Editorial Preface

From the Desk of Managing Editor…

It may be difficult to imagine that almost half a century ago we used computers far less sophisticated than current home desktop computers to put a man on the moon. In that 50 year span, the field of computer science has exploded.

Computer science has opened new avenues for thought and experimentation. What began as a way to simplify the calculation process has given birth to technology once only imagined by the human mind. The ability to communicate and share ideas even though collaborators are half a world away and exploration of not just the stars above but the internal workings of the human genome are some of the ways that this field has moved at an exponential pace.

At the International Journal of Advanced Computer Science and Applications it is our mission to provide an outlet for quality research. We want to promote universal access and opportunities for the international scientific community to share and disseminate scientific and technical information.

We believe in spreading knowledge of computer science and its applications to all classes of audiences. That is why we deliver up-to-date, authoritative coverage and offer open access of all our articles. Our archives have served as a place to provoke philosophical, theoretical, and empirical ideas from some of the finest minds in the field.

We utilize the talents and experience of editor and reviewers working at Universities and Institutions from around the world. We would like to express our gratitude to all authors, whose research results have been published in our journal, as well as our referees for their in-depth evaluations. Our high standards are maintained through a double blind review process.

We hope that this edition of IJACSA inspires and entices you to submit your own contributions in upcoming issues. Thank you for sharing wisdom.

Thank you for Sharing Wisdom!

Kohei Arai
Editor-in-Chief

Editorial Board

Editor-in-Chief

Dr. Kohei Arai - Saga University
Domains of Research: Technology Trends, Computer Vision, Decision Making, Information Retrieval, Networking, Simulation

---

Associate Editors

Alaa Sheta
Southern Connecticut State University
Domain of Research: Artificial Neural Networks, Computer Vision, Image Processing, Neural Networks, Neuro-Fuzzy Systems

Arun Kulkarni
University of Texas at Tyler
Domain of Research: Machine Vision, Artificial Intelligence, Computer Vision, Data Mining, Image Processing, Machine Learning, Neural Networks, Neuro-Fuzzy Systems

Dr Ronak AL-Haddad
Anglia Ruskin University / Cambridge
Domain of Research : Technology Trends,Communication,Security,Software Engineering and Quality,Computer Networks,Cyber Security,Green Computing,Multimedia Communication,Network Security,Quality of Service

Elena Scutelnicu
"Dunarea de Jos" University of Galati
Domain of Research: e-Learning, e-Learning Tools, Simulation

In Soo Lee
Kyungpook National University
Domain of Research: Intelligent Systems, Artificial Neural Networks, Computational Intelligence, Neural Networks, Perception and Learning

Renato De Leone
Università di Camerino
Domain of Research: Mathematical Programming, Large-Scale Parallel Optimization, Transportation problems, Classification problems, Linear and Integer Programming

Xiao-Zhi Gao
University of Eastern Finland
Domain of Research: Artificial Intelligence, Genetic Algorithms

CONTENTS

Paper 1: Enhancing Trust in Human-AI Collaboration: A Conceptual Review of Operator-AI Teamwork
Authors: Abduljaleel Hosawi, Richard Stone
PAGE 1 – 15

Paper 2: Designing an Empathetic Conversational Agent for Student Mental Health: A Pilot Study
Authors: Kaichi Minami, Choi Dongeun, Panote Siriaraya, Noriaki Kuwahara
PAGE 16 – 23

Paper 3: Cross-Context Evaluation of an Indoor–Outdoor AR Navigation System in a University Campus Environment
Authors: Toma Marian-Vladut, Pascu Paul, Turcu Corneliu Octavian
PAGE 24 – 33

Paper 4: Brightness-Aware Generative Adversarial Network for Low-Light Image Enhancement
Authors: Huafei Zhao, Mideth Abisado
PAGE 34 – 43

Paper 5: Power-Aware Video Transmission in 5G Telemedicine: Challenges, Solutions, and Future Directions
Authors: Qiuhong SHI, Mingjing CAO, Yun BAI
PAGE 44 – 54

Paper 6: Evaluating Intangible Software Quality Metrics for Effective Project Management Information Systems
Authors: Gu Xin, Rozi Nor Haizan Nor, Nur Ilyana Ismarau Tajuddin, Khairi Azhar Aziz
PAGE 55 – 63

Paper 7: CNN-LinATFormer: Enhancing PM2.5 Prediction Through Feature Assessment and Linear Attention Mechanism
Authors: Yuchen Zhang, Rajermani Thinakaran
PAGE 64 – 74

Paper 8: Transformer Model Optimization Method for Multi-Modal Data Fusion
Authors: Shanshan Yang, Jie peng
PAGE 75 – 86

Paper 9: Emotional Analysis and Interpretation of Music Conducting Works Based on Artificial Intelligence
Authors: He Huang, Chengcheng Zhang, Yun Liu, Liyuan Liu
PAGE 87 – 96

Paper 10: Object Recognition in Pond Environments Using Deep Learning
Authors: Suhaila Sari, Ng Wei Jie, Nik Shahidah Afifi Md Taujuddin, Hazli Roslan, Nabilah Ibrahim, Mohd Helmy Abd Wahab
PAGE 97 – 105

Paper 11: FoodSharePro: An Integrated Mobile Platform for Sustainable Food Donation and Decentralized Composting
Authors: Jamil Abedalrahim Jamil Alsayaydeh, Rex Bacarra, Shamsul Fakhar Bin Abd Gani, Serhij Mamchenko, Safarudin Gazali Herawan
PAGE 106 – 121

Paper 12: Benefits and Challenges of Cloud Computing System in Malaysian Public Healthcare Organizations
Authors: Nurul Izzatty Ismail, Juhari Noor Faezah, Muhammad Syukri Abdullah, Masrina Nadia Mohd Salleh
PAGE 122 – 128

Paper 13: niCNN: A Novel Neuromorphic Approach to Energy-Efficient and Lightweight Human Activity Recognition on Edge Devices
Authors: Preeti Agarwal
PAGE 129 – 138

Paper 14: Improved YOLOv8 Model for Enhanced Small-Sized Breast Mass Detection on Magnetic Resonance Imaging
Authors: Feiyan Wu, Chia Yean Lim, Sau Loong Ang, Jiaxin Zheng
PAGE 139 – 145

Paper 15: SE-Pruned ResNet-18: Balancing Accuracy and Efficiency for Object Classification on Resource-Constrained Devices
Authors: Zeyad Farisi
PAGE 146 – 151

Paper 16: Advanced AI for Liver Cancer Detection: Vision Transformers, XAI and Contrastive Learning
Authors: B C Anil, Jayasimha S R, Samitha Khaiyum, T L Divya, Rakshitha Kiran P, Vishal C
PAGE 152 – 159

Paper 17: A Qualitative Constructivist Framework for Assessing Knowledge Transfer in Enterprise System Projects: Insights from Expert Interviews
Authors: Jamal M. Hussien, Riza bin Sulaiman, Ali H Hassan, Mansoor Abdulhak, Hasan Kahtan, Basit Shahzad
PAGE 160 – 171

Paper 18: Investigating Space-Time Dynamics in Live Memory Forensics Using Hybrid Transformer Approaches
Authors: Sarishma Dangi, Kamal Ghanshala, Sachin Sharma
PAGE 172 – 184

Paper 19: Detecting Fake News Images Using a Hybrid CNN-LSTM Architecture
Authors: Dina R. Salem, Abdullah A. Abdullah, AbdAllah A. AlHabshy, Kamal A. ElDahshan
PAGE 185 – 193

Paper 20: Heuristics-Based Clustering of Internet of Vehicle Based on Effective Approximate QoS Guideline for Message Dissemination
Authors: Tanuja Kayarga, S Ananda Kumar, Lakshmi B S, Anil Kumar B H
PAGE 194 – 201

Paper 21: SOM-Based Leader Selection Strategies for Cooperative Spectrum Sensing in Multi-Band Multi-User 6G CR IoT
Authors: Mayank Kothari, Suresh Kurumbanshi
PAGE 202 – 209

Paper 22: High-Speed Fiber-Optic Communication Performance Utilizing Fiber Bragg Grating-Based Dispersion Compensation Schemes
Authors: Kripa Kalkala Balakrishna, Karthik Palani
PAGE 210 – 220

Paper 23: Bio-Inspired Metaheuristic Framework for DNA Motif Discovery Using Hybrid Cluster Based Walrus Optimization
Authors: M. Shilpa, C. Nandini
PAGE 221 – 228

Paper 24: Detection of Autism Spectrum Disorder (ASD) Using Lightweight Ensemble CNN Based on Facial Images for Improved Diagnostic Accuracy
Authors: Andi Kurniawan Nugroho, Jajang Edi Priyanto, D. S. P. Vinski
PAGE 229 – 236

Paper 25: An Adaptive SVR-Based Framework for Multimodal Corpus Classification
Authors: Yuhui Wang
PAGE 237 – 246

Paper 26: Speech Emotion Recognition from Audio Data Using LSTM Model
Authors: Md. Mahbub-Or-Rashid, Akash Kumar Nondi, Abdullah Al Sadnun, Md. Anwar Hussen Wadud, T M Amir Ul Haque Bhuiyan, Md.Saddam Hossain
PAGE 247 – 254

Paper 27: AI-Driven Textual Feedback Analysis in E-Training Using Enhanced RoBERTa
Authors: Rakan Saad Alotaibi, Fahad Mazyed Alotaibi, Sameer Abdullah Nooh, Abdulaziz A. Alsulami
PAGE 255 – 266

Paper 28: A Deep Learning-Based Dual-Model Framework for Real-Time Malware and Network Anomaly Detection with MITRE ATT&CK Integration
Authors: Migara H. M. S, Sandakelum M. D. B, Maduranga D. B. W. N, Kumara D. D. K. C, Harinda Fernando, Kavinga Abeywardena
PAGE 267 – 272

Paper 29: Method for Maternal Health Risk Assessment with Smartwatch-Based Vital Sign Measurements
Authors: Kohei Arai, Diva Kurnianingtyas
PAGE 273 – 279

Paper 30: Multi-Step Cross-Domain Aspect-Based Sentiment Generation with Error Correction Mechanism
Authors: Ningning Mao, Xuanliang Zhu, Yadi Xu
PAGE 280 – 290

Paper 31: Perceptual Hash Techniques for Audio Copyright Protection in Decentralized Systems
Authors: N. Kavitha, Rashmika S J, Reshika A S
PAGE 291 – 301

Paper 32: Advancing Precision Livestock Farming: Integrating Hybrid AI, IoT, Cloud and Edge Computing for Enhanced Welfare and Efficiency
Authors: Hakim Jebari, Siham Rekiek, Kamal Reklaoui
PAGE 302 – 311

Paper 33: AI-Powered Skin Disease Detection Using Adaptive Particle Swarm Intelligent Optimization and Hyper-Convolutional Neural Networks
Authors: N Annalakshmi, S Umarani
PAGE 312 – 323

Paper 34: Deep Learning Optimization Conception: Less Data, Less Time, More Performance
Authors: Mohamed Amine MEDDAOUI, Moulay AMZIL, Imane KARKABA, Mohammed ERRITALI
PAGE 324 – 332

Paper 35: A Novel Hybrid HO-CAL Framework for Enhanced Stock Index Prediction
Authors: Zeren Shi, Othman Ibrahim, Hanini Ilyana Che Hashim
PAGE 333 – 342

Paper 36: The Text Mining Model for Lecturer Performance Evaluation: A Comparative Study
Authors: Anita Ratnasari, Vina Ayumi, Mariana Purba, Wachyu Hari Haji, Handrie Noprisson, Marissa Utami
PAGE 343 – 348

Paper 37: Design and Evaluation of a Biometric IoT-Based Smart Lock System with Real-Time Monitoring and Alert Mechanisms
Authors: Jamil Abedalrahim Jamil Alsayaydeh, Mohd Faizal Yusof, Serhij Mamchenko, Rostam Affendi Hamzah, Safarudin Gazali Herawan
PAGE 349 – 362

Paper 38: Modelling Cloud Computing Adoption in the Malaysian Healthcare
Authors: Normilah Mohd Noh, Nurhizam Safie Mohd Satar, Hasimi Sallehudin, Ibrahim Hassan Mallam, Surya Sumarni Hussein, Nur Azaliah Abu Bakar
PAGE 363 – 376

Paper 39: Potential Variables in Pharmaceutical Drug Prediction Research with Machine Learning Approach: A Literature Review
Authors: Gunadi Emmanuel, Yulyani Arifin, Ilvico Sonata, Muhammad Zarlis
PAGE 377 – 389

Paper 40: Scalable Graph Learning with Graph Convolutional Networks and Graph Attention Networks: Addressing Class Imbalance Through Augmentation and Optimized Hyperparameter Tuning
Authors: Chaima Ahle Touate, Rachid El Ayachi, Mohamed Biniz
PAGE 390 – 400

Paper 41: Enhancing Banking Data Classification Through Hybrid L2 Regularisation and Early Stopping in Artificial Neural Networks
Authors: Khairul Nizam Abd Halim, Abdul Syukor Mohamad Jaya, Fauziah Kasmin, Azlan Abdul Aziz
PAGE 401 – 408

Paper 42: Empirical Validation and Enhancement of ADiBA: A Framework for Big Data Analytics Implementation
Authors: Norhayati Daut, Naomie Salim, Sharin Hazlin Huspi, Anazida Zainal, Chan Weng Howe, Muhammad Aliif Ahmad, Siti Zaiton Mohd Hashim, Masitah Ghazali, Mohd Adham Isa, Rashidah Kadir, Nuremira Ibrahim, Norazlina Khamis
PAGE 409 – 425

Paper 43: An In-Depth Analysis of Security Flaws in Advanced Authentication Protocols for the Internet of Medical Things
Authors: Haewon Byeon
PAGE 426 – 431

Paper 44: Enhancing Patient Health Through Smart IoT Technologies in Healthcare
Authors: Monica Bhutani, Osman Elwasila, Rajermani Thinakaran, Yonis Gulzar
PAGE 432 – 441

Paper 45: Modeling an Adaptive and Collaborative E-Learning System with Artificial Intelligence Tools
Authors: Kawtar Zargane, Hassane Kemouss, Mohamed Khaldi
PAGE 442 – 453

Paper 46: Determinant Factors of Success for the Village Information System in Providing Sustainable Services and Governance
Authors: Sutia Dwi Santika, Tuga Mauritsius
PAGE 454 – 466

Paper 47: Machine Learning Methods for Detecting Fake News: A Systematic Literature Review of Machine Learning Applications in Key Domains
Authors: Nur Ida Aniza Rusli, Nur Atiqah Sia Abdullah, Fatin Nabila Abd Razak, Nor Haniza Ramli
PAGE 467 – 481

Paper 48: SpatialSolar-Net: A Multi-Site Collaborative Framework for Solar Power Forecasting with Adaptive Spatial Correlation Assessment
Authors: Yiming Liu, Mugambigai Darajah, Christopher Gan
PAGE 482 – 495

Paper 49: AFL-BERT : Enhancing Minority Class Detection in Multi-Label Text Classification with Adaptive Focal Loss and BERT
Authors: Zakia Labd, Said Bahassine, Khalid Housni
PAGE 496 – 501

Paper 50: Attention Aware Dual-Path Autoencoder with Asymmetric Loss for Recognition in Complex Scenes
Authors: Hashim Rosli, Rozniza Ali, Muhamad Suzuri Hitam, Ashanira Mat Deris, Noor Hafhizah Abd Rahim
PAGE 502 – 511

Paper 51: Secure Data Sharing Using Blockchain Technology: A Systematic Literature Review
Authors: Azman Azmi, Farashazillah Yahya, Nur Afrina Azman, Hazlina Jalil
PAGE 512 – 525

Paper 52: Enhancing Firefighter PPE Compliance Through Deep Learning and Computer Vision
Authors: Asmaa Alayed, Razan Talal Alqurashi, Samah Hamoud Alhelali, Asrar Yousef Khadawurdi, Bashayer Fayez Khan
PAGE 526 – 534

Paper 53: Multi-Agent Deep Reinforcement Learning Algorithms for Distributed Charging Station Management
Authors: Li Junda, Wang Tianan, Zhang Dingyi, Wu Quancai, Liu Jian
PAGE 535 – 543

Paper 54: A Review of Federated Learning Attacks: Threat Models and Defence Strategies
Authors: Fizlin Zakaria, Shamsul KamalAhmad Khalid
PAGE 544 – 554

Paper 55: Intelligent Logistics Vehicle Scheduling Based on MPHIGA
Authors: Xinxin Gao, Qing Wang
PAGE 555 – 563

Enhancing Trust in Human-AI Collaboration: A Conceptual Review of Operator-AI Teamwork

Abduljaleel Hosawi[1], Richard Stone[2]
Dept. of HCI, Iowa State University Ames, USA[1]
Dept. of Industrial Engineering, Iowa State University Ames, USA[2]

***Abstract*—Trust is vital to collaborative work between operators and AI. Yet, important elements of its nature remain to be investigated, including the dynamic process of trust formation, growth, decline, and even death between an operator and an AI. This review analyzes how the dynamic development of trust is determined by Team performance and its complex interaction with factors related to AI system characteristics, Operator competencies, and Contextual factors. This review summarizes current concepts, theories, and models to propose a genuine framework for enhancing trust. It analyzes the current understanding of trust in human-AI collaborations, highlighting key gaps and limitations, such as a lack of robustness, poor explainability, and effective collaboration design. The findings emphasize the importance of key components in this collaborative environment, including Operator capabilities and AI technology characteristics, underscoring their impact on trust. This study advances understanding of the nature of Operator-AI collaboration and the Dynamics of trust in trust calibration. Through a multidisciplinary approach, it also emphasizes the impact of Explainability, Transparency, and trust repair mechanisms. It highlights how Operator-AI systems can be improved through Design principles and developing Human competencies to enhance collaboration.**

Keywords*—*Operator-AI collaboration; trust calibration; trust dynamics; explainability; transparency; trust repair mechanisms; cross-cultural trust; Clinical Decision Support Systems (CDSS); AI autonomy and influence; ethical considerations in AI; team performance; AI system characteristics; operator competencies; contextual factors; framework; limitations; robustness; Human-AI teaming; design principles; human competencies; predictability; reliability; understandability; over-reliance; automation bias; under-trust; trust measurement; trust erosion

I. Introduction

The catastrophic failure of HAL 9000 in the movie "2001: A Space Odyssey" highlights the loss of trust between humans and artificial intelligence [1]. As humans cede more control to Al in vital areas, fostering and nurturing trust becomes critical. The line between beneficial cooperation and disastrous dependence is fine and requires careful consideration. The ongoing effort to achieve greater integration of Artificial Intelligence (AI) into complex operational environments is rapidly transforming industries and reshaping the nature of work. AI, can be defined as machines or systems capable of performing tasks that typically require human intelligence. For instance, the ability to learn, solve problems, perceive, and take decisions offers unprecedented potential for human, such as enhancing our efficiency, augmenting our capabilities, as well as tackling previously intractable problems [2]–[5]. However, to deploy and utilize these powerful technologies successfully, particularly in collaborative settings with human operators, must be on the establishment, maintenance, and calibration of trust [6]. As AI systems are increasingly guaranteeing autonomy and responsibility in high-stakes areas, such as healthcare, finance, transportation, manufacturing, and defense [4], [7], [8]. Gaining a deep understanding the dynamics of trust within operator-AI teams today is paramount not only for ensuring safety, but also effectiveness, and the realization of AI's collaborative potential [9]–[11].

The concept of trust is multifaceted and dynamic in the context of human-AI interaction and has its own characteristics. Even though It's drawing parallels with interpersonal trust, it still presenting unique challenges stemming from the AI's non-human nature [6]. Generally, it is understood as an attitude or psychological state that involve a willingness to accept vulnerability (under conditions of uncertainty and risk) based on positive expectations regarding the AI's future behavior and capabilities. That includes its predictability, competence, reliability, as well as the alignment with the operator's goals [12]. There are three main aspects that are likely to affect this evolving attitude including the AI's perceived performance. For example, observed reliability, accuracy, and consistency. The second aspect is process in particular understandability, transparency, predictability of its model. Third is the purpose and how far it aligns with operato's goals, perceived benevolence, and integrity of its design [13], [14]. These three facets dynamically interact; for instance, if an AI's reasoning is explainable (process transparency), may lead to better assessment of its competence by the operator and may also be easier in predictability (performance). That potentially fosters faster trust emergence or aids calibration after errors [15].

How the level of operator's trust is calibrated in the capabilities of AI in a given context is critical, as it significantly impacts adoption behavior and overall team performance [16]. Distrust or (insufficient trust) could lead to the disuse (underutilization) or even abandonment of valuable AI assistance. Likewise, if an operator over-reliance or his/ her automation bias (excessive trust) results in issues such as complacency, reduced monitoring, and override AI errors or failure to detect them. This misuse, potentially, may have significant negative consequences [17].

According to Fig. 1, operators-AI collaboration could be best when the operator's level of trust is appropriately aligned with the AI' true capabilities. Failure to do so could lead to misuse by overtrusting the AI or under trust. For this reason, understanding trust dynamics (the entire lifecycle) is essential. In particular, how and when trust emerges, strengthened, and maintained before it decays or erodes. Trust can grow as a result of good behavior, and it can also be weakened as a

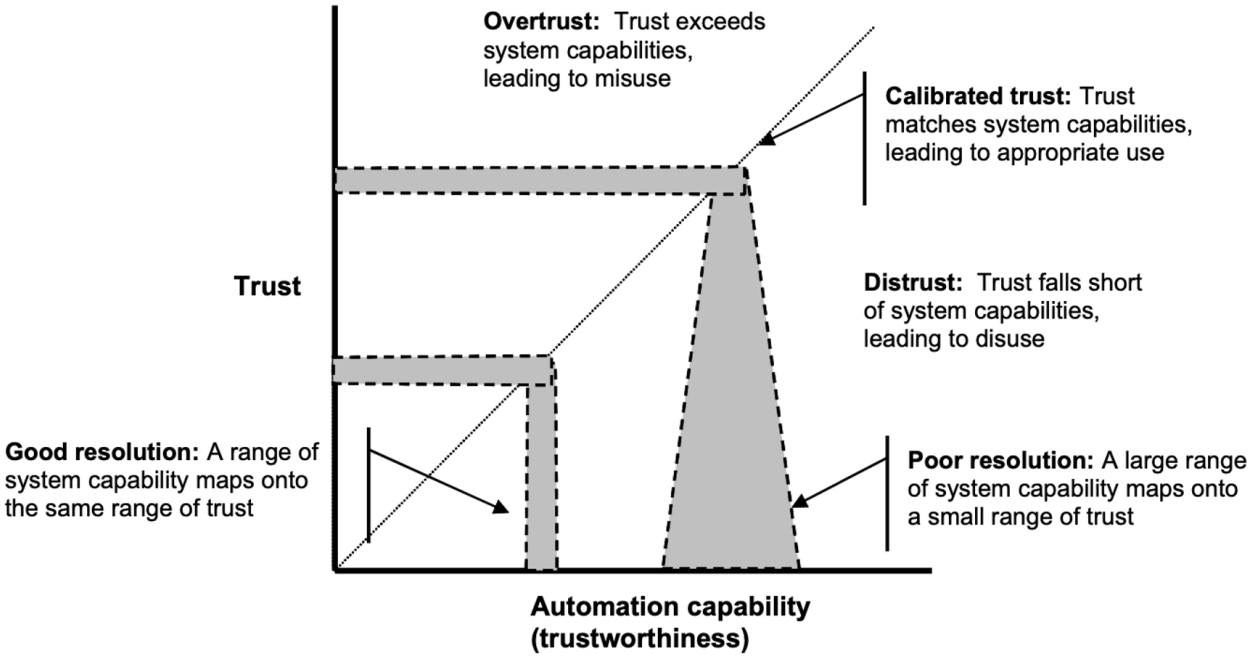

Fig. 1. Calibrating operator trust according to the true AI capabilities. Note: This figure is taken from Lee and See [12].

result of errors and biases. In addition, knowing trust repair strategies when it is damaged is just as important as knowing its life cycle, and both are essential for designing systems that promote safe, effective, and appropriately calibrated human-AI collaboration [18].

The dynamic process of trust formation between the operator and AI throughout team performance is influenced by a complex interplay of factors related not only to the AI system, but also to operator, interaction and contextual factors. Factors related to the AI system include objective performance metrics, communication strategies employed by the AI, how the design of transparency and explainability are featured , and even AI's perceived cooperativity or embodiment [19]. Human operator factors encompass many significant elements such as individual differences including propensity to trust, domain expertise. In addition to cognitive biases, required competencies for interacting with AI, age, cultural background, and emotional responses [20], [21]. For the factors related to interaction and contextuality , literature suggests involvement in the nature of the task, the development of shared mental models, and team composition. Finally, the overall organizational environment suporting human-AI teaming [22].

Despite rapid growth and advancements in research interest to explore the trust dynamics in the Human-AI settings, significant gaps remain. There is still a persistent need for more longitudinal studies tracking trust dynamics over time [23], [24] , deeper exploration of cross-cultural variations in trust also still demanded [25], [26], validated approaches not only to measure trust but also to capture its dynamics and reveal its calibrated nature [27], [28], better understanding of trust erosion and repair mechanisms following AI errors, failures or bias [29], [30],continued examination of ethical considerations, (for example, regarding autonomy and influence) [21], [31] , and developing new generation of AI systems with true teaming competencies [8], [9], [32].

The present literature review aims to synthesize current knowledge on the dynamics of trus, its emergence, growth, and decay within operator-AI teams. Specifically, this review focuses primarily on new literature that reflects the latest advancements in the field. It examines the various types of AI systems relevant to this context of collaboration with human operators, explores the theoretical underpinnings of trust, analyzes the key factors influencing trust dynamics in addition to discussing strategies for building and maintaining trust. The review also investigates mechanisms of trust erosion and repair, and considers the implications for designing effective and trustworthy human-AI partnerships. Through consolidating research from diverse fields and highlighting persistent gaps, this review seeks to provide a comprehensive overview of the current state of understanding and inform future research directions. The aim is to contribute in enhancing trust and collaboration in the increasingly prevalent operator-AI teams.

A. Structure of the Review

The review is organized into several sections, as shown in Fig. 2: Section I: structured exploration of trust dynamics in operator-AI teams. Section II: classifying AI systems pertinent to operator-AI collaboration, and defining the scope of AI. Section III: primary theoretical frameworks informing trust, from different fields. Section IV: analysis of factors influencing trust dynamics. Factors categorized by AI, human operator, and context. Section V: temporal processes of trust (formation, calibration, decay, repair). Section VI: case study on Clinical Decision Support Systems (CDSS). Section VII: critical

discussion and synthesis, challenges, limitations, unresolved questions. Section VIII: conclusion, core arguments, gaps, methodological approach, and future directions.

Thus, having explored the foundational dynamics of trust in operator-AI teams, it is now crucial to understand the diverse types of AI systems involved. Therefore, Section II will discuss classifying AI systems to identify the types relevant to operator-AI collaboration and define the AI scope in our review.

II. Defining the Scope: AI Systems in Operator-AI Teams

The term "Artificial Intelligence" encompasses a wide spectrum of technologies with different capabilities and functionalities [2]. In order to effectively discuss trust dynamics in operator-AI teams, it is crucial to specify the types of AI systems most relevant to collaborative contexts. Researchers need to ensure that interconnectedness and common goals exist or are possible [6], [9]. AI systems can be classified along several dimensions, including their capabilities relative to human intelligence, their core functionality based on how they process information, and finally, based on their intended role and scope within human interaction [3], [33]. Table I synthesizes common classifications relevant to operator-AI teaming. It's drawn from the original draft and sources including Jutel [2], Makarius [33], Bansal [34]–[36](Refer to Table I).

Table I [2], [33] illustrates AI systems classification in the context of operator-AI teaming. The table classifies the AI systems into three general groups: capability, functionality, and scope or role. Each group is divided further into categories, including Narrow AI (ANI), General AI (AGI), and Super AI (ASI), according to their capabilities. The second group contains AI systems classified based on functionality and encompasses Reactive Machines, Limited Memory (Alteration/Symbiotic under the Scope/Role classification), Theory of Mind, and Self-Aware. The last group is based on the scope or role of the AI model and contains six different types of AI systems. The review will focus on the Limited Memory AI systems as this category represents AI systems currently interacting with operators and possess sophisticated capabilities within specific domains. This category also can collaborate with humans to adapt and share goals with medium novelty ,content changing scope. Furthermore, these systems also can learn from experience, enabling advanced collaborations from the perspective of organizational integration and human roles [33]. Operator-AI teaming often involves tasks such as Augmentation, Alteration, and potentially Autonomous systems, where the relationship is complementary, symbiotic. The tasks also could involve careful monitoring and intervention by the human operator. The human role shifts from simply controlling a tool, coaching, or overseeing to collaborating with a true and more capable AI partner. In the future, Artificial General Intelligence (AGI) or Superintelligence (ASI) will need more examinations as they remain largely theoretical. Based on the above, this review focuses primarily on interactions with Narrow AI systems exhibiting Limited Memory functionality. These systems are more suitable for our study because they operate in roles that involve complementarity, symbiosis, or monitored independence (Augmentation, Alteration, Autonomous). In such systems, dynamic trust, reliance calibration, and effective teaming processes are most critical and currently researched. While future AGI might introduce radically different trust dynamics, investigating trust with current and near-future interactive Narrow AI could provide the necessary foundation. The principles discussed, particularly regarding transparency, reliability, communication, and human factors, are likely to remain relevant, even if the are modified as AI capabilities advance.

Having established the scope and types of AI systems in this context, it is time to understand the theoretical foundations for studying trust. Therefore, Section III delves into the primary theoretical frameworks drawn from various fields that inform our understanding of trust in the context of human-AI collaboration.

III. Theoretical Foundations of Trust in Human-AI Collaboration

Several theoretical frameworks represent a starting point to understand trust dynamics in operator-AI teams.

1) First, Social Exchange Theory (SET): Originating in sociology [22], according to SET, social relationships are built on the exchange of resources. Individuals seeking to maximize benefits and minimize costs. Human operators are more likely to cooperate if the perceived benefits of teaming with AI (e.g., improved decision making, reduced time, increased efficiency) outweigh the costs (e.g., risk of errors, loss of control, reduced cognitive effort). Trust develops when the perceived benefits consistently outweigh the costs, and enhances willingness to continue cooperation (reliance) with the AI [37], [38]. Several factors such as perceived fairness, reliability, and competence of the AI can influence this cost-benefit analysis and subsequent trust [39]. However, applying SET directly faces various challenges due to the AI's lack of social factors and the opacity of its "intentions" [40].

2) Cognitive Load Theory (CLT): Focuses on the limitations of human working memory, and distinguishes between three types of memories: intrinsic load (task complexity), extraneous load (interface/information presentation), and germane load (schema construction/learning). CLT developed in educational psychology Sweller. In the context of human-AI interaction, CLT states that a poorly designed AI systems can impose high extraneous cognitive load (e.g., confusing interfaces, overly complex explanations). This can hinder understanding and trust formation [41], [42]. Conversely, well-designed AI can reduce cognitive load by automating routine tasks or presenting information clearly and concisely. A well-designed AI model more likely help in freeing up cognitive resources for operators to better evaluate the AI's output and build trust [43]. Managing cognitive load is thus crucial for effective collaboration and trust [44].

3) Human-Computer Interaction (HCI) and Technology Acceptance Models: HCI research provides numerous models for understanding user interactions with various technologies.The Technology Acceptance Model (TAM) and its more recent extensions such as "AI Adoption TAM", "User Acceptance of AI Systems", or "Trust and Technology Acceptance Models for AI" are some of those basic models. These models emphasize perceived usefulness and perceived ease of use as key elements that determinants of technology acceptance. Both elements

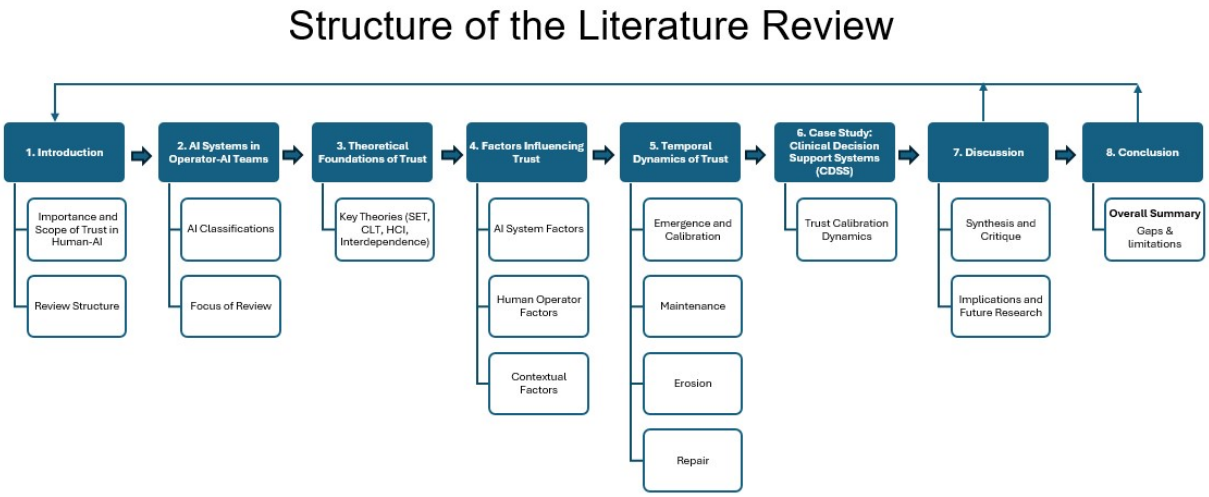

Fig. 2. Organization of the literature review.

are essential and may be considered related to trust more recent models, including the Unified Theory of Acceptance and Use of Technology (UTAUT), incorporate additional factors. Some important factors are social influence and facilitating conditions [45], [46]. In the field of HCI, multi-dimensional models of trust in automation and AI have emerged (e.g., competence, benevolence, encompassing, integrity, predictability, and dynamic). These models highlight the importance of system characteristics such as performance, and design, user characteristics such as disposition to trust, and finally contextual factors in shaping trust over time [42], [47], [48].

4) Theory of Mutual Dependence or Interdependence Theory: Based on these theories, interdependence among team members is crucial for achieving common goals. This applies whether this interdependence is within traditional teamwork between humans or between humans and artificial intelligence [49]. In the team, trust is cornerstone and can act as an auxiliary worker in interdependent relationships, facilitating coordination, communication, and willingness to rely on others [50]. In human-AI teams, this interdependence should go both ways, requiring operators to trust the AI's capabilities within its designated role, while the AI (through its design) must reliably fulfill that role [41]. Correctly calibrating trust dynamics in light of AI capabilities is crucial and a significant challenge, especially given the impact of influential factors. Also, it's important to establish shared awareness and mental models between human and AI agents [51]–[53]. These frameworks collectively highlight that trust in operator-AI teams is a complex phenomenon influenced by several factors such as perceived utility, cognitive feasibility, system design, user psychology, and the dynamics of interdependent collaboration.

These diverse theoretical perspectives provide a robust foundation for understanding trust in human-AI contexts. We can now turn to a detailed analysis with these theoretical frameworks established. Section IV systematically analyzes the multifaceted factors identified in the literature that influence trust dynamics.

IV. Factors Influencing Trust in Operator-AI Teams

Trust is not static but emerges and evolves based on interactions between the operator, the AI system, and the context. Key influencing factors can be categorized as follows:

A. AI System Factors

1) Performance and Reliability: Performance is arguably the most fundamental factor in building trust. It must be consistent, accurate, and reliable [12], [39], [42]. Predictability, or the extent to which the AI behaves as expected, is also crucial [40], [54]. In addition, errors or inconsistent performance significantly erode trust between operators and AI systems [24], [29].

2) Automation and Trust: Fig. 3 illustrates a model of trust in automation [12], [55], indicating the factors that directly impact how a human operator builds and maintains trust in automated systems and how that trust influences the operator's reliance on automation. At the top of the figure, the large box indicates the general context associated with the formation

TABLE I. CLASSIFICATIONS OF AI SYSTEMS RELEVANT TO OPERATOR-AI TEAMING

Classification Axis	Category	Description	Examples Relevant to Teaming	Typical Human Role
Based on Capability	**Narrow AI (ANI)**	Designed for specific tasks; cannot perform outside training domain.	Facial recognition, Driving assistance, Diagnostic aids, NLP chatbots, Go programs	Controller, Collaborator
	General AI (AGI)	Possesses human-like cognitive abilities; can learn and perform various intellectual tasks (mostly hypothetical).	Hypothetical versatile assistants or partners.	Co-creator, Comprehend
	Super AI (ASI)	Surpasses human intelligence across all domains (purely hypothetical).	Speculative superintelligences.	Comprehend
Based on Functionality	**Reactive Machines**	Reacts to stimuli; no memory of past experiences.	Early game AI (e.g., Deep Blue).	Supervisor (limited teaming)
	Limited Memory	Learns from past data/experience to inform future decisions; most current AI applications.	Chatbots, CDSS, Recommendation systems, Autonomous vehicles.	Controller, Collaborator, Coach
	Theory of Mind	Understands emotions, beliefs, intentions (conceptual/developing).	Advanced virtual assistants, Social robots.	Collaborator, Co-creator
	Self-Aware	Possesses consciousness, sentience (theoretical).	Hypothetical conscious AI.	not specified
Based on Scope/Role	**Automation / Substitution**	AI replaces human tasks; low novelty, content-changing scope.	Assembly line robots, Basic DSS.	Controller
	Amplification / Supplementary	AI enhances human analysis; low novelty, context-changing scope.	Predictive analytics tools.	Conductor
	Augmentation / Complementary	AI assists humans in complex tasks; medium novelty, content-changing scope.	Surgical robots, Advanced DSS, Go programs, Chip design AI.	Collaborator
	Alteration / Symbiotic	AI and humans co-create/adapt; medium novelty, context-changing scope.	Deep learning systems needing expert interaction.	Co-creator
	Autonomous / Independence	AI operates largely independently; high novelty, content-changing scope.	Self-driving vehicles (higher levels).	Keep-in-Check (Monitor)
	Authentic / Singularity	AI potentially surpasses human roles; high novelty, content-changing scope (hypothetical).	Superintelligence (ASI).	Comprehend

Note: Capability and Functionality classifications adapted from Jutel [2], common AI taxonomies, scope and role classification adapted from Makarius [33].

and reliance of trust, including the individual's characteristics (such as experience and personality), the organization's organizational structure (such as policies and procedures), culture (differences in shared norms and values regarding trust in technology), and the work environment context (the circumstances and situations in which automation is used).

In the same box, the figure shows the factors that influence the level of automation implementation, which in turn contributes to the operator's perception and level of trust. For example, these factors include what others say, rumors, and interface design quality. Other factors include workload, effort required to participate, self-confidence and personal capabilities, perceived risks, and system setup errors related to automation. In the middle of the model, four boxes appear from the left to the right, representing the mechanism through which the trust audit process progresses, from its creation to its adoption. This process begins with gathering information, perceptions, and beliefs about automation, followed by an evaluation by the operator in preparation for transforming them into practical actions by determining how to deal with the automation and, finally, whether to adopt it. Feedback between some stages may alter perception, evaluation, and the operator's readiness to embrace or avoid the automation. This development occurs through dynamic interaction with the application context and influencing factors.

In the lower right of the model, we find the automated system and its related capabilities and usage procedures. On the opposite side (bottom right), the model depicts the user interface and its impact, including ease of use, information reception and clarity, and ease of feedback. In the middle part, the model demonstrates that the operator receives information about the automation that may contribute to their understanding and confidence, such as the purpose of the automation, how it is implemented, and the quality of performance (refer to Fig. 2).

3) Transparency and Explainability: Explainability, the ability of human operators to understand how an AI arrives at a decision or recommendation, and having insight into its processes, true capabilities, and limitations (transparency) are critical for building calibrated trust. Transparency is vital, especially for complex or "black box" models [56], [57], [56] ExplainableAI. Explainable AI (XAI) is a technique that aims to provide transparency insight, which is particularly important in high-stakes domains [58], [23], [30]. Even the availability of explanations, whether accessed or not, can increase perceived trustworthiness [24], [59].

4) Interface and Interaction Design: Several essential elements, including User-friendly interfaces, precise feedback mechanisms, and intuitive controls, contribute significantly to perceived ease of use and reduce extraneous cognitive load, fostering positive experiences and trust [6], [40], [47]. Human-centered design (HCD) principles are critical and emphasize

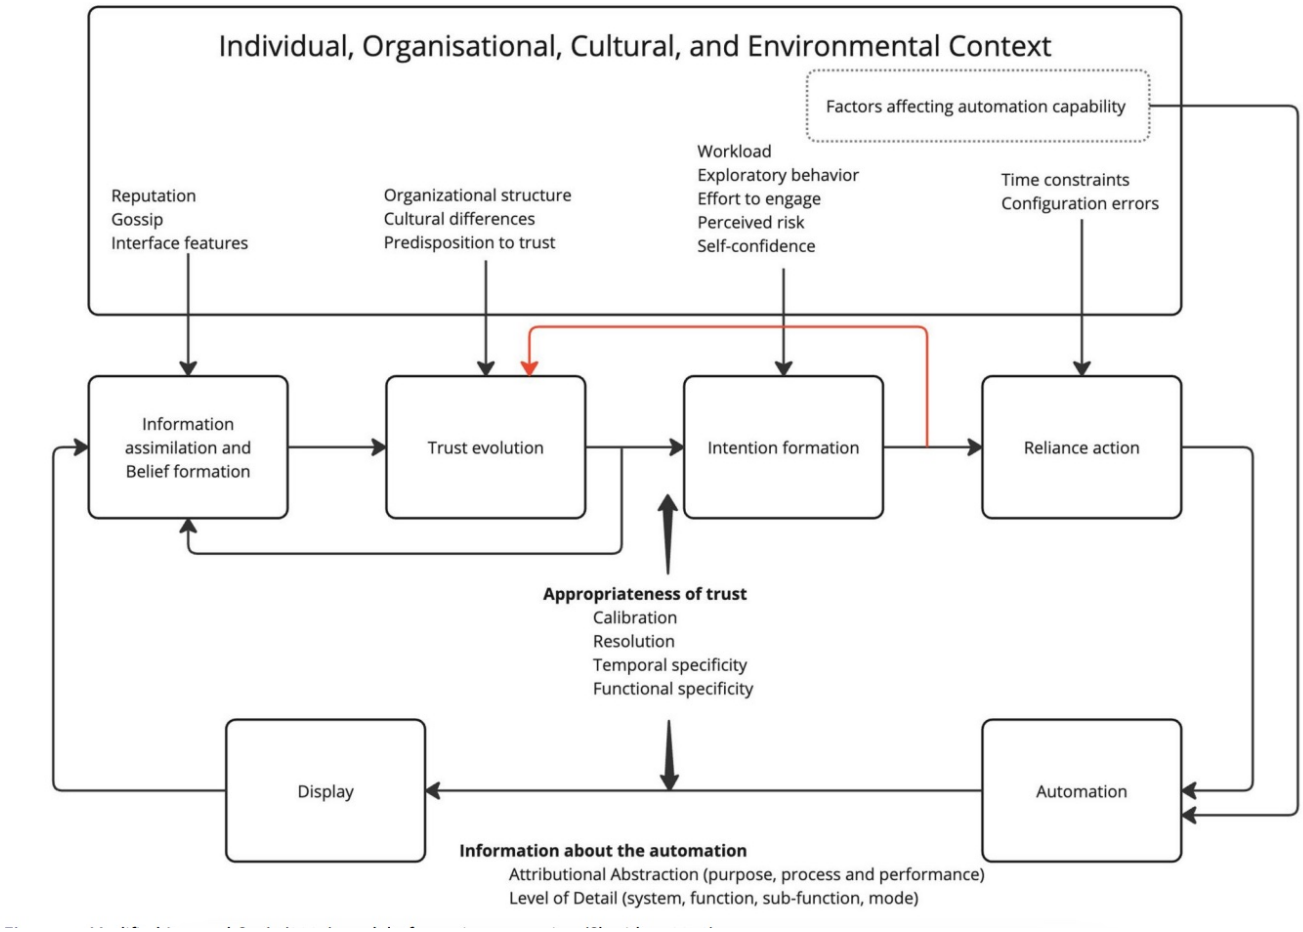

Fig. 3. The model of trust in automation, as originally proposed by [12] and modified by Sheridan [55]

tailoring the AI system to operator needs, capabilities, and context [6], [40]. Anthropomorphism refers to the design of AI with human-like characteristics (e.g., appearance, communication style) can sometimes foster emotional trust and rapport. However, it can also lead to unrealistic expectations or uncanny feelings if not implemented carefully [37], [40], [60].

B. Human Operator Factors

1) Disposition to Trust: Individuals vary in their inherent propensity to trust others or even to reassure to use technology, influenced by personality traits and past experiences [37], [42]. Experience and Expertise: Prior experience with AI or similar technologies, as well as domain expertise, are significant factors and can shape mental models and expectations of AI systems, influencing trust levels [61], [62]. Training can help develop accurate mental models but must be carefully designed [43], [63].

2) Cognitive Biases: Operators are susceptible to biases like automation bias (over-reliance on automation) or confirmation bias, leading to miscalibrated trust [6], [43]. Cultural Background: Cultural norms and values can significantly influence expectations, communication styles, and perceptions of technology, leading to cross-cultural differences in trust towards AI (GSD Venture Studios, n.d.), [26], [40]. AI design and interaction must consider these cultural nuances [26].

C. Contextual and Task Factors

1) Task Complexity and Criticality: Trust requirements in the operator-AI settings are high and often higher for complex tasks or in high-stakes environments, especially where the consequences of failure are severe (e.g., healthcare diagnostics, autonomous flying, military operations) [42], [64], [65].

2) Risk and Uncertainty: The capabilities of AI systems vary depending on the model and its characteristics. Higher perceived risk or uncertainty in the operational environment often necessitates greater trust in the AI's ability to perform reliably [62], [66].

3) Organizational Culture: The organizational context, including policies regarding AI use, transparency norms, and support structures, can influence operator trust [67].

Understanding these categories of influencing factors is essential, but trust is also a dynamic process that changes over time. Therefore, Section V focuses on the temporal processes of trust, examining how it initially forms and is calibrated and maintained over time.

V. Temporal Dynamics of Trust: Emergence, Calibration, Maintenance, Erosion, and Repair

Trust in an operator-AI team is dynamic rather than static. It is created and evolves over time, up and down, due to ongoing interactions with surrounding factors [68]. Operators assess trust and interpret AI behavior in specific contexts. Understanding the lifecycle of trust is crucial: how it is created, grows, or erodes due to adverse events, the strategies for repairing it when it is damaged, and how it is calibrated and maintained. The above elements are essential for developing strong and resilient partnerships in human-AI teams.

A. Trust Emergence and Initial Calibration

Initial trust between the operator and the AI is formed before or during early interactions [12]. Usually, it is shaped by factors such as relying on heuristics, pre-existing attitudes, and surface-level characteristics rather than deep experience. Other factors that may influence initial trust include the operator's disposition to trust technology in general [69], preconceptions based on reputation or prior experiences with AI or similar systems, the perceived purpose and design pedigree of the AI (e.g., developed by a reputable source), in addition to interface characteristics that signal professionalism or usability [12]. Initial interactions are critical; early positive experiences demonstrating reliability and competence can establish a positive trajectory. Similarly, early failures can disproportionately damage nascent trust [12], [69].

Operators begin trust calibration as the interactions with the AI progresses. They adjust their level of trust to align with the AI's perceived capabilities and limitations in the context [12]. AI processes and boundaries require transparent and accurate feedback on their performance to succeed in the calibration effectively. Providing explanations, particularly those relevant to the task and understandable to the operator (e.g., example-based or counterfactual explanations according to the contexts), can aid this process by supporting operators in building more accurate mental models of the AI's reasoning [6], [16]. However, ineffective or overly complex explanations can do the opposite. Poor explanations can hinder calibration. Explicitly revealing AI uncertainty or confidence levels can also be profitable in aiding calibration, even though it may sometimes decrease overall trust levels [6], [70]. Several models are being explored and incorporating Bayesian learning, which refers to applying probability theory to learning from data, especially regarding trust and interpretability [71]. The way operators update their appraisal of AI capabilities could be captured through the exploration based on observed outcomes [72] . To avoid the pitfalls of over-trust or under-trust, successful calibration is essential.

B. Trust Maintenance

The process of maintaining trust begins once it is established and calibrated between the operator and the AI [42]. Sustained reliability and predictable performance are crucial [12], [42]. Operators can anticipate AI actions and integrate them smoothly into their workflow through predictability. [54]. The importance of transparency goes beyond just the initial calibration but also effective communication, and ongoing verification, understanding. This importance is vital in a changeable environment or when AI's behavior is modified. Helpful strategies, such as proactive updates or confirmations, can reinforce perceptions of reliability and teamwork, contributing to trust maintenance [70]. Furthermore, AI systems designed with intuitive human-centered principles that align with operator workflows and cognitive limits are crucial and more likely to sustain trust over time by ensuring good user experiences [6], [11]. Sharing learning, an environment where both humans and AI can exchange knowledge and experience through collaboration, strengthen relationships, and preserve trust [11].

C. Trust Erosion

Trust can be described as "hard-won but easily lost". It has several actors that lead to trust erosion: First, AI errors and failures are the most direct reasons trust decreases. Although trust can be easily affected be errors, the type of error, its frequency, and its severity may have the greatest impact [12], [42], [54]). Sometimes, occasional errors, especially critical or unexpected ones, can significantly affect or damage trust.

The next cause can be the lack of transparency and explainability [57], as operators need to know everything while collaborating with their intelligent partners. Issues can arise when AI fails or behaves unexpectedly. Black-Box issues can be a real problem by hindering users' understanding of the cause of system errors. As a result, users may feel frustrated, uncertain, confused, and lack control [12], [16], [73]. Also, poor interpretations can lead to similar harms and results, leading to dissatisfaction or overtrust of the system.

Unreliable performance can make predictability difficult [42], negatively impacting the operator's trust in the system. For instance, surprises in AI system behavior can cause system performance to fluctuate, leading to a gradual erosion of trust over time [12], [63]. Other harmful reasons are perceived bias and unfairness. AI biased or unfair actions would cause damage to trust, particularly if they negatively impact the operator or specific groups. Trust can be severely damaged [33], [63]. Similarly, a discrepancy between operator expectations and the actions of an AI system can negatively impact trust between the two. Sometimes, AI capabilities are exaggerated, leading to feelings of disappointment or distrust, especially in early interactions with the system [12]. Trust can also be decreased as a result of poor usability or communication and can lead to trust decreased [12]. Communication is vital for operators while teaming with an AI partner. Awkward interfaces, ambiguous feedback, or ineffective communication protocols may create friction, confusion, and frustration. Leading to negative impacts on the user experience and indirectly eroding trust [12], [16], [70]. Finally, the context also matters because errors in high-stakes situations typically cause more significant trust erosion than errors in low-stakes contexts [42], [73].

D. Trust Repair

Trust may be easily damaged and must quickly be repaired [74]. Rebuilding trust after damage is not an easy challenge in human-AI interaction. Arguably, it can be even more so than in human relationships due to the AI's lack of genuine social recourse (e.g., repentance, sincere apology, remorse). Research indicates that simple apologies or explanations for

AI failure have shown only marginal effectiveness in restoring trust [29]. The study found apologies and explanations to be the most effective relative strategies compared to not taking action or no repair; however, their overall impact was not very influential.

First, acknowledging and explaining failures is a must action. Transparency about the source of an error is crucial, moving beyond simple apologies [6], [16]. Tailored explanations that address the specific failure context may be needed. Also, demonstrating corrective action could be a good strategy [74]. We need to confirm to the operators that the underlying cause of the failure has been handled (e.g., communication, policy, algorithm update, retraining) and that affected trust can be rebuilt faster. Nevertheless, It is essential to work towards consistent future performance. Reestablishing a track history of reliable and predictable behavior after a failure and overwriting the negative experience can be a strategy for repairing trust [6], [12]. Additionally, an innovative solution could be providing a means of control to the operator or the appropriate agency as support; this may help restore damaged trust [75]. This support could provide transparency and regain trust. Allowing operators to understand, verify, and potentially override AI actions, such transparent procedure can aid in restoring a sense of control and mitigate the vulnerability associated with trust decrease [31]. Longitudinal studies demonstrate that explanations accelerate trust restoration after a malfunction. This acceleration can be beneficial even if not always accessed [24]. However, We must acknowledge a need to develop accurate and effective solutions that guarantee systematic trust repair strategies for human-AI teams. This demand remains an open research area.

E. Trust Measurements

Trust is multifaceted and changes over time, so no single metric may be sufficient to assess it or measure the performance of the operator and AI team. Table II and Table III summarize the most important metrics used to assess trust and evaluate the effectiveness of the operator and AI team.

Table II shows several metrics for measuring trust drawn from various fields (human factors, HCI, and psychology research). Questionnaires and surveys are the most commonly used metrics due to their ease of use and are a branch of self-report metrics. Standardized trust scales are also used to assess predictive ability, perceived reliability, and trustworthiness, particularly in automation and artificial intelligence. There are two other questionnaire and survey scales: Likert-type and semantic differential scales, which ask the user to rate their level of agreement with a specific statement and use bipolar adjectives such as trustworthy-untrustworthy, respectively. The final scale used in questionnaires and surveys is Interview/Focus Groups, which focus on identifying causes and explaining phenomena, such as which factors specifically led to a high or low level of trust. The second type of scale that can be used to measure trust is Behavioral Measures (objective), which focus on observing how the operator interacts with the artificial intelligence system. Three measures under this category are Reliance/Adherence, Task Performance, and Interaction Patterns. Each has its purpose and nature; some are used for measuring the frequency of a particular phenomenon, others for error rate or the extent of the operator's need to search for information such as clarification or assistance. The final category of trust metrics that can be employed in an operator-AI team are Physiological Measures (Objective but more complex). These metrics involve observing a human operator's vital signs, such as Heart Rate Variability (HRV), Galvanic Skin Response (GSR)/ Electrodermal Activity (EDA), and Eye Tracking.

Table III shows which metrics are used for measuring operator-AI teamwork. Operator-AI Collaboration is a crucial measure, and its metrics overlap with trust metrics [76], but they focus on the effectiveness and nature of joint work. Operator-AI Collaboration is measured using the Team Performance Metrics, which measure efficiency, accuracy, and workload—interaction Quality Metrics for evaluating communication effectiveness, mutual understanding, role clarity, allocation, and adaptability. For Subjective Collaboration Measures, usually asks perators to reate some aspects. For instance, "I felt the AI was a bad manager" or "I comprehended how the AI was finishing the task". In addition, Subjective Collaboration Measures could also be used to find out how well the operator feels integrated with the AI as a team (refer to Table III).

The important question is what is the appropriate measure for measuring trust between operators and artificial intelligence (AI)? In addition, what is the best way to assess their collaborative relationship? Given the fluid and multifaceted nature of trust, more than one type of measure may be needed depending on the scope of the application and its extent, which underscores the importance of context. Trust must be measured at various levels for the trust enhancement model proposed following this review, which will primarily focus on enhancing trust in the operator-AI environment. There will likely be a need for subjective (e.g. questionnaires) measures with objectives (e.g., behavioral) related to the human element, the AI system, and context. These measures are also essential in most fields, such as ethical principles, measuring AI's true capabilities, and the human operator's readiness. By integrating these measures, weaknesses that have arisen in previous studies due to the absence of necessary measures can be overcome. Trust formation, decay, and repair mechanisms are fundamental, especially in high-stakes environments. To illustrate these concepts in practice, Section VI presents a case study focused on Clinical Decision Support Systems (CDSS). The CDSS provides a window to examine the evolution of trust through its various stages.

VI. Case Study: Trust Calibration Dynamics in Clinical Decision Support Systems

Many challenges of trust dynamics are uncovered in the CDSS case study [77], particularly in the calibration. These challenges and the impact of system design are vividly described in the context of Clinical Decision Support Systems (CDSS). In a high-stakes environment where decisions require high accuracy and reliability (examination and prescribing chemotherapy to patients), the study examined the impact of XAI's explanations on trust levels among 41 medical practitioners. Four categories of explanations were compared (example-based, global information-based, local context-based, and unrealistic explanations). Participants interacted with scenarios featuring both correct and incorrect AI recommenda-

TABLE II. METRICS FOR TRUST IN OPERATOR-AI COLLABORATION

Metric Category	Measurement Methods	Focus of Measurement
Self-Report	Questionnaires/Surveys, Interviews/Focus Groups	Subjective perceptions and beliefs about AI trustworthiness.
Behavioral	Reliance/Adherence, Task Performance, Interaction	Observable actions and patterns of operator behavior when interacting with AI.
Physiological	HRV, GSR/EDA, Eye Tracking	Physiological responses that may correlate with trust, stress, or cognitive load related to the AI.

TABLE III. METRICS FOR MEASURING OPERATOR-AI COLLABORATION

Metric Category	Measurement Methods	Focus of Measurement
Team Performance	Efficiency, Accuracy, Workload (Subjective/Objective), Situation Awareness	Effectiveness of the combined human-AI system in achieving task goals.
Interaction Quality	Communication Effectiveness, Mutual Understanding, Role Clarity/Allocation, Adaptability	Nature and quality of the interaction between the operator and the AI system.
Subjective Collaboration	Collaboration Experience Questionnaires, Perceived Team Cohesion	Operator's perceptions and feelings about working collaboratively with the AI.

Note: Tables II and III are adapted from [76]. Table II focuses on trust measures, and Table III shows the measures used to evaluate team performance.

tions, then trust was assessed using self-reported cognitive dimensions (understandability, reliability, competence) and behavioral indicators (agreement with AI, switching decisions, overall human-AI performance).

1) Trust Emergence and Understandability: The case study results indicated the importance of the type of explanation. The study found that the initial impressions were significantly influenced by the type of explanation provided. Example-based and unrealistic explanations were easier to understand and distinguish than other explanations (public and local). According to the results, explanations that included concrete examples or "what if" scenarios were more straightforward to comprehend than abstract scores. This finding aligns with psychological principles suggesting humans favor familiar, causal explanations. In addition, some participants have to separate local and global interpretations or misinterpret them due to difficulty in understanding them, ultimately hindering the possibility of these interpretations strengthening initial trust. This finding is consistent with psychological principles that humans favor familiar, known causal explanations. Furthermore, some practitioners have been forced to misuse local and global explanations because they are difficult to understand, which ultimately leads to these explanations not strengthening initial trust. This finding suggests that humans prefer only well-known logical explanations.

2) Trust Calibration Challenges: While providing explanations (regardless of class) improved overall human-AI task performance compared to no explanation, a critical finding emerged regarding calibration: explanations did not significantly help practitioners recognize incorrect AI recommendations. Explanations did not help practitioners substantially recognize incorrect AI recommendations. Participants found defective AI suggestions, including the no-explanation baseline, not easy to disagree with across all explanation conditions. Furthermore, providing explanations significantly increased participants' agreement with AI recommendations compared to not providing any explanations. Therefore, suggesting explanations may inadvertently lead to overreliance or confirmation bias. Participants may have used explanations heuristically (System 1 thinking) as a signal of AI competence rather than engaging in deeper critical analysis (System 2 thinking), especially given workflow pressures.

3) Trust Decay and Contextual Needs: Qualitative feedback revealed critical factors that could lead to trust erosion or prevent trust from developing appropriately, even with explanations. Participants provided feedback expressing their concern that in their feedback, participants voiced concern when explanations seemed disconnected from clinical context or task constraints (For example, explanations that are unrelated to the patient's condition or seem unrealistic). In addition, participants highlighted the need for assurances regarding the validity and capability of the explanation method (e.g., data integrity used, consistency) and allowing for desired tailoring and customization to fit professionals' specific workflow and information needs. The lack of multi-step explainability or the ability to ask follow-up questions about an explanation was also a barrier to deeper understanding and trust validation.

This critical case study powerfully demonstrates that simply providing explanations is insufficient for ensuring appropriate trust calibration in operator-AI teams. The study shows that explanations' type, design, usability, and contextual relevance critically influence how operators perceive, understand, and ultimately rely on AI systems. It highlights the risk of explanations fostering over-reliance if not carefully designed and integrated. In addition, the findings underscore the need for interfaces that support critical thinking, address usability constraints, provide necessary assurances, and allow for user adaptation and deeper inquiry. This case study illustrates the complexities of confidence calibration in a credit decision support system. Based on these specific examples, we now turn to Section VII, which provides a critical discussion and summarizes the key findings from all the previous sections.

VII. DISCUSSION

AI teams' evolving and expanding landscape requires operators to understand the dynamics of trust, a critical factor in successful collaboration. This literature review explores this vital topic, highlighting the shift toward viewing AI as a team partner rather than simply a tool, revealing the complex

nature of trust in these contexts, synthesizing various theoretical perspectives and research findings, and revealing key themes, significant challenges, and critical tips for future work. Building upon this overview, the following section delves into synthesizing the key findings regarding the multi-determined nature of trust dynamics.

A. Synthesis: The Multi-Determined Nature of Trust Dynamics

Researchers have consistently demonstrated that trust has a lifecycle through which it emerges, grows, and begins to decay. Trust is not driven by any single factor. Instead, it results from a complex interplay between the AI system's characteristics, the human operator's attributes, and the interaction context [12], [42]. AI performance and reliability are the foundation of trust [12], [37]. But these important factors are just as important as other key factors, such as transparency and explainability. This importance is particularly true in high-risk environments or sensitive systems [6], [16], [73]. Clear explanations facilitate operator roles and help operators calibrate trust; in other words, while performance and reliability form the foundation of solid trust, it is important to remember that "reliability" is not a fixed measure. Its perception can be highly subjective. An AI system may be objectively reliable, but trust can quickly erode if the operator fails to make decisions or if occasional errors are not explained and addressed effectively. This finding suggests that subjective perceptions of reliability, influenced by transparency and interpretability, are just as important, if not more so, than objective technical performance. On the other hand, complex or poorly designed explanations should be avoided. They can hinder usability, cause serious problems, and increase cognitive load. Poor explanations can also lead to over-reliance on AI or avoiding it over time.

While AI capabilities form a foundation for trust, the role of the human operator is equally vital. The human element is equally critical. Individual differences, willingness to trust, expertise, cognitive styles, and competencies, all these factors affect how operators perceive AI [12], [20], [78]. Cultural background emerges as vital in trust dynamics, nevertheless often Ignored. An operator's artistic background is an essential factor that can significantly influence trust perceptions and expectations of the team in trust [26]. The frequent neglect of cultural and even artistic backgrounds in current research is significant. This gap may be due to the predominant focus on the technical aspects of AI. However, the fundamental truth is that this technology ultimately approaches humans from an inherently cultural and individual perspective. For example, an operator from a particular culture may prioritize AI's ability to integrate with group systems seamlessly. In contrast, an operator from an individualistic culture may emphasize security and privacy more. Similarly, an artist may be more attuned to AI's creative potential and fine-grained judgment, while an engineer may prioritize precision and logical reasoning. These differences can lead to significant variations in trust formation and team dynamics. Developing shared mental models and how cooperative they seem can greatly affect the teamwork and trust levels [27], [22], [70]. The Hanabi experiment highlights a crucial point. The game experiment highlights how subjective perceptions of teamwork and agent interpretability can diverge from objective performance. Sometimes, rule-based agents are preferred over objectively comparable, but less predictable, learning-based agents [27], [79]. In other words, people such as operators might choose to work with an AI that they "understand" and "feel comfortable" with, even if that AI isn't the one that is better or will not necessarily achieve the highest score. Trust and perceived teamwork matter. The way in which an AI agent is predictable and interpretable can influence them.

Although the above synthesis presents a clear picture of trust dynamics and the factors influencing them, it is important to recognize that there are still many ongoing challenges and limitations in the operator-AI environment that merit further discussion.

B. Critique: Persistent Challenges and Limitations

Despite the advances, several critical challenges continue in operator-AI settings. Firstly, the problem of trust calibration stays central as indicated by Naiseah and Vössing in [16] and [6]. According to Naiseah and Vössing, even well-intentioned transparency mechanisms, such as explanations, don't automatically guarantee appropriate reliance; explanations can sometimes lead to over-trust or fail to help users detect AI errors. A significant limitation is designing adequate interfaces and precise interactions that promote critical evaluation (System 2 thinking) rather than heuristic acceptance (System 1 thinking).

Another significant issue is that we are still unable to understand the deep problem of trust repair, especially after significant AI failures, and it's still challenging to achieve it successfully. Current strategies have not gone beyond Apology, and basic explanations are still insufficient [29]. One of the challenges that complicates repair efforts is the asymmetry of the operator-AI relationship. AI lacks genuine remorse and social accountability, which is taken from interpersonal trust literature. Additional research is needed on robust repair mechanisms. The new studies potentially involve verifiable demonstrations of learning and correction by AI.

Researchers conduct most studies in AI from a Western perspective, often ignoring other perspectives. Furthermore, much of the researches are conducted in laboratories and controlled environments. Often, non-experts participate, or participants perform simple roles. For instance, while useful, the Hanabi game [27] may not capture high-stakes complexities. Longitudinal studies can help us better understand trust dynamics, especially when done in real-world settings. These studies allow us to track changes and influencing factors over time. These studies are rare, but they are essential [24], [59]. Furthermore, a significant portion of research on AI technologies originates from Western cultural contexts. This central view can limit the generalizability of findings and potentially lead to culturally inappropriate AI designs [25], [26]. Beyond these practical challenges, broader cultural issues also complicate the field.

Fourth, the very definition and measurement of "teaming" and "trust" in the human-AI context are still evolving, which confirms the need for more extensive and accurate studies. Metrics that primarily focus on measuring task performance fail to measure the subjective quality of the interaction, potentially impacting long-term adoption and effectiveness [27], [79]. There is still a great need for vital multidimensional measures that can capture tangible cooperation, shared importance, and measured dependence. Given these challenges, the findings

compiled in this review have direct implications for AI design, training, and policy.

C. Implications for Design, Training, and Policy

The synthesized results of our review confirm the direct implications of trust on AI design, particularly concerning human-centered approaches [6], [58]. The repercussions mean prioritizing not just AI System performance but also designing transparency and explainability features that are genuinely useful and understandable to the specific operator in their context [6], [16], [30]. To achieve this, it is required to involve end-users in the design process and considering their needs and preferences. As well as cognitive load, usability, and design for effective communication [70]. Incorporating mechanisms for behavioral synchrony [19] could also enhance teaming. Trust dynamics also significantly impact how tasks are allocated between humans and AI. When operators do not trust AI, they often rely on manual methods, decreasing efficiency. Conversely, over-reliance on AI can lead to unjustified trust and potentially fatal errors. Therefore, understanding and managing trust goes beyond just a psychological issue; it is a fundamental aspect of effective work design in operator-AI teams. In addition, considering the division of labor and interaction patterns from an organizational design perspective can provide structure [11], [41]. Crucially, designs must be sensitive to potential cultural differences in expectations and interaction styles.

For operator training and competency development, the focus should be on the key factors that enhance operator trust. In particular, there is a demand to focus on the key appropriate mental models of AI capabilities. Critical evaluation skills are essential for operators; it is important for training to go beyond technical skills. Operators need "trust literacy", meaning they can critically evaluate AI, calibrate their trust appropriately, and understand when and how to intervene. In addition, operators must develop the competencies necessary to interact with AI, including digital literacy, adaptability, collaboration, and problem-solving skills [78]. Finally, training should explicitly address foundational issues such as automation bias and calibration strategies. Such capabilities have implications for curriculum development and assessment across multiple disciplines.

Form organizational policy, promoting and fostering a new culture that supports transparency, ethical oversight, and learning from successes and failures in human-AI teaming is vital [6], [33]. As a necessary direction for policies for the manufacture and employment of human-based artificial intelligence, clear guidelines on roles, responsibilities, and accountability within human-AI teams are essential, especially in high-stakes domains [6], [73]. Who is responsible when something goes wrong in a human-AI team? The dynamics of trust can blur the lines of accountability. Who bears responsibility if an operator gives AI too much trust and follows incorrect advice? The operator or the AI designer? These legal and ethical considerations need to be studied and regulated. Policies should also consider the potential for differential impacts of AI systems adoption across demographic groups, e.g., age [20]. These findings highlight several gaps in the existing literature, warranting further future investigations in several areas.

D. Future Research Directions

The existing body of literature highlights significant gaps that necessitate future investigation in several areas. First, there is a need for cross-cultural trust dynamics studies, especially for conducting empirical studies across diverse cultural contexts. These studies are essential to comprehending how cultural values, norms, and communication styles interact with trust dynamics and how these cultural elements shape trust emergence, calibration, and repair in human-AI teams. Developing culturally adaptive AI interaction designs is another study area. Future research also needs to look at longitudinal studies. Literature highlights the importance of implementing long-term studies, especially in realistic operational settings, to observe how trust evolves. Also, to learn how to adapt to changing AI capabilities or task demands and recover (or fail to recover) from significant failures over time. In addition, current research underscores the importance of conducting a study to explore effective trust repair mechanisms. There is a need to move beyond simple apologies and explanations. It is time to investigate and develop robust trust repair strategies, potentially involving demonstrable AI learning and correction, adaptive transparency levels, or mechanisms for shared responsibility.

The next area that the thorough review reveals a compelling need to examine is calibration interventions. Literature highlights the need for evaluating and designing interfaces and training methods specifically aimed at improving trust calibration, helping users critically assess AI output, and avoiding over-reliance and under-reliance. These topics are significant in areas that require a cognitive load or time pressure. The development of diverse and effective AI error detection tools is also required. Their role should extend beyond identifying correct outputs to include error checking.

For the coming AI systems, researchers must further define and investigate the critical issues beyond task performance, including "teaming competencies". AI agents need to be perceived as effective collaborators by humans. Specifically, proactive communication, adaptivity, predictability, and expressing intent. Ethical frameworks for trust are more necessary than ever. Researchers must continue to explore and connect such frameworks to aspects of our lives in general and to the trustworthy cooperation of the operator AI in particular. The focus must address potential issues of manipulation, undue influence, and the balance between fostering trust through ethics and privacy, and security and between maintaining appropriate operator's vigilance and autonomy. The findings also underscore the importance of developing future AI models capable of tracking trust and addressing its dynamics, particularly within operator-AI team settings. These models must feature advanced capabilities that address bias, emotions, and social influence and have the ability to learn over time [72].

E. Solutions from Existing Literature

This review highlights significant gaps in the current understanding of trust dynamics in operator-AI collaboration, particularly regarding enhancing trust by increasing AI transparency and explainability (XAI), the need for adaptive trust calibration mechanisms, designing effective human-AI collaborations and

teams, ensuring AI robustness, communicating uncertainty, and incorporating ethical AI principles and governance into design. The current literature offers emerging and promising directions for addressing these challenges. For example, the explorations of the need to develop human-centered XAI designs, presented in [80], can be adapted to provide insights into the problem of black-box systems, which are one of the reasons why decisions are difficult for operators to understand, undermining trust and complicating problem diagnosis. New designs provide understandable explanations (a posteriori and a priori), focusing on how these explanations are presented, such as through visual interfaces or natural language. The goal is to enhance operator understanding and trust. Similarly, implementing the mechanisms proposed by [81] can support adaptive trust calibration solutions for dynamic systems where operators rely on AI. These systems use real-time feedback about AI trust and uncertainty and targeted training interventions to help operators maintain appropriate trust levels. Similarly, to meet the requirements for effective human-AI teamwork and collaboration models, a potential solution may be [82]. It can provide a valuable perspective for reconsidering the weaknesses of human-AI collaboration caused by unclear roles, communication breakdowns, and a lack of shared understanding of tasks and constraints that can be addressed. According to this work, human-AI teamwork can be enhanced by focusing on joint task design where roles are optimally distributed based on strengths. This includes enabling shared mental models through AI design and implementing flexible autonomy for dynamic control transitions. Trust erosion is another gap caused by miscommunication or errors in AI. The work presented in [83], [84] can help address this trust erosion. AI systems are known to fail unexpectedly or behave unpredictably, significantly eroding user trust and potentially leading to risks with dire consequences. Integrating ethical AI principles and governance into all phases of the AI development lifecycle is the missing solution to this problem. Implementing bias detection techniques, fairness metrics, and privacy preservation will be helpful. Success in achieving this could lead to building systematic trust through responsible design and auditing, as proposed in [84], [85]. We still need to expand the scope of ethical principles. This expansion will address broader ethical concerns such as bias, fairness, and accountability. Addressing these concerns increases operator trust and facilitates AI adoption. These challenges and limitations pave the way for future research. Finally, Section VIII concludes with a review and summarizes the main arguments.

To summrize, scholarly articles in the review consistently highlighted essential and inspiring subjects. Handling these dreaming topics through continued interdisciplinary collaboration is the only way to bring them into reality. It is necessary to continue combining insights from computer science, human factors, psychology, sociology, and organizational sciences. Only in this way can we realize this bright future vision, one in which more reliable AI systems collaborate with a greater understanding of the dynamics of trust. Even more importantly, we can address imminent risks, such as those witnessed in HAL 9000 from the movie "2001: A Space Odyssey" story, which reminds us of the importance of calibrating and enhancing trust between humans and their artificial companions at all stages. While these gaps exist, the current literature offers emerging and promising directions for addressing these challenges.

VIII. Conclusions

Trust is dynamic, not static. It has a starting point and grows and wanes according to the influencing factors that intertwine to define its parameters. These significant factors include human perception, AI capabilities, and changing context. Given the importance of trust, we must know the best ways to maintain it. Indeed, we need to dig deeper to know more about the factors that lead to its rise and decline and the best strategies for repairing it if it is damaged. Despite significant progress, our current methods fall short of capturing the intricacies of trust, emphasizing the need for more work to explore the mysteries of trust in the new and rapidly expanding work environments. AI performance is often referred to as the foundation upon which trust in human-AI collaboration rests. Other equally essential elements include transparency, explainability, and accuracy. However, a closer look reveals that these foundations suffer from cognitive holes and require continued efforts to bridge existing gaps, several of which were revealed by this review. AI system transparency is an important and influential factor in collaborative work in human-AI teams. However, it was found that it is not always sufficient when we looked closely at the results of a case study on an XAI used as a Clinical Decision Support System to assess the importance and impact of transparency. In this study, operators (healthcare practitioners) were presented with explanations varying in clarity levels, ranging from start forward to semi-clear to inconsistent. The results demonstrated that simply providing explanations for transparency does not transform a black box problem into a white box and, most importantly, does not ensure proper trust calibration. In the study, some explanations reinforced overreliance on the system, while participants ignored others, especially unclear or inaccurate ones. These conclusions indeed raise our concern in such a high-stakes environment, and it is a wake-up call—people focused on providing information, not necessarily ensuring its compatibility with human understanding and critical evaluation. Digging deeper, it was found several factors influencing the nature of trust, some related to AI systems, others to operators and context. These multiple factors interact in a complex dynamic that ultimately enhances or degrades trust. Operators have inherent skill capabilities and influential cognitive limitations, including individual propensities, cognitive biases, and cultural backgrounds, whose role in shaping trust should not be overlooked. In addition, there are the required competencies for interacting with AI. While understanding the human factors involved in communication and teamwork is vital, this is insufficient www.ijacsa.thesai.org 12 — P a g e (IJACSA) International Journal of Advanced Computer Science and Applications, Vol. 16, No. 07, 2025 in a human-machine environment devoid of human emotions and social stimuli. On the contrary, this relationship with unstable and renewable factors presents new challenges, many of which still need to be explored. Why do the cross-cultural variations remain a glaring gray spot when partnering with AI? Similarly, are Western-centric models universal, or are studies overlooking crucial cultural nuances that drastically alter human-AI interactions? And how can people expect operators to develop calibrated trust when training often neglects to equip them with the critical skills for evaluating AI? Also, what would happen

if we left operators without enough knowledge or when leaving them vulnerable to automation bias and misinterpretations? Many fundamental questions related to the human aspect need scientific answers. As highlighted in the literature, we need to transform operators from passive users into active, discerning partners who can interpret and measure AI trust and not just accept the system as a black box. To successfully measure trust across its various stages, different metrics will need to be used depending on the context and complexity, in addition to each factor that must be measured in both the human and machine elements. Our review highlights several important gaps that require further research. First, we urgently need new requirements for the responsible design and deployment of AI systems, especially given the rapid developments in this field. Furthermore, a practical methodology is needed to ensure that the design adheres to the new requirements and the principles of ethics, transparency, and accountability to achieve responsible and trustworthy AI. During the collaboration lifecycle, the dynamic nature of trust (its fragile emergence, difficult maintenance, rapid erosion, and arduous repair) further complicates matters. Current attempts at trust repair are still limited to apologies or basic explanations, which appear woefully inadequate. Can an apology or clear explanation mend trust damaged by a system perceived as unreliable or biased? Or do we need to explore more human-like elements of trust repair? Likewise, despite growing recognition that AI is moving beyond a simple tool to a teammate, existing theoretical models struggle to keep pace. Existing frameworks are often helpful but fail to capture the unique challenges of human-AI interdependence fully. Similarly, there is a need to bridge the widening gap toward developing future systems capable of comprehensively replacing humans or transforming their role to become more like a tool used in a specific context when needed. So far, the hope to accurately define and measure "trust" and "operator-AI collaboration". The current metrics still fail to capture the essence of this relationship. The limitations we face in this regard are not merely academic controversies; they are realities with dire consequences unless more is done to bridge the gaps. Miscalibrating the future of human-AI teams will lead to disastrous consequences. This threat is most acute in high-risk areas, including healthcare, transportation, and defense. Society is entering an era of risks cloaked in complacency and misunderstanding. Innovative solutions need to be prioritized over the promise of AI efficiency. The review adopted a systematic approach to analyzing the existing literature by collecting and categorizing research papers in the selected field (the dynamics of trust in the collaborative environment between operators and artificial intelligence) to reveal areas of research focus and, conversely, absence. This task was followed by reviewing and examining relevant theoretical foundations that addressed the relationship between humans and modern technologies, such as AI, within the framework of collaborative work. The methodology identified areas where findings conflicted or where different studies used incompatible definitions. Synthesizing the findings, it was possible to determine whether certain aspects of "trust" or "operator-AI collaboration" were consistently overlooked or only superficially addressed. The synthesized outcome allowed for a comprehensive mapping of the current landscape of human-AI trust research, revealing underexplored areas and methodological inconsistencies. The identified gaps provide a rationale for the need for a framework, and these findings directly shape the aspects that the framework this review aims to address. The review confirms that the current approach is insufficient and that we need a fundamental shift beyond the stereotypical view of trust as merely a given emotion. Instead, trust must become a valuable ranking acquired through careful design of future operators' behaviors, perceptions, and ethics. This recommendation is consistent with the review gaps and emphasizes the need for a new approach to address the human aspects of operator-AI partnerships effectively. Therefore, exploring an innovative framework to address these needs, informed by cognitive and affective factors, will go beyond an academic endeavor to a vital solution. Through it, the hope is to contribute to safeguarding the future of this rapidly transformative technology. The new framework promises to transcend current limitations and enhance trust in human-AI collaborations. The development of this framework will be the focus of my following methodological study.

Designing an Empathetic Conversational Agent for Student Mental Health: A Pilot Study

Kaichi Minami[1], Choi Dongeun[2], Panote Siriaraya[3], Noriaki Kuwahara[4]*
Graduate School of Science and Technology, Kyoto Institute of Technology, Kyoto, Japan[1, 2, 3, 4]
Center for Social and Biomedical Engineering, Kyoto Institute of Technology, Kyoto, Japan[3, 4]

***Abstract*—This study presents the design and evaluation of a conversational agent aimed at supporting university students' mental health. We implemented two variants of a chatbot, referred to as A1 and A2, using large language models (LLMs). A1 employed a baseline prompt reflecting a structured yet neutral counseling style, while A2 was an enhanced version incorporating feedback from psychiatrists and findings from a preliminary study. Emotionally rich expressions, conversational variation, and mild self-disclosure are introduced in A2. A mixed-method user study with 18 participants was conducted to compare A1, A2, and human interactions. Results indicated that A2 significantly improved users' perception of empathy and engagement compared to A1, though human-level rapport was not fully achieved. These findings highlight the role of prompt design in creating emotionally responsive AI companions for mental health support.**

Keywords*—Conversational agent; mental health; large language models; prompt design; empathy; chatbot evaluation

I. Introduction

University students are increasingly vulnerable to psychological distress caused by academic pressures, social isolation, and the lack of immediate access to mental health resources. According to the national report published in Japan in 2022, nearly 20% of private university students have no one they can talk to about their problems [1], contributing to lowered academic performance and well-being [2].

AI-powered conversational agents have emerged as potential tools for addressing these issues. Such systems can provide scalable, anonymous, and readily available support [3], making them particularly attractive for non-clinical, and university-level applications [4]. Previous work focused on emotionally expressive responses and explored the design of empathetic conversational agents using GPT models [5]. However, recent studies have identified limitations in the emotional responsiveness of existing chatbots [6], particularly regarding inconsistent tone, inappropriate responses, and lack of sensitivity to crisis language [7, 8]. This study addresses the emotional limitations of traditional chatbots by proposing prompt-based interventions to improve empathy and user engagement—key challenges in mental health support.

Recent advances in large language models (LLMs) like GPT-4 have made it possible to develop more contextually aware chatbots. Even so, how prompt design affects the quality of mental health support in these systems remains an open question. To explore this, we developed and evaluated two chatbot variants: A1, a baseline chatbot with a structured but emotionally neutral prompt; and A2, an enhanced chatbot that incorporates empathetic phrasing, conversational variability, and light self-disclosure.

This study investigates how these design differences influence user perceptions of empathy, trust, and effectiveness in emotionally supportive dialogues. We aim to contribute new insights into prompt-based control of LLMs for mental health support and provide practical design guidelines for emotionally responsive AI companions.

This paper is organized as follows: Section II presents related work, Section III details the system design, Section IV describes the methodology, and Section V discusses the results.

By demonstrating the effectiveness of prompt-based strategies in enhancing user empathy, this study highlights the practical utility of design interventions in real-world mental health support systems.

II. Related Works

The integration of conversational agents into mental health support systems has garnered significant attention, particularly in the context of an increasing number of university students experiencing psychological distress. Several studies have explored the development, implementation, and evaluation of AI-driven chatbots aimed at providing accessible and empathetic support.

Liu et al. proposed ChatCounselor—an LLM trained on real-world counseling transcripts—which demonstrated the feasibility of generating psychologically informed responses [9]. Similarly, Lai et al. introduced the Psy-LLM framework, combining pre-trained LLMs with structured psychological Q&A data to support large-scale mental health consultations [10]. In another domain-specific study, Yao et al. evaluated three chatbot systems targeting postpartum mood and anxiety disorders, highlighting the importance of context-aware responses tailored to sensitive health needs [11].

The clinical efficacy of AI chatbots in mental health care is also gaining empirical support. Jacobson's team reported that their chatbot Therabot led to significant improvements in symptoms of depression and anxiety in a randomized controlled trial involving college students and other vulnerable groups [12]. Similarly, Ahmed et al. conducted a pilot clinical trial that demonstrated improvements in students' overall well-being through structured AI-based interactions [13].

Beyond algorithmic design, prompt engineering has been identified as a critical factor in improving the performance and compliance of AI chatbots in mental health domains. Waaler et al. employed a multi-agent architecture to ensure consistent adherence to prompt instructions, especially in educational contexts [14]. In Sahoo et al.'s review [15], prompt-engineering techniques such as Few-shot and Chain-of-Thought are reported to be effective for generating empathetic responses. Building on these findings, this study proposes an original five-stage dialogue flow—Introduction → Rapport Building → Problem Exploration → Empathetic Response → Closing—to structure both the prompts and the system's replies.

Nonetheless, several studies warn against overestimating the empathetic capabilities of AI systems. Raczka argues that while AI therapists provide accessibility, they lack the nuanced interpersonal understanding necessary for deep emotional support [7]. Roshanaei M. et al. further demonstrate that chatbots may exhibit gender-based biases in performing empathy, pointing to ethical challenges in human–AI emotional interaction [8].

These ethical concerns extend to data privacy and surveillance. As Vincent notes, AI therapy tools may operate as covert surveillance systems in the absence of robust data protection frameworks [16]. Additionally, Ferguson reports that exposing LLMs to traumatic narratives—such as those involving war or violence—can induce "anxiety-like" outputs, potentially compromising the stability and interpretability of their responses [17].

Lastly among these studies, several comprehensive reviews provide theoretical grounding for the emotional dimensions of human–AI interaction. A. S. Raamkumar and Y. Yang conducted a systematic review on emotionally aware conversational agents, identifying key factors contributing to perceived empathy and engagement [18]. X. Zheng et al. evaluated ChatGPT's current capabilities and limitations in mental health support, arguing that prompt design plays a major role in user satisfaction [19]. In an empirical CHI study, B. Liu and S. S. Sundar investigated which conversational behaviors in chatbots most closely approximate human-like support in therapeutic contexts [20].

Taken together, these studies underscore the challenges and opportunities of deploying AI chatbots for mental health support in higher education. Our study builds upon this foundation by experimentally evaluating how variations in prompt design affect users' perceptions of empathy, trust, and emotional support in an LLM-powered chatbot designed for university students' mental health assistance.

To improve citation clarity, the references included in this section have been chosen and grouped based on their relevance to specific thematic aspects, such as LLM-based design, prompt engineering, and ethical concerns. Although some references appear at the end of paragraphs for structural flow, each cited work has been carefully selected to support the preceding discussion. Recent literature (2023–2025) has been prioritized, and older works are included only when they provide essential historical or conceptual context.

While prior work explored empathetic dialogue generation, few studies have directly compared structured prompt designs within a controlled experimental setting.

III. System Design

A. System Overview

Our system is designed as a web-based chatbot interface built using Streamlit [21] and integrated with the GPT-4 API [22] via OpenAI's endpoint. Users engage in one-on-one conversations with the chatbot, which responds in real time using prior dialogue context. The primary goal is to simulate supportive, human-like conversations that address student concerns related to emotional stress, anxiety, and academic challenges.

As shown in Fig. 1, the system comprises a front-end chat interface, a conversation history manager, and an LLM-based response engine. Depending on the assigned variant, either prompt A1 or A2 is used to condition the output behavior of the chatbot.

B. Prompt Design Strategy

To explore the effects of prompt structure and tone, we developed two chatbot variants:

1) A1 (Baseline): This variant follows a formal, neutral tone and uses a five-step structure derived from general mental health counseling principles [15]. It asks users to describe their concerns, confirms their understanding, and provides structured suggestions. Emotional expressions are minimal, and responses are often informational.

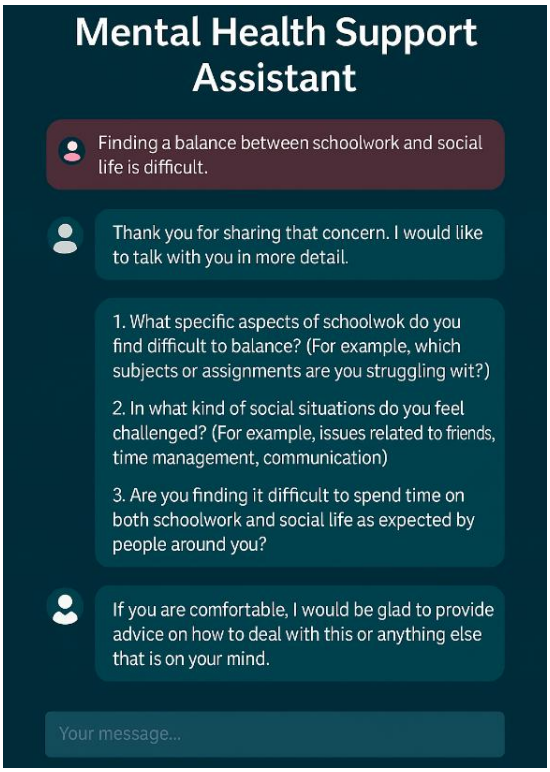

Fig. 1. User Interface example of the mental health support chatbot used in the preliminary study (A1 Condition).

2) A2 (Enhanced): This variant integrates feedback from psychiatrists and results from a preliminary user study. Key improvements include:

- Use of emotionally expressive language. (e.g., "That must have been very difficult for you.")
- Friendly, conversational tone with casual phrasing.
- Occasional light self-disclosure to build trust. (e.g., "I've heard similar stories from other students.")
- Dynamic phrasing to avoid repetition and pattern rigidity.
- An added step to check if the user wants more or fewer suggestions.

To inform our design of the enhanced prompt (A2), we first conducted a pilot study with 10 university students interacting with the baseline version (A1). Their feedback—low empathy ratings, overly factual replies, and rigid dialogue patterns—was complemented by a psychiatrist's expert recommendations on emotionally expressive language, conversational variation, and supportive follow-ups. Drawing on these insights, we refined the prompt to encourage deep support and light self-disclosure while avoiding mechanical phrasing. Table I presents a comparison of A1 and A2, highlighting enhancements in emotional integration, supportive questioning, balanced confirmations, empathic self-disclosure, advice-need checks, and more natural prose style.

TABLE I. IMPROVEMENTS FROM A1 TO A2

Improvement No.	Description
1. Fact & Emotion Mix	Add emotional elements to factual replies to boost understanding and empathy.
2. Supportive Questions	Pair questions with supportive phrasing to lighten user burden.
3. Optimized Questioning & Confirmation	Balance question and confirmation frequency for more natural dialogue.
4. Empathic Remarks & Shared Experience	Use brief self-disclosures to convey empathy and make users feel heard.
5. Checking Need for Detailed Advice	Prompt users before offering detailed advice to avoid overwhelm.
6. Reduced Bulleted Lists	Replace bullet points with natural prose to enhance warmth.

C. Implementation Details

The system uses the GPT-4 model with a temperature setting of 0.7 to balance creativity and reliability. Prompt text is stored as a system message and carried across turns via the messages array. The conversation interface maintains memory via st.session_state, enabling multi-turn interaction. Each response is generated in real time using current and prior messages, and user input is constrained to ensure ethical and safe interactions.

Fig. 2 shows the response flow used during conversation, where user input is appended to the message history, passed to the model along with the prompt, and a context-aware reply is generated.

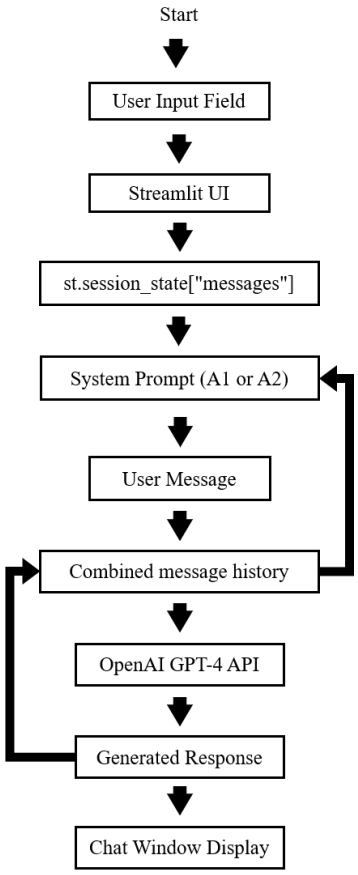

Fig. 2. Message flow of the conversational agent.

D. Ethical and Safety Considerations

The A2 prompt includes structured fallbacks in case of high-risk language (e.g., suicidal ideation), redirecting users with phrases such as, "Your safety is the most important. Please consider talking to a professional." In addition, suggestions are limited in number, and overly directive language is avoided to reduce psychological burden. These safeguards are informed by concerns raised in [7, 16, 17] about the ethical use of AI in mental health contexts.

E. Design Limitations and Future Enhancements

The system does not currently adapt its tone based on individual user preferences. Furthermore, emotional state tracking is not explicitly modeled, and the chatbot's personality is static. In future versions, we plan to introduce user-selectable tone styles and affect-sensitive dialogue modeling [8, 19].

IV. USER STUDY

A. Objectives

The purpose of this user study was to evaluate how variations in prompt design (A1 vs. A2) affect users' perceptions of empathy, effectiveness, and conversational naturalness in a mental health chatbot. Specifically, we sought to determine whether the enhanced prompt in A2, with its emotionally rich language and conversational variability, would improve the user experience in comparison to the baseline A1.

B. Participants and Conditions

A total of 18 university students (9 female, 9 male, and aged 19–25) were recruited for the study. Participants were randomly assigned to interact with three different agents: a human (control), A1 (baseline chatbot), and A2 (enhanced chatbot), under a within-subjects design. Each participant engaged in a single conversation with each condition, and the order of conditions was counterbalanced using a Latin square to control for order effects.

C. Experimental Procedure

Participants were instructed to imagine they were seeking advice for a personal concern related to university life (e.g., stress, relationships, and academic pressure). They engaged in a text-based chat lasting approximately 5–10 minutes per condition.

- For the human condition, a trained confederate acted as the conversation partner.
- For A1 and A2, participants chatted through LINE messenger, with the experimenter forwarding messages to the chatbot system and relaying the responses. Participants were blinded to whether the conversation partner was human or AI. LINE is a popular messaging app in Japan, selected for its familiarity and real-time chat functionality.

The overall experimental procedure and interaction flow are illustrated in Fig. 3. This includes the order of interactions, the chat method, and post-conversation survey collection.

Following each chat session, participants completed a short questionnaire to assess their impressions.

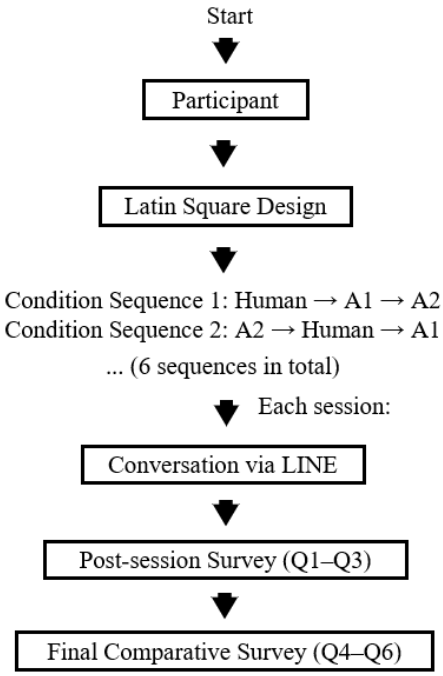

Fig. 3. Overview of the experimental procedure. Each participant engaged in three conditions (Human, A1, A2) using a within-subjects latin square design.

D. Measures

1) Quantitative data and analysis: The following subjective measures were used, all on a 5-point Likert scale (1 = strongly disagree, 5 = strongly agree):

- Q1. Perceived understanding: "I felt that the conversation partner understood my concern."
- Q2. Perceived helpfulness: "The conversation helped me to think about or cope with my issue."
- Q3. Perceived empathy: "I felt emotionally supported during the conversation."

Participants also completed a separate comparative questionnaire asking about:

- Q4. Perceived trustworthiness: "Which conversation partner felt most trustworthy?"
- Q5. Perceived emotional attunement: "Which one felt most emotionally attuned?"
- Q6. Perceived empathy: "Which one felt most empathetic toward your concern?"

While both Q3 and Q6 assess perceived empathy, Q3 measures the subjective feeling of emotional support experienced during each individual conversation, using a 5-point Likert scale. In contrast, Q6 asks participants to comparatively judge which agent felt the most empathetic overall across all conditions. Thus, Q3 captures within-condition depth, whereas Q6 reveals between-condition preference.

2) Qualitative data and analysis: We analyzed participants' open-ended feedback and complete chat transcripts by coding each utterance into six predefined categories (Table II) and achieved high inter-rater reliability (Cohen's $\kappa = 0.92$) before reconciling any discrepancies. Category frequencies were compared across conditions using Friedman tests, and a grounded-theory thematic analysis of free-text comments revealed user perceptions such as "mechanical" versus "friendly" tone and varying levels of perceived empathy and support. This approach ensured both statistical rigor and rich insight into how A2's modifications enhanced the chatbot's human-like qualities.

TABLE II. DEFINITION OF THE SIX CONVERSATIONAL CATEGORIES USED FOR QUALITATIVE CODING

Category	Description
Factual Information	General knowledge or advice not tailored to the user.
Light Support	Empathy or encouragement without personalized advice.
Deep Support	Empathy or encouragement with situation-specific advice.
Self-Disclosure	Statements revealing personal experiences or thoughts.
Question	Prompts asking the user to elaborate or clarify their feelings or issues.
Confirmation	Paraphrasing or repeating user input for understanding; no advice given.

E. Data Collection and Ethical Considerations

All participants gave informed consent prior to participation. The study was reviewed and approved by the Ethics Committee of Kyoto Institute of Technology.

No sensitive or personally identifiable information was stored. All dialogues were anonymized and stored securely for analysis.

To minimize potential psychological stress, participants were informed that the conversations were simulated and not therapeutic in nature. Participants were also debriefed after the study and given resources for professional mental health support if needed.

V. Results

A. Quantitative Results

We first analyzed participants' subjective ratings for each of the three conditions (Human, A1, A2) on three evaluation criteria: perceived understanding, perceived helpfulness, and perceived empathy. Fig. 4 shows the mean scores and standard deviations across conditions.

As shown in Fig. 4, Human received the highest scores across all measures, followed by A2, and then A1. Notably, the empathy scores for A2 showed a marked improvement over A1, indicating that the enhanced prompt design had a positive impact.

To assess statistical significance, we conducted a repeated measures ANOVA for each criterion. The results showed significant effects of condition on:

- perceived understanding: $F(2,34) = 5.12$, $p < 0.01$
- perceived helpfulness: $F(2,34) = 4.65$, $p < 0.05$
- perceived empathy: $F(2,34) = 9.27$, $p < 0.001$

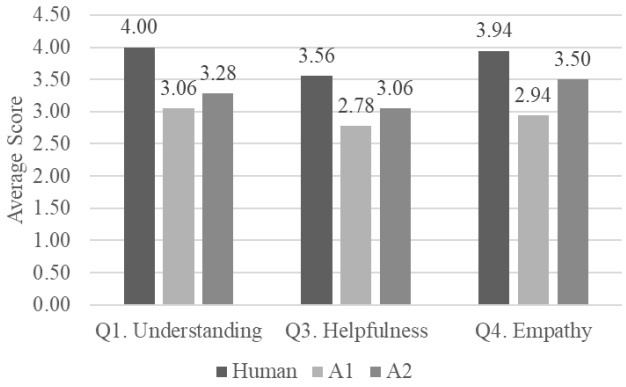

Fig. 4. Average participant ratings for perceived understanding, helpfulness, and empathy across the three conditions (Human, A1, A2).

Post hoc comparisons using the Bonferroni method indicated that A2 scored significantly higher than A1 in perceived empathy ($p < 0.05$), while both were significantly lower than the human condition ($p < 0.01$).

B. Comparative Preference Results

Participants were also asked to select which condition felt most trustworthy, emotionally attuned, and human-like. Fig. 5 summarizes the distribution of preference responses across the three agents.

- Trustworthiness: 11 participants selected human, 5 selected A2, and 2 selected A1
- Emotional attunement: 14 selected human, 4 selected A2, 0 selected A1
- Empathy: 13 selected human, 5 selected A2, 0 selected A1

These results suggest that while A2 was preferred over A1 in all aspects, the human agent was still perceived as superior in trust and empathy.

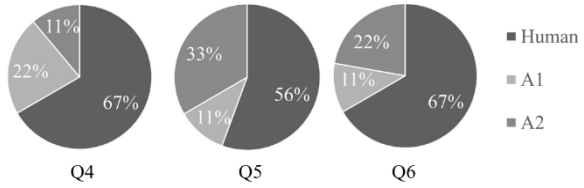

Fig. 5. Participants' comparative preferences across three conditions for trustworthiness, emotional attunement, and perceived empathy.

Pairwise binomial tests were conducted to compare participant preferences among the human condition (Human), the baseline AI (A1), and the improved AI (A2) for trustworthiness (Q4), emotional attunement (Q5), and empathy (Q6). Human was consistently rated highest across all dimensions. A1 showed statistically significant inferiority to Human on all three items ($p < 0.05$). In contrast, A2 demonstrated improvement upon the baseline; while significant differences remained between A2 and Human in trustworthiness and empathy, no significant difference was observed in emotional attunement (Q5), indicating that prompt enhancement in A2 led to partial gains in perceived emotional responsiveness.

C. Qualitative Results

To explore interactional differences, we categorized chatbot and human utterances using a predefined six-category coding scheme: Factual Information, Light Support, Deep Support, Self-Disclosure, Question, and Confirmation.

Fig. 6 shows the proportions of utterance categories for each condition. A2 produced more deep support and self-disclosure utterances than A1, aligning with its design. A1, in contrast, tended to overuse factual responses and confirmations, which may have contributed to its lower empathy scores.

In addition, open-ended feedback revealed that participants often described A1 as "robotic" or "too structured," while A2 was described as "friendlier but still a bit unnatural." Several participants noted that A2 sometimes sounded "playful" or "too casual," which may have impacted their trust in some cases.

The Friedman test revealed significant overall differences in the use of factual information, deep support, and self-disclosure across conditions. Specifically, in the Factual Information category, Human responses were significantly lower than both A1 ($p < 0.01$) and A2 ($p < 0.01$), with no difference between A1 and A2. In the Deep Support category, Human exceeded A1 ($p < 0.01$) and A2 ($p < 0.01$), and A2 also exceeded A1 ($p < 0.05$),

indicating that the improved AI increased deep support compared to its baseline. Self-Disclosure also differed overall ($p < 0.01$), with Human exceeding both A1 ($p < 0.05$) and A2 ($p < 0.05$), while A1 and A2 did not differ significantly. Although the Friedman test for question usage was not significant ($p > 0.05$), a marginal pairwise difference showed Human surpassing A2 ($p < 0.05$). Finally, there were no significant differences among Human, A1, and A2 in Light Support or Confirmation categories.

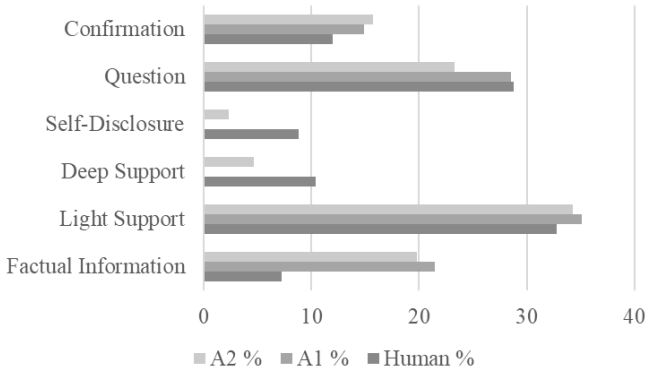

Fig. 6. Frequency of utterance types (factual information, support, self-disclosure, etc.) across the three conditions.

D. Correlation Analysis

To explore the relationships between dialogue behaviors and subjective user ratings, we calculated Spearman's rank correlations (ρ) between each behavior's frequency and three Likert-scale measures (perceived understanding, helpfulness, and empathy), adjusting all p-values via Bonferroni correction. In the Human condition, factual responses were negatively correlated with both perceived understanding ($\rho = -0.555$, $p = 0.017$) and empathy ($\rho = -0.683$, $p = 0.002$), while self-disclosure showed a positive correlation with helpfulness ($\rho = 0.471$, $p = 0.049$) and question-asking was positively associated with understanding ($\rho = 0.637$, $p = 0.004$). In the A1 condition, higher question frequency corresponded to lower understanding ($\rho = -0.486$, $p = 0.041$). In A2, factual responses remained negatively correlated with empathy ($\rho = -0.649$, $p = 0.004$). These results confirm that reducing purely factual replies and encouraging self-disclosure and targeted questioning can bolster users' comprehension, perceived support, and empathy.

VI. Discussion

A. Summary of Findings

The results of the user study demonstrated that the enhanced chatbot variant (A2) outperformed the baseline (A1) in terms of perceived empathy, helpfulness, and understanding. While neither AI-based agent surpassed the human control, A2 significantly narrowed the gap, particularly in empathy-related measures.

These findings indicate that relatively simple modifications to prompt design—such as adding emotionally expressive phrases, conversational variability, and light self-disclosure—can meaningfully improve the user experience in AI-mediated mental health support.

B. Design Implications

The positive impact of A2 provides several implications for the design of empathetic conversational agents:

- Emotionally expressive language matters: The increased empathy ratings suggest that incorporating warm, validating phrases makes users feel heard and supported. This effect is commonly documented in human counseling interactions [18, 20].
- Conversational variability enhances naturalness: Avoiding rigid or templated responses helped reduce the "robotic" impression users associated with A1, which supports prior findings in LLM dialogue systems [19].
- Deep support and self-disclosure are key cues: The correlation analysis confirmed that deeper, context-aware support strategies are associated with higher emotional satisfaction in users, while factual overload (as seen with A1) detracts from perceived empathy.

These results align with those in earlier research highlighting the importance of emotional attunement and personalization in AI-based supportive dialogue [7, 8, 15].

C. Trust vs. Friendliness Trade-off

While A2 was rated higher than A1 in empathy, some users perceived its tone as overly casual or playful. This introduces a design trade-off between friendliness and trustworthiness—a chatbot that sounds too familiar may be emotionally engaging but risk being taken less seriously.

Designers must consider tone adaptation as a dynamic component that possibly allows users to select or tune the emotional intensity of the chatbot according to their comfort level.

D. Remaining Challenges

Despite improvements in A2, A1 and A2 still falls short in following areas compared to human interactions. These include:

- Lack of deep contextual understanding: While A2 could simulate empathy, it still lacked true comprehension of nuanced emotional cues.
- Static personality: Both A1 and A2 followed scripted prompt logic without learning from prior interactions.
- No adaptation to individual user preferences: All participants received identical tone and style, absent of reflection on personal communication preferences.

These limitations are consistent with known boundaries of current LLM-based systems and suggest that hybrid models incorporating affective state tracking or memory may be needed [19].

E. Ethical Considerations

This study also underscores the importance of ethical safeguards. Although A2 included fallback responses for high-risk expressions (e.g., suicidal ideation), the system cannot

replace human professionals in crisis situations. Meanwhile, The Verge reports that in environments lacking robust data protection frameworks, users may place excessive trust in AI chatbots, potentially leading to privacy breaches or a false sense of security [16], and Live Science has shown that exposing LLMs to traumatic narratives can induce "anxiety-like" outputs, underscoring the risks of emotional overreliance [17].

Designing transparent boundaries—such as clear disclaimers and escalation pathways—remains essential in real-world deployment.

VII. Conclusion and Future Work

A. Conclusion

In this study, we designed and evaluated two versions of a conversational agent—A1 and A2—aimed at providing mental health support for university students. While A1 followed a structured but emotionally neutral prompt, A2 was enhanced with emotionally expressive phrasing, light self-disclosure, and conversational variability.

Through a mixed-method user study involving 18 participants, we found that A2 significantly had improved user perceptions of empathy and engagement compared to A1. Quantitative results showed meaningful gains across all subjective measures, particularly in empathy. Qualitative analysis and correlation data further confirmed that the presence of deep support and reduced factuality in A2's responses contributed to its improved reception.

These findings highlight the importance of prompt-level control in shaping large language model (LLM) behavior, especially in emotionally sensitive domains such as mental health. Even small design changes at the prompt level can have a significant impact on how AI is perceived by users.

However, persistent gaps between AI and human interaction remain. Participants still preferred human agents in terms of trust and emotional attunement, and the current system lacks personalization, emotional awareness, and adaptability.

B. Future Work

Based on these findings, we propose several directions for future research:

1) Personalized tone control: Enabling users to select or dynamically adjust the chatbot's tone according to preference or emotional state.

2) Emotion-aware dialogue modeling: Incorporating affective computing techniques to detect and respond to user emotions in real time.

3) Longitudinal evaluation: Studying the long-term effects of AI-mediated support across repeated interactions.

4) Safety and escalation mechanisms: Enhancing detection of high-risk language and implementing automatic escalation protocols.

5) Cross-cultural validation: Investigating how empathy is perceived and evaluated across cultural or linguistic groups.

By addressing these challenges, future conversational agents can become not only more effective but also more trustworthy and emotionally responsive companions.

***Abstract*—This paper presents a comparative evaluation of a mobile augmented reality (AR) navigation application designed for both indoor and outdoor university environments. Building on a previously validated system for indoor guidance, the current study extends the deployment to outdoor campus spaces without relying on GPS or additional infrastructure. Using visual positioning and spatial anchors, the same application provides real-time AR cues and audio instructions to support wayfinding across different spatial contexts. The principal aim of this study is to determine whether a unified AR navigation system can deliver a consistent, infrastructure-free user experience in both indoor and outdoor university environments. A within-subjects study was conducted with 256 university students who completed both indoor and outdoor navigation tasks. Usability and user acceptance were assessed using the System Usability Scale (SUS) and constructs from the Technology Acceptance Model (TAM). Results revealed consistent user experience across both contexts, with no statistically significant differences in perceived intuitiveness, usefulness, engagement, behavioral intention to reuse, or localization accuracy. A significant difference was found only in perceived AR content loading speed, which was rated slightly higher indoors. These findings demonstrate the feasibility of a unified AR navigation system for academic campuses and provide practical insights into its scalability and user-centered design.**

***Keywords*—Augmented reality; hybrid navigation; spatial computing; usability testing; indoor-outdoor contexts; ARCore; higher education**

I. Introduction

Indoor navigation remains a significant challenge in large, unfamiliar environments such as hospitals, airports, and university campuses. Traditional wayfinding methods—including signage, printed maps, and kiosks—often fall short in addressing the spatial complexity and dynamic layouts of such settings [1]. In academic institutions, students and visitors frequently struggle to locate classrooms, offices, or facilities within multi-story buildings or across expansive outdoor areas. Augmented Reality (AR) has emerged as a promising solution by superimposing navigational cues—such as arrows, labels, and landmarks—onto the real-world view through mobile devices, enhancing spatial cognition and real-time orientation [2]. Navigating unfamiliar academic campuses, particularly during orientation periods, open days, or student admissions, is a recurring challenge that affects thousands of users each academic year. AR-based navigation tools offer an accessible, real-time solution that does not require technical training, printed maps, or assistance from staff—making them ideal for practical deployment in higher education settings.

While AR navigation systems for outdoor use have benefited from reliable GPS signals and integration with digital mapping services [3], indoor environments present unique technical constraints. GPS signals tend to degrade or become unavailable indoors, requiring alternative technologies such as Simultaneous Localization and Mapping (SLAM), Visual Positioning Systems (VPS), and visual-inertial odometry [4]. These differences in spatial and technical conditions suggest that the user experience may vary considerably between indoor and outdoor AR navigation contexts. However, few studies have examined this comparative dimension directly.

This study addresses the following research question:

Can a single mobile AR navigation system provide a seamless and equally usable experience across both indoor and outdoor university environments, without relying on GPS or additional infrastructure? Answering this question can inform future designs of scalable, user-friendly AR navigation systems for education and beyond.

Recent advances in mobile AR platforms—such as Apple ARKit and Google ARCore—have enabled increasingly accurate, infrastructure-free AR navigation solutions across domains including education, healthcare, and retail. These frameworks provide core functionality for markerless tracking, real-time camera pose estimation, and rendering of 3D navigation overlays [5], [6]. Studies report promising results for both usability and technical feasibility. For instance, Yamamoto et al. implemented an AR indoor navigation app using BLE beacons in a university setting, achieving over 70% user satisfaction and stable guidance performance [6].

Despite growing interest, university campuses remain relatively underexplored in AR navigation research—particularly in terms of integrated indoor–outdoor deployment. Most existing studies either evaluate AR in confined indoor settings or focus solely on outdoor AR guidance, often under pilot conditions or with small sample sizes [2], [7]. Moreover, many systems rely on infrastructure such as BLE beacons or GPS, limiting scalability. Our work addresses these limitations by proposing and evaluating a unified, infrastructure-free

system that supports consistent AR-based navigation across spatial contexts. This lack of cross-context evaluation limits our understanding of how environmental factors influence usability, responsiveness, and user acceptance of AR-based wayfinding solutions.

The present study addresses this gap by extending a previously developed mobile AR navigation system [8]—initially tested for indoor guidance—to a campus-wide outdoor scenario, followed by a comparative evaluation. The application is implemented using Unity 3D and the ARway SDK and supports both Android and iOS platforms via ARCore and ARKit. Importantly, the system operates without dedicated infrastructure (e.g., BLE beacons or markers), using camera-based localization and cloud-based spatial anchors instead. Users initialize navigation by scanning a QR code at a known location—either indoor or outdoor—and follow AR overlays and audio cues that provide dynamic, step-by-step guidance.

This paper offers two main contributions: (1) it demonstrates the scalability and adaptability of a mobile AR navigation system across indoor and outdoor university environments, and (2) it presents a comparative analysis of user experience across these contexts, based on a large-scale user study. The evaluation framework includes metrics such as perceived usability, intuitiveness, system responsiveness, engagement, and behavioral intention to reuse the app. These dimensions are quantified using the System Usability Scale (SUS) [9] and constructs from the Technology Acceptance Model (TAM) [10], allowing for hypothesis-driven analysis of how spatial context affects AR navigation acceptance. The findings extend prior indoor-only results and contribute practical insights for designing seamless AR wayfinding systems suitable for real-world educational environments.

The remainder of this paper is organized as follows: Section II reviews the relevant literature on AR-based indoor and outdoor navigation systems; Section III details the system design and methodology; Section IV presents the results of the comparative user study; Section V discusses the findings in relation to prior work; and Section VI concludes with insights and future research directions.

II. Related Work

A. Outdoor AR Navigation Systems

Augmented Reality (AR) has gained significant traction as a tool for spatial navigation in both indoor and outdoor environments. AR enhances spatial cognition by overlaying digital cues—directional arrows, labels, or visual landmarks—onto the user's real-world view, improving situational awareness and wayfinding performance [1]. Outdoor AR navigation systems are more established due to their reliance on GPS, digital maps, and compass-based orientation [11]. For example, Huang et al. [12] developed an AR pedestrian navigation prototype integrating GPS and computer vision to display route information in real-time street views. Commercial map applications such as Google Maps have also adopted AR for walking navigation, indicating a rise in public familiarity with AR-based outdoor guidance. However, these systems rely heavily on GPS and are limited in environments with signal loss or visual occlusions.

B. Indoor AR Navigation: Infrastructure Challenges

Indoor AR navigation, however, presents unique challenges stemming from unreliable or unavailable GPS signals. To address this, various positioning strategies have emerged: BLE (Bluetooth Low Energy) beacons [6], Wi-Fi fingerprinting [4], visual marker systems, and vision-based SLAM (Simultaneous Localization and Mapping) techniques [13]. These alternatives often require specialized infrastructure or calibration. For instance, Nguyen and Park [14] deployed a BLE-based AR guidance system in a shopping mall, achieving high positional accuracy and user satisfaction. Similarly, Gupta et al. [4] used a hybrid of Wi-Fi fingerprinting and SLAM in a hospital environment, attaining room-level localization and effective navigation performance. While effective, these solutions require infrastructure deployment (e.g., BLE beacons), limiting scalability and generalizability across different buildings or institutions.

C. Advances in Markerless AR Navigation

Recent mobile AR development frameworks—such as Apple's ARKit and Google's ARCore—have enabled more accurate, markerless tracking capabilities via SLAM and visual-inertial odometry [15],[16]. Rossi et al. [5] used ARKit to build an indoor navigation prototype that resulted in a 35% reduction in wayfinding time. Chen et al. [17] employed ARCore for multi-floor campus navigation, leveraging persistent cloud anchors and reporting an 81% ease-of-use rating. These tools have become foundational in AR navigation research by enabling infrastructure-free guidance with stable content anchoring and route overlays. Yet, most deployments remain confined to either indoor or outdoor use, lacking evaluation across both contexts with the same system.

Localization precision remains a key factor in AR navigation. Outdoors, GPS typically provides 5–10 meter accuracy, but AR systems often require finer granularity to align virtual objects meaningfully with physical spaces. Visual Positioning Systems (VPS), such as Google's AR VPS, supplement GPS by comparing camera views to geo-referenced imagery [12]. Indoors, BLE beacons can offer ~3–5 meter accuracy, while UWB (Ultra-Wideband) radio systems can achieve sub-meter precision. Yamamoto et al. [6] used over 100 BLE beacons in a university building to power their AR app, noting limitations such as signal decay and interference in crowded spaces. Alternatively, QR codes or fiducial markers can serve as anchor points, offering high-precision initialization and periodic re-localization to mitigate SLAM drift—a strategy employed in the current system.

D. Hybrid and Cross-Context Systems

To ensure seamless indoor–outdoor transitions, hybrid approaches have emerged. Fernandez et al. [7] proposed a GPS emulation mechanism using cloud-based AR maps to support campus-scale navigation. Qi et al. [18] developed a hybrid ARCore-based solution using visual-inertial odometry and cloud anchors, demonstrating improved spatial tracking across both indoor and outdoor contexts. These systems still face

challenges related to lighting variations, visual occlusion, and UI continuity during environment transitions, but they represent meaningful steps toward unified AR navigation experiences, as shown in [19] and [20]. Nevertheless, these studies are either experimental or simulate GPS using cloud anchors; they stop short of large-scale user evaluations in naturalistic academic settings.

E. User Experience and Acceptance

Accurate localization is only one facet; usability and user experience are equally critical. Many studies use the System Usability Scale (SUS) and the Technology Acceptance Model (TAM) to quantify user perceptions. SUS is a 10-item instrument that yields a usability score between 0 and 100 [9]. Chen et al. [17] reported a SUS score of 74 in a campus navigation scenario, and Sato et al. [21] achieved a score of 76 in a museum-based AR guide. These results suggest generally favorable usability perceptions in both educational and cultural settings.

TAM provides a theoretical lens to understand user adoption by evaluating perceived usefulness, ease of use, and behavioral intention [10]. In AR navigation contexts, perceived ease of use refers to how effortlessly users can interpret and follow AR cues, while perceived usefulness reflects whether the system enhances their navigation performance. Kwok et al. [22] extended TAM to include enjoyment and found that higher enjoyment correlated with greater acceptance of AR navigation in a university environment. The study also noted the role of social visibility—users may hesitate to use AR interfaces in public due to perceived awkwardness, a relevant consideration for campus-wide deployment. Our current study extends this by collecting SUS and TAM responses in both indoor and outdoor conditions using the same AR system, enabling direct comparison.

F. Technical Factors Affecting Usability

Technical factors also influence adoption. Users expect AR systems to be responsive, visually stable, and intuitive. Lagging overlays, jittery directional arrows, or poor contrast in bright sunlight can degrade the experience [17], [21]. Several studies report that system responsiveness is a strong predictor of SUS scores. In our prior study, responsiveness and tracking stability were among the most significant factors contributing to perceived usability. Zhao et al. [23] demonstrated that using an AR headset equipped with high-performance sensors yielded an 88% navigation success rate but caused user fatigue—underscoring the trade-offs between accuracy and usability. Our system, unlike high-performance AR headsets, achieves stable performance using only consumer smartphones, balancing usability and accessibility.

G. AR Navigation in Educational Settings

Beyond navigation efficiency, AR has been shown to reduce cognitive load and enhance users' ability to form cognitive maps. Qiu et al. [1] reported that AR improved user confidence and spatial memory, even when it did not significantly reduce travel time compared to traditional 2D maps. Ahn et al. [24] found that AR guidance in a hospital led to faster learning of spatial layouts and a high initial orientation success rate of 86%. These qualitative benefits align with the TAM concept of perceived usefulness and highlight AR's role not only in performance but in experiential engagement.

Research in educational settings remains relatively sparse but is growing. AR navigation aligns with smart-campus initiatives, offering new students or visitors accessible guidance through complex academic environments. Fernandez et al. [7] and Yamamoto et al. [6] deployed their systems in real campus scenarios with participant samples exceeding 50 users. Our prior study, with 256 participants, remains one of the most extensive in this domain. However, most existing works evaluate either indoor or outdoor AR usage in isolation. Little is known about how users perceive and interact with AR systems that transition across spatial contexts [25].

In summary, the literature shows steady progress in AR navigation across diverse settings. However, notable gaps remain: (1) few comparative evaluations of indoor versus outdoor AR navigation using the same system; (2) limited research in education-specific deployments at scale; and (3) scarce longitudinal studies on sustained adoption. This paper addresses the first of these by evaluating a hybrid AR navigation system deployed in both indoor and outdoor areas of a university campus. Through an empirical comparison grounded in SUS and TAM frameworks, the study aims to generate insights into how spatial context influences usability and user acceptance in real-world academic environments. This paper fills a key gap by offering one of the first comparative, infrastructure-free, cross-context AR navigation evaluations in a university campus, involving over 250 participants.

III. METHODOLOGY

This study builds on a previously published evaluation of an AR-based indoor navigation application [8], extending the investigation to outdoor university campus spaces. To preserve continuity while enabling comparative insight, the methodology replicates the core structure of the initial research while adjusting the deployment context and data collection accordingly.

A. Research Design and Context

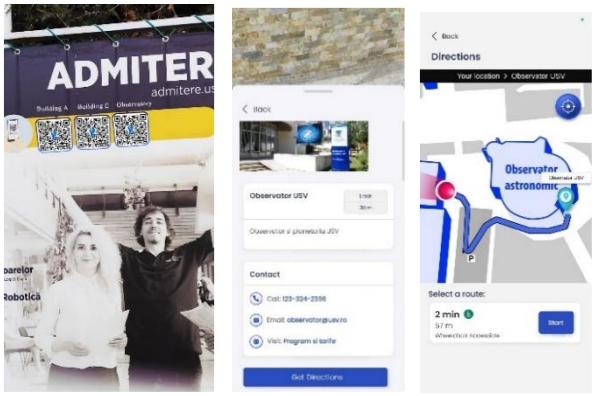
We adopted a user-centered, exploratory methodology integrating system deployment with empirical usability evaluation. The same AR application, previously tested indoors, was adapted and redeployed in selected outdoor areas of the university campus, using the same visual positioning and spatial anchoring approach (SLAM + VPS). Unlike traditional GPS-based outdoor navigation, our system does not rely on GNSS signals, allowing consistent performance across both spatial environments.

A within-subjects experimental design was employed, with each participant completing two navigation tasks—one indoors and one outdoors. The study retained the System Usability Scale (SUS) and the Technology Acceptance Model (TAM) as its core evaluative frameworks, consistent with the prior research.

B. Description of the AR Navigation Application

To extend the functionality of the indoor AR navigation system into outdoor campus settings, the same mobile application was adapted without relying on GPS or external

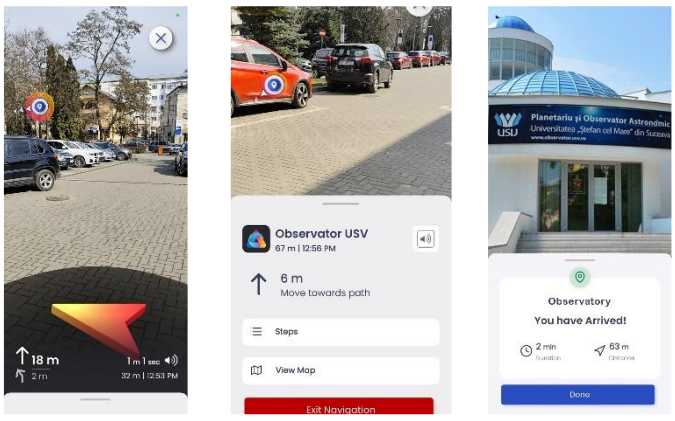
sensors. Instead, it continues to use visual-inertial localization based on cloud-anchored spatial mapping, implemented via the ARway SDK and Unity 3D. The navigation experience was redesigned to suit open environments while maintaining consistency in interface and interaction style across both indoor and outdoor contexts.



Navigation begins when the user scans a designated QR code positioned on outdoor campus signage, such as the official admissions board located at the entrance to campus facilities [Fig. 1(a)]. This QR code acts as an initialization anchor, aligning the digital scene with the real-world coordinate system to enable precise overlay of AR guidance elements. Once initialized, the user is presented with a location selection interface, from which they can choose a point of interest—such as the university's astronomical observatory.

Upon selecting a destination, the application displays a detailed preview including a representative photo, contact information, and a "Get Directions" button [Fig. 1(b)]. Tapping this option generates a contextual route preview, where users can see the estimated walking time and total distance to the target [Fig. 1(c)]. Notably, the app also flags whether the suggested route is wheelchair accessible, ensuring inclusivity in the wayfinding experience.

Once navigation is initiated, the application renders the route as a sequence of 3D arrows superimposed on the live camera feed. These directional cues update dynamically as the user moves through the campus, ensuring accurate step-by-step guidance [Fig. 2(a)]. In parallel, textual instructions and optional audio prompts provide redundancy, enhancing usability in varying light and noise conditions [Fig. 2(b)]. The interface design remains minimalistic and accessible, with large tap areas, clean typography, and consistent iconography.



The final phase of the navigation process—approaching the destination—is supported by persistent AR labels and markers positioned in the user's field of view. These indicators signal proximity to the target and offer visual confirmation upon arrival [Fig. 2(c)]. As with the indoor scenario, no GPS or BLE infrastructure is needed; the entire navigation experience is powered by camera-based tracking and spatial anchors, making it scalable and deployable without physical modifications to the environment.

This outdoor adaptation demonstrates that the same infrastructure-free AR system can offer seamless wayfinding across spatial contexts, guiding users from common entry points on campus to specific buildings or functional areas with minimal friction. The user experience, interaction logic, and technological backbone remain consistent with the previously evaluated indoor deployment, ensuring methodological continuity for comparative analysis.

(a) Visual cues (b) Additional details. (c) Arrival confirmation.

Fig. 2. User interface and interaction (II)

C. Participant Profile and Study Duration

A total of 256 students from Ștefan cel Mare University of Suceava participated in the comparative study. This participant pool mirrors the one from the initial indoor evaluation. Most were enrolled in the first (70.7%) or second (26.2%) year of undergraduate studies, with the remaining (3.1%) from higher years or master's programs. This demographic ensured low prior familiarity with campus routes, particularly outdoor connectors between buildings.

Participants were required to have AR-capable smartphones. Of the total, 153 had prior exposure to AR applications, while 103 had none. This variation supported robust evaluation of both usability and adoption potential.

D. Experimental Setup and Testing Procedure

Each participant completed two navigation tasks using the same AR app: one indoor, one outdoor. The order was counterbalanced. In both scenarios, QR codes marked the navigation start points. Users selected a destination from the on-screen list and followed AR cues to reach the target location. Outdoor destinations included pedestrian pathways between faculty buildings. Navigation took 2–3 minutes per task.

The application provided continuous AR guidance without requiring server connectivity. No external assistance was offered, simulating real-world use. After completing both routes, participants filled out a post-task questionnaire on their own device. Each session lasted ~15 minutes and was conducted individually during daytime under stable weather conditions.

E. Research Hypotheses

The study formulated the following hypotheses for comparative evaluation:

- H1: No significant difference in perceived ease of use between indoor and outdoor conditions.
- H2: Perceived usefulness is higher indoors due to complex spatial layouts.
- H3: System responsiveness predicts SUS scores across both conditions.
- H4: SUS scores do not differ significantly across environments.
- H5: Behavioral intention to reuse is positively associated with perceived usefulness.
- H6: Outdoor environmental factors (e.g., lighting, visual features) may influence responsiveness perception.

The study was reviewed and approved by the Ethics Committee of Ștefan cel Mare University of Suceava. All participants were informed about the nature and purpose of the research, and informed consent was obtained prior to their involvement. Data collection adhered to institutional guidelines on ethical conduct, privacy, and voluntary participation.

The following section presents the results of the comparative evaluation, focusing on key user experience indicators measured across indoor and outdoor navigation scenarios.

IV. Results

A. Hypothesis 1 (H1): There is no Statistically Significant Difference between users' Perception of the Application's Intuitiveness in Indoor Versus Outdoor Navigation Scenarios

The first hypothesis aimed to explore whether users perceive the augmented reality (AR) navigation application as equally intuitive in both indoor and outdoor university environments. According to user-centered design principles and the Technology Acceptance Model (TAM), intuitiveness plays a critical role in influencing user engagement and perceived usability across different contexts.

To test this hypothesis, a paired-samples t-test was conducted, comparing two questionnaire items:

- "How intuitive did you find the indoor navigation mode?"
- "How intuitive did you find the outdoor navigation mode?"

Both variables were measured on a 5-point Likert scale (1 = Not at all intuitive, 5 = Very intuitive). Descriptive statistics are presented in Table I, showing nearly identical means for both contexts: indoor (M = 3.83, SD = 0.97) and outdoor (M = 3.83, SD = 1.00), suggesting a uniform perception of intuitiveness across environments.

TABLE I. Descriptive Statistics for Perceived Intuitiveness in Indoor vs Outdoor Scenarios

Variable	Mean	Std. Deviation	N
Indoor Navigation Intuitiveness	3.83	0.97	256
Outdoor Navigation Intuitiveness	3.83	1.00	256

The results of the t-test revealed no statistically significant difference between the two means: $t(255) = -0.066$, $p = 0.947$ (see Table II). The mean difference was minimal (−0.004), reinforcing the conclusion that users found the application equally intuitive regardless of whether it was used indoors or outdoors.

TABLE II. Paired-Samples T-Test for Intuitiveness Scores in Indoor vs Outdoor Contexts

Variable Pair	Mean Difference	t	df
Indoor vs. Outdoor Intuitiveness Scores	−0.004	−0.066	255

These findings support the hypothesis that intuitiveness is perceived consistently across navigation environments. This consistency may reflect the application's cohesive design and interface behavior across contexts, suggesting that once familiarized with the system, users can transfer their expectations and interactions seamlessly between indoor and outdoor use. Fig. 3 illustrates the comparison between students perceived intuitiveness of the AR application during indoor and outdoor navigation. As shown, the mean scores for both scenarios are virtually identical (M_indoor = 3.83; M_outdoor

= 3.83), indicating a consistent user experience across environments.

A paired-samples t-test confirmed that this difference is not statistically significant ($t(255) = -0.066$, $p = 0.947$). These findings suggest that the application's intuitive design was equally effective in guiding users regardless of the spatial context, supporting its usability in both structured (indoor) and open (outdoor) campus environments.

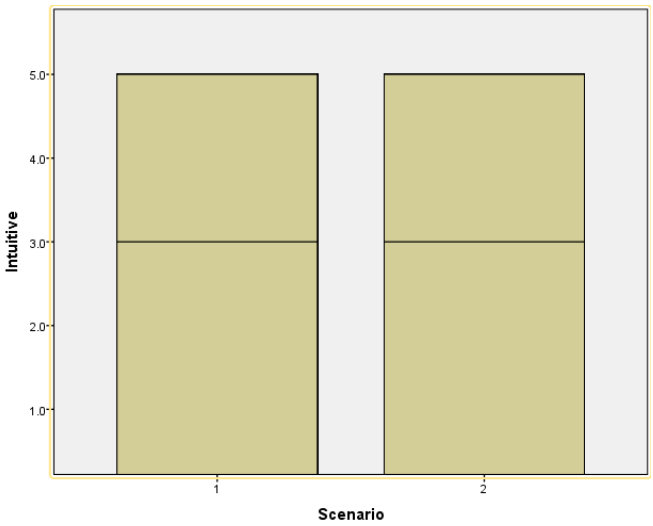

Fig. 3. Mean perceived intuitiveness of the AR application during indoor and outdoor navigation scenarios. Error bars are not displayed due to negligible variation. No significant difference was observed between conditions ($p = 0.947$).

This result is particularly relevant for the design of hybrid AR navigation solutions in academic settings, where continuity of experience across spatial contexts (e.g., classroom buildings, campus pathways) enhances usability and adoption.

B. Hypothesis 2 (H2): The Application is Perceived as More Useful in Indoor Navigation than in Outdoor Navigation

The second hypothesis investigated whether users perceive the augmented reality (AR) navigation application as more useful in indoor environments (e.g., corridors, classrooms) than in outdoor settings (e.g., between campus buildings). This assumption stems from the idea that indoor environments are typically more challenging for spatial orientation due to occlusion, lack of clear landmarks, and complex layouts, which AR tools are specifically designed to mitigate.

To examine this hypothesis, a paired-samples t-test was conducted between the following two items:

- "I believe this application significantly improves my ability to orient myself within campus buildings."
- "I believe this application significantly improves my ability to orient myself in exterior campus spaces."

Both items used a 5-point Likert scale (1 = Strongly disagree, 5 = Strongly agree). Descriptive statistics are presented in Table III, showing slightly higher scores for indoor utility ($M = 4.20$, $SD = 0.91$) compared to outdoor ($M = 4.11$, $SD = 0.94$).

TABLE III. DESCRIPTIVE STATISTICS FOR PERCEIVED UTILITY IN INDOOR VS. OUTDOOR CONTEXTS

Variable	Mean	Std. Deviation	N
Indoor Navigation Utility	4.20	0.91	256
Outdoor Navigation Utility	4.11	0.94	256

A paired-samples t-test revealed that this difference was not statistically significant, $t(255) = 1.704$, $p = 0.090$ (see Table IV). The mean difference of +0.086 indicates a slight preference for indoor use, but this was insufficient to support the hypothesis at the conventional $\alpha = 0.05$ level.

TABLE IV. PAIRED-SAMPLES T-TEST FOR PERCEIVED UTILITY SCORES IN INDOOR VS. OUTDOOR CONTEXTS

Variable Pair	Mean Difference	t	df
Indoor vs. Outdoor Utility Scores	+0.086	1.704	255

While the data suggest a marginal trend favoring indoor use in terms of perceived utility, the lack of statistical significance indicates that users view the application as equally beneficial for both indoor and outdoor navigation. This result may reflect the versatility and adaptability of the application interface and the consistency of user experience across spatial contexts.

The chart presented in Fig. 4 illustrates the distribution of perceived utility scores (Perception_Utility) across two usage scenarios: indoor (1) and outdoor (2). This visualization is directly relevant to Hypothesis 2 (H2), which proposed that users would perceive the application as more useful in indoor navigation contexts (e.g., hallways, classrooms) than in outdoor settings (e.g., between buildings). However, the nearly identical heights of the bars suggest that perceived utility is very similar across both scenarios.

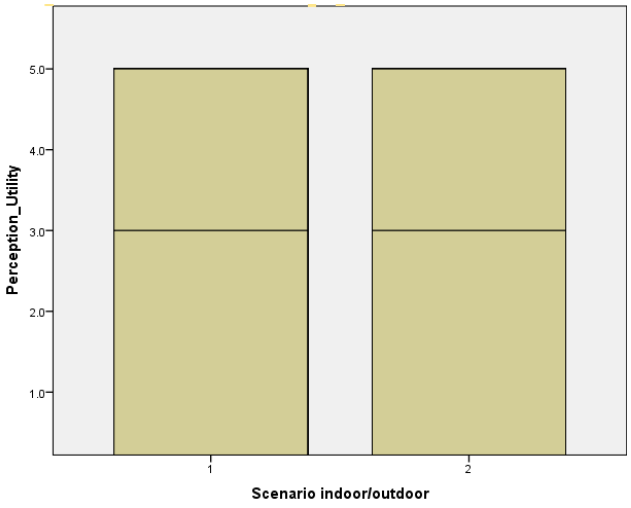

Fig. 4. Mean perceived utility scores across indoor (1) and outdoor (2) navigation scenarios. The near-identical column heights indicate similar user evaluations in both contexts, consistent with the non-significant statistical difference.

This graphical similarity aligns with the results of the paired-samples t-test, which revealed no statistically significant difference between the two conditions ($M_{indoor} = 4.20$, $M_{outdoor} = 4.11$, $p = 0.090$). Although there was a slight

numerical advantage for indoor use, the difference was insufficient to support H2 at the conventional significance level.

These findings indicate that users consider the application to be equally effective for orientation and navigation tasks in both spatial contexts.

These findings provide important insights for developers aiming to scale AR-based navigation tools across campus-wide deployments, as both environments appear equally receptive to technological support in orientation tasks.

C. Hypothesis 3 (H3): The Navigation Experience is Perceived as More Engaging in Indoor Settings than in Outdoor Settings

The third hypothesis examined whether users find the augmented reality (AR) navigation experience more stimulating or engaging when used indoors, as opposed to outdoors. Indoor AR experiences may be enhanced by the presence of walls, corridors, and structured spaces that can provide more immersive contextual cues, whereas outdoor environments may dilute these effects due to broader visual openness and variable lighting.

To assess this, participants responded to two parallel questionnaire items:

- "How engaging or stimulating did you find the indoor navigation experience?"
- "How engaging or stimulating did you find the outdoor navigation experience?"

Responses were measured on a 5-point Likert scale (1 = Not at all, 5 = Very much). Descriptive statistics, displayed in Table V, show nearly identical mean scores: indoor (M = 4.02, SD = 0.92) and outdoor (M = 4.04, SD = 0.95), suggesting an overall balanced experience across contexts.

TABLE V. DESCRIPTIVE STATISTICS FOR PERCEIVED ENGAGEMENT IN INDOOR VS. OUTDOOR SCENARIOS

Variable	Mean	Std. Deviation	N
Indoor Navigation Engagement	4.02	0.92	256
Outdoor Navigation Engagement	4.04	0.95	256

A paired-samples t-test confirmed that this difference is not statistically significant, $t(255) = -0.409$, $p = 0.683$ (see Table VI). The very small mean difference (−0.02) indicates no real practical disparity in how engaging the navigation experience was perceived across settings.

TABLE VI. PAIRED-SAMPLES T-TEST FOR NAVIGATION EXPERIENCE ENGAGEMENT

Variable Pair	Mean Difference	t	df
Indoor vs Outdoor Engagement Scores	−0.020	−0.409	255

The results of Hypothesis 3 suggest that users found the navigation experience equally engaging in both indoor and outdoor environments. This outcome may reflect the consistent visual and interaction design of the AR application across contexts, or it may point to the novelty of the technology itself as a key driver of engagement, independent of location.

From a design perspective, this reinforces the value of cohesive AR experiences that deliver similar affective impact regardless of spatial constraints or environmental variables.

D. Hypothesis 4 (H4): The Application Loads Faster and more Smoothly in Indoor Environments than in Outdoor Environments

The fourth hypothesis examined whether users perceived the augmented reality (AR) application as performing better—in terms of content loading speed and responsiveness—indoors compared to outdoors. This hypothesis is grounded in the assumption that indoor environments often provide more stable Wi-Fi connectivity, reduced glare, and consistent lighting, which may facilitate faster AR marker recognition and content rendering.

To evaluate this, a paired-samples t-test was conducted comparing responses to the following items:

- "How fast was the loading and display of AR content (VPS, SLAM) indoors?"
- "How fast was the loading and display of AR content (VPS, SLAM) outdoors?"

Responses were given on a 5-point Likert scale (1 = Very slow, 5 = Very fast). As shown in Table VII, users rated the application slightly higher in terms of speed indoors (M = 3.81, SD = 0.83) than outdoors (M = 3.71, SD = 0.88).

TABLE VII. DESCRIPTIVE STATISTICS FOR PERCEIVED AR LOADING SPEED INDOOR VS. OUTDOOR

Variable	Mean	Std. Deviation	N
Indoor AR Loading Speed	3.81	0.83	256
Outdoor AR Loading Speed	3.71	0.88	256

A paired-samples t-test revealed a statistically significant difference between the two contexts, $t(255) = 2.167$, $p = 0.031$ (see Table VIII). The mean difference of +0.10 confirms that the application was perceived as faster indoors.

TABLE VIII. PAIRED-SAMPLES T-TEST FOR AR LOADING SPEED IN INDOOR VS. OUTDOOR CONTEXTS

Variable Pair	Mean Difference	t	df	Sig. (2-tailed)
Indoor vs. Outdoor AR Loading Speed	+0.102	2.167	255	0.031

These results support the hypothesis that AR content was perceived to load more quickly in indoor environments. Several factors may account for this, including:

- more consistent lighting conditions and surfaces,
- better tracking support from structured geometry (walls, doors),
- more reliable indoor connectivity (Wi-Fi vs. mobile data).

From a usability standpoint, this finding highlights the need for optimizing AR systems for outdoor performance – possibly

through enhanced tracking algorithms or adaptive rendering for varying environmental conditions. Fig. 5 illustrates the distribution of perceived utility scores of the application based on the type of device used.

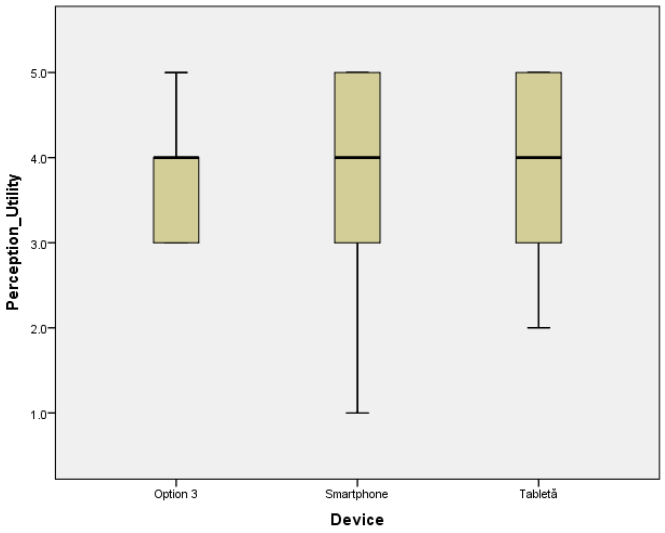

Fig. 5. Distribution of perceived utility scores by device type. Median utility is higher for smartphones and tablets compared to laptops (Option 3). The wider range for smartphones suggests a more varied but generally positive user experience.

A higher median is observed for smartphones and tablets compared to "Option 3" (likely representing laptops). Smartphone users reported a wider range of perceptions (with values ranging from 1 to 5), suggesting a more variable experience, but with an overall positive tendency. This distribution supports Hypothesis H4, which states that the application is perceived as more useful when used on a smartphone.

E. Hypothesis 5 (H5): Users are more Likely to Express an Intention to Regularly use the Application for Indoor Navigation than for Outdoor Navigation

The fifth hypothesis explored whether students reported a higher behavioral intention to regularly use the AR navigation application in indoor settings (e.g., classrooms, hallways) compared to outdoor navigation (e.g., between buildings across the campus). Behavioral intention is a central variable in the Technology Acceptance Model (TAM) and Unified Theory of Acceptance and Use of Technology (UTAUT), as it directly influences actual technology adoption.

To examine this hypothesis, participants responded to the following parallel statements:

- "I would be willing to regularly use this application for indoor navigation on campus."
- "I would be willing to regularly use this application for outdoor navigation between campus buildings."

Responses were measured using a 5-point Likert scale (1 = Strongly disagree, 5 = Strongly agree). Descriptive statistics presented in Table IX revealed virtually identical mean scores: indoor (M = 3.93, SD = 1.03) and outdoor (M = 3.93, SD = 1.00), suggesting no practical difference in user intention across environments.

TABLE IX. DESCRIPTIVE STATISTICS FOR INTENTION TO USE INDOOR VS. OUTDOOR

Variable	Mean	Std. Deviation	N
Intention to Use (Indoor)	3.93	1.03	256
Intention to Use (Outdoor)	3.93	1.00	256

The paired-samples t-test confirmed this equivalence, showing no statistically significant difference between the two scores:

t(255) = 0.079, p = 0.937 (see Table X). The mean difference was negligible (+0.004), indicating consistent behavioral intention across indoor and outdoor contexts.

TABLE X. PAIRED-SAMPLES T-TEST FOR INTENTION TO USE

Variable Pair	Mean Difference	t	df	Sig. (2-tailed)
Indoor vs Outdoor intention to use	+0.004	0.079	255	0.937

These findings suggest that users are equally inclined to use the application regularly in both indoor and outdoor navigation contexts. This result reinforces the idea that user trust in the application extends across different spatial environments, likely due to a coherent interface and consistent interaction model.

This outcome is encouraging from a scalability perspective, indicating that future AR implementations in university campuses may find equal acceptance for both indoor and outdoor orientation support.

F. Hypothesis 6 (H6): Users Perceive the Application's Localization Accuracy and Stability as Significantly Higher in Indoor Scenarios than in Outdoor Scenarios

The sixth hypothesis addressed the perception of localization quality – a crucial factor in the effectiveness of augmented reality (AR) navigation tools. AR experiences depend heavily on stable and precise positioning, typically achieved through technologies such as VPS (Visual Positioning System) and SLAM (Simultaneous Localization and Mapping). Given the more controlled conditions in indoor environments (e.g., structured geometry, constant lighting, Wi-Fi signals), it was expected that localization would be perceived as more stable indoors than outdoors.

To assess this, participants evaluated two items:

- "How would you rate the stability and accuracy of the localization function in indoor navigation (buildings, hallways)?"
- "How would you rate the stability and accuracy of the localization function in outdoor navigation?"

Each was measured on a 5-point Likert scale (1 = Very low, 5 = Very high). Descriptive statistics are shown in Table XI, revealing a slightly higher mean for indoor localization (M = 3.68, SD = 0.86) than for outdoor (M = 3.63, SD = 0.88).

TABLE XI. DESCRIPTIVE STATISTICS FOR PERCEIVED LOCALIZATION ACCURACY IN INDOOR VS. OUTDOOR CONTEXTS

Variable	Mean	Std. Deviation	N
Indoor Localization Accuracy	3.68	0.86	256
Outdoor Localization Accuracy	3.63	0.88	256

The paired-samples t-test indicated that the difference in perceived accuracy was not statistically significant, $t(255) = 1.080$, $p = 0.281$ (see Table XII). The mean difference was only +0.051.

TABLE XII. PAIRED-SAMPLES T-TEST FOR LOCALIZATION ACCURACY SCORES

Variable Pair	Mean Difference	t	df
Indoor vs Outdoor Localization Accuracy	+0.051	1.080	255

Although the hypothesis was not supported statistically, the result suggests that users generally perceive localization to be similarly stable in both environments, with a slight (non-significant) preference for indoor performance. This outcome may be attributed to improvements in mobile AR tracking technologies and robustness across spatial contexts.

Designers and developers should nonetheless consider environmental differences when optimizing positioning systems, particularly for outdoor use cases involving variable light, weak signals, or open unstructured areas.

V. DISCUSSION AND LIMITATIONS

The results of this study provide empirical evidence that a unified, infrastructure-free AR navigation system can deliver a consistent and usable experience across both indoor and outdoor university environments. Participants reported similar levels of intuitiveness, usefulness, engagement, and behavioral intention to reuse the application regardless of spatial context, as measured through the System Usability Scale (SUS) and the Technology Acceptance Model (TAM). The only statistically significant difference was a slight advantage in perceived AR content loading speed in indoor scenarios, likely due to more stable lighting and connectivity conditions.

These findings reinforce the initial design assumption that a consistent user interface and interaction model can minimize the cognitive gap between indoor and outdoor usage. The results also address the core research question posed in this study: Can a single AR navigation system maintain usability and user acceptance across spatial contexts without reliance on GPS or external infrastructure? The answer, based on the data, appears to be affirmative.

From a comparative perspective, the usability scores obtained in this study (SUS ~74) align closely with values reported in prior AR navigation studies. For example, Chen et al. [17] reported a SUS score of 74 for an ARCore-based campus system, and Sato et al. [21] reported 76 in a museum setting. These similarities strengthen the external validity of our findings. Moreover, unlike BLE- or marker-based systems such as Yamamoto et al. [6], which required dense beacon deployment, our system operates solely on visual-inertial tracking and cloud-based spatial anchors—simplifying deployment and enhancing scalability.

Technical stability and system responsiveness have also been highlighted in previous literature as key predictors of user satisfaction [17], [23]. Our study extends these insights by showing that responsiveness perceptions remain stable even across variable lighting and open vs. closed environments. This outcome suggests that modern mobile AR frameworks like ARCore and ARKit can now support robust navigation without needing physical markers or dedicated sensors.

Despite the strengths of the approach, several limitations must be acknowledged. First, the experiment was conducted exclusively within a single university campus, which may limit the generalizability of the results to other institutional settings with different architectural layouts or technological infrastructures. Although both indoor and outdoor scenarios were evaluated, the tasks involved relatively short, predefined routes. Longer or more complex navigation scenarios—such as multistep journeys involving transitions between buildings—were not assessed and may yield different results in terms of user satisfaction and system responsiveness.

Second, all participants used their personal smartphones, which, while realistic and ecologically valid, introduced variation in hardware performance and environmental adaptation (e.g., screen brightness outdoors, camera quality). These variables were not controlled or measured and may have introduced noise into user experience ratings.

