) activation function, which introduces non linearity into the network, enabling it to learn more complex patterns. Max pooling layers with 2×2 filters are used after certain convolutional layers to reduce the spatial dimensions of the feature maps while preserving essential information. This pooling operation helps control overfitting and improves computational efficiency.

2) Activation Functions: ReLU activation functions are applied in all hidden layers of the network. ReLU is chosen due to its effectiveness in addressing the vanishing gradient problem, a common challenge in deep learning. It enables deeper networks to learn efficiently by allowing gradients to propagate effectively during backpropagation.

3) Loss Function: To optimize the custom CNN during training, Mean Absolute Error (MAE) and Mean Squared Error (MSE) are used as the loss function. MAE and MSE are the widely adopted metric in regression tasks as it calculates the average of the squared differences between predicted and actual values. In this context, it penalizes larger errors more heavily, which is particularly important in medical applications such as bone age estimation. The objective during training is to minimize the MAE and MSE, thereby reducing the discrepancy between the predicted bone age and the ground truth labels.

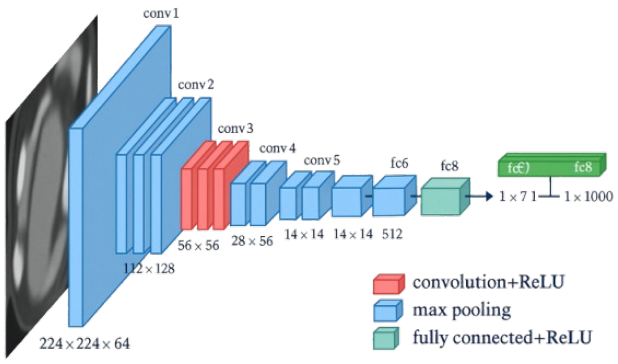

Fig. 8. Proposed CNN architecture for the development of BAGDD system.

D. ResNet50

ResNet50 is a widely recognized Convolutional Neural Network (CNN) architecture known for its use of residual blocks [35]. These residual connections allow the network to skip over certain layers, enabling the successful training of very deep networks without encountering vanishing or exploding gradient issues. The core concept behind residual learning is the identity mapping, or the propagation of residual signals secondary signals that carry unaltered information from earlier layers. This approach ensures that subsequent layers do not waste computational effort relearning features that have already been captured in earlier stages of the network. As a result, ResNet50 achieves improved training efficiency and performance, particularly in deep architectures. The architecture of ResNet50 is illustrated in Fig. 9.

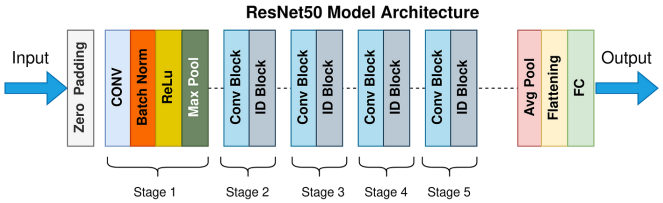

Fig. 9. Architecture of CNN ResNet50 model [35].

In the present study, ResNet50 was trained on the RSNA Bone Age Dataset. The model was initialized with pre-trained weights from the ImageNet dataset, which contains millions of labeled natural images. To adapt the model for the bone age prediction task, fine-tuning was performed by freezing the early layers responsible for learning general features such as edges and textures and retraining the deeper layers to capture domain specific features such as growth plates and bone structures visible in X-ray images.

ResNet50 was evaluated alongside the proposed custom CNN and other transfer learning models. Despite its complex architecture and deep residual connections, ResNet50 proved to be an effective tool for feature extraction, particularly in cases where the dataset is large and diverse, as is true for the RSNA Bone Age Dataset.

E. VGG19

VGG19 is another deep CNN architecture used in this study for comparative analysis. It consists of 19 layers, primarily composed of convolutional and fully connected layers. One of the key advantages of VGG19 is its uniform architecture: all convolutional layers utilize 3×3 filters. This consistent filter size enables the model to capture fine grained image details, which is particularly beneficial in bone age prediction where subtle variations in bone density and morphology can significantly impact the results. The architecture of VGG19 is illustrated in Fig. 10.

Like ResNet50, VGG19 was pre-trained on the ImageNet dataset and fine-tuned on the RSNA Bone Age Dataset. The final fully connected layers of VGG19 were replaced to adapt the model specifically for the bone age prediction task [36]. Due to its dense layer wise structure, VGG19 is capable of capturing intricate bone structure details, making it well suited for this application. However, unlike ResNet50, it lacks residual connections, which can make training deep architectures more challenging and susceptible to vanishing gradient issues.

F. InceptionV3

InceptionV3 is an advanced CNN architecture that improves upon its predecessor, InceptionV2, through the use of inception modules. These modules allow the network to perform convolutions of multiple sizes simultaneously, enabling it to capture features at multiple spatial scales. This

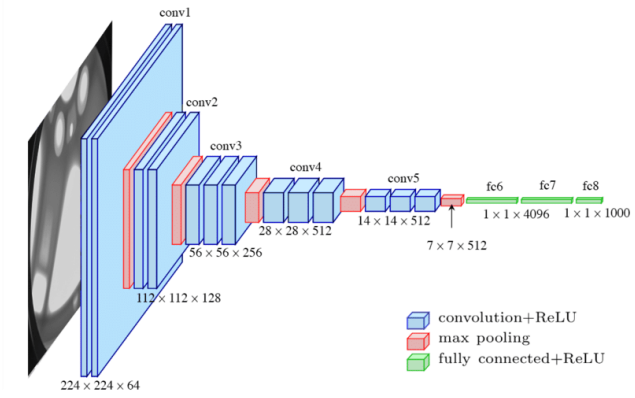

Fig. 10. Architecture of CNN VGG19 model [36].

is particularly advantageous when dealing with images of varying resolutions, such as hand X-rays. The architecture is highly efficient in both image classification and regression tasks due to its multi scale feature extraction capability [37]. The architecture of InceptionV3 is illustrated in Fig. 11.

For this analysis, InceptionV3 was initialized with its original weights from the ImageNet dataset and additionally trained on the RSNA Bone Age Dataset. This part of the model allows it to identify fine and overall features in hand radiographs, helping it to be very accurate at bone age estimation. Like the other transfer learning models, the final layers of InceptionV3 were customized for the regression problem and improvements were made to minimize prediction error during training [38].

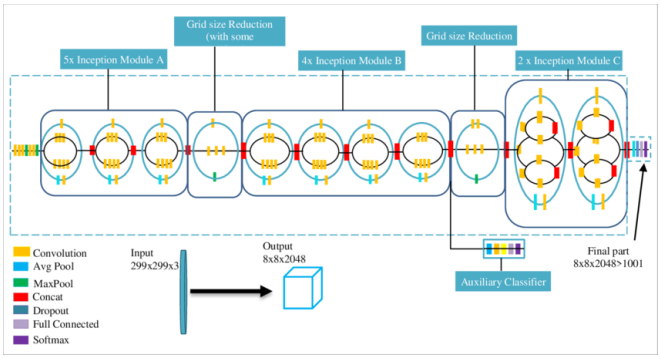

Fig. 11. Architecture of CNN InceptionV3 model [37].

G. Measures for Performance Evaluation

In order to assess how well the models performed in this study, Mean Absolute Error (MAE) and Mean Squared Error (MSE) were used as important regression evaluation measures. They gauge the accuracy of bone age prediction models using comparisons between their predictions and the real ages of the bones in the dataset.

1) Mean Absolute Error (MAE): Since the problem is structurally suited to it, Mean Absolute Error (MAE) was chosen as the main metric. MAE simply checks the average of the absolute errors for each bone age, independent of whether the error was positive or negative. The authors treat MAE as the average difference between the forecasted and true values, expressed in months.

For regression tasks, MAE is reliable because it is simple to interpret: the model is more accurate when the MAE is low. As a result, MAE is a powerful approach for judging the practical value in using bone age imaging for clinical needs.

The formula for MAE is as follows:

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \quad (1)$$

Where,

yi is the actual bone age for the ith instance.

ŷi is the predicted bone age for the ith instance.

n is the total numbers of predictions.

2) Mean Squared Error (MSE): Given the nature of the problem, Mean Squared Error (MSE) was also employed as a key performance metric. MSE measures the average of the squared differences between the predicted and actual bone ages, placing greater emphasis on larger errors due to the squaring operation. MSE is particularly effective for regression tasks where penalizing large deviations is critical. In the context of the proposed study, MSE helps highlight instances where the model's predictions deviate significantly from the true bone age, making it especially valuable for assessing reliability in clinical scenarios where minimizing large prediction errors is essential.

The formula for MSE is as follows:

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \quad (2)$$

As for the assessment of the models, MSE was combined with MAE. Whereas MAE can be used in simple and easy to interpret appraisal of the accuracy of the prediction, MSE has more weight on the larger errors as it provides more information about the distribution of the errors.

H. Proposed BAGDD Model's Pseudocode

Begin
Phase 1: Data Preprocessing
1. Load RSNA Bone Age Dataset
2. Split dataset into Training Images and Testing Images
3. For each image in Training and Testing sets:
    a. Apply CLAHE for image enhancement
    b. Resize image to standard input size
4. For each enhanced image:
    a. Apply YOLOv3 to extract features
5. Store the resulting features as Training and Testing Data
Phase 2: Training Phase of Deep Learning Models
6. Initialize Deep Learning Models:
    a. Proposed Custom CNN
    b. ResNet50
    c. VGG19
    d. InceptionV3
7. For each model in the list:

a. Train the model using Training Data
b. Validate the model using Testing Data
Phase 3: Models Evaluation Phase
8. For each trained model:
a. Predict outputs on Testing Data
b. Calculate Mean Absolute Error (MAE)
c. Calculate Mean Squared Error (MSE)
d. Store evaluation metrics
9. Compare all models based on MAE and MSE
End

IV. Results

The primary objective of this research was to develop a deep learning model capable of automating bone age prediction with greater precision than currently available methods. To this end, a custom Convolutional Neural Network (CNN) specifically designed for this task was developed and compared against widely used pre-trained models in transfer learning namely, ResNet50, VGG19, and InceptionV3. While transfer learning models have shown promising results in general computer vision tasks, bone age prediction presents a domain specific challenge that a tailored CNN model is better suited to address.

All models were trained on a carefully preprocessed version of the RSNA Bone Age Dataset to ensure both accuracy and generalizability. Preprocessing steps included resizing, normalization, Contrast Limited Adaptive Histogram Equalization (CLAHE), and data augmentation to improve input quality and reduce overfitting. Additionally, a YOLOv3 based Region of Interest (ROI) detection was applied to isolate the hand region from irrelevant background details in the X-ray images. This work evaluated the performance by using two standard measures for regression, Mean Absolute Error (MAE) and Mean Squared Error (MSE) which are right for predicting continuous tasks like these. The ease of understanding MAE in clinical situations led to select it as this works' primary index. This work uses MSE which catches more outliers, as an additional method to estimate error variance.

In the following section, this work outline the way the custom CNN was put together and the conditions for conducting the transfer learning studies. Both ResNet50, VGG19 and InceptionV3 models prepared on the RSNA dataset, along with proposed custom CNN, are evaluated and compared closely. The results confirm that the proposed methodology is effective. Results from the study highlight that a CNN customized for bone age prediction is more precise than similar transfer learning methods, when metrics like MAE, MSE and total predictive performance are used.

A. Performance Evaluation of Proposed CNN

The performance of the custom CNN was measured using Mean Absolute Error (MAE) and Mean Squared Error (MSE). For this study, a public dataset called the RSNA Bone Age Dataset, containing pediatric hand X-rays, was applied to judge the accuracy and dependability of the model's age predictions.

The custom CNN was trained for 100 epochs and the predictions were checked by using the validation data. High predictive accuracy was demonstrated with low MAE and MSE results in the model. The results suggest that the custom CNN correctly identifies significant features in hand X-rays, so it can be used for automated bone age estimation.

To present the performance of the custom CNN model clearly, the results are summarized in Table I:

TABLE I. Performance of Proposed CNN Model

Metric	Training Set	Validation Set
Mean Absolute Error (MAE)	3.27 Months	3.08 Months
Mean Squared Error (MSE)	20.54 Months	18.23 Months

On the training set, the custom CNN achieved a Mean Absolute Error (MAE) of 3.27 months and an even lower MAE of 3.08 months on the validation set. These results demonstrate the model's strong generalization capability and its ability to produce predictions that closely align with actual bone age values. In addition to the MAE results, the MSE values were recorded as 20.54 for the training set and 18.23 for the validation set. These relatively low MSE values indicate that the model is not significantly impacted by large prediction errors or outliers, further supporting its reliability and robustness for clinical applications. Figures 12 and 13 illustrate the MAE and overall loss trends for both the training and validation sets, showing consistent performance of the model across epochs.

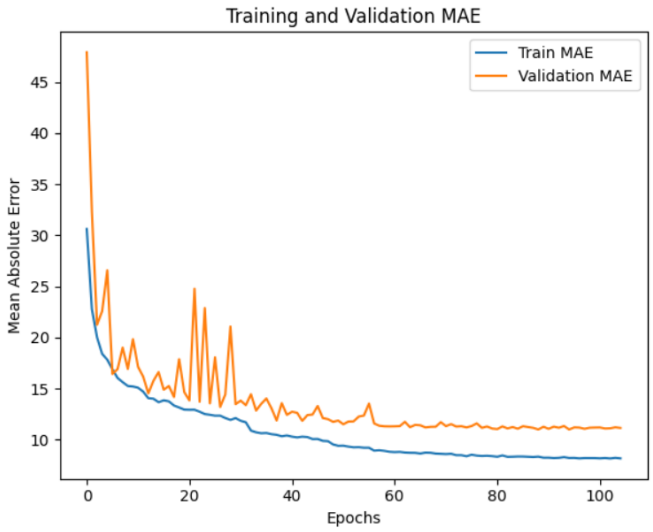

Fig. 12. Mean Absolute Error (MAE) of training and validation set.

Overall, the custom CNN model demonstrated strong and consistent performance across both evaluation metrics. Its low MAE reflects high predictive accuracy, while the stable MSE indicates the model's robustness in handling outliers effectively. These results validate the generalizability of the model on pediatric hand X-ray images, supporting its suitability to automate the bone age prediction process. Figure 14 presents a comparison of the actual and predicted bone age values.

B. Performance Evaluations of ResNet50

The bone age prediction task was also addressed using ResNet50, a widely used transfer learning model known for

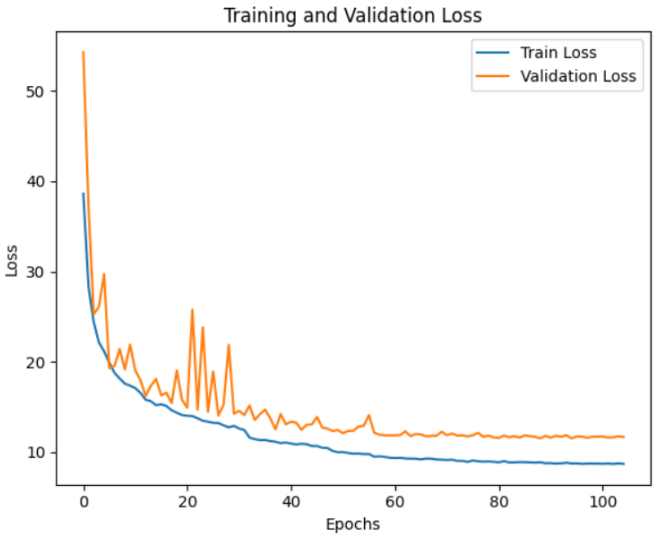

Fig. 13. Overall loss of training and validation set.

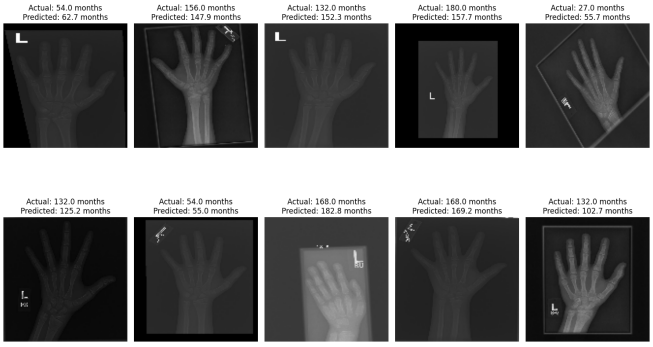

Fig. 14. Actual and predicted results obtained by the proposed CNN.

its bottleneck and residual connections. Fine-tuning was performed on the RSNA Bone Age Dataset to adapt the model to the specific requirements of pediatric bone age estimation. The inclusion of residual connections in ResNet50 facilitates the training of deeper networks by enabling the flow of gradients across layers, effectively mitigating the vanishing gradient problem. While ResNet50 possesses architectural advantages, it did not surpass the performance of the custom CNN model in this study. The performance of ResNet50 over 100 epochs based on the MAE and MSE training loss is shown in Table II.

TABLE II. PERFORMANCE OF PROPOSED RESNET50 MODEL

Metric	Training Set	Validation Set
Mean Absolute Error (MAE)	4.12 Months	3.36 Months
Mean Squared Error (MSE)	16.54 Months	17.53 Months

The results indicate that ResNet50 performed well on both the training and validation sets, achieving a training MAE of 4.12 months and a validation MAE of 3.36 months. These values suggest that the model was able to generalize effectively to unseen data, aided by its residual connections, which help alleviate the vanishing gradient problem commonly encountered in deep neural networks. Although ResNet50 demonstrated solid performance, it did not outperform the custom CNN model specifically designed for the bone age prediction task. Figures 15 and 16 present a comparison between the actual and predicted bone age values obtained by ResNet50 on the RSNA bone age data set.

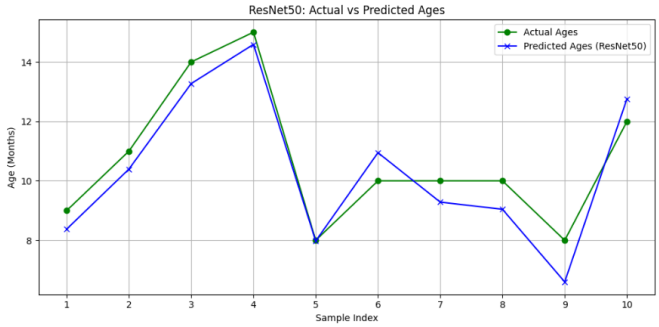

Fig. 15. Line chart of the actual and predicted results obtained by the ResNet50.

Although ResNet50 delivered strong performance, the custom CNN tailored specifically for the bone age prediction task achieved superior results in terms of both MAE and MSE. ResNet50 benefited from its residual connections, which improved generalization and mitigated the vanishing gradient problem, it did not attain the same level of predictive precision as the custom built solution. The custom CNN's architecture, designed explicitly for analyzing pediatric hand X-rays, proved more effective for this specialized task.

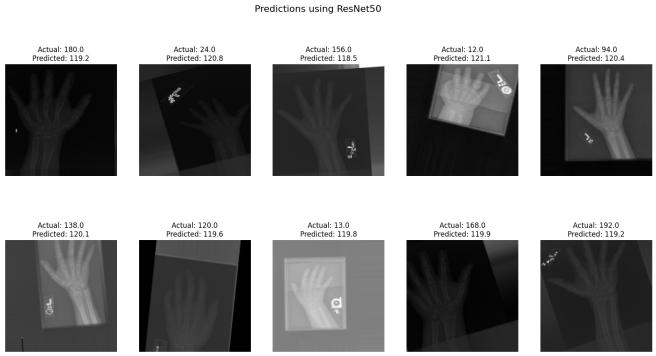

Fig. 16. Actual and predicted results obtained by the ResNet50.

C. Performance Evaluations of VGG19

In this study, VGG19 is a well known deep CNN architecture with 19 layers that was utilized to predict bone age as part of the transfer learning evaluation. Due to its depth and pretraining on the large scale ImageNet dataset, VGG19 is considered a strong candidate for transfer learning tasks. However, in the context of this study, VGG19 exhibited a tendency to overfit the RSNA bone age data set, resulting in suboptimal performance compared to both the custom CNN model and ResNet50. The performance of VGG19 based on the training and validation MSE and MAE over 100 epochs shown in Table III.

TABLE III. PERFORMANCE OF PROPOSED VGG19 MODEL

Metric	Training Set	Validation Set
Mean Absolute Error (MAE)	4.59 Months	3.91 Months
Mean Squared Error (MSE)	27.24 Months	19.26 Months

The VGG19 model performed consistently throughout the training process. It achieved a final training MAE of 4.59 months and a validation MAE of 3.91 months. After 100 epochs, the training MSE reached 27.34, while the validation MSE was recorded at 19.26. These results indicate that the model was able to generalize reasonably well; however, its deep architecture also showed signs of overfitting an expected challenge when working with relatively small datasets like the RSNA bone age dataset. Figures 17 and 18 display the actual versus predicted bone ages as obtained by the VGG19 model on the RSNA dataset.

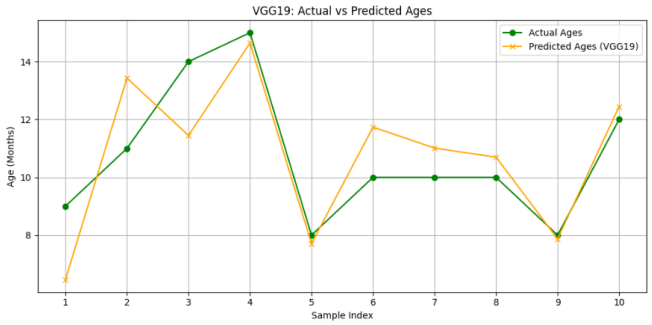

Fig. 17. Line chart of the actual and predicted results obtained by the VGG19.

Although VGG19 is a strong general purpose image classification model, its complexity characterized by 19 layers and a large number of parameters proved less suitable for bone age prediction compared to the custom CNN. Overfitting was observed, particularly in the later stages of training, as evidenced by a noticeable gap between the training and validation errors. While VGG19 demonstrated reasonable predictive ability, it was outperformed by the custom CNN in both accuracy and generalization. These findings suggest that while deep architectures like VGG19 can be effective on large scale datasets, they may not be optimal for specialized tasks such as bone age estimation. This highlights the advantage of using task specific architectures tailored to the domain.

D. Performance Evaluations of InceptionV3

This study evaluated the performance of InceptionV3 that is highly sophisticated model composed of inception modules designed to learn multi scale features on the RSNA Bone Age Dataset. Although InceptionV3 generally outperforms custom CNNs in complex image classification tasks by capturing features at multiple scales within a single layer, its performance in the bone age prediction task did not surpass that of the custom CNN. This suggests that, despite its architectural complexity, InceptionV3 is less effective for specialized regression tasks like bone age estimation when compared to a domain specific model. Table IV illustrates the training and validation MAE and MSE for InceptionV3 over 100 epochs.

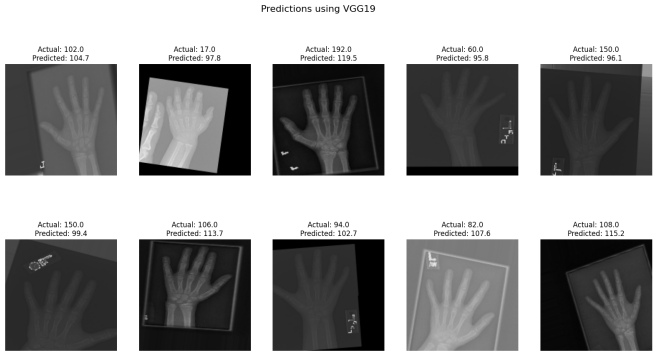

Fig. 18. Actual and Predicted Results Obtained by the VGG19.

TABLE IV. PERFORMANCE OF PROPOSED INCEPTIONV3 MODEL

Metric	Training Set	Validation Set
Mean Absolute Error (MAE)	4.72 Months	3.94 Months
Mean Squared Error (MSE)	28.01 Months	19.87 Months

The training results of InceptionV3 compared with the custom CNN, indicate relatively lower performance. By the 100th epoch, InceptionV3 achieved a training MAE of 4.72 months and a validation MAE of 3.94 months. The model recorded a training MSE of 28.01 and a validation MSE of 19.87, suggesting that it struggled with generalization and was more prone to overfitting compared to the custom CNN. Figures 19 and 20 illustrate the actual versus predicted bone ages obtained by the InceptionV3 model on the RSNA Bone Age Dataset.

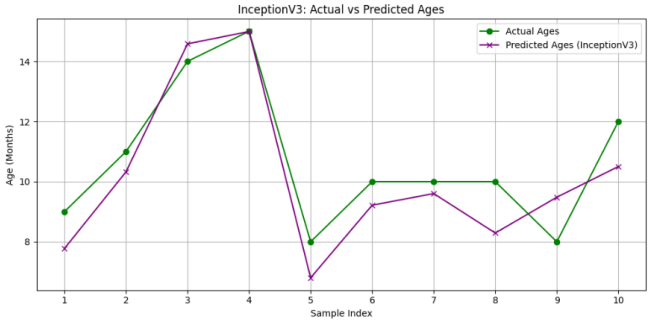

Fig. 19. Line chart of the actual and predicted results obtained by the InceptionV3.

Although InceptionV3's inception modules are powerful tools for multi scale feature extraction, their architectural complexity did not translate into improved performance for the bone age prediction task. Moreover, the RSNA Bone Age Dataset is relatively small in size, making it important to balance model complexity with generalization capability. Despite its sophisticated design, InceptionV3 was unable to outperform compared to the custom CNN, which was specifically built and fine-tuned for this domain specific task. The comparative results demonstrated that the simpler, more focused architecture of the custom CNN achieved superior accuracy and generalization.

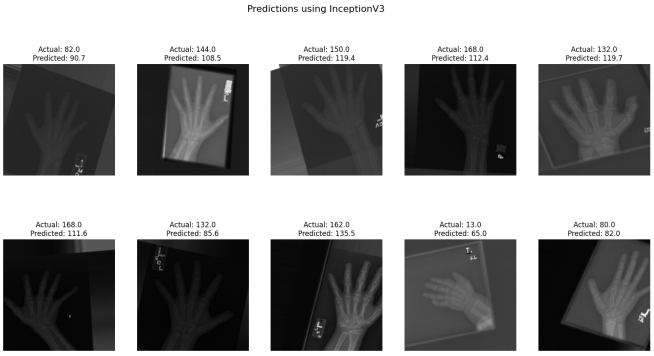

Fig. 20. Actual and predicted results obtained by the InceptionV3.

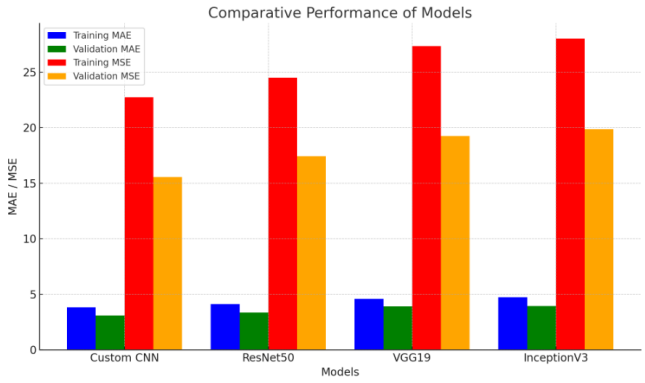

Fig. 21. Comparative performance of models on RSNA bone age dataset.

E. Comparative Experimental Results

The custom CNN outperformed all other models across both evaluation metrics MAE and MSE as shown in Table V. Its lower error values indicate that the model was more effective in learning features relevant to bone age prediction and demonstrated superior generalization to unseen data. These results also highlight the limitations of transfer learning in this specific application. Although, the models like ResNet50, VGG19, and InceptionV3 have achieved success in various domains, their general purpose architectures proved less effective than a task specific design for bone age prediction. This underscores the advantage of developing customized deep learning models tailored to the unique characteristics of medical imaging tasks.

TABLE V. PERFORMANCE COMPARISON OF DIFFERENT MODELS

Model	Train MAE	Valid MAE	Train MSE	Valid MSE
Proposed CNN	3.27	3.08	22.73	15.56
ResNet50	4.12	3.36	24.51	17.43
VGG19	4.59	3.91	27.34	19.26
InceptionV3	4.72	3.94	28.01	19.87

Figure 21 presents a bar chart comparing the performance of the four models including Custom CNN, ResNet50, VGG19, and InceptionV3 based on both mean absolute error and mean squared error across the training and validation phases. The custom CNN, which was specifically designed to capture the unique characteristics of pediatric hand X-ray images, outperformed the pre-trained models in both metrics. Its task specific architecture contributed to more accurate and reliable predictions, highlighting the benefits of developing specialized models for domain specific applications like bone age estimation.

V. DISCUSSIONS

The proposed custom Convolutional Neural Network (CNN) model performed better than the transfer learning models and its validation Mean Absolute Error (MAE) was 3.08 months, compared to 3.36, 3.91, and 3.94 months of ResNet50, VGG19 and InceptionV3, respectively. This leads to the advantage of the design of domain-specific architectures as opposed to working with general-purpose models. The task-specific architecture of CNN, preprocessing algorithms, such as CLAHE and ROI detection using YOLOv3 multi-scale models, led to acquired precision because it emphasized attention on pertinent anatomical zones. These results are correlated with previous studies that indicated that transfer learning models often underperform on specific medical imaging tasks. Nonetheless, the research is restricted to the study of one dataset. The model needs to be proved in the future on other data and in other clinical contexts to determine the extent to which it can be generalized. The findings indicate that special CNNs are better for giving more accurate and consistent bone age estimation, and implementing them as a part of clinical decision-support systems.

VI. CONCLUSION AND FUTURE WORK

This research demonstrates that deep learning based customized CNN architecture trained on the RSNA pediatric bone age can significantly enhance the accuracy with respect to demographic invariance, effectively reducing biases related to gender and age. On the validation set, the proposed custom CNN achieved the lowest mean absolute error of 3.08 months, outperforming all pre-trained models including ResNet50, VGG19, and InceptionV3. While ResNet50 and VGG19 produced respectable results, their deeper and more complex architectures led to overfitting, which negatively impacted their generalization performance. The success of the custom CNN can be attributed to its task-specific design, which effectively captured the intricate features in pediatric hand X-ray images that are critical for accurate bone age estimation. Additionally, this study contributes to the growing body of literature exploring transfer learning in medical imaging. While transfer learning models offer certain advantages, the results reinforce the notion that custom-built architectures, tailored to specific datasets and clinical tasks, often outperform general purpose models. Furthermore, the study validated the importance of preprocessing techniques such as Contrast Limited Adaptive Histogram Equalization (CLAHE) and Region of Interest (ROI) detection using YOLOv3. These steps significantly improved the model's ability to extract meaningful features, contributing to its overall performance. The results indicate that deep learning approaches particularly custom CNNs hold considerable promise for automating and improving the precision of bone age prediction.

The next step in the research should be to verify the

presented model using multi-institutional and multi-ethnic data to guarantee a high degree of generalizability and power over a variety of clinical environments. Inclusion of other clinical characteristics in age or patient height, weight, and hormonal information would presumably enhance prediction accuracy and clinical relevance further. Furthermore, it would be useful to implement the system into a real-time clinical efficiency and to assess its effects on diagnostic efficiency and inter-observer variability. Lastly, investigation of lightweight/edge-optimized architectures may help enable implementation in low-resource/point-of-care setting.

Intelligent Agents in Disaster Risk Management: A Systematic Review of Advances and Challenges

Hssaine Hamid, ELouadi Abedlmajid
Advanced Systems Engineering, National School of Applied Sciences,
Ibn Tofail University, Kenitra, Morocco

***Abstract*—Artificial Intelligence (AI) has emerged as a transformative technology in the domain of Disaster Risk Management (DRM), offering new possibilities for forecasting, preparedness, and rapid response in the face of increasingly frequent and complex natural disasters. This systematic literature review synthesizes the state-of-the-art advances in AI-driven intelligent agents applied to DRM, covering domains such as early warning systems, geospatial analysis, damage assessment, evacuation planning, and decision support. It critically examines the technological innovations, implementation methods, and interdisciplinary approaches that have shaped the evolution of intelligent agent-based solutions in disaster scenarios. Through the analysis of over 7,800 scientific publications indexed in Scopus, Web of Science, and OpenAlex between 2010 and 2025, the review identifies key patterns, application domains, and persistent gaps such as data scarcity, lack of model interpretability, and limited operational deployment. The study also addresses ethical concerns related to AI deployment in high-stakes environments and proposes a roadmap for future integration of intelligent agents with IoT, UAVs, and real-time decision infrastructures. The findings contribute to a deeper understanding of how AI and multi-agent systems can reinforce disaster resilience and inform sustainable and adaptive disaster management strategies at both global and local levels.**

Keywords*—*Intelligent agents; Artificial Intelligence; disaster risk management; predictive analytics; resilience; early warning systems; geospatial AI; disaster response; ethical challenges; machine learning; climate change adaptation

I. Introduction

The frequency and intensity of natural disasters have increased markedly over the past two decades, driven by accelerating climate change, rapid urbanization, and environmental degradation. From floods and wildfires to earthquakes and pandemics, recent events have exposed critical vulnerabilities in existing disaster risk management (DRM) systems. Traditional DRM approaches, while foundational, often fall short in handling the complexity, scale, and uncertainty of modern disaster scenarios.

Artificial Intelligence (AI) presents a significant opportunity to address these shortcomings. By leveraging techniques such as machine learning, natural language processing, computer vision, and multi-agent systems, AI can enhance situational awareness, enable predictive analytics, automate decision-making processes, and facilitate real-time response. However, despite the growing interest in AI for DRM, most existing studies focus on isolated use cases, neglecting to provide a comprehensive and structured analysis of the broader ecosystem of intelligent agents and their integration into disaster response frameworks.

This study responds to that gap by conducting a systematic literature review of intelligent agents applied to DRM, with the goal of mapping key advances, identifying implementation challenges, and highlighting future research opportunities. It contributes an interdisciplinary synthesis that goes beyond technical innovation to include organizational, ethical, and operational dimensions. Furthermore, the article distinguishes itself by focusing on intelligent agent architectures, their decision-making capabilities, and how these agents interact within multi-layered, real-world DRM systems.

The remainder of this paper is structured as follows: Section II presents the review methodology based on PRISMA guidelines; Section III details the main findings, categorized by application domains, technologies, and limitations; Section IV discusses current gaps and future research directions; and Section V concludes with practical implications and strategic recommendations for stakeholders.

II. Methodology

Recent advances in artificial intelligence (AI) have fueled the development of intelligent agents capable of enhancing decision-making, coordination, and automation in disaster risk management (DRM). Numerous studies have investigated the role of AI in supporting early warning systems, damage assessment, and emergency response. For example, Abid et al. [1] and Pang [3] emphasized how AI, especially machine learning and geospatial analysis, supports real-time monitoring and improves situational awareness during disasters. Similarly, Wheeler and Karimi [4] explored the application of deep learning models in satellite image interpretation to assess post-disaster damage at the building level.

Despite these contributions, existing literature often focuses on narrowly defined applications or specific types of disasters, without offering a global and systematic synthesis of intelligent agent architectures. Ramchurn et al. [5] introduced the concept of Human-Agent Collectives (HACs), highlighting the potential of mixed human-AI coordination, while Rashid et al. [15] developed a multi-agent flood forecasting system based on reinforcement learning, showing that intelligent agents can make autonomous, context-sensitive decisions in real time.

However, comprehensive overviews mapping the landscape of AI agent integration across the DRM cycle remain limited. Many reviews omit key issues such as trust, ethical risks, and system interoperability. Moreover, the challenges of implementing agent-based systems under data scarcity and infrastructural limitations—particularly in low-resource or high-risk regions—are not adequately addressed.

This review seeks to fill these gaps by synthesizing over 7,800 scientific publications from 2010 to 2025 and offering a structured analysis of intelligent agent applications in DRM. By covering both technological innovations and deployment barriers, it contributes to a deeper understanding of how agent-based AI can reinforce resilience, operational efficiency, and adaptive capacity across multiple disaster contexts.

This SLR followed strict methodological standards to ensure transparency, reproducibility, and comprehensiveness. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines was used to guide the review study selection process through three major stages: IDentification, Screening, and Inclusion.

A. Data Sources and Search Strategy

The bibliographic search was conducted in three academic databases: SCOPUS, Web of Science, and OpenAlex. These sources were chosen because they cover a wide range of peer reviewed material, conference papers and book chapters spanning artificial intelligence (AI), disaster risk management (DRM) and related studies. The search string was intentionally designed to retrieve a complete corpus of AI applications in disaster management literature. The query used was: Query: (”artificial intelligence” OR ”machine learning” OR ”deep learning”) AND (“disaster management” OR “disaster risk reduction” OR “natural disaster” OR “catastrophe naturelle” OR “emergency management” OR “hazard mitigation” OR “resilience” OR “early warning system”) This search resulted in a total of 13,880 articles.

B. Screening and Eligibility Criteria

A two-step screening process was applied:

1) Inclusion Criteria:

- Articles published between 2010 and 2025.
- Publications limited to peer-reviewed journal articles, conference papers, and chapter books.
- Only publications written in English were considered to maintain consistency in analysis.

2) Exclusion Criteria:

- Duplicate entries were removed.
- Articles outside the scope of the research theme (i.e., those not addressing AI or intelligent agents in the context of disaster risk management) were excluded after title, abstract, and, where necessary, full-text reviews.

After applying the inclusion and exclusion criteria, 7,991 articles were deemed eligible for detailed analysis.

C. Final Selection

A total of 7,823 articles were ultimately included for bibliometric, thematic and qualitative analysis after a comprehensive selection and validation process. This is the empirical basis for the findings and discussions in this study.

The complete selection process is presented (Figure 1, PRISMA flow diagram), which is sufficient to show transparency and clarity in the research methodology adopted.

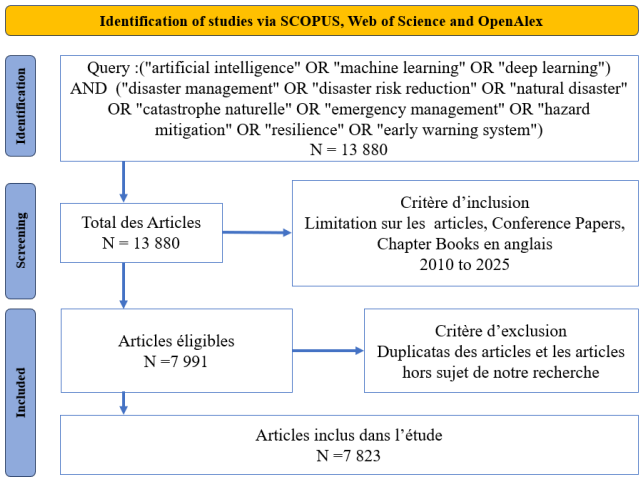

Fig. 1. Prisma approach.

III. Results and Discussion

The use of artificial intelligence (AI) has revolutionized the approaches to disaster management providing valuable resources to effectively foresee, respond, and recover for both natural as well as man-made disasters. AI is the intelligence exhibited by computer systems in order to act and think like humans in a multitude of interconnected machines and an intelligent [1]. Incorporation of AI in disaster management has significantly improved the capability to predict disasters in advance and support the affected during the disaster, giving birth to what is known as Intelligent Disaster Management (IDM) [2].

RAPID AI Summit 85 Intelligent Agents for disaster management use various AI methods, such as AI for robotics, AI for drones, machine learning, deep learning, sensing, and algorithms to predict disasters, and speed rescue operations [1]. These technologies have developed from primitive tools with poor decision-making abilities to fully automated and artificial intelligent systems capable of analyzing data and operating independently [1].

The underlying merit of AI in disaster management is the capability to track and analyze huge volumes of heterogeneous data types such as geospatial data, social media, and sensor data of wireless networks [3]. For example, the machine learning algorithms can learn models in change detection in satellite images to detect the areas mostly affected by disasters for coordinating disaster relief more efficiently [1]. Deep learning-based computer vision models [4] can evaluate building damage post-natural disaster with pre- and post-disaster satellite

images, which automates a key step in decision support for disaster response.

Contemporary paradigms in disaster management admit that neither human beings nor machines working alone can meet the demanding requirements of disasters. Rather, meaningful disaster management calls for a combined effort between humans and intelligent sys- tems in an environment that is often referred to as a Human-Agent Collective (HAC) [5]. Such mechanisms interleave human and machine decision making and allow control to be flexibly transferred between human and agent members of agile teams, tracked through information infrastructures that author accountability [5].

Applications exist in all the stages of disaster management: the pre-disaster measures (like predictions and risk analysis), the in-disaster ones (like classifications and modeling) and the post-disaster ones (like assessing the damages) [2], Such as during the COVID-19 pandemic, drones or autonomous robots have been used in multiple disaster-response activities [6], and in the building fire, AI-based fire detection systems are implemented for real-time guidance of occupant evacuation [7].

While AI has tremendous potential to improve disaster management, there are some critical new challenges. Learning reliable predictors from noisy, heterogeneous and limited annotated data is a major challenge[8]. Moreover, there have been worrisome warnings on the potentially negative effects of unrestricted deployment of AI, which may even cause increased disaster impacts if improperly handled [2]. However, continued progress and sensitive use of intelligent agents in emergency response and management applications have great potential to enhance our ability to predict, respond and recover from disaster collectively.

A. Design Approaches for Intelligent Agents

The design of intelligent agents Figure2 for disaster management should carefully consider architectural approaches able to deal with the complexity and uncertainty of emergency scenarios. One widely used model of reasoning is the Belief-Desire-Intention (BDI) approach to reasoning about agents, which offers us a natural and expressive way of specifying agent behaviours in complex environments through describing the agent's mental states. The BDI model provides an effective means for agents to maintain a representation of their environment (beliefs), express desires and reasons for action (goals), and to express their decision of what to do in terms of a course of action (intents), strong to the case of disaster management [9]. This reasoning enables agents to have 'situational awareness' and adapt to changing situations without starting processing from scratch each time the situation changes [9] [10].

Agents are classified into careful agents, model based agents, goal based agents, utility based agents, and learning agents [11]. These agents fall into four further architectural categories; logic-based agents (relying on logical deduction to determine actions), reactive agents (mapping situations directly to actions), belief-desire-intention (BDI) agents (operating on structures representing mental states) and hybrids which utilize multiple architectures [11].

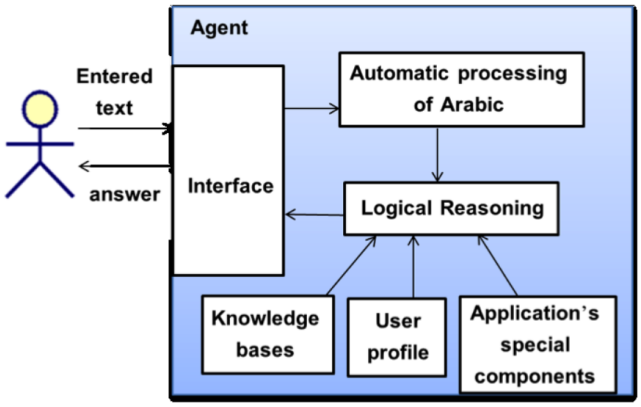

Fig. 2. General design approaches for intelligent agents.

Multi-agent systems (MAS) have become an effective paradigm for designing disaster management systems, where different specialists agents can cooperate to solve complex crisis situations[9]. These systems generally utilize a combination of heterogeneous dedicated agents such as situation assessment agents, resource agents, decision support agents, coordination agents, and prediction agents, which are specialized to address different aspects of disaster management [12]. The multi-agent nature allows for distributed knowledge and resource reasoning that are especially valuable in emergency situations of natural or human-caused disasters [9, 13].

Awareness-based modeling is also a critical design issue and is reflected in work like MAAP (Multiagent Awareness-based Process model), which keeps agents aware of relevant policies in support of better cooperation in disaster scenarios [14]. awareness enables agents to identify relevant information to consumer demands and coordinate in a crisis response.

Recent achievements in artificial intelligence have enabled the progress of more sophisticated design techniques. The multi-agent deep reinforcement learning (MADRL) integrates the multi-man formalized logic and deep reinforcement learning for managing the and uncertainty where high-dimensional data is involved in disaster situations [15]. This approach allows the agent to maximize its expected reward in an uncertain and noisy environment, where an approximate action value function is learned by agents using neural networks as function approximators [15].

Another important design pattern is represented by intelligent agent Decision Support Systems (DSS). These systems are commonly characterized by multi-level agent designs, with each level having a different role. For instance, a representation layer can describe the environment as a set of entities, the states of which evolve over time, and domain agents observe those states with respect to the domain informationodies [16]. These systems try to identify threats in uncertainty and under partial perception, so that crises can be avoided [16].

Contemporary agent architecture for disaster management also focuses on the important qualities of autonomy, complexity of decision making, adaptability, and impact power [17]. Autonomy enables agents to function without the need for human input, performing the ability to process real-time data and allocate resources. The intricacy of decision-making

allows them to maneuver complex environments, weighing, for instance, regarding affected populations, available resources, and infrastructure limitations. Adaptability allows agents to adapt strategies in real time to changing conditions, while impact potential describes the ability to take actions that have consequences in terms of lives affected, economic damage, and long-term recovery [17].

The agentic AI systems are the state-of-the-art intelligent agent design for disaster management. Such systems would be able to process environmental data in real-time under crisis, allocate resources and change at the same time strategically as conditions and the input data change [18]. This self-scheduling ability is essential in efficient rapidity need based disruption response.

One of the major challenges in developing an intelligent agent for disaster control is to make the designing of the intelligent agents in way where it is can successfully work in uncertain and complex environments, compatible with different platforms and scenarios [19][20]. Meetin this challenge, modern design approaches focus in generic frameworks that can be extended to multiple domains with little adaptation, counting with domain knowledge provided by experts while retaining core capabilities that enable the autonomous changes in agent behavior code [19].

B. Implementation Methods and Technologies

Disaster intelligent agentsIn the research of disaster management, there are a series of artificial intelligence technologies that are applied to the depth of work on the problems of disaster predicting, rescue and recovery. The implementation of Decision Support Systems (DSS) is one of the fundamental frameworks for transferring human expertise to computers and for constructing models from this knowledge [21]. These systems attempt to reduce prospective risks through the early reconnaissance and the preparation of actions.

Numerous AI techniques are widely used to handle the inter-related problems in disaster management. These methods include Bayesian networks for more probabilistic reasoning, fuzzy logic for approximate reasoning with vague information and metadata techniques such as artificial neural networks, machine learning, genetic algorithms and swarm intelligence [21]. Hybrid methods in which fuzzy IF-THEN rules and optimization are coupled, are particularly useful for the acquisition and handling of fuzzy information in disasters.

Agents are a promising paradigm due to their distributed, parallel, collaborative, hybrid, flexible, recursive, adaptive, cooperative, and intelligent processing [22] Figure3 and a powerful implementation of disaster management systems. The fact that disaster management activities consist of physically and logically distributed tasks makes multi-agent systems (MAS) systems especially suited, enabling specialized agents to be allocated to specific tasks, and hence supporting scalable and collaborative decision making.

One usage of Multi-Agent Systems and Anytime Algorithms can be found with the advancement of reliable, fast, and robust distributed decision support system in disaster management [22]. This coupling renders such systems especially well-suited for flood early warning and forecasting systems, since

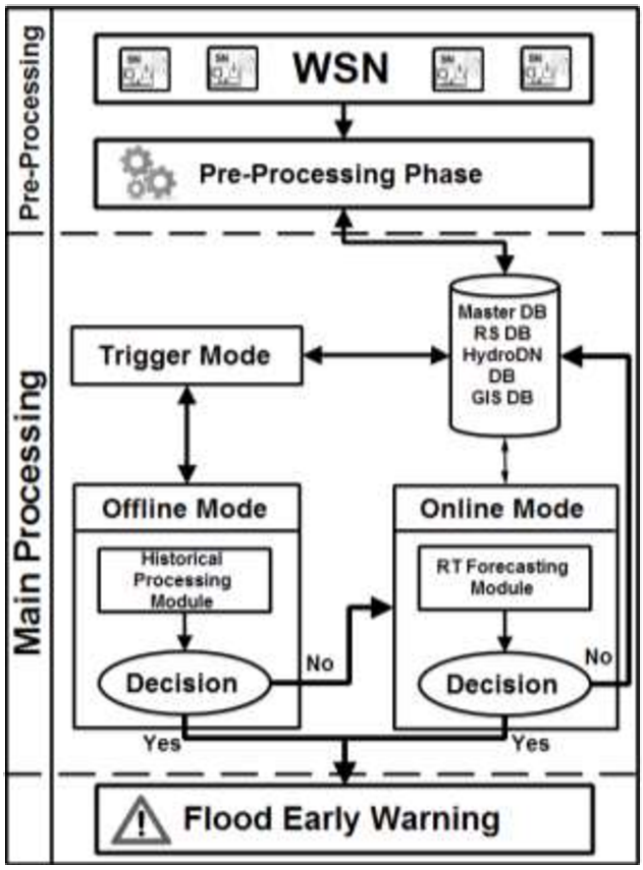

Fig. 3. General architecture of our decision support system.

that agents carry out intelligent, distributed, adaptive, scalable processing to take cooperative and collective decisions.

Putting it to Practice The more recent approaches take advantage of the sophisticated artificial intelligence algorithms, for example deep reinforcement learning. Multi-agent deep reinforcement learning (MADRL) allows agents to maximize their expected rewards in presence of uncertain environments which learn action values by using neural networks as function approximators [15]. This strategy is especially useful in the case of flood prediction, for which the data is of high-dimension and uncertainty is high. One interesting solution applies multi-agent actor-critic and deep deterministic policy gradient algorithms on those problems.

From a technical point of view, AI-based disaster management solutions can be partitioned into a continuum between supervised learning [23] [24] In the most ideal conditions, the reference points for operations on a large-scale disaster dataset would be provided as the ”correct”, or ”desired”, or ”target” output of a system. For instance, higher than normal temperatures in the previous week, were associated with an increased risk of hospitalization ahead of a summer heatwave[23]Figure4.

The adoption of AI in disaster management is more and more realized by new algorithms and high performance computing (HPC) in order to predict the geospatial and temporal patterns of disasters with precision [25]. The machine learning and deep learning methods that are frequently used for tasks

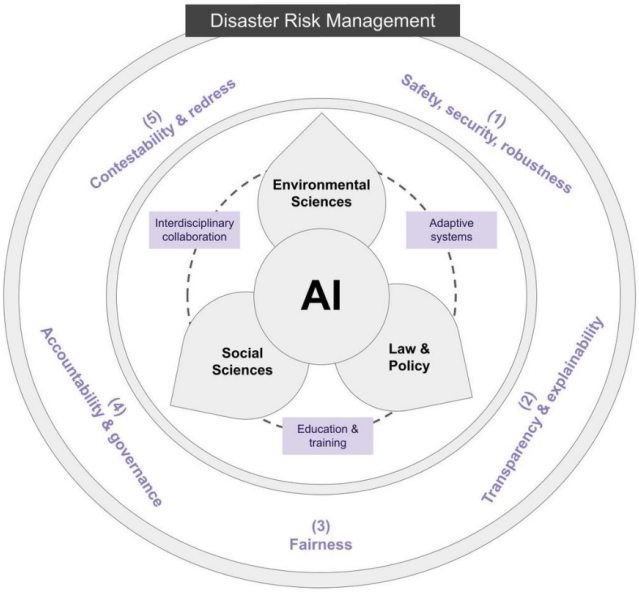

Fig. 4. Principles for regulating AI use in disaster risk management.

such as disaster prediction, risk evaluation, early warning systems, and disaster damage detection have increased the prediction accuracy, reduced computation time, and saved model generation costs [26].

These technologies are indeed promising but their application encounters many difficulties. These challenges include the requirement and quality of data, data diversity, integration with existing systems and technologies, ethical and social considerations, as well as the continued need for research and development [26] [27]. Privacy and security issues are especially important, because AI in disaster management may require the collection and analysis of privacy-sensitive data [26].

In spite of these difficulties, AI models have been successful in dealing with non-linear and large datasets hence are fitting for disaster management and monitoring (Kamolov, 2024). Technologies and methods such as big data analysis, machine learning and deep learning can be used to visualize, analyze and predict natural disasters through developed system [26]-[28].

Good design and deployment of agent systems for disaster needs to take account of how efficiently and synergy agents can be harnessed for action. This requirement calls for an unambiguous responsibility assignment among the agents and making the organizational structure of the MAS explicit [15]. Future work includes detailed development of the components, especially the forecasting decision-making and warning dissemination components; and integration of systems with external databases using APIs [15]. The following Table1 show the all general challenges

C. General Technological Challenges and Limitations

1) Data-related challenges:

a) Quality and availability of data: AI models need high-quality and diverse data for effective prediction and management of disasters, but acquiring comprehensive disaster data is still difficult [26, 27].

b) Dynamic datasets: There are significant difficulties in dealing with data rapidly changing due to disasters especially with noisy, heterogeneous and limited annotations [8].

c) High dimensionality of data: Information integration from multiple sources are considered as a challenging task in view of the large volume of data which is high dimensional and extracting useful features from this data becomes challenging to learn profitable patterns for prediction [8].

d) Bias in training data: Training data can be biased and hence lead to biased prediction or predictions that are unfair against under-represented regions or communities [8].