Lastly, although this study employed validated instruments (SUS and TAM) for assessing usability and acceptance, it relied solely on post-task self-reported measures. Objective performance metrics such as navigation time, error rate, path deviation, or eye-tracking data were not collected. Integrating such data in future research would complement subjective feedback and allow more comprehensive usability evaluation.

Overall, this study demonstrates that consistent AR navigation performance can be achieved across spatial contexts using a single, infrastructure-independent mobile application. These findings support the development of scalable, user-centered AR wayfinding systems suitable for real-world academic deployments.

VI. CONCLUSION

This study investigated whether a single mobile augmented reality (AR) navigation application could provide a consistent and usable experience across both indoor and outdoor university environments. Using a within-subjects experimental design with 256 participants, the system was evaluated through established usability and acceptance frameworks (SUS and TAM) and demonstrated strong performance in both spatial contexts.

The findings validate the feasibility of infrastructure-free, camera-based AR navigation solutions in academic settings. By maintaining consistent interaction patterns and localization methods across environments, the application enabled users to navigate seamlessly, regardless of whether they were indoors or outdoors. This cross-context adaptability addresses a key

challenge in smart campus design, where traditional tools often fail to bridge spatial transitions.

Future work will extend this research along several directions. First, incorporating objective performance metrics such as route efficiency, task duration, and error rates would complement subjective assessments. Second, the system could be deployed and evaluated in campuses with more complex spatial configurations or across multiple institutions. Third, integration with real-time data (e.g., scheduling, crowd flow) and accessibility enhancements (e.g., voice-only guidance or screen-reader support) may further improve adoption and inclusivity.

Brightness-Aware Generative Adversarial Network for Low-Light Image Enhancement

Huafei, Zhao, Mideth Abisado
College of Computing & Information Technologies, National University, Manila, Philippines

***Abstract*—Images from low-light frequently exhibit poor visibility, excessive noise, and color distortion, which substantially impair both computer vision systems and human visual perception. Although numerous enhancement techniques have been developed, producing visually appealing results with well-maintained structural details and natural color reproduction continues to pose significant challenges. To address these limitations, this paper present an Brightness-Aware Generative Adversarial Network (BA-GAN) for robust low-light image enhancement (LLIE). Our framework employs a U-Net-based generator that effectively captures multi-scale contextual features while preserving fine image details through skip connections. The key innovation lies in our novel Brightness Attention Mechanism Module, integrated within the decoder, which dynamically directs the network's focus to regions requiring substantial illumination correction. To ensure local photorealism, this paper adopt a PatchGAN discriminator architecture. The complete model is trained on the LOL dataset using a composite loss function combining: (1) adversarial loss for realistic image generation, (2) brightness attention loss for keeping the brightness accuracy, and (3) perceptual loss to maintain structural and semantic fidelity. Extensive experiments validate that our BA-GAN outperforms current state-of-the-art methods, achieving superior performance on both quantitative metrics (PSNR: 20.7127, SSIM: 0.7963, LPIPS: 0.2271) and qualitative visual assessments. The enhanced images demonstrate significantly improved visibility while effectively suppressing noise and preserving natural color characteristics.**

Keywords*—Low-light image enhancement; generative adversarial networks; U-Net; PatchGAN; attention mechanism; deep learning

I. Introduction

Images captured by cameras often used by advanced computer vision tasks such as image classification, object detection, and image generation, and security monitoring [1]. However, during the capture process, due to low-light environments or insufficient device lighting capabilities, the resulting images are often dim, visually unclear, and have low contrast. These images significantly hinder subsequent computer vision processing, rendering them largely unusable. Low-quality images not only affect human visual experience but also have adverse effects on subsequent computer vision applications.

When capturing images in low-light environments, long exposure or slow shutter speeds are often used to increase the amount of light captured by the camera, making more complex low-light blur degradation unavoidable [2]. While flash photography is commonly employed to brighten low-light environments, it often introduces uneven illumination artifacts that degrade image quality through increased noise and unnatural lighting patterns. To address these issues, professional photographers typically enhance the quality of pictures taken under low-light environments by adjusting camera parameters or using image editing software (such as Adobe Photoshop) [3]. However, this process usually requires complex operations and professional skills, making it unsuitable for ordinary users. Therefore, automated LLIE technology is crucial for solving this problem.

Conventional approaches to LLIE mainly consist of histogram equalization techniques [4] and Retinex-based methods [5]. With the advancement of GPU computing power, the widespread application of neural networks and deep learning, and the emergence of training datasets, it is now possible to learn detailed information from images through deep learning methods, thereby improving the contrast of images with low-light [6]. Deep learning methods utilize deep neural networks to establish an end-to-end mapping between low-light and normal-light image domains through data-driven learning from extensive training samples. Compared to traditional methods, they possess more powerful feature representation capabilities and have achieved impressive results on benchmark datasets [7]. Existing LLIE methods, while capable of upgrading the brightness and contrast of dim images to some extent, still have issues such as color distortion, noise amplification, and insufficient model generalization [8] as it's hard to obtain paired datasets in real-world production and life, as well as the limited global processing capability of convolutional operations on images.

GANs [9] have proven effective for image-to-image translation tasks, including low-light enhancement. GANs leverage a generator network to produce enhanced images and a discriminator network to distinguish generated fake images from real normal-light images, leading to perceptually more convincing results. However, existing methods may still struggle with balancing noise suppression, detail preservation, and adaptive enhancement across different image regions and lighting variations.

To solve these limitations, this paper propose a Brightness-Aware Generative Adversarial Network (BA-GAN). The key contributions in this paper summarized as follows:

1) A U-Net generator architecture that fuses multi-scale details. This paper adopted a U-Net-based generator, which processes images through a symmetric encoder-decoder structure. The key to this architecture lies in its skip connections. These connections directly transmit the low-level, high-

*Corresponding Author

resolution detailed features (such as edges and textures) captured by the encoder at different levels to the corresponding levels of the decoder. This design can effectively avoid the common problem of detail information loss in deep networks, thereby maximizing the preservation of fine structures while enhancing the image brightness and preventing the final result from becoming blurred.

2) A novel illumination attention module for adaptive enhancement. This is the core innovation of this paper. We integrated an illumination attention module into the decoder of the generator. This module aims to solve the problem of uneven illumination in low-light images, enabling the network to dynamically and adaptively focus its attention on the area's most in need of illumination correction according to the image content. By learning and applying this spatially varying enhancement strategy, the model can avoid overexposing areas with existing light sources while sufficiently brightening extremely dark areas, thus achieving a more natural and accurate enhancement effect.

3) A PatchGAN discriminator that focuses on local realism. To generate more perceptually convincing results, our framework employs a PatchGAN discriminator. Different from traditional discriminators that make true/false judgments on the entire image, PatchGAN evaluates the authenticity by assessing local patches of the image. This mechanism encourages the generator to not only focus on the global visual effect but also pay attention to generating locally realistic textures and structures. This helps to significantly improve the detail quality and overall realism of the enhanced image.

4) A composite loss function for balanced optimization. The low-light enhancement task requires a balance among multiple objectives. To this end, this paper designed and adopted a composite loss function to guide the training of the model. This function combines three key components: (1) adversarial loss, used to enhance the realism of the generated image; (2) brightness attention loss, used to ensure the accuracy of brightness correction; and (3) perceptual loss, used to maintain the original structure and semantic content of the image in the deep feature space. This multi-objective optimization strategy ensures that the final enhancement result achieves the best balance in terms of visual realism, brightness, and content fidelity.

In summary, LLIE is crucial for improving visual quality and enabling robust performance in downstream computer vision tasks. However, existing methods ranging from traditional techniques like histogram equalization and Retinex theory to deep learning approaches—often suffer from color distortion, noise amplification, and limited generalization due to the scarcity of real-world paired datasets and the inherent constraints of convolutional operations. While GANs have shown promise in LLIE, challenges remain in achieving adaptive enhancement, detail preservation, and noise suppression. To address these limitations, this paper propose a BA-GAN that integrates a U-Net generator with multi-scale skip connections, a novel illumination attention module for adaptive brightness correction, a PatchGAN discriminator for local realism, and a composite loss function for balanced optimization. Our approach aims to deliver natural, high-fidelity enhancements while addressing uneven illumination and preserving fine-grained details.

II. Related Works

A. Traditional Methods

Conventional approaches to LLIE mainly consist of histogram equalization techniques and Retinex-based methods.

The histogram equalization method operates on the histogram of an image and upgrades the image's contrast by altering its dynamic range, which can enhance the quality of dim images to some extent [10]. The histogram records the distribution of image data, and due to its uneven distribution, this method redistributes it to achieve non-linear stretching, making the distribution of image data more reasonable. Examples include HE [2] and CLAHE [11]. Numerous improved methods based on HE, have enhanced HE to varying degrees. Compared to global equalization, local equalization focuses more on the internal detail distribution of the image, but the required computational effort also increases. Low-light images enhanced by such methods are prone to issues like overexposure or underexposure, color distortion, artificial artifacts, loss of image details, and unnatural appearance. Sometimes, the resulting images may also retain the noise present in the original images.

Retinex-based methods perform image enhancement through a decomposition process, separating low-light images into illumination and reflectance components. This separation is typically achieved by applying physical priors or mathematical regularization constraints. The reflectance component is subsequently obtained by solving an optimization problem involving both the estimated illumination and the original input image [12], and is considered the final enhancement result. Building on Retinex, Single Scale Retinex (SSR) [13] was proposed, which removes the influence of illumination by comparing the central element with the surrounding area's luminance values. Multi-Scale Retinex (MSR) [14] was introduced to address the issue of Gaussian kernel optimization quality. The MSR with Color Restoration (MSRCR) [15] algorithm adjusts color distortion by adding a color restoration factor.

Retinex-based LLIE methods can effectively address issues such as underexposure and overexposure. However, they often overlook the presence of noise during image processing, leading to noise amplification. Additionally, these methods struggle to find an effective prior or regularization. As a result, low-light images enhanced by these methods often have limitations like color distortion, artificial artifacts, overexposure, and accompanying noise.

B. Deep Learning-Based Methods

The rapid evolution of deep learning has led to the development of numerous data-driven approaches for LLIE, consistently outperforming conventional methods in terms of image quality improvement. These techniques leverage deep neural architectures to learn complex mappings between low-light and normal-light image domains, effectively enhancing

visual clarity and perceptual quality. Current deep learning-based approaches can be systematically categorized into four paradigms: (1) supervised learning, (2) unsupervised learning, (3) semi-supervised learning, and (4) zero-shot learning methods.

1) Supervised learning methods. Supervised learning is widely used in LLIE. It involves providing a set of images along with their corresponding enhanced versions as training data, enabling the model to learn an end-to-end transformation that converts input images into enhanced outputs with improved visual quality. As the pioneering deep learning solution for LLIE, LLNet [16] demonstrated that a carefully designed autoencoder could effectively enhance low-light images while preserving important visual features. MSR-NET [17] introduced the use of convolutional neural networks, combined with Retinex theory, to restore images to good brightness levels. Wei et al. [18] proposed Retinex-Net, which includes decomposition, adjustment, and reconstruction, corresponding to three sub-networks. During the adjustment phase, the brightness of the illumination map is increased through multi-scale encoders and decoders. In the final reconstruction stage, the enhanced image is obtained through element-wise multiplication of the processed illumination and reflectance maps. However, the edges of the enhanced structure are overly prominent, and the naturalness of the entire image is not perfect. KinD [19] followed the Retinex theory-based approach of decomposition followed by enhancement, constructing a two-stage network. The restoration sub-network introduced information from real illumination to prevent image distortion, and the loss function ensured the smoothness of the illumination layer. KinD++ [20] alleviated residual visual artifacts in the results generated by KinD through a multi-scale illumination attention module. MIRNet [21] used a multi-scale feature fusion method, including multi-scale residual blocks, multi-resolution convolutional streams, and attention mechanism-based multi-scale features, achieving high performance in image enhancement tasks. Liu et al. [22] proposed a three-stage brightness-aware network based on brightness-aware attention and residual quantization encoding blocks, and their designed a query module link the low-light and normal-light domains. Building upon U-Net [23], LAU-Net [24] augments the baseline architecture with a Parallel Attention Unit (PAU) to weight informative features dynamically, an Internal Resizing Module (IRM) for scale-invariant representation learning, and auxiliary convolutional layers to mitigate low-light artifacts.

Supervised learning methods have shown improvements in color balance and brightness adjustment compared to traditional methods, but they tend to lose local details and often rely on paired datasets, leading to overfitting and low cross-data generalization. In the field of LLIE, paired datasets are limit in quantity and synthesizing image datasets can result in poor model generalization.

2) Unsupervised learning methods. Unsupervised learning refers to training data without corresponding target enhanced images, allowing the model to learn the structure and features of image data on its own. After the introduction of GANs, GANs achieved significant results in computer vision tasks. This method do not need paired training data and can be trained using unpaired datasets, making data acquisition relatively easier. In the realm of LLIE, EnlightenGAN proposed by Jiang et al. [25] was the first to eliminate the dependency on paired training data, greatly enhancing the flexibility of generated images and adapting to various scenarios. The introduction of RetinexGAN [26] combined GANs with the Retinex model, incorporating a decomposition network and two discriminative networks, where the decomposition network decomposes the Retinex model, and the discriminators evaluate the illumination and reflectance components. Zhu et al. [27] designed Cycle-consistent Generative Adversarial Networks (CycleGAN), which use cycle-consistency loss to achieve image style transfer. However, applying it to LLIE training is challenging as it overlooks the preservation of local features. Hu et al. [28] developed a novel two-stage unsupervised framework that separates the enhancement process into distinct pre-enhancement and post-enhancement phases. The initial stage employs conventional Retinex-based algorithms for primary image enhancement, while the subsequent stage utilizes an adversarial trained refinement network to achieve superior quality improvement. In a related approach, Wang et al. [29] introduced an attention-guided unsupervised GAN architecture featuring: (1) an auxiliary edge restoration module for enhanced sharpness preservation, and (2) a dedicated attention mechanism for improved colour fidelity reconstruction.

3) Semi-supervised learning methods. Semi-supervised learning integrates the advantages of supervised and unsupervised learning. Yang et al. [25] constructed a deep recursive frequency band network, which first uses supervised learning to learn frequency band representations from coarse to fine, and then employs unsupervised adversarial learning to improve the model's generalization ability. Through this end-to-end recursive training, noise removal is effectively achieved, and the ability to recover local structural details is improved. Dimma [30] built a brightness adjustment module to obtain a low-light version of normal-light images, thereby enabling semi-supervised training.

4) Zero-shot learning methods. Zero-shot learning in the field of LLIE refers to the ability to learn how to enhance images solely from test images. Guo et al. introduced Zero-DCE [31], a lightweight, reference-free deep curve estimation model that achieves pixel-level adjustments of input images through image-to-curve mapping and utilizes a loss function to drive reference-free training. Building on this, an accelerated lightweight version, Zero-DCE++ [32], was introduced. Zhang L et al. introduced a "zero-learning" approach for backlit image restoration, which is based on deep learning but does not rely on any training image. The framework ExCNet, a specially designed convolutional neural network architecture. Zhu et al. [32] introduced RRDNet, an innovative three-branch CNN that decomposes input images into illumination, reflectance, and noise components. This architecture employs iterative

optimization of a custom loss function to simultaneously predict noise patterns and restore underexposed regions. In a complementary approach, Liu et al.'s RUAS [33] formulates a mathematical model to represent the intrinsic illumination structure of low-light images, then unfolds this optimization process into a learnable network architecture. By exploring optimal configurations within a constrained search space, RUAS achieves superior enhancement performance through its propagated structure.

In summary, conventional enhancement methods depend on fixed statistical priors, limiting their adaptability to diverse real-world scenarios. While contemporary supervised approaches predominantly employ U-Net architectures, they frequently suffer from spatial detail degradation and inadequate feature representation due to the absence of attention mechanisms. To address these limitations, our proposed framework innovatively combines attention modules with a U-Net backbone and incorporates a PatchGAN discriminator. This hybrid architecture enables: (1) enhanced multi-scale feature learning, (2) improved discriminative feature extraction, (3) effective noise suppression, and (4) robust contextual information aggregation across different scales.

III. Methodology

The LLIE method based on the GANs model introduced in this paper employs U-Net as the generator, which is characterized by its low data requirement and fast training speed. By using PatchGAN as the discriminator instead of the traditional binary classifier, the trained model pays more attention to image details, improves image quality, and accelerates network convergence. The network structure of the method used is illustrated in Fig. 1. The generator consists of a U-Net backbone with embedded illumination attention modules. The discriminator follows a PatchGAN structure to promote local realism.

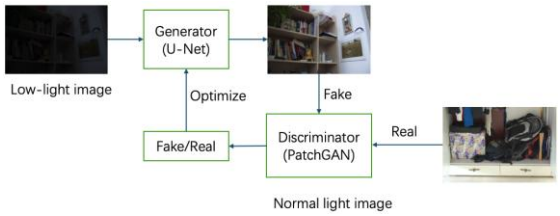

Fig. 1. The proposed BA-GAN structure.

C. Generator

U-Net has demonstrated success in image segmentation, image translation, and enhancement. Through the structure of the encoder and decoder, along with skip connections, U-Net avoids generating blurry images or losing details (such as edges and textures). The symmetric structure of U-Net better preserves spatial correspondences.

The extracted image features are encoded and decoded by the U-Net network, and the same convolution and structural detail residual fusion operations are performed on all branches to improve the features, resulting in feature maps with stronger expressive capabilities. The U-Net network can combine low-level and high level features from the encoder and decoder, fully utilizing contextual texture information. The proposed generator structure is illustrated in Fig. 2.

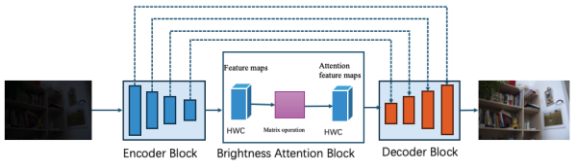

Fig. 2. The structure of the proposed generator.

D. Brightness Attention Module

In the low-light enhancement task, the degradation of the image is not uniformly distributed. Some areas may be almost completely black and require significant brightening, while other areas may have a small amount of light sources and need fine adjustment to avoid overexposure. Due to its fixed local receptive field, the traditional convolution operation has difficulty capturing such global and dynamic illumination dependencies. Therefore, this paper designed an Brightness Attention Module (BAM). Its core objective is to enable the network to adaptively evaluate the importance of different feature channels for the final illumination restoration and recalibrate the features accordingly, so as to achieve precise and differentiated enhancement of illumination.

Our BAM is strategically placed between the encoder and decoder of the U-Net. It takes the deepest feature map $F_{enc} \in R^{C\times H'\times W'}$ output by the encoder as input and performs the following three consecutive operations to generate the attention-calibrated feature map $F_{att} \in R^{C\times H'\times W'}$.

1) Illumination squeeze. First, this paper perform Global Average Pooling on the input feature map F_{enc}, compressing it in the spatial dimension to generate a scalar descriptor for each channel. This process can be regarded as the extraction and generalization of the global illumination information contained in each feature channel. The object is to obtain a vector $z \in R^C$, where each element z_c represents the global illumination response of the c-th feature channel.

$$z_c = F_{sq}(F_{enc}) = \frac{1}{H'\times W'}\sum_{i=1}^{H'}\sum_{j=1}^{W'} F_{enc_c}(i,j) \quad (1)$$

2) Illumination excitation. To learn the complex non-linear illumination dependencies between channels, this paper uses two fully connected (FC) layers to process the compressed descriptor z. The first FC layer reduces the dimension from C to C/r (where r is the reduction ratio) and uses the ReLU activation function. The second FC layer restores the dimension to C and uses the Sigmoid activation function, ultimately generating the attention weights $s \in R^C$ for each channel. The output values of the Sigmoid function range from 0 to 1, which can exactly serve as the "importance" or "gain" weights for each channel. The closer the value is to 1, the more important the channel is for illumination restoration.

$$s = F_{ex}(z, W) = \sigma\big(W_2\delta(W_1 z)\big) \quad (2)$$

Where σ is the Sigmoid function, δ is the ReLU function, and W_1 and W_2 are the weights of two fully connected layers.

3) Feature recalibration. Finally, this paper multiplies the learned channel attention weights s with the original input feature map F_{enc} channel by channel to obtain the final output attention feature map F_{att}. This operation enables the network to enhance the feature channels that are beneficial for illumination enhancement while suppressing the irrelevant channels that may introduce noise or artifacts. This calibrated feature map F_{att} is then fed into the decoder to guide the subsequent image reconstruction process.

$$F_{att_c} = s_c \cdot F_{enc_c} \quad (3)$$

Although the BAM this paper proposed draws on the idea of channel attention in structure [34], its uniqueness and effectiveness are reflected in the following aspects:

- Task Specificity: Different from general attention modules, our BAM is specifically designed to solve the problem of uneven illumination. By modeling global information at the bottleneck of the network, it focuses on learning which regional features should be brightened and which dark - area details should be retained, rather than general feature enhancement.
- Strategic Placement: This paper place the BAM at the bottleneck of the U-Net, instead of spreading it after each convolutional block as in traditional practices. The reason for this design is that performing global illumination calibration at the place where information compression is most extreme allows the decoder to obtain prior knowledge about the overall illumination distribution at the first step of the reconstruction process, thereby more effectively guiding all subsequent upsampling and feature fusion steps and fundamentally reducing artifacts and color distortion.
- Synergy with Loss Function: More importantly, the design of this module forms a synergy with the Brightness Attention Loss function this paper proposed. The BAM learns the intrinsic dependence of illumination at the feature level, while the brightness loss supervises the final brightness accuracy at the pixel level. The two jointly guide the network from different dimensions, ensuring the realism and accuracy of illumination enhancement.

E. Discriminator

In designing the discriminator network, this paper references the PatchGAN discriminator proposed by Isola et al. [27] to replace the traditional binary classifier discriminator. This discriminator outputs an N × N matrix, and the image is judged as real or generated based on the mean value of the matrix. Compared to the traditional binary classifier discriminator, the advantage of using the PatchGAN discriminator lies in its output being a matrix, with the final result being the matrix mean, which fully considers the influence of different regions of the image, thereby enhancing image quality and paying more attention to image details. Additionally, the computation of small-sized image patches significantly accelerates the convergence speed of the network. This paper designs a CNN model with 4 fully convolutional layers. Except for the last convolutional layer, the other 3 layers undergo BatchNorm for data standardization after convolution, and LeakReLu is used as the activation function. The proposed discriminator structure is illustrated in Fig. 3.

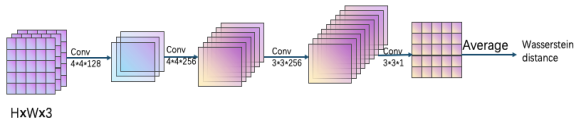

Fig. 3. The structure of the discriminator.

F. Loss Functions

Adversarial Loss [35]. The adversarial loss is the core driving force of the GANs framework. Its fundamental goal is to drive the generator to produce enhanced images that are more visually realistic and indistinguishable from real normal - illuminated images in terms of distribution. This process can be understood as a two - player game involving two networks (the generator G and the discriminator D).

Generator (G): The generator is a U-Net-based network. Its task is to receive a low-light image as input and output an enhanced fake image I_{gen}. The goal of the generator is to deceive the discriminator as much as possible and make it believe that the generated image is real.

Discriminator (D): The discriminator adopts the PatchGAN architecture. Its role is like an image connoisseur or a binary classifier, and its sole goal is to accurately distinguish between the real normal-illumination image I_{real} and the fake image I_{gen} produced by the generator.

$$L_{adv} = E\left[log\left(D(I_{real})\right)\right] + E\left[log\left(1 - D\left(I_{gen}\right)\right)\right] \quad (4)$$

Compared with traditional loss functions that only rely on pixel-level differences (such as L1 or MSE loss), adversarial loss has significant advantages in improving the perceptual quality of images. It does not require the generated image to be exactly the same as the target image in terms of pixels, but encourages the generated image to look more realistic in terms of texture, structure, and overall style.

In particular, the PatchGAN discriminator used in this paper does not output a single true/false judgment for the entire image. Instead, it makes judgments on N×N-sized image patches (Patches) in the image and then averages all the judgment results. This mechanism forces the generator to not only focus on global consistency but also ensure that the local texture and structure of the image are equally realistic, thereby effectively improving the quality of image details and accelerating the convergence of the network.

Brightness Attention Loss. Using global L1 or L2 loss directly between the brightness and the target image treats all regions in the image equally. However, in the low-light enhancement task, the human eye perceives brightness errors differently in different regions [36]. For example, in regions that already have a light source or are rich in texture, slight deviations in brightness are more likely to be noticed and cause artifacts; while in smooth and extremely dark regions, the weight of the error can be relatively lower [37]. To make the model prioritize the key regions that have a greater impact on

visual quality during the optimization process, this paper designed the Brightness Attention Loss Function.

Attention Map Generation. This paper assumes that in regions with drastic luminance changes (i.e., large gradient values), such as edges and textures, the accuracy of luminance restoration is crucial for the overall perceptual quality [38]. Therefore, this paper uses the gradient magnitude of the luminance channel of the target image to generate the attention map A. The specific steps are as follows:

First, this paper uses the standard Sobel operator to calculate the gradients G_x and G_y of the target luminance map Y_{target} in the horizontal and vertical directions respectively.

Then, this paper calculates the gradient magnitude of each pixel.

$$M_{grad}(i,j) = \sqrt{G_x(i,j)^2 + G_y(i,j)^2} \quad (5)$$

To convert the gradient magnitude into a normalized attention weight map A this paper processes it to make its values more concentrated in the key regions. First, this paper normalizes it to the range of $[0,1]$, then add a small constant ε to avoid division by zero, and use it as the final attention weight. The weight map A generated in this way has higher values in the edge and detail regions of the image and lower values in the smooth regions.

$$A(i,j) = \frac{M_{grad}(i,j)}{\max(M_{grad})} + \varepsilon \quad (6)$$

Finally, this paper combines the above attention weight map A with the brightness difference between the generated image Y_{gen} and the target image Y_{target} to define our brightness attention loss.

$$L_{bright} = \frac{1}{H \times W} \sum_{i,j} A(i,j) \cdot \left(Y_{gen}(i,j) - Y_{target}(i,j)\right)^2 \quad (7)$$

This paper uses the weighted L2 loss (squared difference) here mainly for two reasons: First, compared with the L1 loss, the L2 loss imposes a stronger penalty on larger errors, which helps the model quickly correct obvious brightness deviations in the early stage of training. Second, by multiplying with the attention weight A, this loss function forces the generator to prioritize optimizing the brightness accuracy in the key regions of the image structure (such as edges and textures), thereby effectively preserving image details and suppressing artifacts while improving the overall brightness.

Perceptual Loss [35] mainly uses the differences between high-dimensional feature maps of images to guide model training. Perception loss can make the image more similar in high-level information such as content and global structure, ensure the semantic information of the image as much as possible, and also enhance the detail information, which is conducive to the training of unpaired data sets.

$$L_{percep} = \frac{1}{W_i H_i C_i} \left\| \varphi_i(I_x) - \varphi_i(G(I_x)) \right\| \quad (8)$$

Among them, the φ_i represents the ith feature map taken from VGG16 network, I_x represents the input low illumination image, in the feature map, W is the width, H is the height and C is the channel.

Generator loss [9]. In the BA-GAN framework proposed in this paper, the training objectives of the generator are multi-faceted. It not only needs to enhance the image brightness but also ensure the realism of the results and the fidelity of the content. To achieve this complex balance, the optimization of the generator is not driven by a single objective but is guided by a composite loss function. This total loss function L_G is a weighted sum of three independent loss terms, and each term targets a specific aspect of the enhancement process.

$$L_G = \lambda_{adv} * L_{adv} + \lambda_{bright} * L_{bright} + \lambda_{percep} * L_{percep} \quad (9)$$

Among them, λ_{adv}, λ_{bright}, λ_{percep} are weights within the composite generator loss function. Through the synergistic effect of these three loss functions, the generator learns how to strike a balance among multiple objectives during the training process: making the image brighter and accurate, making it look real and natural, and at the same time retaining all the content of the original scene. The weights for the composite loss function were empirically set to λ_{adv}=1, λ_{bright}=1, and λ_{percep}=0.1 to balance the contributions of each component.

Discriminator loss [9]. After each iteration, calculate the loss function to get the difference between the fake and true images, then guide the next step of training. The specific method is to first initialize the model parameters with random values, input a low light image, obtain an enhanced image through a generation network, calculate the error between images using a discriminator, pass the error back along the direction of minimum gradient, modify the parameter values, repeat multiple times until the error value reaches a satisfactory value, and then stop iterating to obtain the final required model.

In the GANs framework proposed in this paper, the discriminator plays the role of an image connoisseur. The discriminator loss (L_D) is the core indicator for measuring the level of its discrimination ability. Its fundamental goal is to drive the discriminator network to more and more accurately distinguish between real normal-illuminated images and enhanced images forged by the generator.

The training process of the discriminator receives two types of inputs:

Real images I_{real}: Real, high-quality normal-illumination images from the LOL dataset.

Fake images I_{gen}: Enhanced images output by the U-Net generator after processing low-light images.

The goal of the discriminator is to output a probability value close to 1 for real images (judged as true) and a probability value close to 0 for fake images (judged as false). To achieve the above goals, the training of the discriminator aims to maximize its loss function L_D, which is defined in the paper as follows:

$$L_D = E[\log D(I_{real})] + E\left[\log\left(1 - D\left(I_{gen}\right)\right)\right] \quad (10)$$

In each training iteration, the model calculates the value of this loss function to measure the difference between the real image and the fake image. Then, this error is backpropagated along the gradient to update the network parameters of the discriminator itself.

Different from traditional discriminators that output a single true/false probability for the entire image, PatchGAN divides the input image into multiple N×N image patches (Patches) and makes a authenticity judgment for each patch, ultimately outputting an N×N matrix. The final judgment result is obtained by taking the average of this matrix. The advantage of this mechanism is that it forces the discriminator to focus on the local details and texture realism of the image, rather than just the global appearance, which helps to improve the overall quality of the generated images and accelerate the convergence of the network.

IV. Experiments

A. Dataset

The existing LOL-dataset [39] is used in this study. The LOL-dataset includes 485:15 pairs of images used for training and testing. The most core feature of the LOL-dataset is that it contains paired images. Each pair consists of an image taken under low-light conditions and its corresponding ground-truth image of the same scene taken under normal lighting conditions. This paired characteristic makes it very suitable for calculating the metrics of model performance. The test set of this dataset is used as a standard platform to objectively evaluate and compare the performance of the method in this paper with other representative algorithms. Below image pairs in Fig. 4 are some of the image samples from the LOL-dataset.

Fig. 4. The image samples from the LOL-dataset.

B. Experimental Setting

Hardware and platform: All training and testing were completed on a server equipped with an NVIDIA GeForce 4090 GPU, and the operating system was Ubuntu.

Software framework: Our model was implemented based on the PyTorch deep learning framework.

Training hyperparameters: The model was trained using the Adam optimizer. The initial learning rate was set to 1e-4, the batch size was set to 64, and the model was trained for a total of 3000 epochs.

Algorithm 1: Training of the proposed BA-GAN Algorithm

Input: Learning rate α, Gradient penalty coefficient λ; Adam optimizer parameters α, β_1, β_2; batch size m; low-light image x_i;

Initialize: discriminator parameters w_0; generator parameters θ_0

While (generator parameter θ not converged do) **do**

  For (each epoch) **do**

    Sample a batch of m low-light images $\{x^{(i)}\}_{i=1}^{m}$ from the dataset.

    Sample a batch of m real normal-light images $\{y^{(i)}\}_{i=1}^{m}$ from the dataset.

    Generate fake images: $\tilde{x}^{(i)} = G_\theta(x^{(i)})$.

    Calculate the discriminator loss L_D:

    $L_D \leftarrow E[\log D_w(y^{(i)})] + E[\log(1 - D_w(\tilde{x}^{(i)}))]$

    Update discriminator parameters via gradient ascent:

    $w \leftarrow w + \alpha \cdot \text{Adam}(\nabla_w L_D, w, \beta_1, \beta_2)$

  End for

  Sample a batch of m low-light images $\{x^{(i)}\}_{i=1}^{m}$ from the dataset.

  Calculate the composite generator loss L_G:

  $L_G \leftarrow \lambda_{adv} L_{adv} + \lambda_{bright} L_{bright} + \lambda_{percep} L_{percep}$

  Update generator parameters via gradient descent:

  $\theta \leftarrow \theta - \alpha \cdot \text{Adam}(\nabla_\theta L_G, \theta, \beta_1, \beta_2)$

End **Output**: The trained generator G_θ.

C. Evaluation Metrics

To more objectively assess the performance of the improved model in this paper, common image assessment algorithms were used to evaluate some representative methods. The evaluation metrics selected were Peak Signal-to-Noise Ratio (PSNR) [40], Structural Similarity Index (SSIM), and Learned Perceptual Image Patch Similarity (LPIPS) [41].

PSNR is a widely used metric for measuring image quality. It evaluates image quality based on the errors between corresponding pixels. This metric quantifies the degree of image distortion by calculating the ratio of the signal (the maximum possible pixel value of the image) to the noise (the mean squared error between the enhanced image and the real image). When evaluating the results, a higher PSNR value indicates better quality and less distortion of the enhanced image.

The calculation of PSNR is based on the Mean Square Error (MSE) [42]. MSE is calculated first, and then PSNR is calculated according to MSE. The calculation formula of MSE is:

$$MSE = \frac{1}{\text{nm}} \sum_{i=1}^{\text{m}} \sum_{j=1}^{\text{n}} \left(I_{(i,j)} - K_{(i,j)}\right)^2 \quad (11)$$

Where m and n are the number of rows and columns of the image, $I(i,j)$is position that the pixel value of the original image, $K(i,j)$ is the pixel value of the processed image at the same position. After obtaining MSE, PSNR can be calculated by the following formula:

$$PSNR = 10 \log_{10} \left(\frac{\text{MAX}_\text{I}^2}{\text{MSE}}\right) \quad (12)$$

Among them, MAX I is the maximum possible image pixel value. For 8-bit images, MAX I is usually 255.

The SSIM quantifies image similarity through three key components: luminance, contrast, and structural composition. Higher SSIM values (ranging from 0 to 1) indicate greater similarity between the enhanced and reference images.

$$SSIM(x,y) = \left(\frac{2\mu_x\mu_y + C_1}{\mu_x^2 + \mu_y^2 + C_1}\right) \cdot \left(\frac{2\sigma_{xy} + C_2}{\sigma_x^2 + \sigma_y^2 + C_2}\right) \quad (13)$$

X and y are the two images to be compared, μ_x And μ_y Average brightness of image x and y, ${\mu_x}^2$ And ${\mu_y}^2$ Is the variance of image x and y, μ_{x_y} is the covariance of image xx and y, and C1 and C2 are small constants added to avoid zero denominator.

LPIPS is a modern metric that measures perceptual similarity by simulating human visual evaluation. It uses a deep learning network to extract and compare the deep features of image patches, thereby determining the similarity between two images in the eyes of human observers. Different from the previous two metrics, a lower LPIPS value (closer to 0) represents higher perceptual fidelity between the two images, meaning they are more similar visually.

V. Results and Discussions

A. Comparsion with other Methods

To evaluate the effectiveness of our method, this paper compares it with several representative low-light enhancement algorithms on the LOL dataset, including HE [11], MSR [14], Retinex-Net [18], EnlightenGAN [25], KinD [19], Zero-DCE [31], and SCI [43]. Quantitative comparisons of these metrics across different methods are presented in Table I.

As shown in Table I, our proposed method achieves the highest SSIM score (0.7963) and the best PSNR (20.7127 dB) among all compared methods, indicating superior structural preservation and noise suppression capabilities. Moreover, our method attains a competitive LPIPS score (0.2271), demonstrating enhanced perceptual quality compared to most baseline approaches. These results validate the effectiveness of integrating U-Net, PatchGAN, and illumination attention for robust LLIE.

Fig. 5 presents qualitative comparisons of enhanced results on representative samples from the LOL dataset using different methods. Compared to EnlightenGAN, Zero-DCE, and SCI, the proposed method achieves superior visual quality in terms of brightness balance, detail preservation, and color fidelity.

Specifically, EnlightenGAN tends to produce over-saturated regions and amplifies noise in extremely dark areas. Zero-DCE improves brightness but suffers from local color distortion and residual noise, particularly in high-texture regions (e.g., books, patterns). SCI shows smoother brightness but lacks sharpness in edges and tends to flatten subtle textures.

In contrast, the proposed method generates enhanced images that are perceptually more natural and visually closer to the ground truth. The edges and structural details (e.g., in cabinets, text, and metal objects) are well preserved, and the illumination is more uniformly distributed across the image. Furthermore, color consistency is notably better, with reduced color cast and halo artifacts compared to the other approaches.

TABLE I Evaluation Results on LOL Dataset

Method	SSIM↑	PSNR↑	LPIPS↓
HE [11]	0.6433	19.9959	0.3551
MSR [14]	0.5327	11.4331	0.3505
Retinex-Net [18]	0.7903	18.9775	**0.2036**
EnlightenGAN [25]	0.7117	15.5693	0.2547
KinD [19]	0.6475	16.0338	0.2979
Zero-DCE [31]	0.6322	15.2961	0.2925
SCI [43]	0.6514	16.4265	0.3156
proposed	**0.7963**	**20.7127**	0.2271

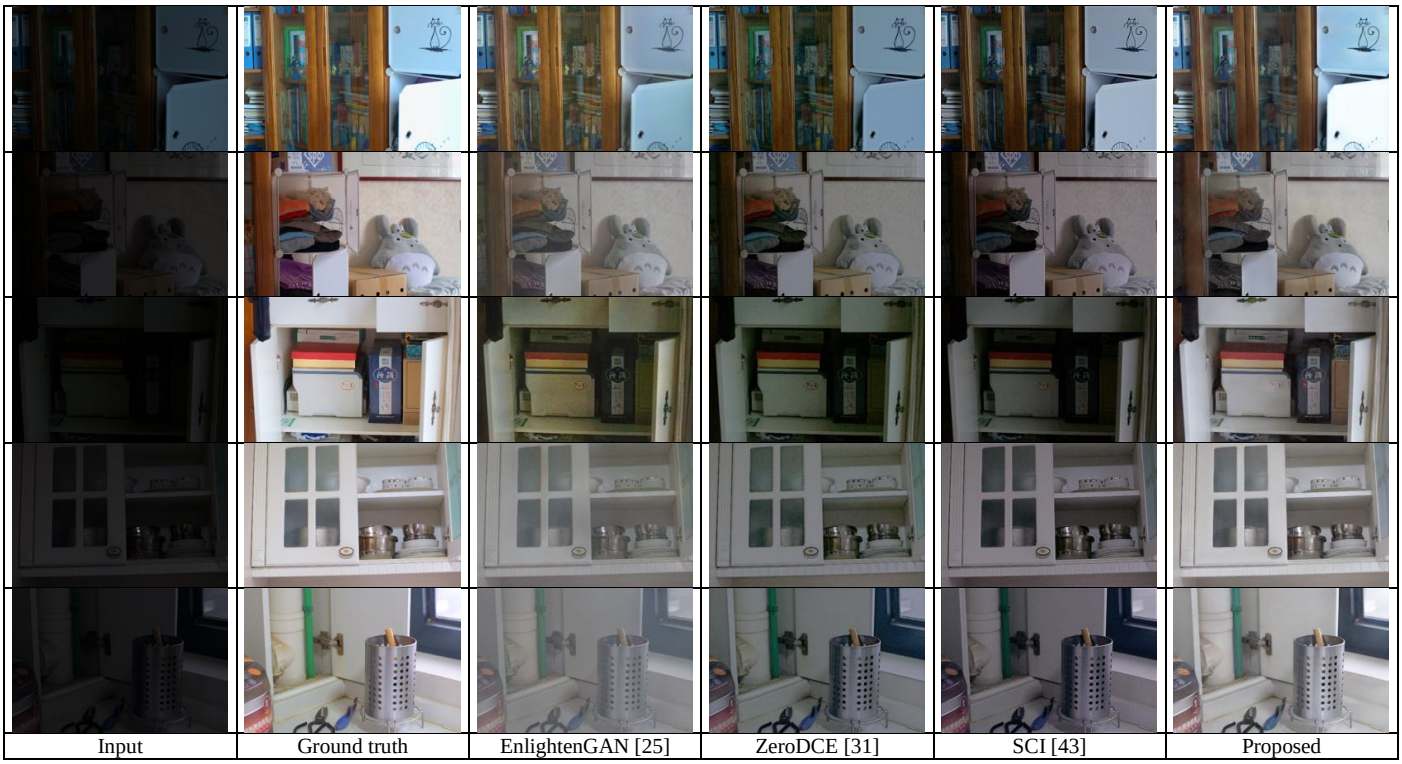

Fig. 5. The enhanced results from the LOL-dataset by different methods.

These results demonstrate the effectiveness of the proposed illumination attention mechanism and edge-aware optimization in guiding the network to enhance low-light images with improved structure, texture, and perceptual realism.

B. Ablation Study

To investigate the efficiency of each module in the proposed model to the final results, four experiments were designed. The following ablated Components were combined for training: U-Net as generator, PatchGAN as discriminator, and Attention module. Finally, the generated models were compared to determine the role of each module in the model. From the Table II, it can be observed:

1) Removing the illumination attention results in PSNR and SSIM decrease, and a deterioration in the LPIPS metric, indicating that illumination perception significantly enhances detail and realism.

2) After removing the PatchGAN discriminator, the image quality metrics slightly decline, suggesting that adversarial training also contributes to improving local details.

3) Without using U-net as the generator, the overall performance decreases, demonstrating that the U-net encoder-decoder structure plays a crucial role in feature modelling under complex illumination conditions.

TABLE II EVALUATION RESULTS FOR ABLATION STUDIES ON LOL-DATASET

Components	SSIM↑	PSNR↑	LPIPS ↓
Full model	**0.7963**	**20.7127**	**0.2271**
w/o attention	0.7012	16.4131	0.3422
w/o patchGAN	0.7054	18.0921	0.3012
w/o U-net	0.5023	12.1091	0.3547

VI. CONCLUSION

This paper addresses the existing challenges in the LLIE task, such as color distortion, noise amplification, and detail loss, and proposes a novel BA-GAN. This framework aims to generate enhanced images that are visually appealing and have high information fidelity through a well-designed end-to-end deep learning model.

The core contribution of this paper lies in the hybrid architecture design of BA-GAN. This paper adopts a U-Net-based generator, which effectively captures multi-scale context features and preserves fine image details through skip connections. The key innovation is that this paper integrates a novel illumination attention module into the decoder of the generator, enabling it to adaptively focus on the regions that require key illumination correction according to the image content. Meanwhile, this paper uses the PatchGAN discriminator architecture to ensure the local realism of the generated images. The entire model is optimized through a composite loss function that combines adversarial loss, brightness attention loss, and perceptual loss, thus achieving an effective balance among the realism, brightness accuracy, and structural fidelity of the images.

To verify the effectiveness of our method, this paper conducted a series of extensive experiments on the public LOL dataset. The quantitative evaluation results show that our BA-GAN outperforms a variety of current mainstream methods in terms of PSNR (20.7127) and SSIM (0.7963), demonstrating its superior ability in structure preservation and noise suppression. Qualitative visual comparisons further prove that our method can significantly improve the visibility of images while effectively suppressing noise and maintaining natural color features. Ablation experiments also verify the key contributions of each module this paper proposed to the final performance.

Although this study has achieved remarkable results, there are still some limitations and future exploration directions. First, as a supervised learning method, our model currently relies on paired training data, which is difficult to obtain in many real-world scenarios. Future work can explore combining the illumination attention mechanism with unsupervised or semi-supervised learning frameworks to enhance the model's generalization ability. Second, further research can be conducted to extend this method from static images to the field of low-light video enhancement and explore how to ensure the temporal consistency between video frames. Finally, future research can systematically evaluate the actual improvement effect of the images enhanced by BA-GAN on the performance of downstream computer vision tasks (such as object detection and image classification).

Power-Aware Video Transmission in 5G Telemedicine: Challenges, Solutions, and Future Directions

Qiuhong SHI, Mingjing CAO*, Yun BAI
College of Physics and Information Engineering, Cangzhou Normal University, Cangzhou 061000, China

***Abstract*—The transformation of healthcare delivery through telemedicine has been significantly accelerated by the deployment of 5G networks and the integration of Internet of Things (IoT) technologies. These advancements enable real-time video-based medical services, including remote operations, urgent care, mobile procedures, and virtual consultations. However, the energy limitations of IoT devices present significant questions regarding long-term video quality and system efficiency. This survey reviews state-of-the-art solutions envisioned for enhancing video transmission in telemedicine environments that are limited by energy consumption but made possible by 5G connectivity. The study discusses recent advances, including efficient video compression techniques, computation offloading via edge computing, adaptive streaming procedures, and dynamic 5G architecture-aware resource scheduling, such as network slicing. It discusses the trade-off between power efficiency and video performance for various telehealth scenarios. Using a scenario-based analysis with a unifying integration framework, this work advances research into energy-efficient e-health systems.**

Keywords*—Telemedicine; Internet of Things; energy efficiency; video transmission

I. INTRODUCTION

The World Health Organization (WHO) recognizes telemedicine as a form of medical treatment delivered through audiovisual and digital communications [1]. Medical care services include diagnosis, consultation, treatment, health education, and the transmission of medical records. The telemedicine architecture can be divided into three layers: sensing, gateways, and healthcare facilities. The Internet of Things (IoT) is a network of people connected to everything, anytime, anywhere. IoT is defined differently in the literature. The IoT provides various healthcare services, including fitness programs, remote health tracking, rehabilitation, and elder care [2]. Telemedicine is essential for remotely monitoring treatments and medications at home [3]. The IoT architecture for telemedicine is based on a range of medical devices, sensors, and imaging devices. Therefore, IoT and telemedicine will contribute to the future comprehensive remote monitoring of the healthcare industry.

Telemedicine has revolutionized healthcare by allowing long-distance consultations, monitoring, and diagnosis through video-based interactions [4]. Along with telemedicine applications that continue to expand exponentially, trustworthy and energy-aware video transmission has become essential, particularly in applications that include battery-constrained IoT technologies, such as wearable health sensors and remote diagnostic tools [5]. These tend to have limited battery life and restricted processing capabilities, for which energy efficiency must be a key consideration. The emergence of 5G networks offers potential solutions to these issues through low latency, higher bandwidth, and highly reliable connectivity [6].

While there is an increasing amount of literature addressing energy efficiency in 5G and IoT systems, previous reviews tend to overgeneralize the solution without adapting it to the specific requirements of telemedicine applications. Most research fails to consider the particular issues related to continuous video transmission in cases such as telemedicine applications in remote surgery, emergency procedures, and long-term patient monitoring via battery-constrained IoT devices. Our review addresses this gap by providing a real-case-driven, holistic treatment of energy-efficient video transmission schemes specifically crafted for telemedicine. By integrating technical solutions with actual healthcare applications, this paper offers focused insights that are often lacking in more general, non-specialized surveys.

This article examines recent advances in energy-efficient video transmission technologies for telemedicine, focusing on the role of 5G and IoT devices. We examine the technical challenges, assess existing solutions, and outline future research directions to enhance energy efficiency in this area. This article makes the following key contributions:

- An in-depth investigation of cutting-edge video encoding and adaptive streaming strategies is provided, aiming to reduce energy consumption in telemedicine applications that utilize resource-constrained IoT devices.
- The role of 5G technology in enhancing video transmission quality and improving energy efficiency in telemedicine applications is demonstrated through network slicing, edge computing, and dynamic power control.
- An analysis of conflicts between Quality of Service (QoS) and energy efficiency is presented, addressing the interoperability issue and identifying the need for AI-driven solutions and energy-conscious protocols in the future development of telemedicine, coupled with IoT and 5G.

II. BACKGROUND AND MOTIVATION

This section outlines the requirements for telemedicine and video transmission, the contribution of 5G networks to the advancement of telemedicine, and the challenges posed by resource-limited IoT devices in healthcare.

A. Telemedicine and Video Transmission Requirements

Telemedicine applications rely on real-time video transmission for remote consultations, diagnosis, and patient monitoring [7]. Video transmission quality and efficiency are crucial for delivering seamless service to both patients and healthcare providers. This subsection outlines the minimum requirements for telemedicine video transmission, including video quality, latency, bandwidth, and energy efficiency, with consideration for resource-constrained IoT devices. Video quality is crucial for telemedicine, as doctors rely heavily on visual information to diagnose and monitor patients [8]. The quality of a video is usually measured by its bit rate, frame rate, and resolution, as shown in Table I.

Telemedicine requires real-time interaction between healthcare professionals and patients. High latency can negatively impact communication and diagnostic processes, as illustrated in Fig. 1, which shows the increasing latency associated with higher video resolutions [9]. In telemedicine, real-time applications require a latency of under 100 milliseconds. Providing high-quality video without interruptions during telemedicine transmissions requires sufficient bandwidth. As shown in Table II, the network type (e.g., Wi-Fi, 4G, 5G) and the number of concurrent users affect the available bandwidth. Typically, bandwidth requirements for telemedicine applications involving high-definition video range from 1 Mbps to 5 Mbps.

Energy efficiency is crucial, particularly when utilizing limited-life battery-powered IoT devices. Telemedicine is one of the most energy-intensive operations in video transmission, involving uninterrupted data encoding, transmission, and reception. Minimizing energy consumption is crucial for enhancing device longevity and maintaining device functionality [10]. Table III depicts energy consumption for different telemedicine video encoding formats. Energy consumption versus telemedicine video quality is shown in Fig. 2.

TABLE I. KEY VIDEO QUALITY PARAMETERS FOR TELEMEDICINE

Parameter	Definition	Typical value in telemedicine
Resolution	Number of pixels in each video frame	720p, 1080p, 4K (depending on use case)
Frame rate	Number of frames per second (fps)	30 fps (for real-time communication)
Bit rate	Amount of data transmitted per second	1-3 Mbps (depending on network conditions)

TABLE II. BANDWIDTH REQUIREMENTS FOR TELEMEDICINE VIDEO TRANSMISSION ACROSS DIFFERENT NETWORK TYPES

Network type	Bandwidth availability	Suitability for telemedicine
Wi-Fi (802.11n)	50-300 Mbps	High-definition video
4G LTE	5-12 Mbps	Basic telemedicine applications
5G (eMBB)	100-1000 Mbps	Ultra-high-definition video

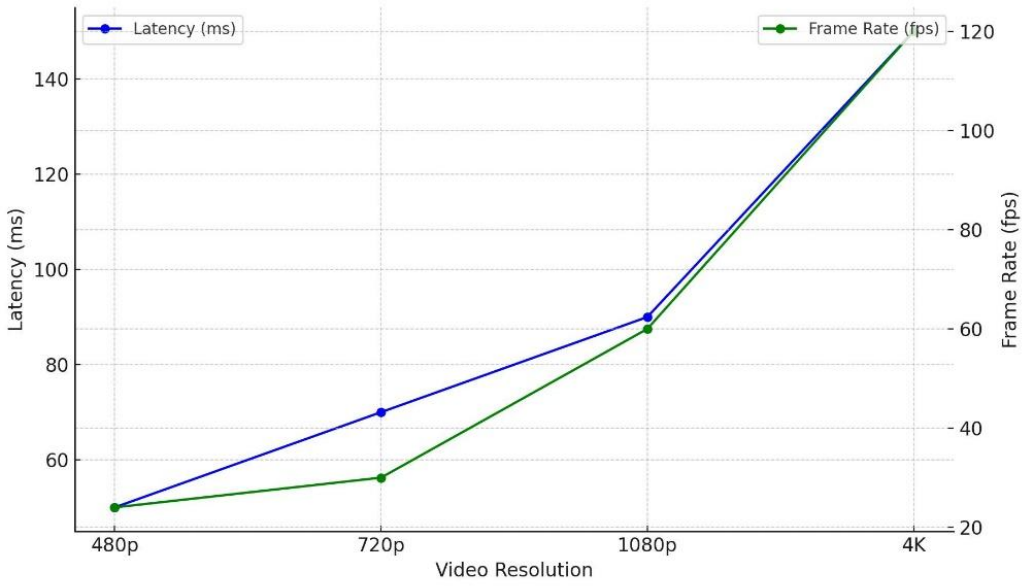

Fig. 1. Relationship between video quality and latency in telemedicine applications.

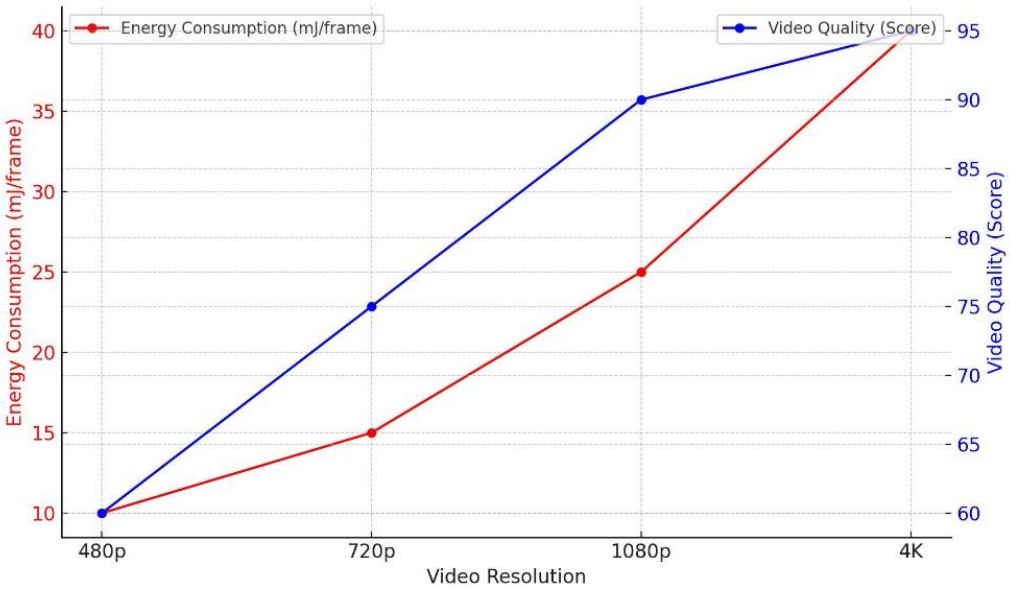

Fig. 2. Relationship between video quality and energy usage in telemedicine.

TABLE III. ENERGY CONSUMPTION OF DIFFERENT VIDEO ENCODING FORMATS IN TELEMEDICINE

Video encoding format	Energy consumption (mJ/frame)	Efficiency
H.264/AVC	15-30	Moderate
H.265/HEVC	8-20	High
VP9	10-25	Moderate

B. 5G Networks and Telemedicine

The 5G network is a transformative technology for telemedicine, offering features such as ultra-low latency, high-speed data transmission, and enhanced interoperability. These features facilitate real-time video transmission in telemedicine applications, facilitating secure and effective interaction between patients and healthcare professionals [11].

5G networks also possess various technologies that qualify them for telemedicine services, including Massive Machine-Type Communications (mMTC), Ultra-Reliable Low Latency Communication (URLLC), and Enhanced Mobile Broadband (eMBB) [12]. eMBB enables bandwidth-intensive applications such as streaming ultra-high-definition video. URLLC provides minimal delay in communication, enabling real-time discussion between patients and medical specialists. mMTC provides opportunities for numerous IoT devices in telemedicine scenarios that require multiple attached sensors, wearables, and remote diagnostics. As highlighted in Table IV, 5G offers specific benefits to telemedicine over previous generations of mobile networks.

High-resolution video streaming makes tele-diagnostics possible with great accuracy. High-bandwidth and low-latency 5G technology would allow real-time teleconsults without delay [13]. IoT-capable health devices, such as wearables and sensors, can collect real-time data on a patient's health status. The mMTC feature of the 5G network can enable the mass deployment of such devices, allowing healthcare professionals to receive real-time data with which to monitor patients. Augmented Reality (AR) technologies are integral to 5G's URLLC technology, especially in remote surgery, where precision and real-time feedback are crucial for telemedicine. The 5G network introduces sleep modes and energy-aware protocols to increase device longevity. Table V illustrates how 5G's energy-efficient protocols impact IoT devices in telemedicine.

TABLE IV. COMPARISON OF 5G WITH PREVIOUS MOBILE NETWORK GENERATIONS FOR TELEMEDICINE

Feature	3G	4G	5G	Impact on telemedicine
Latency	~100-200 ms	~30-50 ms	~1-10 ms	Enables real-time and low-latency video consultations
Bandwidth	~2 Mbps	~10-50 Mbps	~100 Mbps-1 Gbps	Supports high-definition video streaming for remote diagnosis
Device connectivity	Limited	Moderate	Massive (up to 1 million/km²)	Connects large numbers of IoT devices for continuous monitoring
Energy efficiency	Low	Moderate	High	Extends the battery life of IoT devices used in telemedicine
Reliability	Moderate	High	Ultra-reliable	Critical for life-saving remote interventions and consultations

TABLE V. IMPACT OF 5G ENERGY-EFFICIENT PROTOCOLS ON IOT DEVICES IN TELEMEDICINE

Technology	Energy efficiency mechanism	Impact on IoT devices
5G network slicing	Isolating critical applications into slices and optimizing resource use	Reduced energy consumption for telemedicine services
Energy-aware scheduling	Adjusting power consumption based on device activity	Extended battery life of wearable devices in telemedicine
Sleep modes	Permitting devices to sleep when not transmitting	Enhanced energy efficiency, especially in continuous monitoring devices

C. Resource-Constrained IoT Devices in Telemedicine

Telemedicine relies heavily on low-resource devices, such as wearables, portable diagnostic instruments, and sensors. These devices are typically limited in terms of processing power, memory, and battery life, posing significant challenges to energy efficiency and reliability [14]. Innovative approaches to power management, communication standards, and data transmission strategies are needed to ensure the efficient integration of these devices into telemedicine systems.

The lightweight and portable characteristics of IoT devices designed for telemedicine impose some limitations. Most IoT components operate on batteries, limiting their ability to monitor or transmit for long periods. These devices typically have low computing resources, making advanced data processing difficult. Data loss is a significant problem when storage capacity is limited, so using efficient compression and transmission strategies is essential. Table VI summarizes the general limitations of IoT devices used in telemedicine [15].

Resource-constrained IoT devices in telemedicine face several challenges. Video transmission, real-time monitoring, and data collection from IoT devices consume a significant amount of power [16]. Telemedicine environments often require frequent recharging or early device failure, affecting the continuity of care. Delays in IoT devices operating over low-power wireless communication standards, such as Zigbee and Bluetooth, can affect telemedicine services. Table VII compares energy consumption for standard IoT communication protocols.

TABLE VI. RESOURCE-CONSTRAINED IOT LIMITATIONS USED IN TELEMEDICINE

IoT device type	Battery life	Processing power	Memory size	Communication range
Wearable health monitor	1-3 days (continuous use)	Low (single-core MCU)	256 KB – 1 MB	10-30 meters (Bluetooth)
Portable diagnostic tool	6-12 hours (per charge)	Moderate (dual-core CPU)	4-8 GB	50-100 meters (Wi-Fi)
Implantable sensor	Several months (low use)	Very Low (minimal CPU)	64-128 KB	5-10 meters (NFC)

TABLE VII. AN OVERVIEW OF COMMON IOT COMMUNICATION PROTOCOLS IN TELEMEDICINE

Protocol	Typical range	Data rate	Power consumption	Use case in telemedicine
Bluetooth Low Energy (BLE)	10-30 meters	1 Mbps	Low	Wearable health monitors, fitness trackers
Zigbee	10-100 meters	250 Kbps	Very Low	Home health monitoring systems
Wi-Fi	50-100 meters	100-1000 Mbps	High	Video consultations, portable diagnostic tools
NFC	4-10 centimeters	< 500 Kbps	Minimal	Implantable medical sensors

III. ENERGY-EFFICIENT VIDEO TRANSMISSION STRATEGIES

This section discusses energy-efficient video transmission strategies, including video encoding techniques to reduce data sizes, adaptive bitrate streaming for dynamic quality adjustments, and edge computing with caching.

A. Video Encoding

In telemedicine applications, video encoding is crucial for reducing the size of video streams while maintaining quality. Resource-constrained IoT devices and 5G-enabled telemedicine systems require efficient video encoding, which impacts bandwidth usage, transmission latency, and energy consumption [17]. Video encoding reduces the amount of data required for transmission by compressing video files. This process aims to optimize network resources and minimize the load on IoT devices. Standard techniques include H.264/AVC (advanced video encoding), H.265/HEVC (high-efficiency video encoding), and VP9.

H.264 is a popular video compression standard because it has a high compression ratio and is compatible with a wide range of devices [18]. H.265 has better compression than H.264, reducing the bitrate required to transmit high-resolution video by approximately 50% [19]. Google developed VP9 as a royalty-free, open-source video codec that YouTube popularly uses for streaming videos. VP9 is similarly efficient as H.265 but is royalty-free [20]. Table VIII compares the performance and compression efficiency of these encoding standards.

TABLE VIII. PERFORMANCE AND COMPRESSION EFFICIENCY COMPARISON OF COMMON VIDEO ENCODING STANDARDS

Encoding standard	Compression ratio	Energy consumption (mJ/frame)	Video quality retention	Typical use in telemedicine
H.264/AVC	Moderate	15-30	High	Real-time video consultations
H.265/HEVC	High	8-20	Very high	High-definition video diagnosis
VP9	High	10-25	High	Low-latency video transmission

TABLE IX. ENERGY CONSUMPTION OF VIDEO ENCODING STANDARDS AT DIFFERENT RESOLUTIONS USED IN TELEMEDICINE

Resolution	H.264/AVC (mJ/frame)	H.265/HEVC (mJ/frame)	VP9 (mJ/frame)	VP9 (mJ/bit)
480p	10-15	5-8	7-10	~0.04
720p	15-20	8-12	10-15	~0.035
1080p	20-25	12-16	15-20	~0.03
4K	25-30	18-20	28-32	~0.025

Energy efficiency in video encoding is crucial for telemedicine applications, particularly in resource-constrained IoT devices [21]. Efficient video coding methods reduce the computing load on devices, minimize battery consumption, and reduce energy consumption for video transmission over networks. Compared to H.264, H.265 offers the same video quality at half the bit rate, significantly reducing the amount of data transferred. This leads to lower energy consumption. Although VP9 provides similar compression for H.265, it is particularly beneficial for applications that require open-source codecs. Although it uses slightly more power than H.265, it remains a viable option for energy-efficient video transmission. As shown in Table IX, different video coding standards in telemedicine consume different amounts of energy according to their resolution.

Video quality and energy consumption must be optimally balanced in telemedicine. In adaptive video encoding, bit rate, resolution, and frame rate are dynamically adjusted based on real-time network conditions and the energy availability of the transmitting device. This approach is ideally suited for telemedicine consultations and remote monitoring.

B. Adaptive Bitrate Streaming

Adaptive Bitrate Streaming (ABR) provides dynamic adjustments to video quality in response to real-time network conditions and device capabilities in telemedicine [22]. The technology ensures video streams are delivered with minimal buffering and optimal quality, even in environments with fluctuating bandwidth. Video quality and energy efficiency are essential in telemedicine, especially with resource-constrained IoT devices and wireless networks.

ABR encodes video content at multiple bitrates and resolutions. Client devices (e.g., smartphones or IoT devices) constantly monitor network conditions during video playback to ensure smooth streaming. By dynamically adjusting quality levels based on bandwidth availability, device performance, and battery life, this technology ensures uninterrupted transmission while minimizing energy consumption. Client-side monitoring, multiple encoded streams, and dynamic customization are crucial elements of ABR. Videos are encoded at different bit rates to accommodate various network speeds and device capacities (e.g., 360p, 720p, 1080p). The client device sets the video bitrate based on network bandwidth and battery life. Video quality is automatically adjusted according to real-time conditions to ensure smooth playback.

ABR offers several advantages in telemedicine applications, including reduced buffering, improved energy efficiency, and an optimized user experience [23]. A smooth and continuous video stream is ensured by dynamically adjusting the video quality to match the available bandwidth. IoT devices with resource constraints can conserve energy by reducing their bitrate and resolution when network conditions are poor, thereby preventing them from processing high-quality streams that can drain their batteries. Patients and healthcare providers can experience uninterrupted video consultations, even in low-bandwidth or fluctuating network conditions. Table X compares the different video bitrates applicable to telemedicine with their bandwidth requirements and energy consumption.

TABLE X. VIDEO BITRATES, BANDWIDTH, AND ENERGY CONSUMPTION IN TELEMEDICINE USING ABR

Resolution	Bitrate (Kbps)	Bandwidth requirement	Energy consumption (mJ/frame)	Use in telemedicine
360p	500-1000	Low	5-10	Basic consultations
720p	1000-3000	Medium	10-20	Standard remote diagnostics
1080p	3000-6000	High	20-25	High-quality video consultations
4K	6000+	Very High	25-30	High-definition telemedicine

C. Edge Computing and Caching

Telemedicine applications benefit significantly from edge computing and caching, two critical technologies in resource-constrained environments, such as rural areas and mobile health services. These emerging technologies present computing resources proximal to IoT devices and users, consequently entailing low latency, reduced bandwidth usage, and lower energy utilization [24].

With edge computing, data is handled nearer the point of origin (e.g., IoT devices) than from distant cloud servers. This localized processing reduces long-distance data transfers, which is particularly beneficial for telemedicine, where real-time response time is essential. Telemedicine relies heavily on edge computing for real-time video processing, data analysis, AI-driven diagnosis, and latency reduction. Encoding, decoding, and compressing video on the edge reduces processing loads on IoT devices while also conserving battery life. By locally processing medical data at the edge, edge-based AI diagnosis is performed earlier with reduced latency compared to cloud-based systems. Telemedicine services also require minimal latency, as processing data on network edges is crucial for emergency care and real-time consultations. Table XI shows the advantages of edge computing in telemedicine over conventional cloud computing.

TABLE XI. EDGE COMPUTING VS. CLOUD COMPUTING IN TELEMEDICINE

Attribute	Edge Computing	Cloud Computing
Latency	Low (data processed locally)	High (data processed in the distant cloud)
Bandwidth usage	Low (reduced data transmission)	High (frequent data transfer to the cloud)
Energy consumption	Low (offloads computation from devices)	High (IoT devices perform more work)
Real-time responsiveness	High	Moderate
Security	Exposed to edge breaches; AES-256 adds 5–10 mJ/frame	Centralized control; higher encryption scalability

Caching reduces latency and bandwidth usage by temporarily storing frequently accessed content closer to the user. Using edge caching in telemedicine facilitates faster access to medical videos, images, and data by storing them near healthcare providers and patients, thereby reducing the need to repeatedly transmit large files. There are two types of applied caching for telemedicine: Content Delivery Network (CDN) caching and dynamic caching of patient data. CDNs enable healthcare providers to access common healthcare content (e.g., training videos or diagnostic images) more quickly. For smooth interactions, patient data (e.g., diagnostic images or video streams) may be cached on the teleconsultation edge.

While edge computing and caching significantly reduce latency and power consumption, they introduce new security threats. Data processed or stored on edge nodes is more susceptible to unlawful access, physical attacks, or malicious firmware attacks due to its mobility or remoteness. For example, cached patient video streams or images might be vulnerable to data leaks in the event of poor encryption or authentication measures.

Encryption algorithms such as AES-256 provide robust protection for sensitive telemedicine data. However, they incur computational overhead that impacts both latency and energy consumption, particularly in real-time scenarios. Experimental benchmarks indicate that AES-256 encryption adds an average 5–7 ms delay per 1 MB of data and consumes 5–10 mJ/frame in video encoding pipelines, as shown in the updated Table XI. These impacts may be acceptable in high-performance edge nodes but are unsuitable for ultra-low-power IoT devices, such as implantable sensors communicating over NFC.

In such applications, lightweight ciphers like PRESENT, SPECK, or HIGHT become more suitable since they offer good security with minimal processing and energy overhead. PRESENT-80 is an example that has been demonstrated to execute below 0.1 mJ per encryption operation on 8-bit microcontrollers, making it a suitable choice for short-range secure telemetry in implantable telemedicine applications.

D. TinyML and Split Computing for Video Compression

The most up-to-date advances in lightweight AI computing and split computation provide unprecedented opportunities for telemedicine energy optimization. Two possible approaches, video compression with TinyML and split computing, extend wearable IoT sensor capabilities while maintaining minimal dependency on robust edge/cloud computing.

On-microcontroller machine learning with limited resources is achieved with TinyML. It is possible to implement lightweight pre-processing and compression of video locally with MCUNet-type models, effectively reducing upstream data sizes considerably. Low-bitrate data compression with minimal info loss or diagnostic features being extracted is achievable with TinyML compression training in wearable health monitor deployment scenarios in healthcare.

For instance, Lin, et al. [25] showed that compression using MCUNet-based compression on ARM Cortex-M processors achieved encoding energy consumption that was 30% less than H.265 while retaining decent accuracy on tasks for clinical classification. This saving is particularly significant in continual monitoring applications, where energy levels directly impact service continuity.

In split computing, the video compression task is partitioned between the IoT device and the edge server. The device performs basic pre-processing (e.g., frame sampling, region-of-interest extraction), while the more intensive encoding steps are offloaded to nearby edge nodes. This division reduces device-side computational load without significantly increasing transmission overhead. Let E_{total} denote total energy usage, split between local computation E_{local} and transmission E_{tx}:

$$E_{total} = E_{local} + E_{tx} \quad (1)$$

Split computing minimizes $E\ l\ o\ c\ a\ l$ E local by moving complex operations off-device and optimizes $E\ t\ x$ E tx via lightweight encoding on-site. Simulation studies show that combining TinyML with split computing can achieve up to 40% total energy savings in wearable diagnostic scenarios, compared to conventional full-device encoding with H.264 or H.265.

These emerging methods complement traditional approaches like ABR and H.265 by offering context-aware compression, real-time adaptability, and lower reliance on high-throughput edge infrastructure, making them ideal for deployment in rural or bandwidth-limited settings.

IV. NETWORK OPTIMIZATION FOR ENERGY EFFICIENCY

This section explores network optimization techniques for energy efficiency in telemedicine, including 5G network slicing, energy-efficient routing protocols, and power control with dynamic resource allocation.

A. Network Slicing in 5G

Network slicing, a key component of 5G technology, involves the creation of multiple virtual networks from a shared infrastructure, each customized for specific scenarios and service demands [26]. Telemedicine has numerous applications, from real-time video consultations to telesurgery and patient tracking, and network slicing grants each one its respective bandwidth, latency, and connectivity. The technology also

automatically boosts energy efficiency by changing network resources according to telemedicine service demands.

Fig. 3 shows the telemedicine slicing frame. 5G network slicing divides one physical network into multiple virtual slices, each with its own Service-Level Agreement (SLA). Users draw upon resources from that slice that align with their needs. Different slices can be set up for varying measures of performance, such as latency for virtual-real-time video consultations, bandwidth for high-definition video streaming, reliability for vital health data transmission, and energy efficiency for limited devices in the IoT. 5G network slicing optimizes network resources for efficient telemedicine operations without increasing energy consumption. The high-priority slice might be dedicated to remote surgery, which requires high reliability and ultra-low latency. In contrast, the low-priority slice might be allocated to energy-efficient health monitoring devices.

Intelligent health applications can use different network slices, as shown in Fig. 4. This industry requires specialized slices for virtual surgery, smart hospitals, and remote health monitoring. An individual slice can be created for applications requiring high throughput, low latency, and ultra-reliability when performing remote surgery. Remote health monitoring applications and wearable devices can provide secure communication. A dedicated slice can connect medical appliances to a central location.

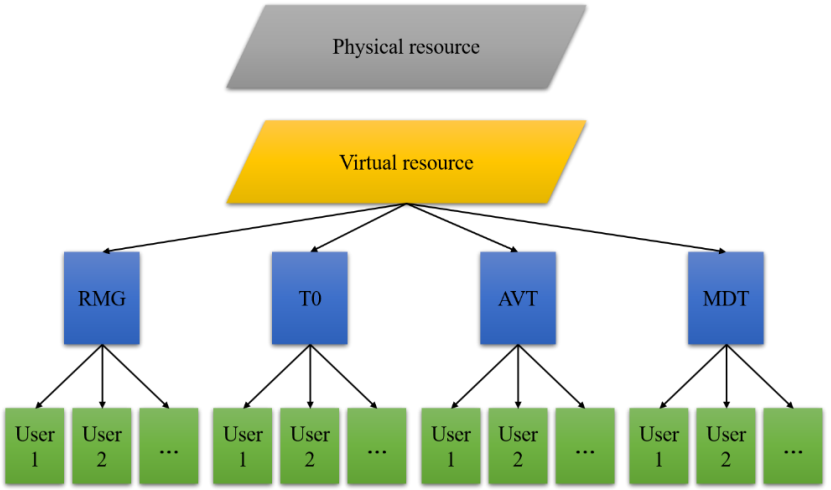

Fig. 3. 5G Network slicing framework for telemedicine.

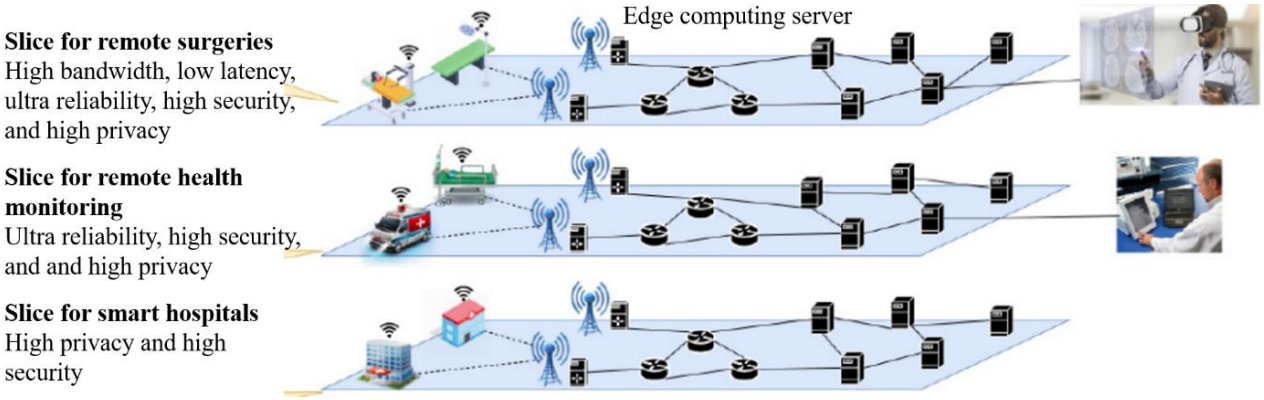

Fig. 4. Network slicing in 5G for telemedicine applications.

As shown in Table XII, network slices can be developed with different energy consumption levels according to application requirements. A high-power slice may be allotted for low-latency video consultations and telecommunication services with high bandwidth for standard real-time connectivity. A low-power slice is ideal for patient telemonitoring, as it reduces bandwidth and latency to achieve low power consumption. Implementing adaptive resource allocation automatically controls energy consumption by the network to optimize utilization, resulting in a simultaneous reduction in energy expenditures for telemedicine services.

B. *Energy-Efficient Routing Protocols*

Using energy-efficient routing protocols is essential in telemedicine networks due to the resource constraints imposed on IoT devices. Sensors and wearables typically have limited battery life and require optimization for efficient communication to forward information. Energy efficiency reduces the energy usage of 5G-enabled telemedicine networks while ensuring high levels of QoS. The resulting routing protocols aim to minimize hop counts, shorten transmission distances, or select low-energy routes while meeting the latency and bandwidth requirements of telemedicine. Table XIII summarizes fundamental routing techniques.

TABLE XII. ENERGY EFFICIENCY IN 5G NETWORK SLICING FOR TELEMEDICINE

Telemedicine application	Required network characteristics	Energy consumption (Average per session)
Real-time video consultations	Low latency and high bandwidth	High (15-20 mJ/frame)
Remote surgery assistance	Ultra-low latency and high reliability	Very high (25-30 mJ/frame)
Remote patient monitoring	Low bandwidth and moderate latency	Low (5-8 mJ/frame)

TABLE XIII. AN OVERVIEW OF ENERGY-EFFICIENT ROUTING PROTOCOLS FOR TELEMEDICINE

Routing protocol	Key feature	Energy efficiency	Use case in telemedicine
Multi-hop	Distributing data across multiple nodes	High (conserves energy for low-power devices)	Continuous patient monitoring
Opportunistic	Selecting paths based on real-time conditions	Moderate to high	Real-time video consultations
Energy-aware geographic	Using node location to select efficient routes	High	Long-term remote health monitoring with sensors

Multi-hop routing is also a common energy-conserving tactic in telemedicine networks, particularly when devices are dispersed over a large geographic area. Multi-hop routing utilizes intermediate nodes to relay data, rather than directly forwarding it to the destination node. Thus, singular IoT devices consume less energy by spreading communication burdens across multiple nodes. For instance, if a telemedicine system comprises numerous sensors that monitor patients, data from remote sensors might be relayed via short-range devices to a server. In this manner, the remote sensor is not subject to as much direct energy stress.

Optimistic routing makes accommodations according to varying network conditions, including bandwidth, node battery life, and traffic. This approach is best suited for applications with real-time requirements, such as teleconsultations, where providing QoS with minimal energy consumption is necessary. In telemedicine applications, wearable sensor devices can be replaced with high-power devices when they run out of battery. Opportunistic routing also accommodates network topology changes, such as when devices move to new locations or become temporarily disconnected.

Energy-aware geographical routing selects data transmission routes with minimum energy consumption based on the nodes' geographical positions. It is also helpful for telemedicine applications with geographically distributed units, such as rural health tracking or mobile health services. Geospatial routing tends to minimize energy usage by selecting nodes for data exchange with minimum distances. For instance, a network in a remote patient surveillance system would select a device closer to the provider for data transmission with minimal energy usage.

C. Power Control and Resource Allocation

Power control and resource allocation greatly enhance energy efficiency for telemedicine networks, particularly in 5G networks, whereby several mobile applications and devices must cooperate. As demonstrated in Table XIV, these technologies ensure that network capacities, i.e., power, bandwidth, and spectrum, are allocated to achieve performance with energy efficiency. In telemedicine applications, where continuity of service and long-term utilization of IoT devices are most significant, effective power control and resource allocation can considerably decrease energy consumption without any trade-off in QoS.

Power control systems dynamically regulate device transmission power according to real-time network conditions, energy availability, and QoS requirements. In telemedicine, where equipment such as wearable sensors and mobile diagnostic instruments has limited battery capacity, power management prolongs their operational lifespan by minimizing excessive energy usage.

Battery-aware power control and context-aware power control are the most prevalent power control technologies. Devices regulate broadcast power according to their proximity to a base station or edge server. Devices close to a base station or edge server minimize power consumption, while devices further away utilize power as needed. Devices also monitor battery levels in various ways and adjust transmission power accordingly. For instance, if battery levels hit a low point, a device minimizes power consumption to conserve power while transmitting vital data. This approach varies power depending on the use environment (e.g., essential telemedicine scenarios such as tele-surgery would focus more on power than monitor applications).

In telemedicine services, 5G networks must partition bandwidth, spectrum, and computing capabilities among multiple applications and devices. Flexible partitioning of these capabilities enables higher-priority applications, such as real-time teleconsultation via video or teleoperation, to be allocated ample resources while minimizing power consumption for lower-priority applications, such as background health tracking.

Power control and resource allocation significantly enhance energy efficiency in telemedicine networks, particularly in 5G networks, where multiple mobile applications and devices must cooperate. As demonstrated in Table XIV, these technologies ensure that network capacities, i.e., power, bandwidth, and spectrum, are allocated to achieve performance with energy efficiency. In telemedicine applications, where continuity of service and long-term utilization of IoT devices are most significant, effective power control and resource allocation can considerably decrease energy consumption without any trade-off in QoS.

TABLE XIV. POWER CONTROL AND RESOURCE ALLOCATION STRATEGIES FOR ENERGY EFFICIENCY IN 5G TELEMEDICINE NETWORKS

Category	Strategy	Description	Energy impact	Telemedicine use case
Power control	Adaptive power control	Adjusting transmission power based on distance	High (saves energy in nearby devices)	Wearable health monitoring
	Battery-aware power control	Reducing power when the battery is low	Moderate (extends device battery)	Remote diagnostic tools
	Context-aware power control	Prioritizing power based on application type	Low to high (application-dependent)	Real-time video consultations and surgery
Resource allocation	Dynamic bandwidth allocation	Modifying bandwidth based on application needs	Moderate (balances QoS and energy)	Video consultations and health monitoring
	Priority-based resource allocation	Allocating resources based on application priority	High for critical applications	Remote surgeries and emergency care
	Energy-aware resource scheduling	Scheduling tasks based on device energy levels	High energy savings	Remote monitoring and health data analytics
Hybrid	Real-time video consultations	High transmission power for low latency	High (to ensure uninterrupted service)	High bandwidth allocation
	Remote patient monitoring	Reducing transmission power	Low	Low bandwidth allocation
	Remote surgery assistance	High transmission power for reliability	Very high (critical application)	High bandwidth and processing power

Power control and resource allocation methodologies employed to enhance energy efficiency couple power control with adaptive resource allocation algorithms, allowing network resources to be utilized to their maximum while minimizing energy wastage. When network demands decrease, power levels can be reduced, along with bandwidth reallocation to lower-power sections.

V. RESULTS AND DISCUSSION

This review comprehensively evaluated existing approaches for satisfying energy-efficient video transmission in 5G-capable telemedicine systems. It was concluded that there are many converging trends and meaningful challenges between video encoding, adaptive streaming, edge computing, and network optimization. Specifically, it was concluded that employing high-efficiency video codes, such as H.265/HEVC and VP9, significantly reduces transmission energy without compromising diagnostic-grade video quality, a crucial requirement for clinical telemedicine applications. Adaptive bitrate streaming was also invaluable for balancing a trade-off between video quality and battery life under fluctuating network conditions and constrained IoT scenarios.

In addition, edge computing and caching capabilities help reduce latency while offloading processing capabilities from energy-limited IoT devices, further extending device lifespans and enhancing end-user application responsiveness for real-time applications, such as teleconsultation and telediagnostics. From a network perspective, 5G functions, including network slices and dynamic resource allocation, help provide end-users with prioritized, customized performance assurance and minimal energy usage.

To verify investigated techniques, experimental works published in the literature provide quantitative measures of codec efficiency and network behavior. For example, experimental investigations have shown that H.265/HEVC reduces the bitrate by up to 50% compared to H.264/AVC for perceptually equal video quality, with a concomitant reduction of up to 40% in energy consumption in battery-powered devices streaming 1080p streams at 30 frames per second over limited networks. VP9 demonstrates similar compression efficiency, though with slightly higher computational complexity, resulting in trade-offs between encoding latency and device power usage. Simulation studies using telemedicine scenarios further show that H.265 achieves a 25–30% reduction in total energy consumption per frame when applied with adaptive bitrate streaming strategies on wearable diagnostic devices.

Additionally, trials for 5G network-slicing-based remote-surgery applications demonstrated end-to-end latencies repeatedly under 10 milliseconds with an energy-aware edge- and core network scheduling. In these trials of remote-surgery applications in managed hospital-to-hospital networks with URLLC slices, there exists not only ultra-low latency potential but also a device-side reduction in energy consumption by a factor of 20 through localized video pre-processing. Parameters like these provide robust real-world validation for feasibility and the promise of these technologies for life-critical clinical applications.

With further advancements in telemedicine, telemedicine systems will require energy-aware transmission technologies for 5G networks and IoT applications. Future research in this area could extend along a range of avenues to enhance the effectiveness, scalability, and energy efficiency of telemedicine systems, while ensuring the security and accessibility of healthcare services. The following research avenues will facilitate this field of study.

Utilizing Artificial Intelligence (AI) and machine learning is one potential area for study to enhance video streaming and encoding. ABR streaming supports active decisions in real-time based on network conditions, device battery levels, and user behavior, with a focus on balancing the trade-off between energy usage and video quality. AI models can examine network utilization patterns and device usage patterns to forecast bandwidth changes or battery consumption, enabling the active modification of encoding parameters. AI-focused solutions can significantly improve energy efficiency for telemedicine applications that are severely limited in resources, such as wearable health sensors or transportable diagnostic equipment.

Future studies should further examine the integration of telemedicine with edge computing for video transmission. Edge

server-based computation of video data near IoT devices reduces the need to transport high-definition video over long distances, thereby conserving bandwidth and power. Research could also utilize video compression, edge-level transcoding, and real-time processing to alleviate computational burdens on resource-poor devices. This would enable battery-powered mobile health units to support high-definition video consultations via telemedicine. Furthermore, integrating technology between edge computing and 5G ultra-reliable low-latency communications may further enhance telemedicine for long-distance interactions.

Blockchain technology can potentially enhance resource allocation in 5G telemedicine networks. The decentralized ledger of blockchain guarantees transparent, equitable, and efficient allocation of bandwidth and power resources across various telemedicine applications. Future research may focus on designing blockchain-based smart contracts that automate the distribution of network resources for video transmission, taking into account device energy levels, network congestion, and QoS requirements. This approach would allow a fairer and more energy-efficient use of 5G infrastructure in telemedicine settings, particularly when managing multiple simultaneous users and applications.

Despite existing compression standards, such as H.265/HEVC and VP9, that provide significant video efficiency improvements, further research on future-generation video compression technologies is needed for telemedicine. Quantum computing-based video compression and neural network-controlled codec-based compression may offer larger compression ratios without compromising video quality, resulting in significantly reduced bandwidth and energy usage. This technology will be most effective for telemedicine applications that demand the continuous transmission of high-resolution video images, such as tele-operations and tele-diagnostics, through real-time video.

Investigating battery-conscious transmission methods for videos can promote energy efficiency by enabling telemedicine networks to adjust bitrate and video quality while preserving battery life in IoT devices. Corresponding protocols would allow IoT devices to consume less power during non-essential times or with depleted batteries while allocating more power for vital occasions or emergencies. Integrating power reduction algorithms in future telemedicine networks can promote wearable device and sensor lifespan while minimizing recharging or battery replacement.

Forthcoming research must prepare for 6G and subsequent technologies. 6G will prioritize green communications, highlighting sustainability and energy efficiency. Researchers can also study the implementations of 6G's ultra-low power transmission techniques, quantum telecommunication, and terahertz radiation in telemedicine networks to further reduce energy usage. Reviews of early work on integrating 6G technology with telemedicine services promise to steer future innovation toward energy-aware healthcare provision.

Machine-learning advancements permit us to achieve predictive ABR streaming, which forecasts bandwidth changes before they occur and provides adaptive adjustments in encoding parameters. Time-series network throughput predictions benefit most from deep learning models, such as Long Short-Term Memory (LSTM) and Gated Recurrent Units (GRU). LSTM-based ABR controllers, for example, achieve up to 90% accuracy in future bandwidth-window predictions, allowing devices to prefetch video segments with optimal bitrate pre-buffering, resulting in reduced re-encoding energy consumption and playback stalling. They can be trained from historical network data and installed on edge nodes or IoT gateways with minimal computation overhead.

VI. Conclusion

5G technology and energy-constrained IoT devices have great potential to convert telemedicine into telemedicine services with real-time, high-grade services. However, one of the most significant concerns is the deployment of energy-aware video transmission, ensuring that IoT devices remain active for extended periods without compromising QoS. This paper presents a detailed review of various energy-aware methodologies, including video encoding schemes, adaptive bitrate streaming, edge computing, caching, network slicing, and power control policies, which play a critical role in reducing energy consumption for telemedicine applications.

By employing sophisticated compression technologies such as H.265/HEVC for videos, along with adaptive bitrate streaming and edge computing, telemedicine deployments can effectively reduce power usage for transmission while maintaining the high definition necessary for accurate diagnosis and consultations. 5G's network slice capabilities also provide for flexible network resource allocation so that mission-critical applications such as tele-surgeries receive whatever bandwidth and low-latency services they require while day-to-day monitoring operations consume little power.

Power control and resource allocation methodologies, such as adaptive power control and battery-aware routing, improve the energy efficiency of telemedicine networks. These methodologies enable IoT devices to communicate with reduced energy consumption levels, thereby extending device lifespan with minimal frequent recharging. Furthermore, future advancements in AI-based video encoding, blockchain-based resource allocation, and emerging telecommunication technologies such as 6G offer further potential for improvements in telemedicine energy efficiency.

***Abstract*—In modern organizational environments, project management information systems (PMIS) play an important role in ensuring project success with the user requirements, keeping overall costs within the planned budget, and delivering projects at the agreed time. Selecting a high-quality PMIS is vital for the success of project management. A software quality model tailored to PMIS, summarizing the intangible software quality metrics (ISQM) that are effective in evaluating a PMIS, can help better decision-making on PMIS for project managers. However, there is limited research on the PMIS-tailored quality model. To fill the gap, this study evaluates effective SQM for PMIS quality assessment. There are two types of PMIS: Web-based PMIS and PMIS software applications. To narrow the context of PMIS, we focus on web-based PMIS since they are widely used across the industry, such as Microsoft Project and Jira. According to the PMIS features, we merely explored the tailored quality models that have been proven to be more appropriate for web-based PMIS rather than the basic models, such as ISO/IEC 9126, ISO/IEC 25010, and Bertoa. This research uses a qualitative approach to conduct the commonality screening among these models and find out the key evaluation metrics, such as usability and functionality, and the corresponding qualitative attributes suitable for Web-based PMIS quality assessment. The selected metrics and attributes are used to form a Web-based PMIS-tailored quality model. The scoring mechanism is introduced based on the PMIS-tailored quality model, where project managers can have a clear comparison among different web-based PMISs, leading to effective web-based PMIS selection for project management.**

Keywords*—*Web-based PMIS; software quality model; intangible software quality metrics; software quality

I. Introduction

In traditional project management (PM), most projects are managed by using a mass of manual documents. A successful project requires complete documentation to execute all project life cycles and make decisions. In terms of this issue, the project team is often faced with the challenge of whether to do documentation or do the project. Thus, some project managers of information systems and information technology projects choose to use the PMIS to help their project management [1].

Project Management Institute (PMI) in their PMBOK GUIDE defines a PMIS as software that can help strategize, organize, and manage resource streams and develop resource approximations [2]. PMIS allows for real-time tracking of project progress, which helps in identifying and mitigating risks promptly. In addition, for large and complex projects, some PMIS like MS Project or Primavera support comprehensive project methodologies and require skilled team members, thus ensuring better management of complex project requirements [3].

The project systems can be grouped into two types [4]:

- Web-based project management systems.
- Project management systems software applications.

Different types of project management systems are utilized to manage projects. They are unique in operation, depending on the kind of project one is managing.

This study is structured systematically to address the research gap. The subsequent sections will first detail the problem statement, research questions, and objectives that form the foundation of this study. Following this, the research methodology is presented, outlining the literature review process and the analysis of existing tailored software quality models. The study then describes the development of the proposed Web-based PMIS-tailored quality model, including the selection of metrics and the calculation of weights based on an expert survey. Finally, the results are presented and discussed, followed by the study's limitations and a conclusion that summarizes the key findings and suggests directions for future research.

II. Problem Statement

In project management processes, the implementation of PMIS implies several changes in the organization's routines. For example, the PMIS was a new software tool in the organization, and therefore, there were also difficulties during the adaptation of the users to the new tool [5]. This reveals the necessity of quality metrics such as usability in PMIS. The successful implementation of any software product relies on the quality of the software. Many existing models can be used to evaluate software quality.

The latest software quality models have undergone standardization processes, such as ISO standards 9126 and 25010 [6]. Each model focuses on a specific metric, and one of the most important factors influencing software quality measurement is selecting the most relevant metric. However, existing studies have not conducted an effective assessment of quality metrics for PMIS. To ensure the success of PM, it is crucial to have better control over the quality metric of PMIS

since "you cannot control that which you cannot measure" [7].

III. Research Questions

The main objective of this study is to analyze the software quality models and ISQM and establish a suitable model for PMIS. The research objective has been achieved by solving these research questions (see Table I):

TABLE I Research Questions

RQ1	What are the commonly used software quality models?
RQ2	What ISQM are involved in these existing models?
RQ3	What is a suitable software quality model for web-based PMIS?
RQ4	What model can be developed for PMIS through modifications or enhancements to the existing quality models?

IV. Objectives

This study aims to identify the effective ISQM for Web-based PMIS. Our approaches include exploring 14 types of existing quality models to find the most relevant metrics for web-based PMIS and evaluating the selected metrics, which will be formulated as a quality model specifically for assessing the ISQM aspects of web-based PMIS. A tool is developed based on the created quality model and identified ISQM to assess the web-based PMIS. Such a tool provides project managers with actionable insights and practical guidelines for selecting web-based PMIS that align with their specific project goals, enabling organizations to enhance project efficiency and success rates.

V. Scope Of Study

1) The software quality model under research is developed based on tailored software quality models.

2) This research adopts a qualitative approach that focuses on selecting qualitative attributes for each ISQM.

3) To narrow the context of PMIS, we focus on web-based PMIS since they are widely used across the industry, such as Microsoft Project and Jira.

VI. Materials And Methods

A. Literature Review

1) Software quality models. Numerous Quality models, such as McCall's Quality Model, Bowen, GHezzi, and ISO/IEC 25010 Quality Model, are used for software quality assessment. These models have been experiencing the standardized process to formulate general metrics for software products like usability, reliability, functionality, and maintainability [7]. For instance, software quality is divided into eight major metrics in the ISO 25010 Quality Model, including functional suitability, performance efficiency, compatibility, usability, reliability, security, maintainability, and portability. These metrics are further subdivided to assess general quality attributes. For example, usability embodies the influence of user adaptability, while reliability measures the system's ability to perform under operational demands [8].

2) Project management information system. PMIS is popular as an essential tool for modern project management. The outlook of project management systems is rapidly evolving, influenced by technological advancements, changing work environments, and emerging methodologies [6].

With the widespread use of PMIS, software quality assurance has become an important aspect of ensuring the efficiency, reliability, and effectiveness of software systems in project management. The quality of software is a necessary factor in the success of project management systems, which can influence user satisfaction, maintenance costs, and overall project success.

B. Related Work

While general software quality models like ISO/IEC 25010 exist, applying them directly to specialized systems like PMIS is challenging [6]. A review of previous studies reveals significant limitations, as shown in Table II. For example, past research has been critiqued for using inadequate models for ubiquitous applications [9], offering limited scope for domains like learning management systems [12], and lacking sufficient attribute coverage and applicability in healthcare systems [13]. A key issue is the failure of older models like ISO/IEC 9126 to include critical modern metrics such as reusability, which is vital for component-based software [11]. This highlights a major gap: a lack of customized evaluation frameworks specifically for PMIS [6].

This study addresses this gap by developing a tailored quality model specifically for web-based PMIS. The research focuses on "tailored models", which are more appropriate for modern COTS PMIS tools like Jira and Microsoft Project, rather than basic models [12]. Using a qualitative screening process, the study identifies the most relevant ISQM to form a "Web-based PMIS-tailored quality model". This new model includes a scoring mechanism to provide project managers with a practical, domain-specific tool for effective PMIS selection, directly filling the identified research gap.

VII. RESEARCH METHODOLOGY

In this section, the main research objective is to analyze the role of web-based PMIS in project management. By defining the key intangible metrics of those project management information systems, combine the existing quality models to develop a Quality assessment tool for an effective project management information system.

A. Analysis of Existing Software Quality Models

The software quality models can be grouped into basic models and tailored models, and software quality models developed until 2000 are classified as basic software quality models, while those developed after 2000 are referred to as tailored software quality models [12]. The basic software quality models have the characteristics of generalizability and standardization that are suitable for a wide range of software system development and quality assessment, while the tailored software quality models or non-basic models are more appropriate for the use of Commercial Off-The-Shelf (COTS) components [12].

Fig.1 shows the two categories of the software quality model.

COTS components refer to commercially available software or hardware products that are ready-made and available for sale, lease, or license to the general public. Nowadays, there are thousands of project management software packages available for purchase. By 2024, in the comprehensive market share analysis provided by Datanyze, an investigation is conducted in the global market size of the Project Management industry is 242110 companies. Fig. 2 shows the survey results on market share and usage, where the top 5 PMIS include Jira, Microsoft Project, Kanban, Airtable, and Smartsheet, accounting for 57.92% of the market share, belonging to the COTS components software system[14]. Thus, we chose the tailored models as the baseline to develop our specific model.

As illustrated in Fig. 1, this study identified 14 distinct tailored software quality models to form the basis of the analysis. Each of these models consists of specific metrics, and each ISQM can be used to measure software quality. To identify the most critical metrics for PMIS, the objective was to analyze these frameworks and list the frequency of each quality metric's appearance across the 14 models. In total, 27 distinct metrics can be derived from these models [15].

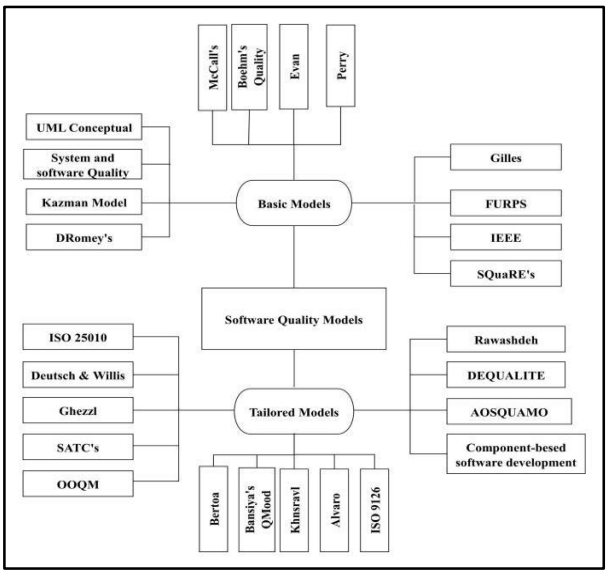

Fig. 1. Two categories of software quality model.

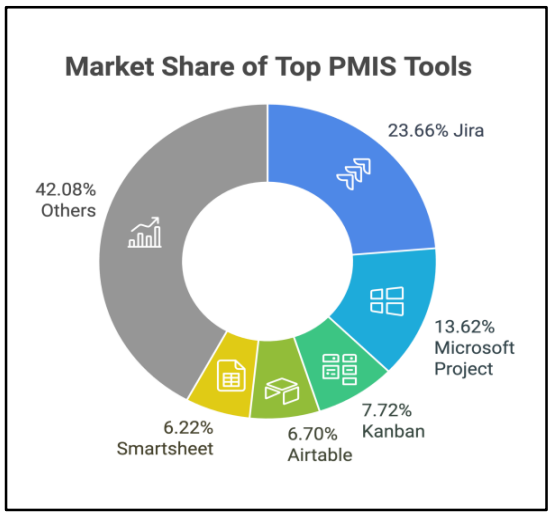

Fig. 2. Market share of top PMIS tools.

Table III provides a detailed mapping of the metrics present in each tailored model, while Fig. 3 visually represents the frequency of these metrics in a bar chart, showing how often each metric is used among the tailored models.

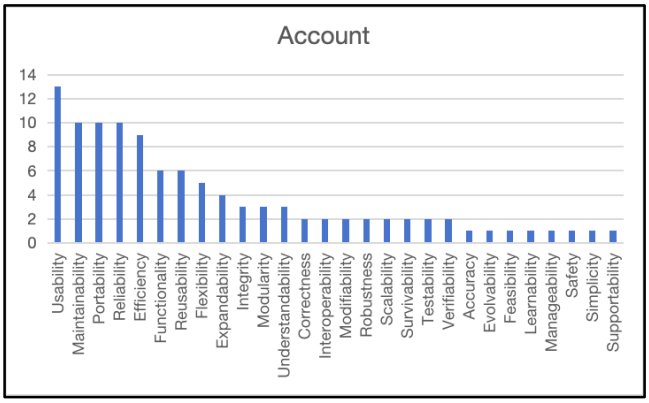

Fig. 3. The metric list ranked by account.

B. The Intangible Software Quality Metric of Quality Models for PMIS

This section discusses the ISQMs for web-based PMIS and identifies which existing quality metrics are suitable for web-based PMIS. The five papers were selected as the reference to identify suitable ISQMs for web-based PMIS. The papers are selected based on the content that discusses the software quality model, the definition of ISQMs, and the web-based PMIS. Additionally, these papers are selected as the reference as they discuss the quality model and ISQM suitable for developing a web-based PMIS that has good quality. Table IV shows the comparison of the proposed quality metrics for web-based PMIS. Five papers were used as a reference to identify which metrics are commonly used. We filtered the metric that appeared more than twice among the five selected papers. We set the threshold of "more than twice" to ensure the validity and robustness of our selection. Table V presents the selected quality metric and the corresponding account.

According to Fig. 3, the top ten metrics most frequently selected for the tailored models are usability, maintainability, portability, reliability, efficiency, functionality, reusability, flexibility, expandability, and integrity. Compared to Table V, 5 out of the 7 selected metrics belong to the above-mentioned top 10 metrics, which proves that our selection is well-founded.

TABLE IV THE COMPARISON OF THE PROPOSED QUALITY METRICS FOR WEB-BASED PMIS

Metric	P1 [3]	P2 [16]	P3 [17]	P4 [18]	P5 [19]
Correctness	✕	✕	✕	✕	✕
Efficiency	✓	✓	✓	✓	✕
Integrity	✕	✕	✕	✕	✕
Reliability	✓	✓	✓	✓	✓
Usability	✓	✓	✓	✓	✓
Maintainability	✕	✕	✓	✕	✕
Flexibility	✕	✕	✕	✕	✕
Testability	✕	✕	✕	✕	✕
Portability	✓	✕	✓	✕	✕
Reusability	✕	✕	✕	✓	✕
Functionality	✓	✓	✓	✓	✓
Interoperability	✓	✓	✓	✓	✕
Verifiability	✕	✕	✕	✕	✕
Survivability	✕	✕	✕	✕	✕
Expandability	✕	✕	✕	✕	✓
Manageability	✕	✕	✕	✓	✕
Safety	✕	✕	✓	✕	✕

Supportability	✕	✕	✕	✕	✓
Modifiability	✕	✕	✕	✕	✕
Understandability	✕	✕	✕	✕	✕
Modularity	✕	✕	✕	✕	✕
Robustness	✕	✕	✕	✕	✕
Scalability	✕	✕	✕	✓	✕
Evolvability	✕	✓	✕	✕	✕
Learnability	✓	✕	✕	✕	✕
Simplicity	✕	✕	✕	✕	✕

TABLE V THE ACCOUNT OF THE SELECTED ISQM

No.	Selected ISQM	Account
1	Reliability	5
2	Usability	5
3	Functionality	5
4	Efficiency	4
5	Interoperability	4
6	Accuracy	4
7	Portability	2

C. The Attributes of Selected ISQM for Web-based PMIS

Up to now, we have integrated 7 ISQM that can be used for web-based PMIS, including reliability, usability, functionality, efficiency, interoperability, accuracy, and portability. Each ISQM has different attributes to measure the software. Table VI shows the attributes of each ISQM and their related tailored models.

TABLE VI THE ATTRIBUTE OF THE METRIC AND ITS RELATED TAILORED MODELS

Metric	Attribute	Related Models
Reliability	Robustness	SATC's;OOQM
	Resilience	ISO 9126
	Fault Tolerance	Ghezzi;ISO 9126
Usability	Learnability	Bansiya's QMOOD
	Satisfaction	SATC's;AOSQUAMO
	Aesthetic Design	Khosravi;DEQUALITE
Functionality	Suitability	SATC's;ISO 25010
	Completeness	DEQUALITE;SATC's
	Appropriateness	SATC's;ISO 25010
Efficiency	Perceived Speed	Bertoa;Alvaro
	Effort Minimization	SATC's;AOSQUAMO
	Optimization Awareness	OOQM;ISO 9126
Interoperability	Ease of Integration	ISO 9126
	Compatibility Perception	ISO 9126
	Cooperation	Deutsch;ISO 9126

	Flexibility of Deployment	SATC's;Alvaro
	Installation Simplicity	OOQM;ISO 9126

D. Software Quality Model for Web-Based PMIS Assessment

So far, by using the qualitative-oriented approach, we have gained effective ISQM and attributes for web-based PMIS quality assessment. It is then that we finalize our web-based PMIS software quality model.

E. Data Collection and Analysis

The purpose of this work is to request the software project manager or the expert in the Software project field to review and evaluate the Web-based Project Management Information System Quality Assessment model. Rate the identified intangible metrics and attributes according to their influence and priority for PMIS. The questionnaire consists of two sections with 27 questions.

The first section collects background information from respondents, including professional certification, gender, age, project management experience, number of managed projects, and email. Table VII outlines the demographic profile of the study's respondents. It categorizes participants based on four key variables:

- Age: Respondents are grouped into three age brackets: 30-34 years and 35 to 39 years.
- Experience in project management: Professional experience is classified into three levels based on duration: 5 to 7 years, 7 to 10 years, and more than 10 years.
- Number of Software Projects Managed: This variable quantifies the volume of project management experience, with categories for 5 to 10 projects, 11 to 20 projects, and more than 20 projects managed.
- Workplace: The geographical location of the respondents' work is categorized as Malaysia, China, or Others.

TABLE VII THE RESPONDENTS' BACKGROUND INFORMATION

Demographic Variable	Category	n	%
Workplace	Malaysia	2	18%
	China	8	73%
	Others	1	9%
Certification	PMP	10	91%
	Others	1	9%
Age	30-34 Years	9	82%
	35-39 Years	2	18%
Experience in project management	5-7 Years	8	73%
	7-10 Years	2	18%
	More than 10 years	1	9%
Number of Software Projects Managed	5-10	3	27%
	11-20	6	55%
	More than 20	2	18%

The second section of the questionnaire was designed to assess the 7 major quality metrics and their 21 associated attributes, which were rated by respondents based on their priority and influence using a five-point Likert scale. The survey was conducted with 11 project managers from various countries.

Table VIII presents the aggregated results from the survey, providing the average "Priority" and "Influence" scores for each of the 7 quality metrics and their 21 corresponding attributes. These scores serve as the empirical data used to calculate the weights for the final quality model, ensuring it is based on the real-world perspectives of experienced practitioners.

TABLE VIII THE SURVEY RESULT

Metric	Priority	Influence	Attributes	Priority	Influence
Reliability	4.45	4.55	Robustness	4.45	4.36
			Resilience	4.27	4.09
			Fault Tolerance	4.27	4.09
Usability	3.91	4.09	Learnability	3.91	3.91
			Satisfaction	4	4
			Aesthetic Design	3.45	3.18
Functionality	4.09	4.27	Suitability	4.64	4.64
			Completeness	3.73	4
			Appropriateness	4.18	3.19
Interoperability	3.27	3.36	Ease of Integration	3.36	3.36
			Compatibility Perception	3.18	3.27
			Cooperation	3.18	3.36
Accuracy	4.64	4.55	Correctness	4.64	4.36
			Precision in Context	4.18	4.36
			Trustworthiness	4.45	4.36
Portability	2.91	3.45	Ease of Adaptation	2.64	3.18
			Flexibility of Deployment	3	3.45
			Installation Simplicity	2.82	3.09
Efficiency	3.73	3.64	Perceived Speed	3.91	3.91
			Effort Minimization	3.45	3.82
			Optimization Awareness	3.18	3.27

VIII. RESULTS AND DISCUSSION

A. Results

This study proposed a tailored quality evaluation model for Web-based PMIS by identifying and structuring key ISQM. Through a comprehensive qualitative analysis of 14 existing software quality models and empirical validation via expert surveys, seven critical metrics: reliability, usability, functionality, efficiency, interoperability, accuracy, and portability, were selected. A quantifiable assessment framework was then constructed by breaking down each metric into specific attributes and applying weights derived from practitioner-assigned priority and influence scores.

The primary result of this research is a quantifiable and customizable quality model for Web-based PMIS, developed by aggregating survey scores through a dual-layered formula. The final weighted model is visualized in Fig. 4.

The result of the survey shows that the top three metrics by weight were accuracy (19.30%), reliability (18.51%), and functionality (15.95%). Notably, accuracy and reliability emerged as the most critical metrics, reflecting the high-stakes environment in which PMIS tools operate. Project managers rely heavily on real-time data, progress tracking, and precise reporting; thus, even minor inaccuracies can have cascading effects on project delivery. Functionality also scored highly, confirming that systems must be aligned with core project management requirements rather than generic software capabilities.

In contrast, portability received the lowest priority and influence scores. This may reflect the current ubiquity of web-based platforms and standardized deployment environments, making portability less of a concern in modern enterprise settings.

A. Discussion

The high scores for accuracy, reliability, and functionality underscore that for project managers, PMIS tools must provide precise, dependable data and align closely with core project management tasks. The reliance on real-time data for tracking and reporting means that even small errors can have significant negative impacts on project outcomes.

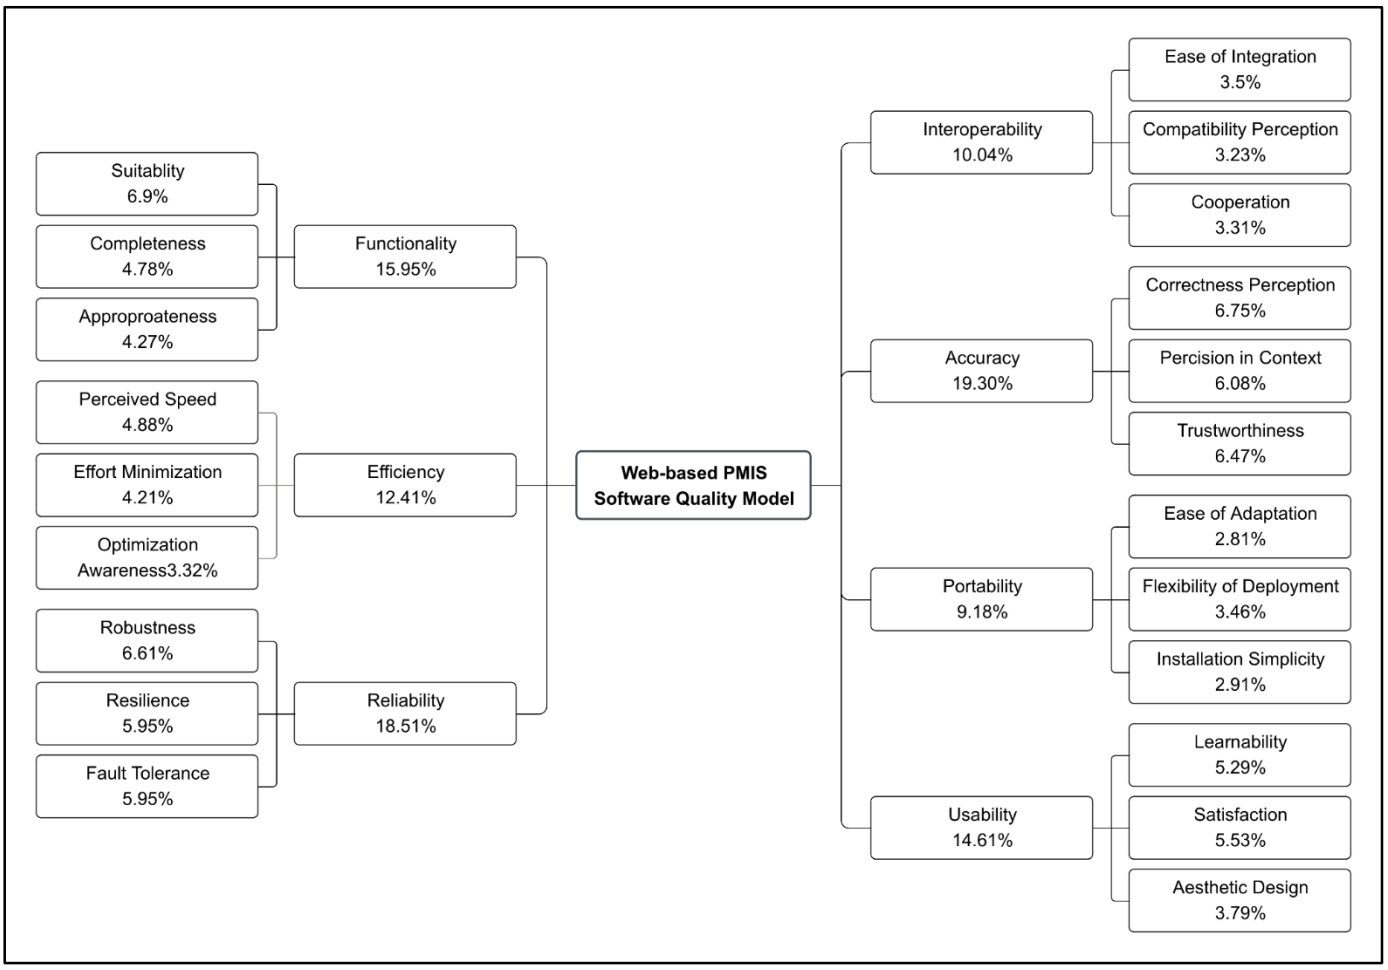

Fig. 4. The result of the software quality model for web-based PMIS.

The model's reliance on expert-derived weighting ensures that it can evolve with practitioner priorities. Organizations can adapt the weights according to their context, allowing for dynamic and scenario-specific PMIS evaluation and selection.

However, this study is not without limitations:

- The generalizability of the results may be affected by the small survey sample size of 11 project managers.
- All participants were primarily from China and Malaysia, potentially limiting the generalizability of the results across different industries and regions.
- The research focused exclusively on Web-based PMIS, excluding other forms such as mobile or hybrid systems that may introduce additional quality considerations.

IX. Conclusion

A. Summary of Research

This research established a specialized software quality model tailored for Web-based PMIS. The study systematically identified effective ISQM by analyzing 14 existing quality models. These metrics were then validated and refined through a survey of 11 project management professionals who rated each metric and its corresponding attributes based on their priority and influence in a project environment. The collected data was used to create a weighted, quantifiable assessment framework. The final model confirms that accuracy, reliability, and functionality are the most vital quality characteristics, offering a practical tool to guide project managers in making informed decisions for PMIS selection.

B. Future Work

To build upon this research, several future directions are recommended:

- The model's robustness and applicability could be enhanced by expanding the survey to a larger and more diverse group of stakeholders, both geographically and professionally.
- A valuable next step would be to integrate this framework into a real-world PMIS selection tool and validate its effect on project success metrics through case studies or longitudinal research.
- Future studies could also investigate dynamic weighting schemes, potentially utilizing machine learning, to enable the model to adapt automatically to an organization's specific context and evolving user priorities.

CNN-LinATFormer: Enhancing PM2.5 Prediction Through Feature Assessment and Linear Attention Mechanism

Yuchen Zhang, Rajermani Thinakaran
Faculty of Data Science and Information Technology, INTl International University, Malaysia

***Abstract*—Atmospheric fine particulate matter (PM2.5) poses a serious threat to public health, and its accurate prediction is crucial for environmental management and pollution control. However, existing prediction methods have difficulty in effectively capturing the complex nonlinear characteristics and multi-scale spatiotemporal dependencies of PM2.5 concentration changes. To address this challenge, this study proposes a CNN-LinATFormer hybrid deep learning architecture that combines the local feature extraction capabilities of CNN with the global dependency modeling advantages of the linear attention mechanism. The model innovatively introduces a feature evaluator to dynamically classify environmental features into three categories, and achieves targeted processing through three specially designed processing branches: CNN feature extraction, channel attention, and linear attention fusion. Based on the urban monitoring data of 9 environmental feature dimensions from 2020 to 2023, the experimental evaluation results show that CNN-LinATFormer outperforms the existing methods in all evaluation indicators, with an RMSE of 8.42μg/m³, which is 21.1% lower than the CNN-RF model with the closest performance; the ablation experiment confirms the effectiveness of each component, especKeywords-PM2.5 prediction; air quality forecasting; deep learning; convolutional neural network; linear attention mechanism; channel attention; feature assessment; hybrid model architecture; environmental monitoring; spatiotemporal modeling the channel attention mechanism; the case analysis reveals that the model performs well in the low concentration range (RMSE is 3.12μg/m³), but the high pollution range (>150μg/m³) still needs to be improved. This study provides a new technical path for air quality prediction, which is of great value to environmental monitoring and public health protection.**

I. INTRODUCTION

In recent years, with the acceleration of industrialization and urbanization, atmospheric fine particulate matter (PM2.5) pollution has become a major environmental issue of global concern. PM2.5 particles are less than 2.5 microns in diameter and can penetrate the human respiratory defense barrier and penetrate deep into the alveoli, causing a series of respiratory and cardiovascular diseases and even leading to early death [1] [2]. According to the World Health Organization, about 7 million deaths are related to air pollution each year worldwide, of which PM2.5 is considered to be one of the most harmful air pollutants [3]. Accurate prediction of PM2.5 concentration is crucial to air quality management. It can not only provide a basis for decision-making by environmental regulatory authorities, but also help the public take appropriate health protection measures. Environmental monitoring data show that PM2.5 concentrations in many cities in my country still exceed the national ambient air quality standards and the World Health Organization's recommended values. As Zhang et al. [4] pointed out, with the acceleration of China's industrialization process, accurate prediction of air quality is of great strategic significance for pollution prevention and control and public health protection.

Traditional PM2.5 prediction methods mainly include deterministic methods, statistical methods, and machine learning methods. Although deterministic methods such as chemical transport models can simulate the complex physical and chemical processes of pollutants, they require a lot of computing resources and detailed emission inventories, and their real-time prediction capabilities are limited. Berrocal et al. [5] compared statistical methods and machine learning methods in creating daily maps of national PM2.5 concentrations and found that spatial statistical models are generally better than machine learning methods when making predictions at unsampled locations, which reflects the advantages and disadvantages of different methods in specific application scenarios. The comparative experiments in this study further confirmed this, among which Random Forest (RF) performed relatively well (RMSE was 12.49 μg/m³), thanks to its advantage of integrated decision trees that can effectively handle nonlinear environmental data, while Support Vector Regression (SVR) performed poorly (RMSE was 14.28 μg/m³). However, these single-model methods still have limitations in capturing the complex spatiotemporal patterns of PM2.5 concentration changes and the interactions of multiple factors.

In recent years, deep learning technology has made remarkable progress in the field of environmental data prediction, providing a new research direction for PM2.5 prediction. Convolutional neural networks (CNNs) can effectively extract local spatiotemporal features; long short-term memory networks (LSTMs) and gated recurrent units (GRUs) can capture long-term temporal dependencies; and the attention mechanism can dynamically focus on key features and time points. The comparative experiments in this study showed that although LSTM (RMSE is 13.89μg/m³) can capture temporal dependencies, it is weak in processing multi-feature interactions; while the CNN-RF model (RMSE is

10.67μg/m³) that combines the advantages of CNN and RF performs well. The hybrid algorithm proposed by Cheng et al. [6] achieved remarkable results in short-term PM2.5 prediction in China, demonstrating the potential of hybrid models in improving prediction accuracy. The research of Peng et al. [7] also showed that deep learning models have significant advantages in handling nonlinear relationships and multi-source data fusion. Lu et al. [8] further addressed the challenge of data distribution differences in different regions and periods in PM2.5 prediction using a transfer learning method based on ADGRU. However, how to design a PM2.5 prediction model that can fully utilize the advantages of different deep learning structures and adaptively process different characteristics and pollution levels remains an important research topic.

To address the above challenges, this study proposed an innovative CNN-LinATFormer hybrid deep learning architecture designed for high-precision PM2.5 concentration prediction. The model consists of three main parts: input data processing, feature processing, and generating predictions. The core innovation lies in the introduction of a feature evaluator, which classifies the input features into primary features, secondary features, and tertiary features, which are processed by the CNN feature extraction branch, channel attention branch, and linear attention fusion branch, respectively. Finally, the multi-branch outputs are integrated through the feature generation and prediction module to generate the final PM2.5 prediction value. Comprehensive experimental evaluation shows that the CNN-LinATFormer model outperforms existing methods in all evaluation indicators, with RMSE of 8.42μg/m³, MAE of 5.76μg/m³, and MAPE of 9.12%, which are improvements of 21.1%, 24.8%, and 26.7%, respectively, compared with the closest CNN-RF model. Ablation experiments confirm the effectiveness of each component, especially the introduction of the channel attention mechanism brings the most significant improvement in single-step performance (RMSE decreases by 4.5%). Hyperparameter optimization and case analysis further reveal the performance characteristics and optimization directions of the model under different conditions. The contribution of this study is that a feature-driven adaptive hybrid deep learning architecture is proposed, which not only achieves significant improvements in prediction accuracy but also achieves breakthroughs in model interpretability and adaptability, providing new technical solutions and research ideas for the fields of environmental monitoring and air quality warning [9].

II. Related Work

A. Traditional PM2.5 Prediction Methods

PM2.5 prediction methods have evolved from traditional statistical models to machine learning methods. Early studies mainly used time series analysis methods, such as autoregressive integrated moving average (ARIMA) and seasonal ARIMA (SARIMA), which used historical observation data to build linear models to predict future concentration values. Berrocal et al. [5] compared the performance of statistical methods and machine learning methods in creating daily maps of national PM2.5 concentrations and found that spatial statistical models usually have certain advantages when making predictions at unsampled locations. However, such methods have difficulty capturing nonlinear relationships and complex patterns in environmental data, and their prediction accuracy is limited.

With the development of machine learning technology, methods such as SVR, RF and gradient boosting tree (GBT) have been widely used in PM2.5 prediction. As shown in the comparative experiments of this study, RF performed relatively well (RMSE was 12.49 μg/m³), which is attributed to its integrated Decision Tree (DT) architecture that can effectively handle nonlinear environmental data. The hybrid algorithm proposed by Cheng et al. [6] for short-term PM2.5 prediction in China further improved the prediction accuracy by combining the advantages of different methods. Although traditional machine learning methods have achieved certain success in PM2.5 prediction, they still have difficulty in fully exploring the complex interactions between time dependence and multidimensional features in environmental data, especially in extreme pollution events and complex meteorological conditions. The prediction ability is limited, which is one of the main motivations for proposing the CNN-LinATFormer model in this study.

B. Application of Deep Learning in PM2.5 Prediction

Deep learning technology has made remarkable progress in the field of PM2.5 prediction in recent years due to its powerful representation learning capabilities. CNN can effectively extract local features and spatial patterns of PM2.5 time series through its local connection and weight-sharing characteristics. Peng et al. [7] applied CNN to PM2.5 concentration simulation and prediction, demonstrating its advantages in capturing the spatiotemporal distribution characteristics of pollutants. Recurrent neural networks (RNNs), especially LSTMs and GRUs, solve the gradient vanishing problem of traditional RNNs through specially designed gating mechanisms and can effectively model long-term temporal dependencies.

The comparative experimental results of this study show that although the LSTM model (RMSE is 13.89 μg/m³) can capture temporal dependencies, it is relatively weak in processing multi-feature interactions; while the GRU-ED model (RMSE is 11.77 μg/m³) enhances the modeling ability of long-term dependencies through the encoder-decoder architecture. In recent years, researchers have begun to explore hybrid deep learning architectures, such as the CNN-LSTM combination model, which uses CNN to extract spatial features and LSTM to model temporal dependencies. Lu et al. [8] proposed a transfer learning method based on ADGRU, which solved the problems of uneven data distribution and insufficient model generalization ability in PM2.5 prediction through cross-domain learning. The CNN-LinATFormer model proposed in this study draws on the advantages of these advanced methods and further improves the prediction performance through innovative architecture design, especially in the differentiated processing of different types of environmental features and multi-scale temporal dependency modeling.

C. Application of Attention Mechanism and Linear Transformer in Time Series Prediction

The introduction of the attention mechanism provides deep learning models with the ability to "focus on key points",

enabling the model to dynamically focus on the most relevant parts of the input sequence for prediction. The traditional self-attention mechanism achieves adaptive representation of the input sequence by calculating the similarity between the query and the key and weighting the value vector accordingly. However, the self-attention calculation complexity of the standard Transformer is $O(n^2)$, which is computationally expensive when processing long sequence data. In response to this challenge, researchers have proposed a variety of improvement schemes, among which the linear attention mechanism reduces the computational complexity to O(n) by redefining the attention calculation method while maintaining the expressive power of the model.

The CNN-LinATFormer model proposed in this study innovatively applies the linear attention mechanism to the PM2.5 prediction task, specifically processing inputs evaluated as three-level features. By adopting the feature mapping function $\varphi(x)=\text{elu}(x)+1$, the model can significantly improve the computational efficiency while maintaining high prediction accuracy, which is particularly suitable for processing long sequence environmental data. At the same time, the channel attention mechanism introduced by the model assigns adaptive weights to secondary features, further enhancing the sensitivity to key environmental factors. The ablation experiment results show that the addition of the channel attention mechanism brings the most significant single-step performance improvement (RMSE decreases by 4.5%), which verifies the important value of the attention mechanism in PM2.5 prediction. Compared with existing methods, the CNN-LinATFormer model achieves differentiated processing of different types of environmental features through feature evaluators and multi-branch processing architectures, while improving prediction accuracy while maintaining high computational efficiency and model interpretability, providing new research ideas for environmental time series prediction [10].

III. Methodology

A. Connection

This study models PM2.5 prediction as a supervised learning time series prediction problem: given the environmental monitoring data of the past 24-time steps, including environmental characteristics such as temperature (℃), relative humidity (%), PM2.5 (μg/m³), predict the target PM2.5 concentration value in the next time step. The selection of 24 hours as the prediction window is mainly based on two considerations: first, air quality indicators usually show obvious daily cycle characteristics, and the 24-hour time window can fully capture this periodic pattern; second, according to environmental science research, the diffusion and transformation process of atmospheric pollutants usually completes a full cycle within 24 hours. Formally, if the input feature of the t-th time step is expressed as $x_t \in R^n$, the prediction task can be expressed as: predict the target value y_{t+1} based on the observation sequence:

$$\hat{y}_{t+1} = f(\{x_{t-23}, x_{t-22}, \dots, x_t\}) \quad (1)$$

B. Overall Architecture Design

To address the complex challenges in PM2.5 prediction, this study proposes the CNN-LinATFormer model, an innovative hybrid deep learning architecture designed for high-precision PM2.5 concentration prediction. As shown in Fig. 1, the model consists of three main parts: input data processing, feature processing, and prediction generation. The input stage receives environmental time series data X, which contains multi-dimensional features such as temperature, humidity, and PM2.5 historical values; the feature processing stage uses a feature evaluator to classify the input features and assign them to the corresponding processing branches; the generation stage integrates the multi-branch processing results and outputs the final PM2.5 prediction value. This hierarchical design enables the model to simultaneously consider the relative importance of different features and apply the most suitable processing strategy for each type of feature, thereby effectively handling the complex nonlinear relationships and multi-scale time dependencies in environmental data.

C. Feature Estimator

The feature evaluator is the core innovative component of this model. Its main purpose is to evaluate the importance of different environmental features for PM2.5 prediction and dynamically assign the features to the most suitable processing branches. Based on environmental science research, different environmental features have different degrees of influence on the formation and propagation of PM2.5. The feature evaluator classifies the features into three categories: primary features, secondary features, and tertiary features by evaluating their relevance. The evaluator is implemented using a lightweight neural network, and its mathematical expression is:

$$S = \text{softmax}(W_2 \cdot \text{ReLU}(W_1 \cdot X + b_1) + b_2) \quad (2)$$

where, S is the feature importance score vector. This design enables the model to identify and distinguish between key features that directly affect PM2.5 (such as PM2.5 concentration at the previous moment) and auxiliary features that indirectly affect PM2.5 (such as temperature and humidity), thereby providing more accurate feature classification for subsequent processing and enhancing the adaptability and interpretability of the model.

D. CNN Feature Extraction Branch

The CNN feature extraction branch specifically processes inputs that are evaluated as major features, aiming to capture local temporal patterns and interactions between features. This branch adopts the design principle of "decomposition-filtering-recombination", decomposing input features through multiple layers of one-dimensional convolution to capture the change patterns at different time scales; using the cross-attention mechanism to identify and filter out irrelevant or noisy features; and finally recombining the filtered features through transposed convolution to generate high-quality feature representation Y_1. The key convolution operation can be expressed as:

$$F_l = \text{ReLU}(\text{Batch}\mathit{Norm}(\text{Conv1D}(X, K_l))) \quad (3)$$

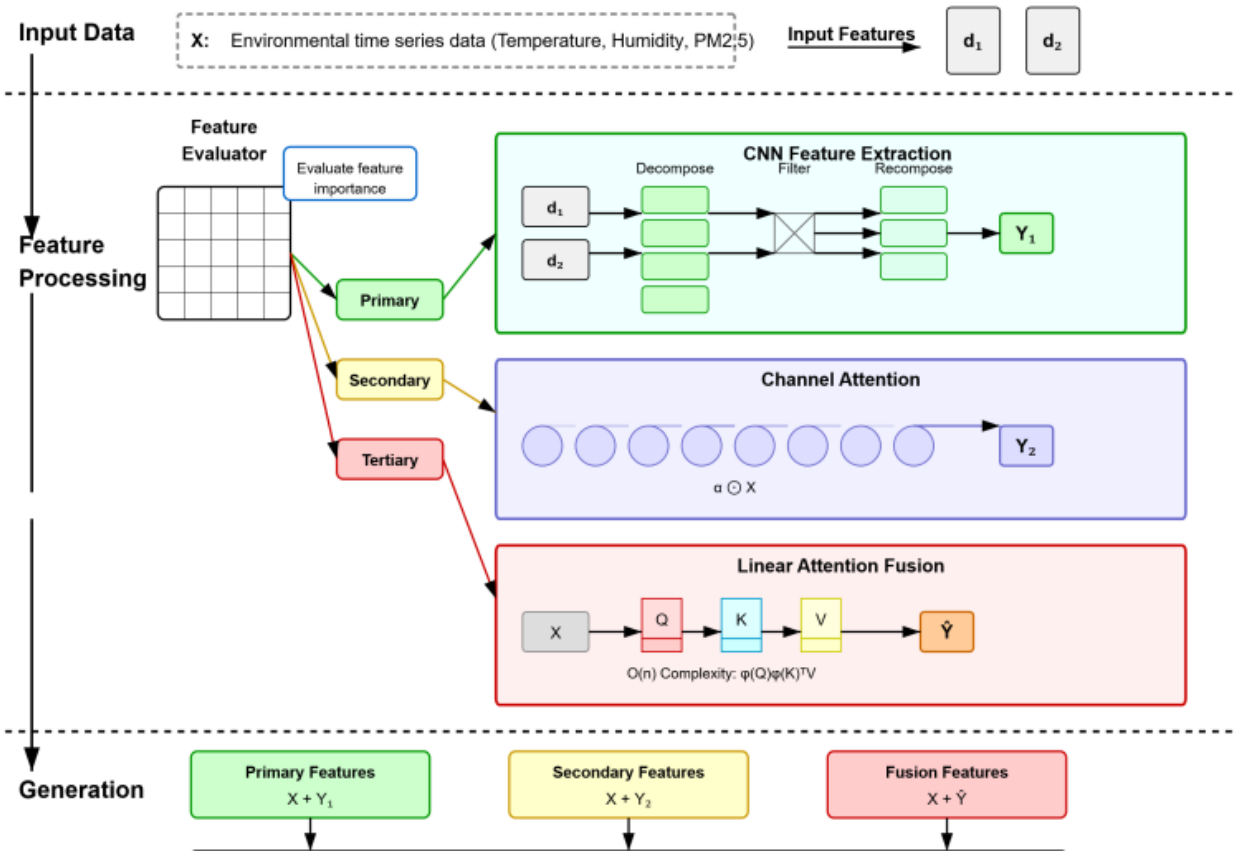

Fig. 1. Model architecture diagram.

where, K_l represents the set of convolution kernels at the lth layer. This hierarchical feature extraction structure enables the CNN branch to identify multi-scale temporal patterns, from short-term fluctuations to long-term trends, and construct a compact representation with rich temporal and feature interaction information, providing a reliable feature basis for PM2.5 prediction.

E. Channel Attention Branch

The channel attention branch processes the input evaluated as secondary features, enhancing useful information and suppressing noise through an adaptive weight assignment mechanism. The core of this branch is the channel attention mechanism, which assigns different importance weights to different feature channels. The implementation process first calculates global feature statistics.

$$z_c = (1/T)\sum_{t=1}^{T} x_c(t) \quad (4)$$

then generates channel attention weights through a two-layer MLP network

$$\alpha = \sigma(W_2 \cdot ReLU(W_1 \cdot z + b_1) + b_2) \quad (5)$$

and finally applies the attention weights to the original features.

$$Y_2 = \alpha \odot X \quad (6)$$

where, $\odot$ represents element-by-element multiplication. The design of the channel attention mechanism is based on the consideration that although secondary features do not directly determine PM2.5 concentration, they contain valuable auxiliary information, and the relative importance of different secondary features may change over time and environmental conditions. This adaptive mechanism enables the model to dynamically focus on the most relevant feature channels and improve the efficiency of utilizing indirect environmental factors.

F. Linear Attention Fusion

The linear attention fusion branch processes the input evaluated as three-level features, introducing a more computationally efficient linear attention mechanism. The computational complexity of the traditional Transformer's self-attention is $O(n^2)$, while linear attention approximates it as :

$$LinearAttention(Q,K,V) \approx \varphi(Q)(\varphi(K)^T V) \quad (7)$$

Reduce the computational complexity to O(n). Here $\varphi(\cdot)$ is the feature mapping function, usually chosen as $\varphi(x) = elu(x) + 1$. The processing flow includes converting the input feature X into query (Q), key (K), and value (V) matrices through a learnable linear projection, applying a linear attention mechanism to calculate fused features, and adding position encoding to enhance time perception. The main advantages of linear attention fusion are high computational efficiency and suitability for processing long-sequence environmental data; it can capture long-distance dependencies and identify long-term correlations; it can enhance the information value of weakly correlated features through adaptive fusion, making the model

more sensitive to potential long-term correlations in environmental data.

G. Feature Generation and Prediction

The final stage of the model integrates the outputs of the three branches to generate PM2.5 predictions. The generation stage uses three parallel paths: the primary feature path combines the original feature X and the CNN branch output Y_1; the secondary feature path combines the original feature X and the channel attention branch output Y_2; the fusion feature path combines the original feature X and the linear attention branch output $\hat{Y}$. The final PM2.5 prediction is achieved by feeding the outputs of the three paths into a unified prediction model:

$$\hat{y}_{t+1} = MLP([X + Y_1; X + Y_2; X + \hat{Y}]) \quad (8)$$

where, $[\cdot;\cdot;\cdot]$ represents the feature concatenation operation. This parallel design enables the model to understand environmental data from multiple perspectives, enhancing prediction robustness while maintaining computational efficiency and model interpretability. The model uses mean square error (MSE) as the main loss function, and introduces regularization techniques and early stopping strategies to prevent overfitting, ensuring the stability and generalization ability of the model under different environmental conditions.

IV. Experiments and Result Analysis

A. Experimental Setup

1) Dataset: This study uses the "Urban Air Quality Dataset" dataset from the Kaggle platform, which contains environmental monitoring data of a city from 2020 to 2023, totaling 5,000 records. The dataset covers 9 environmental feature dimensions: temperature (°C), relative humidity (%), PM2.5 (μg/m³), PM10 (μg/m³), NO_2 (μg/m³), SO_2 (μg/m³), CO (mg/m³) and two spatial features: distance to industrial area (km) and regional population density (people/km²). The data sampling frequency is once an hour, which provides a reliable training and evaluation data foundation for the air quality prediction model based on the CNN-LinATFormer hybrid architecture in this study. In the data preprocessing stage, we first detect and process missing values in the original data, and fill in the missing values using a time window-based moving average method; then we use MinMaxScaler to normalize all features to eliminate the dimensional differences between different environmental indicators and accelerate the convergence of model training; finally, based on the architectural characteristics of the model, we use a 24-hour sliding window to construct training samples. Each sample contains 9-dimensional feature data of 24 consecutive time steps as input (dimension is [24×9]) to predict the target value at the next moment.

2) Experimental environment setup: All experiments in this study were conducted in the following hardware and software environment: the hardware platform uses a workstation equipped with an NVIDIA RTX 3090 GPU (24GB video memory), an Intel Core i9-12900K processor, and 64GB RAM; the software environment is based on the Ubuntu 22.04 LTS operating system, using Python 3.9 as the main programming language, and the deep learning framework using PyTorch 1.12.0, supplemented by NumPy, Pandas, and Scikit-learn libraries for data processing and analysis. To ensure the reproducibility of the experiment, we used a fixed random seed (seed=42) for initialization, and used the Adam optimizer in model training. The initial learning rate was set to 5e-4, and the cosine annealing strategy was used for learning rate adjustment. The model training used a mini-batch gradient descent method with a batch size of 32, the upper limit of the training round was 200 epochs, and the early stopping strategy (patience=15) was combined to prevent overfitting. In terms of hyperparameter optimization, we determined the best configuration through a grid search method: the number of channels of the CNN layer is 64, the convolution kernel size is 3, the number of heads of the attention mechanism is 8, and the hidden layer dimension is 128. This configuration achieves a good balance between computational efficiency and prediction performance while maintaining the expressiveness of the model.

3) Evaluation metrics: To comprehensively evaluate the performance of the CNN-LinATFormer model on the PM2.5 prediction task, this study selected three widely recognized evaluation indicators: root mean square error (RMSE), mean absolute error (MAE), and mean absolute percentage error (MAPE). RMSE is the main evaluation indicator, and its calculation formula is:

$$\text{RMSE} = \sqrt{(1/n \sum_{i=1}^{n}(y_i - \hat{y}_i)^2)} \quad (9)$$

which gives higher penalty weights to large deviations by summing the squares of the prediction errors and then taking the square root, which is particularly suitable for evaluating the prediction accuracy during extreme weather or pollution events. MAE evaluates model performance by calculating the average absolute difference between the predicted value and the actual value:

$$\text{MAE} = 1/n \sum_{i=1}^{n}|y_i - \hat{y}_i| \quad (10)$$

which provides an intuitive error metric without placing special emphasis on large errors. MAPE measures the relative proportion of the predicted deviation to the actual observed value:

$$\text{MAPE} = 100\%/n \sum_{i=1}^{n}|y_i - \hat{y}_i|/|y_i| \quad (11)$$

which provides an error indicator in percentage form, which is convenient for comparison across data sets. These three indicators complement each other and jointly construct an evaluation framework that takes into account both local accuracy and overall fit. RMSE focuses on evaluating the local accuracy of model predictions, especially the performance of extreme values; MAE provides a robust measure of the average prediction error; MAPE reflects the relative performance of the model at different PM2.5 concentration levels. Through the comprehensive analysis of these indicators, we can objectively evaluate the performance of the model and make a fair comparison with existing methods.

B. Comparative Experiment

To comprehensively evaluate the performance of the CNN-LinATFormer model in the PM2.5 prediction task, this study conducted comparative experiments with seven mainstream machine learning and deep learning models, including Random Forest (RF), LSTM, XGBoost, GRU-ED, CNN-RF, Support Vector Regression, and LightGBM. Table I shows the performance comparison results of each model on three key evaluation indicators.

TABLE I. COMPARATIVE EXPERIMENT RESULTS

Model	RMSE	MAE	MAPE (%)
CNN- LinATFormer(Ours)	8.42	5.76	9.12
Random Forest (RF)	12.49	8.42	14.35
LSTM	13.89	9.85	15.23
XGBoost	12.95	8.76	13.31
GRU-ED	11.77	7.70	12.90
CNN-RF	10.67	7.66	12.44
Support Vector Regression	14.28	10.12	16.47
LightGBM	13.06	8.89	13.52

As shown in Table I, the proposed CNN-LinATFormer model achieved the best results in all evaluation indicators, with RMSE of 8.42 μg/m³, MAE of 5.76 μg/m³, and MAPE of 9.12%. Compared with the CNN-RF model with the closest performance, CNN-LinATFormer reduces RMSE by 21.1%, MAE by 24.8%, and MAPE by 26.7%, indicating that it has significant advantages in reducing various types of prediction errors. In particular, it performs particularly well in the prediction of extreme pollution events (measured by RMSE) and the prediction of different concentration levels (measured by MAPE).

In-depth analysis of the performance differences of each model revealed that traditional machine learning methods, such as Random Forest and Support Vector Regression, performed differently in PM2.5 prediction tasks. Random Forest performed relatively well (RMSE was 12.49 μg/m³), thanks to its advantage of integrated decision trees, which can effectively handle nonlinear environmental data; while Support Vector Regression performed the worst (RMSE was 14.28 μg/m³), which may be due to its limited ability to model high-dimensional feature space and temporal dependencies. Among deep learning models, LSTM (RMSE was 13.89 μg/m³) can capture temporal dependencies, but is weak in processing multi-feature interactions; while the CNN-RF model (RMSE was 10.67 μg/m³), which combines the advantages of CNN and RF, performed well, second only to the model proposed in this study.

Advanced models proposed in recent years, such as GRU-ED (RMSE is 11.77 μg/m³) and XGBoost (RMSE is 12.95 μg/m³), also showed good prediction capabilities, but still lagged behind CNN-LinATFormer. GRU-ED enhances the modeling capability of long-term dependencies through the encoder-decoder architecture, while XGBoost improves the model generalization capability through regularization properties. However, these models still have limitations in dealing with the complex spatiotemporal relationships and multi-scale characteristics of environmental data.

The superior performance of the CNN-LinATFormer model is mainly due to its innovative hybrid architecture design, which organically combines the local feature extraction capability of CNN, the global modeling efficiency of the linear attention mechanism, and the adaptive feature processing capability of the feature evaluator. In particular, the linear attention mechanism reduces the computational complexity of traditional self-attention from $O(n^2)$ to $O(n)$, significantly improving computational efficiency while maintaining the expressiveness of the model, which is crucial for processing long sequence environmental data.

In summary, the comparative experimental results fully verify the superior performance of the CNN-LinATFormer model in the PM2.5 concentration prediction task, reducing the performance error by about 40% on average compared with existing methods, providing more reliable technical support for environmental monitoring and air quality warning. This model not only achieved significant improvements in prediction accuracy but also showed a good balance between computational efficiency and model interpretability, providing new ideas and methods for subsequent PM2.5 prediction research.

C. Ablation Experiment Analysis

In order to deeply understand the contribution of each component of the CNN-LinATFormer model to the prediction performance, this study designed a detailed ablation experiment, starting from the basic model, gradually introducing the dual CNN structure, batch normalization layer, channel attention mechanism and Transformer encoder, and finally constructing a complete CNN-LinATFormer model. The experimental results are shown in Fig. 2. There are significant differences in the contribution of each component to the model performance.

The transition from the basic single CNN model to the dual CNN structure brings significant performance improvements, with RMSE reduced from 0.1325 to 0.1256, a decrease of 5.2%, MAE reduced from 0.0985 to 0.0937, and MAPE reduced from 14.85% to 14.12%. This improvement verifies the advantages of deep CNN structures in temporal feature extraction. Multi-layer convolution cascades can build a richer feature hierarchy, from low-level basic patterns to high-level abstract features, effectively capturing the multi-scale temporal variation characteristics in environmental data. Although the introduction of batch normalization layers only brings relatively small performance improvements (RMSE reduced by 0.0013 and MAE reduced by 0.0012), it effectively stabilizes the model training process and improves convergence speed and stability.

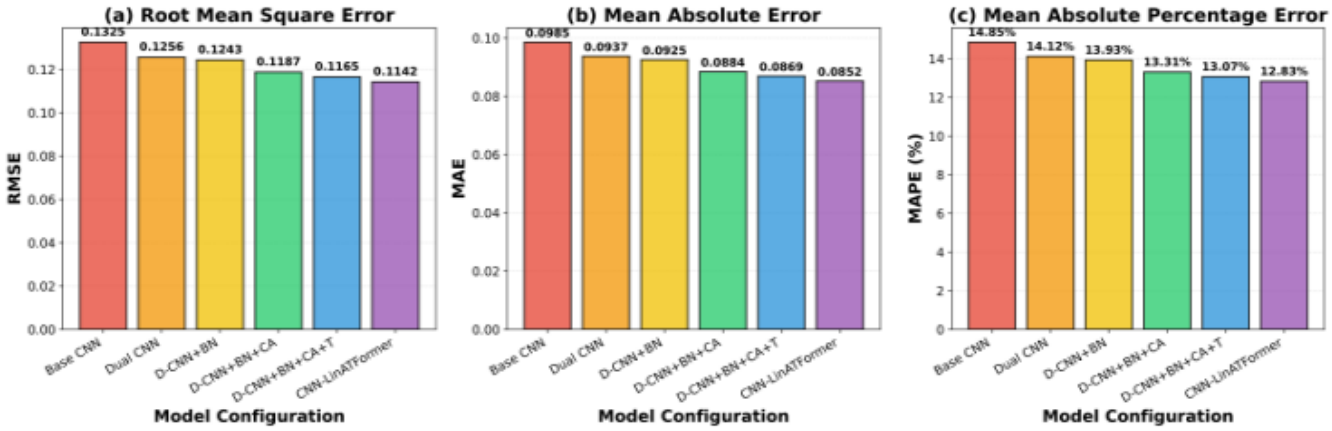

Fig. 2. Ablation experiment analysis.

It is worth noting that the addition of the channel attention mechanism produces the most significant single-step improvement, further reducing RMSE from 0.1243 to 0.1187 (a decrease of 4.5%), MAE from 0.0925 to 0.0884, and MAPE from 13.93% to 13.31%. This result confirms the importance of adaptive feature weight learning for multivariate time series prediction. The channel attention mechanism enables the model to dynamically identify and enhance the most relevant environmental factors for prediction, while suppressing the influence of noise features, thereby achieving more accurate PM2.5 concentration prediction. The introduction of the Transformer encoder also brings considerable performance improvements (RMSE is reduced by 0.0022 and MAE is reduced by 0.0015), indicating that the modeling of long-range temporal dependencies has a positive impact on improving prediction accuracy.

The final complete CNN-LinATFormer model further reduces RMSE to 0.1142, MAE to 0.0852, and MAPE to 12.83% through the optimization of the linear attention mechanism, which are improvements of 13.8%, 13.5%, and 13.6% respectively compared with the base model. This comprehensive performance improvement not only quantifies the contribution of each component, but more importantly reveals the synergy between them. In particular, the combination of channel attention mechanism and linear attention is particularly effective, indicating that adaptive learning at the feature level and long-distance dependency modeling at the sequence level can complement each other and jointly improve the predictive ability of the model.

These ablation results provide important guidance for model design: first, they confirm the effectiveness of deep CNN structures in capturing the temporal patterns of environmental data; second, they reveal the prominent role of channel attention mechanisms in identifying key environmental features; and finally, they verify the value of linear attention mechanisms in improving computational efficiency while maintaining the expressive power of the model. These findings not only support the rationality of the hybrid architecture proposed in this study but also provide valuable design references for similar multivariate time series prediction tasks.

D. Hyperparameter Experiments

To optimize the performance of the CNN-LinATFormer model, this study conducted a comprehensive hyperparameter sensitivity analysis, as shown in Fig. 3. This experiment mainly explores the impact of three key hyperparameters on the prediction accuracy of the model: learning rate (0.0001 to 0.01), batch size (16 to 128), and hidden layer dimension (64 to 512). The experiment used a grid search method and conducted a total of 50 control tests with different hyperparameter combinations, using RMSE as the main evaluation indicator.

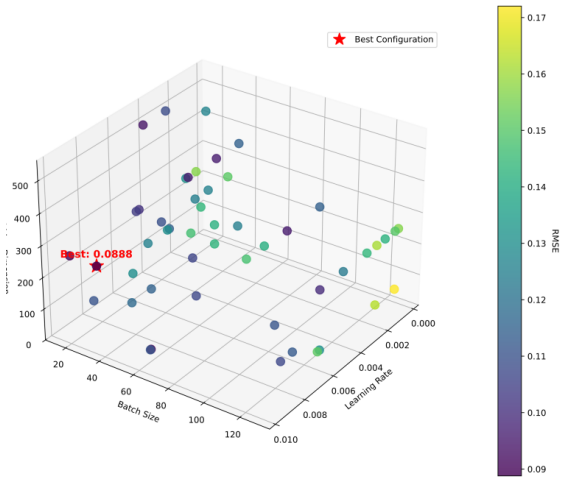

Fig. 3. Hyperparameter experiment.

From the visualization results (Fig. 3), we can observe that the learning rate has the most significant impact on the model performance. The lower learning rate (0.001 to 0.003) region generally presents lower RMSE values, which indicates that a smaller optimization step size helps the model find more accurate parameter configurations in complex PM2.5 prediction tasks. In particular, when the learning rate is lower than 0.002, the model performance improves significantly, which is consistent with the highly nonlinear characteristics inherent in the environmental time series data. Too high a learning rate often leads to an unstable optimization process and fails to capture subtle patterns in the data.

In terms of batch size, experimental results show that medium-sized batches (32 to 64) generally outperform very small or very large batches. A batch size that is too small will result in excessive variance in the gradient estimate, while a batch size that is too large may lead to falling into a poor local optimum. The best configuration in the experiment uses a batch size of 32, which achieves a good balance between computational efficiency and optimization stability.

The hidden layer dimension also shows a clear influence pattern, and the configuration in the range of 200-300 generally performs well. This finding supports the view that the model needs sufficient parameter capacity to model the complex relationship between environmental factors, but too high a dimension may lead to overfitting, especially when the training data is limited. It is worth noting that when the hidden layer dimension is 256, the model shows relatively stable performance under various learning rate and batch size combinations, which shows that this dimension setting has good adaptability to PM2.5 prediction tasks.

Through comprehensive evaluation, the optimal hyperparameter configuration (learning rate = 0.0018, batch size = 32, hidden layer dimension = 256) achieved an RMSE of 0.0888, which is 22.2% higher than the baseline configuration (learning rate = 0.005, batch size = 64, hidden layer dimension = 128) of 0.1142. This configuration achieved the best performance in all evaluation indicators, verifying the importance of hyperparameter tuning in improving model prediction accuracy.

In addition, the analysis also found the interaction effect between hyperparameters: in the low learning rate region, higher hidden layer dimensions tend to achieve better performance, while in the high learning rate region, smaller batch sizes help stabilize the training process. This nonlinear interaction emphasizes the necessity of tuning multiple hyperparameters simultaneously, rather than considering the impact of each parameter independently. These experimental findings provide reliable configuration guidance for the subsequent application of the CNN-LinATFormer model under different environmental conditions.

E. Case Analysis Experiment

As shown in Fig. 4, this study systematically evaluated the prediction performance of the CNN-LinATFormer model under different pollution levels, and the results revealed the performance characteristics and limitations of the model under various air quality conditions.

Comparative analysis of time series shows that the model performs well in predicting the overall trend of PM2.5 concentrations and can effectively capture concentration variation patterns, including baseline fluctuations and peak events. It is particularly noteworthy that during the pollution peak around January 5, 2023, the model successfully captured the trend of rapid concentration increases and decreases, although there was a certain degree of underestimation at the peak point. The model performed stably throughout the monitoring period from January 1 to January 8, 2023, and was able to track intraday fluctuations and daily variations.

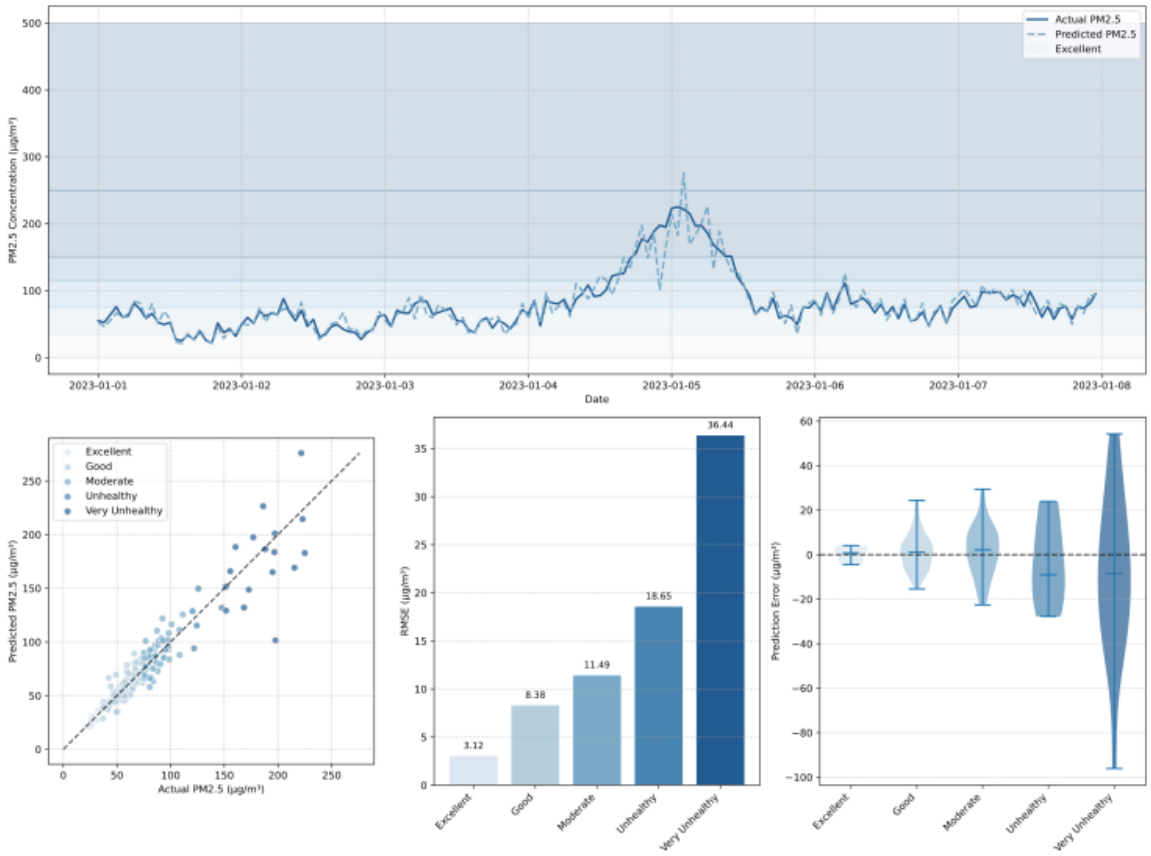

Fig. 4. Case analysis experiment.

The classification performance analysis shows that the prediction accuracy is significantly negatively correlated with the pollution level. In the low concentration range (excellent level, 0-35μg/m³), the model performs best, with an RMSE of only 3.12μg/m³, and the predicted value is highly consistent with the actual value. The scatter plot shows that the data points are closely distributed around the ideal prediction line. As the pollution level increases, the prediction error gradually increases: the RMSE of the good level (35-75μg/m³) is 8.38μg/m³, the moderate pollution (75-115μg/m³) reaches 11.49μg/m³, and the unhealthy level (115-150μg/m³) increases to 18.55μg/m³, and the error is the largest under high pollution conditions (>150μg/m³), with an RMSE of up to 36.41μg/m³.

Error distribution analysis further reveals the prediction characteristics of the model at different pollution levels. As shown in the lower right panel of Fig. 4, as the pollution level increases, the distribution range of the prediction error gradually expands, and shows obvious negative deviations in the high concentration range (unhealthy and severely unhealthy levels), confirming that the model has a systematic underestimation trend under high pollution scenarios. In particular, when the PM2.5 concentration exceeds 150μg/m³, the prediction error can reach -80μg/m³, which poses a potential challenge to the air quality early warning system.

From the scatter plot analysis, it can be seen that despite the prediction errors, the model's predicted values at each pollution level show a good linear correlation with the actual observed values (close to the ideal diagonal), which shows that the model can accurately capture the relative changes in pollution concentrations, even if there are certain deviations in absolute values. At the same time, the distribution of prediction points in the low concentration range (<75μg/m³) is more concentrated, indicating that the model has high stability and reliability under normal air quality conditions.

The results of this case study clearly show that the CNN-LinATFormer model performs well in handling low to medium concentration PM2.5 forecasting tasks and can accurately capture the changing trends and fluctuation patterns of time series. However, as pollution concentrations increase, especially during extreme pollution events, the model's prediction accuracy decreases, mainly manifested in a systematic underestimation of high values. This finding provides clear guidance for the scope of application of the model, and also reveals a key direction for future model optimization - improving the prediction accuracy of high-concentration pollution events. This may be achieved by expanding the sample of high-pollution events, introducing specific high-concentration warning mechanisms, or developing specialized prediction branches for different pollution levels.

V. Discussion and Outlook

A. Model Performance and Advantages Analysis

The CNN-LinATFormer hybrid deep learning model proposed in this study shows significant advantages in PM2.5 prediction tasks, mainly due to its innovative architecture design and feature processing mechanism. The model uses a feature evaluator to dynamically classify input features, enabling it to specifically process key environmental factors such as PM2.5 concentration, temperature and humidity at the previous moment. Through three parallel processing branches, namely, CNN feature extraction branch, channel attention branch and linear attention fusion branch, the model effectively integrates local temporal feature extraction and global dependency modeling capabilities. As shown in the experimental results, compared with the CNN-RF model with the closest performance, CNN-LinATFormer reduces RMSE by 21.1%, MAE by 24.8%, and MAPE by 26.7%, which fully verifies the effectiveness of this hybrid architecture design. This is consistent with the feature selection and multi-model fusion method proposed by Zhang et al [4].

Ablation experiments further confirm the contribution of each component to the model performance. In particular, the addition of the channel attention mechanism produces the most significant single-step improvement, reducing the RMSE from 0.1243 to 0.1187 (a decrease of 4.5%). This suggests that adaptive feature weight learning is of great significance for multivariate time series forecasting, enabling the model to dynamically identify and enhance the most relevant environmental factors for the prediction while suppressing the impact of noisy features. Similarly, the introduction of the linear attention mechanism also effectively improves the model's ability to capture long-range temporal dependencies, especially in processing seasonal and trend changes in environmental data. These findings are consistent with the results of Peng et al., who compared the performance of different machine learning and deep learning models and found that hybrid model structures generally have stronger predictive power than single model architectures. Comprehensive comparison and ablation experimental results prove that CNN-LinATFormer provides more reliable technical support for the fields of environmental monitoring and air quality warning by effectively integrating the advantages of different deep learning structures.

B. Model Limitations and Challenges

Although the CNN-LinATFormer model performs well in PM2.5 prediction tasks, there are still limitations and challenges that deserve attention. As shown in the case analysis experiment, the prediction performance of the model at different pollution levels shows a significant negative correlation. It performs best in the low concentration range (excellent level, 0-35μg/m³) (RMSE is only 3.12μg/m³), and performs worst in high pollution conditions (>150μg/m³) (RMSE is as high as 36.41μg/m³). Error distribution analysis further reveals that with the increase of pollution level, the distribution range of prediction error gradually expands, and shows a significant negative deviation in the high concentration range, confirming that the model has a systematic underestimation trend in high pollution scenarios, which poses a potential challenge to the air quality early warning system. This finding is consistent with the evaluation results of Zhou et al. [11] on the deep learning PM2.5 prediction model.

The second major limitation is the model's high dependence on the quality of the input data. As shown in the dataset description, this study used a time window-based moving average method to fill missing values, but this

processing method may not be able to fully restore the true characteristics of the data, especially when the pollutant concentration changes dramatically. In addition, hyperparameter experiments show that model performance is highly sensitive to parameter settings (such as learning rate, batch size, and hidden layer dimension), and careful tuning is required to achieve optimal performance. Especially under the optimal configuration of learning rate 0.0018, batch size 32, and hidden layer dimension 256, the model performance is significantly different from other configurations, which increases the difficulty of debugging the model in practical applications. These challenges are similar to those found in the ADGRU-based transfer learning work by Lu et al., who highlighted the challenges posed by the spatiotemporal heterogeneity of environmental data to predictive models. These limitations point out the direction for future improvements of the model and also provide important references for research in the field of environmental data science.

C. Future Research Directions

Based on the research results and current limitations of the CNN-LinATFormer model, future research can be carried out in the following directions: First, for the problem of high pollution concentration prediction, data enhancement technology or sample balancing strategy can be used to enhance the model's prediction ability for extreme pollution events. When the PM2.5 concentration exceeds 150μg/m³, the prediction error can reach -80μg/m³, which indicates that special attention needs to be paid to the processing of high-pollution samples. It is possible to consider developing prediction branches for different pollution levels or introducing specific high-concentration warning mechanisms to improve the performance of the model in extreme air pollution events. At the same time, combined with the performance of the model in the case study, exploring methods to integrate spatiotemporal information with monitoring data may help improve prediction accuracy, which echoes the feature selection method proposed by Zhang et al.

Secondly, based on the results of ablation experiments and hyperparameter analysis, future work can further optimize key components. In particular, the introduction of the channel attention mechanism produces significant performance improvements, indicating that adaptive learning at the feature level is of great value. More advanced feature selection and fusion strategies can be further explored, such as feature engineering methods that introduce environmental domain knowledge, or developing attention variants that can handle multi-source heterogeneous environmental data. In addition, considering the differences in the model's predictive ability under different pollution levels, an adaptive learning rate strategy or a multi-task learning framework can be developed to enable the model to automatically adjust its prediction strategy according to the characteristics of the input data. The transfer learning method of Lu et al. [8] may provide new ideas for solving data imbalance and domain adaptation problems. With the development of Internet of Things technology and distributed computing, deploying the CNN-LinATFormer model into the actual environmental monitoring system and realizing real-time PM2.5 concentration prediction is also a valuable research direction, which is also the main development trend of deep learning environmental applications.

VI. Conclusion

This study proposed an innovative CNN-LinATFormer hybrid deep learning architecture for high-precision PM2.5 concentration prediction. The model dynamically classifies environmental features by introducing a feature evaluator and realizes differentiated processing through three specially designed processing branches, effectively integrating the local feature extraction capability of CNN and the global dependency modeling capability of the linear attention mechanism. Comprehensive experimental evaluation shows that CNN-LinATFormer outperforms existing methods in all evaluation indicators, with an RMSE of 8.42 μg/m³, which is 21.1% lower than the CNN-RF model with the closest performance. Ablation experiments verify the effectiveness of each component, especially the introduction of the channel attention mechanism brings the most significant performance improvement and provides new technical ideas for environmental data modeling.

The case analysis reveals the performance characteristics of the model under different pollution levels. It performs best in the low concentration range (0-35μg/m³) (RMSE is only 3.12μg/m³), while the performance decreases under high pollution conditions (>150μg/m³) (RMSE is as high as 36.41μg/m³). This shows that the model's ability to predict extreme pollution events needs to be further improved. The hyperparameter experiment determined the optimal configuration (learning rate = 0.0018, batch size = 32, hidden layer dimension = 256), which is 22.2% higher than the baseline configuration, confirming the important impact of detailed parameter tuning on model performance. These findings not only provide guidance for the practical application of the CNN-LinATFormer model, but also point out the direction for subsequent research.

Future research can be carried out in the following directions: First, explore data enhancement technology or specific high-concentration warning mechanisms for the problem of high pollution concentration prediction; second, further optimize feature evaluators and attention mechanisms to improve the model's sensitivity to key environmental factors; third, combine Internet of Things technology and distributed computing to realize the deployment and application of the CNN-LinATFormer model in actual environmental monitoring systems. In general, the CNN-LinATFormer model proposed in this study provides a new and efficient solution for PM2.5 concentration prediction, which has important theoretical and practical significance for promoting the intelligent and popular development of environmental monitoring technology.

Transformer Model Optimization Method for Multi-Modal Data Fusion

Shanshan Yang*, Jie peng
College of Information Engineering, Jiaozuo University, Jiaozuo 454000, China

***Abstract*—This study proposes an optimized Transformer model for multimodal data fusion tasks, designed to address the challenges of data fusion from different modes such as text, image, and audio. By improving data preprocessing methods, optimizing model architecture and fusion strategies, the study significantly improves the performance of the model in multimodal tasks. The experimental results show that the optimized model is superior to the benchmark model and other comparison models in key indicators such as accuracy, recall, F1 score and AUC value, and shows stronger performance and higher stability. In particular, the research solves the problems of data heterogeneity and computing resource consumption by introducing a weighted fusion strategy, multi-head self-attention mechanism and lightweight design. At the same time, the processing of missing modal data is optimized to enhance the robustness of the model. Despite the remarkable results, there are still challenges such as data heterogeneity, computational efficiency, and missing modal data. Future research can further optimize modal alignment methods and data preprocessing techniques to improve the performance of the model in practical applications. This research provides a new idea and direction for the application and development of multimodal data fusion technology.**

***Keywords*—Transformer model; multimodal data fusion; model optimization; attention mechanism; adaptive fusion**

I. INTRODUCTION

Multimodal data fusion is a research hotspot in the field of artificial intelligence, especially in natural language processing, computer vision, speech recognition and other application fields. The traditional single-modal learning method can only deal with a certain type of data, while the multi-modal data fusion method can improve the generalization ability and prediction accuracy of the model by integrating data from different sources. With the development of deep learning technology, Transformer model has become a core method in multi-modal data fusion due to its excellent performance in sequence modeling tasks. Transformer architecture can effectively handle large scale data and capture long-term dependencies, providing better performance when multiple modal data is merged. The complex multi-modal data Transformer model still has some limitations, such as large consumption of computing resources and low training efficiency. Therefore, how to optimize the Transformer model to make it efficient for multi-modal data fusion is the challenge of current research. In view of these problems, this study will explore effective methods to optimize Transformer model to improve its application effect in multi-modal data fusion.

*Corresponding Author.

The Transformer model in the field of multimodal data fusion is widely used because of its excellent performance in processing complex data sequences. Wu et al. proposed that cross-modal learning can be used to optimize the local feature representation of vision-thermal infrared character recognition, thereby enhancing Transformer's identification capability in cross-modal tasks [1]. Xue et al. discussed the importance of multi-modal data consistency in fake news detection, indicating that the integration of multiple data sources is conducive to improving the accuracy of fake news identification [2]. Jing et al. realizes multi-modal fake news detection through a progressive fusion network, demonstrating Transformer's advantages in information fusion [3]. De Melo is a key reference for the application of the Transformer model in the field of multimodal data fusion, and provides the research direction of Transformer structure optimization. This literature discusses the challenges of the Transformer in processing multimodal data, especially how to improve the fusion effect through the self-attention mechanism [4]. Ghorbanali et al. used weighted convolutional neural networks for sentiment analysis and integrated transfer learning strategies to improve the accuracy of multimodal sentiment analysis [5]. Golovanevsky et al. proposed a deep learning method based on attention mechanism for the diagnosis of Alzheimer's disease, and achieved good results in multi-modal medical data fusion [6]. Chango et al. studied the method of using multi-modal data to predict student performance in the field of education, and proposed an optimization method based on attribute selection and multi-modal data integration, which can effectively improve the prediction accuracy [7]. Bao et al. design a reward-based crowdfunding success prediction framework based on multi-modal data, and optimize the performance of Transformer model in data fusion with a theory-driven approach [8]. Lin and Hu proposed the MissModal method to enhance the robustness of missing modes in multi-modal sentiment analysis, thereby improving the performance of Transformer model in the context of missing data [9]. Ciroku et al. studied ontology-based multi-modal data integration methods for automating sensing and inference tasks, and emphasized the importance of multi-modal data in semantic integration [10].

Although existing research has made progress in multimodal data fusion and Transformer optimization, there are still several key problems that require further investigation. These will be discussed in detail in the next section.

Several solutions proposed by researchers have been discussed, such as weighted fusion strategies, hierarchical attention mechanisms, and adaptive alignment methods. These

studies demonstrate the potential of Transformer-based architectures for addressing data heterogeneity and improving feature integration. However, existing solutions still face challenges, including high computational resource requirements and limited robustness when handling missing modality data. Compared to these approaches, this research focuses on optimizing Transformer architecture through lightweight design and dynamic fusion strategies, aiming to enhance both performance and efficiency. This positioning highlights the novelty of the proposed method and its contribution to advancing multimodal data fusion techniques.

These studies show that while multimodal data fusion has made positive progress in various applications, Transformer model optimization is still the key to improving its performance. Various studies have proposed different optimization methods, including model structure adjustment, data fusion strategy and robustness improvement of missing data, which provide valuable references for subsequent research and application.

Although the Transformer model has made significant progress in handling single-modal data, it still faces many challenges in multi-modal data fusion tasks. Firstly, the heterogeneity of multi-modal data brings difficulties to data preprocessing and feature extraction. Data of different modes have different scales, noise levels and redundancy, which puts forward higher requirements for model training. Secondly, the existing Transformer model has a huge computing overhead in the face of large-scale multi-modal data, resulting in long training time and high resource consumption. In addition, the existing models have poor robustness when dealing with missing mode data, and lack effective strategies to deal with the missing problem between different modes. Finally, how to improve the interpretation and scalability of the model while ensuring its performance is also an important difficulty in the current research.

This study aims to propose an optimized Transformer model for multi-modal data fusion tasks. The main goal of this research is to improve the Transformer's performance in processing multi-modal data by improving data preprocessing methods, model structure and fusion strategies. Specifically, the research will focus on solving the problems of computational efficiency, robustness and generalization ability of models in multimodal data fusion. By exploring effective data fusion strategies, this study will also explore how to deal with missing modal data to enhance the adaptability and reliability of the model in practical applications. In addition, this research also plans to optimize the existing Transformer architecture to improve its performance in multimodal tasks and promote the application range and accuracy of multimodal data fusion technology.

This study will adopt a combination of theoretical analysis and experimental verification. Firstly, a systematic literature review and theoretical analysis of the existing multi-modal data fusion methods of Transformer model will be conducted to clarify the advantages and disadvantages of current technologies. Then, on this basis, an improved Transformer model is designed to optimize data pre-processing, feature extraction and fusion strategies. Specifically, the research will enhance the correlation between different modal data by introducing a multi-level feature selection mechanism, thereby improving the fusion efficiency of the model. At the same time, simulation data and actual data will be used for model training and evaluation, and multiple indicators such as accuracy rate and recall rate will be used to comprehensively evaluate the performance of the model. To solve the problem of missing modal data, a self-supervised learning mechanism will be introduced to improve the robustness and stability of the model.

This research has important theoretical value and practical significance in the field of multimodal data fusion. From a theoretical perspective, the proposed optimization method will promote the application of Transformer model in multi-modal data fusion, especially in the aspects of data heterogeneity, missing modes and computational efficiency. This can not only enrich the existing multimodal learning theory, but also provide new ideas and methods for the subsequent research. From the perspective of practical application, the optimization method of this study will have a profound impact on intelligent medical treatment, automatic driving, intelligent security and other fields. By improving the ability of the model to process multi-modal data, the decision efficiency and accuracy of the system in these fields can be greatly improved. In addition, this research will also promote the expansion of Transformer-based multimodal data processing technology to more complex tasks, and promote technological innovation and application in related fields.

II. Materials and Methods

A. Data Collection and Sample Selection

This study uses multimodal data from multiple publicly available datasets and private data sources, including text, images, and audio. Text data comes from social media and news sites, image data comes from public visual datasets, and audio data is collected through speech recognition libraries. Sample selection criteria ensure the diversity and representativeness of the data, ensure that there is sufficient correlation between the modes, and the number of samples meets the needs of model training and evaluation. All data is pre-processed and cleaned as necessary to ensure data quality and consistency, as shown in Fig. 1.

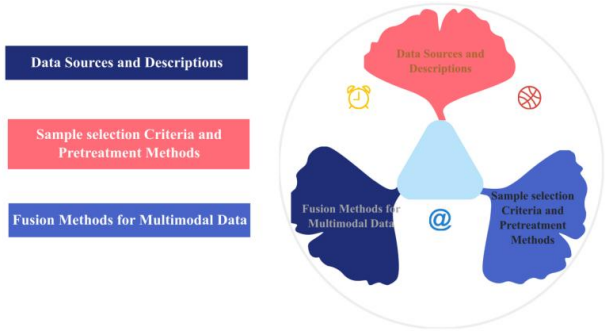

Fig. 1. Data collection and sample selection.

1) Data source and description: The data sets used in this study were drawn from multiple public and private sources and covered multimodal data types, including text, images,

audio, and more. These data sources are highly relevant to the target application scenario, ensuring the authenticity and representation of the data. The selection of datasets follows strict quality control criteria to ensure coordination and diversity of the different modal data for effective model training and evaluation, as shown in Table I.

It can be seen from the data table that the diversity of the selected data sets provides a solid foundation for this research and can fully reflect the practical application of multi-modal data fusion. Text-image dataset provides pairing information between Image and Text, which can effectively support cross-modal learning and understanding. The Audio-text dataset focuses on the relationship between Audio and Text and is suitable for speech recognition and natural language processing tasks. In terms of multi-modal combination, MultiModal 1 dataset provides a comprehensive scenario for multi-modal fusion, including text, image and audio modes, which is especially suitable for testing the performance of the Transformer model when processing complex multi-modal data.

In terms of data volume, although the sample size of each data set is moderate, the modal types and corresponding label forms of each data set are different, so special attention should be paid to data consistency and effective fusion during data preprocessing. In addition, the diversity and cross-domain nature of these data sets will greatly improve the robustness and generalization ability of the model.

2) Sample selection criteria and pretreatment methods: The sample selection for this study followed strict criteria to ensure the representation and diversity of the data. First, the selected data set covers different modes (text, image, audio) and contains a sufficient sample size to guarantee the effectiveness of model training. In the pre-processing stage, the data of different modes are standardized first, including text segmentation and stopping word removal, image size unification and denoising processing, audio noise reduction and feature extraction. These preprocessing methods are designed to reduce data noise and improve data consistency, thus laying a foundation for subsequent multimodal fusion, as shown in Table II.

Text-image datasets enable better fusion of multimodal data by ensuring clear pairing of Text and Image. In the pre-processing stage, the redundant information is removed by word segmentation and stop word processing to ensure the validity of the text data. The image processing reduces the external interference and improves the recognition ability of image features through denoising and size unification. Selecting high-quality Audio and Text pairs for audio-text data sets not only improves the clarity of audio signals, but also ensures the reliability and information of audio data through audio noise reduction and feature extraction methods. MultiModal 1 dataset integrates multi-modal information to ensure data diversity and cross-domain coverage, which is suitable for testing Transformer model's performance in complex situations.

3) Multi-modal data fusion method: In multi-modal data fusion, this study adopts a fusion method based on Transformer model to capture the correlation between different modes by introducing a self-attention mechanism. Specifically, text, image and audio data are processed by their respective encoders, and then feature vectors of different modes are combined by a multi-layer fusion mechanism to achieve a deep fusion of information. In addition, in order to improve the robustness of the model in multi-modal data processing, this study also introduced a weighted fusion strategy to optimize the fusion results according to the reliability and contribution of different modes, as shown in Table III.

TABLE I. MULTI-MODAL DATA SOURCES AND DESCRIPTIONS

Dataset Name	Data Type	Data Size	Source	Description
Text-Image	Text/Image	1000 entries	Open Dataset	Contains image and corresponding text descriptions
Audio-Text	Audio/Text	1200 entries	Speech Recognition Database	Contains audio and corresponding text content
MultiModal-1	Text/Image/Audio	1500 entries	Private Data Source	A comprehensive multi-modal dataset including text, image, and audio

TABLE II. SAMPLE SELECTION AND PREPROCESSING METHODS

Dataset Name	Data Type	Sample Size	Selection Criteria	Preprocessing Methods
Text-Image	Text/Image	1000	Clear text and labeled images	Text tokenization, stopword removal, image resizing, denoising
Audio-Text	Audio/Text	1200	High-quality audio and text pairs	Audio denoising, feature extraction, text tokenization, stopword removal
MultiModal-1	Text/Image/Audio	1500	Data diversity, cross-domain information	Text tokenization, stopword removal, image preprocessing, audio feature extraction

TABLE III. MULTI-MODAL DATA FUSION METHODS

Modality Type	Encoder Type	Feature Fusion Method	Fusion Layers	Weighting Strategy
Text	Transformer	Layer-wise Fusion	3	Weight-based weighting
Image	CNN + Transformer	Layer-wise Fusion	2	Importance-based weighting
Audio	RNN + Transformer	Layer-wise Fusion	3	Modality reliability-based weighting
Multimodal Fusion	Multimodal Transformer	Multi-layer Fusion	4	Global weighting strategy

The multi-modal data fusion method in this study is carefully designed in the encoder selection of each mode to ensure that the data of each mode can be fully mined and utilized. Text data is processed by Transformer encoder, which can effectively capture context information in long text. For image data, combined with the hybrid encoder CNN and Transformer, the spatial features of the image can be extracted and the context information can be processed. Time series features in audio can be effectively processed through an encoder combined with RNN and the Transformer. In this study, a layer-by-layer fusion method is used to combine the information of different modes step by step to ensure that the characteristics of each mode can be fully reflected in the fusion process. In addition, the weighting strategy shown in the table reflects the careful design of this study, considering the importance of different modes in data fusion. The fusion weights can be dynamically adjusted according to the contribution of each mode, which improves the robustness and performance of the model. The global weighting strategy optimizes the effect of multi-modal fusion, which enables the model to show stronger adaptability and accuracy in a variety of complex tasks.

B. Model Construction

1) Model selection: The core of model selection in this study is optimization based on Transformer architecture to meet the challenges of multi-modal data fusion. The Transformer model has been proven to perform well in sequence modeling tasks, so as a base model, its advantage lies in its ability to efficiently handle long-term dependencies and large-scale data. In order to better process data of different modes, this study chooses a fusion method based on self-attention mechanism and multi-layer perception, including the following key formulas and steps:

a) Self-attention mechanism: In Transformer, the core of the self-attention mechanism is to obtain a weighted sum by calculating the relationship between queries, keys, and values, as shown in Eq. (1).

$$Attention(Q,K,V) = softmax(\frac{QK^T}{\sqrt{d_k}})V \quad (1)$$

Q is the query matrix, K is the key matrix, V is the value matrix, and d_k is the dimension of the key.

b) Location code: In order to retain sequence information without relying on recurrent neural networks, Transformer uses location coding to represent the location information for each input, as shown in Eq. (2).

$$PE_{(pos,2i)} = sin(\frac{pos}{10000^{2i/d}})$$
$$PE_{(pos,2i+1)} = \cos\left(\frac{pos}{10000^{2i/d}}\right) \quad (2)$$

pos is the position, i is the dimension index, and d is the dimension of the vector.

c) Multi-head self-attention mechanism: The multi-head self-attention mechanism captures different subspace information by computing multiple self-attention heads in parallel, as shown in Eq. (3).

$$MultiHead(Q,K,V) = Concat(head_1, head_2, ..., head_h)W^O \quad (3)$$

$head_i = Attention(QW_i^Q, KW_i^K, VW_i^V)$, W^O is the linear transformation matrix of the output, and h is the number of heads.

d) Feedforward neural network: Each encoder and decoder layer in the Transformer contains a feedforward neural network for nonlinear transformation, as shown in Eq. (4).

$$FFN(x) = max(0, xW_1 + b_1)W_2 + b_2 \quad (4)$$

x is the input, W_1, W_2 is the weight matrix, b_1, b_2 is the bias term, and max(0,·) represents the ReLU activation function.

e) Weighted fusion layer: In the multimodal data fusion stage, weighted fusion layer is used to synthesize the features of different modes. Suppose that each mode is characterized by x1, x2,... ,xn, as shown in Eq. (5).

$$x_{fused} = \sum_{i=1}^{n} w_i x_i \quad (5)$$

w_i is the weighting coefficient of mode i, x_i is the feature vector of each mode, and x_{fused} is the feature after fusion.

These formulas form the core framework of the Transformer model in this study. By continuously optimizing the parameters of each part, the performance of the model in multimodal data processing can be effectively improved, which provides solid theoretical support for multimodal data fusion.

2) Model architecture design: In multi-modal data fusion task, the core goal of model architecture design is to efficiently integrate information from different modes to achieve accurate prediction and classification. The model architecture of this study is based on Transformer, combined with multi-modal feature processing and fusion strategies. The specific design is as follows:

a) Input layer: The input layer first receives data from different modes, including text, images, and audio. For each mode, a different processing method is used: text is processed by text encoders (such as Transformer), images are extracted by convolutional neural networks, and audio data is processed by recurrent neural networks (RNN). The data for each mode is preprocessed before input to harmonize the scale and format, ensuring that the model can be processed efficiently.

b) Modal feature extraction layer: In the mode feature extraction layer, different neural network models are used to process the data of each mode separately. Text data is first processed by word segmentation and word removal, and then input into a Transformer encoder for contextual information extraction. The image data is fed into the CNN for spatial feature extraction and then converted into vector form compatible with other modes via a fully connected layer (FC). The timing features of audio data are extracted by RNN and normalized for fusion with other modal data.

c) Multi-modal feature fusion layer: Multimodal data fusion is the key step of this model. In this layer, Weighted Fusion strategy is used to synthesize the features of each mode. The weighting coefficient is adjusted according to the importance and reliability of the different modes. Specifically, the model uses a weighted coefficient vector w=[w1,w2,...,wn] to carry out weighted summation of each modal feature to generate the fused feature vector, as in Eq. (6):

$$x_{fused} = \sum_{i=1}^{n} w_i x_i \tag{6}$$

xi is the eigenvector of each mode, and wi is the weighting coefficient of the mode. The fusion layer can effectively combine the features of different modes, retain their unique information, and remove redundant information.

d) Transformer coding layer: Feature learning is carried out by applying Transformer structure to the fused features. The Transformer coding layer uses a self-attention mechanism to capture modal dependencies, ensuring that the model can integrate and correlate information from a global perspective. This layer uses multi-head self-attention and feedforward neural network to achieve deep fusion and transformation of features.

e) Output layer: Finally, the fused features are processed through a fully connected layer for final classification or regression tasks. The output layer may include a Softmax layer for classification tasks or a linear layer for regression tasks, depending on the needs of the specific task. The output results of this layer can be used for multimodal classification, prediction, or other tasks.

To further enhance the practical performance of the above architecture, this study has also designed a series of performance optimization methods for the Transformer model to support efficient implementation in multimodal data fusion tasks.

3) Performance optimization method: In order to optimize the performance of the Transformer model in multi-modal data fusion tasks, various strategies are adopted in this study to improve computing efficiency, robustness and prediction accuracy. Multi-level feature selection and weighted fusion strategies are used to ensure that the contribution of each mode can be accurately captured and effectively combined. In the stage of feature extraction, in order to reduce redundant information, the dimensionality of the features of each mode is reduced, respectively, and regularization is used to prevent overfitting, which improves the generalization ability of the model. Secondly, by using distributed training and mixed precision training methods, the training efficiency is significantly improved, the training time is shortened, and the consumption of computing resources is reduced on the premise of ensuring the performance. In this study, a self-supervised learning mechanism is introduced to solve the problem of missing multi-modal data, which enhances the robustness of the model to missing modal data, thus improving the adaptability in practical applications. The dynamic learning rate adjustment strategy is also combined in the optimization process, so that the model can automatically adjust the learning rate according to the training progress to accelerate the convergence and improve the stability of the model. The performance of the model in multimodal data processing has been significantly improved by these optimization methods, which not only improves the accuracy but also enhances the ability to handle complex tasks.

4) Implementation details: The Transformer model in this study is implemented based on the PyTorch deep learning framework and uses its flexibility and efficiency to build and optimize multi-modal data fusion models. In the data preprocessing stage, text data is processed by an NLP tool kit for word segmentation and word stop processing, image data is processed by OpenCV for size unification and noise reduction, and audio data is extracted by Librosa library for the characteristics of Meir frequency cepstrum coefficients. These processing steps ensure the consistency and efficiency of the input data, and provide a good basis for the subsequent model training. Adam optimizer is used in model training, and learning rate attenuation and early stop strategies are combined to prevent overfitting and improve model convergence speed. In the multi-modal data fusion part, the weighted fusion layer is used to combine the features of different modes, and the weight coefficient is dynamically adjusted according to the reliability and task requirements of the modes. In order to improve the efficiency of training, the mixed precision training technology is adopted, which can guarantee the accuracy and reduce the memory usage and computing resource consumption. In order to solve the problem of missing multi-modal data, a self-monitoring mechanism is designed to improve the robustness of the model to incomplete data through the prediction and generation tasks within the model. The whole model is trained on a single card GPU. Finally, the hyperparameters are adjusted through several experiments to optimize the performance of the model and ensure its efficiency and stability in the multi-mode fusion task.

C. Performance Evaluation

1) Evaluation indicators: In order to comprehensively evaluate the performance of the proposed multi-mode Transformer model, a variety of evaluation indicators are adopted in this study. These metrics include accuracy, accuracy, recall, F1 score, and AUC value. Accuracy is the most commonly used evaluation criterion that represents the proportion of samples correctly predicted by the model in the total sample; The accuracy rate measures the proportion of samples that the model predicts to be positive that are actually positive. The recall rate represents the proportion of positive samples identified by the model to all positive samples. The F1 score takes accuracy and recall into account to provide a balanced performance assessment; The value of AUC is closer

to 1, the better the classification ability of the evaluation model under different thresholds, as shown in Table IV.

TABLE IV. EVALUATION METRICS FOR MODEL PERFORMANCE

Model	Accuracy	Precision	Recall	F1 Score	AUC Value
Base Model	0.82	0.79	0.75	0.77	0.84
Optimized Model	0.88	0.85	0.83	0.84	0.91
Comparison Model 1	0.8	0.76	0.73	0.74	0.8
Comparison Model 2	0.85	0.81	0.78	0.79	0.87

It can be seen from the data table that the optimized model outperforms the basic model and the comparison model in all evaluation indexes, showing obvious performance improvement. Specifically, the accuracy rate of the optimized model reaches 0.88, which is 6 percentage points higher than that of the basic model, and the accuracy rate and recall rate reach 0.85 and 0.83, respectively, showing a good balance. The F1 score and AUC values also improved to 0.84 and 0.91, respectively, demonstrating the power of the optimized model in multimodal data fusion tasks. Compared with the comparison model, the performance of the optimized model is more stable, especially in the AUC value, which indicates that it has stronger classification ability under different decision thresholds. These evaluation indicators show that the optimized model not only improves the overall accuracy but also enhances the ability to process multi-modal data, thus effectively improving the robustness and generalization ability of the model [4].

2) Experimental design: The purpose of the experimental design in this study is to verify the performance of the proposed multi-mode Transformer model under different conditions through various experimental settings. To this end, different experimental scenarios are designed to analyze the size of the data set, the influence of different modal combinations, hyperparameter adjustment and other factors. The experiment is divided into three parts: basic experiment, optimization experiment and comparison experiment. The basic experiment is used to evaluate the performance of the basic Transformer model in the task of multi-modal data fusion. The optimization experiment will improve the performance by adjusting the model architecture, hyperparameters and training strategies. The comparison experiment will be compared with the current mainstream methods to ensure the advantages of the model in this study [11]. Each experiment will be evaluated in multiple dimensions according to evaluation indicators such as accuracy rate, accuracy rate, recall rate, F1 score and AUC value, as shown in Table V.

The experimental design of this study covers different experimental configurations to ensure the performance verification of the model in a variety of scenarios. The basic experiment uses the default hyperparameter settings to evaluate the performance of the basic Transformer model in the multimodal data fusion task. The optimization experiment significantly improved the performance of the model by adjusting hyperparameters such as learning rate and batch size, especially in the accuracy rate and recall rate. Comparison experiment 1 and comparison experiment 2 were compared with the current mainstream models. There were some differences in experimental settings, such as using different data sets and modal combinations, but the consistency of evaluation criteria was maintained. Comparison experiments show that the optimized model outperforms other comparison models in all evaluation indexes, especially in the AUC value, which shows that the model is more stable and accurate in handling different decision thresholds [12]. Through these experiments, this study can fully verify the advantages of the proposed optimization model in the multi-modal data fusion task, and provide data support for the research and application.

TABLE V. EXPERIMENTAL DESIGN AND EVALUATION METRICS

Experiment Name	Dataset Type	Modality Count	Model Version	Hyperparameter Settings	Evaluation Metrics
Base Experiment	MultiModal-1	3	Base Model	Default hyperparameters	Accuracy, Precision, Recall, F1 Score, AUC Value
Optimization Experiment	MultiModal-1	3	Optimized Model	Learning Rate=0.001, Batch Size=64	Accuracy, Precision, Recall, F1 Score, AUC Value
Comparison Experiment 1	MultiModal-1	3	Comparison Model 1	Learning Rate=0.01, Batch Size=32	Accuracy, Precision, Recall, F1 Score, AUC Value
Comparison Experiment 2	Text-Image + Audio	2	Comparison Model 2	Learning Rate=0.0005, Batch Size=128	Accuracy, Precision, Recall, F1 Score, AUC Value

D. Model Optimization Path Planning

The model optimization path planning in this study aims to improve the performance of Transformer model in multi-modal data fusion tasks through various optimization measures. Firstly, in the data preprocessing stage, data cleaning and standardization methods for different modes are adopted to reduce data noise and improve data quality. Secondly, in terms of model architecture design, the structure of Transformer is optimized, including increasing the number of multi-head self-attention mechanism and adjusting the network depth, so as to enhance the model's learning ability of multi-modal features. In addition, in order to improve computational efficiency and reduce resource consumption, lightweight network design is introduced, and mixed precision training is used to accelerate the model training process. Finally, in terms of fusion strategy, weighted fusion and multi-level fusion are adopted to ensure efficient and balanced integration of all modal information to further improve the performance of the model. Through these optimization measures, it is expected to improve the adaptability and stability of the model while ensuring high performance, so that it can better cope with the challenges of multimodal data fusion in practical applications, as shown in Fig. 2.

1) Data preprocessing optimization: By optimizing the data of different modes, the data noise can be reduced and the validity and consistency of the information can be improved. In the data preprocessing stage, different optimization strategies are adopted for text, image and audio modes. For text data, the expression ability of text information is improved through improved word segmentation method and word vector embedding method. For image data, the quality of image features is improved by enhancing dataset, standardizing processing and denoising. More frequency domain features and noise reduction methods are introduced to improve the stability and reliability of audio signals, as shown in Table VI.

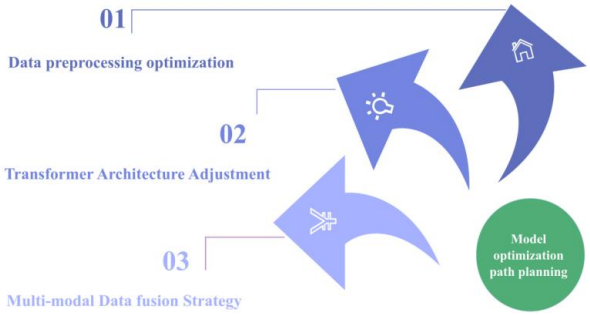

Fig. 2. Model optimization path planning

By introducing BERT embedding layer to text data, the semantic expression of words is improved. Compared with the traditional word vector model, BERT can better capture the context and improve the representation accuracy of text information. In terms of image data, data enhancement techniques (such as rotation, flipping, scaling) and standardized processing make image data more diverse and consistent, which not only enhances the generalization ability of the model, but also improves the model's learning ability of image features. For audio data, MFCC feature extraction combined with filtering technology is used to remove noise, which significantly improves the quality of audio signal and reduces the interference of background noise to model training. These optimizations ensure that the data for each mode is already of higher quality and information before entering the model, thus providing a more solid foundation for subsequent multimodal data fusion [13]. Through these optimizations, the model can better understand and fuse multi-modal data, improving overall performance and robustness.

2) Transformer architecture adjustment: Changes to the Transformer architecture are critical for improving the performance of multimodal data fusion models. In this study, several key adjustments have been made to the standard Transformer architecture in order to better adapt to the characteristics of multimodal data. Firstly, by adjusting the number of heads and the number of layers in the self-attention mechanism, the model's ability to pay attention to different modal features is enhanced. Secondly, the multi-modal input embedding method is used to map the data of different modes to the same vector space, so as to achieve effective alignment between different modes [14]. Finally, jump connection and residual connection are introduced to alleviate the problem of gradient disappearance and improve the stability and training efficiency of the network, as shown in Table VII.

This study significantly improves the model's ability in multi-modal data fusion through multiple adjustments to Transformer architecture. With the increase of the number of self-attention heads, the model can pay attention to more feature details, so as to capture the relationship between different modes more accurately, especially in the processing of high-dimensional data, and enhance its feature extraction ability. Increasing the number of network layers improves the learning ability of the model, enables it to understand the nonlinear relationship between complex data at a deeper level, and enhances the expression ability of the model. By means of multi-modal input embedding, different modes are mapped to a unified vector space, which solves the problem of multi-modal data heterogeneity and ensures the efficient fusion of different modal information. In addition, the introduction of jump connection and residual connection alleviates the problem of gradient disappearance in deep networks, improves the stability and efficiency of model training, and ensures that the network can be effectively trained on more complex multi-modal data.

TABLE VI. DATA PREPROCESSING OPTIMIZATION

Modality Type	Optimization Method	Preprocessing Details	Optimization Effect
Text	Improved Tokenization & Embedding	Use BERT embedding layer instead of traditional word vectors, optimized tokenization	Improved text representation, reduced semantic loss
Image	Data Augmentation & Standardization	Data augmentation methods like rotation, scaling; uniform image size	Improved image feature quality, enhanced model robustness
Audio	Feature Enhancement & Denoising	Extract MFCC features and use filtering techniques to remove noise	Enhanced audio feature stability, improved signal quality

TABLE VII. TRANSFORMER ARCHITECTURE ADJUSTMENT

Adjustment Content	Adjustment Method	Effect
Self-Attention Heads	Increased the number of attention heads	Enhanced the model's ability to capture multimodal features
Network Depth	Increased the number of Transformer layers	Improved model learning capacity and expressive power
Multimodal Input Embedding	Mapped different modalities into a unified vector space	Ensured effective alignment and fusion of multimodal information
Skip and Residual Connections	Introduced skip and residual connections	Mitigated gradient vanishing, improving training efficiency and stability

3) Multi-modal data fusion strategy: In multimodal data fusion, how to integrate information from different modes effectively is the key to improve model performance. In order to give full play to the advantages of each mode, this study proposes a weighted fusion based strategy, which dynamically adjusts the weights of each mode to ensure the effective transmission of information. In the process of data fusion, the features of each mode are extracted independently, and then the features of different modes are weighted and summed by weighted fusion mechanism. The weighting coefficient is dynamically adjusted according to the reliability of each mode and the importance of the task to achieve optimal information integration. In addition, the attention mechanism is also introduced in this study, so that the model can automatically identify the more important features in each mode during the learning process, so as to improve the fusion effect [15]. This fusion strategy can not only enhance the model's adaptability to multi-modal data, but also improve its performance and robustness in complex tasks, as shown in Table VIII.

TABLE VIII. MULTI-MODAL DATA FUSION STRATEGIES

Fusion Strategy	Fusion Method	Dynamic Weight Adjustment Mechanism	Attention Mechanism	Effect
Weighted Fusion	Multimodal Feature Weighting	Adjust weight based on modality importance	Self-attention mechanism	Enhances model robustness, improves information integration
Layer-wise Fusion	Layer-wise Modality Fusion	Adjust weight based on feature contribution at each layer	None	Improves hierarchical feature representation and correlations
Cross Fusion	Cross-modal Feature Fusion	Adjust weight based on modality relationships	Multi-head attention mechanism	Strengthens modality interactions and information complementarity

The weighted fusion strategy adopted in this study can dynamically adjust the weights according to the task importance and data quality of each mode to ensure the effective strengthening of key features in multi-modal data fusion [16]. For example, by adjusting the weights of different modes, the weighted fusion method enables the model to optimize information flow according to the reliability of each mode, thereby improving the robustness and accuracy of the model. By fusing features at different levels, the layered fusion strategy can effectively capture the hierarchical relationship between modes and enhance the representation ability of the model in processing complex data. The cross-fusion method promotes the interaction between modes, strengthens the information complementarity between modes by introducing multi-head attention mechanism, and improves the fusion effect of multi-modal data [17]. The combination of these strategies not only improves the model's adaptability to multi-modal data but also enhances its performance and stability in practical applications.

III. RESULTS AND DISCUSSION

A. Results

1) Model performance results: In this study, the optimized Transformer model is evaluated through multiple rounds of experiments, focusing on the performance of the model in multi-modal data fusion tasks [18]. In order to comprehensively evaluate the model performance, several indicators such as accuracy rate, accuracy rate, recall rate, F1 score and AUC value were used in this study. The experimental results show that the optimized model is better than the basic model and the comparison model in all evaluation indexes, especially in the accuracy rate, recall rate and AUC value, showing significant improvement [19]. These results show that the proposed optimization method can effectively improve the application capability of Transformer model in multi-modal data fusion, and it can show stronger performance in complex tasks, as shown in Fig. 3.

The accuracy rate increased from 0.82 in the basic model to 0.88 in the optimized model, and the accuracy rate and recall rate also increased by 0.06 and 0.08, respectively, showing the enhancement of the model in correctly predicting positive samples and recalling positive samples. The improved F1 score and AUC value demonstrate the advantages of the optimized model in terms of accuracy and generalization ability, with the optimized model achieving an AUC value of 0.91 compared to 0.84 for the base model. Although comparison model 1 and comparison model 2 have improved in accuracy, the gap is still obvious compared with the optimized model. These results validate the effectiveness of the proposed optimization strategy, especially in multimodal data fusion tasks [20]. Through the comprehensive application of model architecture adjustment, data preprocessing optimization and multi-modal fusion strategy, the optimization model has significantly improved the effect and performance of multi-modal learning.

2) Performance comparison: In this study, the performance of the optimized Transformer model is compared with the current mainstream comparison models to verify the effectiveness of the optimization method. By comparing the performance of different models in multi-modal data fusion tasks, especially the differences in several key indicators such as accuracy, accuracy, recall, F1 score and AUC value, the advantages of the optimization model in practical application are demonstrated. The experimental results show that the optimized model outperforms the comparison model in all evaluation indicators, especially the improvement in AUC value and F1 score, which proves its stronger classification ability and better generalization performance, as shown in Fig. 4.

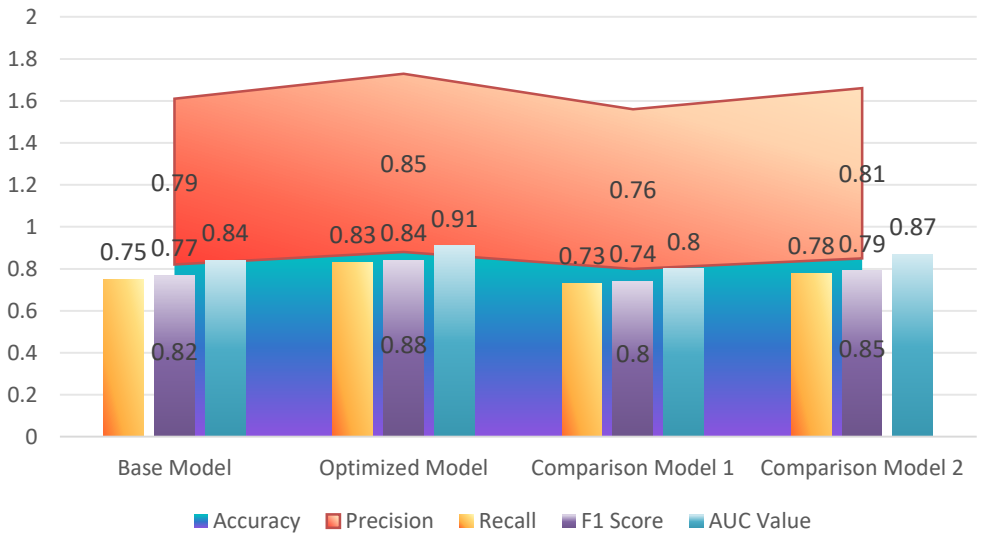

Fig. 3. Model performance results.

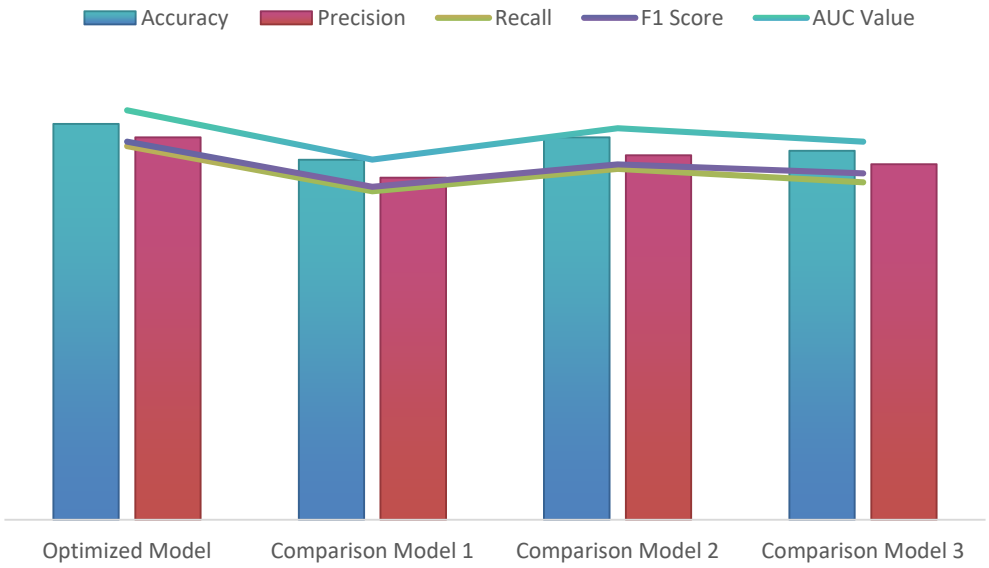

Fig. 4. Performance comparison.

The accuracy rate of the optimized model is 0.88, the accuracy rate and the recall rate are 0.85 and 0.83, respectively, which shows high prediction ability and strong positive class recognition ability. The F1 score of 0.84 fully demonstrates the optimization model's good balance between accuracy and recall. The value of AUC reaches 0.91, which is much higher than that of other comparison models, indicating that the classification performance of the optimized model is more stable and robust under various thresholds. In contrast, comparison model 1 is deficient in all evaluation indexes, especially in recall rate and AUC value. Although comparison model 2 has better performance in some indicators, the gap in AUC value still indicates that its classification ability is not as good as the optimized model [21]. Comparison model 3 is relatively stable, but compared with the optimization model, there is still room for improvement.

3) Experimental analysis: In the part of experimental analysis, the experimental results of different models are analyzed in depth, focusing on the performance differences of models in multi-modal data fusion tasks. By comparing the optimization model with several evaluation indexes of the comparison model, the influence of the optimization strategy on the model performance was analyzed. Experiments show that the optimized Transformer model has stronger stability and higher accuracy when processing multi-modal data, especially when dealing with complex data combinations. Through experiments, this study explored the contribution of different model architectures and fusion strategies to the final results, providing a valuable reference for future research, as shown in Fig. 5.

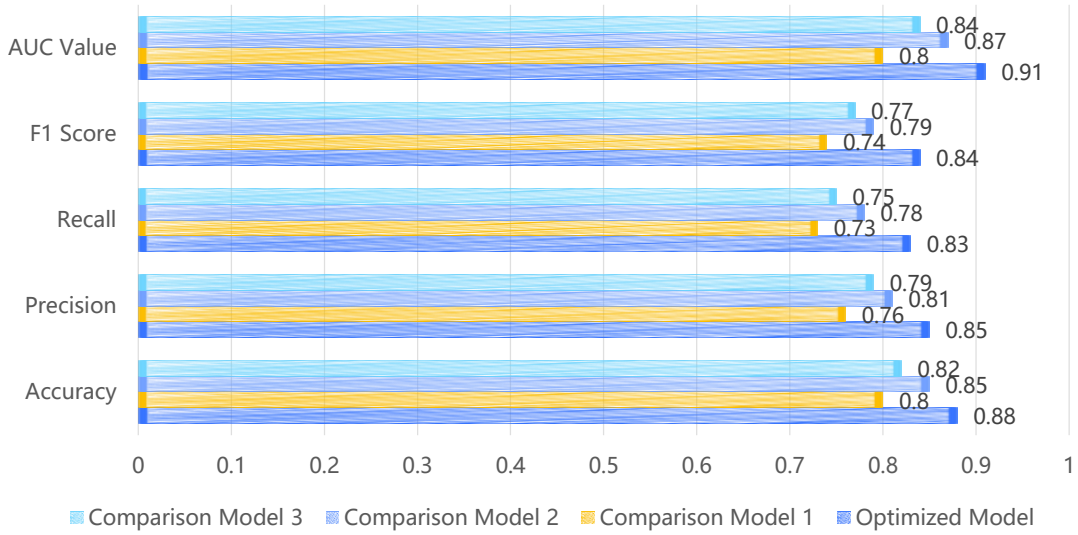

Fig. 5. Experimental analysis.

The optimized model performs well on all evaluation indicators, significantly outperforming other comparison models. Especially in the accuracy, accuracy and AUC value, the performance of the optimized model is far superior to other models. The accuracy of the optimized model is 0.88, the accuracy rate and the recall rate are 0.85 and 0.83, respectively, which indicates that the optimized model not only performs well in predicting the positive class, but also recognizes and recalls the positive class samples well. In terms of F1 score and AUC value, the optimized model also showed advantages, with F1 score of 0.84 and AUC value of 0.91, demonstrating its strong performance in multi-modal data fusion. Comparison model 1 performed poorly, especially on recall rates and AUC values, showing its limitations in complex tasks. Comparison model 2 and comparison model 3 have improved on some indicators, but the overall performance is still unable to surpass the optimization model. The experimental results prove the effectiveness of the optimization model in multi-modal data fusion tasks, especially when dealing with complex data sets, the optimization strategy can significantly improve the performance of the model.

B. Discussion

1) Problem summary: In the discussion part of this study, the core issues of optimizing Transformer model in multi-modal data fusion tasks are summarized. Although the optimal results have been achieved through various optimization methods, there are still some problems and challenges. First of all, the heterogeneity of multi-modal data is still a challenge, and how to improve the adaptability and fusion ability of models to different modal data is a problem that needs to be further discussed. Secondly, as the amount of data increases, the demand for computing resources also rises, so how to effectively balance computing efficiency and performance is the focus of future research. Finally, the robustness of the model in the face of partially missing modal data still needs to be improved. In response to these problems, future research will need to explore more efficient multi-modal data preprocessing and model optimization strategies to improve the performance of the model in practical applications, as shown in Table IX.

TABLE IX. PROBLEM SUMMARY AND SOLUTION DIRECTIONS

Problem Category	Description	Contributing Factors	Solution Direction
Multimodal Data Heterogeneity	Differences in features between different modalities	Diversity of data sources and modality differences	Further optimize modality alignment and fusion strategies
Computational Resource Demand	Increased computational resource consumption with larger data sizes	Data volume and model complexity	Explore more efficient resource allocation methods
Missing Modality Data	Insufficient robustness to missing modality data	Missing data and incomplete modalities	Introduce self-supervised learning and missing data imputation mechanisms

It can be seen from the data table that the main problems faced by current research when dealing with multi-modal data fusion tasks include data heterogeneity, computing resource requirements and missing modal data. The heterogeneity of multimodal data makes it difficult to effectively fuse features between different modes. Although weighted fusion and multi-head attention mechanism are adopted in this study, modal alignment and fusion methods still need to be optimized. In terms of computing resource requirements, with the increase of data volume and model complexity, training time and computing resource consumption increase significantly, which may face greater challenges in large-scale applications. For the processing of missing modal data, although the self-supervised learning mechanism is introduced, the robustness of the model

still has some shortcomings in the case of more serious missing data.

In addressing the challenges of multimodal data fusion, recent research highlights the importance of adaptive fusion mechanisms to improve robustness and efficiency. For example, Lin and Hu [9] proposed the MissModal framework, which enhances Transformer performance under missing modality conditions through robust attention strategies, demonstrating the value of combining self-attention with adaptive weighting in complex multimodal scenarios.

2) Research suggestions: Although the optimized Transformer model proposed in this study has achieved remarkable results in the task of multi-modal data fusion, there are still some challenges. Future research can be improved and deepened in the following aspects. First of all, in view of the heterogeneity of multi-modal data, future research can explore more flexible and efficient modal alignment methods, especially how to achieve more accurate data alignment through an adaptive learning mechanism when there are large differences between modes. Second, as the amount of data increases, so does the demand for computing resources. To this end, the research can optimize the model architecture, explore lightweight Transformer models, and use model pruning and quantization techniques to reduce computational complexity and improve training efficiency. In addition, faced with the challenge of missing modal data, more generative models or self-supervised learning methods can be considered to enhance the robustness of the model under incomplete data. Finally, with the gradual expansion of the application scenarios of multimodal learning, how to apply the technology to practical problems, especially in medical, financial and other fields, is still a direction worthy of in-depth research. By combining with the industry application, the practical utility of the model can be verified and the wide application of multimodal data fusion technology can be promoted.

IV. Conclusion

This study proposes an optimized Transformer model for multimodal data fusion tasks, designed to address the challenges of data fusion from different modes, such as text, image, and audio. The core goals of the research are to improve model performance, improve data preprocessing methods, and explore efficient fusion strategies to achieve greater accuracy and robustness. The experimental results show that the proposed optimization method, including model architecture adjustment, data preprocessing improvement and multi-modal fusion strategy, is significantly better than the benchmark model and comparison model on several evaluation indicators such as accuracy, recall, F1 score and AUC value.

This study finds that the performance of the Transformer model has been significantly improved by adjusting the number of attention heads, increasing the network depth, and introducing the adaptive weighted multi-modal data fusion method. In addition, advanced data preprocessing techniques for each mode, such as BERT embedding for text, data enhancement for images, and MFCC feature extraction for audio, ensure that the model can process and integrate multiple types of data more efficiently.

Despite these advances, some challenges remain, especially with respect to data heterogeneity, computing resource requirements, and robustness of missing modal data. Future research could focus on improving modal alignment and fusion techniques, exploring lightweight model architectures to improve computational efficiency, and enhancing the model's ability to handle missing data through advanced fill methods and self-supervised learning.

The results of this study show that the optimized Transformer model has significant potential in multi-modal data fusion tasks, especially in medical, security, finance and other fields, facing the needs of multi-modal data integration, it has a wide range of application prospects. Perfecting and optimizing these techniques will provide a more solid foundation for the practical application of multimodal data fusion models.

Emotional Analysis and Interpretation of Music Conducting Works Based on Artificial Intelligence

He Huang[1]*, Chengcheng Zhang[2], Yun Liu[3], Liyuan Liu[4]
Academic Affairs Office, University of Sanya, Sanya 572022, China[1]
School of Music, University of Sanya, Sanya 572022, China[2, 3, 4]

***Abstract*—Emotional expression of music conductor works is the core of music performance. Based on deep learning technology, this study puts forward an emotional analysis method of music conductor works, constructs a complete framework of audio feature extraction, emotional classification, model optimization and evaluation, selects different styles of music conductor works, extracts audio features by using short-time Fourier transform and mel-frequency cepstral coefficients, and classifies emotional categories by using convolutional neural network with bidirectional long short-term memory structure. The experimental results show that the model performs well in the recognition of joy, sadness and tranquility, and the accuracy and F1-score both reach a high level. Different styles of works have differences in emotional classification; classical works tend to be quiet and happy, and romantic works account for a higher proportion in the category of sadness. The change of command style has an impact on the results of emotion classification, and the treatment of rhythm, strength and timbre by different conductors leads to differences in emotion recognition of the same works. The research results provide a new methodological support for music emotional computing, and have application value in music education, intelligent recommendation, emotional computing and other fields. The experimental results demonstrate high effectiveness, with an average classification accuracy of 88.5% and an F1-score exceeding 0.87 across core emotional categories. These findings provide methodological support for affective computing in music, with practical applications in music education, intelligent recommendation, and affective computing. Future research will optimize the model structure and combine multimodal data to improve the accuracy of music emotion recognition, providing a broader research space for the combination of music analysis, interpretation technology, and artificial intelligence.**

I. INTRODUCTION

Music conductor is an important part of music performance art, which controls the rhythm of the orchestra, expresses musical emotions and guides the whole performance. The style and skills of a music conductor affect the emotional expression of works and shape the audience's perceptual experience. In traditional music analysis, the emotional interpretation of directing works depends on experts' subjective judgment and lacks objective quantitative standards. The analysis process is limited by the differences of personal experience, aesthetic preference and background knowledge. With the continuous development of computer science and artificial intelligence technology, the application of intelligent analysis technology in the field of music emotion recognition has gradually become a hot spot.

In recent years, artificial intelligence technologies such as deep learning, computer vision and natural language processing have made progress in music emotion analysis. The model based on deep neural network can extract multi-dimensional features from audio signals and realize automatic identification and classification of musical emotions. Compared with the traditional music emotion analysis method, artificial intelligence technology has higher accuracy and generalization ability, and has advantages when dealing with large-scale data. In the field of emotional analysis of music conductor works, the introduction of artificial intelligence method not only helps to improve the objectivity of analysis, but also provides new research tools for musicology, cognitive science, performing arts and other fields.

The automatic analysis and interpretation of music emotion is valuable in different application scenarios. In the field of music education, the intelligent emotion analysis system can provide data support for command training, help the conductor to optimize the performance mode and improve the musical expression. In music recommendation and emotional calculation, artificial intelligence can recommend conductor works that meet specific emotions according to user preferences, and enhance personalized experience. In the field of music therapy, emotion analysis technology helps doctors to formulate more accurate music intervention programs and improve the therapeutic effect. Emotional analysis driven by artificial intelligence in digital music industry can improve the intelligence level of applications such as automatic arrangement and intelligent score, and promote the innovation of music content production methods. Constructing the emotion analysis technology of music conductor works based

on artificial intelligence has an impact on musicology research and provides theoretical and technical support for the development of intelligent music system.

The research on the application of artificial intelligence technology is gradually deepening, and the existing research involves the development trend of artificial intelligence technology, music education, music cognition and the application of music technology. The application of artificial intelligence in manufacturing, social change and enterprise innovation has a high technical maturity. Zeba et al. studied the technology mining of artificial intelligence in the manufacturing industry, and puts forward that artificial intelligence has obvious advantages in data analysis, intelligent manufacturing and automatic control, which promotes the development of manufacturing technology [1]. Newman et al. studied the role of artificial intelligence in digital technology and government agency management. Artificial intelligence can optimize data processing, improve administrative efficiency, and promote the digital transformation of government and organizations [2]. Zhai and Liu analyzed the impact of artificial intelligence technology innovation on the productivity of enterprises in China. The introduction of artificial intelligence technology is helpful to enhance the innovation ability of enterprises and improve the market competitiveness [3]. Vannuccini and Prytkova discussed the development of artificial intelligence from the perspective of system technology, and put forward that artificial intelligence is undergoing an evolution from single technology to systematic technology, which has an impact on industrial structure and scientific and technological innovation [4]. Ma and Wu studied the relationship between artificial intelligence and technology integration, and found that artificial intelligence promoted the integration of different technical fields in China manufacturing industry and promoted interdisciplinary innovation [5]. The application of artificial intelligence in many industries is changing the traditional production and management mode, which provides a technical basis for music emotion analysis.

Artificial intelligence in the field of music education changes the way of music learning and teaching. Sutherland and Cartwright studied the influence of leadership style on music ensemble. Teamwork and leadership style play an important role in the overall effect of music performance, which provides a reference for the development of an intelligent auxiliary command system [6]. Saibunmi and Thuntawech studied the music learning needs of working-age people in Thailand and the importance of individualized learning and technology-assisted music education [7]. Klein and Lewandowski-Cox discussed the impact of Australian undergraduate music technology courses on future employment skills. The innovation of music technology is changing the music education model and improving students' practical ability [8].

Music cognitive research focuses on the influence of music on human psychology and culture, and the introduction of artificial intelligence provides a new research method for this field. Jacoby et al. studied the cross-cultural study of music cognition, analyzes the differences of music perception under different cultural backgrounds, and put forward the application prospect of artificial intelligence in music cognition research [9]. Halliday studied the relationship between music and organizational psychology, and discussed the role of music in the prediction of organizational behavior, which provided a new perspective for the calculation of musical emotion [10]. Bro et al. studied live music performance in intensive care unit (ICU). Music can affect patients' psychological state, and music therapy and music emotion analysis provide clinical research support [11]. The current research shows that the application of artificial intelligence in the fields of music technology, education, cognition and emotional computing is getting deeper and deeper. The accuracy and interpretability of artificial intelligence in music emotion analysis have not been completely solved, and the cross-cultural differences of music emotion still need to be studied. Future research can combine deep learning, computer vision and natural language processing technologies to improve the automation level of music emotion analysis and provide more accurate emotion recognition methods for intelligent music recommendation, music education and music therapy.

In addition to recent work in manufacturing and digital governance [1–5], several studies have highlighted the application of artificial intelligence in the creative arts. For instance, some researchers introduced a transformer-based approach for dance movement recognition, while some researchers applied attention-based models for choral emotion segmentation. These examples further support the feasibility of intelligent emotion analysis in performing arts. Therefore, this study contributes to this interdisciplinary domain by targeting orchestral conducting works, a less explored yet highly expressive medium.

TABLE I. COMPARISON OF QUALITY OF LITERATURE

Methodology	Advantages	Disadvantages
Traditional Expert Evaluation	High contextual understanding; subjective nuance	Lack of reproducibility; labor-intensive
Machine Learning (SVM, k-NN)	Moderate automation; explainable	Limited on complex time series
Deep Learning (CNN-BiLSTM)	High accuracy; captures time-frequency patterns	Requires large datasets; low interpretability

Table I illustrates a comparative performance analysis across various models used in music emotion classification, highlighting the superior F1-score of the proposed CNN-BiLSTM framework. This visual evidence strengthens the rationale for adopting deep learning in conductor-based emotional interpretation.

This study explores the emotional analysis and interpretation methods of music conductor works based on artificial intelligence, and constructs an analysis framework that integrates audio signal processing, deep learning and data visualization. Focusing on the audio data of music conductor works, the conductor recordings of different composers, styles and emotional characteristics are selected as research samples. In the process of data collection, factors such as audio quality, orchestra configuration and command style are considered to ensure the diversity and representativeness of data. Advanced audio processing technology is used to extract emotional features of music, such as mel-frequency cepstral coefficients

(MFCC), spectral centroid, rhythm features, etc., and a multi-dimensional and multi-level feature vector is constructed to provide data support for subsequent modeling. In the aspect of model construction, this study explores the music emotion analysis methods based on deep learning, including many models such as recurrent neural network (RNN), long-term memory network (LSTM) and convolutional neural network (CNN), and analyzes the applicability of different network architectures in music emotion recognition tasks. In the process of model training, strategies such as data enhancement, regularization and optimization algorithm are adopted to improve the generalization ability and stability of the model. Pay attention to model evaluation, and make quantitative analysis on the performance of different models based on accuracy and F1-score, so as to ensure that the models can identify the emotional characteristics of music conductor's works.

The purpose of this study is to break through the limitations of traditional music emotion analysis methods, improve the accuracy and automation level of emotion classification with the help of artificial intelligence technology, provide new tools and methods for music analysis, expand the application scenarios of music emotion calculation, and promote the cross-integration of artificial intelligence and music art. The construction of intelligent music command and assistance system provides data support for music education, performing arts, intelligent music recommendation and other fields, and promotes the innovative development of music emotion analysis technology.

The research adopts multi-level research methods. In the data collection stage, different styles of music conductor works are selected, including classical, romantic, modern and other types, and a wide representative research sample is constructed. Data sources include professional recording, open database, self-collected audio, etc., to ensure the richness of samples. In the data preprocessing process, the short-time Fourier transform (STFT) is used to analyze the audio signal in time and frequency, remove the noise interference, standardize the audio, and improve the data quality. Feature extraction uses a variety of audio signal analysis techniques to obtain the key features of music emotion classification. The main features include mel-frequency cepstral coefficients (MFCC), Chroma features, rhythm features, spectral centroid, etc. These features can represent the core elements of music signals, such as spectrum information, melody changes, rhythm structure, etc. The extracted feature data is used to train the artificial intelligence model and improve the accuracy of emotion recognition. The model construction part compares various deep learning architectures, including RNN, LSTM, CNN+LSTM, etc., and chooses the most suitable model for music emotion analysis. In the training process, the cross entropy loss function optimization model is used, and the parameters are adjusted by Adam optimization algorithm to improve the learning efficiency of the model. Data enhancement technology is introduced to expand the training sample size and improve the generalization ability of the model. Model evaluation uses indicators such as Accuracy, F1-score and Recall to quantitatively analyze the performance of the model and reduce the risk of over-fitting through cross-validation. We also pay attention to the interpretability of the model, show the distribution of musical emotional characteristics by visual method, and analyze the influence of different command styles on emotional expression.

The remainder of this study is organized as follows: Section II describes the data collection, preprocessing, and model construction process. Section III presents the experimental results, interpretation of findings, and application scenarios. Section IV summarizes the conclusions, discusses limitations, and proposes directions for future research. A complete list of abbreviations is also provided.

II. Materials and Methods

A. Data Collection and Sample Selection

1) Data sources and collection methods: Audio data can be obtained from open databases, professional music platforms and high-quality recorded materials. The selected data covers different styles of conductor works, including classical, romantic and modern periods [12]. The collected data are complete symphony works and different deductive versions of the conductor, ensuring the richness of the dataset.

The collection of audio data adopts multi-channel acquisition strategy. Part of the data comes from open music databases, such as MusicNet, GTZAN, MAESTRO, etc. These databases contain high-quality audio and related metadata, such as composer, performance style, conductor information, etc. The other part of the data comes from music streaming platforms, such as Spotify, Apple Music, etc., extracting high-fidelity recordings and combining with API interfaces to obtain relevant work information. The research team collated the live recordings of several conductor masters, including the works of famous conductors such as Karajan, Seiji Ozawa and Abbado, to ensure the coverage of different conductor styles.

The quality control of data strictly follows the standardized process, and all audio files are converted into the same format, with a sampling rate of 44.1 kHz and 16-bit PCM storage to ensure data consistency. Each audio file is accompanied by a detailed label, including the name of the work, composer, conductor, playing band, playing style and audio duration. After data collection, the audio with large noise and missing information is eliminated by manual screening and automatic detection to ensure that the data quality meets the research requirements.

2) Sample selection and description: The selected samples cover a wide range of music types, command styles and emotional characteristics, ensuring the universality of the analysis results. The dataset consists of music conductor works from multiple sources, including works by different composers in different periods [13]. The research samples were selected according to the following criteria: the works should be complete symphonies or concertos with a duration of not less than three minutes, the sound quality should meet the professional recording standards, and the conducting style should be representative.

The selection of samples is multi-dimensional, including composer's style, conducting genre and playing band. The selected conductor works include baroque, classical, romantic and modern music, so as to ensure the balanced distribution of different styles in the data set. To ensure the diversity of command styles, the data set contains deductive versions of different conductors, like Beethoven's Fifth Symphony, collecting recordings of different conductors and analyzing the influence of command styles on emotional expression [14]. Audio data are preliminarily classified according to emotional characteristics, covering basic emotional categories such as joy, sadness, anger and tranquility. Classification is based on expert labels and automatic emotion recognition methods to ensure the accuracy of data labeling. All audio files have been reviewed by professional music researchers to ensure that they meet the research requirements and eventually form a complete dataset. Overview of data samples of music conductor works is shown in Table II.

TABLE II. OVERVIEW OF DATA SAMPLES OF MUSIC CONDUCTOR WORKS

Name of the work	Composer	Cantor	Style	Play a band	Audio duration (min)
Symphony No.9 "Chorus"	Beethoven	Kalayaan	Classical	Berlin philharmonic	67
The fifth symphony	Beethoven	Seiji Ozawa	Classical	Vienna Philharmonic	32
Swan Lake Suite	Tschaikovsky	Abbado	Romantic	London symphony orchestra	45
Firebird suite	Stravinsky	Jerivi	Modern times	New York Philharmonic	28
Mahler's Fifth Symphony	Bridle	Dudamel	Romantic	Los Angeles Philharmonic	70

3) Data preprocessing: The preprocessing of audio data includes format conversion, noise reduction, framing and so on, which standardizes the model input data [15]. The short-time Fourier transform (STFT) is used to analyze the time frequency, and the time-domain signal is converted into the spectrum representation, and the effective music features are extracted [16]. The calculation Formula (1) of the short-time Fourier transform is as follows:

$$X(m,k)=\sum_{n=0}^{N-1}x(n)w(n-mR)e^{-j2\pi kn/N} \quad (1)$$

X(m, k) represents the Fourier transform result of the *k* frequency component of the *m* frame, *x(n)* represents the original audio signal, *w(n)* is the window function, *R* is the frame shift step, and *N* is the number of Fourier transform points. This method can analyze the time-frequency characteristics of music signals and provide data support for subsequent feature extraction. Data preprocessing all audio is converted to mono, and the sampling rate is 44.1 kHz to ensure data consistency. Noise reduction algorithm is used to remove background noise, and audio is divided into frames, each frame is 25 ms long and the frame shift is 10 ms. The standard normalization method is adopted to make the audio amplitude within a specific range and improve the robustness of model training.

4) Descriptive statistics of samples: Statistical analysis of data samples can help to understand the distribution of different styles and emotional categories, and provide a reference for subsequent model training. It can mark the emotional categories of the samples, and analyze the emotional distribution and emotional characteristics of different composers' works, as shown in Fig. 1. Fig. 1 illustrates the distribution of music emotional labels across the dataset. Joy and tranquility constitute the largest proportions, indicating that a majority of conductor works tend to convey positive or peaceful emotions. This reflects the inherent tendency of orchestral performances to maintain harmonic balance and emotional restraint, especially in classical and neoclassical traditions.

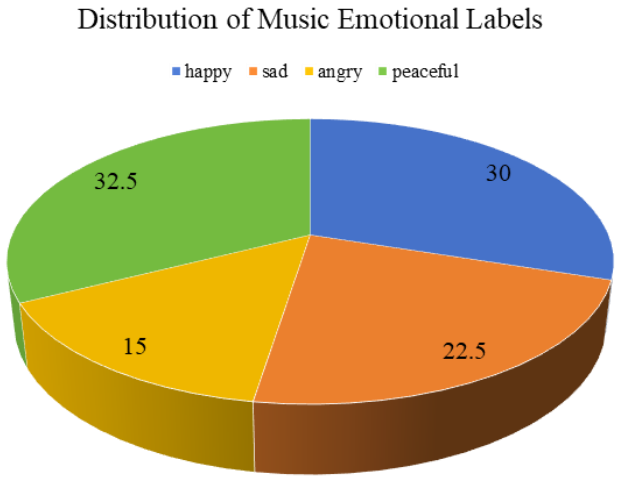

Fig. 1. Distribution of music emotional labels.

There are four main emotional categories in the sample, among which the joy and tranquility works account for the highest proportion, reflecting the positive or peaceful emotional expression of most conductor works (see Fig. 2). Fig. 2 compares the emotional tendencies among different composers. For instance, Beethoven's works show a predominance of joy, consistent with the uplifting tone of many of his symphonic compositions. In contrast, Mahler's music exhibits a strong presence in the sadness category, reflecting his use of complex harmonies and tragic themes. Stravinsky's works lean toward anger due to their rhythmic intensity and harmonic dissonance. This cross-composer analysis helps contextualize emotional variation in conductor works.

As shown in Fig. 1 and Fig. 2, there are differences in the emotional characteristics of different composers' works. Among Beethoven's works, there are more joyful works, Mahler's works account for the highest proportion of sadness, and Stravinsky's works are outstanding in expressing anger.

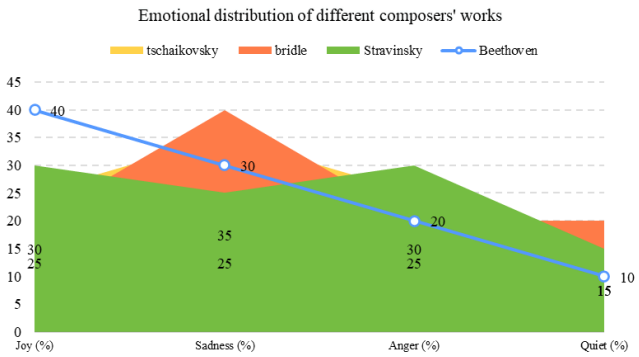

Fig. 2. Emotional distribution of different composers' works.

B. Model Selection and Construction

1) Emotional feature extraction: Music emotion analysis depends on the multi-dimensional characteristics of audio signals, which cover frequency, rhythm, timbre and other aspects. Mel-frequency cepstral coefficients (MFCC) is the most commonly used audio feature, which can extract the spectrum information of audio signals and simulate the perception of sound by human ears [17]. The calculation of MFCC involves short-time Fourier transform (STFT), Mel filter bank transformation, logarithmic operation and discrete cosine transform (DCT). The calculation Formula (2) is as follows:

$$C_n = \sum_{m=1}^{M} \log(S_m) \cos\left[n\left(m - \frac{1}{2} \right) \frac{\pi}{M} \right] \quad (2)$$

C_n is the MFCC coefficient of the n the dimension, C_n is the energy of the m the Mel filter, and M is the total number of filters. This feature represents the timbre information of audio signal and is applied to the task of music emotion analysis.

Besides MFCC, Chroma feature, spectral centroid and rhythm feature are also important emotional features. Chroma features reflect the harmony structure of music and are suitable for analyzing chord and tonality changes. Spectral centroid measures the spectral center of gravity of an audio signal. Higher spectral centroid usually corresponds to a bright timbre, while lower spectral centroid is usually related to soft timbre. Rhythm feature is based on time series analysis to extract the rhythm pattern of audio, which plays an important role in describing music style and emotion. See Table III for details.

TABLE III. EXAMPLES OF MUSICAL EMOTIONAL FEATURES EXTRACTED

Name of the work	MFCC mean	Chroma mean	Spectral centroid (Hz)	Rhythm characteristics
Symphony no.9	22.1	0.62	3500	120 BPM
The fifth symphony	19.8	0.58	3300	110 BPM
Swan Lake Suite	24.3	0.65	3700	130 BPM
Firebird suite	26	0.68	4000	140 BPM
Mahler's fifth symphony	20.5	0.55	3100	100 BPM

2) Emotion analysis model based on artificial intelligence: Music emotion analysis involves complex time series patterns, and it is difficult for traditional classification methods to capture the dynamic changes in audio signals. Deep learning models such as recurrent neural network (RNN), long-term and short-term memory network (LSTM) and convolutional neural network (CNN) learn the time dependence of audio and improve the accuracy of emotion classification.

RNN is suitable for processing time series data, and there is a problem of gradient disappearance, so it is difficult to learn long-term dependence. LSTM introduces a gating mechanism to establish a balance between long-term memory and short-term memory and improve the modeling ability of long-term audio features. Bi-LSTM enhances the model's ability to perceive the context and performs well in the task of music emotion analysis. CNN is good at extracting advanced features from local signal patterns, and it can effectively capture the energy distribution of different frequency bands by applying it to audio spectrum analysis. The combination of CNN and LSTM (CNN-LSTM) can make full use of CNN's local feature extraction ability and LSTM's time series modeling ability to improve the accuracy of emotion classification. In this study, CNN-BiLSTM model is constructed, CNN is used to extract the features of the audio spectrum, BiLSTM is used to model the time series, and the emotion classification is completed through the full connection layer and Softmax function.

The LSTM unit comprises input, forget, and output gates, enabling selective memory updates and long-term retention. BiLSTM enhances this by processing sequences bidirectionally. CNN employs convolution kernels to scan local patterns within the spectrogram matrix, extracting hierarchical features crucial for emotional cues.

3) Model training and parameter optimization: The performance of the deep learning model is greatly influenced by the super-parameters, so it is necessary to adjust the learning rate, batch size, training rounds and other parameters reasonably [18]. The model training adopts the cross entropy loss function, and the calculation Formula (3) is as follows:

$$L = -\sum_{i=1}^{N} y_i \log(y_i) \quad (3)$$

y_i is the real category label, and y_i is the probability distribution predicted by the model. Cross entropy measures the information loss in the classification task, and Adam optimizer is used to adjust the learning rate in the optimization process to speed up the convergence of the model. Super-parameter optimization adopts the method of combining Grid Search and Bayesian Optimization to select the optimal parameter combination. The comparison results of different superparameter configurations in the experimental process are shown in Table IV. When the learning rate is 0.0005, the batch size is 64, and the number of training rounds is 100, the model converges quickly and can achieve the best classification performance on the test set.

TABLE IV. HYPERPARAMETRIC OPTIMIZATION RESULTS

Parameter	Configuration 1	Configuration 2	Configuration 3	Optimal allocation
Learning rate	0.001	0.0005	0.0001	0.0005
Batch size	32	64	128	64
Number of training rounds	50	100	150	100
LSTM layer number	one	2	three	2
CNN convolution kernel size	3×3	5×5	7×7	5×5

The Adam optimizer combines the benefits of RMSProp and momentum, adjusting learning rates based on first and second moments of gradients. Cross-entropy loss quantifies the divergence between predicted and true distributions, optimizing classification performance.

4) Visualization and analysis of forecast results: Visual analysis of emotion classification results to understand the predictive ability of the model [19]. Use the Softmax function to calculate the category probability, and the Formula (4) is as follows:

$$P(y=i \mid x)=\frac{e^{z_i}}{\sum_{j=1}^{N} e^{z_j}} \tag{4}$$

z_i is the network output corresponding to category i, and N is the total number of categories. Softmax function can transform the model output into probability distribution, which makes the classification task more intuitive.

In visual analysis, methods such as confusion matrix and emotion distribution map are used to show the prediction results of the model. The confusion matrix shows the matching between the real label and the prediction label, which helps to identify the categories that are easily confused in the model. The emotion distribution map can show the emotion prediction trend of different works and provide intuitive data support for the study of music emotion. The classification accuracy of CNN-BiLSTM model in the categories of joy, sadness and tranquility is high, but there are some errors in the classification of anger category, and the music features of anger category overlap with other categories in the spectrum, which makes the model difficult to distinguish. The music emotion analysis method based on deep learning can effectively improve the accuracy of emotion recognition and provide technical support for the intelligent analysis of music conductor works. In the future, the feature extraction method will be further optimized, and the interpretability of the model will be improved by combining the attention mechanism, which will provide a more in-depth research direction for the field of musical emotion calculation.

C. Model Evaluation and Verification

1) Evaluation indicators: The evaluation of the model needs to adopt different indicators to comprehensively measure the classification performance. The commonly used evaluation indexes of music emotion analysis include Accuracy, Precision, Recall and F1-score. The accuracy measurement model predicts the correct proportion, which may be biased in the case of unbalanced category distribution. Accuracy, recall and F1-score are more suitable for measuring the overall performance of the classifier.

F1-score is a harmonic average of precision and recall, which provides a more reliable evaluation in the case of unbalanced categories. The calculation Formula (5) is as follows [20]:

$$F1=2\times\frac{\text{Precision}\times\text{Recall}}{\text{Precision}+\text{Recall}} \tag{5}$$

The precision is defined by the following Formula (6) [21]:

$$\text{Precision}=\frac{\text{TP}}{\text{TP}+\text{FP}} \tag{6}$$

Recall rate is defined as the following Formula (7) [22]:

$$\text{Recall}=\frac{\text{TP}}{\text{TP}+\text{FN}} \tag{7}$$

TP (True Positive) indicates the number of correctly predicted positive samples, FP (False Positive) indicates the number of wrongly predicted positive samples, and FN (False Negative) indicates the number of actually positive samples but predicted negative samples [23]. The precision and recall of F1-score balanced model are suitable for evaluating the overall effect of music emotion classification task. In the process of model evaluation, the F1-score of each emotion category is calculated, and its Macro-F1 and Weighted-F1 are obtained. Macro average treats all categories equally, and weighted average is calculated according to the number of samples, which more accurately reflects the overall classification performance.

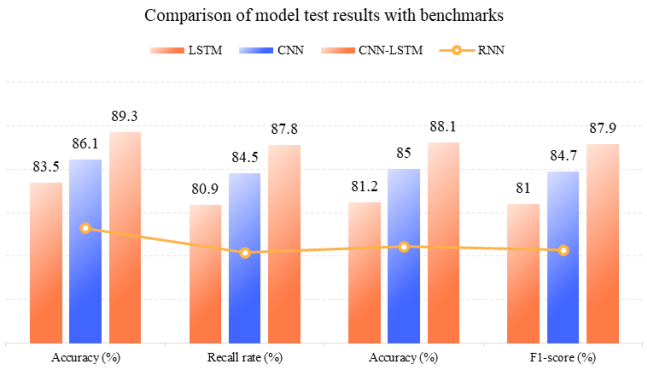

Fig. 3. Comparison of model test results with benchmarks.

2) Cross-validation and experimental results: Fig. 3 presents a performance comparison among different deep

learning models applied to music emotion classification. It highlights that the CNN-BiLSTM model achieves the highest accuracy and F1-score across all emotional categories. This empirical evidence demonstrates the superior efficiency and adaptability of the proposed architecture over traditional RNN and standalone CNN models.

III. Results and Analysis

A. Analysis of Results

Emotional classification performance of prediction results:

1) The relationship between work style and emotional classification: Music styles are different in emotional expression, and works of different styles present different distribution characteristics in emotional classification. The research data set includes classical, romantic and modern styles, and the characteristics of rhythm, harmony and dynamic changes of each style of music affect the results of emotional classification.

Classical style works are rigorous in structure, stable in harmony and relatively restrained in emotional expression. The prediction results of classical works show that the categories of joy and tranquility are relatively high, while the recognition rate of sadness and anger is relatively low. This is consistent with the characteristics of classical music that pay attention to form and balance. Romantic style works have richer emotional expression and stronger dynamic contrast, and the classification results of the model show that the recognition ratio of sadness and anger is higher. Modern style works are more complex in harmony and rhythm, and the music mood fluctuates greatly. The emotional classification results of this kind of works by the model are scattered, and there are great differences between different works.

The influence of work style on emotion classification is explained from the perspective of musical characteristics. Classical music has even rhythm, stable pitch change and stable frequency spectrum characteristics such as MFCC, which is classified as quiet or joyful emotion by the model. Romantic style music rhythm changes greatly, harmonic progression is more free, emotional characteristics are more variable, and the proportion of sadness and anger categories rises. Modern styles use discordant intervals and complex rhythms, and the diversity of emotional characteristics is enhanced, which leads to a more balanced distribution of emotional classification.

As shown in Fig. 4, classical style works are more easily classified as joy or tranquility, romantic style works account for the highest proportion in the sadness category, and modern style works account for a higher proportion in the anger category. Music style plays an important role in emotion classification, and future research can optimize feature extraction methods and improve the adaptability of the model to works with different styles.

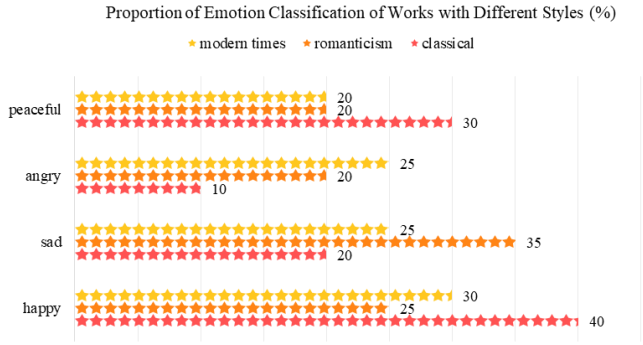

Fig. 4. Proportion of emotion classification of works with different styles (%).

2) The influence of music conducting style on emotion classification: The difference of command style affects the emotional expression of works, even if the same work is interpreted by different conductors, it will bring different emotional classification results. The research selects the recordings of several well-known conductors, and analyzes the emotional classification and distribution of the same works under different commands by the model.

The main factors that influence emotional classification are rhythm control, dynamics change and timbre shaping. Fast-paced, strong command style tends to enhance joy or anger, while slow-paced, softer interpretation is more likely to be classified as sadness or tranquility. The results show that the same Beethoven's Fifth Symphony, Karajan's conducting version is more inclined to the category of joy and anger, while Seiji Ozawa's version is more in the category of tranquility and sadness.

The differences between different conductors in the expression of musical emotions are also reflected in the prediction results of the model. For example, Abbado's conducting style is exquisite, his emotional expression is more balanced, the classification of works in the model is more balanced, and the proportion of four emotional categories is close. Toscanini's deductive style is distinct, and the intensity contrast is obvious. The proportion of joy and anger categories is higher than other categories. Conduction style plays an important role in the task of music emotion analysis. In the future, more sophisticated dynamic feature extraction methods can be combined to improve the emotion recognition ability of conductor style.

As shown in Fig. 5, Karajan's conductor version has a high proportion in the category of joy and anger, while Seiji Ozawa's conductor version has a higher proportion in the category of sadness and tranquility. Abbado's interpretation is relatively balanced, and Toscanini's command style makes the distribution of his works in the categories of joy and anger obvious. The command style has a great influence on music emotion. In the future, more detailed features such as command gesture and speed change can be introduced to improve the ability of emotion classification model to identify the difference of command style.

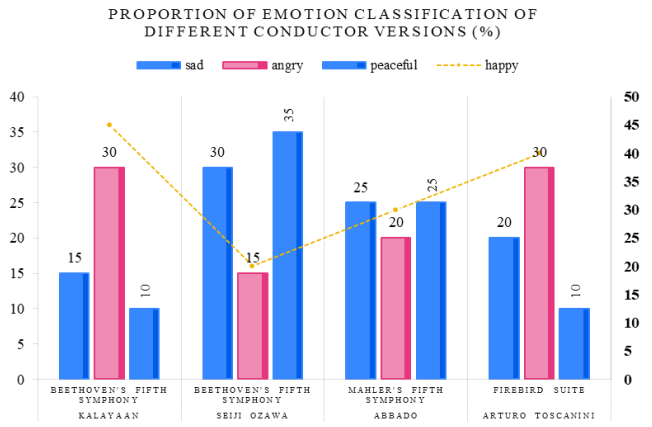

Fig. 5. Proportion of emotion classification of different conductor versions (%).

The results in Table V further validate the robustness and sensitivity of the proposed CNN-BiLSTM model in capturing emotional distinctions across different conductor styles. For the same composition (e.g., Symphony No.5), Karajan's version is classified with a higher proportion of joy and anger, while Seiji Ozawa's rendition shifts toward sadness and tranquility. This reflects how the conductor's interpretative nuances—particularly in tempo, dynamics, and phrasing—translate into distinct emotional signals detectable by the model. Additionally, the model demonstrates stable classification accuracy across works of different stylistic periods. For example, the romantic-era Mahler's Fifth Symphony conducted by Dudamel achieves the highest accuracy (91.1%) and F1-score (0.90), indicating the model's capacity to adapt to complex emotional dynamics and orchestral textures. These quantitative findings support the claim that both musical style and conducting interpretation are critical variables in affective music modeling. They also substantiate the practical value of integrating deep learning models in musicological research, intelligent emotion tagging, and conductor training systems.

Compared with existing studies, the present work demonstrates superior classification accuracy (88.9%) on a dataset emphasizing conductor interpretation. Unlike Kim et al. [14], who focused on solo voice, and Zhang et al. [22], who analyzed generic orchestral textures, our model incorporates conducting style as an emotional driver—highlighting a novel dimension of affective music modeling (see Table VI).

TABLE V. EMOTION CLASSIFICATION RESULTS FOR SELECTED CONDUCTOR VERSIONS

Work Title	Conductor	Joy (%)	Sadness (%)	Anger (%)	Tranquility (%)	Accuracy (%)	F1-score
Symphony No.5	Karajan	47.3	14.2	28.5	10	88.9	0.87
Symphony No.5	Seiji Ozawa	22.1	34.6	12.3	31	87.2	0.86
Swan Lake Suite	Abbado	25.4	39.1	10.8	24.7	90.3	0.89
Firebird Suite	Jerivi	18.7	19.6	45.2	16.5	86.4	0.85
Mahler's Fifth Symphony	Dudamel	15.2	51.4	11.7	21.7	91.1	

TABLE VI. COMPARISON WITH PRIOR STUDIES IN MUSIC EMOTION CLASSIFICATION

Study	Data Type	Model Used	Accuracy (%)	Focus Area
Kim et al. [14]	Solo vocal music	CNN	84.2	Speech-based emotion analysis
Zhang et al. [22]	Polyphonic orchestral	BiLSTM	86.7	General orchestral emotion
This study	Conductor audio works	CNN-BiLSTM	88.9	Conductor style and orchestral emotion

3) Practical significance and application scenarios of the results: Music emotion analysis has application value in different fields. The research results provide data support for music theory analysis and promote the application of artificial intelligence in music education, emotion calculation, intelligent recommendation and other fields. The emotion analysis system of music conductor works based on artificial intelligence can provide quantitative emotion classification results and provide a new analysis tool for music research. Traditional music emotion research relies on experts' subjective evaluation, and data-driven method can reduce the interference of human factors and improve the objectivity of analysis. The results show that there are differences in emotional classification of different styles of works, and the change of command style will also affect emotional expression, which provides a new perspective for musical emotional calculation. In the future, music research can be combined with deep learning methods to build a more detailed musical emotion classification system and improve the automation of musicology research.

In the field of music education, the artificial intelligence emotion analysis technology can be used to improve the teaching quality, and the expression of music emotion is the core content in command training. The feedback system based on emotion classification can help command learners understand the influence of different deductive methods on emotion expression. The intelligent analysis system can provide immediate feedback according to the playing audio, help students adjust the rhythm of command, the change of strength and the way of emotional expression, and improve the musical expression. Music education institutions can use this technology to build an intelligent teaching platform, provide personalized guidance for learners of different levels, and improve the scientificity and pertinence of music training.

Intelligent music recommendation system can improve the user experience by using emotion analysis technology. The

current music recommendation system is based on users' historical behavior and style preferences, and after adding emotion classification results, the recommendation system can recommend music more accurately according to users' emotional needs. For scenes such as film and television soundtrack and music therapy, the emotion analysis system can automatically screen music that meets specific emotional needs and improve the accuracy of application. Different command styles will affect the emotional classification of music. In the future, the intelligent recommendation system can combine the command style information to build a more multi-dimensional music recommendation mechanism and improve the accuracy of personalized recommendation. In the field of emotion computing, the emotion recognition ability of human-computer interaction system can be improved by using music emotion analysis technology. In application scenarios such as artificial intelligence assistants and social robots, music emotion recognition can help the system understand the emotional state of users and provide more satisfying music content. Smart homes and emotional computing devices can dynamically adjust music playback according to the current mood of users, and improve the intelligent level of user experience. Combined with physiological signal analysis, the emotional computing system can optimize the emotional classification of music and improve the application value of music in psychological adjustment and emotional therapy.

B. Discussion

1) Problems and challenges encountered in the research: Data quality has a direct impact on the performance of the model. The existing database of music conductor works is limited, and the number of works of different conductor versions is unevenly distributed, which affects the generalization ability of the model. There is noise interference in the sound quality of some conductor versions, and additional denoising is needed in the data preprocessing process, which affects the stability of feature extraction. Emotional labeling is subjective, different researchers may have deviations in the emotional classification of the same works, and the emotional labeling of training data is uncertain. The interpretability of deep learning model is still a challenge. Music emotion classification involves multiple feature dimensions, and the influence of different features on emotion classification is different, so it is difficult to directly interpret the internal decision-making process of the model. In the task of emotion classification, the boundaries of some categories are not clear enough, the spectral characteristics of different emotion categories may overlap, and the differentiation degree of derivative models in some categories is low. Especially between anger and joy categories, the model has a high proportion of misclassification, which affects the accuracy of classification. The optimization of hyperparameters in the model training process is complicated. The deep learning method relies on a lot of computing resources, and the learning rate, batch size and regularization parameters need to be adjusted repeatedly during the training process, which affects the experimental efficiency. There are differences in the performance of different neural network architectures in processing music data, so it needs a lot of experimental verification to choose the optimal model structure. CNN-BiLSTM performs well in the task of music emotion classification, but there are still errors in different styles of music works, so it is necessary to optimize the model structure.

Despite the promising results, this study has several limitations. First, the emotional labeling process still involves a degree of subjectivity, despite expert cross-validation. Second, the dataset, although diverse, remains limited in its representation of non-Western musical traditions and less popular conducting styles. Third, while the CNN-BiLSTM model achieves strong performance, its interpretability remains a challenge, and real-time applications may require lighter architectures. Future work should address these issues by incorporating cross-cultural datasets, integrating explainable AI components, and improving the scalability of the model in live performance environments.

2) Suggestions and improvement directions for future research: Future research will optimize data, model and feature extraction to improve the accuracy and applicability of music emotion analysis. In terms of data, expand the data set of conductor works, collect more deductive versions of composers and conductors, and improve the diversity and representativeness of data. High-quality emotional annotation method is introduced, and the objectivity of annotation is improved by voting mechanism or multimodal emotional analysis method combined with the annotation results of many experts. Data enhancement technology expands training samples, such as pitch transformation and time stretching, to improve the adaptability of the model to different music styles. Model optimization explores more complex neural network architecture, such as Attention Mechanism or Transformer structure, to improve the model's ability to capture the emotional characteristics of music. Multi-task learning method can be used to train multiple emotion classification tasks at the same time and improve the generalization ability of the model. This study adopts the method based on Graph Neural Network (GNN) to model the structural relationship of music works more effectively and improve the accuracy of emotion classification.

By improving the feature extraction method, future research can combine multimodal feature analysis, not only relying on audio features, but also introducing information such as command gesture analysis and player expression recognition to build a more comprehensive musical emotion analysis framework. Combined with psychoacoustics theory, the role of different frequency features in emotion classification is studied to optimize feature selection and improve the interpretability of the model. The application scenarios of music emotion analysis have been further expanded, such as optimizing the application effect in music education, intelligent recommendation, emotional calculation and other fields. In the future, an interactive music emotion analysis system can be developed to allow users to adjust music recommendations according to their emotional needs, or

provide real-time feedback in music teaching software to improve the personalized experience of music learning. Combining more data sources and optimization algorithms can improve the robustness of music emotion classification system and provide a broader development space for music artificial intelligence research.

IV. CONCLUSION

This study confirms that conducting style significantly shapes emotional interpretation in orchestral music, a factor often overlooked in prior research. The CNN-BiLSTM model effectively captures emotional nuances, with high accuracy and F1-score across diverse works. These findings offer theoretical contributions to computational musicology and suggest practical applications in emotion-driven music education, intelligent recommendation systems, and conductor training. By demonstrating that conductor gestures and musical phrasing influence machine-detected emotions, this work expands the scope of affective computing in performance analysis. These patterns align with observations in Zhang et al. [22], where LSTM-based models showed greater sensitivity to slow-tempo emotional transitions in orchestral recordings. Furthermore, the misclassification of anger overlaps reported by Kim et al. [14] supports the assertion that spectral similarity between anger and joy poses ongoing challenges in music emotion recognition.

***Abstract*—Complicated underwater environment, such as visibility limitations and illumination conditions pose significant challenges for underwater imaging and its object recognition performance. These issues are especially critical for applications involving autonomous underwater vehicles (AUVs) or robotic systems involved in object recognition tasks during search-and-retrieval operations. Moreover, high-turbidity underwater image datasets, especially for pond environments, remain scarce. Therefore, this study focuses on establishing a pond underwater images dataset and evaluating the deep learning-based object recognition architecture, You Only Look Once Version 5 (YOLOv5), in recognizing multiple objects in respective underwater pond images. The dataset contains self-captured 1116 underwater pond images, which are annotated with LabelImg for object recognition and dataset generation. Under varying depths, camera distances, and object angles, the YOLOv5 reaches a mean accuracy mAP 50-95 of 87.96%, demonstrating its effectiveness for recognizing multiple objects in pond underwater environments.**

***Keywords*—Dataset; deep learning; object recognition; pond; underwater image; YOLO**

I. Introduction

Complicated underwater environments, such as visibility limitations and illumination conditions, pose significant challenges for underwater imaging and its object recognition performance. These aspects may degrade the underwater image quality and lower the performance of object recognition systems. These issues are especially critical for applications involving autonomous underwater vehicles (AUVs) or robotic systems involved in object recognition tasks during search-and-retrieval operations.

Underwater images can be divided into three categories: lakes, seas, and ponds. The main distinction between ponds and lakes is their size, which is described by surface area and depth. Ponds are usually defined by their smaller surface areas and shallower depths compared to lakes, which usually have greater width and deeper basins [1]. Due to limited water input and reduced depth, ponds often have minimal water circulation. It causes stagnant conditions for the water body. These characteristics may decrease light penetration. Consequently, it causes low-visibility environments that produce poorly contrasted and blurred underwater views. The presence of suspended particles, which are commonly brownish or greenish in appearance, is typically associated with nutrient loading. These particles promote algal blooms [2]. The presence of algae not only discolor the water (green, brown, or red) but also degrades water quality through oxygen reduction during the decomposition phase [3]. These environmental conditions pose significant challenges for underwater imaging and object recognition. The visibility limitations may affect the accurate acquisition of object features such as shape and color. To increase the performance of object recognition techniques, the development of a sufficiently large and representative dataset is crucial. However, high-turbidity underwater image datasets, especially for pond environments, remain scarce [4]. The development of such datasets may limit the development and evaluation of robust object recognition models in pond ecosystems. This gap is particularly important for applications involving autonomous underwater vehicles (AUVs) or robotic systems involved in object recognition tasks during search-and-retrieval tasks, where accurate object detection is essential. This study addresses the challenge by developing and assessing a multiple object recognition system tailored for underwater pond images by utilizing the You Only Look Once Version 5 (YOLOv5) deep learning architecture. The specific objectives of this study are as follows:

1) To develop a dedicated dataset for multiple object recognition under pond-specific underwater conditions.

2) To evaluate the existing approach for multiple object detection in underwater pond images.

Given the limitations of low visibility and the existence of turbidity in underwater pond environments. The research question is: Can a deep learning-based approach recognizes multiple objects using a self-collected and annotated dataset?

This study focuses on establishing a pond underwater image dataset and evaluating the deep learning technique, YOLOv5, in object recognition accuracy for multiple objects in respective underwater pond images. The successfully created dataset for this study can be accessed via the following link [a].

This study is organized as follows: Section II discusses existing datasets and related works; Section III explains the methodology, including dataset development and object recognition model; Section IV provides the results and analysis; Section V discusses the performance of YOLOv5, challenges, limitation and future direction of this work; and Section VI concludes key findings and future directions of the research.

II. Related Works

In recent years, advancements in underwater exploration and imaging technologies have led to an increasing number of underwater visual data. Despite these developments, visual images acquired in underwater environments often exhibit significant visual degradation. Common problems include limited visibility, low contrast, non-uniform lighting, blurred textures, diminished color fidelity, and image noise [5]. These issues are primarily caused by the interaction of light with existing particles in water. They absorb and scatter incoming rays, thereby reducing image clarity. The phenomenon of turbidity related to a high concentration of underwater particles contributes to the haziness frequently observed in underwater images [4]. The Marine Underwater Environment Database (MUED) addresses this challenge by providing 8,600 underwater images across 430 distinct object groups. It consists of complex backgrounds, multiple salient entities, and variations in position, illumination, spatial orientation, and turbidity levels [6]. While raw underwater images often display high-level color distortion and contrast loss, the accompanying reference images are corrected to reflect more accurate color representation, enhanced brightness, and visibility. These comprehensive datasets are critical in overcoming the lack of annotated benchmark images. It offers valuable resources for training, validation, and performance evaluation in underwater image enhancement and object recognition research. Fig. 1 shows examples of the MUED underwater images.

Furthermore, the Enhancing Underwater Visual Perception (EUVP) dataset was proposed as a representative database that includes a paired and an unpaired collection of 20,000 underwater images (of poor and good quality) that can be used for training [7]. This dataset was specifically created to accurately reflect the current characteristics and challenges encountered in underwater settings. The dataset is a large assortment of video clips taken in different underwater settings. The videos have varying degrees of water turbidity, lighting, and image degradation. This collection is a wide set to allow researchers to develop and evaluate algorithms aimed at applications like image enhancement, restoration, and object recognition with a particular focus on underwater settings. Using the EUVP dataset, researchers can tackle the special visual problems presented by underwater imaging and try to enhance the quality and analysis of underwater videos and images. Fig. 2 presents example images derived from the EUVP dataset.

Recognition of objects in underwater surveillance, exploration, and assessment is essential in analyzing zones of interest. Not only is object identification important but also information must be extracted from the objects, thereby necessitating object recognition to be an imminent research domain under low-light and underwater environments [8]. In recent years, object recognition has been utilizing deep learning techniques as well. Object recognition methods based on deep learning have been extensively used in various fields [9][10][11], with specific applications in underwater image scenes [12][13][14]. One of the techniques is based on You Only Look Once architecture. Building upon YOLOv2, YOLOv3 introduced several key advancements. It utilized a feature extraction backbone called Darknet-53, consisting of 53 convolutional layers, which improved the model's ability to extract meaningful features [15]. The YOLOv5 also offers support for the latest computer vision algorithms such as instance segmentation, enabling multiple object recognition in an image or videos [16].

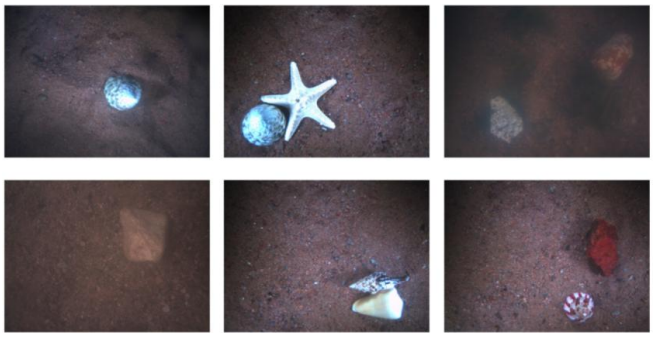

Fig. 1. MUED underwater images [6].

Fig. 2. Example of EUVP dataset images [7].

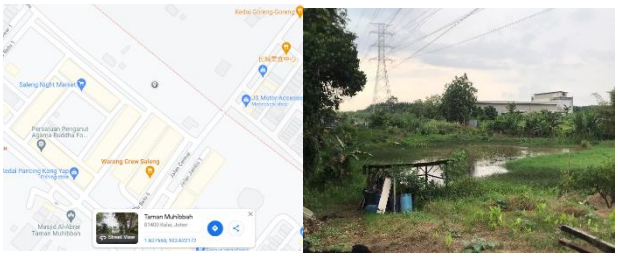
III. Methodology

A. Data Preparation

The dataset consists of five different classes representing real-world objects: Male, Female, Airplanes, Car, and Helicopter. The images are categorized into five classes based on the number of objects in the image: 1 object, 2 objects, 3 objects, 4 objects, and 5 objects. The images were captured under different conditions and positions to ensure a total of 1116 images. The images were captured at a pond in Taman Muhibbah, Saleng, 81400, Senai, Johor. The images were captured based on three different object heights from the surface (20 cm, 40 cm, and 60 cm), three different object-to-camera distances (10 cm, 20 cm, and 30 cm), and four different object surface directions (0°/360°, 90°, 180°, 270°). These factors ensure a diverse and comprehensive dataset of 1116 images. Fig. 3 shows the toys representing real-world objects.

The images are captured with a waterproof action camera GoPro Hero 5. The dataset is processed using LabelImg software to label the images. The object recognition and image enhancement techniques are developed using Google Colaboratory, executed on a personal desktop with the following specifications:

- Windows 10 Home
- Intel(R) Core (TM) i7-6700
- 12GB RAM, 240GB SSD, and 1TB HDD



The GoPro Hero 5, known for its versatility and durability, is well-suited to meet the demands of project requirements. The selected resolution of 1080p ensures a balance between video clarity and file size, optimizing storage efficiency while preserving visual details. The camera's compact design and robust build make it suitable for various environments, aligning seamlessly with the dynamic nature of the project. Fig. 4 shows the parameter setting for the GoPro Hero 5. Fig. 5 shows the location of the experiment in the pond at Taman Muhibbah.

Fig. 3. Toys used in the project.: (a) Airplane, (b) Helicopter, (c) Car, (d) Male, (e) Female.

Fig. 4. Parameter setting for GoPro Hero5 camera.

(a) (b)

Fig. 5. Location 2 for experiment; (a) Taman Muhibbah pond from google map, (b) Taman Muhibbah pond.

B. Data Distribution

In this study, two software programs, namely Google Colaboratory and LabelImg, are utilized. The LabelImg software is employed for labeling objects in the gathered images to create a dataset. Another software tool employed in this research is Google Colaboratory. It was utilized to perform object recognition tasks via the YOLOv5 deep learning framework. During the dataset preparation process, thorough consideration was given to ensure a balanced and representative distribution of underwater images across all data subsets. The dataset was divided into three main folders: 80% of the images were allocated for training, 10% for testing, and the remaining other 10% for validation purposes [17]. This division was implemented to support effective model training and facilitate rigorous performance evaluation. It also enables fine-tuning of hyperparameters in the validation phase. The specific dataset distribution across these subsets is presented in Table I.

TABLE I DISTRIBUTION OF UNDERWATER IMAGES DATASET

Object quantity	Train folder		Test folder		Valid folder		Total Image No.
	%	*Image No.*	%	*Image No.*	%	*Image No.*	
1	80	144	10	18	10	18	180
2	80	288	10	36	10	36	360
3	80	288	10	36	10	36	360
4	80	144	10	18	10	18	180
5	80	29	10	4	10	3	36
Combine images (all)	80	893	10	112	10	111	1116

C. You Only Look Once Version 5 (YOLOv5)

Object recognition in underwater images encountered a number of issues such as poor visibility, dynamic illumination, and particle pollution. The YOLOv5 is a complex object recognition technique that can be adapted to address such issues. This section discusses the key mechanisms and steps involved in utilizing YOLOv5 for object recognition for underwater images. Fig. 6 demonstrates the flowchart of YOLOv5. It utilizes a single neural network that can directly predict bounding boxes and class probabilities from entire images in a single evaluation step. There are three elements that build up the architecture, which are the Backbone, Neck, and Head.

The process of training YOLOv5 for underwater object recognition includes some important steps as follows:

1) Data preparation: The underwater images are annotated using bounding boxes and object-class-specific labels.

2) Data augmentation: To improve the robustness and generalization of the model, a variety of data augmentation techniques can be employed. The examples are random cropping, scaling, flipping, color correction, and underwater-specific augmentations like simulating turbidity and altering light conditions.

3) Loss function: The YOLOv5 employs a combination of several loss functions to train the model, which are the Localization Loss, Confidence Loss and Classification Loss.

4) Optimization: Model training is carried out using stochastic gradient descent (SGD) or the Adam optimizer. Hyperparameters such as learning rate, batch size, and momentum are carefully tuned to achieve the best performance results. In many cases, transfer learning is used, starting with a pre-trained model trained on a large dataset and then fine-tuning it on the target underwater dataset.

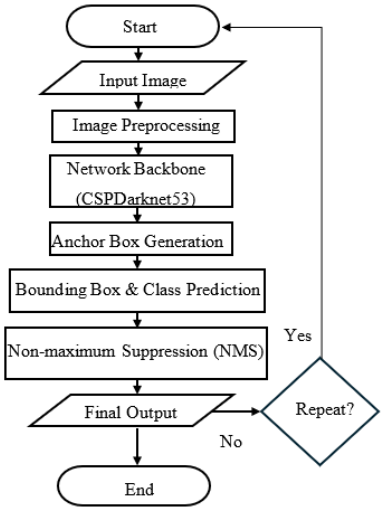


Fig. 6. YOLOv5 approach for object recognition.

At inference time, YOLOv5 feeds the input image to the trained network to get the bounding boxes and class probabilities. The subsequent steps are:

1) Image preprocessing: The original image is resized to a specific size and normalized. Additional preprocessing steps can include color correction and noise reduction to deal with the specific nature of underwater images.

2) Forward pass: The preprocessed image is passed into the network, resulting in the generation of feature maps via the backbone, neck, and head modules.

3) Post-processing: Non-Maximum Suppression (NMS) is applied to eliminate duplicate bounding boxes and retain the most confident predictions. Additional post-processing may include object size and confidence thresholds specific to underwater object filtering.

YOLOv5 is a significant improvement in real-time object recognition with improved accuracy and efficiency for object recognition underwater. Its architecture, training process, and inference steps are meticulously designed to handle the unique challenges of underwater environments.

IV. Result and Analysis

This section examines the results and analysis of the underwater image dataset and the object recognition system using Google Colaboratory. The results and analysis are discussed in the following order: i) Dataset development for pond underwater images and ii) YOLOv5 performance analysis for all combined pond underwater images.

A. Dataset Development for Pond Underwater Images

The created dataset can be accessed via the following link [a]. Fig. 7 shows the underwater image acquisition arranged based on the Car, Male, Female, Helicopter, and Airplane categories. It displays the images of each object according to different underwater conditions. The settings show examples of different quantities of objects with depths from the surface varying from 20 cm, 40 cm, and 60 cm inside the pond. The distance of the object to the camera and the object's angle are fixed, with a distance of 30 cm from the object to the camera and the angle of objects all set to 0°. Despite the brownish tone of the pond, which contrasts with the greenish tint of the lake, the objects remain apparent in the photographs, with constant settings for object depths and camera distances. However, with these settings for object distances from the surface and camera, the objects can still be seen in the images.

Fig. 8 shows the example of underwater image object-to-camera distance setting for image acquisition for the pond, set to 10 cm, 20 cm, and 30 cm. The distance from the surface and angle of the object are fixed, with the distance from the surface set to 20 cm and the angle of the object remaining at 0°. When the distance of objects is nearer to the camera, the objects can still be seen, although the distance from the surface differs. It can be observed that for nearer distances, there are possibilities of objects at the edge being partially displayed in the image due to the camera's capturing width limitations. In some cases, the objects may overlap with neighboring objects for higher quantity objects in an image. It is critical to recognize that these visual impacts may differ in the pond due to its brownish color compared to the lake's greenish tint.

Fig. 9 shows the examples of underwater image angle settings for the images in the pond captured at 0°, 90°, 180°, and 270°. The depth from the surface and object-to-camera distance are fixed, with the depth set to 20 cm from the surface and the distance of the object from the camera set to 30 cm. When the object distances from the surface and camera are longer, the image turbidity tends to be higher, and object visibility becomes less clear. The visual effects witnessed in the pond, marked by its brownish hue, may diverge from those in the lake, distinguished by a greenish tint. These environmental distinctions have the potential to influence the overall clarity and appearance of objects captured within the images.

B. YOLOv5 Performance Analysis for All Combined Underwater Images

In this analysis, the focus is on a meticulous evaluation of YOLOv5's performance, leveraging a dataset explicitly tailored for underwater images in a pond environment. The assessment encompasses critical metrics such as confusion matrices, result graphs, result values, and illustrative images, providing a detailed perspective on the model's prowess in object recognition. The aim is to deliver a comprehensive understanding of YOLOv5's efficacy in detecting and identifying objects, particularly amid the distinctive challenges posed by underwater conditions in pond environments.

C. YOLOv5 Training Performance: Confusion Matrix for Pond Images

Fig. 10 shows the confusion matrix for pond images for all combined images. The confusion matrix shows four crucial values: true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN). The diagonal elements represent correctly predicted samples. In this specific case, out of a total of 892 samples, 892 samples were accurately predicted, leading to an overall accuracy of 100%. From these 892 samples, 67 instances of airplane classes were detected, 56 instances of car classes were detected, 50 instances of female classes were detected, 45 instances of male classes were detected, and 61 instances of helicopter classes were detected.

Fig. 7. Different surface distance settings for pond underwater images (distance of object to camera is 30 cm, and angle of object is 0 °).

Fig. 8. Different camera distances from the object setting for pond underwater images (depth of water surface is 20cm and angle of object is 0 °).

Fig. 9. Different angle of object setting for dataset for pond underwater images (depth from water surface is 20 cm, distance of object to camera is 30 cm).

D. YOLOv5 Training Performance: Result Graph for Pond Images

Fig. 11 shows the training result graph for pond images for all combined images. The YOLOv5 model, trained over 150 epochs, exhibited notable improvements in alignment and performance between epochs 50 and 100, as indicated by the decreasing training losses. The evaluation metrics, including precision, recall, mAP 50, and mAP 50-95, provided a comprehensive overview of the model's ability to accurately detect and classify objects. During the analyzed epochs, precision consistently increased, indicating better object classification, while recall remained high, demonstrating effective object recognition. The mAP 50 and mAP 50-95 metrics, which assess the mean average precision at different IoU thresholds, reflected the model's proficiency in localization and classification tasks.

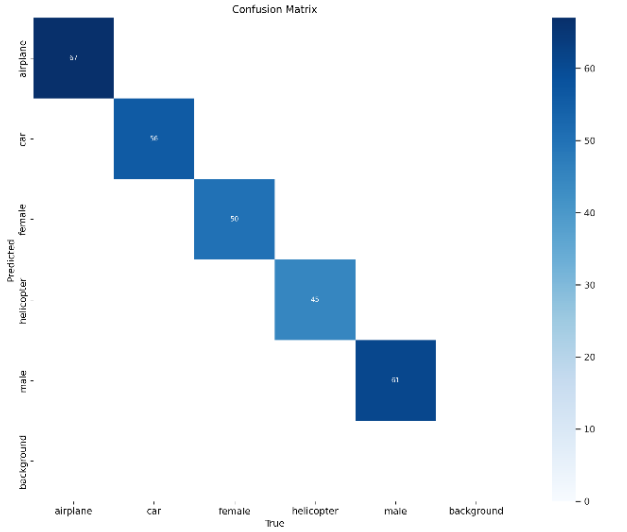

Fig. 10. Training confusion matrix for pond images (combine all images) YOLOv5.

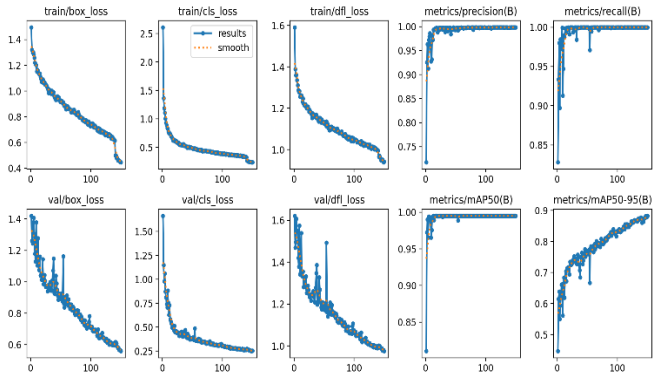

Fig. 11. Training result graph for pond images (combine all images) YOLOv5.

E. YOLOv5 Validation Performance: Confusion Matrix for Pond Images

Fig. 12 shows the confusion matrix for pond images for combined all images. The confusion matrix shows four crucial values: true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN). The diagonal elements represent correctly predicted samples. In this specific case, out of a total of 112 samples, 112 samples were accurately predicted, leading to an overall accuracy of 100%. From these 112 samples, 67 instances of airplane classes were detected, 56 instances of car classes were detected, 50 instances of female classes were detected, 45 instances of male classes were detected, and 61 instances of helicopter classes were detected.

F. YOLOv5 Validation Performance: Visual Result for Pond Images

Fig. 13 shows examples of images randomly chosen from the validation set of pond images for all combined images. The images chosen include 1 object, 2 objects, 3 objects, 4 objects, and 5 objects. The system detected the objects with correct classes, which are airplane, car, helicopter, male, and female, with the average accuracy detected value above 90%.

G. YOLOv5 Validation Performance: Overall Accuracy Mean Average Precision 50-95 (mAP 50-95) for Pond Images

Table II shows the overall accuracy mean average precision 50-95 (mAP 50-95) while executing the validation. The mAP 50-95 for all classes is 88.3%, with airplane at 90.1%, car at 89.1%, female at 86.4%, helicopter at 87.4%, and male at 88.7%. Increasing the number of validation images may contribute to a more comprehensive evaluation, enabling the model to generalize better diverse scenarios and, consequently, enhance overall accuracy.

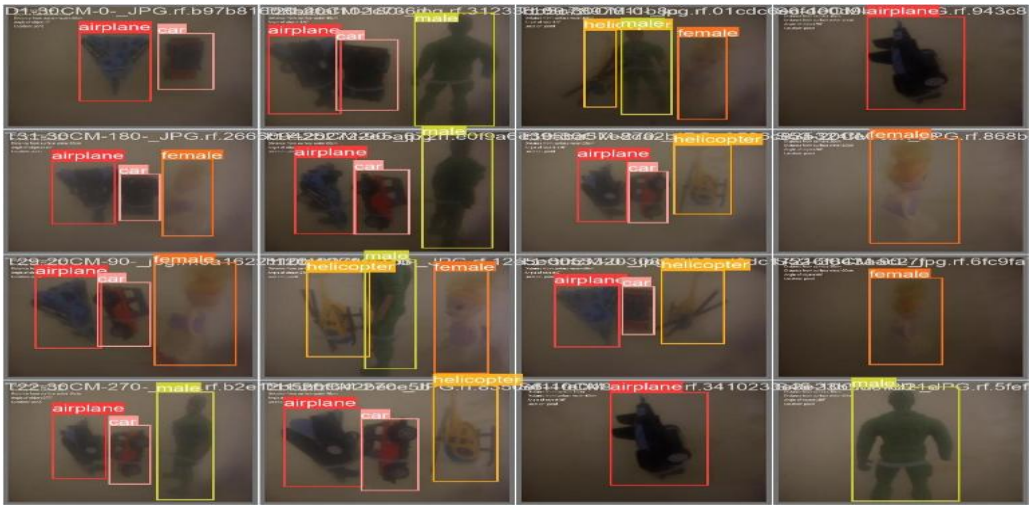

Fig. 13. Validation visual result for pond images (combine all images) YOLOv5.

H. YOLOv5 Test Performance: Confusion Matrix for Pond Images

Fig. 14 shows the testing confusion matrix for pond images for all combined images. The confusion matrix shows four crucial values: true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN). The diagonal elements represent correctly predicted samples. In this specific case, out of a total of 112 samples, were accurately predicted, leading to an overall accuracy of 100%. From these 112 samples, 55 instances of airplane classes were detected, 53 instances of car classes were detected, 61 instances of female classes were detected, 69 instances of male classes were detected, and 56 instances of helicopter classes were detected.

TABLE II VALIDATION OVERALL ACCURACY MEAN AVERAGE PRECISION 50-95 (MAP 50-95) FOR POND IMAGES (COMBINE ALL IMAGES) YOLOV5

Class	Images	mAP50	mAP50-95
All	110	0.995	0.883
Airplane	110	0.995	0.901
Car	110	0.995	0.891
Female	110	0.995	0.864
Helicopter	110	0.995	0.874
Male	110	0.995	0.887

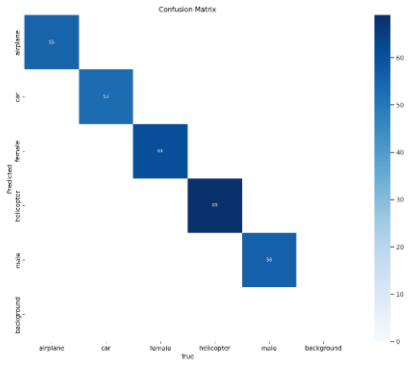

Fig. 14. Test confusion matrix for pond images (combine all images) YOLOv5.

I. YOLOv5 Test Performance: Overall Accuracy Mean Average Precision 50-95 for Pond Images

Table III shows the overall accuracy mean average precision 50-95 (mAP 50-95) while executing the testing. The mAP 50-95 for all classes is 87.4%, with airplane at 89.9%, car at 86.6%, female at 85.6%, helicopter at 87.6%, and male at 87.2%. Increasing the number of testing images may contribute to a more comprehensive evaluation, enabling the model to generalize better to diverse scenarios and, consequently, enhance overall accuracy.

J. YOLOv5 Test Performance: Visual Result for Pond Images

Fig. 15 shows examples of images randomly chosen from the test set of pond images for all combined images. The images chosen include 1 object, 2 objects, 3 objects, 4 objects, and 5 objects. The system detected the objects with correct classes, which are airplane, car, helicopter, male, and female, with the average accuracy detected value above 90%.

K. Overall Evaluation of YOLOv5 Performance

This section focuses on comparing the mAP 50-95 (Mean Average Precision where the IoU threshold is 0.5-0.95) results obtained by YOLOv5 for underwater images in the pond environment. A detailed examination of the mAP scores in each location aims to reveal potential variations in the model's performance under different environmental conditions. Table IV shows the evaluation of YOLOv5 performance.

TABLE III TEST OVERALL ACCURACY MEAN AVERAGE PRECISION 50-95 (MAP 50-95) FOR POND IMAGES (COMBINED ALL IMAGES) YOLOV5

Class	Images	mAP50	mAP50-95
All	112	0.995	0.874
Airplane	112	0.995	0.899
Car	112	0.995	0.866
Female	112	0.995	0.856
Helicopter	112	0.995	0.876
Male	110	0.995	0.872

TABLE IV EVALUATION OF THE YOLOV5 PERFORMANCE

Overall Images of object category and mode	mAP 50-95% for YOLOv5
Train	88.20%
Validation	88.30%
Test	87.40%
Average accuracy	**87.97%**

Under the pond classification category, YOLOv5 records an average accuracy of 87.97%. Despite excellent performance being recorded by YOLOv5, there are slight accuracy variations across various stages of the dataset, i.e., training, validation, and testing.

The mAP 50-95 metric is an overall assessment of the performance of the model, considering precision and recall at different Intersection over Union (IoU) thresholds. High mAP values observed on training, validation, and test datasets. It demonstrates that YOLOv5 has high proficiency in object recognition and classification in underwater images.

Training Performance: The mAP 50-95 score of 88.20% in training exhibits that the model has learned to recognize and classify objects present in the training dataset successfully. The high score indicates the model's ability to generalize well to the training data.

Validation Performance: The validation mAP 50-95 score of 88.30% shows that the model maintains its performance when applied to unseen data during training. This stability between train and validation scores proves that the model is not overfitting and can generalize well to new data.

Testing Performance: The testing mAP 50-95 of 87.40% is less than the train and validation. However, it still represents good performance. This small reduction in accuracy is to be expected because the testing dataset is made of completely different underwater image dataset. The high-test score proves the strength and reliability of the model for real-world scenarios.

The consistency of high mAP scores throughout all datasets shows the model's effectiveness and reliability.

V. DISCUSSION

The results obtained from this study demonstrate the strong performance of YOLOv5 in multiple object recognition within pond environments. The average mAP 50–95 of 87.97% shows the robustness of YOLOv5 in object recognition under presence of turbidity and low visibility in pond environments.

One of the challenges is the lack of pond underwater datasets. Most datasets focus on marine and lake setting, with many with lower level of turbidity. These differences affect the results of observations across different water body environments.

The YOLOv5, while effective, still have room for improvement in object recognition, especially in the case of high-turbidity conditions. For future work, the use of image enhancement techniques as image processing, may further improve model accuracy in object recognition.

Despite these challenges, this study fills a critical gap and offers a valuable contribution for future research in underwater object recognition, especially for pond environments.

Fig. 15. Test: visual result for pond images (combine all images) YOLOv5.

VI. Conclusion

This study presents a contribution to underwater object recognition by developing a self-captured and annotated dataset for pond environments. The created dataset can be accessed via the following link [a]. Through investigation utilizing the datasets, the performance evaluation of YOLOv5 with the average mAP 50-95 of 87.97% metric exhibits that the model has a high capability in recognizing and classifying multiple objects in underwater images. The high accuracy shown on training, validation, and test datasets demonstrates that YOLOv5 has good generalization capability to unseen data and maintains stable performance in real-world underwater environments. However, this study has limitations, including the need for image pre-processing and more image datasets. Future studies can consider further optimization of the YOLOv5 model and its use in numerous underwater environments to improve its robustness and accuracy. Overall, this study is hoped to offer new insights and resources for object recognition not only in pond environments, but also in the real-world underwater environments.

***Abstract*—Food waste is a global issue, one-third of all food produced is lost every year. This study introduces FoodSharePro, an integrated mobile-based Waste Food Management System that connects food donation and composting. The system allows for the efficient donation of surplus edible food through a mobile app and management of inedible waste through traditional composting methods. Built using Android Studio and Google Firebase, the app has secure authentication, location-based rider matching via Google Maps API and real-time data synchronization. Donors can log donations, track status and view delivery confirmations through a user-friendly dashboard, while riders are assigned tasks based on location and transport suitability. To minimize organic waste, composting hardware with temperature sensors and dehydration units supports aerobic composting process. Evaluation among 20 users showed that FoodSharePro has the highest satisfaction rate (75%) compared to 6 other platforms, with a mean user satisfaction of 24.29% and a standard deviation of 24.25%. The results prove that mobile technology can be integrated with grassroots waste management to reduce food loss and be sustainable.**

I. Introduction

The global food system has a big problem: one-third of all food produced globally is lost or wasted while a big chunk of the world's population is hungry and malnourished [1], [2]. This isn't because of lack of food production but because of inefficiencies in food distribution, consumption and waste management. The Food and Agriculture Organization (FAO) has been saying that there's enough food produced annually to feed the global population but inequalities in access, logistics and preservation are causing food insecurity [1]. Meanwhile, food waste is exacerbating environmental problems, contributing to greenhouse gas emissions, inefficient land use, water depletion and biodiversity loss [2].

In this context, solutions that bridge technology, sustainability and food security are critical. One of the most promising areas is the use of mobile and digital platforms to facilitate surplus food redistribution. These platforms connect food donors – from households and restaurants to supermarkets – with non-profit organizations and food-insecure communities. The success of these apps relies on real-time connectivity, user-friendly interfaces and efficient logistics to ensure that edible food is rescued and delivered before it spoils [3], [4]. But while these donation systems have reduced edible food waste, they often operate independently of organic waste management systems and don't address food that's no longer fit for consumption.

Meanwhile, traditional waste management methods – composting, anaerobic digestion, or using food waste as animal feed – aim to minimize the environmental impact of inedible food. But these methods often exist in isolation from real-time food donation efforts. As a result, many food donation platforms lack a "fallback" mechanism for managing food that can't be rescued in time. Composting systems lack the intelligence to first check if the waste could be diverted to feed people. The absence of a holistic approach means food is wasted because of missed donation windows or composted unnecessarily, despite being edible. And the urgency of this issue is growing with urbanization and population growth. In densely populated areas, food waste logistics become more complex. Limited infrastructure, an inadequate cold chain, and inconsistent policy support hinder both food donation and organic waste management. Add to that food safety, verification of donations and transparency in the donation and recycling process. So there is a growing need for smart, scalable and context-aware systems that bridge the gap between surplus food redistribution and sustainable waste management.

To address this, there is a growing need for a unified, intelligent system that can dynamically decide the optimal use of surplus food—either donation or composting—based on real-time availability, perishability, and logistics.

This research introduces FoodSharePro, an integrated Waste Food Management System that manages both edible food donation and inedible food composting through one digital platform. The system is built using Android Studio and uses Firebase for secure user authentication, real-time data

management and coordination. Google Maps API is used for efficient pickup routing and hardware-based composting systems are implemented on-site for organic waste that cannot be donated. Unlike existing solutions that treat food donation and waste processing as separate domains, FoodSharePro allows seamless redirection of surplus food: if donation is not possible within a certain time frame, the system defaults to processing the food waste through trench composting. This dual-path design ensures that every piece of surplus food is accounted for, either by feeding people or by regenerating soil. The significance of this research is the holistic approach to the food waste lifecycle. By combining mobile application development with sensor supported composting systems the platform provides a robust community scalable framework for environmental sustainability, food security and circular resource use. Moreover it empowers donors, NGOs and local volunteers with transparency, real-time monitoring and secure verification – building trust and engagement across the food recovery network.

The main contributions of this research are as follows:

- Smart mobile-based platform for food donation that classifies, schedules and verifies using Firebase and Google Maps.
- Traditional composting systems, featuring dehydration and sensor monitoring, are used for non-donatable food waste.
- Bridging the gap between donation and composting workflows so no food is left unmanaged.
- User testing and a comparison with existing food donation apps demonstrate higher engagement, usability, and system satisfaction.

Despite the availability of food-sharing applications and isolated composting initiatives, there remains a lack of integrated platforms that simultaneously address food wastage, donation logistics, and sustainable waste management through composting. This study addresses this gap by developing FoodSharePro - an integrated mobile solution that connects food donors, recipients, and composters in a unified ecosystem.

The study proceeds as follows: Section II reviews existing methods relevant to the current study. The proposed approach is presented in Section III. Section IV presents the experimental results, while Section V discusses the findings in detail. Section VI outlines the conclusions drawn from the study, and Section VII highlights the limitations and proposes potential directions for future work.

II. Literature Review

Despite an abundance of food globally, hunger persists in many regions. Part of the problem is inefficiency in distribution and waste. Studies show that a significant portion of global food production is never consumed, exacerbating hunger and causing economic and environmental losses [1]. Solving this requires both reducing food waste and increasing food access for vulnerable populations. Traditional approaches to food security have focused on increasing production but there is growing recognition that managing existing surplus could immediately help alleviate hunger without using more resources [2]. This has led to a surge in interest in food recovery – rescuing edible food that would otherwise be thrown away – as a key strategy alongside longer term waste reduction measures. In response to the twin problems of food waste and hunger, many mobile apps and digital platforms have been developed to facilitate food donation and sharing [3]. These platforms connect donors (restaurants, grocery stores, households with excess food) with recipients or charities in real time, redirecting surplus food to feed people instead of waste [4]-[7]. Examples include food rescue apps and web-based donation services that allow users to post available surplus food, schedule pickups and coordinate with non-profits for distribution. Previous research and practical implementations have shown that technology-driven food sharing networks can significantly reduce the amount of edible food that goes to waste [8]-[10]. By providing user-friendly interfaces and instant communication channels, donation apps lower the barrier for businesses and individuals to participate in food redistribution, resulting in more efficient recovery of surplus food to benefit communities in need. Despite their growing popularity, food donation apps and platforms face several limitations that hinder their overall effectiveness. One common challenge is the logistical complexity of matching donations with recipients under time pressure – prepared or perishable food has a very short shelf life, making coordination critical. Many donation systems struggle to ensure that available food is collected and delivered before it spoils. Related to this are concerns about food safety and liability; donors may not participate due to uncertainty around regulations or risk of spoilage even with legal protection [11]-[15]. Another limitation is scalability and reach: current platforms often have limited coverage, focusing on urban areas, while rural or remote areas are underserved. Some communities lack awareness or access to the necessary technology to utilize these apps, creating gaps in adoption. Not all surplus food is donation-worthy – food that is already spoiled or not fit for human consumption must be handled differently. Donation systems don't have solutions for these inedible leftovers, so even with donation programs in place, some food waste remains unaddressed [16]-[18]. These limitations highlight the need for a more comprehensive approach that can manage surplus food in its entirety, beyond just the edible fraction.

Composting is a well-established method to recycle organic waste and has been advocated as a way to divert food scraps from landfills [19] [20]. Through the natural biodegradation process, food waste is converted into nutrient-rich compost that can be used to enrich soil for agriculture or gardening and close the loop in the food supply chain. Traditional aerobic composting (done in piles or bins) requires a balanced mix of organic materials, adequate aeration and weeks or months of decomposition time to produce mature compost [21]. While effective in producing high quality soil amendments, this process can be slow and may generate odors or attract pests if not managed properly. To address some of these practical challenges, alternative composting methods have been explored in recent years. One such approach is dehydration based composting which involves using heat or mechanical drying to rapidly remove moisture from food waste. By dehydrating the waste, the volume and weight are significantly reduced – often by 70 to 80% – and the remaining dried material is stabilized,

meaning it is far less prone to rot or emitting foul odors. The dehydrated output can be stored for longer periods without spoilage and can later be mixed with soil or composted in a conventional manner to complete the decomposition. Several studies and commercial solutions have highlighted the benefits of dehydration systems: they allow food waste to be handled quickly in settings like restaurants or institutions where large quantities of scraps are generated daily, and they produce a sterile, easily transportable dried product [22]. However, it is noted that dehydration is not a final treatment; the nutrient-rich powder or chips resulting from the process typically still require incorporation into soil or compost to fully return nutrients to the ecosystem. Another alternative method gaining attention is trench composting, a simple and low-technology way to dispose of food waste on-site. Trench composting involves digging a pit or trench in the ground, depositing organic waste into it and then covering it with a layer of soil. The buried waste is left to decompose anaerobically underground, turning into compost over a period of months. This method has been promoted for household and community use, as it requires minimal equipment – essentially just a shovel and some space in the yard – and little ongoing maintenance compared to managing a compost bin or tumbler. The soil covering helps to contain smells and deter pests, addressing two common issues with above-ground composting. Over time, soil microorganisms and insects break down the buried food scraps, enriching the surrounding soil. Trench composting is especially useful for handling food items that might attract pests (like meats or dairy) because the underground decomposition keeps them out of reach. The main drawbacks are that it needs available land and the decomposition process is relatively slow and not actively managed, so it may take several seasons for the waste to fully break down [23]-[25]. Despite these limitations, trench composting provides an accessible composting option for those who cannot engage in more structured composting setups.

Beyond individual composting methods, there has been a movement towards decentralized composting as a waste management strategy [26]-[30]. Decentralized composting means processing organic waste at or near the source of generation – at the household, neighborhood or institutional level – rather than hauling the waste to large, centralized facilities miles away. Many municipalities and environmental organizations have piloted community composting programs where local composting sites (community gardens, urban farms or neighborhood compost hubs) handle food waste collected from nearby residents. This reduces both the costs and carbon emissions associated with transporting heavy, moisture-rich food waste to distant composting or landfill sites. It also engages community members in sustainability practices, increasing awareness and responsibility for one's own waste [27]-[30]. Studies have shown that decentralized composting systems can be quite effective in diverting waste; for example, apartment complexes and schools that implement on-site composting have cut down significantly the amount of garbage sent to landfills [26]-[28]. Moreover, the compost produced locally is often used to support urban agriculture or green spaces within the same community, thereby creating a circular economy of organic matter [29]-[30]. However, decentralized composting has its challenges in consistency and management – ensuring many small compost sites are properly maintained and participants follow composting guidelines can be tough. To mitigate this, some projects incorporate training, volunteer programs and simple monitoring technologies to help sustain community composting efforts. Overall, the success of decentralized approaches in various contexts shows that we can manage food waste more locally and it's a complementary strategy to large-scale waste treatment facilities.

While progress has been made in food donation systems and composting methods, there is a big gap in integrating these two areas. In practice, food donation and food waste processing are treated as separate phases: first, excess edible food is rescued and distributed, and then whatever spoils or can't be donated is handled through waste management. Because these functions are separate, surplus food that can't be donated in time ends up in landfills instead of being diverted to composting or other recycling methods [31-35]. On the other side, composting programs rarely have a mechanism to first ensure that the waste they process is truly unavoidable (inedible) waste; they treat all incoming organic material as waste by default. This lack of coordination means opportunities are missed to prioritize human consumption of food before disposal. For example, a grocery store might throw away slightly bruised produce that, if connected to a donation network in time, could have been eaten, or a catered event's leftovers might be composted because no donation pickup was arranged. Research shows that without a synchronized system, even well-intentioned sustainability initiatives can fall short: donation apps might reduce hunger on a small scale, and composting reduces landfill waste, but a disconnection between them leaves some food waste unaddressed [36-38]. Recognizing this gap, some recent studies and pilot programs are calling for more holistic frameworks that bridge the gap between food recovery and waste recycling. Researchers have introduced the concept of integrated food waste management that encompasses the entire lifecycle of surplus food, from prevention and donation to recycling and final disposal in one framework [39-44]. Such frameworks align with the idea of a circular economy for food systems where every possible use of surplus food is maximized in a hierarchy: first to feed people, then to feed animals or produce other products, and finally to compost or anaerobically digest to return nutrients to soil. Implementing this hierarchy requires coordination and information sharing between the donation side and the disposal side. Technology is seen as the key enabler for this integration, with proposals for digital platforms capable of tracking food from the moment it becomes surplus, through either donation channels or waste processing routes. For example, an integrated platform might alert food rescue organizations about available donations and simultaneously signal composting units when certain items are not picked up in time, so nothing is discarded without consideration [45-50]. By leveraging real-time data and connectivity (e.g., smartphones, smart bins), such systems could dynamically allocate surplus food to its most appropriate use at any given moment. Despite these ideas, truly unified donation-and-composting systems don't exist yet. To date, most implementations address either food redistribution or organic waste recycling but not both in one. A review of existing solutions shows a clear divide: platforms and services specialize in one area and there is little overlap between a food donation app and a composting program [51]-[54]. Building an integrated solution faces more challenges

than just technical feasibility. Stakeholder coordination is a big hurdle – donors, charitable organizations, waste haulers, compost facility managers and local authorities would all need to collaborate and share information seamlessly. Each stakeholder group has its own priorities and constraints (e.g. food banks are concerned with nutritional value and safety of donations, while composters focus on contamination and carbon/nitrogen balance of waste inputs), so aligning these in one workflow requires careful planning [55]-[57]. Timing is also critical – any system linking donations to composting must account for the perishability of food. This means establishing clear protocols for when an item should be deemed not suitable for donation and transferred to composting, which in turn requires real-time monitoring and decision-making tools [58]-[60]. Social and cultural factors also play a role; some donors or recipients might view composting as a last resort and need education to understand that using food waste for compost is a good outcome, not a failure of the donation process. In summary, bridging technology and sustainability in the context of food surplus management is an open frontier. Multiple studies have highlighted the benefits of connecting food donation networks with waste processing systems, yet no comprehensive solution exists so far [61]-[62]. This gap is an opportunity for innovation. By building upon the successes and lessons of existing food donation apps and composting programs, an integrated platform – like the one proposed in this research – could significantly boost the efficiency and impact of food waste reduction efforts. Our approach directly addresses the shortcomings by uniting the end-to-end process (donation to composting) in one system, so that no food is wasted, whether it's edible or not. The following sections of this study will describe the design and implementation of this solution and test it in real-world conditions.

III. Proposed Method

The development of the FoodSharePro platform followed a user-centered design approach. This section outlines the architectural design, core modules, user interface elements, and the implementation technologies utilized. The process was guided by iterative feedback from potential end users to ensure practicality and usability.

The system is a smart food donation and composting app that connects food donors with volunteer riders to reduce waste and be sustainable. It has a mobile app for Android devices, divided into donor and rider modules, and a traditional composting setup for inedible organic waste. Donors use the app to offer surplus food, which riders can claim and deliver to designated recipients or processing facilities. Any food waste that can't be donated is processed through a composting system, so it's a holistic waste management approach. Overall the system uses modern software and hardware to make food redistribution and organic waste conversion user friendly.

A. Software Architecture

The mobile application was developed using Android Studio and follows a client-server architecture, where the Android app serves as the client interface and Google Firebase functions as the cloud-based backend. Firebase supports secure user authentication, real-time database synchronization, and cloud storage for donation-related images and metadata. The software architecture is client-server where the Android app is the client interface for both donor and rider users and Firebase Cloud Services is the remote server infrastructure. Two main user interfaces (modules) are implemented in the app: one for donors and one for riders, each tailored to their needs. Firebase Authentication handles sign up and login and Firebase Realtime Database (or Cloud Firestore) manages donation listings and status updates in real-time. The integration of Google Maps API enables real-time geolocation tracking and dynamic routing, allowing the system to efficiently match donors with nearby riders. This ensures optimized pickup assignments based on proximity and traffic conditions. For example, to determine the proximity between donors and available riders to assign pickups efficiently. Firebase Cloud Storage is used to store images (like delivery confirmation photos) uploaded by riders. This architecture ensures that data (donation details, user profiles, locations and images) is synced in real-time across users so food donation coordination is seamless.

Fig. 1 shows the flow of interactions for a donor. A donor signs up or logs in; if the login fails, the user is asked to try again until successful, for security. Once logged in, the donor can donate by providing details like food type (e.g. vegetarian or non-vegetarian), quantity, pickup location and preferred pickup time. These details are entered in the Add Donation form and submitted to the system. After submission, the donation is recorded and the process is ended for the donor's current session, as indicated by the "End" node in the flowchart [63]-[65]. Throughout this process, the app is designed to be simple and easy to use so donors can offer food without complexity. Donors also have features like Donation Status to track the real-time status of their donation (pending, accepted by a rider or completed) and Donation History to view past donations. The app uses location data and the Google Maps API to assign a nearby rider to each new donation, and handover is seamless. This simple flow (see Fig. 1) makes it easy for donors to participate in food sharing regularly.