2) Model development and accuracy issues: Unclear statistical definition of 'extreme' event, which is challenging for the AI models to capture, and thus a standardization is harder to achieve [8].

a) Accuracy limitations: Despite the promising capabilities of AI in processing the nonlinear data for disaster monitoring, attaining credible prediction accuracy still is a challenging task [26], [28].

b) Incorporation of physics models: Incorporating AI with classical model based physics is challenging though may improve the accuracy [8].

c) Generalization in other contexts: The AI solutions which are trained on specific types of disasters or location can face difficulty in performing well in other form of disaster contexts [8].

3) Trust and interpretability concerns: Advanced AI models often operate as "black boxes" that are not, or may not even be, interpretable, thus may not be acceptable for critical decision-making contexts [8].

a) Uncertainty quantification: Most AI models are not good at quantifying uncertainty in their predictions, which is important for disaster relief [8].

b) (iii) Stakeholder trust: It is a challenge in developing AI models which are trusted by the stakeholders and compliant with regulations [8].

c) Reluctance in implementation: Reluctance to utilize AI in disaster management settings is due to the uncertainty of reliability and fairness [8].

4) Operational and implementation challenges: Connecting AI systems to the current disaster management technologies and infrastructure is subject to numerous technical challenges [26], [27]. Real-time Data Integration: Real-time integration of data in rapidly evolving disaster scenarios is a technically challenging task [8].

a) Deployment brokers: There are many practical challenges to transition from research models to operational deployment in the field of disasters [8].

b) Interpretation by non-experts: AI outputs could be hard for non-expert stakeholders and decision makers to interpret [8].

5) Ethical and social considerations: Data Privacy and Security: The gathering and analysis of private data during disasters pose notable privacy challenges [26], [27]. Fairness and Equity: Ensuring that disaster management systems based on AI are fair and equitable for all affected communities is challenging [26], [27]. Ethical Guidelines: Comprehensive guidelines are required to support transparent and ethical use of AI insights in disaster decision-making [28]. Challenges: The disaster risk analysis community needs to be aware of pitfalls in AI solutions [24], [26].

D. Multi-Agent Systems for Disaster Management

The multi-agent system is an effective framework for disaster management because they are capable of solving complex, distributed problems through collaborative intelligence. These systems are common and have a lot of advantages and can provide distributed, parallel, collaborative, hybrid, flexible, recursive, adaptive, cooperative, and intelligent processing in scalable environments and can be good candidates for multiple facets of disaster management [22].

The main benefit of MAS is their macroscopic nature, in which knowledge and resource reasoning can be distributed among specialized agents [9], [29]. A typical MAS for disaster management integrates different sorts of agents which are specific agents, including situation assessment agents, resource agents, decision support agents, coordination agents, and prediction agents. Each agent is trained in its own way and can model multimodal or unimodal data. Among the tasks they perform are receiving and processing situation updates, resource optimization, decision options generation, emergency control coordination and disaster trajectory prediction [12]. The BDI reasoning architecture is an important component in many multi-Agent systems for disaster management. This approach offers a natural means to define agent behavior in unstructured environments which are described in terms of mental states influenced by decision-making [9]. Your approach seems to be very useful in dynamic disaster scenarios as agents can continue to follow goal driven paths, without having to recalculate from the beginning when the world changes. This reinforces the situation-awareness characteristics of agents, such as in the ability to observe a dangerous alarm, take an intelligent action and prepare preventive acti ons in situations with limited time [9].

In the latest years, novel MADRL architectures that fuse deep reinforcement learning with multi-agent systems have emerged. Such advanced systems are very useful in dealing with problems of uncertainty in disaster prediction and management. In MADRL, multiple agents compete to maximize their expected total discounted rewards under uncertain or noisy transition and reward models. (d) Agents estimate action values using multilayered neural networks as function approximators [15]. This kind of method appears to be very promising in flood forecasting since it copes with complex high-dimensional data and uncertainty. To deal with these issues, the combination of MARL algorithms, like actor-critic algorithms and DDPG algorithm, is introduced to fulfill these requirements [15].

The architecture features multilayer-based agents with each serving a different functionalities for disaster management. For example, a representation layer could model the environment as a series of entities, that evolve over time, and factual agents are able to sense those changes as described in domain ontologies [16]. This layered strategy allows the system to identify threats in ambiguous or only partially perceived environments, before they develop into crises.

Organizations in MAS on the one hand need to specify how agent roles should interoperate and interact, but also need a mechanism to enforce interacting of roles. This involves specifying roles for each agent and developing procedures for information-sharing and joint decision-making [15]. As an illustration, when agents apply intelligent, distributed, adaptive, and scalable processing that help them in order to come up with cooperation or collective decision they help in flood forecasting and warning systems [22].

One such effective integration is that of multi-agent systems with Anytime Algorithms, thus producing dependable, efficient distributed DSS. This indissoluble link has been particularly exploited in the context of flood disaster management, where agents cooperate to execute different activities are make consensus in an efficient way [22].

Multi-agent systems are especially beneficial for disaster management, but face challenges such as addressing issues of interoperability, coordination mechanisms and inconsistent information. Future work will be focused on improving certain aspects, such as forecast decision making and warning dissemination, as well as on connecting systems to the outside world through the cloud to be able to use data from any organization also providing capabilities for full disaster management [15].

E. Intellent Agents Application and Use Cases

1) Early warning and predicting systems: Smart agents have been widely used especially in early earthquake warning by means of pattern recognition and data mining. Among other applications, AI-based systems can help predict the occurrence of natural disasters (e.g., hurricanes) and forecast their paths using weather data, satellite images, social network activities, and geolocated information [30]. Wildfire risk assessment AI algorithms process historical records of weather and vegetation cover and human activities to predict area with high risk of a break [30]. Machine learning algorithms that are applied on big data sets can predict with better accuracy for efficient disaster risk management [31]. For example, underwater seismic monitoring systems extract acoustic radiation of seismic events in order to provide the early tsunamigenic alerts based on fault feature identification [32], [33].

2) Damage monitoring and assessment: The AI systems which are based on computer visions are able to offer indispensable powers for post-disaster damage assessment. Deep learning models can semantically infer the extent of damage in individual buildings from before and after disaster satellite images, thus automating a significant bottleneck in decision support in disaster response [1] [4]. Convo- lutional neural networks (CNNs) based change detection models can identify the most impacted regions from disasters, aiding in disaster management [1]. Segmentation of buildings and damages using airborne light detection and ranging (lidar) data has also reached high accuracy rates in the case of heavily damaged areas [1] [34].

TABLE I. TECHNOLOGICAL CHALLENGES

Papers	[27]	[8]	[8]
Technological Challenges	Technological challenges in AI for disaster risk management include data quality, system interoperability, and model transparency.	Challenges include data scarcity, model interpretability, and integrating AI with existing systems.	Developing accurate predictors from noisy, heterogeneous, small sample sizes.
Operational Limitations	Operational limitations in implementing AI for disaster management include computational resource constraints, integration challenges, real-time processing demands, explainability and transparency requirements, bias and fairness concerns, and issues of responsibility and accountability.	Noisy, heterogeneous data, limited data, real-time integration challenges.	Limited data, real-time integration, model understandability, stakeholder trust.
Data Requirements	High-quality, diverse, and real-time data are essential for effective AI application in disaster risk management.	High-quality, diverse, and real-time data are essential for effective AI applications in extreme event analysis.	Noisy, heterogeneous, small samples, limited annotations, real-time integration.
Risk Reduction And Preparedness [45]	AI plays a significant role in predicting disasters, optimizing response efforts, and improving preparedness by analyzing data and providing early warnings.	AI plays a crucial role in enhancing flood management systems, improving predictions, and communication strategies for better risk reduction and preparedness for natural disasters.	AI improves disaster response, communication, and enhances disaster readiness and risk reduction.
Model Reliability And Trust	Concerns related to the accuracy, transparency, and trustworthiness of AI models used in disaster risk management.	Challenges include accuracy, transparency, and trustworthiness of AI models in disaster risk management.	Accurate, transparent, and reliable models crucial for stakeholder trust.

3) Evacuation planning and operations: EvacuationSim and evacSim Intelligent agents under evacuation simulation may employ advanced modelling and route optimisation used in evacuation planning. And with emergency tools that integrate inundation maps with semantic segmentation, it provides more information to first responders pre-, during and post-hurricanes, and help them to gain more insights in human-level decision-making [35]. These systems process heterogeneous data with hydrological inundation models and computer vision techniques in order to serve stakeholders with timely, rich and accurate knowledge [35]. AI Agent-based simulations explore different evacuation strategies, facilitating early detection of risks and decisions on the optimal planning of evacuation routes [36].

4) Reaction systems autopoietic ones: Robots and automation have obtained a larger attention in disaster response. Flying machines can penetrate deep into disaster areas to survey the damage and supply aid [1]. Several robot generations have led to the development of more sophisticated machines, moving from robots that could hardly make decisions to those that are fully automated, intelligent and artificial [1]. Autonomous robots have been particularly utilized amidst the COVID-19 pandemic to support a number of response efforts [1][6]. Ground, aerial, surface and underwater swarm robots collecting big data of the environmental data at disaster-stricken sites, and then processed by deep learning model for object classification and decision making [1][37] Figure5.

5) Safety building and fire detection: AI's role in building safety AI applications in building safety are all about early detection and response to disasters such as a fire. The Smart Building and Town Disaster Management Systems based on augmented reality (AR) allow for visibility and tracking of the occupants during a building fire [1][7]. Physical-virtual linked (PVL) disaster management services via AR technology in buildings These systems provide visualization information and optimal guidance for initial rapid response by interweaving the physical and virtual space in the buildings [1][7] Figure6 . Convolutional Neural Networks Automatic fire recognition systems based on convolutional neural networks for fire detection in surveillance video respond and alert suitably [1][21].

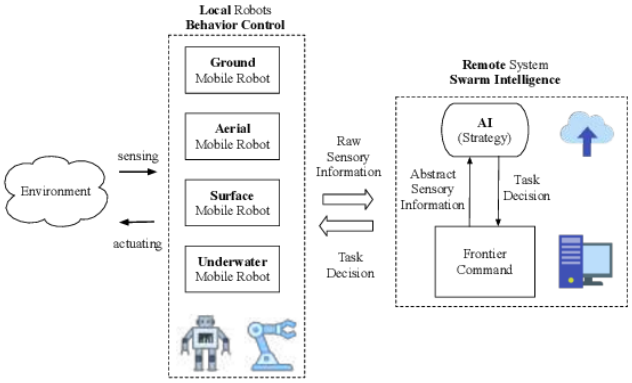

Fig. 5. Remote swarm AI and local robotic behaviour control.

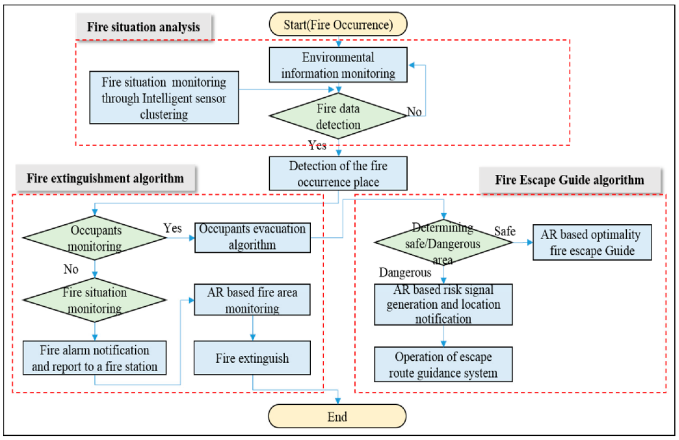

Fig. 6. The Fire extinguish and fire escape guidance algorithm.

6) Allocation of material and logistics: In climate related disasters, AI systems corner real time data regarding Effects of Disasters, Population dissemination, and Resources can utilized to optimize resource allocation [38]. These systems aid emergency responders in making rapid data-informed decisions about how best to allocate manpower, supplies, as wells as

in prioritizing the rescue operations, indentifying the location of high-risk victims and the most vulnerable population in need of emergency help [38-40]. AI systems can give real-time situation updates, disaster location and intensity, and generate information about affected people and infrastructures and support logistics planning [30].

7) Simulated and training environments: Disaster-Rescue simulations are also a practical application area in which in silico tools are used to determine policies for emergency response and management in the physical world [39]. Such simulations have widely been adopted in academia, government, and industry for contingency peril anticipation, planning, and policy making [39]. Emergency simulation using AI Agent-based technology can provide a more realistic training of simulated victim care and in future will see a holistic approach to using the AI for training in more security personnel, gaining as close a simulated experience as possible to actual conditions [36].

8) Multi-hazard risk reduction: Then, more recently, AI applications have shown promise in better managing multiple-hazards, that are when two or more hazards occur at the same time and interact together to lead to larger scale impacts, or cascading hazard scenarios, that are when a first high-impact hazard sets off a successive chain of other hazards or events that spread through time, see [32][40]. Such applications can be considered in the context of building sustainable infrastructure, safer and resilient cities and human settlements complementing various Sustainable Development Goals [32].

F. Challenges in Deploying Intellent Agents

Despite their potential benefits, implementing intelligent agents for disaster management presents several significant challenges:

1) Data quality and availability: One challenge is simply getting enough great data to train the AI models. One of the challenges in disaster scenarios is there is usually either very little, unreliable or disparate data, which would make it difficult to train robust models to estimate the required predictions [27]. Learning to predict can be particularly difficult when dealing with noisy and heterogeneous data, in the presence of very limited annotations [8]. This is particularly a problem for rare events such as extreme weather events in which there may be an insufficient amount of historical data.

2) Privacy and security concerns: The application of AI in DRM generally means processing huge amounts of personal data, posing crucial issues for privacy and security [27]. Data privacy is a key concern as such systems collect and process sensitive data and privacy regulations and individual rights need to be taken into account[26]. Finding ways to collect data in a manner that is both robust and respects privacy continues to present difficulties.

3) Computational resource requirements: Numerous advanced AI methods, especially deep learning algorithms, require extensive computation resources [27]. This creates a problem in disaster areas especially in remote or inaccessible areas where computational infrastructure is either scarce or not available. Critical AI solutions that are needed most, when and where they are needed can be hampered by resource constraints.

4) Integration with existing systems: Smart agents should be able to seamlessly interoperate with existing service infrastructure for emergency management such as command and contro l centers, dispatch functions, and sensor networks [27]. Integration in turn is taken rather difficult by data structure and nature of systems that are heterogeneous making deployment cumbersome to implement [26].

5) Real-time performance requirements: Disaster situations require instant processing and analyzing massive datasets for quick response and situational awareness [27]. Finally, timely information integration is critical in immediate Response, which however is not an easy task [8]. Since time is of the essence in many disaster response scenarios, there is an inherent tradeoff between speed and accuracy.

6) Explainability and transparency: Intelligent predictive solutions for high-stake disaster scenarios should be transparent and explicable to gain trust from decision-makers [27]. Developing authentic, interpretable and trustworthy AI-models is not trivial [8]. First responders must be able to comprehend AI recommendations and their underlying rationales to meaningfully integrate such information into their decision processes.

7) Ethical implications: The broader ethical dimension of containing AI with respect to disaster management will also have to be addressed [26]. There are fears that unrestrained use of AI can have detrimental effects and may increase the potential impact of calamity if not properly regulated [2]. Ensuring that AI systems are designed and deployed in a manner that is fair and equitable and achieves impact on disaster reduction is a key challenge.

8) Local implementation challenges: There are particular challenges to using AI models to inform policy and decision-making at the local level, where effects of climate change are dynamic and location specific [41]. Local peculiarities might face specific priorities, facilities, and available resources and skills to deploy AI-based disaster management systems.

9) Risks of AI-Caused digital disasters: An unusual new worry is the possibility that AI systems might itself cause, or exacerbate, catastrophes. While [2] demonstrates the bright side of the AI in disaster management, the unlimited applications of the AI may face the transference of challenges and threats, which can turn the AI benefits into detriments and deteriorate disaster impacts. This risk calls for a prudent governance and overseeing of deploying AI in life threatening emergency systems.

G. Future Opportunities and Trends

Looking toward 2025, artificial intelligence applications, Intelligent Agents Figure7 in disaster risk management (Table II) are poised for significant advancement across multiple dimensions. The integration of AI with emerging technologies is expected to revolutionize how societies predict, respond to, and recover from disasters. One of the most promising developments is the continued refinement of prediction and early warning systems that analyze diverse data sources—including weather patterns, satellite imagery, and social media—to make increasingly accurate forecasts about natural disasters such as hurricanes, earthquakes, and tsunamis [27].

TABLE II. SUMMARY OF METHODOLOGIES, TECHNOLOGIES, DISASTER TYPES, AND INNOVATIONS IN DISASTER RISK MANAGEMENT PAPERS

Papers	Methodology	Technology Utilized	Disaster Types Addressed	Risk Management Strategies	Opportunities and Innovations	Case Studies or Examples
[1]	AI and GIS in disaster management.	AI, geospatial tech, GIS, remote sensing, ML.	Floods, earthquakes, virus outbreaks.	Risk assessment, mitigation, response by intelligent agents.	Innovations in intelligent agents for risk management.	Real-world AI applications in disaster management.
[35]	AI, geospatial data, semantic segmentation, ML for emergency response.	Open-source geospatial data, ML algorithms, computer vision, semantic segmentation.	Hurricanes, wildfires, earthquakes, other crisis events.	Geospatial encoding and route optimization.	Open-source geospatial data integration for emergency response.	Hurricane Florence in Lumberton, NC.
[6]	Visual analysis of 15 YouTube videos from 12 countries.	Autonomous robots, 4IR technologies.	COVID-19 pandemic.	4IR innovations to enhance disaster risk reduction.	Infrastructure improvements via 4IR innovation.	Analysis of 15 videos across 12 countries.
[37]	AIoT architecture with robots and deep learning.	AIoT, DL models, swarm robotics.	Fukushima nuclear disaster, Wenchuan earthquake, Taiwan disasters.	Data collection and decision-making with AIoT coordination.	Disaster response using AIoT and swarm robotics.	Fukushima and Wenchuan examples.

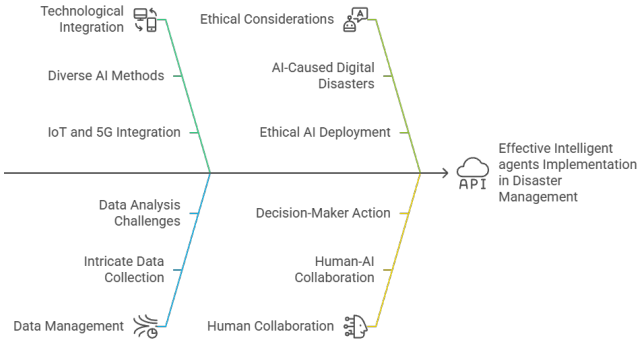

Fig. 7. Effective intelligent agents implementation in disaster management.

Automated damage assessment represents another area of significant future potential, with AI algorithms analyzing satellite imagery to rapidly evaluate disaster impacts and prioritize response efforts. This capability will be further enhanced through integration with unmanned aerial vehicles (UAVs), which can provide immediate visual data from affected areas, enabling faster and more targeted response [27]. The synergy between AI and UAVs extends beyond damage assessment to include the delivery of supplies and aid to affected communities, potentially transforming humanitarian logistics during disaster scenarios.

The convergence of AI with Internet of Things (IoT) devices and 5G networks is expected to create powerful new capabilities for real-time information gathering and rapid response coordination. These technologies working in concert will enable more comprehensive situational awareness and facilitate faster communication among response teams and affected populations [27]. This technological integration aligns with several United Nations Sustainable Development Goals, including SDG 11 (Sustainable Cities and Communities), SDG 13 (Climate Action), and SDG 15 (Life on Land), by enhancing prediction capabilities and improving resource distribution to reduce disaster impacts [31].

Personalization of disaster response represents a significant emerging trend, with AI systems analyzing community-specific vulnerabilities to develop targeted interventions. This approach moves beyond one-size-fits-all disaster management toward strategies tailored to the unique needs and characteristics of affected populations [27]. Similarly, AI-driven resource allocation systems will optimize logistics and supply chain management during disasters, ensuring critical resources reach those most in need when traditional distribution channels are compromised [27]. Enhanced collaboration between humans and AI systems is expected to be a defining characteristic of future disaster management approaches. Technologies such as chatbots and voice assistants will facilitate communication between response organizations and affected communities, while AI systems will augment human responders' capabilities by providing real-time information, automating routine tasks, and reducing response times [27]. This represents a significant evolution from AI as merely an "enhancer factor" toward truly intelligent disaster management (IDM) systems that can address increasingly complex disaster scenarios [2].

The future of AI in disaster management must also address the growing complexity of modern disasters, including hybrid events and potentially AI-caused digital disasters. As conventional methods give way to AI-informed practices across all disaster phases—pre-disaster (predictions, risk assessments), in-disaster (classifications, modeling), and post-disaster (damage assessments, resource allocation)—the field will require new approaches that balance technological advancement with ethical considerations [2].

Despite these promising developments, challenges remain in implementing AI for disaster management, including diverse AI methods and hazards [44], intricate data collection processes, and ensuring decision-makers act on AI-generated information [31][42][43]. Addressing these challenges will require interdisciplinary collaboration among technologists, disaster management professionals, policymakers, and affected

communities to develop systems that are both technologically sophisticated and contextually appropriate. As we move toward 2025, the trajectory of AI in disaster risk management points toward more integrated, responsive, and human-centered systems that leverage technological capabilities while remaining attentive to ethical considerations and sustainability goals. This evolution promises to transform disaster management from reactive response to proactive risk reduction, potentially saving countless lives and reducing the economic and social impacts of disasters worldwide.

IV. Conclusion

Artificial Intelligence (AI) and intelligent agents are catalysts for transforming the way we manage disaster risk and response, through their potential to enhance prediction, early warning, preparedness, real-time response and recovery. During the last decade AI technologies have advanced from self-contained, domain specific tools to integrated, adaptive systems that are up to the task to cope with growing complexity and urgency with which disaster scenarios are experienced around the globe. In particular, agents provide mechanisms for distributed decision-making, adaptability and autonomous coordination in disaster management systems, thus facilitating quick, scalable response to crises.

This systematic review has revealed significant progress made in utilising cutting-edge advances in machine learning and deep learning in order to forecast disasters, the use of robotics and UAV for damage assessment and search and rescue activities, natural language processing for real time social media analysis and geospatial data analytics for situational awareness. It has also drawn attention to the development of multi-agent learning techniques and deep reinforcement learning strategies as important solutions to handling dynamic and complex disaster environments.

But there are big holes and challenges. Quality and coverage of data still represent significant challenges, especially in low-resource settings and for rare types of disasters. Ethical considerations such as bias, privacy, and fairness remain important factors for the responsible use of AI in disasters. There is just as much pressing emphasis on technological challenges such as model interpretability, real-time performance, system interoperability and trust building among decision makers. Additionally, the changing nature of disasters — such as the development of hybrid crises and AI-facilitated digital disasters — calls for increasingly complex, humane, and ethically led AI solutions.

The future is promising as AI integrated with IoT, 5G technologies, autonomous systems and individualized analytics offer unprecedented opportunities to change the way disasters are managed. There is a trend towards more adaptable, anticipatory and resilient systems, being no longer a focus on only reacting to disasters, however looking at reducing risk and vulnerability. However, realizing this future vision will depend on multidisciplinary teamwork, ethical foresight, stakeholder engagement, and relentless innovation.

In summary, intelligent agents and artificial intelligence will change the way we will handle disaster risk management. By tackling the current technological and operational challenges and addressing the ethical dilemmas and risks, while building inclusive and sustainable innovation, AI has the potential to greatly improve global resilience and help protect human lives, the natural world and built infrastructural systems from an increasingly volatile and uncertain future.

Artificial Intelligence in Disaster Risk Management: A Scientometric Mapping of Evolution, Collaboration, and Emerging Trends (2003–2025)

Hssaine Hamid, ELouadi Abedlmajid
Advanced Systems Engineering, National School of Applied Sciences,
Ibn Tofail University, Kenitra, Morocco

***Abstract*—Recent years have seen a dramatic increase in the number of and severity of natural disasters, driven in part by climate change and urbanization. Artificial Intelligence (AI) appears to be a promising new technology that can transform disaster risk management (DRM) and provide new opportunities for prediction, monitoring, response, and recovery. The present work performs a bibliometric review of applications of AI to DRM, from a total collection of 7842 scientific articles extracted from Scopus, Web of Science and OpenAlex databases from the year 2003 to the year 2025. Exploring the trends of publications, authorship, international collaboration, and research topics, the study reveals the development and current status of AI incorporating disaster management. The results illustrate an apparent growth in interest in the field of science, how machine learning and deep learning methodologies are leading, and the raise of geospatial AI, remote sensing, and social media analysis in disaster preparedness and response. Other issues including data quality, ethics, technology and trust in AI systems are also considered. This paper offers helpful perspectives on the status quo and future development of AI-based DRMs.**

***Keywords*—Artificial Intelligence; disaster risk management; machine learning; deep learning; remote sensing; bibliometric analysis; natural disasters; geospatial AI; early warning systems**

I. Introduction

Rapid, Sustainable and Effective DRM in a World Subject to a Wide Range of Natural Disasters The growing frequency and intensity of natural disasters around the world, influenced by factors such as climate change and the expansion of urban risk, creates the need for innovative and effective DRM approaches. Only in 2021, more than 98.4 million people were affected by natural disasters with high human and economic costs [1]. Although conventional DRM methods are precious, in the case of complex and dynamic hazard scenarios, they are limited in its speed, accuracy, and flexibility for adaptation.

Artificial Intelligence (AI) is now recognised as a game-changing technology that can transform each phase of the disaster management cycle – from prediction and early warning through to response and recovery. This is where the state-of-art machine learning (ML), deep learning (DL), geospatial analysis, and real-time data processing has brought out capabilities that can advance the efficiency, accuracy and responsive to DRM operations. More recently, authors such as [2] and [3]highlight that the use of AI is not a question of incrementing the efficiency, but of covering the gap of the dearth of such tools in 21st century AD projects, like managing climate-induced emergencies.

The inclusion of AI in DRM encompasses various technologies and applications, including predictive modeling of natural hazards, automated image analysis based damage assessment, sensor network based real-time monitoring, social media based situational awareness, and the application of flying drones and rescue robots to accompany human agents. Taken together,these technologies lead to better, safer decision-making, better allocation of resources, improved emergency response times and more resilient communities.

With the rapid change of research in this area, an extensive bibliometric study is urgently necessary for overviewing the development of AI applications in DRM, as well as revealing the newly emerging directions and potential research gaps. The current analysis seeks to bridge that gap by providing a systematic review of literature from 2003 to 2025, in an effort to provide detailed snapshot of how AI technologies will influence the future of disaster risk management.

This study aims to answer the following research questions:

- How has the scientific production on AI applied to disaster risk management evolved from 2003 to 2025?
- What are the major thematic trends, technologies, and application domains that have shaped this field?
- Which countries, authors, and institutions are leading the research, and how do they collaborate?
- What are the emerging challenges, opportunities, and knowledge gaps?

This paper is structured as follows: Section II reviews the related work. Section III presents the methodology. Section IV results the main findings. Section V critical discussion reflections. Section VI concludes the paper.

II. Related Work

A. The Growing Importance of AI in Disaster Risk Management

Such natural disasters are becoming more commonplace, in part, thanks to climate change and population expansion in cities. Disasters affected more than 98.4 million people in 2021, resulting in more than 15,000 deaths and an economic damage of USD 171.3 billion [1]. With such disastrous events

increasingly exposing communities to immense risks across the globe, artificial intelligence (AI) has found its way as an important means of Disaster Risk Management (DRM).

AI technologies in disaster management [11] are increasingly not just useful, but necessary. As Singh et al. comment that "Recent breakthrough in AI provide great potential tools in disaster management, which is important as the occurrence of climate-related disasters is more and more frequent" [2]. Raut also claims that "The use of AI in disaster management is not just useful – it is essential" [3].

The roles of ML and DL in different areas of natural disaster management have been well established [4-6]. Such methods allow massive data-sets from previous disaster events to be analysed, patterns to be discerned and generalisations about forecasting to be extended[7]. For instance, cutting-edge AI methods have been used on flood data to learn how floods behave, increase flood resilience, avoid damage and save lives[7].

Geospatial data is an essential ingredient in DRM in terms of mapping of vulnerable populations and infrastructure, identification of at-risk areas and for planning emergency responses [8] [1] The integration of AI and geographic information systems (GIS) provide effective hazard preparedness and real-time responsive decisions in crisis management [9], [10]

AI technologies in disaster management cover the whole disaster life cycle from early warning and damage assessment, to monitoring and forecasting, post-disaster response and coordination, long-term risk assessment [5].These technologies can process large volumes of data and detect trends to produce forecasts for a wide range of natural disasters, including earthquakes, flood, wildfire, and others [3].

The increasing use of AI in disaster relief efforts holds the promise of greatly improved resource planning, preparedness, and mitigated economic impact by improving the emergency response and building stronger, more resilient communities in the face of ever more frequent and more severe natural disasters [7][9.]

B. Specific AI Technologies and Methods Used in Disaster Management

1) Machine learning and deep learning:

- Machine Learning (ML) techniques analyze large historical datasets to identify patterns, make predictions, and improve flood forecasting with minimal inputs [12][13] These approaches are less time-consuming to develop while maintaining accuracy in predictions [14].
- Deep Learning (DL) algorithms process complex disaster-related data, particularly for image classification and pattern recognition in disaster-affected areas [12][5].
- Artificial Neural Networks (ANNs) are employed for various applications including flood forecasting [15], water level prediction [16], and earthquake magnitude prediction using deep learning neural networks [17].
- Nonlinear Autoregressive Network with Exogenous Inputs (NARX) models capture the dynamic characteristics of flood water levels by incorporating feedback from network outputs[18]
- Extended Kalman Filters (EKF) optimize neural networks to overcome nonlinearity problems in flood water level prediction [16]

2) Computer vision and image analysis:

- Convolutional Neural Networks (CNNs) analyze text and images from disaster areas for classification and damage assessment [19].
- Automated 3D Crack Detection systems assess building damage post-disaster [20].
- Image-based 3D Reconstruction methods detect and analyze surface damages [17].

3) Geospatial AI and remote sensing:

- Geographic Information Systems (GIS) with AI map flood hazards and susceptibility, supporting strategic planning and hazard preparedness
- Remote Sensing AI Applications utilize satellite imagery for disaster monitoring, risk assessment, and damage evaluation [21].
- Terrain Mapping Algorithms create 3D models of disaster-affected areas to support navigation and assessment [22].

4) IoT and sensor networks:

- Internet of Things (IoT) networks collect real-time data for disaster monitoring and prediction [23][24].
- Wireless Sensor Networks (WSN) create distributed sensor nodes for smart sensing and real-time disaster surveillance [25].
- Integrated Information Systems combine geoinformatics with IoT for early warning, particularly for snowmelt floods [24].

5) Robotics and autonomous systems:

- Unmanned Aerial Vehicles (UAVs/drones) conduct post-disaster inspections and damage assessment [26].
- Swarm Robotics communicate with each other to map disaster areas and create connected networks [23].
- Autonomous Helicopters perform remote sensing and sample collection in disaster zones [22].
- Underwater Robots inspect submerged structures like bridge foundations after floods [27].
- Mobile Rescue Robots carry out surveillance missions in hazardous environments like nuclear disaster sites [28].

6) Cloud computing and big data analytics:

- Cloud Storage and Distributed Computing overcome limitations of traditional storage and computation capabilities for disaster data processing [25].
- Big Data Frameworks (Apache Hive, Hadoop, Mahout) provide scalable distributed storage and computing environments to process massive social media data [29].
- Predictive Analytics sift through historical and real-time data to identify emerging disaster trends [30].

The following Table1 will present a Literature Comparison.

TABLE I. SUMMARY OF SELECTED PAPERS ON DISASTER MANAGEMENT APPLICATIONS

Papers	Disaster Type	Application Stage	Outcomes and Implications
[21]	Flood disasters	Prediction and disaster risk reduction	Enhanced flood forecasting model design for disaster risk reduction
[32]	Earthquake in Al Haouz, Morocco, 2023	Disaster preparedness, response, and recovery	Real-time data, data scarcity, interdisciplinary collaboration challenges, community-call for action
[26]	Flooding in Jakarta due to river overflow	Prediction and early warning stage for flooding	Improved prediction by 1%, potential for future early warning systems
[12]	Floods	Prediction of flood water levels	NARX model outperforms EKF in flood prediction; informs future disaster management
[13]	Four major natural disasters	Damage assessment stage during natural disasters	High classification accuracy for damage assessment using social media imagery
[29]	Hurricane Sandy	Disaster management including tracking, mapping, and analysis of events	CyberGIS framework supports big data analytics for disaster management

III. METHODOLOGY

The methodological framework applied in this bibliometric study was developed to describe the scientific publications landscape related to the use of Artificial Intelligence (AI) in natural disaster risk management. The search was performed in three key, academically reputable bibliographic databases—Scopus, Web of Science, and OpenAlex. These sources were chosen for their wide coverage of relevant publications in a variety of disciplines and geographical locations. Structured query using keywords of "core AI technologies and disaster risk management" was used as a search strategy. The search string employed was: ("artificial intelligence" OR "machine learning" OR "deep learning") AND ("disaster management" OR "disaster risk reduction" OR "natural disaster" OR "catastrophe naturelle" OR "emergency management" OR "hazard mitigation" OR "resilience" OR "early warning system"). This search was employed to collect all papers between 2003 and 2025, obtaining an initial corpus of 13,880 documents. Selection process: The selection was performed with a systematic process that is described below according to the PRISMA in the Figure1 (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) strategy (Figure1). In the first round of selection work, all the retrieved files were filtered by inclusion criteria which narrowed the set of documents to articles, conference papers, and book chapters in English within the time frame. After that, 8,491 papers were left. A second phase of exclusion was applied to remove redundant records and articles – based on their titles and abstracts – that were deemed to be irrelevant, resulting in 7,842 articles included in the systematic review.

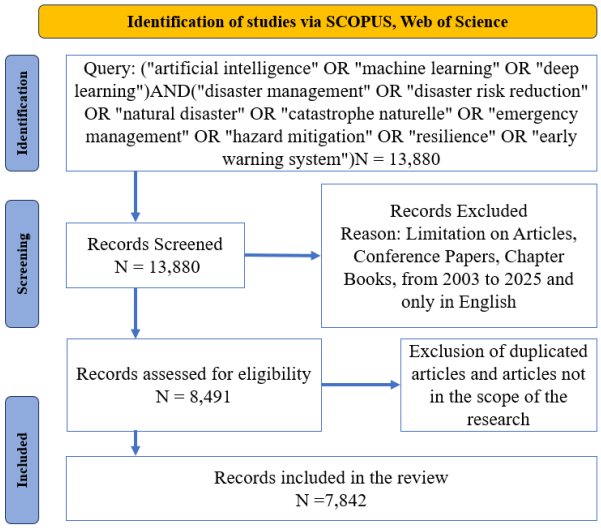

Fig. 1. PRISMA diagram.

The bibliometric analysis was completed using the Bibliometrix R-package, which is available as part of the Biblioshiny graphic user interface, a programme valued for quantitative study of literature. It was targeted to seek a series of descriptive and relational indicators pertaining the annual scientific production, the origin of sources of origin, authorship patterns andthe collaboration networks developed along time. Final corpus Figure2 : corpus properties The final corpus covered a time period from 2003 to 2025, and comprised 7,836 documents from 2,403 distinct sources. The trend of the scientific output was very dynamic, with an annual growth rate of 31.35%, which suggests an increasing attention to the convergence of AI with the disaster management. The authorship of manuscripts was conducted by 26,875 unique authors, international co-authorship rate was 25.79%, and a mean of 4.19 authors per manuscript indicated high amount of collaborative research. The dataset also included 2,773 author keywords and about 191,858 references. The articles had an average of 10.68 citations and 2.39 years old on average which indicated a not so old and dynamic area of investigation.

Through this robust methodological approach, the study aimed to capture a representative and high-quality sample of the literature, enabling a detailed analysis of the thematic evolutions, emerging trends, and collaborative networks in the field of AI-driven disaster risk management.

Timespan 2003:2025	Sources 2403	Documents 7836	Annual Growth Rate 31.35 %
Authors 26875	Authors of single-authored doc 1041	International Co-Authorship 25.79 %	Co-Authors per Doc 4.19
Author's Keywords (DE) 2773	References 191858	Document Average Age 2.39	Average citations per doc 10.68

Fig. 2. Descriptive statistics of the bibliometric dataset.

IV. Results

A. Annual Scientific Production (2003–2025)

The trend of the annual scientific production in application field of Artificial Intelligence in DRM is characterised by multi-phase meanwhile growth. Between 2003 and 2015, the historically low and static publication trend indicates an immature upstart in which AI technologies were finding their own legs and face the testing ground of application to disaster scenes. A clear increasing trend appears around the same time as the burst of progress in machine learning and deep learning techniques, and growing awareness of the impacts of climate change. A surprising 'explosion' occurs between 2020 and 2023 with the number of publications increasing exponentially (around 800-1000 articles in 2020, around 1500 in 2021 and 2000+ in 2023). This increase is driven by the technological readiness, increased frequency of disasters which are COVID-19 pandemic and climate-induced extreme events, as well as increasing governmental and institutional investments in AI emergency management solutions. The slight fall in 2025 is due to missing data for that year, rather than a true decline in research output. This production rate Figure3 reflects a research field that is ever more active and proposes that the use of AI for disaster management is moving from the realm of the theoretical to the domain of an essential component of operational disaster risk strategies at global scale.

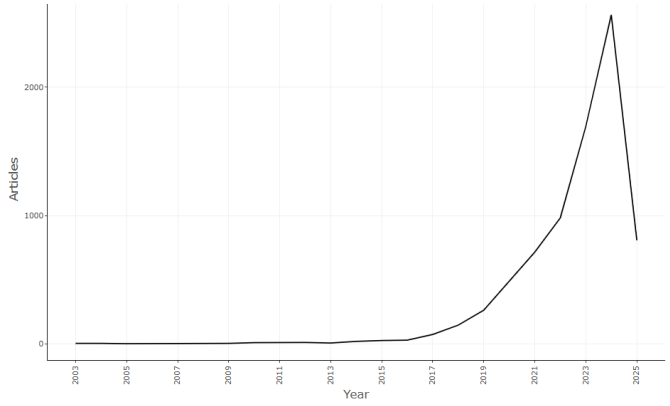

Fig. 3. Annual scientific production.

B. Average Citations Per Year (2003–2025)

One aspect of interest to highlight is the trend of increasing (or decreasing) number of yearly citations. Early publications (2003–2006) indicate a high number of citations, likely reflecting more fundamental research at an earlier stage in a new and undiscovered scientific field. Such landmark papers are cited slowly in that they are pioneers.

However, as the field has been maturing a sudden surge in publications from the end of 2017, there is a decrease noticed in average number of citations per paper. This tendency is accounted for by the "citation dilution effect," where the proliferation of published works leads to citation focus on a larger pool of articles. In addition, the more recent papers will be more time dependent as they will have had less time to be cited, particularly for papers published 2022 onwards.

Nevertheless, the stable citation averages in the mid-2010s demonstrate that the research in the field is still relevant and has had, and continues to have, impact on both academia and practice. The pattern observed confirms the strength of the field as well as the trend that higher-quality innovative studies are needed to survive in an environment of increasingly tight publication competition. As shown in Figure 4, the trend of average citations per year highlights early foundational contributions and recent publication dilution effects.

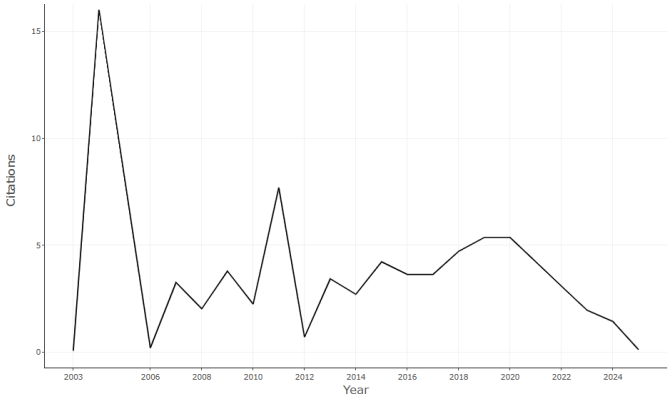

Fig. 4. Average citations per year.

C. Three-Field Plot (Authors – Sources – Keywords)

The Tri-field plot provides an integrated representation of interactions between prolific authors, top pub-lication venues, and main research topics. See for instance, Rachid Guerraoui, Alina Oprea, Ali Mostafavi as key contributors to leading sources such as arXiv (Cornell University) and Research Square.

Thematically on the thematic side, terms like "resilience", "robustness", "early warning system", "vulnerability" prevail, demonstrating the community's focused work on the development of AI-based solutions to enhance disaster preparedness and response.

The prevalence of "resilience" as a keyword reflects the increasing attention being paid to both the short-term response to disaster and the long-term adaptation of communities and infrastructure. Beyond this, the inclusion of terms such as "pandemic" and "sustainability" for the first time on the supplement panel might reflect a broadening of the types of disasters being considered beyond traditional hazards to the more systemic risks they are generating.

This visualisation suite illustrates the multidisciplinary facets of the field,êmphasising the variety of disciplinary

contributions toÅI research in disaster management from computer science, environmental science,ênginееring and social sciences. Figure 5 presents the three-field plot linking top authors, publication venues, and major keywords.

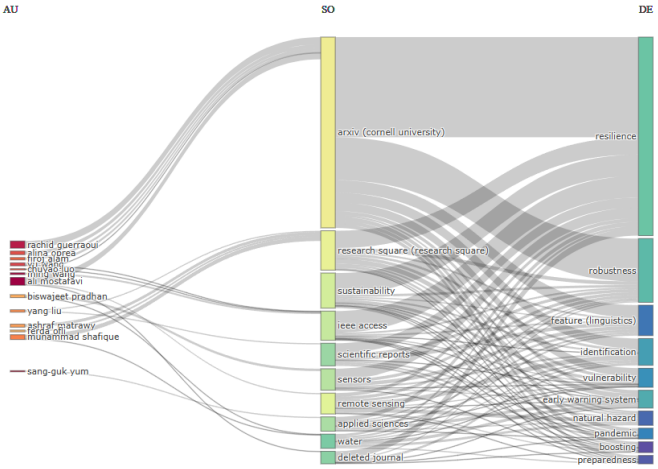

Fig. 5. Three-Field plot.

D. Most Relevant Sources

The examination of the most important sources, by document identity, indicates a clear shift towards fast dissemination and open acces in the papers and documents. ArXiv (Cornell University) and Research Square lead the field, indicating that quick transmission of information is an important consideration for researchers in disseminating their results in the context of the immediacy of disaster risks challenges. Journals, such as Remote Sensing, Sustainability and IEEE Access, exemplify the interdisciplinary nature of this science, the new technology development with environmental and social applications. The inclusion of journals such as Scientific Reports and Applied Sciences points to the importance of multidisciplinary channels wed to a wide variety of methodologies, from remote sensing and geo-informatics to data science and decision support systems.

These data suggest that traditional peer-reviewed journals are relevant, preprint platforms play an increasingly important role in expediting transmission of knowledge in times of disaster, reflecting the urgency of the research in the time of disaster. According to Figure 6, the most relevant sources include arXiv and IEEE Access, reflecting interdisciplinary focus.

E. Sources' Production Over Time

In the time course of source productivity, the central role of the open-access repository in the surge of AI-disaster management research in the past few years is also underlined. The explosive development of ArXiv after 2019 reveals the increasingly indispensable role of preprint repositories as infrastructures for timely sharing of knowledge, especially in times of crisis, such as the COVID-19 pandemic. Other sources, including Remote Sensing and Research Square, reveal noticeably steeper but more mild growth trajectories, indicating the sustained commitment of the remote sensing and sustainability

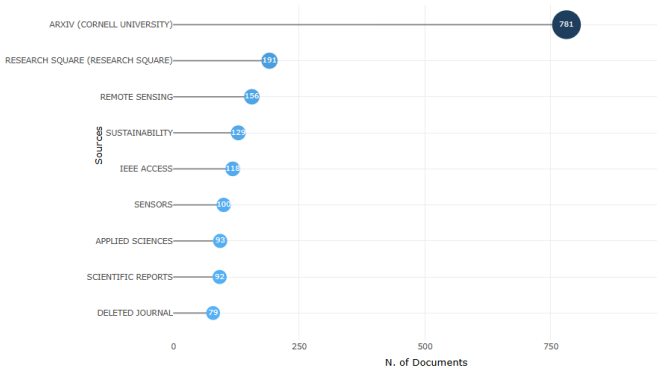

Fig. 6. Most relevant sources.

literature to disaster-related research. This evolution points to a strategic change among researchers towards platforms with faster publication cycles and more accessible, a necessity when the research outputs are poised to directly feed into emergency planning and crisis management.

As depicted in Figure 7, source productivity increased significantly after 2019, led by open-access repositories.

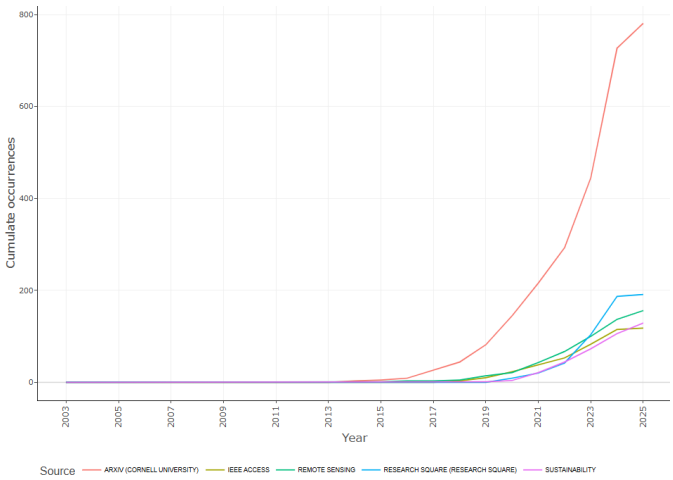

Fig. 7. Sources' production over time.

F. Most Relevant Authors

If we look at the main sources by document count, there is a clear trend here towards fast, open-access spread. ArXiv (Cornell University) and Research Square are the most popular venues, which imply that researchers choose the fastest channels in which to publish their findings because of how pressing disaster risk issues can be. Publications such as Remote Sensing, Sustainability, or IEEE Access (just to name a few), exemplify the interdisciplinarity of this field, combining technological breakthroughs with environmental and social realities. The existence of journals such as Scientific Reports and Applied Sciences illustrates the fundamental necessity for multidisciplinary (inclusive of all (or most) of them).The presence of journals like Scientific Reports and Applied Sciences points to the crucial role that multidisciplinary outlets covering a wide range of methodologies ranging from remote sensing and

geoinformatics to data science and decision support systems play.

The statistics demonstrate that while traditional peer-reviewed journals matter, academics are increasingly also dependent upon preprint servers that can expedite the circulation of knowledge during disaster-laden times, underscore the urgency of their work in the real world. Figure 8 displays the most prolific authors contributing to the field.

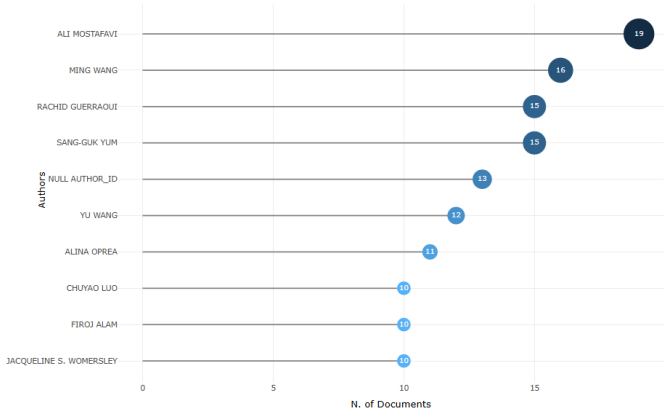

Fig. 8. Most relevant authors.

G. Authors' Production Over Time

The time signals of author productivity further illustrate that the closely-knit and the active research community on AI and disaster risk management is quite young. Most of the top authors started to publish in this area by 2017, with highest activity between 2021 and 2024. This time period also aligns with global initiatives that focus on climate resilience, smart cities and sustainable development goals (SDGs) that have been drivers of multidisciplinary engagement.

The data also reveal that many of the researchers in this area have and sustain a "publication cadence" that suggest a move from practical, one-time contributions to a more mature, programmatic commitment to disaster-related AI research. As seen in Figure 9, most top authors became active after 2017.

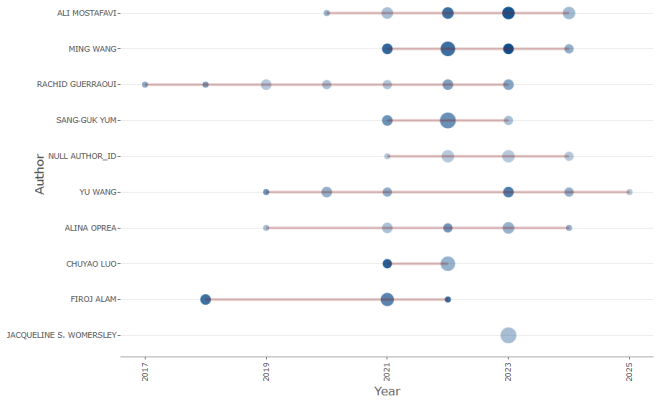

Fig. 9. Authors' production over time.

H. Affiliations' Production Over Time

The institutions' affiliations also substantiate this worldwide dispersion of expertise. Top universities including Harvard Medical School, Stanford University and University of California drive consistent leadership efforts, frequently combining AI investigations with health resilience, infrastructure surveillance and community risk analysis. The growth of independent researchers and "Not Reported" affiliations indicates the opening of the field to input from practitioners, think tanks, and private sector organizations, illustrating the cross-sectoral and interdisciplinary urgency of DRM challenges. This move toward spread and inclusivity of research will potentially spur innovation and accelerate solutions by infusing scientific inquiry with diverse viewpoints and on-the-ground urgency. Figure 10 shows institutional contributions with leading roles from top U.S. universities.

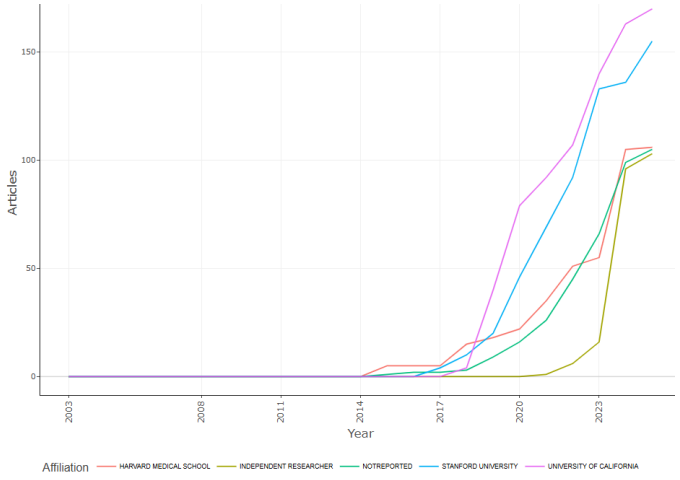

Fig. 10. Affiliations' production over time.

I. Most Cited Countries

The examination of the top-cited countries shows a clear geographical imbalance in the research impact in AI applications for disaster risk management. The United States is the dominant country in the production of the cited work, counting 10,941 citations, followed by China (5,979 citations) and the United Kingdom (3,086 citations).

This clustering around only a handful of leading countries means that much innovative, highly influential research comes predominantly from mature academic ecosystems with state-of-the-art technological infrastructure and significant research investment.

Australia, Italy, and South Korea also occupy the top positions, evidencing their significant contributions to disaster research and the development of this field in high-risk areas.

However, those contributions by the likes of India and Iran are not little, but significant, if their total among citation number still can not be compared with the existing top leaders. This expanding diversity suggests that high-impact research in the field is becoming more globally distributed. According to Figure 11, the United States leads in citations, followed by China and the UK.

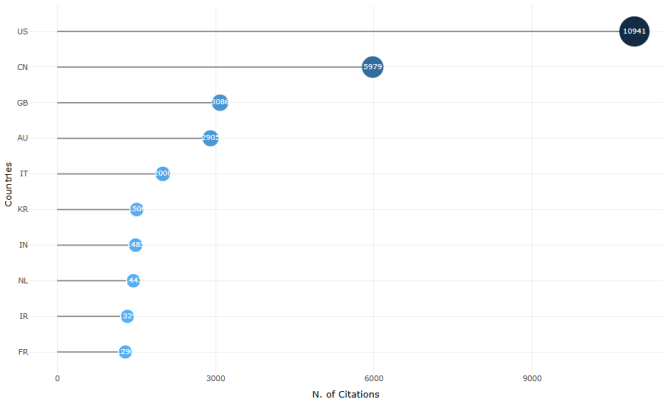

Fig. 11. Most cited countries.

J. Most Frequent Words (Author's Keywords)

The most common words are a corpus in focusing theme priorities in the sector. The most prevalent key term "resilience" (over 1,360 hits)Most used key term "resilience" (over 1,360 hits)points towards a change of paradigmparadigm change when it comes to the management of disasters, where the emphasis has recently turned to long-term systemic adjustment, not just to reacting to current acute threats.