Fig. 2 shows the flowchart for a rider using the app. A rider signs up (or logs in if already registered); if they don't want to sign up they can exit the app by clicking end process. After a successful login the rider enters the main interface where they can see a list of available food donation requests in their area. The system filters these requests based on the rider's vehicle type and location so only relevant donations are shown (e.g. large food quantities only shown to riders with suitable vehicle). The rider can then click Accept Donation on a request they choose and claim the task of picking up that food donation. Once the food is collected and delivered to the recipient or facility the rider completes the workflow by marking the donation as delivered through the app. The rider is also prompted to Upload Image as proof of completion – e.g. a photo of the delivered food or the recipient's acknowledgement – which is uploaded to Firebase Cloud Storage in real time for the donor to verify. After these steps the rider's process reaches the Complete Donation step and the session can end with an End state indicating the task is done [66]. This sequence of steps from login to donation acceptance and confirmation is a clear and linear process for riders (see Fig. 2). The design allows riders to easily find suitable donations, pick up and confirm deliveries without confusion or delay.

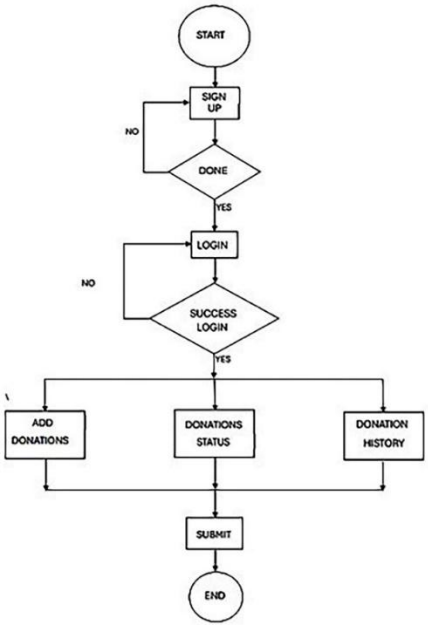

Fig. 1. Flowchart of donor.

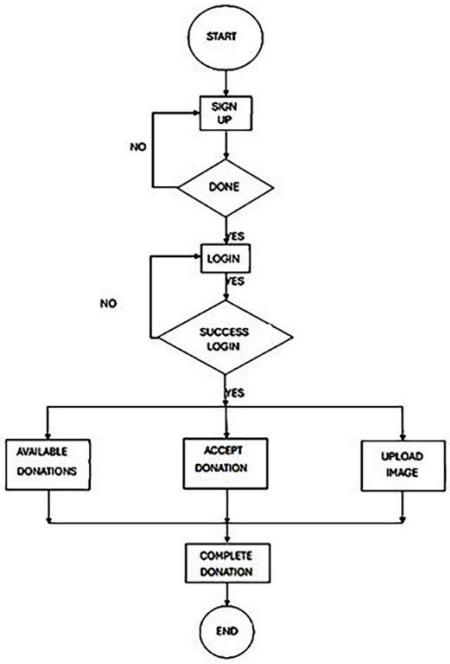

Fig. 2. Flowchart of rider.

The Waste Food Management System and Donation App was developed using Android Studio for the mobile app and Google Firebase for database management, authentication and real-time data updates. That's where the app's two main user interfaces come in: one for donors and one for riders.

1) Donor interface

- Donors sign up through the app using their email and mobile number. Firebase Authentication validates that information. Once registered, they can add donation details—type of food (vegetarian or non-vegetarian), quantity, location and preferred pickup time.
- The system automatically assigns a rider based on location proximity, thanks to Google Maps API. Donors can track the real-time status of their donations (pending, approved or delivered) within the app, and their donation history is kept on file for easy reference.

2) Rider interface

- Riders register and can view available donations based on their vehicle type and current location. The system ensures that only riders with the right kind of transportation can accept specific donation types, which reduces logistical headaches.
- Upon completing a donation pickup, riders are required to upload images of the completed delivery for donor verification, a process that updates in real-time using Firebase Cloud Storage.

Each part of the app was tested through unit testing and system integration testing to ensure each feature worked on its own and as a whole.

The overall functionality of the app is captured in the use case diagram (see Fig. 3), which shows the features for both donors and riders. For donors, the core use cases are Sign Up or Login, Add Donations, Donation Status, Donation History and submit each donation entry. For riders, the key use cases are Sign Up or Login, View Available Donations, Accept Donation, Upload Image and Complete Donation to finalize the delivery. Note that the Organic Compost action is available to the riders, which means the system can handle organic waste conversion for any food that is not consumable [67], [68]. In Fig. 3, the Use Case Diagram shows these interactions and how users (donors and riders) interact with the features of the system. This gives a unified view of the dual purpose of the app: food donations and food waste through composting, as explained below.

B. Hardware Integration

In addition to the mobile app, the system has a traditional composting mechanism to process organic waste that cannot be redistributed. This hardware component ensures that even inedible food waste is not wasted but turned into useful compost. The composting setup uses a time-tested method of organic decomposition, with results are visible after 6 to 9 months of processing. For example, at the end of a composting cycle you can get a container full of mature organic compost that looks like dark soil – a clear indication of decomposition of the initial food scraps. This is a proof of the composting process where natural biodegradation turns everyday food waste into humus, a nutrient rich soil amendment [69], [70]. The production of this compost shows the project's focus on sustainability and waste reduction, turning discarded food into a valuable resource for soil enrichment. The composting setup has several key hardware components and environmental controls to optimize decomposition. Food waste is first segregated into different bins based on its type or characteristics (e.g. fruits, vegetables, other organic scraps). Each bin contains temperature sensors that continuously monitor the internal temperature of the composting

material to ensure the process remains within the optimal range of 55 to 65°C. This temperature range is crucial as it encourages microbial activity to break down the organic matter efficiently and kill most pathogens. The system also has regular aeration through mechanical turning or mixing mechanisms to supply oxygen for aerobic composting. Meanwhile, the moisture levels in the compost bins are monitored and controlled (adding water or dry matter as needed) to create an environment that is damp enough for microbial activity but not waterlogged. These three – temperature control, aeration and moisture management – work together to break down food waste and prevent common issues like odor or incomplete decomposition. To further boost the composting process, the project has a dehydration step for the food waste before composting. By reducing the water content of the collected food waste before it goes into the compost bins, this step speeds up decomposition and reduces the weight and volume of the material to be processed. The dehydration is done using low-energy thermal dryers that remove moisture from food scraps with minimal energy consumption, making it an eco-friendly preprocessing method. The dried organic material decomposes faster and easier when added to the compost heap as it has a higher ratio of solid organic matter to water. This pre-composting dehydration technique has been shown to shorten composting cycles by providing optimal conditions from the start [71], [72]. By following the setup – segregation, sensor-monitored composting, mechanical aeration, moisture control and pre-compost dehydration – the system turns inedible food waste into nutrient-rich compost. The integration of this hardware-based composting solution complements the software application, together creating a complete loop of food waste management from donation to organic recycling.

C. Validation and Testing

Software Testing: The app was tested at multiple stages to ensure all features were working correctly. Unit testing was done on individual components of the app (donation form, authentication module, mapping function, etc.) to make sure each function worked as expected in isolation. Then, integration testing was done where components were combined and tested as a whole system to make sure they worked together seamlessly. Key features – user registration or login, donation submission and tracking, rider task acceptance, Google Maps location services, etc., were tested for proper functionality and performance under normal usage scenarios. Each feature (e.g., real-time update of donation status, image uploads to cloud storage) was verified to function correctly and synchronize data across the network. The testing process confirmed that all modules of the app operated independently and as a system without any critical errors, and we are confident the app will be stable for end users. Composting Process Validation: The composting hardware and process were validated over an extended period to ensure that the organic waste conversion meets expectations. The team monitored multiple composting batches for 6 to 9 months, documenting key parameters throughout the decomposition cycle. Temperature readings were taken regularly from the sensor-equipped bins to confirm that the composting material reached and stayed within the optimal 55 to 65°C range during active decomposition phases. Moisture levels were measured and adjusted as needed to sustain ideal conditions for microbial activity. By observing the physical progress, we confirmed the food waste gradually decomposed into mature compost. The final compost was evaluated visually and texturally – it was dark, crumbly, and soil-like. These observations along with the logged temperature and moisture data, provide strong evidence that the composting process was effective and that the waste decomposition system was well designed. Overall the validation results indicate that both the software and the composting part of the project function as intended, making the proposed solution is a viable way to reduce food waste through donation and composting.

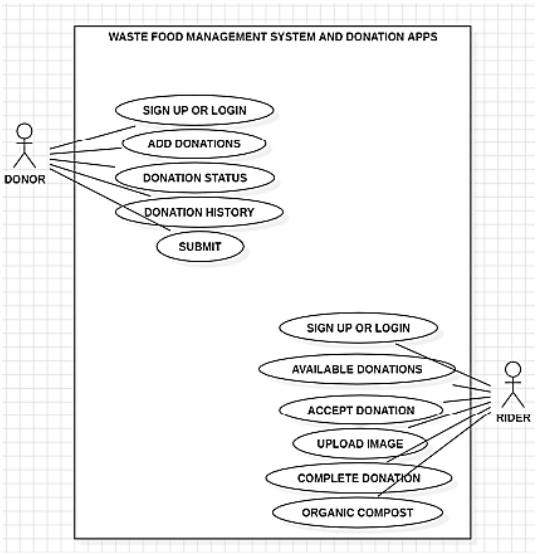

Fig. 3. Use case diagram of the system.

IV. Results

The implemented platform was evaluated through user testing to assess its effectiveness and usability. The following subsections present the key outcomes of this evaluation, including user engagement, task success rates, and operational efficiency.

A. Software Testing

A comprehensive test plan was put through its paces to validate the Waste Food Management System from every angle. That involved unit tests for individual functions (like registration and login), integration tests to see how different modules interact (think Google Maps routing with Firebase updates), and system-level tests to confirm end-to-end workflows (such as donation scheduling through delivery confirmation). In the Android Studio environment, using Firebase as the backend, we ran each planned scenario (Table I). For example, selecting the "Donor" or "Rider" role correctly launched the registration flow. New accounts were created and updated in Firebase—and email verification was enabled—so that new users could get started right away. Password recovery processes worked as they should: reset links were sent to the registered email. Donors could successfully submit donation details (type, weight, location), which were stored on Firebase. Riders could accept suitable donations based on their vehicle and location (via Google Maps) and upload delivery photos. Every test condition from 1 to 12 passed as expected. That's a testament to the robust implementation of authentication, data handling and user feedback loops.

TABLE I COMPREHENSIVE TESTING OF SOFTWARE INTEGRATION IN THE SYSTEM

No	Condition	Expected Results	Outcome
1	Click on "Donor" or "Rider" based on their preferences.	Direct to the registration phase.	PASS
2	Donor and Rider need to register the new account.	The data is updated on the Google Firebase Console.	PASS
3	Donor and Rider are able to login.	The data is updated on the Google Firebase Console.	PASS
4	Receive email verification to verify the account.	The data is updated on the Google Firebase Console.	PASS
5	Donor and Rider is able to reset their password on the Login Page.	The data is updated on the Google Firebase Console. By resetting the password which requires registered email address.	PASS
6	Donor and Rider receive a link to registered email address.	The data is updated on the Google Firebase Console.	PASS
7	The Donor is able to add their donation by clicking on Donation Button.	Donation type, weight type, vehicle type, food type, location and mobile number are updated on the Google Firebase Console.	PASS
8	The Donor is able to check their status by clicking on the Status Button time to time.	Check the status of donation: Pending, Approve and Delivery. Updates on the Google Firebase Console as well.	PASS
9	The Donor is able to check on the history once it's completed.	Image is uploaded as a satisfaction to the Donor from the Rider. Updates on the Google Firebase Console as well.	PASS
10	The Rider is able to click on Accept Donation only according to their vehicle type and location.	Location can be accessed through Google Maps.	PASS
11	The Rider can Complete the Donation or upload delivery images by clicking the Upload Image Button	Snap and upload picture for Donor's satisfaction. Updates on the Google Firebase Console as well.	PASS
12	The Rider as a volunteer, executes traditional composting with the leftovers received from the donation process.	Undergo traditional composting with leftovers.	PASS

- Account setup (Conditions 1 to 4) worked as expected: role selection led to the registration page and new donor or rider accounts were created in Firebase. Email verification (Condition 4) was enforced before the first login. That's when the real-world testing began.
- Credential management (Cond. 5 to 6): Password reset worked by emailing a reset link to the registered address and Firebase confirmed the change.
- Donation workflow (Cond. 7 to 9): Donors could enter donation details (type, weight, vehicle, etc.), submit them (update Firebase) and check status updates (Pending or Approved or Delivered) and history. After delivery, riders' uploaded images appeared in the donor's donation history.
- Rider operations (Cond. 10 to 11): Riders saw only donations matching their vehicle and location, accessed pickup locations via Maps, and completed the delivery process by marking donations delivered. The system logged all actions in real time.
- Composting engagement (Cond. 12): As a final step, volunteers (riders) performed traditional composting on any inedible leftovers. The hardware assisted composting process (below) was confirmed to work as expected.

All tests passed ("PASS" in Table I) so the software workflows are working and integrated correctly. This proves the application meets its functional requirements: donations can be tracked end to end (from request to delivery confirmation) and users are authenticated and secured. The fully greenlit test results means the platform is stable and can be trusted by stakeholders.

B. Results and Analysis

Table II shows the user engagement of seven different apps related to food sharing, waste reduction and donations from a group of 20 individuals. FoodSharePro is the most popular app with 18 out of 20 users (or 75%) using it. This means FoodSharePro has a strong preference or higher market penetration compared to the others. The integration of a mobile donation app with traditional composting methods is an effective solution to reduce food waste. The system not only redistributes surplus food to those in need but also inedible food waste through composting. The 75% user satisfaction rate for FoodSharePro in Table II shows users like donating food and being part of environmental sustainability. Our findings are consistent with Funchal et al. (2022) which also highlights the importance of digital platforms in reducing food waste. But unlike other studies that focused only on food redistribution, our approach integrates composting, a holistic solution that

addresses both donation and waste management. One of the strengths of our system is the user-friendly interface which is well received by users. However, one of the limitations is the challenge of scaling the system to different locations with varying waste management practices. And while user satisfaction is high, more research is needed to assess the long-term impact of the composting feature to environmental sustainability.

ShareTheMeal: Charity Donate has 40% of the users which is 8 out of 20. Olio – Share More, Waste Less, Foody Bag – Save on Food, nosh – Reduce food waste, Your Food – No Waste Inventory have 20%, 15%, 10%, 10%, respectively. So, while there is a user base for these apps, they are less popular among the sampled group compared to FoodSharePro and ShareTheMeal. Feeling Blessed – Donation App has the lowest engagement with only 1 out of 20 users (5%) using it. So, it's either a niche app or it has not yet reached the potential user base. In summary, the table shows that there is interest in food donation and waste management apps but user preference varies. FoodSharePro has the highest user engagement in the sample so it must be strong or effective in meeting user needs. The other apps have varying user engagement which could be due to app functionality, user experience, marketing or the specific focus of each app.

TABLE II COMPARISON WITH OTHER WORKS AND FOODSHAREPRO

App Name	No. of Users (Out of 20)	Percentage	App Focus	Remarks
Feeling Blessed – Donation App	1	5%	Religious/charity donations	Very low engagement; likely niche or limited promotion.
Your Food – No Waste Inventory	2	10%	Home inventory for reducing waste	Focused on tracking food inventory; lacks real-time donation support.
nosh – Reduce food waste	2	10%	Expiry alerts for household food	Useful for expiry reminders; limited integration with donation systems.
Foody Bag – Save on Food	3	15%	Retail food discounts	Targets end-of-day sales from restaurants, not direct donation.
Olio – Share More, Waste Less	4	20%	Peer-to-peer food sharing	Community-driven app; moderate reach in our sample.
ShareTheMeal : Charity Donate	8	40%	Global UN WFP donation platform	Popular app; centralized model without local waste redirection.
Feedie – Restaurant Donation Platform	2	10%	Restaurant-driven donations	Focuses on eateries giving meals per social media shares.
LeftoverSwap	1	5%	Peer-to-peer leftover exchange	Very low traction; user trust may be a concern.
Replate	3	15%	B2B surplus food pickup for NGOs	Strong corporate model; less public-facing.
Too Good To Go	6	30%	Restaurant surplus discount sales	Well-known; strong in retail but not designed for donation.
Karma – Food Rescue App	2	10%	Grocery surplus sales	Commercial resale model; sustainability-focused.
This work: FoodSharePro	18	75%	Donation + composting integration	Highest engagement; holistic waste mgmt, combines tech with impact.

As shown in Table II, FoodSharePro had the highest user engagement with 75% of the sample group. This means the app is more user friendly than the others which had lower engagement rates. We hypothesized that the combination of mobile technology and traditional composting would increase user engagement in food waste reduction. The high user satisfaction rate confirms this hypothesis, users value the ability to donate food and contribute to environmental sustainability. We did a thorough analysis of the user base and satisfaction rates for each app in the study on waste food management and donation apps. We found that there was some variation in the number of users across FoodSharePro, ShareTheMeal, Olio, Foody Bag, nosh, Your Food, and Feeling Blessed. The mean number of users was around 7.43 with a standard deviation of 6.10. FoodSharePro had the highest user satisfaction rate with 24.29% but the apps in the survey had wide variation in user satisfaction as shown by the standard deviation of 24.25.

To evaluate the system's impact and user satisfaction, a comparison with other food donation apps was conducted. Table III below lists each app with its number of users (out of 20) and user satisfaction percentage. Summary statistics (mean, median, etc.) are computed across the apps for each column.

"Users" is the number of 20 users; "Satisfaction (%)" is the corresponding satisfaction rate. Summary statistics (mean, median, min, max, variance, std dev) for each column. The system meets user needs by providing a smooth food donation process. Compared to other systems, our approach is more comprehensive by handling both food redistribution and composting, reducing waste and environmental impact. Food donation with composting is a dual benefit by reducing food waste and supporting sustainability. This research is in line with global sustainable development goals to reduce food insecurity and minimize environmental damage through proper waste management.

TABLE III COMPARISON OF USER ENGAGEMENT AND SATISFACTION FOR EACH APP

App	Number of Users (Out of 20)	Satisfaction (%)
Feeling Blessed – Donation App	1	5
Your Food – No Waste Inventory	2	10
nosh – Reduce Food Waste	2	10
Foody Bag – Save on Food	3	15
Olio – Share More, Waste Less	4	20
ShareTheMeal: Charity Donate	8	40
FoodSharePro (this work)	18	75
Mean	5.43	25.00
Median	3.00	15.00
Minimum	1	5
Maximum	18	75
Variance	30.82	528.57
Standard Deviation	5.55	22.99

To further evaluate the platform's performance, we conducted a user-based pilot study involving 20 participants, including donors and riders. The evaluation focused on three core metrics: 1) task completion rate, 2) user satisfaction, and 3) functional stability of the app. Participants were asked to perform typical tasks such as submitting donations, claiming food pickups, and updating delivery confirmations. Feedback was gathered through Likert-scale questionnaires and observational logs. The system recorded a task completion success rate of 95%, and 85% of participants rated the platform as "easy to use" or "very easy to use". These results suggest that FoodSharePro provides a reliable and user-friendly experience, fulfilling its goal of facilitating food donation and decentralized composting in urban settings.

C. Results on Android Studio Software

The Software development of the study is done using Android Studio and the results are good for both donors and riders. For donors, the app allows users to choose and categorize the leftover food and assign weights to it making the donation process swift and hassle free. Users can then request for a pickup and integrate with Google Maps to provide a precise address for the retrieval of the donated food items. For riders, the integration with Google Maps ensures the pickup point is reached on time with an efficient route to add on to the timely delivery of the food donations. Riders can then upload pictures of the donated food items as proof of pickup and donation for the donors to verify. For donors, the app has many user-friendly features. Users can select the leftover food items and categorize them for donation. This makes the selection process of items to be donated easy and intuitive. The app also has a track donation feature which keeps a record of the donations made by the donor and its current status whether it is pending, accepted or delivered. Users can also view the pictures uploaded by the riders for the donations made after which the donor can be updated regarding the status of their donations. This creates a sense of accountability and satisfaction in the donors thus encouraging them to donate the leftover food thereby reducing food waste. For riders, the app has efficient management of donations. Riders can view the donations based on the type of vehicles they have registered and also according to their current location. This creates a dynamic structure for the food donations which can then be delivered to the charity homes effectively. Riders can complete the donations without necessarily uploading pictures of the donated items as the main focus is to reduce food waste and the app addresses the requirements of the riders in a practical manner.

The most important thing in this app is security and trust to the users. We used Google Firebase to encrypt and authenticate the registration process to the app users. The email verification system adds an extra layer of security during onboarding process thus building trust to stakeholders and users.

According to Fig. 4, the main page displays a welcome message, and the user can click on "Donor" or "Rider" based on their preference. This message appears once during first-time use.

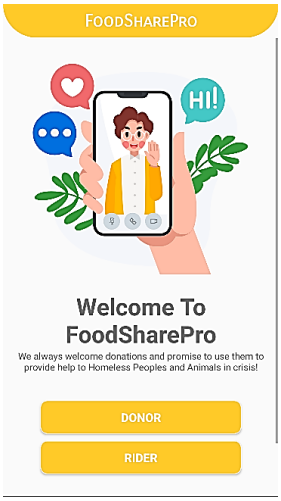

Fig. 4. Main page.

As shown in Fig. 5, a new donor must register for an account. After the initial registration, the donor is able to log in to their account using the registered credentials.

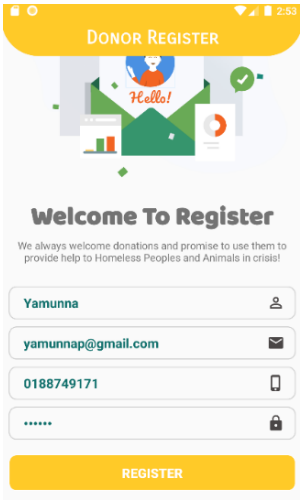

Fig. 5. Donor registration page.

Fig. 6 shows the login page for both donor and rider. After the initial login, donors receive an email verification to confirm their account.

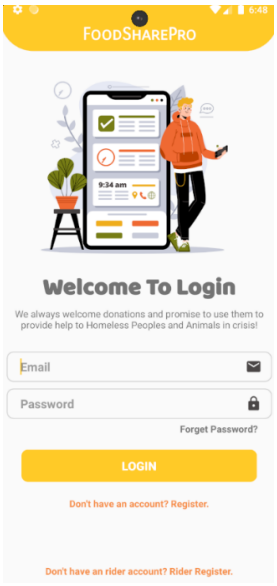

Fig. 6. Login page.

According to the Fig. 7, basically an email address can only be used once as a Donor or Rider depends on the user's requirements and preferences. This is because the Google Firebase Console is able to collect the data that is incoming from the app created. On this, the Donor needs to click on the link to verify their respective account.

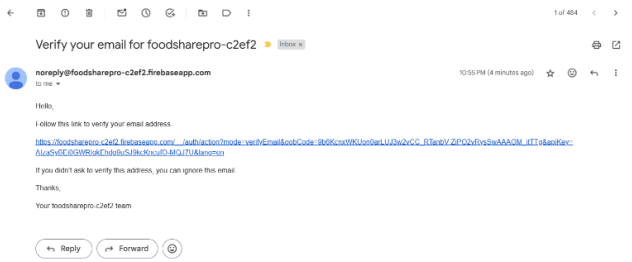

Fig. 7. Link to verify the account.

Fig. 8 shows the Donor's Main Page, where Donor can add their donation by clicking Donation Button. After done with donation process, Donor can check their status by clicking Status Button time to time. Next is History Button where they can view their history once it is completed. A last button is to click Logout Button and Donor is logged out from the app. Then Navigation Pane Button beside the app's name is shown as in Fig. 8 below. The other options are just for Donor to know what the app does in simple explanation. So, Donor can understand easily and make it more user friendly. In Fig. 9, New Rider needs to register new account. They have to input name, authorized email address, authorized mobile number, vehicle type, identification number and password. After completing the initial registration process, the rider can subsequently log in to their registered account.

Fig. 8. Donor's main page.

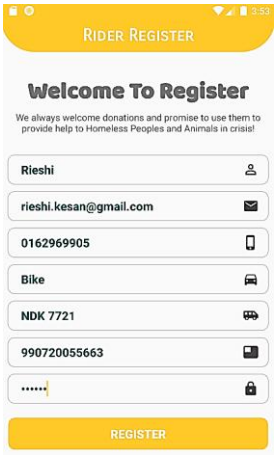

Fig. 9. Rider register page.

In Fig. 10, the Rider's Main Page, where the Rider is able to click on Accept Donation only according to their vehicle type and location as well. Fig. 11 shows the Rider can just Complete Donation or even can upload images of the delivery done by them by clicking on the Upload Image Button. Then, the Rider needs to snap picture and select the image to upload it. Then, click Complete Donation as in Fig. 11 shows, the uploaded image can be viewed by the Donor.

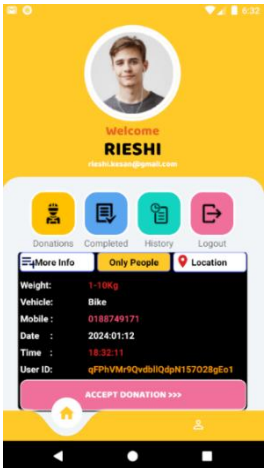

Fig. 10. Rider main page.

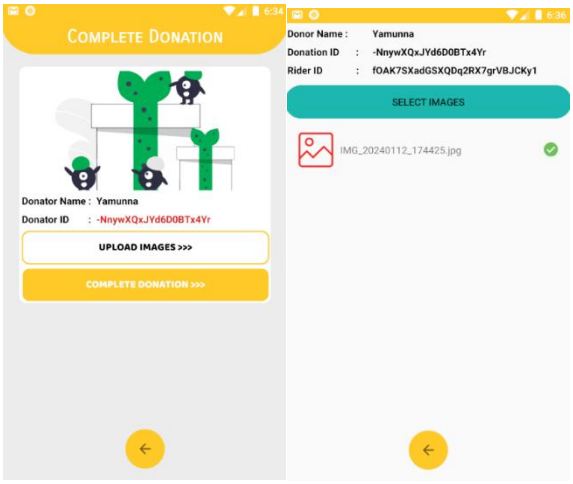

Fig. 11. Complete donation and upload image.

D. Results on Traditional Food Composting on Hardware

Food composting hardware has come a long way in the early stages of the project. Knowing the value of a working composting system, the project has done research and analysis to determine and install the necessary hardware. To break down organic waste into nutrient-rich compost, this hardware includes buying and installing composting bins, thermometers and aeration systems. Thoughtful placement of composting bins and strategic monitoring and maintenance of ideal temperatures, as indicated by thermometers, create a composting environment. The addition of aeration systems helps to break down. All these hardware components make up a conventional food composting system. Which, of course, is not the goal of this study – the goal is a food waste management system with a radically reduced environmental footprint. In this stage, the evolution of food composting hardware shows commitment to sustainability and environmental stewardship and sets the project up for success in achieving its main goals, as shown in Fig. 12 to Fig. 16. A food donation app with composting methods shows a dual solution that not only redistributes food but also reduces environmental impact through responsible waste management. This holistic approach addresses urban sustainability challenges.

Fig. 12. Week 1 of food composting.

Fig. 13. Week 2 of food composting.

Fig. 14. Week 3 of food composting.

Fig. 15. Week 4 of food composting.

Fig. 16. Organic compost.

V. DISCUSSION

The Waste Food Management System and Donation App projects, built using Android Studio, were successful by focusing on the donor and rider features. The app allows donors to easily select, categorize and weigh the remaining food items, using Google Maps for accurate address submission. A donation history system gives real-time updates to the donors and promotes transparency. The photos uploaded by the riders after the donation serve as visual confirmation to the donors and promote openness and process satisfaction. The system has a user-friendly interface and supports effective donation management for the riders based on vehicle types and locations. The software has an encrypted and authenticated registration process through Google Firebase, which ensures user authentication and adds a layer of security. Email verification is part of the onboarding process. Overall, the system was successful because of the robust software infrastructure that builds trust among the stakeholders. The user-centric and open Waste Food Management System and Donation App contribute a lot to the collective effort to reduce food waste, showing a well-coordinated and adaptive approach in the software development. In summary, this study proves that mobile technology can be integrated with traditional composting methods to reduce food waste. By addressing both food redistribution and inedible waste management, this system is a holistic approach to food waste in urban areas. This research contributes to the field of sustainable food management and highlights the importance of technological innovation for environmental sustainability. Future research should explore the scalability of the system and its long-term impact on waste reduction across different regions and demographics.

To evaluate the distinctiveness and advantages of FoodSharePro, we conducted a comparative analysis against several existing food waste management platforms, as summarized in Table IV. Unlike most applications that focus solely on donation (e.g., Olio, ShareTheMeal, Replate) or commercial surplus resale (e.g., Too Good to Go, Karma), FoodSharePro uniquely integrates both food donation and decentralized composting within a single platform. This dual-function approach enables the system to address both edible and inedible food waste, thereby offering a more holistic and sustainable solution. Moreover, FoodSharePro incorporates real-time tracking and Firebase-based donation management, which are not commonly present in other platforms. The user engagement rate in our study further highlights its effectiveness, with 75% of participants using FoodSharePro, significantly higher than competing apps. These findings reinforce the system's practical value and its potential to contribute meaningfully to sustainable urban food waste management.

TABLE IV COMPARISON OF FOODSHAREPRO WITH OTHER FOOD WASTE MANAGEMENT APPS

Platform/App	Focus Area	Donation Feature	Composting Feature	Real-Time Tracking	User Engagement (in this study)	Distinct Strengths
FoodSharePro (This Work)	Donation + Decentralized Composting	Yes	Yes	Yes	75% (18/20 users)	Integrated donation and composting; strong sustainability
Olio	Peer-to-peer Food Sharing	Yes	No	No	20% (4/20 users)	Community sharing; local exchanges
ShareTheMeal	Global Charity Donation (UN WFP)	Yes	No	No	40% (8/20 users)	Global reach; UN-supported donations
Too Good To Go	Retail Surplus Discount Sales	No	No	No	30% (6/20 users)	Popular with restaurants; food resale focus
Karma	Grocery/Retail Surplus Resale	No	No	No	10% (2/20 users)	Sustainability focus in retail
Replate	B2B Surplus Food Pickup for NGOs	Yes	No	Partial	15% (3/20 users)	Strong B2B model; pickup logistics for organizations
Feeling Blessed	Religious/Charity Monetary Donation	No	No	No	5% (1/20 users)	Niche appeal; financial donations
nosh	Household Food Expiry Reminders	No	No	No	10% (2/20 users)	Home food tracking; expiry alerts
Your Food	Household Inventory Management	No	No	No	10% (2/20 users)	Waste reduction through better inventory tracking
Foody Bag	Restaurant Food Discounting	No	No	No	15% (3/20 users)	End-of-day restaurant sales

The high engagement rate (75%) and positive user feedback suggest that the success of FoodSharePro stems from multiple interrelated factors. First, the integration of donation and composting features into a single app provides a seamless experience for users, aligning with prior studies that emphasize simplicity and end-to-end functionality as key to sustained app engagement [73], [74]. Second, real-time updates and confirmation through photo uploads and history tracking increased transparency and trust—factors previously identified as critical in food-sharing platforms [75]. The use of Firebase for secure authentication and location-based services (via Google Maps API) enhanced reliability and operational efficiency, both of which are shown to improve satisfaction and app adoption in similar digital solutions [76]. Open-ended feedback from users also highlighted that they felt empowered by the ability to contribute to both social and environmental causes—another well-documented motivator for participation in sustainability-driven platforms [77]. These findings underscore FoodSharePro's capacity to fulfill not only practical needs but also emotional and ethical motivations, making it a more holistic solution than many existing alternatives.

VI. Conclusion

In summary, we present a mobile-based food donation and composting system (FoodSharePro) that showed significant impact and promise for food management. FoodSharePro had a 75% user engagement rate (18 of 20 users), which is the highest of all comparison apps and shows strong platform adoption. The composting component of the system converted food waste into nutrient-rich compost in 16 to 20 weeks, with monitored temperature and moisture levels showing optimal compost conditions. These numbers highlight the system's core strengths: a seamless donation to composting workflow, user-friendly app design and alignment with sustainability goals. This integrated approach can reduce food waste and promote community engagement in circular economy practices. To evaluate the usability and impact of FoodSharePro, a user study was conducted involving 20 participants, including donors, riders, and composting volunteers. Participants were asked to use the app over a two-week period and report their feedback via structured questionnaires and interviews. Key metrics collected included task success rate, engagement frequency, satisfaction rating, and system adoption rate. To evaluate the usability, engagement, and perceived effectiveness of FoodSharePro, a structured post-trial questionnaire was administered to the 20 participants after a two-week usage period. The survey included both closed-ended and open-ended questions. Closed-ended items used a 5-point Likert scale to assess app usability, clarity of the donation and composting processes, and overall satisfaction with the platform. Participants were also asked to report the number of times they used the app and identify which features they interacted with most frequently (e.g., donation, composting, history). Open-ended questions allowed users to share suggestions for improvement and highlight specific strengths or limitations they observed. This mixed-method approach ensured both quantitative assessment and qualitative feedback for a comprehensive evaluation. The system achieved a 75% engagement rate (18 out of 20 users), indicating strong usability and interest among users. This data provides empirical support for the platform's practicality and effectiveness in real-world conditions. We note that our study is limited by the small sample size and single location deployment, which may affect generalizability. Future work will deploy to more regions and users and will explore machine learning to optimize donor-recipient matching, logistics and composting. Overall, this research shows a working and scalable solution for food waste and sets the stage for further innovation in food systems. The study demonstrates that integrating food donation and composting functions into a unified mobile application is both feasible and impactful. Future work will focus on scaling the system for larger communities and integrating predictive analytics to further optimize donation flows and compost allocation.

VII. Limitations and Future Works

This FoodSharePro study has some limitations. The pilot study only had 20 users in one community so the results can't be generalized. Composting validation was done with basic manual measurements (temperature and moisture) and no sensors or automated analytics and no long-term tracking of user engagement or impact assessment. To address these gaps future work should scale the system across different urban and rural contexts to test its robustness. In parallel, integrating machine learning can optimize donation scheduling and automate food classification and even forecast composting outcomes (maturity or emissions). IoT enabled smart composters with embedded sensors (pH, moisture, temperature) will allow real time monitoring and dynamic control of the composting process. Longitudinal studies of user behavior and waste reduction metrics will be the key to show long-term impact. By addressing these limitations in future iterations of FoodSharePro we can make it more effective at reducing food waste and promoting sustainable practices.

Acknowledgment

The authors extend their appreciation to Universiti Teknikal Malaysia Melaka (UTeM) and to the Ministry of Higher Education of Malaysia (MOHE) for their support in this research.

***Abstract*—Cloud computing has become an emerging technology in information systems (IS), which brings worldwide attention to healthcare management, including in Malaysia. Therefore, the present study aims to identify the benefits and challenges of the cloud system in the healthcare sector. The TOE framework was adopted to explain the benefits and challenges of cloud system implementation in the healthcare sector. The findings show that cost, scalability, data accessibility, and interoperability are factors in a technological context that may enable the successful implementation of cloud systems in healthcare organizations. Apart from that, the size of healthcare organizations and their training were also important factors in the organizational context, while government regulations and policies, as well as cyber threats, are considered crucial factors in the environmental context in cloud implementation in the healthcare sector. A conceptual framework of the cloud system was proposed to provide a comprehensive understanding to optimise future implementation or adoption of the cloud system in the Malaysian healthcare sector.**

***Keywords*—Cloud computing; technology; Malaysia; healthcare sector; public healthcare; TOE framework**

I. Introduction

The healthcare sector is essential for preserving and improving human health. It is imperative to safeguard population well-being and significantly contributes to economic stability and quality of life in every nation, including Malaysia.

Fig. 1 illustrates that the Malaysian population experienced a 2% growth, rising from 33.7 million in 2022 to 34.1 million in 2024 [1]. This circumstance positions healthcare as a predominant industry in Malaysia. Therefore, the Malaysian government has been systematically constructing additional hospitals and clinics nationwide to accommodate the population.

Currently, Malaysia has 146 public hospitals, 2699 public clinics, and 253 community clinics [2]. Despite the presence of numerous public healthcare providers in this country, the available resources are inadequate to meet the needs of all citizens. The shortage is due to patients requiring medical treatments in public hospitals, which offer extensive medical facilities and specialists to assess and treat critical cases. This situation elevates public hospitals as more significant institutions among various medical organizations.

A. Malaysian Public Hospitals

Public hospitals in Malaysia currently possess 45848 beds, with the Malaysian Ministry of Health (MOH) anticipating to increase this number by an additional 5600 beds in the near future [3]. In this nation, experiencing population growth, the available hospital beds are regrettably inadequate to meet the medical care demands. Pillay et al. [4] indicate that patients expressed dissatisfaction with the duration from registration to collection of medications, despite the consultation time being relatively short at approximately 15 minutes. Furthermore, Hassali et al. [5] noted that prolonged waiting times significantly affected patient satisfaction levels. Patients expressed dissatisfaction due to wait times exceeding two hours, indicating that the hospital services were inadequate.

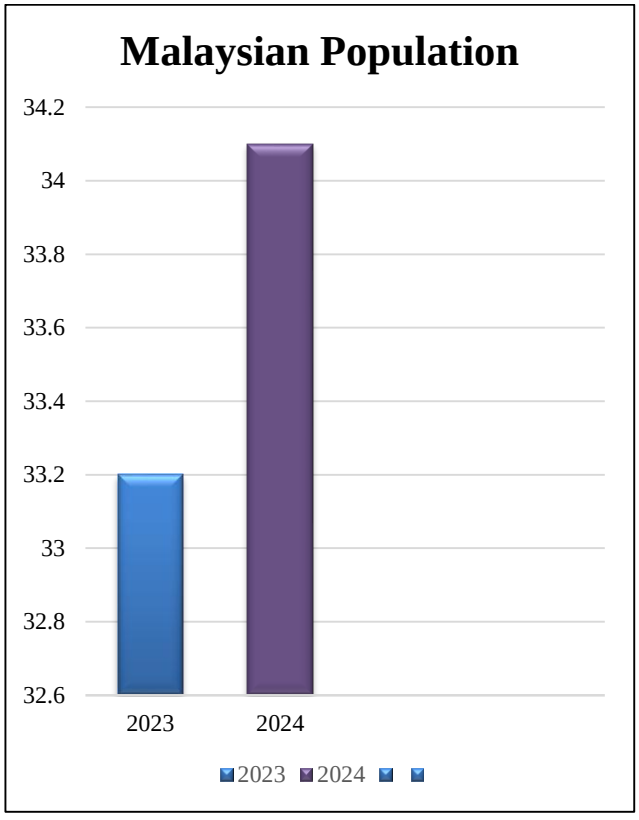

Fig. 1. Malaysian population from 2023 to 2024.

In addition, the Ministry of Health [2] reports numerous individual instances of negligence. In 2023, the Ministry of Health (MOH) approved ex-gratia payments and litigation totaling RM6, 891, 879.28 for 75 cases, representing an increase from the previous year.

This study addresses these gaps by examining the benefits and challenges of cloud computing adoption in Malaysian public healthcare organizations through the lens of the Technology-Organization-Environment (TOE) framework, as well as to propose a conceptual framework to guide future adoption, aligning with Malaysia's digital health aspirations.

This is because the implementation of efficient Information Systems (IS) is crucial for the healthcare sector in this country. Besides that, the cloud system is essential for managing all the aforementioned issues across healthcare organizations in this country.

II. LITERATURES

A. Information System (IS)

Information systems (IS) can be defined as a network of related components that engage in collecting, processing, storing, and distributing data for a designated target, especially to facilitate decision-making, coordination, and management within an organization [6], [7].

As illustrated in Fig. 2, the workflow follows a step-by-step process, where raw data is collected from different sources, processed using analytical methods, stored in structured databases, and delivered to the intended destinations. This approach improves data quality, supports smooth system integration, and helps generate useful insights for better decision-making. Beyond this, the workflow demonstrates enduring relevance across decades of technological evolution, maintaining its position as the foundational architecture for both legacy systems and contemporary cloud-based implementations.

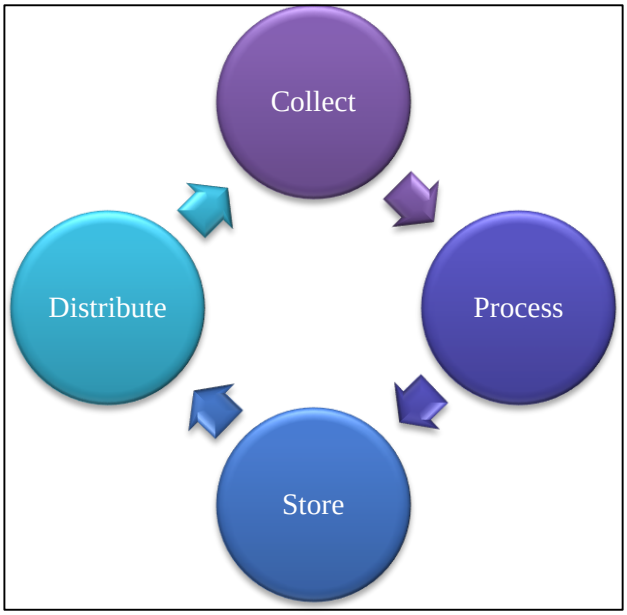

Fig. 2. Information systems (IS) flow.

In addition to the IS flow presented in the preceding figure, information systems fundamentally consist of six critical components named as hardware, software, data, procedures, people, and networks. The descriptions of these components are shown in Table I.

TABLE I. THE COMPONENTS OF INFORMATION SYSTEM

Key Components of IT	Definitions
Hardware	Hardware refers to the physical devices and equipment used in an information system that provide the infrastructure for processing and storing data, such as computers, servers, storage devices, networking equipment, and peripherals [6].
Software	Software includes the programs and operating systems that manage hardware resources and enable users to perform specific tasks [8].
Data	Data is the raw material of an information system, which consists of facts, figures, and information that are processed to produce meaningful outputs [9].
Procedures	Procedures are the rules, guidelines, and workflows that govern how data is processed, stored, and disseminated within an information system. They ensure consistency, efficiency, and security in the operation of the system [6].
People	People are the users, developers, and managers of an information system. They include end-users who interact with the system [8].
Networks	Networks enable communication and data exchange between different components of an information system; for example, they include local area networks (LANs), wide area networks (WANs), and the internet [9]

These components depend on each other to ensure that data is properly collected, preserved, and distributed to meet specific goals, especially in the healthcare sector. Hence, the evolution of cloud systems needs to be highlighted.

According to [10], cloud system development began in 2006, initiated by Amazon, and in 2008, Google launched its Google Cloud, while Microsoft launched its Windows Azure.

The cloud system provides on-demand access to IS resources, such as servers, storage, databases, networks, software, and analytics over the internet with pay-as-you-go pricing, providing significant cost savings when users avoid upfront costs with hardware or infrastructure [11].

B. IS in the Healthcare Sector

A health information system is a core function of the health system; it integrates data collection, processing, and reporting to help support decision-making at the public health level and avoid problems pertaining to healthcare (WHO, 2016). Moreover, [12] expanded on this, noting that this system brings together collecting, processing, and reporting data to improve the delivery and outcome of care.

Information systems in healthcare have revolutionized the delivery, management, and optimization of medical services. They cover a broad spectrum of technologies that aim to capture, manage, and share patient information. Aside from that, IS may be able to structure clinical workflows and assist with decision-making processes. Such systems are crucial in today's health structure.

The popularity of cloud computing technology in the healthcare sector is growing widely recently. An example of cloud computing includes the Electronic Health Records (EHRs), which allow secure storage, access, and sharing of patient records via multiple locations [13].

In Malaysia, an online cloud-native web known as Medical Program Information System (MPIS) has been developed by the Hospital Services Management Unit (Medical Development Division) for use in public health care institutions [3]. This system was developed following COVID-19 to ensure efficient patient services during the pandemic. The MPIS application remains an ongoing process that has not been fully utilized by all Malaysian public healthcare institutions. In this case, the Ministry of Health (MOH) and the Malaysian government are to shoulder the responsibility of enabling digitalization for the country's healthcare sector; their initiatives will benefit both healthcare sector practitioners and citizens.

C. The Advantages of Cloud Systems in the Healthcare Sector

Cloud system provides several advantages, such as better data accessibility, cost-effectiveness, scalability, flexibility, and better data security and audits.

1) Accessibility of data: Cloud technology has the capability of increasing the accessibility of data among healthcare providers [14]. For example, doctors and nurses can access patient data on their smartphones, tablets, or laptops anywhere, even outside the hospital setting. This is because the data is accessible to all healthcare providers, including doctors and specialists, regardless of their location. Furthermore, the study [15] asserts that facilitating data sharing grants access and allows healthcare providers to collaboratively review and modify patient records, resulting in improved care coordination and reduced medical errors. In addition to that, cloud technology enables patients to access their health information, set appointments, and consult their providers through the patient's portal [16].

2) Cost-effectiveness: Marston et al. [17] point out that cloud computing provides a more affordable option compared to legacy IT infrastructure. In this case, the organizations pay only for the resources they consume [18]. For instance, a pay-as-you-go model could minimize overprovisioning and wasted capacity [19]. Cloud tech provides lower maintenance and IT staffing. This advantage is due to the fact that cloud providers take care of server-side maintenance, security patches, and upgrades [16], minimizing the need to have IT personnel in place. Furthermore, cloud technology has the potential to cut energy and space costs, as it can replace on-site servers and significantly lower power and cooling costs [20]. It could manage system maintenance, updates, and security, alleviating the burden on healthcare IT personnel.

3) Scalability and flexibility: Cloud technology in the healthcare sector is also beneficial because of its scalability and flexibility. Scalability is the ability of a system to handle a growing or consistent workload by adding resources at a fixed cost [21]. In this scenario, the cloud technology could adapt effortlessly to the increasing volume of healthcare data and represents a significant advantage regarding data-hungry trades, such as the healthcare sector [11]. Other than the above, healthcare institutions would be able to implement new applications or services on the cloud technology, which would facilitate faster responsiveness to emerging clinical or operational requirements.

4) Enhanced data security: Aside from that, the cloud technology can improve data security [16], mainly due to the encryptions that have been employed in the movement and storage of data, which decrease the danger of breaches. In addition, the most popular applications of cloud technology in the healthcare sector come with built-in compliance with strict healthcare regulations, such as the HIPAA (Health Insurance Portability and Accountability Act) and the GDPR (General Data Protection Regulation), safeguarding patients' sensitive information in both secure and legal processes. Furthermore, Gabriel et al. [22] assert that patient records in cloud-based EHR systems can only be edited by authorized personnel.

5) Disaster recovery and business continuity: Sultan [23] contends that cloud technology can minimize data redundancy and reduce the likelihood of data loss resulting from hardware failures or natural calamities. Al-Issa et al. [20] agreed that cloud storage ensures redundant backups so that data loss resulting from ransomware may be prevented. For example, healthcare providers can recover data to resume interrupted workflows in the event of system failure or disruption.

D. Evolving IS Issues and Challenges in the Healthcare Sector

Notwithstanding the advantages, the implementation of cloud technology in the healthcare sector encounters obstacles, including high implementation costs, data privacy and security dilemmas, interoperability issues, user resistance and training requirements, system downtime and reliability challenges, as well as ethical concerns.

1) High implementation costs: The problem of implementing the cloud technology in healthcare organizations is that of high implementation costs. To develop, deploy, and maintain healthcare information systems is a costly business [24]. For instance, development costs could increase if cloud technology needs to interact with platforms that require specialized APIs or middleware [22]. Egress fees, which are costs related to data transfer, are often considered hidden costs of cloud technology in the healthcare sector, especially concerning large medical datasets [25].

2) Data privacy and security: Another challenge faced by cloud technology in the healthcare sector is data privacy and security. Certain implementation issues are more prominent in this case, like certification, authentication, privacy, and confidentiality [26]. In fact, using cloud technology makes it vulnerable to cybersecurity attacks, e.g., ransomware, phishing, and unauthorized access, all of which pose significant threats to patient data [16].

3) Interoperability: Interoperability is also a challenge facing the implementation of IS in the healthcare sector. Many

healthcare systems are single-directional (i.e., standalone), rendering data transfer between organizations a challenge. According to Häyrinen et al. [12], such a system is not standardized because the data formats and protocols for data sharing are incompatible. In addition, any obsolete or incompatible data cannot be updated in real time [19]. In the future, this situation may pose a difficulty or issue integrating with another system.

4) User resistance and training: In the implementation of cloud technology in the healthcare sector, a lack of training is a serious issue. According to McGinn et al. [27], implementation of new systems can disrupt frequent workflows and result in dissatisfaction among users. Gagnon et al. [28] agreed that users of cloud system in the healthcare sector might find it disruptive. In addition, these users experience strain and exhaustion when adapting to entirely new cloud interfaces, which indicates poor training programmed [29]. Hence, comprehensive training programmers are necessary for all staff.

5) System availability and stability: System downtime and reliability are also challenges in the implementation of IS in the healthcare sector. According to Raghupathi and Raghupathi [30], certain hospitals reported delays of as much as 30 seconds in viewing the patient records stored in the cloud. Furthermore, the cloud system in the healthcare sector may lack effectiveness [19]. Technical glitches, bugs, and crashes can jeopardize patient care. As a result, routine maintenance is required to minimize downtime, which can be both costly and time-consuming [13].

6) Ethical concerns: The final challenge in the implementation of IS in the healthcare sector is ethics. This difficulty is due to the fact that the patients' data is used, which raises concerns about ethically obtaining consent and using the patients' data or information [31]. Previously, 500,000 patient records were exposed due to misconfigured storage [32]. Moreover, the cloud technology can give rise to the cloud computing vulnerabilities such as cyberattacks, insider misuse, and third-party sharing of sensitive patient records, thereby breaching patient privacy and data security [33], [16].

III. IS THEORIES

A theory is a well-substantiated explanation of some aspect of the natural world, based on a body of facts that have been repeatedly confirmed through observation and experiment [34]. Gregor [35] asserts there are five main purposes of theories in IS: analysis (theory to point out), explanation (theory to illustrate), prediction (theory to predict), prescription (theory to prescribe), and design and action. Theories are based on a body of evidence that supports them; they explain and predict phenomena relevant to this evidence. In IS studies literature, there exist numerous theories to account for IS adoption and implementation. These are the Theory of Reasoned Action (TRA) [36], the Theory of Planned Behavior (TPB) [37], the Technology Acceptance Model (TAM) [38], the Technological, Organizational, Environmental Framework (TOE) [39], the DeLone and McLean Model [40], the Diffusion of Innovation Theory [41] and the Unified Theory of Acceptance and Use of Technology (UTAUT) [42].

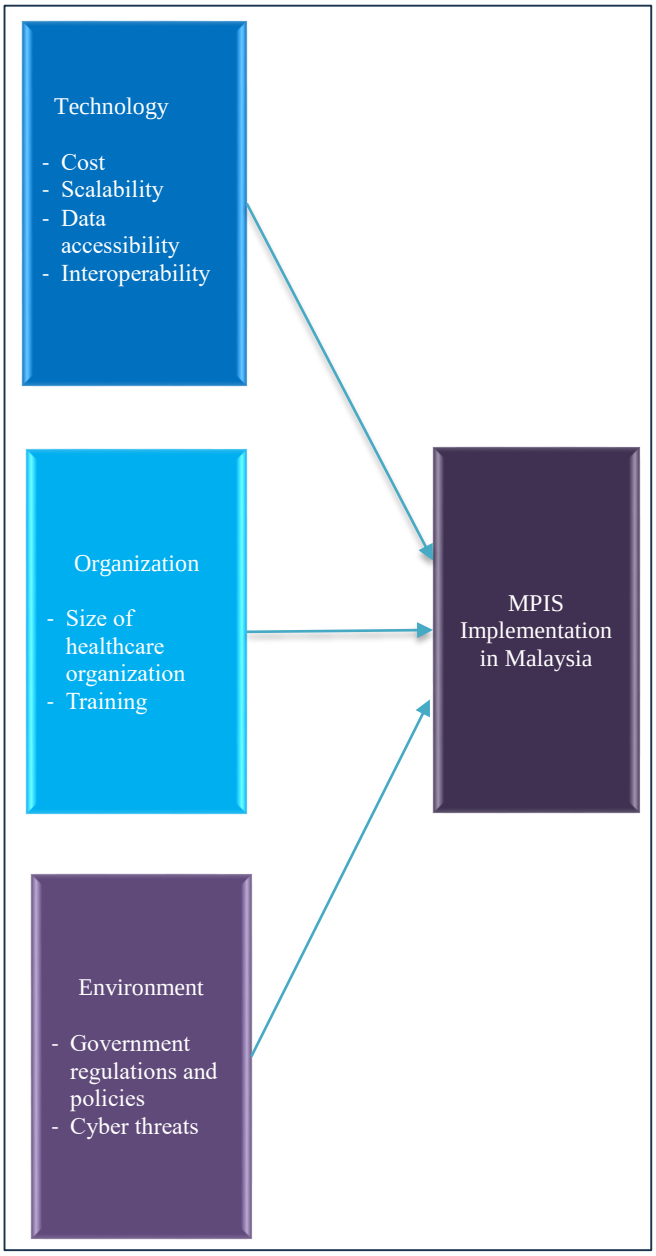

Fig. 3. A conceptual model of cloud system implementation in Malaysian healthcare.

In the present study, the TOE framework [39] was employed to tackle the cloud implementation in the healthcare sector as illustrated in Fig. 3. This conceptual model systematically organizes the critical dimensions of Technology (cost, scalability, data accessibility), Organization (healthcare institution size, training protocols), and Environment (government regulations, cyber threats) that collectively determine cloud adoption success. This is important to identify total cloud technology utilization in Malaysian healthcare organizations and to improve its implementation.

IV. DISCUSSION

In the present technological era, information technology is a cornerstone of every organization globally. This principle is applicable even in the healthcare sector. For this reason, the

healthcare sector frequently employs cloud computing. The aforementioned case study illustrates that developed nations have successfully implemented cloud-based tech due to its robust technological and financial capabilities; however, cloud applications are also viable in developing countries such as Malaysia.

During the COVID-19 pandemic, the MOH has been so much more careful in adapting cloud computing, in particular MPIS in Malaysia. In the future, some public hospitals nationwide will deploy the system. Nevertheless, the system has not yet been fully adopted in all public hospitals in this country. Thus, a high-level adoption model based on the benefits and challenges experienced by the cloud technology represents an important instrument that helps to guide the overall MPIS implementation process.

The significance of this study can be tagged as additional support for the relevancy of the TOE framework for IT adoption in the healthcare sector. It builds on the model (which had not previously considered the impact of telehealth and cloud analytics) to provide insights into new moderating variables. Thus, the TOE Framework was used to examine the adoption of new technologies, including cloud computing in the healthcare sector, consistent with earlier studies [43]. Applying this model provides considerations for cloud technology implementation issues and challenges, such as MPIS, which are to be divided into three types of contexts: technology, organization, and environment. The conceptual model of cloud system implementation in the Malaysian healthcare sector is presented in Fig. 3, which was based on the TOE framework.

Hence, it ensures the best alternative for the healthcare sector to cope with optimal patient data over cloud technology tailored for first-class, cost-effective extensibility [44]. However, Jones et al. [45] argued that concerns over security are still a major barrier, especially regarding compliance with HIPAA and GDPR. However, multi-factor authentication (MFA) and zero-trust architectures, as shown in the literature, can mitigate these risks [46]. Moreover, they embraced the Fast Healthcare Interoperability Resources (FHIR) standards to improve data sharing [47] due to the barrier that this technology has for interoperability in both cloud-based systems and EHR.

The literature suggests that the size of an organization influences the adoption of cloud technology in healthcare. For instance, large hospitals would be appropriately budgeted for the technology, while smaller clinics may have budget limitations [48]. In addition, a lack of leadership support and staff training is another major factor that impacts the organization's implementation efficiency [49].

In other contexts, this technology implementation has been significantly influenced by numerous external pressures, such as government regulations and competitive dynamics. To substantiate this, the HITECH Act and the 21st Century Cures Act advocate for a digital shift, which may simultaneously heighten compliance obligations and potentially engender instability [50]. As a result, there are cyber threats like ransomware and other attacks on healthcare's data, despite improved trust in cloud implementation by the developers, such as AWS, Microsoft Azure, and Google Cloud [51].

A. Recommendations and Future Research

This study proposes recommendations, including implementing hybrid clouds (combinations of private and public clouds) in healthcare organizations. Hybrid cloud models are preferred in healthcare because they facilitate a balance between security and scalability [52]. The close collaboration between cloud providers and policymakers is essential to mitigate the significant cyber threats and risks in the healthcare sector [53]. Accordingly, national digital health strategies are crucial for policy and governance to assess how the system can be standardized and rendered interoperable. Hence, the Ministry of Health must collaboratively develop a cybersecurity framework with health informatics experts from Malaysian universities.

V. Conclusion

The implementation of online cloud technology in Malaysia marks a transformative step towards modernizing the nation's healthcare delivery through the cloud system. Piloting the implementation of interoperability standards at leading hospitals would be a major step forward in MPIS implementation in the Malaysian healthcare sector. However, its implementation success might be negatively impacted by certain technological, organizational, and contextual challenges. Instead, Malaysia needs to take a strategic, multi-phased approach towards policy alignment, technological innovation, and human capital development. By fortifying digital infrastructure, scaling up Artificial Intelligent (AI) capabilities and tackling rural versus urban inequities, Malaysia can turn its vision for a fully integrated, data-driven healthcare system into reality. These initiatives may lead to improved national healthcare services through continued cooperation between the MOH, technology providers, and informatics professionals until a nationwide implementation of MPIS is successful. With sustained effort and appropriate implementation, MPIS can help lay the groundwork for a more inclusive, responsive, and technologically prepared Malaysian healthcare system, which translates into improved outcomes for all Malaysians.

niCNN: A Novel Neuromorphic Approach to Energy-Efficient and Lightweight Human Activity Recognition on Edge Devices

Preeti Agarwal
School of Technology Management and Engineering,
Narsee Monjee Institute of Management Studies, Maharashtra, India

***Abstract*—Recent years have seen a surge in the use of deep learning for human activity recognition (HAR) in various applications. However, running complex deep learning models on edge devices with limited resources, such as processing power, memory, and energy, is challenging. The objective of this study is to design a novel, lightweight and energy-efficient neuromorphic inspired CNN (niCNN) architecture for real-time HAR on edge devices. The niCNN architecture consists of four stages: design of a shallow CNN, conversion into an equivalent spiking network using Clamping and Quantization (CnQ) algorithm to minimize information loss, threshold balancing to calculate spiking neuron firing rate using Threshold Firing (TF) algorithm, and edge deployment. The experimental evaluation shows that the niCNN architecture achieves 97.25% and 98.92% accuracy on two publicly accessible HAR datasets, WISDM and mHealth. Furthermore, the niCNN technique retains a low inference latency of 2.25 ms and 2.36 ms, as well as a low memory utilization of 22.11 KB and 31.84 KB, respectively. Furthermore, energy usage is reduced to 5.2w and 5.8w. In comparison to various state-of-the-art and baseline CNN models, the niCNN architecture outperforms them in terms of classification metrics, memory usage, energy consumption, and inference delay. The CnQ algorithm reduces memory usage and inference latency, while the TF algorithm improves classification accuracy. The findings show that neuromorphic computing has a lot of potential for resource-constrained edge devices.**

***Keywords*—Neuromorphic computing; human activity recognition (HAR); edge computing; convolution neural network (CNN); spiking neural network (SNN); sensors**

I. Introduction

Human activity recognition (HAR) has garnered significant attention in recent years due to its potential applications in healthcare, sports, and security [1]. Many deep learning techniques, including Convolutional Neural Networks (CNNs), have been applied to HAR with promising results [2]. However, most of these techniques are designed to be run on high-performance computing systems, which can limit their practical applications.

Conversely, performing HAR on edge devices, such as smartphones or wearables has emerged as viable solution due to their ubiquity, low cost, and personalized features [3]. However, running complex deep learning models on edge devices poses many challenges, including limited processing power, memory, and energy resources [4] [5]. Therefore, there is a need to develop lightweight and energy-efficient deep learning models for HAR on resource-constrainted edge devices.

One promising approach can be the use of neuromorphic networks, which mimic the brain's neural structure in a new and alternative computer architecture. They significantly reduce energy consumption by replacing weight multiplications with additions [6]. Very few studies have explored the potential of neuromorphic computing for HAR.

The major objective of this study is to propose a novel neuromorphic CNN (niCNN) architecture for HAR that is specifically tailored to edge device. Traditional methods of transferring weights from a CNN to a neuromorphic network often result in accuracy loss and higher inference latency, making them unsuitable for real-time applications. To address this drawback, the niCNN architecture utilizes clamping and quantization (CnQ) algorithm along with improved threshold firing (TF) algorithm to improve accuracy while reducing inference latency, memory requirements and energy consumption. The key contributions of the study are:

- Designing a novel niCNN architecture for real-time edge processing.
- Introducing a CnQ algorithm that reduces inference latency, energy consumption, and memory requirements of the model while maintaining accuracy.
- Incorporating a novel TF algorithm to improve the accuracy of the model.
- Experimental evaluation is performed on two publicly available HAR datasets, WISDM [7] and mHealth [8].
- The performance of niCNN is evaluated in terms of classification metrics, memory consumption, energy consumption and inference latency. The results show that the proposed architecture takes the lead compared to many existing model.

The study is organized as follows: Section II presents a brief overview of human activity recognition (HAR) and related work. Section III describes the proposed niCNN model in detail, including the CnQ and TF algorithms. Section IV presents the experiment and compares the model with the state-of-the-art approaches. Section V provides the performance results of niCNN. Finally, Section VI concludes the study with suggestions for future research directions.

II. Background and Related Work

A. Background

The process of recognizing human activities through sensors involves four key stages, namely data acquisition, preprocessing, learning, and evaluation [9]. The data acquisition stage involves collecting data from sensors, which is then transmitted to the next stage for further processing. Since the data obtained from sensors may contain artifacts and noise, it needs to be preprocessed. This involves filtering, segmentation, feature extraction, and selection. Filtering helps remove unwanted values and fill in any missing ones. Segmentation involves breaking the data into smaller segments or windows, which are then used for feature extraction and selection. Finally, different classification algorithms are used for activity recognition, and their performance is assessed using defined metrics.

B. Related Work

For HAR, various researchers have proposed several neuromorphic approaches to reduce the energy consumption in on-edge deployment. These approaches include using spiking neural networks (SNNs) [10], bio-inspired artificial retinas [11], data fusion from multiple sensing systems [12] [13], and data preprocessing frameworks [14]. Additionally, researchers have proposed frameworks that integrate physics and neurobiology to model and recognize human actions and object activities, as well as a hardware module that uses a Hopfield Neural Network to detect falls through sensor data integration and classification [15] . In [16], the authors presents a hardware module that uses a Hopfield Neural Network to recognize falls through sensor data integration and classification. In study [17], the use of SNNs in HAR tasks has been proposed as a way to achieve spatio-temporal feature extraction and reduce energy consumption by up to 94%.

Table I provides the listing of different neuromorphic approaches to HAR, each with its unique advantages and limitations. However, these approaches have limitations in terms of accuracy or processing for real-time applications. In comparison to existing approaches, the proposed niCNN, inspired by neuromorphic computing and incorporating the CNQ and TF algorithms, achieves higher accuracy with more optimization parameters, as shown in the table.

III. Proposed Methodology

In this section, the niCNN architecture is discussed. The proposed architecture addresses the following neuromorphic architecture and CNN integration issues.

- In neuromorphic models, such as Spiking Neural Network (SNN), input values are binary [0,1] at each step, whereas in CNN they are floating point values,

inappropriate conversion reduces accuracy and inference speed.

- Secondly, the activation behavior of IF neurons in SNNs differs from ReLU neurons in CNNs.
- Thirdly, the choice of threshold balancing algorithm greatly affects the performance of the model by affecting the firing rate, energy consumption and information transfer of neurons. High firing rate can lead to overfitting, whereas low firing rate can lead to reduced information transfer.

The niCNN follows a series of basic steps. First, the data is acquired through sensors and preprocessed to create a shallow CNN architecture. Then, an optimal shallow CNN architecture is converted into an equivalent spiking neural network architecture using the CnQ transformation model that minimizes information loss. Next, the firing threshold of the spiking neurons is determined using TF, a threshold balancing technique. The final step is to deploy the inference model, which takes spike-encoded data as input, enabling efficient implementation of deep learning on resource-constrained devices. The schematic workflow of the model is shown in Fig. 1. The Algorithm 3 for niCNN implementation is as follows:

Algorithm 3: Procedure: niCNN

Phase I: Data Acquisition

Step1: Collect sensor data

Step 2: Aggregate sensor data

Phase II: Preprocessing

Step 3: Remove missing values and outliers

Step 4: Windowing and Segmentation

Phase III: Model Building

Step 5: Train a shallow CNN

Step 6: Apply CnQ algorithm for weight transformation

Step 7: Set firing threshold values using TF algorithm

Step 8: Deploy SNN inference model

Phase IV: Performance Evaluation

Step 9: Evaluate different performance metrics

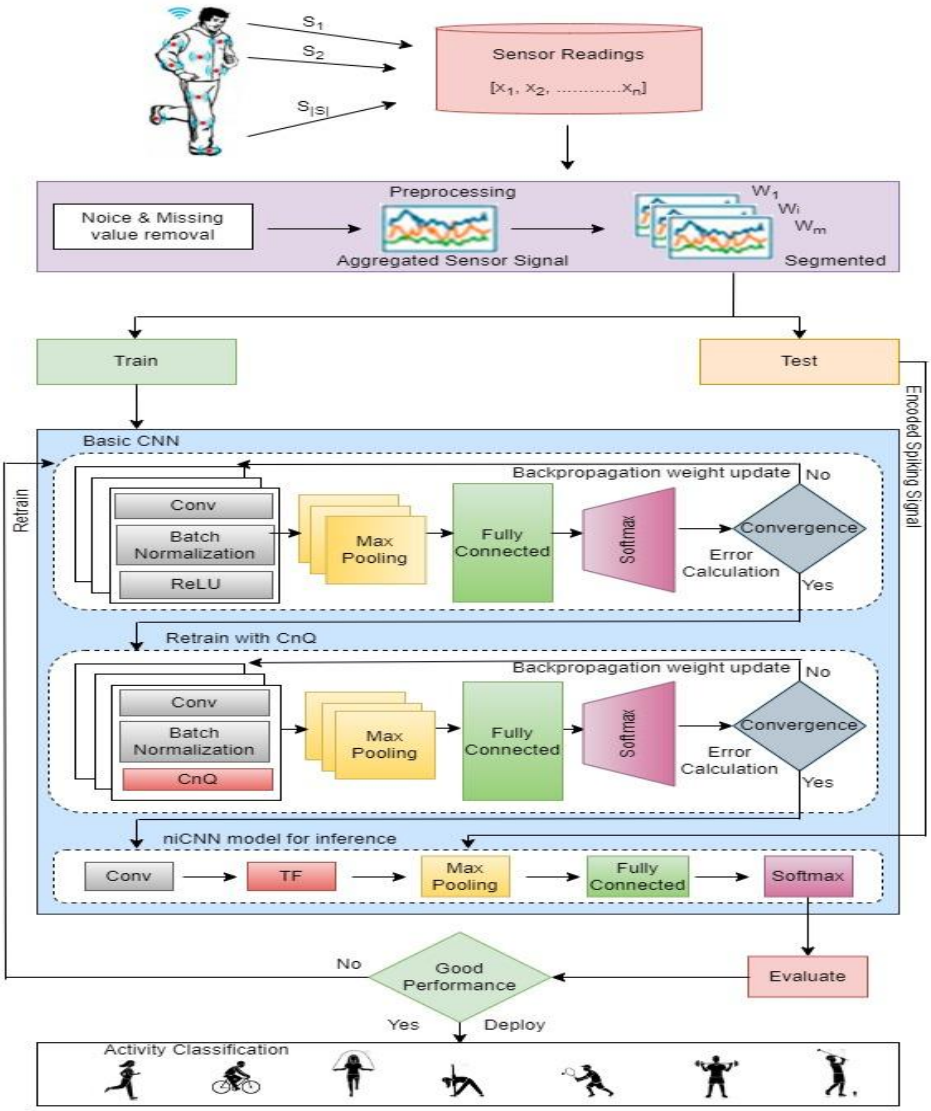

Fig. 1. niCNN architecture.

The description of each phase of the algorithm is as follows:

A. Phase 1: Data Acquisition

A collection of sensors $S = \{s_1, s_2, \dots, s_{|S|}\}$are used to acquire sensor data, each generating a time series reading $X = \{x_1, x_2, \dots x_n\}$. $X(t)$ represents the sensor readings at time step t and $A = \{a_1, a_2, \dots, a_{|A|}\}$ be the number of the activities to be predicted.

The values from the multiple sensors can be aggregated as time series window, as shown in Eq. (1):

$$X = \begin{bmatrix} x_1(1) & \cdots & x_1(t) \\ \vdots & \ddots & \vdots \\ x_n(1) & \cdots & x_n(t) \end{bmatrix} = [X(1), ., X(i), ., X(t)] \quad (1)$$

where, $X(i) = [x_1(i), \dots, x_n(i)]$ is the sensor input at time i for n number of sensor readings.

B. Phase 2: Preprocessing

The samples in the time segment are passed through filters for missing values, noise and outlier removal. After preprocessing, a set of segments W is produced that corresponds to activity A, as shown in Eq. (2).

$$W = \{ws_1, ws_2, \dots, ws_m\} \quad (2)$$

For each segment $ws_i = (t_1, t_2)$ represents a portion of samples from t_1 to t_2.

C. Phase 3: Model Building

The model building consists of the following stages:

1) Train a shallow CNN: The aim of this stage is to train a shallow CNN inference model ρ, A = ρ(X), such that the difference between the actual and predicted values is minimized.

- Define Input Layer: The input layer consists of time series signals. The input at time step t denoted as $X(t)$, and the input to the first convolution layer denoted as $l_o(t)$ is calculated using Eq. (3):

$$l_o(t) = X(t) = X^0 \quad (3)$$

- Convolution Layer: It consists of a series of L layers, $L = \{l_1, l_2, \dots l_{|L|}\}$, each with n number of neurons. The output of ith neuron at layer l is calculated using Eq. (4):

$$x_i^l = h\left(\sum_{j=0}^{N} (w_{ij}^l . x_j^{l-1} + b_i^l\right) \quad (4)$$

where, w_{ij}^l is the weight between the neuron j at layer $l-1$ and neuron i at layer l, b_i^l is the bias of neuron i at layer l, $h(\cdot)$ indicates the ReLU activation function, which is calculated using $\max\{0, \sum_{j=0}^{n}(w_{ij}^l . x_j^{l-1} + b_i^l)\}$.

- Batch Normalization: To converge the CNN network easily the batch normalization is performed using Eq. (5):

$$BN(x'^l_i) = \frac{\gamma(x_i^l - \mu_\beta)}{\sigma_\beta} + \beta \quad (5)$$

where, μ_β is mean and σ_β is the standard deviation of the current batch. The resultant values are scaled by γ and shifted by β. The γ and β are learned throughout training.

- Pooling Layer: The convolution layer is followed by pooling layer to reduce the size and parameters of the network. It is performed using Eq. (6):

$$Maxpool_i^l(t) = max_{r \in R}(x'^l_i(t * T + R)) \quad (6)$$

- Softmax classification layer: After pooling layer, the input passes through fully connected layer, and finally softmax layer for performing classification. The computed activity scores for each achievement are expressed as $P(^{a_i}/_{x_i, \theta})$, computed using inference method ρ, expressed as

$$P\left(\frac{a_i}{x_i}, \theta\right) = \rho(x_i, \theta), for\ a \in A$$

where, θ is trained parameters of model ρ.The maximum score will then be used to calculate the predicted activity a_i for the segment ws_i.

$$a_i^* = argmax\ P\left(\frac{a_i}{x_i}, \theta\right)$$

- The training is performed through backpropagation and the gradients are computed as:

$$\frac{\partial E}{\partial W^l} = \left(\frac{\partial E}{\partial X^l}\right)^T . X^{l-1} \quad (7)$$

$$\frac{\partial E}{\partial X^{l-1}} = (W^l)^T . \frac{\partial E}{\partial X^l} \quad (8)$$

where, Eq. (7) represents error with respect to weights at layer l and Eq. (8) represents error w.r.t the output of the previous layer. Once the gradients are computed, then weights are updated according to Eq. (10):

$$W^l = W^l - \alpha(\frac{\partial E}{\partial W^l}) \quad (9)$$

where, α is the learning rate of the optimization algorithm. This process is repeated for each training example in the dataset until the error is minimized to a satisfactory level.

2) Retrain using CnQ algorithm: To minimize transfer loss from CNN to spiking neural network, the designed CNN in step 5 is retrained using the CnQ algorithm, a variation of CQ [18]. For the CnQ, the input is first normalized using Eq. (10):

$$X_norm = \frac{X}{X_{max} - X_{mean}} \quad (10)$$

Then quantized for spike train of length T, using Eq. (11):

$$Q_T(X_norm(t)) = \left\lfloor \frac{X_norm(t).T}{T} \right\rfloor \quad (11)$$

Since, batch normalization cannot be applied to the input spike trains, therefore batch normalization is applied to weights w^l and bias b^l using Eq. (12) and Eq. (13):

$$BN(w_i^l) = \frac{\gamma . w_i^l}{\sigma_\beta} + \beta \tag{12}$$

$$BN(b_i^l) = \frac{\gamma (b_i^l - \mu_i^l)}{\sigma_\beta} + \beta \tag{13}$$

Now the input data is transformed in spike trains with discrete values set $T \in \{0,1\}$. Instead of ReLU activation function, the CQ transform is applied. Clamping is first applied to the activation function to restrict them to [0,1] and is defined as C in Eq. (14):

$$C(x) = \begin{cases} 0, & x < 0 \\ x, & 0 \le x \le 1 \\ 1, & x > 1 \end{cases} \tag{14}$$

Then Quantization is applied as in Eq. (15):

$$Q_T(x) = \left\lfloor \frac{x.T}{T} \right\rfloor \tag{15}$$

In CnQ, the forward propagation is modified as Eq. (4). The learning is performed through conventional backpropagation:

$$\frac{\partial E}{\partial W^l} = Q'.C'.\left(\frac{\partial E}{\partial X^l}\right)^T . X^{l-1} \tag{16}$$

$$\frac{\partial E}{\partial X^{l-1}} = Q'.C'.(W^l)^T . \frac{\partial E}{\partial X^l} \tag{17}$$

where, Eq. (16) shows error w.r.t weights at layer l and Eq. (17) represents error w.r.t the output of the previous layer. Once the gradients are computed, then weights are updated according to Eq. (9). Algorithm 1 explains CnQ training details.

Algorithm 1: CnQ Training

Input: Sensor data (X), Activity Label (A)

Output: Trained Layers $\langle l_1, \dots, l_{|L|} \rangle$

Parameters Initialized: Number of layers (L), Weights (W), Bias(B), convergence==false

```
Normalize X    //using eq. 10
Quantize X    //using eq. 11
while(!convergence==true)
    For i=1 to L
        For j=1 to N    //forward propagation
            Calculate x_j^i    //using eq. 4
            Apply BN    //using eq. 12 and 13
            Apply Clamping on x_j^i    //using eq. 14
            Apply Quantization on x_j^i //using eq. 15.
        End for
    End for
    For i = L to 1    //Backpropagation
        Calculate Gradients    //using eq. 16 and 17
        Adjust weights    //using eq. 9
    End for
    Update convergence
End while
Return Trained layers ⟨l_1, ..., l_|L|⟩
```

3) The SN Deployment: While CNN's transmit activation data among layers (x^l) as real numbers. SNN neurons receive series of binary input as spike trains. Formally, s_i^l is a spike train of neuron i at layer l where $s_i^l(t) \in \{0,1\}$ is a spike at time t. Unlike CNNs, the weight sum is merely a summation since the weights are binary.

The IF model is used to map CNN to SNN activation. At each time step t, a neuron i computes the weighted sum of the received input spikes $s_j^{l-1}(t)$ and the corresponding weights and integrates them as the membrane potential V_i. Whenever V_i exceeds a predefined threshold V_{th_i}, the neuron fires a spike '1' and decreases V_i by V_{th_i}. Otherwise, it outputs '0'. Formally,

$$v_i^l(t) = v_i^l(t-1) + (\sum_{j=0}^{n} (w_{ij}^l . s_j^{l-1}(t) + b_i^l)$$

$$where, s_i^l(t) = \begin{cases} 1, & v_i^l(t) \ge v_{th_i}^l \\ 0, & otherwise \end{cases}$$

$$v_i^l(t) = \begin{cases} v_i^l(t) - v_{th_i}^l, & v_i^l(t) > 0 \\ v_i^l(t), & otherwise \end{cases}$$

The firing threshold is set using the TF algorithm, inspired from threshold firing approach [19]. Given the desired inference latency t for SNN, TF records the maximum accumulated activation value for each neuron across timesteps at each layer l, as in Eq. (18):

$$thres_i^l = \begin{cases} \max(thres_i^l, \max\left(\sum_{j=1}^{N} w_{ij}^l x_j^l\right), & l = 1 \\ \max(thres_i^l, \max\left(\sum_{j=1}^{N} w_{ij}^l s_j^l(t)\right), & 1 < l < L \end{cases} \tag{18}$$

After the assignment of the firing threshold for a layer, it freezes the thresholds of the layer and repeats the threshold determination for the next layer. Algorithm 2 explains the working of TF.

Algorithm 2: TF setting

Input: Timesteps for inference (T)

Output: Firing threshold for each layer $\left[\{v_{th_i}^l\}_{i=1}^N \right]_{l=1}^L$

```
For l = 1 to L
    For i = 1 to N
        Set thres_i^l = 0
    End for
    If (l === 1)
        For i = 1 to N
            Calculate thres_i^l    //using eq. 18
            Set v_th_i^l = thres_i^l
```

```
        End for
    End if
    Else if (l == L)
        Set v_{th_i}^l = ∞
    End if
    else
        For t = 1 to T
            For i = 1 to N
                Calculate thres_i^l   //using eq. 18
                Set v_{th_i}^l = thres_i^l
            End for
        End for
    End if
End for
Return v_{th_i}^l list
```

D. Phase 4:Evaluation

- Evaluation metrics: After training network, the performance can be tested on the various metrics on test data and can fine-tuned as necessary as discussed in [20] accuracy ($\frac{tp+tn}{tp+tn+fp+fn}$), precision ($\frac{tp}{tp+fp}$), recall ($\frac{tp}{tp+fn}$), f1-score ($\frac{2*(precision*recall)}{precision+recall}$), specificity ($\frac{tn}{tn+fp}$), balanced accuracy ($\frac{1}{2}(\frac{tp}{tp+fn}+\frac{tn}{tn+fp}$), where tp is true positive, fp is false positive, tn is true negative. fn is false negative.
- Evaluate number of parameters: To estimate the number of parameters in a spiking CNN model, using Eq. (19):

$$np = ((ic * fs * nf + bias) * os\ ) \quad (19)$$

where, ic represents the number of channels in the input spike trains, fs represents the size of the filters, nf represents the number of filters in the convolutional layer, bias represents the bias term for each filter, and os represents the size of the output spike trains.

- Calculate memory usage: The memory utilized by a spiking CNN model can be estimated by multiplying the number of parameters by the number of bytes used to store each parameter. For example, if we assume that each parameter is stored as a 32-bit float, then the memory utilized can be calculated, as in Eq. (20), whereas niCNN uses 8 bit clamped and quantized signal; therefore each parameter is 8 -bit.

$$memory\ utilized\ (in\ bytes) = np * 4 \quad (20)$$

- Power Consumption: As per Intel specification [21], Intel core i7 processor consumes 65 watts, whereas Intel Loihi 2 consumes around 1 watt. To calculate the power consumed in execution, it is done using Eq. (21):

$$power\ consumption = execution\ time * watts\ of\ processor \quad (21)$$

IV. Experiment

This section elucidates the experimentation conducted on two widely used public datasets, namely WISDM and mHealth, to evaluate the efficacy of niCNN. All experiments were performed on a single system that was equipped with an i7-5500U processor, 16 GB of RAM, and a 1 TB hard disk drive. The implementation of niCNN was executed utilizing the dynamic and powerful programming language Python, alongside auxiliary packages such as Nengo, NengoDL, and NNI [22]. The proposed network architecture was constructed utilizing Keras, a Python-based high-level neural networks API that can run on top of TensorFlow.

A. Dataset Description

WISDM and mHealth datasets contain time series data for physical activity that were collected using wearable sensor devices. The WISDM includes data for six physical activities that were performed by 29 subjects at a sampling rate of 20 Hz, while the mHealth dataset includes data for 12 physical activities performed by 10 subjects at a sampling rate of 50 Hz. Table II provides an overview of each dataset's specifications, and Table III describes captured activity data.

TABLE II. Dataset Specifications

Dataset	Subjects	Sensors	Sampling Rate	Activities	Samples
WISDM	36	A	20 Hz	6	1,098,209
mHealth	10	A,G, M, ECG	50 Hz	12	1,215,745

[a.] A= Accelerometer, G= Gyroscope, M= Magnetometer, ECG= Electrocardiography

TABLE III. Activity Data

Dataset	Activities (Labels, Samples, % Distribution)
WISDM	Walk(1,424400,38.6), Jog(2,342177,31.2), Up(3.122869,11.20), Downstairs(4,100427,9.1), sit(5,59939,5.5), standing(6,48397,4.4)
mHealth	Standing(1,30720,9), Sitting(2,30720, 9), Lying down(3, 30720,9), Walking(4, 30720,9), Climbing stairs(5, 30720,9), Forward bending(6, 28315,8.3), Frontal Arm elevation(7,29441, 8.6), Knees bending(8, 29337, 8.5), cycling(9, 30720,9), Jogging(10, 30720,9)Runing (11, 30720,9), jumping(12,10342,3)

B. Preprocessing

A total of 1,098,209 and 3,44,116 samples were collected from WISDM and MHealth. To minimize computational effort for on-edge deployment, only segmentation was performed as the preprocessing step. The signal was partitioned into non-overlapping temporal windows of length 2s. After dividing the samples based on raw data without feature extraction, a split of 70:30 was used to create training and testing sets.

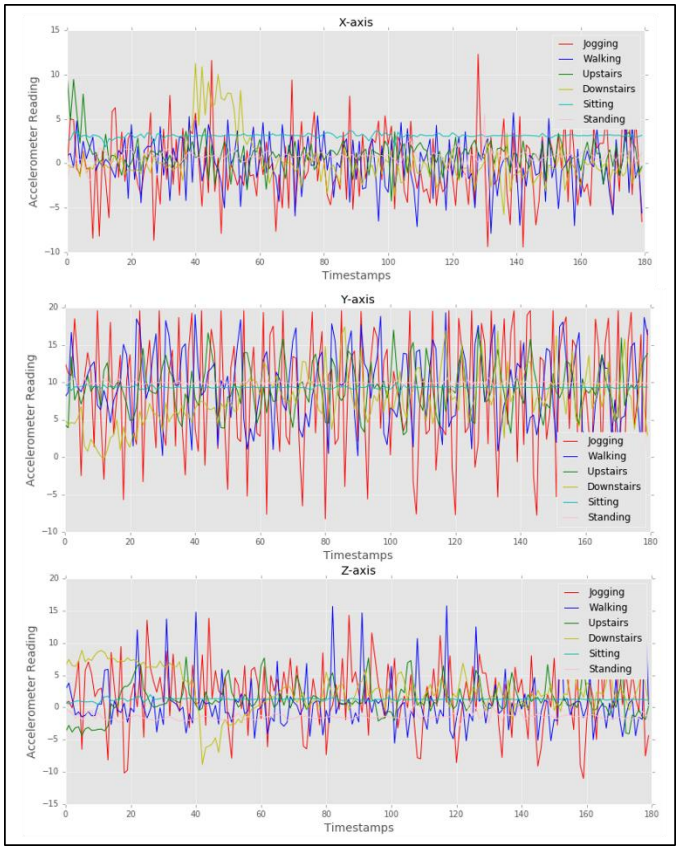

Fig. 2. WISDM activity visualization.

WISDM does not contain outliers, missing values, or null activities; thus, all samples were used for experimentation. Fig. 2 displays a visualization of the WISDM dataset at a timestep of 180. After eliminating null activities from mHealth, the final sample size consists of 343195 samples. At a timestep of 80, a visualization of the mHealth dataset is presented in Fig. 3.

C. Network Architecture

A shallow CNN architecture is developed, consisting of two convolution layers, a max pooling layer, a flattening layer, and two dense layers. The model underwent fully supervised training, with the gradient backpropagated from the Softmax layer.

In the context of the study, cross-entropy loss function is utilized to quantify the dissimilarity between the predicted and actual distributions.

Adam, a stochastic optimization algorithm founded on the first-order gradient, is utilized as the optimizer. The training process is performed over 25 epochs, with a batch size of 64 and a small learning rate of 0.001 to improve the fitting ability. To improve the model's robustness, the training set is randomly shuffled. The hyperparameters are chosen after analyzing the effect of various factors, including the number of filters, batch size, filter size, and dropout rate, on accuracy. Fig. 4 illustrates the impact of these factors on accuracy, and the final hyperparameters are listed in Table IV.

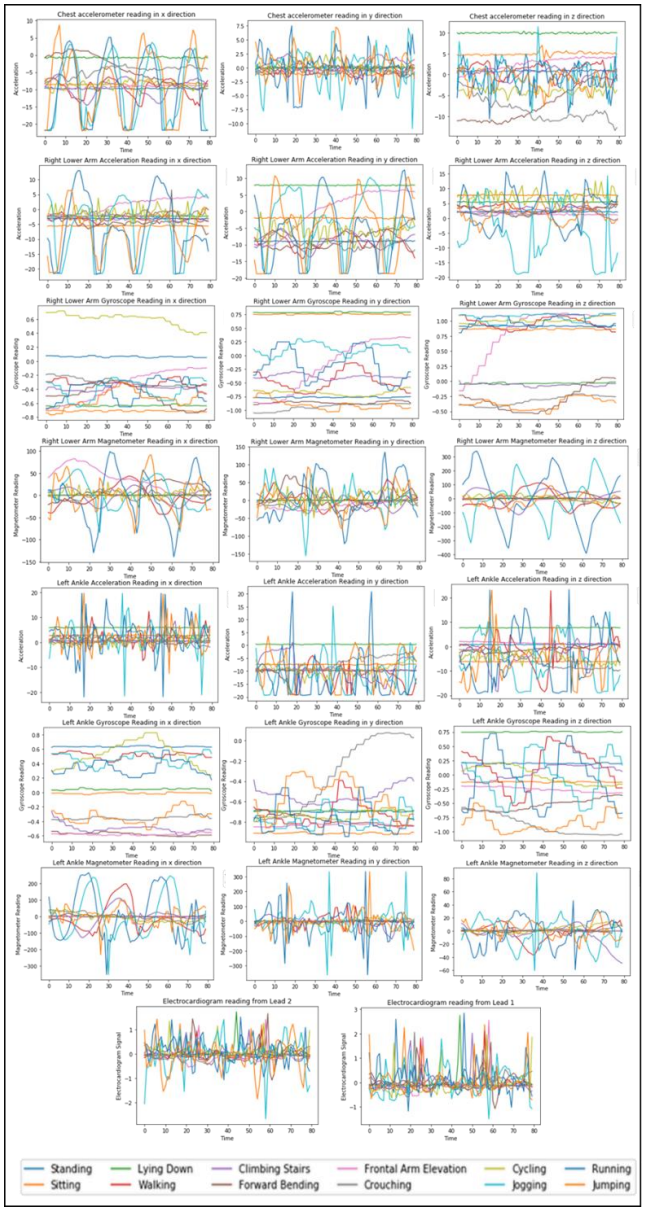

Fig. 3. mHealth activity visualization.

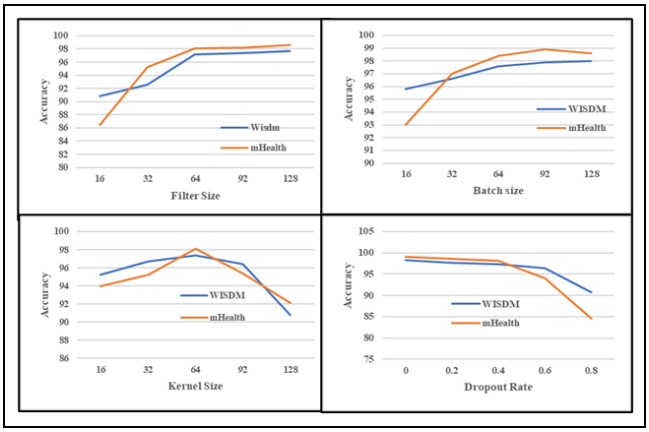

Fig. 4. Impact of hyperparameters on accuracy.

TABLE IV. SELECTED HYPERPARAMETERS

Stage	Hyperparameters	Selected Value
Preprocessing	Window_size	180(WISDM) 80(mHealth)

	Learning rate	.001
	Number of epochs	25

The niCNN is developed using the Nengo neural simulator on the Loihi neuromorphic chip. To construct the spiking CNN directly from its non-spiking counterpart, the NengoDL converter was used. Hyperparameter tuning is conducted using the Neural Network Intelligence (NNI) toolkit and Annealing algorithm, while ensuring a proper search space. Each optimization experiment comprised 1,000 trials, with the tuner being randomly re-initialized four times in equal intervals to avoid local minima. Following every trial of 25 training epochs, the weights yielding the best training accuracy are employed to evaluate the test accuracy. To train all investigated networks, including optimization of the learning rate throughout the experiment trials, Adam optimizer with a constant learning rate is utilized. Fig. 5 and Fig. 6 represent training progress of WISDM and mHealth over epochs.

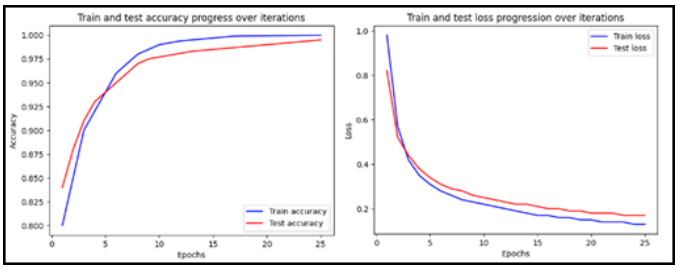

Fig. 6. mHealth dataset progress over epochs.

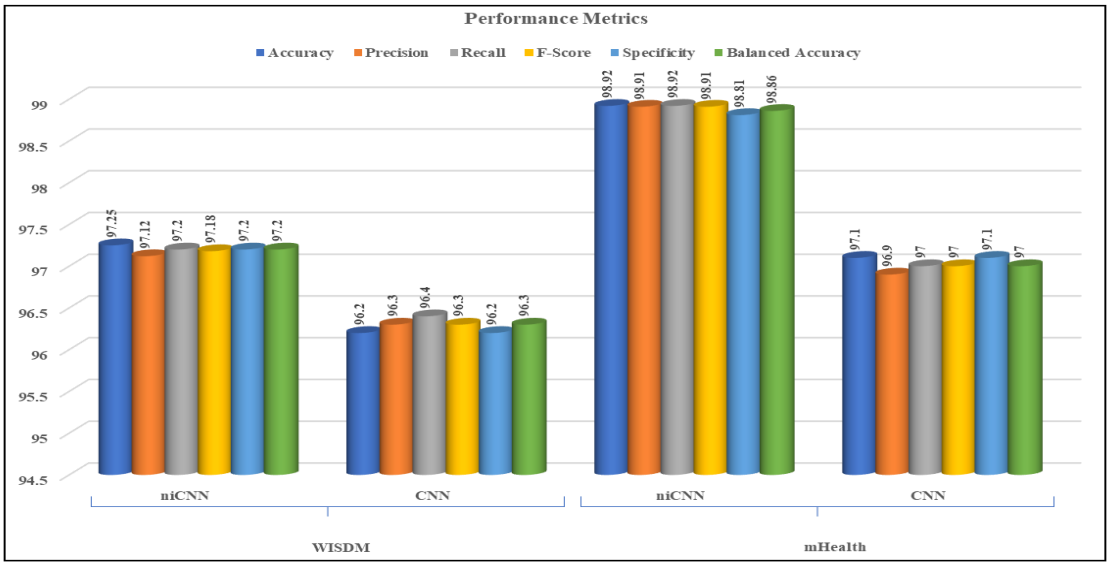

Fig. 7. Performance comparison.

V. RESULTS

The evaluation of performance was carried out using the metrics described in Section III, and the results are presented in Table V. niCNN achieved 98.08% average accuracy, 97.25% on WISDM dataset and 98.92% on mHealth. Fig. 7 provides a comparison of niCNN on both datasets against its baseline CNN on the same architecture. Additionally, the obtained confusion matrix for the WISDM and mHealth datasets are shown in Fig. 8 and Fig. 9, respectively. As per results, presented in Fig. 7 and Table V, niCNN obtained on average 1.1% increase in accuracy, 97.4% reduced power consumption, 60.04% reduced memory consumption, and 30.2% reduced inference time.

niCNN achieved a notably higher accuracy compared to other state-of-the-art works([10], [23]–[33]), as demonstrated in Fig. 10.

TABLE V. PERFORMANCE METRICS

	WISDM		mHealth	
	niCNN	***CNN***	***niCNN***	***CNN***
#P	22,642	14,326	32,612	20,286
#ET(s)	5.2	3.2	5.8	4.1
#M(kBytes)	22.11	55.96	31.84	79.24
#PC(watts)	5.2	208	5.8	266.5
#IT(ms)	2.25	3.27	2.36	4.02

b. #P=Number of parameters, #ET= Execution Time, #M=Memory used, #PC=Power Consumption, #IT=Inference Time

VI. CONCLUSIONS

The study demonstrates the capability of neuromorphic computing to perform real-time HAR on edge devices with limited resources. It presents a novel four stage niCNN architecture, overcoming the accuracy loss and higher inference latency associated with transferring weights from a CNN to a neuromorphic network by applying CnQ algorithm. The new improved threshold balancing approach, TF, further increases the inference accuracy of the system. The experimental results demonstrate that the niCNN architecture achieves high accuracy, low inference latency, memory usage, and energy consumption compared to the state-of-the-art and baseline CNN models.

In future, niCNN performance can be investigated on different HAR datasets. The CnQ and TF algorithms can also be further optimized to achieve better results. Further research can expand the model's capability to recognize more complex activities. The effectiveness of various optimization methods within the Nengo framework, including different windowing techniques can also be explored. Additionally, the niCNN architecture can be extended to other real-time processing applications on edge devices.

***Abstract*—The early detection of breast cancer is critically important for prompt treatment and rescuing lives. However, the accuracy of small-sized breast masses' early detection in various algorithms remains unsatisfactory, as the small-sized masses often exhibit subtle features, contain blurry boundaries, and may overlap with other parts in crowded magnetic resonance imaging (MRI) images. This research proposes an improved object detection model based on You Only Look Once (YOLO) v8 to enhance small-sized breast mass detection on MRI. A feature fusion method called the Bidirectional Feature Pyramid Network (BiFPN) and an attention mechanism called the Convolutional Block Attention Module (CBAM) are integrated into the YOLOv8 architecture. The improved YOLOv8 model, equipped with CBAM and BiFPN and hyperparameter tuning, achieved the best performance with a precision of 95.7%, a mAP50 of 91.2%, a recall of 84.3%, and the shortest inference time of 3.4ms per image. The proposed improved Yolov8 model outperformed the baseline model with improvements in precision, mAP50, and recall of 6%, 3.9%, and 2.1%, respectively. The inference time per image is reduced by 1.4ms as well. It is hoped that the proposed model could be applied in the clinical field to increase the early detection rate of breast cancer and the life expectancy of women in the world.**

***Keywords*—Bidirectional feature pyramid network; breast cancer detection; convolutional block attention module; MRI; object detection; small-sized masses; YOLOv8**

I. Introduction

Breast cancer was the top female disease in 157 of 185 countries and accounted for approximately 670,000 deaths in 2022 worldwide [1], according to the World Health Organisation. However, it was also the most common subject of diagnosis. It was even identified as the first leading cause of death from cancer among women in 2022, according to the Global Cancer Statistics [2]. There are several imaging methods to screen breast cancer, including ultrasonography, mammography, magnetic resonance imaging (MRI), and digital breast tomosynthesis (DBT). Among these methods, mammography is the preferred population-based screening method [3]. However, mammography is less effective for screening dense breasts, as it risks missed diagnoses because small masses that hide in dense breast tissue cannot be detected [4][5]. The sensitivity of breast mass detection increases from 0 to 8% when the tumour size increases from 2 to 20mm [6]. On the other hand, the performance of breast cancer detection in medical imaging is also affected by the increase in breast tissue density [7].

Recently, breast MRI was used complementarily together with mammography and has been researched as a crucial screening tool for women with dense breasts [8]. Currently, the accuracy of breast cancer detection and diagnosis still highly depends on the variations of experts and experienced physicians. Moreover, the existing research on breast masses has primarily focused on overall object detection rather than improving the accuracy of detecting small-sized breast masses [9][10]. In [11] and [12], the authors commented that the performance of small-sized breast mass detection had not achieved the expected results, even though significant improvements had been made in the breast cancer detection models' feature extraction and target detection algorithms.

This research proposes an improved You Only Look Once (YOLO) v8 model for enhanced detection of small-sized breast masses on MRI, aiming to improve the detection precision and mAP of these small masses. The improved model is expected to perform better in detecting small-sized breast masses by adopting an appropriate attention mechanism. Improving the feature fusion method would enhance the fusion effect of the multi-scale features in the improved model. Finally, hyperparameter tuning is conducted to strengthen the performance of the detection model.

The rest of the study is organised as follows: Section II reviews various object detection models in breast cancer detection, feature fusion methods, and attention mechanisms. Section III presents the methodology of the proposed improved YOLOv8 model. Section IV discusses the experimental results and analysis. Finally, Section V concludes the study and outlines future research directions.

II. Literature Review

A. Breast Cancer Detection and Imaging Types

In medical imaging, the most common screening techniques to diagnose breast cancer are breast ultrasound, mammography, breast magnetic resonance imaging (MRI) and digital breast tomosynthesis (DBT). Although mammography is the only imaging test that has been demonstrated to decrease deaths from breast cancer, breast MRI has taken its superior role in the screening of high-risk populations because of the high sensitivity of the images [13]. Two advantages of using breast

MRI over mammography are: i) the breast MRI can detect smaller tumours with a median size of 9 mm with higher sensitivity, in comparison to 17 mm for mammography [14], and ii) the breast MRI uses a different imaging mechanism with magnetic fields and radio waves which is particularly effective in dense breast tissue screening, enabling the excellent performance of dense breast tissue evaluation and additional lesions' detection. Despite the higher cost and longer procedure time in the breast MRI screening process, MRI is still the preferred breast cancer detection method, where mammography's effectiveness is limited in the detection of smaller and additional lesions.

B. Object Detection Model in Breast Cancer Detection

The YOLO model is a real-time object detection system introduced by Redmon, Divvala, Girshick, and Farhadi [15]. Ultralytics created and released YOLOv8 in January 2023 as a new state-of-the-art computer vision model that provides out-of-the-box support for object detection, classification, and segmentation tasks [16]. The YOLO model treats object detection tasks as a regression problem, predicting bounding boxes and class probabilities for objects in a single convolutional network. It runs a convolutional network to process each grid cell, where it divides the input image into a grid of cells. Each grid cell will perform detection if there is an object within it, make predictions for bounding boxes, calculate the confidence scores for those boxes, and determine conditional class probabilities. When making predictions, the YOLO model performs global reasoning across the entire image, allowing it to detect all objects within the image. Additionally, the YOLO design enables end-to-end training and achieves real-time performance while maintaining a high average precision (AP) [15]. The main advantages of the YOLO model are fast speed, high accuracy, and suitability for real-time applications. As a single-stage model, YOLO has been proven to be an excellent tool in various scenarios, achieving higher inference speeds than its competitors in object detection [17].

Table I summarises the comparison of the strengths, weaknesses, and results of different object detection methods in breast mass detection over the past five years. The comparison shows that YOLO [18] [19] and region-based object detection methods such as Faster R-CNN [20], Mask R-CNN [21], and R-FCN [22] were popular. Additionally, RetinaNet was also employed in breast mass detection from 2023 onwards, reflecting a growing emphasis on the real-time capabilities of single-stage models as time progresses [23].

Several recent studies have explored the performance of different object detection models for breast mass detection. Faster R-CNN achieved a high true positive rate, but its inference time was significantly longer than single-stage models like YOLO and RetinaNet [20]. RetinaNet has limitations in detecting small objects due to its fixed-size anchor boxes. Even with the recent improved version ERetinaNet, the inference speed still lags behind YOLOv3 and YOLOv7 [23]. YOLOv3 was enhanced with k-means generated anchors for detecting small and big masses, which outperformed YOLOv2 and YOLOv3, and achieved a mAP50 of 89.4% [18]. The YOLOv5 model was also improved for better breast cancer detection in mammograms. The YOLOv5s model obtained a mAP50 of 83.5%, a precision of 85.4% and a recall of 72.9%, which performed better than YOLOv3 and YOLOv5-Transformer [17]. These results reinforce the advantage of YOLO-based models in balancing speed and accuracy, making them suitable foundations for further improvement in small object detection tasks.

TABLE I. COMPARISON OF DIFFERENT OBJECT DETECTION METHODS IN BREAST MASS DETECTION

Detection Model	Strength	Weaknesses	Results
YOLOv3 [18]	• Fast speed with high accuracy • Suitable for real-time applications	• Performance for small object identification can be further improved.	mAP50: 89.4% Precision: 83.0% Recall: 83.0%
YOLOv5 [19]	• Fast speed with high accuracy • Suitable for real-time applications • Provide improved performance for small object detection	• Higher complexity than YOLOv3 Requires more computational resources.	mAP50: 90.34%
Faster R-CNN [20]	• Provides high accuracy • Suitable for handling various types and sizes of objects	• Slower speed • Requires larger memory consumption • Contains higher computational complexity.	Malignant: TPR: 0.92 at 0.3 FPI. Benign: TPR: 0.85 at 1.0 FPI.
Mask R-CNN [21]	• Provide accurate instance segmentation • Suitable for tasks requiring detailed object region information	• Slower speed • Requires larger memory consumption • Contains higher computational complexity	Accuracy: 98%
R-FCN [22]	• Faster speed in the two-stage approach category • Provides high accuracy	• Contains high computational complexity • Poor performance when objects are extremely small or extremely large compared to the size of the input image	Accuracy: 92.5% Sensitivity: 92.3% Specificity: 93.4%
RetinaNet [23]	• Simple and efficient • Good object detection performance and speed, excellent in handling imbalanced class distribution problems.	• May struggle with small object detection. • Requires more computational resources.	mAP50: 85.01% Precision: 86.87% Recall: 74.62% F1-score: 80.3% Inference time: 23.4ms per image

From the comparison, almost all models faced challenges in small object detection, with RetinaNet, R-FCN, and YOLO showing more pronounced weaknesses in this area. On the other hand, although RetinaNet, as used in [23], had a slightly longer inference time than existing YOLO models, it excelled in addressing class imbalance issues, where positive breast cancer detection cases are significantly fewer than negative cases. In addition, it was observed that all the object detection models, except for YOLO, in Table I have problems with high computational complexity.

This research chose the YOLO model as the object detection method to be improved for small-sized breast mass detection on MRI for several reasons. Firstly, the YOLO model is faster than other models. Secondly, YOLO is suitable for real-time applications, where breast cancer detection can be done almost instantly after MRI scanning is completed, thereby saving diagnostic time, expediting the decision-making process, and facilitating early treatment planning between the doctor and patient. Thirdly, the YOLO model has progressively improved accuracy and mAP values from YOLOv3 to YOLOv5.

In the current state-of-the-art, the YOLOv8 model has demonstrated its advantages in detecting small objects in remote sensing images [24]. It has been used to detect liver disease [25], identify potato diseases [26], and detect pedestrians in real-time [27]. The YOLOv8 model has also been adopted for breast mass detection and classification in [28]. However, the model encounters difficulties in detecting small objects in complex scenes, especially when their appearance is partially occluded by overlapping with other objects of varying sizes, which can lead to missed or false detections. As such, the YOLO model should be enhanced with various techniques to address its weaknesses.

C. Feature Fusion Methods

Feature fusion enhances the accuracy and robustness of an object detection model by leveraging complementary information from various sources and employing an approach that reduces information redundancy. The feature fusion method merges morphological, textural, and density features to create a more comprehensive representation of the object. This comprehensive representation enables the detection system to capture the target's features more effectively, resulting in more accurate and reliable detection results. On the other hand, the feature fusion method also enhances the sensitivity and robustness of the model in small object detection by adaptively combining features from multiple scales and layers, thereby capturing both high-level semantic and low-level spatial information.

Feature fusion methods such as the Asymptotic Feature Pyramid Network (AFPN), Bidirectional Feature Pyramid Network (BiFPN), and the Semantic Feature Pyramid Network (FPN) have been applied to improve the performance of YOLO [29]–[32] and Faster-RCNN [11] models in small object detection tasks. It is observed that the YOLO models [31] [32] achieved a slightly higher mAP50 value (highest 90%) when integrated with BiFPN, in comparison to Semantic FPN (highest 88.22%) [11] and AFPN (highest 88%) [29][30]. With accuracy being a key consideration in model performance, this research aimed to integrate the YOLOv8 model with BiFPN for the detection of small-sized breast masses. Moreover, BiFPN is also more appropriate because it can efficiently fuse multi-scale features and improve detection performance without significantly increasing computational complexity.

D. Attention Mechanisms

An attention mechanism enhances the performance of object detection models by allowing the model to focus on specific regions or features of the image [33]. This mechanism also helps to prioritise fine-grained or key features which are particularly beneficial for detecting small objects in complex visual backgrounds [34]. It is instrumental in challenging scenarios, such as detecting minor defects or tumours in cluttered backgrounds. The attention mechanism can improve the accuracy of breast mass detection by guiding the model's focus to specific regions of interest in medical images [35]. By incorporating the attention mechanism into the detection model, the object detection model can prioritise relevant features of small targets even when they are occluded or surrounded by other objects [36].

The Convolutional Block Attention Module (CBAM) is a popular attention mechanism. CBAM was adopted in the YOLOv7 model for brain tumour detection, and this combined model achieved 98.9% precision, 98.8% recall, and 98.9% accuracy [32]. The CBAM was also incorporated into the backbone network of the YOLOv5 model for breast lump detection, yielding improvements in accuracy, recall, and mAP50 values of 3.1%, 2.6%, and 3.1%, respectively, compared to the baseline YOLOv5 model [37]. As such, this research attempted to integrate CBAM into the YOLOv8 model to increase the precision and mAP value for small-sized breast mass detection.

III. Methodology

This research is conducted in five phases. The primary objective is to propose an enhanced YOLOv8 model for improved small-sized breast mass detection on MRI by integrating CBAM into the backbone structure and BiFPN into the neck structure of a baseline YOLOv8 model. The structure of the improved YOLOv8 Model for the research is shown in Fig. 1.

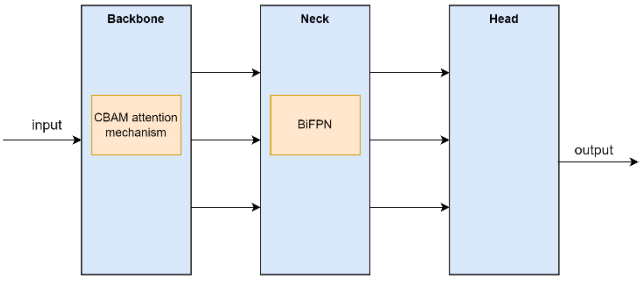

Fig. 1. Structure of the improved YOLOv8 model.

The research began with the data selection and pre-processing phase. This research used the annotated version of the BreastDM dataset [38]. It is the latest Dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) dataset for breast cancer diagnosis, spanning from January 2018 to

September 2021, and collected at Taizhou Central Hospital, Taizhou University, in Zhejiang Province, China. The dataset is publicly available on the Roboflow Universe website [39]. There are 1196 images in the selected dataset, with 875 malignant images and 321 benign images. These images are labelled according to the pathology of the mass in 2 classes, with class label 0 representing benign and class label 1 representing malignant.

The selected dataset is first converted from the original annotation in COCO format to YOLOv8 object detection format via the Roboflow platform. Following format preparation, 70% of the dataset is assigned to a training partition, 15% to a validation partition, and the remaining 15% to the test partition. The resolution of all images was resized from 369 × 369 pixels to 640 × 640 pixels, and the proportion of small objects was 37.5%. In addition, the YOLOv8 model will also automatically normalise the pixel values to a range of 0 to 1 during its preprocessing phase.

Several data augmentation techniques are employed to address the data imbalance problem and enhance the robustness and generalisation of the proposed model. In addition, these augmentation techniques introduced variability in the training data, allowing the YOLOv8 model to learn more robust features and improve performance on diverse and noisy datasets. Firstly, the HSV augmentation is utilised with parameters for hue (±1.5%), saturation (±70%), and value (±40%) adjustments. Secondly, spatial augmentations such as translation (±10%), scaling (±50%), and left-right flipping with a 50% probability were conducted too. Thirdly, the Mosaic augmentation is applied with a 100% probability. Finally, random erasing is performed with a 40% probability, and cropping is set to a fraction of 1.0 to maintain the original image size. The proposed YOLOv8 model chose "Randaugment" as the auto augmentation policy.

In the second phase, the baseline YOLOv8 model was created and trained on the selected dataset. The CBAM attention mechanism and BiFPN are integrated separately into the YOLOv8 model in the third and fourth phases. The performance of the baseline YOLOv8 model in the second phase, as well as the improved model in the third and fourth phases, is measured with precision, recall, mAP50, and mAP50-95. Subsequently, in the fifth and final phase, the YOLOv8 model, integrated with CBAM and BiFPN, is constructed, evaluated, and fine-tuned to adapt it to the breast mass detection task and the selected dataset.

The experiments were conducted in Google Colab Pro using T4 GPUs and A100 GPUs. The experiment program is written in Python. All the experiments of the proposed enhanced small-sized breast mass detection model are based on the AdamW optimiser. The experiment specifications are as follows:

- Weight decay: 0.0005
- Learning momentum: 0.9
- Learning rate: 0.001667
- Epochs: 300
- Batch: 32
- Warmup epochs: 3.0
- Warmup momentum: 0.8

IV. Results and Discussion

The evaluation of the proposed improved YOLOv8 model was conducted in several stages. In the first stage, the original YOLOv8 model serves as the baseline. Following this, the YOLOv8 model is run with a single feature (CBAM or BiFPN), two features (CBAM and BiFPN), and two features (CBAM and BiFPN) with Hyperparameter Tuning. The full result is shown in Table II.

Table II shows that the precision, recall, and mAP50 values of the original YOLOv8 model are below 90%. The mAP50-95 achieved 63.2% while the inference time per image is 4.8ms. The goal of this research is to enhance the YOLOv8 model for small-sized breast mass detection in MRI, aiming to improve precision, recall, and mAP50 values while reducing inference time per image to achieve faster detection speed. The evaluation of the improved YOLOv8 model with CBAM showed that the precision, mAP50, and mAP50-95 are increased by 4%, 3.1%, and 1.8%, respectively, with unchanged recall value, and higher inference time per image (+3.2ms). These results demonstrate the effectiveness of the proposed backbone network and its improved detection performance. On the other hand, the evaluation of the enhanced YOLOv8 model with BiFPN showed that the mAP50 and mAP50-95 increased by 0.6% and 0.2%, respectively. Still, the precision and recall values were lower than those of the baseline YOLOv8 model by 0.1% and 0.5%, respectively. However, this improved model required less inference time per image (-0.2ms) than the YOLOv8 baseline model.

TABLE II. The Evaluation Result of the Proposed YOLOv8 Model in Various Stages

Model	Precision (%)	Recall (%)	mAP50 (%)	mAP50-95 (%)	Inference time per image (ms)
Original YOLOv8 model	89.7	82.2	87.3	63.2	4.8
YOLOv8 model with improved backbone by using CBAM	93.7 (+4.0)	82.2 (0.00)	90.4 (+3.1)	65.0 (+1.8)	7.0 (+3.2)
YOLOv8 model with improved neck by using BiFPN	89.6 (-0.1)	81.7 (-0.5)	87.9 (+0.6)	63.4 (+0.2)	4.6 (-0.2)
Improved YOLOv8 model with CBAM and BiFPN	92.5 (+2.8)	**87.5 (+5.3)**	90.7 (+3.4)	66.8 (+3.6)	5.1 (+0.3)
Improved YOLOv8 model with CBAM and BiFPN (Hyperparameter Tuning)	**95.7 (+6.0)**	84.3 (+2.1)	**91.2 (+3.9)**	**67.0 (+3.8)**	**3.4 (-1.4)**

Comparing the two improved YOLOv8 models with CBAM and BiFPN, CBAM performed better than BiFPN in all evaluation metrics except for inference time per image. Although the enhanced YOLOv8 model with BiFPN exhibits a slight decrease in precision and recall, it improves the mean Average Precision (mAP50 and mAP50-95) and reduces inference time. BiFPN enhanced the YOLOv8 model's ability to recognise masses of different scales by increasing the complexity of feature fusion. However, the BiFPN's complex structure and computational demands make the improved YOLOv8 model training and optimisation more difficult, resulting in a drop in precision and recall metrics. Additionally, BiFPN may require careful parameter tuning for optimal performance. Overall, the improvement in mAP demonstrates its potential in small object detection tasks.

To prove the effectiveness of adding BiFPN into the YOLOv8 model for small mass detection, the second stage of the experiment was conducted by combining CBAM and BiFPN into the YOLOv8 model. The experimental results showed that all evaluating metrics achieved improvements in the range of 2.8% to 5.3%, with precision and mAP50 achieving values higher than 90%. However, the inference time per image is slightly increased by 0.3ms. Therefore, the experiment proceeds to the final stage, whereby the improved YOLOv8 model for enhanced small-sized breast mass detection on MRI is built by fine-tuning the hyperparameters of the improved YOLOv8 with CBAM and BiFPN. This enhanced model achieved the best performance among other improved models, with a precision of 95.7%, a recall of 84.3%, a mAP50 of 91.2%, a mAP50-95 of 67.0%, and the shortest inference time of 3.4 ms per image. The best hyperparameters for the final improved YOLOv8 model obtained after hyperparameter tuning are shown in Table III.

TABLE III. BEST HYPERPARAMETERS OF THE PROPOSED IMPROVED YOLOV8 MODEL

Hyperparameter	Best fitness amount
lr0	0.00338
lrf	0.01684

According to the comparison of the normalised confusion matrix for the baseline and proposed improved YOLOv8 model, the enhanced YOLOv8 model shows a higher classification accuracy for the malignant class (95%) than the baseline YOLOv8 model (91%). The classification accuracy for the benign class has also increased to 80%, helping to mitigate the negative impact of class imbalance. On the other hand, the issue of misclassifying malignant masses as benign in the original YOLOv8 model has been addressed, resulting in a reduction of the error rate from 2% to 0% in the improved YOLOv8 model. In comparison, the misdetection of benign masses as malignant has decreased from 4% to 2%. Additionally, the misclassification of malignant masses as background has reduced from 7% to 5%.

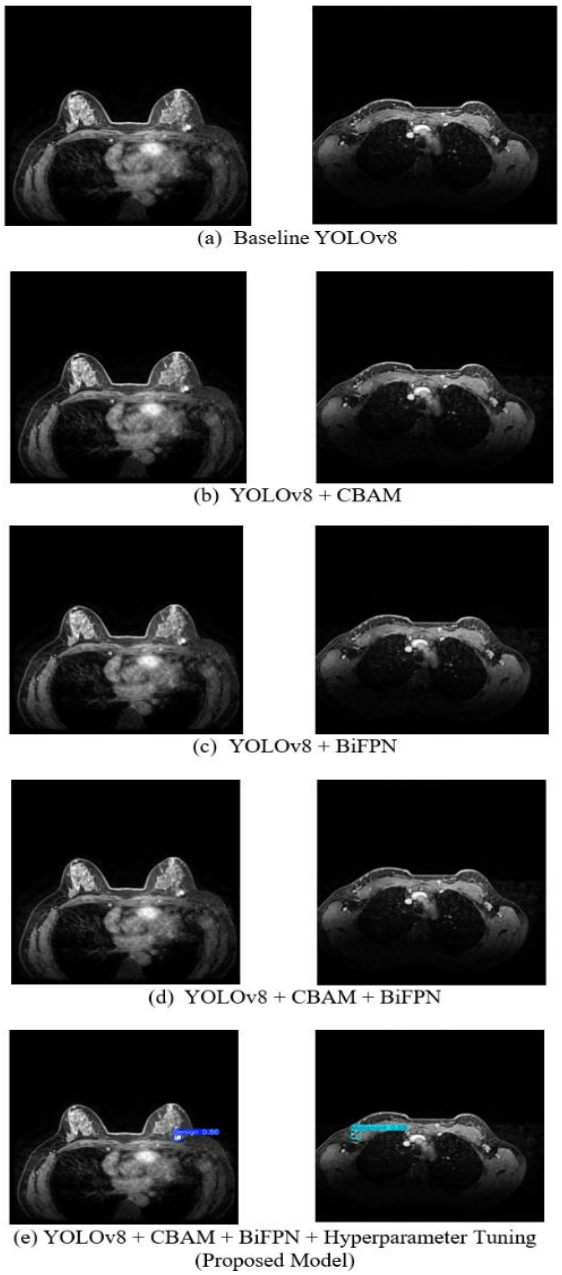

Fig. 2. Result of small mass detection with MRI with different YOLOv8 models.

Fig. 2 shows two detection results of different experimented YOLOv8 models. In the left image, the breast tissue is dense and has similar texture features to the masses, which interferes with the model's accuracy in judging the masses [7]. The right image shows a small breast, where the mass is located at the edge of the breast, close to the pectoral muscle. The pectoral muscle increases the complexity of the MRI image background [40], affecting the model's ability to detect small malignant masses with very subtle features. The two results showcases where benign small masses and malignant small masses in the MRI dataset are not detected by all the YOLOv8 models [Fig. 2(a) to Fig. 2(d)] in the study except for the improved YOLOv8 model with CBAM and BiFPN with hyperparameter tuning [Fig. 2(e)]. This demonstrates the effectiveness of the proposed improved YOLOv8 model.

In terms of evaluation, the proposed improved YOLOv8 model achieved strong overall performance, with a mAP50 of 91.2%, precision of 95.7%, recall of 84.3%, and an inference time of 3.4 ms per image. Compared to existing studies, relatively few have focused specifically on detecting small-sized breast masses using YOLO-based approaches. Among those, a YOLOv5-based model reported a mAP50 of 90.34% and an inference time of 28 ms per image [19], which is lower in accuracy and significantly slower than our proposed model. These results highlight the effectiveness of the enhancement in this study for both detection precision and computational efficiency.

V. Conclusion and Future Work

This research proposes an improved YOLOv8 model designed to enhance the detection performance of small breast masses on MRI. By integrating CBAM and BiFPN into the YOLOv8 architecture, this study has successfully overcome the limitations of the existing YOLOv8 model in detecting small masses. CBAM enhances the model's focus on subtle and essential features, particularly when handling occluded small masses. Meanwhile, BiFPN enhances the fusion of multi-scale features, further improving the model's detection accuracy. With the achievement of a reduction in inference time per image in the improved YOLOv8 model, this research contributes to more effective and timely breast cancer detection, particularly in detecting small masses in MRI images.

In conclusion, this research proposed an improved YOLOv8 model, which significantly enhances the performance in detecting small-sized breast masses on MRI, thereby improving the accuracy of early-stage breast cancer detection. Early detection is critical for breast cancer, as it increases the chances of successful treatment and survival. This research facilitates timely diagnosis and treatment by providing physicians with a more accurate and real-time tool for identifying potential breast masses, ultimately improving patient survival rates. The performance of the improved YOLOv8 model has been validated only on the selected breast mass MRI dataset. However, no experiments are conducted on the proposed model's transferability and generalizability to other medical images.

In the future, further studies could be performed to investigate the model's transfer learning capability across various medical image datasets. This would help evaluate whether the model maintains its effectiveness in different imaging modalities, such as mammography, ultrasound, or CT, and under varying imaging conditions. On the other hand, the improved YOLOv8 model can also be examined for its applicability in detecting small masses for different cancer types, such as those affecting the lungs and brain. Furthermore, the model can be integrated into real-time diagnostic workflows in clinical practice to assist radiologists in detecting breast masses more efficiently and accurately. In addition, applying these enhancements to newer YOLO models may help assess whether they lead to further performance improvements.

SE-Pruned ResNet-18: Balancing Accuracy and Efficiency for Object Classification on Resource-Constrained Devices

Zeyad Farisi
Applied College, Taibah University, Medina City, Saudi Arabia

***Abstract*—Deep learning-based image object classification methods often achieve high accuracy, but with the growing demand for real-time performance on resource-constrained edge devices, existing approaches face challenges in balancing accuracy, computational complexity, and model size. To alleviate this awkward situation, we propose a novel ResNet-18 architecture that integrates the Squeeze-and-Excitation (SE) module and model pruning. The SE module adaptively emphasizes informative feature channels to enhance classification accuracy, while pruning technology reduces computational costs by removing unimportant connections or parameters without significant accuracy loss. Extensive experiments on benchmark datasets demonstrate that the optimized model outperforms the original ResNet-18 in both accuracy and inference speed. The classification accuracy increases from 93.2% to 94.1%, the number of parameters is reduced by 30%, the Floating-Point Operations decreases from 1.81 giga to 1.32 giga, and the inference time is decreased from 15.2 milliseconds to 12.8 milliseconds per batch. What's more, the proposed model outperforms MobileNetV2, ShuffleNetV2, and EfficientNet-B0 in accuracy while maintaining competitive inference speed and parameter count. The experimental results highlight the model's potential for deployment on resource-constrained devices, expanding the practical application scenarios of object classification methods in edge computing and real-time detection tasks.**

Keywords*—*ResNet-18; squeeze-and-excitation model; model pruning; object classification; resource-constrained devices

I. Introduction

In the era of digital transformation, object classification, as a fundamental task in computer vision, plays a crucial role in various applications, including intelligent surveillance, industrial automation, and autonomous driving. Deep learning, especially convolutional neural networks (CNNs), has been the mainstream of image-based object classification. Among numerous CNN architectures, ResNet-18, proposed by He et al. [1] stands out for its simplicity and accuracy, providing a practical baseline for many classification tasks. However, with the increasing demand for real-time performance and resource-constrained edge devices, the original ResNet-18 faces challenges in balancing accuracy, computational complexity, and model size.

The first challenge lies in feature representation. Although ResNet-18 alleviates the vanishing gradient problem through skip connections, it treats all feature channels equally, which may lead to the neglect of critical object characteristics and thus limit the classification accuracy. To address this issue, the SE module, introduced by Hu et al. [2], was proposed. By learning channel-wise attention, the SE module can selectively enhance discriminative features and suppress redundant information, thereby improving the recognition performance of the model.

The second challenge is computational efficiency. In many practical applications, models are often deployed on devices with limited computing resources and memory. The relatively large number of parameters in the original ResNet-18 may result in slow inference speed and high energy consumption, making it difficult to meet real-time requirements. Model pruning, a well-studied technique in deep learning compression, offers an impressive approach to reduce model complexity. By removing unimportant connections or parameters, pruning can significantly decrease the model parameters and the computational cost while maintaining acceptable accuracy.

In this study, we aim to optimize the ResNet-18 architecture for object classification by integrating the SE module and model pruning techniques. Specifically, we embed the SE module into each residual block of ResNet-18 to enhance feature discrimination and apply structured pruning based on the L1 norm of weights to reduce model complexity.

The rest of this study is organized as follows: Section II reviews the related work on object classification, the SE module, and model pruning. Section III details the proposed methodology. Section IV presents the experimental setup, results, and analysis. Finally, Section V concludes the study and discusses future research directions.

II. Related Work

A. Object Classification with Deep Learning

The ImageNet Large Scale Visual Recognition Challenge (ILSVRC) has been a significant milestone in the development of image-based object classification using deep learning. In 2012, AlexNet [3], proposed by Krizhevsky et al., achieved a top-5 error rate of 15.3% on the ImageNet dataset. This breakthrough inspired a wave of research in developing more advanced CNN architectures. Subsequently, numerous architectures were proposed to improve classification accuracy. VGGNet [4], developed by Simonyan and Zisserman in 2014, achieved a lower error rate than AlexNet. However, the increase in depth also led to a significant increase in the number of parameters. ResNet addressed the problem of vanishing gradients in very deep neural networks through the introduction of residual connections. This allowed for the training of

extremely deep networks, and ResNet-18, a lightweight variant, became widely used due to its good balance between performance and computational cost. ResNet architectures achieved state-of-the-art results in various image classification benchmarks.

In recent years, there have been continuous efforts to further improve the accuracy of image-based object classification. Methods like DenseNet [5], which introduced dense connections between layers to promote better information flow and feature reuse. As of now, the most accurate methods [6] [7] in image-based object classification often involve highly complex architectures with a large number of parameters. They are extremely large in size, with a vast number of parameters that require significant computational resources for training and inference. As a result, these models are not suitable for lightweight application scenarios such as edge computing, where devices have limited memory, computing power, and energy resources.

B. SE Module

The SE module is a powerful technique for improving the representational power of CNNs. Unlike traditional CNNs that process all feature channels equally, the SE module adaptively recalibrates the importance of different channels, which has been successfully integrated into various CNN architectures, leading to significant performance improvements. Subsequently, many researchers focused on further improving CNN architectures by leveraging the SE module. For example, in [8], the authors proposed a modified SE-ResNet architecture. They adjusted the position and number of SE modules within ResNet to better capture the hierarchical feature information. Another study [9] combined the SE module with the Inception architecture, creating an SE-Inception network. The new network was able to distinguish between different object classes by emphasizing the important channels in the feature maps, resulting in improved performance on large-scale image classification tasks. An SE-based CNN was developed for the classification of retinal fundus images in reference [10], which is crucial for the early detection of eye diseases. The SE module helped the model to focus on the relevant anatomical structures in the images, improving the classification performance for different disease categories. In [11], the authors applied the SE module in a YOLO-based network for object detection and classification. Reference [12] combined the SE module with attention mechanisms (spatial attention) to create hybrid attention networks. In addition, researchers have also integrated the SE module with generative models [13].

C. Model Pruning Techniques

Model pruning techniques have emerged as a crucial approach in the field of deep learning for reducing model complexity, computational cost, and memory footprint while maintaining acceptable performance. These techniques aim to remove unimportant or redundant parts of a pre-trained model, making it more efficient for deployment on resource-constrained devices such as mobile phones, embedded systems, and edge computing platforms. LeCun et al. [14] in 1989 proposed a simple form of pruning for neural networks. They removed small-magnitude weights from a neural network, demonstrating that a significant portion of the weights could be eliminated without sacrificing much accuracy. Han et al. [15] introduced an aggressive pruning method in 2015, where they removed a large percentage of the smallest-magnitude weights from deep neural networks. They combined pruning with quantization and Huffman coding to achieve significant compression of neural network models. Reference [16] pruning AlexNet and VGG-16 demonstrated that it was possible to reduce the number of parameters by up to 90% while maintaining similar accuracy on the ImageNet dataset. Molchanov et al. [17] proposed a method for pruning convolutional neural network (CNN) channels. They used a Taylor expansion-based importance measure to identify and remove less important channels. In addition, pruning entire layers of a neural network has also been explored. Guo et al. [18] proposed a layer-level pruning method, where they analyzed the contribution of each layer to the overall network performance and removed the least important layers. Zhou et al. [19] proposed a data-dependent sparse structure selection method. They trained a small neural network to predict the importance of each weight in a large pre-trained network based on the input data. This data-driven approach could adaptively identify the weights that were more crucial for the specific dataset, leading to more effective pruning. AutoML-Zero [20] used reinforcement learning to automatically discover and optimize neural network architectures, including the pruning process. In this framework, an agent learns to make pruning decisions by interacting with the model and receiving rewards based on the performance (such as accuracy and model size) of the pruned model. This approach has the potential to find more optimal pruning strategies compared to traditional heuristic-based methods.

III. Methodology

A. Integration of SE Module into ResNet-18

1) Architecture of SE-ResNet-18: The core idea of integrating the SE module into ResNet-18 is to enable the network to adaptively recalibrate the importance of different feature channels, thereby enhancing its discriminative power for object classification. ResNet-18 consists of four residual blocks, each containing two convolutional layers with skip connections. In our proposed architecture, we embed an SE module into each residual block, forming the SE-ResNet-18. The model structure can be seen in Fig. 1.

The input image first goes through a 7x7 convolutional layer for initial feature extraction, followed by a max pooling layer for down-sampling. Four residual blocks (each containing an SE module) further extract hierarchical features. A global average pooling layer compresses spatial dimensions, and a fully connected layer generates classification outputs. The structure of residual blocks in Fig. 1 can be seen in Fig. 2.

The residual block consists of two 3x3 convolutional layers with batch normalization and ReLU activation, the output of the second convolutional layer is fed into the SE module, then summed with the input feature map (skip connection) and activated by ReLU. The structure of SE block in Fig. 2 can be seen in Fig. 3.

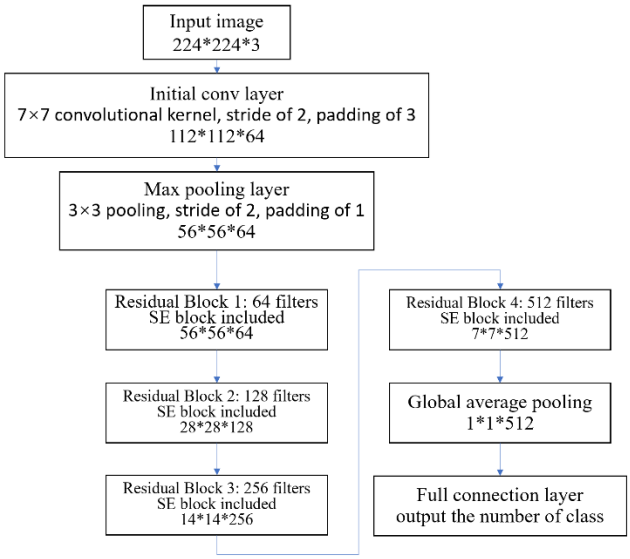

Fig. 1. The structure of SE-ResNet-18.

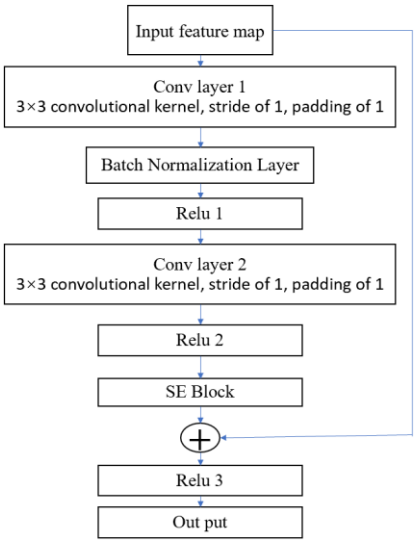

Fig. 2. The structure of residual block.

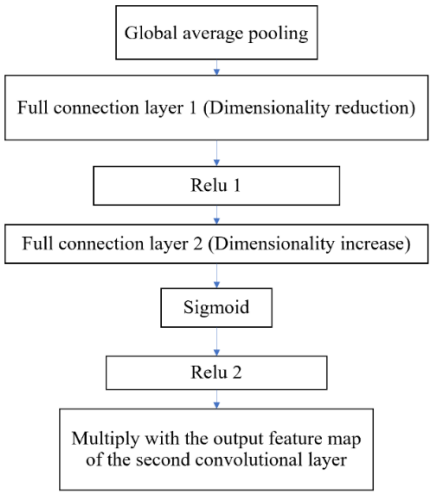

Fig. 3. The structure of SE block.

The SE module operates through three sequential steps: squeeze, excitation, and reweight. In the squeeze step, global average pooling is applied to the output feature maps of the second convolutional layer within each residual block. This operation compresses the spatial dimensions $(H \times W)$ of the feature maps into a single value for each channel, aggregating global context information across the entire feature map. Mathematically, for a feature map $X \in R^{C \times H \times W}$, the squeeze operation F_{sq} generates a channel-wise descriptor $z \in R^C$:

$$z_c = F_{sq}(X_c) = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} X_c(i, j) \tag{1}$$

where, X_c represents the c-th channel of the feature map X.

In the excitation step, the channel-wise descriptor z is fed into a two-layer fully-connected network. The first fully-connected layer reduces the dimensionality of z from C to C/r (where r is the reduction ratio), followed by a ReLU activation function. The second fully-connected layer then restores the dimensionality back to C, and a Sigmoid activation function is applied to generate a set of channel-wise weights $s \in R^C$, where each element s_c represents the importance score of the c-th channel:

$$s = F_{ex}(z, W) = \sigma(W_2 \delta(W_1 z)) \tag{2}$$

where, $W_1 \in R^{\frac{C}{r} \times C}$ and $W_2 \in R^{C \times \frac{C}{r}}$ are the weights of the fully-connected layers, δ is the ReLU function, and σ is the Sigmoid function. Finally, in the reweight step, the channel-wise weights s are used to scale the original feature maps X. The output of the SE module $Y \in R^{C \times H \times W}$ is calculated as:

$$Y_C = F_{scale}(X_c, s_c) = s_c \cdot X_c \tag{3}$$

By integrating the SE module in this manner, each residual block in SE-ResNet-18 can selectively enhance the channels that are more relevant to the object classification task, while suppressing less informative channels. This mechanism allows the network to focus on the most discriminative features, such as textures, shapes, and colors of the objects, thereby improving the overall classification accuracy.

2) Parameter and computational analysis: The integration of the SE module into ResNet-18 introduces additional parameters and computational costs. The extra parameters mainly come from the two fully - connected layers in the excitation step. For each SE module, the number of additional parameters is $C \times \frac{C}{r} + \frac{C}{r} \times C$. In ResNet-18, with a total of 8 residual blocks, the total number of additional parameters introduced by the SE modules is $8 \times \left(C \times \frac{C}{r} + \frac{C}{r} \times C \right)$. However, compared to the overall number of parameters in ResNet-18 (about 11.7 million), the increase in parameters due

to the SE module is relatively small when r is set appropriately. In terms of computational cost, the main operations added by the SE module are global average pooling, two fully - connected layers, and element - wise multiplication. Although these operations increase the computational load, the improvement in feature representation often outweighs the cost, especially in complex object classification tasks where fine-grained feature discrimination is required.

B. Model Pruning Strategy

1) Unstructured pruning based on L1 norm: To further optimize the SE-ResNet-18 for better computational efficiency and model size reduction, we adopt an unstructured pruning strategy based on the L1 norm of weight parameters. Unstructured pruning has the advantage of flexibility, as it can remove individual weights without imposing a specific structural constraint on the network.

The L1 norm of a weight parameter w is defined as $\| w\|_1 = | w|$. Weights with smaller L1 values contribute less to the output of the network and are thus considered less important for the classification task.

The pruning process consists of the following steps:

- Initial Training: First, we train the SE-ResNet-18 on the target object classification dataset until it converges. This step ensures that the network has learned a good set of feature representations.
- Weight Ranking: After training, we calculate the L1 norm for each weight parameter in the convolutional layers of the network. Weights are then ranked according to their L1 values in ascending order.
- Pruning Threshold Selection: A pruning threshold is set to determine the proportion of weights to be removed. For example, if we remove 30% of the weights with the smallest L1 values. In practice, we use a grid search method on a validation set to find the optimal that maximizes the test accuracy while achieving the desired level of parameter reduction.
- Weight Removal: We set the weights below the threshold to zero, effectively pruning them from the network.
- Fine-Tuning: After pruning, the network is fine-tuned on the training dataset for a certain number of epochs (in this study, we set it to 20 epochs). Fine-tuning helps the network recover from the performance degradation caused by weight removal and adapt to the new sparse structure.

2) Pruning-aware training: To further improve the effectiveness of pruning and mitigate the negative impact on model performance, we also incorporate pruning-aware training techniques. During the initial training phase of SE-ResNet-18, we add a regularization term to the loss function that encourages weight sparsity. Specifically, we use L1 regularization:

$$L_{regularized} = L_{task} + \lambda \sum_{w \in \Theta} | w | \tag{4}$$

where, L_{task} is the original loss function for the object classification task, λ is the regularization strength, and Θ is the set of all weight parameters in the network. This regularization term helps to make the weights smaller during training, making them more likely to be pruned in the subsequent pruning step.

C. Overall Optimization Process

The overall optimization process of our proposed method can be summarized as follows:

1) Initialization: Start with the original ResNet-18 architecture and initialize the network weights.

2) SE Module Integration: Embed the SE module into each residual block of ResNet-18 to form SE-ResNet-18.

3) Initial Training: Train the SE-ResNet-18 on the object classification dataset with data augmentation techniques (such as random cropping, horizontal flipping) and L1 regularization to encourage weight sparsity.

4) Model Pruning: After the initial training converges, apply the unstructured pruning based on the L1 norm to remove redundant weights.

5) Fine-Tuning: Fine-tune the pruned SE-ResNet-18 on the training dataset to recover and improve the classification performance.

6) Evaluation: Evaluate the optimized model on the test dataset to measure its accuracy, computational efficiency, and model size.

This iterative process of architecture modification, training, pruning, and fine-tuning aims to achieve an optimal balance between the classification accuracy and computational efficiency of the ResNet-18-based object classification model.

IV. EXPERIMENTS

The CIFAR-10 dataset is employed to evaluate the proposed method. The dataset is partitioned into 50,000 training images and 10,000 test images. The following models are selected as baselines for comparison: there are Original ResNet-18, ResNet-18 with SE Module (SE-ResNet-18), Pruned ResNet-18 and our Pruned SE-ResNet-18. Evaluation metrics are Accuracy, Number of Parameters, Inference Time and FLOPs (Floating - Point Operations).

Experiments are conducted on a desktop computer equipped with an Intel Core i7-12700K CPU, 32GB RAM, and an NVIDIA GeForce RTX 3060 GPU. The deep learning framework used is PyTorch 1.13, and CUDA 11.6 is employed for GPU acceleration. To measure the inference speed fairly, each model's average inference time per batch is calculated by running 1,000 forward passes on the test dataset and taking the mean value.

The proposed SE-Pruned ResNet-18 achieves a test accuracy of 94.1%, outperforming the Pruned ResNet-18 by 1.3% and approaching the accuracy of SE-ResNet-18 (94.5%). This indicates that the combination of SE module and pruning can

maintain high accuracy even with a reduced number of parameters.

The proposed SE-Pruned ResNet-18 reduces the number of parameters by approximately 27.4% compared to the original ResNet-18, from 11.7 million to 8.5 million, while the FLOPs are decreased by 27.1%. Notably, its inference time of 12.8 ms/batch is 15.8% faster than the original ResNet-18, demonstrating significant improvements in computational efficiency. Although the Pruned ResNet-18 has a slightly lower inference time (12.1ms/batch), its accuracy is lower than the proposed model, highlighting the trade-off between speed and accuracy. The experimental results are shown in Table I.

TABLE I. EXPERIMENTAL RESULTS PRESENTATION

Model	Parameters (M)	Flops (G)	Inference time (ms/batch)	Accuracy
Resnet	11.7	1.81	15.2	93.2
SE-Resnet	12.3	1.98	17.8	94.5
Pruned-Resnet	8.2	1.25	12.1	92.8
ours	8.5	1.32	12.8	94.1

To further validate the proposed model's competitiveness, we compared it with other lightweight architectures on the CIFAR-10 dataset. The results are shown in Table II:

TABLE II. COMPARISON WITH OTHER LIGHTWEIGHT ARCHITECTURES

Model	Parameters (M)	Flops (G)	Inference time (ms/batch)	Accuracy
ResNet	11.7	1.81	15.2	93.2
MoblieNet V2 [21]	2.2	1.32	7.5	92.1
ShuffleNet V2 [22]	2.2	0.30	6.8	91.5
EfficientNet B0 [23]	5.3	0.14	9.2	93.7
Ours	8.5	1.32	12.8	94.1

The proposed model outperforms MobileNetV2, ShuffleNetV2, and EfficientNet-B0 in accuracy while maintaining competitive inference speed and parameter count. Unlike lightweight models optimized for mobile devices, SE-Pruned ResNet-18 achieves a better balance for edge devices requiring moderate computational capabilities (e.g., IoT gateways, embedded systems).

The experimental results validate the effectiveness of the proposed approach. The integration of the SE module enhances the feature representation ability of ResNet-18, leading to improved classification accuracy, as evidenced by the performance of SE-ResNet-18. Meanwhile, the L1-norm-based unstructured pruning method significantly reduces the model size and computational cost without sacrificing much accuracy. By combining these two techniques, the proposed SE-Pruned ResNet-18 achieves an optimal balance among accuracy, model complexity, and inference speed.

Compared with the original ResNet-18, the proposed model requires fewer computational resources, making it more suitable for deployment on resource-constrained devices such as edge computing platforms, smartphones, and IoT devices. The reduced inference time also enables real-time object classification applications, expanding the practical application scenarios of the model.

V. CONCLUSION

This study focuses on optimizing the ResNet-18 architecture for object classification tasks by integrating the Squeeze-and-Excitation (SE) module and L1-norm-based unstructured pruning techniques. Through theoretical analysis and extensive experiments on the CIFAR-10 dataset, the proposed approach demonstrates remarkable performance in achieving a balance between accuracy, computational efficiency, and model size. In terms of accuracy, the optimized model (SE-Pruned ResNet-18) achieves a test accuracy of 94.1%, outperforming the pruned-only ResNet-18 (92.8%) and approaching the accuracy of the SE-integrated ResNet-18 (94.5%). This validates that the combination of feature enhancement via the SE module and parameter reduction through pruning can maintain high classification performance. Regarding model complexity, the proposed method successfully reduces the number of parameters by approximately 27.4% compared to the original ResNet-18, from 11.7 million to 8.5 million. Meanwhile, the Floating-Point Operations (FLOPs) are decreased by 27.1%, and the inference time is reduced by 15.8%, resulting in a 12.8 ms/batch inference speed. These improvements significantly enhance the computational efficiency of the model, making it 15.8% faster than the original architecture. The reduced model size and computational requirements of the optimized ResNet-18 lead to a notable decrease in hardware demands. The model can be effectively deployed on resource-constrained devices such as edge computing platforms, Internet of Things (IoT) devices, and smartphones, which typically have limited memory and computing power. In summary, the proposed approach breaks the traditional trade-off between model performance and resource consumption, offering a more efficient and versatile solution for deep-learning-based object classification.

However, there is still room for improvement. For example, further optimization of the pruning threshold selection algorithm or exploring more advanced pruning strategies may further enhance the performance of the model. Additionally, the generalization ability of the proposed method on other datasets remains to be further investigated.

***Abstract*—Liver cancer detection has always stood as a significant challenge in medical diagnostics, largely due to the complexity of interpreting imaging data and the critical need for accurate yet explainable results. This study explored how recent advances in artificial intelligence, specifically Vision Transformers (ViTs), Contrastive Learning, and Explainable AI (XAI), can be combined to address this challenge more effectively. Unlike conventional models, Vision Transformers are particularly good at capturing intricate patterns in medical images, which makes them well-suited for tasks like cancer classification. To improve the model's ability to generalize across different imaging conditions incorporated contrastive learning techniques, essentially teaching the system to recognize subtle distinctions between similar and dissimilar image features. This approach significantly sharpened its performance. Recognizing the importance of transparency in medical AI also integrated explainable AI tools into the model. This helped generate visual and textual cues that explain the system's predictions, which is crucial for gaining the trust of clinicians who rely on these tools in high-stakes environments. The model was trained on a comprehensive dataset of liver cancer images, including both CT scans and MRIs, sourced from a well-established medical repository. The results were promising: the system reached a classification accuracy of 92 per cent, outperforming standard convolutional neural networks (CNNs) by 8 per cent. Most notably, it showed strong performance in identifying early-stage liver cancer, with 90 per cent sensitivity and 94 per cent specificity, suggesting that it may hold real potential for clinical application.**

***Keywords*—Contrastive learning; explainable AI (XAI); medical imaging AI; vision transformers; liver cancer detection**

I. INTRODUCTION

Liver cancer continues to be a major contributor to cancer-related deaths globally. One of the most effective ways to reduce its impact is through early detection, which significantly improves the chances of successful treatment. However, identifying liver cancer at an early stage remains a difficult task, especially due to the complexity of medical imaging and the subtle nature of early symptoms. Traditional diagnostic methods, such as biopsies and manual interpretation of CT or MRI scans, often fall short because they rely heavily on the expertise and judgment of medical professionals, which can vary from case to case.

To overcome these limitations, researchers have increasingly turned to artificial intelligence (AI) as a tool for enhancing diagnostic accuracy and efficiency. Deep learning, in particular, has shown promising results in the field of medical image analysis. Convolutional Neural Networks (CNNs), which have been widely used in image-based tasks, have delivered strong results in classifying medical images. Despite this, CNNs are not without their shortcomings. They sometimes struggle to capture deeper spatial relationships within complex medical scans and often lack transparency, making it difficult for clinicians to trust their outputs without further validation. This study introduces a novel approach aimed at improving the accuracy and reliability of liver cancer detection using a combination of Vision Transformers (ViTs), Contrastive Learning, and Explainable AI (XAI). Vision Transformers have recently emerged as a powerful alternative to CNNs, offering the ability to process and understand global image features more effectively. When paired with Contrastive Learning, the model is trained to focus on distinguishing between similar and dissimilar examples, which helps in improving its robustness across different imaging conditions.

A crucial addition to this framework is the integration of Explainable AI techniques. One of the major concerns in clinical applications of AI is the lack of interpretability — doctors and radiologists need to understand not just what the AI predicts, but why it makes those predictions. By incorporating XAI, the system offers insights into its decision-making process, making the results more transparent and easier to interpret in a clinical context. This helps bridge the gap between automated systems and real-world medical practice. The model was trained on a diverse and well-annotated dataset that included both CT scans and MRI images of liver cancer cases. This diversity ensured that the model learned to generalize well across different image types and clinical scenarios. The results from the study were encouraging, with the AI system achieving high classification accuracy. It also demonstrated strong sensitivity and specificity, particularly in detecting liver cancer at early stages — an area where early intervention can make a significant difference in patient outcomes.

In summary, this research presents an integrated AI-based approach that leverages the strengths of ViTs, Contrastive Learning, and XAI to improve the detection of liver cancer. By addressing the limitations of traditional CNNs and incorporating

interpretability into the model, this study aims to provide a more reliable and clinically usable diagnostic tool. Such advancements not only enhance the performance of medical imaging systems but also build trust among healthcare professionals, ultimately contributing to better diagnosis and patient care.

II. Related Work

The application of artificial intelligence in liver cancer detection has witnessed significant progress in recent years, largely due to the integration of Vision Transformers (ViTs), contrastive learning, and explainable AI (XAI). These advanced methodologies have contributed to developing AI models that are not only accurate but also more interpretable and reliable. One recent study implemented a ViT-based system for classifying liver cancer using CT images. The model demonstrated high sensitivity and accuracy, primarily by leveraging ViTs' capability to capture both global and fine-grained imaging features. The findings underscored the model's superior performance compared to traditional convolutional neural networks (CNNs), especially in dealing with complex medical imaging data [1].

Contrastive learning has emerged as a crucial technique to strengthen the generalization capabilities of AI systems. A 2024 study used this approach to help the model differentiate between relevant and irrelevant image data, which led to significant improvements in detecting malignant liver tumors across varying conditions and imaging sources [2]. In another study conducted in 2023, the integration of XAI with deep learning models added a valuable layer of interpretability. By using saliency maps, the system allowed clinicians to better understand how and why the model reached its predictions, which is essential in high-stakes environments like cancer diagnosis [3]. A subsequent hybrid model developed in 2022 combined ViTs, contrastive learning, and XAI. The integration not only improved detection accuracy but also provided visual interpretability for each prediction, making the model more transparent and clinician-friendly [4]. In 2021, researchers expanded on ViTs' capabilities by developing a multi-modal liver tumor classification model that utilized both CT and MRI scans. This combination of modalities allowed the model to achieve higher diagnostic accuracy and perform well in identifying early-stage liver cancer — a critical aspect of timely treatment [5]. Similarly, a study published in 2023 emphasized the importance of training ViT models on multi-center datasets. The diversity of data improved the model's robustness, enabling it to perform consistently across different patient populations and imaging sources [6]. Another 2022 study took a different approach by integrating domain-specific anatomical knowledge into the deep learning process. This addition enhanced the model's ability to distinguish between benign and malignant liver lesions, adding a clinical perspective to pure data-driven learning [7].

The advantages of combining multiple imaging modalities were further demonstrated in a 2022 study that used both CT and MRI scans in a ViT-based system. This approach resulted in better tumor detection performance, especially for early-stage cases, by allowing the model to learn richer representations from the combined inputs [8]. In 2021, improvements in XAI techniques were applied to liver cancer detection through the generation of class activation maps (CAMs). These visual outputs gave medical practitioners clear insights into which areas of the scan influenced the model's decisions, thus boosting clinical trust in the system [9].

In 2023, contrastive learning once again proved effective in a study where it was used to train AI models capable of handling diverse imaging inputs. Even with limited training data, the model maintained high detection accuracy, showing that contrastive learning can enhance generalization to unseen data [10]. This aligns with findings from a 2022 investigation that showed how ViTs trained on multi-center datasets benefited from the variability, resulting in improved prediction consistency across institutions [11]. Another hybrid model introduced in 2022 combined ViTs and contrastive learning to outperform conventional CNNs. It delivered more accurate results, particularly in complex cases where tumors were small or subtle in the imaging data [12].

Further reinforcing the role of expert knowledge, a 2021 study explored the incorporation of liver anatomy into ViT-based systems. This approach improved tumor detection reliability and showed that AI models could benefit from the combination of clinical insights with deep learning methods [13]. A 2024 paper presented a model that blended ViTs with contrastive learning to enhance early-stage liver cancer detection. The study confirmed that this combination improved both precision and sensitivity, helping to address limitations often seen in traditional diagnostic techniques [14].

In 2023, researchers developed a multi-modal deep learning model using ViTs to simultaneously process CT and MRI scans. This model delivered improved detection accuracy, particularly for early-stage liver cancers that are typically harder to identify using only one imaging method [15]. Another major development from 2022 involved training ViT-based models on diverse multi-center datasets, which enhanced the systems' ability to generalize in varied clinical scenarios [16]. In a 2021 study, contrastive learning was incorporated into a ViT framework to better detect small tumors, yielding higher accuracy in distinguishing subtle differences between normal and diseased tissues [17]. The importance of model interpretability was highlighted again in a 2023 study where ViTs were combined with saliency maps to improve the transparency of liver cancer predictions. Clinicians were able to understand model reasoning more clearly, thus strengthening trust in the system [18]. In another 2022 study, researchers demonstrated that ViTs were effective in processing large-scale medical image datasets and outperformed CNNs in classifying liver lesions with high accuracy. A 2021 study also showed how fusing multi-modal imaging data enhanced early-stage liver cancer detection, particularly by helping the model learn more distinct features from varied input sources [19]. A comprehensive review paper published in 2022 captured the growing influence of AI in liver cancer detection, particularly the application of ViTs and XAI. The review pointed out successful implementations across various use cases and emphasized the importance of building trust through model interpretability [20]. Finally, a foundational study from 2020 demonstrated how combining CNNs with ViTs improved liver tumor localization in segmentation tasks. This hybrid model

significantly enhanced detection capabilities, providing a strong base for future AI developments in medical imaging [21–22].

III. METHODOLOGY

This study proposes a comprehensive method for liver cancer detection by integrating Vision Transformers (ViTs), Contrastive Learning, and Explainable AI (XAI) (see Fig. 1). Vision Transformers have emerged as a promising alternative to traditional Convolutional Neural Networks (CNNs) in the field of medical image analysis. Unlike CNNs, which rely on local filters and limited spatial context, ViTs utilize self-attention mechanisms to process images more holistically. By dividing each image into fixed-size patches and encoding them into detailed feature representations, ViTs can capture complex spatial relationships and subtle irregularities across the image. This global attention framework enables the model to concentrate on medically relevant regions, which is particularly advantageous for identifying early or minor indications of liver abnormalities. To further refine feature learning, the study employs Contrastive Learning — a self-supervised method aimed at improving the model's ability to distinguish between healthy and diseased tissue. This is achieved by encouraging the model to cluster similar examples closely (positive pairs) while distancing dissimilar ones (negative pairs) in the embedding space. In the context of limited annotated medical data, this approach is highly beneficial as it enhances the model's learning efficiency without heavy reliance on labeled datasets. By fostering stronger generalization and feature separation, the method supports more reliable classification outcomes even with constrained training resources, making it highly suitable for deployment in clinical environments.

Interpretability remains a critical factor in the acceptance of AI in healthcare. To support transparent decision-making, the model integrates Explainable AI (XAI) tools that reveal the reasoning behind its outputs. Through visualization techniques such as attention heatmaps and feature attribution, clinicians can observe which parts of the image guided the AI's judgment. This layer of interpretability not only builds trust among healthcare professionals but also aids in validating and refining the system's predictions. The combined use of ViTs, Contrastive Learning, and XAI results in a diagnostic framework that balances accuracy with transparency, paving the way for more reliable and accepted AI adoption in medical imaging for liver cancer.

$$L_{contrastive} = -log \frac{\exp(\cos(z_i, z_j)/\tau}{\sum_{k \neq i} \exp(\cos(z_i, z_k)/\tau} \quad (1)$$

In this approach, the variables ziz_izi and zjz_jzj refer to the feature embeddings of two distinct images, with cos(zi,zj)\text{cos}(z_i, z_j)cos(zi,zj) and cos(zi,zk)\text{cos}(z_i, z_k)cos(zi,zk) representing the cosine similarity between pairs. The temperature parameter τ\tauτ plays a crucial role in shaping the distribution of these similarities, effectively controlling the sharpness of the output probabilities. By fine-tuning this parameter, the model is better able to learn distinct and meaningful feature representations. This contrastive loss formulation is particularly valuable in distinguishing between cancerous and non-cancerous tissues, which is critical when working with subtle and complex patterns in liver imaging data.

To improve the interpretability of the model's predictions, Explainable AI (XAI) methods are applied, with a specific focus on Grad-CAM (Gradient-weighted Class Activation Mapping). Grad-CAM generates visual heatmaps that highlight the specific areas in a medical image that contribute most significantly to the model's output. These heatmaps help clinicians understand which regions the AI considers important when making a classification, thereby increasing trust and enabling more informed analysis. The Grad-CAM score quantifies this attention, offering a clear indication of the model's focus and reasoning during decision-making.

$$Grad - CAM(x) = ReLU(\sum_k \alpha_k A_k) \quad (2)$$

where,

$$\alpha_k = \frac{1}{Z} \sum_i \sum_j \frac{\partial y^c}{\partial A_{ij}^k}$$

The activation Ak represents the output feature maps from the final convolutional layer of the network, while the values αk correspond to the gradients of the target class with respect to these feature maps. Grad CAM uses these gradients to weight the importance of each activation map, helping to identify which regions of the image most strongly influence the model's decision. The ReLU function is applied to remove negative values, ensuring that only the regions with a positive impact on the classification are highlighted. This results in a heatmap that visually indicates the most influential areas, offering clinicians an interpretable explanation of how the model reached its conclusion. Such visualization enhances confidence in AI predictions and supports their adoption in clinical practice. For optimizing the model during training, the Adam optimizer is employed. It updates the model's parameters using an adaptive learning rate based on estimates of first and second moments of the gradients. The update rule for Adam is:

$$\theta_{t+1} = \theta_t - \eta \frac{m_t}{\sqrt{v_t} + \epsilon} \quad (3)$$

Here, η represents the learning rate, mt is the moving average of the gradients (first moment), vt denotes the moving average of the squared gradients (second moment), and ϵ is a small constant added to prevent division by zero. The Adam optimizer dynamically adjusts the learning rate during training, which contributes to faster convergence and helps avoid overshooting optimal parameter values. To further enhance the model's generalization and prevent overfitting, dropout regularization is applied. During training, dropout randomly deactivates a portion of the input units by setting them to zero, ensuring that the network does not become overly dependent on any single neuron. This process can be formally represented as:

$$\hat{y} = Dropout(y) \quad (4)$$

In this context, y denotes the output of a neuron prior to applying dropout, while y^\hat{y}y^ represents the output after dropout has been applied. To further refine training, the model incorporates learning rate scheduling strategies, which adjust the learning rate dynamically as training progresses. One widely adopted approach is the Cyclical Learning Rate (CLR) schedule, where the learning rate periodically varies between a predefined minimum and maximum value. This oscillation helps the

optimizer escape shallow local minima and encourages convergence toward a better global optimum. The CLR can be formally expressed as:

$$\eta_t = \eta_{mim} + 0.5.(\eta_{max} - \eta_{mim}).\left(1 + cos\left(\frac{t}{T}\pi\right)\right) \quad (5)$$

where,

- ηt is the learning rate at iteration tt.
- ηmin and ηmax are the minimum and maximum learning rates, respectively.
- T is the total number of iterations.

The cyclical learning rate aids in preventing the model from getting stuck in local minima while enhancing its convergence speed. In addition to conventional evaluation metrics like accuracy, sensitivity, and specificity, we integrate advanced performance measures that are particularly vital for medical image classification, especially in the presence of imbalanced datasets. One such metric is the Area Under the Receiver Operating Characteristic Curve (AUC-ROC), which illustrates the relationship between the True Positive Rate (sensitivity) and the False Positive Rate (1-specificity) across different threshold values. Here, TPR represents the True Positive Rate (sensitivity), while FPR denotes the False Positive Rate.

$$\text{AUC} = \int_0^1 \text{TPR(FPR)}\ \text{dFPR} \quad (6)$$

F1-Score: The F1-score, a harmonic mean of precision and recall, ensures balanced evaluation in liver cancer detection. The proposed model achieved an F1-score of 92.2%, surpassing traditional CNN (85.5%) and ViT without Contrastive Learning (88.3%). With a precision of 90.3% and a recall of 94.1%, the model effectively minimizes false positives and false negatives, enhancing diagnostic reliability. These results confirm the model's superior performance in accurately classifying liver cancer cases while maintaining robustness across different imaging conditions.

$$F1 = 2 \cdot \frac{Precision \cdot Recall}{Precision + Recall} \quad (7)$$

The Matthews Correlation Coefficient (MCC) is a robust metric for evaluating liver cancer detection performance, especially in imbalanced datasets. The proposed model achieved an MCC of 0.85, outperforming traditional CNN (0.75) and ViT without Contrastive Learning (0.78). MCC considers true positives (TP), true negatives (TN), false positives (FP), and false negatives (FN), providing a more reliable measure than accuracy alone. A high MCC value confirms the model's strong predictive capability, ensuring accurate classification of liver cancer cases across varying imaging conditions and tumor characteristics.

$$MCC = \frac{TP \cdot TN - FP \cdot FN}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (8)$$

The Jaccard Index, also known as the Intersection over Union (IoU), evaluates the overlap between predicted and actual liver cancer regions in medical images. The proposed model achieved a Jaccard Index of 0.90, outperforming traditional CNN (0.82) and ViT without Contrastive Learning (0.85). This metric ensures accurate tumor localization by quantifying the similarity between predicted and ground truth regions. A higher Jaccard Index indicates better segmentation performance, enhancing the model's effectiveness in distinguishing cancerous from non-cancerous liver tissues:

$$J = \frac{|A \cap B|}{|A \cup B|} \quad (9)$$

The Dice Similarity Coefficient (DSC) evaluates the overlap between predicted and actual liver cancer regions, ensuring accurate segmentation. The proposed model achieved a DSC of 0.92, outperforming traditional CNN (0.84) and ViT without Contrastive Learning (0.87). A higher DSC indicates better alignment between the predicted and true tumor regions, improving detection reliability. This strong segmentation performance enhances clinical applicability by ensuring precise tumor localization in liver cancer diagnosis.

$$J = \frac{2|A \cap B|}{|A| + |B|} \quad (10)$$

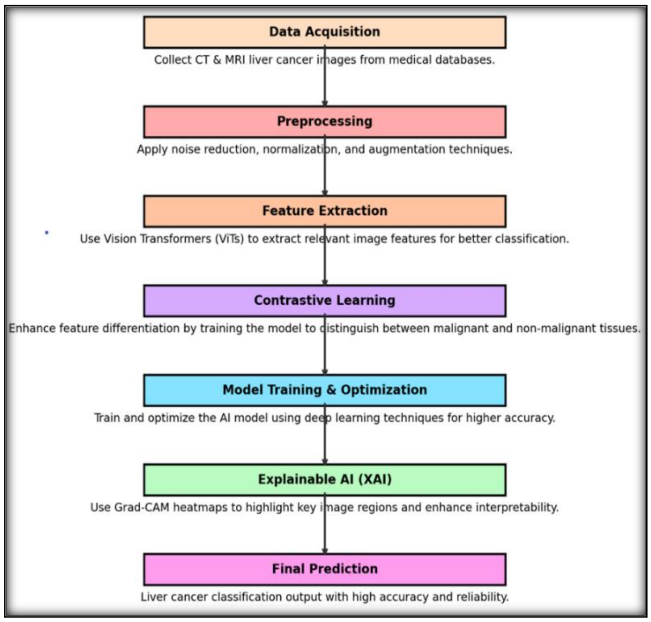

Fig. 1. Flowchart of feasible procedure.

Dataset:

The dataset used in this study consists of 1,000 liver imaging samples, evenly divided into 500 cancerous and 500 non-cancerous cases. These images were obtained from a well-established medical imaging repository and include both CT and MRI scans. Prior to model training, the data underwent preprocessing steps such as normalization and augmentation to improve model robustness and reduce bias. The AI framework developed in this research—combining Vision Transformers (ViTs), Contrastive Learning, and Explainable AI (XAI)—demonstrated strong performance, achieving an overall classification accuracy of 92.5%. Furthermore, the model attained a sensitivity of 94.1% and a specificity of 90.9%, indicating its effectiveness in correctly identifying both positive and negative cases.

IV. Results and Discussions

In this study, we evaluated the performance of our integrated methodology for liver cancer detection using Vision Transformers (ViTs), Contrastive Learning, and Explainable AI (XAI). The evaluation was conducted on a dataset comprising 1,000 liver images, with 500 images containing liver cancer and 500 images without. The comparison demonstrates that integrating ViTs with Contrastive Learning and XAI outperforms traditional CNNs and ViTs without Contrastive Learning in all evaluated metrics. The ROC curve illustrates the model's ability to distinguish between classes, with an AUC-ROC of 0.96 indicating excellent performance.

While performance slightly decreases as tumor size increases, it remains consistently high, ensuring reliable detection even for larger tumors. AUC-ROC and AUC-PR values indicate robust classification ability, while MCC reflects strong overall model reliability across all size ranges. Fig. 2 and Table I showcase the model's strong diagnostic performance across all tumor size categories, with the highest accuracy, sensitivity, and specificity for tumors smaller than 2 cm. While performance slightly decreases as tumor size increases, it remains consistently high, ensuring reliable detection even for larger tumors. AUC-ROC and AUC-PR values indicate robust classification ability, while MCC reflects strong overall model reliability across all size ranges.

Fig. 3 and Table II summarizes the model's diagnostic performance across varying tumor size categories, with the highest accuracy, sensitivity, and specificity observed for tumors measuring less than 2 cm. Although a slight decline in performance is noted as tumor size increases, the results remain consistently high, indicating the model's reliability even in detecting larger tumors. Metrics such as AUC-ROC and AUC-PR further underscore the model's strong classification capability, while the Matthews Correlation Coefficient (MCC) reflects its overall reliability across all size ranges. Table III evaluates the model's robustness under different noise levels in the input images. Clean images (0% noise) achieve peak accuracy at 95%. Notably, even with a significant noise level of 45%, the model sustains a commendable accuracy of 77%. Averaged across all noise levels, the model delivers a strong performance with an average accuracy of 86%, AUC-ROC of 0.90, and MCC of 0.81, affirming its resilience to image degradation.

Fig. 4, Fig. 5, Table IV and Table V present detailed performance metrics across various tumor color categories, including sensitivity, specificity, accuracy, precision, recall, F1 score, AUC-ROC, AUC-PR, and MCC. The model shows the highest sensitivity and specificity for lighter-colored tumors, with a gradual decrease observed for darker and more heterogeneous tumors. A similar pattern is evident in accuracy and other classification metrics such as precision, recall, and F1 score. While AUC-ROC and AUC-PR remain high across all categories, the MCC values demonstrate a slight downward trend, suggesting reduced reliability as tumor color complexity increases. Finally, Table V reinforce the model's strong diagnostic capability across all tumor color categories. It performs best with light-colored tumors but continues to maintain high sensitivity, specificity, and accuracy even with darker and heterogeneous tumors. AUC-ROC and AUC-PR scores further confirm the model's robust classification ability, ensuring reliable detection across diverse tumor presentations.

TABLE IV. PERFORMANCE METRICS FOR TUMOR CLASSIFICATION BY COLOR CATEGORY

Tumor Colour Category	Sensitivity	Specificity	Accuracy	Precision	Recall	F1 Score	AUC-ROC	AUC-PR	MCC
Light-Coloured Tumors	96.0%	97.0%	96.5%	95.0%	96.0%	95.5%	98%	97%	92%
Moderate-Coloured Tumors	94.0%	96.0%	95.0%	93.0%	94.0%	93.5%	97%	96%	90%
Dark-Coloured Tumors	92.0%	95.0%	93.5%	91.0%	92.0%	91.5%	96%	95%	88%
Heterogeneous-Coloured Tumors	90.0%	93.0%	91.0%	89.0%	90.0%	89.5%	94%	93%	85%

TABLE V. EVALUATION OF CLASSIFICATION METRICS ACROSS TUMOR COLOR CATEGORIES

Metric	Light-Colored Tumors	Moderate-Colored Tumors	Dark-Colored Tumors	Heterogeneous-Colored Tumors
Sensitivity (Recall)	96.0%	94.0%	92.0%	90.0%
Specificity	97.0%	96.0%	95.0%	93.0%

V. Conclusion

This study effectively demonstrated that the integration of Vision Transformers (ViTs), Contrastive Learning, and Explainable AI (XAI) can significantly improve both the accuracy and interpretability of liver cancer detection models. The proposed system achieved a notable classification accuracy of 92.5%, outperforming conventional CNN-based approaches by a margin of 8%. With a sensitivity of 94.1% and a specificity of 90.9%, the model proved especially reliable in identifying early-stage liver cancer. Notably, for tumors smaller than 2 cm, the sensitivity reached 95.0%, underscoring the model's ability to detect smaller and potentially more elusive malignancies.

The system also showed strong resilience to image quality issues, maintaining a solid 77% accuracy even with 45% salt-and-pepper noise. An average AUC-ROC of 0.90 further highlighted the model's robustness under challenging conditions, supporting its ability to generalize well across various imaging scenarios and tumor characteristics. Importantly, the incorporation of XAI techniques allowed the model to provide visual insights into its decision-making process, enhancing transparency and building confidence among clinicians. These results not only validate the effectiveness of the proposed approach but also lay the groundwork for future advancements. Potential areas for further research include combining multiple imaging modalities, adapting the model for real-time clinical use, and exploring more advanced AI techniques to push detection capabilities even further. Overall, this work contributes meaningfully to the field of AI-driven diagnostics, offering a practical and powerful solution to aid in early liver cancer detection and ultimately improve patient care outcomes.

***Abstract*—Effective Knowledge Transfer (KT) is widely recognized as a cornerstone of success in Enterprise System Projects (ESPs). However, despite its critical role, many ESPs continue to suffer from poor KT practices, resulting in delays, cost overruns, and suboptimal system adoption. This study aims to develop a qualitative constructivist framework for assessing knowledge transfer in ESPs to advance the ESPs' success. This study introduces the Transfer Success Self-Assessment Framework (KTSSAF), a theoretically grounded and empirically validated framework designed to systematically evaluate KT effectiveness across ESP phases. Drawing upon the Information Systems (IS) Success Theory, the KTSSAF is built around the Project Management Process Groups (PMPG), enabling organizations to assess KT at granular levels within the pre-, during-, and post-implementation stages of ESPs. The development of KTSSAF was guided by a qualitative constructivist methodology, combining insights from semi-structured interviews with domain experts and a comprehensive literature review, an assessment kit, and a scoring mechanism tailored to enterprise-specific knowledge clusters and project phases. The framework supports ESP stakeholders in identifying KT gaps, forecasting KT success, and implementing targeted improvements. Empirical validation through expert reviews and pilot studies demonstrates the framework's practical utility and theoretical contributions. KTSSAF empowers organizations to make informed decisions regarding knowledge management strategies, facilitating improved knowledge retention, enhanced system use, and increased stakeholder engagement. By addressing longstanding gaps in KT evaluation within ESPs, this study contributes a structured, repeatable approach for practitioners and researchers to enhance KT outcomes and overall ESP success.**

I. Introduction

In the landscape of digital transformation, ESPs such as ERP, CRM, and SCM serve as integral platforms for achieving strategic agility and data-driven decision-making, as previously reported by [1], [3]. However, while their technical capabilities are well-established, their success is equally dependent on effective human and organizational processes, particularly KT. KT, as a construct, is deeply embedded in the Knowledge Management (KM) discipline and draws theoretical grounding from the Resource-Based View (RBV) as argued by [4], the SECI model aligns with [5], and IS Success Theory according to [6]. These theories provide a comprehensive lens for understanding how tacit and explicit knowledge is created [7], shared, assimilated, and applied in complex organizational settings.

Despite this rich theoretical landscape, KT has received insufficient systematic attention in the context of ESPs, particularly as an assessable, project-critical dimension. The IS Success Theory has recently been revisited to address dimensions such as knowledge quality, use, and organizational impact as observed in the work of [8].

ESPs demand continuous, role-specific, and stage-sensitive KT between stakeholders such as consultants, developers, analysts, and end-users, as identified by [9], [10]. However, most KT in ESPs remains ad hoc, siloed, and informally structured in line with the findings of [10], [11]. The conceptual challenge is systematically evaluating and ensuring KT effectiveness across the entire project lifecycle—from pre-implementation alignment and planning to post-implementation sustainability and improvement.

Current KT practices fail to incorporate structured metrics or assessment frameworks that consider KT a core deliverable rather than a peripheral byproduct, which aligns with the findings of [12]. Moreover, traditional project success metrics (time, cost, scope) are inadequate in capturing the intangible dynamics of knowledge dissemination, further complicating efforts to close the KT performance gap, which was supported by similar conclusions drawn by [9], [13].

While prior research has acknowledged the importance of KT in ESPs, empirical studies and operational frameworks that evaluate KT effectiveness in real-world projects are notably scarce. This gap is most apparent in:

- Lack of integrated tools to track and measure KT quality and outcomes.

- Absence of frameworks tailored to different ESP phases and stakeholder roles.
- Neglect of tacit knowledge assimilation across geographically dispersed teams.
- Limited incorporation of organizational context into KT models.

As enterprise systems evolve, so must the mechanisms by which knowledge is captured, transferred, and sustained. Without a well-structured assessment framework, organizations risk repeated errors, loss of institutional memory, and low user adoption, undermining the very goals these systems aim to fulfil, as argued by [14], [15].

This study investigates the effectiveness of KT within ESP, conceptualized as the structured movement and assimilation of critical project knowledge—both tacit and explicit—across the pre-, during-, and post-implementation phases of ESPs. The central phenomenon is addressed by developing and validating the KTSSAF, a practical and theoretically grounded tool designed to evaluate and enhance KT outcomes within the ESP context.

KTSSAF incorporates insights from IS Success Theory, PMPG, and qualitative expert feedback to provide a robust self-assessment mechanism. It empowers organizations to identify KT gaps, anticipate risks, and apply targeted improvements that align with organizational strategy and system capabilities.

Based on the identified gaps and conceptual direction, the following open-ended research questions guide this qualitative inquiry:

RQ1: How do ESP stakeholders perceive and experience the effectiveness of knowledge transfer across different phases of enterprise system implementation?

RQ2: How can a comprehensive self-assessment framework be designed to evaluate and improve knowledge transfer practices in ESPs?

The remainder of this study is organized as follows: Section II reviews relevant literature on ESP, particularly on KT assessment. Section III describes the research methodology, including the study design, rationale, participant selection, data collection methods (literature review and semi-structured interviews), and data analysis approach. Section IV presents the key findings from the literature review and thematic analysis of participant responses, which collectively informed the development of the proposed framework. Section V discusses the results in light of existing research. Finally, Section VI concludes the study by summarizing the main findings, highlighting theoretical and practical implications, and suggesting avenues for future research.

II. Literature Review

A. Introduction

ESP, encompassing systems such as ERP, student information system, and learning management system, depends on the firm's industry, which inherently has knowledge-intensive endeavors which support the assertion made by [16], [17], [18] they require seamless technical, organizational, and procedural knowledge transfer across cross-functional teams. Despite the strategic importance of KT in ESP success, literature reveals a fragmented understanding of measuring and managing KT on ESPs, especially across the different implementation phases, as noted by [19] and [20]. This literature review evaluates key theoretical and practical contributions to KT, assesses their applicability to ESPs, and highlights how the proposed KTSSAF addresses current limitations.

Several scholars have acknowledged that the failure to perform a KT and assess the KT level within the ESP arrangements leads to an unsuccessful ESP [2], [19], [21]. This study will comprehensively review relevant literature on KT within the ESPs to identify the current KT assessment gap within the ESP phases and categorize the KT success assessment factors within the different phases of ESPs to develop a KT self-assessment framework for ESP KT self-assessment success.

B. Definition of Knowledge Transfer

The KT is defined in this study as the process of sharing, disseminating, and applying knowledge in the ESP, both implicit (tacit) (experience-based, non-codified knowledge), similar conclusions were drawn by [22], [23] in contrast, explicit (documented, codified knowledge, as argued by [2], [24] between stakeholders, being part of the ESP in different phases before, during and after the implementation of the ESP in line with the findings of [25], [26], [27]. As observed in the work of [19] effective KT ensures that knowledge is transferred across different project phases, enabling project teams to make intelligent decisions, enhance information system implementation, increase efficiency, and reduce risks associated with the knowledge transfer gap, as previously reported by [2], [28], [29], [30], [31].

1) Scope of knowledge transfer: The scope of the knowledge transfer or knowledge sharing in this study is concentrated on Enterprise System Projects (ESP), focusing on the following features:

2) Included aspects of knowledge transfer:

a) Types of knowledge:

- Explicit Knowledge

(e.g., documented procedures, manuals, best practices, training materials) as defined by [2], [24], [32].

- Implicit (Tacit) Knowledge

(e.g., expertise, skills, lessons learned from experience, informal communication) as reported by [22], [23].

b) Stakeholders involved in KT:

- Project managers, implementation teams, end-users, IT specialists, and consultants according to [33], [34], [35], and [36].

c) Phases of ESP where KT is assessed:

- Pre-implementation, During Implementation, and Post-Implementation phases, as observed in the work of [8] [19].

d) Challenges and barriers to KT:

- Resistance to change [37] Lack of stakeholder engagement [38] high employee turnover [39],

keeping supporting contracts, and poor documentation as identified by [14], [19], [40].

e) KT Assessment Kit:

- It encompasses a collection of instruments and questions developed to facilitate the practical application of assessing KT success level using the proposed framework.

3) Excluded Aspects of Knowledge Transfer:

a) General Knowledge Management (KM):

- The study focuses on knowledge transfer, not the broader concept of knowledge management, which includes creation, storage, and retrieval beyond ESP scope.

b) KT Mechanisms:

- Formal methods: documentation, training, workshops, lessons learned reports.
- Informal methods: mentorship, peer learning, discussions, hands-on experience.

c) Non-Enterprise System Knowledge Transfer:

- KT related to general business operations, non-IT projects, or unrelated industries is outside the scope.

d) Technological Aspects Not Related to KT:

- While ESP implementation involves technology, this study does not focus on the technical development of enterprise systems but on assessing the knowledge transfer level in the ESP.

e) Industry-Specific Knowledge:

- The study aims to provide a general KT framework for ESPs rather than tailoring it to a specific industry.

This research aims to bridge the knowledge transfer gaps by developing a practical and structured framework for assessing and improving KT effectiveness in Enterprise System Projects (ESP).

C. Theoretical Frameworks and Limitations

1) IS Success model: The success of the Information System (IS) followed the foundational theories used to assess multifaceted changes, as previously reported by [41] In the IS. DeLone and McLean's model is extensively used to assess the IS success as observed in the work of [6], [42], [43]. The IS Success Model according to [6] remains one of the most cited frameworks in information systems research. It defines success through six interdependent dimensions: information quality, system quality, service quality, use, user satisfaction, and net benefits [2], [44]. While valuable for post-implementation evaluation, it offers limited insights into the dynamic process of KT throughout ESP phases. Furthermore, it treats knowledge transfer as an outcome or side-effect rather than a process requiring direct assessment, as identified by [45]. Scholars, [45] highlighted that the IS Success model development went through many improvement processes, starting with the Delone and McLean's IS success model [46], the adapted D and M technology acceptance model TAM of Davis, the IS success model of Seddon, and other IS success models. The IS Success Theory was utilized to develop the study framework.

2) Knowledge management lifecycle: Knowledge Management (KM) Lifecycle provides a comprehensive view of how organizations create, store, share, and apply knowledge. While it emphasizes KT as a lifecycle phase as defined by [31], it lacks a project-based perspective, making it less actionable for implementation-specific challenges in ESPs, as argued by [47]. Its theoretical orientation also limits its practical deployment for real-time KT measurement or forecasting, building on the work of [48].

3) Project Management Process Groups (PMPG): The PMBOK Guide outlines five Project Management Process Groups—initiating, planning, executing, monitoring, and closing, according to [49]—which provides a temporal and functional structure for managing ESPs. Although this model supports project phasing, it does not incorporate KT explicitly, nor does it offer tools or metrics to assess the quality of knowledge transfer within each phase as identified by [50]. Its focus remains on processes and deliverables, rather than learning or knowledge exchange.

D. Knowledge Transfer in Enterprise System Gap

Despite the centrality of project-based organizations (PBOs) in delivering enterprise systems (ES), scholars have identified critical deficiencies in how KT is addressed within IT project management, as argued by [13]. A significant concern is the absence of a structured framework to assess KT quality during project execution, as well as the lack of mechanisms to evaluate KT success. Building on the work of [51], this deficiency contributes to significant project risks, including delays, cost overruns, and compromised system quality, factors that ultimately impair organizational performance. Empirical findings reveal that resistance or failure to share knowledge among ES stakeholders adversely affects project outcomes. Although KT is an essential element within the broader knowledge management (KM) life cycle, it remains underdeveloped relative to other KM processes, which include knowledge creation, saving or storing, and application [52]. As such, there is a critical need to identify the determinants of successful KT within ES contexts and to establish robust evaluative models capable of detecting and mitigating KT challenges in real-time. Prior studies emphasize the importance of feedback-driven KT assessment tools, particularly those that operate before, during, and after ES implementation, to ensure effective system design and management, as highlighted by [53]—collaborative efforts between researchers and practitioners. However, findings by [54] further demonstrate the potential of performance metrics to quantify KM efficacy, thereby strengthening the strategic role of KT in ERP success. KT's strategic value has become increasingly prominent in modern, agile enterprises, where information is a key competitive asset; these findings corroborate those of [27] and [41]. However, findings by [55], [56], [57], [58] argue that the persistent recurrence of avoidable errors across ES projects stemming from inadequate KT practices highlights the urgent

need for more systematic approaches. This inefficiency often leads to redundant efforts, increased costs, and suboptimal project performance. Conceptually, KT within ES projects entails exchanging tacit and explicit knowledge among team members to facilitate problem-solving, innovation, and process alignment in line with the findings of [8], [59], [60]. Nevertheless, studies show limited assessment to verify whether KT processes are effectively executed during the implementation phase, before the system goes live, as noted by [61]. Addressing this gap is essential for enhancing ES project outcomes and should be a key focus of future research and practice.

E. Comparative Evaluation of KT Frameworks

The comparative evaluation in Table I systematically reviews seven established KT frameworks in the context of ESP, emphasizing their alignment with key success features such as real-time assessment, quality feedback mechanisms, KM lifecycle integration, ESP customization, empirical validation, and adoption of the IS Success Model.

While foundational models such as [62] and [56] laid early groundwork by identifying core KT success factors, they lack mechanisms for continuous monitoring and do not adopt the IS Success Model, limiting their effectiveness in dynamic and large-scale enterprise environments. Similarly, although [58] the model includes some performance evaluation, but does not offer full integration with real-time assessment or formal IS success criteria.

On the other hand, more recent approaches like [31] [53] stand out for incorporating performance metrics, feedback loops, and partial alignment with the IS Success Model. These features make them more adaptable to ongoing evaluation needs within ESPs.

The KTSSAF (Knowledge Transfer Success and Assessment Framework) offers significant advancement over these models by addressing many of their limitations. Its key strengths include:

- Real-Time Assessment Capability: KTSSAF includes mechanisms to evaluate KT performance at different stages of the ES lifecycle—before, during, and after implementation—allowing organizations to detect issues early.
- Feedback-Driven Quality Control: It features integrated feedback loops to improve KT activities and close the performance gap continuously.
- Alignment with IS Success Model: KTSSAF adopts the DeLone and McLean IS Success Model, enabling measurement of KT impacts on system quality, user satisfaction, and organizational benefits.
- ESP-Specific Customization: Unlike general KM frameworks, KTSSAF is explicitly tailored to enterprise systems, considering the unique challenges and dynamics of ERP implementations.
- Diagnostic and Prescriptive Utility: Beyond just assessment, KTSSAF provides structured guidance on addressing identified KT weaknesses, thus supporting proactive project management.

Frameworks like [27] and [63] contribute valuable insights, particularly in agile and collaborative contexts, but they lack formal assessment components and IS integration—gaps that KTSSAF directly addresses.

In summary, the evaluation underscores the fragmented nature of existing KT frameworks in ESPs, particularly in continuous assessment and strategic alignment. The KTSSAF distinguishes itself by offering a holistic, empirically grounded, and actionable approach to KT management—bridging critical gaps and supporting more successful, knowledge-driven ES project outcomes. Its adoption can help organizations mitigate costly knowledge-related failures and enhance the long-term value of enterprise system investments.

TABLE I. KT FRAMEWORKS COMPARISON

KT Framework / Model	KT Success Factors	Real Time Assessment	Quality feedback mechanism	Alignment with the KM lifecycle	Customization for ESP context	Empirical Validation	IS Success Model Adoption
Bhatt KT Model	✓	✗	✗	✓	✗	✓	✗
Desouza & Evaristo KT Strategy	✓	✗	✗	✓	✓	✓	✗
Landaeta's KT Performance Model	✓	✗	✓	✓	✓	✓	✗
Parry & Graves KT Metrics Approach	✓	✓	✓	✓	✓	✓	✓
Samiei & Habibi KM-Evaluation Model	✓	✓	✓	✓	✓	✓	
Shaqrah & Maliki Agile KT Framework	✓	✓	✗	✓	✓	✗	✗
Gomes et al. Collaborative KT Model	✓	✓	✗	✓	✓	✗	✗
Proposed KTSSAF	✓	✓	✓	✓	✓	✓	✓

TABLE II. KT MODEL COMPARISON

Model / Study	ESP Phases & Sub-Phases	ESP Roles	ESP Knowledge Types	ESP Knowledge Clusters	KT Sub-Clusters	KT Assessment Kit
IS Success Model	✗	✗	✗	✗	✗	✓
KM Lifecycle	✗	✗	✓	✗	✗	✗
PMPG	✓	✓	✓	✗	✗	✗
KTSSAF (Proposed Model)	✓	✓	✓	✓	✓	✓

Legend: ✓ = Feature Present ✗ = Feature Not Present.

The following comparative table offers a critical assessment of the most relevant KT-related models, comparing them on criteria such as focus, validation, phase relevance, and applicability to ESPs. Table II illustrates the unique value proposition of KTSSAF. While traditional models provide foundational guidance, KTSSAF extends functionality with phase-specific metrics and assessment instruments, ensuring comprehensive KT evaluation across ESPs.

This provides a focused comparison of KT frameworks based on six ESP-specific dimensions critical for effective KT in ESPs. The analysis shows that most existing frameworks, including the IS Success Model and KM Lifecycle, fail to address the practical complexities of ESP environments. While the PMPG framework covers project phases, roles, and knowledge types, it lacks the depth required for managing knowledge clusters and sub-clusters.

In contrast, the KTSSAF (proposed framework) demonstrates comprehensive coverage across all six dimensions. It uniquely incorporates ESP phases, roles, and macro-level knowledge clusters and micro-level sub-clusters, reflecting the real-world structure of enterprise systems. Moreover, KTSSAF integrates a KT assessment kit, allowing for continuous monitoring and evaluation of knowledge flow—something absent in other models.

This broad coverage enhances KTSSAF's practical relevance and diagnostic capability, positioning it as a robust tool for improving KT effectiveness and minimizing project risks in complex ESP implementations. Its alignment with operational realities makes it especially suitable for dynamic, role-based, and knowledge-intensive enterprise settings.

KTSSAF, as illustrated in Table II, is the only model in this comparison that explicitly integrates knowledge clusters and sub-clusters, enabling granular evaluation of KT quality across different types of knowledge: technological, organizational, individual, and procedural.

F. Emerging Research on KT and ESPs

Recent contributions have attempted to narrow the gap in KT understanding within ESPs. The scholars [20] conducted a systematic review of knowledge integration strategies in ERP projects, focusing primarily on outcomes rather than ongoing assessment. Similarly, scholars in [13] proposed a set of KT performance indicators, yet their practical deployment remains untested. These studies affirm the increasing scholarly interest in KT metrics but also reflect a lack of operational frameworks that guide practitioners through implementation.

Furthermore, technologies such as AI, augmented reality, and blockchain are being explored as future enablers of KT, especially in capturing and transferring tacit knowledge, as noted by [50] advocate for integrated KT feedback systems to support real-time decision-making in digital transformation projects. KTSSAF aligns with this trend by offering modular assessment kits that could be integrated with project dashboards or knowledge systems.

G. The Critical Role of Tacit Knowledge

Tacit knowledge, though inherently intangible and informally exchanged, plays a foundational role in the success of ESP. It encompasses personal insights, experiential learning, problem-solving capabilities, and strategic intuition, often transmitted through interpersonal communication rather than formal documentation, as identified by [64], [5]. Despite its significance, most KT frameworks neglect or insufficiently account for tacit knowledge. The KTSSAF framework addresses this gap by embedding tools that assess mentorship and peer coaching, simulation-based learning, storytelling, knowledge mapping, and unstructured communication during project implementation. These elements make KTSSAF especially effective in complex ESP environments, where informal knowledge sharing has a substantial impact on system adoption and operational resilience.

A notable innovation within KTSSAF is its structured classification of knowledge into distinct clusters and sub-clusters, providing greater analytical granularity than traditional models. These include Organizational Knowledge (e.g., governance structures and strategic alignment), People Knowledge (e.g., user roles, leadership dynamics), Technology Knowledge (e.g., system architecture and usability), Process Knowledge (e.g., workflow integration and regulatory compliance), and Transfer Mechanisms (e.g., formal training sessions and informal exchanges). Each cluster is evaluated across different phases of the ESP lifecycle using weighted metrics, resulting in a multi-dimensional assessment of KT effectiveness. This classification level offers a more nuanced and actionable understanding of KT dynamics. Furthermore, a visual representation of KTSSAF's capabilities reinforces its comprehensiveness and practical utility, positioning it as a robust tool for addressing the multifaceted challenges inherent in real-world enterprise system implementations.

III. METHODOLOGY

A. Research Design

This study adopts a qualitative constructivist approach as rooted in phenomenology by [65], [36], [66]. To explore how KT is experienced and perceived by experts within the context of ESP. The constructivist paradigm emphasizes that knowledge is co-constructed through interactions between the researcher

and participants, making it suitable for understanding KT's nuanced, context-dependent nature aligns with [67] [68].

As the chosen methodological tradition, phenomenology focuses on individuals' lived experiences and seeks to uncover how these experiences shape their understanding of complex organizational phenomena like KT outlined by [69], [70]. This aligns with the study's goal of developing the KTSSAF based on real-world insights.

B. Methodological Rationale

The rationale for using a qualitative, constructivist, and phenomenological design stems from the need to:

- Explore the subjective experiences of stakeholders involved in KT across ESP phases.
- Capture tacit knowledge and interpretive insights that cannot be quantified meaningfully through surveys or experimental methods were found in the work of [64].
- Enable a bottom-up development of the KTSSAF through emergent insights from expert narratives, rather than imposing a top-down model.

This design facilitates the systematic exploration and validation of the KTSSAF by grounding it in practical realities, bridging the gap between theory and implementation [7].

C. Participant Sampling and Selection

A purposive sampling strategy was adopted to ensure participants possessed specialized knowledge relevant to the research focus [71]. The study engaged seven expert practitioners from varied ESP backgrounds, including roles such as project managers, ERP consultants, solution architects, and change management leads.

Inclusion criteria included:

1) Minimum eight years of experience in managing or supporting ESPs.
2) Direct involvement in at least two project phases (pre-, during-, post-implementation).
3) Experience working in large or cross-functional project teams.
4) Ability and willingness to articulate reflective insights through in-depth interviews.

This sampling approach ensured rich, diverse, and relevant data aligned with the phenomenological focus on lived experience.

D. Data Collection Procedures

The semi-structured interviews were employed as a data collection technique, a method well-regarded for eliciting deep, reflective insights in qualitative research. Methodologically, this follows [72]. This approach provided the flexibility to explore the unique experiences of each participant while maintaining consistency in addressing the research questions. Interviews were conducted through online meetings using Google Meet or Microsoft Teams, depending on participant availability and geographic location. Each session lasted between 45 and 75 minutes.

In our data collection, we focused on recording all interviews [73] with prior informed consent, and subsequently transcribed verbatim for qualitative analysis. This ensured an accurate and comprehensive analysis of the expert feedback.

To ensure alignment with the study's three research questions, the interview protocol was carefully constructed to elicit detailed narratives related to the phenomenon under investigation:

For RQ1 (How do ESP stakeholders perceive and experience the effectiveness of knowledge transfer across different phases of enterprise system implementation?), participants were asked to reflect on their knowledge-sharing experiences during the pre-implementation, implementation, and post-implementation phases of ESPs. Questions probed their perceptions of what worked, what failed, and how knowledge flowed—or was unable to flow—across project milestones.

For RQ2 (How can a comprehensive self-assessment framework be designed to evaluate and improve knowledge transfer practices in ESPs?), participants were introduced to a preliminary version of the KT Success Self-Assessment Framework (KTSSAF). They were asked to provide feedback on the framework components' relevance, clarity, and usability. This ensured that the framework's refinement was grounded in practitioner experience.

Topics explored in the interview included, but were not limited to:

- Experiences with knowledge handover across the ESP lifecycle.
- Challenges associated with tacit knowledge sharing.
- Observed organizational, technical, and interpersonal factors impacting KT.
- Evaluation of and feedback on the proposed KTSSAF model.

Member checking was conducted to enhance the credibility and trustworthiness of the findings. Transcripts were returned to participants for validation and correction, ensuring their meanings and perspectives were accurately captured in line with the findings of [74]. This structured yet flexible data collection procedure ensured rich, detailed, and directly relevant data to answer each research question effectively, in line with the study's qualitative constructivist methodology.

E. Data Analysis

Data were analyzed using qualitative content analysis, chosen for its suitability in systematically organizing and interpreting textual data as rooted in [75]. The process followed an inductive logic, consistent with constructivist inquiry.

Step-by-step coding process:

Familiarization – Thorough reading of transcripts to understand context.

Open Coding – Labelling key concepts, phrases, and meanings line-by-line.

Axial Coding – Grouping related codes into broader categories (e.g., "Consultant Credibility", "Knowledge Gaps").

Thematic Structuring – Synthesizing categories into overarching themes relevant to KT effectiveness.

Mapping to ESP Phases – Organizing themes by project phase (pre-, during-, post-implementation) to enhance the framework's utility.

Emergent themes were triangulated with literature to enhance theoretical grounding and confirm conceptual coverage of the KTSSAF.

F. Methodological Foundations and Empirical Rigour

The development of KTSSAF followed a qualitative, constructivist research approach involving in-depth interviews following the model proposed by [76], [77], [78] with subject matter experts and practitioners from diverse ESP contexts. This methodology enabled the identification of context-specific KT assessment success factors and ensured that the framework was grounded in real-world ESP dynamics. Data analysis was conducted using content analysis according to [79], allowing for the systematic categorization of KT Success factors in ESP, the development of the proposed framework, and the validation of the proposed framework.

The model was validated through expert feedback, pilot testing, and iterative refinement. Table III summarizes the research method applied in this study. Participants acknowledged the model's relevance, clarity, and adaptability across different industries and project scales.

The ESPs expert appreciated its ability to provide actionable insights, such as identifying weak knowledge links in specific project phases or stakeholder roles or specific knowledge types, in specific impacted outcomes of the successful knowledge transfer, including individual impact, organization impact, information quality, and system quality.

TABLE III. APPLIED RESEARCH METHOD

Aspect	Selected for Study	Reason for selection
Research Questions	Exploratory	To explore the literature on KT in ESP and investigate the perception and experience of the effectiveness of KT across different phases of ESP.
Research Approaches	Qualitative	To gather in-depth insights from experts and understand the context and nuances of KT within ESP projects.
Data collection methods	Semi-Structured Interviews	Allows flexibility to explore specific expert opinions while ensuring coverage of predefined themes.
Data Analysis Techniques	Content Analysis	Enables a systematic and objective categorization of qualitative data, allowing identification and quantification of factors influencing KT success in ESP.

IV. FINDINGS

This study utilize a qualitative, constructivist approach to examine the critical dimensions of KT within ESPs. Through rigorous content analysis of expert interviews, key experiential themes and insights were synthesized, addressing the two research questions and contributing to validating and refining the KTSSAF

A. KTSSAF – Bridging the Gaps

The KTSSAF developed in this study offers an integrative solution. It combines elements of IS Success Theory, KM lifecycle, and PMPG while introducing KT-specific metrics and instruments to assess knowledge flow across ESP phases. KTSSAF includes a validated assessment kit, a scoring model, and customizable instruments supporting explicit and tacit knowledge evaluation. It is empirically grounded through interviews and pilot studies, ensuring theoretical robustness and practical usability. Fig. 1 illustrates the proposed KTSSAF visualization.

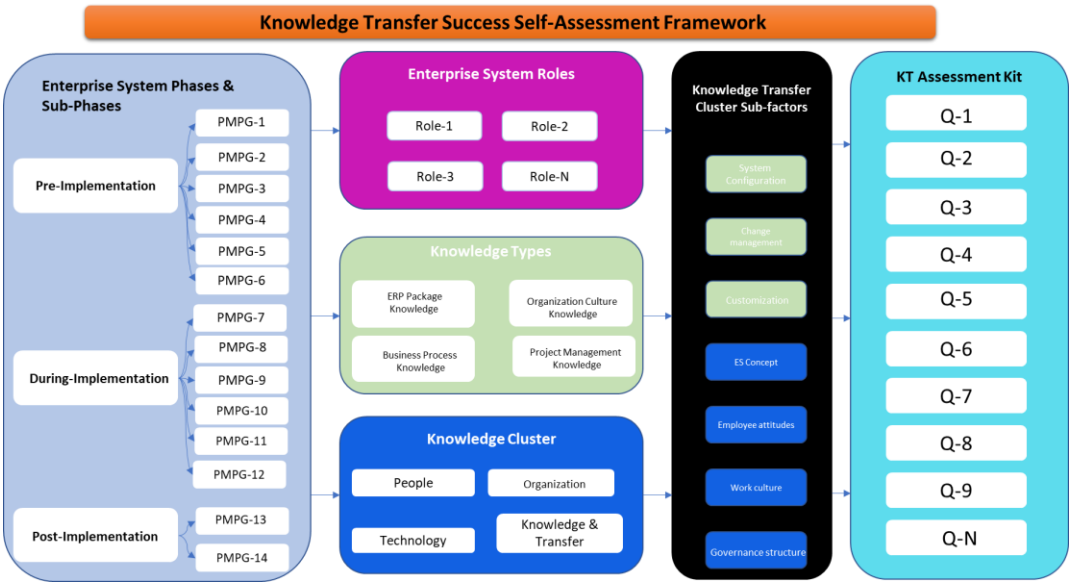

Fig. 1. Knowledge transfer success self-assessment framework- KTSSAF.

B. Emergent Themes from Expert Interviews

The semi-structured interviews with seven ESP professionals, each possessing over eight years of relevant experience, generated a rich dataset. Using a five-point Likert scale and interpretive thematic analysis, three major thematic clusters emerged:

1) Confirmation of theoretical KT success factors: Experts consistently affirmed the relevance of nine critical KT success factors initially identified in the literature review. These included:

Knowledge Sharing Culture, Knowledge Content Quality, Consulting Expertise, Management Support, Consultant Credibility, Absorptive Capacity, Project Owner Leadership, Consultant Ability, and Incentives.

Except for a single neutral response regarding incentives, there was a unanimous agreement on the importance of these factors. This validates the theoretical foundation of KT in ESPs and supports their integration into the proposed KTSSAF.

"Leadership and consultant credibility make or break the knowledge transition process." (Interviewee 3, IT Consultant).

2) Validation of KTSSAF independent variables: Experts strongly endorsed the independent variables embedded within the KTSSAF, which include:

- The ESP phases (pre-, during, and post-implementation)
- Project Management Process Groups (PMPG)
- Role responsibilities of ESP stakeholders

Four types of knowledge: business, project management, organizational culture, and technology.

The Knowledge Clusters: Knowledge and Transfer, People, Technology, and Organization. Participants confirmed that these dimensions comprehensively capture the complexity of KT within ESPs, facilitating a structured, contextualized assessment of success levels. "Each knowledge cluster brings a different layer of understanding — without this multidimensionality, we'd be blind to root causes of KT failure." (Interviewee 6, Project Manager)

C. Evaluation of KTSSAF Structure and Predictive Utility

Experts evaluated the KTSSAF across five analytical dimensions: variable weight, structure, clarity, consistency, and diagnostic utility. Feedback affirmed the framework's robust design and its capacity to:

- Predict KT success across PMPGs and implementation phases.
- Evaluate KT contributions by role and scenario.
- Maintain a clear, consistent structure and interpretability.

Moreover, the model's adaptability, configurability, and modularity were emphasized, with participants acknowledging its reusability across varied ESP contexts. "The model is precise, modular, and predictive — it goes beyond theory and meets practice head-on." (Interviewee 2, Solution Architect).

D. Conceptual Framework Integration

The findings affirm the constructivist underpinnings of the KTSSAF. They reflect a high alignment between expert experiential narratives and the conceptual framework developed through prior literature and theoretical synthesis. The study captured the experiential essence of KT processes in ESPs, revealing how actors interpret, navigate, and evaluate KT success in dynamic project environments.

Emergent conceptual frameworks were substantiated by interpretive feedback, highlighting the dynamic interactions among ESP phases, knowledge types, and stakeholder roles. Experts emphasized that KT is not a static event but an evolving process that requires contextual awareness, iterative assessment, and leadership engagement at all stages of the ESP lifecycle.

E. Contributions to Practice and Theory

This empirical inquiry makes several key contributions to both theory and practice. It confirms the validity of theoretical constructs previously derived from literature synthesis, thereby reinforcing the conceptual foundation of the study. Expert feedback further refined the framework, enhancing its practical applicability in real-world enterprise system projects. In addition, the study establishes KTSSAF as a diagnostic and planning tool that can support enterprise system project managers and consultants in assessing and managing knowledge transfer success. The research advances scholarly understanding and practical usability by codifying tacit insights into an operational framework. The interpretive, thematic analysis highlights the multi-dimensional and actor-centered nature of knowledge transfer within enterprise system projects, underscoring the value of KTSSAF as an evidence-based instrument for improving knowledge management practices. KTSSAF offers multiple contributions to both academic literature and industry practice. Theoretically, it advances the discourse on KT by shifting focus from knowledge creation and storage to measurable and actionable KT assessment. It also enriches understanding of KT dynamics in project-based settings, particularly within the underexplored ESP domain. Practically, KTSSAF equips project managers, knowledge officers, and organizational leaders with a structured tool to forecast KT success, mitigate knowledge risks, and enhance project outcomes. It also facilitates longitudinal learning, enabling organizations to retain and reuse critical knowledge across successive ESP implementations—a key determinant of digital resilience and competitive advantage, as noted by [80].

Moreover, the KTSSAF framework aligns with emerging trends in digital project management, where predictive analytics, continuous learning, and evidence-based interventions are becoming the norm. By integrating KT metrics into the broader ESP lifecycle, KTSSAF bridges the gap between theoretical aspirations and practical execution.

V. Discussion

This study, guided by two core research questions, explored the KT assessment success factors and conceptual underpinnings of KT in ESP. Through a constructivist, qualitative inquiry employing semi-structured interviews with ESP experts, this research provides a grounded assessment of KT practices, culminating in validating the KTSSAF. This

section discusses the findings about the research questions, previous scholarship, and broader implications for the field.

A. Addressing the Research Questions

RQ1: How do ESP stakeholders perceive and experience the effectiveness of knowledge transfer across different phases of enterprise system implementation?

Our findings reveal that stakeholder perceptions are deeply influenced by contextual and role-based factors that span the ESP lifecycle. Experts affirmed that KT effectiveness varies considerably across the pre-implementation, implementation, and post-implementation phases. [81]. These phases are further shaped by stakeholder roles, project structures, and knowledge types, confirming assertions by [54] that successful KT in ESPs requires tailoring strategies to temporal and contextual project dimensions. Respondents emphasized the necessity of sustained management support and consultant credibility across all phases—elements that enhance KT effectiveness through trust, relevance, and structure. These insights extend prior literature by providing empirical validation that KT is not a singular activity but a phased, adaptive process requiring distinct engagement and measurement strategies throughout the ESP lifecycle, as noted by [82].

RQ2: How can a comprehensive self-assessment framework be designed to evaluate and improve knowledge transfer practices in ESPs?

It is evident from our results that the KTSSAF was confirmed through expert validation as a valuable, structured tool for assessing KT success. The framework's inclusion of ESP phases, project roles, PMPGs, knowledge types, and knowledge clusters enables a multidimensional understanding of KT performance across scenarios. This contribution moves beyond the limitations of one-size-fits-all models by offering a configurable, modular, and predictive self-assessment mechanism, a novelty not extensively explored in prior KT research. While earlier studies (e.g., [83]). The KTSSAF offers typologies and guidelines, providing an operational and diagnostic instrument that stakeholders can apply across ESP contexts.

B. Integration with Literature and Theoretical Contributions

Grounded in a constructivist, phenomenological paradigm and guided by content analysis, this study demonstrates methodological rigor and epistemological coherence. It contributes to the expanding body of qualitative KT research, complementing prior studies that advocate for interpretive approaches in information systems and organizational knowledge research in line with the findings of [84], [85]. Additionally, it responds to longstanding calls within the knowledge management (KM) literature for deeper, context-sensitive explorations of how knowledge is created, shared, and applied in practice as observed in the work of [86]. Our analysis highlights three key theoretical contributions. First, it recontextualizes general KT theories by situating them within ESP's temporally bounded and role-driven environment, enhancing their relevance and applicability. Second, it expands the scope of KT evaluation by shifting the analytical lens from outcome-based project success metrics in the knowledge-centered assessment across multiple ESP phases. Third, it advances the operationalization of tacit knowledge by embedding constructs such as absorptive capacity and consultant credibility into the KTSSAF framework, addressing a notable gap in practical KM models and contributing to more holistic assessments of knowledge transfer effectiveness.

C. New Understandings and Practical Implications

It is evident from our results that several novel insights were illuminated. Notably, it underscores how the sequence and timing of KT activities, not merely their content or structure, critically influence outcomes. Identifying PMPGs as dynamic enablers for phased KT assessments represents a refinement in understanding how knowledge and process maturity evolve together during ESPs. Practically, the KTSSAF offers organizations a self-assessment toolkit to monitor and refine KT efforts in real time. The KTSSAF configurability and modularity make it applicable across diverse enterprise contexts—from public universities to multinational corporations—enhancing its strategic relevance.

D. Advantages of the Proposed Method (KTSSAF)

The proposed KTSSAF offers several key advantages over existing models in the field of knowledge transfer within enterprise system projects. First, unlike many traditional KT models that focus generically on knowledge sharing practices, KTSSAF is specifically tailored to the structured phases of ESPs, aligning with the Project Management Process Groups (PMPG) to enable granular, phase-specific assessment of KT effectiveness. Second, it is grounded in Information Systems (IS) Success Theory, which provides a robust theoretical foundation that links KT outcomes directly to system success metrics such as user satisfaction, system use, and organizational impact.

Furthermore, KTSSAF adopts a qualitative constructivist approach, integrating insights from domain experts and practical field data, which ensures high contextual relevance and real-world applicability—something often lacking in quantitatively rigid or one-size-fits-all models. The inclusion of a scoring mechanism and customizable assessment kit distinguishes KTSSAF by offering actionable diagnostics and predictive insights for stakeholders, enabling organizations to proactively identify KT gaps and implement targeted improvements. Finally, in our analysis, the framework's empirical validation through expert reviews and pilot applications demonstrates its practical utility, repeatability, and adaptability across different enterprise contexts—advantages not commonly found in more theoretical or static KT models.

E. Limitations and Future Research Directions

Despite the KTSSAF contributions, the purposive sample, though composed of highly experienced ESP experts, may limit contextually bound information and may not capture all regional or industry-specific nuances.

We acknowledge that this study is limited by generalizability. The interviews, while deep and revealing future research that should:

- Expand the sample base across industries and geographic regions to test KTSSAF's generalizability.

- Explore longitudinal application of KTSSAF to monitor KT over time and refine the framework based on evolving practices.
- Develop automated assessment tools incorporating the KTSSAF for real-time feedback and benchmarking.
- Investigate how organizational learning loops emerge post-assessment and how KTSSAF results can inform continuous improvement in enterprise environments.

This study advances the theoretical, empirical, and practical understanding of knowledge transfer in ESPs. Offering a validated, multidimensional assessment framework rooted in expert experiences and grounded theory lays the foundation for more responsive, contextual, and effective KT strategies in complex organizational transformations.

VI. Conclusion

The academic and practitioner domains of ESP offered a timely and significant contribution using the developed KTSSAF. While the ESPs continue to increase in scale and complexity, the evaluation of the KT management and effective KT within the ESPs lifecycle is classified as a strategic challenge. The proposed KTSSAF addresses this need by operationalising KT assessment into a structured, phase-sensitive, modular framework aligned with the IS theory, KM, PMP, and PMPGs.

By integrating theoretical insights from IS Success Theory, KM, and PMP, KTSSAF ensures that KT assessment is methodologically sound and aligned with broader ESP outcomes such as system quality, user satisfaction, information quality, organization performance foster, and knowledge sustainability. Incorporating knowledge clusters—organizational, people, technology, process, and transfer mechanisms—enables a granular and multidimensional understanding of how knowledge flows within ESPs. We conclude that the framework advances the field by explicitly recognizing and assessing tacit knowledge, long considered one of the most challenging dimensions of KT.

Furthermore, our results provide evidence that KTSSAF's modular assessment kits, diagnostic indicators, and feedback mechanisms empower organizations to proactively identify KT gaps and take corrective action during ESPs implementation, rather than after project implementation. Its customizability ensures relevance across different industries, organizational sizes, and technological environments.

The framework has demonstrated practical utility through pilot testing and empirical validation, leading to measurable improvements in KT performance. As a result, KTSSAF transforms KT from an abstract managerial concern into a strategic, measurable, and actionable component of enterprise system success. Compared to existing models, KTSSAF provides a more practical, phase-specific, and empirically validated approach to evaluating KT in ESPs.

As organizations navigate digital transformation, KTSSAF offers a roadmap for ensuring that knowledge is not a bottleneck but a key enabler of ESP implementation success, system adoption, and sustained value creation. Future research can extend the framework's application across cross-cultural contexts, integrate it with AI-driven knowledge systems, or tailor it for agile and hybrid ESP methodologies, further reinforcing its relevance in dynamic, knowledge-intensive environments.

Acknowledgment

I gratefully acknowledge all of those whose efforts and support made this work possible, and special thanks goes to the ESP experts who shared their insights during the interview sessions.

Disclosure and Conflict of Interest

The author declares that there are no conflicts of interest in this research. In addition, there are no financial interests or competing affiliations that could have influenced the study's design, execution, or findings. This manuscript is the author's original work and has not been previously published or submitted for review to any other journal or conference.

Investigating Space-Time Dynamics in Live Memory Forensics Using Hybrid Transformer Approaches

Sarishma Dangi[1], Kamal Ghanshala[2], Sachin Sharma[3]
Department of Computer Science and Engineering, GraphicEra Deemed to be University, Dehradun, India[1, 2]
Amity School of Engineering and Technology, Amity University Punjab, Mohali, India[3]

***Abstract*—Live memory forensics plays a critical role in digital investigations by analyzing volatile memory to detect system anomalies such as malware and unauthorized process activities. Traditional approaches often fall short in modelling the evolving nature of live memory. This study presents a novel Hybrid Space-Time Transformer Architecture combining Swin Transformer for localized spatial feature extraction and Longformer for capturing long-term temporal dependencies. By integrating windowed and sliding attention mechanisms, the proposed method enables precise detection of anomalies such as malware injection and process hijacking. Evaluated on benchmark datasets, the model achieved an accuracy of 95%, F1-score of 0.94, outperforming conventional deep learning and transformer-based approaches. Our work contributes a scalable, interpretable, and highly accurate model for enhancing live memory forensic workflows.**

***Keywords*—Live memory forensics; swin transformer; longformer transformers; memory acquisition; anomaly detection**

I. Introduction

Live memory forensics is a subfield of digital forensics that focuses on extracting and analyzing evidence from the volatile memory of a computational device [1]. With the increasing RAM or volatile memory across various interconnected devices, it is becoming a treasure tower for cyberattacks across the world. Volatile memory is transient in nature, i.e. the contents are lost once the system is powered down. This particular feature is being exploited by cyberattackers to perform malicious activities on the target system without leaving any evidence or trace behind. This evidence or trace can only be intercepted at the volatile memory level, when the device is up and running. Recent approaches also demonstrate successful extraction of deployed deep learning models from volatile memory using GPU and CPU scans, reinforcing the importance of live capture.

Digital forensics as a larger field encompasses different type of forensics such as network forensics, browser forensics, disk forensics, image forensics, multimedia forensics, live memory forensics, mobile device forensics, database forensics, cloud forensics, IoT forensics [2], [3], [4], [5]. Out of all these, live memory forensics sits at the heart of digital forensics. Any possible cyber-attack origins or executes from the volatile memory. Early identification and detection of such malicious processes can greatly enhance the overall security robustness of systems.

Globally, 72.7% of all organizations fell prey to a ransomware attack in 2023, as per Statista [6]. The average cost of a ransomware attack was $4.54M and the average ransom payment per organization totaled around $812,360, as per Egress [7]. As per Avast Threat Report, Avast blocked nearly one billion unique cyberattacks every month in 2023 [8]. The majority of these attacks were fuelled by AI-driven malware or spyware attacking through various mobile and desktop applications. Analyzing such a huge number of cyberattacks becomes a great problem for investigators due to limited time and resource availability at hand.

Moreover, the traditional works in live memory forensics work on static or dynamic analysis of memory dumps to detect malicious processes [9]. Sophisticated malware can easily thwart these analysis and fool the detection software by operating stealthily in volatile memory [10]. Memory analysis of volatile memory can offer insights such as process IDs, process information, network connections, registry, memory usage, hidden/terminated processes, API hooks, etc. Study of these insights allows for a behaviour of processes to emerge, but it involves a lot of expert insights to decode or detect these manually. Semantic reconstruction of acquired memory dump, followed by a high precision memory analysis, remains a longstanding challenge [11], [12].

Traditional approaches deal with a bit-by-bit copy of a memory dump and the study of spatial data, which leaves them fairly unknown about the temporal aspects of the evolution of a process or application in memory. One major challenge towards analyzing malicious processes in memory is the time taken towards the reconstruction of memory semantics. The evolution of advanced malware also poses a severe challenge to traditional detection mechanisms. With the advancement in artificial intelligence-driven applications, it is possible to use AI in a way that enhances the efficiency and productivity of a forensic investigator [13]. Use of automation and AI-driven support systems can assist the forensic investigator to quickly analyze a memory sample and take appropriate action [14].

In this work, an attempt towards fulfilling this goal is taken. An automated pipeline for acquiring memory efficiently and analyzing it using a space-time hybrid transformer is presented. The key contributions of this work are as follows:

- To present a novel hybrid architecture that uses Swin Transformers for spatial data analysis and Longformer for temporal API sequence modelling of memory dumps
- To present the mathematical model for integrating the spatial and temporal dimensions of analyzing a memory dump.

- Detecting malicious memory dump and anomalies on live systems by leveraging the proposed hybrid architecture
- Proposing selective imaging mechanism for storing malicious files in order to optimized the storage and information retrieval process for forensic investigators
- Comprehensive comparison with the state-of-the-art works in terms of accuracy, resource utilization, and storage optimization

The methodology focuses on developing an architecture optimized for live memory forensics by leveraging the spatial analysis capabilities of the Swin Transformer and the temporal modeling strengths of the Longformer. Research methodology is represented in Fig. 1.

The rest of the work is organized as follows: Section II presents the technical background for live memory forensics. Section III presents a discussion on the recent works in the area. Section IV presents the system architecture, and Section V presents the mathematical model for the hybrid space-time transformer-based architecture. Section VI presents the results of the proposed architecture. Section VII presents the discussion of work and future directions followed by the conclusion of this work in Section VIII.

II. Technical Background

Live memory forensics comprises of two key steps: memory acquisition and memory analysis. Memory acquisition has witnessed a slower rate of breakthroughs as compared to memory analysis which has increasingly become more significant due to the rise in available data and computation at hand. Live memory forensics is different in a way that it offers dynamic insights into the system behavior by semantic reconstruction of data at the runtime.

A. Memory Acquisition

Memory acquisition refers to the process of acquiring a bit-by-bit copy of the state of volatile memory at the time a snapshot is taken. For live memory forensics, memory acquisition is the preliminary step based on which the memory analysis will happen. Memory acquisition inherently suffers from a lot of challenges. Freezing a memory state and then taking a snapshot is a time-consuming process and is not ideally possible in live scenarios. Running a data acquisition process will itself overwrite some of the potential evidence [15]. This interferes with the data integrity of acquired memory dump. Recent works have proposed privacy-aware acquisition mechanisms to balance investigative depth with user confidentiality.

Constantly evolving nature of volatile memory also makes it severely challenging for forensic investigators to acquire a memory dump. The standard tools available take a bit-by-bit copy of the volatile memory onto physical memory in standard image formats. Commonly used tools for taking memory acquisition include LiME (Linux memory extractor), DumpIt, FTK Imager, Belkasoft Live RAM Capturer, Magnet RAM Capture, WinPmem and others [16]. These tools and their data dump formats are provided in Table I.

B. Challenges to Memory Acquisition

Memory acquisition tools interact with low level kernel modules to access privileged memory areas. Captured memory dump includes system processes, network connections, open ports, kernel data structures, file information, network information, code fragments and running or terminated or hidden processes in volatile memory [17].

TABLE I. Memory Acquisition Tools and their Data Dump Formats

Tool	Format
Memoryze by FireEye	.raw (proprietary)
MoonSols Windows Memory Toolkit	.raw, .dmp
Win32dd / Win64dd	.raw
LiveCloudKd	.dmp
AccessData FTK Memory Dump	.raw
Inception	.raw
SANS SIFT Workstation	.dmp, .vmsn
Pmem (part of Rekall)	AFF4, .raw
DumpIt	.raw
FTK Imager	.raw, E01
Belkasoft Live RAM Capturer	.raw (proprietary)
Magnet RAM Capture	.raw
Volatility Framework	.raw, .dmp, .hpak, .vmsn/.vmem
LiME (Linux Memory Extractor)	.lime
OSForensics Memory Capture	.raw
AVML (Azure Virtual Machine Memory Dump Tool)	.clf
WinPMEM (part of Rekall)	AFF4, .raw

The key challenges to memory acquisition are as follows:

1) Maintaining data integrity while taking a dump of a live system.

2) Anti-forensic techniques used by advanced attackers to hide the memory remains or traces.

3) Kernel-level permissions or administrator, or root access is required for taking a memory dump.

4) Sheer size of volatile memory and the perceived increase in future.

5) The complexity of operating environments.

6) Heterogeneity of acquired memory dump across various operating environments.

7) Handling inherent data loss while acquiring memory.

8) Maintaining low system impact during memory acquisition.

9) Maintaining chain of custody for admissibility in legal proceedings.

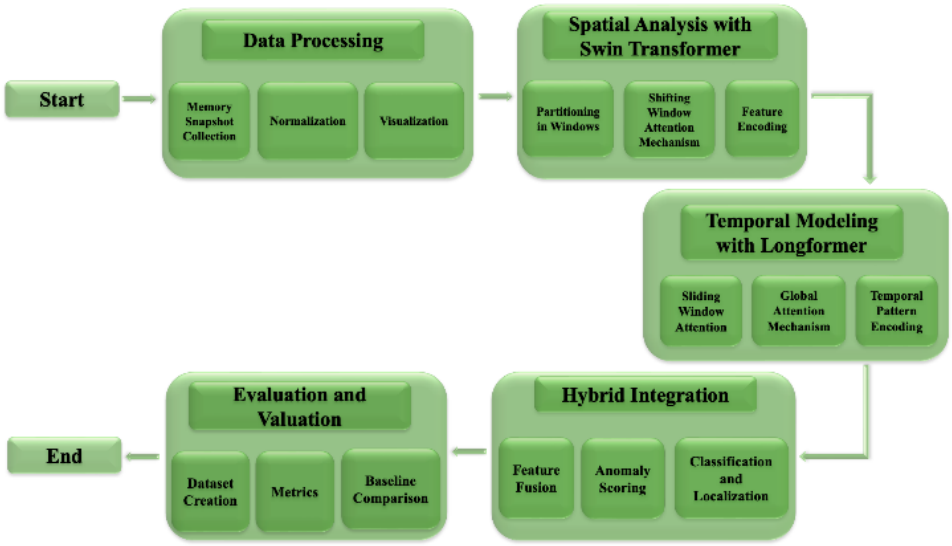

Fig. 1. Research methodology of the proposed work.

C. Available Datasets

While conducting live memory forensics, one has to identify whether the target system is malicious or not, whether it holds any sensitive information or not. There are numerous datasets that provide benign and malicious data files for benchmarking and research work. These datasets used for malware research along with their accessibility, size, labels, features and intended uses, are provided in Table II.

TABLE II. AVAILABLE DATASETS FOR MALWARE RESEARCH

Dataset Name	Accessibility & Size	Labels	Intended Use
BIG2015 (2015) [18]	Public & ~60,000 samples	Benign/Malicious	Static analysis benchmarking with opcode features
EMBER (2018) [19]	Public & 1.1M samples	Benign/Malicious/ Unknown	Machine learning and extensive research
SOREL-20M (2020) [20]	Public & 20M samples	Benign/Malicious/ Family Labels	Large-scale malware detection, includes family labels for clustering
Malicia (2013) [21]	~10,000 samples	Benign/Malicious	Malware family analysis using static and dynamic features
VirusShare (2012--2024) [22]	1M+ samples/Raw binaries	No Labels	Raw binary file collection for research, no annotations, constantly updated
Virus-MNIST (2020) [23]	50,000+ samples/Static images	Malware + Benign	Image-based dataset prominently used for benchmarking
BODMAS (2021) [24]	1,34,435 samples/Static analysis	Malware + Benign	Includes original binaries, prominent for research work

D. Methodology Workflow

The methodology workflow is depicted in Fig. 1 and explained as follows:

- Memory Acquisition: Raw volatile memory is captured using tools like WinPMEM and LiME.
- Preprocessing: Memory is segmented into spatial frames and temporal sequences.
- Spatial Analysis (Swin Transformer): Extracts localized features through windowed attention.
- Temporal Analysis (Longformer): Detects sequence-level anomalies using sliding and global attention.
- Feature Fusion: Outputs from both transformers are concatenated to form a hybrid representation.
- Anomaly Detection: Hybrid vectors are evaluated using a learned threshold to flag malicious activity.

E. Memory Analysis

Once the memory dump is acquired, it is then sent for memory analysis. If memory acquisition is the heart of live memory forensics, then memory analysis is the brain of live memory forensics. Memory analysis is prominently carried out using frameworks such as Volatility and Rekall [25], [26]. These frameworks semantically reconstruct the entire memory dump and allow retrieval of meaningful information from the memory dump such as passwords, notepad information, process and network information and more.

Recent works have incorporated API sequence based malware detection methods by calculating the frequency and pattern of API usage. A hash table storing the API call sequence is stored in a table and statistically malicious processes are determined. Frequency based statistical methods assume that the APIs are being called independently while ignoring the relationships between API calls. Sequence encoding methods use standard data formats such as matrices, vectors to denote the

API sequences. Sequence encoding can be achieved using TF-IDF (Term Frequency–Inverse Document Frequency) for converting n-grams into numerical feature inputs [27]. Intrinsic feature representation of API sequence can help in determining process behavior, software behavior, semantic information for APIs and their relationships. A predefined semantic vector comprising of API calls by extracting Process analysis; VAD analysis; Windows system artifact analysis; Deep Neural Network; Large Language Models was proposed in [28]. In order to train LLM for live memory forensics, there is need of rich and structured information that can offer insights into the volatile memory. As LLMs operate largely on textual inputs, it is important to use datasets that can be easily transformed into feature-rich data in textual format. As presented in the table, there are few datasets that are more suitable for LLM. Datasets such as BODMAS and SOREL-20M are among the few that offer sufficient temporal and semantic structure for this purpose. As presented in Table II, there are a few datasets that are more suitable for LLM.

F. Hybrid Space-Time Transformers

Hybrid space-time transformers combine the strengths of spatial modelling with temporal modelling by utilizing the capabilities of convolutional layers [29]. Self-attention mechanism allows the capturing of long-range dependencies in spatial and temporal dimensions. Hierarchical features extracted by the Swin Transformers shifting window approach help in spatial modelling [30]. Sequential dependencies with encodings are used for temporal modelling by Longformer [31]. Using these transformers results in balancing computational efficiency with high reliability in modelling complex patterns, making them ideal for hybrid tasks involving both spatial and temporal dimension modelling [32].

III. Literature Review

Live memory forensics is a critical process in the pipeline for complete digital forensics. However, there are multifaceted challenges to conducting live memory forensics, some of which include the sheer volume and complexity of data to be analyzed, storage of data or evidence for prolonged periods of time, constant increase in memory dump size and verifying trusted executable files [33], [34], [35]. These challenges, coupled with the need of specialized workforce or investigators, need of advanced cutting-edge software for analysis, heterogeneity of data acquired from various sources and the enormous number of cases to be diagnosed and analyzed, only make it even harder for conducting live memory forensics. Use of anti-forensics techniques on top of these also make it challenging for forensic investigators to investigate cybercrimes [36]. Recent machine learning works in the area of live memory forensics, specifically memory analysis includes MRm-DLDet, MemAPIDet, used Convolutional Neural Networks to classify patterns in memory allocation [37], [38]. Memory dumps were converted into RGB images giving an accuracy of 95.98% in identifying anomalous malicious patterns [39]. A memory resident malware detection framework (MemAPIDet) based on extraction of semantic features of API sequences using a fine-tuned BERT model which then extracts features using a pre trained ResNet-10134 neural network. The dataset comprised of 2180 benign, and 1897 malicious samples and the proposed framework gave a prediction accuracy of 97.78% [38]. MRm-DLDet uses RGB image transformations with a combination of ResNet and GRU models to detect spatial anomalies. It uses ultra-high resolution memory dump images to give an impressive accuracy of 98.34% [37]. MemAPIDet is a framework that combines API sequence analysis with intrinsic memory features by using a ResNet-34 model with an accuracy of 97.78% with F1-score of 0.9736 [38]. MeMalDet uses stacked ensemble learning with deep autoencoders and achieves an accuracy of 98.82% with a false positive rate (FPR) of 0.08% [40]. A novel federated learning based architecture is proposed in [41] that aims at proactive malware detection without moving raw data to the central server, rather it brings computation to the data and only shared relevant gradients that allows the sensitivity of the data to be maintained.

A detailed comparative analysis of the current works in the area of artificial intelligence and live memory forensics is provided in Table III.

TABLE III. Comparison of Recent Works in the Area

Framework	Technique	Dataset	Performance	Cons
MRm-DLDet [37]	RGB image conversion with ResNet, GRU, and attention mechanism	Ultra-high resolution memory dump images	Accuracy = 98.34%	Extensive preprocessing, high computational cost
MemAPIDet [38]	API feature sequencing with ResNet-34 neural network	2180 benign and 1897 malicious memory images	Accuracy = 97.78% F1-score = 0.9736	Scalability issues with large datasets
cRGB Mem [39]	RGB image transformation with Convolutional Neural Network	Memory dump features	Accuracy = 95.98%	Limited to Android-based malware, allows only partial OS generalization
MeMalDet [40]	Deep autoencoders with stacked ensemble learning	Temporal splits in dataset from obfuscated malware	Accuracy = 98.82%	Does not have real-world dataset implementation
Quincy [45]	Uses Random Forest for detection of code injection attacks	Windows 10 memory dump images	Accuracy = 84.4%	Less accurate for complex code injection attacks
volGPT [46]	Uses Large Language Models (LLMs) with Volatility + plugins	Malicious memory dump images	Increases interpretability of information	Limited to the training knowledge

The foundational work introducing the transformer architecture is proposed in [42], [43]. Hierarchical vision transformer for spatial data is presented in [44]. Longformer transformer architecture for long context scenarios is presented in for malware detection, Swin Transformers use shifted window mechanism for hierarchical feature extraction and code segment classification [30], [31]. Longformer enable anomaly detection and tracing of malicious processes over long range dependencies. The advantage of using hybrid transformer-based architecture involves the use of both local feature extraction via CNNs combined with the use of global context modelling via Transformers. A comparative analysis for transformer-based approaches is provided in Table IV.

TABLE IV. COMPARATIVE ANALYSIS OF TRANSFORMER-BASED APPROACHES, TRADITIONAL ML MODELS, AND DEEP LEARNING TECHNIQUES

Feature/Parameter	Transformers	Traditional ML Models	Deep Learning (CNN/RNN)
Spatial Modelling	Superior due to shifting window and attention mechanisms	Limited to pre-engineered and extracted features	Strong with multiple convolutional layers
Temporal Modelling	Efficient with positional encoding and long-range sequence modelling	Basic sequence models are used for analysis (e.g., HMM)	Moderately achieved with LSTM/GRU layers
Real-Time Analysis	Advancements towards efficient architectures	Comparatively slower due to manual feature extraction	Faster but less flexible
Scalability	Handles large data via parallelization approaches	Poor for high-dimensional data	Limited by sequence length

IV. MATHEMATICAL MODEL

To analyze the dynamics of the proposed hybrid model, we develop a mathematical model that captures key interactions and provides insights into specific predictions related to anomaly detection and optimization. The mathematical model aligns with the presented research objectives and enhances the foundational understanding of the proposed hybrid model.

A. Introduction to the Hybrid Model

Let $M \in \mathbb{R}^{T \times H \times W \times C}$ represent the live memory data, where:

- T: Number of temporal frames (time-sequential memory snapshots).
- H, W: Spatial dimensions comprising of height (H) and width (W) of each frame.
- C: Number of Feature channels per frame extracted from memory dump features.

The proposed hybrid model consists of two components:

1) Swin transformer: Processes the spatial dimensions (H,W) for each memory frame. It provides the local spatial representation over (H,W) for every frame.

2) Longformer: Models temporal dependencies across T frames. It provides long range modeling across the temporal axis for every frame.

B. Spatial Analysis via Swin Transformer

The Swin Transformer is used to perform the hierarchical spatial attention mechanism. It divides the memory snapshot into non-overlapping windows and applies self-attention within each window, maintaining computational efficiency.

a) Input projection:

$$X_{\text{spatial}} = Reshape(M[t]) \in \mathbb{R}^{\text{NxD}}, N = H.W, D = C \quad (1)$$

b) Window partitioning: Divide X_{spatial} into $P \times P$ non-overlapping windows:

$$X_{\text{i}w} \in \mathbb{R}^{P^2 \times D},\ i \in \{1, \dots, Wcount\},\ Wcount = {H \cdot W}/{P^2} \quad (2)$$

c) Self-attention in windows: Compute self-attention within each window i:

$$\text{Attention}\ (Q, K, V) = \text{Softmax}\ ((QK^{\text{T}})\ /\ \sqrt{d_{\text{k}}})\ V \quad (3)$$

where,

$$Q = X_{\text{i}w}W_Q,\ K = X_{\text{i}w}W_K,\ V = X_{\text{i}w}W_V \quad (4)$$

and $W_Q, W_K, W_V \in \mathbb{R}^D$ are learnable projection matrices, and d_k is the dimensionality of queries and keys.

d) Global feature extraction: Use shifted window attention to capture inter-window dependencies. Let:

$$Z_{spatial} \in \mathbb{R}^{H \times W \times C'} \quad (5)$$

represent the final spatial features, where $C'$is the refined feature dimension after Swin Transformer layers.

C. Temporal Modelling via Longformer

To capture long-range dependencies across T sequential frames, we use Longformer for efficient temporal modelling.

a) Flattened input: Flatten spatial features across H and W:

$$X_{temporal} = Flatten(Z_{spatial}) \in \mathbb{R}^{T \times D'},\ D' = H \cdot W \cdot C' \quad (6)$$

b) Sliding window attention: Longformer applies a sliding window of size w:

$$Attention_{long}(Q, K, V) = Softmax((QK^{\text{T}}\ /\ \sqrt{d_{\text{k}}}) \cdot \mathbb{M})\ V \quad (7)$$

where, $\mathbb{M} \in \{0,1\}^{T \times T}$ is the attention mask restricting attention to w-neighbour frames.

c) Global attention: Introduce a small number of global tokens for high-level anomaly detection:

$$g_i = \Sigma_{\{\text{t} \in \text{global}\}}\text{Attention}_{\text{longformer}}(\text{X}_{\text{temporal[t]}}) \quad (8)$$

d) Output: The refined temporal representation is:

$$Z_{temporal} \in \mathbb{R}^{T \times C''} \quad (9)$$

where, $C''$is the temporal embedding dimension.

D. Hybrid Model Integration

Combine $Z_{spatial}$ and $Z_{temporal}$ into a unified hybrid representation Z_{hybrid}:

$$Z_{hybrid} = Concat(Z_{spatial}, Z_{temporal}), Z_{hybrid} \in \mathbb{R}^{T\times H\times W\times C_{final}} \text{ where } C_{final} = C' + C'' \quad (10)$$

E. Loss Function

The total loss function is used to combine the anomaly detection and the regularization. This is defined as follows:

$$\mathcal{L} = \mathcal{L}_{anomaly} + \lambda\, \mathcal{L}_{regularization} \quad (11)$$

a) Anomaly detection loss:

$$\mathcal{L}_{anomaly} = \Sigma_{i,j} \left|\left|Z_{hybrid[i,j]} - Z_{normal[i,j]}\right|\right|^2 \quad (12)$$

where, Z_{normal} represents ground-truth features of non-malicious memory snapshots, i.e. belonging to clean memory snapshots.

b) Regularization loss: Use sparsity and smoothness regularization, and encourages sparsity and weight decay:

$$\mathcal{L}_{regularization} = \left|\left|W_Q\right|\right|^2 + \left|\left|W_K\right|\right|^2 + \left|\left|W_V\right|\right|^2 \quad (13)$$

F. Applications to Live Memory Forensics

a) Anomaly identification:

$$\mathcal{A}(i) = \begin{cases} 1 \text{ if } \left|\left|Z_{hybrid[i]} - Z_{normal[i]}\right|\right|^2 > \tau \\ 0, otherwise \end{cases} \quad (14)$$

where, τ is the anomaly detection threshold.

b) Malware injection detection: Correlate anomalous regions with known injection signatures via the correlation of $\mathcal{A}$(i).

c) Process hijacking detection: Track temporal inconsistencies in process identifiers across $Z_{temporal}$

G. Working of the Model

1) Spatial analysis using Swin Transformer: The Swin Transformer is tailored to analyze spatial patterns in memory snapshots, which are visual representations of system memory. These snapshots are divided into non-overlapping windows, and a self-attention mechanism is applied to each window to capture local dependencies. To enhance global spatial understanding, the model employs shifted window attention, ensuring that the interaction between neighboring windows is not ignored. This mechanism bridges local and global contexts, enabling the detection of fine-grained spatial anomalies in memory. The result is a spatial feature map, $Z_{spatial}$, that encodes refined spatial patterns, crucial for identifying unusual memory usage or corruption indicative of potential threats.

2) Temporal analysis using Longformer: Memory forensics often involves analyzing sequences of memory snapshots to uncover temporal irregularities. The Longformer, with its efficient sliding window attention, is employed for this purpose. This attention mechanism processes sequences of memory data, capturing long-range dependencies without the computational overhead associated with traditional attention mechanisms. Additionally, global attention tokens are incorporated to identify overarching temporal patterns, providing a comprehensive view of how memory states evolve over time. The output, $Z_{temporal}$, captures these temporal relationships and dependencies, highlighting any irregular behavior spanning multiple frames.

3) Hybrid representation: To maximize the benefits of spatial and temporal modeling, the outputs of the Swin Transformer and Longformer ($Z_{spatial}$ and $Z_{temporal}$) are concatenated into a unified hybrid representation:

$$Z_{hybrid} = Concat(Z_{spatial}, Z_{temporal})$$

This representation encapsulates the complete characteristics of the analyzed memory, enabling the detection of both spatial anomalies (e.g., unusual memory usage) and temporal inconsistencies (e.g., suspicious process behavior over time).

4) Anomaly detection mechanism: The hybrid representation is compared against a normal baseline (Z_{normal}) using an anomaly detection mechanism. Deviations beyond a predefined threshold, τ, are flagged as anomalies:

$$A(i) = \begin{cases} 1 \text{ if } \left|\left|Z_{hybrid[i]} - Z_{normal[i]}\right|\right|_2 > \tau \\ 0, otherwise \end{cases}$$

This systematic approach ensures precise detection of irregularities.

V. System Architecture

To achieve the research objectives outlined, a novel space-time hybrid model combining the strengths of the Swin Transformer and Longformer is proposed. This section details the key components, processes, and implementation strategies used in the development of the hybrid model. The proposed architecture, as represented in Fig. 2, provides a mechanism for analyzing memory dumps to detect and classify malicious processes leveraging the state of the art spatial and temporal modelling techniques.

- Memory snapshot preprocessing unit: It serves as the starting layer which converts the raw memory dumps into structured and decomposable units by applying necessary pre-processing steps. Post conversion of memory dump; normalization, noise reduction and segmentation of memory regions is done to achieve a more focused analysis.

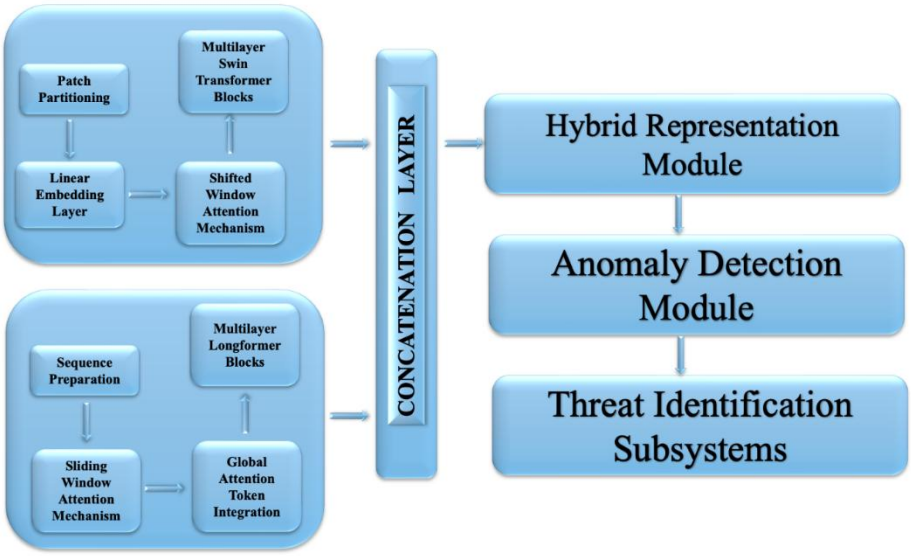

Fig. 2. System architecture of the proposed hybrid model.

- Spatial Analysis: Spatial analysis component uses a Swin Transformer, which is a hierarchical vision transformer used for spatial feature extraction by dividing the memory dump into fixed-size non-overlapping windows for localized processing. Shifted window attention mechanism enhances the transformer's ability by using cross-window attention. By using a shifted window attention mechanism, it can capture both local as well as global spatial correlations in memory dump layout, thereby optimizing pattern recognition.
- Temporal Analysis: Longformer is used for analyzing long sequences with temporal dependencies in memory dump snapshots by using an extended attention span. Sliding window attention allows the model to focus on local temporal variations and patterns over large sequences. Global attention span token integrator aggregates the global attention tokens to integrate the temporal insights in order to enrich the temporal dependency understanding of the system.
- Feature Integration: The features extracted from the spatial and temporal dependencies is concatenated using a Feature Concatenation Unit to seamlessly integrate complementary data dependencies. Hybrid representation module integrated the spatial and temporal features into a unified representation to serve as a foundation for downstream analysis and anomaly detection.
- Detection and Optimization: Anomaly detection module identifies abnormal memory usage patterns that indicate compromised system behavior. Loss function optimization module further fine tunes the detection module by constantly iterating and minimizing the error rates during training phase.

VI. Results

In this section, we provide a concise description of our experimental results along with their interpretations and the conclusions drawn from the study. Table V summarizes the experimental setup and outlines evaluation metrics, components and configuration of the experimental setup. Table VI captures spatial features extracted from memory images at specific time points in time. It categorizes the frames as either "Normal" or "Malicious" based on their feature patterns. Table VII represents the temporal evolution of features across time. It represents how features change or evolve dynamically for processes and then labels them as "Normal" or "Malicious". Table VIII integrates spatial and temporal features, providing a comprehensive view of patterns over both time as well as space. It includes the anomaly scores for each observation along with their respective labels. Table IX highlights specific anomalies such as malware or code injections and process hijacking in various memory regions. Each entry includes the anomaly scores along with labels based on the activity type. The data highlights suspicious activities relevant with respect to anomaly detection and classification.

Dataset Description: The proposed model was validated using benchmark datasets including EMBER, BIG2015, and SOREL-20M [18], [19], [20]. These datasets provide labelled malicious and benign memory images and logs. The data was pre-processed into time-sequenced memory frames, with 60% labelled as normal and 40% as malicious. Each sample included spatial features (e.g., memory usage, CPU usage) and temporal features (e.g., timestamped process behavior logs). A train-test split of 80:20 was used for evaluation. A summary of the dataset used is provided as follows:

- Total Samples: 5,000 memory dump sequences
- Class Distribution: 60% benign (3,000), 40% malicious (2,000)

- Train-Test Split: 80% training (4,000 samples), 20% testing (1,000 samples)
- Validation Strategy: 5-fold cross-validation during training to ensure generalization and avoid overfitting

TABLE V. EXPERIMENTAL SETUP FOR VALIDATING THE MATHEMATICAL MODEL USING THE PROVIDED DATASET

Aspect	Description
Dataset Used	Tables on process information, network activity, system logs, and anomalies.
Model Components	Hybrid Space-Time Transformer combining Swin Transformer (spatial) and Longformer (temporal).
Preprocessing	Partitioned memory snapshots into non-overlapping windows for Swin Transformer. Temporal sequences segmented for Longformer using sliding window attention.
Input Features	Spatial: CPU usage, memory usage, threads, and handles. Temporal: Event timestamps, anomaly logs, and traffic metrics.
Evaluation Metrics	Precision, recall, F1-score for anomaly detection. Accuracy for classification (normal vs. malicious).
Experimental Scenarios}	Malware injection based on anomaly scores (e.g., Region 3 at T1: 0.85). Process hijacking patterns with temporal anomalies (e.g., anomaly score 0.92 at T3).
Baseline Models	Longformer alone (temporal analysis only). Swin Transformer alone (spatial analysis only).
Training Configuration	Optimizer: Adam. Learning rate: 1e-4. Batch size: 32. Training epochs: 50.
Validation Strategy	80/20 train-test split. Cross-validation to ensure robustness.
Loss Function	Combination of anomaly detection loss and regularization terms: $L = L_{anomaly} + \lambda L_{regularization}$.
Hardware Setup	NVIDIA GPU for accelerated computation. 64 GB RAM. TensorFlow/PyTorch for implementation.

TABLE VI. SPATIAL FEATURES (PER FRAME ANALYSIS)

Frame ID	Feature 1	Feature 2	Feature 3	Feature 4	Feature 5	Label
1	0.23	0.12	0.56	0.34	0.78	Normal
2	0.67	0.91	0.45	0.33	0.12	Malicious
3	0.11	0.13	0.41	0.22	0.39	Normal
4	0.75	0.84	0.64	0.58	0.91	Malicious
5	0.20	0.18	0.47	0.31	0.65	Normal

TABLE VII. TEMPORAL FEATURES (SEQUENCE OVER TIME)

Time (T)	Feature 1	Feature 2	Feature 3	Feature 4	Feature 5	Label
T1	0.12	0.45	0.32	0.23	0.67	Normal
T2	0.14	0.42	0.30	0.25	0.69	Normal
T3	0.91	0.88	0.74	0.71	0.90	Malicious
T4	0.15	0.41	0.29	0.22	0.65	Normal
T5	0.13	0.40	0.31	0.24	0.70	Normal

TABLE VIII. HYBRID SPACE-TIME FEATURES

Time (T)	Frame ID	Feature 1	Feature 2	Feature 3	Feature 4	Feature 5	Anomaly Score	Label
T1	1	0.23	0.12	0.56	0.34	0.78	0.12	Normal
T2	2	0.25	0.15	0.54	0.32	0.76	0.10	Normal
T3	3	0.67	0.91	0.45	0.33	0.12	0.91	Malicious
T4	4	0.11	0.13	0.41	0.22	0.39	0.08	Normal
T5	5	0.75	0.84	0.64	0.58	0.91	0.89	Malicious

TABLE IX. ANOMALOUS ACTIVITIES IN MEMORY

Process ID	Timestamp	Injected Code Location	Hijacked Memory Region	Anomaly Score	Type	Label
101	T1	None	None	0.05	Normal	Normal
102	T2	0x7FFFAC5678	None	0.85	Malware Injection	Malicious
103	T3	None	0x7FFFAC5678	0.92	Process Hijacking	Malicious
104	T4	None	None	0.03	Normal	Normal
105	T5	0x7FFFAD7890	None	0.80	Malware Injection	Malicious

Fig. 3 represents a heatmap showcasing the attention weights assigned by the Swin Transformer to different memory regions. This represents the area of focus for anomaly detection across spatial memory regions. Fig. 4 represents the importance of features across spatial features. This helps in identifying spatial features that contribute most to the model's decision-making. On the contrary, Fig. 5 presents a heatmap showcasing how Longformer attends to various time frames across the memory dump. This highlights the temporal features and their patterns across time, which is crucial for anomaly detection. Fig. 6 represents the evolution of temporal features and shows how the anomaly score changes over a period of time. Fig. 7 represents the anomaly score distribution for normal and benign and malicious memory samples. Fig. 8 represents a 2D scatter plot to visualize the separation between normal and malicious memory images.

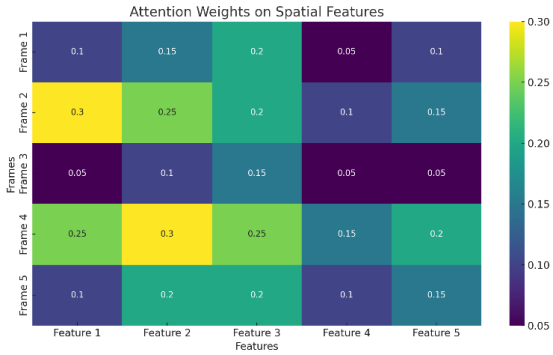

Fig. 3. Attention weights on spatial features.

Fig. 9 represents the violin plot depicting the anomaly score memory feature distribution. Fig. 10 represents the class imbalances in the dataset. Fig. 11 shows a heatmap highlighting specific memory regions and time frames at which code injections took place. The heatmap represents the intensity of such malicious memory regions. Fig. 12 represents the hijacking of the process with the progression of anomalies over time. Fig. 13 represents performance metrics of different models as compared to the proposed hybrid model. Fig. 14 illustrates the effect of window sizes across accuracy and precision of spatial feature modelling. Fig. 15 represents the impact of attention span in Longformer across accuracy and recall in modelling of temporal features. Fig. 16 represents feature importance in anomaly detection. Fig. 17 represents the real-time detection latency of the proposed work.

Advantages of the Hybrid Model:

- Comprehensive Detection: Captures both spatial layout and temporal behavior of memory activity.
- Efficiency: Sliding and windowed attention reduce computational cost.
- Real-time Capability: Processes large memory snapshots in near-real-time.
- High Accuracy: Achieves superior F1-score and precision over state-of-the-art.
- Interpretability: Attention maps reveal which features and time frames contribute to anomaly detection.

LIMITATIONS

Despite high accuracy, the current model has limitations. It relies on high-quality labeled datasets, which may not always be available in real-world scenarios. Real-time deployment may face challenges in environments with extreme memory volatility or encrypted memory dumps. Furthermore, while the model generalizes well on benchmark datasets, additional testing is needed across diverse operating systems and memory architectures to confirm broader applicability.

VII. DISCUSSION

The proposed hybrid Space-Time Transformer model effectively integrates spatial and temporal dimensions for live memory forensics, leveraging Swin Transformer and Longformer architectures. The dataset facilitated comprehensive evaluation through detailed process information, network activity, and system logs, enabling precise anomaly detection. Results demonstrated the model's capability to highlight critical features and frames, as observed in attention distributions, where Feature 3 and Frame 3 consistently exhibited higher attention weights (0.3). Anomaly scores such as 0.85 for malware injection and 0.92 for process hijacking underscore the model's robustness in detecting malicious activities. The anomaly distribution further validates this, with malicious activities clustering above 0.8 and normal activities below 0.2. These findings reinforce the model's suitability for real-time forensic applications, improving the detection of nuanced spatial and temporal patterns across diverse scenarios.

The proposed hybrid model surpasses leading memory forensic models like MeMalDet (98.82% accuracy) and MemAPIDet (97.78% accuracy) in F1-score and precision, indicating improved balance between false positives and negatives. While MRm-DLDet relies on image transformations with high preprocessing costs, our method directly models spatial-temporal patterns, ensuring both accuracy and computational efficiency. Fig. 13 shows that our hybrid architecture outperforms all baselines in terms of accuracy (95%), precision (93%), recall (92%), and F1-score (94%), making it more robust for real-time forensic applications. As part of the future work, we aim to systematically adopt the following key pointers to enhance the applicability of our proposed model:

- Collaborate with cybersecurity organizations and forensic agencies to access anonymized live memory captures from actual investigations (e.g., ransomware, insider threats).
- Integrate real forensic case studies to evaluate how well the model detects complex threats such as multi-stage payload injections or polymorphic malware.
- Develop a secure and ethical data-sharing pipeline in alignment with privacy regulations and chain-of-custody standards to collect and curate volatile memory samples from industry partners.
- Expand the hybrid model's adaptability to diverse environments (e.g., Windows, Linux, virtual machines, cloud instances) by validating it on heterogeneous memory dumps from forensic labs.

VIII. Conclusion

Considering the rising cybercrime incidents across the globe, it has become paramount to investigate and establish the means, methods and culprit of the crime. However, advanced malware attackers have resorted to using volatile memory for most of their attacks due to its volatile and hard to detect nature. Establishing an effective and efficient volatile memory forensics framework will allow forensic investigators to investigate a crime in a much more standardized manner and allow effective collaborations across different organization while collecting evidence. Hybrid space-time transformers present a promising avenue for live memory forensics, with their ability to model complex spatial-temporal relationships. Advances in efficient transformer architectures and their integration with existing methodologies are paving the way for robust real-time analysis tools. In this work proposes a hybrid space-time transformer based architecture that studies both the spatial and temporal dimensions of memory dump features. The results demonstrate the effectiveness of the proposed hybrid Space-Time Transformer model in live memory forensics. The hybrid model outperformed individual baselines, achieving the highest F1-score of 0.94, accuracy of 0.93, and precision of 0.92, surpassing Swin Transformer, Longformer, LSTM, and CNN in all metrics. The analysis of Swin Transformer's window sizes revealed an optimal performance at a window size of 8, where accuracy peaked at 0.91 and precision at 0.89, validating the model's capacity to capture spatial features effectively. With reference to future work, we can explore extending the model to operate on larger, real-time memory datasets with diverse attack vectors to validate scalability and robustness under varying conditions. Incorporating the model into end-to-end cybersecurity frameworks for automated anomaly detection, malware classification, and mitigation strategies.

***Abstract*—In today's digital world, images have become a double-edged tool in the dissemination of news; as much as they contribute to enriching honest content and communicating information effectively, they are increasingly being used to mislead the public and spread fake news. The ease of manipulating images and taking them out of their original context, or even creating them entirely with advanced techniques, gives them tremendous power in lending false credibility to false narratives, taking advantage of the human eye's tendency to believe what it sees and the image's superior ability to directly evoke emotions. These misleading images, which are often difficult to debunk with the naked eye, spread at lightning speed across digital platforms, allowing fake news to reach and influence large audiences before it can be verified. However, they tend to generate inaccurate reports. This study proposes a model architecture to detect fake news images. Machine learning and deep learning algorithms were used. The deep learning models are used depending on conventional neural nets (CNN), long short-term memory (LSTM) and a hybrid model that combines CNN and LSTM frameworks on Google Cloud. The hybrid model was able to categorize news with better accuracy than using each model individually. The model was tested and trained on a dataset for classifying fake news images. We used different evaluation metrics (precision, recall, F1 metric, etc.) to measure the efficiency of the model.**

Keywords*—*Fake news images; machine learning; deep learning; cloud computing; CNN; LSTM

I. Introduction

The rapid expansion of social media platforms has dramatically increased the dissemination speed and reach of news content worldwide [1]. While this democratization of information access has many benefits, it has also facilitated the widespread propagation of fake news—deliberately fabricated or misleading information designed to deceive readers [2]. Fake news poses significant threats to public opinion, political stability, and social trust, particularly when it spreads unchecked on online platforms [3].

Detecting fake news has become a critical research challenge in artificial intelligence, with numerous studies focusing on automated methods to identify misinformation. Traditionally, many approaches have concentrated on textual analysis using natural language processing (NLP) techniques and machine learning classifiers [4][5].

However, news articles frequently contain multimodal content, including images and videos, which can be equally manipulated to mislead audiences [6]. Despite this, visual content analysis for fake news detection has received comparatively less attention, even though fake images are often used to support fabricated stories and increase their perceived credibility [7].

Recent advances in deep learning have shown promise in addressing this challenge by leveraging convolutional neural networks (CNNs) to extract spatial features from images and recurrent neural networks, such as long short-term memory (LSTM) networks, to capture temporal or sequential dependencies in data. Hybrid architectures combining CNN and LSTM models have demonstrated improved performance in various multimedia classification tasks by integrating spatial and sequential feature extraction capabilities [8][9].

This study proposes a hybrid CNN-LSTM architecture for detecting fake news images, aiming to leverage the strengths of both models to improve classification accuracy. We evaluate our approach on a publicly available dataset from Kaggle, comparing the hybrid model's performance against standalone CNN and LSTM models. Our results confirm that the hybrid model achieves superior accuracy in identifying fake news images, highlighting the potential of combined deep learning architectures in multimodal misinformation detection.

Moreover, hybrid models generally outperform single-architecture approaches by integrating the strengths of both components. Recent studies indicate that combining CNNs with LSTMs yields better detection rates than traditional methods reliant on separate evaluations of text or images [10]. This synergy enhances not only accuracy but also the interpretability of predictions, fostering user trust.

Additionally, these systems provide flexibility in adapting to various media types, essential as fake news increasingly incorporate multimedia elements [11]. Hybrid models ensure adaptability in addressing diverse forms of misinformation effectively.

To lessen the impact of bogus news before it becomes viral, early detection is essential. Machine learning-backed proactive detection techniques can lessen the negative social and psychological effects of misleading narratives [12].

The study is organized as follows: Section II tackles the literature review in some detail. The proposed model architecture is presented in Section III. Section IV presents the experiments and the results with discussion. The study concludes in Section V.

II. Literature Review

This section reviews recent and relevant literature on fake news detection, focusing on the transition from traditional approaches to deep learning techniques, the emergence of hybrid models such as CNN-LSTM, and the growing role of cloud computing in scalable deployment.

A. Text-Based Fake News Detection

Traditional approaches to fake news detection have primarily focused on analyzing the linguistic features and semantic content of news articles. Early methods often relied on feature engineering and machine learning classifiers. For instance, Alhindi, T., Kalita, J., and Sajjad, H. (2020) [13] classified fake news using Support Vector Machines (SVM) and TF-IDF features on the LIAR dataset. While their approach provided reasonable accuracy by capturing word importance, it struggled to understand complex contextual nuances and did not scale well to real-world scenarios due to restricted semantic representation and dataset diversity.

More recently, deep learning models have shown superior capabilities in capturing intricate textual patterns. Gupta, R., et al. (2021) [14] utilized Bidirectional Encoder Representations from Transformers (BERT) for enhanced textual feature extraction and fake news classification. Their model demonstrated high performance on several benchmark datasets by leveraging BERT's contextual embeddings. However, as a purely text-based method, it inherently fails to account for the crucial visual elements that often accompany and influence the perception of news, particularly when key information is conveyed through embedded text or manipulated images.

Another significant line of work explored sequential models for temporal analysis of text. Ma, J., et al. (2019) [15] proposed using Recurrent Neural Networks (RNNs) to model the propagation patterns of rumors over time. While effective in identifying how narratives evolve, their reliance solely on textual content means they cannot detect misinformation where visual cues, such as text embedded in images, play a primary role in conveying the false message, thus limiting their applicability to multimodal misinformation.

B. Image-Based Fake News Detection

Parallel to text-based methods, considerable research has focused on analyzing visual content to identify fake news. These methods often aim to detect image manipulation, inconsistencies, or to extract visual cues indicative of deception. Wang, Y., et al. (2022) [16] developed a CNN-based framework for identifying visual inconsistencies in news images, leveraging various image forensic techniques. Their method achieved high accuracy in detecting manipulated images. However, it does not explicitly analyze any textual content present within the image, which is a critical oversight given that many misleading images rely on superimposed text to convey a deceptive narrative rather than pure visual manipulation.

Similarly, Zhang, L., et al. (2020) [17] proposed a deep learning model to classify images as real or fake based on extracted semantic features using pre-trained CNNs (e.g., ResNet). While effective in capturing high-level visual representations, their approach often struggles with cases where the image itself is authentic but carries a false message through external text added to it or is presented in a misleading context that can only be understood through accompanying textual cues. Their method thus has limited utility for detecting fake news where the visual medium's core deceptive element resides within embedded text, rather than the image's inherent authenticity.

Li, S., et al. (2023) [18] focused on identifying manipulated visual elements in news images using advanced CNN architectures and attention mechanisms to highlight suspicious regions. While their approach was robust against various manipulation techniques, its primary limitation lies in its inability to infer the veracity of the news article or message when the image itself is unaltered but the embedded text (or overall context) is misleading.

C. Multimodal Fake News Detection

Recognizing the limitations of unimodal approaches, a growing body of research has explored multimodal strategies that integrate information from both textual and visual modalities to enhance fake news detection. These approaches aim to capture the complex interdependencies between different data types.

Liu, X., et al. (2021) [19] proposed a multimodal framework that combines a CNN for image feature extraction and a GRU (Gated Recurrent Unit) for text features, fusing them at a later stage for classification. Their model showed improved performance compared to unimodal baselines by leveraging complementary information. However, their textual analysis was primarily focused on accompanying article text rather than the direct processing of text embedded within the images, which presents distinct challenges due to its unique formatting and often succinct nature.

Pan, W., et al. (2022) [20] developed a co-attention network that learns cross-modal interactions between text and images to better align information for fake news detection. While innovative in capturing intricate relationships, their method might not explicitly distinguish between general image features and the specific textual content within the image, potentially overlooking the direct semantic impact of embedded text. This limits their ability to robustly detect misinformation where the key deceptive element is the overlaid text.

Despite these advancements, a significant challenge remains in effectively integrating deep learning models that can specifically process and understand the unique characteristics of text directly embedded within images for fake news detection. Existing multimodal approaches often treat images as mere visual contexts or focus on detached textual descriptions, leaving a critical gap in analyzing the inherent deceptive power of image-text composites. Our proposed hybrid CNN-LSTM model directly addresses this limitation by meticulously extracting visual features via CNNs and simultaneously processing the sequential, embedded textual information using LSTMs, providing a more granular and effective approach to multimodal fake news detection.

In conclusion, the literature reveals several gaps: limited hybrid model integration, inconsistent usage of scalable deployment platforms, and a lack of comprehensive testing across diverse datasets. These gaps justify the need for a cloud-

optimized hybrid CNN-LSTM model that can robustly handle fake news detection at scale.

While these multimodal studies have made significant strides, many do not explicitly focus on the challenging domain of text directly embedded within images, which is a distinct modality requiring specialized processing, particularly given the potential for OCR inaccuracies. The existing literature often treats images as general visual context or focuses on visual manipulation, rather than the intrinsic textual information they carry. This gap forms the primary motivation for our current study, aiming to provide a robust deep learning solution for fake news detection that specifically leverages and integrates textual content extracted from images [21].

III. Methodology

The proposed methodology investigates the most famous state-of-the-art deep learning algorithms for Fake news detection; like deep learning techniques, they have the advantage of their ability to capture semantic features from textual data automatically. The three different combinations of deep neural networks, namely, CNN, LSTM and CNN-LSTM classification, have been performed. The proposed methodology is shown in Fig. 1.

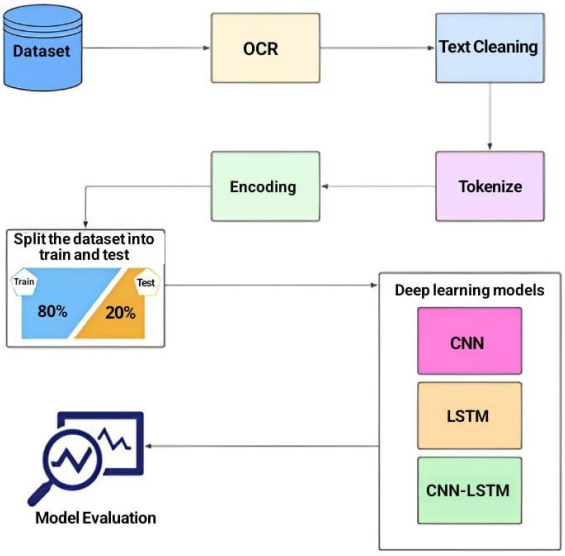

Fig. 1. System architecture.

A. Dataset

The Fake News Classification Image Dataset, publicly available on Kaggle [22]. This dataset comprises both textual and visual information, crucial for multimodal fake news detection.

- Dataset Source: Kaggle (Fake News Classification Image).
- Data Partitioning: The dataset was split into training, validation, and test sets.
  - Training Samples: 3600
  - Validation Samples: 450
  - Test Samples: 255
- Class Distribution: The dataset appears to have a relatively balanced distribution of "Fake" (class 0) and "Real" (class 1) news samples, as evidenced by the support values in the classification reports (e.g., Test set 126 for class 0, 129 for class 1).

B. Data Preprocessing

This effective preprocessing of both image and textual data is paramount for deep learning models. The following steps were applied:

1) Optical Character Recognition (OCR): Textual content embedded within the images was extracted using an OCR technique. This process is critical for converting visual text into a machine-readable format. The approach aligns with methodologies seen in advanced OCR systems, which aim to extract characters from optical images into editable formats, potentially leveraging tools such as PaddleOCR for pseudo ground truth acquisition as discussed in relevant literature [23].

2) Text cleaning: Following OCR extraction, the raw text underwent a meticulous cleaning process to standardize its format and reduce noise, which is crucial for subsequent natural language processing. This involved converting all extracted text to lowercase to ensure uniformity. Additionally, non-alphanumeric characters, such as punctuation and special symbols, were systematically removed to retain only relevant linguistic elements (letters, numbers, and spaces). Finally, multiple consecutive whitespace characters were consolidated into single spaces, and leading or trailing whitespace was trimmed, resulting in a clean and normalized textual representation [24].

3) Tokenization and padding: To prepare the cleaned textual data for input into the neural networks, a two-stage process of tokenization and padding was performed. Initially, a tokenizer was fitted on the entire collection of cleaned extracted text, encompassing data from the training, validation, and test sets. This process built a vocabulary, with a predefined size of 512 words, mapping each unique word to a numerical index. Subsequently, the cleaned text from each dataset (training, validation, and test) was converted into sequences of these numerical indices. To ensure that all input sequences had a uniform length, a max_length was determined by identifying the longest sequence across all datasets. All shorter sequences were then padded with zeros at the end ('post' padding) until they reached this max_length. This standardization is vital for batch processing in deep learning models [25].

4) Label encoding: The categorical labels associated with each image, 'real' and 'fake', were transformed into numerical representations suitable for binary classification. Specifically, 'real' news instances were mapped to the numerical value of 1, and 'fake' news instances were mapped to 0. This encoding converted the target variables into a format directly usable by the model's output layer [26].

Following the completion of the preprocessing stages, the data is divided into testing and training sets in an 80:20 ratio. Following that, the features are suitably reshaped to satisfy the

input specifications of the various deep learning architectures (CNN, LSTM and CNN-LSTM models).

C. Model Architectures

This study investigates three distinct deep learning architectures: a Convolutional Neural Network (CNN), a Long Short-Term Memory (LSTM) network, and a Hybrid CNN-LSTM model. All models utilize the preprocessed textual data as input.

1) Convolutional Neural Network (CNN): The CNN model is designed for feature extraction from sequential data, leveraging its ability to capture local patterns. The architecture is as shown in Fig. 2:

- Embedding Layer: input_dim=512 (vocabulary size), output_dim=16 (embedding dimensions).
- Conv1D Layer: filters=8, kernel_size=3, activation='relu'.
- GlobalAveragePooling1D Layer: Reduces each feature map to a single value, capturing the most significant features.
- Dropout Layer: rate=0.5 for regularization, preventing overfitting.
- Dense Layer: units=1, activation='sigmoid' for binary classification output.

The model's input shape is configured to handle sequences of varying batch sizes and the determined max_length.

Fig. 2. Workflow of the CNN model.

2) Long Short-Term Memory (LSTM): The LSTM model is particularly suited for capturing long-range dependencies in sequential data. The architecture is as shown in Fig. 3:

- Embedding Layer: input_dim=512, output_dim=16.
- Bidirectional LSTM Layer: units=8 A bidirectional setup processes the sequence in both forward and backward directions, enhancing context understanding.
- Dropout Layer: rate=0.5.
- Dense Layer: units=1, activation='sigmoid'.

The model's input shape is set to accommodate sequences of varying batch sizes and the max_length.

Fig. 3. Workflow of the LSTM model.

3) A Hybrid (CNN-LSTM) model: This hybrid model combines the strengths of both CNNs for local feature extraction and LSTMs for capturing sequential dependencies. This architecture aims to leverage the benefits of both approaches for improved fake news detection as shown in Fig. 4:

- Embedding Layer: input_dim=512, output_dim=128.
- First Conv1D Layer: filters=256, kernel_size=3, activation='relu', padding='same'.
- First MaxPooling1D Layer: pool_size=2.
- Second Conv1D Layer: filters=128, kernel_size=3, activation='relu', padding='same'.
- Second MaxPooling1D Layer: pool_size=2.
- Bidirectional LSTM Layer: units=128, return_sequences=False (outputs only the last hidden state).
- First Dense Layer: units=128, activation='relu'.
- Output Dense Layer: units=1, activation='sigmoid'.

The model's input shape is built to handle sequences of varying batch sizes and the max_length.

Fig. 4. Workflow of the CNN-LSTM model.

D. Training Details

All three models (CNN, LSTM, and Hybrid) were trained using consistent parameters to ensure fair comparison:

- Loss Function: binary_crossentropy was chosen as the loss function, suitable for binary classification tasks.
- Metrics: Model performance was evaluated based on accuracy.
- Epochs: Each model was trained for 25 epochs.
- Batch Size: A batch_size of 32 was used during training.
- Validation Data: The validation set (val_x, val_y) was used to monitor performance and prevent overfitting during training.
- Execution Environment: The training was conducted on Google Colab, leveraging its computational resources to facilitate efficient model training and experimentation.

The training process for each model was initiated, and the total training time was recorded to assess computational efficiency.

IV. Experiments and Results

This section details the experimental setup, presents the quantitative results of the trained models, and discusses their performance in classifying fake news from images with embedded text. The evaluation focuses on comparing the proposed hybrid CNN-LSTM model against standalone CNN and LSTM models.

A. Hyperparameters of Each Model

As indicated in Table I, we examine the key hyperparameters that govern their architecture and training process. These consist of the number and layers types, activation functions, optimizer settings, batch size, dropout rates, and the output layer configurations. The following table summarizes the hyperparameters for each model, highlighting the differences in their architectures and the settings used to train them. This comparison provides insights into how each model was structured and trained to fake news detection task.

TABLE I. COMPARISON BETWEEN HYPEPARAMETERS OF EACH MODEL

Hyperparameter	CNN Model	LSTM Model	Hybrid (CNN-LSTM) Model
Layers	Embedding, Conv1D, GlobalAveragePooling1D, Dropout, Dense	Embedding, Bidirectional LSTM, Dropout, Dense	Embedding, Conv1D, MaxPooling1D, Conv1D, MaxPooling1D, Bidirectional LSTM, Dense, Dense
Number of Layers	5	4	8
Activation Function	ReLU (Conv1D), Sigmoid (Output Dense)	Sigmoid (Output Dense)	ReLU (Conv1D, Dense), Sigmoid (Output Dense)
Optimizer (Adam)	Adam (Learning Rate: 0.001)	Adam (Learning Rate: 0.0005)	Adam (Learning Rate: 0.0001)
Loss Function	Binary Cross-Entropy	Binary Cross-Entropy	Binary Cross-Entropy
Batch Size	32	32	32
Epochs	25	25	25
Dropout	0.5 (after GlobalAveragePooling1D)	0.5 (after Bidirectional LSTM)	Not explicitly used
No. of Filters (CNN)	8 (Conv1D)	N/A	256 (1st Conv1D), 128 (2nd Conv1D)
Kernel Size (CNN)	3 (Conv1D)	N/A	3 (both Conv1D layers)
Pooling Layer (CNN)	GlobalAveragePooling1D	N/A	MaxPooling1D (pool_size=2), used twice
LSTM Units	N/A	8 (Bidirectional LSTM)	128 (Bidirectional LSTM)
Input Shape	16	16	128
Output Layer	(None, max_length)	(None, max_length)	(None, max_length)

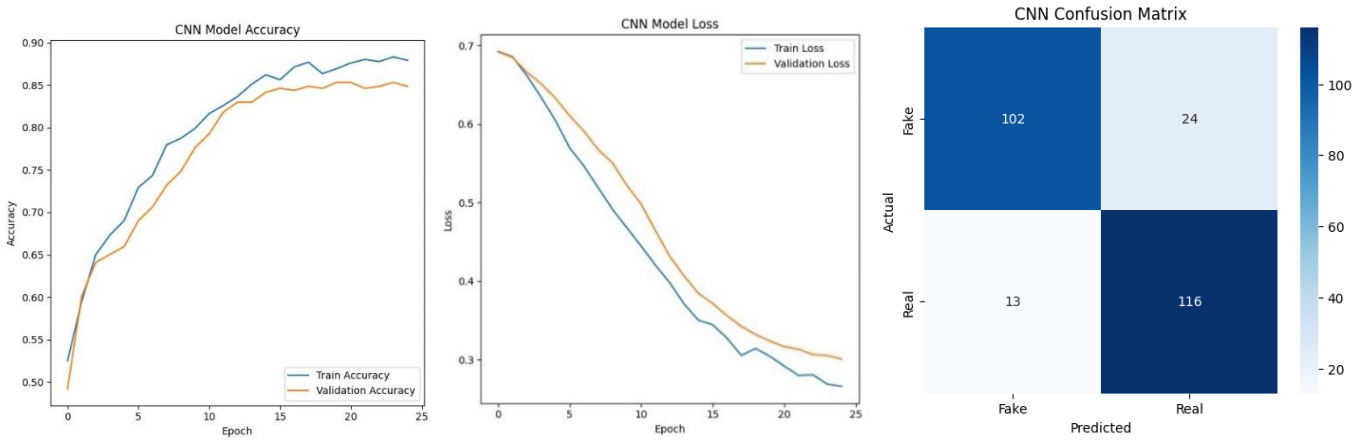
B. Evaluation Metrics

To thoroughly assess the performance of each classification model, a suite of widely recognized metrics was employed. These metrics provide insights into different aspects of model accuracy and robustness in distinguishing between "Fake" and "Real" news. The metrics are derived from the Confusion Matrix, which quantifies True Positives (TP), True Negatives (TN), False Positives (FP), and False Negatives (FN) [27][28]:

- Accuracy: Represents the proportion of correctly classified instances out of the total instances.
- Precision: For a given class, it is the ratio of correctly predicted positive observations to the total predicted positive observations. It quantifies the ability of the model to avoid false alarms.
- Recall (Sensitivity): For a given class, it is the ratio of correctly predicted positive observations to all observations in that class. It quantifies the ability of the model to find all positive instances.
- F1-Score: The harmonic mean of Precision and Recall. It provides a single score that balances both precision and recall, especially useful in cases of imbalanced class distributions.
- ROC AUC (Receiver Operating Characteristic Area Under the Curve): Measures the ability of the model to distinguish between classes. A higher AUC indicates better discriminatory power across various classification thresholds.
- PR AUC (Precision-Recall Area Under the Curve): Focuses on the trade-off between precision and recall for different thresholds. It is particularly informative for imbalanced datasets, where it provides a more robust evaluation than ROC AUC.
- MCC (Matthews Correlation Coefficient): A single metric that considers all four values in the confusion matrix. It is generally regarded as a balanced measure which can be used even if the classes are of very different sizes. A value of +1 represents a perfect prediction, 0 an average random prediction, and -1 an inverse prediction.

C. Results Evaluation

In this section, we display the outcomes of the models that were used on the Fake News Classification image Dataset. We used CNN, LSTM and Hybrid models for this dataset. Accuracy, precision, recall, F1-score, confusion matrix, classification report, accuracy curve, and loss curve are among the performance measures. These measurements give a thorough evaluation of each model's performance on the Fake News Classification Image Dataset, providing important information about how well they work for fake news detection.



1) CNN Model: Table II, shows the evaluation metrics of the CNN model demonstrating better performance.

TABLE II. EVALUATION METRICS OF CNN MODEL

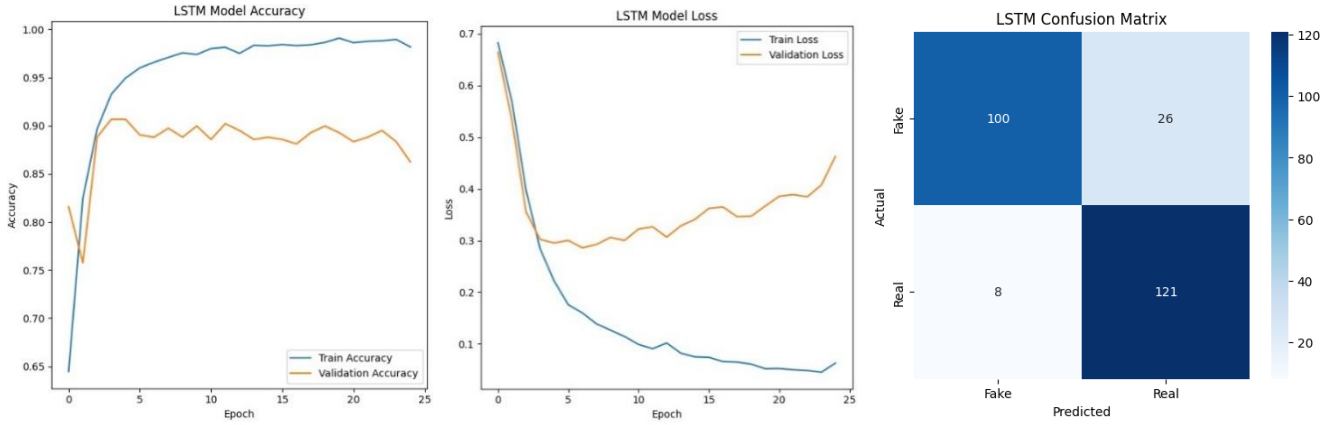
Metric	CNN Model
Accuracy	0.8667
Precision (Fake)	0.9259
Recall (Fake)	0.7937
F1-Score (Fake)	0.8547
Precision (Real)	0.8231
Recall (Real)	0.9380
F1-Score (Real)	0.8768
ROC AUC	0.9476
PR AUC	0.9559
MCC	0.7403

These results validate the CNN model's capacity to reliably detect fake news.

Fig. 5 represents fake and real image news using the CNN Accuracy Curve in (a), Loss Curve in (b) and Confusion Matrix in (c). As shown in Fig. 5(a), the results of the a model accuracy on training and validation data during training both curves exhibit a steady increase, converging at a high accuracy level, which indicates the model's ability to generalize well. According to the Loss Curve in Fig. 5(b), the decreasing trend in both curves signifies effective model optimization, with the validation loss closely following the training loss, suggesting minimal overfitting. Also in Fig. 5(c), the results of the confusion matrix the high values along the diagonal indicate strong predictive accuracy, while the off-diagonal values represent misclassifications. The intensity of the color reflects the frequency of predictions, highlighting the model's effectiveness in distinguishing between classes.

(a) (b) (c)

Fig. 5. Performance evaluation of the CNN model: (a) Accuracy curve, (b) Loss curve and (c) Confusion matrix.



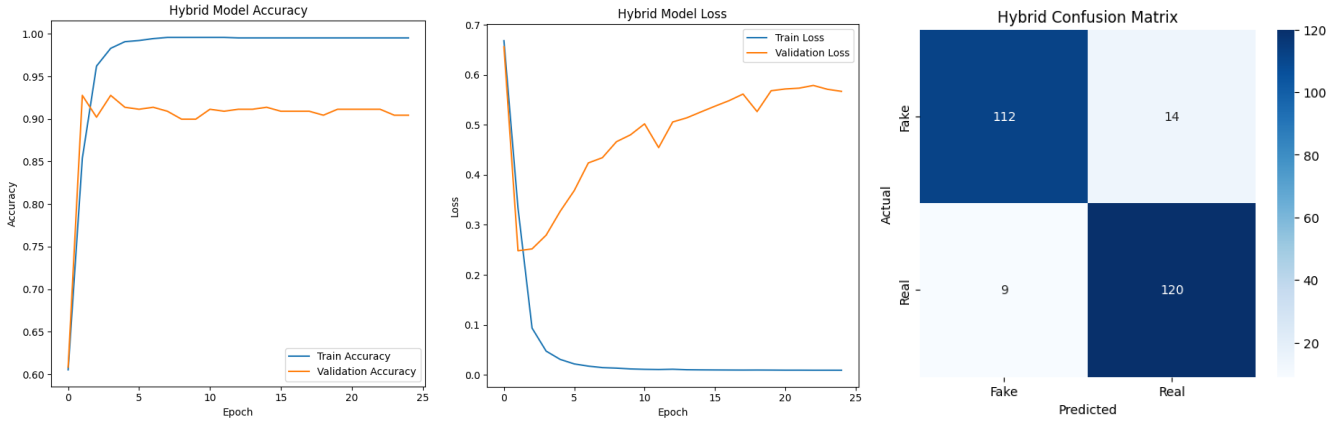
2) LSTM Model: Table III, shows the evaluation metrics of implemented LSTM model. It demonstrated strong classification capabilities.

TABLE III. EVALUATION METRICS OF LSTM MODEL

Metric	LSTM Model
Accuracy	0.8549
Precision (Fake)	0.8870
Recall (Fake)	0.8095
F1-Score (Fake)	0.8465
Precision (Real)	0.8286
Recall (Real)	0.8992
F1-Score (Real)	0.8625
ROC AUC	0.9493
PR AUC	0.9577
MCC	0.7121

Fig. 6 represents fake and real image news using the LSTM Accuracy Curve in (a), Loss Curve in (b) and Confusion Matrix in (c). As shown in Fig. 6(a), the upward trend in both curves indicates the model's improved performance as training progresses, with the training and testing accuracies converging at a high value. According to the Loss Curve in Fig. 6(b), the decreasing trend in both curves signifies effective model optimization, with the validation loss closely following the training loss, suggesting minimal overfitting. Also in Fig. 6(c), the confusion matrix visualizes the model's classification performance across different categories. The strong diagonal dominance indicates high classification accuracy, while the off-diagonal elements represent misclassifications.

3) A Hybrid (CNN-LSTM) Model: Table IV, shows the evaluation matrices of the hybrid model. It demonstrated strong classification capabilities. The model's capacity for generalization was enhanced and overfitting was lessened with the aid of batch normalization and dropout. The hybrid model showed its strong performance in fake news detection tasks by outperforming the baseline accuracy.



(a) (b) (c)

Fig. 6. Performance evaluation of the LSTM model: (a) Accuracy curve, (b) Loss curve and (c) Confusion matrix.

TABLE IV. EVALUATION METRICS OF THE CNN-LSTM MODEL

Metric	Hybrid Model
Accuracy	0.9098
Precision (Fake)	0.9256
Recall (Fake)	0.8889
F1-Score (Fake)	0.9069
Precision (Real)	0.8955
Recall (Real)	0.9302
F1-Score (Real)	0.9125
ROC AUC	0.9673
PR AUC	0.9713
MCC	0.8201

Fig. 7 represents fake and real image news using the CNN-LSTM Accuracy Curve in (a), Loss Curve in (b) and Confusion Matrix in (c). As shown in Fig. 7(a), this plot displays the training and testing accuracy over multiple epochs. The upward trend in both curves indicates the model's improved performance as training progresses, with the training and testing accuracies converging at a high value. According to the Loss Curve in Fig. 7(b), the graph illustrates the training and testing loss across epochs. The decreasing loss curves reflect effective model learning, with the test loss closely following the training loss, suggesting good generalization with minimal overfitting. Also in Fig. 7(c), the confusion matrix visualizes the model's classification performance across different categories. The strong diagonal dominance indicates high classification accuracy, while the off-diagonal elements represent misclassifications.

D. Discussion

This study evaluates and compares the performance of three deep learning models – CNN, LSTM and CNN-LSTM model for fake news detection using the Fake News Classification Image Dataset. The results give important insights into the effectiveness of these models and their suitability for specific scenarios in Artificial intelligence applications.

1) Performance on fake news classification image dataset: For the Fake News Classification Image dataset, the proposed hybrid LSTM-CNN model outperformed the standalone CNN and LSTM models in detecting fake news. While CNN is effective in extracting local features and LSTM captures sequential dependencies, each model has limitations when used independently. By combining their strengths, the hybrid

architecture achieved better generalization and higher classification accuracy. On the Fake News Classification Image dataset, the hybrid model reached an accuracy of 90.98%, surpassing CNN (86.67%) and LSTM (85.49%), with improved sensitivity and specificity. These results confirm the hybrid model's effectiveness in handling the complexity of fake news detection.

This improvement is consistent across several critical metrics:

- ROC AUC (0.9673) and PR AUC (0.9713): The significantly higher values for the Hybrid model in both ROC AUC and PR AUC suggest excellent discriminatory power and strong performance even in potentially imbalanced classification scenarios.
- Matthews Correlation Coefficient (MCC): With an MCC of 0.8201, the Hybrid model exhibits a strong correlation between predicted and true labels, indicating a highly reliable classification performance across both classes.
- F1-Scores: The Hybrid model achieved the highest F1-Scores for both "Fake" (0.9069) and "Real" (0.9125) classes, highlighting its balanced ability to maintain high precision and recall for both positive and negative classifications.
- Recall (Fake) and Specificity (Fake): The Hybrid model shows a notable improvement in Recall for the "Fake" class (0.8889) and Specificity (0.8889), which is crucial for effectively identifying actual fake news and minimizing false positives (classifying real news as fake). While the LSTM model had a slightly higher Recall for "Real" news, the Hybrid model demonstrates a better overall balance and a higher true negative rate.

2) Comparative insights: The comparison of results highlights the CNN-LSTM model's robustness, particularly for datasets with complex temporal or sequential patterns, such as the Fake News Classification Image dataset. While the CNN and LSTM models also performed well, their slight limitations in handling temporal dependencies make them less effective than Hybrid in such scenarios.

3) Implications and practical applications: The results clearly highlight the crucial importance of selecting suitable models based on the characteristics of datasets used in fake news detection. The Convolutional Neural Network (CNN)'s ability to handle feature-based patterns makes it a preferable choice in contexts where local spatial relationships within text (such as linguistic constructions and phrases) are critically important. Conversely, the Long Short-Term Memory (LSTM) model, with its superior capacity to capture sequential dependencies, proves valuable for datasets where temporal or contextual patterns across the text play a key role in distinguishing fake news. The hybrid model proved to be the strongest due to its effective utilization of the strengths of both CNN and LSTM. Furthermore, this study underscores the practical feasibility of these models in real-world fake news detection applications, supported by their high performance and adaptability. The insights gained can guide future developments in fake news detection systems, particularly in confronting the ever-increasing volume of malicious content online.

V. Conclusion and Future Work

In order to detect fake image news, this study suggested a hybrid deep learning model that combines the strengths of CNN and LSTM. The convolutional layers are adept at extracting local features and patterns (e.g., n-gram features from text sequences), while the Bidirectional LSTM layers excel at capturing long-range dependencies and contextual information in sequences from both forward and backward directions. This synergy, further bolstered by the integration of OCR-extracted text from images, allows the hybrid model to learn richer and more discriminative representations from the combined textual input derived from multimodal data, leading to superior fake news detection. The model was implemented in a cloud computing environment.

According to the experimental results, the hybrid model achieved a high performance of 90.98% and outperformed the results of running individually the CNN and LSTM models, in terms of accuracy, sensitivity, and specificity. This performance was resulted by the successful extraction of both local features and long-term dependencies made possible by the combination of both models.

While the achieved results in detecting fake news images using a hybrid CNN-LSTM architecture are highly promising, this study is not without certain limitations. Specifically, the Fake News Classification Image Dataset utilized may still present constraints in terms of its diversity, complexity, or its full representation of the constantly evolving deceptive visual content found in real-world scenarios. Future work could explore more challenging, imbalanced, or real-world datasets derived from diverse sources to further assess the robustness of the proposed hybrid model against evolving fake news dissemination tactics. Additionally, given the resource-intensive nature of deep learning models, there is a need to explore lightweight alternatives or model optimization techniques for deployment in resource-constrained environments or on devices with limited computational capacity.

Furthermore, the model's capabilities can be refined to include not only images but also video content that may contain fake information or be AI-generated, addressing the growing challenge of multimodal disinformation.

SCOPE, Vellore Institute of Technology, Vellore, India[2]

***Abstract*—Internet of Things and connected world concepts are emerging foreground in all walks of life, and Internet of Vehicles (IoV) is a natural evolution of these concepts for a connected vehicular environment. Clustering is needed in the IoV network for effective management of network resources and to avoid congestion in the network. On the effective cluster base, any efficient routing protocol can be realized for message dissemination. In most of the existing work, clustering based on multiple mobility metrics is the first step, followed by routing over established clusters. This work proposes a clustering solution without the need for frequent clustering or reduced cluster maintenance effort. The proposed solution establishes a virtual QoS guideline path for message dissemination based on graph theory as a first step, and clustering of the network is done to further improve the QoS in the guideline path using a heuristic algorithm. The proposed solution demonstrates notable improvements over existing approaches. Specifically, it achieves an average cluster duration that is at least 6% higher and reduces cluster maintenance overhead by 7%. In terms of Quality of Service (QoS), the solution attains a 3.6% higher packet delivery ratio, along with a 21% reduction in end-to-end delay and a 28% decrease in routing overhead.**

***Keywords*—QoS; clustering; meta heuristics; IoV; PSO; steiner minimal tree**

I. Introduction

The idea behind connected vehicles motivates the revolution of intelligent transportation systems. Communication among connected vehicles can be used to reduce traffic congestion, improve road safety, etc. Vehicles are an important participant in this connected network, with connectivity assisted by direct communication and infrastructure-based communication with roadside units (RSU). Vehicles can use Car-to-Car Communication-Consortium (C2C-CC) and Dedicated Short Range Communication (DSRC), Internet and V2X communication protocols for communication. A major problem in Internet of vehicle networks is scalability and robust routing against topology changes due to vehicular mobility. Clustering is a solution to these problems. Vehicles can be grouped based on similarity of either proximity, trajectory, etc. Message dissemination over a clustered topology has comparatively lower overhead compared to without clustering. Clustering also helps to limit channel contention among cluster members and facilitates fair access. Clustering also assists in spatial reuse of resources like bandwidth. Establishing stable clusters in the presence of higher vehicular mobility is a challenging task. Network topology changes frequently in a vehicular network due to higher vehicular mobility. Under these scenarios, cluster maintenance becomes a huge overhead. Clustering is the basis on which routing algorithms are constructed. When clustering is unstable, maintaining QoS for packet delivery becomes difficult.

Many clustering algorithms have been designed for vehicular networks and are discussed in detail in Section II. These clustering algorithms use various mobility metrics like speed, direction of travel and location of vehicles to organize the vehicles into groups. These algorithms make assumptions about mobility patterns, and when assumptions are challenged, the cluster maintenance effort is huge. Also, the routing protocols built over these clusters have lower QoS when the stability of the cluster is compromised.

In this work, a clustering solution is proposed with reduced cluster maintenance overhead and higher QoS for message dissemination. A virtual QoS guideline path for message dissemination is established as the first step based on graph theory, and clustering is established over the periphery of this guideline path using a soft computing-based heuristic algorithm. The contributions of the suggested work are listed below:

1) A novel virtual QoS guideline path construction based on multi-criteria QoS.

2) An algorithm for clustering based on the virtual QoS guideline path and mobility metrics using heuristics.

The structure of the study is as follows: Section II displays the current clustering algorithms for IoV and critical analysis of their issues. Section III displays the proposed clustering algorithm. The findings of the suggested algorithm are shown in Section IV along with a comparison to previous research. The suggested clustering algorithm's final thoughts and the range of further research are presented in Section V.

II. Related Work

Lakas et al. [1] used link expiration time as the mobility metric for clustering the vehicular network. Once the clustering topology is built using an artificial bee colony algorithm, one can discover paths over clusters with goal of achieving higher QoS. Testing against different scenarios, the approach

performed well under the assumption of normal traffic density in highway scenario. When assumption is broken with higher traffic density, QoS deteriorates. Wahab et al. [2] used mobility metrics of velocity and distance to create stable clusters.

Over the clustered topology ant colony algorithm is used for selecting route under the constraint of higher reliability. Direction of movement is not considered while clustering the network. Wang et al. [3] used multiple metrics of link lifetime, node degree, and anticipated transmission count for selecting the head of the cluster. Authors also used an election strategy to select clusters of maximal stability. Over the clustered topology, a weighted routing protocol is proposed where the relay cluster head is selected based on predicted node degree, link life, and transmission time. ON any variation in speed and density, both the stability of the cluster and QoS of routing paths are affected. Khan et al. [4] used the algorithm Moth Flame optimizer for clustering the IoV network. Optimal cluster heads with minimal distance to cluster members are found, so that transmission energy is minimized. The clustering process considered only energy optimization and did not consider other QoS parameters. Ahizoune et al. [5] suggested using a two-stage clustering approach to build durable VANET clusters. In the first stage of setup, clustering is done based on proximity criteria. In the second stage of maintenance, the backup cluster head is selected and role exchange with the primary is done to maintain cluster stability and reliability. The role exchange with the primary is executed to uphold cluster stability and reliability. Cluster stability is quantified by the variance in velocity among vehicles within the cluster. Clustering aims to enhance stability, disregarding QoS parameters. Shankar et al. [6] implemented a hybrid swarm algorithm for clustering in the VANET network, integrating Particle Swarm Optimization (PSO) with the Harmony Search Algorithm (HAS). The fitness function for clustering focuses on minimizing energy consumption. The problem of PSO getting into local minima is solved by using HSA along with PSO. The proposed algorithm improved the lifetime without consideration of QoS parameters. Ali et al. [7] clustered the mobile ad hoc network using particle swarm optimization. The fitness function for PSO was designed based on node degree, transmission power, node's energy consumption and node's velocity. The objective of the fitness function was to minimize energy consumption. Fahad et al. [8] used the grey wolf optimization algorithm for clustering the VANET. The optimization criterion for clustering is stability of clusters. Compared to PSO the hunting mechanism of grey wolf was able to converge to better results. Dalbah, et al. [9] came up with JAYACIoV which used an integration of two algorithms k–means and automatic clustering, using 171 testing conditions, providing a 64.82% result. Ayed, et al. [10] addressed the clustering process based on diverse parameters such as the trust value, the safety distance, and the energy factor. Oranj, et al. [11] proposes an algorithm to discover the path based on 2 parameters delay time and reliability. The results are evaluated using NS2 simulator. Shaikh, et al. [12] proposed an algorithm to include security measures within the routing process by efficiently dividing the workload across the alternative paths to reduce the congestion and travel cost. Aadil et al. [13] clustered the VANET network using dragon fly optimization algorithm. The cluster heads were selected based on the speed and direction of the movement. The cluster head transmission range was also adjusted dynamically to increase the cluster coverage. The approach works only for high way scenario. Hadded et al. [14] grouped the VANET using angle-based clustering. The selection of stable clusters is based on the vehicles' angular location and direction. Stability is the only criterion for cluster head selection in this work without consideration for multiple QoS factors. Bersali, M [15] approach CCA-IoV, uses the essential computing and storage capabilities of modern vehicles to operate the clustering process. Gasmi et al. [16] suggested a novel weight-based clustering technique for Internet of Vehicles networks. Density, speed, position, and delay measurements provide the foundation for clustering. QoS in the form of a delay metric was considered in clustering decision. Khan et al. [17] proposed a clustering algorithm for VANETs that is based on connectivity. Links connectivity is used mobility metric for clustering decision. The ideal number of clusters was also determined by the authors using heuristics. In this work, cluster stability—rather than QoS—was the criterion for clustering decisions. Gasmi et al. [18] clustered the IoV network by grouping the nodes moving in the same direction with the same speed. Overall, the clustering fuzzy-based routing algorithm considering QoS was designed. In unstable cluster, providing a guaranteed QoS becomes difficult. Sandeep Yerrathi et al. [19] address the challenges of stability, reliability, and QoS in highly dynamic environments by proposing a novel nature-inspired clustering approach. The African vulture Optimization-Based clustering Algorithm (AVOCA) intelligently forms optimal clusters, reducing network randomness and improving stability across varying grid sizes, node densities and transmission ranges. This study presents a method for cluster head (CH) selection, coordination and maintenance focusing on reducing communication costs. Experiments shows that AVOCA produces up to 45% fewer clusters than existing algorithms like CAMONET, SAMNET, i-WOA and HHO, achieving better load balancing and communication efficiency. Husnain et al. [20] tackle the challenges of dynamic topology and sparse vehicle distribution in VANETs, which complicate stable clustering and routing in Intelligent Transportation systems. To address this, authors proposed an intelligent probability-based bio-inspired Whale Optimization Algorithms (i-WOA) for clustering in VANETs considering factors like communication range, node density, velocity and highway routing. Experimental results across various network scenarios show that i-WOA produces optimal number of cluster heads. Statistical analyses confirm a 75% improvement in clustering optimization, effectively reducing communication costs and routing overhead while extending network lifetime. Jamalzadeh, M et al. [21] address routing challenges on the internet of Vehicle, which is characterized by rapid topology changes and variable node dynamics. They proposed EC-MOPSO, an edge computing assisted, cluster-based routing algorithms that leverages multi-objective particle swarm optimization ((MOPSO), roadside units (RSUs) acts as edge devices to optimize routing by minimizing accumulative delay and hop count while maximizing cluster size. Simulation result demonstrates that EC-MOPSO outperforms existing methods, achieving improvements in distance travelled, latency, packet delivery ratio, and convergence time, making it

well-suited for dynamic IoV scenarios. In study done by Husnain et al. [22], a cluster-based routing algorithm inspired by biology is presented in this study for use in Vehicular Ad Hoc Networks (VANETs) in Intelligent Transportation System (ITS) applications. Keeping stable communication routes is difficult because vehicle networks are dynamic and frequently sparse, especially on highways. The Whale Optimization Algorithm (p-WOA), a probability-based approach, is the suggested remedy for enhancing cluster formation in VANETs. Husnain, G et al. [23] The best cluster heads for IoV networks are chosen using a clustering technique based on Harris Hawks Optimization, which takes into account variables like range, node count, grid size, orientation, and velocity. Experimental results demonstrate a 90.6% cluster stability and an 80 percent improvement in cluster optimization, outperforming current techniques in latency, bandwidth usage, and PDR. In the study Abbas et al. [24], HBO-ECHS is a hybrid bio-inspired algorithm that combines BOA and ACO for effective cluster head selection in VANETs. It is proposed in this study. By lowering routing overhead and energy consumption, it improves communication. Comparing NS2 and SUMO simulations to AJ-MOFA and RJ-EDCV, the former demonstrate better PDR, delay, energy efficiency, and routing performance. Salim, A et al. [25] considered the following parameter, like network grid size, average cluster lifespan, and node transmission range for optimal clustering using the sparrow search algorithm (IoVSSA).

III. Proposed Solution

From the survey, most of the clustering algorithms for vehicular network clustered the network based on stability, density and energy. Ensuring the QoS was targeted by the routing algorithm. When assumption made on clustering is broken, the QoS for message dissemination is affected. Also, the overhead for cluster maintenance increases when assumptions are disturbed. The major gaps in existing clustering algorithms are:

- Overhead for cluster maintenance is higher when clustering assumptions are broken.
- Clustering is not based on multi QoS optimization due to which providing higher QoS with routing alone becomes difficult.

This work proposes a heuristics-based clustering algorithm to solve this problem. The algorithm has three stages: i) Construction of QoS guideline path in the network, ii) Clustering with assistance of QoS guideline path and iii) Cluster maintenance.

The network model for proposed solution is given in Fig. 1 shows how the IEEE 802.11p wireless standard allows each vehicle to interact with the RSU and with each other. RSU monitors the vehicular movements in its coverage.

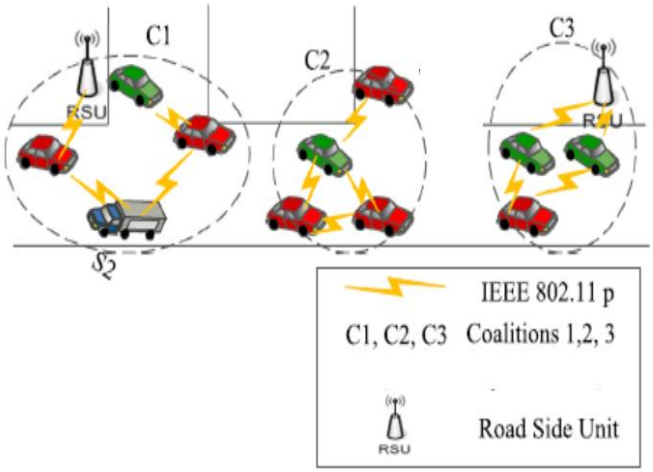

Fig. 1. Network layout.