Other commonly found words such as "robustness," "early warning system," "vulnerability," and "pandemic" alsoreflect current concerns particularly in the perspective after 2020, when the COVID-19 pandemic drew attention to the urgent need for adaptable, predictive, and robust disaster management approaches.

"natural hazard" "preparedness" In addition to disaster management, natural hazard and preparedness are included here to represent this comprehensive field which covers from hazard identification to emergency response planning. Figure 12 highlights the most frequent keywords, led by "resilience" and "vulnerability".

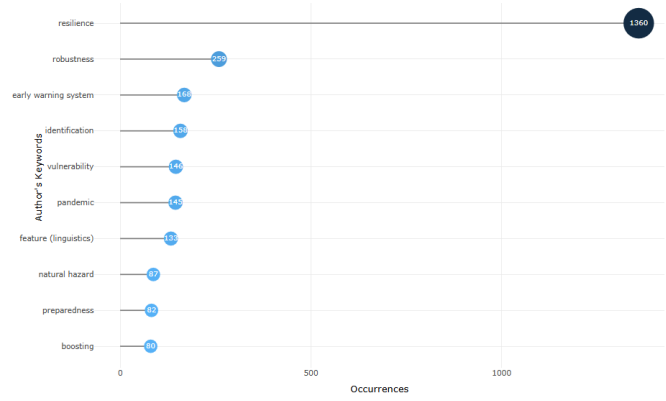

Fig. 12. Most frequent words.

K. Trend Topics

In addition, trend analysis reveals the hot topics appearing in this field. There's also growing interest in metaphors around learning, particularly "transformative learning" and "resilience," that have emerged since 2020 as part of what's become a significant and interdisciplinary combination of AI with the behavioral science and educational literatures on disaster preparedness.

"anomaly detection (physics)" "flood warning" "aerial image analysis." demonstrate the growing use of AI for monitoring, real-time risk assessment, and decision-support systems.

The advent of terms such as "swarm robotics" and "quantum byzantine agreement" reflects the potential futuristic orientation of the field in exploiting vastly distributed, decentralized AI systems in handling complex disaster worlds. As shown in Figure 13, emerging trends include "anomaly detection" and "swarm robotics".

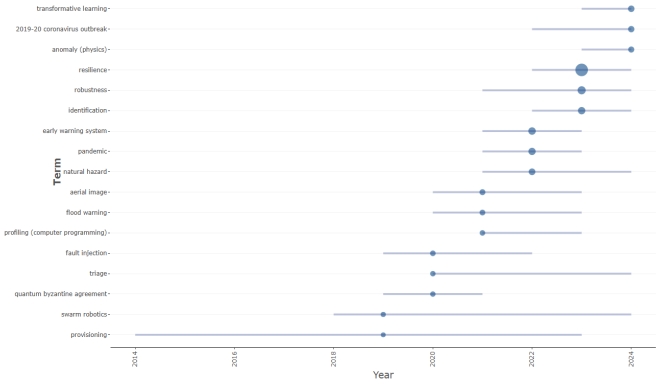

Fig. 13. Trend topics.

L. Clustering by Coupling

The thematic clustering map based on bibliographic coupling provides deep insight into the intellectual structure of the field. Three distinct clusters can be identified:

- One focused on "resilience," "preparedness," and "benchmarking," indicating foundational studies anchoring the field around risk reduction and system evaluation frameworks.
- A second cluster addressing "vulnerability" and "ethics," emphasizing the social and ethical dimensions of AI deployment in disaster scenarios.
- A third emerging cluster around "robustness" and "federated learning," suggesting an increasing interest in privacy-preserving, distributed AI models for disaster prediction.

The diversity of these clusters reflects the multidisciplinary and socially sensitive nature of AI applications in disaster management. Figure 14 identifies thematic clusters around resilience, ethics, and federated learning.

M. Co-occurrence Network

The co-occurrence network shows a dense and interconnected knowledge structure centered around "resilience," which acts as the major thematic hub. Keywords such as "vulnerability," "pandemic," "preparedness," and "situation awareness" cluster tightly around resilience, demonstrating

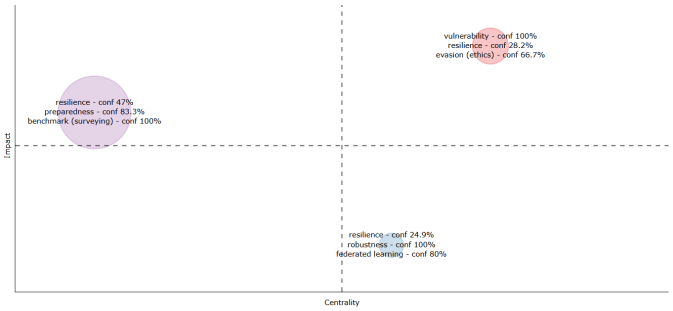

Fig. 14. Clustering by coupling.

the interdependence of these concepts in operationalizing AI solutions.

Peripheral nodes like "flash floods," "earthquake prediction," and "ensemble learning" indicate specialized application areas branching from the central resilience discourse. This network structure suggests that although the field is converging around resilience-building, it maintains a rich diversity of application-specific subfields. In Figure 15, the keyword network demonstrates interconnections between resilience, preparedness, and vulnerability.

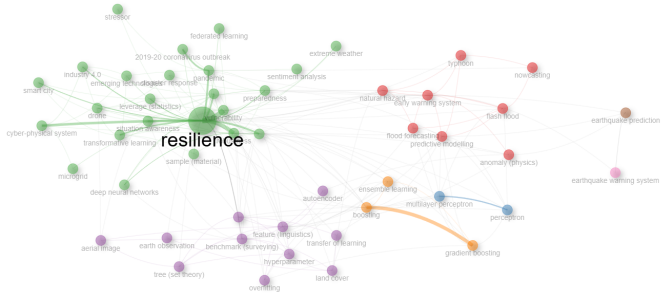

Fig. 15. Co-occurrence network.

N. Historiograph

The historiograph highlights key intellectual lineages within the field. Early influential works by Ferda Ofli (2016) and Bernd Resch (2017) laid critical methodological foundations, focusing on data-driven disaster mapping and social media analytics. More recent influential papers by Vasileios Linardos (2022) and Amine Belhadi (2021) show a shift toward integrating resilience models and predictive analytics at scale. This evolution reflects a progression from descriptive analytics towards prescriptive, action-oriented AI applications that not only model but also influence disaster risk reduction practices. Figure 16 outlines key intellectual lineages in the field, showing shifts from mapping to predictive AI models.

O. Collaboration Network

The global hub-nation analysis based on the collaboration network shows that the United States is the top country which is connected with other leading countries such as China, United Kingdom, Australia, and France. The presence of clusters of intense collaboration between Western countries and emerging economies is a perfectly sane cross-fertilization of ideas and a

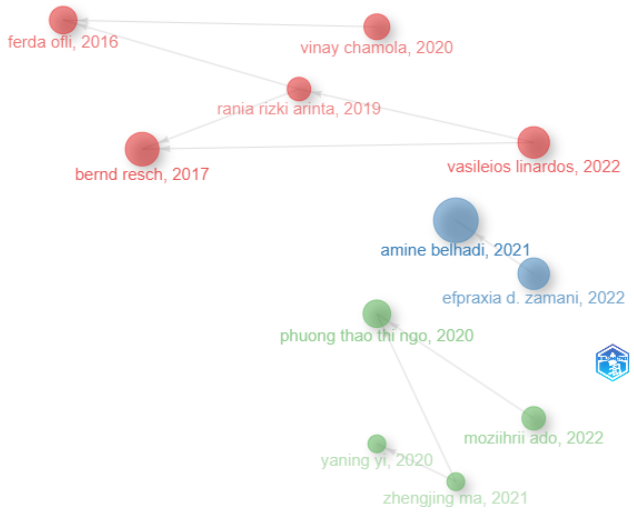

Fig. 16. Historiograph.

sharing of research investment. Strikingly, a large fraction of partnerships are with Asian nations, where exposure to natural hazards is most high and their active role in developing AI-based disaster resilience tech. This densely connected network, reflects the growing global and collaborative character of scientific production in this area, crucial for addressing the transboundary disaster risks. Figure 17 illustrates the international collaboration structure, centered on the US, China, and UK.

V. Discussion

AI has a great potential to contribute for disaster risk management, however, there are some challenges that need to be addressed in order to successfully implement AI. A critical concern relates to a requirement of high-quality, diverse, and representative data in order to train the AI models [31]. In the absence of extensive training data, AI models could make false predictions or have problems generalizing to other disaster types and as such reduce the dependability of these algorithms in critical systems.

Another major challenge comes from technical integration, as AI systems need to be integrated with the current disaster management architecture and technologies [31]. This is especially problematic in low-resourced settings where technolog-

ical infrastructure may be underdeveloped, and where access to AI-enabled disaster management will differ.

Ethical issue is an increasingly concerning challenge in AI application in disaster response. The most important challenge of these systems, however, is dictated by its data privacy and security aspects, since these systems are connected to the processing and/or the analysis of sensitive data about vulnerable people and infrastructures [31]. There is also a potential risk of algorithmic bias, where AI learns biases with historical data, possibly exacerbating the disparities in disaster response and resource distribution [32] [35][36].

Disaster scenarios are complex by nature which adds to the difficulties. Types of natural disasters are the widest from each other, regarding to their types, impacts and geographical dependency, that create a challenge in AI system or algorithm, functioning for a wide range of disaster types in the world [14]. Management of the response disaster is difficult due to the disruption of normal surveillance and communication by damaged infrastructure in their aftermath [33].

Human-related issues further handicap AI's utility for disaster management. The readiness of decision makers to base decisions on AI outputs is still uneven: some actors are reluctant to place too much trust in algorithms to inform decisions with severe consequences [14]. This trust deficit may limit the effectiveness of technically complex AI systems.

Despite advances in technology, accuracy issues remain. Although AI models hold promise in dealing with complex and nonlinear data for disaster monitoring and management, their accuracy of prediction remains restricted, especially with respect to new or rare events 33. With climate change changing the patterns of disaster after disaster, historical data might provide much less of a guide to future predictions, adding another level of difficulty in developing AI models [33][34] .

These problems require further research and development to strengthen the role of AI applications in disaster management [31]. Dealing with these shortcom- ings will require interdisciplinary collaboration among AI practitioners, disaster response specialists, policy makers, and affected communities, which will all be necessary to develop and deploy AI systems in a way that is just, fair, and effective in mitigate disaster impacts [33].

Article Once-rare weather disasters becoming more common There's no such thing as a natural disaster, Anywhere in the world. Artificial intelligence combination with other new technologies is a great opportunity for the transformation of disaster risk management around the world and community resilience [30]. These developments open up the potential for new and more efficient disaster prediction, monitoring, and response systems.

IoT, Big Data analytics, and machine learning stand at the forefront in the wave of digital transformation of disaster management by providing unprecedented capabilities for holistic risk reduction strategies [35]. IoT connected devices and sensors are forming networks that can give us real-time environmental status reports — to identify and assess unfolding disasters faster. These integrated ESNA's, often referred to as the Internet of Emergency Services (IoES), could revolutionize the way emergency services cooperate and act in crisis situations [30].

Another trend that holds potential is predictive analytics using AI, where systems are more equipped to analyze historical and real-time data to identify growing disaster types before they become fully developed [30]. These capabilities will only become more essential as climate continues to change, which will demand more complex models which can adjust to altered environmental conditions (LLM Memory).

Machine learning-based sentiment analysis is becoming more advanced, allowing emergency responders, for example, to understand public reactions during disaster situations, focus on specific concerns, and refute misinformation [30]. This capacity is essential to preserve public trust and coordination during a crisis, when the distribution of accurate information is imperative.

AR and VR technologies have potentials to improve the level of preparedness for a disaster, and community activation [30]. These immersive technology may be used to generate realistic disaster simulation for training emergency responders and raising awareness among the communities on proper reaction to different disaster scenarios (LLM Memory).

In the health sector, AI has become part of disaster risk assessment and emergency health response [36]. While the world is transitioning to an "AI-based world this decade" according to Claus Schwab1, healthcare regulators are now recommended to exploit these new possibilities to optimize outcomes during catastrophic events [36].

GIS and AI would increasingly serve as important tools for mapping spatial distributions of different hazards and their vulnerability [9][10]. Such integrated systems will increasingly support long-term planning and real-time decision making for better preparedness for hazards and management of crises.

Efforts such as MOBILISE are examples of how connected analytical solutions can enhance resilience in the face of disasters and enable responses that can facilitate quicker recovery of affected communities [9][37]. The future disaster management systems may extend these foundations to more advanced platforms with the combination of several technologies.

Deep-learning based image analysis has seen rapid development, and there is great potential for deep CNN (Convolutional Neural Networks) in damage assessment from social media images in disasters [19]. Through these more well-developed systems, disaster impacts can be more rapidly and accurately evaluated and thus will better guide more effective allocation of resources [30].

These technologies are being advanced as "force multipliers" in securing lives and property against disasters [9], [37-39. The future of disaster management belongs to the concerted use of these new technologies in combination to form a smarter, more responsive, and more adaptive disaster management infrastructure able to grapple with the increasingly difficult problems that natural disasters present in our convoluted world [5][40][41].

VI. Conclusion

This study provides a comprehensive scientometric analysis of the evolution, collaboration patterns, and thematic trends

in the application of artificial intelligence (AI) to disaster risk management (DRM) from 2003 to 2025. Based on a final corpus of 7,842 articles extracted from Scopus, Web of Science, and OpenAlex, the findings highlight the exponential growth in scientific output, particularly from 2020 onward, reflecting both technological maturation and an urgent global need for innovative DRM solutions amid intensifying climate-related hazards.

Several major contributions emerge from this work:

- It maps the trajectory of AI in DRM, showing how machine learning, deep learning, and geospatial AI have become core technologies in early warning systems, real-time monitoring, damage assessment, and resource allocation.
- It identifies key actors, countries, and collaboration networks, revealing a concentration of impact in technologically advanced nations while also signaling the rise of new contributors from emerging economies.
- It outlines the main research themes and emerging topics such as federated learning, swarm robotics, and anomaly detection, which suggest a move toward decentralized and adaptive disaster response systems.

However, some limitations must be acknowledged. This analysis, being quantitative and bibliometric in nature, does not assess the operational effectiveness or practical deployment of AI solutions in real-world disaster contexts. The absence of qualitative insights into policy relevance, technological transferability, and user adoption also constrains the conclusions that can be drawn regarding actual impact. Moreover, citation-based metrics may underrepresent innovative or interdisciplinary works that have not yet gained visibility in traditional publication channels.

To address these gaps, future research should:

- Conduct comparative case studies of AI deployment in specific disaster scenarios, evaluating performance, usability, and societal outcomes.
- Investigate the integration of AI with local knowledge systems, especially in low-resource and high-risk regions where disaster vulnerability is most acute.
- Explore the ethical, legal, and governance implications of automated decision-making during emergencies, particularly concerning algorithmic bias, data privacy, and accountability.
- Develop hybrid evaluation frameworks that combine bibliometric analysis with real-time data from disaster events, social media, and satellite imagery to assess responsiveness and situational relevance.

The findings underscore the need for interdisciplinary collaboration among AI experts, disaster response agencies, policymakers, and affected communities to co-design intelligent systems that are not only technically robust but also socially legitimate and context-sensitive.

In a global context where disasters are becoming more frequent, complex, and disruptive, artificial intelligence offers transformative potential. But its promise will only be fulfilled through continuous methodological innovation, transparent governance, and a sustained focus on equity, trust, and long-term resilience.

XPathia: A Deep Learning Approach for Translating Natural Language Into XPath Queries for Non-Technical Users

Karam Ahkouk, Mustapha Machkour
Computer Systems and Vision Laboratory-Faculty of Sciences,
Ibn Zohr University, 80000 Agadir, Morocco

***Abstract*—XPath is a widely used language for navigating and extracting data from XML documents due to its simple syntax and powerful querying capabilities. However, non-technical users often struggle to retrieve the needed information from XML files, as they lack knowledge of XML structures and query languages like XPath. To address this challenge, we propose XPathia, a novel deep learning-based model that automatically translates natural language questions into corresponding XPath queries. Our approach employs supervised learning on an annotated XML dataset to learn accurate mappings between natural language and structured XPath expressions. We evaluate XPathia using two standard metrics: Component Matching (CM) and Exact Matching (EM). Experimental results demonstrate that XPathia achieves a state-of-the-art performance with an accuracy of 25.85% on the test set.**

***Keywords*—Deep learning; XML databases; neural networks; text-to-XPATH; natural language processing**

I. Introduction

The use of databases is the activities' base that the majority of companies rely on. Many types of databases exist in the world, amongst them there are Graph databases, NoSQL databases, Object-oriented databases, XML databases, Relational databases, etc. All this types of databases are based on containers called database management systems that help manipulate these databases and give accessibilities features for users and also for other applications.

Dealing with these systems is not an easy task for people who lack of knowledge on database management. Also the use of these systems requires advanced skills and enough expertise on some specific technical languages, for instance, the ignorance of some languages like XPath or XQuery for getting the relevant information form XML document in XML databases is considered as a big obstacle and can create limitations to get the searched data in a reasonable time.

An ideal solution would be to communicate with the database management systems using only the mother-tongue language; this can be done by using an intermediate interface that handles well organized natural language sentences and translate them to the target script which is in our case XPath. Xpath is one of the languages that help manipulate the XML documents included in XML databases in an easy and straightforward way. In contrast with the other languages, XPath has a very simplified syntax and direct structure; also the possibilities that it affords for extracting data from xml documents helps people get the searched information without complexities. Xpath is the one that can be used with minimal effort; its syntax that is based on Path concept provides 200 built-in functions with expressions and operators to extract XML nodes and their values.

The type of this interface enters in the category of solutions based on Natural Language Processing (NLP) tasks that process NL sentences in order to make a corresponding translation, doing actions, generating codes, etc. There are many sub-tasks of the NLP that deal with natural text transformation. For example, Text classification, Named entity recognition, Information retrieval, Text summarization, Text generation, Sentiment/emotion analysis are all sub tasks of NLP. The objective of all these solutions is the ability to handle the meaning from a raw text and transform it to another form that answers a particular problem. In our case the problem is similar to Text classification and Information retrieval since the goal is to classify the user natural language sentence and get the relevant information in order to build a target XPath query which will be used for extracting the wanted information from an XML document.

The focus in this work is to leverage the ability to interact with XML databases using only the natural language. In other words, the possibility to translate the sentences of users to a runnable and valid Xpath query with all its paths, nodes and expressions. In this paper, we present our solution that handles the problem of using the Natural Language as a source medium to interact with XML Databases. The proposed model is based on Deep learning with a Path-Expression based approach that treat the path, nodes and predicates in an independent manner in order to reduce errors. The work is evaluated against a new XML dataset that we provide publically on GitHub https://github.com/karamsa/XMLSet using two metrics, the CM (Component Matching) and EM (Exact Matching), and achieves a score of 25.85% on the test set of the XML corpus to be a new base for future models for the training and the evaluation.

A. Contribution

In this paper, we present 2 contributions to the task of translating Natural Language to Xpath queries for XML databases using Deep Learning and a Path-Expression based approach to make prediction of nodes, Expression, predicates, operators and values independently and without using the content of the XML Nodes. Our contribution to this area is two fold:

- We propose a new XML Dataset that contains up to 2176 pairs of natural language sentences with their XPath queries and annotations in a well structured and easy-to-use format. We provide this Dataset publicly on GitHub for future models for training and evaluation purposes.
- A new model (we called it Xpathia) that makes predictions of Xpath queries using deep learning and Path-Expression based approach. The model predicts each part of the target query independently using several sub-modules.

B. Outline

The reminder of this paper is structured as follows: The Section 2 presents the related works regarding the previously proposed solutions. Section 3 and 4 presents our contributions on the translation of Natural Language sentences to XPath. Section 5 includes the evaluations of the model. The section 6 discusses the experimental results and the final section contains the conclusions of our work.

II. Related Works

XML is a widely used markup language, valued for its simplicity in data extraction. Originally developed for large-scale electronic publishing ([1]), it is now applied in diverse areas such as data sharing, system communication, and database storage. Its flexible format supports both structured and unstructured content, and its platform- and language-independence have contributed to its broad adoption ([2]).

Recent research in XML has focused mainly on content for tasks like information retrieval and document clustering ([3]), often overlooking the structural aspects. This neglects a key feature of XML—its hierarchical structure and meaningful tag names—which are essential for accurate content interpretation ([4]; [5]). To improve retrieval and analysis, both content and structure should be utilized together ([6]; [7]).

Databases are central to most organizations, ranging from relational and NoSQL to XML and graph databases. These are managed through database management systems (DBMS) that enable access and manipulation of data. However, using such systems can be challenging for users without technical expertise. In particular, querying XML databases requires knowledge of XPath or XQuery—languages that many users find difficult to learn. This creates barriers to accessing information efficiently.

To address this, natural language interfaces (NLIs) have been proposed to translate user-friendly queries into structured query languages. In [8] the authors provides a foundational overview of NLIs, highlighting their potential to make database interaction more accessible, especially for non-experts.

While XML's self-descriptive design enables platform-agnostic data storage and transport, translating natural language (NL) directly into XML structures remains inherently challenging. NL, which is an unstructured language, is governed by grammar and contextual rules that are dedicated for communication purposes, whereas XML organizes data hierarchically for machine readability and data storage. This fundamental mismatch necessitates intermediate query languages like XQuery or XPath in order to create a bridge between Natural Language and XML. This intermediate language can play a pivotal role to remove the semantic as well as the structural gap.

The existing research addressing this challenge falls into two broad categories: the ones that are linguistic and rule-based and the others emerging deep learning methods, though the latter remains underexplored.

The linguistic rule-based approaches is the category of methods that rely on syntax parsing, part-of-speech tagging, and predefined rules to map NL to XML queries.

Tannier et al. ([9], [10]) utilized the INEX 2004 dataset to develop a system combining part-of-speech tagging, context-free grammar rules (e.g., NP for noun phrases), and discourse representation theory (DRT). By constructing discourse representation structures (DRS) from NL sentences and converting them into SQL-like queries, their approach retrieves XML nodes. However, it struggles with lengthy inputs, negations, and requires synonym dictionaries (e.g., mapping "employee" to "emp") to align NL terms with XML schemas.

Li et al. ([11]) introduced NaLIX, a natural language interface leveraging MINIPAR for syntactic parsing and iterative user feedback to refine XQuery outputs. While functional, NaLIX relies on manual rule engineering and interactive prompts, limiting its scalability.

To simplify query generation for non-expert users, Li et al. ([12]) proposed the Meaningful Query Focus (MQF) framework. MQF decouples translations from XML schema specifics, enabling cross-domain compatibility. However, it mandates exact tag names, necessitating synonym substitution layers to align user terminology with schemas.

Joseph et al. ([13]) expanded versatility by supporting multi-sentence queries, yes-no questions, and nested structures. Their system parses dependencies, replaces tokens with XQuery fragments, and uses WordNet ([14]) for synonym mapping. Despite its flexibility, it falters with unseen domains or terms absent from WordNet, underscoring reliance on predefined lexicons.

The hybrid and schema-agnostic approaches is the category of methods that include efforts to reduce dependency on rigid schemas or manual rules. Nassiri et al. ([15], [16]) designed a system to unify queries across data models (including XML) via syntax validation, tokenization, and intermediate universal query generation. While effective for structured inputs, it lacks NL compatibility and relies on manual engineering.

Gupta et al. ([17]) combined dependency parsing with Paninian grammar for semantic parsing, mapping NL chunks to domain models. Though innovative, their hybrid approach lacks adaptability for complex inputs without deep learning integration.

Dorrn et al. ([18]) emphasized data-driven methods, combining XML and NLP techniques for automatic information extraction from corpora. However, limited evaluations and reliance on mixed methodologies hinder practical scalability.

Based on semantic and for cross-Domain databases subhro et al. ([19]) proposed declarative rules to map NL descriptions

to formal queries (e.g., XPath), while Lopez et al. ([20]) developed PowerAqua, a tool translating NL into logical queries across heterogeneous semantic sources. PowerAqua aggregates answers without requiring schema knowledge but faces challenges in web-scale diversity.

XML is a flexible, structured language widely used for data storage and sharing, but querying it requires technical skills in XPath or XQuery. Existing solutions use rule-based or traditional methods to translate natural language into XML queries but often lack scalability and adaptability. Deep learning offers a promising alternative by reducing manual rule dependency and improving cross-domain performance.

III. XML Datasets

As we have previously, presented the base idea is the subdivision of the problem into multiple small problems without following a pre-defined sketch that still in the same time dissociates the tasks and operations done by the main model and create an independency between the output spaces, thing that is essential for a healthy prediction process.

The first problem encountered while working on this problem is the lack of databases dealing with this transformation type; thus creating a database for evaluating the model is mandatory in order to have a robust model that can generalize for unseen inputs. Bridging the natural language to Xpath was another obstacle for the model, since they both have different natures and purposes and Xpath is the intermediate language for extracting content portions from XML documents.

A. Existing Corpuses

The decision to build an XML dataset fully dedicated to answering questions in natural language with structured labels was based on the lack of similar corpuses that can be used for the evaluation of our model. This task was one of the harsh steps done prior the creation of the model and it is essential for a preferment system that must generalize not only to unseen inputs but also for unseen structures in the sets of the dataset.

From the literature, the use of Natural language to extract XML portions using structured languages wasn't deeply considered and has been treated as one of most difficult tasks in the NLP area.

This was mainly due to two reasons; first is the incompatibility of the two languages. Second is the lack of corpuses for the evaluation of the wanted model. In this context, the number of corpuses that were presented in this area in the recent decade was very limited. While these few datasets were created in the first place as a contribution to the task, in the other hand they bear lots of technical issues and difficulties that make their use such an impossible thing especially for the training and the evaluation of our model.

XML retrieval, the process of querying and extracting structured information from XML documents, relies heavily on specialized datasets to advance research, benchmark systems, and refine methodologies. These datasets are tailored to address diverse challenges in handling XML's hierarchical and semi-structured nature, offering varied use cases ranging from algorithmic stress-testing to domain-specific analyses. Among these datasets, the INEX Dataset ([21]) stands out as a foundational resource. Developed through the Initiative for the Evaluation of XML Retrieval, INEX provides standardized test collections that simulate some limited scenarios, enabling researchers to evaluate the precision, recall, and efficiency of XML retrieval algorithms. Its role in academic competitions and collaborative benchmarking has made it a popular dataset for comparing old systems that process structured queries, particularly in environments where granular content extraction—such as retrieving specific sections of documents—is not critical.

For performance-oriented evaluations, the XMark Benchmark ([23]) was proposed for this purpose. This synthetic dataset models an online auction platform, generating XML data with deeply nested hierarchies and scalable file sizes. Its design intentionally incorporates complexity to mimic real-world data structures that is useful for making stress-testing XML databases and query engines. Researchers use mainly use XMark to measure how systems handle large-scale data, complex XPath queries, and join operations, providing insights into scalability and optimization strategies. However that corpus is not intended for making natural language translation to XPath queries as it doesn't has this structure. Complementing this, the SIGMOD Record XML Dataset ([22]), which is another dataset for XML files with focuses on XML query processing techniques. Curated by the ACM Special Interest Group on Management of Data, this dataset supports experiments in query optimization, indexing, and retrieval efficiency, often serving as a testbed for novel methodologies in academic publications. While it is adequate for research targeting query optimization, this cannot be used for our case as there is no samples that handle the translation pairs.

Domain-specific datasets further enrich the landscape of XML retrieval research. The DBLP XML Dataset ([24]), for instance, offers a comprehensive corpus of computer science publication metadata. Covering millions of journal articles, conference papers, and academic references, it enables studies on bibliographic data retrieval, citation analysis, and trends in scholarly communication. Its structured yet semantically rich content makes it invaluable for exploring hybrid approaches that combine XML retrieval with bibliometric analytics. From one hand, it can be seen as a challenging dataset that put together an important volume of XML files, however, it is structure does not involve the natural language questions that are required for handling the task by our model, and thus it is unusable for this kind of training or evaluation. In the same context, the domain specific nature of the corpus creates an obstacle for the model to generalize for unseen domain which is an unwanted behavior for our model.

Similarly, the IMDB XML Dataset ([25]), derived from the Internet Movie Database, provides a heterogeneous collection of entertainment industry data. This includes detailed records on films, TV series, actors, directors, and production crews, offering researchers a platform to tackle challenges in querying diverse entity types, managing cross-linked data, and extracting insights from semi-structured multimedia metadata. Despite having a corpus that contains huge volume of domain specific data structured in XML files, these latter can't be transformed to a structured question-answer dataset to be eligible for the training and evaluation not only for our model but also for future models dealing with the process of translation.

Together, these datasets cannot be used for distinct facets of NLP using deep learning. Benchmarks like INEX and XMark prioritize technical rigor, enabling apples-to-apples comparisons of system performance, while domain-specific resources like DBLP and IMDB facilitate applied research in real-world contexts. For a granular comparison of these datasets—including their scope, structural complexity, and limitations —Table I synthesizes key attributes with a detailed comparison of their features.

TABLE I. AN OVERVIEW OF THE EXISTING DATASETS

Dataset	Cross Domain	Number of Elements	Max-depth	Avg-depth	Limitations
INEX	Yes	12107	-	6.9	irregular tagging, incomplete schemas
SIGMOD Record XML	No	11526	6	5.14107	less useful for cross-domain XML retrieval
XMark Benchmark	No	Depends on configs	Depends on configs	Depends on configs	Artificially generated hierarchies
DBLP XML Dataset	No	3 000 000	5-7	3.5	Not usable for semantic search or xml retrieval
IMDB XML dataset	No	Variable	Variable	Variable	Not usable for semantic search or xml retrieval

For the purpose of compatibility and since all the previous datasets presented in this paper don't offer a base for NLP tasks as well as the lack of XPath as a target language for the translation, we decided to build a new dataset (we called it XMLSet) that can encompasses all the missing things in one corpus and could be used by future models either for validation or training purposes.

B. XMLSet

The corpus is built based on different xml sources and underwent series of steps in order to have a usable dataset in the context of NLP. First, the xml databases have been cleaned and preprocessed automatically in order to remove non-sense names and replace non significant names with the ones that have signification. Second and since all XML databases are collected from existing source from internet as shown in https://github.com/karamsa/XMLSet, we have converted some of the xml sheets to XML databases in order to leverage our dataset with data from real word that is crucial for making a model that can generalize to unseen data; also we have kept the nature of some of the xml data that contain more than one XML root. We consider this as a necessary noise that makes the model more robust for real usage. For the aim of having a cross-domain dataset, we made sure that our new corpus includes a variety of domains from bookstores, purchases, plants, food, movies, journals, and more than 28 distinct topic; the table II shows a general comparison between the existing datasets and the XMLSet created by us. Since the XMLSet differs totally from the existing corpuses, we only show shared properties' statistics, such as the depth of xml nodes, average dept, and number of elements in the dataset and so on.

TABLE II. XMLSET AGAINST THE EXISTING DATASETS

Dataset	Cross Domain	Number of Elements	Max-depth	Avg-depth
INEX	Yes	12107	-	6.9
SIGMOD Record XML	No	11526	6	5.14107
XMark Benchmark	No	Depends on configs	Depends on configs	Depends on configs
DBLP XML Dataset	No	3 000 000	5-7	3.5
IMDB XML dataset	No	Variable	Variable	Variable
XMLSet	**Yes**	**37,788**	**8**	4

The construction of the XMLSet dataset was a prior step in the process of making a model that deals with NL to XML through XPath as an intermediate language. In contrast with the existing datasets that are not dedicated to NLP processing tasks, the XMLSet is the first corpus that can be used for models that rely on deep learning. It contains more than 2176 pairs in form of a natural language sentence and an answer in XPath language. The dataset is also leveraged with a ground truth section for each pair that describes the answer in a structured way making it adequate not only for deep learning processing but also for any XML retrieval form and can be used by models for training and evaluation purposes. The Figure 1 shows an example of a pair from XMLSet including the details about the labels sections (ground truth).

```
{
  "question": "find all addresses but the first two ones",
  "query_id": 2026,
  "xpath": "//address[position()>2]",
  "ground_truth": {
    "slots": [
      {
        "root_type": "//",
        "node": "address",
        "source": "position()",
        "op": ">",
        "value": "2"
      }
    ]
  },
  "schema_index": 3
},
```

Fig. 1. An Example of a natural language question and its answer including the details about the labels sections from XMLSet dataset.

Regarding the pairs statistics, the dataset is built on top of 30 separate XML database files. Some of them are bigger than the others especially in terms of number of elements and this is particularly helpful to ensure a diverse size across the whole corpus that is divided onto 2 sets. The data split of XMLSet is as shown in table III:

In terms of difficulty, we made sure that XMLSet contains a diversified pairs with easy, moderate and difficult queries;

TABLE III. THE DATA SPLIT OF XMLSET

	Train	Test
#Pairs	1472	704
#Unique NLs	1255	673
#Databases	30	30

The table IV shows a detailed analysis of the XMLSet.

TABLE IV. XMLSET'S DETAILED STATISTICS

Dataset	# Relative Paths	# Multi-paths	# Predicates	# Functions
XMLSet	77	**743**	**770**	**324**

In XPath, the difficulty of a query can be measured using different criteria. First we find the number of the nested paths which reflects the number of nodes to be included in the final XPath query. Then comes the number of predicates which has a direct link to the targeted nodes in the XML file. Another element that adds difficulty to XPath queries is the inclusion of functions in the predicates; thus is considered as a double difficulty as it puts together the predicates and functions in one place. Relative paths, that include the '..' are also a factor of complexity in XPath queries; thus adding it to some pairs in the dataset challenge the model on those complex transformations.

In the same context, we built XMLSet to follow the question-answer paradigm; hence not all queries return results as we want to have a system that can work in real situations where a query entered by a user might have no corresponding answer in a database.

IV. THE MODEL

A. Overview

Exploiting XML files using natural language solely, requires an intermediate language that can manage the translation operation by bridging the nature of each language; thus the use of a structured language such as XPath is mandatory for this process. The use of XPath comes from multiple factors. First, its simplicity; XPath is a simple language that relies on paths. It provides the possibility to extract nodes from XML files using a short syntax. Additionally, XPath can be applied directly to XML documents in comparison to other languages like XQuery which requires to be re interpreted. Another reason for choosing XPath is the richness in terms of functions; it provides more than 200 useful functions that can be used along with inherent expressions to exploit XML files effectively.

The conversion of NL sentences into XPath is a thorough task that should take in consideration the meaning inherent in the user sentence. To this end and since the two languages are different in nature, we decided to simplify the problem by adopting an straightforward mapping.

The model should predict the nodes and the predicates to be included in the final XPath query. With nodes the subset of the following items:

$$\text{N=[T; ”null”, ”.”, ”..”, ”*”, ”1”, ”last()”, ”position()”]} \quad (1)$$

In addition to T (the tags from the XML document) we also add to the output space the relative paths '.' and '..', '*' for any tag in the document, '1' and 'last()' for the first and last node and finally the 'position()' that helps select nodes based on a given position.

In the other side, a predicate P is a structure that holds multiple elements: A node from the previous list N, an operator from the set of possible operators O and a value from the list of values V mentioned in the user input.

$$\text{P = [N(i), O(l), V(t)]} \quad (2)$$

We define O as the list of supported operators in the XPath syntax as following:

$$\text{O = [”null”, ”=”, ”<”, ”>”, ”<=”, ”>=”, ”!=”, ”+”, ”-”]} \quad (3)$$

Using those elements and by exploiting the incorporate structure of XPath, we reformulate the problem and we simplify it further by limiting the output space in each item of the target query.

The problem then can be summarized as the prediction of one or multiple paths of nodes and predicates in the following format:

$$Q = //N_1P_1/N_2P_2.../N_nP_n \quad (4)$$

The paths are separated by delimiters of two types; the '//' which refers to selecting elements in the XML document from no matter where they are and that correspond to the current selection in the path. The second type is '/' which provides the possibility to select nodes depending on the root path or the previous one.

For example, if we take an XML file that stores the orders done by clients, the following XPath query will find the last saved order in the document:

$$//orders[last()] \quad (5)$$

We notice that the query contains only one path that includes the 'order' node and a predicate which contains a node as a function 'last()'. The operator and the value for the predicate in this case are optional. This query can take another form. For example selecting the last but one order saved in the XML document:

$$//orders[last() - 1] \quad (6)$$

In this case, the predicate contains a node as a function 'last()', the operator '-' and the value '1'. The table V shows examples of XPath queries with their descriptions.

TABLE V. SOME XPATH QUERIES AND THEIR DESCRIPTION

Query	Description
//orders[last()]	Get the last order wherever it is.
//orders[last()-1]	Get the last order but one from all order in the XML database.
//categories/description	Get the description node of categories nodes.
//cd[year=1985]	get the cds that have been published in 1985.
//company/employee[salary¿5000]	get companyies' employees that have a salary higher than 5000.
//company/employee[1]/*	get all information of the first employee of each company.

The same pattern can be used to represent complex XPath queries that involve different nodes, conditions, and multiple paths in the same XPath request. Hence an XPath query can be split into different parts; each one will be part of a specific predication process independently to the others.

B. Model Details

The goal of this work is the creation of a model that can generate XPath queries effectively using the learned patterns in the training dataset of XMLSet.

Since the translation of the natural sentence to XPath is a problem that can be reformulated as the prediction of one or multiple paths separated by roots and while each path can be represented by a node and a predicated as presented in the previous section, we can then use this powerful structure of XPath to make prediction of the target query in an effective manner that can help the model generate to unseen inputs from users.

We split the problem into several sub-problems in a way that dissociates the inputs and the outputs of each element in the prediction process. In this context and based on an input from the user, the natural language sentence as well as the nodes of the XML file are fed to the model that run a series of prediction operations in order to construct a valid query that can be executed against an XML engine, so the result is returned to the user as shown in figure 2 that displays the architecture of our model (XPathia) in details.

The natural language sentence is tokenized and the XML file is preprocessed to get the XML nodes that make the structure's file then the two inputs are concatenated each other and the Meta data are added. We leverage the combined inputs with separators to distinguish between the user input and the XML datafile. We use [SEP] from the BERT pretrained model [26] to separate the natural language sentence form the structure of the XML file and also for separating each tag automatically extracted from the XML document. The BERT (Bidirectional Encoder Representations from Transformers) is a language representation model that provides pertinent contextualized word embedding in contrast to static one proposed by other models. In addition to the contextualized word embeddings that BERT provides using representation from left and right layers of the transformers model [27], we also leverage our model

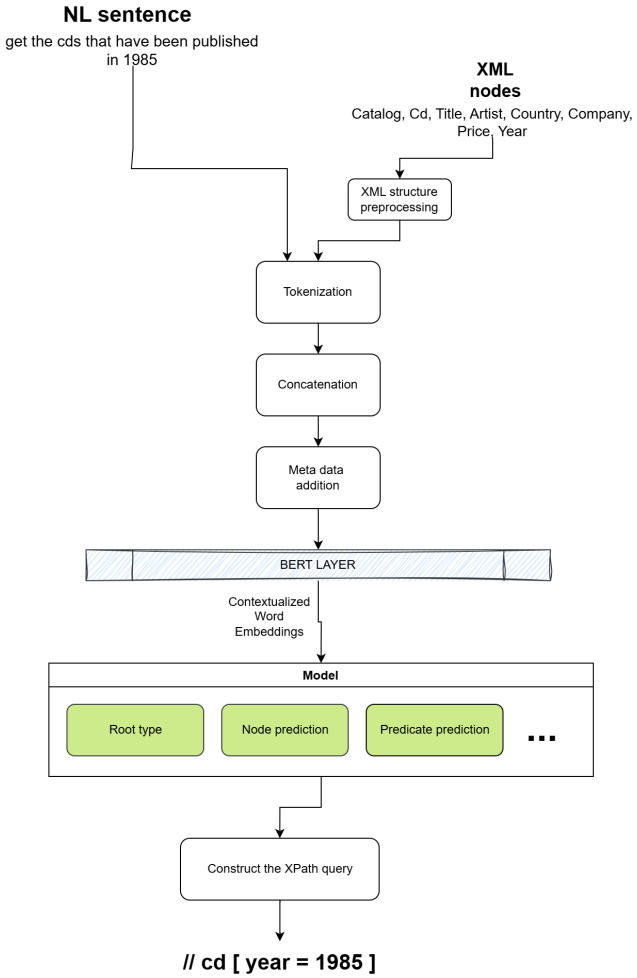

Fig. 2. The Architecture of our system.

with the [SEP] token as a separator as well as the special token [CLS] that holds the whole meaning of the input in one word embeddings. This token can concentrate the representation from both sides as BERT is a bidirectional model. These metadata are essential to get focused representations that will be used in the next step. The query generation process takes place the BERT layer is completed. Our model is composed of several sub modules and each sub-module is dedicated to generate specific elements of the query. We don't use a sketch filling approach as in our case the whole query will be predicted and this will be done once not sequentially. Since the redefined structure of an XPath query is more straightforward as have been shown in the previous section, we define six sub-modules for generating the target XPath query as shown in figure 3.

For each sub-module, the sentence S and the nodes N will be fed as I:

$$I=[[CLS];S;[SEP];n_1;[SEP];n_2... \ [SEP]n_z] \quad (7)$$

The first step consists of predicting the number of paths that will construct the final XPath query. In contrast to what we have done in other works; we are not choosing a template from

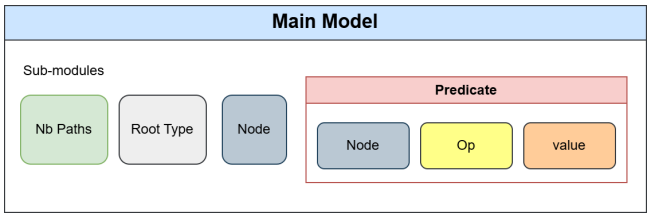

Fig. 3. The Main model and the included sub-modules for the generation process.

a predefined set of possible structures, but we will generate the query structure using a dedicated sub-module. This lets the generation of a non predefined structure possible.

$$P_n(n|I) = softmax(X_n tanh(Y_n EMB_{[\text{CLS}]}))_i \quad (8)$$

we use X and Y as two matrices with separate trainable parameters that help predict the number of paths in the final query. This sub-module is based on the use of the attention mechanism [28] and the work done by sqlnet (2017)). The softmax function normalizes the scores of all probabilities and the top one is selected as the final number of paths in the target XPath query.

As a path in XPath always starts either by '//' or by '/', the root type module is triggered to predict the root types of all the paths in the final query. Using the predefined list of root types ['/', '//'] of each path we put:

$$\begin{aligned} r &= V_{RootType} tanh(W_{RootType} EMB_{[\text{CLS}]}) \\ P_{RootType_{(i)}}(RootType|I) &= softmax(r) \end{aligned} \quad (9)$$

with $\text{EMB}_{[\text{CLS}]}$ the contextualized embedding of the whole input, $\text{V}_{\text{RootType}}$ and $\text{W}_{\text{RootType}}$ are two matrices with isolated trainable parameters fully dedicated to this sub-module. The softmax function normalizes the probabilities for the root types over each path and the highest ones are chosen for each step. In real work almost all XPath queries starts with '//'; hence a great deal of generated root types are '//' for the first path.

The node sub-module is the one in charge of predicting tags that will be included in each path. The tags are predicted based on the list of the fed XML nodes in the first step and using the meaning extracted from the natural language sentence of the user. A node in a specific path can be computed as following:

$$\begin{aligned} z &= S_{node} tanh(T_{node} R_{[CLS]/node(i)}) \\ P_{node_{(i)}}(node|I) &= softmax(z) \end{aligned} \quad (10)$$

with $\text{EMB}_{[\text{CLS}]/\text{node(i)}}$ the representation of a node i in the list of provided nodes and based on the special token CLS that involve the whole representation of the input; this way we enforce the meaning and concentrate the representation for each node extracted from the xml document . S_{node} and W_{node} are two matrices with isolated trainable parameters fully dedicated to this sub-module. The softmax function normalizes the probabilities for the xml nodes over each path and the top candidates are chosen to be predicted as outputs.

Regarding the predicates and since they are composed of three sub-modules (Node, Operator and Value) we decided to use the same structure of modules as before. For instance, the node sub-module within the predicate has the same structure as the one in the path. Both they generate a node based on the list of xml tags from the input and based on the [CLS] token, however the latter is shown before the predicate while the other is inside the predicate. While the two sub-modules use the same structure, they differ in the parameters. We use independent matrices for each sub-module even if they have the same structure; this can be understood as we want to dissociate the training of each module. The node of a predicate can be computed as following:

$$\begin{aligned} x &= M_{node_{predicate}} tanh(N_{node_{predicate}} R_{[CLS]/node(i)}) \\ P_{node_{predicate_{(i)}}}(node_{predicate}|I) &= softmax(x) \end{aligned} \quad (11)$$

The matrices $\text{M}_{\text{node}_{\text{predicate}}}$ and $\text{N}_{\text{node}_{\text{predicate}}}$ contain independent trainable parameters exclusively dedicated to this sub-module and not shared with the others. The softmax function normalizes the probabilities of XML nodes along each path, selecting the top candidates for prediction.

For the operator inside the predicate, we use two separate matrices and the representation of the whole input given by the user. For each path we select one item from the list of possible operators ['null', '=', '¡', '¿', '¡=',' ¿=', '!=', '+', '-'] and we compute:

$$\begin{aligned} q &= E_{Op} tanh(F_{Op} EMB_{[\text{CLS}]}) \\ P_{Op_{(i)}}(Op|I) &= softmax(q) \end{aligned} \quad (12)$$

With E_{Op} and F_{Op} two matrices with trainable parameters specific for this module and will predict an operator for a given path in the target XPath query. The probabilities for each Op(i) are calculated and the top operators are selected for the predicates using the softmax function.

The 'null' element in the list of operators refers to when there is no operator for the predicate; thus the 'null' item will be predicted as the top candidate with the highest probability. In the same context, we leverage all lists with a 'null' value that can be predicted when there is no item to be predicted. For instance, the query bellow doesn't include operator nor a value in the predicate, hence the item 'null' will be predicted for both positions:

$$//messages[1] \quad (13)$$

This gives us the flexibility to stick to the simplified structure of XPath and also run the same number of modules regardless the number of paths and without taking the burden of the structure in the target query.

$$//messages[1, \textbf{null}, \textbf{null}] \quad (14)$$

V. Evaluation Results

Our model (XPathia) is trained using XMLSet dataset that we have presented in previous sections. The training is made on windows OS with a 4G in GPU for the training set of the dataset and for several epochs. The chosen batch size is 4 and we use [29] for the training with default values for the learning and dropout rate, respectively 1e-3 and 0.3. The training process (Figure 4) starts stabilizing after the nineteenth epoch and the accuracy on the training set achieves a score of 29%.

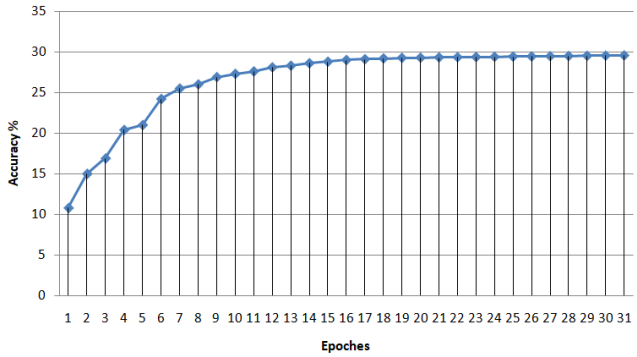

Fig. 4. The Training score on for our model XPathia.

All the sub-modules that composes our model XPathia are trained separately on the pairs of XMLSet that are included in the training set and evaluated against the test set only once.

As we have proposed in our previous work [30] and [31], we use two metrics to evaluate our model. The first metric is the component matching. This metric measures the correctness of outputs of each sub-module and provides an accuracy score on how many parts of the XPath queries have been predicted correctly. Since the XMLSet provides a structured ground truth, the matching is straightforward based on a set matching between the sub-module output and the corresponding item on the ground truth. The loss scores are summed in order to optimize the parameters hence giving better prediction and minimizing the loss score for each sub-module. The table VI shows the performance of XPathia model on the test set of XMLSet dataset using the component matching metric.

TABLE VI. The Performance of XPathia Model on the Test Set of XMLSet Dataset Using the Component Matching Metric

Model	# NB paths	Root types	Node	Predicate		
XPathia	98.86%	66.4%	64.2%	**40.1%**		
				Node	Operator	Value
XPathia	**98.86%**	**66.4%**	**64.2%**	**41.9%**	**91.61%**	**49.00%**

With the 'nb paths', the accuracy of the module that predict the number of steps in the final XPath query. XPathia achieves a score of 66.4% on the prediction of the root types as well as 64.2% of correct answers on the test set for the prediction of the nodes that will construct each path in the query. The accuracy score for the predicates is 40.1% of the correct answers generate by the corresponding sub-module.

Another metric used to evaluate our model XPathia, is the total matching or what we called in our previous works Exact matching. This metric helps measure the correspondency of a generated query by the components of the main model with the ground truth query. The whole output is considered as correct when all parts match exactly all items in the ground truth data.

The table VII shows the performance of XPathia when measured with the Exact matching on the XMLSet dataset.

TABLE VII. The Performance of XPathia When Measured With the Exact Matching on the XMLSet Dataset

Model	Train set (last epoch)	Test set
XPathia	29.0%	25.85%
XPathia-wo-values	**42.8%**	**36.05%**

The model achieves a score of 25.85% of correct queries on all pairs seen in the test set of XMLSet while it achieves a total score of 29.0% on the training set when trained for several epochs. We also explore the evaluation without taking in consideration the generated outputs related to values in the final query. When evaluated without taking in consideration the values, it achieves a score of 42.8% on the training set of XMLSet. **XPathia-wo-values** outperforms the base model by 10.2% on the test set and achieves an accuracy score of 36.05% which becomes the state of the art for the task of translating natural language to XPath for the aim of XML extraction.

VI. Discussion

The evaluation of the existing XML datasets in this work leads to several conclusions:

- The existing Cross-domain datasets are not suitable for XML retrieval using deep learning.
- Some of the datasets are configurable in size and complexity, useful for performance benchmarking but not cross-domain, with randomly generated data.
- Datasets with Large bibliographic corpuses are good for XML data management but not suitable for translation model training.
- The presented corpuses with Variable size and complexity are adaptable for research but not cross-domain.

Given these insights, and since there is no available dataset that can fill the lack of corpuses dedicated to NLP and deep learning, we have proposed XMLSet dataset with all advantages for the training and the evaluation of deep leaning based models. We emphasize on the quality of the corpus in terms of the size as well as the diversification of pairs with a wide coverage in topics like books, products, orders, universities, and more. This dataset is pairing natural language questions with corresponding XPath queries in JSON format and is split into train and test sets. While the XMLSet is a good starting point for future models, we believe that the dataset can be enhanced more by adding more items, creating more complex structures and might be leverage by an intermediate set for fine

tuning the models in the training process. Unlike previous work using XQuery, we introduce XPath to simplify translation, treating it as progressive generation process. We apply this approach based on [30] but with major differences in system architecture, model composition, and problem formulation. We choose a unified XPath structure for any query that can be generated by our model XPathia, and this helped us to reformulate the problem from a complex task to a relatively straightforward one. In comparison to other works that deal with the problem in a totally classical way, we choose to apply deep leaning to our model. The structure of sub-modules plays a pivotal role in the generation process as it provides a total independence between the output spaces. Each sub-module can learn to generate one type of inputs and this helps it enhance the quality of the generated elements as they have separate trainable parameters. In the same context and since all sub-modules parameters are isolated from each other, the errors are not propagated between the models, and thus, having an error in one sub-module doesn't affect the rest of the sub-modules. In relation to the training and as each element is predicted separately from the others, we notice a quick training process. The leaning starts stabilizing after few epochs; this can be understood as the model updates only the faulty parameters of the sub-modules with errors not the whole model, hence the back propagation is limited.

The model XPathia achieves a score of 25.85% on the challenging dataset XMLSet and 36.05% when we omit the values prediction, thing that makes it the new state of the art model. While the accuracy is relatively high for such a task, we believe the model can be more enhanced with exploration of new techniques that can be applied to the model in order to improve the prediction accuracy. We understand that the major improvement can come from the use of LLM models that can have a positive impact to our model. Also we believe that some processing to the input before the starting of the prediction can also have a good impact to XPathia.

VII. Conclusion

In this study, we introduced a new deep learning-based approach for translating natural language into XML queries through an intermediate XPath representation. Our key theoretical contributions include the creation of XMLSet, the first annotated dataset designed for training and evaluating deep models on this task across diverse domains, and the development of XPathia, a novel model that leverages a unified XPath structure for improved generalization. XPathia achieves a 25.85% accuracy on the XMLSet test set, establishing a new benchmark in this domain. Despite these advances, the model still faces limitations in handling complex or nested queries and in generalizing to unseen schema variations. Future research will focus on enhancing the model's ability to understand deeper semantic structures and expanding the dataset with more complex query patterns. This work contributes to the field by introducing scalable, data-driven methods that reduce reliance on manual rule engineering and make XML data querying more accessible to non-technical users.

Conflict of Interest

The authors declare that they have no conflict of interest.