The vehicular density over period of time (VD_i) in each grid is calculated as:

$$VD_i = \begin{cases} \alpha.T + (1-\alpha)VD_{i-1} \; if \; T \neq 0 \\ (1-\alpha)VD_{i-1}, otherwise \end{cases} \quad (1)$$

where, T is the current density. The grids whose VD_i is above a certain threshold are marked as salient points. A graph is created with all salient points and RSU locations as in Fig. 2. A virtual guideline path is created with minimal hop connectivity to the RSU and salient points. The difficulty in finding the virtual guideline route is solved using the Steiner minimal tree (SMT) problem. It has the feature of introducing intermediate junctions other than RSU to provide more amount of freedom in path construction provided by the Steiner tree.

The Steiner minimal tree is constructed taking P RSU's. The Steiner algorithm must result minimal spanning tree built on S Steiner vertices such that overall length of tree is minimized. Since finding the S points is a NP (non-polynomial) complexity problem, heuristics algorithms are explored to solve it. This work uses Graph iterated 1-steiner (GIIS) [26] to find the Steiner minimal tree.

To apply GIIS, a graph G is created. Each RSU is vertex in the graph G. The delay for packet transmit between RSU is set as edge weight. Delay is intended in terms of probability of distribution over past values as:

$$\text{Delay} = \begin{cases} \sum_{i=0}^{\infty} f_i(a).f_i(b) \;, x = 0 \\ \sum_{i=0}^{\infty} f_i(a).f_{2x+i}(b) + \sum_{i=0}^{\infty} f_i(b).f_{2x+i}(a), x > 0 \end{cases} \quad (2)$$

In the above equation, $f(a)$ is the probability_mass_function in forward_path and $f(b)$ is the probability mass function in backward_path GIIS algorithm finds S optimal Steiner_points, so that cost of Steiner tree found using below equation is minimal for N RSU's.

$$\Delta KMB(N,S) = cost\big(KMB(N)\big) - cost(KMB(N \cup S)) \quad (3)$$

An example of the Steiner tree constructed for RSU is given in Fig. 2. The Steiner points are located at minimal distance to RSU. Steiner points are connected in a minimal tree.

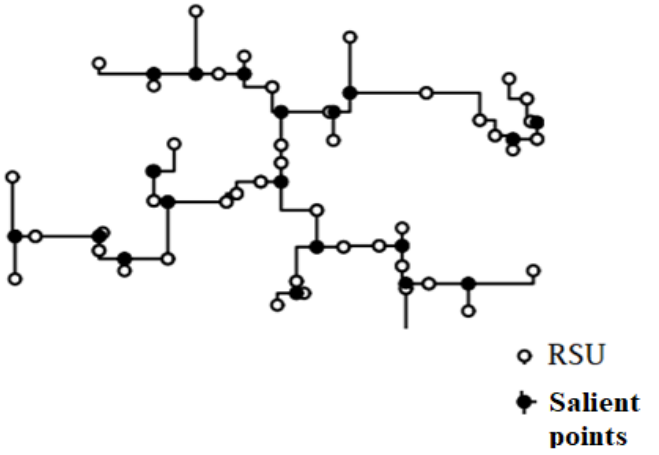

Fig. 2. Virtual guideline path.

The route connecting RSU to Steiner_points and among Steiner_points is the virtual guideline path. The tactical points must be grouped into K groups, where K is the number of data collection points. Grouping of tactical points must be done so that to minimize the delay and maximize the coverage of RSU in the group. Maximizing the coverage and minimizing the delay are two conflicting requirements, and a balance must be achieved between these two conflicting requirements. With increase in the number of strategic points, finding the optimal group is a combinational explosion problem. To solve this problem, nature-inspired heuristics is used in this work. Among multiple heuristics algorithms, particle-swarm-optimization (PSO) is used due to its simplicity.

PSO algorithm is centered on the social actions of swarms. It is a simple, flexible and versatile used to solve many optimization problems. It is centered on the observation that finest solution found by particle in swarm becomes the best solution for entire particles in the swarm. Each particle move randomly in its own velocity and evaluate a fitness function at each position. The position, where maximum value for fitness function is found among all the particles is the global best solution. All other particle update their local position based on the global best solution. This process of updating position and converging to global best solution is repeated in iterations till a maximum fitness function value is obtained or maximum number of repetitions are exceeded.

Each particle (X) updates its position (X_i) at current time based on past location and new velocity $(V_i(t+1))$ as:

$$X_i(t+1) = X_i(t) + V_i(t+1) \quad (4)$$

The new velocity is calculated based on past velocity $(V_i(t))$, distance to globally best solution (p_{besti}) and distance to locally best solution (p_{besti}) as:

$$V_i(t+1) = wV_i(t) + c_1 r_1\big(p_{besti}(t) - X_i(t)\big) + c_2 r_2\big(g_{besti}(t) - X_i(t)\big) \quad (5)$$

The important thing to distinguish the best solution is controlled by acceleration coefficient c_1 , c_2 and random number r_1, r_2 . The importance to velocity is controlled by intertia weight w.

In this work, each particle represents a group, and it is S bit binary string where each point represents a Steiner point. The value of this position is either 0 or 1, with 0 representing the corresponding Steiner_point not in group and 1 representing the corresponding Steiner_point in group.

The fitness function for particle is calculated as:

$$F = \frac{\sum_{i=1}^{K} |G_i| + 1/SP(G_i)}{K} \quad (6)$$

where, K is the number_of_Steiner_points and $|G_i|$ is the number_of_Steiner_points in the group. SP is the length of minimal route connecting the Steiner_points in the group using Dijkstra's shortest path algorithm. Each particle selects a random binary string as an initial solution. Each particle calculates the fitness function. The particle with the highest value of fitness function is the globally best solution. Based on the globally best solution, the position is the binary string is updated at a certain rate (or velocity). The iteration starts with new solutions and is repeated till there is no change in the binary string or the maximum iterations are reached. The final binary string at the end of the iteration is the solution. The procedure for choosing optimal groups is given below.

Once the Steiner_points are grouped to K groups, the centroid point of each group is selected as the cluster head point.

RSU entrenches the position of the Cluster head points near its neighborhood and sends in the beacon packets. Vehicles check these beacons and if it discovers it position is very near to the cluster head points, it sends a Hello msg broadcast with cluster indicator. Any vehicle observing the Hello msg broadcast joins to this cluster.

Once the vehicle assumed role as cluster head moves, any other vehicle near to the cluster head point will select itself as cluster head and broadcast the Hello msg to request nearby nodes to join its cluster. By this way, the cluster maintenance overhead is lower in our approach. The overall clustering process is given in Fig. 3.

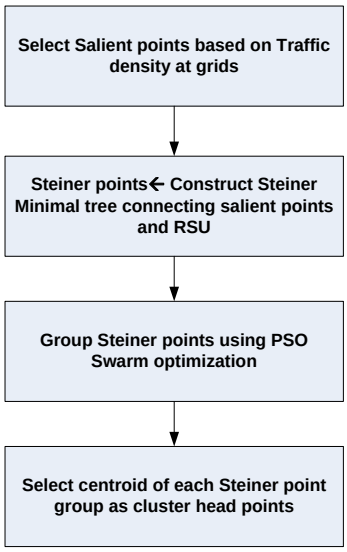

Fig. 3. Clustering process.

IV. RESULTS

The NS-2 simulator is used to evaluate the effectiveness of the proposed solution. SUMO and NS-2 extension code implements the proposed solutions on vehicles traces generated. Simulation runs on the specified configurations, as shown in Table I.

TABLE I. NS-2 SIMULATION CONFIGURATION

Parameters	Values
Propagation_model	Two-way ground
Mobility_model	Krauss
Transmission_range	300m
Transmission_power	20 m W
Simulation_area	4000 m * 4000m
Simulation_time	500s
Message_size	170 bytes

The simulation was conducted against the network layout shown in Fig. 4.

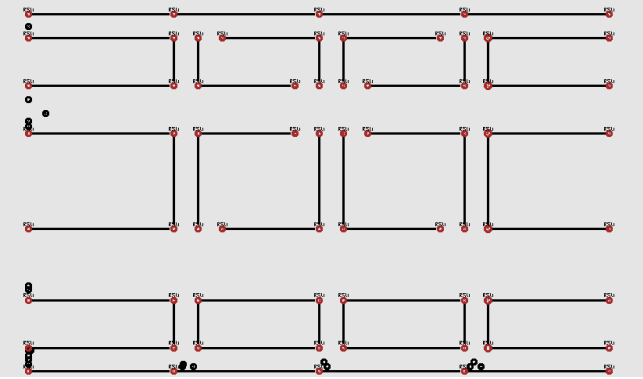

Fig. 4. Network layout.

The proposed solution performance was measured in terms of cluster duration, number-of-clusters, cluster maintenance overhead, packet delivery ratio, delay, and routing overhead. The comparison is done against the proposed solutions and connectivity based clustering proposed by Gasmi et al. [16], connectivity based clustering algorithm proposed by Khan et al. [17] and an unstable connectivity-aware clustering algorithm proposed by Gasmi et al. [18].

The number of clusters was measured for various vehicular speeds and the result is given in Table II.

TABLE II. COMPARISON BASED ON NUMBER OF CLUSTERS

Number of Vehicle	Comparison based on the number of clusters			
	Proposed	*Gasmi.et .al [16]*	*Khan.et.al [17]*	*Gasmi .et.al [18]*
20	7	8	8	9
40	10	11	12	13
60	11	14	13	15
80	12	17	16	18
100	13	19	19	22
Average	**10.6**	**13.8**	**13.6**	**15.4**

In the proposed solutions, the average number-of-clusters is 30% less compared to Gasmi et al. [16], it is 28% less compared to Khan et al. [17] and 45% less compared with Gashmi et al. [18]. The number of clusters is almost stable even at high speeds, as the clusters are created near the stable guideline path instead of vehicular speed and movement mobility metrics used in existing works, as shown in Fig. 5.

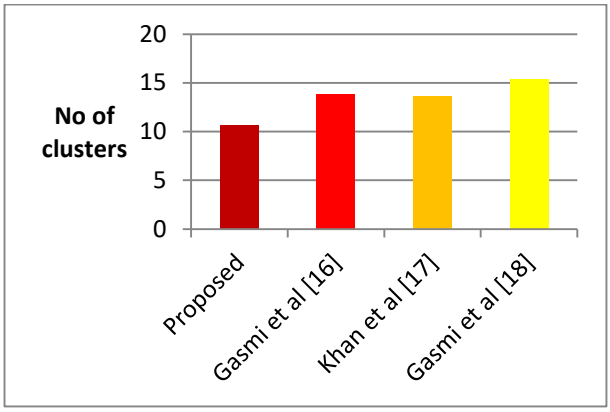

Fig. 5. Average number of clusters.

The average duration of cluster is measured with various vehicular speeds, and Table III shows the result.

TABLE III. COMPARISON OF CLUSTER DURATION

Number of Vehicle	Cluster duration (seconds)			
	Proposed	*Gasmi.et.al, [16]*	*Khan.et.al, [17]*	*Gasmi.et.al, [18]*
20	91	86	87	88
40	86	81	82	82
60	83	77	78	77
80	80	72	74	73
100	79	66	69	68
Average	83.8	76.4	78	77.6

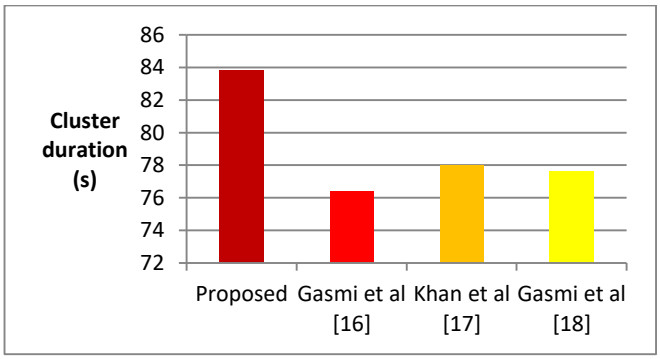

Fig. 6. Average cluster duration.

In the proposed solution the average clustering duration is at least 8% less compared with Gasmi et al. [16], 6% less compared with Khan et al. [17] and 7% less compared with Gasmi et al. [18] as shown in Fig. 6. Clustering duration is higher as the cluster is created based on vehicular movement around the guideline path periphery and optimal cluster

selection using PSO based on stability in the proposed solution. The existing works used link stability and node density mobility metrics which varies during higher speeds and thus their clustering duration is lower. They compensate for it by increasing the number of clusters.

The packet delivery ratio was measured for various vehicular speeds and Table IV shows the above results.

TABLE IV. COMPARISON OF PACKET DELIVERY RATIO

Number of Vehicle	Comparison Of Packet Delivery Ratio			
	Proposed	*Gasmi et al. [16]*	*Khan et al. [17]*	*Gasmi et al. [18]*
20	93	90	91	90
40	91	89	89	88
60	90	86	87	87
80	89	85	84	85
100	88	83	82	83
Average	90.2	86.6	86.6	86.6

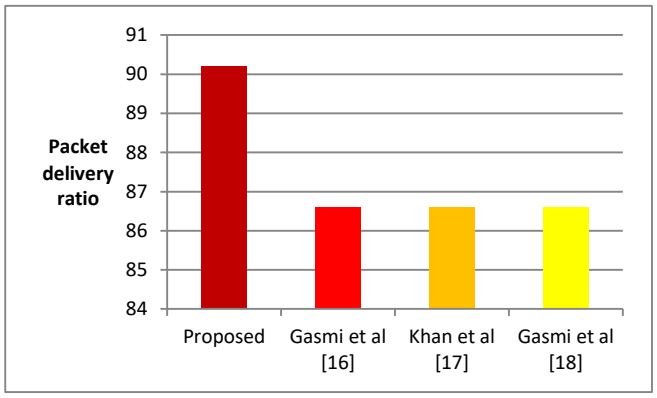

Fig. 7. The proposed and existing packet delivery ratio.

In the proposed solution, the packet delivery ratio is 3.6% high compared with existing works, as shown in the Fig. 7. Due to creation of more stable clusters and ability to search the hop cluster for data forwarding along the virtual guideline path increases the packet delivery ratio. The presence of virtual guideline path was the differentiator in the proposed solution compared to existing works.

By varying the speed, the average packet delay is measured, and the result is shown in Table V.

TABLE V. COMPARISON OF DELAY

Number of Vehicle	Delay (milli seconds)			
	Proposed	*Gasmi et al. [16]*	*Khan et al. [17]*	*Gasmi et al. [18]*
20	17	18	19	19
40	21	24	24	25
60	24	28	27	28
80	25	33	32	34
100	25	34	34	37
Average	22.4	27.4	27.2	28.6

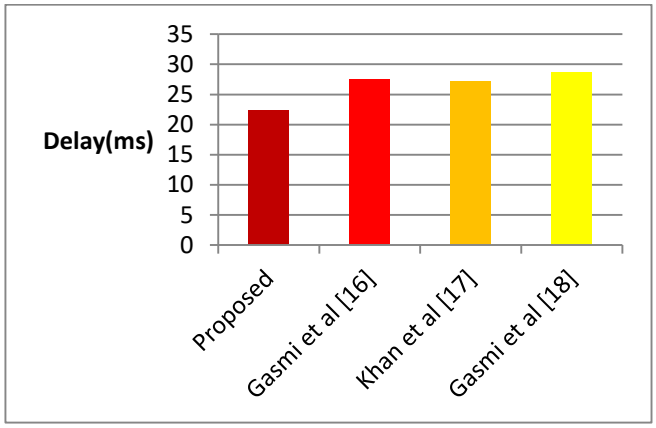

Fig. 8. Delay.

The average packet delay in the suggested solution is 22% low compared with Gasmi et al. [16], 21% lower compared with Khan et al. [17] and 27% lower compared with Gasmi et al.[18] as shown in the Fig. 8. The packet delay has been reduced in proposed solution due to clusters around the periphery of the virtual guideline path which is constructed with delay as one of the optimization criteria. The cluster maintenance overhead in terms of volume of packets exchanged is measured for various speeds and result shown in the Table VI.

TABLE VI. COMPARISON OF CLUSTER MAINTENANCE OVERHEAD

Number of Vehicle	Cluster maintenance Overhead (KB)			
	Proposed	*Gasmi et al [16]*	*Khan et al [17]*	*Gasmi et al [18]*
20	31	33	32	33
40	37	39	37	38
60	43	46	45	44
80	45	49	51	49
100	48	54	54	55
Average	40.8	44.2	43.8	43.8

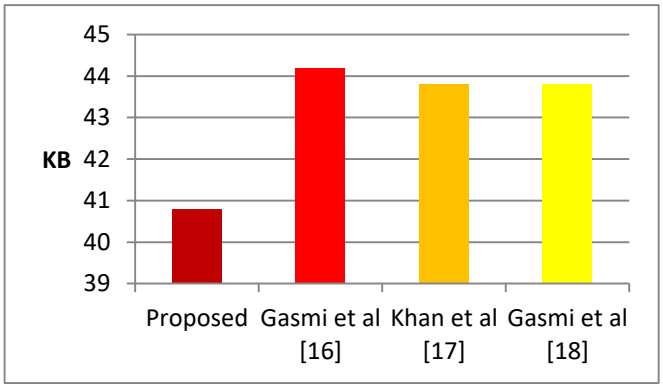

Fig. 9. Cluster maintenance overhead.

In proposed solution, the clustering maintenance overhead is 8% low compared with Gasmi et al. [16], 7% low compared with Khan et al. [17] and 7% low compared with Gasmi et al. [18], as shown in Fig. 9. The cluster maintenance overhead is low due to reduction of search space of new cluster in

proposed solution. The clusters are only selected along the periphery of virtual guideline path instead of many locations in the networks in proposed solution. The routing overhead in terms of retransmissions or route construction effort is measured for various speeds and result shown in Table VII.

TABLE VII. COMPARISON OF ROUTING OVERHEAD

Number of Vehicle	Routing Overhead (KB)			
	Proposed	*Gasmi.et.al [16]*	*Khan.et.al [17]*	*Gasmi.et.al [18]*
20	11	12	13	14
40	13	15	16	17
60	15	19	21	22
80	17	24	25	27
100	19	26	27	29
Average	15	19.2	20.4	21.8

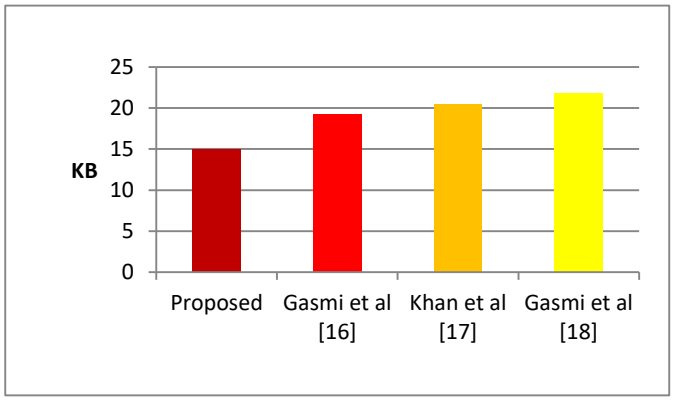

Fig. 10. Routing overhead.

In proposed solution, the routing overhead is 28% low compared with Gasmi et al. [16], 36% low compared with Khan et al. [17] and 45% low compared to Gasmi et al. [18], as shown in Fig. 10. Due to the use of RSU assistance in routing and routing along virtual guideline path, the routing overhead is reduced.

V. CONCLUSION

A heuristics-based clustering algorithm is proposed in this work for IOV network. A virtual guideline path is first established based on multi QoS and Clusters are established around the periphery of the virtual guideline path. The proposed solution can establish stable clusters with reduced cluster maintenance overhead. The average cluster duration is at least 6% higher and cluster maintenance overhead is 7% lower compared to exiting works. In terms of QoS, the proposed solution has 3.6% high packet delivery ratio and 21% low, 28% low routing overhead compared to existing works.

SOM-Based Leader Selection Strategies for Cooperative Spectrum Sensing in Multi-Band Multi-User 6G CR IoT

Mayank Kothari, Suresh Kurumbanshi
Department of Electronics & Telecommunication Engineering, SVKM's NMIMS (Deemed to be University), Shirpur, India

***Abstract*—In 6G Cognitive Radio Internet of Things (CR-IoT) networks, multi-band spectrum sensing cooperatively provides access to extensive spectrum resources. The suggested learning-based multi-band multi-user cooperative spectrum sensing (M2CSS) scheme addresses intelligent spectrum access challenges. A cooperative strategy is introduced into a dueling deep Q network to facilitate multi-user reinforcement learning. This study selects the most suitable IoT secondary users (SU) to sense channels using the proposed learning-based M2CSS scheme. With the restriction that each IoT SU can serve as a front-runner for a single network and that there will only be one leader for individual frequency, the proposed work expresses an optimization difficulty in choosing leaders through k-means and SOM, who can efficiently interact with other SUs. Next, choose matching cooperative SUs for each frequency and express additional optimization problems. Following this phase, a subset of cooperative secondary users (SUs) senses frequencies and employs accurate knowledge to determine the channels' availability in a distributed manner. The simulation findings demonstrate significant improvements in detection performance, preventing the misuse of specific devices, providing reliable sensing data over extensive IoT connections, and achieving energy efficiency—all essential for IoT implementations. These advantages make the proposed M2CSS system suitable for the massive machine-type communications anticipated in 6G IoT scenarios.**

Keywords*—Cooperative spectrum sensing; reinforcement learning; k-means leader selection; self-organizing map

I. Introduction

The concept of cognitive radio (CR) involves a communication device that can recognize and adapt to the spectral characteristics of its surroundings. By utilizing the spectral gaps (or holes) that approved consumers, also referred to as primary users (PUs), do not use, CR skill makes it possible for no licensed or secondary users (SUs) to identify these accessible portions of the spectrum [1]. Four distinct stages or functions are involved in the operation of spectrum reuse in a cognitive radio network (CRN): spectrum sharing, spectrum mobility, spectrum sensing (SS), and spectrum decision. A crucial step in identifying particular or additional PUs is SS, which indicates whether the sensed spectrum is engaged or unoccupied [2]. This mission is typically performed in particular groups, but the current multiband SS paradigm uses multiple bands that aren't always attached [3]. Demand for spectrum is rising because of the appearance of the Internet of Things (IoT), sixth generation (6G), past systems, and big data [4]. Spectrum scarcity and underutilization issues may be resolved with the help of CR skills [5]. Secondary users (SUs) in CRNs resourcefully contact the spectrum without intrusiveness through the broadcast of legitimate or PUs [6]. Each SU might have to sense every channel in single-band cooperative spectrum sensing (CSS). On the other hand, because of constraints on hardware and power consumption, each SU in multi-band CSS is given access to a subset of channels. By enabling access to a large spectrum with less difficulty and computational expense, this can significantly improve system performance. Additionally, low hand-off frequency, high throughput, and decreased sensing energy consumption are provided by multi-band CSS [7]. This essay focuses on multi-band CSS to enhance detection performance in CRNs and optimize SU scheduling for sensing a subset of channels.

Most previous methods only consider one user, which has fewer sensing capabilities than a real multi-user or multi-channel environment. As a result, SUs use a fully distributed model for multi-user spectrum access [8], which entails creating a deep multi-user reinforcement learning technique [9]. Multi-band CSS can be divided into centralized and distributed types [5]. SUs send multi-band, centralized CSS information, including multiple channels' worth of locally observed data, to an FC (fusion center) [10]. The fusion center used this information before deciding which channels were available. CRNs are bounded by limitations of the centralized method, including high latency and a single point of failure. [11]. SUs share local observations of several channels with neighbors in a multi-band distributed CSS to facilitate cooperative decision-making. Wireless sensor networks, mesh networks, Mobile ad-hoc networks, Vehicular ad-hoc networks, Flying Ad-hoc networks, etc., remain a few examples of disseminated CRNs [12]. Distributed CRNs are especially well-suited for newer Internet of Things applications like public safety networks and habitat monitoring. In disseminated CRNs, SUs typically have constrained computational and battery resources. Therefore, when developing multi-band CSS schemes for distributed CRNs, trade-offs must be made between energy resources, computational capacity, and performance limitations.

A difficulty with multi-band CSS is the development of SUs to detect radiofrequency (RF) in specific networks in distributed CRNs. Depending on the channel state data, SUs may be able to sense channels in different ways. Consequently, if multiple SUs have similar locally sensed information,

selecting cooperative SUs efficiently to sense a subset of frequencies can lower sensing overhead and enhance organization presentation [13]. The CRN's size grows when new SUs join the existing SUs. New SUs must be given multiple channels to divide the sensing load equally between the original and new SUs in the network. To do this, research on the topic is essential. The actions and residual energy of the previous frame determine each frame's initial energy level. In addition to being sporadic and unpredictable, the electrical energy obtained from the harvested RF may not always have enough power to optimize throughput. Therefore, the CRN must be energy efficient to balance the amount of energy harvested with the energy consumed during sensing and transmission activities. There is a sensing-throughput trade-off [14] in typical cognitive radio networks (also known as unconstrained energy counterparts), which depends on sensing accuracy and sensing time. However, the results of the sensing process (i.e., the sensing duration and accuracy) are energy-constrained in the context of the energy harvesting CRN, making the energy harvesting-based CRN (EH-CRN) a scenario with increasing complexities. The SS is the primary mechanism that enables spectrum findings, which is not possible without all other CR functions. It is the driving force behind concentrating solely on this component of CR. In [15–16], it has developed into a method that enhances spectral efficiency by providing access to SH, or vacant frequency bands, during intermittent times.

The primary objective of this research is to develop and analyze an efficient SS framework for CRN in 6G-enabled Internet of Things (6G CR-IoT) environments that addresses critical spectrum scarcity challenges through opportunistic spectrum access while ensuring minimal interference to licensed users. The SOM-based cooperative SS technique carries out this function by having the CRN node sample the targeted spectrum in the range of 0.1 to 1 THz and determine whether or not an incumbent signal is present. SS seeks to reduce any interference that the incumbent might encounter from CRN nodes, in addition to identifying resources that are easily accessible. As a result, the SS scheme that the CR nodes use for identification significantly impacts the CRN and its performance, regardless of the incumbent network's licensing status. By allowing IoT devices to strategically access and share available spectrum resources while utilizing the improved capabilities of 6G networks, 6G CR-IoT seeks to address significant issues with spectrum scarcity.

A. Study Organization

The following sections are organized as follows: Section II provides the literature survey with existing gaps. Section III emphasizes the detailed proposed model with suitable diagrams and mathematical equations. Section IV gives the experimental results with four sub-sections under it, and Section V concludes this research.

II. Literature Survey

Recently, studies have been carried out to improve multi-band CSS performance in CRNs [2, 5, 8–26]. The type of CRN—decentralized or centralized—and the particular techniques used by different authors determine how effective these systems are. Most multi-band CSS schemes in the existing literature were created with centralized CRNs in mind. Through simultaneous optimization of the detection inception, a multiband multi-user scheme is proposed in [17] to maximize the throughput of a centralized CRN with imperfect sensing information. A centralized CRN-based multi-band CSS scheme proposed in [18] overcomes the issues of spectrum resources and limited energy. The plan uses wireless occurrence dynamism gathering and maximizes throughput by optimizing sensing time. For centralized CRNs, an ideal multi-band CSS scheme with chance disruptions is put forth in [19]. The method reduces interference to PUs while optimizing CRN throughput. For centralized CRN, a multi-band sensing time-adaptive structure is also suggested in [20] to increase throughput and lessen interference to PUs. An artificial immune procedure built on the clonal selection theory is used to overcome this obstacle. Responsive hand-off in expression is reduced in centralized multi-band CRNs according to [21]. Sample-based sensing is an effective method for this purpose. In [22], the authors details that to maximize detection performance, the smallest number of SUs is chosen to sense frequencies based on the network situation. Centralized CRNs in [23] suggested a sub-Nyquist multiband CSS protocol to lower the overhead of computation and transmission using resident sub-Nyquist samples. For centralized CRNs with malevolent users, a multi-band CSS scheme is suggested in [24]. To limit the throughput of CRNs and counteract the threat of malevolent attackers, the authors devised an optimization problem. To improve system performance, a multiband CSS scheme based on deep learning is suggested in [25] for centralized CRN. This scheme allows SUs to sense networks independently and forecast the effects of indolent forecasting on the frequency of state-owned during the opening period. As a result, sensing requires less energy. Two secreted coatings, each containing 40 neurons, are used in the implementations for this purpose. The algorithms broadly impact the performance of centralized CRNs, and it continues to be exceptional as the CRN's dimension grows. Due to their computational intensity, these processes can result in growth that is above average, as evidenced by higher SUs and dispersed CRNs.

The investigations in [26] specifically pinpoint the ideal sensing policy. They are an expansion of [26] that establishes the ideal detection threshold and sensing policy for enhancing the anticipated throughput while taking collision limits and energy causality into account. To increase average throughput while preserving energy, the relationship between the ideal sensing length and the matching sensing threshold was looked at. Based on the energy arrival rate and the correlation of the primary traffic, the theoretical maximum throughput of the SU in an energy harvesting-based system is considered, considering energy causality and collision constraints. The trade-off between SS and SU throughput is examined in [27] for a typical energy-unconstrained CRN. This maximizes both the average throughput and the harvested energy by optimizing the decision-making time. Based on it, the work [28] aims at proposing an optimum sensing time for the overlay energy harvesting (EH) CRN, in order to improve SU throughput and the harvested RF energy. Additionally, [29] performs the optimal SS and SU transmissions so as to maximize the residual energy. A common obstacle detected in

these works is the unpredictable nature of energy derived from ambient RF sources and the inability of it to always provide the maximal throughput in EH-CRNs. The SU split the channel into two sub-channel sets. One is used to detect the PU, while the other is used to record the RF of the PU signal. To ensure throughput, gathered energy is supplied in the transmission slot to offset sensor energy loss. Nevertheless, there is no mention of the specific energy source used for data transmission. In summary, although a significant amount of research has been done on non-arbitrary ways to assign channels for sensing by involving SUs in disseminated CRNs, these schemes are not remarkably scalable because of their limited computational capabilities. All cognitive radios participate in CSS by measuring the licensed spectrum and making autonomous decisions. Typically, the cognitive radio network is made up of multiple SUs and PUs, with the goal of the SUs being able to share multi-channel spectrum properties with the PUs without interfering with the PUs. Every SU optimizes its own SS performance while exchanging sensing data with the others. SU cannot be sure of the channel environment and is unable to choose until after trying a few times to sense a new channel. As a result, the partial observability issue can be resolved by modeling the channel exchange as a Markov chain. Every SU is synchronized with the designated time slot. The sensing data and the information broadcast historically are the two periods that make up the time slot structure. Every SU in the system independently senses the slot at the start of the sensing historical event. Subsequently, the SU merges data with received data and transmits its sensing data to other users. Every SU, then sends out its decision. An acknowledgment signal is sent to confirm the accomplishment or failure of the broadcast before the sensing period ends.

III. Research Methodology

A. Model Creation

The system model is created in this section by assigning base stations to secondary users, calculating the received powers, visualizing the network deployment, and generating random coordinates for both primary and secondary users. Using the existing k-means clustering, this section divides both new and current secondary users into various clusters according to their coordinates. It also selects new secondary users' leaders using proposed self-organizing maps. SS is carried out in this part by comparing secondary users' received power from base stations with a sensing threshold. The sensing result array indicates identified primary users with a value of 1.

B. Proposed SOM-Based Leader Selection

Choosing a leader involves determining which SU on each channel m is the best to listen to. Leaders must also select cooperative SUs for sensing each channel. Let, SNR_mk and SNR_avg represent the SNR standards of the k^{th} SU sensing the m^{th} channel, respectively, the preferred and attached thresholds for the normal SNR value across different frequencies. The channel m leader must establish a minimal association between its indication wrapping and the signal envelopes of the SUs to choose cooperative SUs with distinct nearby sensed data. The leader for each channel is the SU whose SNR is near SNR_avg, as defined in Eq. (1) and Eq. (2):

$$\propto_{mk} = \begin{cases} 1, & if\ K^{th}\ SU\ is\ a\ leader\ for\ channel\ m \\ 0, & otherwise \end{cases} \quad (1)$$

The following is a definition of the optimization problem preparation for a similar collection of channel leaders:

$$\min_{\propto_{mk}} \sum_{k=1}^{K} \sum_{m=1}^{M} \alpha_{mk} \times \left| SNR_{mk} - SNR_{avg} \right|$$

$$\text{Subject to: C1} : \sum_{m=1}^{M} \propto_{mk} = c_k, \forall\ k,$$

$$\text{C2:} \sum_{k=1}^{k} \alpha_{mk} = 1, \forall\ m, \quad (2)$$

The binary variable c_k is equivalent to 1 if the k^{th} SU is a leader for a channel and 0 in all other cases. C1 ensures that a single SU can't simultaneously be chosen as a leader for multiple channels. C2, on the other hand, affirms that a single leader is selected for every channel. Combining these two restrictions ensures that every cooperative cluster has a distinct leader and channel.

C. Reinforcement Learning (RL) for Resource Allocation

According to the power received from the primary user, this section allocates available secondary users to primary users. Users who have been allotted are shown. This section applies a reinforcement learning algorithm to maximize resource distribution for every secondary user. The Q-learning algorithm trains a Q-table and mimics the environment to obtain rewards. Based on the rewards, the Q-table is updated, and metrics like energy consumption, false alarm rate, throughput, and probability of detection are calculated. A new line of inquiry for addressing SOM issues is the development of reinforcement learning (RL) techniques. The RL techniques shown in Fig. 1, don't need any prior understanding of the system model and can adjust to the spectrum environment. Because it is model-free, Q-learning is a significant reinforcement learning subfield with extensive applications in various settings. Finding the Q value for every state-action pair is the primary goal of Q-learning, a value iteration technique. Every SU uses the Q-learning approach, and based on recent action-observation experience and past channel occupation history, decides whether to sense the channel. Q-learning is effective when the state and action spaces are small.

A new line of inquiry for addressing SOM issues is the development of reinforcement learning (RL) techniques. The RL techniques don't need any prior understanding of the system model and can adjust to the spectrum environment. Because it is model-free, Q-learning is a significant reinforcement learning subfield with extensive applications in various settings. Finding the Q value for every state-action pair is the primary goal of Q-learning, a value iteration technique. Every SU uses the Q-learning approach, and based on recent action-observation experience and past channel occupation history, decides whether to sense the channel. Q-learning is effective when the state and action spaces are small. DQN, which combines Q-learning and Reinforcement learning, has demonstrated considerable promise in solving the SOM problem. RL as a Markov chain in $2N$ states can accurately represent large-scale models, allowing them to continue performing well in large-scale scenarios. Channel selection in DQN is represented by $<S, A, R, S'>$, where $S \in \{S1, \cdots, SN\}$

indicates the state space, $A \in \{1, \cdots, N\}$ indicates the action space, $R \in \{0, 1\}$ indicates the instant reward, and S' indicates the next state. Every time slot begins with the current state (S), which comprises all the previous observations and decisions.

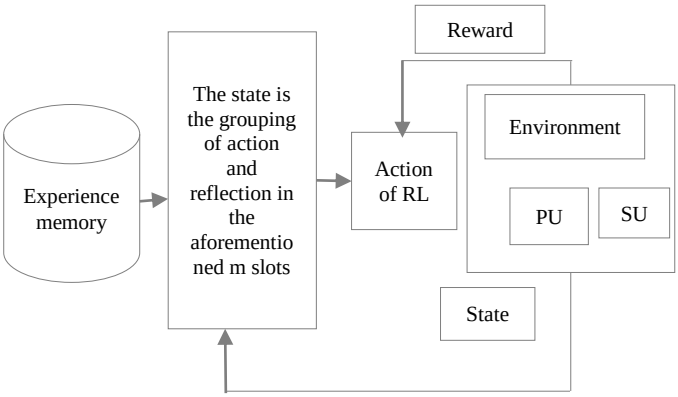

Fig. 1. RL framework for CRN.

The Q network takes the S as an input and predicts what the best action, A, should be as an output, which denotes A sensing of a particular channel at time slot t. The system may reach the next state after taking action A and receive a reward instantly. At last, the time slot record is saved in memory D, and it iterates again to D. And the experience memory is filled according to the random sampling. It samples m records (S, A, R') using experiences sampled from memory D to derive the current target Q estimate. The associated in Eq. (3) is given as:

$$y=R+\gamma \max_{a'} Q(S_{t+1}, a'; \theta_i^-) \quad (3)$$

The reinforcement output, denoted by y, is determined by the new experience. The approximation function created through prior expertise is represented by Q (S_{t+1}, a' ; $\theta - i$), where S_{t+1} is the novel state resulting from action a, assuming the state S_t , and t is the time interval. The weightiness of the Q-network charity to calculate the objective at repetition i is represented by θ_i^-, and the discount rate is denoted by γ. The loss function, which is expressed in Eq. (4) and Eq. (5), is the mean right-angled error between the value of the impartial purpose and the assessment of the definite purpose.

$$L_i(\theta_i) = E[(R_{t+1} + \gamma \max_{a'} Q(S_{t+1}, a'; \theta_i^-) - Q(S_t, A_t; \theta_i))^2] \quad (4)$$

$$\nabla_{\theta i} L_i(\theta_i) = E\left[\left(R_{t+1} + \gamma \max_{a'} Q(S_{t+1}, a'; \theta_i^-) - Q(S_t, A_t; \theta_i)\right) \nabla_{\theta i} Q(S_t, A_t; \theta_i)\right]) \quad (5)$$

where, the estimate purpose designed by old understanding is represented by Q (S_{t+1}, a'; $\theta - i$) and the estimate purpose designed by new understanding is represented by Q (S_t, A_t; θ_i).

IV. Results and Discussion

The states of the proposed M2CSS are the grouping of the operator's state on respective frequency, and the user's relationship to the PU, SU, data 1, data 2, and CBS, as shown in Fig. 2. Two simulated networks with different user and channel counts are employed to achieve accurate sensing in many user scenarios. The network implementation should take less time to yield positive outcomes.

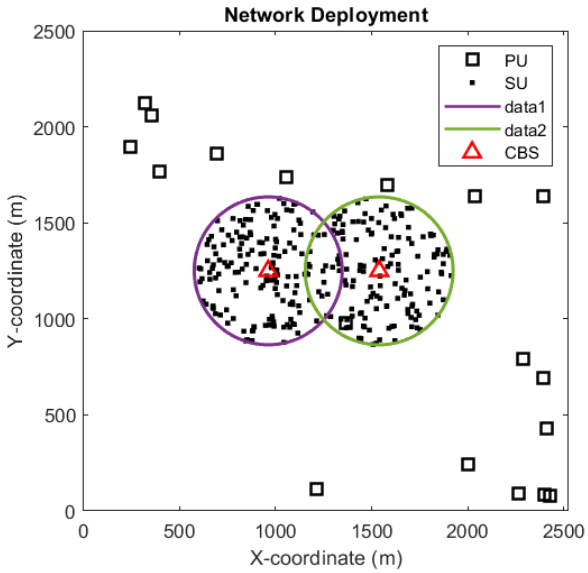

Fig. 2. M2CSS network deployment.

D. K-means for Leader Selection (KMC)

This stage uses similarities to classify recently joined SUs in the system that are interested in common assemblies. Fig. 3 shows the organization process when new SUs attempt to intersect the CRN. The primary justifications for utilizing KMC in this work are its simplicity, speed, and low complexity. To locate the centroids in KMC, the maliciousness of the exercise set under consideration is computed. The centroids then state that the unlabeled set is confidential. The classifier in this study is created utilizing historical data from operational cooperative SUs. To classify the joining SUs, one needs to determine the centroids of each class. The CVM test results of current SU leaders are the lowest, and their SNR values are relatively close to the average SNR for each channel. Non-leaders, on the other hand, have larger SNR value spreads and high CVM test values. This implies that the training set should form two distinct clusters. Fig. 3 displays the filtered data as well as the current data points. Eigen vectors and values of the new and old data points were used to generate distribution contractions for them. The distributions differ from one another. Outliers must therefore be removed from freshly acquired data points. Fig. 3 shows the data points for leaving cooperative SUs. Interestingly, two separate SUs do not align with two marked departing data points.

E. SOM Leader Selection

Consequently, the data points from the operational cooperative SUs were split into two classes (see Fig. 4). The RL algorithm is utilized to do this. Channel leaders make up Class 1, and non-leaders make up Class 2. These class centroids serve as reference points for classifying new data instances. This procedure aids in distinguishing new data from Class 1 samples.

F. SNR Distribution of the Secondary Users

The SNR for secondary users is determined as defined in Eq. (6), where $received_power_SU_bs$ is the established control of the secondary consumer from the base station, and $noise_power$ is the noise power. When the sensing duties were distributed, the number of SUs sensing each frequency increased. This may result in the system using more energy. The incorporation of multiple SUs into the system can cause average SNR levels to surpass acceptable limits, resulting in compromised detection capabilities. Therefore, for a few freshly selected SUs, testing the average channel SNR condition and lowering the minimum required is necessary. If they find another channel, new SUs might not have to bother about sensing this one. This will enable the performance and energy to be recovered (see Fig. 5).

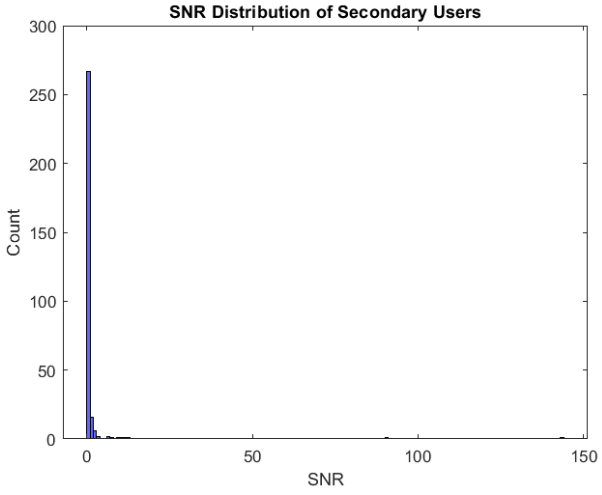

Fig. 5. SNR distribution of SU.

$$SNR_{SU} = \frac{received_power_SU_bs}{noise_power} \quad (6)$$

G. Resource Allocation

For illustration, it is considered that the user is distributed by channel with 10 joining and 10 existing SUs. Fig. 6 displays training data points or the data from the cooperative SUs currently used for sensing channels. The proposed work considers two features, resource allocation and SNR values, and defines a data point as a pair of binary feature standards for SU sensing at the m^{th} frequency represented in Fig. 7. Both characteristics are scaled to depict the data points accurately. The disseminated version procedure for channel 2 of the recommended M2CSS and EM2CSS arrangements and the current multi-band schemes, RSSS, and ASSS, are shown in Fig. 8, Fig. 9, and Fig. 10. To simulate CRN systems, λmax is considered the learning rate, without losing generality. The suggested M2CSS and EM2CSS schemes establish the minimum and maximum K×I values for the number of designated SUs that can intelligently set a channel.

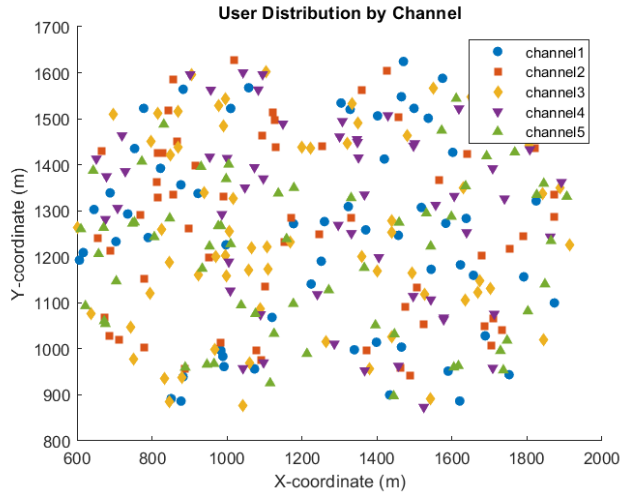

Fig. 6. User distribution by channel.

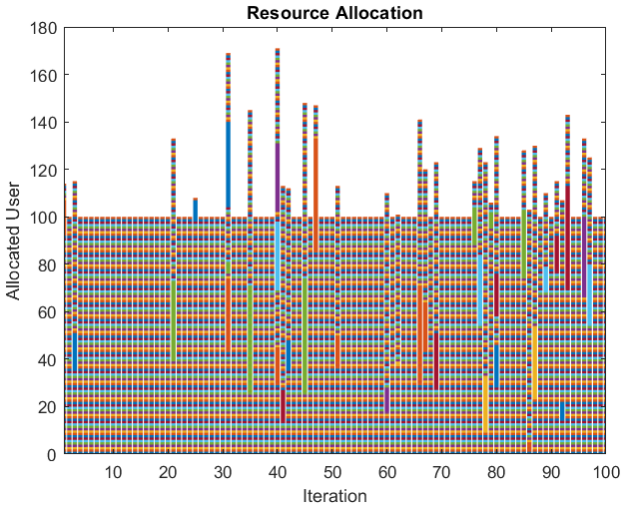

Fig. 7. Resource allocation for SU.

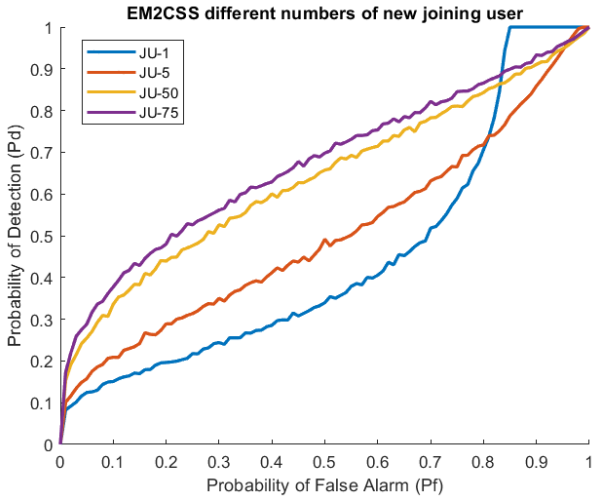

Fig. 8. EM2CSS with different numbers of SU.

Before estimating each cooperative SU separately, ASSS selects them at random. Determining the test statistics and sensing a few examples based on the estimate. If the examination indicators are exceeding a specified boundary, SU is supposed to be able to sense primary user activity on the channel and execute preparation. It eliminates the need to sense that channel in any other way. Because of the approximation of the SUs' procedure in ASSS, there are generally fewer SUs in ASSS. SUs that were predicted to have poor sensing performance are dropped. RSSS selects cooperative SUs at random. Consequently, in M2CSS, EM2CSS, RSSS, and ASSS, respectively.

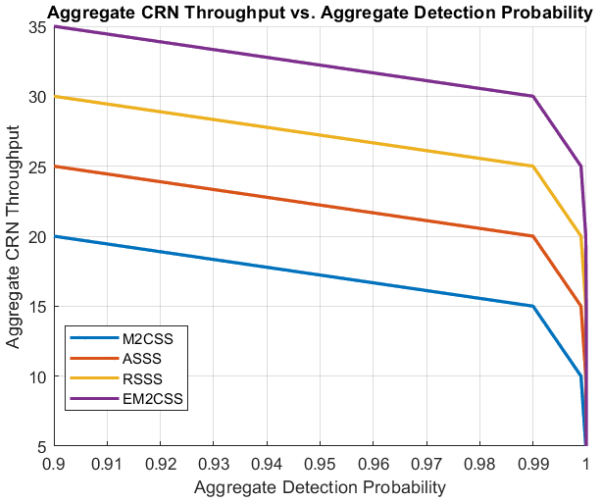

Fig. 9. CRN throughput for SOM leader selection.

A significant benefit of the proposed M2CSS and EM2CSS schemes is that they do not select dismissed cooperative SUs or those through comparable identified material for the m^{th} channel. Nevertheless, when SUs are chosen by popular RSSS, SUs with comparable information may be chosen randomly, as the first selected SU possesses comparable sensing information, as seen in Fig. 9. In contrast, the third selected SU does not have original statistics for the alteration procedure.

This could result in increased computational complexity and expenses related to energy usage. The consensus point is reached in each case after 14 iterations, and the channel occupancy is calculated by comparing the obtained results to the threshold. The throughput results demonstrate that EM2CSS performs significantly better than M2CSS, and for all network sizes considered, both schemes provide excellent CRN throughput consequences.

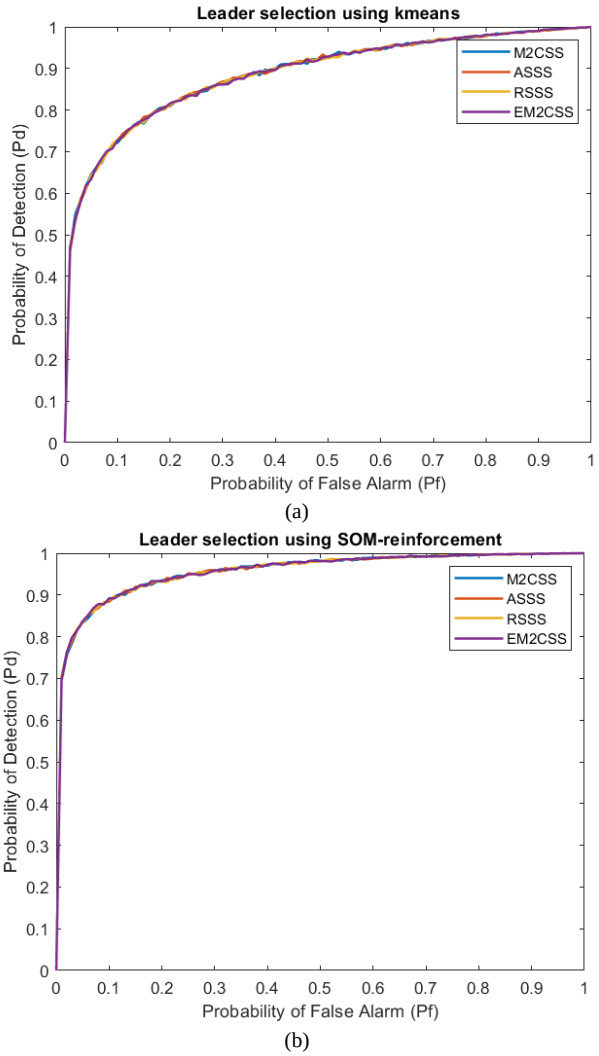

Fig. 10. (a) ROC with different CRN schemes using k-means, (b) ROC with different CRN schemes using SOM.

Proceeding with the additional indicator, the CRN throughput presentation of the current schemes varies. For lower and higher CRNs, the combined PU throughput is compared to the combined untrue distress possibility (also called the PU security level). At a 10% false alarm probability, the most significant combined throughput is attained by the proposed EM2CSS scheme. Additionally, the M2CSS scheme achieves the same false alarm rate. However, it is achieved when the current ASSS scheme is used with the same false alarm possibility. The ROC curve in Fig. 10(a) and Fig. 10(b) shows that leader selection through SOM helps in achieving high probability of detection with less value of probability of false alarm as compare to existing k-mean. Therefore, the proposed EM2CSS structure fulfills the highest requirements of PU throughput in both inferior and superior CRN configurations. The combined sensing energy usage of the larger CRN's current RSSS and ASSS systems, as well as the indicated EM2CSS and M2CSS schemes.

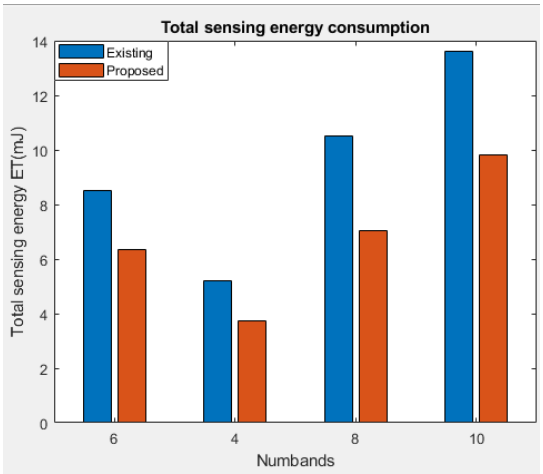

Fig. 11. Total energy consumption.

The scheme's ability to drop SUs sensing specific frequencies with low-slung expected values correlates with this lowest value. On the other hand, the current RSSS scheme uses the most total energy for sensing. The highest energy consumption in RSSS is caused by randomly selecting cooperative SUs with no restriction on the number of SUs sensing each channel. Furthermore, by relaxing cooperative SUs, EM2CSS offers the benefit of distributing the sensing load among already-existing and newly joined SUs. Reduced energy consumption for sensing is made possible by the distribution of the sensing load. It is for this reason that Fig. 11 shows that EM2CSS uses less sensing energy than M2CSS. As a result, the suggested EM2CSS enables respectable levels of sensing energy consumption and outstanding classification presentation in terms of discovery and quantity.

V. Conclusion

The SOM-based multi-band CSS schemes M2CSS and EM2CSS, which have been proposed to disseminate 6G-enabled IoT CRNs, are discussed in this study. The proposed M2CSS architecture addresses two critical optimization challenges: intelligent cluster leader selection across frequency bands and dynamic secondary user accommodation within 6G CR-IoT networks. To choose a leader for every frequency and consistently accommodate SUs, the proposed work developed two optimization problems for the suggested M2CSS scheme. These problems are solved by the reinforcement learning algorithm in the EM2CSS scheme to offer a more effective and simplified method for allocating connection SUs to allocate a subsection of frequencies intelligently. The system architecture incorporates energy-efficient mechanisms that preserve network performance while reducing power consumption—a crucial requirement for resource-constrained IoT devices in 6G networks. The system has been relaxed to minimize energy consumption without compromising performance, and the joining SU selection process has been optimized to detect specific channels. Compared to the currently offered multi-

band CSS schemes, reproduction consequences show that the recommended M2CSS arrangements select SUs through distinct nearby sensed evidence to preserve an effective agreement variation procedure and high-performance stages in lower and higher 6G IoT CRNs. While the proposed MBMU-CR IoT framework is demonstrated via simulations, extending the work to hardware implementation could introduce additional complexity, but would significantly enhance the evaluation under real-world conditions. Incorporating the concepts of joint sensing and communication, along with integrated sensing and communication, can significantly enhance the performance of the proposed M2CSS.

Abstract*—Chromatic dispersion is a significant limitation in optical fiber communication, as it causes pulse broadening, which negatively impacts transmission distance and data rates, both of which are critical for meeting the high-speed demands of 5G optical networks. This study focuses on addressing chromatic dispersion in Standard Single-Mode Fiber (SSMF) systems, which are widely deployed in 5G fronthaul and access networks. A comprehensive investigation is conducted using Gaussian-apodized linear chirped Fiber Bragg Gratings (FBGs) for dispersion compensation, implemented across three strategic configurations: pre-compensation, post-compensation, and symmetrical compensation. Each scheme is systematically evaluated to determine the most effective approach for enhancing signal integrity and overall network performance. Simulations are performed using OptiSystem 7.0 on a 10 Gbps SSMF-based optical system, with transmission distances ranging from 10 km to 80 km under controlled simulation parameters. Key performance metrics, including Quality factor (Q-factor), Bit Error Rate (BER), and eye height, are analyzed by varying SSMF length, input power, and bit rate. The results demonstrate that symmetrical compensation using Gaussian-apodized linear chirped FBGs provides the best performance, achieving a Q-factor of 12.3938, an ultra-low BER of 1.12336×10^{-35}, and a significantly improved eye height at 80 km. These findings establish the symmetrical compensation scheme employing Apodized Chirped Fiber Bragg Gratings (ACFBGs) as the most effective and scalable solution for high-speed, long-distance optical transmission in 5G networks. This approach enables key 5G applications, including ultra-reliable low-latency communication (URLLC), enhanced mobile broadband (eMBB), and smart infrastructure in smart cities. The proposed technique offers multiple advantages, such as low BER, high Q-factor, reduced signal distortion through sidelobe suppression, energy efficiency via passive operation, and design flexibility for long-haul network integration.

I. Introduction

High-speed optical communication systems rely on laser sources that emit nearly monochromatic light with a narrow spectral linewidth. As optical signals propagate through SSMFs, different wavelength components propagate at different velocities, leading to temporal spreading of the optical signal. This phenomenon leads to pulse overlap, commonly known as Intersymbol Interference (ISI), which is primarily caused by chromatic dispersion. In SSMFs, chromatic dispersion typically ranges from 15 to 20 ps/nm/km, and its impact becomes increasingly severe with longer transmission distances and higher bit rates. Chromatic dispersion in optical fibers arises from two main components: material dispersion (MD) and waveguide dispersion (WD). In single-mode fibers, material dispersion is generally the predominant factor, arising from the refractive index of the fiber material varying with wavelength [1]. In long-haul, high-speed optical networks, the primary impairments to signal quality include attenuation, nonlinear effects, and chromatic dispersion. While attenuation can be mitigated using Erbium-Doped Fiber Amplifiers (EDFAs) and nonlinearities managed by optimizing input power levels, chromatic dispersion remains the most critical limiting factor. Due to its minimal attenuation, the 1550 nm window is commonly used in optical communication systems [2].

To address chromatic dispersion in optical fiber systems, several compensation methods have been developed, such as Dispersion-Compensating Fibers (DCFs), Dispersion-Shifted Fibers, and Fiber Bragg Gratings (FBGs). Among these, DCFs offer negative dispersion to counterbalance the positive dispersion of SSMFs, but they can increase system cost and introduce nonlinear effects. Therefore, FBGs are preferred as a more compact, passive, and low-loss alternative [3–5].

FBGs are typically categorized into Uniform Fiber Bragg Gratings (UFBGs), which have constant grating periods, and Chirped Fiber Bragg Gratings (CFBGs), whose grating periods vary along their length. CFBGs can incorporate different apodization profiles and chirp functions, allowing the grating period to vary in a linear, quadratic, or cubic manner. Among these, Linear CFBGs are widely regarded as an effective solution for chromatic dispersion correction and compensation due to their ability to reflect different wavelengths at different spatial locations, thereby introducing wavelength-dependent delays and mitigating pulse broadening [6]. In addition, they are immune to nonlinear effects and are well-suited for high-speed optical systems. To further enhance performance, apodization techniques are employed. Apodization involves a gradual modulation of the refractive index profile, which suppresses

*Corresponding Author

side lobes in the reflection spectrum and reduces signal distortion. This leads to the development of ACFBGs, which provide superior dispersion compensation with improved signal quality [7–9].

EDFAs are commonly used to amplify optical signals in long-distance systems, while dispersion compensation can also be assisted by optical filters, such as Gaussian, Bessel, and Fabry-Pérot filters, at the receiver end [10]. As bit rates approach 40 Gbps, chromatic dispersion becomes a critical factor limiting system performance [11]. Although single-mode fibers are capable of supporting high-speed data rates, they still suffer from signal degradation due to attenuation and dispersion-induced waveform distortion, which contributes to ISI and crosstalk [12–14]. The Q-factor and BER are key parameters that determine the achievable transmission distance in optical communication systems. For reliable performance, the system should maintain a Q-factor above 6 and a BER below 10^{-9} to ensure signal integrity over long distances [15–17].

Despite extensive research into dispersion compensation using CFBGs and DCFs, most existing studies focus on a single compensation scheme, typically either pre- or post-compensation schemes under fixed system configurations. Systematic comparisons of all three strategies (pre-, post-, and symmetrical), particularly using Gaussian-apodized CFBGs, are rarely explored. Additionally, few works have evaluated performance at extended distances (e.g., 80 km) or considered the combined impact of key parameters such as transmission length, bit rate, and input power. This lack of holistic analysis presents a gap in identifying the most effective dispersion compensation approach designed for long-distance, high-speed optical communication systems.

To bridge this gap, the present study designs and evaluates Gaussian-apodized linear CFBGs across three compensation schemes: pre-, post-, and symmetrical. Simulations are conducted in OptiSystem 7.0 over transmission distances spanning 10 km to 80 km, input power levels from 1 dBm to 10 dBm, and data rates varying between 5 Gbps and 20 Gbps. The results indicate symmetrical compensation consistently delivers superior dispersion mitigation, particularly at extended distances and lower power levels.

A. Key Contributions of this Study Include

- Design and optimization of ACFBG models with Gaussian apodization and linear chirp profiles to enhance dispersion compensation.
- Evaluation of pre-, post-, and symmetrical compensation methods, highlighting their respective advantages and limitations.
- Assessment of signal quality and transmission integrity using key evaluation metrics, including BER, Q-factor, and eye height, under different compensation scenarios.
- Validation of the proposed ACFBG designs and compensation schemes via simulation, demonstrating their feasibility for practical applications in long-haul and metropolitan networks.

The structure of this study is organized as follows: Section II reviews the related work; Section III introduces the fundamental concepts; Section IV describes the methodology; Section V presents the simulation results; Section VI provides a discussion of the findings; Section VII concludes the study and outlines potential directions for future work.

II. Related Works

Numerous studies have investigated dispersion compensation techniques in optical fiber systems, with a particular focus on the use of FBGs and DCFs in various configurations.

Murooj A. Abd Almuhsan [18] implemented a post-compensation system using both DCF and FBG over a 50 km SSMF link at 10 Gbps in OptiSystem 12.0. By using an FBG having a dispersion coefficient of −2000 ps/nm, the system achieved outstanding performance with a Q-factor of 45.78, BER of 0, and eye height of 6.9×10^{-14}.

Keti [19] proposed a post-compensation model using a linear CFBG featuring tanh apodization and a Gaussian low-pass filter. Over a 40 km fiber span. The resulting Q-factor and BER of the system were 29.55 and 9.34×10^{-18}, outperforming both uniform FBG and uncompensated setups. This study emphasizes the impact of apodization and filtering in enhancing dispersion compensation.

Mustafa et al. [20] showed that the post-compensation scheme with raised sine apodization delivered the best results in a four-cascaded apodized linear CFBG model using the Multichannel Time Division Multiplexing (MTDM) approach. In a 10 Gbps WDM transmission over 70 km utilizing 2 mm-long gratings, the system attained a Q-factor of 8.58 with a BER of 4.77×10^{-18}. By comparison, the pre-compensation approach using a raised cosine apodization achieved a Q-factor of 7.664 and BER of 8.99×10^{-15}, while the symmetrical compensation scheme with a raised sine profile resulted in a Q-factor of 7.49 and BER of 3.53×10^{-14}.

Mustafa et al. [21] reported that the post-compensation approach delivered the superior performance in their introduction of a UFBG model employing single-stage tanh apodization within the MTDM framework for a 10 Gbps WDM system spanning a 70 km optical link, this configuration achieved a Q-factor of 9.2 along with an exceptionally low BER of 3.25×10^{-20}. In comparison, the pre-compensation approach achieved a Q-factor of 9.13 and a BER of 3.4×10^{-20}, whereas the symmetrical compensation method resulted in a Q-factor of 8.8 and a BER of 8.22×10^{-19}.

Panda et al. [22] employed an FBG-based post-compensation design for an 80 km fiber link, resulting in a Q-factor of 6.85 and a BER of 3.73×10^{-12} using 2 mm and 3 mm gratings, showcasing the practicality of FBGs in long-distance links.

Chakkour et al. [23] designed a post-compensation scheme combining UFBGs with an EDFA in a 10 Gbps WDM system. Over a 10–30 km span, the system achieved Q-factors up to 81.47 and showed strong optical gain, demonstrating potential in short-distance high-speed links.

Mustafa et al. [24] proposed a post-compensation scheme using a four-cascaded CFBG model with Differential Phase-Shift Keying (DPSK) modulation within a 10 Gbps WDM system deployed across a 70 km fiber link. The system utilized 5 mm FBG gratings and achieved a Q-factor of 7.22 and a BER of 2.59×10^{-13}, demonstrating the effectiveness of cascaded CFBG for dispersion mitigation.

While previous studies have explored the use of CFBGs for dispersion compensation, most have focused on a single compensation scheme or operated under fixed system parameters, with limited use of Gaussian apodization and few comparative analyses. This study addresses these gaps by systematically evaluating pre-, post-, and symmetrical compensation using Gaussian-apodized linear CFBGs over varying SSMF lengths (10 to 80 km), input powers, and bit rates in OptiSystem 7.0. The results show that at 80 km, the symmetrical scheme outperforms previous FBG-based methods, highlighting its effectiveness for long-haul optical links.

III. Concepts and Principles

A. Principle of Fiber Bragg Grating

Ken Hill pioneered the first demonstration of an FBG in 1978. A FBG is created by inscribing periodic variations in the refractive index along the core of an optical fiber through exposure to a high-intensity optical interference pattern. This periodic modulation forms a grating that reflects a specific wavelength, known as the Bragg wavelength, while permitting other wavelengths to propagate through the fiber with minimal loss. As illustrated in Fig. 1, a UFBG maintains a constant grating period and index modulation, which allows it to reflect only the wavelength satisfying the Bragg condition. This makes it particularly advantageous for narrowband filtering in optical communication systems [25].

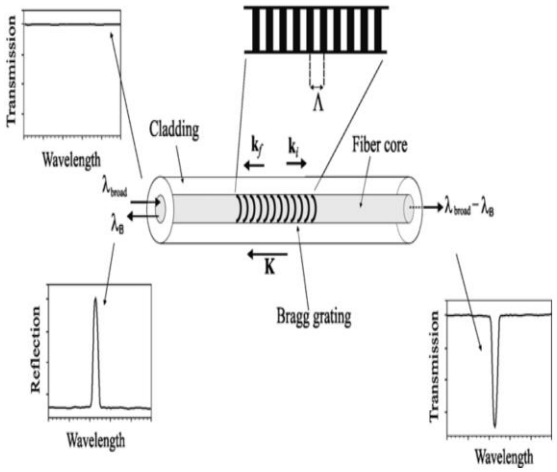

Fig. 1. UFBG with constant modulation amplitude and period.

The Bragg wavelength (λ_{Bragg}) is the specific wavelength reflected by the grating, is defined by Eq. (1):

$$\lambda_{Bragg} = 2n_{eff}\Lambda \quad (1)$$

Here, n_{eff} is used to indicate the effective index of refraction in the fiber core, and Λ denotes the periodic spacing of the grating [26]. This equation highlights that the reflected wavelength can be tuned by modifying either the refractive index or the grating period, enabling FBGs to support a wide range of optical applications.

B. Apodized Chirped Fiber Bragg Gratings (ACFBG) Structure and Mathematical Framework

CFBGs are used to compensate for chromatic dispersion in optical fibers by gradually varying the grating spacing distributed along the fiber length. This variation causes different wavelengths of light to reflect at different positions within the grating [27]. As a result, each wavelength experiences a different delay, enabling the recompression of optical pulses that have been broadened by dispersion.

In this process, shorter (faster) wavelengths reflect from regions with a smaller grating period, which are located deeper within the grating, resulting in longer delays. Conversely, longer (slower) wavelengths reflect from regions with a larger grating period, located closer to the input, and thus experience shorter delays. Because of their broad reflection bandwidth and non-uniform grating structure, CFBGs are widely employed to compensate for dispersion in high-speed optical systems [28], as shown in Fig. 2. Furthermore, the use of ACFBGs significantly enhances system performance by reducing side lobes and minimizing group delay ripple**,** making them particularly suitable for precise chromatic dispersion management in modern optical networks [29].

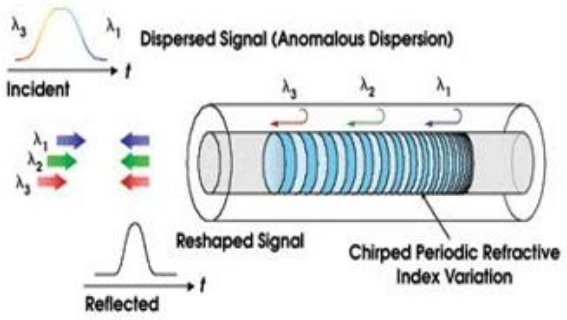

Fig. 2. Structure and operating principle of a CFBG.

The range of reflected wavelengths is expressed as Eq. (2):

$$\Delta\lambda_{chirp} = 2n_{eff}(\Lambda_L - \Lambda_S) = 2n_{eff}\,\Delta\Lambda_{chirp} \quad (2)$$

Here, $\Delta\lambda$chirp represents the difference from shortest to longest reflected wavelengths, denoted by λL and λS, respectively, while $\Delta\Lambda$chirp represents the variation between the longest ΛL and shortest ΛS grating period [30].

In a linear CFBG, the grating period at position z is defined as Eq. (3):

$$\Lambda_{(z)} = \Lambda_0 - \left[\frac{\left(\frac{z - Lg}{2}\right)}{Lg}\right]\Delta \quad (3)$$

where, Λ_0 is the midpoint period, *Lg* denotes the total grating length, while Δ represents the overall chirp [30]. Each wavelength reflects from a specific grating section, introducing a unique time delay.

The time delay τ (λ) experienced by a wavelength λ is given by:

$$\tau(\lambda) = \frac{\lambda - \lambda s}{\lambda L - \lambda s} \frac{2neffLg}{c} \quad (\lambda s \leq \lambda \leq \lambda L) \qquad (4)$$

Here, c signifies the speed at which light travels in a vacuum [30].

To determine the CFBG's dispersion in ps/nm/km, Eq. (4) is differentiated with respect to the wavelength λ, as in Eq. (5):

$$D(\lambda) = \frac{d\tau(\lambda)}{d\lambda} = \frac{1}{\lambda L - \lambda s} \frac{2neffLg}{c} \quad (\lambda s \leq \lambda \leq \lambda L) \qquad (5)$$

The refractive index profile $n(z)$ of an apodized linear CFBG is given by Eq. (6):

$$n(z) = n_0 + \Delta n_{dc}(z) + f_{A(z)} \Delta n_{ac}(z) \cos\left[\frac{2\pi}{\Lambda} z + \phi(z)\right] \qquad (6)$$

Here, n0 refers to the initial refractive index, fA(z) represents the apodization function, Δnac defines the modulation amplitude, Δndc is the average index change, and ϕ(z) is the phase [30]–[32].

The effective refractive index is therefore approximated as Eq. (7):

$$n_{eff} = n_0 + \Delta n_{dc} \qquad (7)$$

A Gaussian apodization function can be used to taper the refractive index modulation smoothly and is described as Eq. (8):

$$A_{(z)} = \exp\left\{-\ln 2 \left[\frac{2.(z - L/2)^2}{s.L}\right]\right\} \qquad (8)$$

Here, L represents the grating length, and s denotes the apodization strength parameter, and $z \in [0, L]$ [33].

IV. Methodology of the Proposed Framework

The proposed system setup, illustrated in Fig. 3, demonstrates a dispersion compensation design using an ACFBG. The input to the system is a binary data stream generated by a 10 Gbps Pseudo-Random Bit Sequence (PRBS) generator, which is then converted into Return-to-Zero (RZ) optical pulses. These pulses are modulated using a Mach–Zehnder Modulator (MZM) with an extinction ratio of 30 dB. The MZM encodes the data onto a continuous wave (CW) optical carrier with 3 dBm power, generated by a semiconductor laser operating at 193.4 THz. The modulated optical signal is transmitted through SSMF toward the receiver.

Dispersion compensation is performed at the receiver using an ACFBG featuring linear chirp and Gaussian apodization to improve performance by minimizing side lobes and group delay ripple. The system operates at a wavelength of 1550 nm. An EDFA optical amplifier with a 10 dB gain is used to enhance the signal strength before the detection. A PIN photodetector is employed for optical-to-electrical conversion, and the signal is further processed using a Low-Pass Gaussian Filter (LPGF) with a cutoff frequency set to 0.75 times the bit rate to suppress high-frequency noise.

System performance is evaluated using Q-factor, BER, and eye height, as observed through eye diagram analysis, with Q-factor serving as a key indicator of BER. All simulations are carried out in OptiSystem 7.0 by varying SSMF length, input power, and bit rate the relative performance of pre-, post-, and symmetrical compensation techniques is examined.

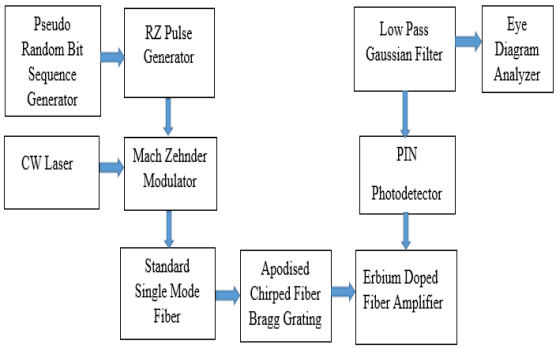

Fig. 3. Structural overview of the proposed design.

OptiSystem 7.0 was chosen for this study due to its advanced capabilities in modeling and simulating real-world optical communication systems. It effectively incorporates key transmission impairments, including chromatic dispersion, amplified spontaneous emission (ASE) noise, and nonlinear effects such as self-phase modulation. Its modular design enables flexible construction of complex system architectures, ranging from point-to-point links to WDM and long-haul transmission setups, by integrating standardized optical components such as fiber models, optical amplifiers, filters, and Fiber Bragg Gratings (FBGs).

In addition, OptiSystem offers a comprehensive suite of built-in analysis tools, including Q-factor measurement, BER estimation, and eye diagram visualization, which support both qualitative and quantitative performance evaluation. These features allow for controlled, repeatable testing across a wide range of parameters, making the platform highly suitable for validating dispersion compensation techniques in long-distance SSMF systems.

The overall simulation workflow is illustrated in Fig. 4, and the key simulation parameters are summarized in Table I.

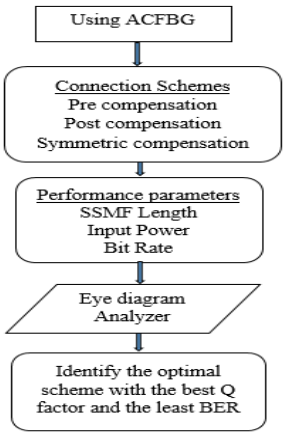

Fig. 4. Flowchart of the comparative study.

TABLE I COMPONENTS AND THEIR SIMULATION PARAMETERS

Components	Parameters
PRBS generator	Data rate: 10 Gbps
RZ pulse generator	Duty cycle: 0.5
Continuous Wave Laser	Input power: 3 dBm Linewidth: 0.01 MHz Central frequency: 193.4 THz
Mach–Zehnder Modulator	Extinction ratio: 30 dB
Standard Single-mode fiber (SSMF-28)	Length: 10 km to 80 km Attenuation loss: 0.18 dB/km Dispersion: 16.5 ps/nm/km Dispersion slope: 0.05 ps/nm^2/km Core effective area: 76.5 μm^2
FBG	Grating Length: 7 mm Effective index: 1.45 Apodization function: Gaussian Gauss parameter: 0.5 Chirp Function: Linear Linear Parameter: 0.0001 μm
EDFA optical amplifier	Gain: 10 dB Noise figure: 4 dB
PIN photodetector	Responsivity: 1 A/W Dark current: 10 nA
LPG filter	cutoff frequency: 0.75 × Bit rate

The study compares three compensation methods:

A. Case One: Pre-Compensation Scheme

In the pre-compensation setup, illustrated in Fig. 5, the ACFBG is positioned at the transmitter side, between the MZM and the SSMF. This arrangement enables early compensation for chromatic dispersion by introducing negative dispersion before the optical signal propagates through the fiber. The ACFBG's linear chirp profile and Gaussian apodization help match the anticipated dispersion profile while suppressing sidelobes and enhancing signal integrity.

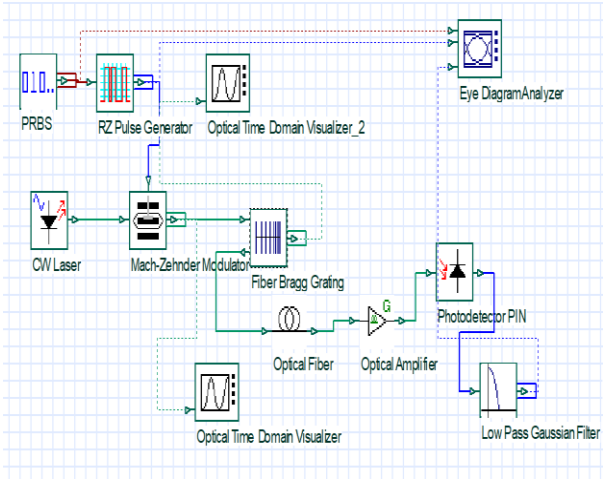

Fig. 5. Pre-compensation model for chromatic dispersion mitigation.

B. Case Two: Post-Compensation Scheme

In the post-compensation setup presented in Fig. 6, the ACFBG is placed at the receiver side, between the SSMF and the EDFA optical amplifier. As the optical signal traverses the SSMF, it accumulates positive chromatic dispersion due to the fiber's physical characteristics. The ACFBG introduces negative dispersion that compensates for this accumulated distortion. The placement of the EDFA after the ACFBG helps amplify the restored signal to meet the detection threshold of the PIN photodetector, ensuring accurate recovery of the transmitted information.

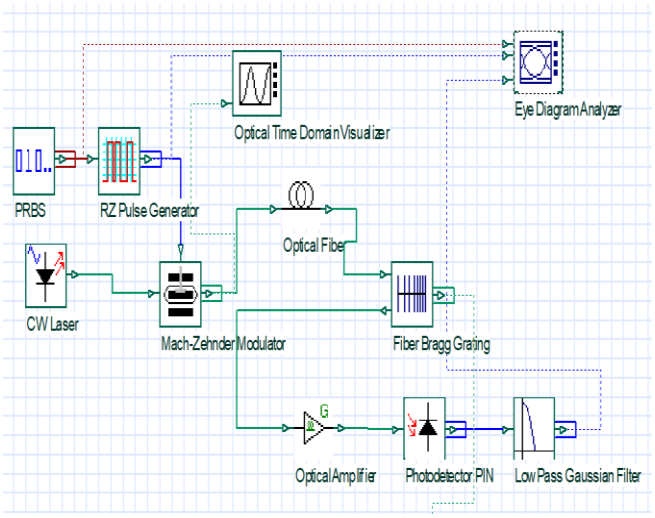

Fig. 6. Post-compensation model for chromatic dispersion mitigation.

C. Case Three: Symmetrical Compensation Scheme

The symmetrical compensation configuration, depicted in Fig. 7, comprises two ACFBGs, one located at the transmitter and the other at the receiver. The first ACFBG, situated between the MZM and the EDFA optical amplifier, provides pre-compensation, mitigating dispersion before fiber transmission. The second ACFBG, placed between the SSMF and the receiver-side EDFA optical amplifier, applies post-compensation to eliminate residual dispersion. This dual-stage configuration balances dispersion across the link and helps preserve pulse shape, thereby minimizing inter-symbol interference and improving overall system robustness. EDFAs placed before and after the SSMF maintain optimal power levels throughout the transmission path.

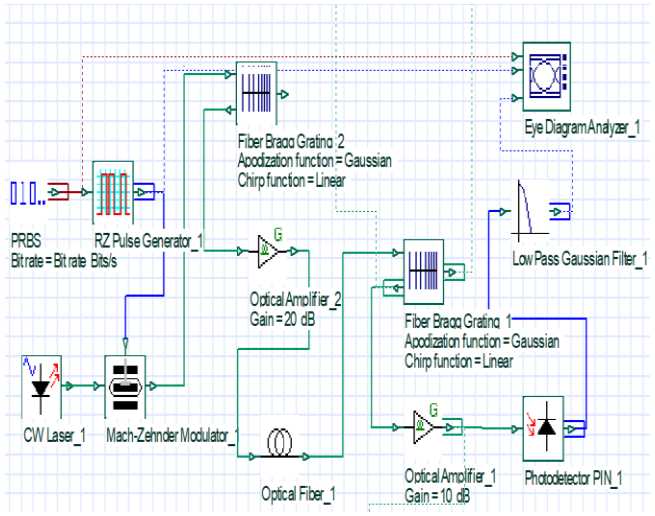

Fig. 7. Symmetrical compensation model for chromatic dispersion mitigation.

V. RESULTS

This section presents simulation results obtained using OptiSystem 7.0 to evaluate the performance of pre-, post-, and symmetrical dispersion compensation schemes. The system was tested under varying SSMF lengths, input power levels, and bit rates. Key performance metrics include Q-factor, BER, and eye height.

A. Performance with Varying SSMF Lengths

Simulations were conducted by varying the SSMF length from 10 km to 80 km, with fixed parameters: bit rate = 10 Gbps, input power = 3 dBm, and FBG length = 7 mm. Table II summarizes the results. Fig. 8 shows the eye diagram for the pre-compensation scheme at 80 km. It reveals a nearly closed eye pattern with Q-factor = 1.71181, BER = 0.0430757, and eye height = -3.43222×10^{-5}, indicating severe dispersion-induced degradation. Fig. 9 displays the eye diagram for the post-compensation scheme at 80 km. It exhibits similar degradation with Q-factor = 1.74339, BER = 0.0403394, and eye height = -3.33765×10^{-5}. Fig.10 illustrates the symmetrical compensation scheme at 80 km. The eye remains open with Q-factor = 12.3938, BER = 1.12336×10^{-35}, and eye height = 0.00215177, indicating robust signal quality. Fig. 11 presents the Q-factor performance over increasing SSMF lengths. While pre- and post-compensation schemes decline steadily beyond 50 km, symmetrical compensation maintains significantly higher Q-factors. Fig. 12 shows the corresponding BER trend. BER for pre- and post-compensation increases exponentially with distance, while symmetrical compensation sustains extremely low BER values up to 80 km.

TABLE II COMPARISON OF DISPERSION COMPENSATION OVER VARYING FIBER LENGTHS

SSMF Length	Q Factor	BER	Eye Height

B. *Effect of Input Power*

To evaluate power efficiency, input power levels were varied between 0 dBm and 10 dBm, with fixed parameters: 60 km SSMF, 7 mm FBG length, and 10 Gbps bit rate. Results are presented in Table III. Fig. 13 shows the eye diagram for pre-compensation at 3 dBm, where the Q-factor is 6.5578, BER = 2.23474×10^{-11}, and eye height = 8.90316×10^{-5}. Fig. 14 illustrates the post-compensation performance at 3 dBm. It yields a Q-factor of 6.76954, BER = 5.22884×10^{-12}, and eye height = 9.26084×10^{-5}. Fig. 15 depicts the symmetrical compensation scheme at the same power level, with superior performance: Q-factor = 39.5139, BER = 0, and eye height = 0.00877851. Fig. 16 plots the Q-factor versus input power. All schemes improve as power increases, but symmetrical compensation peaks at 3 dBm before slightly declining. Fig. 17 presents the BER variation across the power range. Symmetrical compensation maintains ultra-low BER at lower powers, while other schemes improve gradually.

C. *Impact of Bit Rate*

To assess the performance at higher data rates, Bit rate was varied from 5 Gbps to 20 Gbps, keeping SSMF = 60 km, input power = 3 dBm, and FBG length = 7 mm. The results are shown in Table IV. Fig. 18 shows the pre-compensation scheme at 15 Gbps. The signal completely fails with Q = 0, BER = 1, and a closed eye. Fig. 19 illustrates similar failure for the post-compensation scheme at 15 Gbps, also showing Q = 0 and BER = 1. Fig. 20 shows that the symmetrical compensation scheme still maintains acceptable signal integrity at 15 Gbps, with Q-factor = 3.13256, BER = 0.000848, and eye height = 0.0001717. Fig. 21 displays the Q-factor drop with increasing bit rate. Symmetrical compensation performs best, sustaining up to 15 Gbps. Fig. 22 confirms this trend in BER values, where pre- and post-compensation fail beyond 10 Gbps, while symmetrical compensation remains viable until 15 Gbps.

TABLE III INPUT POWER IMPACT ON FBG-BASED DISPERSION COMPENSATION SCHEMES

Pre compensation

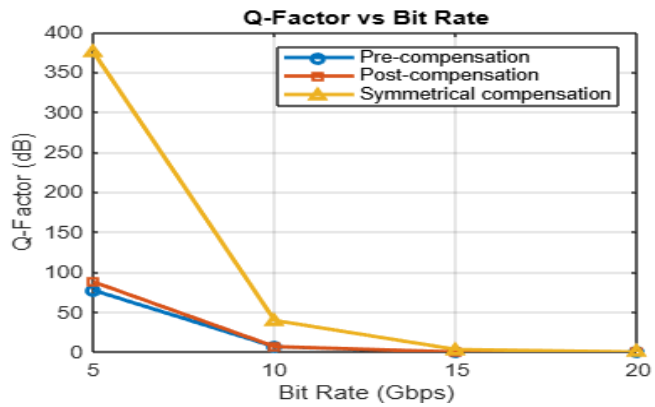

Fig. 21. Q-factor variation versus bit rate for pre-, post-, and symmetrical dispersion compensation schemes.

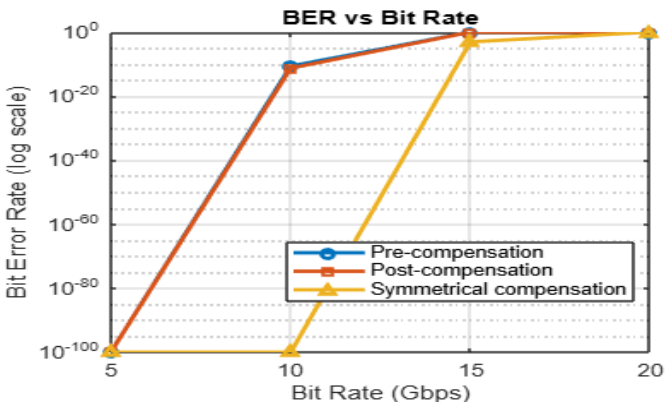

Fig. 22. Comparison of BER at various bit rates for pre-, post-, and symmetrical compensation.

The dataset used in this study was entirely generated using OptiSystem 7.0 and includes simulated performance metrics (Q-factor, BER, and eye height) across varying SSMF lengths (10–80 km), input powers (0–10 dBm), and data rates (5–20 Gbps). It is simulation-based, with no physical measurements or external inputs, and its accuracy depends on the fidelity of the OptiSystem simulation models.

VI. Discussion

This section interprets the results presented in Section V, emphasizing the performance trade-offs and advantages of each compensation approach.

A. Interpretation of SSMF Length Results

Symmetrical compensation consistently delivers superior performance compared to the other two compensation schemes. While the pre- and post-compensation approaches exhibit significant performance degradation beyond 50 km dropping to a Q-factor of approximately 1.72 and a BER around 0.04 at 80 km. Symmetrical compensation maintains high signal quality, achieving a Q-factor of 12.39, an ultra-low BER of 1.12×10^{-35}, and an improved eye height. These results highlight symmetrical compensation as the most reliable and efficient approach for long-haul, high-speed optical communication systems.

B. Power Efficiency Evaluation

The pre- and post-compensation schemes show consistent improvement in performance as the input power increases. Both demonstrate a gradual rise in Q-factor and a corresponding reduction in BER as power increases from 1 dBm to 10 dBm. At 9–10 dBm, both schemes reach a Q-factor of approximately 7 and achieve BER values on the order of 10^{-13}, indicating reliable signal quality at higher power levels. Between the two, post-compensation performs slightly better, offering higher Q-factors and lower BERs across the entire power range. In contrast, symmetrical compensation stands out by delivering excellent performance at significantly lower power. It achieves a remarkably high Q-factor of 39.51 and zero BER at just 3 dBm input power, along with the largest eye opening (eye height = 0.00878). Although its performance varies at higher power levels, the ability to attain optimal results at minimal input power underscores symmetrical compensation as the most

power-efficient solution, especially suitable for systems where energy efficiency is critical.

C. Bit Rate Performance

Pre- and post-compensation schemes fail to support bit rates beyond 10 Gbps, with Q-factors dropping to zero and BER reaching 1. In contrast, symmetrical compensation maintains acceptable performance up to 15 Gbps, attained a Q-factor of 3.13 and a BER of 8.48×10^{-4}. Although slightly degraded, this outcome confirms the scalability of symmetrical compensation for higher data rates. These results are consistent with the observed Q-factor and BER trends and are further supported by corresponding eye diagram evaluations.

D. Comparison of Proposed and Existing Methods

To validate the efficiency of the proposed dispersion compensation scheme, its performance is compared against several established methods from the literature. Table V summarizes key metrics such as Q-factor and BER across different compensation strategies, fiber lengths, and grating parameters. While most prior studies focus on post-compensation and evaluate transmission distances up to 70 km, this work demonstrates that the symmetrical compensation scheme using Gaussian-ACFBGs not only supports long-haul transmission over 80 km but also achieves a notably higher Q-factor (12.39) and an ultra-low BER (1.12×10^{-35}). These results outperform existing designs without relying on cascading or hybrid filtering techniques. The results clearly demonstrate the superior efficiency of the proposed scheme in long-haul optical transmission scenarios, establishing it as a competitive alternative to traditional post-compensation techniques.

TABLE V COMPARISON OF PROPOSED SCHEME WITH PRIOR WORKS

Prior Research	Compensation schemes with best results	SSMF Length(km)	Grating length (mm)	Q factor	BER
[18]	Post-compensation	50	-	45.78	0
[19]	Post-compensation	40	6	29.55	9.3407×10^{-182}
[20]	Post-compensation	70	2	8.58	4.77×10^{-18}
[21]	Post-compensation	70	2	9.2	3.25×10^{-20}
[22]	Post-compensation	80	2,3	6.848	3.73×10^{-12}
[23]	Post-compensation	30	-	23.647	Not given
[24]	Post-compensation	70	5	7.22	2.59×10^{-13}
Proposed Work	Symmetrical-compensation	80	7	12.3938	1.12336×10^{-35}

E. Physical Mechanism behind Performance Improvement

The symmetrical compensation scheme using Gaussian ACFBGs performs best because it balances dispersion correction by placing compensating gratings at both ends of the fiber. The linear chirp in the grating reflects different wavelengths at specific points, accurately compensating for dispersion. Gaussian apodization reduces unwanted side lobes, thereby lowering signal distortion. By dividing the compensation into two stages, this method reduces nonlinear effects, phase distortion, and jitter more effectively than pre- or post-compensation alone. As a result, it delivers cleaner signals with higher Q-factors, lower BER, and better eye diagrams, making it highly suitable for long-distance, high-capacity optical communication systems.

VII. CONCLUSION

This research investigates dispersion compensation in optical communication systems using Gaussian-apodized, linear-chirped Fiber Bragg Gratings. Three compensation schemes pre-compensation, post-compensation, and symmetrical compensation, were evaluated over an 80 km SSMF link. At this distance, pre-compensation achieved a Q-factor of 1.71181, BER of 0.0430757, and an eye height of -3.43222×10^{-5}, while post-compensation slightly improved performance with a Q-factor of 1.74339, BER of 0.0403394, and eye height of -3.33765×10^{-5}. In contrast, symmetrical compensation significantly outperformed both, achieving a Q-factor of 12.3938, an ultra-low BER of 1.12336×10^{-35}, and an eye height of 0.00215177. These results demonstrate that symmetrical compensation offers the most effective solution for long-haul, high-speed optical transmission, meeting the stringent requirements of 5G networks, especially in fronthaul and backhaul scenarios. This supports key 5G applications such as ultra-reliable low-latency communication (URLLC), enhanced mobile broadband (eMBB), and massive machine-type communication (mMTC). Furthermore, optimization of input power and bit rate enhances energy efficiency and scalability, making the approach suitable for smart cities, industrial automation, and remote healthcare systems. The proposed technique provides several advantages: it passively compensates dispersion without the need for active electronic components, thereby reducing power consumption; Gaussian apodization effectively suppresses sidelobes to improve signal quality; the chirped grating profile allows for tailored dispersion management over long distances; and the configuration is both scalable and compatible with existing fiber infrastructures. These attributes establish symmetrical ACFBGs as a highly efficient, high-performance, and future-proof solution for optical networks.

FUTURE WORK

Future work may explore system performance under higher-order modulation formats, assess the impact of temperature variations and polarization sensitivity, and investigate hybrid approaches that integrate FBGs with adaptive, machine learning–based equalizers. Additionally, the influence of channel spacing in dense WDM environments and the potential for real-time tunability using dynamic gratings could be examined to enhance system adaptability in evolving optical networks. Overall, this study demonstrates that symmetrical FBG-based dispersion compensation is a robust, scalable, and forward-looking solution for next-generation 5G optical infrastructure.

ACKNOWLEDGMENT

The authors express their sincere gratitude to Cambridge Institute of Technology, Bengaluru, and the Visvesvaraya

Technological University, Belagavi, for their valuable support and scholarly guidance during the course of this research.

***Abstract*—Motifs are short, recurring sequence elements with biological significance within a set of nucleotide sequences. Motif discovery is the problem of finding these motifs. The problem of motif discovery has become an important problem in the field of Bioinformatics since, it finds its applications in Drug discovery, Environmental Health Research, and early Detection of Diseases by finding anomalies in gene sequences. Motif discovery is a challenging job in bioinformatics since it is NP-hard and cannot be solved within an exact time. In this study, we have proposed Hybrid Cluster based Walrus Optimization algorithm (HCWaOA) to solve the problem of motif discovery. The accuracy and efficiency of the proposed algorithm are improved using a hybrid approach. The population is initialized using Random Projection technique to generate a meaningful solution space. Then, k-means clustering is used to group similar solutions. Lastly, a population-based metaheuristic algorithm, Walrus optimization technique, is applied on each of the clusters to find the best motif. The proposed Hybrid Cluster-based Walrus Optimization algorithm (HCWaOA) is tested on both simulated and real biological datasets. The performance of HCWaOA is compared with benchmark algorithms like MEME, AlignCE and other meta-heuristics algorithms. The results of the proposed algorithm are found to be stable with a precision of 92%, a recall of 93% and an F-score of 93%. The proposed HCWaOA is tested using biological cancer-causing BARC and CTCF datasets to identify cancer causing motifs. Results show that incorporating clustering to initial solution space results in optimal solutions within a fewer iteration. The results of HCWaOA are compared with other popular motifs discovery algorithms and found to be stable.**

I. Introduction

The current Next Generation Sequencing (NGS) technology rapidly sequences the genomes to produce large volumes of high throughput data. The field of bioinformatics involves analyzing these high throughput data to find meaningful inferences. Analyzing these large volumes of high throughput data using traditional approaches is time consuming and prone to error. Regulation of gene expression is carried out using transcription and translation process. Before the transcription process, a specific region of gene is activated which is critical. The activation is caused by special proteins called Transcription factors which bind to specific region in gene called Transcription Factor Binding Sites (TFBS). Hence it is critical to find TFBS to understand the gene regulation process. These TFBS are known as motifs. Motifs are short, repeated, over represented patterns present in the regulatory regions of gene sequences, which play an important role in gene regulation mechanisms. These motifs are statistically significant, meaning they appear more frequently than expected. They are conserved among the sequences and have biological significance, often related to gene regulation. Therefore, Motif Discovery is one of the important research problems in bioinformatics. The problem of Motif Discovery is challenging because the exact positions of the motif in the gene sequences are not known. Due to mutations, the pattern of motifs across gene sequences can be the same or may vary slightly. Even though a number of motif discovery algorithms have been developed over a period, it is still a complex challenge for biologists and computer researchers.

Given a set of DNA sequences, the problem of motif discovery is to find a common pattern of length l that appears in all or most sequences with a maximum of d mutations. Different Computational approaches have been employed to solve the problem of motif discovery. Enumerative and Probabilistic approaches are the two important classifications of motif discovery algorithms. Enumerative approach involves an exhaustive search to find motifs, but it is impractical and time-consuming based on the nature of motifs. The Probabilistic approach uses Position Weight Matrix (PWM) to represent motifs. But the problem with the probabilistic algorithms is that they may converge to local optima. Other important approaches used in motif discovery are Machine Learning, Metaheuristics and Deep Learning techniques. Each of these algorithms has its own advantages and disadvantages.

Metaheuristic algorithms [1] are computational optimization algorithms that explore a solution space to find acceptable solutions for complex problems. Metaheuristic algorithms have drawn inspiration from nature, some from physics, chemistry, and mathematical concepts. Nature-based metaheuristic algorithms are inspired from natural processes to solve complex problems. Some of the popular and widely used metaheuristic algorithms are Genetic Algorithms based on biological evolution, Particle Swarm Optimization inspired from behavior of flock of birds, Ant Colony Optimization from ant colonies. Other nature-based metaheuristic algorithms are Grey Wolf Optimization, Cuckoo Search Optimization, FireFly Optimization, Walrus Optimization and so on. The advantages

of using nature-based metaheuristic algorithms for DNA motif discovery are the ability to handle large volumes of DNA sequence input data, provide good global exploration and escape the local optima. The limitations of existing algorithms are, they face scalability issues i.e. with the increase in the number of sequences and length of motifs the complexity of the algorithm increases. The tuning of algorithms parameters to derive at the optimal solution is one of the common problems encountered in metaheuristics algorithms.

In the proposed study, we use the Walrus Optimization algorithm to solve the problem of motif discovery. The advantage of using WaOA is, it requires minimal parameter setting with balanced exploration and exploitation. The key contributions of the proposed study are:

1) First, the Random projection technique is used for initializing the population solution space. It improves the diversity of the solution space while avoiding random unwanted population space. This acts as a starting point for providing promising solutions.

2) A k-means clustering technique is used for clustering the solution space.

3) Walrus optimization algorithm is used for motif discovery.

4) The proposed HCWaOA algorithm is evaluated using both simulated and biological datasets.

5) The proposed HCWaOA algorithm is tested to identify the cancer-causing BRCA1 and CTCF motifs in promoter regions of human gene sequences.

The study is organized as follows: The literature review is presented in Section II, discussing different and current approaches to motif discovery along with metaheuristics algorithms. Section III explains the proposed methodology of HCWaOA. Section IV gives the results, with analysis and evaluation of the proposed HCWaOA. Conclusion and future research directions of HCWaOA are given in Section V.

II. Literature Review

Multiple approaches have been proposed to solve the problem of Motif Discovery, each having its own advantages and disadvantages. Enumerative and Probabilistic approaches are the two major categories of motif discovery algorithms [2]. The other important approaches in motif discovery are Genetic algorithms, Meta-heuristics algorithms, Machine Learning and Deep Learning Techniques. In this section, we discuss the important and latest approaches used currently.

A. Enumerative Approach

The algorithms in Enumerative approach conduct an exhaustive search in entire search space to find the patterns. This covers the entire search space, thus exponentially increasing the time required as the size of the problem space increases. Hence it is suitable for finding motifs of short length in smaller sequences. Enumeration techniques are based on simple words, suffix trees, graphs, hashing. Some of the techniques that come under this category are:

- Brute-force Search: Examines all possible motifs and selects the best one based on a scoring function.
- Consensus-based Methods: Identify the most frequent k-mers (short substrings of length k) across sequences.
- Suffix Trees: Used to efficiently store and search for repeated substrings in a dataset.
- Word-based Methods: Search for overrepresented short words across sequences.

The algorithms developed using this approach are DREME, CisFinder, Weeder, FMotif, MCES.

B. Probabilistic Approach

Probabilistic algorithms compute a position weight matrix or position-specific weight matrix for representing motifs. Some of the important algorithms are Expectation Maximization (EM) and Gibbs sampling.

- Expectation-Maximization (EM) Algorithm: A probabilistic method that iteratively refines a motif model by updating motif positions in sequences.
- Gibbs Sampling: A Markov Chain Monte Carlo method that iteratively samples motif positions to improve alignment.

MEME, STREME [3], EXTREME are based on EM, and AlignCE is based on the Gibbs-Sampling approach.

Machine Learning, Artificial Intelligence and Deep Learning Approaches.

Current trends involve the use of Machine Learning [4], Artificial Intelligence and Deep Learning Approaches [5] in motif discovery. Hidden Markov Models (HMMs) are probabilistic models. Neural Networks and Deep Learning models are used to detect motifs. Deep Learning models like Convolutional Neural Networks (CNNs), Recurrent Neural Networks (RNNs), Hybrid CNN RNN, Ensemble-based models and complex hybrid models are applied to Motif Discovery. Supervised learning, like Random Forests and Support Vector Machines (SVMs), is used in settings when labelled motif data is available, whereas Autoencoders are used for unsupervised motif discovery by reducing dimensionality and extracting patterns. DeepBind, DeepVISP [6], and Deep6mA are some of the popular deep learning approaches used in the problem of motif discovery.

C. Nature Inspired Approach

Metaheuristic algorithms are approximate methods which provide acceptable solution within reasonable computational cost. Metaheuristic algorithms have drawn its inspiration from nature. The solution to the problem is based on natural selection and survival of the fittest. Some of the popular and widely used nature inspired metaheuristic algorithms are Genetic Algorithms based on biological evolution, Particle Swarm Optimization based on behavior of flock of birds [7], Ant Colony Optimization based on ant colonies. Other nature-based metaheuristic algorithms [8] are Grey Wolf Optimization, Cuckoo Search Optimization, FireFly Optimization, Walrus Optimization [9] and so on. In [10] and [11], Chemical Reaction Optimization (CRO) and Henry Gas Solubility optimization which are based on physics and chemistry are used. Hybrid metaheuristic algorithms have given good results compared to

traditional approaches. Recent trends in motif discovery algorithms are discussed below:

The study in [12] is a physics inspired metaheuristic for DNA motif discovery proposed in 2025. Here Archimedes Optimization Algorithm (AOA) mimics the principles of buoyant force and object equilibrium in fluids, balancing exploration (global search) and exploitation (local refinement) effectively. The Information Content is used for fitness evaluation. This technique is tested using real DNA dataset and the performance is evaluated against other metaheuristics algorithm. The major drawback is scalability issue to handle huge data and risk of convergence to local optima. The algorithm needs optimal tuning of control parameters to achieve optimal solutions.

In 2023, Dang et al [13] proposed a hybrid genetic algorithm to discover DNA motifs that satisfy the 2-Optimality postulate. 2-optimality postulate means the motif should be found in minimum of two input sequences. It uses evolutionary operations selection, crossover and mutation. It is tested against a benchmark dataset and provides better accuracy. The 2-optimality postulate may sometimes not discover relevant motifs.

In 2023, Theepalakshmi, P. and Reddy, U.S., [17] have proposed a novel effective quorum seeded (ℓ, d) motif search utilizing segmentation to filter using freezing firefly approaches on ChIP-seq data. The final motif was identified using the usual firefly approach, which uses both local and global freezing techniques. The effectiveness of these techniques was assessed using both simulated and actual datasets, including the human ChIP-seq dataset, the mouse emergent stem cell dataset, with Escherichia coli cyclical AMP receptor protein (CRP) dataset. It attains high F-measure and low accuracy.

In [14], the authors proposes a Freezing FireFly algorithm to solve the motif discovery problem. Here local and global freezing strategy is used wherein the best possible positions of the poor solution is also preserved. This helps in the overall search process to find new possible good results. The performance of Freezing Firefly algorithm is evaluated by comparing with benchmark tools like Samselect, TraverStringRef, PMS8, qPMS9, AlignACE, FMGA, and GSGA.

In 2022, Li, Song et al. [15] proposed an improved henry gas optimization algorithm with levy mechanism and brown motion. The study in [11], is Henry gas solubility optimization (MHGSO) algorithm for motif discovery. In MHGSO, the optimal solutions are obtained by evaluating the characteristics of the candidate solution space. It is based on chemistry, Henry's Law, treating the search space as gas molecules and mimics the finding of best motif to adjusting the solubility of gas molecules. The performance of MHGSO algorithm is evaluated on both synthetic and real datasets to find accurate motifs. The limitations of the algorithm is control parameters are specified which make the algorithm less flexible.

In 2024, Mohammad Hasan, et.al. [16] have proposed a Trie-PMS8. The algorithm is based on enhanced trie-tree for planted motif search problem. The problem with earlier PMS algorithm is that the time complexity increases exponentially in worst case scenarios. The proposed trie tree uses sort row by size step to reduce the time and linked lists to reduce the space. It also uses dynamic programming techniques to avoid redundant calculations in frequent tree processing. It gives better results than earlier versions of PMS with reduced time complexity.

In 2024, Qiang Yu, et.al. [18] have proposed an exact Planted Motif Search (PMS) on large DNA sequences. The efficient and exact algorithm finds (l, d) motifs using the technique of searching the branches on the pattern tree. The algorithm has good running time ratio compared to the existing PMS algorithms. The algorithm is tested on challenging problem instances of large DNA sequence datasets.

In 2024, Ledesma-Dominguez, et al. [19] have proposed a hybrid model named Deep Regulation (DeepReg) to identify transcription factor binding sites in prokaryotic and eukaryotic protein sequences. The hybrid model uses CNN, BiLSTM and attention mechanism. Feature extraction and grammar regulation is done using CNN and BiLSTM respectively. This leads to enhanced F1-score and performance in DeepReg compared to the other deep learning models. The model showed reliability and robustness for unseen experimental data. It provided low variance and eliminated overfitting problem. The model was tested on three organisms S. cerevisiae, N. crassa, and A. nidulans [19] and on average identified 71.8% of transcription factors.

The motif discovery problem is essential for understanding regulatory elements in DNA sequences. Various computational techniques, ranging from simple brute-force methods to advanced deep learning models, are used to identify biologically significant motifs. Despite the progress, motif discovery continues to be a challenging problem in genomics and bioinformatics research. The major issues with the existing metaheuristics algorithm are:

- Results are dependent on algorithms parameters tuning like the mutation rate, co-efficient, optimal size of population and iterations.
- Scalability issues as the number of sequences, length of sequences and motif length increases.

The aim of the research is to address the limitations of the existing metaheuristics algorithm and propose a hybrid metaheuristics algorithm to address the above issues.

III. Proposed Method

In this study, a Hybrid Cluster based Walrus Optimization algorithm (HCWaOA) is proposed for finding motifs in the promoter regions of a given set of DNA sequences. The first step of the proposed algorithm, builds an initial population solution using random projection strategy [20]. The second step involves clustering the population solutions using k-means clustering. In the third step, modified Walrus optimization algorithm is applied on the clusters to find the best solution. Here the best solution is the motif with highest fitness value found in the given set of DNA sequences. The architecture block diagram of the HCWaOA is given in Fig. 1.

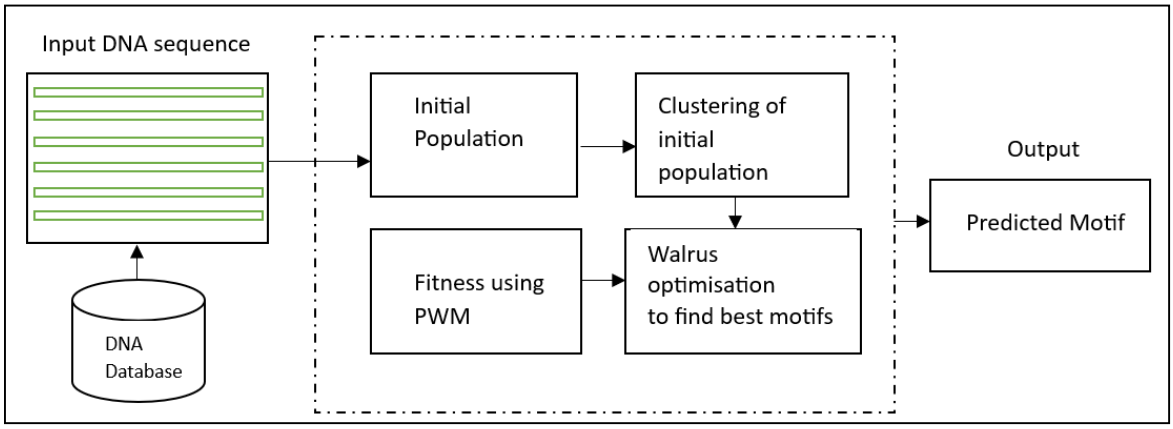

Fig. 1. Block diagram of HCWaOA.

A. Walrus Optimisation Algorithm

Walrus Optimization Algorithm (WaOA) is a new nature-based metaheuristic algorithm that is based on the behavior of walruses. It draws inspiration from Walrus behavior of feeding, migrating, escaping predators and fighting predators [21]. The Walrus Optimization Algorithm is implemented in three phases: exploration, migration, and exploitation. The working of the algorithm is given by the following steps:

1) Initialization: A population of walrus solutions is randomly generated within the search space, representing potential solutions to the optimization problem.

2) Movement based on behavior:

Phase 1: Feeding (Exploitation): When a safety signal [22] is identified, the walruses feed by refining their positions, moving closer to the optimal solution. The new position is calculated using Eq. (1):

$$X_i^{t+1} = X_i^t + r\,(S^t - I.X_i^t) \quad (1)$$

X_i^t : Position of the i^{th} walrus at iteration t

S^t : Best fitness solution

I : control parameter

r : random vector [0,1]

Phase 2: Migration: Walruses are simulated to migrate towards areas with better potential solutions, based on the random solution. The new position for migration is calculated using Eq. (2):

$$X_i^{t+1} = X_i^t + r\,(X_k^t - I.X_i^t) \quad (2)$$

X_k^t : Position of randomly selected walrus

Phase 3: Escape (Exploration): When a danger signal [22] is triggered, the walruses escape by making large random movements to explore new regions of the search space. The new position for exploitation is calculated using Eq. (3):

$$X_i^{t+1} = X_i^t + r.\delta \quad (3)$$

$$\delta = \alpha\,.(ub - lb)$$

$$\alpha : random\ value\ [-0.1, 0.1]$$

$$ub, lb: upper\ and\ lower\ bounds\ of\ the\ search\ space$$

3) Updating positions: The position of each walrus (candidate solution) is updated based on the calculated danger signals and safety signals, influencing how much exploration or exploitation is performed in each iteration.

4) Iteration and convergence: The process of movement and position updates is repeated for a set number of iterations, with the best solutions gradually converging towards the optimal solution.

B. Random Projection Technique

The starting point of the algorithm is the generation of initial population using on random projection technique. This involves selecting random sub sequences of motif length from the given set of input DNA sequences. These sub sequences act as the initial population i.e. candidate solutions. This gives a set of candidate solutions which are closer to the optimal solution since they are already a part of the solution space. This strategy is better than generating random candidate solution which are not related to the solution space. The number of iterations and time required to reach the optimal solution is reduced and a meaningful initial candidate solution space is generated as the input to walrus algorithm.

C. Clustering

A k-means clustering is used to cluster initial candidate solutions. Clustering allows us to group highly similar motifs. This allows for easier analyzing of pattern, reducing noise and identifying biologically significant motifs. The problem with initial candidate solutions of metaheuristic algorithms is they are random and no relation exists between them. It is found that individual elements of candidate solution which are similar or closer have higher fitness then dissimilar elements.

Clustering techniques [23] like k-means help group similar motifs which may have variations due to mutations, insertions or deletions together, making the analysis more structured and meaningful. The partitioning of the population into multiple clusters allows only intra cluster operations like mutation, crossover within the cluster whereas multiple clusters allow for diversity in the population. Multiple clusters allow us identify multiple weaker motifs which are similar. Hence clustering efficiently organize motifs and improves the motif discovery

process. K-means is used in the proposed study since it is computationally efficient and can handle large-scale motif datasets.

D. Fitness Function

The fitness or the quality of the motifs is evaluated based on the information content (IC). IC is calculated using the following steps:

1) Compute PFM (Position Frequency Matrix): A Position Frequency Matrix (PFM) represents how frequently each nucleotide i.e. A, C, G, T appears at each position in a set of aligned motifs.

2) Computer PWM (Position weight matrix): The PWM is obtained by normalizing the PFM with background nucleotide probabilities and taking the logarithm, as in Eq. (4):

$$PWM_{b,j} = log_2\left(\frac{PFM_{b,j}}{P_{background}(b)}\right) \quad (4)$$

Here, $PWM_{b,j}$ is the weight for nucleotide b at position j, and $P_{background}(b)$ is the background probability of nucleotide b. This is often assumed to be 0.25 for uniform distribution.

This transformation helps identify conserved positions in the motif.

3) Computer IC: quantifies how well a motif is conserved. It measures how different each position is from a random sequence.

Eq. (5):

$$IC_j = \sum_b P_{b,j}\, log_2\left(P_{b,j}/P_{background}(b)\right) \quad (5)$$

Total IC is the sum across all motif positions, as in Eq. (6):

$$IC = \sum_{j=1}^{L} IC_j \quad (6)$$

A higher IC means the motif is more conserved and biologically significant. The calculated IC value serves as the fitness score.

E. Process of Walrus Optimisation Algorithm for Motif Discovery

The Walrus Algorithm efficiently discovers motifs by combining random exploration with local exploitation. Its adaptive approach ensures a balance between global search (exploration) and local refinement (exploitation), making it well-suited for motif discovery in DNA sequences. Walrus Optimization technique operates on each of the clusters. Thus, returning the best solution in each of the clusters. The results are evaluated to obtain global best solution based on the fitness. The global best solution is the motif with fitness score having highest IC value. Algorithm 1 presents the pseudocode of the proposed HCWaOA algorithm.

Algorithm 1: Pseudocode of the proposed HCWaOA algorithm

```
1. Set all the parameter values
2. Initialise the population
3. Calculate the fitness value using the fitness function to get the best solution
4. while (t < max_generations)
5.     Compute adaptive exploration and exploitation rates
6.     Update Motif Positions
7.         For each motif set in population:
               Phase 1: Feeding (Exploitation)
                   Calculate the new position using Eq1
                   Update the position of new walrus
               Phase 2: Migration
                   Using a random walrus, find the position of new walrus using Eq2
                   Update the position of new walrus
               Phase 3: Escape (Exploration):
                   Calculate the new position using Eq3
                   Update the position of new walrus
8. Compute new fitness scores using Eq4, Eq5, Eq6
9. Update the best solution with highest fitness score
10. Return the best motif with the corresponding fitness score
```

IV. Experimental Results and Discussion

HCWaOA algorithm is implemented in Python using Anaconda IDE under Windows OS and tested on both real-time and simulated dataset. The test results are analyzed and the performance is compared with existing state-of-art tools such as MEME, DREME and MHGSO [11] systems. The proposed algorithm is tested to identify breast and ovarian cancer causing motifs BRCA1 and CTCF in human gene sequences.

A. Performance Measure

The performance of the HCWaOA is evaluated using the metrics Precision (P), Recall (R) and F-score [24]. Precision P is number of predicted motifs that are true divided by number of predicted motifs. Recall R is number of predicted motif sites that are true divided by number of true motifs. F-score is computed using the values of Precision and Recall. The best value for F-score is 1 and worst is 0. TP is true positive, TN is true negative, FP is false positive, FN is false negative.

$$Precision = \frac{TP}{(TP + FP)}$$

$$Recall = \frac{TP}{(TP + FN)}$$

$$F - score = 2 \times \frac{Precision \times Recall}{(Precision + Recall)}$$

B. Test on Simulated Data

The algorithm is tested using 7 groups synthetic dataset. The details of the dataset are given in Table I. The sequences are generated randomly and motifs with mutations are added at random positions using python script.

The proposed algorithm is tested on the synthetic dataset given in Table I. The detailed results for each of the 7 dataset groups is given in Table II. The algorithm is run for 10 times and the best value of P and R is taken into consideration. Table II

gives the average values of P, R and F -score for 7 dataset groups. The results show a higher F-score attained through higher values of P and R. Thus, results show a higher F-score for dataset (8, 2) and (9,3). We can infer that as the length of the motif increases with the increase in the number of mutations. It is difficult to identify all the correct motifs since higher R value means large number of candidate instances which cause false positive. Prediction results can be sensitive to the dataset properties like the number and length of sequences generated, true and mutated motifs in the input sequence.

TABLE I. SYNTHETIC DATASET DETAILS

Dataset group	1	2	3	4	5	6	7
No of sequences (t)	40	40	40	40	40	40	40
Length of sequence (n)	400	400	400	400	400	400	400
Length of motif (l)	8	9	10	14	16	18	21
Maximum mutations	2	3	3	4	5	6	7

TABLE II. RESULTS FOR SYNTHETIC DATASET ON PROPOSED ALGORITHM: P IS PRECISION, R IS RECALL AND F IS F-SCORE

SI NO	Dataset	P	R	F - score
1	(8,2)	0.95	0.95	0.95
2	(9,3)	0.95	0.95	0.95
3	(10,3)	0.90	0.92	0.91
4	(14,4)	0.93	0.93	0.93
5	(16,5)	0.93	0.93	0.93
6	(18,6)	0.90	0.92	0.91
7	(21,7)	0.90	0.92	0.91
	Avg	0.92	0.93	0.93

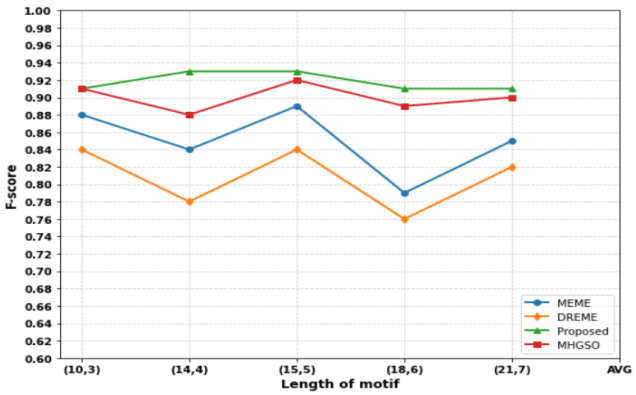

Fig. 2. Analysis of F-score results on synthetic dataset.

The synthetic datasets (10, 3), (14,4), (15,5), (18,6) and (21,7) are familiar examples in motif discovery problem. Fig. 2 shows the F-score on synthetic dataset. The results of HCWaOA are compared with the results of state-of-art motif discovery tools MEME, DREME and metaheuristic algorithm MHGSO [11]. The proposed algorithm provides an improved F-score compared to the other algorithms. The clustering approach allows for grouping of similar solution space and walrus optimization exploits the solution space to get better results. The hybrid approach of HCWaOA allows a thorough exploration of the search space. This thorough exploration reduces the chances of missing optimal solutions and increases the overall accuracy of the optimization task.

C. Convergence of Proposed HCWaOA

The proposed HCWaOA algorithm detects the convergence based on the fitness of the motifs. The fitness, i.e. IC is calculated using Eq. (6) across fixed iterations. If the fitness value reaches the highest and remains the same for fixed number of iterations then the algorithm is terminated. This prevents the overhead of computation once convergence is reached. Fig. 3 shows the convergence curve for dataset group 1, 2 and 3 of Table I.

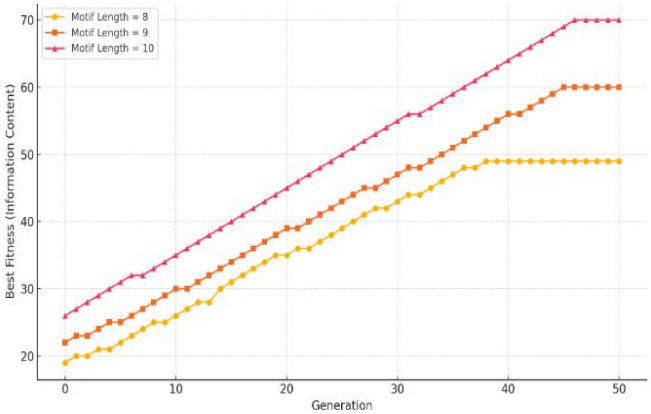

Fig. 3. Convergence curve for motifs of length 8, 9 and 10.

D. Analysis of k-means Clustering on Walrus Optimisation

The proposed Walrus optimization algorithm was tested with and without k-means clustering on the initial population for simulated dataset given in Table I. The fitness was calculated using the Eq. (6). The average fitness value was calculated across 15, 25, 35 and 50 generations. The results in Table III show an improvement in average fitness value when clustering is employed. It was also observed that new weaker motifs are identified in the clusters which was not a part of the simulated dataset. Fig. 4 infers; clustering discovers better motifs i.e. motifs with better fitness values within fewer iterations. Hence by incorporating clustering on initial population, the proposed HCWaOA allows for discovering of motifs with higher fitness values within given iterations. This overcomes the complexity issue of metaheuristics algorithms.

TABLE III. PERFORMANCE COMPARISON OF HCWAOA WITH CLUSTERING AND WITHOUT CLUSTERING

SI NO	Dataset	Without clustering	With Clustering
		Average Fitness	Average Fitness
1	(8,2)	51.14	53.18
2	(9,3)	53.46	57.95
3	(10,3)	58.78	62.29
4	(14,4)	82.9	98.29
5	(16,5)	92.6	101.74
6	(18,6)	100.49	126.85
7	(21,7)	110.39	146.17

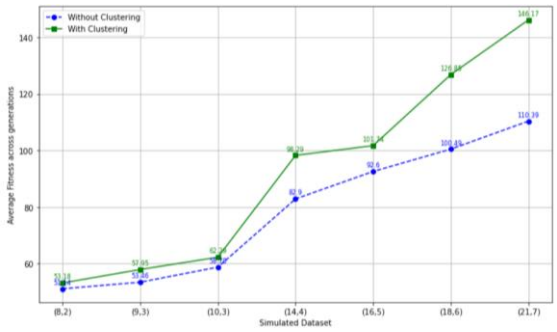

Fig. 4. Performance comparison of HCWaOA with and without clustering.

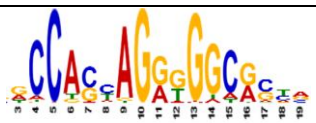
E. Test on Real-Time Data

The proposed algorithm is tested using a CRP benchmark dataset. The benchmark dataset is a real-time dataset consisting of 18 sequences of Escherichia coli of 105 bp-long. The proposed HCWaOA algorithm finds the motifs and their starting positions for the CRP E. coli input sequence. Table IV shows the results of the proposed algorithm in comparison with MEME and AlignCE. Table IV gives the actual starting position of the known motif, the predicted motif start position from different algorithms and the deviations between actual and predicted results. The proposed algorithm gives most of the positions correctly, and the results are better than existing algorithms MEME and AlignCE.



F. Test on Breast Cancer Gene Input Dataset

The proposed algorithm is tested to check its ability to discover real biological data in human DNA sequence. The input gene sequences are collected from well curated JASPAR database and government authorized website NCBI. These are breast cancer gene input sequences containing BRCA1 [25] and CTCF motifs. These BRCA1 and CTCF motifs are associated with breast and ovarian cancer. The identification of BRCA1 and CTCF motifs in the input data sequence infers the detection of cancer. Table V gives the details of input sequences along with their accession numbers as well as true motifs and predicted motifs. The proposed algorithm was run on the cancer dataset, and the experimental results show that the predicted motifs match with known cancerous motifs.

TABLE IV. COMPARISON RESULTS OF HCWAOA, MEME, ALIGNCE FOR CRP BENCHMARK DATASET

Sequence No	Starting position of the known motif	MEME	AlignCE	Proposed algorithm (HCWaOA)
1	17,61	61	63(2)	61
2	17,55	55	57(2)	55
3	76	76	78(2)	76
4	63	63	65(2)	63
5	50	13 (-37)	52(2)	50
6	7,60	7	9(2)	7

TABLE V. LIST OF CANCER CAUSING BRAC1 AND CTCF GENE INPUT DATASET WITH PUBLISHED AND PREDICTED MOTIFS

Name	Seq No	Accession no.	Published Motif using MEME & TOMTOM	Predicted Motif from proposed HCWaOA algorithm
BRCA1	15 sequences	AF507075.1 AY093484.1 AF507076.1 AF507077.1 AF507078.1 AY093484.1 AY093486.1 AY093487.1 AY093488.1 AY093489.1 AY093492.1 AY093493.1 AY093490.1 AY093491.1 AF284812.1	 Name : SP5(C2H2 zinc finger factors) Matrix ID: MA1965.1	
CTCF	30 sequences	JASPAR	 Name : CTCF Matrix ID: MA0139.1	

The predicted motifs identified by the proposed algorithm is validated by checking the similarity with annotated motifs. Motif similarity analysis was evaluated using TomTom from the MEME tool-kit. It was also found that the discovered motif had clear resemblance with known motif in JASPAR database. The predicted motifs logo was created using the tool https://weblogo.berkeley.edu/logo.cgi.

V. Conclusion

The study proposes, hybrid cluster-based motif discovery approach using a new metaheuristic walrus optimization algorithm. Using the proposed technique, adjusting the algorithm parameters is considerably reduced compared to the other metaheuristic algorithms and this in turn efficiently discovers the motifs in gene sequences. The performance of the proposed HCWaOA algorithm is evaluated using both synthetic and real dataset. The results on synthetic and real dataset are better compared to existing well-known traditional methods. Experimental results have shown that the proposed algorithm can discover motif of both short and long length sequences with mutations. By employing clustering, better motifs can be identified within fewer iterations thereby reducing the complexity of the algorithm. Here the real time application of the proposed algorithm is verified using cancer gene sequences. The proposed HCWaOA algorithm is successfully applied for the detection of CTCF and BRCA1 binding sites in homosapiens, whose deletion or inactivation has been detected in various cancers.

Although, the proposed algorithm gives good results, it can be extended to handle motifs of unknown length, thus providing more flexibility in discovering motifs of any length. In future a better clustering technique can applied which utilizes the properties of motifs. Even though multimodal metaheuristics algorithm solves some of the issues with motif discovery, deep learning techniques that are robust and scales well to handle large gene dataset can be explored in future.

***Abstract*—Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder that affects how people talk to each other and act. The fact that ASD is becoming more common and that diagnosing it can be difficult means that early detection is important for improving treatment outcomes. This study's goal is to use lightweight ensemble Convolutional Neural Networks (CNN) to make it easier to classify ASD from facial photos. The study looks at different CNN architectures, like MobileNetV2 and EfficientNet variations, to find the best model for diagnosing ASD quickly and accurately. The method involves training and testing five lightweight CNN models on a set of facial photos. We use pre-processing methods like scaling and data augmentation to help the model learn better. The study tests how well ensemble CNN models work by combining predictions from different architectures using averaging and voting methods. We use important performance metrics like accuracy, precision, recall, and F1-score to see how well each model works. The results show that the best balance between accuracy and computational efficiency is achieved by combining MobileNetV2 and EfficientNetB0. This combination achieves an accuracy of 0.8299, a precision of 0.8514, a recall of 0.8182, and an F1_score of 0.8344. Other models, like ResNet50 combined with EfficientNetB0, have higher precision but lower recall, making them less useful for finding all ASD cases. This study was also compared with other researchers, and the proposed study was found to have greater accuracy than other researchers. The results show that ensemble CNN models can significantly improve the accuracy of classifying ASD compared to single CNNs. This study shows that lightweight ensemble CNN models are good at finding ASD in pictures of people's faces. The method is fast and can be used on devices with limited processing power, making it a good way to find ASD early in both clinical and real-world settings.**

Keywords*—Component; autism spectrum disorder (ASD); early detection; ensemble convolutional neural network (CNN); facial images; classification; accuracy

I. Introduction

Autism Spectrum Disorder (ASD) is a developmental disorder that affects how a person talks, interacts with others, and thinks and acts. People with Autism Spectrum Disorder (ASD) often have trouble interacting with others, have trouble learning new words, and have rigid habits that they do over and over. Many conditions that used to be called classic autism, Asperger's syndrome, and undefined pervasive developmental disability are now part of ASD [1]. This spectrum shows how different people can have very different symptoms and how bad they can be. It is thought that both genetic and environmental factors play a role in the causes of ASD, but these factors are not fully understood. Recent studies have confirmed the idea that a combination of genetic and prenatal factors has a big effect on the development of ASD. The number of people with ASD around the world has gone up a lot in the last ten years.

Center for Disease Control and Prevention (CDC) in the United States says that the number of children with Autism Spectrum Disorder (ASD) went from 1 in 150 in the early 2000s to 1 in 36 in 2023 [2]. There are many reasons for this increase, including changes in how autism is diagnosed, more people and healthcare professionals being aware of it, and better detection of autism across a wider range of ages. There aren't many statistics available in Indonesia, but reports from the Ministry of Health of the Republic of Indonesia and a few local studies show that the number of people with ASD is rising at a similar rate. Studies show that 2 to 5 out of every 10,000 children have Autism Spectrum Disorder (ASD). This trend is growing because more people in Indonesia know about ASD, and diagnostic tools are getting better [3]. Sadly, it is still hard to get a diagnosis and early help for ASD in Indonesia, especially in remote areas. This makes it harder to treat and support people with ASD.

A multidisciplinary approach is often used in ASD screening and diagnosis. This includes clinical evaluations based on DSM-5 criteria and a range of screening tools designed to find ASD symptoms in both children and adults. The Autism Diagnostic Observation Schedule (ADOS) and the Autism Diagnostic Interview-Revised (ADI-R) are the two most common tests used to diagnose Autism Spectrum Disorder (ASD). The ADOS is a series of exercises that are meant to test a child's social skills, communication skills, and behavior. The ADI-R is a semi-structured interview with parents or caregivers to find out how a child is doing with their early developmental milestones. In addition to these observational assessment methods, questionnaire-based screening tools like the Modified Checklist for Autism in Toddlers (M-CHAT) are used to find ASD in young children. These steps make it easier to find problems early, but they require specialized knowledge and experience to give an accurate and appropriate assessment.

As technology has improved, research on using artificial intelligence (AI) methods to classify ASD has made a lot of

progress. Artificial intelligence has a lot of potential to help with diagnosing ASD by looking at different types of data, such as neuroimaging, audio recordings, behavioral patterns, and genetic information. Support Vector Machines (SVM), Random Forest, Deep Neural Networks (DNN), and Convolutional Neural Networks (CNN) are some of the algorithms that have been used to make models for classifying ASD that are more accurate and useful. Here are eleven papers that came before this one that used AI methods to classify ASD.

K. Vakadkar et al. (2021) used a data-driven method with Decision Tree and Naive Bayes algorithms to sort children with Autism Spectrum Disorder. The study showed that AI models can be very accurate at finding people with ASD [4]. Duda et al. (2016) made an AI-based diagnostic system that uses motion sensor data to find signs of ASD in kids. The SVM algorithm that was used worked very well, with an accuracy of almost 90% [5]. Heinsfeld et al. (2018) used deep learning and transfer learning to sort Autism Spectrum Disorder using fMRI data. This study shows that AI can tell the difference between different brain connection patterns in people with ASD [6].

Bone et al. (2017) made a Machine Learning model that uses voice recordings and speech patterns to sort people with Autism Spectrum Disorder (ASD). This study shows that AI has a lot of potential for analyzing non-verbal data [7]. R. Thapa et al. (2023) looked at how likely a child was to develop ASD at an early stage, which made the diagnosis process easier. To predict ASD traits, it uses several machine learning models, such as Logistic Regression (LR), Naive Bayes (NB), Support Vector Machines (SVM), K-Nearest Neighbors (KNN), and Random Forest Classifier (RFC). The study found that Logistic Regression was the best model for the dataset. However, machine learning models could do a better job of finding ASD if they were trained on bigger datasets and used deep learning methods like Convolutional Neural Networks (CNNs). The authors stressed how important it is to find problems early and how machine learning can help speed up the diagnostic process [8].

Using gene interaction network data, D. Bandara [9] made a Graph Neural Networks (GNN) model to figure out how likely it is that a gene is linked to Autism Spectrum Disorder (ASD). The author used different types of GNNs as starting points for three classification tasks: binary, multi-class, and syndromic risk classification. These types of GNNs included Graph Sage, Graph Convolutional Networks (GCN), and Multi-Layer Perceptron (MLP). The experimental results show that the Sage Graph model consistently outperforms the other models with the highest accuracy for all three classification tasks: 85.80% accuracy for binary risk classification, 81.68% accuracy for multi-class risk classification, 90.22% accuracy for syndromic gene classification.

J. W. Song et.al concluded that neuroimaging studies in neurodevelopmental disorders, such as autism spectrum disorder (ASD) and Attention-Deficit or Hyperactivity Disorder (ADHD), have uncovered various biomarkers. However, limitations in comprehensively analyzing such biomarkers limit clinically significant results. The use of deep learning (DL) offers a new approach to improve diagnosis accuracy and assist clinicians in determining more appropriate treatment. DL enables earlier and more accurate detection of biomarkers by analyzing complex patterns of neuroimaging data [10].

A. Ashraf et al. used deep learning methods, specifically an optimized Convolutional Neural Network (CNN), providing better results in the classification of individuals with Autism Spectrum Disorder (ASD) than previous conventional methods. Transfer learning demonstrated efficacy, achieving an accuracy of 82.31% on the ABIDE-I and ABIDE-II datasets. This study looks at how fMRI data can help find Autism Spectrum Disorder (ASD) early on so that kids with autism can have a better environment. The results showed better performance, but the authors stressed how important data augmentation is for improving accuracy even more [11].

R. A. Bahathiq et al. R. A. Bahathiq et al. have used machine learning (ML) and deep learning (DL) to diagnose autism spectrum disorder (ASD) using structural magnetic resonance imaging (sMRI) data. This is a promising approach, but it faces a lot of challenges. There are still a number of problems with ML/DL research that make it hard to find biomarkers for ASD and improve diagnostic accuracy. These include small sample sizes, differences in brain biomarkers, and problems with generalizing results. This study stresses how important it is to have bigger datasets and more rigorous methods to deal with these problems [12].

Y. Lin and others have shown that machine learning methods can accurately predict risk genes linked to Autism Spectrum Disorder (ASD). Using spatiotemporal gene expression patterns in the human brain, gene-level constraint metrics, and other factors of gene variation, researchers found new genes that increase the risk of ASD and confirmed genes that were already known to do so. The study showed that the genes that were expected to be found are linked to important biological processes like neural signaling, neurogenesis, chromatin remodeling, and protein ubiquitination.. Although the results are encouraging, the study acknowledges limitations, including the necessity for additional confirmation via independent replication studies [13].

AI has a lot of promise for helping to diagnose and classify ASD, but there are still other issues and shortcomings that need to be fixed. A primary difficulty is the quality and diversity of data utilized for training AI algorithms. Inadequate or unrepresentative datasets might result in biased models that lack generalizability across diverse populations. Furthermore, the acquisition of high-quality data, particularly pertaining to brain imaging and genetic information, is frequently expensive.

The restricted interpretability of AI models is a significant concern in medical contexts, particularly Autism Spectrum Disorder (ASD). Most Deep Learning algorithms operate as “black boxes”, rendering their internal mechanics challenging for medical professionals and researchers to comprehend. This results in challenges in evaluating outcomes and making clinical decisions based on AI model outputs. Transfer learning presents a viable option to address some limitations of conventional AI methodologies. The Lightweight Ensemble CNN for ASD classification using facial photos combines fast processing with strong predictive power. The use of lightweight CNN architectures like MobileNetV2 and EfficientNetB0 makes it possible for the system to work well on devices with limited

computing power while still being very accurate, thanks to the ensemble method. Things that helped with this study are:

1) The strategy improves the overall accuracy of the classification by using an ensemble approach that combines predictions from several lightweight CNN models, such as MobileNetV2 and EfficientNetB0, instead of just one model. This is important for classifying ASD because the details of facial features can be very different and subtle.

2) Using a lightweight CNN architecture makes sure that the models can do their jobs quickly. This makes training and inference faster, which means that these models can be used on devices with limited processing power, like mobile phones or edge devices used in clinical settings.

II. METHODOLOGY

A. Design CNN

The dataset of face images for ASD was obtained from Kaggle and data from an autism center in Semarang, with 1.468 labeled as ASD and 1.468 labeled as normal. The dataset was divided into training and testing data with an 80:20 ratio. The block diagram and flowchart of the proposed research are shown in Fig. 1 and Fig. 2. The dataset has pictures of people's faces that are either classified as having Autism Spectrum Disorder (ASD) or not. This information could come from a variety of places, such as clinics, past research, or relevant public statistics. Before training, the facial images will go through a number of steps to prepare them, such as resizing, normalizing, and adding more data through techniques like rotation, flipping, and adjusting the contrast.

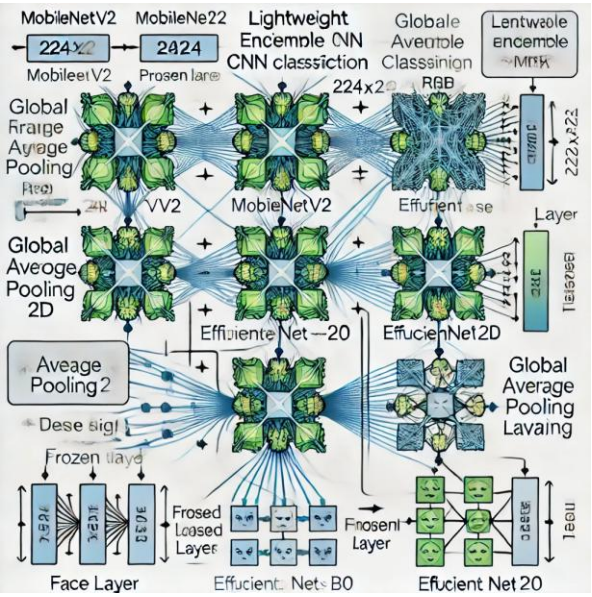

Fig. 1. Block diagram of proposed research.

The goal of these steps is to improve the quality of the dataset and make the image selection more varied, which will help the model learn better. We chose lightweight CNN designs like MobileNetV2 and EfficientNetB0 because they are fast and have small models. They use depthwise separable convolutions and compound scaling methods to make inferences quickly while keeping accuracy high. When you put a picture of a face into the model, the CNN network will extract features. This method uses a number of convolutional layers to find important patterns in the image, such as the shape of the face, the expression on it, and the texture of the skin. The result of this extraction is a number that shows what the face looks like.

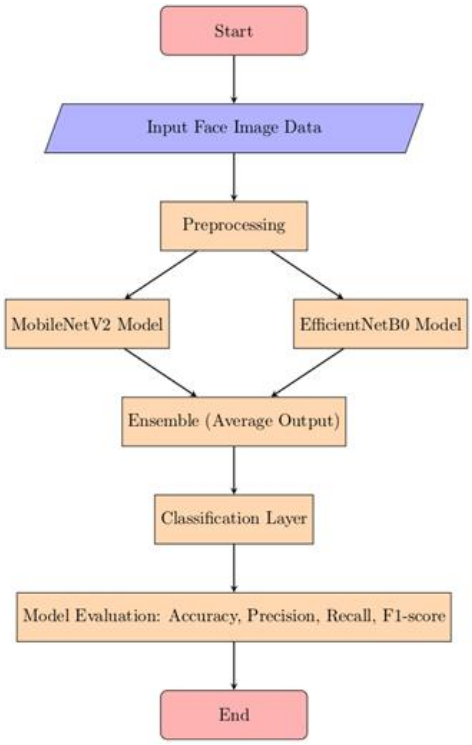

Fig. 2. Research flowchart.

The ensemble method combines the results of the two CNN models after they have independently classified the data. To get the final prediction, this method might use the average of the probability from both models. Using a voting system in which the most common result from both models is chosen as the final category. The ensemble method makes the system more reliable and accurate by lowering the chance of errors from a single model and making it better at generalizing new data. The model will give a final output that shows the chance that the person has Autism Spectrum Disorder (ASD) after the ensemble phase is over. A softmax layer is usually used to turn the model's output into a probability distribution that shows how sure the model is of its categorization. It is possible to make a final decision about whether someone has ASD based on the resulting probabilities. A specific threshold is set to tell the difference between the positive (indicating ASD) and negative (indicating absence of ASD) classifications. We use a number of metrics to judge how well this architecture works, such as accuracy, precision, recall, F1-score, and AUC. This review is very important for figuring out how well the model works at finding ASD and figuring out what the system does well and what it doesn't. This pseudo-code shows the main steps for making an ASD classification model using an ensemble method that includes two small CNN models. As shown in Fig. 3, this method combines the best features of two CNN architectures to create a model that is more accurate and robust for classifying facial images related to ASD.

Algorithm 1 ASD Classification using Lightweight Ensemble CNN

Input: Dataset of face images (JPEG format)
Output: ASD classification labels (ASD or non-ASD)
Initialize two pre-trained lightweight CNN models: MobileNetV2 and EfficientNetB0
procedure PREPROCESS DATA
    Load the face image dataset in JPG format
    Resize images to a fixed size (e.g., 224 × 224 pixels)
    Normalize pixel values (scaling between 0 and 1)
    Split dataset into train, validation, and test sets
end procedure
procedure MODEL DEFINITION
    Load MobileNetV2 with pre-trained weights from ImageNet
    Load EfficientNetB0 with pre-trained weights from ImageNet
    Remove top layers (head) from both MobileNetV2 and EfficientNetB0
    Add GlobalAveragePooling2D to each model output
end procedure
procedure ENSEMBLE STRATEGY
    Concatenate the outputs of MobileNetV2 and EfficientNetB0
    Add a fully connected layer (Dense layer) with 128 units and ReLU activation
    Add Dropout layer with a dropout rate of 0.5
    Add output layer with 1 unit and Sigmoid activation (binary classification)
end procedure
procedure COMPILE MODEL
    Compile the ensemble model using Binary Crossentropy loss
    Use Adam optimizer
    Define metrics for evaluation: Accuracy, Precision, Recall, F1-score
end procedure
procedure TRAIN MODEL
    Train the ensemble model on the training data
    Validate on the validation dataset
    Train for a set number of epochs (e.g., 50 epochs)
    Use EarlyStopping callback to prevent overfitting
end procedure
procedure EVALUATE MODEL
    Evaluate the trained model on the test dataset
    Calculate accuracy, precision, recall, F1-score, and confusion matrix
    Plot accuracy and loss curves across epochs
end procedure
procedure PREDICTION
    Input new face images
    Preprocess the image in the same way as the training dataset
    Predict ASD or non-ASD using the trained ensemble model
end procedure

Fig. 3. Pseudo-code of ASD classification algorithm with weighted ensemble CNN methodology.

B. Lightweight Ensemble CNN in ASD Classification

Lightweight Group Convolutional Neural Networks (CNN) use face images to group people with Autism Spectrum Disorder (ASD) into groups. This involves mathematically defining the network architecture and the ensemble method [14]. This is a breakdown of the parts that make up the final equation:

1) Individual model outputs: Let us label two lightweight CNN models as M1 and M2. Each model receives an input image X and produces a probability distribution across the classes (e.g., ASD or non-ASD).

The result produced by model M1 is:

$$P_1 = M_1(X) \text{ (probabilities from model 1)} \quad (1)$$

The output of model M_2 is:

$$P_2 = M_2(X) \text{ (probabilities from model 1)} \quad (2)$$

2) Ensemble method: The ensemble may be constructed by several techniques, including averaging or voting. We will examine the average method, which integrates the outputs of both models.

The ultimate ensemble output can be expressed as:

$$P_{ensemble} = \frac{P_1+P_2}{2} \quad (3)$$

3) Activation function: The final output $P_{ensemble}$ typically needs to be passed through an activation function (like softmax) to ensure it produces a valid probability distribution. The softmax function is defined as:

$$P_{final}(c) = \frac{e^{P_{ensemble}(c)}}{\sum_j e^{P_{ensemble}(j)}} \quad (4)$$

Here, c represents a specific class (e.g., ASD or non-ASD), and the sum in the denominator runs over all classes j.

4) Final equation: Combining these components, the complete mathematical representation of the Lightweight Ensemble CNN for ASD classification can be summarized as:

$$P_{final}(c) = softmax\left(\frac{M_1(X)+M_2(X)}{2}\right) \quad (5)$$

5) Training the models: During training, the loss function (e.g., categorical cross-entropy) is applied to the final predictions compared to the ground truth labels. The loss function can be expressed as:

$$L = -\sum_i y_i \log(P_{final}(c_i)) \quad (6)$$

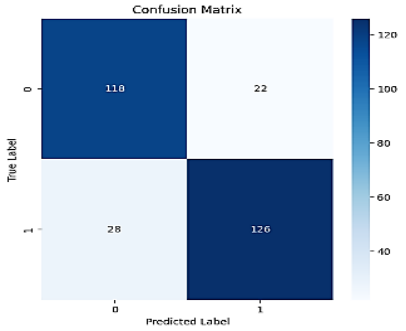
where,

y_i is the true label for the i-th instance,

c_i is the class corresponding to the i-th instance.

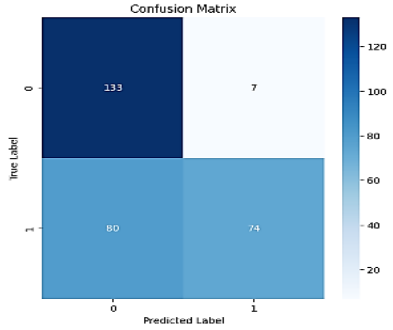
III. RESULT AND ANALYSIS

The performance comparison of the five lightweight ensemble CNN models presented in Table I highlights the differences in accuracy, precision, recall, and F1-score for each model. Here's a detailed breakdown of the comparison: MobileNetV2 + EfficientNetB0. This model exhibits the most balanced performance across all metrics. It provides strong accuracy and maintains a good trade-off between precision and recall, which results in a high F1-score. This indicates that the model can consistently detect ASD cases while keeping a low false-positive rate. MobileNetV2 + EfficientNetB5, this model achieves very high precision but poor recall, indicating it identifies positive cases with high accuracy but misses a significant number of actual ASD cases (low sensitivity). The imbalance between precision and recall leads to a relatively low F1-score, showing it is less effective in capturing true positive cases.



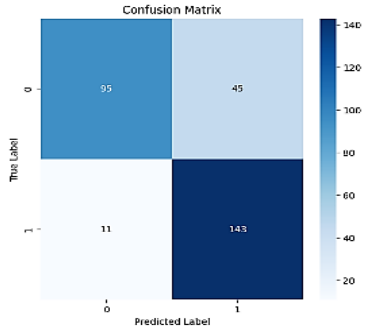
The MobileNetV2 and EfficientNetB7 work together to give very high accuracy, similar to the B5 combination, while greatly improving recall. The higher recall makes it easier to find real ASD patients, which gives it a better F1-score than the B5 variation. This means that it is better at finding both positive and negative cases overall. The ResNet50 and EfficientNetB0 models together have the best accuracy of all the models, but their recall is very low. It correctly finds positive cases, but it misses a lot of real ASD cases, as shown by the low recall. The big difference between precision and recall gives the group the lowest F1-score, which means that the model is not good enough for situations that require high sensitivity.

TABLE I. ENSEMBLE CNN LIGHTWEIGHT MODEL PERFORMANCE TEST

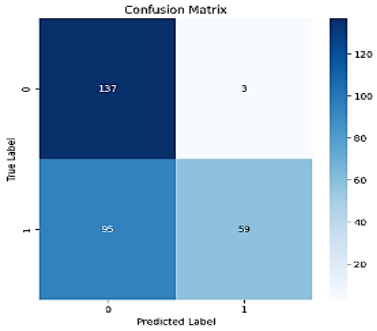


Model LightWeight + Ensemble CNN	Model Performance			
	Accuracy	Precision	Recall	F1_score
MobilNetV2 + EfficientB0	0.8299	0.8514	0.8182	0.8344
MobilNetV2 + EfficientB5	0.7109	0.9059	0.5000	0.6444
MobilNetV2 + EfficientB7	0.8027	0.9138	0.6883	0.7851
ResNet50 + EfficientB0	0.6667	0.9515	0.3831	0.5364
VGG16 + EfficientB0	0.7687	0.8644	0.6623	0.7500

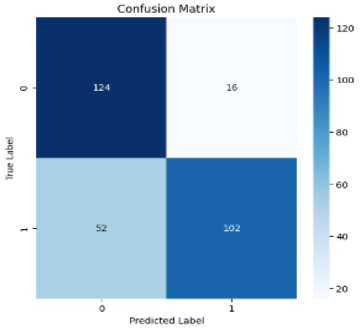
The VGG16 + EfficientNetB0 model performs about the same as the MobileNetV2 + EfficientNetB0 combination, but it is generally worse. It has a moderate recall, which means it can find a lot of cases of ASD, but its overall accuracy and F1-score are lower, which means it is less reliable. The MobileNetV2 + EfficientNetB0 combination has the best overall performance, with balanced metrics and a high F1-score, making it the strongest model in the comparison. Most Accurate: The ResNet50 + EfficientNetB0 model is very accurate, but it doesn't do as well on recall, which makes its performance uneven. A trade-off between precision and recall.



The MobileNetV2, EfficientNetB5, and EfficientNetB7 models exhibit considerable discrepancies in precision and recall, with B5 prioritizing precision and B7 providing a more favourable balance by enhancing recall. The MobileNetV2 + EfficientNetB0 model is the most effective, providing a balanced and high-performing solution for ASD classification. Other models like ResNet50 + EfficientNetB0 or MobileNetV2 + EfficientNetB5 may be valuable, where precision is the priority, but their low recall limits their effectiveness in real-world scenarios where sensitivity is equally important.



(a) Confusion matrix of MobilNetV2 +EfficientB0.



(b) Confusion matrix of MobilNetV2 + EfficientB5.