***Abstract*—Diabetes mellitus presents a growing prevalence at the global level, representing a significant public health challenge. Despite the availability of specific treatments, it is imperative to develop innovative strategies that optimize early detection and management of the disease. The research aims to develop a model that allows for the early detection of diabetes using the Random Forest algorithm, using the Knowledge Discovery in Databases (KDD) methodology, which comprises the phases of selection, preprocessing, transformation, data mining, interpretation and evaluation. The dataset used include 520 randomly selected patient records. The model achieved robust performance, with an accuracy of 85%, sensitivity of 75%, and an F1-score of 78%, indicating an adequate balance between precision and sensitivity. Specificity was 78%, while the area under the ROC curve (AUC) reached 86%, demonstrating a high discriminative ability between positive and negative cases. The balanced accuracy was 82%, and the Matthews correlation coefficient (MCC) registered a value of 0.72, confirming the strength and reliability of the model even in the presence of class imbalance. These results demonstrate the effectiveness of the machine learning-based approach for the early detection of diabetes mellitus, with potential application in clinical decision support systems.**

***Keywords*—Data mining; decision tree; diabetes mellitus; machine learning; random forest**

I. Introduction

Diabetes has been recognized by the World Health Organization (WHO) as a major global health concern. It currently affects around 9.3 % of adults worldwide, with an increasing number of cases reported in low- and middle-income regions. The condition shows a slight difference between genders, with a prevalence of 9.6% in men and 9.0% in women. Furthermore, the likelihood of developing diabetes rises significantly with age, especially among individuals over the age of 45 [1]. This disease poses serious health risks, contributing to complications such as heart disease, kidney damage, vision loss, and limb amputations, all of which generate considerable health care burdens and socioeconomic consequences. Diabetes is a long-term illness that continues to grow in prevalence worldwide and can lead to severe health issues if not identified and treated in its early stages. This research is relevant because it addresses the critical need for early diagnosis, which plays a key role in minimizing complications and improving the overall well-being of those affected. Detecting the disease early is not only beneficial for individual patients but also essential for improving public health outcomes [2].

Diabetes is a chronic condition characterized by high blood glucose levels due to the body's inability to produce or effectively use insulin. Diagnosis is made through fasting blood glucose tests, the glucose tolerance test, and hemoglobin A1c levels [3]. The main causes of diabetes include genetic factors, obesity, lack of physical activity, and poor dietary habits, particularly in individuals with a family history of the disease. The consequences of poorly managed diabetes are severe, as it can lead to complications such as cardiovascular diseases, kidney damage, blindness, amputations, and a higher risk of infections. Additionally, it significantly impacts the patient's quality of life and represents an economic burden on healthcare systems worldwide [4].

This study offers both theoretical and practical contributions. On the theoretical side, it explores how machine learning—specifically the Random Forest algorithm—can be effectively used to predict the risk of diabetes by analyzing various clinical and demographic factors. On the practical side, the results can support healthcare providers by offering a reliable tool for early risk identification, helping to streamline diagnostic procedures and support preventive healthcare strategies.

Methodologically, the research is grounded in the Knowledge Discovery in Databases (KDD) process, which provides a step-by-step framework for extracting useful patterns from large datasets. By following the KDD stages—data selection, cleaning, transformation, mining, and interpretation—the study ensures that the model development is systematic, robust, and applicable to real-world healthcare scenarios. The objective of the research is to develop an early detection model for diabetes using the Random Forest algorithm, then the aim is to apply machine learning techniques to identify significant patterns within clinical and personal patient data that contribute to accurate and timely diagnosis.

II. Literature Review

In this section, the findings of different authors who have researched diabetes are analyzed.

A. Theoretical Bases

1) Diabetes mellitus: In the context of health, diabetes mellitus is classified as a chronic metabolic disease, primarily characterized by elevated blood glucose levels (hyperglycemia). This condition, if not properly controlled, can trigger severe long-term complications affecting various organs and systems of the body, such as the cardiovascular, renal, ocular, and peripheral nervous systems [5]. From a physiological point of view, insulin is a hormone produced by the beta cells of the islets of Langerhans in the pancreas, whose main function is to

facilitate the transport of glucose from the bloodstream into the cells to be used as an energy source. In patients with diabetes, this function is compromised due to a deficiency in insulin production (Type I diabetes) or resistance to its action (Type II diabetes), which prevents the proper entry of glucose into the cells, causing its accumulation in the blood and altering energy metabolism [6].

Type I diabetes is characterized by the self-destruction of the beta cells of the pancreas, which are responsible for insulin production. This destruction is mistakenly caused by the immune system, which identifies these cells as foreign agents. As a consequence, an absolute insulin deficiency occurs, preventing proper glucose metabolism and leading to elevated blood glucose levels [7]. Besides, Type II diabetes mellitus, the pathophysiology is different. This condition is characterized by insulin resistance in peripheral tissues, accompanied by a progressive dysfunction of the pancreatic beta cells responsible for its secretion. As a result, glucose cannot be effectively utilized by skeletal muscle, adipose tissue, and the liver, leading to chronic hyperglycemia. This metabolic disturbance worsens over time, as the pancreas's ability to compensate for insulin resistance by increasing insulin production becomes progressively impaired [8].

2) Random forest: Random Forest is a machine learning algorithm that works by combining many decision trees to obtain more accurate and stable results. Through a process called bagging, the model learns from multiple samples of the same dataset and makes decisions considering different combinations of variables, which allows it to be more reliable and less prone to errors [9][10]. This technique is especially useful in the healthcare field, as it enables the analysis of a large amount of clinical and personal information from patients, detecting complex patterns that may not be evident at first glance [11]. In this research, Random Forest is used as a tool to support the early diagnosis of diabetes, aiming to facilitate timely interventions and improve people's quality of life.

B. Related Work

The author [12] aimed to identify systemic risk factors associated with diabetes mellitus (DM) and to predict the onset of diabetic retinopathy (DR) by implementing a classification model based on Random Forest (RF). Patients diagnosed with DM who attended a specialized retina consultation for DR screening for the first time were included. Clinical and demographic variables were collected, including age, sex, type of diabetes, metabolic control, family history, and comorbidities. The presence of DR and vision-threatening diabetic retinopathy (VTDR) was established through a dilated fundus examination. The dataset, consisting of 1,416 patients, was split into 80:20 proportions for training (1,132 cases) and testing (284 cases). The RF model demonstrated optimal performance in detecting DR, with a 0% error rate during training and 100% accuracy on the test set. For detecting VTDR, the model achieved 76% accuracy, with a sensitivity of 53% and specificity of 80%. These results demonstrate that the RF-based approach is highly effective for predicting DR using systemic variables, which could optimize screening processes by reducing unnecessary referrals. However, the need to validate the model in larger and more diverse populations to confirm its clinical applicability is emphasized.

Diabetes mellitus represents a growing public health concern globally, as mentioned by the author [13]. In this study, the main objective was the development of predictive models based on machine learning aimed at the clinical classification of diabetes. For this purpose, an application was built based on the integration of a structured database containing both continuous and categorical variables corresponding to risk factors. Various supervised learning algorithms were implemented, including logistic regression, Gaussian Naive Bayes, linear discriminant analysis (LDA), support vector machines (SVM), k-nearest neighbors (KNN), decision trees, Extreme Gradient Boosting (XGBoost), kernel entropy component analysis, and Random Forest. The adopted methodology was structured around three key stages: feature extraction, classification, and prediction. Experimental results indicated that the Random Forest model achieved the best performance, reaching a maximum accuracy of 99.84% on imbalanced data and 96.75% on balanced data. Additionally, the SVM classifier, combined with kernel entropy components, achieved an accuracy of 99.64% on the balanced dataset. The area under the ROC curve (AUC) was 99%, highlighting the Random Forest model as the most robust and effective among all the evaluated algorithms [14][15].

Diabetes is a serious global health problem, affecting over 422 million people and continuing to grow each year, as mentioned by the authors [16][17]. Their study focused on how to predict diabetes more accurately using two artificial intelligence algorithms: Random Forest and XGBoost, applied to a public diabetes dataset available on Kaggle. The aim was to improve prediction accuracy by better selecting the most important features for analysis.

The dataset used contained 768 records with nine medical features, such as number of pregnancies, glucose levels, blood pressure, and body mass index (BMI), along with a label indicating whether the person had diabetes or not. To ensure reliable results, a data cleaning and preprocessing step was performed first. Then, two advanced techniques were applied to select the most relevant features: the Genetic Algorithm (GA) and Particle Swarm Optimization (PSO).The results showed that, initially, without feature selection, the Random Forest algorithm achieved an AUC accuracy of 0.8120, and XGBoost reached 0.7666. After applying PSO, accuracy improved to 0.8582 for Random Forest and 0.8250 for XGBoost. When using the Genetic Algorithm, the results were even better: 0.8612 and 0.8351, respectively. That is, accuracy improved by up to 8.9%, showing that GA was more effective than PSO. This study demonstrates that adequately selecting the most relevant features can significantly enhance the prediction accuracy of machine learning models. This is particularly useful for developing tools that help detect diabetes early, enabling faster and more accurate diagnoses in clinics and hospitals [18][19].

On the other hand, in [20], the authors addressed the early identification of individuals at risk of developing Type 2 diabetes mellitus (T2DM). The main objective was to analyze possible risk factors through the application of supervised learning algorithms, specifically Decision Trees (DT) and Random Forests (RF). The study was based on data from the

Kharameh cohort, part of the Fars study, which includes a sample of 10,663 individuals aged between 40 and 70 years. Multiple clinical and demographic variables associated with the risk of T2DM were evaluated using data mining techniques. Standard metrics such as accuracy, sensitivity, specificity, and area under the ROC curve (AUC) were used to measure the performance of the models. Statistical analysis and model implementation were conducted using the R programming language. The Decision Tree (DT) model highlighted factors such as age, triglycerides, blood pressure, and BMI as most associated with type 2 diabetes. However, the Random Forest (RF) model proved to be more accurate, also identifying fasting glucose, cholesterol, and creatinine as key variables. With an accuracy of 73.5

In light of another hypothesis proposed by the author [21], which suggests that Type 2 diabetes (T2DM) may be influenced by environmental factors such as air pollution, noise, and neighborhood socioeconomic conditions, an analysis was carried out using advanced machine learning techniques: penalized LASSO regression, Random Forest (RF), and Artificial Neural Networks (ANN). Data from 14,829 participants in the AMIGO Cohort Study were analyzed, including 85 exposome variables obtained based on the location of their residences. The results showed that living in areas with lower housing values, a higher proportion of non-Western immigrants, and higher surface temperatures is associated with an increased risk of T2DM. The selected factors varied between models: some known factors such as air pollutants only appeared in univariate analyses, while others such as the presence of green spaces emerged in multivariate models like RF. Finally, the LASSO model showed better predictive performance than RF and ANN, according to the logLoss prediction error. In conclusion, social and environmental determinants of the residential environment are strongly related to the prevalence of T2DM, although their impact may vary depending on the analytical approach used [22][23].

Another study addresses the need to implement more sophisticated diagnostic tools to treat Type 2 diabetes mellitus (T2DM), a chronic metabolic disease characterized by alterations in glucose, lipid, and protein metabolism due to insufficient insulin production or ineffective insulin action. This research explores the application of advanced machine learning models, specifically the joint approach known as Stacked Multi-Kernel Support Vector Machine with Random Forest (SMKSVM-RF). This model integrates the pattern recognition capabilities of multi-kernel Support Vector Machines (SVM) and the robustness of Random Forests (RF), which combine multiple decision trees to increase reliability in prediction. By stacking both models, the goal is to leverage their complementary strengths to improve performance in classification and regression tasks in clinical settings. The results show that the SMKSVM-RF model achieved an accuracy of 73.37 per cent in the confusion matrix, a recall rate of 71.62 per cent, an individual precision of 70.13 per cent, and an F1 score of 71.34 per cent. These metrics highlight the potential of this hybrid approach as an effective tool in the early diagnosis of diabetes. Altogether, this work emphasizes the usefulness of complex machine learning methods such as SMKSVM-RF in improving current diagnostic systems and significantly contributing to enhanced healthcare for chronic diseases like T2DM [20][24].

Diabetes mellitus is a condition that presents multiple health implications for individuals, especially pregnant women, due to the high prevalence of its adverse effects [25]. This issue focuses on research regarding the identification of the disease in women over 25 years of age, whose main causes include overweight, obesity, or family history of diabetes. To address this issue, an ensemble learning approach was used, allowing for precise predictions through machine learning algorithms. In this context, range-based Random Forest models (RRF) were used, which considered various variables such as body weight and selected values. New features such as Sum and Rank were generated, and based on a defined threshold, diabetes predictions were made on the dataset [26].

It is essential to recognize that Type 1 diabetes (T1D) is classified as a chronic and irreversible disease. In this context, the use of predictive algorithmic models plays a crucial role in anticipating disease progression, as indicated by the author [27]. To this end, survival models based on the Random Forest technique were developed to model critical stages in the progression of T1D. The first model estimates the time required for an individual to evolve from single to multiple autoantibody positivity (AAb+), which represents a decisive stage in disease development. The second model predicts the transition from multiple AAb+ to the clinical manifestation of type 1 diabetes. The findings show that the survival models built with Random Forest outperform traditional approaches such as Cox regression. Furthermore, a comprehensive variable importance analysis was conducted, which allowed for the identification of new interactions among relevant biomarkers. Ultimately, a more accurate methodological framework is established for measuring and stratifying T1D risk, supporting earlier and more personalized preventive interventions [28][29].

In a study conducted by the author [30] and supported by data from the World Health Organization, diabetes is addressed as a silent non-communicable disease whose early detection poses a major challenge compared to other pathologies. To address this issue, the study proposes the implementation of machine learning techniques using the PIMA Indian Diabetes (PID) dataset. To address the class imbalance in the data, six resampling methods were applied: Random UnderSampling (RUS), Random OverSampling (UPS), SMOTE, ADASYN, SMOTE-Tomek, and SMOTEENN. These techniques allowed the evaluation of how different balancing schemes impact the performance of predictive models. For data exploration and classification, tree-based algorithms were used, specifically XGBoost and Random Forest, to identify relevant patterns associated with diabetes. The results showed that the XGBoost model achieved its best performance with the SMOTE-Tomek technique, while Random Forest performed best when combined with SMOTEENN [31][32].

Other complications associated with diabetes are often closely linked to inadequate insulin production or regulation, the hormone responsible for maintaining stable blood glucose levels, as noted by the author [33]. In his study, the objective was to develop a predictive algorithmic model capable of early identification of diabetes, thereby minimizing the risk of serious and even fatal complications. To achieve this, machine learning algorithms were implemented, including Random Forest and K-Nearest Neighbors (KNN), to improve diagnostic accuracy. The strategy was based on combining multiple

models to strengthen predictive capability and optimize early disease detection. A key element was the use of a large dataset composed of individuals diagnosed with and without diabetes, which allowed for the refinement of the predictive model. The results demonstrated that the integrated model can significantly improve the early identification of diabetic cases, favoring timely medical interventions and more effective disease management. Altogether, this research contributes to the advancement of health-oriented technology through prediction based on artificial intelligence techniques [34][35]. Fig. 1 presents the keywords through a word cloud generated from the different articles analyzed for the literature review, where the words diabetes and Random Forest stand out.

Fig. 1. Word cloud.

III. Methodology

A. Definition of the KDD Methodology

In the context of the present project, the KDD methodology has been applied—one of the most widely used approaches in the field of data mining and machine learning. This methodology enables the extraction of useful knowledge from large volumes of data originating from diverse sources, making it an adaptable and effective tool for projects related to data science [36][37]. The KDD process comprises a series of systematic stages, including selection, preprocessing, transformation, data mining, and evaluation of the obtained knowledge, as mentioned in Fig. 2. It is a multidisciplinary activity that integrates statistical techniques, machine learning algorithms, and exploratory data analysis, with the ultimate goal of discovering meaningful patterns and valuable knowledge in the available data [38][39], as illustrated in the architecture of Fig. 3.

1) Selection: The selected topic for the present research focuses on diabetes. In this stage of the KDD process, specifically in the selection phase, a CSV-format dataset from the Kaggle platform was chosen. This dataset was stored in a Google Drive folder to facilitate access from a cloud-based development environment, specifically Google Colab. Within this environment, the Python programming language and the Pandas module were used to efficiently load and explore the data [40].

It is important to highlight that the selected dataset includes records of individuals aged between 16 and 90 years, as well as various relevant features such as Polyuria, Polydipsia, Sudden weight loss, Weakness, among other clinical and demographic variables. This initial data selection was carried out to ensure

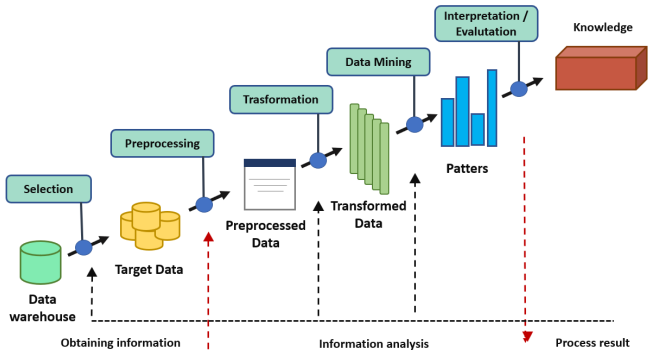

Fig. 2. KDD Methodology.

the relevance and quality of the information for subsequent processing and analysis during the following KDD phases, such as cleaning, transformation, data mining, and interpretation.

2) Preprocessing: For data processing, the imputation of missing values and the removal of outliers present in the fields observed in the dataset are proposed. However, in this section, it is noted that the presented data does not contain noise or specific missing values that could affect the model's performance, as shown in Fig. 4.

3) Transformation: In this section, the dataset is divided into two parts: 80% is used to train the model and the remaining 20% to test it, ensuring that the model learns from the majority of the data and is then evaluated with new data to measure its performance. Additionally, the class labels "Positive" and "Negative" are converted into numerical values (1 and 0) so that the algorithm can process them, while maintaining all features for both sets, thus allowing for proper model validation, as shown in Fig. 5. On the other hand, Fig. 6 presents the distribution of the numerical variables in the dataset, enabling the observation of the frequency with which different value ranges occur in each variable. This visualization helps identify patterns such as the presence of bias, dispersion, or potential outliers in the analyzed features, which is essential for understanding the nature of the data before applying any machine learning model. Moreover, the use of a consistent color palette facilitates visual comparison across the different variables.

4) Data mining: Fig. 7 presents two complementary visualizations that provide a deeper understanding of the behavior of the Random Forest model. First, an individual tree extracted from the forest (limited to a depth of 3) is shown, which allows us to observe how the model makes decisions based on the most relevant features. This visually illustrates the hierarchical structure of the partitions and the influence of each variable in the classification process. Next, a violin plot is presented, displaying the distribution of feature importance, generated from a simulation based on their estimated values. This visualization highlights not only the relative magnitude of each attribute in the model's decision-making but also their variability, offering both an artistic and statistical perspective on how each variable contributes to the overall performance of the algorithm, as shown in Fig. 8.

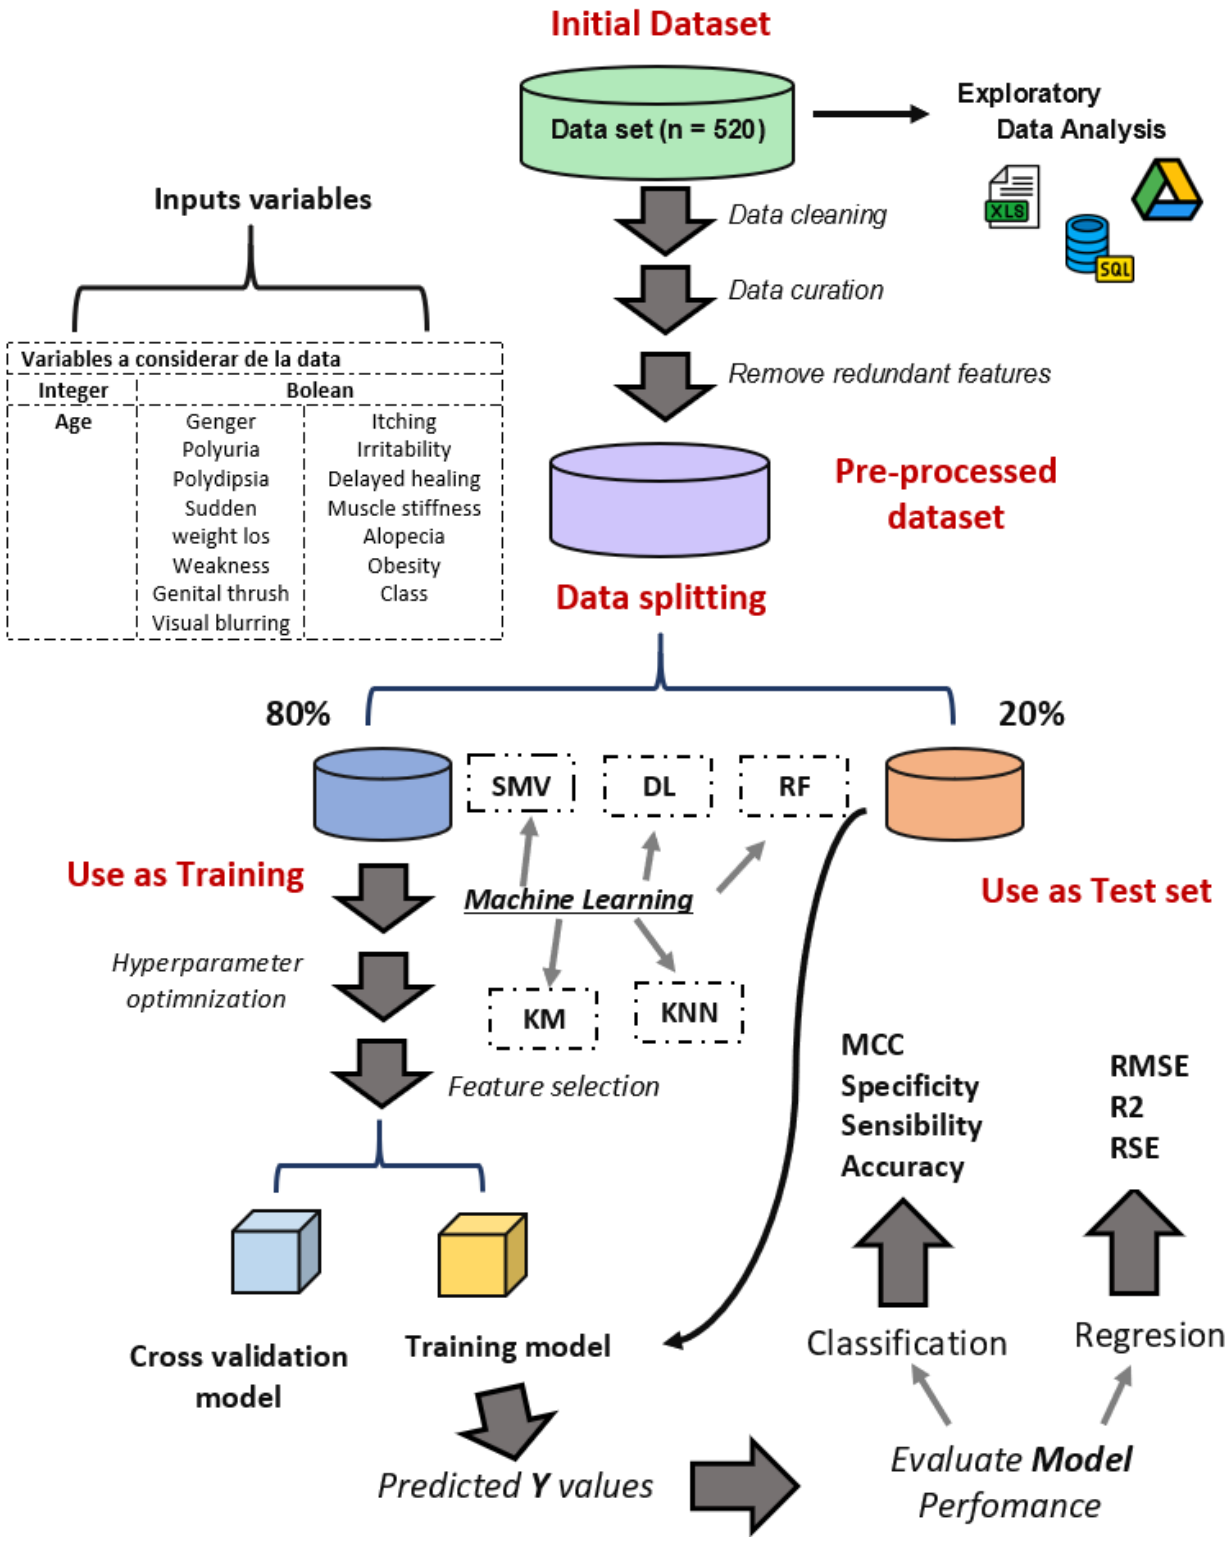

Fig. 3. Machine learning architecture.

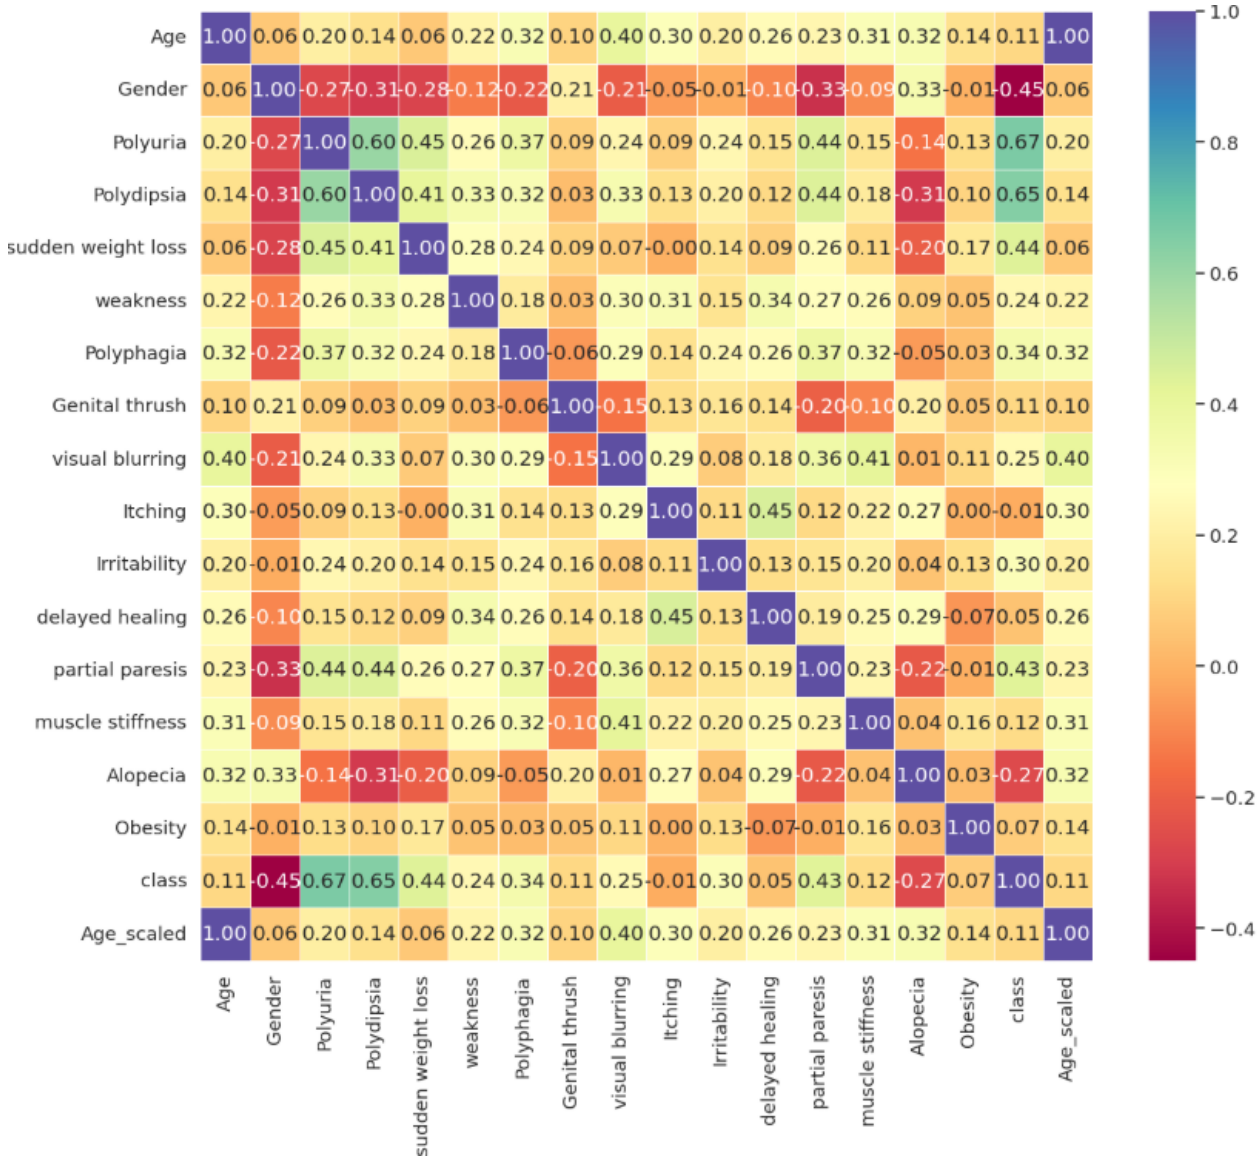

Fig. 4. Data preprocessing.

B. Random Forest Mathematical Formulas

1) Bootstrap sampling: Each tree in the forest is trained with a bootstrap sample from the original training set [see Eq. (1)].

$$D_b \sim \text{Bootstrap}(D), \quad \text{para } b = 1, 2, \ldots, B \tag{1}$$

where, D is the original training set, and D_b is the data set for the tree T_b, obtained by sampling with replacement.

Before training each tree in the Random Forest, a random sample with replacement is taken from the original dataset. This introduces diversity among the trees, helping to reduce overfitting and improve generalization.

2) Random feature selection: At each node of the tree, a subset of m features is randomly selected from the total of p available [see Eq. (2)].

$$\mathcal{M} \subseteq \{1, 2, \ldots, p\}, \quad |\mathcal{M}| = m \ll p \tag{2}$$

p: total number of variables (features) in the original set.

M: random subset of m features considered in each node.

m: number of variables randomly selected at each node of the tree.

Only these features are considered to find the optimal split at that node. Instead of using all variables to split a node. A small subset of variables is randomly selected. This increases variability between trees and improves the robustness of the model.

3) Division criteria:

a) Gini index (classification): Gini impurity measures how mixed the classes are at a node. A low value indicates

Fig. 5. Distribution of positive and negative classes training and test sets.

that the node contains mostly data from a single class [see Eq. (3)].

$$Gini(S) = 1 - \sum_{i=1}^{C} p_i^2 \tag{3}$$

where, p_i is the proportion of elements of class i in the set S, and C is the total number of classes.

b) Entropy (classification):

$$H(S) = -\sum_{i=1}^{C} p_i \log_2(p_i) \tag{4}$$

H(S): Entropy of the data set S. C: Total number of possible classes.

p i : Proportion of elements of the class i in the set S.

$\log_2(p_i)$: Base-2 logarithm (used to measure information in bits). Entropy $H(S)$ measures the degree of impurity or disorder in a data set. $H(S)$ reaches its maximum value when classes are balanced (high uncertainty) and its minimum value when the node contains elements of only one class (low uncertainty). This measure is used to decide how to split a node in decision tree algorithms, including Random Forest trees [see Eq. (4)].

c) Variance (regression):

$$Var(S) = \frac{1}{|S|} \sum_{i \in S} (y_i - \bar{y})^2 \tag{5}$$

where, $\bar{y}$ is the mean of the outputs at the node.

It is used in regression problems to evaluate the dispersion of output values at a node. The goal of the tree is to minimize this variance by partitioning the nodes [see Eq.(5)].

4) Model prediction:

a) Classification (majority vote):

$$\hat{y} = \text{mode}\left(\{T_b(x)\}_{b=1}^{B}\right) \tag{6}$$

Prediction is the most common class among the predictions of B trees [see Eq.(6)].

b) Regression (average): Eq. (7) represents the regression process in a Random Forest model. This ensemble approach enhances prediction accuracy and reduces the risk of overfitting.

$$\hat{y} = \frac{1}{B} \sum_{b=1}^{B} T_b(x) \tag{7}$$

where,

- B is the total number of trees in the forest.
- $T_b(x)$ is the prediction of tree b for input x.
- $\hat{y}$ is the final prediction of the Random Forest.

5) Error Out-of-Bag (OOB): El error OOB se estima sin necesidad de un conjunto de validación externo [see Eq.(8)]

$$\text{Error}_{\text{OOB}} = \frac{1}{n} \sum_{i=1}^{n} \mathbb{I}\left(\hat{y}_{\text{OOB}}^{(i)} \neq y_i\right) \tag{8}$$

where, $\hat{y}_{\text{OOB}}^{(i)}$ is the prediction for x_i using only the trees that did not use it in their bootstrap, and $\mathbb{I}(\cdot)$ is the indicator function.

IV. Result

A. Evaluation of Result

In Fig. 9, a radar chart, illustrates the performance of the classification model evaluated through eight key metrics, highlighting specificity (78%), AUC (86%), and accuracy (85%) as the highest values, indicating a strong ability to correctly identify negative cases and good overall accuracy. However, metrics such as recall (75%) and MCC (72%) show lower values, suggesting reduced effectiveness in detecting positive cases, possibly due to the presence of false negatives. Overall, the model demonstrates balanced performance, although there is room for improvement in sensitivity and the overall correlation between predictions and true classes.

In Fig. 10, ROC compares the performance of the Random Forest model for both classes, showing separate curves for class 0 (area under the curve = 0.98) and class 1 (AUC = 0.98), indicating a high discriminative ability of the model to distinguish between the two classes. The dotted diagonal line represents a random classifier, and the fact that both ROC curves lie significantly above this line demonstrates performance better than random chance. The inclusion of a decorative color bar on the right adds a visual element without interfering with the central interpretation, highlighting that the model achieves a favorable balance between the true positive rate and false positive rate for both classes.

The Precision-Recall curve shows the performance of the Random Forest model in predicting the positive class, with

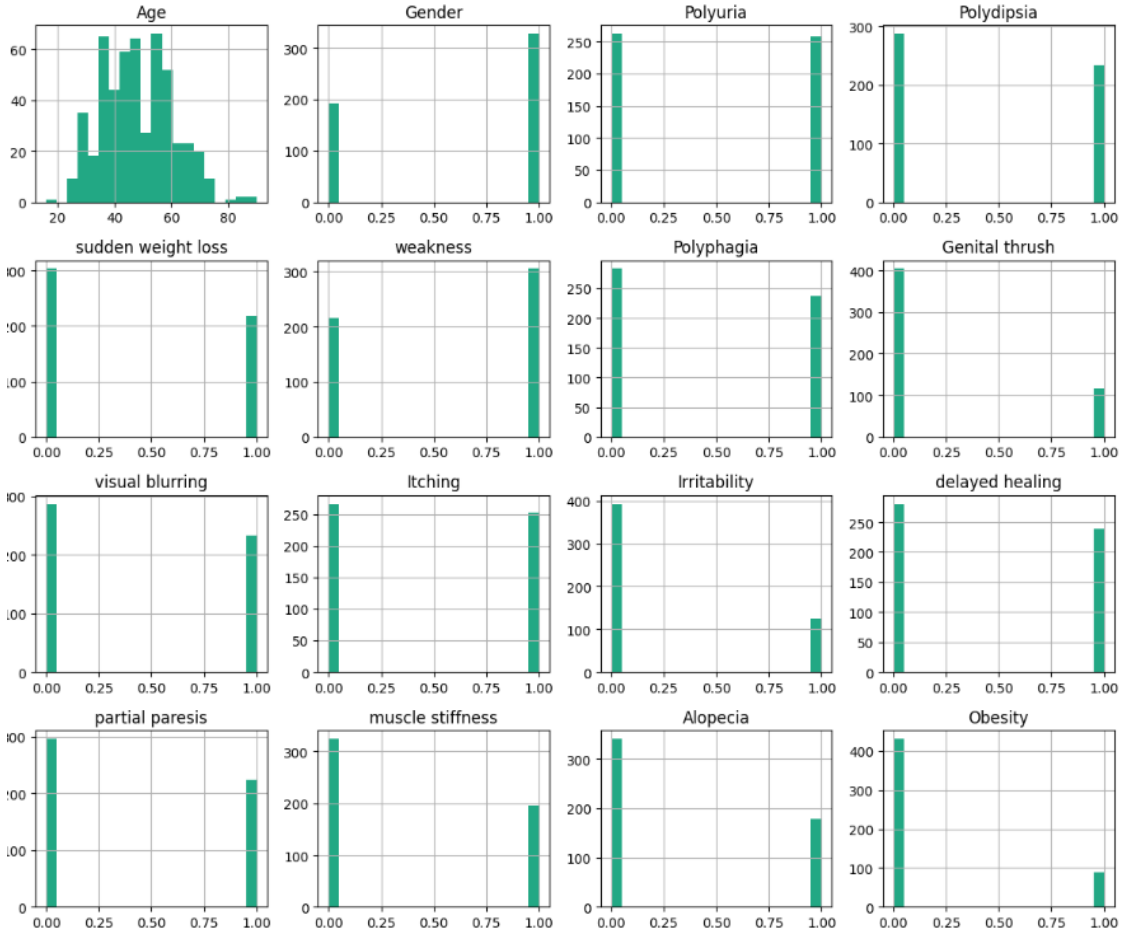

Fig. 6. Distribution of numerical variables.

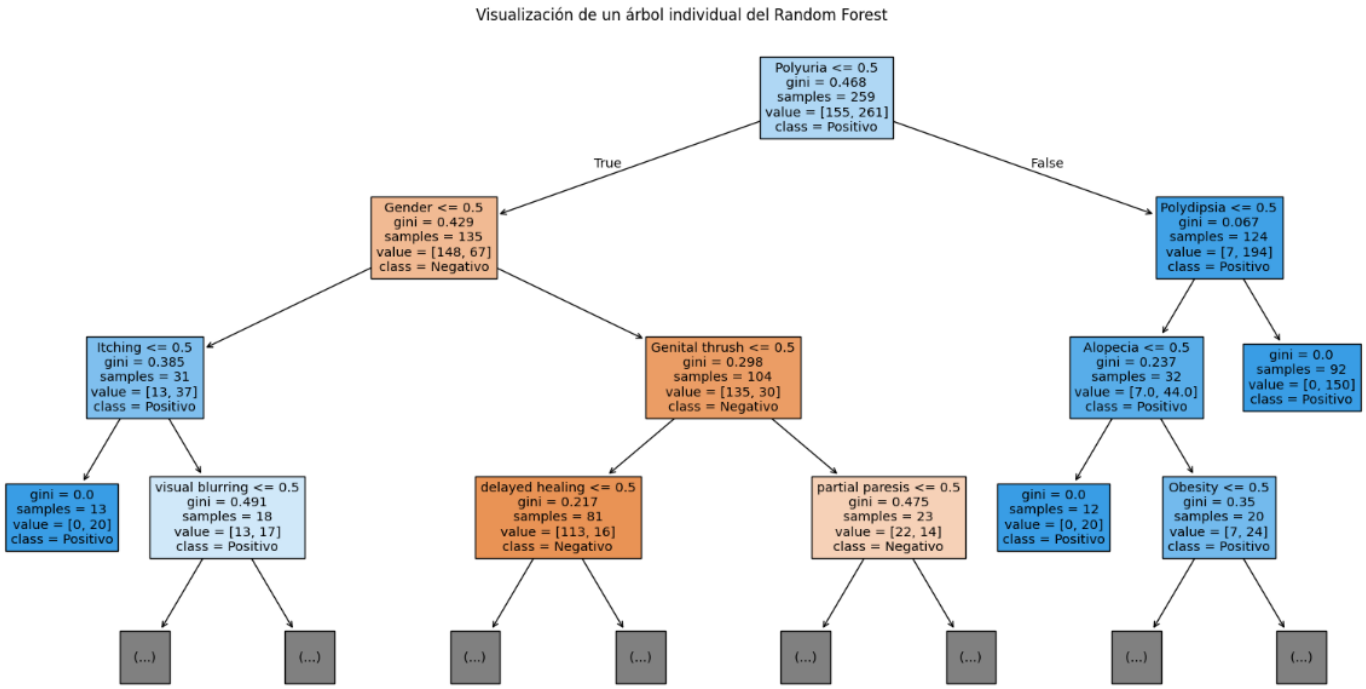

Fig. 7. Visualization of an individual tree from the random forest.

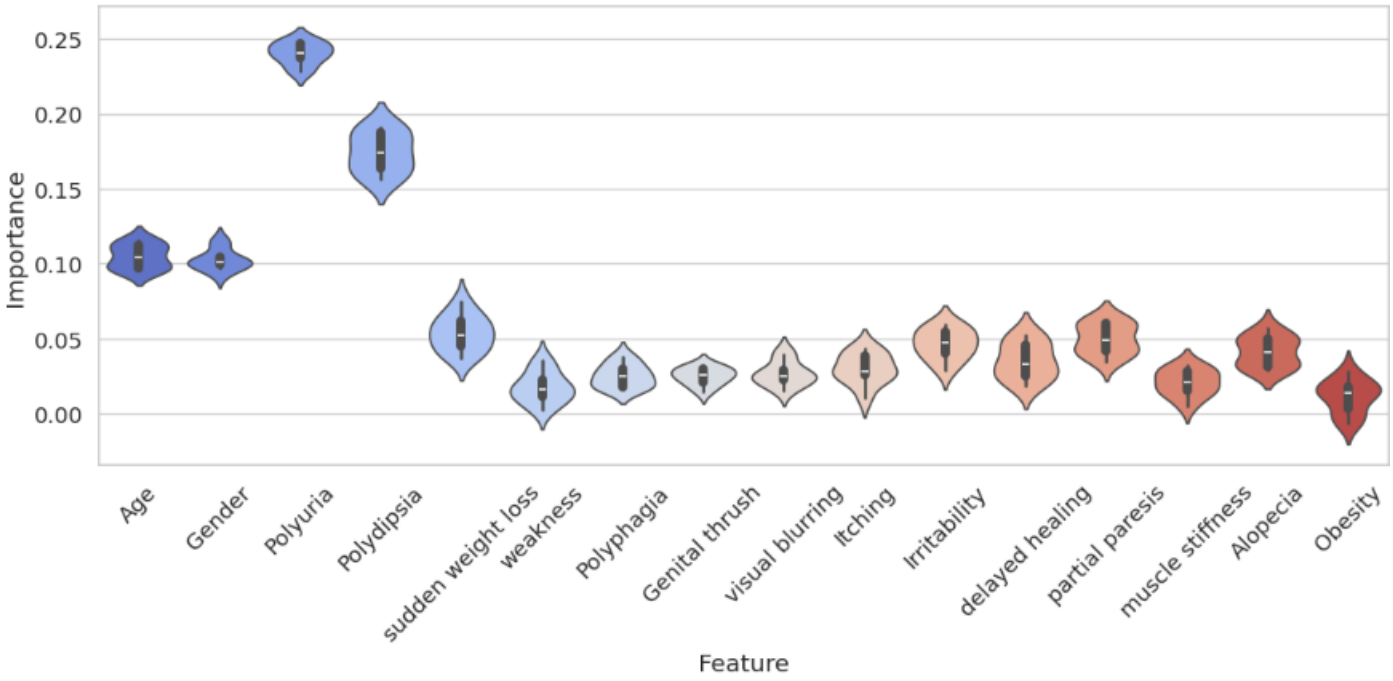

Fig. 8. Artistic visualization of importance - violin plot.

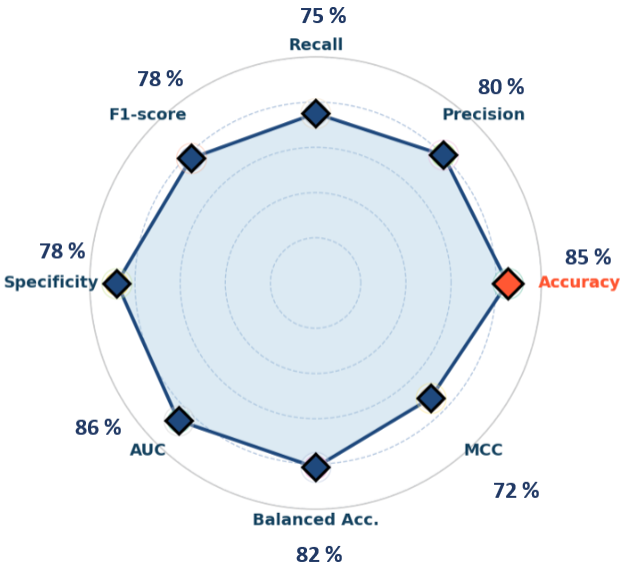

Fig. 9. Distribution of positive and negative classes training and test sets.

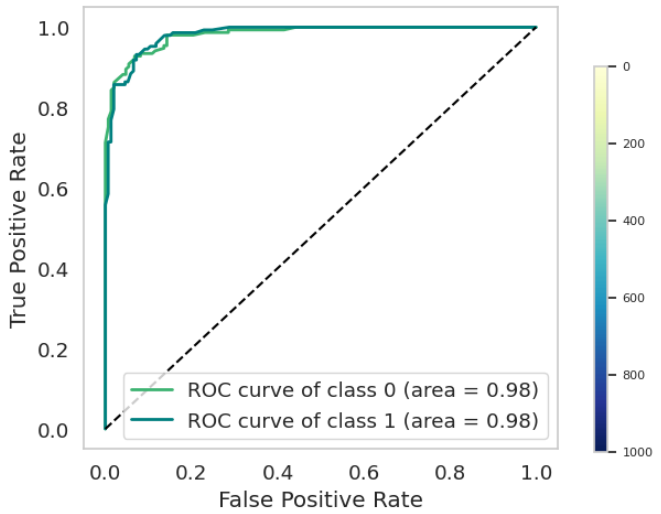

Fig. 10. ROC comparison of performance of Random Forest model for both classes.

an average precision (AP) of 0.98 for class 0 and 0.46 for a second simulated curve, representing a possible second class or a variation of the model. Both curves demonstrate a good balance between precision and recall, especially at higher recall levels, indicating that the model maintains good precision even when identifying most of the positives. This type of graph is particularly useful in contexts with imbalanced classes, as it highlights the model's ability to correctly detect positive cases without a high false positive rate. The presence of a decorative color bar does not affect the central interpretation, which confirms a robust performance of the model in terms of precision and recall, as shown in Fig. 11.

B. Comparison of Methodologies

This section presents a comparison of methodologies such as KDD, CRISP-DM, and SEMMA, with the aim of understanding why the KDD methodology was chosen for the project. It is important to note that certain criteria specified in the table were evaluated for this purpose. This summary can be examined in detail in Table I.

TABLE I. COMPARISON OF METHODOLOGIES: KDD, CRISP-DM AND SEMMA

Attribute	Methodology KDD	Methodology CRISP-DM	Methodology SEMMA
Structure and sequence	Includes selection, cleaning, transformation, and data extraction, as well as evaluation and application of knowledge, although its structure is not as rigorous.	It consists of six steps: business understanding, data understanding, data preparation, modeling, evaluation, and deployment.	Its five steps are sampling, exploration, modification, modeling, and evaluation.
Business orientation	Recognizes the importance of business objectives and seeks to learn in order to gain a competitive advantage.	Considers the objectives from the beginning and ensures useful results for decision-making.	Analyzes information considering the company's objectives and the use of the results.
Flexibility	Broad and less structured approach, offering a general framework for knowledge discovery.	Adaptable to various contexts and projects, extendable for commercial use.	Although it follows a predefined sequence, it is adaptable to different projects.
Interaction	Requires repetition but lacks an evident structure like CRISP-DM or SEMMA.	Iterative use of results, adapts to projects in constant evolution.	Step-by-step procedure adjustable throughout the process.

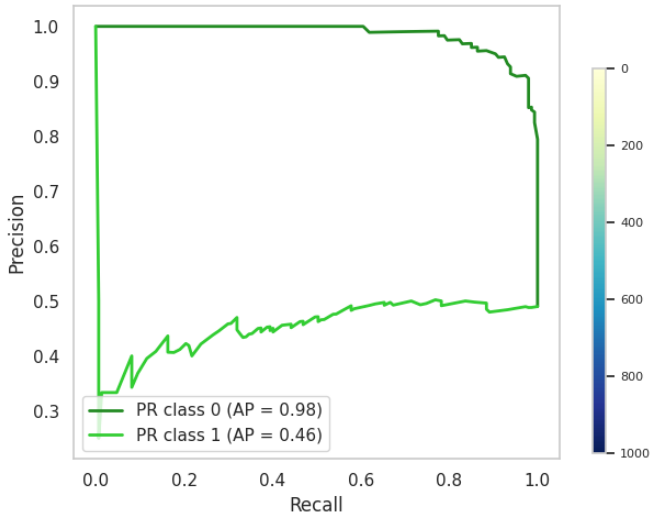

Fig. 11. Random forest precision-recall curve.

V. DISCUSSION

Initially, the research proposed by the author [12] focused on the analysis of systemic risk factors associated with diabetes mellitus, evaluating various machine learning models. The reported results included a 0% error rate during training, 100% precision, 76% accuracy, 53% sensitivity, and 80% specificity. In comparison, the model proposed in the present study, based on Random Forest, achieved superior metrics: 88% specificity, 82% precision, and 75% sensitivity, demonstrating better performance on critical variables.

Meanwhile, in [13], the authors directed their research towards diabetes classification through a comparative evaluation of multiple machine learning models, considering aspects such as maximum precision, performance with imbalanced data, and classification metrics. Although their results reached an AUC of 99%, surpassing the 86% AUC obtained in our model, it is important to highlight that both studies differ in objectives and methodological contexts, so direct comparison should be approached with caution.

Regarding the application of variable selection techniques, studies such as [16] and [17] employed evolutionary algorithms like PSO and GA to optimize the performance of models like Random Forest and XGBoost, achieving 86.12% precision and an AUC of 0.8612. In contrast, the present study obtained an AUC of 86% and accuracy of 85% without applying advanced selection techniques, evidencing the efficiency of the proposed model in terms of simplicity and performance. However, the 75% sensitivity obtained suggests opportunities for improvement in detecting true positives, making it advisable for future studies to consider integrating methods like GA to enhance this metric without compromising specificity.

Likewise, when compared to the study by [18], whose Random Forest model achieved a precision of 73.5% and an AUC of 79.1%, our approach showed superior performance (precision of 85% and AUC of 86%), which could be attributed to a better preprocessing strategy and variable selection. While Jawza identified variables such as fasting glucose, cholesterol, and creatinine as key determinants, our study used a comprehensive set of 9 clinical variables selected more systematically. Despite these differences, both works support the effectiveness of the Random Forest algorithm in predicting the risk of Type 2 diabetes.

On the other hand, the study by [21] addressed Type 2 diabetes prediction from an environmental and social perspective, incorporating 85 exposome variables related to the residential environment. Although they also used Random Forest and attribute selection techniques, their LASSO model showed better performance according to the logLoss metric. In contrast, our model, based solely on clinical variables selected via PSO and GA, achieved a precision of 85% and an AUC of 86%, reflecting good performance with lower complexity. This comparison highlights how context (clinical vs. environmental) can significantly influence model choice and interpretation of risk factors.

Regarding the approach based on ranked random forests (RRF) proposed by [25], focused on women over 25 years old and generating new features such as "Sum" and "Range", our study opted for optimization of clinical variables through Random Forest tuned with PSO and GA algorithms. Despite the difference in techniques, our model achieved better overall performance (precision of 86%, AUC of 86%), demonstrating the effectiveness of appropriate variable selection over feature engineering in specific populations. Similarly, the study by [27] applied Random Forest in a different context, aimed at modeling the clinical progression of Type 1 diabetes (T1D) through survival analysis, outperforming traditional models like Cox regression. Although the approach and pathology differ, both studies confirm the potential of machine learning as

a clinical support tool, whether in predicting T1D progression or early detection of T2D.

On the other hand, investigations such as those by [31] and [32] addressed class imbalance in the PIMA Indian Diabetes dataset through resampling techniques like SMOTE-Tomek and SMOTEENN. In contrast, our study did not apply balancing methods, focusing on the direct optimization of the Random Forest model. Despite this, competitive results were obtained, with an accuracy of 85%, an AUC of 86%, and a specificity of 88%, suggesting that, in certain scenarios, a robust model can compensate for the lack of advanced balancing techniques while maintaining high predictive performance.

Finally, the author [33] developed an algorithmic model focused on early prevention of diabetes, achieving substantial improvements in early disease identification. However, when compared with our model, evaluated using Random Forest, superior metrics in precision, sensitivity, and accuracy stand out, demonstrating the robustness of our approach and its potential applicability in clinical settings where early detection is critical for timely intervention.

VI. Conclusion

Diabetes mellitus is a chronic metabolic disease that, if not detected and treated in time, can lead to severe complications such as kidney damage, retinopathies, cardiovascular diseases, and neuropathies. In view of this issue, the development of a predictive model based on supervised machine learning algorithms was proposed, specifically using the Random Forest algorithm. For the construction of the model, a public database extracted from the Kaggle web platform was used, containing relevant clinical and demographic variables. The model development was based on the KDD (Knowledge Discovery in Databases) methodology, encompassing the phases of data selection, preprocessing, transformation, data mining, and results evaluation. Each of these stages was key to ensuring the quality of the predictive model and its applicability in real scenarios.