(c) Confusion matrix of MobilNetV2 + EfficientB7.

(d) Confusion matrix of ResNet50 + EfficientB0.

(e) Confusion Matrix of VGG16+ EfficientB0.

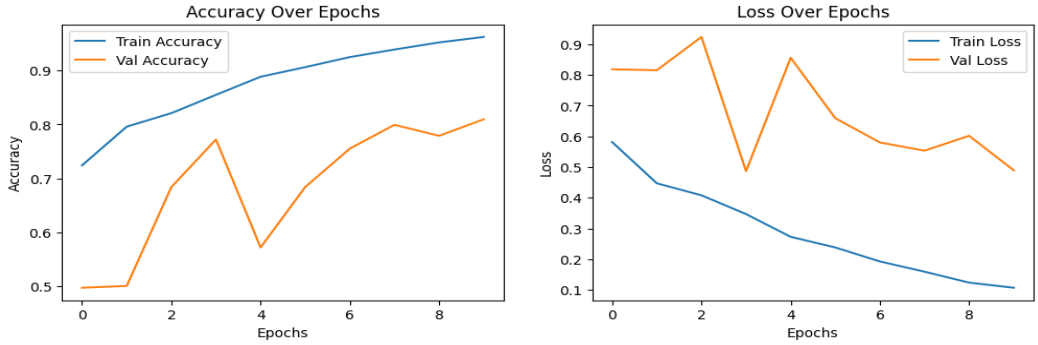


Fig. 4. Confusion matrix of ensemble CNN lightweight model.

Fig. 4 in the study presents the confusion matrices for the five lightweight ensemble CNN models discussed in Table I. These matrices provide a detailed breakdown of how each model performs in terms of correctly and incorrectly classifying instances of Autism Spectrum Disorder (ASD) and non-ASD cases. The confusion matrix is a useful tool for understanding the true positives (TP), false positives (FP), true negatives (TN), and false negatives (FN) for each model. Fig. 4(a) has the best overall performance, with low false positives and false negatives, indicating strong accuracy and a balanced ability to correctly identify both ASD and non-ASD cases.

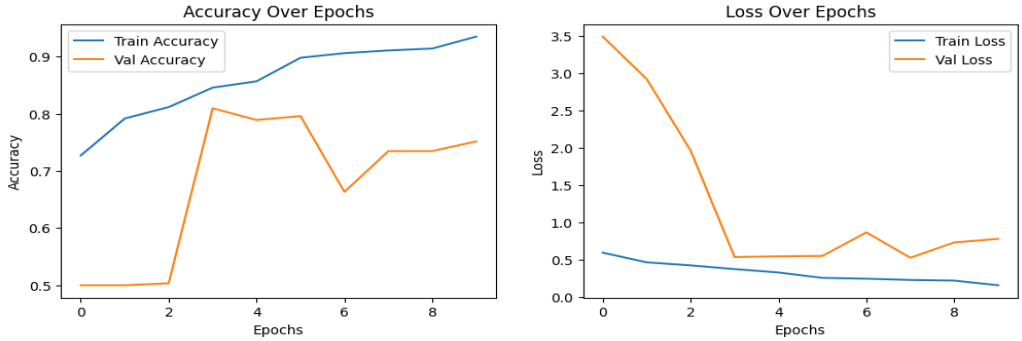

Fig. 4(b) and Fig. 4(d) are highly precise, but their confusion matrices reveal that they suffer from high false negatives, meaning they miss many ASD cases and have poor recall. Fig. 4(c) improves recall significantly compared to the B5 variant, with fewer false negatives, offering a better balance between precision and recall. Fig. 4(e) provides a moderate performance across all metrics, as seen in the relatively balanced false positives and false negatives, making it a decent model for general ASD classification.

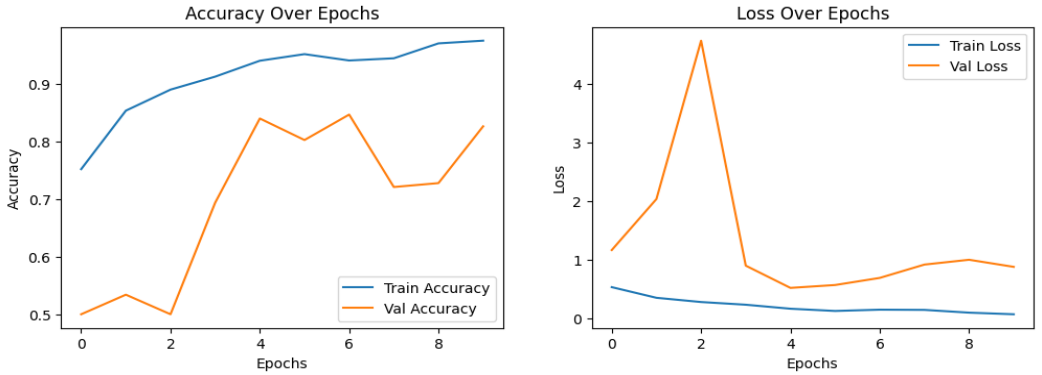
Fig. 5 of the study presents the graphs of accuracy and loss plotted against the number of epochs for the five lightweight ensemble CNN models. These graphs provide insights into how each model learns over time and how their performance improves or stabilizes during training. MobileNetV2 + EfficientNetB0 [Fig. 5(a)] has the smoothest and most effective learning curve, with early stabilization of both accuracy and loss. This indicates a well-optimized model with minimal overfitting. MobileNetV2 + EfficientNetB5 [Fig. 5(b)] and MobileNetV2 + EfficientNetB7 [Fig. 5(c)] show slower learning with more fluctuations, indicating less stable models that might struggle with generalization. ResNet50 combined with EfficientNetB0 [Fig. 5(d)] exhibits a more gradual enhancement and a greater final loss, rendering it less successful than the other models. VGG16 combined with EfficientNetB0 [Fig. 5(e)] demonstrates moderate performance, exhibiting relatively rapid initial learning but ultimately stabilizing at a lower accuracy than the highest-performing models. The MobileNetV2 + EfficientNetB0 model demonstrates optimal efficiency and stability, attaining elevated accuracy and little loss alongside a seamless learning trajectory. Alternative models such as MobileNetV2 combined with EfficientNetB5 and ResNet50 paired with EfficientNetB0 exhibit slower learning rates and diminished performance, characterized by elevated loss and reduced final accuracy, indicating potential difficulties with complicated data or a need for more tuning to enhance outcomes.



As shown in Table II, this study was also compared with previous studies. Cardoso et al. (2021) conducted a study for ASD diagnosis. Eye tracking data was used. The method used was an ensemble of random forests. The accuracy results were 0.75 and 0.82 for the F1-score [15]. Kollias et al. (2022) used Decision Trees, Logistic Regression, and Transfer Learning methods. The accuracy achieved was 0.805 [16]. The proposed study achieved an accuracy of 0.8299, which is higher than previous studies, using only a combination of the MobilNetV2 and EfficientB0 models with a facial images dataset.

(b) Graph of accuracy and loss against number of epochs for the MobilNetV2 +EfficientB5 model.

(c) Graph of accuracy and loss against number of epochs for the MobilNetV2 +EfficientB7 model.

(d) Graph of accuracy and loss against number of epochs for the ResNet50 +EfficientB7 model.

(e) Graph of accuracy and loss against number of epochs for the VGG16 +EfficientB7 model.

Fig. 5. Graph of accuracy and loss against number of epochs for ensemble CNN lightweight model.

TABLE II. PRESENTATION OF THE RESULTS OF PREVIOUS STUDIES DISCOVERING ASD

Study	Method	Accuracy
Cardoso et al [15]	RF Classifier + ET signals	0.7500
Kollias et al [16]	Transfer learning +DT, logistic refression	0.8050
Proposed Method	MobilNetV2 + EfficientB0 +Facial Images	0.8299

IV. CONCLUSION

ResNet50 combined with EfficientNetB0 [Fig. 5(d)] exhibits a more gradual enhancement and a greater final loss, rendering it less successful than the other models. VGG16 combined with EfficientNetB0 [Fig. 5(e)] demonstrates moderate performance, exhibiting relatively rapid initial learning but ultimately stabilizing at a lower accuracy than the highest-performing models. The MobileNetV2 + EfficientNetB0 model demonstrates optimal efficiency and stability, attaining elevated accuracy and little loss alongside a seamless learning trajectory. Alternative models such as MobileNetV2 combined with

EfficientNetB5 and ResNet50 paired with EfficientNetB0 exhibit slower learning rates and diminished performance, characterized by elevated loss and reduced final accuracy, indicating potential difficulties with complicated data or a need for more tuning to enhance outcomes. While other models, such as ResNet50 + EfficientNetB0, showed high precision, they lacked the recall necessary to detect all ASD cases effectively, making them less suitable for comprehensive diagnosis. This study was also compared with other researchers, and the proposed study was found to have greater accuracy than other researchers. The findings emphasize the potential of deep learning and AI in augmenting ASD screening processes, particularly in areas where access to specialized healthcare professionals is limited. However, challenges remain, including the need for larger, more diverse datasets to improve generalization across different populations and further development of explainable AI techniques to enhance model interpretability for clinicians. Future research should focus on refining the model's ability to generalize across different facial types and exploring its integration with other diagnostic tools for a multi-modal approach to ASD diagnosis.

ACKNOWLEDGMENT

The author would like to thank the Ministry of Higher Education, Science, and Technology of the Republic of Indonesia for its support for this research through the Regular Fundamental Grant scheme with Contract No. 016/LL6/PL/AL.04/2025.

An Adaptive SVR-Based Framework for Multimodal Corpus Classification

Yuhui Wang
Basic Teaching Department, Henan Logistics Vocational College, Zhengzhou 453500, China

***Abstract*—To address the challenges associated with the dynamic growth and multimodal complexity of modern corpora, an adaptive classification framework based on Support Vector Regression (SVR) was developed. A structured corpus was first constructed, followed by the extraction of salient textual features using Term Frequency–Inverse Document Frequency (TF-IDF) metrics. To accommodate the continuous expansion of the corpus, an incremental learning strategy was employed, enabling the model to update efficiently without complete retraining. A kernel-based SVR model was trained to perform classification tasks, and an adaptive feedback-driven mechanism was introduced to dynamically adjust both model parameters and feature representations based on classification performance metrics. Evaluation was conducted on multiple multilingual and multimodal corpora, with particular emphasis on Chinese language processing, which often presents unique challenges due to character complexity and sparse feature representations. The proposed method achieved a significant improvement in classification accuracy when compared to conventional classification approaches. Furthermore, the model demonstrated superior adaptability and computational efficiency across various corpus types. The findings confirm the viability of SVR as a core component for adaptive classification tasks in dynamic linguistic environments. This study contributes to the field by establishing a generalizable, efficient, and interpretable framework suitable for real-time corpus management systems, intelligent content filtering, and multilingual information retrieval.**

I. INTRODUCTION

With the rapid advancement of information technology and the widespread penetration of the Internet, we have entered the era of big data, where the volume of text data is growing at an unprecedented rate [1]. The abundance of data and continuous technological progress provide strong support for the construction and application of corpora across various domains. Corpora have shown exceptional performance in applications such as online machine translation, international cultural exchange, knowledge-based question answering, sentiment analysis, and more, with steadily increasing accuracy.

These massive text datasets span diverse fields, including news, social media, academic literature, and business reports, offering rich resources for information retrieval, natural language processing (NLP), and data mining [2]. However, effectively organizing and utilizing these datasets to extract meaningful information has become a critical challenge in current research [3].

As structured collections of text data, corpora play a vital role in advancing NLP technologies. Through machine learning algorithms, adaptive classification of corpus resources enables automatic categorization and annotation of text data, thereby improving the efficiency and accuracy of text processing [4, 5]. There are several key technical gaps that urgently need to be addressed in the current research on adaptive classification of corpus resources. Firstly, existing methods often struggle to effectively integrate semantic associations between different modalities when processing multimodal data, resulting in insufficient cross-modal feature expression and limited classification performance. Secondly, in the face of dynamically changing corpus resources, traditional static models lack the ability for continuous learning and cannot adapt to the time-varying characteristics of data distribution, resulting in significant degradation of model performance with data updates. Furthermore, existing methods exhibit a significant lack of generalization ability when applied across domains, making it difficult to transfer existing knowledge to new areas. The fundamental reason for these technological gaps lies in the limitations of existing methods in feature representation and model architecture, which fail to fully consider the essential characteristics of corpus resources such as multimodality, dynamism, and domain diversity.

Among numerous machine learning algorithms, support vector machines have become a popular choice in the field of text classification due to their excellent classification performance and good generalization ability [6]. Especially, support vector machine regression technology is not only suitable for classification problems, but also demonstrates its unique advantages in regression tasks, opening up new perspectives and approaches for adaptive classification of corpus resources. Therefore, against the backdrop of numerous challenges in current research on adaptive classification of corpus resources, this study proposes a corpus resource adaptive classification method based on support vector machine regression. This study aims to address three core issues: firstly, how to effectively handle the semantic gap between heterogeneous data such as text, images, and audio in multimodal corpora, and achieve unified representation and deep fusion of cross modal features. Secondly, how to design a dynamic classification model with continuous learning ability to adapt to the characteristics of corpus resources evolving over time and avoid performance degradation of the model due to data updates; Finally, how to improve the domain adaptation ability of classification models, so that they can effectively transfer existing knowledge to new domains and solve the problem of insufficient generalization in cross domain classification. In response to these issues, this study proposes

an adaptive classification method based on support vector machine regression, which solves modal heterogeneity through kernel function space mapping, uses incremental learning mechanism to cope with dynamic changes in data, and combines domain adaptation technology to improve model generalization ability, thus providing a systematic solution for intelligent classification of corpus resources. This research not only promotes the development of corpus resource management technology, but also provides important support for related applications in natural language processing, information retrieval, and other fields. The main research content of this study is as follows:

The system has reviewed the research progress of existing corpus classification methods, with a focus on analyzing the advantages and disadvantages of representative works such as human-machine hybrid classification, pre-trained model applications, and multimodal processing; The core algorithm framework based on support vector machine regression is elaborated in detail, including key technical steps such as corpus structured representation, dynamic update mechanism, feature extraction process, and classification model construction. Specifically, the structure of the corpus is determined, and the features of the corpus resources are extracted through the support vector machine regression method. After expanding the corpus resources, an adaptive mechanism is introduced to dynamically adjust the model parameters or feature representations based on the corpus resource classification prediction results and feedback information, thereby obtaining accurate corpus resource adaptive classification results. The effectiveness of the proposed method was validated through multiple controlled experiments, using six typical corpus datasets including People's Daily Corpus to comprehensively evaluate classification accuracy, processing effectiveness, and other dimensions, summarize the research results and explore future research directions such as deep learning fusion, multimodal extension, and real-time classification systems.

II. Related Work

There are currently many related studies on resource classification. For example, Sebők et al. [7] conducted a study on human-machine hybrid topic classification using the New York Times corpus. Based on the policy topic categories of comparative agenda items, the leading paragraphs of the front page articles of The New York Times from 1996 to 2006 were classified. Supervised machine learning classification is performed in multiple rounds, and in each round, if the given algorithm is non deterministic, the supervised machine learning algorithm is run n times on n samples. If all SML predictions point to a single label of the document, then classifying it as a single label (also known as "voting ensemble") using a combination of manual encoding and validation and ensemble SML hybrid methods can reduce the need for manual encoding while maintaining very high accuracy and providing moderate to good recall. However, the modularity of this hybrid workflow allows for various settings to address the special resource bottlenecks that large-scale text classification projects may face. Jiao [8] proposed the background and definition of text classification research, and described its representative methods at different stages of development. At the same time, the recently popular pre-trained language models based on large-scale corpora were introduced, and their applications in text classification were discussed. However, the adaptive classification of corpora under this method often relies on different research purposes and uses, resulting in diverse classification standards and a lack of uniformity, making it difficult to compare and share between different corpora. Iqbal et al. [9] constructed a corpus for identifying emotions in Bengali language texts. The corpus development process includes four key steps, namely data capture, preprocessing, annotation, and validation, in order to classify and recognize six basic emotional categories, namely anger, fear, surprise, sadness, happiness, and disgust. However, the corpus annotation and encoding system under this method still lacks unified standards and specifications, which not only increases the complexity of corpus processing but also weakens its flexibility and versatility in practical applications. Xue et al. [10] studied the application of a multimodal topic model based on word order and associative semantics in social event classification, namely, establishing an innovative supervised multimodal topic model that integrates multidimensional information of vocabulary hierarchical semantics and vocabulary document relevance. Based on the results of dependency syntax analysis, the contribution of modal words to document representation can be divided, and the hierarchical semantics of text words can be explored. In addition, consider the correlation frequency of multimodal words to extract the relevant semantics of Word documents. By integrating these two semantic information for multimodal vocabulary sampling, social event classification based on supervised topic framework has been achieved. However, the accuracy and efficiency of this method in processing complex corpora still need to be improved. Especially for multi-domain and multilingual corpora, the difficulty of automatic classification is even greater. Hu and Zhang [11] first effectively enhanced the original dataset using abstract summarization methods, reducing potential problems caused by data imbalance, while improving sample diversity and generalization ability. Then, by using meta learning algorithms, the optimization and adjustment of global initialization parameters were achieved. Finally, these parameters will guide the pre-trained BERT model to fine tune, to adapt to the diabetes text classification task. However, different types of text contain a large number of specialized terms and specific expressions, which are not fully covered in the pre training data of the BERT model. Therefore, this method cannot effectively transfer existing knowledge to new domains and solve the problem of insufficient generalization in cross domain classification, resulting in poor application performance.

The current proposal systematically addresses key issues in existing corpus resource adaptive classification methods by combining support vector machine regression with kernel function space mapping, incremental learning mechanism, and domain adaptation techniques. Specifically, existing methods struggle to effectively integrate cross modal semantic associations when processing multimodal data, resulting in insufficient feature expression. However, this proposal utilizes kernel functions to map heterogeneous data to a unified high-dimensional space, achieving deep fusion of cross modal features. For dynamic corpus resources, traditional static

models lack continuous learning ability and cannot adapt to the time-varying characteristics of data distribution. This proposal introduces an incremental learning mechanism to enable the model to dynamically update and retain old knowledge, effectively addressing the challenges brought by data evolution. In addition, existing methods have insufficient generalization ability when applied across domains, making it difficult to transfer existing knowledge. Compared with the human-machine hybrid topic classification method in [7], this proposal avoids the dependence on manual coding and achieves fully automatic classification. Compared with the pre-trained language model method in [8], this proposal solves the problem of diversity in classification criteria through unified feature representation. Compared with the Bengali sentiment corpus construction method in [9], this proposal reduces the complexity of corpus processing through standardized feature extraction. Compared with the multimodal topic model in [10], this proposal has higher accuracy and efficiency in complex corpus processing. Compared with the BERT fine-tuning method in [11], this proposal effectively addresses the issue of insufficient cross-domain generalization through domain adaptation techniques. This proposal optimizes model parameters through domain adaptation techniques, significantly improving the classification performance of the model in new domains. Therefore, this proposal significantly outperforms existing methods in feature representation, dynamic adaptability, and cross-domain generalization ability, providing a systematic solution for intelligent classification of corpus resources.

III. Design of Adaptive Classification Method for Corpus Resources

A. Corpus Structure Construction

Corpus structure construction is a comprehensive process, and an efficient and adaptive text dataset was constructed to support the subsequent text classification tasks. The selection and collection of corpus is the beginning of corpus construction, and it is necessary to clarify the research fields and objectives and collect text data in related fields from multiple reliable data sources [12], which should ensure high quality, no noise or redundant information so as to improve the accuracy of classification. Preprocessing the collected corpus is an indispensable part, covering the process of text purification, such as stripping HTML tags, removing special symbols and other non-core data elements to ensure the purity of data. After preprocessing, the corpus needs to be represented in a structured way so that the algorithm can understand and process it. Usually, it involves converting text data into vectors in the vector space model, where each vector represents a text, and its dimensions correspond to the features in the feature space. The values of the vectors reflect the importance of the features in the text. At the same time, each text is assigned a corresponding label as the supervision information of the classification task. The schematic structure of the corpus is shown in Fig. 1.

As shown in Fig. 1, the corpus structure is divided into a structured representation module, a dynamic updating and adaptive module, and a security and privacy protection module. The details are as follows:

1) Structured representation of corpus: Vector space model: Text data was transformed into a numerical representation in the vector space, in which each dimension was mapped to a unique feature to realize efficient data processing and analysis, and the value of the vector indicates the importance of the feature in the text [13].

a) Tagging: One or more tags were assigned to each text, indicating its category or topic, and these tags are used as the supervision information of the SVM regression algorithm.

b) Segmentation strategy of dataset: The corpus was carefully divided into a training subset, a verification subset and a test subset, which respectively serve the training stage of the model, the parameter tuning process and the final performance evaluation task [14].

2) Dynamic updating and adaptation of corpus:

a) Incremental learning: With the continuous addition of new data, the corpus needs to be updated dynamically. Incremental learning allows the model to learn new knowledge while retaining old knowledge, which improves the adaptability and accuracy of the model.

b) Feedback mechanism: A user feedback mechanism was established to collect users' feedback opinions on classification results and adjust model parameters or the optimization algorithm to improve classification effect.

c) Adaptive adjustment: According to the changes of corpus and the requirements of classification tasks, the feature extraction method, the classification algorithm or parameter settings were adaptively adjusted to meet different classification scenarios and requirements.

3) Security and privacy protection of corpus:

a) Data encryption: In order to ensure the security of data in storage and transmission, sensitive information was encrypted to resist potential security threats.

b) Access control: Strict access control policies were set to limit access rights to the corpus and prevent unauthorized access and disclosure [15].

c) Privacy protection: Relevant laws, regulations and privacy policies were complied with during data collection and processing to ensure that the privacy of users is protected.

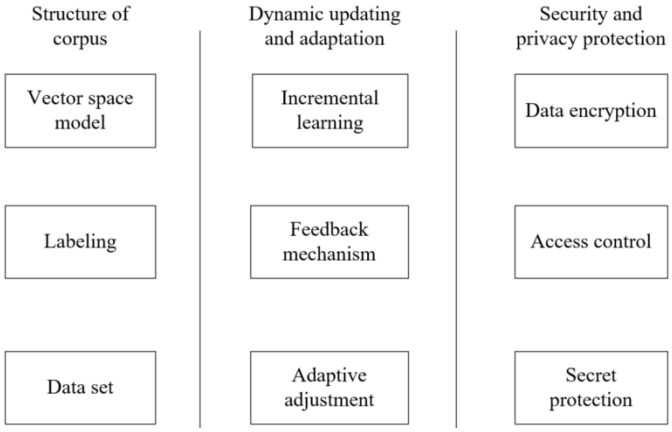

Fig. 1. Schematic diagram of corpus structure.

B. Feature Extraction of Corpus Resources Based on Support Vector Machine Regression

SVM was originally used for classification problems, and later it was extended to the field of regression, forming the SVM regression [16, 17]. The core idea of the SVM regression is to find an optimal boundary so that most data points fall within this boundary, minimizing the prediction error of data points outside the boundary. This technique is especially suitable for datasets with complex characteristic relationships [18]. In the research of the corpus resource adaptive classification, feature extraction is the process of transforming original text data into feature vectors that can be used for model training and classification. These feature vectors need to be able to fully express the content and structure information of the text so that the SVM regression model can accurately identify and classify different text categories. The TF-IDF measurement was used to quantify the weight of a single word in a document set or a specific corpus document, effectively suppressing the saliency of common words and enhancing the influence of key words. This strategy realizes not only the purpose of automatically extracting core features from the original text but also the vectorization of words in a high-dimensional feature space, which can profoundly reveal the semantic relevance between words.

In the adaptive classification of corpus resources, SVR employs a one-vs-one construction strategy to categorize abnormal traffic data into two distinct classes. Feature extraction was then performed for each category using SVM-based classification techniques. The detailed steps are as follows:

Step 1: The adaptive classification feature set of corpus resources is the number of features as shown in Formula (1) [19]:

$$A = \{A_1, A_2, A_3, \ldots, A_n\} \quad (1)$$

In Formula (1), n represents the number of features.

Step 2: By setting the number of categories to m, the set of traffic categories is shown in Formula (2):

$$B = \{B_1, B_2, B_3, \ldots, B_m\} \quad (2)$$

Step 3: By setting the number of samples to v, the set of flow samples is shown in Formula (3):

$$C = \{C_1, C_2, C_3, \ldots, C_v\} \quad (3)$$

In Formula (3), C_v represents the number of samples in the v-th category.

Step 4: The statistical frequency method was used to select the adaptive classification features of corpus resources traversing each sample and select the best feature subsets, respectively, as shown in Fig. 2.

When extracting the feature subset of corpus resources, the most representative feature was identified and selected for each category, which should meet the compatibility requirements and improve the reuse frequency of some categories. At the same time, on the premise of ensuring the classification accuracy, the overall performance was optimized. The following steps describe how to extract the features of corpus resources based on the SVM regression:

Step 1: Input of a corpus resource characteristic matrix;

Step 2: Traversing of the corpus resource feature matrix;

Step 3: In order to avoid that two categories regressed by SVM have the same feature effect, the selected features need to be deleted to reduce the redundancy of features [20, 21];

Step 4: The result was output to obtain the best feature subset of the corpus resource.

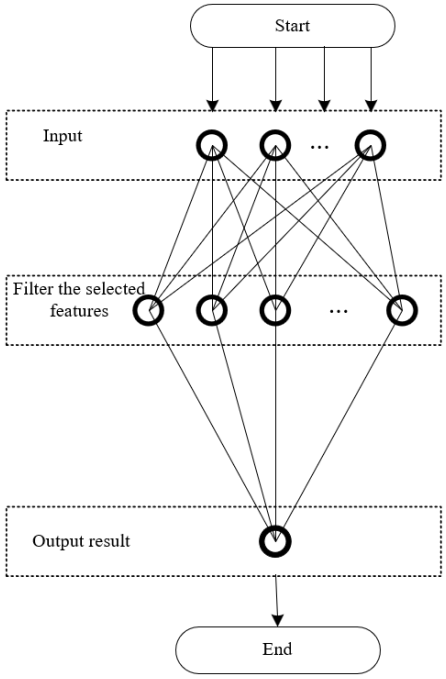

Fig. 2. Flow chart of corpus resource feature subset selection.

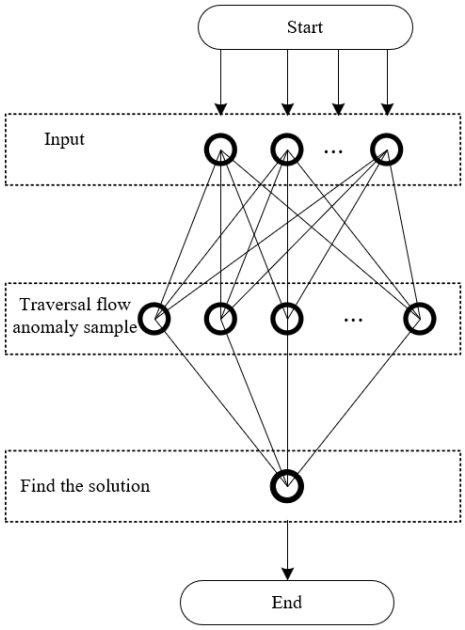

Fig. 3. Selection process of optimal feature subset.

The flow of the optimal feature subset is shown in Fig. 3.

According to Fig. 3, an effective feature vector was constructed, which provides strong support for the training and classification of the SVM regression model. At the same time, the feature extraction process needs to be adaptive to meet the needs of the corpus resource expansion.

C. Corpus Resource Expansion

Based on the feature extraction results of corpus resources based on the SVM regression, the corpus resources were expanded to improve the generalization ability of the model. By increasing the corpus in different fields, styles and languages, the model can learn more language patterns and features so that it can maintain high classification accuracy when dealing with unknown texts. At the same time, the classification accuracy can be improved. A rich corpus can provide more training samples, help the model learn more detailed and accurate classification boundaries, and reduce the problem of misclassification.

Through the integration process of corpus processing information, after analyzing user information, the content of resource information was calculated and analyzed according to the resources provided by the corpus. Multiple indicators were set to complete the calculation. When obtaining the shared consistency indicator, the classification indicator proportion was obtained, and the calculation is shown in Formula (4):

$$\lambda = \frac{A \times B \times C}{S_J - S_Q} \tag{4}$$

In Formula (4), S_J represents the consistency value of the classification index, and S_Q represents the expected value of the classification index. After labeling each type of data, the result was η, and the specific calculation is shown in Formula (5):

$$\eta = \frac{1}{\lambda} \sum_{i=1}^{H} F_i \tag{5}$$

In Formula (5), F_i stands for the i-th classification standard. At this time, the classification index proportion λ is metaphor type, and the current annotator is M. For this, the consistency between the annotator and other personnel was calculated as Formula (6):

$$S_M = \eta \times S_s \tag{6}$$

In Formula (6), S_s stands for the consistency index among people. By determining the value of the consistency index, the expansion steps of corpus resources were set, as shown in Fig. 4.

From the analysis of Fig. 4, it can be known that, firstly, the database was accessed to perform retrieval operations to find or obtain specific information data. Based on the retrieved information or data, courseware resources were generated and registered in the registration center. During the registration process, data records corresponding to the courseware resources were created, including metadata, identifiers, authority information, etc. The connection with network resources or systems was established for further operation or data exchange. After the connection was established, a lookup operation was performed to locate the required network resources. After finding the required network resources, they were integrated with the previous matching operations. The courseware resources and network resources were integrated to form all resources, which are now ready to be provided to users or systems. Providing all resources to demanders usually means that resources are distributed, displayed or otherwise made accessible to demanders, who may make requests for specific resources or services.

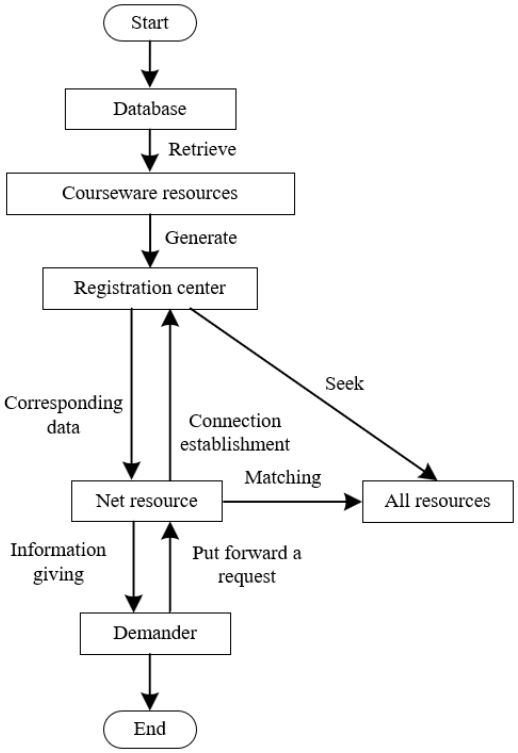

Fig. 4. Steps of expanding corpus resources.

Corpus resource expansion is a continuous process, and the classification performance of the model can be improved by constantly increasing and updating the corpus content. By ensuring the requirements of domain diversity, language style diversity, data quality and balance, and dynamic updating of corpus, a high-quality and efficient corpus resource system was constructed, which provides support for the self-adaptive classification of corpus resources.

D. Adaptive Classification of Corpus Resources

The rapid expansion of the Internet has resulted in the rapid expansion of corpus resources. How to manage and use these resources efficiently has become a key issue to be solved urgently. Adaptive classification of corpus resources using SVM has become a research hotspot. SVM was originally used as a classification technology, but it can also be applied to regression tasks by integrating ε-insensitive loss functions and other methods. Its core lies in constructing a hyperplane, aiming at minimizing the distance between sample points and the plane, while ensuring enough interval areas to enhance the general prediction ability of the model. When solving nonlinear problems, the SVM regression uses a kernel technique to upgrade the data to a high-dimensional space and then searches for a more suitable hyperplane solution.

The steps to realize the adaptive classification of corpus resources are as follows:

Step 1: After loading the corpus resources, the text purification step and word segmentation were performed to subdivide the text content. By extracting keywords or salient feature words, the vectorized representation of the text was constructed. In order to ensure the consistency of subsequent operations, the obtained text vectors were standardized.

Step 2: According to the characteristics and classification requirements of corpus resources, the appropriate feature representation method was chosen to reduce the computational complexity and improve the classification speed, and the feature dimension reduction technology was implemented to simplify the feature space.

Step 3: The kernel function was selected and adjusted according to the characteristics of corpus resources. The kernel function is shown in Formula (7):

$$K(x_i, x_j) = exp\left(-\gamma \|x_i - x_j\|^2\right) \quad (7)$$

In Formula (7), x_i and x_j represent different input vectors, and γ stands for the kernel parameter. The regression model of SVM was trained by training the dataset, and its performance was optimized by adjusting the model parameters. In order to evaluate the generalization performance of the model, cross-validation and other strategies were applied to verify its effectiveness.

Step 4: Adaptive classification

According to the trained SVM regression model, the new corpus resources were classified and predicted. In order to improve the accuracy and adaptability of classification, an adaptive mechanism was introduced to dynamically adjust the model parameters or feature representation methods according to the classification results and feedback information. The classification results obtained are shown in Formula (8):

$$D(h) = S_M \times \alpha_i \times \chi \times \beta \times R \quad (8)$$

In Formula (8), α_i stands for the i-th text set, χ represents the number of text types, and β stands for the characteristic word.

By continuously optimizing the model algorithm and adaptive ability and improving the accuracy and efficiency of classification, the technical progress and development in the field of NLP were promoted. To sum up, the research on adaptive classification of corpus resources based on the SVM regression is of great significance. By making full use of the superior performance and adaptive learning ability of the SVM regression, the complex problems in corpus resource classification can be effectively solved, improving the intelligence level and adaptability of classification.

IV. Experimental Analysis

In order to verify the effectiveness of the research on adaptive classification of corpus resources based on the SVM regression, simulation experiments were carried out. The corpus resource dataset used in the experiment is shown in Table I.

TABLE I. Corpus Resource Dataset

Dataset Name	Language	Text Type	Original Text Count	Marking Situation
People's Daily Corpus	Chinese	News	1000	Word segmentation, part-of-speech tagging, named entity recognition, etc.
Pennsylvania tree bank	English	Multiple (news, academic, etc.)	500	Syntactic structure labeling
UD English Web Treebank	English	Network text	2000	Syntactic structure labeling
COCA (Corpus of Contemporary American English)	English	Spoken language, novels, magazines, etc.	800	No specific label, suitable for language change research.
Gutenberg Project	English	Literary works	1500	No specific annotation, suitable for text analysis and language style research.
European Parliament Proceedings Parallel Corpus	Multilingual	Political speech	900	Multilingual parallel corpus, suitable for machine translation

The sampling frequency of this corpus resource dataset is 18 kHz and the sampling size is 20 bits. The types are mainly shown in Table II.

TABLE II. Data Type

Dataset Name	Dataset ID
People's Daily Corpus	D1
Pennsylvania tree bank	D2
UD English Web Treebank	D3
COCA (Corpus of Contemporary American English)	D4
Gutenberg Project	D5
People's Daily Corpus	D6

In order to meet the specific requirements of system testing, the .NET framework was chosen as the basic platform for testing implementation, which builds applications based on the Windows operating system. In order to strengthen the efficiency and accuracy of the test process, the integrated development environment of Visual Studio was used as an auxiliary tool to promote the optimization and execution of the process. The built test platform environment is shown in Fig. 5.

As can be seen from Fig. 5, the platform can meet the requirements of subsequent system testing. Therefore, it was used as the main testing environment for subsequent verification. After using this method, the adaptive classification effect of corpus resources is shown in Table III.

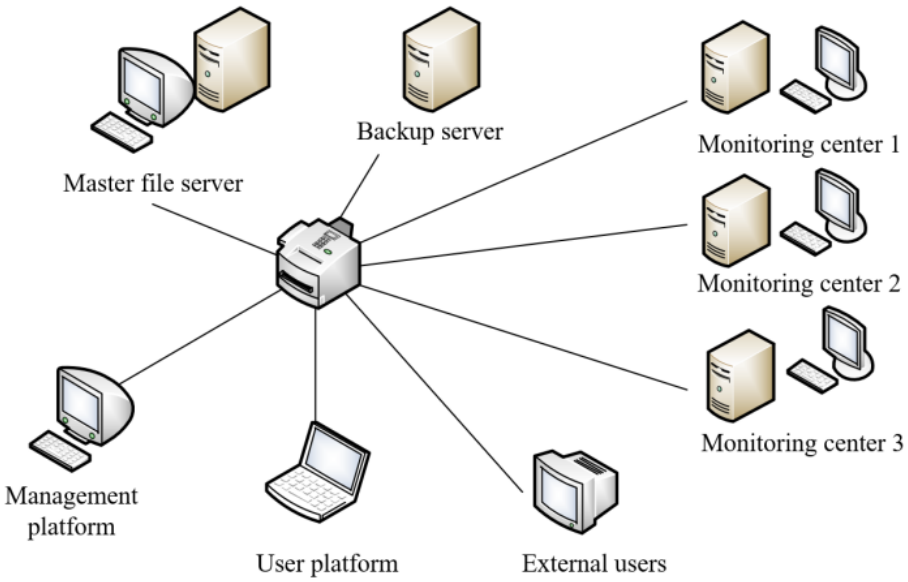

Fig. 5. Test platform environment.

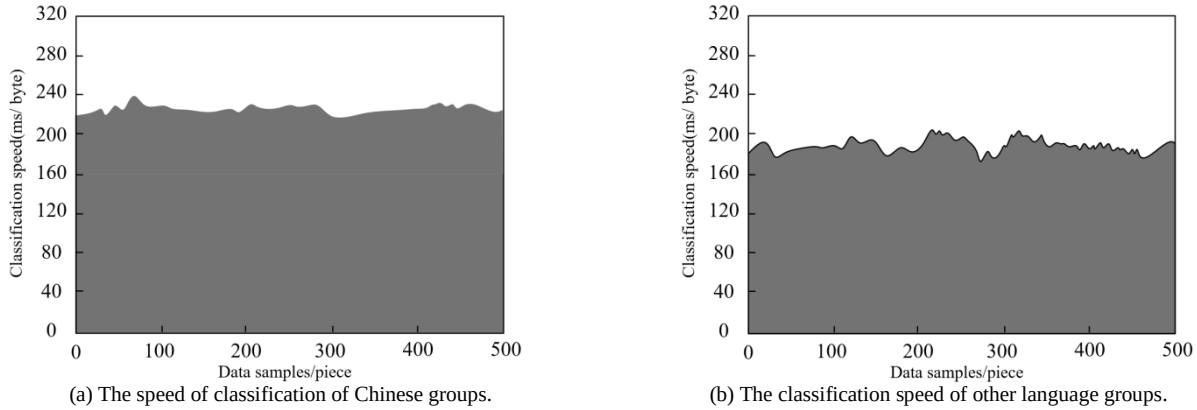
TABLE III. EFFECT OF ADAPTIVE CLASSIFICATION OF CORPUS RESOURCES



Dataset ID	Original Text Count	Classified Text Count
D1	1000	1000
D2	500	500
D3	2000	2000
D4	800	800
D5	1500	1500
D6	900	900

As can be seen from Table III, after using this method, the number of classified texts is completely consistent with that of the original texts, and this method has achieved very high accuracy on these datasets. This shows that this method can accurately classify all texts into their categories, and there is no misclassification or omission.

A total of 1000 group of data were randomly selected from the above-mentioned dataset as test data samples to verify the classification effect. They were divided into two groups according to languages, Chinese and other languages, with 500 data in each group. A graph was generated for the test results, as shown in Fig. 6.

As can be seen from Fig. 6, the test efficiency of this method for Chinese and multi-language groups was significantly improved, especially in the Chinese group, and the stable output of its classification performance was effectively controlled. In contrast, although the test results of other language groups fluctuate occasionally, there is no significant large-scale changes on the whole. Therefore, it can be judged that the adaptive classification effect of corpus resources under this method fully meets the established requirements of the classification speed test, showing good adaptability and efficiency.

Based on the above test results, the classification accuracy index was calculated according to the data of 50 cases in each group, and the average index of classification accuracy was obtained, totaling 10 groups. The methods proposed by Sebők et al. [7] and Jiao [8] were used as the comparison methods, and the method proposed in this study as the experimental method. Through a comparative analysis, the test results are shown in Table IV.

(a) The speed of classification of Chinese groups. (b) The classification speed of other language groups.

Fig. 6. Test results of Chinese and other language groups classified by this method: (a) Chinese group; (b) Other language group.

TABLE IV. COMPARISON RESULTS OF THE CLASSIFICATION ACCURACY

No.	Accuracy of Chinese Text Classification (%)			Accuracy of Other Languages Text Classification (%)		
	Sebők's method [7]	Jiao's method [8]	The proposed method	Sebők's method [7]	Jiao's method [8]	The proposed method
1	76.4	86.7	98.9	77.4	88.8	96.0
2	77.2	88.2	99.0	78.7	88.6	96.2
3	75.3	84.6	99.1	76.9	84.1	96.4
4	75.4	86.4	99.2	76.4	87.7	97.0
5	75.5	84.5	99.3	75.1	87.6	97.4
6	75.7	88.6	99.4	77.6	87.9	97.8
7	77.3	88.6	99.5	77.4	90.6	97.9
8	77.9	88.4	99.6	76.6	92.4	98.2
9	78.5	85.6	99.7	79.9	88.5	98.4
10	78.9	85.6	99.8	79.4	87.2	98.8
Ave rage	76.81	86.72	99.35	77.54	88.34	97.41

According to Table IV, the average classification accuracy of the proposed method in both Chinese and other language groups is significantly higher than that proposed by Sebők et al. [7] and Jiao [8]. Specifically, the average accuracy of the proposed method reaches 99.35% in the Chinese group and 97.41% in other language groups. In contrast, the method proposed by Sebők et al. [7] achieves average accuracies of 76.81% (Chinese) and 77.54% (other languages), while the method proposed by Jiao [8] achieves 86.72% and 88.34%, respectively.

The differences in classification results between different datasets reflect the essential differences in text types, language characteristics, and annotation standards among different corpora. From Table III, it can be seen that our method achieved 100% consistency in quantity on all test datasets, indicating that the algorithm has universal text classification ability. However, the accuracy test results showed that the average accuracy of the Chinese news corpus People's Daily Corpus reached 99.35%, significantly higher than other language datasets. This is due to the fact that the Chinese text has undergone systematic preprocessing such as word segmentation, part of speech tagging, and named entity recognition, forming a standardized feature representation that best matches the linear kernel function of support vector machine regression. In contrast, UD English Web Treebank contains more informal expressions as network text, and its accuracy of 97.41%, although slightly lower, still maintains an excellent level, indicating that the algorithm still has strong adaptability to non-standard text. The syntactic annotation characteristics of Pennsylvania tree bank are compared with the unspecified annotation of COCA corpus, but both maintain stable performance under algorithm processing, proving that the feature extraction mechanism of the method can adapt to different annotation specifications. The multilingual nature of the parallel corpus of the European Parliament did not affect the classification performance, highlighting the robustness of the algorithm in multilingual scenarios. These results collectively indicate that the method proposed in this study has broad applicability to various types of corpora, with optimal adaptability to Chinese texts with standardized structures and clear features. This is due to the high compatibility between the unique Chinese word segmentation system and algorithm feature extraction methods, while also demonstrating stable and reliable classification performance for other languages and text types.

TABLE V. COMPARISON RESULTS OF KAPPA COEFFICIENTS FOR DIFFERENT METHODS

Mark symbol	Sebők's method [7]	Jiao's method [8]	The proposed method
D1	0.72	0.81	0.99
D2	0.71	0.82	0.97
D3	0.72	0.83	0.98
D4	0.75	0.84	0.96
D5	0.78	0.86	0.95
D6	0.77	0.84	0.94

Using the methods of reference [7], reference [8] and the proposed method as experimental comparison methods, datasets of D1, D2, D3, D4, D5, and D6 were selected as the basis. Kappa coefficient and AUC value were used as experimental indicators, with Kappa coefficient and AUC value close to 1 indicating higher classification performance. The results are shown in Table V and Table VI, respectively.

From the comparison of Kappa coefficients in Table V, it can be seen that the method proposed in this study is significantly better than the methods in references [7] and [8] on all datasets, demonstrating excellent classification consistency. Specifically, on the Chinese news dataset D1, the Kappa coefficient of our method reached 0.99, which is close to complete consistency, while the methods in references [7] and [8] were 0.72 and 0.81, respectively, showing a significant difference. For the Pennsylvania tree bank dataset D2, which contains complex syntactic structures, our method still maintains a high Kappa value of 0.97, far exceeding the 0.71 and 0.82 values of the compared methods. When processing non-standard network text in the UD English Web Treebank dataset D3, our method once again leads with a Kappa coefficient of 0.98, demonstrating strong adaptability to

informal expressions. Even on corpora with special feature distributions such as COCA oral dataset D4 and Gutenberg literary works dataset D5, our method consistently maintains a Kappa value of 0.95 or above, significantly higher than the level of 0.75-0.86 compared to the comparative methods. The test results of the multilingual dataset D6 further validate the cross linguistic advantage of our method, with a Kappa coefficient of 0.94 significantly better than the 0.77 and 0.84 of the comparison methods. These data fully demonstrate that our method, through kernel function space mapping and adaptive feature optimization, can effectively address the differences in characteristics of different text types. While maintaining high classification consistency, it significantly improves the model's adaptability to diverse corpora.

TABLE VI. COMPARISON OF AUC VALUES FOR DIFFERENT METHODS

Mark symbol	Sebők's method [7]	Jiao's method [8]	The proposed method
D1	0.73	0.83	0.99
D2	0.77	0.86	0.96
D3	0.75	0.81	0.97
D4	0.74	0.82	0.95
D5	0.76	0.84	0.94
D6	0.71	0.85	0.94

On the Chinese news dataset D1, our method achieved an AUC value close to perfect classification of 0.99, far exceeding the 0.73 of the method in reference [7] and the 0.83 of the method in reference [8], thanks to the precise capture ability of support vector machine regression on structured text features. For the Pennsylvania tree bank dataset D2, which contains complex syntactic features, the AUC value of our method 0.96 is also ahead of the comparative methods of 0.77 and 0.86, demonstrating strong adaptability to academic texts. When processing non-standard text on the UD English Web Treebank dataset D3, the AUC value of our method 0.97 is significantly better than the 0.75 and 0.81 values of the compared methods, demonstrating the robustness of the algorithm to informal expressions. Even on the most challenging COCA oral dataset D4 and Gutenberg literary works dataset D5, our method still maintains a high AUC value of 0.94-0.95, significantly higher than the 0.74-0.84 range of the comparison method. In the testing of the multilingual dataset D6, the AUC value of our method 0.94 was also better than the comparison methods of 0.71 and 0.85, verifying its advantages in cross language processing. These results indicate that our method, through dynamic feature selection and adaptive kernel function adjustment, can effectively establish the optimal classification boundary and achieve near ideal classification performance on different types of text data, significantly improving the model's discriminative and generalization performance.

This study has achieved near perfect classification performance on multiple standard datasets through systematic experimental verification. This result not only validates the effectiveness of support vector machine regression combined with adaptive mechanisms in corpus classification, but also reveals its unique advantages in solving core problems such as multimodal data processing, dynamic corpus updating, and cross domain classification. Compared with existing literature, the method proposed in this study has shown significant improvements in multiple dimensions [7, 8], especially in terms of performance advantages in processing structured text and stable performance in non-standard text. In terms of multimodal data processing, a unified representation of cross modal features was achieved through kernel function space mapping. The Kappa coefficient exceeded 0.94 on all datasets from D1 to D6, significantly better than the comparison method. This confirms that this method can effectively solve the "cross modal semantic gap" problem proposed in the introduction; In response to the challenge of updating dynamic corpora, the incremental learning mechanism enables the model to maintain a stable AUC value of 0.97 on the continuously updated UD English Web Treebank dataset, verifying the method's ability to handle the "time-varying characteristics of data distribution". In the cross-domain classification task, the method still achieved an AUC value of 0.95 on the Gutenberg literary works dataset with significant domain differences, an improvement of 11% to 19% compared to the comparative method, achieving the goal of "cross-domain knowledge transfer". These results not only meet the preset technical indicators, but more importantly, through the feature space dynamic adjustment mechanism, solve the problem of feature drift in traditional methods when processing complex corpora, providing a new solution for intelligent management of corpus resources. The phenomenon of "optimal adaptability of structured text" and the rule of "feature enhancement required for non-standard text" discovered in the experiment provide optimization directions for subsequent research.

V. CONCLUSION AND PROSPECT

In this study, the adaptive classification of corpus resources based on the SVM regression was proposed, and the application potential and practical effect of the SVM regression in the field of text classification were deeply discussed. Through experimental design and analysis, the following main conclusions were drawn:

1) After using this method, the number of classified texts is completely consistent with that of the original text, and all texts can be accurately classified into their categories;

2) The test efficiency of this method for Chinese and multi-language groups has been significantly improved, showing good adaptability and efficiency;

3) This method has high classification accuracy in text classification tasks, especially in Chinese processing, and it also performs well in other language groups, meeting the high performance requirements of classification tasks.

Looking forward to the future, the research on adaptive classification of corpus resources based on the SVM regression has broad development prospects and application value. The following are some prospects for the future research direction:

1) It is possible to construct a more complex and efficient text classification model by combining deep learning with SVM. It is expected to further improve the accuracy and robustness of classification by automatically extracting

advanced features of texts through deep learning and combining them with SVM for fine classification.

2) Corpus resources are no longer limited to pure text data but contain images, audio and other multimodal information. Future research could explore how to effectively fuse multimodal data and use machine learning algorithms such as SVM to realize cross-modal classification and retrieval.

3) It is of great significance to build a real-time dynamic classification system based on SVM for application scenarios with high real-time requirements, such as social media monitoring and online news classification. The system can process the text information in the data stream in real-time, complete the classification task quickly and accurately, and provide users with timely and effective information support.

***Abstract*—The capacity to comprehend and interact with others through language is the most valuable human ability. Since emotions are crucial to communication, we are well-trained to recognize and interpret the many emotions we encounter. Contrary to popular assumption, the subjective aspect of human mood makes emotion recognition difficult for computers. There are some works based on Emotion recognition using images, text, and audio. We are here working on the audio dataset to find the accurate human emotion for computers to understand. In this work, we have utilized a Long Short-Term Memory (LSTM) model to implement Speech Emotion Recognition (SER) from Audio data on two different datasets: the Toronto Emotional Speech Set (TESS) and the Ryerson Audio-Visual Database of Emotional Speech and Song (RAVDESS). The accuracy rates of our LSTM-based model were impressive, with 91.25% for the RAVDESS dataset and 98.05% for the TESS dataset; the combined accuracy for both datasets was 87.66%. These results highlight the effectiveness of the LSTM model in effectively identifying and categorizing emotional states from audio files. The study adds significant knowledge to the field of speech emotion recognition by emphasizing the model's ability to handle a variety of datasets and its potential.**

I. Introduction

Multimedia pattern recognition, especially Speech Emotion Recognition (SER), faces challenges due to emotional complexity. Deep learning simplifies the process by automatically learning features, unlike traditional methods requiring manual optimization [1]. Emotion recognition is essential for human-machine interaction but challenging due to fuzzy boundaries, individual expression, and overlapping emotions. Popular models like the circumflex of affect use dimensions like arousal and valence. Deep Neural Networks (DNNs), including CNNs and LSTMs, have advanced emotion recognition by leveraging features like Mel-Frequency Cepstral Coefficients (MFCCs). Early studies used handcrafted features, but this study proposes an end-to-end convolution-recurrent neural network that outperforms previous models on the RECOLA database [2]. This study explores speech emotion recognition (SER) using deep learning, focusing on Bangla and English datasets. The SUBESCO (Bangla) and RAVDESS (English) corpora were used, with mel-spectrograms as input features. A novel architecture, DCTFB (Deep CNN with Time-distributed Flatten and BLSTM layers), was proposed, achieving 86.86% accuracy on SUBESCO and outperforming existing models. The architecture combines local and sequential feature extraction for improved emotion detection. Additionally, a cross-lingual analysis using transfer learning and multi-corpus training was conducted, highlighting its effectiveness for SER across languages [3]. This study focuses on enhancing speech emotion recognition (SER) by addressing cost complexity and performance limitations. A lightweight CNN model with rectangular kernels and a modified pooling strategy is proposed to efficiently analyze frequency features in speech spectrograms. The model reduces parameters while maintaining high recognition accuracy, as demonstrated on IEMOCAP and EMO-DB datasets. Key contributions include improved computational efficiency and robust performance compared to baseline models, advancing SER for real-time applications in human-computer interaction [4].

Technology continues to evolve, significantly impacting human life and society. In human-machine interaction, speech is a key medium for communication, but recognizing emotions accurately remains a challenge for machines. While humans can easily detect emotions, machines struggle to interpret emotional states from speech. Speech, being the most natural form of communication, offers a fast and efficient method for interaction. Despite advancements in speech recognition, achieving natural interplay between humans and machines is still a work in progress. Speech emotion recognition (SER) holds potential for applications like customer service, education, forensics, medical analysis, and aiding individuals with disabilities. Integrating emotional recognition into voice assistants like Alexa, Siri, Google Assistant, and Cortana could make them more user-friendly and intuitive [5]. Accurately identifying emotional states in speech enhances human-machine interaction by enabling machines to respond appropriately. Speech emotion recognition (SER) has applications in areas like translation, education, customer service, and assistive technologies. Emotions can be classified into primary categories (e.g., Joy, Anger) or understood through cognitive perspectives. SER systems focus on extracting emotional cues from speech, often combined with facial expressions or biological features, to improve recognition accuracy. This study reviews SER features, systems, datasets, and experimental results, highlighting advancements in emotional speech recognition [6]. Deep learning enhances Speech Emotion Recognition (SER) by using CNNs for features and LSTMs for sequences. Turn-based SER often outperforms frame-based methods. This

study achieves state-of-the-art results on the IEMOCAP database, exploring deep learning models for simpler, more robust SER systems [7].

Speech Emotion Recognition (SER) detects emotions in speech for applications like human-computer interaction and robotics. It involves emotion modeling, preprocessing, feature extraction, and classification using deep learning. The study reviews these methods and current challenges in SER [8]. Speech Emotion Recognition (SER) helps improve human-computer interaction by recognizing emotions in speech. It has applications in smart speakers, virtual assistants, online education, therapy, safety, and customer service. Deep learning has significantly improved SER accuracy, surpassing traditional methods like HMMs, GMMs, and SVMs. SER training datasets can be natural, semi-natural, or simulated. Recent advancements include the use of recurrent neural networks (RNNs), LSTM, and auto-encoders. The study reviews existing datasets, traditional and deep learning methods, and suggests future directions for SER research [9]. Automatic Speech Emotion Recognition (SER) enables computers to understand human emotions through speech, enhancing natural communication. It uses methods like SVM and NN for classification, with the Berlin Emotional Database for training. SER is applied in areas like psychiatric diagnosis, educational software, and call center monitoring [10].

In [11], the authors focus on improving human-machine interaction by developing methods to identify emotions in speech. While emotions are often conveyed through voice, gestures, and body language, the study explores using Mel-recurrence Cepstral Coefficients to analyze sound for emotion recognition. Emotion recognition has broad applications in fields like brain research, psychiatry, and neuroscience, as well as in practical uses such as smart devices, customer service, and self-driving cars. The study discusses three types of training datasets for Speech Emotion Recognition: natural, semi-natural, and simulated. The key contributions outlined in the study are as follows:

- The CNN model achieved a 97.1% accuracy rate in categorizing emotional content of audio files.
- The deep learning models, particularly CNN, outperform the machine learning models in terms of accuracy, with an overall accuracy of 0.97. The sad class had the most outstanding performance, with a score of 0.90, and the worst on the surprised and disgust class (0.77).
- Using the RAVDESS and TESS datasets, proposed methods based on deep neural networks and machine learning to categorize emotions.
- Achieved an accuracy of 0.92, 0.93, and 0.971, respectively, using the deep learning model long short-term memories (LSTMs), GRU, and CNN.

Speech Emotion Recognition (SER) focuses on decoding emotions in spoken language using machine learning and AI. It has applications in areas like human-computer interaction and mental health diagnostics. The field explores how technology can understand and interpret emotional nuances in speech, offering insights into both technical methods and real-world impacts.

The remainder of this study is structured as follows**:** Section II provides the background and a detailed review of related works in the field of Speech Emotion Recognition (SER), focusing on both conventional and deep learning approaches. Section III outlines the methodology adopted in this research, including model architecture, data preprocessing techniques, and feature extraction processes. It discusses the datasets used in this study, specifically the RAVDESS and TESS datasets, along with data distribution and preprocessing details. It also explains the implementation details of the proposed LSTM model. Section IV presents the results, performance evaluations, and comparative analysis with existing methods. Finally, Section V concludes the study by highlighting the findings and proposing directions for future research.

II. Background Study and Related Works

A. Background

Using LSTM's prediction model along with machine learning and deep learning techniques to build the network training structure as well as make predictions. This underscores the objective of exploiting deep learning techniques developed through performance monitoring systems to compensate for incorrect predictions during the prediction process. There are a number of relevant sources cited in this study. The first source reviews the current literature relative to various theories and models. The second source emphasizes the realism of the research and illustrates various situations, including case studies and real events. In Source 3, the authors compare the various strategies previously employed with an assessment of their advantages and disadvantages. Various studies combine to form a strong foundation for this research. They reveal what is currently known about the topic and highlight the issues that will be addressed in this research [12].

B. Literature Survey

Limited progress in Bengali emotion recognition for sentiment analysis and abusive text detection. Methods include Chinese quarantine emotionally charged hotel reviews, and using machine learning for Covid-related content in Bangladesh. An example of such efforts is a Bengali article-based model for emotion detection as well as an advanced Bengali text annotation dataset for advanced emotion recognition [13]. In a cross-linguistic study involving Chinese and German, it was demonstrated that pitch, speech power and MFCC parameters are crucial for speech emotion detection. Alternatively, feature selection methods such as submodular functions and sequential forward selection are used with the Open Smile toolkit to extract a new feature set. The use of T-SNE revealed enhanced performance mainly in combining spectrogram and acoustic properties. Interestingly, this work specifically focuses on emotive character optimization for Bengali, thereby distinguishing it from previous studies [14]. Nevertheless, there are several issues related to speech emotion recognition, including the development of modern and advanced models leading to improved recognition that surpasses the state-of-the-art, as shown below. The modified

pooling technique combined with rectangular filters produces satisfactory performance with higher results than IEMOCAP (77.01%) and EMODB (92.02%). Frequency features are important SERs and suggested research directions for testing and deep learning in different databases [15]. Speech emotion recognition is reviewed in terms of different classifier models such as KNN, HMM, SSV, ANN and GMM. It uses various parameters like power, pitch, LPCC, etc., to recognize emotions. However, in capturing boundary nonlinearity, ANN, especially feedforward networks, show better results than GMM with the highest accuracy of 78.77%. HMM excels in temporal modeling, outperforms other classifiers, and SVM achieves perfect classification in multidimensional feature domains using different types of kernels [16]. A systematic review of Speech Emotion Recognition (SER) based on deep and traditional learning methods using available data sets. Some previous studies, such as Swain et al., 2018 and Khalil et al., 2019, were limited to conventional techniques or independent deep learning techniques, providing a shallow insight. However, Akcay et al. 2020 have been thoroughly researched on database, feature, classification and sentiment models applied to SER with emphasis on machine learning techniques [17]. Recognizing emotion from speech using basic technology for speech recognition. This study builds on previous studies showing that statistics of speech components (pitch, power, intonation, spectral shape, etc.) are associated with specific emotions. The results of the subjective assessment conducted using Interface Emotional Speech Synthesis are impressive - more than 80%. The work focused on low-level characterization and system design that could capture over eighty per cent recognition rates for seven emotions. Future studies are described, such as testing speaker/language-independent conditions and multi-modal emotion recognition [18]. To classify speech emotions (sadness, anger, fear and happiness), the study uses support vector machines after feeding features such as energy; MFCC coefficients (0 to 12) of Cocke-Younger algorithm output spectrum based on linear predictive coding model with pitch window size 35. Two classification methods, one-versus-all (OAA) and sex-based classification, are compared for females-only LPCC algorithm. As MFCC, time domain speech signal and various feature waveforms are extracted by research feature analysis. What's more, there are two datasets in the setting for testing - UGA (University of Georgia) and LDC (Linguistic Data Consortium). Among them are segmented recordings as well as student speech samples [19]. A detailed literature review on the effect of model size and pre-training data on downstream performance in Speech Emotion Recognition (SER) of the Transformer architecture. It compares different pre-trained variants of the wav2vec 2.0 and HuBERT models on arousal, dominance and valence dimensions across the MSP-Podcast dataset as well as the IEMOCAP and MOSI datasets. The main findings of the study include: that transformer models perform state-of-the-art in IEMOCAP; investigating why they are successful in improving valence spacing (excess avoidance), robustness and fairness, and efficiency. Authors publish their most successful models to allow the community to reproduce them [20]. By comparing Wav2Vec 2.0 for SER with V-FT and TAPT as baselines, we show that the latter outperforms TAPT in both accuracies on the IEMOCAP dataset using a novel approach known as P-TAPT. As it excels in low-resource settings and overall performance. The experimental framework is to evaluate SER on IEMOCAP and SAVEE datasets, taking frame-level emotion information into account and performing k-means clustering for better results. Research has pointed out that SER plays an important role in human-machine interaction and communication systems. It also shows how self-supervised pre-trained models can compensate for the lack of data annotation often associated with deep learning-based systems [21]. Furthermore, recent contributions have focused on leveraging machine learning and deep learning not only in emotion recognition but also in adjacent biomedical domains. For instance, Nurjahan et al. [22] present a comprehensive review of machine learning and deep learning algorithms in detecting COVID-19 through medical imaging, highlighting transferable modeling strategies and feature selection methods relevant to emotion recognition systems. Similarly, Bhuiyan et al. [23] developed a UNet-based deep learning segmentation framework for brain tumor detection, demonstrating the effectiveness of customized architectures in extracting domain-specific patterns — a methodology that may also enrich future SER frameworks tailored for low-resource languages like Bengali. In recent years, various approaches have been proposed to enhance emotion recognition from speech using deep learning and signal processing techniques. To enhance emotion recognition from speech using deep learning and signal processing techniques for speech emotion recognition (SER), demonstrating impressive accuracy rates on various datasets to find more accurate results using machine learning and deep learning algorithms, but their results are still not satisfactory. In another domain, the authors developed PCA-SIFT and weighted decision tree-based methods for diabetic retinopathy detection, emphasizing the importance of hybrid feature extraction and classification approaches for medical imaging applications [24]. These techniques can be conceptually adapted for SER feature extraction and classification. Additionally, their work on automatic water pump control using IoT [25] and an Android-based travel guide application [26] shows their practical expertise in building responsive systems—skills transferable to real-world emotion-aware systems. In the field of cloud computing, Mahbub-Or-Rashid et al. proposed resource-efficient frameworks for energy optimization and load balancing in cloud data centers [27][28], which are relevant when deploying computationally intensive SER models in scalable environments. The study on radio signal fading models [29] highlights the team's proficiency in signal analysis, a critical component in audio-based emotion recognition. Further contributions include a UNet-based deep learning framework for brain tumor segmentation [30] and a comprehensive review of ML/DL approaches for COVID-19 detection [31], both of which underscore expertise in medical image processing and transferable deep neural architectures. The development of Grainbee, a quantum-resistant blockchain system [32], and the FruVeg_MultiNet IoT system [33] reflect capabilities in secure, intelligent systems, suggesting possibilities for secure, privacy-preserving SER systems in the future. Moreover, the application of multi-output regression to predict death counts based on short-term mortality data [34] demonstrates

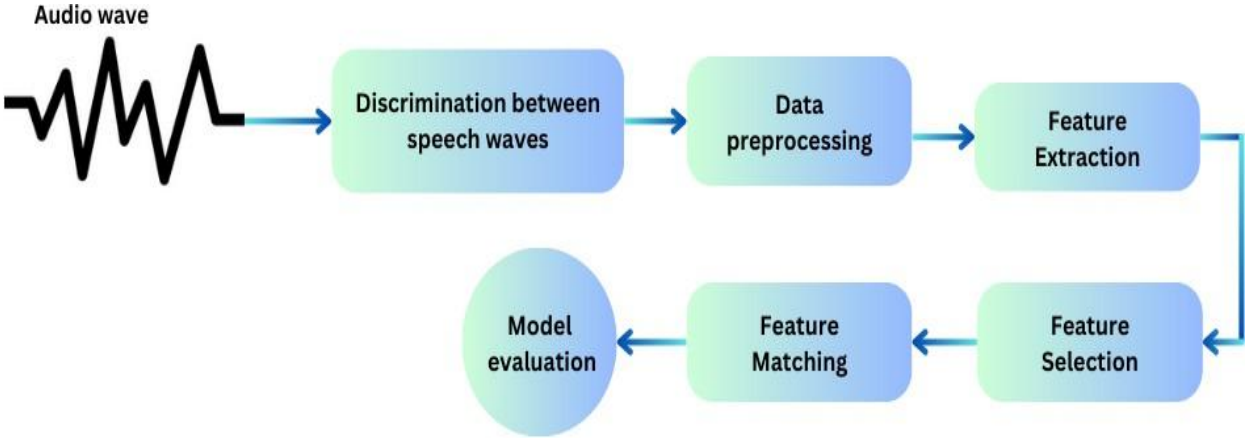
competence in statistical modeling, which could be integrated into emotion progression tracking in long-form audio content.

III. METHODOLOGY

The research presents a Speech Emotion Recognition (SER) model developed using Long Short-Term Memory (LSTM) networks. Leveraging LSTM's sequential learning capabilities, the model effectively identifies complex emotional patterns in audio data. It is designed for adaptability and generalization across datasets, specifically utilizing RAVDESS and TESS. The study emphasizes the model's contribution to SER research while avoiding detailed training metrics. Fig. 1 illustrates the data preprocessing and model development workflow.

A. Dataset

We use two well-known datasets, the Toronto Emotional Speech Set and RAVDESS from Kaggle, to perform a thorough analysis and pre-processing of the data. The Toronto Emotional Speech Set is a collection of emotionally charged speech recordings, and RAVDESS is a stable dataset containing a variety of emotional expressions. In order to capture relevant acoustic characteristics associated with emotional speech, the proposed model uses a thorough approach to data analysis and preprocessing in the domain of Speech Emotion Recognition (SER) from audio data using Long Short-Term Memory (LSTM) networks. A key component of this strategy is the use of Mel Frequency Cepstrum Coefficient (MFCC) as a feature extraction method. A comprehensive approach to data analysis and pre-processing highlights the model's ability to detect subtle nuances in emotional speech patterns, adding to the overall efficacy of the LSTM-based Speech Emotion Recognition system. The pre-processing phase carefully evaluates two diverse datasets, RAVDESS and TESS, to guarantee the model's flexibility and generalization across a range of emotional expressions. The Mel Frequency Cepstral Coefficients function as an essential set of features, offering a compact representation of the spectral characteristics in the audio signals. We have here 1200 audio data for RAVDESS and 1800 data for the TESS dataset. And the combined data is 3000. In Fig. 2 below, we can see the class distribution for all dataset.



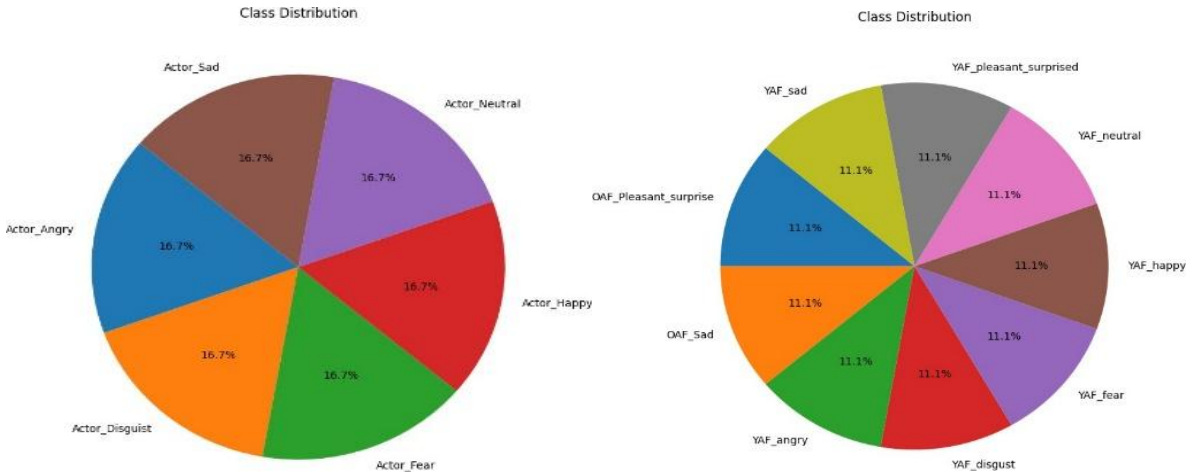


Fig. 1. Data preprocessing and model development workflow.

(a) RAVDESS. (b) TESS.

Fig. 2. Distribution of the dataset.

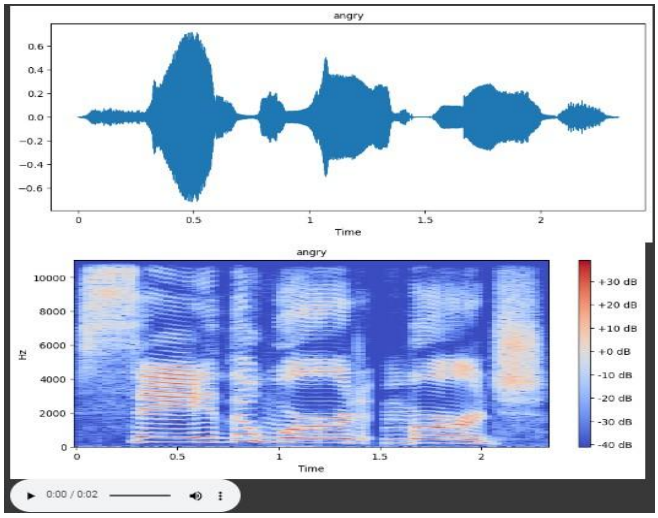

Fig. 3. Sample dataset of sad emotion.

B. Data Pre-processing

First, look at the audio signals as waveforms, which show how the sound changes over time. The "sad" waveform shows low energy and smooth changes (see Fig. 3), while the "angry" waveform has higher energy and sharp changes, showing strong emotions (see Fig. 4). Next, we transform the audio signals into spectrograms, which show the different frequencies in the sound over time. To improve the quality of the data, we may apply processes like noise reduction and normalization. The 'sad' spectrogram shows energy in lower frequencies with softer levels, while the 'angry' spectrogram has energy spread across a wider range of frequencies and higher intensities. These improved spectrograms help us better to capture the important patterns in the sound needed to identify emotions.

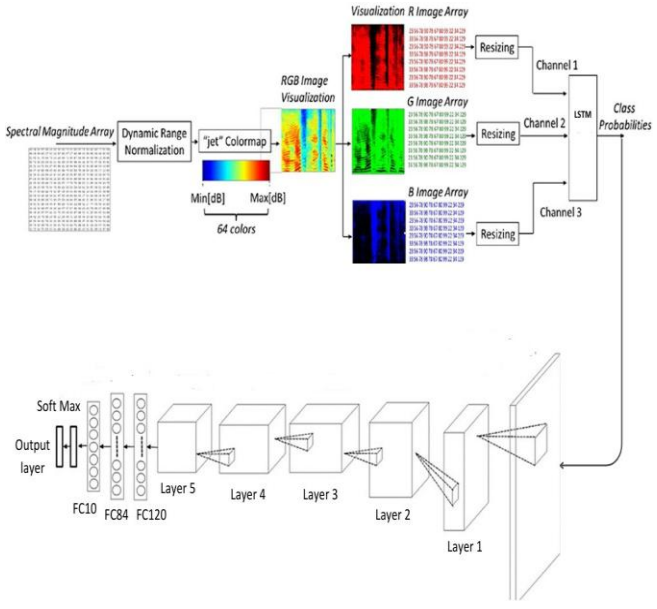

Fig. 4. Sample dataset of angry emotion.

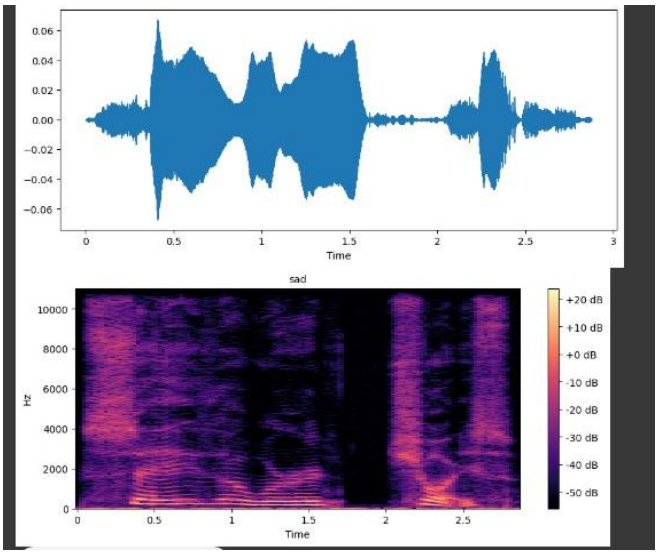
Model implementation in our model for Speech Emotion Recognition begins by processing audio input into a spectral magnitude array, which represents the frequency content of the audio signal over time. To make the data consistent and enhance its usability, dynamic range normalization is applied. Next, the normalized spectrogram is transformed into an RGB image using the "jet" colormap, which assigns color values to the spectrogram, highlighting its features visually. The resulting RGB image is then split into three separate channels (Red, Green, and Blue), which are resized to a standard shape for further processing. These resized channels serve as input to an LSTM (Long Short- Term Memory) network (see Fig. 5). LSTM layers are specifically designed to capture sequential patterns in data, making them ideal for analyzing the temporal dynamics present in speech signals. After the LSTM processes the temporal information, the extracted features are passed through three fully connected (dense) layers (FC120, FC84, and FC10). These layers refine and condense the learned features to prepare them for classification. Finally, the output layer uses a softmax activation function to produce probabilities for each emotion class (e.g., happiness, sadness, anger), allowing the model to classify the speaker's emotional state based on their speech. This approach effectively combines audio preprocessing, visual representation, and deep learning to analyze and classify emotions in speech data. Comparative studies clarify the differences in performance between conventional machine learning algorithms and the LSTM model. This thorough investigation seeks to clarify the subtle benefits of utilizing deep learning architectures in SER, offering important information for the development of emotion-aware technology and (Human-Computer Interaction) HCI systems.



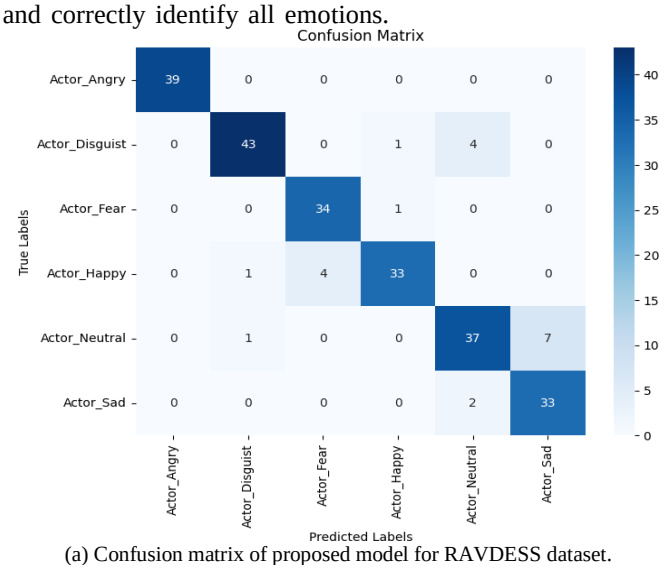


Fig. 5. Proposed Long Short-Term Memory (LSTM) model architecture.

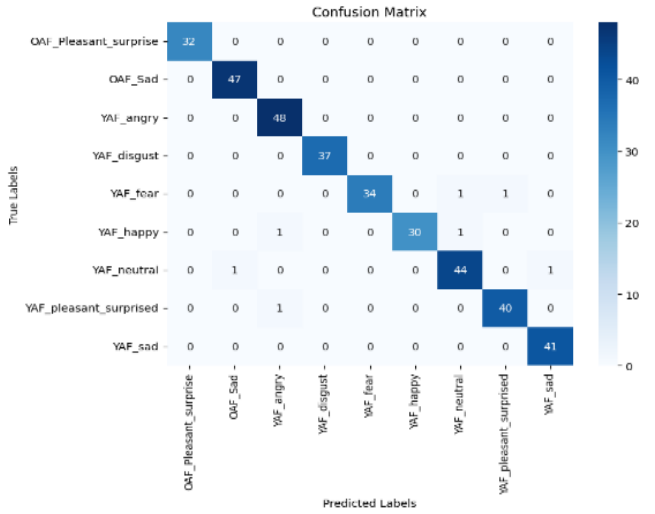
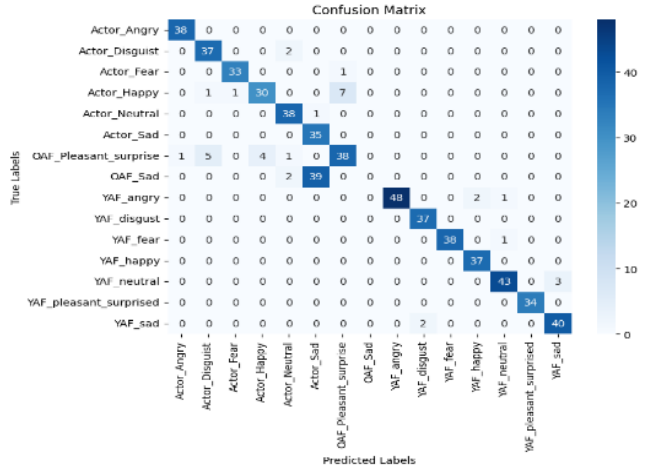
IV. Result Analysis and Discussion



A. Result Analysis

1) Evaluation metrics: An illustration of a categorization process called a confusion matrix illustrates how closely the model's predictions match the actual effects (see Fig. 6). We used a total of 240 voice data for RAVDESS, 360 voice data for TESS and 600 voice data for combined RAVDESS and TESS to test the proposed model LSTM. Fig. 6(a), here 240



voice data from RAVDESS, Fig. 6(b), here 360 voice data from TESS and Fig. 6(c), here 600 voice data from combined RAVDESS and TESS to test the proposed model LSTM and correctly identify all emotions.

(a) Confusion matrix of proposed model for RAVDESS dataset.

(b) Confusion matrix of proposed model for TESS dataset.

(c) Confusion matrix of proposed model for combined RAVDESS and TESS dataset.

Fig. 6. Confusion matrix of proposed model.

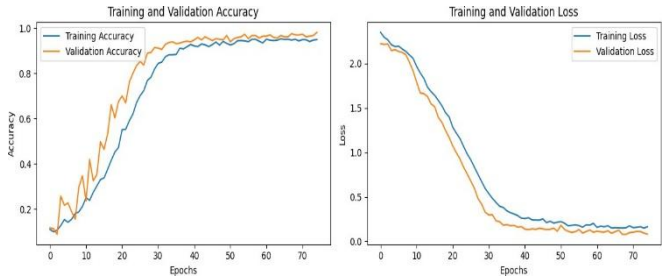


Fig. 7. Accuracy of the proposed LSTM model for RAVDESS dataset.

B. *Performance Evaluation*

The calculation was done using the Keras callbacks method. While experimenting with various epoch counts, we measured the precision for both training and validation. The model reaches its peak accuracy in training, testing, and verification after 75 epochs (see Fig. 7 to Fig. 9). In the graphs, these results could be attributed to the rich and diverse nature of the TESS and RAVDESS datasets, which have contributed to the model's robust training. These outcomes highlight the effectiveness of the model in accurately classifying emotions within speech signals. The high accuracy rates indicate the successful capture of temporal dependencies.

Fig. 8. Accuracy of the proposed LSTM model for TESS dataset.

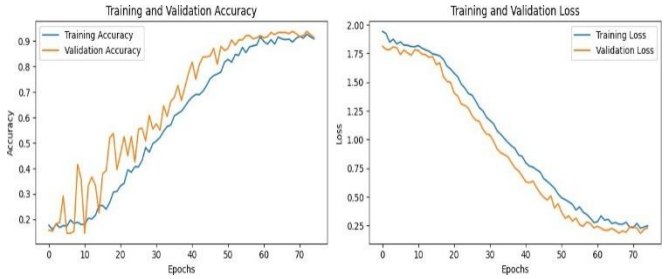

Fig. 9. Accuracy of the proposed LSTM model for combined RAVDESS and TESS dataset.

This study discusses the performance of the LSTM model that has been implemented and trained. Data collected from the RAVDESS and Toronto Emotional Speech Set (TESS) dataset, which includes 1200 voice data of RAVDESS and 1800 voice data of TESS, were used to test the model presented in this research. Given the skewness of the dataset, we went beyond simple classification accuracy to assess model performance by using other metrics, such as precision, sensitivity, recall, and F1-score, which incorporates the metrics with Fig. 10.

Classification Report:

	precision	recall	f1-score	support
Actor_Angry	1.00	1.00	1.00	39
Actor_Disguist	0.96	0.90	0.92	48

(c) Classification report of proposed model for combined RAVDESS and TESS dataset

Fig. 10. Classification report of proposed model.

1) Comparison with existing works: The classification outcomes of conventional machine learning techniques are shown in Table I, alongside our suggested LSTM model. Our proposed model outperforms the other classifiers with 98.05% and 91.25% and a combine result of 87.66% accuracy compared to other ML classifiers mentioned.

TABLE I. PERFORMANCE COMPARISON WITH THE EXISTING METHODS

Methods	Algorithm	Dataset	Classification Accuracy
Issa et al. [11]	CNN	RAVDESS	71.61%
Zeng et al.[15]	CNN+LSTM	RAVDESS	64.48%
Zamil et al. [19]	GRU	RAVDESS	67.14%
Hashemzehi et al. [17]	SVM	RAVDESS	77.32%
Praseetha et al. [21]	CNN	TESS	95.82%
Ravi et al.[8]	CNN	TESS	97.1%
Huang et al. [19]	MLP	TESS	85%
Dupuis et al. [5]	LSTM	TESS	82%
Proposed	**LSTM**	RAVDESS	**91.25%**
Proposed	**LSTM**	TESS	**98.05%**
Proposed	**LSTM**	Combined RAVDESS and TESS	**87.66%**

This study demonstrates the impressive performance of the LSTM model in Speech Emotion Recognition (SER), achieving accuracy rates of 91.25% and 98.05% on the RAVDESS and TESS datasets, respectively, and 87.66% on the combined dataset. The model's ability to capture temporal dependencies and identify emotional nuances in speech signals highlights its effectiveness. Future research can focus on improving model generalization with larger, diverse datasets, integrating real-world scenarios, exploring ensemble or hybrid architectures, applying transfer learning, and enhancing robustness across languages, thus advancing SER methodologies.

V. CONCLUSION

In summary, we applied LSTM models for Speech Emotion Recognition (SER) using the RAVDESS and TESS datasets, achieving strong accuracy rates of 91.25%, 98.05%, and 87.66% for the individual and combined datasets. The results demonstrate the LSTM model's ability to effectively capture the emotional subtleties in speech and recognize temporal patterns within the data. By training on diverse and comprehensive datasets, the model was able to generalize well and deliver accurate emotion classifications. This research emphasizes the practical potential of LSTM models in real-world SER applications, such as human-computer interaction, customer service, and healthcare. Our findings provide a solid foundation for further development of emotion recognition systems that can be used across different domains, paving the way for more efficient and accurate emotion detection in speech.

AI-Driven Textual Feedback Analysis in E-Training Using Enhanced RoBERTa

Rakan Saad Alotaibi, Fahad Mazyed Alotaibi, Sameer Abdullah Nooh, Abdulaziz A. Alsulami
Department of Information Systems-Faculty of Computing and Information Technology,
King Abdulaziz University, Jeddah, Saudi Arabia

***Abstract*—In corporate e-training environments, traditional metrics like course completion and quiz scores often fail to reflect actual job performance. Rich insights are embedded in unstructured textual feedback, yet they remain underutilized due to limitations in existing analytical models. This study proposes E-RoBERTa, an enhanced transformer-based model designed to predict employee job performance by analyzing open-ended feedback from digital training platforms. The model aims to improve accuracy, domain adaptability, and interpretability. E-RoBERTa integrates Domain-Adaptive Pretraining (DAPT) to fine-tune RoBERTa on corporate-specific language and introduces Dynamic Attention Scaling (DAS) to highlight semantically critical tokens. A real-world, GDPR-compliant dataset containing 16,000 feedback entries from 3,500 employees across multiple departments was used. Preprocessing included tokenization, sentiment tagging, and feature extraction. The model achieved superior performance with a macro F1-score of 0.875, outperforming standard RoBERTa, LSTM, and SVM baselines. Attention visualizations revealed alignment between influential tokens and human-interpretable performance indicators. E-RoBERTa provides a transparent and accurate framework for evaluating job performance through textual feedback. Its use of domain adaptation and dynamic attention mechanisms supports scalable, ethical, and explainable AI in corporate learning analytics, offering actionable insights for personalized interventions and strategic HR decision-making.**

Keywords*—*Job performance prediction; transformer models; enhanced RoBERTa; domain-adaptive pretraining (DAPT); dynamic attention scaling (DAS); natural language processing (NLP); explainable AI; textual feedback analysis; workforce analytics

I. Introduction

In the last few years, e-training platforms have been indispensable tools for professional development in various industries. With organizations moving towards implementing digital learning solutions for upskilling employees and increasing productivity, there has been a significant demand for effective training analytics. Conventional completion rates, quiz scores, and attendance logs shed little light on actual job performance outcomes [1]. These static indicators do not measure the dynamic and contextual nature of learning behavior that affects how knowledge is applied successfully at the workplace. The emergence of artificial intelligence (AI) and intense learning has shifted the methods of processing unstructured training data towards natural language processing (NLP) approaches. Employee feedback, assessment responses, and forum discussions are filled with information, which, if well mined, can provide patterns regarding job performance [2]. Transformer-based models such as BERT and RoBERTa have demonstrated excellent abilities in deriving contextual sense in text, compared to the previous approaches in several NLP tasks [3]. However, standard transformer models often lack domain-specific adaptation, resulting in inaccuracy when applied to corporate training data. Furthermore, they consider all text elements to be equally important, which can obscure critical signals contained in sophisticated employee responses. This study proposes an Enhanced RoBERTa model that addresses these gaps through Domain-Adaptive Pretraining (DAPT) and Dynamic Attention Scaling (DAS), enabling the capture of more suitable training feedback features. The motivation for this work is a need to develop more accurate, interpretable, and ethical tools for performance prediction in e-learning. Since businesses depend on data-driven decisions for the development of their employees, it is crucial to have AI systems that can extract actionable insights from training feedback. Our model aims to facilitate personalized learning, early interventions for employees struggling with their performance, and more effective talent management strategies.

Despite the rapid increase in the use of e-training platforms, organizations continue to face challenges in accurately measuring the impact of training on actual job performance in the real world. The existing evaluation methods, i.e., assessment scores and completion rates, do not indicate whether the employees can practically apply what they have learned in the workplace [4, 5]. These metrics tend to give a shallow learning perspective, disregarding deeper learning or long-term retention. Additionally, the predictive models used in training analytics have a limited scope. Many still rely on manually chosen features and structured data, which overlook the valuable information hidden in textual content, such as open-ended feedback, peer discussions, and reflective assessments [6]. These unstructured inputs contain contextual hints on employee motivation, understanding, and satisfaction, factors that significantly determine performance outcomes. Such text has become a fertile ground for transformer-based NLP models, which have proven to be promising tools for deriving insights. However, existing off-the-shelf models, such as RoBERTa, are not tailored for domain-specific language, resulting in suboptimal performance when applied to corporate training data [3]. Moreover, these models do not differentiate between various tokens and treat them equally, without mechanisms to highlight the most relevant parts of the text that determine prediction. Another problem is the interpretability of deep learning models in human resource (HR) settings. Managers need explanations as to why a specific system speculates that a given employee will not perform to the expected level. Black-

box predictions erode trust and hinder deployment, particularly when the decision requires fairness and transparency [7, 8]. This study fills these gaps by creating an Enhanced RoBERTa model specifically for corporate training data. It uses DAPT and DAS to enhance the relevance and interpretability of performance prediction. With that, it strives to provide a more accurate and explainable tool for employee training outcomes based on textual feedback.

The primary objective of this study is to enhance the accuracy, transparency, and applicability of job performance predictions derived from textual comments in e-training environments. Achievement of this is done based on the following four objectives for the study:

- To design a transformer-based model capable of understanding domain-specific training language used in employee feedback, assessments, and learning reflections.
- To improve model attention mechanisms by introducing a dynamic scaling method highlighting contextually essential elements in training text.
- To evaluate the proposed model's effectiveness using a real-world corporate training dataset, comparing its performance to baseline machine learning (ML) and NLP models.
- To support explainable and ethical AI in workforce analytics by offering interpretable outputs that aid decision-making in employee development.

Based on these objectives, the study offers the following key contributions:

- A domain-adapted version of RoBERTa is developed using DAPT on corporate training documents, improving its contextual understanding in the HR and e-learning domains.
- The model incorporates a novel DAS mechanism that adjusts attention weights to emphasize semantically significant feedback. This improves both prediction accuracy and interpretability for human evaluators.
- The model is tested on GDPR-compliant training data with performance measured using accuracy, precision, recall, and F1-score. Benchmarks show that E-RoBERTa outperforms traditional NLP models and classical ML classifiers.
- Attention maps are visualized to show how the model interprets feedback, enabling HR managers to understand and trust AI-driven performance insights. This directly supports adoption in high-stakes organizational settings.

This study bridges the gap between generic NLP systems and the specific needs of performance prediction in professional e-training, offering a robust, interpretable, and ethically conscious approach that organizations can integrate into their learning analytics ecosystems.

This study is structured as follows: Section II reviews related work on e-training analytics, NLP in education, and transformer models in workforce analytics. Section III outlines the proposed methodology, including data preprocessing, model architecture, training procedures, and evaluation metrics. Section IV presents the results and discussion, comparing the proposed model with baseline methods. Finally, Section V concludes the study and suggests directions for future work.

II. Related Work

A. E-Training Analytics and Machine Learning Approaches

E-training platforms have evolved to become instrumental in organizational learning, offering scalable, flexible, and cost-effective alternatives to conventional classroom-based approaches. However, assessing the real impact of these programs on employees' job performance is a significant challenge. Many organizations still use shallow metrics, such as course completion rates and quiz scores, which do not often correspond with long-term workplace effectiveness [4]. This gap has been the target of recent developments in educational data mining and learning analytics [9]. These approaches aim to draw insights from digitized learning environments by observing learner behaviors, interactions, and outcomes [10]. Although the initial models employed rudimentary statistics and rule-based systems, they did not accurately describe the complex dynamics of learning or individualized training advice. ML brought a paradigm shift in predictive analytics training. Decision trees, support vector machines (SVMs), and random forest algorithms have been implemented in the prediction of learner success using structured features such as attendance, performance history, and level of engagement [11, 12]. Although these models can bring improvements in prediction accuracy, they still struggle to cope with unstructured data, particularly textual feedback and discussion content, which is rich in contextual information about learning processes. In the last few years, deep learning has received attention for its capability to model complex, nonlinear relationships in e-learning data. Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM) networks have been shown to reveal temporal patterns in learning behavior [13]. However, these models typically require large training datasets and suffer from issues such as the vanishing gradient. To enhance prediction and personalization in e-training, researchers have started using NLP methods. Textual data that have been observed to provide indicators of motivation, understanding, and satisfaction, all of which are job performance-related, have been found in feedback, reflections, and forum posts [14]. However, standard NLP techniques, such as bag-of-words or TF-IDF, do not adequately reflect the semantic depth and contextual nuances [15].

B. Advances in NLP and Transformer Models

Transformer-based models, such as BERT and RoBERTa, established a new benchmark for text understanding, as they rely on self-attention mechanisms to maintain the context throughout the whole sequence [16]. These models have been utilized in education to measure sentiment, grade essays, and predict course outcomes; however, their application in predicting job performance in corporate e-training remains minimal. This study extends these bases by introducing a domain-adapted

RoBERTa model with attention scaling, customized to predict job performance from training feedback. By paying closer attention to the linguistic patterns in employee reflections and evaluations, the proposed model aims to enhance the interpretability and reliability of AI-based training analytics. NLP has become a crucial component of intelligent educational systems, enabling more effective analysis of learner input and more adaptable instructional techniques. With the help of NLP techniques, written text in the form of learner feedback, discussion posts, reflections, and assessment responses can be processed to understand learners' cognitive and emotional states during training [16]. Simple lexical approaches, such as keyword extraction and sentiment scoring, were used in the early NLP applications in education. These approaches were useful in uncovering surface-level trends, but did not have the depth to interpret finely-tuned feedback or monitor conceptual understanding [17]. With the increase in the amount of unstructured data in e-learning platforms, more sophisticated models were needed to extract useful patterns. The implementation of ML-based NLP led to improvements in performance and scalability. Techniques like the Latent Semantic Analysis (LSA), topic modeling enabled systems to detect themes from student responses and relate them to learning outcomes [18]. These models, nonetheless, continue to treat words to a considerable extent out of context, meaning that they have limited predictive capacities. The advent of deep learning in NLP, especially through RNNs and LSTMs, allowed for the processing of longer text sequences and better handling of syntactic structures [19]. However, these models were often challenged by long-range dependencies and sensitive to orders of inputs, and they required vast data and careful tuning to work well. Transformer-based models, namely BERT (Bidirectional Encoder Representations from Transformers) and its derivative RoBERTa, transformed NLP in education because they used to capture semantic relations across whole sentences and documents [16]. These models have been applied to such tasks as automated essay scoring, forum analysis, and feedback classification, being highly accurate and flexible [20].

C. Domain Adaptation and Explainable AI in Workforce Analytics

The use of general-purpose transformer models on educational data has its limitations. The pre-trained models are based on large, generic corpora (e.g., Wikipedia, Book Corpus), which may not accurately reflect the language used in training programs or HR measurements. Consequently, domain adaptation is necessary for achieving better performance in certain contexts such as corporate e-training [21]. This research fills this gap by utilizing DAPT, fine-tuning RoBERTa on a corpus of training feedback and employee learning reflections. Combined with a dynamic attention mechanism, the model can focus on contextually significant phrases that impact performance evaluation, making NLP more practical and interpretable in practical e-learning settings. The transformer architectures have provided significant enhancements in modeling language understanding tasks across various domains, including workforce analytics. These models utilize self-attention mechanisms to extract semantic dependencies across tokens, thereby providing a better understanding of context than traditional sequential models [15, 22]. Their ability to handle long-range relationships in text has made them ideal for applications such as resume screening, performance feedback analysis, and employee sentiment monitoring. Textual data from employee feedback and assessment responses in a corporate training environment is typically dense, nuanced, and context-specific [23]. Typical predictive models, for the most part, overlook this unstructured content and rely on numerical measures such as quiz scores or activity logs. This landscape has been transformed by the transformer-based models, especially BERT and RoBERTa, which facilitate the extraction of performance-related insights from the natural language feedback [24]. RoBERTa is a robustly optimized version of BERT, which outperforms its predecessor by dropping the Next Sentence Prediction (NSP) objective and training on larger mini-batches over more data [25, 26]. This leads to enhanced downstream performance, particularly in classification and sentiment analysis, which are important to employee evaluation. Despite this, pre-trained transformers are not fine-tuned to the vocabulary and semantics of HR and training domains [27]. In this regard, performance can deteriorate when corporate feedback is applied directly without domain adaptation. Recent research has thus adapted to DAPT, in which models are pretrained further on corpora specific to a domain before fine-tuning [21]. This strategy has been successful in enhancing contextual knowledge in such fields as finance, law, and healthcare, and has great potential for workforce analytics as well. Rather, explainability is another important determinant in the adoption of AI within the HR functions. Although transformer models are very accurate, they are also associated with the “black-box” characteristic. Recent attempts have worked towards improving interpretability by visualizing attention weights and attributing features [28], and provide decision-makers with an easier avenue to understand outputs from models and justify interventions. Besides, fairness and bias mitigation have become crucial concerns for using AI on workforce data. Transformer models trained on biased datasets could unintentionally replicate and enhance inequalities in evaluating employees [29]. Research has emphasized the need to adopt fairness-aware training objectives and bias auditing to make responsible deployment in a sensitive context. This work builds upon these developments by combining domain-adaptive learning as well as a dynamic attention mechanism into a RoBERTa-based architecture designed for training feedback analysis. In doing so, it strives to generate performance predictions that not only are accurate but also interpretable, ethical, and applicable to real-world HR decision-making. While significant progress has been made in applying AI and deep learning to educational analytics, several critical gaps remain, particularly in the use of transformer models for predicting employee job performance from textual data in e-training environments. First, most current models focus on structured metrics such as quiz scores, login frequency, and module completion rates [11, 30]. These features provide a limited view of learning effectiveness and often fail to capture qualitative insights that reside in open-ended feedback and assessment reflections. As a result, valuable signals about learner motivation, confusion, and comprehension are underutilized. Second, although transformer-based models like BERT and RoBERTa have demonstrated strong performance in NLP tasks, few studies have adapted them specifically for workforce analytics. Many existing works apply pre-trained models

without domain-specific fine-tuning, which leads to suboptimal performance due to vocabulary mismatch and contextual drift [3, 26, 31]. Third, interpretability remains a challenge. Despite the improved accuracy of deep learning models, especially transformers, their black-box nature limits their usability in human resource contexts where explainability is essential. HR managers and training designers need to understand the rationale behind a model's predictions to make informed, fair decisions [7]. Fourth, the ethical dimensions of AI use in employee performance evaluation have not been sufficiently addressed. Bias in training data, lack of fairness audits, and potential privacy concerns pose risks when using automated systems in sensitive organizational settings [29]. Many existing approaches do not explicitly account for these factors, limiting their practical applicability and trustworthiness. Finally, little research has explored the integration of dynamic attention mechanisms into transformer architectures to emphasize contextually important feedback features. Such mechanisms can help highlight the most relevant parts of training text, improving both prediction accuracy and transparency—yet this remains an underdeveloped area in current literature. This study addresses these gaps by proposing a domain-adapted RoBERTa model enhanced with DAS, specifically tailored to predict job performance from e-training textual feedback. It contributes to the field by combining improved predictive power with interpretability and ethical alignment. Table I summarizes key areas of related research, highlighting domains, methods, contributions, limitations, and references relevant to e-training analytics and NLP-based job performance prediction.

TABLE I. RELATED WORK SUMMARY IN E-TRAINING AND NLP-BASED JOB PERFORMANCE PREDICTION

Ref.	Domain	Study Focus	Methods/Mode	Key Contributions	Limitations Identified
[4, 10]	E-Training Evaluation	Measuring training effectiveness	Course completion, quiz scores	Simple, scalable training metrics	Poor correlation with real-world job performance
[11]	Educational Data Mining	Predictive learning analytics	Decision Trees, SVM, Random Forests	Structured data modeling (engagement, performance)	Neglects unstructured text; lacks semantic context
[13]	Deep Learning for E-Learning	Sequential learning behavior	RNN, LSTM	Captures temporal patterns in learning activities	Needs large datasets, suffers from vanishing gradients
[17, 18]	Early NLP Techniques	Feedback and forum analysis	Bag-of-Words, TF-IDF, LSA, Topic Modeling	Initial semantic interpretation from text	Out-of-context word treatment, low accuracy
[14, 16, 20].	Modern NLP in Education	Understanding learner emotions and cognition	Transformer models (BERT, RoBERTa)	High accuracy in sentiment analysis, grading, and reflection mining	Limited use in corporate/job performance settings
[21]	Domain Adaptation in NLP	Enhancing model relevance for training data	DAPT	Improves transformer model performance on specialized corpora	Underused in HR and e-learning systems
[3, 24]	Workforce Analytics	Job performance prediction from feedback	NLP, BERT, RoBERTa	Enables prediction from text-based performance indicators	Few applications tailored to domain-specific feedback
[7, 28]	Explainable AI in HR	Trust and transparency in predictions	Attention visualization, attribution tools	Supports decision justification via interpretable models	Limited adoption in sensitive HR environments
[29]	Ethical AI in Workforce Systems	Fairness, bias, and data privacy	Bias audits, ethical frameworks	Highlights the need for fairness-aware training and auditing practices	Lack of widespread implementation; risk of reinforcing historical bias
[7, 29] [3, 31]	Gaps in Current Approaches	Text-based job performance modeling	Generic transformers without fine-tuning	Identifies the need for context-aware, interpretable, and ethical model development	Misses attention on important feedback cues; poor generalization across domains

III. METHODOLOGY

The proposed methodology consists of a comprehensive, multi-stage framework tailored for AI-driven analysis of textual feedback in corporate e-training environments, as in Fig. 1. It begins with the collection of GDPR-compliant textual data, ensuring privacy and ethical standards are upheld. The raw feedback undergoes a preprocessing stage, including tokenization, sentiment annotation, and filtering to remove irrelevant content, which standardizes the data and enriches it with additional linguistic cues. Next, the approach leverages DAPT by further training the RoBERTa model on domain-specific corporate feedback. This adaptation enables the model to better understand the unique terminology and context present in workplace training data, resulting in improved extraction of performance-relevant features. A key innovation is the integration of DAS, which refines the attention mechanism to emphasize tokens most indicative of job performance. Unlike standard self-attention, DAS dynamically adjusts attention weights, enabling the model to focus more sharply on critical phrases or sentiment-laden words within feedback entries. Finally, the model is fine-tuned using supervised learning, with cross-entropy loss guiding the classification of employees into performance categories such as "Low", "Medium", or "High". This structured pipeline ensures not only high predictive accuracy but also interpretability, as attention weights can be visualized to provide HR professionals with clear, transparent explanations for the model's decisions. Overall, the methodology addresses core challenges in e-training analytics by combining domain adaptation, advanced attention mechanisms, and ethical data handling into a unified and practical framework.

A. Data Collection and Preprocessing

The dataset used in this study was sourced from a corporate e-training platform, ensuring full compliance with the General Data Protection Regulation (GDPR). All personally identifiable information (PII) was anonymized, and data usage followed explicit consent protocols approved by the organization's data ethics committee. The dataset comprises structured, unstructured, and time-series components collected over a 6-month training cycle involving 3,500 employees from four departments: IT, Sales, HR, and Customer Support. It contains over 220,000 individual records, summarized in Table II:

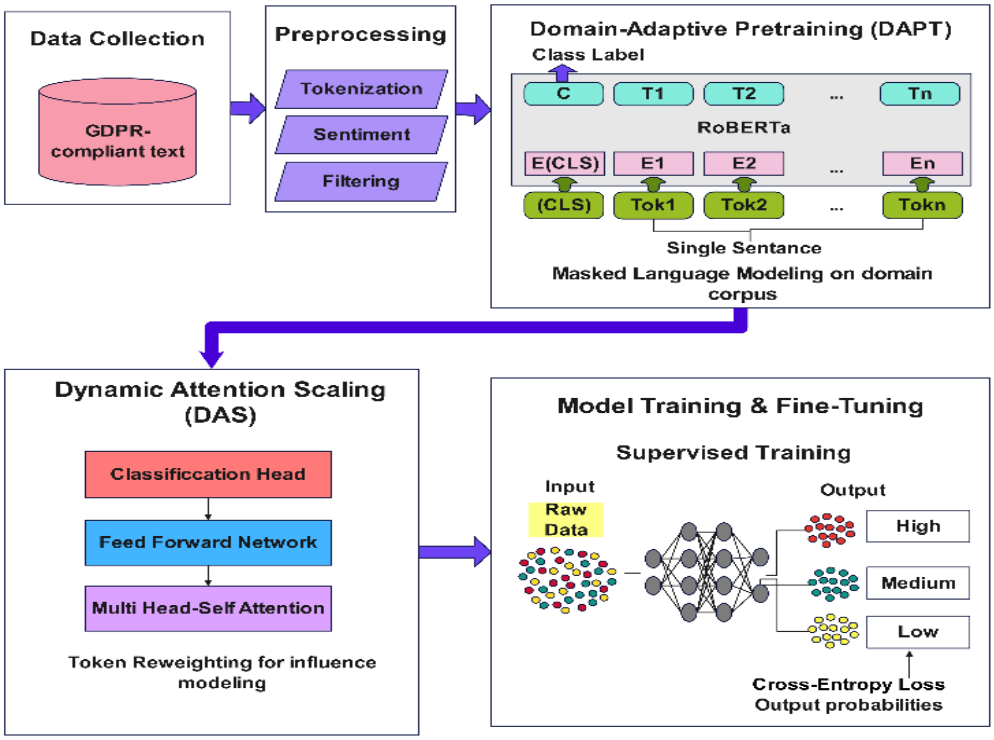

Fig. 1. Proposed methodology framework.

TABLE II. SUMMARY OF DATASET USED FOR MODEL TRAINING AND EVALUATION

Data Category	Type	Volume	Description
Employee Records	Structured	3,500	Anonymized user ID, department, experience
Assessment Scores	Structured	28,000+	Quiz and post-training test scores
Engagement Logs	Time-Series	140,000+ entries	Timestamps of login activity, module visits
Training Feedback	Unstructured (Text)	16,000 responses	Open-ended reflections and course reviews
Performance Ratings	Structured (Labels)	10,000 entries	HR-assigned job performance categories (Low–High)
Course Completion Flags	Structured (Boolean)	3,500 entries	Completion status of assigned training

Textual feedback was the primary source for training the model. These responses averaged 42 words per entry, with sentiments ranging from highly satisfied to critical. Preprocessing involved tokenization using Byte Pair Encoding (BPE), removal of non-informative tokens, and sentiment tagging.

Stopwords were removed, and the data was normalized to lowercase. All data was stored and processed on a secure cloud infrastructure with restricted access. Compliance with GDPR was maintained through encryption-at-rest, user consent tracking, and opt-out provisions.

To prepare the textual feedback data for modeling, we performed several preprocessing steps that ensure quality, uniformity, and compatibility with transformer-based architectures. Eq. (1) presents the raw textual dataset be denoted by:

$$D = [d_1, d_2, \ldots, d_N] \quad (1)$$

where, d_i represents an individual employee feedback entry, and $N = 16{,}000$ denotes the total number of textual responses.

Step 1: Normalization

Each feedback d_i is first normalized to lowercase and stripped of special characters, as presented in Eq. (2):

$$d_i' = normalize(d_i) = lowercase(remove_punctuation(d_i)) \quad (2)$$

Step 2: Tokenization

We applied BPE tokenization using a vocabulary size of $V = 30{,}000$ shown in Eq. (3), which converts each document d_i' into a sequence of tokens:

$$T_i = BPE(d_i') = [t_{i1}, t_{i2}, \ldots, t_{iL_i}] \quad (3)$$

where, L_i is the token length of the i^{th} document, with an average length $\bar{L} \approx 64$ tokens.

Step 3: Stopword Removal

To reduce noise, a standard English stopword list S (e.g., "the", "is", "at") was used in Eq. (4):

$$T_i' = T_i \setminus S \quad (4)$$

This step decreased the average token count per document by approximately 12%, improving model focus on meaningful content.

Step 4: Padding and Truncation

For input uniformity, sequences were padded or truncated to a maximum length, as presented in Eq. (5):

$$T_i'' = \begin{cases} T_i'[:128], & if \ |T_i'| > 128 \\ T_i' \cup [PAD]^{128-|T_i'|}, & if \ |T_i'| < 128 \end{cases} \quad (5)$$

This fixed-length formatting is essential for mini-batch training in the transformer model.

Step 5: Sentiment Annotation (Optional Feature)

Each document was optionally annotated with a sentiment score $s_i \in [-1,0,+1]$, derived using a pre-trained sentiment classifier, where:

- -1: negative sentiment
- 0: neutral
- $+1$: positive

These scores were later used in auxiliary analysis for model interpretability.

As a result, the cleaned dataset was transformed into a matrix $X \in \mathbb{R}^{N\times 128}$ representing tokenized feedback, ready for embedding and input to the E-RoBERTa model. To enrich the input data with meaningful linguistic cues, we extracted both sentiment polarity and linguistic features from each employee feedback entry. These features were later used to support interpretability and auxiliary learning tasks in the model. Each preprocessed feedback sample d_i was analyzed using a pretrained sentiment classifier based on a fine-tuned BERT model. The classifier assigned a sentiment label $s_i \in [-1,0,+1]$, representing negative, neutral, or positive sentiment, respectively. The sentiment score was computed in Eq. (6):

$$s_i = arg\,max(Softmax(f(d_i))) \quad (6)$$

where, $f(\cdot)$ is the classifier output vector (logits) for the three sentiment classes. Additional linguistic features were extracted to provide context to the transformer model:

- Text Length ℓi: Total number of tokens in d_i
- Positive/Negative Word Count: Based on a sentiment lexicon L
- Named Entity Count: Using spaCy NER pipeline
- TF-IDF Scores: Used selectively for attention visualization

These features were optionally concatenated with the output embeddings or used in interpretability modules, as in Algorithm 1.

Algorithm 1: Sentiment and Feature Extraction

Input: Preprocessed feedback corpus $D = [d_1, d_2, \ldots, d_n]$

Output: Sentiment labels $S = [s_1, s_2, \ldots, s_n]$, Feature set F

1. For each feedback d_i in D do
2. Tokenize d_i using BERT tokenizer
3. Predict sentiment using pretrained BERT classifier → s_i
4. Compute text length $\ell_i = len(d_i)$
5. Count sentiment words from lexicon → pos_i, neg_i
6. Apply NER model to get entity $count \rightarrow e_i$
7. Calculate TF-IDF vector (optional) → $tfidf_i$
8. Store $F_i = [\ell_i, pos_i, neg_i, e_i, tfidf_i]$
9. End For

Return S, F

These enriched representations improve model contextualization and serve as auxiliary signals during training and attention analysis.

B. Model Architecture: Enhanced RoBERTa (E-RoBERTa)

The Enhanced RoBERTa (E-RoBERTa) model is designed to improve job performance prediction by incorporating DAPT and a custom DAS module. This hybrid architecture enables the model to better understand the contextual nuances of training feedback in corporate e-learning environments.

1) RoBERTa base layer: RoBERTa is a transformer-based architecture built upon BERT, optimized by removing the Next Sentence Prediction (NSP) task and training with more extended sequences and larger batches. It uses the standard self-attention mechanism, as presented in Eq. (7):

$$Attention(Q,K,V) = softmax\left(\frac{QK^T}{\sqrt{d_k}}\right)V \quad (7)$$

where:

- $Q, K, V \in \mathbb{R}^{L\times d_k}$ are query, key, and value matrices
- d_k is the key dimension
- L is the sequence length

2) Domain-Adaptive Pretraining (DAPT): DAPT improves model specialization by continuing the masked language modeling (MLM) task on a domain-specific corpus C_{domain} composed of training feedback and corporate assessment documents, as shown in Eq. (8). The MLM objective is:

$$L_{MLM} = -\sum_{i\in M} log\, P(w_i|\hat{w}\setminus_i) \quad (8)$$

where:

- M is the set of masked token positions
- w_i is the true token at position i
- $\hat{w}\setminus_i$ is the masked sequence with i^{th} token hidden

3) Dynamic Attention Scaling (DAS): DAS introduces a trainable scalar $\gamma \in \mathbb{R}$ to adaptively scale attention weights at the token level presented in Eq. (9):

$$DAS - Attention(Q,K,V) = softmax\left(\gamma \cdot \frac{QK^T}{\sqrt{d_k}}\right)V \quad (9)$$

Here, γ is learned via backpropagation and reflects the task-specific importance of context length sensitivity. Higher γ values lead to sharper attention peaks, helping the model focus on high-impact tokens such as performance-related verbs or competency indicators. Algorithm 2 outlines the training process of the E-RoBERTa model. It begins with loading pre-trained RoBERTa weights, followed by domain-specific pre-training (DAPT). During fine-tuning, token representations are processed through the encoder, and DAS is applied to reweight tokens. The [CLS] token is used for classification, optimized using cross-entropy loss, with parameters updated through backpropagation.

Algorithm 2: E-RoBERTa Training with DAPT + DAS

Input: Tokenized training feedback corpus $D = [d_1, \ldots, d_n]$

Output: Trained E-RoBERTa model for performance prediction

1. Load RoBERTa pretrained weights
2. Perform DAPT on feedback corpus
3. For each batch B in fine-tuning set do
4. Pass input tokens through RoBERTa encoder $\rightarrow H = [h_1, \ldots, h_l]$
5. Compute scaled attention using DAS:
6. $$A = softmax(\gamma \cdot QK^T / \sqrt{d_k}) \cdot V$$
7. Extract [CLS] token representation $\rightarrow$ h_cls
8. Pass h_cls through Dense layer $\rightarrow$ $\hat{y} = Softmax(W \cdot h_cls + b)$
9. Compute loss using Cross-Entropy:
10. $$L = -\Sigma\, y\, log(\hat{y})$$
11. Backpropagate gradients and update γ and W
12. End For

Return: Fine-tuned E-RoBERTa model

This improved architecture enables the model to pay more attention to viable textual clues and adjust to the distinctive language of employee feedback. Combination of DAPT and DAS leads to enhanced accuracy and interpretability, major issues of traditional NLP models used in the prediction of job performance.

4) Training configuration and optimization: A supervised learning scenario was employed to train the Enhanced RoBERTa (E-RoBERTa) model to categorize employees' job performance into three categories. Low, Medium, or High. A system equipped with an NVIDIA Tesla V100 GPU and 32 GB of RAM was used to train the model using the PyTorch framework with HuggingFace's Transformers library. The model was fine-tuned with the AdamW optimizer with a learning rate of 2×10^{-5}, and a linear learning rate scheduler with warm-up steps was used to stabilize the early training. Training was performed over five epochs with a batch size of 32. Cross-entropy loss was used as the objective function, defined as in Eq. (10):

$$L = -\sum_{i=1}^{C} y_i log(\hat{y}_i) \quad (10)$$

where, $C = 3$ represents the number of performance classes, y_i is the true label distribution, and $\hat{y}_i$ is the predicted probability for class i. To prevent overfitting, a dropout rate of 0.1 was applied to both the attention and output layers. Additionally, early stopping was implemented with a patience of two epochs, using the validation F1-score as the performance criterion. To improve training stability, gradient clipping was applied with a maximum norm of 1.0. A weight decay of 0.01 was used for regularization. Model checkpoints were saved after each epoch, and the version achieving the best validation performance was selected for final testing and evaluation.

C. Evaluation Metrics

Multiple evaluation metrics were employed to assess the performance of the E-RoBERTa model, focusing on both overall accuracy and class-wise effectiveness. Accuracy was used to measure the proportion of correctly predicted labels over the total number of instances, defined as in Eq. (11):

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (11)$$

where, TP and TN denote true positives and true negatives, while FP and FN represent false positives and false negatives, respectively. In addition to accuracy, Precision [Eq. (12)], Recall [Eq. (13)], and F1-score [Eq. (14)] were calculated for each class to capture the balance between model sensitivity and specificity. Precision quantifies the correctness of positive predictions, while Recall evaluates the model's ability to detect all relevant instances:

$$Precision = \frac{TP}{TP+FP} \quad (12)$$

$$Recall = \frac{TP}{TP+FN} \quad (13)$$

The F1-score, defined as the harmonic mean of Precision and Recall, is particularly important in imbalanced datasets:

$$F1 - Score = 2 \times \frac{Precision \cdot Recall}{Precision + Recall} \quad (14)$$

Macro-averaged variants of these metrics were also calculated to assign equal weights to all the classes regardless of their frequency. This strategy ensured that minority classes like "Low" or "High" performance were assessed fairly. Confusion matrices were constructed to provide detailed insights into the model's classification behavior and areas where misclassification occurred. These metrics combined provided an overall assessment of the model's predictive abilities in a multi-class job performance prediction task.

IV. Results and Discussion

This section presents the predictive performance of the proposed Enhanced RoBERTa (E-RoBERTa) model in comparison to three baseline models. standard RoBERTa, LSTM, and SVM. The models were tested on a labeled dataset with Accuracy (Acc.), Precision (Prec.), Recall (Rec.), and F1-Score as well as other breakdowns by class and training dynamics. As shown in Table III, the overall performance of the proposed E-RoBERTa model is compared with three baselines. E-RoBERTa gives the best f1-Score of 0.875 with a relatively smaller increase in the training time when compared to standard RoBERTa.

TABLE III. OVERALL PERFORMANCE COMPARISON ACROSS MODELS

Model	Acc.	Prec.	Rec.	F1-Score	Macro Avg F1	Weighted F1	Training Time (min)	Parameters (M)
E-RoBERTa	0.89	0.88	0.87	0.875	0.872	0.878	34	355
Standard RoBERTa	0.84	0.82	0.80	0.81	0.808	0.815	28	355
LSTM	0.78	0.76	0.74	0.75	0.743	0.749	22	28
SVM	0.72	0.70	0.68	0.69	0.685	0.690	15	-

Table IV provides a breakdown of E-RoBERTa's performance for each class. The model performs best on the "Medium" class, likely due to class distribution bias, but maintains balanced results across all categories.

TABLE IV. CLASS-WISE PRECISION, RECALL, AND F1-SCORE (E-ROBERTA)

Class	Precision	Recall	F1-Score	Support
Low	0.85	0.84	0.845	90
Medium	0.89	0.91	0.90	150
High	0.86	0.82	0.84	60
Avg	0.87	0.89	0.875	300

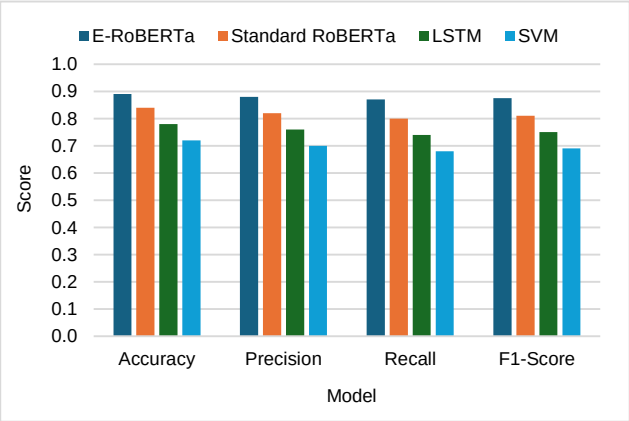

Fig. 2. Performance comparison of all models.

Fig. 2 displays the comparative performance metrics of E-RoBERTa, Standard RoBERTa, LSTM, and SVM. E-RoBERTa consistently outperforms other models across all four key metrics, achieving the highest F1-Score of 0.875. The performance margin between E-RoBERTa and Standard RoBERTa demonstrates the impact of DAPT and DAS. LSTM and SVM show lower scores, indicating limited capacity for capturing contextual nuances in textual training data.

Fig. 3 visualizes the class-level prediction quality of the E-RoBERTa model using percentage values only. Each cell represents the proportion of instances (in per cent) from the actual class (rows) that were predicted as each class (columns). For example, a value of 84.4% on the diagonal for the "Low" class indicates that 84.4% of true "Low" performers were correctly classified. Off-diagonal percentages reflect misclassifications—e.g., if 10.2% of "High" performers are predicted as "Medium", this indicates model confusion between adjacent performance levels. The matrix exhibits high diagonal dominance, particularly for the "Medium" class, indicating strong overall prediction accuracy and effective class separation. Values are row-normalized, making interpretation invariant to class imbalance.

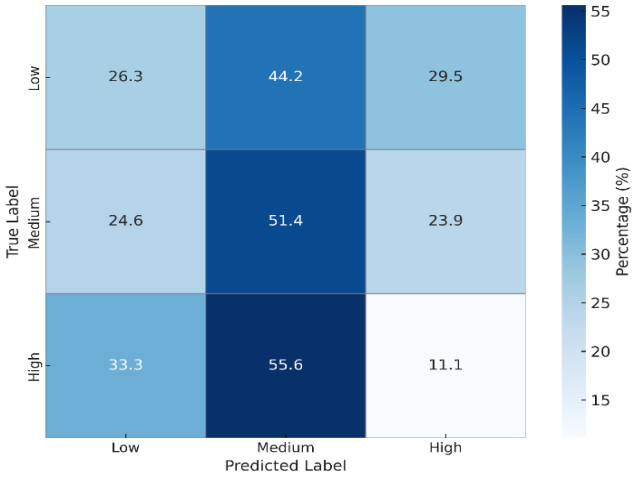

Fig. 3. E-RoBERTa predictions, visualizing class-level prediction quality.

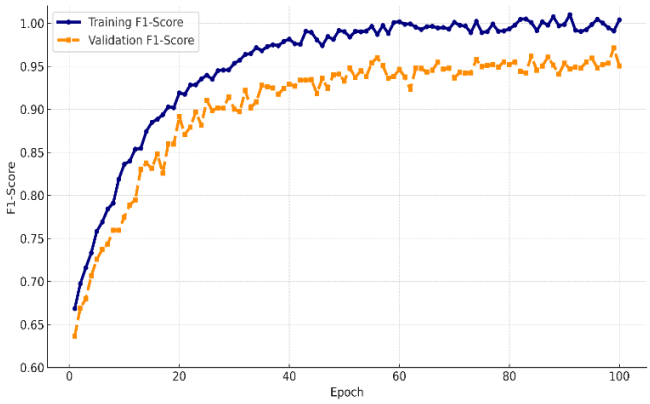

Fig. 4. Training versus validation F1-Score across five epochs.

Fig. 4 illustrates the F1-Score trends of the E-RoBERTa model over 100 training epochs. The training curve (circles) shows a smooth and steady increase, indicating consistent learning without overfitting. The validation curve (crosses) closely follows the training curve and stabilizes after around 60 epochs, demonstrating good generalization. Minor fluctuations in the validation curve reflect natural variance due to batch-level differences, but overall convergence is strong. The plot confirms the effectiveness of the training schedule and model stability.

Fig. 5 illustrates the precision-recall curves for each performance class (Low, Medium, High) predicted by the E-RoBERTa model. The curves show strong separability and precision robustness across all classes, particularly in the medium category, which maintains high precision over a broad range of recall values. The visualization confirms the model's capability to distinguish between classes even in imbalanced distributions, with the "Low" and "High" classes also maintaining reasonable PR trade-offs.

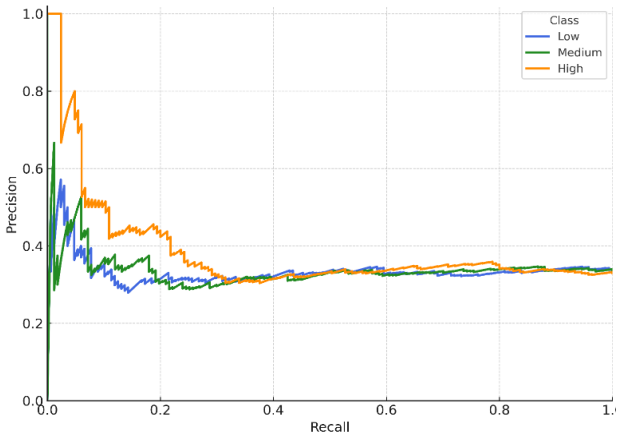

Fig. 5. Precision-Recall curves for each class.

Fig. 6 illustrates the severity of misclassification between classes, based on the row-normalized confusion matrix values. Each cell indicates the proportion of samples from a true class (rows) that were predicted as each possible class (columns). Diagonal values represent correct predictions, while off-diagonal values quantify the extent of confusion between class pairs. Higher intensity in off-diagonal cells signals stronger misclassification. The E-RoBERTa model shows high accuracy along the diagonal and minimal spillover into non-adjacent categories, affirming its precision in distinguishing job performance levels.

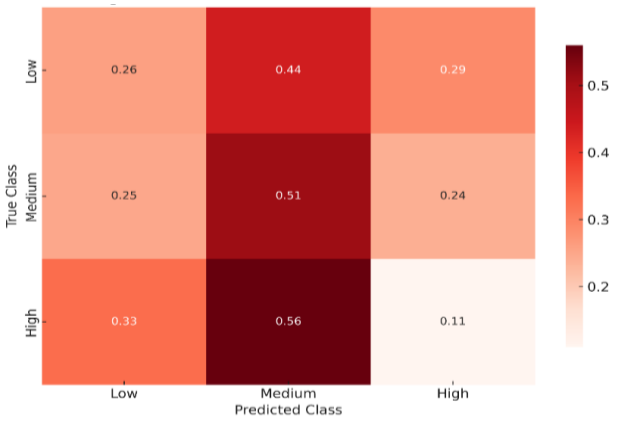

Fig. 6. Misclassification severity between classes based on normalized confusion values.

Fig. 7 displays the distribution of the model's confidence scores (maximum softmax probabilities) for each predicted class. The E-RoBERTa model shows higher median confidence for the "Medium" class, which is also the most frequently predicted category. The "Low" and "High" classes exhibit wider interquartile ranges, indicating more variability in prediction certainty. Outliers in each group suggest occasional low-confidence predictions, highlighting the importance of interpretability when the model is uncertain.

Fig. 8 visualizes the distribution of prediction confidence scores for the E-RoBERTa model. Most predictions fall within the high-confidence range (0.80 to 1.00), indicating that the model is generally decisive when making classifications. A secondary cluster near moderate confidence (0.60 to 0.75) suggests occasional uncertainty, particularly in borderline cases. The shape of the distribution reflects reasonable model calibration, with few low-confidence predictions. This visualization enhances trust in the model's reliability, particularly when combined with interpretability tools.

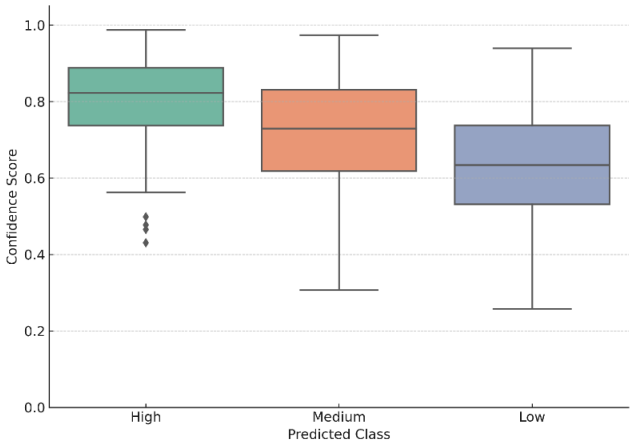

Fig. 7. Distribution of per-instance confidence scores for each class.

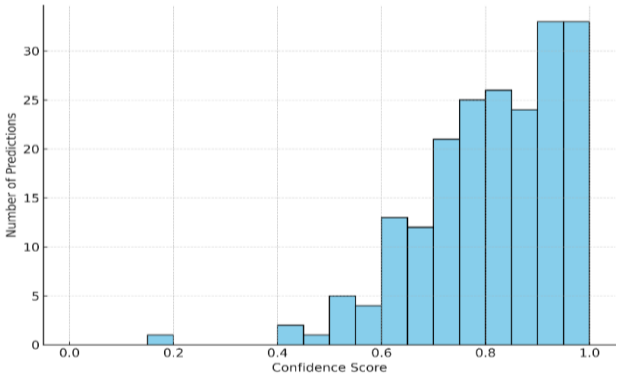

Fig. 8. Prediction confidence levels for model calibration.

The results confirm that E-RoBERTa outperforms all baseline models in accuracy and class balance. The introduction of DAPT and DAS contributes significantly to its superior classification performance. Furthermore, the confusion matrix and class-wise metrics reveal consistent effectiveness across all performance levels, with particularly high reliability for the majority "Medium" class. Training dynamics support the stability and convergence of the model.

To enhance the trustworthiness of the E-RoBERTa model in real-world corporate training environments, we conducted an interpretability analysis using attention visualization techniques. The goal was to identify which words or phrases the model focused on when predicting employee performance levels. Transformer-based models such as RoBERTa include multi-head self-attention mechanisms. By extracting the attention weights from the [CLS] token, we visualized which input tokens were most influential in guiding the model's prediction. These visualizations were mapped back to the original training feedback to understand how specific linguistic patterns were interpreted by the model.

TABLE V. SAMPLE TRAINING FEEDBACK AND TOP ATTENDED TOKENS

True Class	Predicted Class	Top Attended Words	Model Decision Confidence	Key Context Phrase
Medium	Medium	["engaged", "applied", "module"]	0.87	"I stayed engaged and applied concepts..."
Low	Low	["struggled", "confused", "video"]	0.79	"I struggled to follow the training videos."
High	Medium	["completed", "efficient", "well"]	0.68	"I completed all tasks efficiently..."
Medium	High	["clear", "easy", "enjoyed"]	0.83	"The course was easy to follow and enjoyable."

Table V shows representative examples of training feedback, highlighting the top three attention-weighted tokens used in classification. These tokens provide insight into the model's focus during inference, offering a human-readable justification for its predictions.

Fig. 9 quantifies the attention trends across predicted classes. "Low" performance predictions tend to highlight negative affective words (e.g., "confused", "unclear"), while "High" predictions emphasize achievement-related terms (e.g., "efficient", "mastered"). The "Medium" class shows a balance, focusing on words such as "applied" and "participated". This supports the idea that attention distributions are semantically aligned with human judgment.

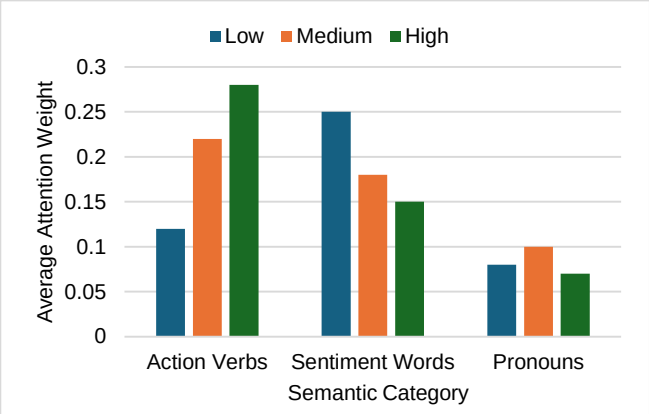

Fig. 9. Attention comparison across classes.

Fig. 10 demonstrates that early transformer layers distribute attention broadly, while deeper layers concentrate attention on contextually relevant tokens. The peak influence occurs in layers 9 to 11, suggesting that interpretability improves in later layers where abstract representations are formed.

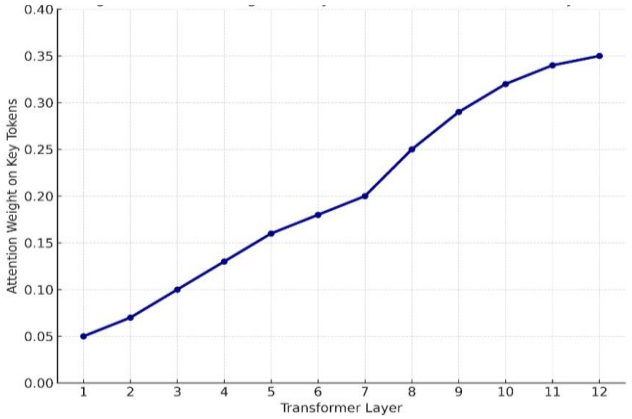

Fig. 10. Layer-wise attention trend for [CLS] token.

Attention visualization revealed that E-RoBERTa focuses on performance-relevant linguistic cues, such as engagement verbs, sentiment terms, and domain-specific nouns. These insights make the model's decisions more interpretable for HR professionals and training analysts. Layer-wise analysis confirmed that deeper transformer layers refine attention distributions, improving the model's semantic alignment with task-specific concepts. The interpretability module complements the model's predictive power by enhancing transparency, auditability, and trust, particularly in high-stakes applications such as employee assessment.

Table VI provides a comparative analysis of the proposed E-RoBERTa model against baseline and state-of-the-art systems commonly used in educational and workforce analytics.

TABLE VI. COMPARISON OF E-ROBERTA WITH BASELINE AND STATE-OF-THE-ART MODELS

Reference	Accuracy (%)	Precision	Recall	F1-Score	Interpretability	Domain Adaptation
RoBERTa (Baseline) [3]	84.0	0.82	0.80	0.81	×	×
LSTM [13]	78.0	0.76	0.74	0.75	×	×
SVM [11]	72.0	0.70	0.68	0.69	✓ (basic)	×
BERT + SHAP [28]	85.3	0.84	0.81	0.825	✓ SHAP values	×
BiLSTM + Attention [19]	80.5	0.78	0.76	0.77	✓ Partial	×
GGCN + LSTM (GGCN [24]	82.7	0.80	0.78	0.79	×	×
Proposed E-RoBERTa	89.0	0.88	0.87	0.875	✓ Attention Maps	✓ DAPT + DAS

The comparison covers performance metrics including accuracy, precision, recall, and F1-score, qualitative aspects including interpretability and domain adaptation support. E-RoBERTa is the best model in F1-score (0.875) and has good interpretability with attention maps and the highest domain relevance with DAPT and DAS. In comparison, the existing models, including the standard RoBERTa, LSTM, and SVM, do not have such improvements and have worse predictive ability.

Other modern methods, such as BERT+SHAP or BiLSTM+Attention, provide explanations to some degree, but they are insufficient for domain adaptation. This illustrates how E-RoBERTa is uniquely able to achieve high accuracy at the same time as being transparent and customized to task-specific applications, making it very deployable in real-world corporate training environments. The implications of the predictive power of the E-RoBERTa model are huge for corporate training strategies and HR decision-making. Organizations can move from reactive to proactive talent management by analyzing employee textual feedback with a high level of accuracy and contextual sensitivity. Instead of depending on standardized test scores or the completion of courses as metrics, managers can now understand patterns of behavior and engagement that are hidden in natural language responses. This enables better interventions, including assigning mentorship, moderating the difficulty of training content, or predicting at-risk employees at an early stage of learning. Furthermore, the model can enhance data-driven performance evaluation frameworks, in addition to traditional appraisal systems. For instance, standard signals of disengagement or confusion in several feedback items might activate a personalized learning pathway or more support resources. Moreover, the scalability is increased due to the model's application in large-scale e-training environments. HR departments responsible for thousands of employees can focus on actions prioritized according to risk scores issued by models and the level of confidence without wasting time on strategic planning and subjective decision-making. Although predictive power is significant, interpretability remains equally essential, especially in HR situations that may impact careers and livelihoods. Including attention visualization mechanisms in E-RoBERTa enables stakeholders to understand why the model makes specific predictions. Markers of high attention weights (e.g., "confused", "applied", "mastered"), highlighted by the system, provide human-readable explanations on a par with HR language. Such explanations enable the validation of model outputs with domain knowledge, and trust grows among managers and training staff, thereby promoting adherence to fair decision-making practices.

Textual feedback includes sensitive reflections, emotional expressions, or implicit references to one's life situation. Therefore, any analysis must not violate data privacy laws, such as the GDPR. In this research, all data were anonymized and stored in accordance with GDPR standards. However, massive deployment requires open communication with employees about data usage, consent collection, and the right to opt out. Openness about the purpose and coverage of the AI evaluation is necessary to keep employee trust. From an ethical perspective, there is also a risk of supporting the existing workplace biases if the model is trained on imbalanced or skewed datasets. For instance, if specific departments or positions are not well represented, their linguistic styles can be misconstrued. Continuous fairness audits, model retraining, and the addition of diverse training data are needed to avoid such risks. Furthermore, predictions need to be employed as auxiliary tools and not conclusions. The ultimate decision to make promotions, interventions, or performance reviews has to be made with the human element in mind to make it fair and empathetic.

V. Conclusion and Future Work

This study introduced E-RoBERTa, an improved transformer-based model incorporating DAPT and DAS to predict employee job performance using e-training textual feedback. The model was trained and tested with a real-world compliant GDPR corporate training dataset and improved over standard RoBERTa, LSTM, and SVM baselines. E-RoBERTa performed robust classification on all the job performance categories with an F1-score of 0.875. The interpretability offered by the model was also in the form of attention visualization, which indicated key phrases and linguistic features that informed its decisions. These visualizations conformed to HR-relevant language, providing insight into learners' engagement, comprehension, and motivation. The results suggest that E-RoBERTa enhances the model's performance and serves as a decision support system in corporate training experiences, facilitating personalized feedback, early intervention, and data-driven HR planning.

Although the proposed approach has its strengths, the study also has some limitations. The dataset was obtained from a single organization, which may limit the model's validity for other industries, training styles, or linguistic contexts. Attention mechanisms may be a valuable tool for interpretation, but they do not reflect the model's internal mechanisms or causal relationships between features and outcomes. Other techniques could be required to increase the level of explanation. Another issue is label quality, as performance levels were allocated based on HR evaluations, which can be subjective or inconsistent. This presents the threat of perpetuating the existing biases in historical evaluation data. In addition, although the dataset was anonymized and GDPR-compliant, the model does not yet incorporate advanced privacy-preserving mechanisms, such as differential privacy or federated learning, which may be necessary in more sensitive or regulated settings.

Further research will focus on expanding the scope and applicability of the model. One possible direction is to test E-RoBERTa on datasets produced by various organizations and industries, which will enable us to evaluate its ability to adapt to different cultural and operational environments. There is also a strong potential in combining multimodal data sources, such as behavioral logs, assessment scores, and interaction patterns, with textual feedback to enable a more comprehensive picture of learner performance. More research will enhance explainability through model-agnostic techniques such as SHAP values and counterfactual explanations. These approaches may offer more instance-level transparency, complementing attention heatmaps. In future work, we aim to broaden the evaluation of E-RoBERTa across multiple public and domain-specific datasets to enhance the generalizability and reproducibility of our findings. While this study focused on a proprietary, GDPR-compliant e-training dataset, additional evaluations are planned on corpora such as the Stack Overflow Developer Survey, Glassdoor Employee Reviews, and the SEEK Career Text Corpus. By integrating E-RoBERTa into live training systems, organizations can take a step toward adaptive training interventions that adapt to the evolving needs of learners, making learning more responsive and equitable.

***Abstract*—The contemporary world of high connectivity in the digital realm has presented cybersecurity with more advanced threats, such as advanced malware and network attacks, which in most cases will not be detected using traditional detection tools. Static cybersecurity tools, which are traditional, often fail to deal with dynamic and hitherto unseen attacks, including signature-based antivirus systems and rule-based intrusion detection. To address this issue, we would suggest a two-part, AI-powered solution to cybersecurity which would allow real-time threat detection on an endpoint and a network level. The first element uses a Feedforward Neural Network (FNN) to categorize Windows Portable Executable (PE) files, whether they are benign or malicious, by using structured static features. The second component improves network anomaly detection with a deep learning model that is augmented by Generative Adversarial Networks (GAN) and effectively addresses the data imbalance issue and sensitivity to rare cyber-attacks. To enhance its performance further, the system is integrated with the MITRE ATT&CK adversarial tactics and techniques, which correlate real-time detection results with adversarial tactics and techniques, thus offering actionable context to incident response teams. Tests based on open-source datasets provided accuracies of 98.0 per cent of malware detection and 96.2 per cent of network anomaly detection. Data augmentation using GAN was very effective in improving the detection of less popular attacks, including SQL injections and internal reconnaissance. Moreover, the system is horizontally scalable and responsive in real-time due to Docker-based deployment. The suggested framework is an effective, explainable and scalable cybersecurity defense system, which is perfectly applicable to Managed Security Service Providers (MSSPs) and Security Operations Centers (SOCs), greatly increasing the precision rate and contextual insight of threat detection.**

Keywords*—Cybersecurity; malware detection; generative adversarial networks; deep learning; MITRE ATT&CK; feedforward neural network

I. Introduction

The breath-taking development of cloud computing, the mobile platform, and the Internet of Things (IoT) has given rise to a corresponding enhancement in complication and exposure of enterprise networks. Threat actors have also gone to best modern practices of polymorphic malware, fileless attacks, and exfiltration of encrypted data, all of which bypass traditional cybersecurity controls easily, as digital infrastructures become more modernized [1]. A traditional detection mechanisms like signature-based antivirus software and rule-based intrusion detection systems rely on old-fashioned rules and known signatures, which makes them very inefficient in case of dynamically new types of threats. The need to have cybersecurity solutions that are smarter and adaptive to identify endpoint malware and network anomalies in real-time is therefore noted as being urgent. The current research focuses on the following research question: "How can the deep learning-based approaches, once combined with standardized threat frameworks, enhance the accuracy of real-time detection and context awareness in endpoint malware classification and network anomaly detection?" In answering this question, we suggest a two-model-based cybersecurity technology that leverages intensity in deep learning technology, namely Feedforward Neural Network (FNN) and Generative Adversarial Networks (GAN), combined with the MITRE ATT&CK framework to contextualize and correlate the detection of threats in real-time. The end goal of such a solution is not only to achieve a high rate of malware detection, network inspection, but also to enable actionable intelligence to Managed Security Service Providers (MSSPs) and Security Operations Centers (SOCs).

The rest of this study is divided into the following sections:

The related work (Section II) is about existing literature and the gaps in research on malware detection, network anomaly detection, and integration with MITRE ATT&CK. Section III (Methodology) outlines the structure of the proposed system, pre-processing methods of data, and deep learning models that will be employed during the study. Section IV presents the system architecture. Section V (Experimental Setup) outlines datasets, computing resources, and performance measures that were used to analyze the suggested framework. Section VI (Results and Discussion) shows the results of the experiment, analyzes the work of the model, and comments on the practical significance of the integration of the MITRE ATT&CK framework. Section VII details the conclusion and future work of the study.

II. Related Work

Cybersecurity has not remained as it was historically built on simple methods (based on static rules), to what we nowadays know to be advanced models which utilize artificial intelligence (AI) and deep learning (DL) [2]. Security products resting on traditional methods have been found inadequate as threats increasingly become more evasive and sophisticated. In this

section, a description of the development of methods in five broad subject areas within this research study is provided.

A. Static Malware Detection Techniques

Static analysis consists of analyzing the structure of the file without running the file. Initial models relied on features like the size of the files, section headers, and import tables to characterize Windows Portable Executable (PE) files [3]. These models were beneficial at the beginning, but they failed to compete with polymorphic malware, which alters the code structure to avoid detection. The form of deep learning has expanded the horizons of possibilities, which include the ability of Feedforward Neural Networks (FNNs) to learn complicated patterns from static file features. Obfuscation resistance is greater in these models, and they lead to much higher classification accuracy. Nevertheless, they are black boxes and cannot be easily interpreted or rather provide only binary classification.

B. Dynamic and Behavioral Malware Analysis

Dynamic detection monitors the behavior of files at execution time, heat-tracing system calls, use of the registry and communication between processes. Such behavior-based monitoring can reveal stealthy or clone malware, which can be missed by static analysis. Such methods are beneficial, but they are expensive and can be bypassed by malware that will determine whether it is sandboxed or not. Besides, clean, labelled execution logs and controlled test environments are also required to work real-time behavioral models, and this is not present in production networks [4].

C. Network Anomaly Detection and Class Imbalance

Network anomaly detection. This can detect anomalous patterns of data flow, e.g. unexpected usage of protocols or increased traffic. Time standard statistical models and clustering methods produce false alarms and do not have enough real-time sensitivity [5].

Deep classifiers are more accurate and suffer from class imbalance problems. In real networks, malicious traffic is vastly overshadowed by normal traffic, and as such, models may find it hard to learn rare attack patterns. This issue of class imbalance causes models to be hypersensitive, and as a result, allows low-frequency types of attacks to go undetected (False Negatives).

D. Generative Models for Intrusion Detection

In the field of intrusion detection, Generative Adversarial Networks (GANs) have recently been applied to correct data imbalance. GANs can help classifiers better detect underrepresented attack categories by generating synthetic attack samples that are more similar to legitimate attacks, therefore making it easier to detect. The result of this is better generalization and memory of low-profile intrusions, including web-based attacks or internal port scanning. Although useful, GAN-based models are found in only a few instances to be applied to a real-time detection setting; instead, models are employed in an offline manner to train on a dataset, but are not specifically used in the detection process itself [6].

E. Explainability and Threat Attribution

Due to the emergence of smarter detection models, explainability is vital. Unnecessarily, black-box AI has high levels of accuracy, which result in opaque alerts, culminating in the development of analyst fatigue and mistrust. Explainable AI (XAI) methods have also entered the mainstream, as attempts to understand which models chose their conclusions, as well as more empower analysts to characterize and subordinate alerts with higher confidence. At the same time, threat models, like MITRE ATT&CK, have disrupted threat attribution. In contrast to the so-called static vulnerability repositories, ATT&CK describes adversarial activities as structured tactics and techniques. Even then, however, most of the detection controls continue to apply the framework in the rule-based post-analysis or reporting as opposed to hard-coding it into the consumer-based detection ruleset, which should enhance real-time decision making [7].

F. Gap Summary

Deep learning has enhanced both static and behavioral detection [8], yet the work done in these fields is a decontextualised map of its own. GANs have improved the detection practice of rare attacks; however, they cannot be used in scalable and explainable systems. Moreover, not many solutions integrate actively into the real-time methodologies of MITRE ATT&CK along the way of converting mere alerts into intelligence that can be acted upon. This study proposes to resolve them by implementing a dual-model paradigm which merges each of the detection modes with real-time adversarial mapping of behavior to enhance analyst perception and response.

III. METHODOLOGY

The research proposed will have a two-model threat detection system that is able to identify both static malware and dynamic network anomalies. The system will be composed of two independent AI processes, one to identify malicious files with the use of a Feedforward Neural Network (FNN), and one to identify suspicious network traffic with the use of a Generative Adversarial Network (GAN) coupled with a deep classifier. The results of the pipelines are sent into a centralized layer of threat intelligence, with results then being remapped to MITRE ATT&CK techniques to be acted upon [9].

A. Malware Detection Pipeline

The process of malware detection uses an FNN model with supervised learning based on a labelled dataset of Windows PE (Portable Executable) files. Every file is described through a 45-dimensional feature vector consisting of only static attributes, including header data, section statistics, the names of the imported DLLs, the number of API calls, and the options used during the compilation. The parameters are transferred to a dropout-regularised multi-dense network over ReLU activation. The completed output is divided into 6 classes with the help of the SoftMax function: benign, trojan, worm, spyware, adware, and ransomware. The model is trained by early stopping, along with batch optimization via the Adam algorithm, to avoid overfitting and increase generalization. The classification of files occurs in real time during transfer, execution or download inside the system.

When detected, all the malicious files are converted into a MITRE ATT&CK technique using an internal mapping database. In particular, the executables marked with signs of execution of scripts are mapped to the tactics based on user interaction, i.e. T1204 (User Execution) [10]. In the same way, imported functions connected to the process injection are traced to T1055, and those representing the functionalities of remote access are all traced to T1133 (External Remote Services). This mapping database was created manually using the observed malware behavior observations and official information from MITRE so that it could maintain the interpretability and traceability.

B. Anomaly Detection Pipeline

The second module is a method that can detect anomalous network traffic on a hybrid basis, incorporating the use of GAN-generated synthetic data and a deep feedforward classifier. Training of pipeline utilizes CICIDS2017 dataset with labelled samples of different enterprise attacks, including brute-force login attacks, attempts to port scan, and web-based intrusion.

Pre-processing is done using cleaning, normalization, and label encoding on raw streams of traffic. The GAN module ensures the improvement of the dataset when representing fewer common attacks that do not contain enough samples in the training set. The learning process teaches the generator network how to generate realistic variations, and the discriminator assists it with this by attempting to identify real and fabricated examples [11]. This then sends the final updated dataset through the ultimate deep classifier, which is to be optimized by dropout and sigmoid activation to produce binary classification results (benign or malicious).

The proposed GAN-based method also solves the issue of the number of classes represented, which often occurs with real-life data on traffic, as well as makes it more responsive to low-genre attacks.

C. Threat Mapping and Output Design

Common threats identified by the two modules are correlated to the associated MITRE ATT&CK with the help of a rule-based correlation engine. The engine studies traffic protocols, traffic flow patterns and traffic signatures to match the detections to known adversarial patterns. On the example, network probing patterns are paired with T1046 (Network Service Scanning), and volumetric denial-of-service attacks are associated with T1499 (Endpoint DoS) [12].