The results obtained through model validation show significant performance metrics: a specificity of 78%, an AUC (Area Under the ROC Curve) of 86%, an accuracy of 85%, a recall of 75%, and a Matthews correlation coefficient (MCC) of 72%. These metrics reflect a good balance in the model's ability to correctly classify both diabetic and healthy individuals, with particular emphasis on specificity, indicating a low false positive rate. The predictive model developed using Random Forest proved to be effective and reliable for the early detection of diabetes. Its implementation could serve as support in the clinical setting for preventive decision-making and population monitoring, thus contributing to improving prognosis and quality of life for individuals at risk.

Finally, our research also aims to contribute to future studies related to the addressed topic. Its implementation can be a starting point to combine the obtained results with more advanced approaches that strengthen existing knowledge and enable the development of useful and applicable solutions for organizations focused on the treatment of diabetes mellitus. The analysis of large volumes of data, through approaches such as Big Data, can significantly enhance the interaction with the predictive model developed using the Random Forest algorithm. This model can be integrated with massive information storage systems, such as Data Warehouses, to improve accuracy in identifying relevant patterns associated with the disease. Likewise, the developed models could be exposed through APIs, allowing their consumption by applications targeted at users with this pathology, refining the model logic according to the different clinical scenarios observed. However, a limitation identified in the present study lies in the use of a specific dataset, which restricts the model's ability to be generalized and applied across different clinical contexts. Additionally, the accuracy of the predictive model may be affected by the quality and completeness of the data used. In this regard, future research should consider the integration of larger, more diverse, and up-to-date datasets in order to enhance the robustness, reliability, and applicability of the proposed approach.

Phishing Simulation as a Proactive Defense: A Customizable Platform for Training and Behavioral Analysis

Abdulrahman Alsaqer, Hussain Almajed, Khalid Alarfaj, Mounir Frikha
Department of Computer Networks and Communications, College of Computer Sciences and Information Technology,
King Faisal University, Al-Ahsa, 31982 Saudi Arabia

***Abstract*—Phishing is one of the most persistent threats, but a lot of awareness programs still use generic, static training. This paper fills in the gap identified above by existing studies through the introduction of a phishing simulation platform that provides personalized, role-based simulation with real-time behavioral tracking. It is a multi-channel delivery (Email, Short Message Service (SMS), (WhatsApp) and can dynamically generate messages using placeholders to simulate realistic attack scenarios. User interactions are visualized on an integrated dashboard to let organizations judge the individual's risk and provide immediate awareness feedback. Due to ethical restrictions, real user testing could not be performed, and the system was tested using simulated data found to work with a cloud-ready front end. The solution shows great potential for being adopted by enterprises due to its potential to adopt an approach towards cybersecurity training in a more adaptive and engaging way.**

***Keywords*—Phishing; simulation; awareness; analytics; cybersecurity**

I. Introduction

Phishing is among the most persistent and damaging of today's cyber threats, and it is responsible for a great deal of the world's data breaches and financial losses. Data from recent studies shows that more than 30 percent of cyber security attacks and billions are lost owing to credential thefts, ransomware, and fraud [1], [2]. Phishing persists even though organizations make investments in technical defenses such as email filters, spam detectors, and firewalls since they leverage the human element, including trust, emotion, and behavioral habits [3], [4].

Generic security awareness training provided by most organizations rarely changes user behavior or provides a contextual learning experience [1], [5]. These methods ignore individual vulnerabilities as well as fail to validate the simulation of realistic attack scenarios. Traditional training methods have been found to be ineffective in stopping users from clicking on links to phishing [2].

Phishing simulations are a more dynamic and effective way to address these gaps. Simulations are used by simulating real-world attacks in a controlled environment in order to build awareness and help the users produce proper responses to the threats [6], [3]. However, most of the existing platforms only support email phishing, do not support mobile-based attacks such as SMS or WhatsApp phishing, and do not collect or analyze user behavior for adaptive training [4], [7].

We further propose a new approach, which is a customizable, multi-channel phishing simulation platform with behavioral analytics. Our platform is unlike conventional tools as it supports simulation through email, SMS, and WhatsApp and tracks user interactions in terms of response time, clicks, and risk metrics as per role. Motivated by recent research, we propose a platform that makes cybersecurity training more appealing, adaptive, and conforming to the actual needs of an organization.

A. Background on Phishing Threats and their Evolution

Phishing is a deceptive scheme employed by cyberattackers who manipulate users into providing sensitive information to them, such as login credentials, financial information, personal information, etc. Fig. 1 illustrates an overview of phishing attacks. In the past, phishing was more dependent on poorly written emails with generic messages and links that were suspicious. However, these early attacks were easy to detect because there were visible red flags such as spelling errors and strange formatting [3]. Phishing has now become more complex and a multi-channel threat.

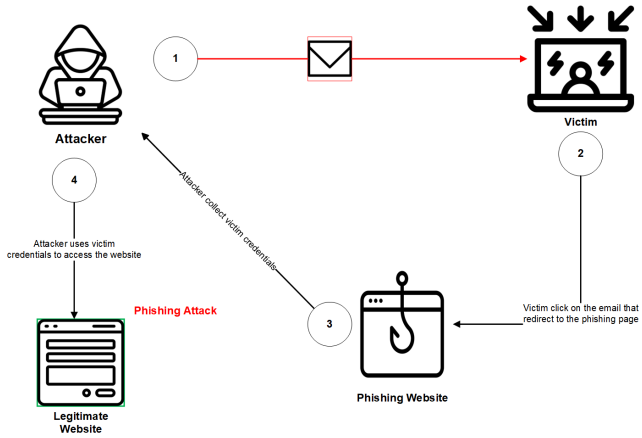

Fig. 1. Overview on phishing.

Phishing campaigns have gone beyond email and now involve SMS (smishing), social media platforms, messaging apps such as WhatsApp, and even phone calls Voice phishing (Vishing) to reach users in more personalized ways [6], [7]. Email spoofing, brand impersonation, and the use of HTTPS-secured malicious websites bring the ability to distinguish

between legitimate and fraudulent communications to the level of sophistication [4], [8]. This evolution of spear phishing takes the next step by sending a tailored message to a specific person based on his/her job role, behavioral patterns, or personal information scraped from public sources [1], [2].

All these advancements make it increasingly easy for phishing attacks to appear more convincing and more difficult to detect, even for a trained group. Psychological triggers, such as urgency, authority, or fear, are being increasingly used by attackers to induce an immediate action without critical thinking [3], [2]. Phishing methods are changing all the time to get around technical filters and to exploit human vulnerabilities, and traditional security measures are not enough. Finally, it is necessary for organizations to adopt proactive, scenario-based training models that resemble actual attack patterns and focus on the behavior of the users [5], [9].

B. Behavioral Importance and Limitations of Current Awareness Training

With the advancement of technical defense such as firewalls, intrusion detection systems, and anti-phishing filters, the attacks of phishing are still going on and thrive due to human nature, not the system itself. In fact, we know from studies that employees still remain vulnerable to phishing emails and clicking malicious links by habit, curiosity, or urgency even after formal training sessions [1], [3]. Because human decision-making is complex and unpredictable, it is difficult to 'patch' users like one would patch the software vulnerabilities.

Common awareness programs, on the other hand, operate on the basis of one-time, passive training modules that do not adapt to a changing threat or lead to practicing good security habits [5]. Typically, these programs are rushed through or forgotten and have limited long–term impact on user behavior [3]. On the other side, interactive and ongoing training approaches, especially phishing simulations, have been more effective in creating user awareness and response [5], [4]. Organizations can provide experiential learning through the simulation of real-world attack scenarios, reinforce the correct response, and immediately provide feedback on mistakes through the simulation.

Most importantly, behavioral-based training allows organizations to monitor user engagement, identify risky behavior patterns, and push targeted interventions to the highest-risk users [1], [9]. Because phishing attacks have become more targeted and more realistic, having a human firewall in place is more important than ever and means adaptive training is key. The shift from compliance-based awareness to behavior-driven education is the one that will not only help to build organizational resilience to social engineering threats but also other types of security threats [5], [9].

C. Purpose of the Study

This study aims to develop a customizable phishing simulation platform based on the limitations of traditional phishing awareness programs that deliver realistic, multi-channel attack scenarios and analyze users' behavior to improve the training outcome. Unlike static training, this platform will interact with users through simulations sent through email, SMS, and WhatsApp, which mimic real-world phishing vectors. It also includes behavioral analytics that tracks user actions, including click rates, response times as well as reporting behavior. These insights could be leveraged to provide subsequent training with a basis in individual risk profiles such that high-risk users are supported. This study combines simulation, customization, and behavioral analysis to offer proactive, adaptive, and user-centric solutions that improve organizational resilience against phishing attacks.

D. Research Questions

The following research questions are formulated to guide the development and evaluation of the proposed phishing simulation platform.

- RQ1: What are the effects of phishing simulations on long-term cybersecurity awareness and a decrease in risky user behaviors?
- RQ2: When phishing attacks that simulate an environment are devised, what communications and behavioral patterns emerge, and how can such patterns be used to create personalized training exercises for those individuals?
- RQ3: What makes a customizable simulation platform better than one generic simulation fit for all awareness programs in terms of engagement as well as learning outcomes?
- RQ4: What difference does user engagement and threat recognition of a mobile phishing simulation (such as SMS, Whatsapp) compare to an email phishing simulation?
- RQ5: What are effective methods for using behavioral analytics and real-time feedback to change the phishing training approach as well as enhance long-term awareness and response accuracy?

The current paper explores the structure of the system and experimental application of simulated data. Subsequent stages will be real-user validation.

E. Paper Structure

The rest of this paper is organized as follows: Section II first reviews related work and then describes the limitations of existing phishing awareness solutions. In Section III, research methodology and the process to identify the system requirement is described. In Section IV, the proposed solution is presented along with system objectives and architectural overview. In Section V, the system design is detailed with diagrams, components and workflow. In Section VI, the system's contribution to the research questions is discussed. Section VII discussed key challenges met during the development. The paper concludes in Section VIII and describes the future work directions.

II. Literature Review

In order to get a more effective solution, there are recent developments that must be understood within the realm of phishing awareness and simulation-based training. Twelve studies were reviewed as relevant that were published between

2021 and 2024. The number of publications grew in the year 2022, as shown in Fig. 2, which shows that phishing detection and user-focused cybersecurity training is receiving increased academic interest. This paper suggests the strengths and limitations of existing approaches with an emphasis on simulation techniques, analysis of user behavior, and delivery through the multi-channel. The results of this review guided the design decisions for the proposed phishing simulation platform.

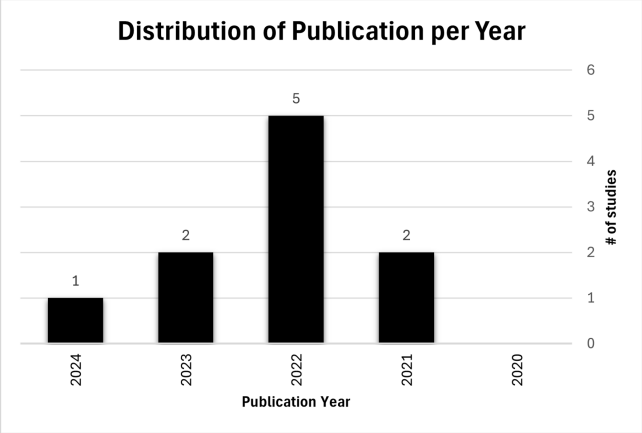

Fig. 2. Papers per year of publication.

Yeng et al. [10] develop a framework for exploring incentive-based methods to reduce phishing susceptibility in the healthcare sector through a review and in-the-wild simulation. The authors analyzed 16 tools and six previous simulation studies using hybrid methodologies combining surveys and field tests. Findings highlight the dominance of deception-based phishing, where employees responded most to simulated attacks involving malicious links. However, the research reveals that while behavioral theories like protection motivation have been examined, incentive-based strategies remain largely unexplored. Ethical concerns were prominent, especially regarding deceptive simulations. Although the framework provides practical direction for future training implementations, the study is limited by its lack of real-world validation of incentive models. This reveals a clear gap: existing healthcare phishing simulations do not incorporate adaptive, personalized, or multi-channel behavioral incentives.

Sutter et al. [11] investigate influential factors of phishing awareness training by analyzing over 31,000 participants across 144 phishing simulations. It introduces a data-driven machine learning model that predicts email difficulty perception using structural and Natural Language Processing (NLP) features. Results show that most users avoided credential-based phishing after 12 weeks of training and that user-specific training is more effective than broad, group-based approaches. The model enables pre-deployment assessment of email "convincing power," addressing a key challenge in designing fair simulations. However, the study is limited to email-based vectors and lacks long-term behavior tracking. While it advances adaptive difficulty estimation in simulations, it does not extend beyond email, omits behavioral logging, and offers no user feedback customization.

Ahmad et al. [12] presents a web-based phishing simulation platform integrated with embedded learning tools to enhance user awareness and real-time response. The system includes user roles, scenario-based phishing modules, and a database-backed structure that enables immediate engagement during simulated attacks. Through iterative testing and deployment, the study demonstrates significant improvement in users' ability to detect phishing attempts. Embedded learning — training users in the context of their actual digital environments — proves more effective than standalone awareness sessions. However, the study focuses exclusively on email phishing and does not include data on user behavior patterns post-training or adaptivity based on user history. This gap emphasizes the need for customizable, behavior-tracked multi-channel simulations.

Kävrestad et al. [13] evaluates the effectiveness of two phishing awareness training methods—game-based learning and Context-Based Micro-Training (CBMT)—through a simulated experiment using eye-tracking. Participants were asked to detect phishing emails before and after undergoing training. Results show that CBMT, which delivers short and relevant content at the moment of need, led to more secure user behavior than game-based learning. Nonetheless, despite training, many participants still failed to identify phishing attempts, highlighting that training alone is insufficient. The research is limited in scale and scope, focusing solely on desktop-based email simulations with no integration of adaptive or personalized feedback. This reinforces the research gap addressed in the current work: the need for a multi-channel, customizable phishing simulation system that integrates behavioral analytics and adaptive interventions beyond static training formats.

Chatchalermpun and Daengsi examine the use of simulated phishing attacks to improve cybersecurity awareness among users in a real-world training context [14]. Conducted as a case study, the simulation helped measure participants' susceptibility and learning outcomes following exposure to various phishing email templates. The study highlights increased awareness and reduced click rates post-simulation, suggesting that experiential exposure is beneficial. However, the simulation was limited to credential-based email phishing and did not assess behavioral change over time or account for alternative phishing channels such as SMS or voice. Moreover, the system lacks embedded feedback mechanisms or personalization. These limitations underscore the importance of developing a simulation environment that not only mimics real attacks but also tracks behavioral metrics and offers adaptive content across multiple platforms, as proposed in this research.

Canham et al. [15] introduce Phish Derby, a gamified phishing awareness initiative conducted at a U.S. university designed to explore employee motivation and reporting behavior in phishing simulations. Participants competed to detect phishing emails, with rewards incentivizing participation. Key findings reveal that prior simulation performance, age, and device consistency influenced reporting accuracy. Interestingly, users with high extraversion or agreeableness scored lower, while those with a learning-oriented mindset underperformed compared to reward-driven peers. The study effectively highlights how individual traits affect detection performance. However, it is narrowly focused on desktop email reporting and omits broader behavior tracking or multi-platform phishing vectors. The absence of post-simulation adaptive learning or customizable challenge levels marks a

research gap that this project addresses through its dynamic, behavior-aware simulation design.

Tinubu et al. [16] introduces PHISHGEM, a mobile game-based learning application developed to promote phishing awareness through interactive gameplay. The game engages users in scenarios that mimic phishing attacks, requiring them to identify deceptive messages and make real-time decisions. Evaluations show significant improvements in user awareness, particularly among younger participants with high mobile engagement. The gamified approach enhanced motivation and retention, suggesting a promising direction for immersive learning tools. However, the study is limited to mobile platforms and does not capture longitudinal behavioral data or cross-channel phishing patterns. Additionally, the training lacks real-world simulation integration and adaptive feedback. These omissions highlight the need for a multi-device, behavior-tracked platform—an aspect central to the proposed research's focus on customizable, context-aware simulation environments.

Yeoh et al. [17] presents a combined approach using simulated phishing attacks and embedded training to raise awareness among organizational users. The campaign involved multiple simulation rounds, each followed by immediate educational interventions within the user's workflow. This embedded model led to measurable reductions in click-through rates and improved user recognition of phishing content over time. The study emphasizes the effectiveness of just-in-time learning, contextual reinforcement, and iterative exposure. However, the scope is confined to email-based simulations and lacks adaptability to individual behavior or phishing variants beyond email, such as voice or SMS. Furthermore, it does not log behavior traits or personalize content delivery. These limitations reinforce the necessity for an adaptive, multi-channel training model with behavioral analytics, which this research aims to introduce.

Ciupe and Orza report on a large-scale phishing simulation conducted at a higher education institution involving over 20,000 users [18]. The campaign used multiple social engineering tactics delivered via Office 365 services, simulating realistic attacks to evaluate click rates, report behaviors, and user confidence. Results indicate a varied level of cybersecurity awareness, with participants showing inconsistent ability to detect phishing attempts. The study emphasizes the value of experiential learning and reflective feedback but acknowledges the ethical challenges of covert simulations and the limitations of one-size-fits-all training. Importantly, the simulation lacked multi-channel attack vectors, behavioral tracking, and individualized training paths. These gaps underscore the importance of customizable and adaptive simulations with analytics-based feedback loops.

Rizzoni et al. [19] analyze phishing simulations conducted in a large Italian hospital with over 6,000 staff members. Three campaigns were launched, comparing responses to generic versus customized phishing emails. Results showed a markedly higher success rate for personalized attacks, demonstrating that contextual cues significantly influence user susceptibility. The study stresses that phishing simulations can be effective but also complex to execute, particularly in sensitive environments like healthcare. Challenges included operational disruptions, resistance from staff, and ethical concerns about using deception. While it confirms the value of customization in phishing training, the study was restricted to static email scenarios and lacked any adaptive learning paths, post-simulation behavior tracking, or integration with non-email phishing vectors such as SMS or voice. These omissions highlight critical limitations that the current research addresses through its proposed dynamic, multi-channel, and behavior-aware simulation framework.

Table I shows the summary of existing works in phishing simulation.

TABLE I. SUMMARY OF REVIEWED PHISHING SIMULATION STUDIES AND IDENTIFIED GAPS

Paper	Objectives	Identified Gap	Method Used
Yeng et al. [10] (2023)	Incentive-based email phishing simulation in healthcare.	Lacks adaptive training and multi-channel support.	Email-based phishing
Sutter et al. [11] (2022)	Email difficulty prediction model using machine learning.	No behavioral tracking; email-only channel.	Email-based phishing
Ahmad et al. [12] (2023)	Embedded simulation tools with real-time feedback.	No user behavior adaptation; lacks mobile simulation.	Email-based phishing
Kävrestad et al. [13] (2022)	Eye-tracking study comparing contextual micro-training and games.	No role customization; no long-term behavior analysis.	Email-based phishing
Chatchalermpun and Daengsi [14] (2021)	Real-world email-based simulation campaign.	No feedback personalization; no multi-channel phishing.	Email-based phishing
Canham et al. [15] (2022)	Gamified competition to improve phishing reporting.	No adaptive content; email-only; no analytics integration.	Email-based phishing
Tinubu et al. [16] (2022)	Mobile game for phishing awareness and education.	Lacks behavioral tracking and role-based simulation.	Mobile game-based
Yeoh et al. [17] (2021)	Embedded training after phishing simulations.	No adaptivity or multi-channel simulation.	Web-based email phishing
Ciupe and Orza [18] (2024)	University-wide phishing simulation via Office 365.	Static training content; no personalized feedback.	Web-based email phishing
Rizzoni et al. [19] (2022)	Phishing simulation in a hospital using custom messages.	No behavior tracking or dynamic learning; ethical constraints.	Web-based email phishing

III. RESEARCH GAP AND CONTRIBUTION

Despite increased interest in phishing awareness strategies, current literature continues to reveal foundational limitations that hinder effective long-term defense.

1) Limited multi-channel phishing simulations: Most studies focus exclusively on email-based phishing simulations, overlooking other attack vectors such as SMS and messaging platforms commonly exploited by modern attackers.

2) Short-term awareness measurement only: The majority of studies evaluate user awareness immediately after simulation or training without assessing long-term retention or behavioral change over time.

3) Lack of targeted phishing training for diverse workforce types: Existing platforms and studies often adopt a one-size-fits-all model, failing to deliver tailored simulations or feedback based on role, risk exposure, or behavioral patterns.

A. Contribution

This research addresses the above gaps by developing a next-generation phishing simulation platform with the following contributions:

1) Extending beyond email: The platform supports phishing simulations across Email, SMS, and WhatsApp, reflecting the evolving multi-channel nature of phishing threats.

2) Customization for diverse needs: The system enables simulation customization based on organizational roles and contextual risks, providing more relevant and effective training experiences.

3) Holistic, proactive training: By combining real-time phishing simulations with behavioral insights and feedback, the platform supports continuous learning and improved cybersecurity readiness.

IV. Proposed Framework

In order to address the identified limitations in existing phishing training systems, this section proposes a framework for a customizable phishing simulation platform. Phishing simulation across multiple communication channels (Email, SMS, WhatsApp) intends to collect user interaction data and provide behavior-based feedback. This constitutes the conceptual basis for system implementation and evaluation. The framework is built around four main components: simulation design, message delivery, behavior tracking, and adaptive training.

A. Objectives

The main goal is to develop a Comprehensive, customizable, and behavior-aware phishing simulation framework that is inclusive of traditional limitations of existing phishing awareness training methods. Specifically, the framework aims to:

1) Simulate multi-channel phishing attacks: Deliver many realistic phishing attack scenarios via delivery channels of Email, SMS, and WhatsApp, just as an attacker would do today.

2) Enhance user awareness through real-time feedback: Redirect users that interact with phishing links immediately to awareness pages that have educational content relating to the type of attack, thus enhancing learning retention and behavioral change.

3) Track and analyze user behavior: Observe user interaction and log user interaction such as click activity and response time to know the phishing susceptibility and behavioral trend of the user.

4) Support role-based simulation targeting: Allow for customizing simulations by organizational role to allow training to be more relevant to the user's context of work and risk exposure.

5) Classify risk based on role clicks interaction: The organization's performance is categorized as per the risk levels like high, medium, and low, and identifies which role may need more training.

6) Generate actionable reports for administrators: To provide detailed analytics and reports via a centralized dashboard to help plan all the campaigns for security teams to track campaign performance, compare role-level results, and make a decision.

7) Design for scalability and future integration: It creates a framework that is made modular and extendable enough so that new attack vectors or learning mechanisms can be integrated in the future

B. System Design

The creation of a phishing simulation platform is based on modularity, scalability, and tracking of behavior. The system is composed of several components that, when combined, provide users with the ability to send simulated phishing attacks, capture user responses, and generate reporting. It ensures separation between the admin functionalities, simulation engine, tracking mechanism, and awareness content.

C. Context Diagram

A high-level overview of the core entities involved in the phishing simulation platform and their interactions are provided by the context diagram. It focuses on how the administrative action, user action, and message delivery process operate on the system. As shown in Fig. 3 there are three main entities that the system interacts with:

1) Administrator: It creates user roles, adds users, designs phishing templates, configures simulation campaigns, and initiates simulation runs to manage the system. Upon execution, the admin gets statistics and behavioral data for analysis.

2) Target users: The system sends phishing messages to you through email or SMS. If a phishing link is clicked, they are redirected to an awareness page, and their interactions (e.g., clicking links, time-to-response) are monitored.

3) Mobile and email channel Application Programming Interface (API): Acts as a delivery mechanism for sending phishing messages across multiple communication channels. It handles message dispatch requests from the system and returns delivery status updates.

The Phishing Simulation Awareness System manages all logic inside of the system, ranging from template customization, tracking link generation, data logging, user behavior analysis, and real-time redirection to awareness pages.

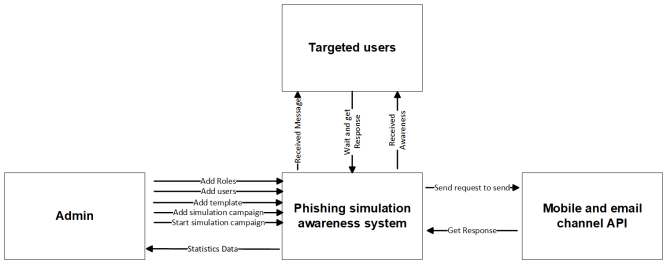

Fig. 3. Context diagram of the phishing simulation awareness system.

D. Use Case Diagram

The functional overview of the use case diagram answers the question of how the primary actors, which are the administrator and the targeted user, interact with the phishing simulation platform. The system is described from campaign configuration through to user interaction all the way to delivery of user feedback.

Fig. 4 shows the use case diagram, and the administrator responsibilities are listed in Table II.

TABLE II. ADMINISTRATOR USE CASES

Functionality	Description
Manage Roles	Decide what different user groups (e.g., Sales, Marketing) should be able to simulate.
Manage Users	Set and assign users to pre-defined roles for campaign targeting.
Manage Templates	Build Email, SMS, and WhatsApp phishing templates for delivery along with placing holder to substitute with a link generated by the system and a targeted user name.
Create Campaigns	Create phishing simulations and link them to roles.
Launch Simulation	Initiate an immediate phishing simulation.
View the Campaign List and Details	Check on all current and past campaigns with status updates.
View Tracking Data	Look into link clicks and response times of users.

The targeted user responsibilities are listed in Table III.

TABLE III. TARGETED USE CASES

Functionality	Description
Receive Message	The assigned communication channel is used to message users with phishing messages.
Click the Link	on the interaction with the phishing link, the user behavior is tracked.
View Awareness Page	Upon clicking a phishing link, the user is automatically directed to an awareness page for immediate feedback.

From this diagram, the system will cover all functional requirements of the system as well as support interaction between administrative users and end-user participants.

E. System Architecture

The proposed phishing simulation platform uses a layered and modular architecture to make sure that the system is scalable, maintainable, and secure. As depicted in Fig. 5, the system consists of many interconnected components that are partitioned into six key layers.

1) Frontend layer – admin dashboard: Administrators have a secure, web-based interface to this layer. It enables:

- User and role management.
- Template design.
- Campaign creation and tracking.
- Real-time navigation across simulation statistics.

The dashboard is constructed by modern web technologies and hence responds and provides intuitive interaction.

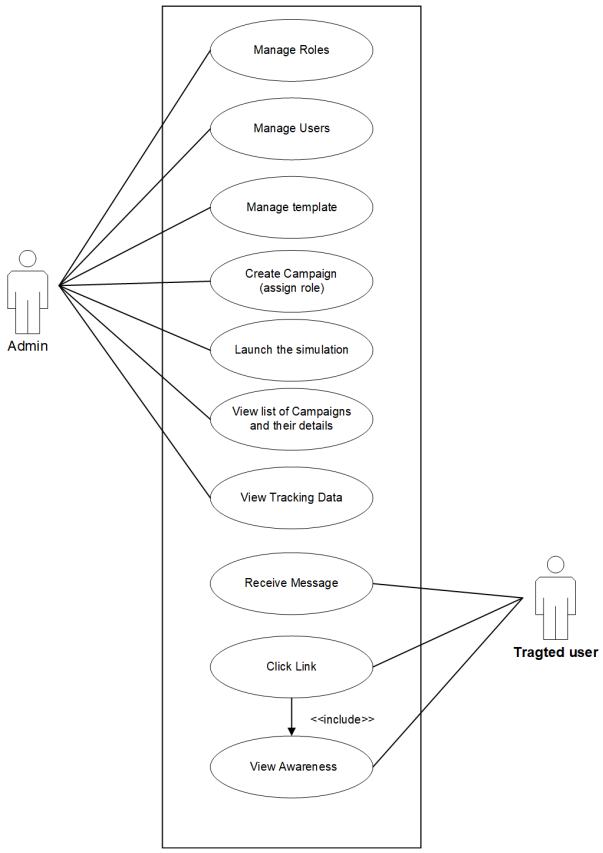

Fig. 4. Use case diagram of the phishing simulation platform.

2) Backend logic layer: Implemented using React.js, this layer:

- Handles campaign logic.
- Creates a unique phishing link for each user template pair.
- Logs user activity (clicks, timestamps).
- Assigns behavior-based risk scores.

3) Communication API layer: It is responsible for sending phishing messages via using resend API for sending email and looking for SMS and Whatsapp.

This layer communicates with the backend, acting as a middle layer to dispatch phishing content and log delivery status using a secure request-response mechanism.

4) Tracking engine:

- It creates individualized URLs for every user.
- To capture the users' actions, such as response time and frequency of clicks.

5) Awareness module: In case of a user interaction with a phishing simulation:

- This redirects them to a tailored awareness page.
- The page provides microlearning content or training tips delivered just in time to reinforce security behavior.

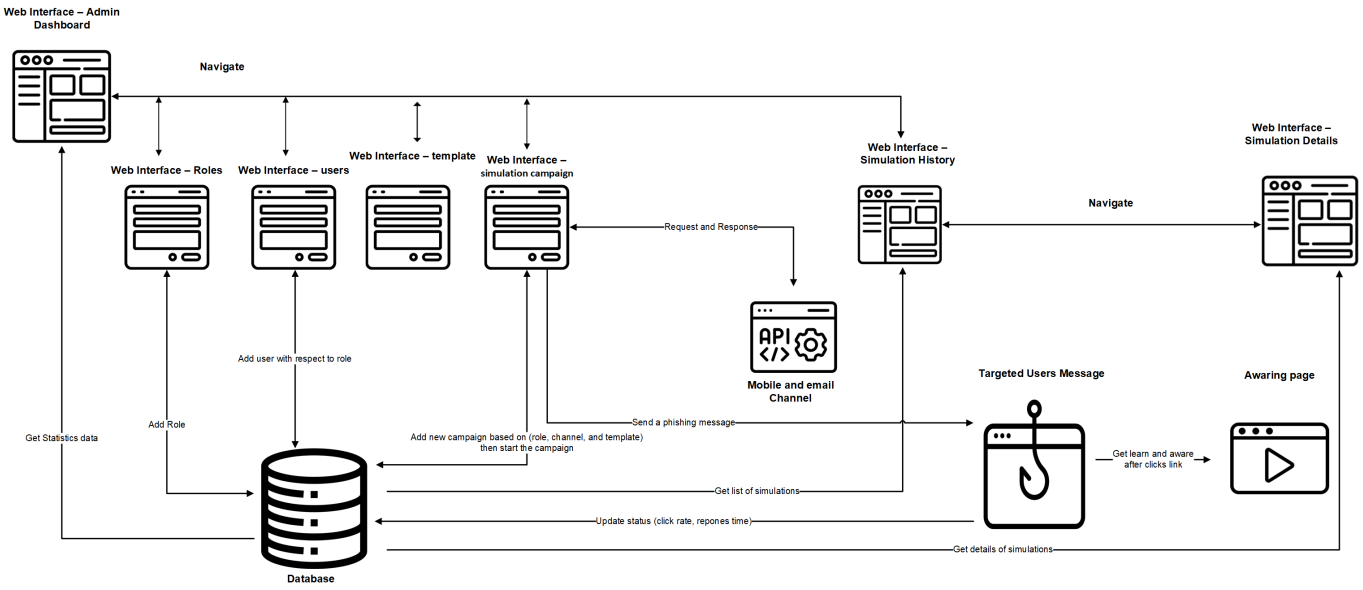

Fig. 5. System architecture of the phishing simulation platform.

6) Database layer: All simulation data, including is stored and secured on the system.

- User roles and profiles.
- Campaign settings and templates.
- Click activity and behavioral logs.

F. Database Design

Designing the database for the phishing simulation platform is based on the normalized relational model to ensure data integrity, efficient querying, and scalability. It is capable of catching main entities like users, roles, simulations, templates, and behavior tracking. In this section, we present an Entity Relationship (ER) model at a high level, as well as the corresponding relational schema to be used for the implementation.

1) ER Diagram: As shown in Fig. 6, the logical structure of the data used in the simulation system is modeled by the ER diagram.

Table IV captures the key relationship between the entities involved.

TABLE IV. THE RELATIONSHIPS BETWEEN KEY ENTITIES.

Entity	Goal
Users	those who are phished in phishing simulations. A user can be assigned to one of the roles.
Roles	Determine user categories (e.g., HR, IT) to target for simulation.
Phishing Templates	Using pre-defined messages for each campaign based on their type and delivery channel.
Simulations	The admin will create a campaign using templates and targeting specific roles.
Simulation Tracking	Tracking individual users' interactions with phishing simulations (delivery status, response time, and click behavior).

Key relationships include:

TABLE V. PHYSICAL IMPLEMENTATION OF THE PHISHING SIMULATION DATA MODEL WITH PK AND FK RELATIONSHIPS

Table	Role
Users	Contains basic user details along with the details of role association.
Roles	The definition of roles used to group users.
Phishing Templates	Stores the message content, channel type, and creation date.
Simulations	Metadata about the campaign, including channel, name, and the link to templates.
Simulation Tracking	Records user responses in the form of click_time (initial NULL value), track_id, and delivery status.
Simulations_Targets	Connects simulations to targeted roles.

- One-to-many relationship between Roles and Users.
- Many-to-one between Simulations and Templates.
- Users and Simulations, they are many-to-many relationships, and we will resolve this through Simulations Tracking.

2) Database schema diagram: Fig. 7 illustrates the way the ER model is implemented using the Structured Query Language (SQL) relational tables. It describes what the data types are, the Primary Keys (PK) and Foreign Keys (FK) throughout the system.

The schema adheres to the normalization principles of the Third Normal Form (3NF), aiming at eliminating redundancy and ensuring relational consistency. It makes possible user performance tracking, report generation, and behavior analysis at individual and group levels. Table V represents the tables and role of each for the system.

G. Workflow Diagram

The phishing simulation platform is a streamlined, direct execution workflow that keeps administrators able to initiate

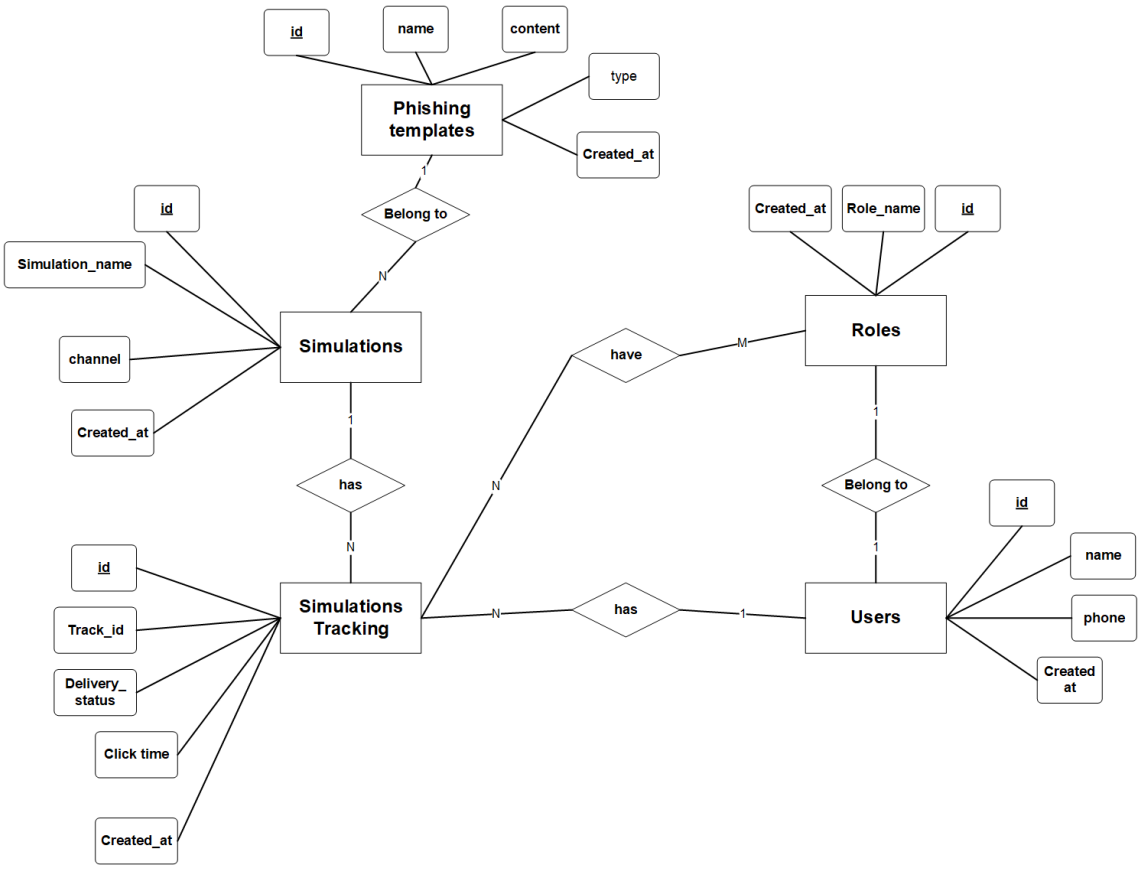

Fig. 6. ER Diagram of the phishing simulation system.

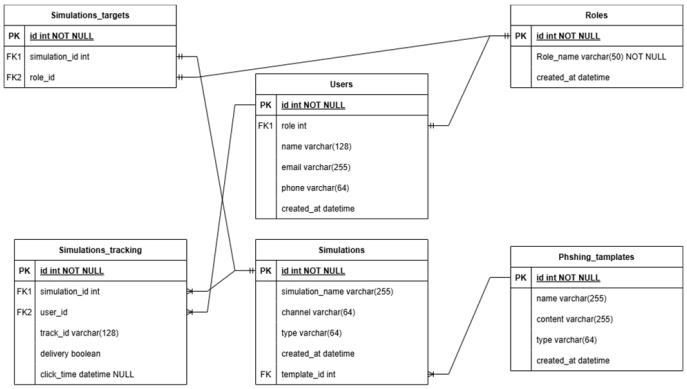

Fig. 7. Database schema diagram of the phishing simulation system.

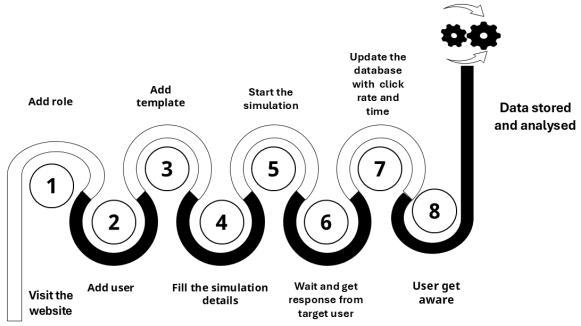

Fig. 8. System workflow of the phishing simulation platform.

and monitor phishing simulations without much delay in configuration. The workflow shown in Fig. 8 details the workflow as eight steps in succession: administrative setup, campaign launch, user interaction, and behavior tracking.

1) Step-by-step workflow:

a) System access: The process is initiated by logging into the platform via a secure web interface by the administrator.

b) User registration: User profiles are set up and assigned to pre-defined (organizational) roles like HR and Finance so that specific simulations can be run against them.

c) Template configuration with placeholders: Phishing templates with dynamic placeholders are created by the administrator. The backend system automatically replaces these placeholders at runtime.

- {{user_name}}: Replaced with the targeted user's name.
- {{tracking_url}}: Replaced with a unique tracking link generated for the user-template pair and simulation campaign.

- {{random_number}}: Generate a random number (Fake invoice or verification code etc).

Using this mechanism allows a simulation to be more realistic and more personalized, thus making it more effective in emulating real phishing attempts.

d) Simulation setup: By selecting a template, delivery channel, and target user groups (roles), it is the admin who configures the simulation. It is saved and immediately ready for launch.

e) Immediate campaign execution: Once the backend is launched, it dynamically fills in the placeholders with actual values and dispatches the phishing messages through Email, SMS, or WhatsApp API. A customized message with a user's personal data and a unique tracking link is sent to each user.

f) User interaction logging: The system records user actions including: delivery status, link click events, and time to response.

g) Behavioral data collection and risk scoring: The data of user interaction is stored in the database. For instance, the system calculates risk scores and classifies an organization's risk level according to predefined thresholds.

h) Awareness feedback delivery: Upon interacting with phishing links, users are redirected to a training page with immediate awareness content. The reinforcement of learning through real-time feedback and behavioral reinforcement is reiterated by this step.

This is a behavior-focused and fully dynamic workflow that allows for the multi-channel delivery of phishing simulations. It makes use of placeholders to increase the realism of messages and its supportable and scalable deployment.

V. System Implementation

Thereafter, the phishing simulation platform was implemented by translating the proposed architecture and system design into a working web-based system. The development took a modular approach to allow for each component to be developed, tested, and improved independently: user management, template creation, simulation launch, behavior tracking, and reporting.

A. Technology Stack

Table VI shows the tools and technologies used for building the platform.

TABLE VI. List of Tools and Technology

Component	Technology / Tool
Backend Development	React.js
Frontend Development	HTML and CSS
Database	PostgreSQL
Message Delivery APIs	resend API for email
Development Environment	Visual Studio Code
Diagram Modeling	Microsoft Visio and draw.io.

B. Development Modules

Several modular components were used to implement the platform, and each module plays a particular role in the phishing simulation workflow.

- Admin Dashboard: Fig. 9 shows the web interface for administrators to navigate users, roles, other interfaces, and review reports.

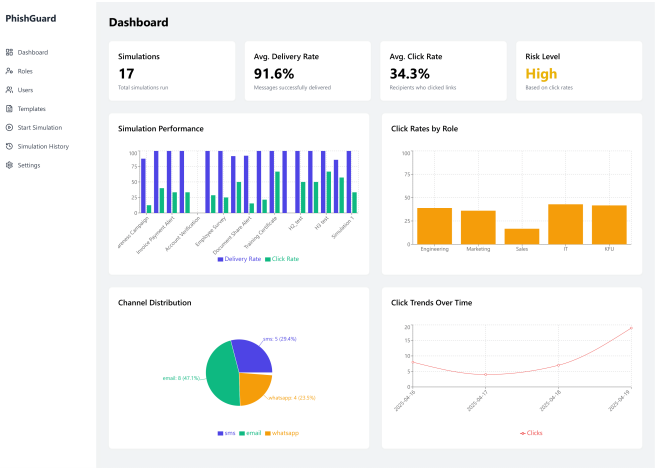

Fig. 9. Phishing simulation admin dashboard.

- Template Engine: Enables dynamic placeholder injection such as {{user_name}}, {{tracking_url}} and {{random_number}} which leaves room for maximizing personalization. Fig. 10 shows an example from the system.

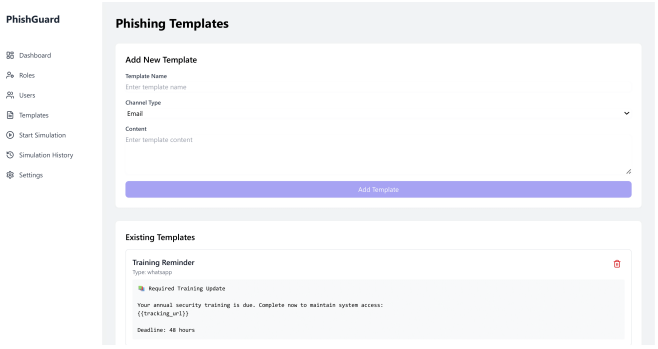

Fig. 10. Phishing simulation adding template page.

- Simulation Dispatcher: It sends out phishing messages through integrated Email, SMS, and WhatsApp APIs. Fig. 11 shows the interface of creating a new simulation, and this gets triggered after clicking the button.
- Tracking Mechanism: Unique tracking links record the user clicks, the timestamps, and response metrics. Fig. 12 shows the email received from the system after the launching of the simulation.
- Awareness Module: Immediately trains users who fall for simulations by redirecting them to an awareness page as shown in Fig. 13.

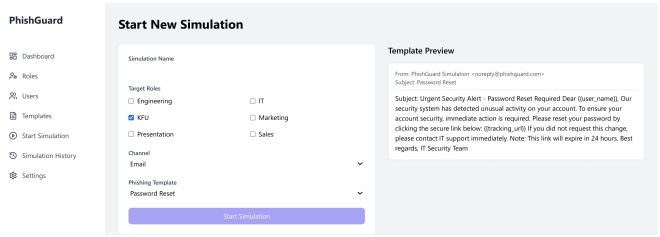

Fig. 11. Configuration setting of the simulation campaign.

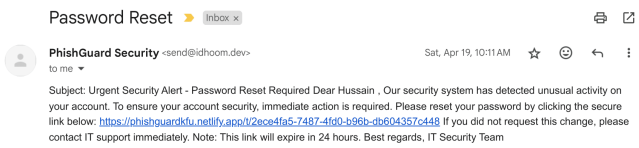

Fig. 12. Phishing simulation email received with a unique tracking link.

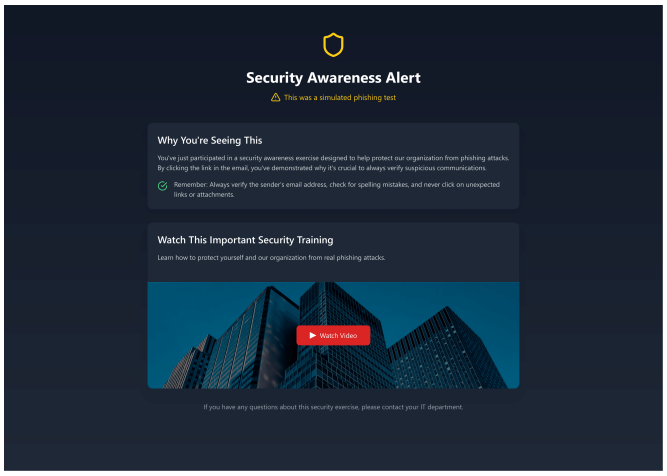

Fig. 13. The awareness page from the system.

- Database Integration: It normalizes the storage of all simulation data, logs, and user profiles.

C. Testing and Verification

To verify, individual core modules were tested.

- Correct rendering and substitution of template placeholders.
- A reliable way of interacting with an API for message delivery.
- Make sure accurate tracking of click events and response time.
- User interface that is responsive and compatible with browsers Chrome, Firefox, and Edge.

D. Deployment

The platform was deployed using Netlify, a cloud service platform that is known for being simple and powerful when deploying web applications. Finally, Netlify was used to host frontend components (admin dashboard and awareness pages), as they allowed for really fast, continuous deployment. This approach made for easy updates and a reliable way to host the web interface.

This section contains data and visuals generated from sample values to show the capabilities of the system. No real user interaction was recorded.

E. Behavioral Analytics and Reporting

The phishing simulation platform also includes a set of in-depth analytics that allows administrators to measure user behavior, campaign performance, and phishing awareness in terms of users, roles, and communication channels. The collection of data happens in real-time and creates an intuitive dashboard to visualize the data.

1) Admin dashboard reports: The key visual and statistical insights are available on the admin dashboard, which are:

- Total number of simulations conducted.
- The average delivery and click-through rates for each Simulation campaign.
- Low, Medium, High risk classification levels.
- Email, SMS, WhatsApp channel usage summary.
- Click trends over time.
- Click rate by role.

These visualizations that are shown before in Fig. 9 enable organizations to discover vulnerable users, assess the efficiency of training campaigns, and decide on the follow-up intervention.

2) Simulation history and detailed reports: All of the simulations executed within the platform are maintained on a complete history, which administrators can view:

- Simulation campaign names and associated templates.
- The targeted roles.
- Delivery rate and click rate performance.
- Channel of communication type used.
- Date and time of execution.

Fig. 14 shows lists of past simulation campaigns with delivery and engagement metrics across targeted roles.

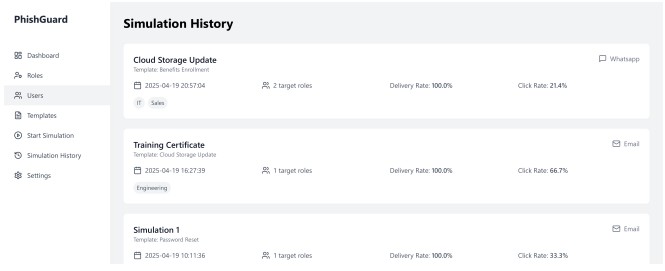

Fig. 14. Simulation history log – sample data.

By selecting a simulation campaign, you can discover detailed analytics and view these analytics:

- Date and time of execution of the simulation.
- Number of targeted roles.
- Delivery rate and click rate performance of the simulation campaign.
- The click rate per role as a bar chart.
- Overall response to the phishing message by click.
- List of users tragedy respect to user role along with delivery Status, click Status and the response date and time.

Fig. 15 shows an individual simulation campaign with its information and analytics.

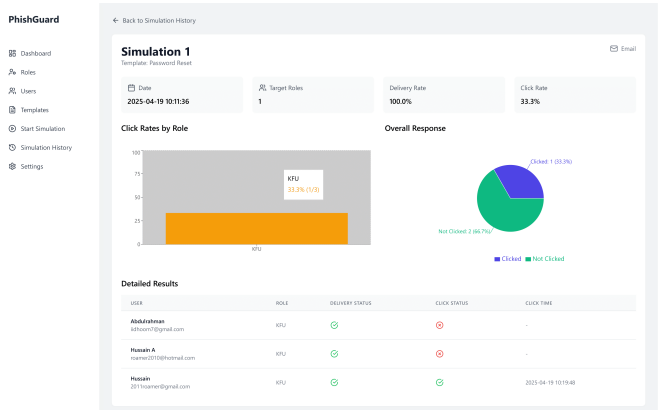

Fig. 15. Specific simulation campaign - analysis – sample data.

VI. Discussion

As a result, in this study, a customizable phishing simulation platform was presented for the improvement of user-specific cybersecurity awareness by means of targeted phishing and real-time behavioral analytics through multi-channel delivery. The proposed approach improves the traditional awareness methods by providing personalized simulations of the attacks through Email, SMS, and WhatsApp, which are a real attack vector. It generates phishing content dynamically using placeholders such as {{user_name}} and {{tracking_url}}, increases the user's engagement and offers an authentic environment to recognize phishing in familiar scenarios. Also, the behavioral tracking engine assists organizations in identifying click patterns and response times and identifies high-risk individuals with whom training intervention data can be linked. Furthermore, this also provides immediately awareness feedback to support just in time learning to reinforce safe practices when the users are the most vulnerable. Being adaptable, realistic and insightful at the user level, this directly fills the gaps in current generic, one-size-fits-all, one size fits all training programmes. Moreover, the system is deployed using a cloud-ready frontend with Netlify and has a modularity in the architecture that would make it a good candidate for real-world product adoption in enterprise environments where ongoing, customized phishing awareness is needed.

RQ1-RQ5 were created to serve as the system development framework and future evaluation. This paper is focused on the design, architecture, and demonstration of the platform through computational simulation. The above specifies the way each of the questions is answered at this step:

- RQ1 (long-term awareness and behavioral change): The proposed platform has modules of behavioral-tracking (e.g., click behavior, response time), which are proposed as a precondition to assess the long-term awareness and the following behavioral change of users.
- RQ2 (emerging behavioral patterns): The behavioral data produced on the platform enables a researcher to record the user response patterns based on the role and channel. These patterns provide a basis where emergent trends of behavior are identified.
- RQ3 (advantages of customization): The current platform enables the customization of simulations by the role and behavior of the user, unlike the standard, non customized training environment.
- RQ4 (engagement across platforms): Support multi-channel, but the study has not explored the differences between engagement across the channels.
- R5: (real-time feedback and analytics): The current platform delivers real-time awareness pages upon phishing link, but the study has not address the effectiveness and consider as future work.

The discussion in the current paper provides that the platform in question is intentionally designed in such a way that it can address the technical concerns identified, but its general effectiveness has not been tested and consider as future work.

VII. Challenges to the Study

Several challenges were faced in developing the phishing simulation platform. However, because of ethical restrictions, the system was not tested with real users, and all behavioral data were simulated inputs that restricted the ability to measure training effectiveness on real users. The platform was developed to support multi-channel delivery through Email, SMS, and WhatsApp, however, it was not possible to see how users might react differently on these platforms. Furthermore, the awareness page that is opened when a phishing link is clicked is also created with basic informational content and does not yet have interactive features like quizzes or scenario training. These improvements are slated for future versions in order to drive warmer engagement and better learning outcomes. In addition, there is no public dataset found that contains phishing simulation analytics or user behavioral responses with which to benchmark the system outputs against real-world baselines.

VIII. Conclusions

In this study, we design and implement a customizable phishing simulation platform to tackle challenges associated with traditional cybersecurity awareness training. From a review of the existing literature and tools, the research gap was identified that most of the awareness programs are

generic, limited to email simulation, not personalized, and do not provide real-time behavioral insights. The proposed platform then comes up with the multi-channel simulation delivery via Email, SMS, and WhatsApp, role-specific targeting, and dynamic template generation using placeholders such as {{user_name}} and {{tracking_url}}. All of these features make the simulation more realistic and engaging to the user. A behavioral tracking engine is also integrated within the system to track user interactions, assess risk levels, and provide immediate feedback via an awareness page, thus supporting just-in-time learning. The platform provides an administrator dashboard to analyze in detail campaign performance as well as user behavior for a given campaign and help to make the platform adaptable to a particular organization's needs. Due to ethical restrictions, the platform was tested with simulated data. Nevertheless, a cloud-ready frontend was deployed, and the platform shows potential for real-world use. Future work will be to conduct live evaluations, to enhance the awareness content with interactivity learning, and to complete integration of all communication channels for full multi-platform simulation capability.

FUNDING

This work was funded by King Faisal University, Saudi Arabia. [Project No. GRANT KFU252300].

ACKNOWLEDGMENT

This work was supported through the Annual Funding track by the Deanship of Scientific Research, Vice Presidency for Graduate Studies and Scientific Research, King Faisal University, Saudi Arabia [Project No. GRANT KFU252300].

Reducing Computational Complexity in CNNs: A Focus on VGG19 Pruning and Quantization

Md. Mijanur Rahman[1], Anik Datta[2], Md. Sabiruzzaman[3], Md Samim Ahmed Bin Hossain[4]
Assistant Professor, Dept. of CSE, Southeast University, Dhaka, Bangladesh[1]
Dept. of CSE, Southeast University, Dhaka, Bangladesh[2,3,4]

***Abstract*—The Convolutional Neural Network (CNN) models are effective in computer vision strategies and have gained popularity due to their strong performance in visual tasks. Nevertheless, models with architectures such as VGG19 are expensive in terms of computational resources and require huge memory, which limits their usage on low-end devices. The study examines how efficiency can be increased in the model VGG19 by using model compression techniques, like pruning (structured and unstructured) and quantization (8-bit and 4-bit Quantization-Aware Training - QAT). The efficiency of the individual compression approaches was tested by thoroughly exploring the VGG19 with the MNIST, CIFAR-10, and Oxford-IIIT Pet datasets. Each model was evaluated against the baseline based on measures of accuracy, model size, inference time, and complexities of the model, CPU usage, and memory usage. The applied QAT approach reduced the model size by 75% with a drop in computational cost across all methods. In addition, the 8-bit quantitative assessment allowed for substantial system compression alongside increased speed delivery with minimal impact on accuracy. The highest compression and sparsity achieved by 4-bit QAT was 48%, which was not effective as it reduced accuracy on complex datasets, with additional computational overhead on T4 GPU. Structured pruning resulted in faster inference, but unstructured pruning also demonstrated a good result in retaining accuracy and even improving it. To simplify the VGG19 structure, pruning and quantization mechanisms are suggested in order to simplify the architecture to implement the model on edge devices sufficiently, without compromising prediction performance.**

Keywords*—*VGG19 Model optimization; model compression; pruning, quantization; structured pruning; unstructured pruning; memory management; quantization-aware training; 8-bit; 4-bit

I. Introduction

CNNs have experienced significant advancements during the last few years to solve a wide range of computer vision [1] problems that include simple image classification [2] tasks alongside complex object detection [3] problems. The VGG19 CNN model stands among multiple models as a significant impactor because it significantly contributes to deep learning by accurately addressing challenging image classification tasks [4]. Although efficient, direct deployment of VGG19 on resource-limited devices, i.e., smartphones and edge computing setups, is infeasible because of its enormous parameter size and excessive computational demands in terms of floating-point operations per second (FLOPs) [5]. Model compression methods, which include pruning and quantization, have addressed these challenges effectively. Quantization achieves maximum savings in memory usage plus computation requirements through its usage of weight and activation bit widths, which makes it ideal for devices with minimal resources [6], [7]. Model performance enhancement through pruning strategies involves connection reduction for both size reduction and computational complexity reduction [8].

Although the advancement in model compression has been remarkable, most of the current research mainly concentrates on large-scale data and high-resource computing settings. However, their performance is hardly well-tested in environments where datasets are comparatively small and computer resources are modest. The testing of their performance needs more investigation in situations that use small datasets alongside minimal computer resources. Different pruning techniques like layer-wise pruning [9], structured pruning [10], activation-based pruning [11], and different quantization techniques like mixed-precision and post-training quantization [12], [13], have been studied separately on different models. There is limited modeling understanding of where the efficiency of these techniques is jointly implemented on the VGG19 model with constrained availability of resources. This study attempts to solve this gap by making a thorough evaluation of pruning and quantization techniques performed on VGG19.

To address this gap, the following research questions are asked:

- RQ1: What level of impact do various pruning methods (structured versus unstructured) have on the performance considering trade-offs of VGG19 on resource-limited datasets?
- RQ2: Which bit-width (8-bit QAT versus 4-bit QAT) of the encoded quantization is the best to keep the accuracy and simultaneously maximize the compression?
- RQ3: What are the performance of these optimization methods on data with different complexities (MNIST, CIFAR-10, Oxford-IIIT Pet)?

The gap is to be filled by comparing the accuracy, size, and processing costs of models, then evaluating the weight distribution and parameter sparsity norms [14]. To the best of our knowledge, such an in-depth, visual comparison of VGG19 with different reporting conditions, namely structured and unstructured pruning and 8-bit and 4-bit QAT.

This study compares and contrasts these approaches and studies their behavior under both isolated and combined settings and resource-limited data. The key contributions of this study are: i) an empirical evaluation of many pruning and quantization techniques on VGG19 and ii) their analysis of utility-by-constraints of usefulness under resource-constrained conditions, hence generalizing beyond the large-scale studies

done typically in the literature on model compression techniques.

The structural framework of the study is as follows: the literature review is given in Section II, methodology in Section III, the experimental results in Section IV, detailed discussion of the results in Section V, the future directions in Section VI, and conclusion with final remarks in Section VII.

II. Related Work

Research into deep learning model improvement seeks to enhance VGG19 and its contemporaries. Different research studies investigated pruning alongside quantization and transfer learning methods to minimize complex model sizes with no negative impact on accuracy levels. Resource-restricted devices such as mobile devices and embedded systems benefit most from optimization techniques because optimizing performance takes priority on such devices.

Researchers adopted VGG19 for detecting defects on strip steel surfaces through successive solutions of restricted datasets, according to study [15]. The team obtained 97.8% accomplishment in accuracy through the implementation of new preprocessing approaches and model enhancement strategies. Until it conducted another training process, the detection model failed to detect recently introduced defect types and missed apparent defects in its evaluation. The authors conducted a comprehensive research study of diverse pruning and quantization methods in [16]. According to the research findings, model pruning results in an accurate yet significantly smaller model, approximately 13 times smaller compared to the original version, while quantization offers efficiency benefits, although this comes at a cost to precision levels [17].

The fusion filter and channel pruning approach from reference number [18] eliminated 83.8% of model parameters and 71% of computations but obtained slightly better accuracy results. The reinforcement learning-based pruning techniques [19] use automatic management for pruning speeds to achieve 73% maximum computation reduction before accuracy starts to degrade beyond traditional methods of kernel pruning along with guided pruning and soft filter pruning. Scientists across the board have conducted substantial research that led to the development of various quantization techniques. Many scientists have extensively researched and developed various techniques for quantization. The study in [20] analyzed VGG19 along with MobileNet when their parameters were quantized to 8 bits. VGG19 demonstrated higher quantization resilience since it maintained only an 8.58% decline in accuracy, whereas MobileNet experienced substantial accuracy degradation. Research indicates that combined quantization and pruning methods create effective solutions for the objective. Using a 4-bit quantization on the models, it has shown more than 30% variable reduction and as much as 50% memory reduction in CNN models, with minimal damage to accuracy on real-world edge devices [21].

The improvement of VGG19 and ResNet34 model accuracy and complexity comes from Minimax Concave Penalty (MCP)-based pruning techniques [22]. The technique adopted DeepPruningES by [23] along with its evolutionary strategy-based method to achieve up to 80.89% FLOPs reduction on ResNet56 through the generation of multiple model variants with various trade-off selections. A technique that merges weight and feature-level pruning with quantization methodology benefits MobileNetV2 by sustaining a 0.37% accuracy decrease after pruning 50% of the weights while improving operational performance [24].

VGG19 demonstrates its deployment capabilities in real-world applications apart from optimization purposes, thus showcasing its usable nature and versatility. Several improved forms of VGG19 demonstrate high performance levels when used for medical diagnosis applications. The proposed E-VGG19 system by Kandhro et al. detected skin cancer in real-time through pooling/dense layers and the combination of CNN features and SVM and KNN classifiers [25]. The collaboration between Faghihi and colleagues led to 98.18% skin lesion classification accuracy when using VGG19/VGG16 together with feature-modified AlexNet through transfer learning and dropout [26]. The combination of VGG19 along with morphological features and Otsu thresholding and watershed segmentation resulted in more than a 99% success rate for parasitic organism detection per Kumar et al. [27]. Tuned VGG19 models showed better performance than pipeline workflow combinations of previous architectural models for the detection of COVID-19 and pneumonia on X-ray dataset analysis [28], [1]. Research findings proved VGG19's superiority in medical imaging applications over newer structures, DenseNet and ResNet [29]. Enhancing the performance on imbalanced COVID-19 datasets greatly relied upon data augmentation along with hyperparameter optimization techniques [30].

The study by Ahmad et al. demonstrated how VGG19 successfully detected tomato leaf diseases by fine-tuning its last layers when trained on combined field and laboratory samples [31]. Remote sensing technology reached peak performance in small aerial target detection under class imbalance through the hybrid VGG19 and ResNet50 architecture combined with the Spiral Search Grasshopper Algorithm [32]. Accounting for road infrastructure monitoring involved the optimization of VGG19 through Q-learning applied on a two-layer optimizer that managed redundancy in filters and reached a 96.4% F1-score in drone-based road damage detection [33]. The VGG19 network underwent minor modifications to create a face anti-spoofing system, which achieved a 100% success rate in detecting spoofed attacks [34]. The Table Extraction Model (TEM) developed by Iqbal et al. used VGG19 as its base structure to exceed heuristic scanning methods in extracting document tables [35]. The VGG19 model functions as part of content-based image retrieval (CBIR) systems for image retrieval purposes. By adding texture and color features to its design, the model delivered better accuracy for images with semantic similarities [36].

Despite its dated design, VGG19 remains a flexible and effective baseline for optimization research. The model's basic design makes it an optimal choice for optimization research through pruning and quantization and transfer learning and hybrid approaches. The analyzed studies possess various areas that still need improvement. However, some of the biggest VGG19 struggles are in the sense that it has not worked on small datasets or subsets of datasets as appropriate, imbalances, compromises with precision and compression, and not being able to generalize outside of the domain without transfer learning, and there do not exist efficient compression frameworks.

Constructing accurate and highly deployable VGG19 versions requires the resolution of particular challenges to service data-scarce and resource-limited systems.

III. Methodology

The research applied pruning and quantization processes to VGG19 architecture when assessing three benchmark datasets consisting of MNIST, CIFAR-10, and Oxford-IIIT Pet. The datasets contain visual data categories with original dimensions of 28×28 and 32×32 pixels, thus providing efficient computation while supporting complex image identification. Data augmentation procedures and preprocessing methods allowed all images to be uniformly resized to 224×224 pixels, even though VGG19 maintained its fixed input requirements. Among the available datasets, the MNIST provides 70,000 grayscale digits of handwriting distributed across 10 classes, and CIFAR-10 shows 60,000 color object pictures divided into 10 categories. A total of 7,349 images derived from the Oxford-IIIT Pet dataset with 2 classes were utilized, but training and evaluation occurred using 5,000 strategically chosen illustration samples from each collection. The data was split into training and experimental samples, where the data partitioned itself into training and experimental parts, keeping an 8:2 ratio, which ensured model training with diverse datasets while maintaining testing reliability on new data samples. The decision to split the data 80:20 was made by evaluating how training robustness relates to testing strength.

The torchvision library in PyTorch provides comprehensive image processing capabilities through data loading and preprocessing features that contain built-in functionality to control datasets alongside transform functionalities and augmentation options.

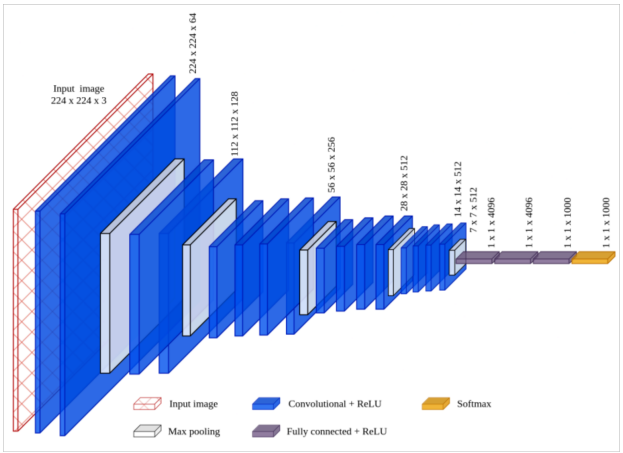

Fig. 1. VGG19 Architecture.

The VGG19 convolutional neural network developed by the Oxford Visual Geometry Group introduces a total of 19 layers composed of 16 convolutional layers together with 3 fully connected layers and 5 max-pooling layers (see Fig. 1) [37].

Through its 3x3 kernel with 1 stride, the model can master small-scale spatial features within each layer. After each convolutional layer, the model passes through ReLU non-linearity for introducing complexity. The max-pooling layers progressively shrink the spatial dimensions but keep the most important of the feature representations. To begin the multi-class classification process, the last fully connected (FC) layer will include the final softmax activation function, and binary classification will be applied to the Oxford-IIIT Pet dataset.

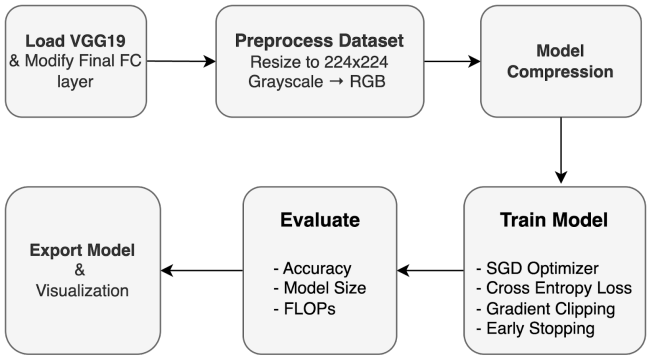

Fig. 2. VGG19 Model optimization and evaluation pipeline.

Fig. 2 represents the operational sequence of modifying, compressing, training, and evaluating the VGG19 model. Testing and training using optimization methods serve as intermediate steps before exporting the model using compression methods.

A. Pruning

The model simplification technique of pruning functions by removing insignificant weights and layers or neurons to maintain performance quality. This process substantially decreases both memory usage and computational expenses for the model. Deploying models on low-end devices makes for efficient performance and function use.

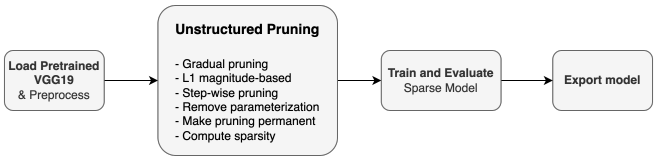

Fig. 3. Unstructured pruning training.

1) Unstructured pruning: In unstructured pruning, the importance of the weights is analyzed, and less important weights are removed. This is usually determined by a gradient-based method during backpropagation. Although this technique significantly reduces the size of the model, the sparse weight matrix has a limited impact on improving the efficiency of standard hardware implementations.

The removal of unimportant weights through unstructured pruning produces reduced models that preserve most of their operational accuracy. Fine-tuning post-pruning is used to recover any possible accuracy loss.

The methodology for unstructured pruning implementation on a pre-trained VGG19 model is illustrated in Fig. 3. L1 magnitude-based pruning uses step-wise methods to remove parameterization before enforcing permanent sparsity, followed by training and evaluation to export the model.

a) Mathematical representation: L1-norm Based Unstructured Pruning: For each weight tensor w in a module, the importance of each weight is computed as the L1-norm, as shown in Eq. (1).

$$\text{importance} = |W| \tag{1}$$

b) Gradual pruning strategy: In the implementation of this strategy, the pruning is applied in several iterations and does not remove a fixed percentage of the weights in one pass, as shown in Eq. (2). The pruning amount is gradually increased over a series of steps, starting from an initial amount and progressing to a target amount, as shown in Eq. (3).

$$\text{Step Increment: } A_{\text{steps}} = \frac{A_{\text{final}} - A_{\text{init}}}{S} \tag{2}$$

$$\text{Pruning Amount Update: } A_i = A_{\text{init}} + i \times A_{\text{steps}} \tag{3}$$

c) Sparsity calculation: After applying pruning, the sparsity of each module is calculated as Eq. (4) as the percentage of weights that have been set to zero.

$$\text{sparsity} = \left(\frac{\text{number of zero weights}}{\text{total number of weights}} \right) \times 100 \tag{4}$$

d) Overall pruning summary: Individual layers are then pruned, a summary is calculated overall, and parameters are aggregated across all layers, as given by Eq. (5).

$$\text{overall_sparsity} = \left(\frac{T - R}{T} \right) \times 100 \tag{5}$$

where, T = total parameters and R = remaining parameters

2) Structured pruning: Structured pruning functions differently from unstructured pruning because it removes entire neurons, channels, or filters, which results in hardware-friendly and deployment-ready implementation. The implementation of this technique becomes more feasible in practical applications because hardware compatibility surpasses unstructured pruning methods. The method shows outstanding success in minimizing accuracy losses while reducing the convolutional layers of VGG19.

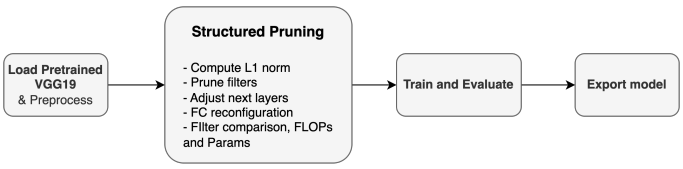

Fig. 4. Structured pruning training.

Fig 4 illustrates structured pruning on VGG19 pretraining. The system first calculates L1 norm values to locate insignificant filter elements for pruning while it readjusts subsequent layers, reorganizes the fully connected layers, measures FLOPs and parameter reduction, and then retrains and generates an exported model.

Structured pruning creates compatibility with hardware accelerators because it allows stable memory patterns that enhance inference speed significantly. The process cuts down the model size with computational complexity because it omits unnecessary channels and neurons to maintain both model performance levels and feature extraction capacity.

3) Mathematical formulation: Filter Importance Computation: For each convolutional filter, its importance is measured by the L1-norm of its weights, Eq. (6).

$$I_i = \sum_j |w_{ij}| \tag{6}$$

a) Pruning decision: For a convolutional layer with n_{filters} filters and a pruning ratio r, the number of filters to prune is given by Eq. (7).

$$n_{\text{prune}} = \lfloor r \times n_{\text{filters}} \rfloor \tag{7}$$

Filters are ranked by their L1-norm importance $I_i = \sum_j |w_{ij}|$, and the n_{prune} filters with the smallest I_i are removed.

b) Adjusting subsequent layers: The input channels for the next convolutional layer are modified according to the output channels that were previously trimmed, according to Eq. (8). This is done by re-indexing the weight tensor along the channel dimension:

$$\text{new input channels} = \text{previously kept indices} \tag{8}$$

B. Quantization

Quantization is a model compression technique that takes high-precision 32-bit floating-point weights and activations to low bit-value such as 8-bit or 4-bit integer. This heavily cuts down the memory usage and computational cost at the price of a little loss of accuracy in edge devices. So it is possible to guarantee good performance along with model functionality.

1) Precision-based quantization: Precision-based quantization, especially fixed-point quantization, is widely used to reduce the bit-width of weights and activations. When applied to the convolutional, activation, and fully connected layers of VGG19 [38]. The model implements 8-bit and 4-bit quantizations for all its convolutional layers in addition to ReLU activations and fully connected layers.

2) Quantization-aware training: QAT is a training procedure in which the quantization operation is applied during the forward operation of the model, i.e., the low-bit representation used for inference[39]. But the full precision of the parameters is saved in the backward pass, that is, the back-propagation, so that the model can learn and correct the quantization errors. This allows the model to be aware of quantization effects during the training phase, and it retains high performance and efficiency at the inference period. Mathematically, the quantized forward pass is represented as Eq. (9).

$$x_{\text{quant}} = q(x) \tag{9}$$

$q(x)$ is the quantization function. This way, inference-time quantization's accuracy is preserved, and QAT is one of the best methods for compressing deep learning models.

3) Module fusion: Efficient quantization, together with faster inference speed, needs module fusion to serve as a critical preparation step. The model gains advantages from reduced overhead, lower quantization error, and improved runtime efficiency through single fused modules retaining the same computed output resulting from combining convolution and ReLU layers.

4) Quantization and dequantization: These equations describe the dictionary defining the mapping of floating-point numbers to their integer representation: The quantized value was calculated with Eq. (10), and the dequantized float value was calculated with Eq. (11).

$$\text{Quantization: } q = \text{round}\left(\frac{x}{s}\right) + z \tag{10}$$

$$\text{Dequantization: } x = s \times (q - z) \tag{11}$$

5) 8-Bit QAT: The forward pass of quantized VGG19 models is composed of a sequence of quantized convolutions and fully connected layers, with in-between ReLUs and average pooling.

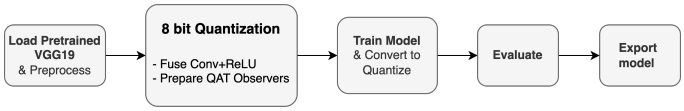

Fig. 5. 8-bit Quantization aware training.

Fig. 5 shows the pipeline for the quantization of 8-bit VGG19 models during preprocessing. The quantification method starts with convolutions and ReLUs before preparing QAT observers, then conducts training followed by quantized model conversion and evaluation and final export processing.

6) Kaiming normal initialization for weights: This method makes the weights have the appropriate value such that the variance of the activations remains roughly the same across layers. It is also good at signalling in deep nets using ReLU activations, helping to deal with issues with the vanishing or exploding gradients. The weights w are sampled from a normal distribution defined as Eq. (12).

$$w \sim \mathcal{N}\left(0, \frac{2}{n_{\text{in}}}\right) \tag{12}$$

7) 4-Bit QAT: A structure similar to the 8-bit configuration was followed, but all quantization functions and weight representations were replaced with their 4-bit counterparts.

The workflow for 4-bit QAT to apply on the VGG19 model appears in Fig. 6. The procedure starts with importing the model while performing the required input preparation.

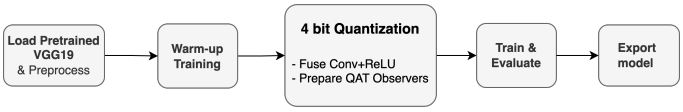

Fig. 6. 4-bit Quantization Aware Training

After weight stabilization, the short warm-up training begins. The implementation of QAT begins when 4-bit quantization combines convolution and ReLU layers and then adds QAT observers for all the layers. The model proceeds to fine-tuning through a training and evaluation stage, after which it becomes exportable for deployment.

The choice of pruning rates and quantization bits was done under the premise of preliminary testing that optimized the trade-offs. It was found that a pruning rate of 30% yields the best trade-off between compressing and maintaining the accuracy gained from the preliminary experiments. Training the hyperparameters was performed based on known model compression methods. In the process, it was found that cosine annealing learning rate is an absolute requirement for achieving stable QAT convergence.

8) Cosine annealing learning rate equation: Eq. (13) gives the dynamical learning rate during the period of training epochs by implementing a cosine that provides a progressive decay within the process of learning.

$$n_t = n_{\min} + \frac{1}{2}(n_{\max} - n_{\min})\left(1 + \cos\left(\frac{T_{\text{cur}}}{T_{\max}} \times \pi\right)\right) \tag{13}$$

C. Combined Metrics for Performance Evaluation

1) Model size: Eq. (14) was used in calculating the model size.

$$\text{Model Size (MB)} = \sum_{p \in \text{parameters}} \frac{\text{numel}(p) \times \text{element_size}(p)}{1024^2} \tag{14}$$

2) Inference Time (T): Eq.(15) defines the inference time.

$$T_{\text{batch,avg}} = \frac{\sum_{i=1}^{N} T_{\text{batch}}^{(i)}}{N} \tag{15}$$

3) Parameter Reduction (R): The percentage decrease in model size due to compression [see Eq. (16)]:

$$R = \left(1 - \frac{S_{\text{compressed}}}{S_{\text{original}}}\right) \times 100 \tag{16}$$

4) Incremental memory usage: Eq. (17) defines incremental memory usage.

$$\Delta M = M_{\text{current}} - M_{\text{baseline}} \tag{17}$$

5) FLOPs counting: Eq. (18) defines FLOPs counting.

$$\text{FLOPs} = 2 \times \sum_{p \in \text{parameters}} \prod_{i=1}^{\text{ndim}(p)} \dim(p) \tag{18}$$

6) Early stopping: The early stopping mechanism continuously monitors the validation loss $L_{\text{val},t}$. If, for a given epoch t, the loss difference

$$L_{\text{val},t} - L_{\text{val},t+\Delta t} \tag{19}$$

Eq. (19) is less than min_delta for patience consecutive epochs, the algorithm concludes that further training is unlikely to yield significant improvements and stops the training process.

IV. Experimental Results

The evaluation in this part utilizes experimental tests on VGG19 optimizations to study structured and unstructured pruning together with quantization effects on performance outcomes. Three popular benchmark datasets—MNIST, CIFAR-10, and Oxford-IIIT Pet Dataset—are used for the evaluation to measure the actual performance of these optimizations. The tests are mainly conducted based on several important indicators, including model size, FLOPs, classification accuracy, inference latency, CPU utilization, and memory consumption.

In this study, the training and evaluations are run on Kaggle P100 GPUs to maximize computational efficiency. After the training phase, the developed models were exported and subsequently subjected to evaluation. The experimental benchmarking of the models was conducted using CPUs on Google Colab. The 4-bit model inference overhead was specifically measured on Google Colab CPUs during this evaluation phase. Although 4-bit quantization significantly reduces model size and memory consumption, the overhead arises because standard CPUs are optimized for 8-bit or higher precision operations. In the absence of native 4-bit hardware support, additional computational cost is incurred due to packing, unpacking, and emulating low-bit arithmetic during inference.

The optimization process of VGG19 baseline models starts through standard training interventions on each dataset. The model then undergoes both structured and unstructured pruning procedures, which enhance resource utilization. The efficiency of parameter utilization in the model has improved since unnecessary parameters are now being removed. Tests of both 4-bit and 8-bit quantization techniques seek to enhance the model compression efficiency.

The collected findings help to determine the impact of these optimization methods on system performance. Model efficiency faces an opposing force against inferential performance when implementing these optimization techniques. The findings from the research demonstrate valuable information regarding the realistic implementation prospects of the optimized VGG19 model.

1) Model efficiency summary: Examination of the advantages of pruning and quantization on the VGG19 architecture was conducted via inspection of performance metrics, including decreased parameters, increased FLOPs, and overall sparse network. Eq. (14) was used in calculating the model sizes of each configuration. The performance metrics of the baseline model and its structured and unstructured pruning implementations appear in Table I, Eq. (16), and Eq. (17).

TABLE I. Model Efficiency Comparison

Metric	Original	Structured	Unstructured	8-bit	4-bit
Parameters (M)	139.58	98.70	80.27	139.58	139.58
Pruning Rate (%)	–	30	30	–	–
FLOPs (G)	0.28	9.77	0.28	0.28	0.28
Sparsity (%)	0	0	42.50	1.59	48.10
Model Size (MB)	532.57	376.64	532.57	133.42	133.20
Size Reduction (%)	–	29.28	0	74.95	74.99

The VGG19 system requires 139.58 million model parameters and computation of 0.28 GFLOPs Eq. (18). A structured pruning technique with a 30% rate allows our model to maintain 98.70 million parameters while lowering FLOPs to 9.77 GFLOPs. In contrast, the unstructured pruning presents a higher pruning ratio of 42.50%; thus, the total parameter in the compressed model is reduced to 80.27 million. Overall sparsification of the pruned network is 42.50%, greatly reducing computational complexity. For 8-bit QAT and 4-bit QAT, the observed model size reduction is almost 75% [38].

For training efficiency, the pruned model was trained over 30-45 epochs with early stopping with a batch size of 32. The optimization method decreases algorithm processing complexity without affecting accuracy performance[40].

2) Best weight distribution after model quantization: These experiments show that this approach effectively can compress the model, reduce the number of FLOPs, and keep a balance between efficiency and performance, potentially demonstrating the most effective technique to compress deep neural networks with a slight loss in accuracy.

3) Best layer comparison after model compression: In summary, the results from Fig. 14 and Fig. 13 show that, although it offers compression benefits, structured pruning keeps accuracy. Excessive quantization methods, like using 4-bit, need exact calibration precision when working with challenging dataset materials.

4) Inference performance and norm-based metrics: Table III shows the effect of the comparison depending on inference time [Eq. (15)], CPU consumption, memory consumption, norm-based weight measures (L1, L2), and sparsity.

The best way for real-time inference with a minimal loss of model goodness was 8-bit quantization, which reliably delivered the fastest inference time and less memory usage across all datasets. 4-bit quantization provided the highest sparsity (up to 48%) and considerable model compression along with competitive inference speed with overhead.

The structured pruning method decreased inference time and memory consumption, though it did not introduce weight sparsity because it primarily modified network architecture instead of parameter numbers.

TABLE II. CLASSIFICATION PERFORMANCE

Dataset	Approach	Epochs	Accuracy	Top-1 Acc.	Top-5 Acc.
MNIST	Baseline Model	13	98.00%	98.00%	100.00%
	Structured Pruning	30	97.60%	97.60%	100.00%
	Unstructured Pruning	16	98.10%	98.10%	100.00%
	8-bit Quantization	17	97.50%	97.50%	100.00%
	4-bit Quantization	9	98.30%	98.30%	100.00%
CIFAR-10	Baseline Model	11	86.30%	86.30%	99.80%
	Structured Pruning	30	71.80%	71.80%	98.10%
	Unstructured Pruning	19	86.50%	86.50%	99.70%
	8-bit Quantization	21	85.70%	85.70%	99.60%
	4-bit Quantization	11	71.80%	71.80%	84.80%
Oxford-IIIT Pet	Baseline Model	9	96.74%	96.74%	–
	Structured Pruning	18	94.02%	94.02%	–
	Unstructured Pruning	15	97.96%	97.96%	–
	8-bit Quantization	13	97.42%	97.42%	–
	4-bit Quantization	10	89.67%	89.67%	–

Note: Top-5 accuracy was not computed for the Oxford-IIIT Pet dataset due to its binary classification nature.

TABLE III. INFERENCE PERFORMANCE AND NORM-BASED METRICS

Dataset	Approach	Inference Time (ms)	CPU Usage (%)	Peak Memory (MB)	L1 Norm	L2 Norm	Sparsity
MNIST	Baseline Model	849.286	98.530	41.762	772058	100.57	0%
	Structured Pruning	483.952	99.700	35.641	536877	83.23	0%
	Unstructured Pruning	829.155	99.547	24.812	665095	98.75	7.93%

	Unstructured Pruning	836.408	99.533	36.816	664427	98.67	0.66%
	8-bit Quantization	471.534	99.866	0.258	771024	100.01	1.59%
	4-bit Quantization	488.039	99.521	0	648955	100.61	48.11%

The results from unstructured pruning methods were inconsistent because memory consumption improved in certain use cases, yet inference speed boosts, along with sparsity degrees remained dependent on the dataset and generally low. Considering smaller and less redundant models, all optimization methods lowered L1 and L2 norms from the baseline.

V. DISCUSSION

This research demonstrates that both pruning and quantization methods are effective in improving the VGG19 model efficiency for deep learning functions. The experimental figures make visible the different trade-offs and benefits produced by each optimization method implemented in this study.

Fig. 7 demonstrates. Both quantization techniques reduced the model size extensively, although they left the actual parameter count unchanged because quantization modifies computational bit representation instead of parameter number. Structured pruning maintained a higher parameter count at

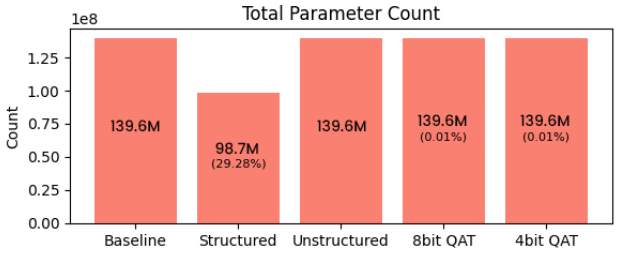

Fig. 7. Total parameter count of VGG19 variants.

98.7 million, but the parameter total in unstructured pruning dropped to 80.27 million.

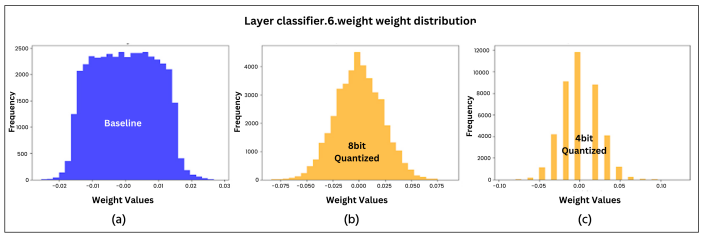

Fig. 8. Best QAT weight distribution.

The effectiveness of QAT was depicted in Fig. 8 by its weight distribution. The baseline distribution is plotted as shown in Fig. 8(a), and the 8-bit quantization, which is plotted in Fig. 8(b), still has a relatively smooth distribution. Fig. 8(c), however, shows that the use of 4-bit quantization leads to the doubling of weights around the zero value, which means that the model weights itself to the larger quantization error and reduced precision.

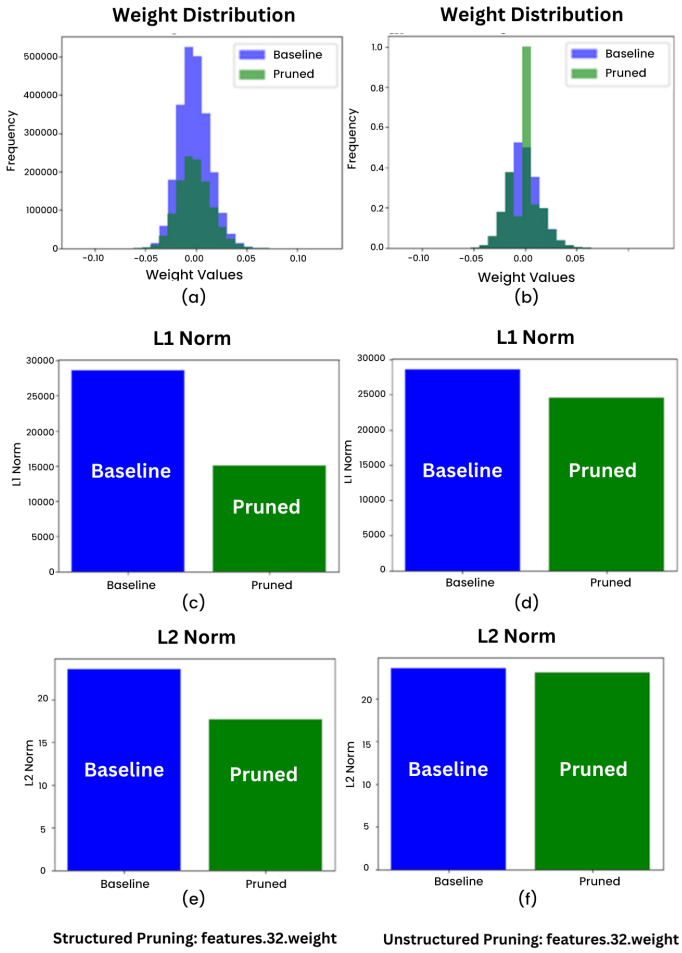

Fig. 9. Best pruned layer compression.

Fig. 9 displays particular impacts of pruning, since this model compression comparison acts at the level of a layer. Structured pruning [Fig. 9(a),Fig. 9(c),Fig. 9(e)] preserved the functionality of convolutional layers by removing the most redundant parts of deeper fully connected layers. In particular, Fig. 9(a) is the distribution of weight before and after pruning, Fig. 9(e) and Fig. 9(c) show the decreasing L2 and L1 norms, which means sparsity of parameters. The effect of unstructured pruning is shown in Fig. 9(b),Fig. 9(d) and Fig. 9(f), with the more focused post-pruning weight distribution shown in Fig. 9(b) and the L2 and L1 norm comparison seen in Fig. 9(d) and Fig. 9(e), respectively. The pruning was used to maintain the feature extraction capability of the model and to trim its structure.

As it is presented in Table II, five different architectures of VGG19 were assessed on three different datasets: MNIST, CIFAR-10, and Oxford-IIIT Pet Dataset. The models will be denoted as Baseline, Structured Pruning, Unstructured Pruning, 8-bit Quantization, and 4-bit Quantization. All tested models in the MNIST evaluation exceeded 97.5% accuracy levels. With a 4-bit quantized model, the accuracy level reached 98.30% while exceeding baseline standards at 98.00%. The 9-epoch training duration marked the minimum needed for this model. Unstructured pruning added slightly to the baseline with the accuracy of 98.10%, indicating sparsity-based pruning also works for lesser complexity of datasets. Despite being marginally reduced (97.60% and 97.50% in structured trimming and 8-bit quantization, respectively), they maintained complete top 5 accuracy. Using unstructured pruning proved to be a slightly better option when it was applied to CIFAR-10 as multi-class (86.50% vs. 86.30%). This was because it could keep the accuracy high for the more complicated dataset. 8-bit quantization hit a good accuracy (85.70%) with just small losses. The performance of the models deteriorates extensively to 71.80% when applying structured pruning and 4-bit quantization techniques to the dataset. The Oxford-IIIT Pet dataset by binary classification proved the substantial performance improvement brought up through unstructured pruning, achieving 97.96%, better than the basic 96.74%. Both 8-bit quantization and structured pruning resulted in comparable results to the baseline, with performances of 97.42% and 94.02%, respectively. However, 4-bit quantization decreased the most.

1) Results: Training figures using MNIST, Oxford-IIIT Pet, and CIFAR-10 datasets appear in Fig. 10(a), Fig. 11(a), Fig. 12(a) to show training behavior and validation and corresponding training and validation accuracies are presented in Fig. 10(b), Fig. 11(b), Fig. 12(b) to show training and validation accuracies. The training curves show that unstructured pruning techniques, together with other pruning methods, brought stability to training operations while achieving accurate test results throughout all epochs. The results in Fig. 12 show that structured pruning and 4-bit QAT [41] struggle on the complex CIFAR-10 dataset because they produce slow convergence and an enlarged generalization gap during aggressive compression efforts.

Devices that operate at edge points need maximum performance throughout inference procedures to qualify for deployment. The optimization algorithms in Fig. 14 reveal lower norm values than basic model protocols for L1 and L2 norm metrics. Their functionality depends on parameter sets, which must be minimal and simple. The structured pruning approach

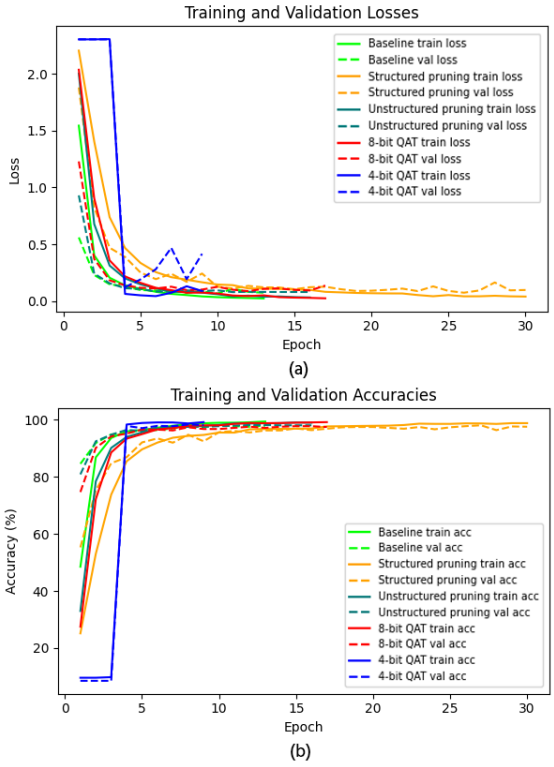

Fig. 10. MNIST training and validation.

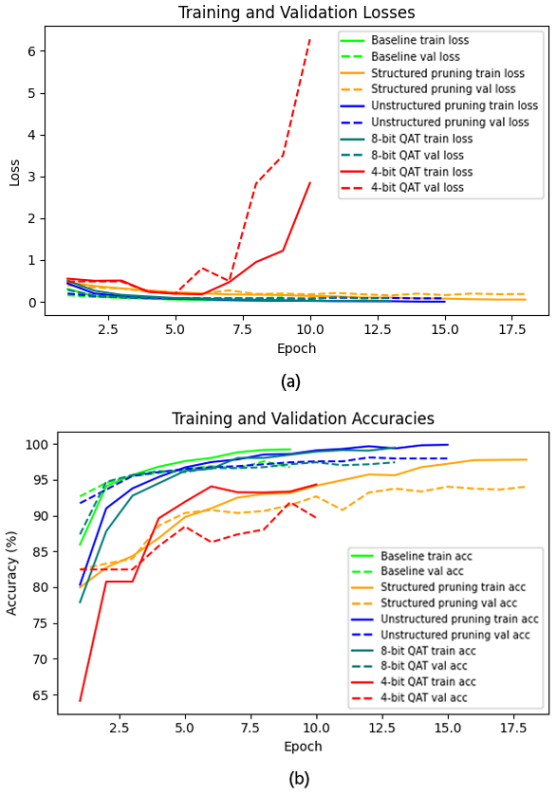

Fig. 11. The Oxford-IIIT pet training and validation.

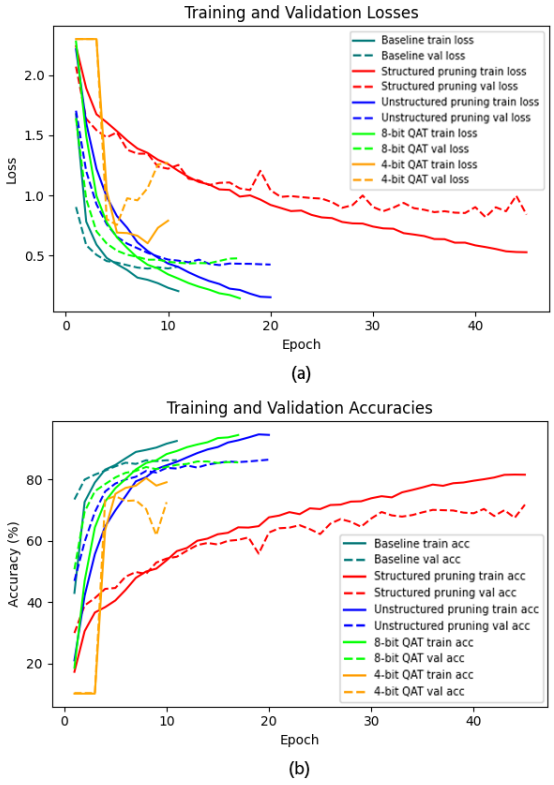

Fig. 12. CIFAR-10 training and validation.

effectively reduces both norms while preserving parameter density because network reduction outperforms weight removal in performance improvement.

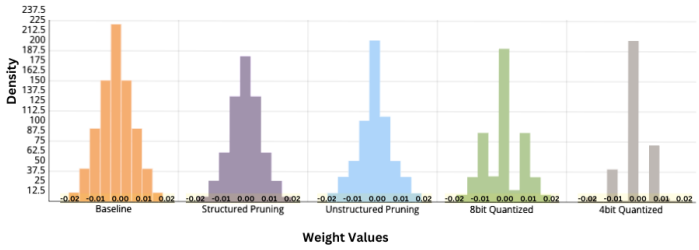

Fig. 13. Average weight distribution of VGG19 variants.

Fig. 13 shows the typical weight distribution statistics across all variants, which validates this observation. The precise and uniform weight distribution that occurs when pruning methods are structured leads to better hardware efficiency and more foreseeable inference behavior. The weight bins of the 4-bit quantized model became discrete from heavy quantization because of this pattern, which allowed it to achieve sparsity levels exceeding 48%, according to performance data.

The numerical data found in Table III proves the findings presented previously. The deployment times for 8-bit quantization kept its approximate duration at ≈472 milliseconds while simultaneously demonstrating zero memory consumption and minimal deviations in L1 and L2 norms when compared to the baseline model. 4-bit quantization outpaced 8-bit QAT

regarding inferential speed, even though it achieved peak sparsity levels together with minimum memory usage. This makes 8-bit QAT the most effective option for achieving performance-quality equilibrium.

Pruning methods that do not follow structured guidelines prove to be the most suitable techniques for preserving exact accuracy on complex datasets. The sparse retraining technique achieved superior results to baseline measurements across the Oxford-IIIT Pet data through its 97.96% accuracy, which surpassed the 96.74% baseline score, thus indicating that the method enhances generalization effectiveness. The model limitation was reduced through data augmentation and early stopping techniques, although no regularization methods such as dropout or L2 penalties were implemented. A minor degree of model bias may result from this implementation when applying it to complex datasets.

The use of four bits during quantization resulted in substantial accuracy deterioration when implementing it for CIFAR-10 and Oxford-IIIT datasets. Researchers need to develop complex quantization methods that choose the best quantization parameters when sensitivity levels change between different network parts.

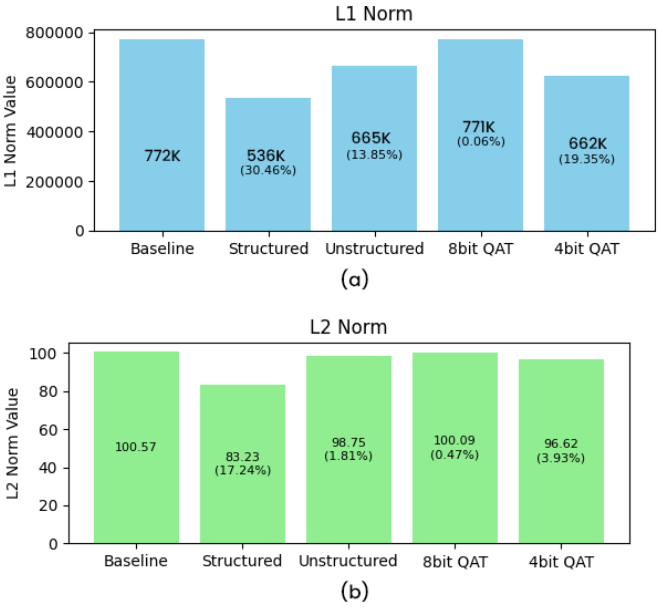

Fig. 14. L1, L2 norm of VGG19 variants.

The computational efficiency of quantized models is undeniable, according to Fig. 14 and Table III, thus making them optimal picks for mobile devices that require energy-efficient approaches, research shows.

A. Parameter Influence Analysis

According to our findings in the three datasets:

1) Pruning rate (30%): The one chosen when unsuccessful experimental tests indicated optimum accuracy-compression balance. Both the larger rates (40%) resulted in a significant loss in accuracy on the CIFAR-10, and the lower ones (20%) did not provide enough beneficial compression.

2) Quantization precision: Inference speed remained high on 8-bit with the same baseline accuracy as the more digitally prioritized architectures. The 4-bit had the best compression (75%), but it experienced brittle accuracy loss (10 to 15%) and overhead, as non-native compute code had to run on the T4 GPU.

3) Learning rate schedule: Cosine annealing was crucial to quantized models, and a fixed learning rate was not working well during QAT fine-tuning runs.

4) Batch size (32): Trade-off memory limitations and stability of training under all compression methods and data sets.

VI. Future Work

Future investigations should explore mixed-precision quantization methods, a scenario in which various layers of the network are quantized (i.e., encoded to reduce precision) at different bit depths in order to achieve the best out of precision and out of the computational budget. The search for hardware acceleration optimization methods, like Tensor Processing Units (TPUs) or Application-Specific Integrated Circuits (ASICs), might enable the adoption of quantum models, especially in resource-constrained environments. An additional and more promising region of research is the development of adaptive rephrase precision in real-time in accordance with the behavior of the input or application-defined constraints, thus providing robust and flexible models.

Moreover, combining structured pruning with QAT is an attractive research area that can achieve the highest computational efficiency with little loss of model accuracy. Benchmarking those optimization techniques against huge sets of various types of datasets, including realistic large-scale ones, would bring valuable knowledge to their generic acceptability. Finally, energy usage trend analysis among available quantized models in the deployment environment will be done to identify which models are energy efficient. This would be a major step in making greener artificial intelligence (AI) solutions without sacrificing AI performance and with less environmental impact of deep learning models.

VII. Conclusion

In this study, we optimized the model VGG19 by model compression techniques, structured pruning, unstructured pruning, and QAT 8-bit and 4-bit precision. We aimed at speeding up deep convolutional networks through limited resource platforms without compromising the accuracy of classification.

Experimental tests performed on the three benchmarks MNIST, CIFAR-10, and Oxford-IIIT Pet have shown that unstructured pruning and 8-bit QAT provided the best tradeoff between model sizes and predictive accuracy. The inference time and the model size were well-traded, and the same produced an acceptable accuracy by structured pruning. At the same time, the 4-bit QAT achieved the best compression rate (approximately 75%) and sparsity (approximately 48%), but degradation in accuracy occurred on more complex datasets, such as CIFAR-10 and Oxford-IIIT Pet.

These findings indicate that structured connectivity and lower-bit quantization-based pruning have the potential to greatly improve deploying VGG19 to edge devices and that

they can be further improved with the help of training strategies such as early stopping and cosine annealing. Nonetheless, the active quantization, such as 4-bit QAT, has to be tuned a little further to eliminate the inaccuracy, particularly with complex visual information.

Future work will look at the hybrid approaches to the compression of neural networks, especially at the intersection of mixed-precision quantization and structured pruning, towards pursuing an ideal balance between performance and intellectual accuracy of the inference. In addition, evaluating energy usage and optimization in comparison to edge-concentrated hardware acceleration will also be ideal in making these techniques practical in real-world low-power applications.

***Abstract*—Focusing events are sudden, impactful occurrences that spark widespread discussions. Analyzing fake news during such events is challenging due to limited and short-lived datasets. Online fact checkers are slow in identifying fake news, and internet communities and forums become the primary source of news, allowing unchecked dissemination. This study proposes a machine learning approach to predict fake news during the revocation of Article 370 in Kashmir as a focusing event. Small dataset from 20th August till 2nd September is collected and user profile parameters are utilized for effective classification. Five classifiers were employed, with Random-Forest and Logistic-Regression achieving the highest F1 scores of 74 per cent. Results identifies prevalent words in true and false news tweets, aiding in fake news detection. This approach mitigates misinformation during events with limited data, contributing to a reliable online environment. The research is valuable for major geopolitical shifts, natural disasters, and social movements.**

***Keywords*—Classification algorithm; fake news; Kashmir issue; machine learning techniques**

I. Introduction

Focusing events are short lived events that capture public attention and direct it towards a specific aspect of a problem [1]. They can sway politics by mobilizing public support for one side of a debate, potentially influencing political outcomes [6]. Internet communities and forums have become a powerful and cost-effective platform for sharing news, leading to the dissemination of both real and fake information [32], [11]. Fake news detection involves predicting misleading articles intended to deceive readers [40], [62]. During Hurricane Sandy, a study found that 86 per cent of tweets sharing fake images were re-tweets, illustrating the alarming speed at which misinformation spreads [44].

Fake news aims to mislead readers by presenting false information, posing a high risk as it is driven by motives such as social popularity, political agendas, or manipulation of public opinion [43] [39] [50]. Detecting fake news on social media is an emerging research field of great importance to mitigate its adverse impact on the public and the news ecosystem [42].

However, existing research on fake news detection [59], [60], [26] has primarily focused on general-purpose datasets or misinformation in stable, long-term contexts (e.g., elections or health crises). Very limited studies explore detection during focusing events — short, high-impact political developments where data is sparse and rapidly evolving. This creates a significant gap in developing real-time fake news detection methods tailored for such scenarios [19]. This leaves an important gap in the development of real-time fake news detection techniques that are specific to these situations. Our research study tries to address this gap by applying conventional machine learning methods to short-term time series data on Twitter, focusing on the revocation of Article 370 in Kashmir.

In the field of natural language processing (NLP) and computational linguistics, Machine learning(ML) and Deep learning(DL) techniques are being used as powerful analysis tools for identification, classification and detection of language related issues [51] [41]. Our research focuses on Article 370 revocation by India in the state of Jammu and Kashmir as a significant event [29]. In August 2019, the Indian government abolished Article 370, bringing the region under direct central government control [8]. The event generated extensive discussion on Twitter, with a bombardment of visual and textual data [18]. For scenarios like focusing events, where limited data size is available. Traditional ML techniques are effective in classification problems, as DL models require a large amount of training data to produce quality results [40], [59]. Recently, these techniques have been explored as the starting point towards the automation of task selection mechanism of Crowd-Sourced software development (CSSD) platforms [45].

The research question in focus in this study is: What are the performance levels of traditional machine learning models in identifying fake news in high-impact short-duration political events when applied to event-specific social media data?

This study utilizes User profiles on the Twitter social network, for measuring fake news identification using explicit and implicit features [41] [53]. For news tweet dataset, data of twitter users responses and news sources on the revocation of Article 370 in Kashmir was collected. Motivation behind the data collection is identification of fake and real news spread across the platform in the backdrop of the event. Data collection period ranged from 20th August to 02 September, 2019 [52]. The credibility of collected tweet news was checked using Google News search engine, through valid sources and parameters, such as the presence of a "Verified" symbol on twitter account sharing the news [47], friends and following counts of the twitter account [16], re-tweet counts, tweet

creation date, and user reviews about the given tweet [10] [36] [13].

This study introduces a system that automatically detects and evaluates fake news on Twitter, specifically focusing on the revocation of Article 370 in Kashmir. The system captures tweets from various sources and utilizes profile parameters to classify them as fake or real. It trains a model by extracting relevant features and employs selected classifiers. F1 score is used to evaluate model performance.

Our research primarily contributed in:

- Affirming the credibility of traditional ML techniques to analyse "focusing events". The framework identifies fake tweets from different sources and enhance the ability to discern the credibility of news.
- Classification of the most prevalent words in true and false news tweets, highlighting the linguistic patterns that can aid in detecting fake news.

Our study integrates various ML techniques to effectively detect and evaluate fake news on Twitter. We compared five different ML algorithms based on their F1 scores and accuracy. The study presents research outcomes, system limitations, and utilizes word clouds and statistics to classify prevalent words in news tweets, highlighting linguistic patterns for fake news detection, the process is shown in Algorithm 1 on the task of fake news detection.

The rest of the study is organized as follows. The background information about the Kashmir conflict, fake news, and machine learning methods are provided in Section II. The proposed methodology such as data collection, feature extraction and classification algorithms are explained Section III. The results are discussed in Section IV and compared in terms of classifier performance. The study ends with the limitations and future directions in Section V.

II. Background

The related work can be divided into three sub-sections; Conflict of Jammu and Kashmir and revocation of Article 370 of Indian constitution as its focusing event, Fake news and its widespread impact in the backdrop of such events and lastly ML techniques as effective approaches for mitigating the spread and impact of fake news.

A. Conflict of Jammu and Kashmir

Territory of Jammu and Kashmir has been a source of contention between Pakistan and India for over 70 years, leading to four wars in 1948, 1965, 1971, and 1999[56]. Additionally, various groups within Kashmir have their own agenda, which span from seeking affirmative discrimination to advocating for a separate political status or even outright secession [38]. This intricate mix of factors contributes to the intricate nature of the Kashmir conflict.

In August 2019, the Indian government made a significant move by revoking Article 370 of the Indian Constitution. This decision eliminated region's separate constitution and flag, bringing it under the direct control of the central government of India. The decision received both support and opposition, sparking debates about its impact on the region's identity, security, and relations with the rest of India [8]. The event triggered a widespread response across the world and on social media, particularly on Twitter, with an influx of visual and textual data [18].

B. Fake News and its Impact

Cognitive theories [15], [20] suggest that due to our inherent gullibility, people are prone to believing information that aligns with their pre-existing views (confirmation bias). Consequently, individuals may readily share such information without proper verification, further distorting facts that do not align with their beliefs. In the past, foreign actors primarily used fake news for political manipulation. However, it is now increasingly being leveraged across various domains [2] [25] to influence public opinion. During COVID-19 pandemic, misleading and fake information spread all across social media which resulted in false claims and a surge in pseudo scientific health treatments related to the virus and potential remedies [7]. The landscape of fake news has undergone a significant transformation in recent years[55], [35]. Traditionally, the dissemination of misinformation was primarily through conventional media channels. However, the rise of online news platforms and social media has drastically altered the ecosystem of fake news [4] [33] [27]. Hence, the detection of fake news has garnered significant attention in recent years.

C. Machine Learning Techniques

Previously, ML models are being used for prediction problems [30] [37] to eventually help organizations with decision making and identifying future trends. [10] proposed a system utilizing 45 features to predict news accuracy, capturing tweet author specifications, tweet stream properties, contextual aspects, and trends. In [22], the authors proposed a modest approach to fake news detection using the naive Bayes classifier, incorporating user accounts, reverse image searching, and cross-verification of sources. In [12], the authors discussed DL algorithms such as RNN and LSTMs. In Twitter account and bot detection, [14] introduced a system using Support Vector Machine Neural Network (SVM-NN) and other ML

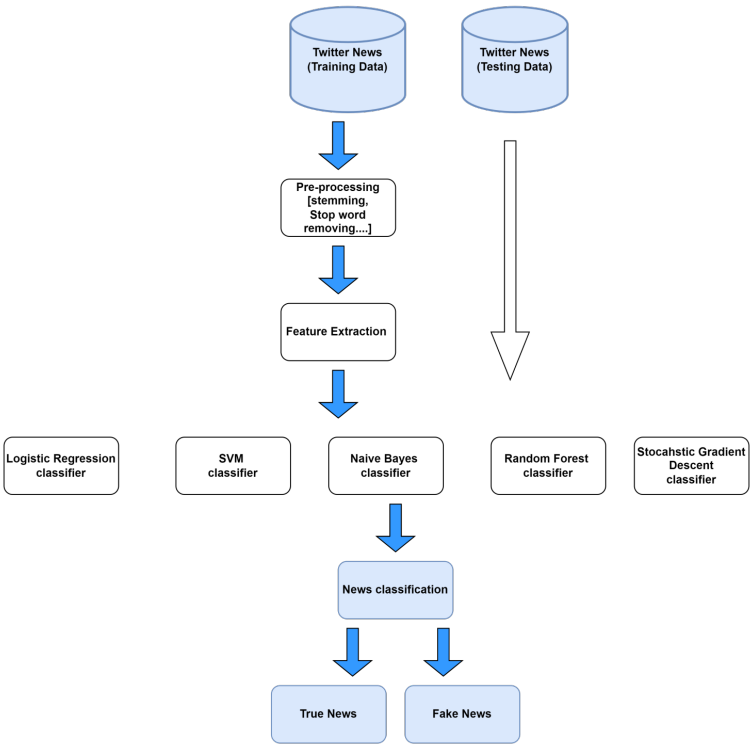

Fig. 1. Machine learning based process of fake news classification.

algorithms. In [17], [46], and [21], the authors explored similar techniques for detecting fake accounts. In [41], the authors measured trust levels of users to identify fake news, employing explicit profile features. In [49], the authors proposes an improved decision tree by changing threshold for their bi-criteria optimization. These improved decision trees are useful for fake news detection.Recently, [45] [54] proposes multi-modal fake news detection using ensemble learning. Modal exploits publicly available dataset and uses NLP techniques for textual information pre-proccessing and gauging the sentiment from each news.

III. Proposed System

An initial set of 6570 general tweets on the revocation of article 370 was collected. During the pre-processing step, tweet redundancy was removed and relevant tweet news content was kept. Graphical data was excluded from dataset due to the challenges in determining the authenticity of images and the complexity involved in assessing hidden objects within them [51], [24]. As a result, 402 news tweets are obtained for model training. Tweet news dataset was filtered to include English news content and remove any unwanted columns and empty rows. Before training, some hyper parameters are fixed for classification and filtered dataset was distributed into train and test data. Table I provides initial distribution of our real and fake news tweets dataset. Fig. 1 shows a high-level overview of the machine learning-based process used to classify fake news.

A. Data Pre-Processing

Fig. 1 illustrates the classification process of the proposed system. After tweet news dataset collection, data pre-processing techniques are applied to remove URLs, extra spaces, hashtags, and other intricacies. The tweets are further refined using stop word and punctuation removal, sentence segmentation, lower casing, and tokenization. These techniques removed all data redundancies and transformed tweets into a unified form for ML algorithms [23]. Additionally, N-gram features were extracted and using TF (Term Frequency) and TF-IDF (Term Frequency-Inverted Document Frequency) a feature matrix is formed. At the end, results of five different ML algorithms - Stochastic Gradient Descent (SGD), Logistic Regression (LR), Random Forest (RF) classifiers, Linear SVM and Naive-Bayes (NB) were compared based on F1 score and accuracy using the Python Natural Language Toolkit (NLTK).

Main steps of data pre-processing techniques being used are:

1) Splitting: This step involves breaking a text document into individual words or tokens [9].

2) Stop words removing: Stop words are used words with no significant meaning in given context. Removing stop words reduces noise and improve the efficiency of text analysis [17].

3) Stemming: Stemming reduce the words to the word base form called “Stem”. For classification method speed and accuracy, we used the commonly used Porter stemmer [28].

4) N-gram model: N-gram model represents a sequence of two words or 2-grams. N-grams store spatial information and serve as an ordered document representation [10]. In

proposed methodology, Bag of words and N-grams are used to represent the documents and do the classification [48]. An N-gram classifier is built and used to differentiate between fake and real news tweets.

5) Features extraction method: However, high dimensionality is a challenge for text categorization since documents which often contain large number of words and phrases. To address this issue, two primary feature selection methods are investigated: Term Frequency (TF) and Term Frequency-Inverted Document Frequency (TF-IDF) [31]. They can mitigate the impact of redundant and irrelevant features on classifier accuracy and performance [34].

B. Prediction Algorithm

Prediction model for fake tweet news identification is built by implementation of five ML classifiers from scratch. These algorithms include LR model, NB classifier model, SVM model, RF model, and Stochastic Gradient Descent. Classification and prediction of fake news was checked across each classifier. To achieve consistency and reproducibility of experiments, we applied standardized hyperparameter configurations to all machine learning models, which are the default parameters in scikit-learn.

C. Tweet Analysis

To understand the distribution of real and fake news feature over the dataset, the study on each feature has been made using tools and packages such as seaborn, wordcloud and NLTK. Fig. 2 shows the total distribution of extracted tweets from 20th August to 30th August, 2019. A higher frequency trend of tweets is visible between 23rd August and 30th August as well as the frequency of true and false news tweets during this time period are visualized in Fig. 3. Table I illustrates the distribution of followers and re-tweet counts of the twitter user and created tweet respectively in true and false news.

TABLE I. FAKE AND REAL TWEETS DISTRIBUTION

Label	Count
True	175
False	125

It is evident from the chart that false news tends to have more followers compared to true news, indicating a higher level of dissemination for false information. Overall, these analysis help to characterize (and patterns) real and fake news in the included tweet news dataset. The analysis also represent a baseline for sentiment prediction of twitter users when a focusing event occurs [3].

D. Most Repeated Words in Extracted Tweets

Using word clouds, display the most frequent words related to the Kashmir conflict. Additionally, separate word clouds are created for true and false news categories in training data, as depicted in Fig. 4, respectively.

E. Tweet with more Re-tweets and Favourite Counts

Within the corpus, tweet with most number of favourite counts and re-tweets was selected and visualised using numpy max function as shown in Table II.

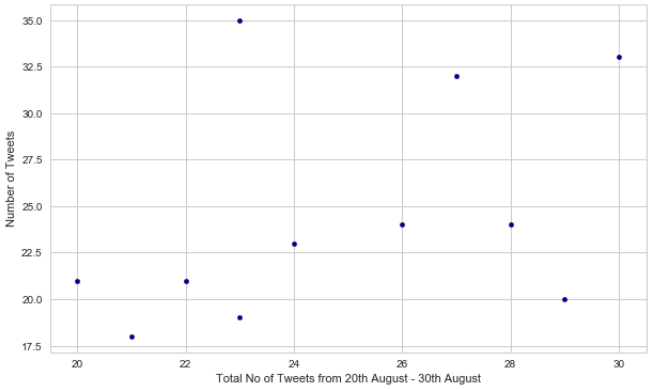

Fig. 2. Total number of tweets from 20th to 30th August.

TABLE II. TWEET HAVING MORE FAVOURITE COUNTS AND RE-TWEETS

The tweet with more likes is:
"Foreign Journals need permit to work in Kashmir. So all the hostile anti-india coverage in Western liberal media has been feed to them by their minions in India". Number of likes: 168
The tweet with more re-tweets is:
"Pakistani Envoy to U.S says world should take notice to avoid new conflict with India over Kashmir". Number of re-tweets: 488

F. Most Engagement of Twitter Users in a Given Time

Level of user engagement is identified using python 2D plotting library Matplotlib to plot a time series of tweet between given date and number of likes and re-tweets within news dataset. As per Fig. 5 , the most favourite tweet counted is between 23rd and 30th August.

G. Sources

To identify the geolocation of the tweeter users creating the tweet, different sources of extracted tweets are plotted in Fig. 6. Pakistan with the ratio of 24.52 is the The highest generator of relevant tweets with India being second highest generator of relevant tweets i.e, 23.56. Fig. 7 provides break down of true and false tweets generated from these location.

H. Results

We conducted experimentation and analysis on a dataset of 6,570 tweets relating to the revocation of Article 370 of Indian constitution by India in disputed territory of Jammu and Kashmir. After data cleaning, removing redundancy and non English tweets, five classifier models were trained on a refined dataset of 402 tweets. The overall efficiency of our classifiers is presented in Table III. We compared the F1 scores achieved by our classifiers and obtained the highest score of 74 per cent by RF classifier and LR classifier. In terms of accuracy, the RF classifier and LR classifier also achieved the highest accuracy of 82 per cent.

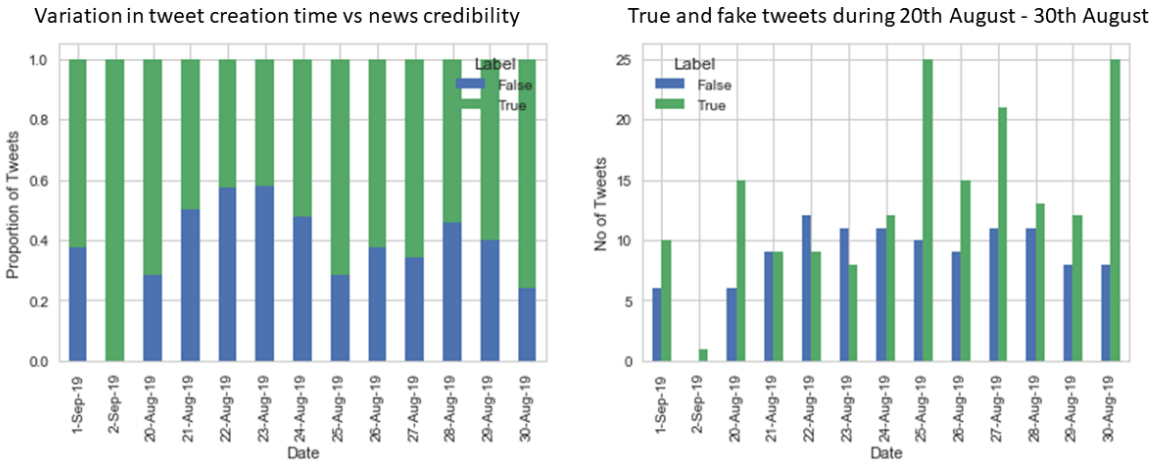

Fig. 3. Analyzing temporal variations in twitter time creation: News credibility and spread of True versus Fake tweets (Aug 20 to Aug 30).

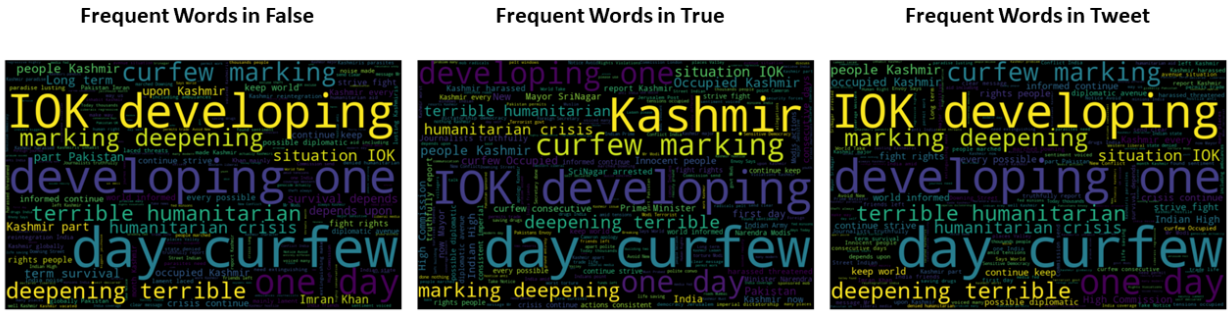

Fig. 4. Comparison of frequent words in fake and real tweets.

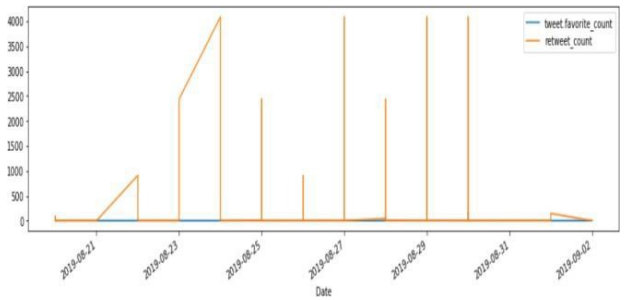

Fig. 5. Most engagement of Twitter user within the selected time span.

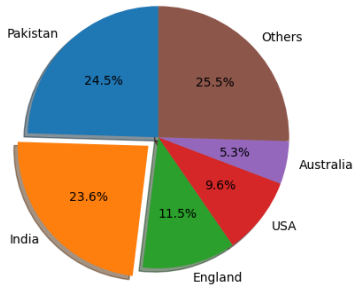

Fig. 6. Tweets percentage based on active Twitter user location.

IV. Discussion

The F1 scores achieved by our best models is 74 per cent which can be attributed primarily to the limited size of our training dataset. Since the tweets on Kashmir Conflict span over few weeks, obtaining a large dataset was not possible, and it was not sufficient to train a DL model. However, our traditional ML models have demonstrated promising results.

Furthermore, our dataset specifically focused on textual

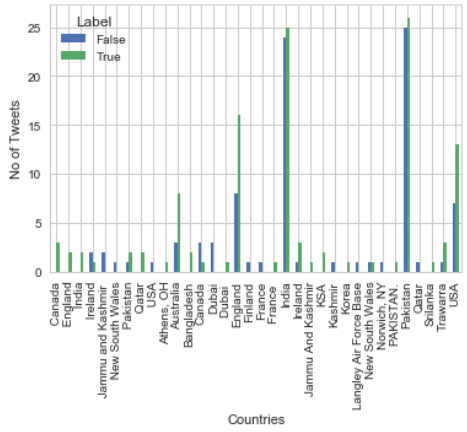

Fig. 7. Comparison of true and fake no. of tweet based on country.

TABLE III. COMPARISON OF DIFFERENT MACHINE LEARNING MODEL BASED ON PERFORMANCE METRICS ON FAKE NEWS DETECTION TASK

Model	F1-Score	Precision	Recall	Accuracy
Random forest	0.74	0.68	0.82	0.82
Naïve Bayes	0.71	0.67	0.76	0.62
SVM	0.73	0.67	0.79	0.79
Logistic regression	0.74	0.68	0.82	0.82
stochastic gradient decent	0.64	0.64	0.63	0.69

data. It is worth noting that existing online fact-checkers, primarily concentrate on fact-checking statements pertaining to American politics [5]. Hence, verifying credibility of real-time news content presented a challenge. Consequently, the task of maintaining an available dataset for our research proved to be challenging, resulting in a decrease in performance when using the "Kashmir Dataset" with a relatively smaller number of instances. Despite these limitations, our research demonstrates the potential of ML techniques in detecting fake news, especially given the constraints of the dataset. We believe that with larger and diverse datasets, our models could achieve higher accuracy and F1 scores.

When data is small, traditional ML has several advantages over deep learning approaches, which typically require large annotated datasets and extensive computational resources. First, it performs well with an F1-score of 74% and accuracy of 82% on a small, event-specific Twitter dataset that represents focusing events. Secondly, our system achieves interpretability and robustness, which cannot be obtained by many end-to-end neural models given that we combine textual features with user profile attributes (e.g., follower ratio, re-tweet count, and verification status). These advantages are reflected in recent comparative studies [61], that compared classical ML algorithms (RF, LR, etc.) to transformer-based models on several real-world datasets and concluded that the traditional ones are still competitive. Likewise, the survey [58] of ML and DL architectures found that Logistic Regression exceeded transformer models in limited environments. Our results confirm these findings because it has been proved that traditional ML is frequently more feasible, more resource-friendly, and interpretable in low-resource, high-impact settings.

V. CONCLUSION

We have developed a system that uses traditional ML techniques to automatically detect and assess the credibility of fake news on Twitter using a comparatively smaller dataset. Our system achieved the highest accuracy of 82 per cent, with RF and LR classifiers. Our study is a contribution to the combating of fake news because we offer a strong system of identification and evaluation of news credibility that gives impressive outcomes using a small dataset. Our experimental results affirm the credibility of traditional ML techniques to analyse "focusing events". Moreover, classification of the most prevalent words in true and false news tweets is useful in highlighting the linguistic patterns that can aid in detecting fake news.

These results indicate the success of our method in real-time, event-specific detection of misinformation, particularly, in the situation when data is scarce. The accuracy and interpretability were achieved by the combination of user profile features and linguistic patterns. Our evaluation does not only provide powerful predictive performance but also adds practical knowledge of how to design lightweight detection systems that can be applicable to political crises and other rapidly changing environments. The framework can be incorporated into early warning systems by journalists, fact-checking organizations, or policy response teams to track misinformation in real-time during political or crisis events. Theoretically, it helps to fill the gap in the under-researched field of fake news detection in focusing events, proving that even in the conditions of limited data, the standard ML models can be effective.

Although the results are promising, this research has limitations. The dataset was small and narrow, only concerned with English tweets during a certain time frame. Such limitations can influence the applicability of the model to more extensive or multilingual fake news detection procedures. Future work will focus on expanding the dataset, incorporating additional feature selection methods, and diversifying language coverage. Additionally, employing different DL techniques, such as fine-tuning a pretrained model can potentially improve the results.

***Abstract*—Document classification using supervised machine learning is now widely used on the internet and in digital libraries. Several studies have focused on English-language document classification. However, Arabic text includes high variation in its morphology, which leads to high extracted features and increases the dimensionality of the classification task. Towards reducing the curse of dimension in Arabic text classification, a wrapper feature selection method is proposed in this study. In more detail, a hybrid metaheuristic model based on the Wind Driven and Simulated Annealing is designed to solve FS task in Arabic text, known as WDFS. The Wind Driven method is initially introduced to optimize the Fs task in the exploration phase. Then, WD is hybridized with simulated annealing as a local search in the exploitation phase to enhance the solutions located by the WD. Three classifiers are utilized to evaluate the selected features using the proposed WDFS: K-nearest Neighbor, Naïve Bayesian, and Decision Tree. The proposed WDFS method was assessed on selected four groups of files from a benchmark TREC Arabic text newswire dataset. Comparative results showed that the WDFS method outperforms other existing Arabic text classification methods in term of the accuracy. The obtained results reveal the high potentiality of WDFS in reliably searching the feature space to obtain the optimal combination of features.**

***Keywords*—Text classification; Arabic documents; wind driven optimization algorithm; simulating annealing; feature selection**

I. Introduction

There is a large and growing amount of machine-readable information out there, which makes it more difficult to use and understand. It provides resources that make it possible to automatically recognize and organize huge amounts of text [1]. Technologies concerning document classification that are automatically applied to huge amounts of diverse document information have grown due to the early progress on the Internet and the escalation of electronic information. Among document classification tasks, Arabic document classification is the most recent challenge in the field of document classification because of the Arabic language's complexity [2]. Additionally, there are a lot of documents conducted almost every day which has made it difficult to accurately detect Arabic documents. Thus, many studies have focused on identifying the difficulties facing compilations of standard Arabic documents classifier [3, 4, 5], encouraging more studies for to improve the performance of the Arabic document classifiers. Most Arabic document classifiers are notoriously difficult to handle huge amounts of documents and to properly identify Arabic documents. As a result, this issue is considered the primary Arabic classification problem. There are two main aspects to the obstacles facing Arabic classifiers. The first is the huge diversity of features resulting from different Arabic word variants, and the second aspect is another operation of the document classification system may be affected by the failure of classifiers to handle stemming. Thus, the algorithm will be used to create a stemming rule that relies on the grammatical rules of speech to address the difficulty of processing the Arabic text while bypassing the morphological and grammatical rules [6].

Arabic document classification task is the process of classifying documents based on their content into predefined category classifications [7]. In this task, large, enormous features are extracted from the text, and they may amount to hundreds or thousands. Due to the high dimensions of the feature space, classifier performance may be affected and more time may be required to replace the term with alternative concepts. By sifting through the text and identifying key semantics, the number of characteristics can be reduced; however, this reduction is not necessarily optimal as some of the omitted terms may be significant characteristics [8]. Choosing the right features is the most critical application in machine learning. Substantially, the most important features identify the learning objective where the attention of the learning algorithm highlights the most useful data for analysis and of the future prediction [1, 9, 10, 11]. Concepts from testing theory were used to create a correlation-based feature selection method and evaluate a set of machine learning algorithms that have been trained on various combinations of real-world and compositional issues. Feature selection (hereinafter referred to as FS) is simple and quick to implement because it removes redundant and irrelevant data while also iteratively improving the performance of learning algorithms. Comparison of the results of this technology with a contemporary feature identified from the literature [12] requires much less calculation.

Although several FS methods have been introduced to assist in Arabic text classification, most of these studies focus on filter FS methods, such as X, which introduced the Chi-square filter for Arabic text classification, and Y, which introduced the cosine similarity for this task. These filter methods were utilized to rank the features but not to select a suitable subset. Using wrapper FS methods with an optimization algorithm assists in choosing an appropriate subset, which increases the performance of text classification.

In designing an FS method, the main goal is to find the most appropriate subset of features; hence, FS problems

are considered NP-hard problems [7]. Using exact search algorithms with the NP-hard problem will generate all possible feature subsets. For instance, assuming we have N text words (i.e., features), then using FS methods such as wrapper methods will generate 2^N subsets of features using a specific learning algorithm (i.e., KNN), which is computationally costly. Whereas FS aims to keep the number of features selected to a minimum while maximizing classification performance, it can be considered an optimization problem. To choose wisely, it is usually necessary to find a middle ground between these two goals. It is best to think of the feature selection process for text classification as a multi-objective task rather than a single-objective task. Numerous meta-heuristic algorithms based on multi-objective approaches have recently been employed to solve text FS issues in an encapsulated framework [3].

The following contributions were made to the classification of documents in this study:

- The stemming process is introduced as a preprocessing step for Arabic text classification, which groups words of the same root into a single word.
- The Bag of Words method is used as a preprocessing technique to extract features from Arabic documents.
- The BWDO-SA wrapper-based FS method is investigated to select the most relevant features from the extracted features. SA is introduced into the BWDO to improve the original BWDO's capacity for exploitation.
- Different learning algorithms, including Decision Tree, Naïve Bayesian, and K-nearest Neighbor, were investigated with BWDO-SA for classifying Arabic documents.

The rest of this study are organized as following; Section II discusses an overview of the related work for text classification. The research methodology considered in this study and the proposed framework of Arabic text classification is provided in Section III. Section IV introduces the experiment dataset and parameter settings and the performance measures. Section V describes the experiment results and discussion. Finally, Section VI contains the conclusion and the future work.

II. Related Works

Several previous studies on classification in Arabic language are reviewed to uncover new classes of classifiers, as well as to address issues related to them, with the aim of bridging the gap between feature selection and the impact of using classifier algorithms, such as optimization feature selection and popular classifiers. An actual evaluation is conducted on studies related to Arabic classifiers to determine the potential for high-performance Arabic classifiers with a small number of selected features. Additionally, the problems and obstacles related to feature selection are identified and discussed, along with their impact on optimization feature selection, by reviewing text classifiers and classifier algorithms. Text categorization (TC) is a type of supervised learning activity that entails classifying documents according to labels already assigned to a set of training documents. Knowledge engineering, in which a manually generated set of rules is used to classify documents into predefined categories, was the most widely used strategy until the development of machine learning approaches in TC.

In [13], the authors explained that the incorporation of machine learning (ML) in TC offers several advantages, such as reducing costs and time by relying on expert workforce only, without compromising precision. K-Near Neighbor Learning (KNN), Decision Tree (DT), Neural Networks, least Squares Fitting (LLSF) and Naive Bayesian (NB) have all been developed and applied to TC [14, 15, 16]. All of these learning strategies perform equally well when there are more than 300 documents in each category, as measured by their comparison. However, when there are less than ten positive training papers in each category, DT, KNN, and LLSF outperform Neural Networks and NB.

The volume of textual data currently available has increased, leading to initiatives such as Arabic language filtering [17] that aim to filter and highlight incoming papers for unwanted or unwelcome content. This has led to the increasing importance of transcript taxonomy (TC). Sentiment analysis [18] which aims to ascertain the overall sentiment expressed in a document, is another use. By providing classification models with examples labeled for the problem at hand, such as appropriate classifications (labels), supervised learning methods can be used to solve problems associated with text classification. Therefore, labels of unlabeled documents can be predicted using these model [3, 19, 17, 20, 21, 16, 10]. The task still requires more work of pre-defining classes and assigning class labels to training set documents, despite the fact that several supervised machine learning algorithms have been applied to TC.

Researchers in [22] compared different Arabic classifiers using BOW as extraction without FS. The comparison showed that NB performs better than DT and tree-based J48. Another study conducted by [23] compared NB, tree based J48, and IB1 using BOW as an extraction. The study reported NB to be better in classification tasks compared to FS methods. In [24], the authors compared DT, AdaBoost, and RF using BOW as extraction and found that DT is the best classifier. In addition, they contrasted IG with Chi-Square and deduced that both methods are comparable when using DT as a classifier and Chi-Square as an FS. However, RF was the best classifier, compared to DT with FS. A study done by [25] utilized six FS methods and two classifiers (DT and NB) on six datasets. The study merged ODFFS and TFFSs to generate a hybrid method (HBM) to propose the FSEPO for parameter optimization. The report showed that NB is the best classifier compared to DT and HBM in enhancing optimal FS. In [26], the authors conducted a comparison among various classifiers for Arabic text. The text preprocessing steps included removing digits, dashes, punctuation marks, and other non-Arabic characters, as well as filtering out stop words without using FS. The results of the comparison revealed that the decision tree (D.T) classifier performed better than the Naïve Bayesian (NB) method, K-Nearest Neighbors (KNN), and NaïveBayes Multinomial (NBM) classifiers. In [27], the authors compared Decision tree (C5.0) SVM using stop words as extraction with Chi-Squared statistic FS. The study reported a Decision tree (C5.0) to be better in classification tasks compared to SVM.

The selection of feature subsets is a common problem for

Arabic classifiers due to the large dimensionality of textual Arabic types. Therefore, the feature selection (FS) process is important to reduce these dimensions and to choose a large number of high-quality attributes without significantly influencing the performance. The investigation of the problem can be in two areas: the first is to focus on the selection of significant features and eliminate redundant ones.

The problem of selecting the best subset of features from the original feature space without affecting the accuracy of the classifiers is known as FS. The second perspective involves enhancing the prediction performance of the classifiers by considering their specific problems. Existing literature has shown that several approaches have been investigated for FS with different techniques of Arabic classifiers. Most importantly, FS methods should consider the properties of the learning algorithm and the problem domain. The effects of different FS methods on different learning frameworks and fields may vary, and therefore, ongoing studies are being conducted to develop new methods for handling FS and addressing dimensionality problems, particularly for Arabic classifiers. Hence, the aim of using FS approaches may include performance enhancement, data simplification, visualization, as well as feature dimensionality reduction [28, 29].

Various approaches have been applied for dimensionality reduction, including IG, Chi-Square Statistic, MI, TS, and DFT. Chi-square scale the level of dependence between a particular term and a particular category, i.e., A measure of how strongly a term is believed to indicate whether a document belongs to a particular category [30]. Several researchers have reformulated the statistic and deployed it for document categorization [30, 31]. In [32], the authors designed a classifier for Arabic document filters by employing Chi-square and IG on ML techniques, namely, BA tree-based J48 and DT. From their report, the Chi-square and IG showed similar performance as the BA and tree-based J48 classifiers, while DT without FS performed better than Chi-square and IG with FS. IG determines the number of bits of information acquired for each prediction class when the presence or absence of a term is determined in a document.

In [33], the authors suggested an improved Feature selection method for Arabic text classification. To enhance the effectiveness of classification, a number of experiments were performed, comparing improved chi-square with three known types of FS, namely chi-square, information gain, and mutual information, using the SVM classifier on a dataset of 5070 Arabic documents. The researchers evaluated these methods using classification measures, The results showed that the Arabic text classification model performs significantly better when the improved chi-square is combined with the SVM classifier. In [34], the authors suggested an innovative and new technique of feature selection that relies on practical swarm optimization to enhance the work of text classification. The proposed method was compared with several other methods, including genetic algorithm, chi-square, and the information gain, using Matlab and the Reuters_21578 dataset. The proposed method efficiency and effectiveness were evaluated using the nearest neighbor classifier. In conclusion, the findings indicated that the proposed method surpassed other methods. Marie-Sainte and Alalyani [35], introduced a new firefly algorithm that relies on FS for Arabic Text Classification (ATC). In this study, various experiments and comparisons were conducted using six feature selection techniques in combination with one state-of-the-art techniques that used the SVM classifier. These techniques were applied to the OSAC dataset, and three different techniques were used to measure execution accuracy. The outcomes showed that the suggested technique (ATC_FA) produced superior performance.

In [36], the authors presented a hybrid method combining the Flower Pollination Algorithm (FPA) and the Adaboost algorithm. Each algorithm served a different purpose, with FPA focusing on feature selection and Adaboost aiming to categorize text contents. The experiments have been made on Reuters-21578, WEBKB, and CADE 12 datasets, and the outcomes demonstrated that the suggested approach outperforms NB-K-Means, KNN-K-Means, and other learning models in terms of FS and performance. In [37], the authors proposed a new hybrid algorithm that combines bee colony optimization (BCO) and ant colony optimization (ACO) to improve FS in 2017. This approach was applied to 13 datasets from the University of California, using Decision Tree (DT) classifiers. The experiments demonstrated that the hybrid model achieved higher categorization accuracy and better feature selection compared to other methods, including ACO Hybrid ACO, ACO-NN Hybrid, Based FS, IQR Bee, CatFish Binary PSO, PSO-SVM, and ABC-FS Swarm based Hybrids such as ACO-PSO Hybrid, and ABC-DE Hybrid, as evidenced by the Prediction Accuracy (PA) measure. In [29], the authors used the improved feature selection technique of whale optimization with SA. The outcomes were contrasted with those of other population-based techniques were outperformed them in terms of data classification performance.

For feature extraction and selection [38], the authors exploited the Aravec embedding model. Aravec is a large dataset trained using an Arabic twitter data domain. The extracted features were exploited to classify twittes using a multilayer bidirectional long short term memory (BiLSTM). The model outperforms the state of the art models.

The authors of Targio and Tubishat [39] proposed an approach that used a hybrid fillter-wrapper method based on Principal Component Analysis (PCA) to filter the features and select relevant ones. These features will be exploited for categorizing Arabic documents. To select more relevant features GreyWolf Optimizer (GWO) as wrapper approach is performed. To evaluate the classification task the Logistic Regression (LR) is used. Three Arabic datasets were exploited to perform the experimentations. These laters show that the approach-based PCA-GWO outperforms the baseline classifiers.

In the work [40], the authors present a feature section approach that is composed of two stages. the first one exploited the filter model. The second one used and the multi-objective wrapper model, an upgraded version of the Whale Optimization Algorithm (WOA) with Particle Swarm Optimization (PSO). Four benchmark text corpora were used to evaluate the proposed approach which shows encouraging results. The study of [41] presents an approach that uses NLP and machine learning methods for text classification. To tune the hyperprameter of machine learning algorithms two techniques were exploited: Grid Search and Random Search. Experimentations were performed using CNN Arabic dataset. The results showed

that random search is more efficient than grid search in terms of accuracy, precision, recall, and F1-score and execution times for some of the algorithms.

In this research we have analyzed a number of previous studies that help us better understand this study. Various concepts, including TC, is one of the most important applications that are in high demand today, and the most used classifiers like k-Nearest Neighbors (KNN), Naive Bayes (NB), and Decision Trees (DT), have been discussed. Given the huge quantity of online information that is constantly increasing, the findings of these studies are valuable in terms of saving effort and reducing costs for users and developers. Additionally, feature selection depends on optimization techniques which result in reducing redundant and unnecessary features in texts.

III. Methodology

The proposed methodology embraces a wrapper-FS method to select the most suitable subset of features from the original feature set to improve the performance of Arabic document classification. Fig. 1 below displays the principal methodology used to conduct this study, which consists of several phases: data pre-processing, feature extraction, feature selection, and finally, the classification phase. The proposed BWDO-SA is introduced within the feature selection phase.

A. Data Pre-Processing

The TC system begins with the pre-processing stage. This step is important for document representation because it pre-processes the collection's text data to determine the indexed features or terms. Several procedures are performed during this phase to clean and clarify the text data [42, 43]: First, a tokenization and normalization procedure is used to remove unnecessary terms such as punctuation marks, non-Arabic letters, diacritics, and digits [44]. Second stop-word removal, which focuses on eliminating unimportant words for machine-learning tasks. The third phase is the stemming phase, which is used in text classification to find the stem word for several related terms. The following steps provide additional details regarding these processes for Arabic document classification.

1) Tokenizing and normalizing of data: When text is divided into separate units by using either space or special symbols. As such, every word in a text is represented in a unit. Such a method is called tokenization. For instance, (خير جليس في الزمان كتاب) it explains the method tokenizing works in a text .(خير_جليس_في_الزمان_كتاب) Furthermore, normalization is beneficial for carrying out before the stemming task, particularly in the Arabic text is being performed due to the text normalization that decreases several types of characters in Arabic languages to enable one uniform character to act to those characters. The following steps followed in the pre-processing.

- Remove diacritics, punctuation marks, hyphens, numbers, digits, and non-Arabic letters.
- Substitute ,آ ,إ as well as أ by ا
- Substitute the last ة by ه.
- Substitute the last ى by ي

2) Stop word removal: The removal of these words will not have any major impact on the document's meanings, but rather will be clearer to smooth the process of the meaning interpretation of the document [6, 44, 45, 43, 46]. Fig. 2 shows the document sample words after the removal of the stop-word.

3) Stemming: A stemming algorithm reduces all the inflectional derivational variants of words into a common form called the stem [45]. For example, the words, 'work', 'works', 'working', 'worked', and 'worker' are taken from the root (stem) 'work'. The root of a word is obtained by removing all or some of the affixes attached to the word. The Light10 stemmer was used in the stemming process following the same steps in [47]. This process applies to words containing additional characters whether suffixes or prefixes to get the root of these words [48]. There are four types of affixes shown in Table I.

B. Feature Extraction

Text pre-processing is a necessary step in TC using ML technologies. This entails converting the text into forms that learning algorithms can use. The document representation vector space model, which is widely used, was first described in [49]. Each dimension in the "d" vector that this model uses to describe each text corresponds to a different term in the document set space term. The text document is often converted into a term frequency vector to implement the document processing process [34, 85]. Each document was represented by a vector, where each term acts as an attribute and the value of the attribute is the document's TF*IDF weight [50] a statistical method for measuring the importance of a term for a document in a group. The most common terminology weighing method (TF*IDF) takes this property into account. According to this method, the term weight in the document d is inversely related to the number of documents in the group where the term appears (IDF) and proportional to the number of times the word appears in the document (TF). When using the TF-IDF weighting strategy, terms are given weight based on their frequency in a document using a factor that ignores their importance if they are present in most documents, especially when the term is thought to have poor discriminatory power [see Eq. (1)].

$$w_i = tf_i . \log(\frac{N}{n_i}) \quad (1)$$

where, N denotes the total amount of documents in the collection, w_i denotes the weight of the term in the document, tf denotes its frequency, and n_i denotes the number of documents in which the term appears. Since each token in each document represents a dimension in the feature space, this transformation raises the problem of high dimensionality of the feature space. As a result, large computational costs significantly reduce classification effectiveness [51].

C. Feature Selection

Choosing a subset of features for an Arabic text classification system is crucial. Generally, in ML, three methods for feature selection: embedded methods, wrapper, and filter. By using these techniques, a cost-effective and accurate text

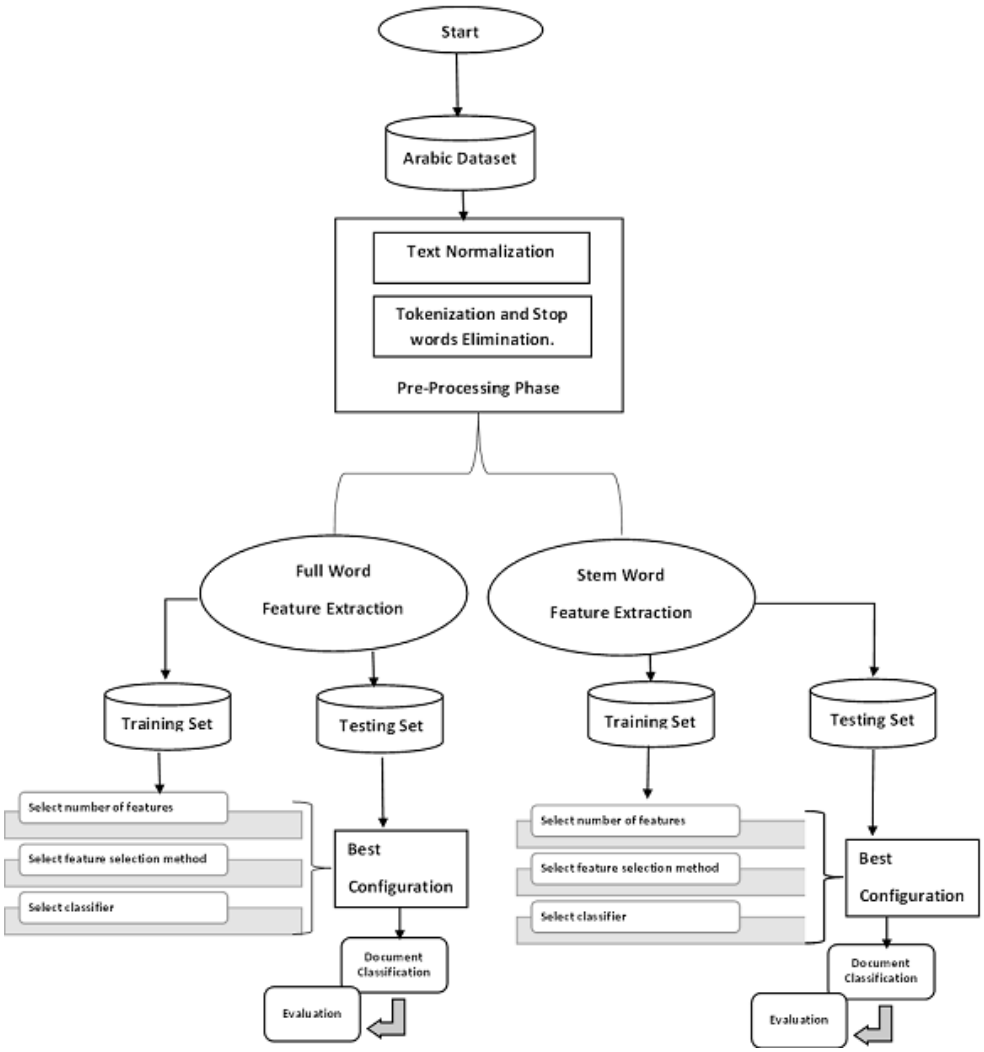

Fig. 1. The primary methodology of this research.

Fig. 2. Document sample words after the removal of the stop-words.

TABLE I. UTTERANCES OF AFFIXES INWORD(مهنوريلي, (مهنوعدخيلي .

Postfix	Suffix	Root	prefix	Antefix
مه	ون	يرى	ي	ل
مه	ون	خدع	ي	ل
Pronoun meaning (they)	Termination of conjugation	يرى meaning (See) and خدع Meaning (Deceive)	A letter meaning the tense and the person of conjugation	Preposition meaning (to)

classification task can be achieved [52]. In this study, wrapper methods were examined.Fig. 3 illustrates the three primary factors used in wrapper methods for identifying the optimal feature set [53]: First, the ideal feature combination from the initial dataset is found using a search approach (for instance, an optimization technique). Second, a machine learning model (such a classifier) is used to assess the produced subset of features by comparing them to the validation dataset. Third, the dependability of the chosen feature subset is evaluated using an objective function criterion.

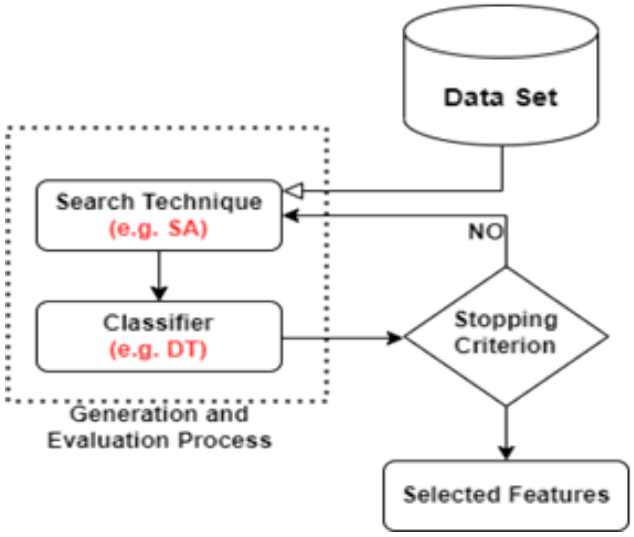

Fig. 3. Wrapper-Based feature selection method using SA and DT classifier.

As the increases in the amount of Arabic language text documents in classification, it is becoming increasingly difficult. Thus, FS techniques play a crucial part in deciding what features are the most relevant for the classification model while ignoring the redundant and the irrelevant ones. This study proposes a hybrid wrapper-based FS method for Arabic document classification, based on a combination of binary wind-driven optimization (WDO) and simulated annealing (SA) algorithms, namely BWDO-SA.

D. The Proposed BWDO-SA for Feature Selection

In this section, the proposed BAWDO-SA method is investigated, and its early stages of standard WDO, solution initialization, binary WDO, simulated annealing, and the proposed BAWDO-SA are discussed in the following:

1) Wind Driven Optimization (WDO): The Earth's atmosphere, where winds blow in an attempt to balance horizontal differences in air pressure, served as the inspiration for WDO [54]. The term "wind" refers to the horizontal movement of air, particularly in the troposphere, which is the lowest layer of Earth's atmosphere. The thickness of the troposphere varies with latitude and extends from the earth's crust to a height of about 18 km [55].

This phase aims to employ supervised WDO for feature selection. In this research, a supervised WDO approach was applied, using the accuracy of classifiers as the objective measure of performance for feature selection. The study suggested using three classifiers by combining feature selections to identify, detect document categories and assess the three classifiers' performance using WDO's supervised feature selection. In other words, this proposed method was designed to detect the most important features that would improve the classifier's performance while reducing the number of features selected. Fig. 4 shows the pseudo-code of WDO as feature selection [55].

The major strengths of the WDO high priority are that it [56]:

- Contains many transactions that facilitate the process of restricting the search field.
- Uses additional terms such as (gravitational and Coriolis force) in the equation of speed update.
- Classifies the population based on their pressure.
- Checks the boundaries to prevent any air expulsion from the search area.
- Affects problems related to both discrete and continuous value parameters [55].

2) Simulated annealing: The escape probability of a local optimum problem served as the basis for the development of the SA employing Hill Climbing-based (HC) techniques [56]. Using the simulated annealing method [57], is a heuristic solution based on the HC technique. Fig. 5 illustrates the algorithm. SA begins by establishing a random number from the available solutions and then generates neighboring solutions based on the same random number.

After generating the surrounding solutions, the algorithm verifies each one's credentials before attempting to select the most acceptable number for the next stage. With the probability defined by the Boltzmann probability value, P=e^(-θ/T), the method also accepts minimum solutions, where θ is the difference between the Solbest and Soltrial evaluations of the objective function. T is the temperature, which, in accordance with a cooling plan, drops periodically during the search phase. In [58], the authors used SA in order to solve numerous attribute reduction issues in SimRSAR. The solution took into account that each case corresponds to a certain set of attributes in SimRSAR, and a nearby arithmetic attribute can be found using the chosen attribute. $T(t+1) = 0.93 * T(t)$.

Set user parameter of the WDO: $P_{opt}, \alpha, g, RT, and\ c\ and\ Maximum_Iteration$.

Create randomly initial population of feature selection using Eq (2, 3)

$$AirParcel\ feature = [X_1, X_2, X_3 \ldots] \quad (2)$$

$$\text{AirParcels of feature} = \begin{bmatrix} AirParcel_1 \\ AirParcel_2 \\ AirParcel_3 \\ \vdots \\ AirParcel_{Popt} \end{bmatrix} \begin{bmatrix} x_1^1 x_2^1 x_3^1 & \cdots & x_{Nfeatures}^1 \\ \vdots & \ddots & \vdots \\ x_1^{Popt} x_2^{Popt} x_3^{Popt} & \cdots & x_{Nfeatures}^{Popt} \end{bmatrix} \quad (3)$$

Randomize the velocity and the position of air parcels

Set the fitness function using Eq (4)

$$fitness = \beta \gamma_R(D) + \alpha \frac{|R|}{|N|} \quad (4)$$

Evaluate the population and find the minimum pressure value for air parcels ($P_0 = min(f(x_i))$)

Set global $P = P_0$

for all i do

for all j do

Update the velocity by Eq (5)

$$u_{new} = (1-\alpha)u_{cur} - gx_{cur} + \left(RT \left|\frac{1}{i} - 1\right| (x_{opt} - x_{cur})\right) + \left(\frac{cu_{cur}^{otherdim}}{i}\right) \quad (5)$$

Choose random dimension

Choose velocity based on random dimension

Check velocity by Eq (6)

$$u_{new}^* = \begin{cases} u_{max} & if\ u_{new} > u_{max} \\ -u_{max} & if\ u_{new} < -u_{max} \end{cases} \quad (6)$$

Update air parcel positions by Eq (4.27)

$$x_{new} = x_{cur} + (u_{new}\Delta t) \quad (7)$$

Call CMAES

Return the new set of WDO coefficients for $i+1$

Evaluate the new solution and update $P(i,j)$ using Eq (4)

if $P(i,j) < P0$ then

global $P = P(i,j)$

end if

end for

Rank air parcels and find the local optimum ($xlocal$)

end for

Rank air parcels and find the global optimum ($global$)

Return the values of $xglobal$ and $fmin = min(f(xbest))$

End of the algorithm

3) Binary WDO for feature selection: The task of FS is a binary discrete problem in which features can be represented by a binary solution or vector. The values of this vector are either one for the selected features or zero for the omitted features, which are not selected, as illustrated in Fig. 6.

The basis of the WDO was initially implemented for continuous optimization tasks. Thus, to implement the WDO for the FS task, a transform function is required to convert the WDO to a binary WDO (BWDO). This study uses a sigmoid transform function, as shown in Fig. 7, to convert the solution to binary format (i.e., 0 or 1).

Eq. (2) illustrates the formula for the sigmoid function for a solution x.

$$T(X_i^j(k)) = \frac{1}{1 + exp(-X_i^j(k))} \quad (2)$$

where, $T(X^j{}_i(k))$represents the transform of the dimension j in the solution x_i (i.e., air particle) at iteration k.

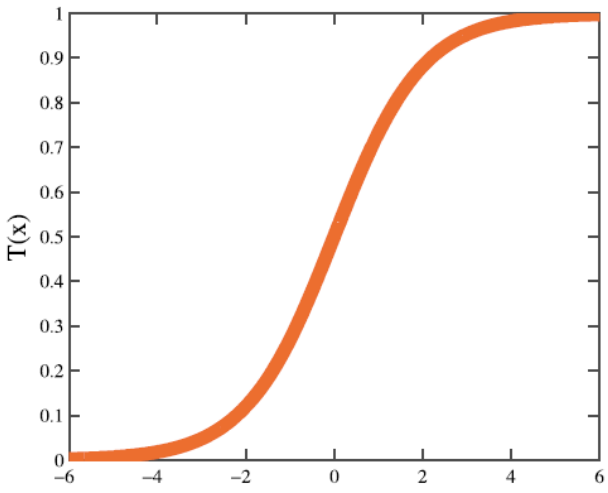

Fig. 7. Sigmoid function.

In the iteration, k, the location of each air particle xik of each pair particle i is converted into binary format using the following equation:

$$X_i^j(k) = \begin{cases} 1 \; rand \; \geq \; T(X_i^j(k) \\ 0 \; rand \; < \; T(X_i^j(k) \end{cases} \quad (3)$$

The above Eq. (3) is utilized in the FS approach in this study to determine the probability of changing the location of the elements in the solution.

The BWSO begins the optimization process with a randomly constructed initial population of N air particles. Each particle designates one solution with a binary vector of dimension D, which represents the candidate features, i.e., a subset of features. In this vector, dimension D characterizes the entire set of features in the original dataset. Fig. 4 shows the pseudocode of WDO as a feature selection.

4) Evaluation using fitness function: The major objective of using the feature selection optimization approach is Reducing the number of selected features while getting the best classification accuracy. In other words, fewer selected features provide better opportunities to improve the solution classification performance.

All possible available solutions are evaluated according to the proposed witness selection procedure and the final publisher, which depends on three classifiers, namely KNN, SVM, and NB [59] to classify the answer correctly based on the amount of features chosen. To achieve the highest level of precision while maintaining an appropriate balance of all features chosen for each of the minimum solutions for feature selection, the fitness function (objective function) in Eq. (4) is utilized for each WDO as well as SA assessment techniques for agent searches.

$$fitness = \beta_{\gamma_R}(D) + \alpha \frac{|R|}{|N|} \quad (4)$$

The BWDO is a population-based metaheuristic method with high exploration performance. However, the main limitation of the BWDO is the degradation of its exploitation capabilities. This is because it employs a blind operator to enhance the local area surrounding the best solutions discovered thus far without regard for the quality of the present solutions. This study introduces an innovative FS method based on the hybridization of BWDO and SA, known as BWDO-SA. This method is applied to the FS task in the domain of Arabic text classification. The SA method, which is a local search algorithm, is utilized within the BWDO to replace the blind exploitation phase. Specifically, the SA seeks the best solution in the vicinity of the best-known and randomly selected solutions.Fig. 8 shows the flowchart of the proposed Hybrid of BWDO-SA algorithm.

E. Classification

We investigated NB, DT and KNN, which are frequently used for text classification and proven to give satisfactory results, to test the effectiveness of the proposed methodology [60]. Additionally, these classifiers meet nearly all of the difficulties encountered in this paper thanks to the following qualities: In supervised algorithms, the categorical structure of a given database is taken to be known beforehand. For the supervised algorithms to map documents into predefined labels, they need a set of labeled documents. As noted earlier, it can be difficult to determine the exact class and naming of training sets, especially in large databases. Therefore, the most popular supervised algorithms, including DT, KNN, and NB, will be the focus of this section.

1) KNN: KNN has been established as a well-liked instance-based learning method and has shown efficacy in a number of text classification tasks [60]. The algorithm flow can be summarized as follows: From the given training documents, KNN first determines the k-nearest neighbors. The flow of the algorithm can be summarized as follows: First, the KNN identifies the k-nearest neighbors from the given training documents. Second, based on the category labels of these neighbors, the category of the test document is established. The proven k-nearest method usually sets the test document with the name of the most common class. Each neighbor's contribution to the weighted KNN is determined by how close it is to the test document. This is an extension of the regular KNN. To determine the class score of a document, the similarities between neighbors in each class are added. Or to put it another way, the category score for document x can be represented as in Eq. (5):

$$score(c_j, x) = \sum_{d_i \subset N(x)} \cos(x_i, d_j), y(d_i, c_j) \quad (5)$$

The training document is =d_i , a collection of the k training documents that are closest to x=N(x), similarity between x and d_i =cos(x,d_i) , value of a=1 in function y(di,c_j) if belongs to category, and otherwise 0. The results of both evaluation methods are presented in the results part of this study, which examined the original KNN as well as its weighted version by varying the values of the parameter k.

2) Naïve Bayesian (NB): NB was constructed as a probability-based model that uses the joint probability of terms and categories in a test document in order to calculate the probability of categories assigned to that document [60]. It is the classifier's assumption that all words in each class are conditionally independent of all words in the other class that gives rise to the "naive" feature of the classifier. In contrast to non-NB classifiers, computational procedures can be made simpler by learning parameter values for each word separately based on the idea of independence.

As per [61], Polynomial modeling and multivariate Bernoulli model were both major models used for text classification using NB. Bayes' rule is used by the two models to accomplish the categorization of documents [60] [see Eq. (6)]:

$$P(c_j|d_j) = \frac{P(c_j) \; P(d_j|c_j)}{d_i} \quad (6)$$

where, d_i= test document, C_j= class. Given d_i is the test document, c_j posterior probability for each category's, i.e., , $P(c_j|d_j)$and d_i assigned to the category with the highest probability. The calculation of $P(c_j|d_j)$ calls for an estimation

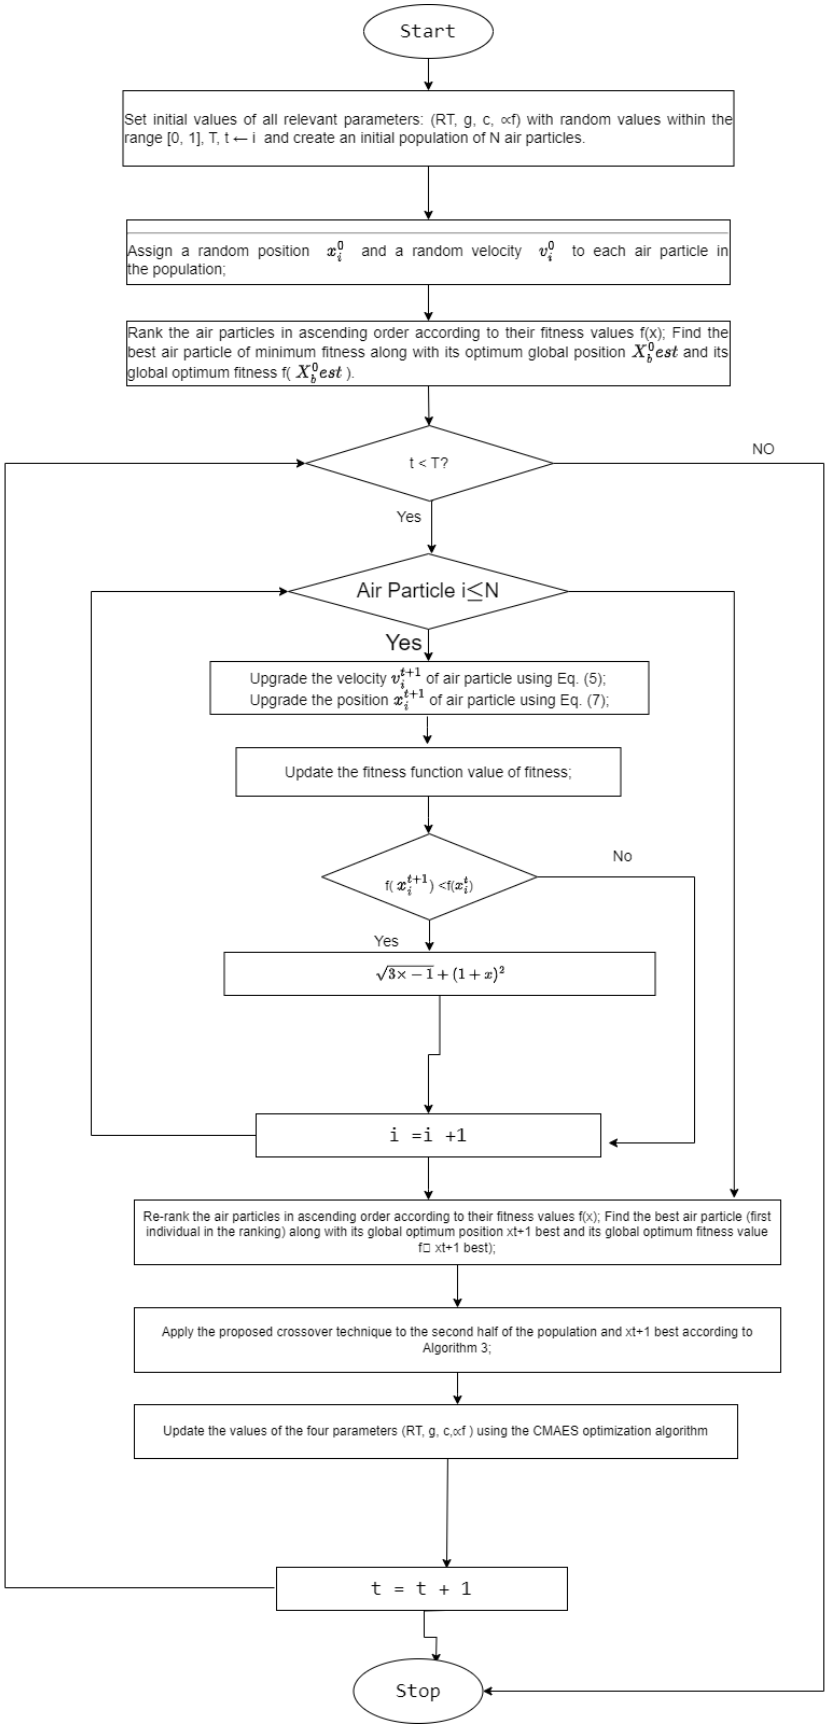

Fig. 8. Flowchart of the proposed hybrid of BWDO-SA algorithm.

of the P(Cj) and $P(c_j|d_j)$based on training set. It should be noted that P(Cj) is the same for each category. Hence, it can be eliminated from the calculation. In doing so, the prior probability of the category P(Cj) will be thus estimated as Eq. (7):

$$pc_j^{\wedge} = \frac{\sum_{i=1}^{N} y(d_i,\ c_j)}{N} \tag{7}$$

where, the amount of training set =N and thus y(di, $c_{j)}$estimated as Eq. (8):

$$y(d_i, c_j) = \begin{cases} d_i \in c_j \\ 0\ otherwise \end{cases} \tag{8}$$

Consequently, the percentage of training set which belongs to Cj is employed to determine the a priori probability of a class Cj. The multinomial model and multivariate Bernoulli model estimate $P(c_j|d_j)$ the parameters in different ways.

3) Decision Tree (DT): A Decision Tree text classifier is a non-parametric supervised learning method, represented as a tree in which the internal nodes are named terms and the leaves are tagged with classes [62]. The decision tree is one of the most popular and successful learning algorithms due to its many features, including lack of parameters, simplicity, ease of understanding, and ability to deal with different types of data. During the learning phase, a decision tree is built by recursively splitting the data based on attribute values and class labels, resulting in a large search space.

A decision tree is a greedy, top-down algorithm and iterative process from the training data entered until it reaches an empty tree. The feature that contains more information about the content is better defined to divide and is considered as the root division feature, Subsequently, subsets satisfying the partitioning features values are generated from the training data. This algorithm works on every subset repeatedly until all instances of a subset belong to the same category [63]. There are many applications in which the decision tree is configured, including its ability to deal with the problem of classification of incomplete data very well . In addition, it can replace statistical procedures to obtain data, extract text, find missing data, enable search engines, and use in many medical fields.

IV. Experiments

A. DataSet

The collection of data contains a set that was created to evaluate the creation of Arabic classifiers by extracting Arabic text, for which 800 documents have been chosen as a portion of TREC 2001 [64]. Realism and Criteria For such a set, TREC queries were developed: TREC 2001 included 25 queries, and relevant appropriate judgments were created using the grouping technique for the set of queries. Accordingly, Table II definition of the classifier's component of TREC includes four categories and the number of documents.

TABLE II. Summary Description of Arabic Data Set

Classes	# documents
1	200
2	200
3	200
4	200

B. Parameter Setting

Regarding the available optimal approach, it could be employed based on the three classification methods of the algorithm, considering this special method. For cross-validation, entire datasets are split. In conclusion, the validations are also categorized, using the evaluation strategy from [65]. While K-fold cross-validation and K-5 folds are utilized for both training and validation, the other folds are employed for testing.

The overall iterations of M could be applied to this process. After that, each optimizer unit could assess the times of K*M per dataset. To obtain the data used for training, the size of all parameters should be determined. Optimum results can be achieved when the number of repetitions reaches 50. The population size in this case should be 28. Each algorithm can be used for five total iterations. For feature selection, random feature selection should be used.

This section explores the algorithmic solution under several settings using 5 vital parameters: P_opt (population size), g (gravitational constant), RT coefficient, C (coriolis effect), and α (constants alpha). The vertical force is the gravitational force (g) directed from highest pressure to lowest pressure. The constant universal gas is represented by RT, where both R and T represent temperature. The constants C and α are utilized in velocity, while P_opt represents the number of Air Parcels. The gravitational force coefficient, g, and the friction coefficient, α, should only vary in the range [0, 1]. However, C and RT might include a wider range of values, such as [0, 5]. This section focused on the effects of variations in one of the parameters. This section focuses on the effects of variations in one of the parameters. Specifically, the three scenarios presented in Table III are evaluated. Furthermore, empirical studies have shown that the best results are achieved when there is a linear relation between P_opt and the number of features. Each scenario is evaluated for 50 iterations, with the cost value of the solution remaining as the fitness function value. The lowest fitness function value [Equation (8)] is considered the best fitness. Among the nine scenarios, the lowest fitness function value was related to scenario S2.3. The evaluation system used for wind-driven feature selection, as indicated in Section 3.3.3 (dmax = 1E03). Accordingly, case S2.3 was selected for conducting tests in this section, while other scenarios had higher fitness function scores. The parameters were set to P_{opt}=6, g=0.2, RT =3, C=0.4 and alph=0.4.

C. Performance Evaluation

The labeled test of the document component often determines the external quality measure, as part of its methodology, the classifiers that are produced are compared to the classes that have been labeled, and the extent to which documents

TABLE III. Parameter Settings of Arabic Data Sets

Scenario	Popt	g	RT	C	A
S1.1	2	0.1	1	0.2	0.1
S1.2	4	0.1	1	0.2	0.1
S1.3	6	0.1	1	0.2	0.1
S2.1	2	0.2	3	0.4	0.4
S2.2	4	0.2	3	0.4	0.4
S2.3	**6**	**0.2**	**3**	**0.4**	**0.4**
S3.1	2	0.3	5	0.6	0.8
S3.2	4	0.3	5	0.6	0.8
S3.3	6	0.3	5	0.6	0.8

from the same class are assigned to the same class is measured. In this work, the employed external quality measure is accuracy, as it is a commonly used quality measure in text mining, along with the number of features. The confusion matrix, also known as the evaluation measures in classification issues, is often defined from a matrix utilizing the number of instances that are properly and incorrectly identified for each class. The confusion matrix for a binary classification issue with just positive and negative classes was displayed in Table IV.

TABLE IV. Confusion Matrix

	The expected Class	
Real class	positive	real class
P	TP	TN
N	FP	FN

There, it is shown how FP, FN, TP, and TN is:

- False Positives (FP): Negative events that are incorrectly seen as positive.
- False Negatives (FN): Positive occurrences that are incorrectly interpreted as bad.
- True Positives (TP): The instances of positivity that are accurately anticipated to be positive.
- True Negatives (TN): The negative occurrences that are accurately predicted as negative.

Percentage Accuracy (ACC) is an evaluation measure widely used in practice that evaluates the effectiveness of a classifier based on the percentage of accurate predictions it makes. Thus, the ACC of the classifier is calculated as Eq. (9):

$$ACC = \frac{TP + TN}{TP + TN + FP + FN} * 100 \quad (9)$$

V. Results and Discussion

The planned contribution of this section is to respond to the research queries raised by the study. The purpose of this section is to achieve the study objective of evaluating the performance of Arabic classifiers NB, DT, and KNN in terms of classification performance, whether with or without selecting features, as well as with and without stemming of words. Additionally, the proposed BWDO-SA algorithm is employed for feature selection to enhance the performance of Arabic classifiers by reducing the dimensions of their features. Finally, the proposed framework of the Arabic classifier evaluated by accuracy and the amount of features. The results of the proposed framework focus on the reduction of the number of features using the optimization FS approach and their enhancement. The results presented in this section highlight the significant implementations using a number of features and the accuracy as evaluation metrics. Evaluation methodology used is also explained, followed by a discussion of the obtained outcomes. In conclusion, The outcomes of the combined WDO and SA techniques are shown in this section. Table V and Table VI present the results of the three classifiers' accuracy with and without the stemmer as a pre-processing step. The results show that DT achieved higher accuracies compared to NB and K-NN in both cases. Without the stemmer, DT achieved an accuracy of 90%, which was higher than NB (33.83%) and K-NN (26.11%). With the stemmer, DT achieved an accuracy of 93%, higher than NB (35%) and K-NN (26.36%). When comparing between the use of stemmer and without stemmer, it can be observed that the stemmer resulted in better accuracy for the classifiers. In terms of feature reduction, without the stemming, the feature count evaluation showed that reducing the feature count was not effective, whereas with the stemmer, better reduction of the number of features was achieved, as shown in Fig. 9 and Fig. 10.

Fig. 11 and Fig. 12 displays the results of integrating various metaheuristic algorithms as feature selection methods with the DT classifier, in terms of precision and the total amount of features, both when a stemmer is used as a preprocessing step and when it is not. The outcomes show that our suggested algorithm, WDO with DT, and SA with DT using the stemmer achieved higher precision compared to other feature selection algorithms. Both WDO with DT and SA with DT obtained the same precision value of 97.01%, which was higher than WOA with DT (94.7%), GA with DT (94.5%), PSO with DT (91.79%), HS with DT (91.5%), and SA with DT (87.2%). Without a stemmer as a preprocessing step with feature selection, WDO with DT and GA with DT achieved the same precision value of 95.02%, higher than WDO with DT (92.2%). In addition, WOA with DT and HS with DT obtained the same precision value of 90.2%, PSO with DT (90%), and SA with DT (85.46%).

Regarding the number of features, using DT classifier, WDO as a feature selection technique method, and using a stemmer as a pre-processing step, achieved outstanding results by significantly reducing the number of features. Specifically, WDO with DT reduced the features to 4231 out of 4616, which was lower compared to our proposed algorithm WDO and SA with DT, where it reduced the features to 8909. HS with DT had 14175 features, SA with DT had 14937 features, PSO with DT had 34787 features, and GA with DT and WOA with DT had the same value of 46167 features without any change in the number of features. On the other hand, the findings revealed that our proposed algorithm WDO and SA with DT, without using a stemmer as a preprocessing step, succeeded in reducing the amount of features and achieved good results. When compared to other algorithms, it produced 7236 out of 91756 features, which was the best result. The distribution of results was as follows: WDO with DT reduced to 9289

TABLE V. THREE CLASSIFIER WITHOUT STEMMER

Classifier	#of features before selected	# of features before selected	Acc.
DT	**91756**	**91756**	**90.298**
KNN	91756	91756	26.119
NB	91756	91756	33.830

TABLE VI. THREE CLASSIFIER WITH STEMMER

Classifier	# of features after selected	# of features before selected	Acc.
DT	46167	46167	**93.781**
KNN	46167	46167	26.368
NB	46167	46167	35.074

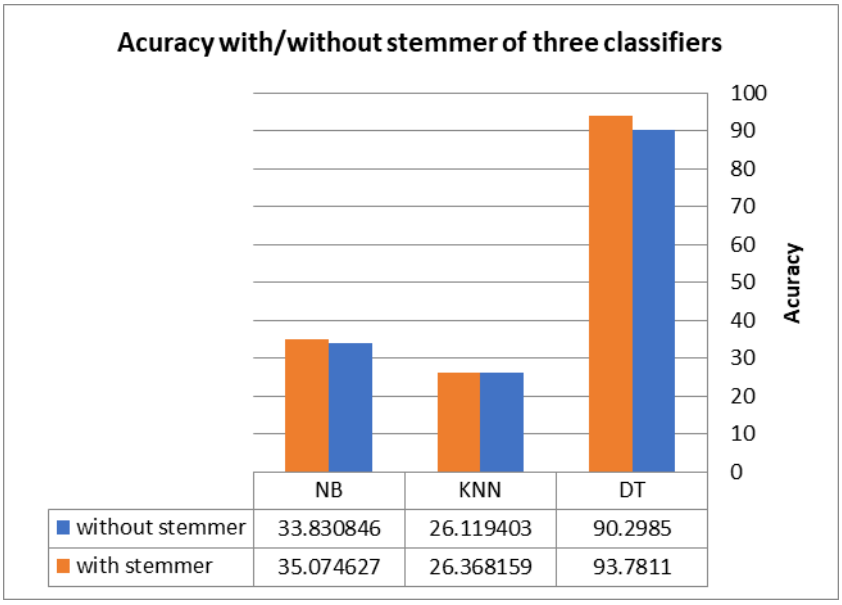

Fig. 9. Accuracy with/without stemmer of three classifiers.

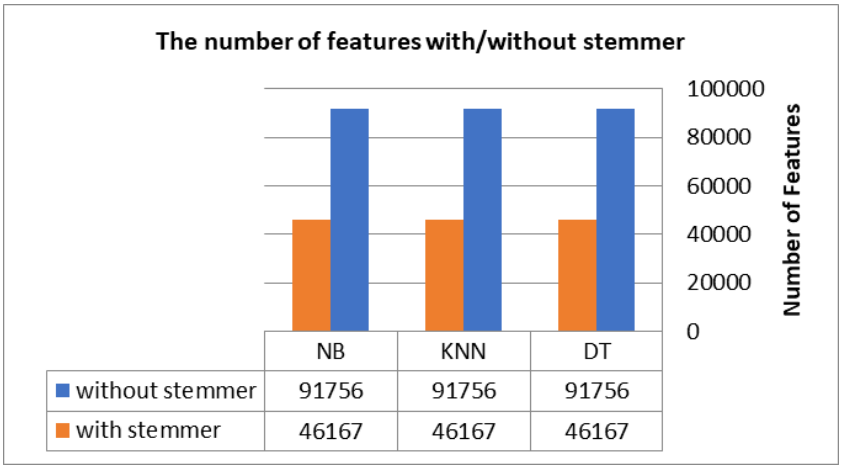

Fig. 10. Number of features with/without stemmer.

features, SA with DT to 19834 features, HS with DT to 28230 features, GA with DT to 45559 features, PSO with DT to 45711 features, and WOA with TD to 45989 features (see Table VII and Table VIII).

When comparing the integration of many metaheuristic algorithms as feature selection methods with DT, with and without stemmer, in terms of accuracy, the algorithms with DT classifier and stemmer achieved better accuracy than those without stemmer as show in Fig. 11.

However, the number of features is another measure for evaluation, It showed that the performance of DT classifier algorithms in feature count reduction was worse when they did not include a stemmer tool, while the algorithms with DT classifier and stemmer performed better, as shown in Fig. 12.

Fig. 13 and Fig. 14 present the results of hybridizing metaheuristic algorithms as feature selection methods with the KNN classifier, in terms of features size and accuracy, with using stemmer and without it as preprocessing. When stemmer was used, it is clear that our suggested algorithm, WDO and SA with KNN classifier, achieved better results compared to other algorithms. Specifically, WDO and SA with KNN obtained an accuracy that was 70.6% higher than WDO and SA with KNN, and HS with KNN, which had the same accuracy of 67.6%. GA with KNN and PSO with KNN had the same accuracy of 25.12%, WOA with KNN had an accuracy of 24.37%, and SA with KNN had an accuracy of 21.64%. However, when without stemmer was used as preprocessing with some optimization algorithms as feature selection, the results revealed that WDO with KNN classifier achieved an accuracy that was 67.6% higher than WDO and SA with KNN (61.9%), HS with KNN (41.5%), GA with KNN (24.6%), PSO with KNN (24.3%), WOA with KNN (24.1%), and SA with KNN (21.6%).

Regarding the size of features, the suggested algorithm WDO and SA with KNN classifier, when using stemmer as preprocessing, demonstrated superior performance as the results showed a significant reduction in the number of features. Specifically, SA with KNN and WDO reduced the features size to 519 out of 46167, which was lower than WDO with KNN (582 features), HS with KNN (633 features), SA with KNN (19528 features), PSO with KNN (23083 features), GA with KNN (23099 features), and WOA with KNN (23143 features). On the other hand, when stemmer was not used as preprocessing, the results showed that WDO and SA with KNN still provided good results in reducing the number of features, with some minor differences. Specifically, WDO and SA with KNN reduced the number of features to 472 out of 91756, while HS with KNN reduced to 243 out of 91756 features, WDO with KNN to 320, SA with KNN to 43859, PSO with KNN to 45454, WOA with KNN to 45939, and GA with KNN to 45994 (see Table IX and Table X).

When comparing different metaheuristic algorithms as feature selection with KNN classifier, using stemmer and without stemmer as pre-processing, it is observed that the algorithms with KNN classifier and stemmer achieved better accuracy, as shown in Fig. 13. However, the number of features is another evaluation measure, which indicates that the results without stemmer were worse in terms of reducing features size, while using stemming is more effective, as results in Fig. 14.

Fig. 15 and Fig. 16 present the results of hybridizing metaheuristic algorithms as feature selection with NB classifier for accuracy and number of features, both with and without the use of a stemmer for preprocessing. With stemmer, it is evident that the proposed algorithm WDO and SA with NB achieved better outcomes in comparison to other algorithms in terms of accuracy. Specifically, WDO and SA with NB showed 38.3% higher accuracy than GA with NB (37.56%), PSO with NB (36.3%), WDO with NB and SA with NB (34.3%), HS with NB (34.07%), and WOA with NB (24.37%).

On the other hand, without stemmer as preprocessing, our proposed algorithm WDO and SA with NB outperformed other algorithms, achieving an accuracy of 37.8%. The results for other algorithms were as follows: GA with NB (33.58%), PSO with NB (33.3%), WDO with NB and HS with NB (33.08%), SA with NB (31.34%), and WOA with NB (31.09%).

Regarding the number of features, the WDO and SA feature selection with NB classifier using stemmer performed well, as evidenced by the results, and reduced the number of features to 5354 out of 46167, which was lower than other algorithms. The results for other algorithms were as follows: HS with NB (15119), WDO with NB (17730), GA with NB (22965), SA with NB (23124), PSO with NB (23162), and WOA with DT (23162). On the other hand, the results without using stemmer showed that the WDO and SA with NB outperformed other algorithms, achieving 6899 features out of 91756, which was less than each of WDO with NB (25589), SA with NB (44358), PSO with NB (45666), GA with NB (45821), WOA with NB (46143), and HS with NB (91756) [see Table XI and Table XII].

In general, when comparing different metaheuristic algorithms as feature selection with NB classifier with and without stemmer, the algorithms with NB classifier with stemmer showed better accuracy, as depicted in Fig. 15. Moreover, the features size is another evaluation measure, which revealed that the results without stemmer were less effective in reducing the features size in comparison to those with stemmer, as shown in Fig. 15 and Fig. 16.

The three classification algorithms, namely NB, KNN, and DT, used in this study were discussed in detail. Additionally, the proposed algorithm, Wind Driven Feature Selection (WDFS), and simulated annealing (SA) were explained in full, including the modifications made to use them as feature selection techniques and the parameters employed in our proposed algorithm. Finally, the results of the research experiments were given, showcasing the impact of using stemmer and feature selection with the three classifiers on our dataset. Furthermore, a comparison was made between the results of WDFS and SA with the three classifiers separately, with/without using stemmer. The findings revealed that using WDFS and SA with stemmer positively affected the accuracy and number of features in classification, leading to improved classifier accuracy and reduced feature count.

VI. Conclusion and Future Work

Arabic text classification is a difficult computational task due to the high content of natural Arabic language text on the Internet. FS is a critical step in the Arabic TC process, as there are thousands of possible features to consider. This study

introduces two wrapper FS methods based on the WDO algorithm for Arabic text classification. The first method uses the binary version of WDO, while the second method improves the binary WDO by hybridizing it with Simulated Annealing (SA) to create WDO-SA. The primary goal of this hybridization is to optimize the best found binary WDO solution after each major iteration. Three famed classifiers, K-NN, SVM, and Naive Bayes, it was used to assess the applicability of each subset of features to Arabic text classification. The proposed methods were validated on a complex Arabic benchmark dataset. The suggested WDO-SA with SVM classifier outperformed other approaches for the FS task in Arabic text categorization, according to the empirical study's findings. Furthermore, investigation results show that incorporating SA into binary WDO methods enhances the search ability to find feasible regions and exploit them. In the future, exploring ensemble machine learning with individual classifiers and investigating different hybridization optimization methods for Arabic text classification could be worthwhile research directions.

Comparison of Conventional Techniques for House Electricity Consumption Forecasting

Sandra Pajares Centeno, Hugo Alatrista-Salas
Escuela De Posgrado Newman, Tacna, Peru

***Abstract*—Electricity consumption monitoring is the automated process of recording, processing, and analyzing electricity usage in real time to make informed decisions. This research aims to implement an artificial intelligence- and deep learning-based methodology to forecast monthly electricity consumption in Tacna, Peru, and generate decision-making indicators. To this end, we used electricity consumption records from Electrosur S.A., the company responsible for electricity distribution and marketing in the departments of Tacna and Moquegua, from February 2015 to December 2022 (a total of 95 months). We compared three artificial intelligence models in this context: (i) eXtreme Gradient Boosting (XGBoost), (ii) Light Gradient Boosting (LGBM), and (iii) Prophet. While all models effectively forecasted electricity consumption, the Prophet model demonstrated superior performance, achieving a mean absolute percentage error (MAPE) of 0.7% compared to actual consumption values. Additionally, the study discusses the potential of recurrent neural networks to further enhance predictive accuracy.**

***Keywords*—Electricity consumption; forecasting; recurrent neural networks; deep learning**

I. Introduction

According to a report by the United Nations Department of Economic and Social Affairs, cities account for up to 80% of global energy consumption and 75% of carbon emissions, despite covering only 3% of the Earth's surface. This problem is prevalent in various countries, including in Peru, which emitted over 91.4 million tons of greenhouse gases (GHGs) in 2018. Peru also has one of the highest per capita GHG emissions in South America, at 2.8 tons. The indiscriminate use of electricity has resulted in our cities having one of the highest carbon footprints in Latin America. Additionally, international organisations such as the UN and the OAS are prioritising issues related to carbon emissions and climate change mitigation.

An increasing number of companies and government agencies are using artificial intelligence to improve the decision-making process [1]. In this sense, extracting information from data representing complex dynamics has been used to predict future events and make informed decisions in several areas, as discussed in [2], [3], [4], [5].

Electricity distribution and marketing companies, in particular, have processes that require continuous monitoring because the results of these processes directly impact the environment [6]. Therefore, it is essential to forecast energy consumption in the short, medium, and long term for environmental impact studies and capacity expansion. Power or energy consumption monitoring involves the automated recording, processing, and analysis of power network data in real time. The purpose of monitoring is to enable informed decision-making. Several algorithms have been implemented to predict electricity consumption [7], [8], [9], [10].

Energy consumption analysis has been applied to various fields, including the analysis of traffic conditions [11], the energy consumption of IoT devices [12], [13], the estimation of electric vehicle consumption [14], [15], and the use of aerial imagery to predict energy consumption [16].

This paper focuses on forecasting time series data. Apart from the classification proposed in [17], machine learning and deep learning techniques have become very relevant in recent years for various prediction tasks [18], [19]. Many works have been proposed for time series prediction tasks, particularly for energy consumption estimation For example, the authors in [20] used deep neural networks, specifically long short-term memory (LSTM) neural networks. In their paper, the authors compare two ways of representing data: classical LSTMs with time series data and sequences using the sequence-to-sequence (S2S) method. Similarly, LSTM models have improved thanks to algorithms based on the bidirectional long-short-term memory (Bi-LSTM) model [21]. In this context, this paper compares three well-known techniques for predicting energy consumption and generating indicators to facilitate better energy management and decision-making in Tacna, Peru.

After the introduction, Section II summarizes the existing literature on the topic. Section III presents the definitions and conceptual framework. Section IV describes the methodology used in this study, and Section V details the dataset and results. The work concludes with the conclusions and suggestions for future work.

II. Related Works

Various authors have used machine learning and deep learning techniques in their literature to predict electricity usage in residential, commercial, and public buildings. For instance, [8] use algorithms such as Support Vector Machine (SVM) and decision trees to predict household-level electricity consumption in the US. Similarly, [10] use support vector regression to estimate electricity consumption in a Turkish city. In [22], the authors use the Random Forests algorithm to predict short-term energy consumption based on five datasets collected over a year from various buildings. Similar studies have been conducted on houses in various countries, including China [23], Malaysia [24], Brazil and Spain [25], France [26], Albania [27] and several countries simultaneously [28], [29].

Additionally, some authors have used a variety of techniques to estimate electrical energy consumption. For example,

in [7], the authors proposed a new fuzzy wavelet neural network model to analyse hourly electricity consumption. The model was validated using a database of electricity consumption from the Greek island of Crete. Similarly, [8] propose a method based on neural network back propagation and the improved particle swarm optimization (IPSO) algorithm for predicting electricity consumption and measuring the impact of changes and imbalances in energy consumption caused by the pandemic.

Other papers focus on more advanced techniques, such as deep learning. For instance, [30] the authors use *Long Short-Term Memory* In this text, the authors discuss the use of LSTM neural networks to predict household electricity consumption and their potential to reduce carbon emissions. The authors also discuss the potential of these networks to reduce carbon emissions. Additionally, they reference a study by [31] that proposes a model for predicting electric vehicle energy consumption using transfer learning. The proposed method utilizes data from the target domain as well as data or a model from a similar domain. The authors used data on electric vehicle trips, including the battery charge state, departure and arrival times at rest areas, and GPS data similar to the predicted training data.

In [32], three energy consumption prediction algorithms were compared: Asynchronous Advantage Actor-Critic (A3C), Deep Deterministic Policy Gradient (DDPG), and Recurrent Deterministic Policy Gradient (RDPG). The algorithms were tested on data collected from an office building. In this context, [33] predict monthly consumption using three deep learning models: Deep Fully Connected, Convolutional Neural Network, and Long Short-Term Memory Neural Networks. The authors also employed pre-processing techniques, such as normalization, to homogenize the input domain. Finally, they applied the algorithms to over 9 million sample datasets. In [34] study, data from 100 civil public buildings in China was used to predict short and medium-term electrical energy consumption. The authors proposed an algorithm based on a deep neural network and compared it with other algorithms such as the back-propagation algorithm, the Elman neural network, and the fuzzy neural network. In another study, [35] proposed integrating two deep learning models, including a long short-term memory (LSTM) model. They claim that combining LSTM and reinforcement learning agents (reinforced learning) is more efficient for predicting energy consumption at the University of Wollongong in Australia.

Additionally, several efforts have been made to propose efficient algorithms in terms of both prediction quality and ease of interpretation, particularly when the results are used to make informed decisions. For example, in [36], the authors use three interpretable models based on long short-term memory (LSTM) with self-attention to predict electrical energy consumption in a dataset related to an office building. Similarly, in [37], the authors use the SHAP tool to analyze the electrical energy consumption of an electric arc furnace used to produce stainless steel after an artificial neural network (ANN) makes a prediction. Through this study, the authors aim to provide practical examples of how SHAP can be used to analyse the contributions of each input variable to the consumption predictions generated by black box machine learning models when the data are associated with steel processes.

Furthermore, the authors of [38] propose a four-component methodology to predict and explain electrical energy consumption over approximately two million minutes collected from 2006 to 2010. These components include a power encoder, an auxiliary encoder for a two-dimensional, interpretable latent space, a deep-learning-based prediction model, and an explainer that identifies the most significant input features for predicting future demand. Finally, in [39], the authors focus on improving the efficiency of existing algorithms - implemented in the Darts library - for predicting the daily, weekly and monthly electricity consumption of 43 customers using the Neural Basis Expansion Analysis for Interpretable Time Series (N-BEATS) technique.

This research underscores the practical importance of adopting automated forecasting techniques for predicting electricity consumption, especially in contexts where current practices still depend on manual projections and basic trend extrapolations. Unlike complex models such as ARIMA, recurrent neural networks (RNNs), or Transformer-based architectures, which often require extensive parameter tuning and substantial computational resources, our findings demonstrate that simpler, well-established models like Prophet, XGBoost, and LGBM can deliver highly accurate results when applied to robust, well-structured datasets. This suggests that advanced forecasting performance does not always require sophisticated models, especially when the data is consistent in quality and time-based patterns. Our objective is not to conduct an extensive comparison of forecasting techniques, propose novel methods, or introduce new evaluation metrics. Instead, we aim to present a practical, evidence-based report reviewing existing algorithms and demonstrating the effectiveness of three simple models with promising results[1].

III. Basic Definitions

A. Electric Energy Consumption: Electrosur Tacna, Peru

The electricity balance illustrates the flow of electricity from generation to final consumption. Electricity travels through transmission and distribution networks. In 2022, Peru generated $59,713$ GWh of electricity and imported 32 GWh from Ecuador. The electrical energy balance, including production, consumption, and losses, is listed below:

- Of the total energy produced in Peru, $57,814$ GWh (97%) came from companies in the electricity market, while $1,898$ GWh (3%) came from industrial companies that produce electricity for their own use.
- Of the total electrical energy available, which includes national production plus imports, 1.4% is used for auxiliary services in power stations. Meanwhile, 11.1% is lost in transmission and distribution, leaving 87.4% to reach the final consumer.
- Of the energy produced by enterprises in the electricity market, 1.2% was used for auxiliary services in power stations, 11.3% was lost and 87.5% reached final consumers.
- Of the energy produced by industrial enterprises for their own use, 7.2% was used for auxiliary services

[1]The code and data are available at https://github.com/huvaso/electricityForecasting

of their plants, 5.78% was lost and 87.7% was used for their operations.

- Of the $48,092$ GWh of electrical energy sold by generation and distribution companies to final consumers, 38% ($18,410$ GWh) was sold on the regulated market, while 62% ($29,682$ GWh) was sold on the free market.

Electrosur S.A.'s main activity is distributing and marketing electrical energy in its concession area, which encompasses the Tacna and Moquegua departments. The company purchases the energy it distributes and markets from nine generation companies and the National Interconnected System of Peru.

In 2022, energy sales amounted to $399,786$ MWh, an increase of 2.3% compared to 2021. This increase is due to the progressive and sustained rise in consumption by both regulated and free customers, resulting from the economic reactivation of commercial activities in Tacna, Moquegua, and Ilo. ENEL Generación Perú was the company's main energy supplier in 2022.

In Peru, the forecast for electrical energy purchases (demand) is currently based on historical data projections, considering new user demand and population growth rates. The electricity distribution company's energy efficiency can be estimated by dividing its energy sales and purchases into periods. Therefore, its energy efficiency is estimated to be 89.97% in the 2022 financial year. One of the main activities undertaken in 2022 to reduce technical losses was the installation of two reactive compensation banks, one in Tacna with a total capacity of 300 kWh and one in Ilo with a total capacity of 300 kWh, for a total capacity of 600 kWh. This reduced technical energy losses to $36,500$ kWh per year.

Another important activity in reducing technical losses has been installing LED lights. A total of $14,084$ units were installed in Tacna ($7,452$), Moquegua ($2,863$), and Ilo ($3,769$). Due to the replacement of LED lights and the program to control losses, change drivers, recover energy, prevent illegal connections, and provide exceptional services, Electrosur S.A. is now among the electricity distribution companies in Peru with the lowest losses, below the average of 87.46%. Additionally, the loss of electrical energy was less than 10%, corresponding to $44,536$ MWh, which equates to approximately 15 million soles in economic terms.

Therefore, using historical data from a specific period and machine learning algorithms will enable more accurate purchase forecasts for annual planning and more confident economic and operational decisions. In terms of energy efficiency, correctly forecasting electricity demand will enable households to reduce their electricity bills.

B. Conventional Classifiers

1) XGBoost (eXtreme Gradient Boosting): This is an open-source library for performing machine learning tasks, especially regression and classification problems. It is based on the boosting algorithm, which combines several weaker models to form a stronger one. XGBoost uses decision trees and employs advanced techniques such as regularisation and gradient optimisation to improve model accuracy and performance. It is also widely used in data science competitions due to its effectiveness.

2) LGBM (LightGBM): This is a decision tree-based machine learning library designed to be efficient and scalable. Unlike XGBoost, LightGBM uses a leaf-wise rather than level-wise growth approach, which significantly improves training speed. It is designed to handle large datasets and high dimensionality.

3) Prophet: This is an open-source library developed by Facebook for time series forecasting. It is designed to handle time series data that may have trends, seasonality, holidays and also allows the inclusion of special events. Prophet can handle missing data and outliers, and it is suitable for short- and medium-term time series forecasting.

C. Evaluation Metrics

After training the model, it is essential to evaluate its performance on unseen data using evaluation metrics. The choice of metrics depends on the problem's specific context and preferences regarding error interpretation. The objective is to minimize these metrics' values to enhance the prediction model's accuracy.

1) MAE (Mean Absolute Error): measures the average size of absolute errors between predictions and actuals in a time series. It is useful for understanding the average size of errors regardless of their direction.

$$MAE = \frac{1}{n}\sum_{i=1}^{n}|y_i - \hat{y}_i| \tag{1}$$

Where: n is the number of observations; y_i is the actual value at time i; and $\hat{y}_i$ is the prediction at time i.

2) MSE (Mean Squared Error): measures the average squared error between predictions and actual values in a time series. The squared term emphasizes larger errors, making it more sensitive to outliers.

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \tag{2}$$

Where: n is the number of observations; y_i is the actual value at time i; and $\hat{y}_i$ is the prediction at time i.

3) MAPE (Mean Absolute Percentage Error): measures the average percentage of absolute errors with respect to the actual values. It is useful to evaluate the relative error in percentage terms.

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\left(\frac{|y_i - \hat{y}_i|}{|y_i|}\right) \times 100 \tag{3}$$

Where: n is the number of observations; y_i is the actual value at time i; and $\hat{y}_i$ is the prediction at time i.

IV. Methodology

Predictive techniques based on temporal data are now fundamental to data science and artificial intelligence because they can model and predict patterns, trends, and behaviors in time series data.

In this context, and after analysing the work presented in the literature [40], the methodology described in Figure 1 was proposed in this paper. The dataset contains the periodic electricity consumption of each subscriber in kWh. The dataset was preprocessed before building a time series. This process can include various steps, such as filling in missing data, detecting outliers, and normalizing. This step depends on the dataset. Next, the time feature is preprocessed. Depending on the algorithm, the dataset must meet certain format specifications. Then, the time series is built according to the desired temporal granularity (daily, monthly, etc.). After building the time series, three forecasting algorithms were compared using the quality metrics described in the previous section. Finally, the predictions were visualized to better understand consumption behavior patterns.

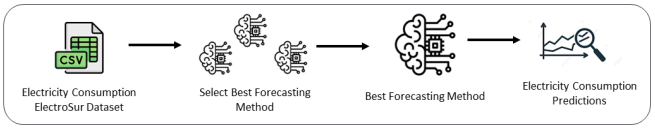

Fig. 1. Proposed methodology.

V. Experiments and Results

This section describes the available dataset. Additionally, the main findigs of our approach were detailed and discussed.

A. Dataset

The required data for the study was provided by Electrosur S.A., Tacna's electricity distribution company in Peru. The data, which corresponded to the electricity consumption data for the district, province, and department of Tacna, was obtained from the commercial system database. It is worth noting that the district's users are subject to a residential tax.

The research will examine data from February 2015 to December 2022. This includes the supply number and active energy consumption in kilowatt-hours (kWh) per user for each month and year within this period. The supply number is a code that identifies the service user. It is also known as the customer number that appears on the electricity consumption voucher. Active energy consumption (AEC) is measured in kWh and corresponds to a user's energy consumption as recorded by an electricity meter, also known as a wattmeter, which is calibrated in billing units. AEC is calculated by subtracting the electric meter reading from the previous month from the current month's reading, resulting in the billed consumption for the month.

It is important to note that there are $8,171$ users, each with 88 months of billing information. These records correspond to active energy consumption from February 2015 to December 2022, resulting in 719,048 total records of electrical energy consumption.

Table I presents the main statistical characteristics of the data by year.

As expected, the number of services increases each year due to the progressive growth of urban centers. However, contrary to urban growth, the average electricity consumption expenditure in Tacna is decreasing. Figure 2 shows a slight increase in 2019; however, the average consumption decreased during the period of the 2020-2021 (Covid-19) pandemic. Furthermore, the maximum annual electricity consumption value in Tacna increases in 2020 and 2021, during the period of the pandemic. Note that the quarantine period began in March 2020.

B. Results

First, any missing, null, or duplicate data in the dataset was addressed. This cleaning process is essential to ensure that the models are based on high-quality data. Next, a data transformation process was performed. This process includes converting data into appropriate formats, creating new features from existing ones, and rescaling variables to facilitate modeling. Since the number of houses has increased over the years, our particular dataset focuses on only those houses with records for each of the 95 months.

Additionally, to explore which model works best with our dataset, the average monthly consumption of all houses was calculated. This produced one time series representing the average consumption of houses in the Tacna districts over the 95 months (see Figure 3).

The training set is used to train the model, while the validation set is used to evaluate its performance (see figure 4). When working with time series, the data set must be divided according to chronological order, not randomly. In this sense, our data sets correspond to:

- Training set: Consumption corresponding to the dates from February 2012 to May 2021 (76 months).
- Validation set: Consumption corresponding to the period from June 2021 to December 2022 (19 months).

Identifying the features (independent variables) that will be used to predict the target variable (dependent variable) is essential for training the model. Then a machine learning algorithm is used to fit the model to the training data. The model learns the patterns and relationships in the data that can be used for predictions.

Moreover, three learning algorithms were chosen: eXtreme Gradient Boosting (XGBoost), Light Gradient Boosting (LGBM), and Prophet. The Mean Absolute Error, Mean Squared Error, and Mean Absolute Percentage Error were used to evaluate performance.

To train the model with XGBoost and LightGBM, new features were generated from the data: Year, Month and Quarter. An example of these new features is shown in Table II.

The Prophet algorithm generates features related to trends and seasonality. These features relate to different components of the model and their prediction intervals: (i) The trend component captures the general direction of the time series.

TABLE I. STATISTICAL FEATURES OF THE DATA SET BY YEAR

Features	2015	2016	2017	2018	2019	2020	2021	2022
Count	6004.00	6156.00	6346.00	6676.00	7437.00	7506.00	8013.00	8247.00
Mean	123.49	123.43	122.18	116.98	117.91	117.23	110.68	106.30
Std.Deviation	175.54	185.99	185.04	172.37	190.08	183.41	197.29	181.57
Minumum	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00
25%	38.63	38.58	39.16	36.39	34.33	34.75	28.75	27.33
50%	91.13	89.00	89.33	84.83	82.41	84.75	77.83	73.33
75%	153.13	150.83	149.02	144.33	142.08	144.33	136.83	129.66
Maximum	4156.45	4312.58	4483.83	3706.41	4052.41	4327.09	9000.00	5075.00

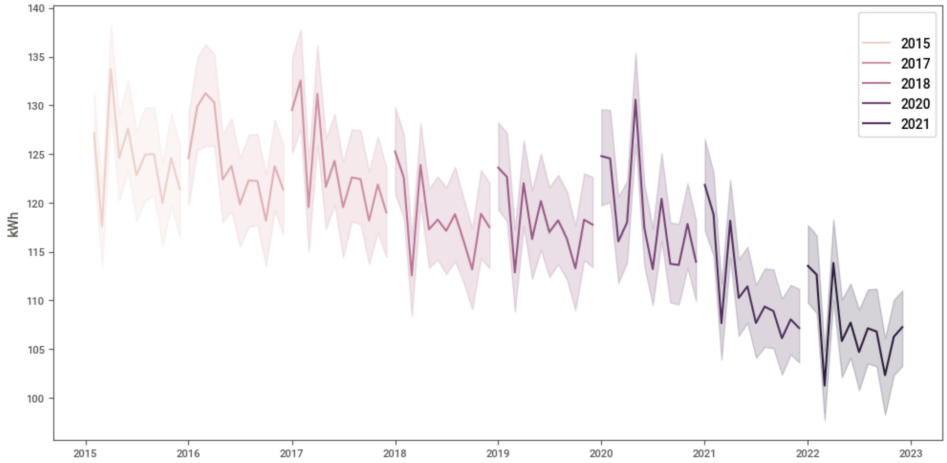

Fig. 2. Electricity consumption per year.

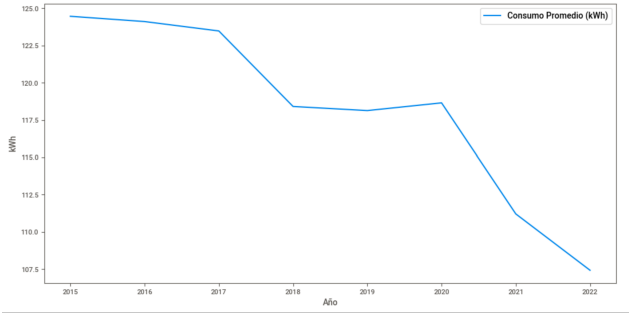

Fig. 3. Time series representing the mean consumption in Tacna.

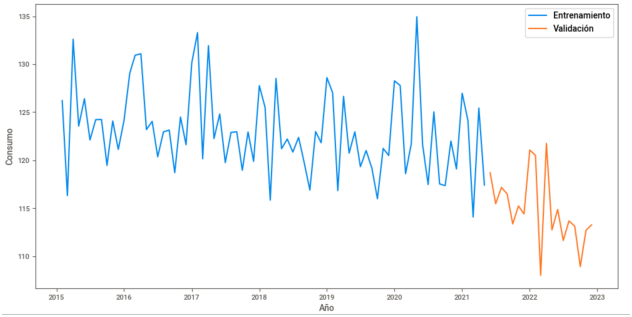

Fig. 4. Splitting the dataset.

It represents the long-term growth or decline trajectory in the data. (ii) Variables representing the additive components of the model, including seasonality and holiday effects. (iii) Variables representing the annual component of the model, which captures seasonal patterns over the years; and (iv) variables representing the multiplicative components of the model.

Table III shows the values obtained for each method according to the evaluated metrics. Based on these results, we can conclude that the Prophet model is the best. Furthermore, Figure 5 shows that the Prophet model's predictions are closer to the actual consumption values than those of the other methods.

C. Discussion

The current methodology for forecasting electricity demand in Peru relies primarily on extrapolating historical data while

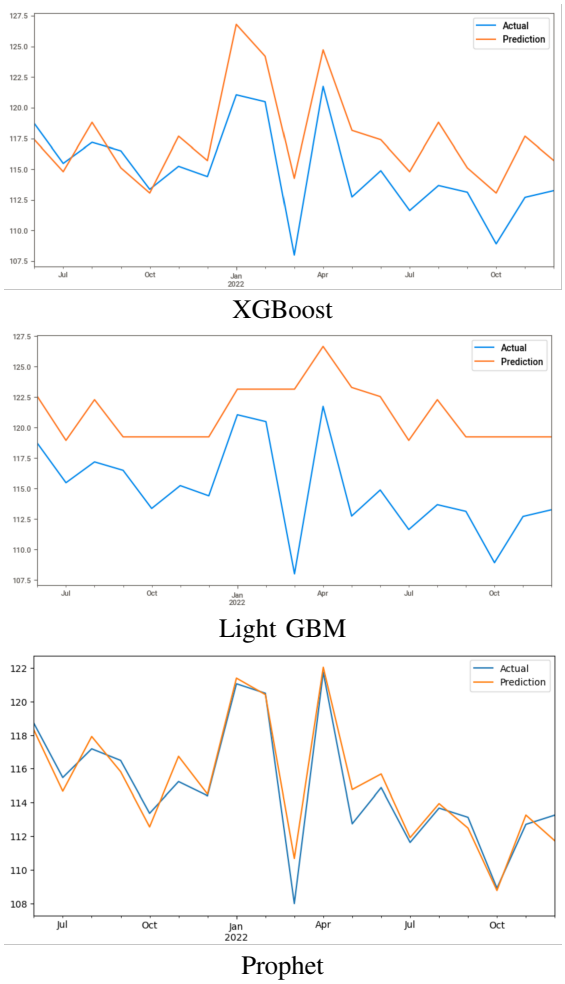

Fig. 5. Forecasting of electricity consumption in validation dataset.

TABLE III. METRICS EVALUATED FOR THE THREE ALGORITHMS

Algorithm	MAE	MSE	MAPE
XGBoost	3.026	12.264	0.027
LGBM	6.196	48.351	0.055
Prophet	0.771	1.056	0.007

considering demographic growth and the addition of new users. While this traditional approach provides a baseline estimation, it often lacks the granularity and adaptability required for dynamic energy consumption environments. In this context, this study research proposes a data-driven methodology that uses machine learning and statistical forecasting models, namely eXtreme Gradient Boosting (XGBoost), Light Gradient Boosting (LGBM), and Prophet, to improve the accuracy of electricity consumption forecasts in Tacna, Peru.

The results indicate that the Prophet model outperforms the other two algorithms across all evaluated metrics (MAPE, MAE, and MSE), with a particularly low MAPE (see Table III), demonstrating its strong suitability for capturing seasonal and trend-based patterns in time series data. The proposed methodology benefits from several strengths. First, the dataset is extensive and consists of monthly active energy consumption records from $8,171$ users over an 8-year period, resulting in over 700,000 observations. This rich dataset allows for robust model training and evaluation. Second, the inclusion of real operational data from Electrosur S.A., a key electricity provider, ensures practical relevance and reflects actual consumption patterns in the region.

However, some limitations must be acknowledged. While the proposed models are effective in forecasting, they do not yet incorporate exogenous factors, such as weather patterns, economic activity, or special events, that could affect consumption behavior. Additionally, while Prophet shows excellent performance, its black-box nature may limit its usefulness to decision-makers who prefer transparent models. From a policy and operational perspective, improving forecasting accuracy could support Electrosur S.A.'s ongoing efforts to reduce technical losses, such as installing reactive compensation banks and LED lighting. Enhanced forecasting could also support targeted interventions for high-consumption users, energy-saving initiatives, and more efficient demand planning.

VI. CONCLUSION

This study presented a data-driven approach to forecasting monthly electricity consumption in Tacna, Peru. The study used nearly eight years of historical data from the Peruvian Electricity Administration Office. Implementing and comparing three machine learning models demonstrated the efficacy of AI-based forecasting techniques in the energy sector. Of the evaluated models, Prophet demonstrated the highest predictive accuracy, achieving a mean absolute percentage error (MAPE) of 0.7%, highlighting its robustness for time series forecasting in this domain.

Future work will focus on exploring deep learning approaches, particularly recurrent neural networks (RNNs) and transformers, to better model temporal consumption patterns, as discussed in [41], [42]. Comparative analyses will be conducted to assess the performance of these models against traditional ensemble methods such as XGBoost and LGBM. Finally, a real-time alert system to identify users with potentially high electricity consumption. This system will allow us to provide targeted energy-saving recommendations and support demand management efforts.