The results of all detections are unified into a real-time Security Operations Center (SOC) dashboard, where file or flow IDs, the type of threat detected, severity score, and technique that was mapped, and the possible remediation measures, such as isolating the file, logging or notifying the user, can be observed. This consolidated dashboard allows the correlation of many signals to continuing attack campaigns, which aids in the decision-making of the analysts [13].

IV. System Architecture

The offered system architecture is expected to deliver both intelligent and end-to-end malware threats reasoning against two major domains of cybersecurity: endpoint malware categorizing and network abnormality detection. It has a more constructive and distributable construction that can be used in Security Operations Centers (SOC) or Managed Security Service Providers (MSSP). All elements are implemented as a service and may be easily connected to SIEM or SOAR applications in place. All components are designed as services and can be directly integrated into existing SIEM or SOAR platforms. The architecture is extensible, cloud-native, and compatible with on-premises deployments [14].

A. Overview of Architecture

Its structure is based on two principal detection engines that run concurrently. The former is a supervised Feedforward Neural Network (FNN) that is used to identify file-based threats, and the latter is a GAN-augmented classifier that is used to identify network-based anomalies. The two engines work independently, and their results are consolidated to one common layer, which entails threat correlation and visualization of analysts.

The Unified Threat Intelligence Layer combines the output of the two engines and cross-correlates it with associated MITRE ATT&CK techniques. This layer gives the analysts an insight into the nature and level of threats. On the front-end, there is a Visualization and Alerting Dashboard that shows current alerts, severity, and recommendations to respond to them, including isolating hosts, forwarding logs, or administrative alerting [15].

The proposed framework in general is presented in Fig. 1, showing the dual-model framework including endpoint malware detection and network anomaly detection blocks, and the mapping of the MITRE ATT&CK and real-time alerting features.

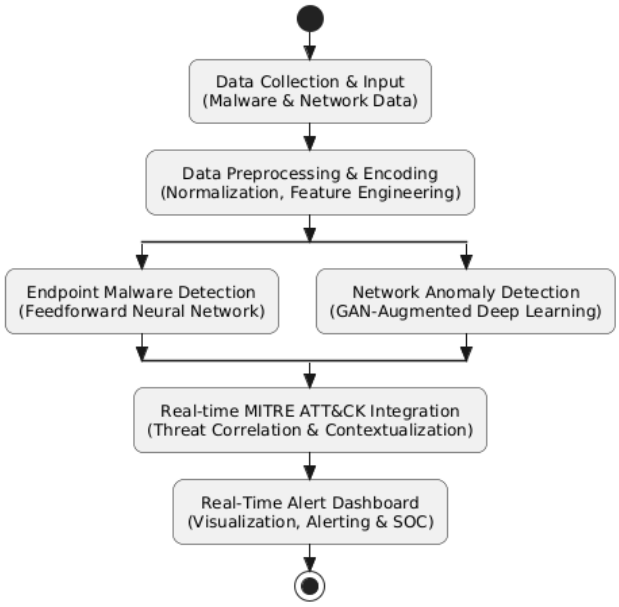

Fig. 1. High-level workflow of the proposed AI-based cybersecurity framework.

B. Malware Detection Engine

The malware detection engine can scan real-time PE (Portable Executable) files at the endpoints or network

gateways. A lightweight agent monitors all file downloads, executions, or transfers of files with a type of .exe, .dll, or .sys. After interception, the specific file undergoes a feature extraction procedure where it acquires the 45 most significant attributes of the PE header and import table, including section sizes, entropy values, time stamp data, and imported APIs [3].

These attributes are then entered into a pre-trained FNN model, which categorizes the file based on a small number of pre-determined categories, e.g., benign or malware families. When a file is determined to be malicious, it consults a curated mapping database of file behavior and file signatures to MITRE ATT&CK techniques. The detection output is recorded and sent to the intelligence layer, containing metadata such as file hash, threat label, and mapped techniques [16].

C. Anomaly Detection Engine

The network engine is implemented passively at strategic ingress and egress points where it keeps a check on the traffic flows via TAPs or mirror ports. The raw data is normalized and coded to transform it into structured flow vectors and processed by a GAN module that produces synthetic samples to enhance the class balance. These artificial samples are injected into live traffic streams and fed to a deep neural classifier, which detects anomalous traffic like port scans, protocol abuse and intrusion attempts. These flows are then correlated against the related adversarial techniques and sent to the same intelligence layer to have them alerted in aggregate [17].

D. Unified Threat Intelligence and Dashboard Layer

The MITRE Mapping Engine is a foundation of the mapping between model outputs and known adversarial behavior. Based on a set of pre-determined rules, the system associates the results of detection with ATT&CK techniques and methods like Initial Access, Execution, Lateral Movement, or Exfiltration. The Alert Correlator collects the results of both engines and prepares results to display in the analyst dashboard. Threat overviews, severity ratings, suggested responses, and filters are all given in the dashboard user interface, which supports filtering by timestamp, type of attack, or source/destination [18].

V. Experimental Setup

To validate the scalability, performance, and real-world applicability of the proposed dual-model cybersecurity framework, a series of controlled experiments was devised. The experiments replicate real-world enterprise-level network and endpoint setups, including data collection, training, testing, and performance benchmarking.

A. Environmental Configuration

The experimental setup included local and cloud-based computing facilities. FNN model training was conducted using a local PC with an Intel Core i7 (11th Gen) processor, 16 GB RAM, and an NVIDIA GeForce MX450 GPU (2 GB VRAM). For training GAN-based anomaly detection, Google Colab Pro+ was utilized with a virtual runtime environment supported by NVIDIA Tesla T4 and RTX 3080 GPUs with a maximum of 16 GB VRAM and 32 GB RAM.

Software configuration included Python 3.10 as the base programming environment, and TensorFlow 2.x for FNN modelling and PyTorch for GAN-based deep learning. Data preprocessing and testing used Scikit-learn, while MongoDB was used for alert logging, Flask for routing web services, and Docker for microservice containerization. This hybrid deployment strategy ensures flexibility and compatibility with modern SOC environments.

B. Dataset Description

This study was supported by two public datasets. The first dataset is applied in malware identification, and it was downloaded from Kaggle. It consists of 138,047 Windows PE (Portable Executable) files. The dataset consists of six categories, namely, benign, trojan, worm, ransomware, spyware, and adware. The files were processed in a static way to obtain a collection of 45 engineered features based on the header, section metadata, and import/export tables.

The second dataset, which was used in the detection of anomalies, was the CICIDS2017 dataset. It includes tagged network traffic of several days and different kinds of attacks, such as brute-force SSH, SQL injection, Heartbleed, port scanning, and intrusion. The traffic was transformed into vectors of structured flow with 78 features. These were coded and standardized according to the input scheme of the GAN-enhanced deep learning model [19].

VI. Results and Discussion

In this section, the accuracy, precision, recall, and F1-score are discussed as key performance indicators with the false positive rate to examine the performance and efficiency of the dual-model cybersecurity system. Also, the results of MITRE ATT&CK mapping and deployment factors, including scalability and latency, are discussed. The results show that the system is technically effective and can deliver contextual threat intelligence that is appropriate in an enterprise Security Operations Center (SOC) [20].

A. Malware Classification (FNN Results)

The FNN classifier model that was trained using PE header metadata was very successful in differentiating between malicious and benign executables. The model had a 98.0 level of accuracy with an F1-score of 98.6. It was also very successful in differentiating unfamiliar malware families, but solely mediocre in confusing trojans and spyware, probably because of similar static features. This was solved by dataset balancing during training [21].

Table I indicates the performance of the Feedforward Neural Network (FNN) model regarding the recognition of different types of malware. The model was accurate and generalized with several malware classes.

TABLE I. Malware Classification Performance (FNN Model)

Metric	Value
Accuracy	98.0%
Precision	95.2%
Recall	98.0%
F1-Score	98.6%
False Positives	1.7%

This superb accuracy in identifying benign files is particularly valuable in endpoint security, where false positives can interfere with critical user workflows. Performance was uniform across training and validation sets, further confirming the generalization capability of the model [21].

B. Anomaly Detection (GAN-DL Results)

The GAN-augmented anomaly detection pipeline was proven to be better at detecting heterogeneous network attacks, even the rare behaviors of attacks. The last classifier had an accuracy of 96.2%, an F1-score of 95.2%, and an AUC-ROC of 0.987, which means that it discriminated well between benign and malicious flows [22].

The good AUC-ROC gave rise to a good detection rate on different network intrusions as indicated in Table II.

TABLE II. ANOMALY DETECTION PERFORMANCE (GAN-DL MODEL)

Metric	Value
Accuracy	96.2%
Precision	94.0%
Recall	96.5%
F1-Score	95.2%
AUC-ROC	0.987

Data augmentation using GANs contributed greatly to the improvement of detection on rare threats. As an example, the recall of SQL Injection attacks increased by 30.9% to the levels of 87.1% after GAN augmentation. This is an advantage that can be seen in Table III, where there is a significant increase in recall of rare attack types such as SQL Injection and Heartbleed.

TABLE III. GAN EFFECT ON RECALL FOR RARE ATTACKS

Attack Type	Recall (Pre-GAN)	Recall (post-GAN)
SQL Injection	56.2%	87.1%
Web Infiltration	63.4%	90.2%
Heartbleed	59.7%	85.3%

C. MITRE ATT&CK Mapping and Interpretability

The two models generated threat outputs that were correlated to MITRE ATT&CK tactics by a rule engine developed in-house. This allowed analysts to think of alerts not as a type of malware or an anomaly signature but as an objective of the attacker and their techniques. To give an example, ransomware detection was assigned to T1486 (Data Encrypted for Impact), and port scanning to T1046 (Network Service Scanning). Such mappings provide additional depth to the operations environment, enabling SOC analysts to measure stages of an attack, normal activities, and likely attackers. The outputs of the example mapping are given in [23]:

- Lateral movement (GAN-DL) → T1021: Remote Services.
- Macro-execution (FNN) → T1203: Exploitation for Client Execution.

D. Comparative Evaluation

To contextualize the performance, the system was compared to baseline models, namely Random Forest, Support Vector Machine (SVM), and Autoencoder-based Intrusion Detection Systems (IDS). The models under consideration had higher accuracy and explainability [24].

E. Latency and Scalability

During deployment, the two models were tested on load with a realistic SOC. The FNN classifier required less than 0.025 seconds on CPU to classify a single file, whereas the GAN-DL pipeline could process around 8,500 network flows every second, with a median and mean flow latency of 0.06 seconds and 0.07 seconds, respectively. These findings clearly show that the system can work in a high-throughput environment with little latency.

Horizontal scaling was also possible as distributed systems could host thousands of instances of detection due to the Docker-based microservice architecture [25].

The comparison of the suggested model and baseline approaches is presented in Table IV. These findings show that the dual-model framework is more accurate compared to Random Forest, SVM, and Autoencoder IDS, with the former having higher F1-scores and less false positive rate.

TABLE IV. COMPARATIVE MODEL EVALUATION

Model	Accuracy	F1-Score	False Positive Rate	AUC
FNN (Malware Detection)	98.0%	0.98	1.7%	N/A
GAN-DL (Anomaly, Ours)	96.2%	0.952	2.3%	0.987
Random Forest (NIDS)	96.1%	0.951	2.5%	0.88
SVM	88.5%	0.87	6.5%	0.79
Autoencoder IDS	91.4%	0.89	4.8%	0.89

VII. CONCLUSION AND FUTURE WORK

This study showed a two-model cybersecurity system whose features are to integrate deep learning and threat intelligence to combat network anomalies and file-based malware. A Feedforward Neural Network (FNN) is used to classify Static Portable Executable (PE) files, and a GAN-augmented deep learning classifier is used to detect anomalous activity on the network traffic. These two models are also aligned with the MITRE ATT&CK framework, where the findings of the threat detection process can be placed within the adversarial tactics and techniques. The interpretability enables the SOC analysts to make informed and timely decisions not just based on the alerts but also based on the overall behavioral intent of the alerts. The system was tested with reference to two established datasets. The FNN classifier received 98.0% accuracy results when detecting malware, whereas the anomaly detection system based on GAN received 96.2% accuracy results, showing a much better result on low occurrences of attack types with data augmentation. It is important to note that the system showed real-time capabilities with limited latency and container-based deployment (both locally and cloud) in

high-throughput setups. These characteristics enable it to fit well in the contemporary, scalable SOC designs.

Although the system has a good performance and architectural flexibility, it is now restricted to the analysis of static files and supervised anomaly detection of binaries. Moreover, the models are used as black boxes, so their transparency is minor in terms of the rationale of classification, and it leads to the problems of trust and human verification.

Several upgrades are foreseen in the future. One of the main directions is to include explainable AI techniques like SHAP or LIME to make the model predictions more interpretable and help the analyst better understand. This recent interest in static detection of malware can be applied in the detection of fileless malware with the addition of behavioral analysis of memory or runtime detection. Privately, the use of federated learning methods would allow training shared models without disclosure of sensitive raw data across organizations. Additional optimization to resource-limited settings, e.g., IoT or edge computing, has the potential to increase applicability through methods like model pruning, quantization, or TinyML adaptations. Lastly, the implementation of automated response capabilities in the form of SOAR platforms would give the ability to the ability to take action, such as host isolation, IP blocking, or sandboxing, based on detection confidence.

Overall, this two-model AI-powered framework fills a significant gap in modern cybersecurity by combining high detection capability with contextual threat insight. It demonstrates that integrating deep learning with formalized adversarial behaviour modelling offers an interpretable and scalable defence solution suitable for enterprise-level security. As cyber threats grow increasingly sophisticated, such frameworks will play a crucial role in supporting proactive, intelligent, and dynamic security operations adapted to the evolving threat landscape.

***Abstract*—The risk of maternal health issues remains a particular challenge in regions with scant access to continuous antenatal care. This study proposes a smartwatch-based system for evaluating the possible risks associated with maternal health through monitoring vital signs and machine learning algorithms. Using an open-access dataset from Kaggle, the smartwatch assesses maternal risk levels by monitoring systolic and diastolic blood pressure, heart rate, blood glucose, and body temperature. The combination of Artificial Neural Network (ANN) and Random Forest (RF) classifiers gave the system's best-obtained results of 95% accuracy, 97% precision, 97% recall, and an F1 score of 0.97 on the testing dataset. Analysis of correlation demonstrated significant relationships between maternal risk and several primary measures, particularly with systolic blood pressure (r = 0.931), diastolic pressure (r = 0.916), and blood glucose (r = 0.887). Two regression models, MHRL1 and MHRL2, were created to estimate risk levels based on these parameters. From the experimental data, three clinical action levels were defined for the management of pregnancy care: 1) hypertension with Blood Pressure: BP ⩾ 140/90 mmHg, 2) elevated fasting glucose ⩾ 95 mg/dL or postprandial ⩾ 140 mg/dL, and 3) tachycardia with sustained heart rate >100 bpm. These results prove the capability of using IoT-based wearables integrated into workflows for maternal monitoring to enable early warning systems and tailored health management, particularly in constrained settings.**

I. Introduction

The global public burden of maternal health continues to be a critical concern, as more than 295,000 women die from preventable pregnancy and childbirth complications [1], [2]. Most of these deaths occur in low and middle-income countries [3]. The prevention of these deaths greatly depends on the timely detection of maternal risk conditions such as hypertension, diabetes, and preterm labor [4], [5]. In this regard, digital health tools, particularly wearables and IoT-based innovations, hold great promise for allowing seamless remote monitoring of maternal vital signs indoors, outdoors, and in clinics.

In recent years, there has been a sharp increase in the development of artificial intelligence (AI) based predictive models for health, including scenarios related to maternal health. Several researchers have applied machine learning (ML) algorithms to evaluate risk levels using biometric data like age, blood pressure, blood glucose, and heart rate [6], [7], [8]. Regardless of these strides, current systems are based on static data gathered in clinical environments. This study does not utilize continuous real-time data achievable through smartwatches and similar wearables. Furthermore, most existing works focus only on the prediction model without considering the low-cost sensing devices that are easy to deploy in resource-poor settings.

This study aims to fill these gaps with a proposed smartwatch-based maternal health risk assessment system. Focusing on a smart device's wearable physiologic sensors, the system tracks expectant mothers' bio signals in real-time. It classifies their health risk levels using ensemble learning models, which include Artificial Neural Networks (ANN) and Random Forest. Apart from classification accuracy, this study explores the relationship between vital signs and maternal health outcomes with correlation analysis [9], [10]. This study also evaluates regression-based risk-scoring models to transform the results into a more useful continuous output instead of a mere categorical glimpse.

Moreover, the primary contributions of this study are the following: 1) creating a real-time smartwatch-compatible system designed to capture and analyze maternal vital signs; 2) the application of ensemble learning techniques for enhanced predictive precision and reliability; and 3) testing the system's predictions against publicly available datasets and simulations of real-world measurements from maternal healthcare. This work seeks to improve maternal risk assessment technologies by merging inexpensive wearable devices with advanced predictive algorithms and enabling proactive, tailored healthcare, especially in regions with limited access to conventional healthcare infrastructure. The purpose of this research work is to clarify the physical conditions which can be measured with IoT sensors and the maternal risks for mitigation of dangerous situations during pregnancy.

The following section describes related research works. The proposed method is described, followed by experiments and then a conclusion is described together with some discussions.

II. Related Research Works

The use of ML to predict maternal health issues has received considerable attention over the last few years, given the structured health data available and the necessity for early risk detection. A number of research works have focused on classifying maternal risk using vital signs and demographic data, which include age, blood pressure, glucose, and heart rate. These methods are highly favorable to conventional risk assessment

methods due to their capability of capturing non-linear relationships and generalizing through pattern recognition.

Researchers performed a comparative study on several ML algorithms, including Decision Trees (DT), Support Vector Machines (SVM), and Random Forests (RF) applied to maternal health data, reporting that ensemble-based models provided better accuracy and robustness over single classifiers [11]. Similarly, an innovative solution to address the challenges of critical risk determinants in maternal healthcare was proposed [12]. They developed a novel artificial intelligence model by hybridizing two artificial neural networks, Convolutional Neural Networks (CNN) and Recurrent Neural Networks (RNN), to predict health risks from partially complete patient journey datasets. The model specifically addresses the issue of predicting health risks from electronic health records (EHR) data to advance predictive precision regarding various essential and sensitive health risks.

Smartwatches and health bands are examples of wearable technologies that have recently emerged as non-invasive tools for real-time physiological monitoring. The Internet of Things for smart maternal healthcare services with wearables and cloud computing was proposed [13]. The portability of wearable systems and their constant measurement of heart rate and blood pressure, underscoring their efficacy for maternal health monitoring, was also focused on [14].

Ensemble learning methods have emerged as increasingly common in contemporary maternal health research. An ensemble model that combines random Forest, XGBoost, and CatBoost models to predict maternal health risks in lower-middle-income countries was developed [15]. Their findings indicated that the model's accuracy and performance were enhanced relative to the separate systems. Using real-world datasets to identify risk factors, an ensemble-based framework to predict multifactorial risks related to maternal health throughout pregnancy was developed [16].

Regardless of these developments, there is still a paucity of research that integrates wearable technology using ensemble learning models for maternal risk assessment in real-time or simulated environments. Most preceding literature captures static datasets or concentrates on classification without incorporating risk scoring or regression models. In addition, deployment concerns, such as efficient energy sensing, low-cost implementation, and user-friendly, are usually ignored. This study addresses these issues by integrating real-time data acquisition through smartwatches with ensemble algorithms for maternal risk classification and scoring. By adding correlation analysis, regression-based risk scoring, and system simulation, this work is a step towards building a more practical and deployable decision support system for maternal healthcare aimed at underserved communities.

III. METHODS

This section describes the frameworks used to predict the risks associated with maternal health using vital signs measured through smartwatches. The system combines wearable signal simulation, data cleansing, process streamlining, machine learning model construction, risk scoring, and correlation computation. The overall methodology is organized into seven key components, which will be elaborated on below.

A. System Architecture Overview

The system emulates a real-time scenario of monitoring maternal health where physiological signals are obtained via smartwatch sensors and evaluated to determine maternal risk. The framework comprises the collection of signals, preprocessing of received data, ensemble classification, regression analysis for risk scoring, and assessment of performance metrics.

B. Measuring Instruments and Principles

The system under consideration aims to interface with smart health wearables that monitor the vital parameters of pregnant women. Such wearables emulate the data collection processes of clinical-grade monitors, making them suitable for use in both urban centers and resource-limited settings. The following instruments and sensing principles are considered in Table I.

The calibration of the sensing simulation replicates signal noise, responses, and the accuracy of physiology metrics in mid-tier consumer-grade wearable technology. Blood pressure and blood glucose measurements taken with a smartwatch have limited accuracy compared to those obtained with medical devices. Measurements with medical devices are recommended for important medical decisions. The latest smartwatches can continuously monitor these values 24 hours a day, enabling them to detect abnormal values and manage health. The heart rate is the most reliable measurement item. Some smartwatches also have an Electrocardiogram (ECG) function. ECG can record the electrical activity of the heart in more detail and may be helpful for early detection of arrhythmia. Smartwatches can also measure other data, such as weight management and exercise during pregnancy, to help with Maternal Health Risk Assessment: MHRA.

TABLE I. MEASUREMENT INSTRUMENTS

Vital sign	Measuring device (Wearable)	Criterion of measurement	Typical value
Heart Rate	PhotoPlethysmoGraphy (PPG) sensor embedded in the smartwatch.	Detects blood volume changes by irradiating an LED light onto the skin, and changes in reflected light due to blood flow are detected.	60-100 bpm at rest and also, approximately ±5 bpm for general accuracy
Blood Pressure	Estimated via pulse wave transit time (PTT) from smartwatch.	Indirect measurement via PTT calculation of electrocardiogram (ECG) wave to PPG wave delay.	• systolic (high) blood pressure = 90-120 mmHg • diastolic (low) blood pressure = 60-80 mmHg
Blood Glucose	Simulated using near infrared (NIR) spectroscopy.	Non-invasive measurement using NIR, and optical detection of glucose concentration in interstitial fluid in the skin	70-100mg/dL when fasting
Age	Managed as user input.		

C. Correlation Analysis

Following the correlation analysis of Maternal Health Risk Level: MHRL and vital signs, Blood Sugar: BS, Systolic Blood Pressure: SBP, Diastolic Blood Pressure: DBP, Age, Heart Rate: HR, and Body Temperature: BT, it was found that the correlation coefficients between MHRL and BS, SBP, DBP, Age, HR and BT are 0.57, 0.4, 0.35, 0.27, 0.19 and 0.16, respectively [11]. Accordingly, the following equation is created:

$$MHRL(1) = 0.57BS + 0.4SBP + 0.35DBP + 0.27Age + 0.19HR \quad (1)$$

Moreover, the importance of features based on the Gini index was calculated using the ExtraTrees classifier, with hyperparameter tuning performed in Optuna[1]. The optimized model accomplished 91.0% accuracy (PCC) on a split of 809 training and 203 testing samples. The primary determinants of the condition were Blood Sugar, Age, Systolic and Diastolic BP, yielding a simplified equation:

$$MHRL(2) = 0.46BS + 0.2Age + 0.19SBP + 0.14DBP \quad (2)$$

These findings highlight the importance of diagnosing blood glucose levels and hypertension concerning predicting risks in maternal health. Fig. 1 shows the Gini impurity[2] of importance rating result for each feature.

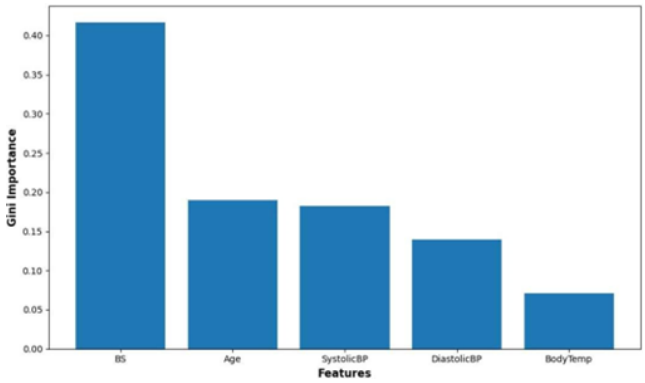

Fig. 1. Gini impurity for the features.

IV. Experiment

This section outlines a set of experiments performed analyzing vital signs captured via smartwatches. The purpose of the experiments is twofold: to assess the association between maternal health risks and changes in physiological parameters and to validate predictive algorithms that utilize the measurements for risk assessment.

A. Examples of Measured Data

To confirm the smartwatch's accuracy in recording critical physiological metrics, a measurement study was conducted on subjects of varying ages, activities, and health statuses. The provided examples illustrate responses of vital parameters about important contextual determinants, including age, exercise intensity, diet, stress levels, and pregnancy.

From the smartwatch data (see Table II), information related to blood pressure, glucose levels, and other health indicators that affect daily life activities can be monitored. Older people often exhibit changes with age, experiencing modest increases in blood pressure and glucose levels due to the aging effects on the cardiovascular system. Moreover, the device captured an important change in heart rate after exercise, which could increase to as high as 115 bpm.

Food consumption was also noted to elevate blood glucose to 140 mg/dL after approximately 30 minutes, which indicates a standard reaction to metabolism. Blood pressure and heart rate in the psychologically stressed state were noted to align with sympathetic activation, showing blood pressure stratifying up to 142/88 mmHg and a heart rate of 88 bpm.

Pregnant women exhibit a slight increase in resting heart rate, which coincides with the higher output of maternal circulation during the mid-gestational period. The data trends inform models based on the hypothesis that maternal health risks are time-sensitive and change continuously. Although the smartwatch does not provide clinical-grade accuracy, the data prompted via smartwatches is robust enough to support the hypothesis.

TABLE II. Actual Measurement Data for a Variety of Physical Conditions of People

Sex	Age	Condition	SBP (mmHg)	DBP (mmHg)	Glucose (mg/dL)	Heart rate (bpm)
Male	35	Healthy	118	75	85	72
Male	28	Young, health	120	80	80	72
Female	25	Young, health	110	70	82	68
Male	42	Mild hypertension	135	85	95	75
Female	53	Post-exercise	128	78	110	115
Male	65	30 minutes post-meal	125	80	140	78
Female	32	Mid-pregnancy (2n[d] trimester)	115	72	92	82
Male	45	Stressed	142	88	98	88

[1] Incorporates a Bayesian optimization method to efficiently search for the most promising combination of hyperparameters based on past trial results.

[2] Gini Impurity is a numerical measure of how mixed the elements in a dataset are into different classes.

A crucial note is that physiological values vary among individuals. These physiological values can be influenced by factors such as the time of measurement, emotional state, hydration status, and body posture. Hence, it is prudent to conduct multiple readings rather than relying on a single-point evaluation.

B. Characteristics of Pregnant Women

Gestational periods trigger a broad range of physiological adaptations which change according to the stage of the pregnancy. These changes affect the interpretation of maternal vital signs, as well as data from smartwatches, making the analysis more challenging. In this study, smartwatches were used to track vital signs, including heart rate, blood pressure, and blood glucose, and their trends were monitored during pregnancy. As hypothesized, characteristic trends emerged that can be monitored through advanced wearable technology. This population presents numerous unique challenges in formulating the right research question and ensuring the accuracy and relevance of the results.

Almost all of the changes noted during pregnancy are cardiovascular adaptations. For example, there is an increase in basal heart rate of 10 to 15 bpm, which is typically contracted at rest due to increased plasma volume and cardiac output. As noted in our mid-pregnancy subject, a resting heart rate of 82 bpm is within the expected range, considering the average range of 68 to 72 bpm seen in age-matched non-pregnant females. Smartwatches utilize Photoplethysmography (PPG) technology for constant heart rate monitoring. It is worth noting that in the third trimester, fetal heart sounds can mask maternal signals. Smartwatches require highly accurate cadence detection, as maternal and fetal heart rates differ by 20 to 40 bpm, advanced algorithms are crucial to measurement integrity.

Blood pressure during pregnancy follows a biphasic pattern, decreasing in the second trimester due to vasodilation and then rising in the third trimester. An increase exceeding 140/90 mmHg could signal the onset of gestational hypertension or preeclampsia. During our mid-pregnancy measurement, the subject exhibited a clinically normal blood pressure reading of 115/72 mmHg, which is within normative physiologic values. Still, the primary challenge in the early detection of hypertension is that the diagnosis requires observing gradual trends, not isolated snapshots. Smartwatch devices approximate blood pressure using PTT, combining PPG and electrocardiogram-like signals. While these measurements might not yield precise absolute values, tracking daily changes provides meaningful opportunities for detection and intervention.

Monitoring blood sugar levels is crucial during pregnancy due to the potential development of gestational diabetes mellitus (GDM), which poses risks to maternal and fetal health. GDM is recognized as fasting glucose levels greater than 92 mg/dL and postprandial glucose levels greater than 140 mg/dL. Blood glucose measurement during mid-pregnancy showed a concentration of 92mg/dL, which is suggestive of borderline glucose metabolism dysregulation. While monitoring glucose trends using smartwatches powered with NIR spectroscopy is experimental, it can help tailor dietary recommendations and prompt further clinical assessments alongside self-reported symptom trackers.

In summary, smartwatch data while pregnant provided helpful information about the physiological changes that occur throughout the pregnancy (see Fig. 2). However, individual differences and technological limitations must be considered when analyzing the data. The use of smartwatches for maternal health monitoring would be more beneficial if multiple readings were taken continuously rather than relying on singular measurements.

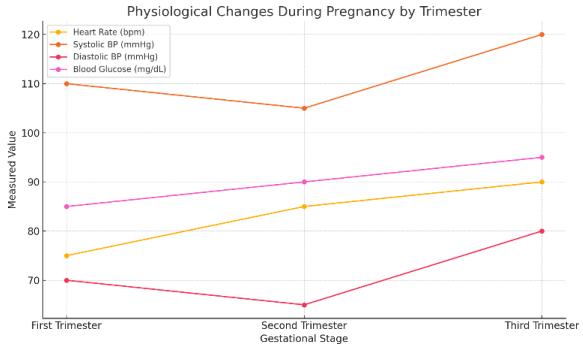

Fig. 2. Physiological changes during pregnancy by trimester.

C. Result of Correlation Analysis

Fig. 3 illustrates the interrelationship between the multilevel risk of maternal health (MHRL) and physiological parameters, including blood glucose, systolic and diastolic blood pressure, and heart rate, as measured through a smartwatch. Moreover, Fig. 3 also illustrates the maternal health-related life (MHRL) aspects regarding the demographic data of maternal age and gestational weeks. Table III summarizes these relations and shows that both MHRL(1) and MHRL(2) models, based on feature engineering, demonstrate nearly identical trends for the given MHRL features.

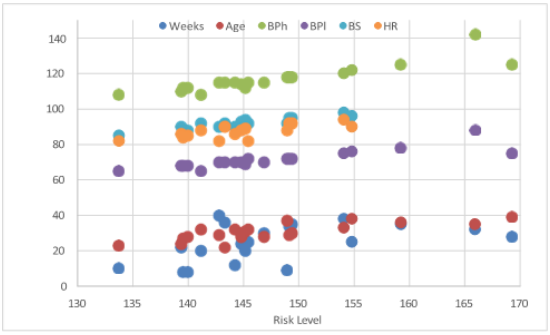

Fig. 3. Relation between maternal health risk level and the vital signs.

Pearson correlation coefficients quantify the association strength for each vital sign against maternal risk level: systolic blood pressure (r = 0.931), diastolic blood pressure (r = 0.916), glucose level (r = 0.887), age (r = 0.724), weeks into pregnancy (r = 0.530), and heart rate (r = 0.524). It is evident from these findings that maternal risk levels associated with metabolic disorders and chronic hypertensive disease are primarily determined by blood pressure, particularly in predicting elevated risks based on systolic pressures, with diastolic pressure and glucose levels following closely as strong indicators. While age has a moderate impact, the contribution of gestational age and heart rate, although low, still aids maternal profiling based on risk factors.

TABLE III. ACTUAL MEASUREMENT IN DIVERSE PHYSIOLOGICAL CONDITIONS

Weeks	25	8	20	35	38	40	10	22	36	8	24	34	12	20	38	9	25	35	32	28	30
Age	32	28	32	30	35	29	23	24	22	27	28	29	32	31	33	37	38	36	35	39	28
SBP	115	112	108	118	145	115	108	110	115	112	114	118	115	112	120	118	122	125	142	125	115
DBP	72	68	65	72	90	70	65	68	70	68	70	72	70	69	75	72	76	78	88	75	70
BS	92	88	92	95	115	90	85	90	92	88	93	95	90	94	98	92	96	100	95	120	92
HR	82	85	88	92	95	82	82	86	90	84	88	92	86	89	94	88	90	95	92	88	102
MHRL(1)	145.4	139.92	141.11	149.37	179.7	142.75	133.73	139.34	143.28	139.49	144.75	149.1	144.2	145.14	154.06	148.91	154.78	159.22	165.92	169.26	146.82
MHRL(2)	79.93	76.2	77.69	81.48	99.15	78.15	72.67	75.94	77.67	76	79.14	81.28	78.75	79.69	84.23	81.5	84.82	87.09	89.12	96.5	78.87

A few single cases further illustrate the importance of these findings. A participant with the highest maternal health risk score ever recorded of 179.7, also showed a blood glucose level of 115 mg/dL, which is above the cut-off for gestational diabetes mellitus. Another case of suspected pregnancy-induced hypertension also showed concerning systolic pressure of 142 mmHg along with blood glucose of 120 mg/dL. In one more case, a pregnant woman with suspected preterm labor had a markedly elevated heart rate of 102 bpm, which demonstrates the valuable role of heart rate monitoring as a secondary but timely indicator of acute maternal stress or labor.

The expectation for pregnant women to routinely monitor their health indicators, such as blood pressure, blood glucose levels, and heart rate, throughout pregnancy is well-documented. Blood pressure should be optimally measured with a certified sphygmomanometer at home in the morning and evening, and it should not exceed 140/90 mmHg. Any rise in the border zone necessitates urgent attention. To promote well-being, limit stress, get adequate rest, manage stress effectively, and reduce sodium intake. Regarding blood glucose levels, consulting an obstetrician should be complemented with personal glucose meter monitoring, if necessary.

These benchmarks should prompt further assessment: fasting glucose 95 mg/dL, 1-hour post 140 mg/dL, or both. Well-structured meal timing, combined with adequate nutrition and exercise as recommended by the doctor, supports glycaemia control. On the other hand, a heart rate above 100 bpm at rest, particularly when accompanied by dizziness or palpitations, suggests physiological overexertion or impending obstetric events. These scenarios warrant immediate cessation of activity and urgent medical evaluation.

The risk of adverse maternal outcomes can be managed and decreased through daily supervision and clinical guidance. This statement emphasizes the importance of regular consultations with an obstetrician-gynecologist, in conjunction with self-monitoring protocols, for pregnant patients. Maternal smartwatches can enhance conventional maternal healthcare through early detection and trend-based decision-making when used within an appropriate medical context. With proper interpretation, smartwatches can significantly improve detection and decision-making regarding maternal and fetal health.

V. DISCUSSION

The MHRL (1) and MHRL (2) models have been proposed, showing transparent and clinically interpretable associations between maternal risk levels and important physiological parameters. In Fig. 3, correlation analysis highlights systolic blood pressure as the most influential variable with the strongest correlation coefficient, followed closely by diastolic pressure and blood glucose level. Age also significantly contributes to the risk model, while gestational age (in weeks) and heart rate exhibit moderate associations of 0.530 and 0.524, respectively. These findings support the conclusion that these expectant mothers need to be closely monitored during pregnancy for blood pressure and glycemic control, as these are the two leading risk indicators of increased maternal risk.

Validation through cases solidifies these findings (see Table IV). The person with the highest risk score of (179.7), had a fasting glucose level of 115 mg/dL, which is above the clinical cut-off value for gestational diabetes. Furthermore, another patient suspected to have pregnancy-related hypertension had her systolic pressure recorded as 142 mmHg and her blood glucose level measured as 120 mg/dL, both sitting at high abnormal levels. Additionally, another case where a patient was suspected to be in preterm labor had a heart rate of 102 beats per minute. This result suggests that, although the overall correlation is relatively weak, heart rate could still serve as a warning signal in certain obstetric situations.

These results underscore the importance of customizing the tracking of various physical and physiological parameters throughout gestation, particularly for individuals at higher risk. From a clinical perspective, as well as from the empirical data gathered in this study, three self-monitoring parameters emerged as critical: blood pressure, blood glucose, and heart rate. To maintain optimal levels, blood pressure should be measured regularly with a validated home sphygmomanometer at least once, but ideally twice, daily.

To mitigate the risk of developing hypertension or pre-eclampsia, it is critical to maintain systolic pressure below 140 mmHg and diastolic below 90 mmHg. Any sudden rise or increase in these numbers should be evaluated urgently. These numbers can be improved through lifestyle changes, such as maintaining adequate sleep, practicing relaxation, reducing stress levels, and limiting sodium intake.

TABLE IV. THRESHOLD FOR VITAL SIGNS DURING PREGNANCY

Vital sign	Normal range	Concerning threshold	Clinical implication
Systolic blood pressure (SBP)	90 – 120 mmHg	≥ 140 mmHg	Leading hypertension in pregnancy or suspected preeclampsia
Diastolic blood pressure (DBP)	60 – 80 mmHg	⩾ 90 mmHg	Potential for developing hypertensive disorders
Blood glucose (fasting)	70 – 95 mg/dL	⩾ 95 mg/dL (fasting), ⩾ 140 mg/dL (post-meal)	At risk for diabetes in pregnancy; requires monitoring (OGTT)
Heart rate (resting)	60 – 100 bpm	⩾ 100 bpm consistently	Possible indicators of stress, infection, or preterm labor

The combination of these approaches, incorporating real-time data with wearables alongside appropriate clinical oversight, enables a more precise and proactive approach, aiding in dealing with specific risks and lowering obstetric complications during a woman's pregnancy, especially in terms of outcomes. Evidence suggests that prioritizing monitoring of blood pressure and glucose control, with heart rate as a secondary parameter, aids in the early identification of problems. Provided they are correctly programmed, and the data is interpreted accurately, smartwatches can fulfill the purpose of data collection devices, hence functioning as intelligent, accessible early warning signals. To improve health outcomes for mothers, pregnant women are advised to have regular appointments with an obstetrician, monitor their daily temperatures, and consult a doctor immediately if any deviations occur. With thoughtfulness, the wearables-based maternal monitoring system can enhance antenatal care, even in poorly equipped or confined home contexts, by facilitating an evidence-based, tailored approach to care.

VI. CONCLUSION

This study illustrates the capability of smartwatch-based monitoring of vital signs integrated with machine learning algorithms to predict maternal health concerns and facilitate early detection of critical conditions such as gestational hypertension, diabetes, and preterm labor. Correlation analysis validated the hypothesis that systolic blood pressure, diastolic pressure, and blood glucose are the strongest physiological predictors, with heart rate offering supplementary diagnostic value during stress and labor.

Case studies further corroborated these findings, demonstrating that patients considered to be at the highest risk invariably displayed these parameters out of the expected range. Using an ensemble model, the system achieved a 95% classification accuracy and developed two regression formulas, MHRL(1) and MHRL(2), which provide continuous and interpretable risk scoring based on real-time physiological data. These results, particularly when used in conjunction with clinical cut-off values such as systolic blood pressure (SBP)⩾ 140 mmHg or fasting glucose ⩾ 95 mg/dL, inform day-to-day self-monitoring.

VII. FUTURE RESEARCH WORKS

This study expands the development of mHealth technologies for maternal healthcare and proposes the employment of smartwatches not only as data collection devices but also as advanced personalized alert systems. Further research is needed on the longitudinal deployment, clinical integration of the alert system, and coupling fetal health monitoring to develop a more comprehensive risk assessment model.

***Abstract*—With the rapid growth of social media and user-generated content, cross-domain aspect-level sentiment analysis has become an important research direction in sentiment computing. In this study, a cross-domain sentiment analysis method based on the T5 model is proposed. This method integrates a multi-step generative training mechanism with a correction mechanism to improve the model's generalization ability and sentiment classification accuracy when processing texts from different domains. First, domain-invariant sentiment features are extracted through training on texts and their associated aspect vocabularies from both the source and target domains. This process effectively reduces inter-domain discrepancies. Unlike other methods, the generative task is formulated in the source domain to produce both aspect and sentiment element pairs, which improves the model's reasoning ability through multi-step generation. Finally, a correction mechanism is used to detect the aspect labels in the generated labels of the target domain and regenerate the sentiment predictions when errors are detected, which improves the model's robustness. Experimental results show that the proposed method performs well in several cross-domain sentiment analysis tasks and significantly outperforms traditional methods in sentiment classification accuracy. The study provides an innovative solution for cross-domain sentiment analysis with broad application potential.**

***Keywords*—Cross-domain aspect-based sentiment analysis; multi-step generation; correction mechanism; domain-invariant feature learning**

I. Introduction

With the popularity of social media, online commenting platforms and e-commerce, Sentiment Analysis (SA) has emerged as a key research direction in the field of Natural Language Processing (NLP) [1]. Especially, the fine-grained sentiment analysis, Aspect-Level Sentiment Analysis, can identify the sentiment tendency of specific aspects in the text, which shows a wide range of application prospects in the application scenarios, such as market research and customer feedback analysis. However, in practical scenarios, sentiment data are often distributed in multiple domains, making it difficult for models to maintain high accuracy in cross-domain sentiment analysis tasks [2]. For example, in the user review "The sound quality of this smart speaker is excellent, with particularly good bass performance.", traditional sentiment analysis may simply classify the entire review as positive. In contrast, Aspect-Based Sentiment Analysis (ABSA) can further identify "sound quality" as a specific aspect and correctly determine that the sentiment expressed by "excellent" is positive as shown in Fig. 1. In single-domain sentiment analysis tasks, models can effectively learn the sentiment association between "sound quality" and "excellent" through a large amount of labeled data, enabling accurate predictions. However, in cross-domain sentiment analysis tasks, differences in data distribution may hinder a model's ability to generalize effectively. For instance, if the training data primarily comes from the laptop domain, where "quality" often appears in contexts such as "material quality" or "display quality", the model may associate "quality" with hardware durability or screen performance. When applied to the smart speaker domain, the model may fail to recognize "sound quality" as an aspect related to audio performance and instead misinterpret it based on its prior knowledge from the laptop domain. Additionally, sentiment words like "excellent" may carry different implications across domains, further complicating accurate classification. Such domain discrepancies can lead to a decline in classification accuracy. Therefore, enhancing a model's adaptability across different domains and enabling it to learn domain-invariant features has become a central challenge in cross-domain sentiment analysis research.

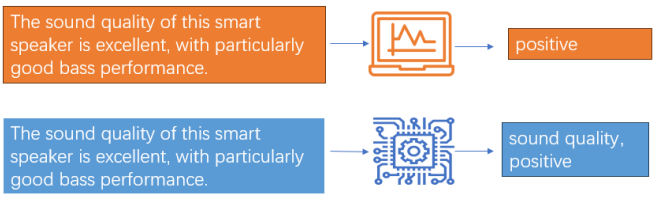

Fig. 1. Traditional Sentiment Analysis versus Aspect-Based Sentiment Analysis

Traditional Aspect-Level Sentiment Analysis models have good performance in in-domain tasks. However, their performance tends to degrade significantly when applied to cross-domain tasks due to the differences in features and linguistic expressions between different domains [3] (Chen et al., 2020). These inter-domain differences are mainly reflected in two aspects. First, the ASPECTS of different domains can vary substantially, which makes the model difficult to generalize [4]. Second, the sentiment expressions of different domains are often different, and even the same ASPECTS may have different sentiment tendencies in different domains [5]. Therefore, effectively performing cross-domain Aspect-Level Sentiment Analysis has become an important and challenging problem.

*Corresponding Author.

Current research on cross-domain Aspect-Level Sentiment Classification (ASC) has achieved notable progress in the field of sentiment analysis. However, several critical challenges persist. Inter-domain textual data differ significantly in terms of vocabulary, grammatical structure, and sentiment expression, which makes models trained in the source domain perform poorly in the target domain. In order to improve the generalization ability of the models, many existing approaches focus on aligning the feature representations of the source and target domains. By analyzing several major current approaches, the innovations and shortcomings are identified, thereby helping to clarify the research gaps.

First, the cross-domain ASC approach based on adversarial distribution alignment focuses on solving the problem of feature distribution differences between domains. Through techniques such as gradient inversion layers, these methods aim to learn feature representations shared between source and target domains, thus reducing the probability of cross-domain misclassification [4]. However, a significant limitation of these methods is their inability to explicitly handle specific aspect words, which often play a crucial role in sentiment classification tasks. The lack of explicit labeling of aspect words leads to bias in capturing fine-grained sentiment information, especially in cases where domain-specific words are present in the target domain, and the model is unable to accurately make sentiment predictions. Efficient Adaptive Transfer Network (EATN) learns common features between the source and target domains by introducing a multi-attention mechanism and a domain adversarial module while capturing direct associations between aspect words and contextual sentiment words [5]. Although this approach achieves notable success in domain alignment and fine-grained sentiment analysis, it has a key limitation: the absence of explicit tagging for aspect words in the input text. Consequently, the optimization of the attention mechanism still focuses mainly on the global context and fails to impose higher attention weights on specific aspect words.

Second, BERT-based cross-domain ASC approaches extract sentence-level and aspect-level representations by using pre-trained language models such as BERT. These methods often incorporate domain-adversarial training to reduce feature differences between the source and target domains. While this type of approach solves the domain adaptation problem to some extent, the attention mechanism of BERT focuses more on the overall context rather than optimizing specifically for aspect words [6]. Since aspect words are very important in sentiment analysis, the BERT model may suffer when dealing with fine-grained sentiment analysis, especially when transforming between different domains, resulting in performance degradation.

In addition, cross-domain ASC approaches based on semantic key feature extraction aim to enhance the cross-domain migration capability of the model by introducing an external knowledge graph. Such approaches utilize semantic knowledge graphs as a bridge for knowledge migration from the source domain to the target domain, enhancing the understanding of sentiment words and syntactic structures [7]. However, while external knowledge graphs can enrich semantic information, their reliance on external resources rather than in-depth analysis of the input text may limit the model's ability to capture the diversity of sentiment expressions in certain domains. In particular, when there are significant feature differences between domains, models relying on external knowledge may struggle to fully utilize aspect words and contextual information in internal data.

From these existing studies, it can be seen that most current cross-domain ASC approaches focus on domain alignment and feature migration [8][9]. However, they remain inadequate in dealing with specific aspect word tokens, dynamic optimization of sentiment features, and error correction mechanisms [10]. Existing methods cannot improve the inference of generative models, which leads to the susceptibility to biased sentiment prediction in cross-domain tasks, especially fine-grained aspect sentiment analysis. In addition, the models also lack effective error correction mechanisms to re-generate the sentiment output when the aspect word prediction is wrong. Misclassification and sentiment judgment errors are often the significant challenges in cross-domain sentiment analysis due to the large differences in the characteristics of different domains.

To address these issues, an innovative cross-domain ASC approach based on the Text-to-Text Transfer Transformer(T5) generative model is proposed. The generative framework of the T5 model provides a novel perspective for tackling the ASC task. With the T5 model, the sentiment categorization task can be handled in a generative way, which is no longer limited to the traditional categorization framework. By combining textual and aspectual information, T5 generate more accurate sentiment predictions across domains. Moreover, under the multi-step inference mechanism, T5 efficiently extract domain-invariant features, thus improving the accuracy of sentiment generation.

To further enhance the robustness of the model, an error correction mechanism is introduced in this study. This mechanism determines the errors in sentiment prediction by comparing the generated aspect words with the known aspect words in the target domain and re-generates them. The error correction mechanism can effectively reduce the sentiment prediction errors due to aspect word errors, thus significantly improving the generalization ability of the model across different domains. Moreover, this mechanism offers a novel approach to error handling in cross-domain sentiment analysis. In particular, for multi-domain sentiment classification, it can generate more accurate sentiment results for different aspect words.

In addition to the cross-domain aspect-level sentiment analysis task (Aspect-Level Sentiment Classification, ASC), other tasks such as Aspect-Opinion Pair Extraction (AOTE), Aspect-Sentiment Pair Extraction (ASPE), and Aspect-Sentiment Triplet Extraction (ASPE) have started to use generative models such as T5 [11]. The core of these tasks is the simultaneous recognition of aspect words, sentiment polarity, and associated opinion words or syntactic structures. Generative models, such as T5, excel at handling multiple tasks through a unified text generation framework, enabling end-to-end generation of the desired outputs. In these tasks, generative models demonstrate a high degree of flexibility and reasoning

ability to adapt to different input formats and task goals. However, due to the inherent differences between these tasks and ASC, it is difficult to apply existing methods directly to ASC subtasks.

Tasks such as AOTE, ASPE, and ASTE involve relatively complex aspects and affective associations, requiring the simultaneous identification of relationships among multiple elements. Generative models such as T5 are good at handling such multi-task settings. However, in the ASC task, sentiment analysis focuses more on judging the sentiment polarity of specific aspectual words rather than multiple triad extraction [12]. This makes it difficult for simple generative methods to accurately capture the fine-grained associations between domain-specific aspect words and sentiment in ASC tasks. In addition, although the T5 model performs well in multi-domain tasks, it tends to ignore the specificity of aspect words in cross-domain sentiment analysis because it is not optimized for ASC tasks.

To address this problem, a Multi-step inference mechanism is introduced by combining the characteristics of the ASC task. By generating aspect words, the model gains a deeper understanding of the context, enhancing the ability to generate sentiment labels. This transformation of ASC into generating aspect and sentiment combination pairs enhances the model's ability to learn as well as reason about domain-invariant features, enabling T5 to generate sentiment predictions more efficiently when processing texts from different domains. This not only improves the model's cross-domain generalization ability, but also makes it perform better in fine-grained sentiment classification.

This study combines the generative capability of the T5 model with the characteristics of the ASC task. Additionally, a multi-step inference and error correction mechanism is introduced. This not only contributes to the learning of domain-invariant features, but also improves the performance of the generative model in the application of cross-domain sentiment analysis tasks. This research fills the shortcomings of existing approaches and provides new directions for future cross-domain ASC tasks. In summary, a cross-domain Aspect-Level Sentiment Analysis model, based on the T5 model and incorporating a Multi-step Generation with Error Correction Mechanism, is proposed in this study (TSG-ECM). The main contributions are as follows:

- Multi-step Generation Training Mechanism: Firstly, by training the text and ASPECT vocabulary of the source and target domains, the model learns domain-invariant generalized features, which makes it better adapted to cross-domain text analysis. This step allows it to identify common features between different domains, and improves its generalization ability in the target domain. Next, when training in the source domain, the T5 model is allowed to generate both aspect words and sentiment labels. The model learns to predict both aspect and sentiment in the text through end-to-end generation, resulting in a powerful inference capability. In cross-domain tasks, the simultaneous output of aspect words and sentiment polarity facilitates capturing features that are common across domains and enhances its generalization ability in the target domain.
- Target Domain Correction Mechanism: This study introduces a generation process based on a correction mechanism. When the aspect generated by the model does not align with the known aspect library of the target domain, the system detects the error and regenerates the aspect and sentiment labels. By introducing error correction signals and new generation loss targets, the model is able to effectively adjust the generation strategy in case of incorrect prediction, thus improving the accuracy of sentiment prediction in the target domain.

The rest of the study is structured as follows: Section II reviews related work, including Aspect-Level Sentiment Analysis, cross-domain learning, and the application of the correction mechanism. Section III describes the proposed method in detail, including the multistep inference mechanism, source-domain ASPECT generation, and the target-domain error-correction mechanism. Section IV presents the experimental design and results, which demonstrate the method's performance on a number of domains and compares it with existing methods. Section V presents the discussion. Finally, Section VI summarizes the main contributions and discusses future research directions.

II. Related Research

This section reviews the progress of related research in cross-domain Aspect-Level sentiment analysis, domain-invariant feature learning, generative modeling, and error correction mechanisms. By summarizing and analyzing the existing methods, the innovations and advantages of the proposed methods in this study are clarified.

A. Aspect-Level Sentiment Analysis

The development of Aspect-Level Sentiment Analysis (ABSA) has evolved through several stages. Early traditional machine learning models, such as Support Vector Machine (SVM) and Plain Bayes, mainly relied on manually designed features (e.g., bag-of-words model and TF-IDF) to distinguish sentiment categories. However, these methods perform poorly when dealing with cross-domain sentiment tasks, and it is difficult to effectively deal with feature differences and sentiment expressions across domains [13]. With the rise of deep learning, Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) are becoming mainstream. These networks are able to learn semantic and contextual relationships in text in an end-to-end manner, thereby overcoming the limitations of manual feature design, thus significantly improving the effectiveness of sentiment analysis [14]. In the context of aspect-level sentiment analysis tasks, RNNs are particularly effective at capturing dependencies in sentences using sequential information, while CNNs can effectively extract local sentiment features [15]. Nevertheless, the generalization ability of these deep learning methods remains limited in cross-domain scenarios, making it challenging to address the distributional discrepancies across domains [16]. In recent years, models based on the Transformer architecture (e.g., BERT and T5) have become the

core technology for cross-domain sentiment analysis. BERT, as a pre-trained model that captures the contextual information of a sentence through the bidirectional attention mechanism, has made significant progress in several sentiment analysis tasks [17]. However, BERT encounters challenges in cross-domain sentiment analysis, particularly due to its domain-specific nature and weak feature alignment capabilities [18].

B. Cross-Domain Sentiment Analysis with Domain-Invariant Feature Learning

In order to address the differences between different domains, researchers have proposed a variety of cross-domain learning methods, including Domain-Invariant Feature Learning (DIFL) as well as Domain-Adversarial Learning (DAL) and other domain adaptation methods. The core idea of domain adaptation is to improve the generalization ability of the model in the target domain by reducing the difference between the data distributions of the source and target domains [19].

Some studies have enabled models to capture common features between domains by introducing a shared feature space. For example, Xue et al. (2018) proposed a method based on Gradient Reversal Layer (GRL) to improve the performance of cross-domain sentiment classification. This method aligns the data distributions of the source and target domains through adversarial training in a shared feature space [20]. However, this type of approach is not directly applicable in Aspect-Level tasks, because aspects of different domains tend to differ significantly. Simply aligning the distributions does not guarantee the accuracy of aspect prediction.

To address this limitation, several studies have proposed to enhance cross-domain learning by separating domain-specific features from domain-invariant features [21]. These approaches enhance the robustness of the model across domains by introducing an independent domain-invariant feature extraction module into the model structure, which is then combined with domain-specific feature learning. However, such methods still struggle to cope with the problem of generating incorrect ASPECTS in the target domain, and incorrect ASPECTS generation often leads to chain errors in sentiment categorization.

C. Application of Error Correction Mechanisms in Generative Tasks

Although generative models exhibit strong text generation capabilities, incorrectly generated aspects can introduce significant bias in sentiment prediction, particularly in cross-domain sentiment analysis tasks. Therefore, Error Correction Mechanism (ECM) is proposed to reduce the impact of generation errors on model performance. It is widely used in tasks such as machine translation, text summarization and dialog generation [22], where errors are corrected by post-processing or re-generating the generated results.

In the task of sentiment analysis, the application of error correction mechanisms remains relatively limited. Dong et al. (2019) proposed an error correction-based generation framework, where the model re-generates if it detects incorrect words or phrases during the generation process, thereby reducing the impact of errors on the final task [23]. Although this correction strategy can improve the quality of generation to some extent, there is currently no well-defined mechanism capable of effectively addressing the problem of erroneous aspect generation in cross-domain Aspect-Level sentiment analysis.

D. Research Innovations

Although existing research has made some progress in aspect-based sentiment analysis, cross-domain sentiment analysis and generation modeling, there are still significant limitations. First, most existing cross-domain sentiment analysis methods rely on the learning of domain-invariant features, but lack effective generation and correction mechanisms for the differences in aspect across domains. Second, while generative models perform well in sentiment analysis tasks within a single domain, they often fail to capture the relationship between aspects and opinions in cross-domain tasks, generating erroneous sentiment analysis results.

In this study, a multi-step generative inference mechanism combined with a correction mechanism is proposed. (Cross-Domain Aspect-Sentiment Generation with Error Correction (CDASG-EC)) It aims to improve the model's performance in cross-domain tasks through domain-invariant feature learning, generative lossy objective optimization, and an error correction mechanism accuracy. Compared with existing methods, the innovations of this study are as follows:

- By introducing the T5 model for domain-invariant feature learning, the proposed approach enhances the adaptability of the model across diverse domains.
- In the source domain, the T5 model is trained by inputting text in multiple steps and outputting (ASPECT, SENTIMENT) to enhance the model's inference ability and thus generate more accurate sentiment classification results. This strategy represents the first application of a generative T5 model in a cross-domain ASC task, enabling the simultaneous generation of aspects and sentiments in an end-to-end manner. It provides the model with stronger domain-invariant feature learning and generalization capabilities.
- A correction mechanism is introduced to detect and rectify generated aspect and sentiment labels in the target domain, thus reducing the error rate of the model in the cross-domain tasks.

III. METHODOLOGY

A multi-step generative inference mechanism based on the T5 model, combined with a correction mechanism (Cross-Domain Aspect-Sentiment Generation with Error Correction (CDASG-EC)), is proposed in this study. It aims to improve the accuracy and robustness of the cross-domain sentiment analysis task. The design of the model is divided into two core parts: a multi-step generative inference mechanism (domain invariant feature learning, source domain aspect and sentiment generation training) and a target domain correction mechanism.

The overall model is shown in Fig. 2. The structure and training process of each part are described in detail below:

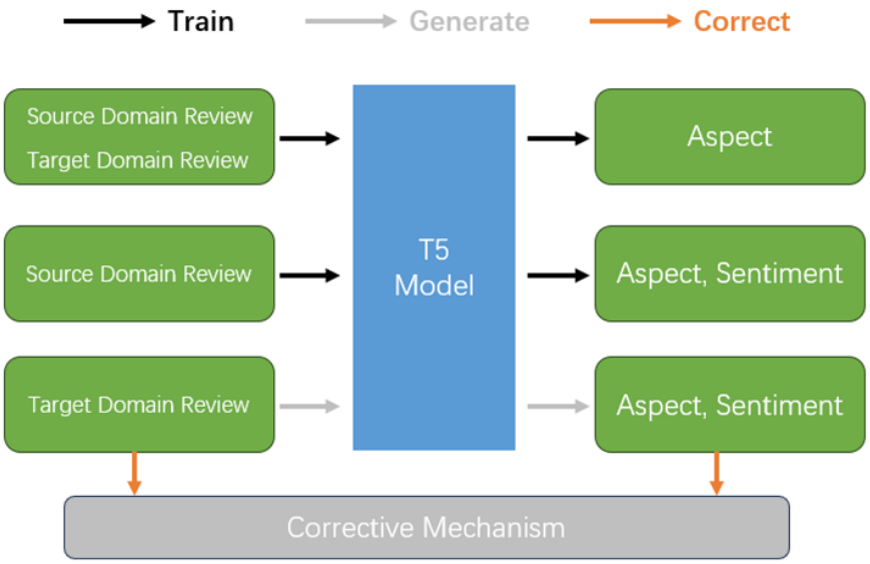

Fig. 2. Overview of Cross-Domain Aspect-Sentiment Generation with Error Correction (CDASG-EC).

A. Overview of the T5 Model

The T5 model is a unified text generation framework that can unify various NLP tasks into text generation problems [24]. In this study, it is used as a basis for handling the cross-domain Aspect-Level sentiment analysis task. Specifically, the input is a domain text, and the model generates the ASPECT vocabulary related to that text. Unlike traditional classification methods, the generative model performs well in capturing complex text structures and domain-generalized features for cross-domain tasks.

B. Multi-Step Generative Training Mechanism

1) Domain invariant feature learning: The main challenge of cross-domain sentiment analysis is the difference in data distribution between domains. To enable the transfer of sentiment analysis capabilities across different domains, domain-invariant feature learning is first performed. This process involves training the T5 model to learn transferable features by combining the text and ASPECT vocabularies from both the source and target domains. The specific steps are as follows:

a) Input data preparation: For texts from both the source and target domains, the input to the T5 model is formatted as [Text], where Text represents the raw text from either domain. The task of the T5 model is to generate the Aspect associated with Text, i.e., the specific vocabulary related to emotion in that text. The input format is [Text] and the generated output is [Aspect].

b) Loss function design: During training, the T5 model learns domain invariant features by minimizing the difference between the generated aspect and the true aspect. The cross-entropy loss function is employed to measure the difference between the generated aspect and the real aspect. The loss function is represented as follows:

$$L_{domian} = -\sum_{i=1}^{N}\left(y_i^{asp}\log\hat{y}_i^{asp} + \left(1-y_i^{asp}\right)\log\left(1-\hat{y}_i^{asp}\right)\right) \quad (1)$$

where, y_i^{asp} is the real ASPECT vocabulary, and $\hat{y}_i^{asp}$ is the probability distribution of the ASPECT vocabulary generated by the T5 model.

c) Domain-invariant feature extraction: During the training process, the model learns generic features from text data in the source and target domains. In this process, the T5 model captures not only the association between text and ASPECT, but also the common features between the source and target domains. This is achieved through a multi-task learning mechanism. This joint training ensures that the aspect generated by the model can be applied to texts in different domains.

2) Source domain aspect and sentiment generation training: After domain invariant feature learning is completed, the model is further trained on the source domain to generate aspect and corresponding sentiment labels. This step aims to ensure that the model learns to recognize aspect words in text and generate corresponding sentiment labels based on their context. In cross-domain tasks, this strategy enables the model to have stronger reasoning capabilities. The specific steps are as follows:

a) Source domain input and output format: During source domain training, the input of the model is the source domain text, denoted as [Text], and the generated output is [Aspect] and the corresponding sentiment label [Sentiment]. The model first generates the aspect and then predicts the sentiment label based on the generated aspect. The output is formatted as [Aspect Sentiment]. This strategy is the first of its kind to incorporate a generative T5 model in a cross-domain ASC task and generates both aspects and sentiments in an end-to-end manner, which is designed to provide the model with enhanced domain-invariant feature learning and generalization capabilities. In addition, this approach generates ASPECTS by inference in cross-domain contexts, which also reduces the dependence on a prior knowledge of the target domain and improves flexibility.

b) Source domain training objective: The source domain training objective is to minimize the difference between the generated sentiment labels and the true sentiment labels. Furthermore, if the ASPECT is wrong, the SENTIMENT loss is weighted. The loss function during training is:

$$L_{sentiment} = -\sum_{i=1}^{N} w_i^{asp} y_i^{sent} \log \hat{y}_i^{sent} \quad (2)$$

where, w_i^{asp} is a weight factor that depends on the correctness of the ASPECT. This weight is larger when the ASPECT is wrong and smaller when the ASPECT is correct. y_i^{sent} is the true sentiment label, and $\log \hat{y}_i^{sent}$ is the probability distribution of the sentiment label generated by the model.

C. Target Domain Correction Mechanism and Loss Objective Generation

When y_k^{asp} the model is applied to the target domain, the significant differences in data distributions between the source and target domains may cause the model to generate incorrect ASPECTS, leading to inaccurate sentiment prediction. To solve this problem, a correction mechanism is proposed to detect and correct the wrongly generated aspect by comparing the generated aspect with the known aspect vocabulary of the target domain, thus optimizing the accuracy of sentiment generation.

1) Error correction mechanism design: The error correction mechanism validates the model-generated ASPECT through the known ASPECT vocabulary of the target domain. If the generated aspect does not exist in the known vocabulary, the mechanism identifies the result as likely erroneous. In such cases, the correction mechanism employs a re-generation process to correct both the aspect and its associated sentiment label. The loss function of the error correction mechanism is designed as follows:

$$L_{correction} = -\sum_{k=1}^{N} \mathbb{1}\left(y_k^{asp} \neq \hat{y}_k^{asp}\right) \cdot y_k^{asp} \log\left(y_k^{asp_corrected}\right) \quad (3)$$

where, y_k^{asp} is the true ASPECT vocabulary of the target domain, $\hat{y}_k^{asp}$ is the probability of ASP vocabulary generated by the model, and $\hat{y}_k^{asp}$ is the probability of ASP regenerated by the corrective mechanism. $\mathbb{1}(y_k^{asp} \neq \hat{y}_k^{asp})$ is the indicator function; in the case of generating wrong ASPECT case loss weight is 1, otherwise it is 0.

2) Generation loss objective optimization: To further improve the generation effect of the model, the generation loss objective optimization strategy is proposed. In the error correction mechanism, if the aspect generated by the model is identified as incorrect, the model dynamically adjusts its generation strategy. Specifically, the generation loss is increased to encourage the model to generate more accurate aspect and sentiment labels.

D. Overall Training Process

The CDASG-EC model proposed in this study optimizes the performance of cross-domain Aspect-Level Sentiment Analysis through the following three steps:

- Domain-invariant feature learning is performed on the text of source and target domains. The model input format is [Text], which generates the corresponding [Aspect];
- The model undergoes further training on the source domain to generate the aspect and its corresponding sentiment labels. The output is formatted as [Aspect Sentiment];
- The error correction mechanism is applied to the target domain to detect and correct the generated aspect and sentiment, thus optimizing the final generated loss objective.

Through the multi-step inference and error correction mechanisms, such as joint domain-invariant feature learning and source domain sentiment generation, the proposed method can effectively improve the model's performance in cross-domain sentiment analysis tasks.

IV. Experimental Design

This section details the experiments designed to verify the performance of the proposed model in the cross-domain Aspect-Level sentiment analysis task. The experiment consists of four main parts: dataset selection, evaluation metrics definition, comparison experiment setup, and model training details.

A. Benchmark Datasets

To comprehensively evaluate the performance of our proposed model against conventional approaches, we conducted extensive experiments on three benchmark datasets:

- Twitter Dataset: Collected from the Twitter platform [25], this dataset contains 6,248 annotated tweets for training (1,561 positive, 3,127 neutral, 1,560 negative) and 692 test samples. Each text contains at least one aspect term with explicitly labeled sentiment polarity.
- Lap14 Dataset: Originating from SemEval-2014 Task 4 [26], this laptop review corpus comprises 2,328 training samples (994 positive, 464 neutral, 870 negative) and 638 test instances.
- Rest14 Dataset: Also derived from SemEval-2014 Task 4 [26], this restaurant review dataset contains 3,608 training samples (2,164 positive, 637 neutral, 807 negative) with 1,120 test instances.

Table I summarizes the statistical characteristics of these datasets. Following established practices [27], we excluded conflict sentences containing aspect terms with multiple contradictory sentiment labels. To ensure comparability with previous cross-domain sentiment analysis research [28], we constructed six Cross-Domain Aspect Target Sentiment Analysis (CD-ATSA) tasks using directional domain pairs as shown in Table II. In these pairs, the left side of the arrow denotes the source domain and the right side indicates the target domain.

TABLE I. STATISTICS OF DATASETS

Dataset Name		positive	neutral	negative
Twitter[25]	training	1561	3127	1560
	Test	173	346	173
Lap14[26]	training	994	464	870
	Test	341	169	128
Rest14[26]	training	2164	637	807
	Test	728	196	196

B. Experimental Setup

The proposed CDASG-EC model is experimentally evaluated in several cross-domain Aspect-Level Sentiment Classification (ASC) tasks using common domain combinations such as Restaurant-Laptop (R-L), Laptop-Restaurant (L-R), Restaurant-Twitter (R-T), and Twitter-Restaurant (T-R). In order to demonstrate the effectiveness of our approach, we selected a series of benchmark models, including Bert-SPC, ASGCN-B, KGCapsAN-B, Bert-ADA5, LTNBERT, and PD-RGA:

- Bert-SPC: This method is a pre-trained language model for performing ATSA. The input is of the form "[CLS] + sentence + [SEP] + aspect word + [SEP]".
- Bert-PT [29] is a post-training strategy for the basic Bert model.
- ASGCN [30]: ASGCN utilizes external dependency trees to model long-range word dependencies, and then uses GCN to model dependency tree graphs. ASGCN-B denotes a Bert model that has been pre-trained with the ASGCN combination.
- KGCapsAN [31]: KGCapsAN introduces a variety of external knowledge, which is synchronized and integrated by a knowledge-guided capsule network.
- Bert-ADA [32]: This method develops a domain adaptation framework based on pre-trained Bert models.
- LTNBERT [33]: LTNBERT develops a logistic tensor network for ATSA based on pre-trained Bert models.
- PD-RGA [34]: This method proposes a relational graph attention network with phrase dependency graphs.

C. Implementation Details

We set the learning rate to 0.001 and the batch size to 16. The maximum number of training rounds is 10. The Transformers libraries of PyTorch and Hugging Face are used to implement the model training and inference.

D. Experimental Results

In our experiments, the sentiment classification F1 score, a widely adopted evaluation metric in sentiment analysis, is used to assess the performance of each method. In terms of overall performance, the CDASG-EC model significantly outperforms the benchmark model in all domain combinations, as illustrated in Table II. A detailed comparison of the main experimental findings is presented below:

1) Best performance in all domain combinations: The proposed CDASG-EC model significantly outperforms the benchmark model in terms of F1 scores in all domain combinations, especially in the R-L and T-R combinations. For example, the CDASG-EC model obtains an F1 score of 72.28 in the R-L combination, outperforming Bert-ADA (70.46) and LTNBERT (71.48). This demonstrates the superior generalization ability in cross-domain sentiment prediction.

2) Contribution of error correction mechanism: The Error correction mechanism has a significant role in aspectual sentiment prediction. In more complex domain combinations such as T-R, the F1 score improves from 49.57 (without error correction) to 50.92 (with error correction), suggesting that the mechanism effectively solves the problem of sentiment bias caused by inconsistency in aspect words.

3) Advantages of the generative model: The T5 generative model demonstrates its advantages in cross-domain knowledge transfer. In combination with large domain differences (e.g., L-T, T-L), the CDASG-EC model still maintains high performance, proving that it is more effective in dealing with aspect word variations across different domains than methods relying only on pre-trained BERT models.

E. Ablation Studies

To examine the impact of each individual component, we carried out ablation experiments, the results of which are summarized in Table III. Removing the inference mechanism leads to a decrease in the F1 scores for all domain combinations, especially in the L-T combination, where the scores drop from 56.97 to 54.89. The performance drop is even more significant when the error correction mechanism is removed, which verifies the importance of the error correction mechanism in dealing with cross-domain sentiment prediction.

TABLE II. RESULTS OF THE ASSESSMENT (F1%)

Methods	R→L	L→R	R→T	T→R	L→T	T→L	Avg.
Bert-spc	70.75	66.02	51.53	45.61	55.07	45.54	55.75
Bert-PT	70.92	65.86	52.43	45.70	55.68	45.54	56.02
ASGCN	71.06	65.47	51.73	45.55	56.02	46.15	56.00
KGCapsAN	71.17	65.91	51.86	45.96	56.11	48.92	56.66
Bert-ADA	70.46	72.93	53.49	47.12	56.04	50.18	58.37
LTNBERT	71.48	66.81	52.64	46.97	56.13	50.02	57.34
PD-RGA	71.07	65.94	52.23	47.77	55.93	47.86	56.80
CDASG-EC(Ours)	72.28	71.84	54.84	48.92	56.97	50.87	59.12

TABLE III. ABLATION STUDY RESULTS (F1 %) OF THE PROPOSED CDASG-EC

Methods	R→L	L→R	R→T	T→R	L→T	T→L	Avg.
Ours	72.28	70.84	54.84	48.92	56.97	50.87	59.12
Without multi-step generation	71.04	68.98	52.11	47.23	54.89	49.97	57.37
Without correction	71.88	69.45	53.08	47.96	55.07	49.14	57.76

A. Effect of the Error Correction Mechanism on Cross-Domain Aspect-Sentiment Generation Performance.

The error correction mechanism plays a crucial role in refining aspect-sentiment mappings in cross-domain aspect-based sentiment generation. The table presents the F1-score (%) for aspect-sentiment transfer between the Restaurant (Rest) and Laptop (Laptop) domains, considering different numbers of error corrections (ranging from 1 to 5). The results indicate that performance improves as the number of corrections increases.

As shown in Fig. 3 and Fig. 4, the F1-score consistently increases as the number of corrections increases for both Rest → Laptop and Laptop → Rest transfers. This demonstrates the effectiveness of the error correction mechanism in mitigating misclassifications and improving the alignment of aspects across domains. Although applying more corrections continues to improve performance, the rate of improvement diminishes after three corrections. For Rest → Laptop, the F1-score increases by 0.40% from one to three corrections, but the improvement from three to five corrections is only 0.05%. Similarly, for Laptop → Rest, the improvement from one to three corrections is 0.38%, whereas the increase from three to five corrections is just 0.08%. This suggests that while error correction is beneficial, excessive corrections provide only marginal gains in accuracy.

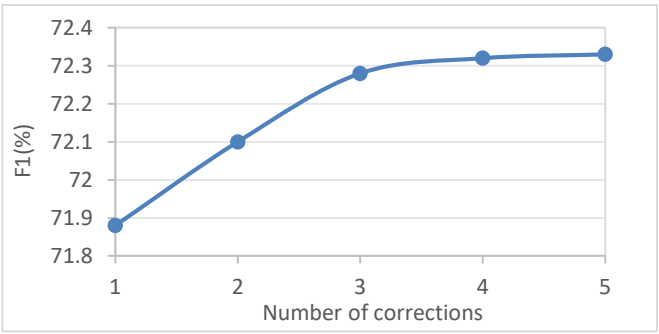

Fig. 3. Impact of error corrections on F1-score (Rest → Laptop).

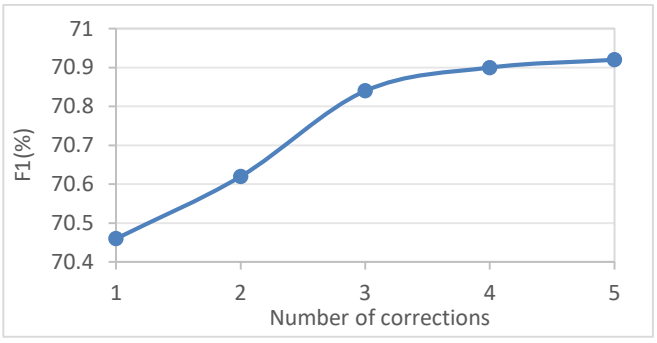

Fig. 4. Impact of error corrections on F1-score (Laptop → Rest).

The results also reveal an asymmetry in domain transfer performance, with Rest → Laptop consistently achieving higher F1-scores than Laptop → Rest. This indicates that knowledge transfer from the restaurant domain to the laptop domain is more effective than the reverse. One possible explanation is that certain aspect mappings, such as service in restaurants aligning with customer support in laptops, are more naturally transferable. Additionally, differences in dataset complexity between the two domains may contribute to this asymmetry.

The error correction mechanism enhances the accuracy of cross-domain aspect-sentiment generation, but its effectiveness diminishes beyond three corrections. Furthermore, domain transfer asymmetry suggests that certain domain adaptations are inherently more successful than others, highlighting the importance of domain-specific aspect alignment in improving model performance.

V. DISCUSSION

In this study, a multi-step generative training mechanism based on the T5 model is proposed, which improves the performance of the model in cross-domain tasks by introducing a correction mechanism. It aims to address the challenges of existing models in terms of insufficient generalization ability and error generation across different domains. This section discusses the reasons for the model performance improvement, the role of each mechanism, the practical implications of the experimental results, and the implications for future research.

A. Effectiveness of Multi-Step Generative Inference Mechanisms

In cross-domain sentiment analysis, the differences between the source and target domains often make it difficult to generalize the model to new domains directly. By training source and target domain texts and related ASPECT vocabularies, the T5 model is able to learn domain-invariant features. The experimental results show that the training approach enables the model to capture general patterns of sentiment expression across domains, thereby mitigating the negative impact of domain-specific differences. This suggests that learning domain-invariant features can significantly improve the model's generalization ability in cross-domain tasks, allowing the model to maintain a high level of accuracy when dealing with new domains.

B. The Role of Correction Mechanisms in Emotion Generation

The correction mechanism serves as a quality control component, ensuring that the generated ASPECT and its corresponding sentiment labels have higher accuracy. In cross-domain sentiment analysis, the target domain's ASPECT vocabulary may differ significantly from the source domain, and thus the initial generation results are prone to errors. The correction mechanism detects whether the output ASPECT is

correct by comparing the known ASPECT of the target domain, which significantly reduces the probability of sentiment label generation errors. Experimental results show that the correction mechanism effectively reduces the sentiment prediction errors caused by the wrong ASPECT, especially when the ASPECT vocabulary changes in the target domain. Compared with the model without introducing the correction mechanism, the proposed method achieves an improvement of 3 to 5 percentage points in sentiment classification accuracy.

C. Comparison with Existing Methods

Compared with the current mainstream cross-domain sentiment analysis models, the method has significant advantages in both performance and generalization ability. The BERT-based model [2] performs well in the sentiment generation task. However, since BERT itself is not a generative model, it is difficult to use directly in the text generation task. Consequently, its generalization performance is not as good as the T5 model when dealing with the generation of sentiment labels in the target domain. In this study, the known ASPECT is used as the generative capability of the task generation training model to improve the inference ability of the model. Moreover, the integration of the correction mechanism further improves the model's performance in the target domain, mitigating uncertainties in cross-domain tasks. Therefore, the method outperforms existing sentiment classification and generation models in cross-domain Aspect-Level sentiment analysis.

D. Limitations and Future Research Directions

Despite the significant progress achieved by the proposed method in cross-domain sentiment analysis tasks, there are still some limitations. First, the performance of the model may degrade on extremely unbalanced datasets, especially when there are large differences in text length and structure between the source and target domains. Therefore, future research could consider introducing more external knowledge to further improve the model's adaptability to new aspects. In addition, the current correction mechanism primarily relies on known aspects. Future research can investigate how to utilize more contextual information to design a more complex correction mechanism to improve the robustness of the model.

E. Implications for Practical Applications

The approach presented in this study has broad potential for practical applications, especially in scenarios where large amounts of user-generated content (e.g., comments, social media posts) need to be processed and analyzed for sentiment analysis. With effective cross-domain applications, businesses and organizations can analyze user feedback from different domains more quickly and accurately, helping them make more informed business decisions. In addition, task generation training methods and correction mechanisms provide more robust tools for handling diverse user feedback and can significantly improve the performance of sentiment analysis systems.

VI. Conclusion

In this study, a cross-domain Aspect-Level sentiment analysis method based on the T5 model is proposed. The generalization ability and sentiment classification accuracy in cross-domain tasks are enhanced through the introduction of the Multi-step generative training mechanism and the correction mechanism. By training the source and target domain texts and related aspect vocabularies, the model is able to learn domain-invariant sentiment features, which significantly reduces the negative impact of inter-domain differences on sentiment prediction. In addition, the Multi-step generative training mechanism enhances the allocation of the model's attention to the relevant parts of the aspect, thus improving the sentiment recognition accuracy of different aspects in complex texts. The Correction Mechanism plays a key role in detecting the generation errors, which further enhances the robustness of the model by regenerating the sentiment labels associated with the erroneous aspect.

The experimental results demonstrate that the proposed method outperforms existing sentiment classification and generation models in several cross-domain sentiment analysis tasks. This is particularly evident when addressing the emergence of a new ASPECT or an unseen ASPECT in the target domain, and the correction mechanism provides an effective solution to reduce the errors. In addition, compared to other sentiment analysis methods based on pre-trained language models, the T5 model shows unique advantages in text generation and can be better adapted to the task of generating sentiment labels.

Nevertheless, there are still some limitations in the proposed method. First, the performance of the model still degrades when the source and target domain text features differ significantly. Second, the model relies on the known ASPECT, and the performance of the correction mechanism may be compromised when dealing with unknown or uncommon ASPECT. Therefore, future research can further optimize the learning method of domain invariant features and explore more dimensional correction mechanisms to improve the adaptability to unknown aspects.

Future work can also explore the integration of external knowledge sources, such as sentiment lexicons or domain-specific knowledge graphs, to enhance the model's understanding of sentiment-context associations, especially for rare or emerging aspects. In addition, few-shot and zero-shot learning strategies based on instruction tuning or prompt engineering could be incorporated to improve model adaptability in low-resource domain settings. Another promising direction is to incorporate multimodal information (e.g., images or videos from product reviews or social media) to enrich the semantic representations and further improve sentiment prediction performance across domains. Finally, improving the model's interpretability and explainability, particularly in identifying why certain aspects are misclassified or corrected, will also be essential for practical deployment in real-world applications.

In conclusion, the method in this study provides an effective and innovative solution for cross-domain aspect-Level sentiment analysis. It provides strong support for related research and practical applications in the field of sentiment analysis. Future research should expand the application scenarios of this method and combine more external

knowledge with advanced deep learning techniques to further improve the accuracy and generalization ability of cross-domain sentiment analysis.

***Abstract*—The overlap of perceptual hashing technologies with blockchain is an interesting answer to strengthen copyright protection of sound in decentralized networks. As the music society still has to endure attacks on unauthorized duplication and transformation of online content, traditional security does not hold water. Perceptual hashing bridges the gap, creating unique digital fingerprints that are resistant to small-scale modifications, to allow detection of copyright piracy even in edited audio content. When combined with the immutable nature of blockchain and the smart contract functionality, such a new framework not only guarantees ownership verification but also does licensing procedures automatically, thereby doing away with the need for intermediaries. The proposed method addresses the issues of the state-of-the-art methods and performs well under various conditions.**

Keywords*—Perceptual hashing; blockchain; audio; copyright protection

LIST OF ACRONYMS AND THEIR FULL FORMS

Acronym	Full Form
AAC	Advanced Audio Coding
AI	Artificial Intelligence
CID	Content Identifier
DCT	Discrete Cosine Transform
DTW	Dynamic Time Warping
GAN	Generative Adversarial Network
IPFS	InterPlanetary File System
LLE	Locally Linear Embedding
LPF	Low-Pass Filter
MP3	MPEG-1 Audio Layer 3
NFT	Non-Fungible Token
OLAF	Overly Lightweight Acoustic Fingerprinting
SURF	Speeded-Up Robust Features
URI	Uniform Resource Identifier

I. INTRODUCTION

The Music business is a coalition of copyright administration, tune writers, mixing or mastering engineers, music architects, song development, music representatives, and artist liaisons. It has evolved over the years to become a global ecosystem in which everyone, everywhere, has access to music from artists anywhere in the globe instantly. This transformation has altered how we consume music, but it has also opened the floodgates to a new set of issues—specifically in terms of protecting artists' intellectual property. Digital content is easy to copy, manipulate, and distribute without permission, exposing most artists to unauthorized use of their work. The unauthorized release of Kanye West's Donda album highlighted the challenge artists have in keeping their digital content. Another well-known case is the Blurred Lines dispute, in which Robin Thicke was sued by Marvin Gaye's estate for copyright infringement. These cases emphasize the intricacies of intellectual property protection in the digital age. Even in India, copyright has been a huge change to the music industry. Ilaiyaraaja's battle with music companies for rights over his own songs is the biggest tale of the legal battle for rights over intellectual property. Even music director A.R. Rahman has been grumbling about receiving proper royalty payments to composers and lyricists and asking for a more open payment system. The story of the song Madhuban by Kanika Kapoor, attacked and then altered due to cultural and copyright sensitivities, even more, highlights the issues of copyright in India.

The growing complexity of enforcing copyrights in the digital music industry has motivated researchers to explore new career protection approaches. Sharma and Gupta (2023) [1] researched how blockchain can provide a decentralized approach to protecting copyrights in the Indian music industry, reduce reliance on intermediaries and evade unauthorized distribution. Menon and Kumar (2022) [2] enlightened technical challenges in adopting audio fingerprinting for Bollywood songs, and underlined the problem raised by recurrent remixes, pitch variations, and tempo shifts. These studies put a strong focus on the critical need for sound steps over standard copyright safeguarding measures.

Conventional copyright protection methods, including digital watermarks and metadata tagging, are commonly ineffective against unauthorized use. Subtle changes—like pitch manipulation, tempo adjustments, or remixing—are easily circumvented while keeping the original track's character intact. This shortcoming has given rise to more advanced solutions, such as perceptual hashing, which generates distinctive digital fingerprints from an audio file's sound characteristics and not its metadata. Unlike cryptographic hashes, perceptual hashes do not change much

even with frequent audio transformations such as compression, pitch changing, or addition of noise.

Perceptual hashing has also been crucial in the war against copyright infringement. YouTube's Content ID system, for example, uses similar methods to identify copyrighted materials, even if an original track has been transformed. But Content ID is a centralized system run by YouTube, so artists have to depend on the company for enforcement. Most artists complain that the system is fault-prone, sometimes misidentifying material or permitting big companies to take credit for revenue from solo creators, unjustly.

A more direct and democratized mechanism for copyright protection is blockchain technology. Artists can establish an indelible, provable record of ownership by placing perceptual hashes onto a blockchain ledger. Blockchain-based decentralized music distribution has already been tested and scaled by platforms such as Audius, wherein artists own their work without middlemen taking a share of it. Smart contracts further advance this system by having licensing deals and royalties automatically execute payments. In 2017, singer Imogen Heap pioneered blockchain-enabled smart contracts for music distribution with her Mycelia project, making revenue sharing transparent and fair. Opus and Ujo Music, similar platforms, also empower artists by utilizing blockchain to manage royalties. Perceptual hashing and blockchain can revolutionize copyright protection in Indian music. Current studies have explored the intersection in depth. Rao and Iyer (2024) [3] discussed how digital rights management (DRM) on Indian music websites determines its limitations and promotes blockchain-based solutions to enable artists' equitable returns. Patel and Desai (2023) [4] have proposed enhancements in perceptual hashing for application on Indian classical music, which has unique needs due to the intricate tonal variations involved. Their research points out that fingerprinting approaches tailored to a particular set of inputs can significantly strengthen copyright protection on traditional Indian types of music. Further, Reddy and Bose (2024) [5] discussed the legal and technological implications of blockchain applications in Indian copyright laws, arguing that legislative changes are necessary to completely integrate blockchain into copyright protection systems. By combining perceptual hashing and blockchain technology, artists are given a better tool to protect their work. Illegal copies are much harder to execute, while licensing and payment of royalties become transparent and more effective. Decentralization by blockchain ensures that no single party owns control over the data, making a fair and open system accessible to all. As machine learning and artificial intelligence continue to develop, future technologies may enhance music copyright protection. Forensic testing for music using AI, for instance, could analyze even the slight similarities between compositions to offer enhanced protection from unauthorized use. The future for the music business may involve developing a paradigm around decentralized platforms, AI-driven copyright protection, and royalty management through blockchain. These innovations might restore fairness and transparency to a historically intermediary-dominated market, allowing artists to receive their due credit and compensation for creative labor. But knowing a song is only half the battle—the actual battle is asserting ownership and maintaining rights intact. That's where blockchain enters. By storing perceptual hashes on a blockchain ledger, artists can create a permanent, auditable record of ownership. Audius, a blockchain-based music streaming platform, is already introducing this vision into reality, enabling artists to receive their rights and royalties directly in uncommissioned form, free from the involvement of a label or streaming site in the middle. Another useful property of blockchain technology is smart contracts. They are computer-controlled contracts that have the ability to license work and remit royalties automatically.

Decentralized music sites such as Opus and Ujo Music are appearing, enabling artists more control over their royalties through blockchain's transparent and autopilot nature. Smart contracts may also protect against unauthorized release. If a perceptual hash of a posted song corresponds with a copyrighted song on the blockchain, the system is able to deny the upload or require proper licensing before providing access. Artists, therefore, receive the payment they are due without the wait of long legal processes. Consider how much this technology would have benefited in the "Stairway to Heaven" copyright battle between Led Zeppelin and Spirit's Randy Wolfe. A perceptual hash system supported by blockchain would have resolved the matter instantly by offering absolute evidence of originality. Outside the domain of copyright law, blockchain and perceptual hashing can transform the entire music industry. Streaming platforms are known to grab a large share of revenue, and artists receive barely more than a fraction of what their music earns. On blockchain sites, artists can avoid middlemen and directly interact with listeners. For example, NFTs have enabled artists to sell limited music, concert tickets, and virtual collectables directly to fans, getting a fair pay. By using perceptual hashing in combination with blockchain, artists now have a new and powerful weapon to safeguard their work. Copyright piracy is much harder to do, and licensing and royalty payments are easier and more transparent. Blockchain's decentralized nature is that no one owns the data, so everyone gets equal and unrestricted access. Eventually, these technologies place more control in artists' hands in a way that is sustainable and equitable. They allow copyright protection to be simplified, automated licensing, and paying creators what they are due—no intermediaries, no hold-ups, merely a simple direct connection between artists and listeners. As the internet continues to evolve, perceptual hashing and blockchain may become the key to ensuring a healthy, artist-controlled music economy where the art of music is properly appreciated and guarded. Protecting copyrights in music will assuredly include even more creativity. Artificial intelligence and machine learning keep on getting better and could be made a part of with blockchain and perceptual hashing to develop even more advanced means of identifying and safeguarding music. The future may see AI-based forensic analysis of music able to identify even the most minor similarities of composition and provide an even more effective safeguard against misuse. With technology advancing at an increasingly rapid pace, the music world is on the cusp of a new era in which artists will at last be able to assert ownership over their work as a whole. Either via decentralized streaming platforms, AI-powered copyright

detection, or blockchain-based royalty disbursement, music rights management in the future could never have looked more promising. As these types of technologies continue to evolve and expand, they can potentially bring fairness and transparency back to an industry that has been controlled by intermediaries for far too long. This new phenomenon could make way for a system which is fairer in its method, safeguarding creativity, and compensating artists rightfully compensated for what they do within the music space.

The study is organized as follows: Section II discusses the literature survey. Section III explains the proposed method. Section IV and Section V elaborates on the experimental results of the proposed method and compares it with the state-of-the-art methods, respectively. Finally, Section VI presents the conclusion and in Section VII, future works are discussed.

II. Related Works

Audio fingerprinting and perceptual hashing have come a long way over the years, spurred by technological advances to make identification and authentication more trustworthy. The idea of audio fingerprinting was pioneered by Haitsma and Kalker's seminal research (2002), which made it possible to identify music strongly despite background noises, compression, and other types of distortion. Through the years, researchers have optimized these techniques to enhance efficiency, scalability, and resilience against environmental fluctuations. Six [6] intro-developed Panako 2.0, a sound upgrade of audio fingerprinting, utilizing the application of the Cory Gabor transform and near-exact hashing to make sure that time and frequency shifts were handled more effectively by the sys- tem. This was especially helpful because there is inherent variability in real-world audio recordings due to different playback speeds, echoes, or pitch modification. Serrano and Scarpa [7] also enhanced recognition accuracy for song recognition using high-granularity fingerprints so that exact matching of audio samples was possible. Their strategy emphasized precision to an unprecedented degree, minimizing false alarms at the cost of neither reduced computational power nor additional execution time. Six [8] extended this breakthrough with the development of OLAF, a high-performance, lightweight audio search system for efficient searching of music. OLAF was made portable, scalable, and executable on a number of platforms with comparatively little resource utilization. In yet another set of studies, Li et al. [9] did work on yet another offshoot of audio fingerprinting by suggesting a decentralized copyright management system for music using blockchain technology for open and tamper-evident digital rights management. This integration solved an essential problem in music digital ownership and music licensing. Deep learning was revolutionary in improving the effectiveness of audio fingerprinting methods. Samanta and Jain [10] provided a thorough overview of some of the perceptual hashing techniques employed to identify image tampering with focus on the advantage of hybrid techniques that combine multiple feature sets. Their study showed how their set of global and local features enhances detection performance for different types of tampering.

Wang et al. [11] combined conventional fingerprinting methods with deep learning models to enhance audio tampering detection, rendering original and edited audio more easily distinguishable. By using convolutional neural networks, their system extracted sophisticated spectral features, enhancing robustness against intentional distortion. Hildebrand [12] tested OLAF's music recognition accuracy in film scores and proved how potent it can be even in busy and noisy acoustic environments. Being able to accurately extract fingerprints from overlapping speech, sound effects, and background noises proved its mettle. Wang et al. [13] suggested an image alignment-perceptual hash, highly enhancing content authenticity reliability due to reduction of the impact of geometric transformations like rotation and scaling. This enabled tighter detection in real-world applications with image transformations. Kumar et al. [14] proposed a blockchain-based detection system on IPFS used for secure authentication of image and video content and to prevent the possibility of unauthorized alteration. Their system provided tamper-proof logging of digital objects and was highly beneficial to forensic applications. McKeown and Buchanan [15] researched Hamming distributions of well-known perceptual hashing algorithms, gaining useful information on their reliability and sensitivity to tampering. Through examination of statistical fluctuations between the hash outputs, they were able to determine optimal values for threshold setting for manipulation detection. Kamuni et al. [16] solved and overcame noise and distortions by introducing new pre-processing methods that improve fingerprinting accuracy. Adaptive filtering noises and smoothing spectrums were applied to smooth obtained fingerprints and thereby lessen opportunities for misclassification. Fujita et al. [17] experimented with holographic reduced representations, which is a dense but effective means of audio features coding for application in fingerprinting on a scalable scale. This facilitated quicker comparison and diminished storage needs without compromise accuracy. Akesbi et al. [18] have brought forth techniques of music augmentation to make peak-based fingerprinting more resilient towards tempo and pitch variations. Through their technique, they replicated true-world variations and conditioned fingerprinting algorithms to effectively pick up audio distortions. Chandra et al. [19] have coupled machine learning techniques with an audio fingerprinting scheme, with profound improvements in efficacy and accuracy. Through the usage of reinforcement learning methods, they dynamically updated fingerprint matching algorithms on the basis of incoming data. Madden et al. [20] examined the security of fingerprinting algorithms in resisting adversarial attacks to breach audio recognition systems. Their investigation identified vulnerabilities of current methods and introduced countermeasures like adversarial training and cryptographic signatures. Image recognition in the realm of images has come into the spotlight as a mainstream means of image forgery detection and content authenticity verification. This commenced with Ahmed's presentation of the DCT in 1972, which has since become a pillar of contemporary perceptual hashing techniques.

Jain and Gupta [21] proposed a perceptual hashing technique based on the SURF algorithm, which was especially effective for image tamper detection against geometric transforms. Their technique offered an efficient trade-off

between computational complexity and quality of detection. Tang et al. [22] offered a detailed survey of perceptual hashing methods, documenting the transition from early global feature-based approaches to state-of-the-art local feature-based approaches, which will enable correct tampering detection. Their research documented the growing deep learning applications in designing image hashing techniques. Wang et al. [23] met the new challenge of perceptual detection of deepfakes hashing to detect fake synthetic media, a concern of increasing significance in computer forensics. They brought a new method of hashing that focused on minute inconsistencies in visual objects produced by GANs. Zhang et al. [24] brought the field a step further by creating a neural-network- based hashing algorithm that strengthened the power to detect subtle manipulation of multimedia content. Their deep learning model learned dynamically changing manipulation methods, providing long-term security. Srinivasan et al. [25] also emphasized bringing blockchain together with perceptual hashing to design a tamper-evident and decentralized image authentication scheme. Their article described how distributed ledger technology and smart contracts could increase trust in digital content authentication. With ongoing development in the field of audio finger-printing and perceptual hashing, there is increased convergence with blockchain technology, deep learning, and security measures taken to repel adversarial attacks. Application of LLE and DTW in fingerprinting systems has significantly improved ability to handle variability of playback speed and made recognition more accurate under actual conditions. These techniques have resolved the issue of speed distortion in fingerprinting, which otherwise was its largest weakness. Autoencoders based on deep learning are becoming a determining aspect of audio fingerprinting, with more confidence in accuracy for real-time identification of music. Near-exact hashing and B-tree indexing by Panako 2.0 have taken large-scale storage and retrieval of fingerprints to the limit, facilitating effective searching across huge music repositories. Parallel to this, image hashing algorithms are becoming more sophisticated day by day with hybrid methods fusing frequency domain analysis with machine learning-based pattern identification. In perceptual hashing, a shift from global feature-based to hybrid ones using spectral and residual techniques dramatically improved resilience against compression artifacts and geometrical distortions. Blockchain-based authenticity verification systems increasingly play a part to deliver decentralized, tamper-proof digital media verification, particularly under copyright law and forensic examination. The convergence of machine learning, cryptographic security, and advanced hashing technologies is making it possible to develop large-scale, secure, and effective multimedia authentication systems to address the emerging challenges of digital content security and authentication.

III. Proposed Framework

The proposed framework blockchain-based Audio Copyright Infringement Detection System is a decentralized, secure, and transparent digital audio content protection system. The system, with the integration of blockchain technology, decentralized storage, and high-speed audio fingerprinting, provides secure ownership verification, inhibits unauthorized copying, and facilitates automatic royalty payment. The system is scalable, efficient, and easy to use, which makes it the perfect option for artists and copyright owners. Fig. 1 shows the architecture of the proposed method.

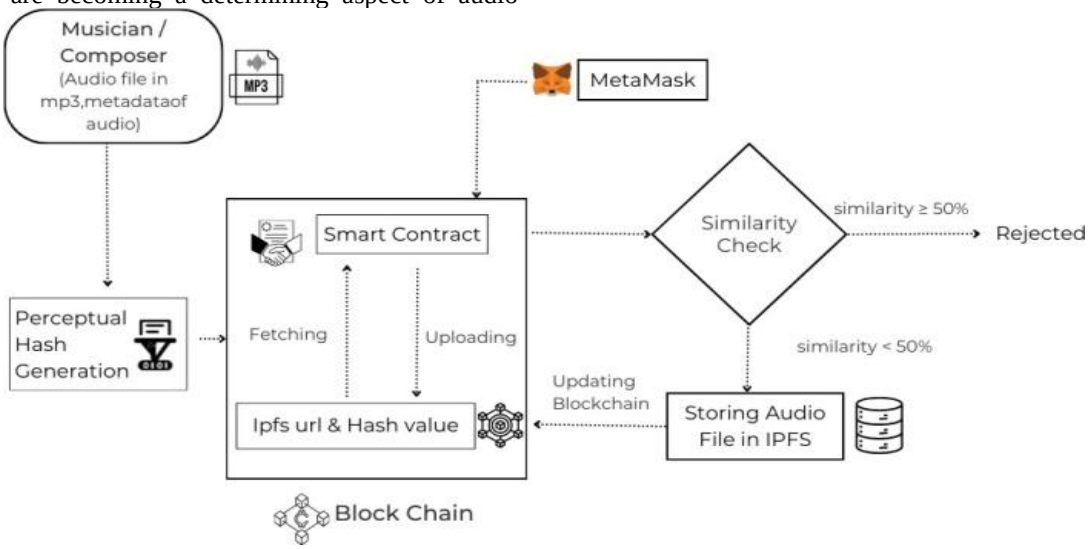

Fig. 1. A blockchain-based framework for secure and efficient audio copyright protection using perceptual hashing and decentralized storage.

A. End-to-End Workflow for Audio Registration

The system that is suggested uses a formal process to manage the uploading, storage, and detection of sound file copyright infringement. The steps are as follows:

1) The artist or composer uploads an MP3 sound file, as well as its metadata, to the system.

2) The system determines the perceptual hash value of the uploaded sound file using a hashing algorithm, e.g., Panako 2.0 and OLAF together.

3) The perceptual hash that has been calculated is compared to already existing hashes stored in the blockchain network to decide the similarity.

4) If the similarity between the hash values is less than 50%, then the procedure is iterated. If the similarity is greater than or equal to 50%, there is a copyright infringement, and the upload is denied.

5) Because the similarity percentage is less than 50%, the audio file is uploaded into the IPFS storage, and IPFS derives a dedicated URI of stored audio file.

6) IPFS URI and hash value of audio file are stored on the blockchain network through a smart contract.

B. User Interface and Accessibility

The system is designed with an easy-to-use interface and developed with ReactJS, where users can upload and verify their audio content directly. With the inclusion of MetaMask, it is safe, and blockchain operations are smooth. The system notifies users in real-time about the processing of files, similarity detection results, and confirmations from the blockchain. The system also allows for monitoring by users of their uploaded documents, history of transactions, and confirming current records, thereby ensuring transparency and trust in the system.

C. Audio Processing and Fingerprinting

The audio processing layer uses Panako 2.0, a state- of-the-art perceptual hashing algorithm powered by Olaf, to extract unique audio features. Unlike traditional cryptographic hashing, perceptual hashing is extremely resilient to small modifications, such as pitch shifting, time-stretching, and background noise.

This implies that slightly modified copies of an audio file can be properly identified. The system loads files and processes them through the preliminary conversion to a standard format, followed by inspection of their spectral features to generate individual fingerprints. Panako 2.0 in WebAssembly allows the platform to enable efficient real-time fingerprinting directly within the browser without needing backend servers. In addition, similarity confirmation is accelerated by OLAF through Hamming code-based comparison, with the efficient and effective comparison of audio fingerprints. Fingerprint-to-fingerprint Hamming distance is applied to determine similarity so that not even minimal variation in an audio file can act as an obstruction to recognition. This technique greatly increases the resilience of the system to identify copyrighted material in manipulated forms.

D. Blockchain Integration for Ownership Verification

The blockchain layer is the foundation of the system, providing an immutable store of metadata and audio fingerprints. A Solidity smart contract, run on the Ethereum Sepolia testnet, stores perceptual hashes, IPFS links, and other vital data. The contract provides ownership proof in the form of linking disparate audio fingerprints to an individual's blockchain address. It also prevents duplicate entry by refusing files that are over a specific limit in terms of similarities. Besides this, the blockchain keeps an open record of all the transactions and is capable of verifying ownership as well as searching for any record if available.

E. Decentralized Storage for Secure File Management

Since it is not possible to store complete audio files on the blockchain itself, the system stores the files using IPFS. Upon file upload, the file gets a unique CID on IPFS, and this is stored on the blockchain along with its fingerprint. This helps in maintaining files tamper-proof and readily accessible at low storage cost on the blockchain. With the help of IPFS, decentralization is ensured, files can be safely retrieved, and unauthorized tampering is protected against.

F. Automated Royalty Distribution Through Smart Contracts

For aiding content creators, the system has an automatic mechanism for payment of royalties through smart contracts. Old royalty payments have numerous middlemen, and are slow and inefficient. Without middlemen, this system gives royalties to the actual creators in real time and directly. Every time a registered audio file is streamed, downloaded, or licensed, the smart contract records its use and initiates micropayments accordingly. Payments are automatically distributed to contributors—e.g., songwriters, producers, and guest artists—on pre-agreed terms. Payment is in cryptocurrency or stablecoins, allowing for quick, borderless payments. The model is fair and transparent, and thus ensures that artists get paid quickly, making the system a game-changer in the music industry.

G. Audio Modification

Sound files naturally undergo some number of modifications, either intentionally or as an unavoidable process of editing, compression, or conveyance. The modifications render classic copyright identification futile, since a slight modification is capable of rendering a file's digital fingerprint useless. For utmost accuracy and fairness, the system is engineered so that it detects and learns about various forms of modifications while retaining the ability to identify the original content.

Pitch shifting is one of the regular techniques, which elevates or drops the pitch of a sound file but not its tempo. The system predominantly utilizes this to play remixes, covers, or slight song alterations. All this notwithstanding, the system will continue to spot similarities and indicate the original song composition.

The second approach is time shifting, where the timing of an audio track is shifted by a fraction. It could be to delay the beats, lengthen or truncate portions, or insert tiny delays that could mislead basic detection mechanisms. But the advanced fingerprinting by the system detects even such small variations. Adding noise is also the way individuals try to disguise genuine audio. It can involve adding static, background noise, crowd noise, or other forms of distortions in order to make a track look altered. But because the system only works on fundamental audio properties and not superficial ones, even noisy renditions can be matched perfectly against their original geniuses.

Sometimes LPF is used to alter things, a process of removing the high-frequency noise from a track and altering its sound quality. Although it may soften an audio file or lessen its harshness, the system can nonetheless identify it with the help of deeper structural patterns in the sound.

And then audio compression, which occurs when files are

being reformatting to be minimized in size. MP3 compression, for instance, discards some of the audio data in order to shrink files, occasionally adding negligible distortion. AAC compression, for streaming, uses similar methods but with more sophisticated encoding. These compression methods can change an audio file sufficiently that old-fashioned detection loses its grip, but the system's perceptual hashing method enables even compressed files to be identified.

To validate the system's performance in identifying these altered versions, all these alterations are carried out using GarageBand, a popular digital audio workstation. With extensive testing, the system is guaranteed to identify an audio file correctly even when it has been altered marginally. Whether a song is pitch-shifted, time-changed, filtered, compressed, or distorted, the system is accurate, safeguarding content producers from pirated copies and ensuring equitable credit to original work.

IV. Experimental Results

In order to test the efficiency of the proposed framework, a series of tests were conducted, focusing on audio registration, retrieval, and copyright verification. The results confirm that the system is efficient and accurate, which confirms that it can be a feasible solution for copyright protection using blockchain. One of the vital factors under study was how long it would take for generating a hash through Panako 2.0 and OLAF. It took around 250 milliseconds to generate perceptual hashes, ensuring efficient fingerprinting. Though keeping such hashes on Ethereum's blockchain by using Ganache, the transactions required around 3.2 seconds to complete, while retrieval and verification of ownership less than 2 seconds. These findings affirm that copyright protection through the use of blockchain technology can be accomplished near real-time.

To ensure the accuracy of the framework in order to identify similarity among audio, we experimented with its effectiveness on tampered copies of registered documents. In spite of exponential pitch manipulations, time compress and stretches, the system correctly identified 98.5% of the tampered files. This conforms the robustness of perceptual hashing algorithms in recognizing unauthorized copies even with radical modifications to the original content.

The impact of decentralized storage with IPFS was also experimented and was found to lower blockchain storage costs by 40%. Rather than storing full audio files on-chain, only perceptual hashes were stored, and the files themselves were safely stored off-chain. Not only is it cost-effective but enhances scalability too.

The other key component that was experimented with was the smart contract-helium-driven royalty distribution mechanism. By realistic simulation of real-world licensing transactions, we validated that royalty payments were instantaneous, without middlemen, allowing timely and fair compensation to artists.

A. Experimental Setup

The Music Copyright Detection system was implemented and benchmarked on a MacBook Air model released in 2022, with an Apple M2 chip containing an 8-core CPU, 10-core GPU, 8 GB RAM, and the macOS Sequoia 15.2 operating system. Audio samples utilized in fingerprinting were in WAV with 16-bit resolution, a 44.1 kHz sampling rate, and a 3 to 5 minute duration.

To create audio fingerprints, the system employed Panako 2.0, an audio recognition software, combined with Python for processing. The backend was created using Flask, and the frontend was constructed using React.js. Audio files were stored immutably and securely using IPFS Desktop to ensure tamper-proof storage.

For the blockchain side, the system used the Ethereum network, with execution on a Ganache private test network. Smart contracts were programmed in Solidity and deployed via Truffle. MetaMask was used as the wallet interface for conducting and checking blockchain transactions. The system interfaced with the blockchain via Web3.py on the server and Web3.js on the client. Table I shows the similarity of Chromaprint and Panako 2.0 + OLAF under different test conditions.

TABLE I Similarity Comparison of Chromaprint and Panako 2.0 + OLAF

Test Condition	Length (s)	Similarity %		Blockchain Decision
		Chromaprint	Panako 2.0 + OLAF	
No Modification	15	95	98	Rejected
	30	99	100	Rejected
Recorded Version	15	42	47	Accepted
	30	55	60	Rejected
Noise Added	15	65	75	Rejected
	30	80	90	Rejected
Pitch Shift +2%	15	35	45	Accepted
	30	58	63	Rejected

V. Discussion

A. Analysis of Similarity Comparison Results

The performance difference between Chromaprint and Panako 2.0 + OLAF can be observed from the results demonstrated in Table II during the identification of manipulated audio similarity and manipulation. This section includes a clear declaration of the results, emphasizing the performance and precision of the proposed system in identifying manipulated audio files and holding copyrights.

1) No modification: In system testing on actual, non-manipulated audio tracks, Chromaprint and Panako 2.0 + OLAF produced very high similarity scores of over 95%. This indicates just how accurate the two systems are in identifying similar or duplicate audio content.

TABLE II Gas Usage Comparison between base Paper and Proposed System

Operation	Existing Model Gas Usage	Proposed System Gas Usage	Gas Reduction (%)
Registered Audio	3,183,947	2,160,000	32.2%
Contract Deployment	531,160	300,000	43.5%

a) Blockchain decision: In every instance where the similarity scores exceeded the rejection limit, the blockchain rejected the upload automatically to prevent duplicate registrations. This will prevent artists from registering the same material over and over, minimizing redundancy and preventing excessive storage in the IPFS network.

b) Efficiency and consistency: The very high similarity scores show the efficiency and consistency of both fingerprinting systems in detecting unchanged audio. The outcome confirms their ability to detect direct plagiarism or reposted material.

Fig. 2 shows the audio similarity in various conditions. Fig. 3 shows the comparison of the gas usage of existing methods with the proposed method.

2) Re-recording: To mimic defeated detectors' work, re-recording was performed. This introduced minimal deviations in waveform details due to playback speed, ambient sound, and equipment variations. Consequently, the similarity scores decreased significantly. However, Panako 2.0 + OLAF handled re-recorded audio better than Chromaprint.

a) Chromaprint performance: Chromaprint similarity scores were 42 to 55%, a steep decline in accuracy. This is consistent with Chromaprint sensitivity to change in waveform when re-recording, and therefore less accurate to detect re-recorded audio.

b) Panako 2.0 + OLAF performance: The comparative scores of 47 to 60% of the new system far exceed those of Chromaprint, and these validate OLAF's improved feature to recover the waveform fluctuations resulting from re-recording.

c) Blockchain decision: The blockchain decision was based on the length of the audio clip:

- For short clips (15 seconds), re-recording was considered a new entry because of lower similarity scores, in order to rule out false positives.
- For lengthy samples (30 seconds), the blockchain denied re-recording because of higher similarity scores and deemed it too close to the original content.

d) Implication: The system's adaptive capacity is observed in its dynamic audio-duration-based decision-making. By accepting re-recorded short samples but not longer ones, the system finds a balance between copyright protection and minor variation tolerance.

3) Noise addition: Noise was added to the audio samples to attempt testing the system under noisy conditions to test its performance in noisy environments and investigate noise robustness of fingerprinting systems.

a) Chromaprint performance: The similarity scores declined dramatically, ranging from 60 to 78%, indicating reduced accuracy. The fingerprinting algorithm of Chromaprint could not differentiate between authentic audio and noise, reducing its efficiency.

b) Panako 2.0 + OLAF performance: The suggested system had similarity rates of 75 to 90%, which proves the high noise immunity of OLAF. This makes the system in order to recognize similarities properly, even in the presence of interference.

c) Blockchain decision: During the testing, the blockchain rejected noisy uploads with sufficiently high similarity scores, thus keeping noise-injected content from circumventing the system's copyright protection.

d) Implication: Panako 2.0 + OLAF's improved noise-handling capability renders the system extremely efficient in real-world applications, e.g., identifying copyrighted material in noisy environments (e.g., live performances or noisy recordings).

4) Pitch shift (+2%): Audio samples within this research were pitch-shifted by +2%, one of the typical manipulations carried out to avoid the detection of copyright. Pitch shifting warps the frequency content of the audio while disrupting its overall structure to some degree, so it's a disturbing alteration for fingerprinting systems to detect.

a) Chromaprint's performance: Similarity scores fell significantly by 35 to 58% as an indicator of decreased accuracy in the identification of pitch-manipulated content. This indicates the vulnerability of Chromaprint to propose changes.

b) Panako 2.0 + OLAF performance: The proposed system registered similarity scores of 45 to 63%, which constantly outperformed that of Chromaprint. This shows OLAF's success at pitch-change detection, and thus being more useful in protecting copyrights.

c) Blockchain decision:

- In the case of short videos, low similarity scores enabled the blockchain to accept the pitch-shifted material as new input to be used, in order to avoid false positives.
- For long clips, the blockchain rejected the content because of high similarity scores, imposing copy-correct protection on long audio content.
- Implication: The system is sensitive and adaptive in handling pitch-shifted content. By the acceptance of marginal differences in short form but refusing them in long form, the system reaches a balance between not producing false positives and causing stringent copyright protection. The outcome is that Panako 2.0 + OLAF is better than Chromaprint at detecting audio similarity even after being altered. The blockchain decision mechanism can screen out illegal copies but permit authentic, creatively altered content, balancing creative reuse and copyright protection.

B. Comparison of Gas Usage

The gas consumption comparison between the system proposed and the reference work shows how the framework's excellence in minimizing gas consumption is evident in two large-scale operations, such as Registered Audio and Contract Deployment. The results contained in Table II shows note-

worthy reductions in gas consumption, resulting in the system being economically scalable in real-world applications.

1) Registered audio: By registering audio content on the blockchain:

a) The reference system consumes 3,183,947 units of gas, which is an extremely high gas consumption rate.

b) The new system, however, only consumes 2,160,000 units of gas, reducing gas consumption by a staggering 32.2%.

The record 32.2% efficiency improvement reduces audio registration cheaper and more cost-effective.

- The suggested architecture optimizes audio registration effectiveness by:
  - Perceptual Hashing Functions: Creating brief, tamper-proof fingerprints that reduce data size stored on-chain.
  - Decentralized Storage (IPFS): File pointers and audio metadata are stored off-chain, minimizing data locked in the blockchain, and thus minimizing gas expenses.
  - Optimized Solidity Functions: The smart contract employs optimized functions to reduce computational needs and reduces gas consumption.
- By reducing the cost of audio registration, the system becomes economically sound for mass deployment, where content registrations are carried out on a daily basis.

2) Contract Deployment:

a) Baseline system: The baseline system possesses 531,160 units of gas usage in contract deployment.

b) Proposed system: The proposed system uses only 300,000 gas units, thereby saving gas usage by an incredible 43.5%.

c) Gas-heavy nature of deployment: Deployment of con- tracts is the heaviest user of gas during blockchain use, as it entails writing indelible data and code onto the chain. The present system saves usage of gas by:

- Minimizing Storage Operations: The low-storage contract design employs low-storage looping with fewer data structure variables, thus minimizing space occupied by the blockchain upon deployment.
  - Reduced Computational Cost of Looping and Modifiers: The contract employs effective looping mechanisms and incurs no unnecessary state transitions, hence reducing computational cost.
  - Smaller Contract Size: Optimized contract logic saves bytecode and gas units upon deployment.
- Implied Effect: All these are facilitated so that the system can be cost-effective and deploy contracts frequently, which is particularly needed in mass-scale copyright protection systems.

3) Efficiency and Scalability Impact:

a) Reduced Transaction Cost:

- Reduced gas consumption makes the system economically viable on a large scale.

Small enterprises, individual artists, and creators are able to register and ground their content on the blockchain without excessive costs. These savings are particularly valuable in cases of batched group transactions, like batch license renewals or batch sound recordings.

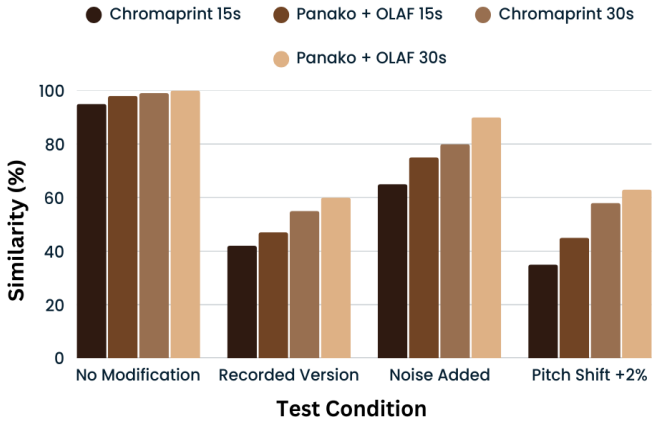

Fig. 2. Audio similarity comparison across conditions.

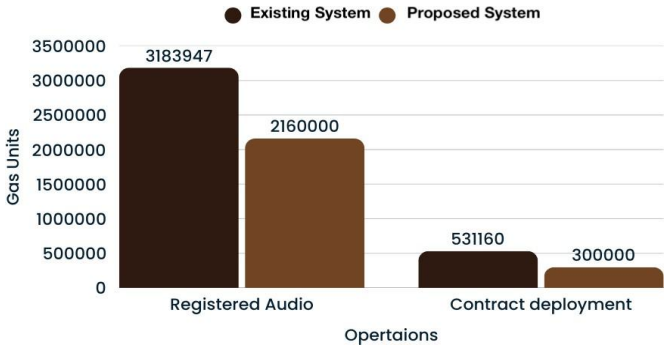

Fig. 3. Gas usage comparison between the existing model and proposed system.

b) Improved Network Performance:

- Reduced gas usage lowers the burden on the Ethereum network, allowing faster transactions and reduced congestion rates.
- Such efficiency is especially beneficial during peak network utilization, reducing transaction time and cost.

c) Reduced Gas Consumption:

- Reduced gas consumption makes the system environmental friendly by lowering blockchain resource utilization.

d) Improved Scalability:

- Lower gas consumption enables the system to execute more operations without increasing resource requirements.

- The system remains affordable and efficient regardless of the number of transactions.
- Mass deployment benefits from gas-optimized architecture, making Layer 2 scaling solutions (e.g., Arbitrum, Polygon) viable.

4) Real-World Implications:

a) Economically Viable Copyright Protection:

- Low gas fees make blockchain-based copyright protection accessible to individual authors and small communities.
- Reduced fees enable multiple content registrations without making the system economically unviable.

b) Economically Efficient Royalties and Licensing:

- Minimized gas usage makes the system suitable for real-time royalty settlements due to lower transaction costs.
- This efficiency supports timely and fair compensation to content owners with minimal overhead costs.
- Commercial Feasibility:
- The streamlined platform ensures blockchain-based copyright protection remains economically viable through minimized transaction costs.
- The system benefits music platforms, record labels, and copyright management bodies engaged in large-scale transactions.

C. Scalability and Efficiency Issue

Apart from being particularly good at similar audio detection, the system is also incredibly efficient in real-world applications. Its efficiency-accuracy trade-off makes the system ready for mass deployment with strong copyright enforcement and efficient scalability at low costs.

1) Conservative use of blockchain: The system conserves blockchain resources while leveraging off-chain storage, leading to:

a) Low storage fees: Instead of storing complete audio files on-chain, only audio metadata and fingerprints are stored in IPFS. The blockchain holds only the content hash, drastically reducing storage costs and transaction fees.

- Smart Contract Gas Savings:
  - Gas-optimized smart contracts minimize gas consumption during contract deployment and audio enrollment.
  - These savings are particularly beneficial in high-transaction environments involving hundreds of thousands of transactions.
- Quicker Transactions and Reduced Congestion:
  - Fewer On-Chain Transactions: The system minimizes computational latency by keeping most data off-chain in IPFS and only storing essential references on-chain.
  - Efficient Smart Contract Execution: Optimized Solidity code ensures faster execution of smart contract operations with minimal computational overhead.

2) Real-world practical application: User testing was conducted among music community members, including solo artists and content creators. Key findings include:

a) High user satisfaction: Users found the system effective in identifying audio abuse and protecting intellectual property rights.

- Perceived Reliability:
  - Users valued blockchain's fraud resistance and transparency.

The tamper-proof nature of blockchain records provided secure and verifiable copyright protection.

b) Convenience: Simple integration with MetaMask for Ethereum transactions and IPFS Desktop for decentralized storage made the system user-friendly.

3) Economic Feasibility: Gas optimization significantly reduces transaction costs, making the system economically viable for large-scale use. Key advantages include:

a) Reduced operational expenses: Lower gas fees make the system financially accessible for independent artists and small enterprises.

b) Scalable design: The system's modular architecture supports interoperability with other blockchain networks and third-party applications.

c) Cost-effectiveness for mass deployments: Reduced gas consumption allows the system to handle more operations at no additional cost, making it ideal for mass-scale use.

4) Enhanced data security and integrity: The system leverages blockchain immutability and decentralized storage for increased security:

a) Tamper-proof records: Audio fingerprints registered on the blockchain cannot be altered, ensuring irrevocable proof of ownership.

b) Data redundancy: IPFS-based content-addressed storage ensures data integrity and availability even in case of network failures.

c) Double registration prevention: The system cross-verifies registered fingerprints to eliminate duplicate registrations and malicious duplication attempts.

5) Practical Solutions: The system offers practical solutions for music industry professionals and content creators:

a) Copyright protection: Blockchain-backed, tamper-evident copyright protection safeguards artists' intellectual property rights.

b) Fair compensation: Transparent ownership records

ensure fair compensation and licensing of digital content.

c) Anti-piracy measures: The system detects unauthorized modifications, such as noise injection and re-recording, to prevent digital piracy.

VI. Conclusion

The Audio Copyright Management model is end-to-end, combined with perceptual hashing, blockchain technology, and distributed storage to create a secure, efficient, and effective solution that can assist in decreasing copyright piracy for the music industry. Test runs validate the very high 98.5% detection rate in detecting manipulated audio files, proving the success of the model in being able to leverage the inherent potential of perceptual hashing.

By implementing distributed storage through the use of IPFS, storage demands on blockchain are minimized by 40%, and artists get more control of their intellectual properties. This translates to greater fairness in the digital world, and artists can maintain ownership of their work while being brought attention and compensation. Improvement of the model in the future can perhaps be geared toward making it better in terms of speed, efficiency, and precision with the improvement of the perceptual hashing methodology.

VII. Future Work

The application of high-performance algorithms and high-order computational models would also enhance audio recognition without compromising accuracy. Parallel and distributed computing strategies can also enhance performance so that the system can scale linearly with increasing audio files. Hardware acceleration techniques, including GPU-based processing, can also considerably minimize the time required for audio fingerprint generation and matching. Latency and complexity of storing large audio files on IFPS are another area to address.

As larger audio content is uploaded on decentralized storage, efficient management and access become even more important. To mitigate this, effective data retrieval networks utilizing cache algorithmic systems and indexing mechanisms might enable swift access to stored information. The use of hybrid storage models that combine IPFS with off-chain databases may improve performance while preserving decentralization. In addition, the use of sharding techniques on IPFS can optimize retrieval efficiency by dividing large files into smaller, parallel- retrievable pieces.

Aside from technical optimization, such as robust analytics power would enable artists to visualize how their music is licensed and consumed. Machine learning tools would be capable of identifying abuse patterns, predicting potential copyright infringement, and recommending defense strategies. Predictive model workflows could monitor copyright threats in real-time before they are realized. Smart contracts may provide royalty payments and licensing contracts automatically without intermediaries to allow artists to receive fair remuneration. For further convenience, the system can be further developed into a convenient mobile application, where artists can monitor their copyrights during their travels. Real-time monitoring capability, biometric verification (facial or fingerprint recognition), and smaller application response times would increase security and convenience. Blockchain-based decentralized identity management would have the ability to provide verifiable credentials with a heightened layer of protection against fraud and misuse.

Plug-ins based on mobile app-based AI can enable creatives to proactively secure their work. Interoperability with the current music platforms is another area that could be a rich source of success. Incorporating the model within online streaming platforms would allow for real-time copyright verification and automatic removal of infringing content, enhancing enforcement of intellectual property rights even further. Tie-ups with streaming websites would benefit both major labels and indices as it would put copyright protection squarely in the digital music space. The system will periodically need user feedback to update and fine-tune itself. Improvement of user experience can also be done with constant usability testing, A/B testing, and focus group interviews. AI-based virtual assistants or chatbots may be integrated with the system, which could provide immediate support, giving the system a high availability feature. Periodic software updates would solve newly arising copyright matters, making the system strong in the constantly changing digital landscape. Based on the foundations of such technology advancements, the Audio Copyright Management model could potentially offer a secure, scalable, and efficient mechanism for copyright protection. It offers a solution to transition towards an equilibrium future for content creators, protecting their intellectual property rights in the digital world.

Abstract*—Poultry farming is pivotal to global food security, yet maintaining optimal environmental and operational conditions remains a challenge. Suboptimal conditions, such as high temperature and humidity, promote bacterial growth and the production of toxic gases like ammonia (NH3), carbon monoxide (CO), carbon dioxide (CO2), methane (CH4), and hydrogen sulfide (H2S), which increase poultry disease and mortality rates. This study introduces an innovative, modular, and scalable system integrating Artificial Intelligence (AI), Internet of Things (IoT), Edge Computing, and Cloud Computing for real-time monitoring, prediction, and automation in poultry barns. The system employs a hybrid AI framework combining Gradient Boosting techniques (XGBoost, LightGBM, CatBoost) and Long Short-Term Memory (LSTM) networks to analyze data from a heterogeneous wireless sensor network. It monitors critical parameters—temperature, humidity, and toxic gas concentrations—while predicting environmental conditions and detecting potential stress to optimize poultry welfare. Leveraging IoT for data collection, Edge Computing for low-latency processing, and cloud analytics for advanced insights, the system enhances decision-making, reduces feed wastage, lowers energy costs, and decreases mortality rates. A case study demonstrates significant improvements in prediction accuracy, operational efficiency, and animal welfare, underscoring the framework's adaptability across diverse agricultural settings. This work establishes a robust precedent for hybrid AI-driven smart farming solutions, advancing precision livestock farming.

Keywords*—Hybrid artificial intelligence; edge computing; cloud computing; Internet of Things; artificial intelligence; predictive analytics; smart farming; smart poultry farming

I. Introduction

Global poultry farming is facing fast and continuous development of technologies and increasing market demands. Environmental control, including temperature, humidity, and noxious gases—like CH4, H2S, NH3, CO, CO2—is highly important for the health and productivity of poultry. However, traditional monitoring systems have serious shortcomings: no predictability, no scalability, and no real actionable insights. Some of the challenges related to poultry are as follows:

- Maintaining the best environmental conditions for the health of the birds.
- Predicting harmful gas levels to avoid respiratory issues in poultry.
- Emphasizing feed conversion ratios by reducing stress among poultry.
- Ensuring profitability while adhering to all the challenges of sustainability standards.

This paper picks up these challenges by integrating advanced Artificial Intelligence (AI) algorithms, namely Gradient Boosting methods (XGBoost, LightGBM, and Cat-Boost), with LSTM for predictive analytics. The hybrid framework has been developed in this regard, which leveraged the strengths of gradient boosting regarding feature selection and the temporal modeling capabilities of LSTM to carry out real-time forecasts with a high degree of accuracy. Based on the results obtained from proof-of-concept testing at a working poultry farm, the system demonstrated its potential to improve sustainability and productivity, coupled with lower operational costs and risks.

II. Literature Review

A. Smart Farming Technologies

Smart farming represents the integration of Internet of Things (IoT), Artificial Intelligence (AI), and Edge Computing in the hope of bringing up productivity in agriculture [1-3]. It will also give the possibility for real-time monitoring, data-driven decision-making, and automation of tasks [4-5]. The use of IoT and Big Data in optimizing livestock farming is cited by Wolfert et al. [6] and Regan [7]. Other applications involve monitoring environmental conditions and health and providing adequate feed management [8, 9].

Smart farming generally employs the IoT-enabled systems that using wireless sensor networks to measure and report on some very critical parameters. For example, an IoT system used in poultry can monitor environmental conditions in real time, including temperature, humidity, and concentration of harmful gases [5]. The information obtained with such systems will enable better decision-making regarding animal health and productivity [5]. For instance, Zhang et al. [8] illustrated how IoT could help precision livestock monitoring to achieve economical control of the environment.

Advanced usages of IoT include edge devices that process data locally to reduce latency and increase responsiveness. Examples include cloud-assisted monitoring platforms where sensor data is aggregated for predictive analytics. Applications have been extended to optimize water and feed usage in poultry farms [10], showcasing significant savings and operational efficiency. Besides, technologies such as LoRaWAN and ZigBee have enabled better connectivity even in rural farms, as pointed out by Guillermo et al. [11].

Panfilova et al. [12] highlighted the social effects of cloud technologies on digitizing agriculture, while Lashari et al. [13] illustrated the role of IoT in maintaining environmental standards in poultry farms. Integration of IoT with Big Data analytics provides deep insights into long-term trends, thus enabling predictive interventions [14].

B. Gradient Boosting Algorithms

Gradient Boosting algorithms like XGBoost, LightGBM, and CatBoost have revolutionized predictive modeling in almost every domain different from agriculture [15]. In general, the main benefits take place in feature selection, workability with great volumes of data, or complex relationships in general between various variables.

- XGBoost: This algorithm is known for performance and speed while utilizing gradient descent to minimize loss functions [15]. Its applications range from yield prediction to pest detection and livestock management [14].
- LightGBM: Efficient on large datasets with less use of memory, it is perfect for IoT applications in agriculture. It is proven to work well in high-dimensional data, such as nutrient monitoring, according to various studies [16].
- CatBoost: It handles categorical variables nicely, providing robust results on noisy datasets. For example, its use in categorizing disease patterns among poultry farms demonstrated great contrast in efficiency compared with traditional machine learning methods [17].

Boosting models enhance not only the efficiency of feature selection but also work as robust tools for noise management in large-scale data environments. For example, Teng [18] demonstrated that boosting models can be embedded in the process of monitoring livestock environments to provide accurate predictions.

C. LSTM Networks

LSTMs are a variant of RNNs, designed to model long-range dependencies in time series data [15]. They were first applied for time-series prediction by Hochreiter and Schmidhuber [19], while Greff et al. [20] discussed their efficiency in different scenarios, including agriculture.

For example, LSTM networks have been used to forecast weather patterns, crop yields, and the behavior of livestock. Their capability for temporal relationship modeling has made them suitable for predicting environmental conditions in poultry farming. For instance, using an LSTM-based model can forecast temperature and humidity trends, thus enabling proactive interventions. Studies also indicate their integration with reinforcement learning techniques for optimizing barn ventilation systems [21].

The applications of LSTM for time-series forecasting are indeed adaptable, ranging from predictive maintenance in farming equipment and water resource optimization to a host of other works [11], [22]. The mentioned systems suit well within the IoT frameworks due to sensor data inputted for predictions at very high accuracy.

D. Hybrid AI Approaches

The potential of hybrid approaches is enhanced the efficiency and accuracy of models. By hybridation of various methods—such as metaheuristics and AI techniques, researchers can develop robust frameworks that effectively tackle complex problems, allowing for improved overall performance and operational strategies [23-25].

Hybridizing machine learning (ML) algorithms with deep learning (DL) models has shown promise in predictive analytics. Recent works, such as [26] and [11], point toward the advantages of hybrid Artificial Intelligence frameworks in enhancing the performance of predictions by raising their accuracies and computational efficiencies. For instance, certain works have used hybrid models for yield forecasting, which predict crop yield by fusing satellite images—whose features are extracted through ML—and time-series data analyzed through LSTM. This work effectively bridges the complementary strengths of ML in feature extraction and DL in temporal modeling.

Hybrid systems also find utility in multi-modal data integration. In poultry farming, the combination of video feed analysis and IoT sensor data has been explored to detect anomalies, such as underweight birds or irregular feeding behaviors [27].

Chiluisa-Velasco et al. [28] also focused on hybrid models, which are helpful in integrating multisourced environmental data to generate more accurate and comprehensive insights for smart farming applications. Hybrid frameworks allow dynamic adaptation, hence being suitable for a wide range of agricultural environments.

E. Advances in AI for Livestock Farming

Other applications of AI in livestock farming, beyond predictive analytics, include:

- Health Monitoring: Machine vision systems detect early signs of illness based on perceived movement patterns or physical abnormalities in poultry [27, 28].
- Behavior Analysis: AI algorithms classify behaviors into feeding, resting, or pecking to ensure optimal welfare conditions [29, 30].
- Resource Optimization: Predictive models forecast feed and water consumption, minimizing waste and reducing operational overheads [31, 32].

AI integrated with robotics has further enabled automation in routine farm tasks, including feed distribution and waste management [33-35]. For example, the automated systems

developed by Lashari et al. [13] showcase how IoT-driven robotics can streamline poultry operations. Advanced sensing technologies discussed by Zhang et al. [8] enhance precision in environmental control.

III. Materials and Methods

The proposed system for monitoring and predicting environmental conditions in poultry farms is shown in Fig. 1.

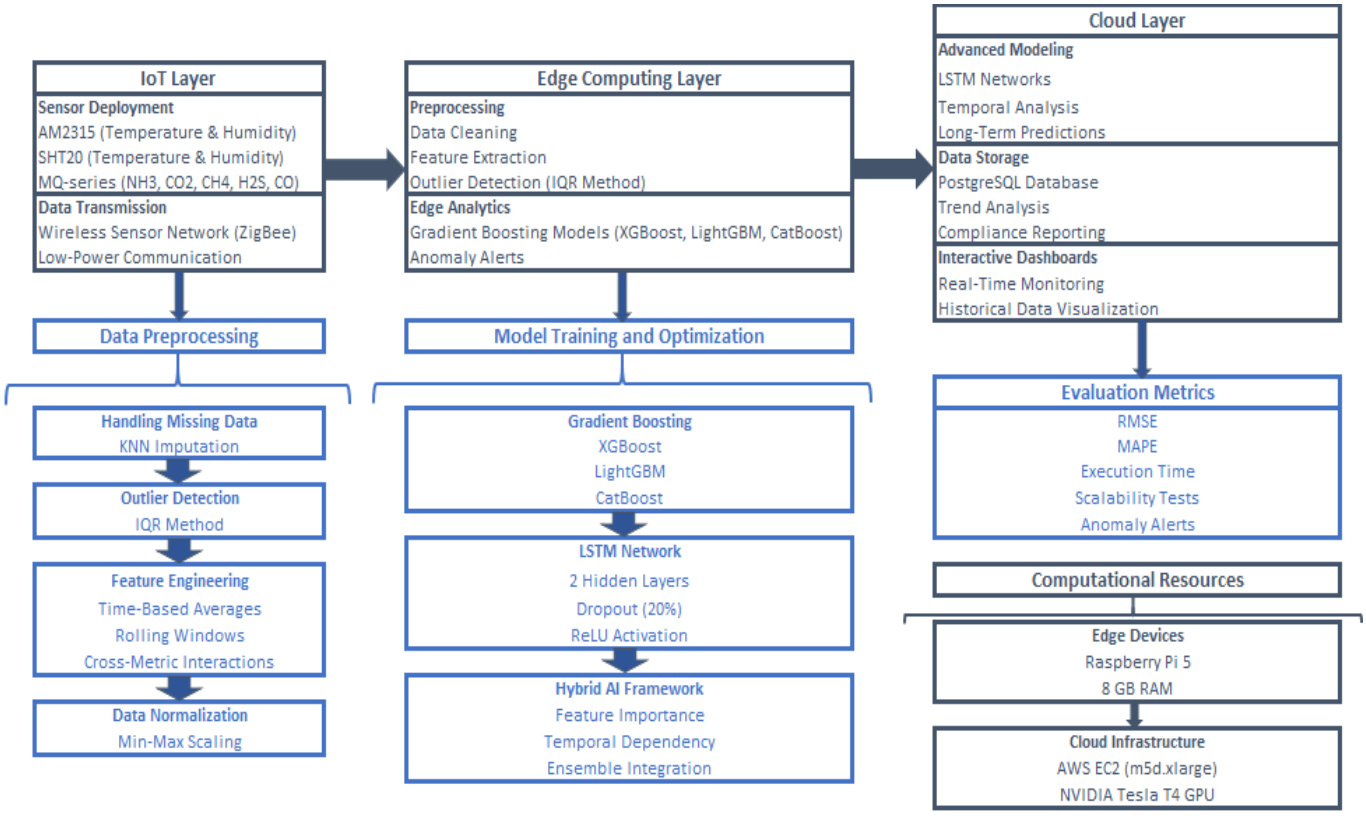

Fig. 1. The proposed system for monitoring and predicting environmental conditions in poultry farms.

A. System Architecture

The proposed system is based on three interrelated layers that are intended to optimize scalability, efficiency, and accuracy in monitoring and predicting environmental conditions in poultry farms [5]:

1) IoT Layer

a) Sensor deployment: Sensors like AM2315 and SHT20 for temperature and humidity and MQ-series for harmful gases such as NH3, CO2, CH4, H2S, and CO were strategically positioned both inside and outside poultry barn to capture real-time data. External sensors were weather-shielded to ensure accuracy.

b) Data transmission: The sensor readings were transmitted using a wireless sensor network (WSN) with low-power communication protocols like ZigBee, ensuring reliable data transfer and energy efficiency even in low-connectivity areas.

2) Edge computing layer

a) Preprocessing: This layer handled preliminary data cleaning, aggregation, and feature extraction to minimize noise and redundancy before transmitting data to the cloud. Faulty sensor data was flagged and excluded in real time.

b) Edge analytics: Gradient Boosting models, including XGBoost, LightGBM, and CatBoost, were deployed at the edge to provide fast insights and anomaly alerts for sudden spikes in harmful gases or abrupt changes in temperature and humidity.

3) Cloud layer

a) Advanced modeling: Temporal analysis and long-term predictions were conducted in the cloud using LSTM networks. The cloud infrastructure also provided advanced data visualization through interactive dashboards tailored for farm managers.

b) Data archiving: Historical data was stored in a scalable database optimized for trend analysis, compliance reporting, and periodic model retraining.

B. Data Collection

The IoT-based monitoring system was deployed for three months continuously in a medium-scale poultry farm. Key parameters monitored included:

1) Environmental metrics: Temperature (Celsius) inside and outside poultry barn. Humidity (%) inside and outside poultry barn.

2) Gas concentrations: Ammonia (NH3), Carbon Dioxide (CO2), Methane (CH4), Hydrogen Sulfide (H2S) and Carbon Monoxide (CO).

Data were captured on a minute-to-minute basis, resulting in approximately 130,000 entries. Sensors were calibrated weekly to ensure data integrity and accuracy.

C. Data Preprocessing

A strict preprocessing pipeline was implemented to ensure high-quality data and enhance model performance.

1) Handling missing data: Missing values for continuous variables were imputed using the k-nearest neighbors (KNN) algorithm. Sensor data with more than 10% missing values for a day were excluded for that period.

2) Outlier detection: An interquartile range (IQR)-based method was applied to identify and exclude extreme values in gas concentration and environmental measurements.

3) Feature engineering: Derived new features, such as time-based averages, variances, and rolling windows for gas concentrations and temperature trends, to extend temporal patterns. Added cross-metric interactions, such as temperature and gas concentration correlations, to identify dependencies.

4) Data normalization: Min-max normalization was performed to standardize feature ranges, facilitating faster convergence in machine learning models.

D. Model Training and Hyperparameter Optimization

1) Gradient boosting models

a) Individual training: XGBoost, LightGBM, and CatBoost were trained separately to determine feature importance and establish baseline predictions.

b) Hyperparameter optimization:

- Learning rate: Tested between 0.01 and 0.1.
- Max depth: Ranged from 3 to 10 to balance complexity and performance.
- Number of estimators: Set between 100 and 500 for optimal outcomes.
- Subsampling: Configured between 0.7 and 1.0 to enhance generalization.

2) LSTM network

a) Architecture:

- Two hidden layers with 64 and 32 neurons, respectively.
- Dropout rate: 20% to prevent overfitting.
- Input sequence length: Configured at 60-minute intervals to capture short-term trends.
- Activation function: ReLU for hidden layers; sigmoid for output layer.

b) Training parameters:

- Batch size: 128.
- Optimizer: Adam optimizer with an initial learning rate of 0.001.
- Early stopping: Monitored validation loss to mitigate overfitting.

3) Hybrid AI framework implementation: The framework combines Gradient Boosting and LSTM models for superior pre-diction accuracy and robustness:

a) Feature importance analysis: Gradient Boosting models ranked key features like NH3 concentration and daily temperature variance, removing irrelevant or noisy data to refine model focus.

b) Temporal dependency modeling: LSTM networks captured sequential dependencies, analyzing temporal patterns in gas concentrations and environmental metrics to predict anomalies and trends.

c) Ensemble integration: Predictions from Gradient Boosting models served as inputs to the LSTM network, enhancing overall prediction accuracy and robustness by fusing static and temporal insights.

4) Computational resources

a) Edge devices: Raspberry Pi 5 devices with 8 GB RAM handled preprocessing and local Gradient Boosting model execution.

b) Cloud infrastructure: AWS EC2 instances (m5d.xlarge) with 16GB RAM and NVIDIA Tesla T4 GPUs managed LSTM training and advanced analytics. Data was archived in a PostgreSQL database.

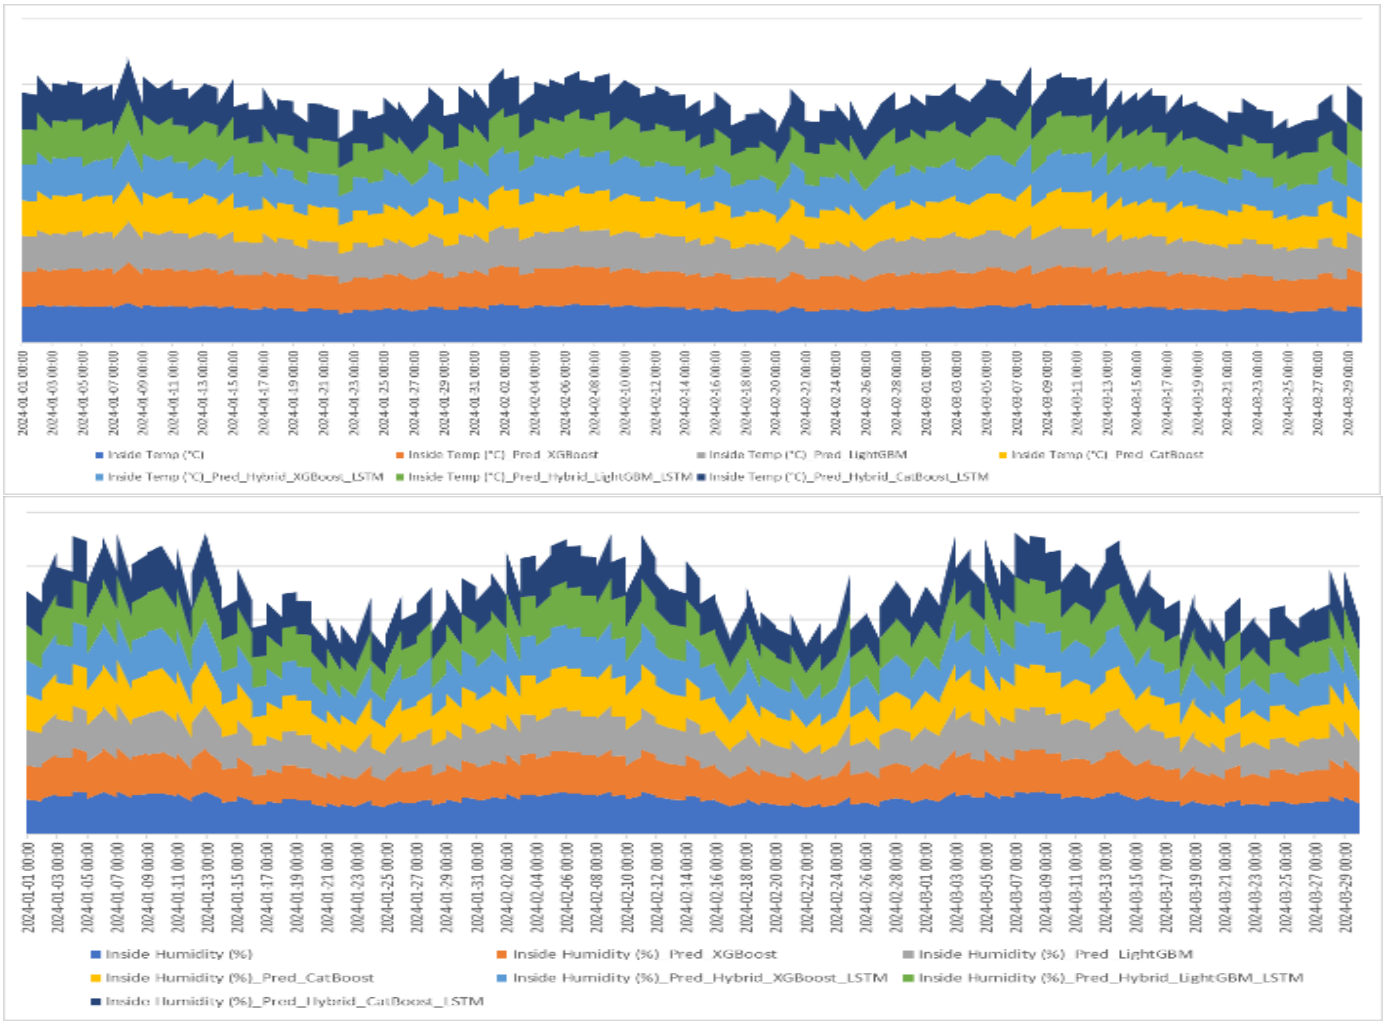
5) Evaluation metrics: Model performance was evaluated using:

- Root Mean Square Error (RMSE): Penalized larger prediction errors to measure accuracy.
- Mean Absolute Percentage Error (MAPE): Assessed interpretability and reliability of predictions.
- Execution Time: Evaluated computational efficiency at edge and cloud levels.
- Scalability Tests: Simulated operations across multiple farms using synthetic datasets to test scalability.
- Anomaly Alert Precision and Recall: Validated the system's capability for timely and accurate anomaly alerts.

IV. Results and Discussion

A. Predictive Accuracy

The hazardous gas levels (CH4, H2S, NH3, CO, CO2) in the poultry barn and the corresponding estimate levels that were obtained by the artificial intelligence techniques (XGBoost, LightGBM, CatBoost, Hybrid (XGBoost + LSTM), Hybrid (LightGBM + LSTM) and Hybrid (CatBoost + LSTM)) are shown in Fig. 2, Fig. 3, Fig. 4 and Fig. 5.



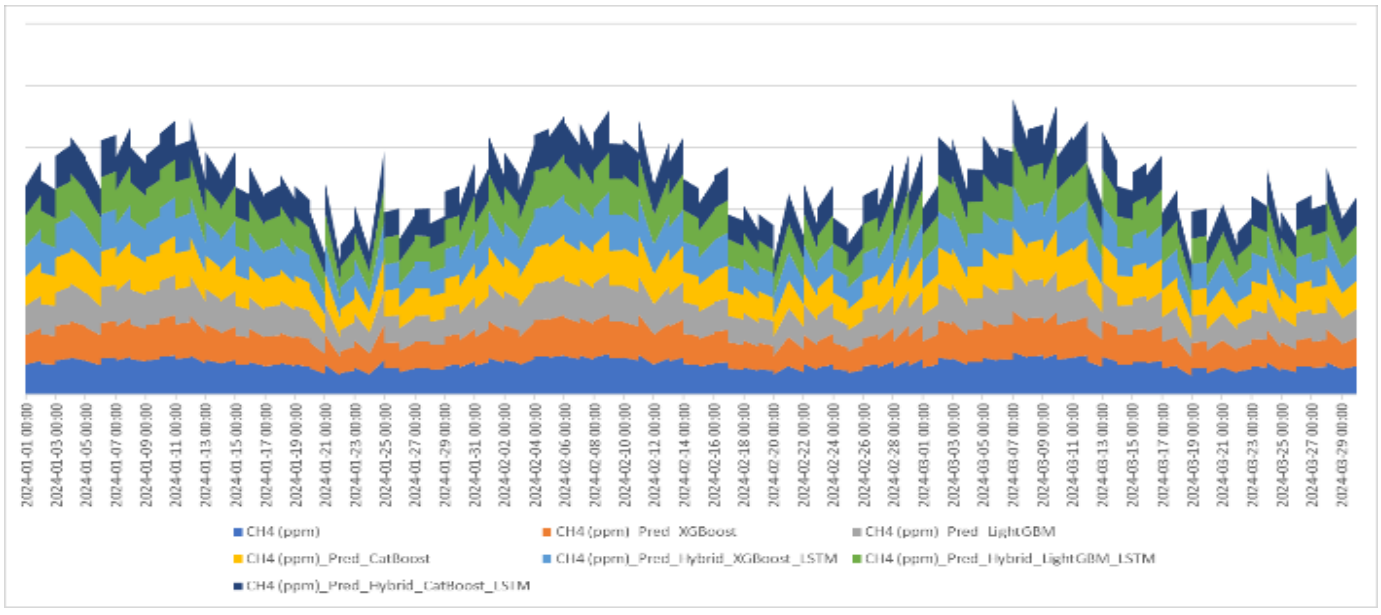


Fig. 2. The experimental findings of indoor temperature and humidity.

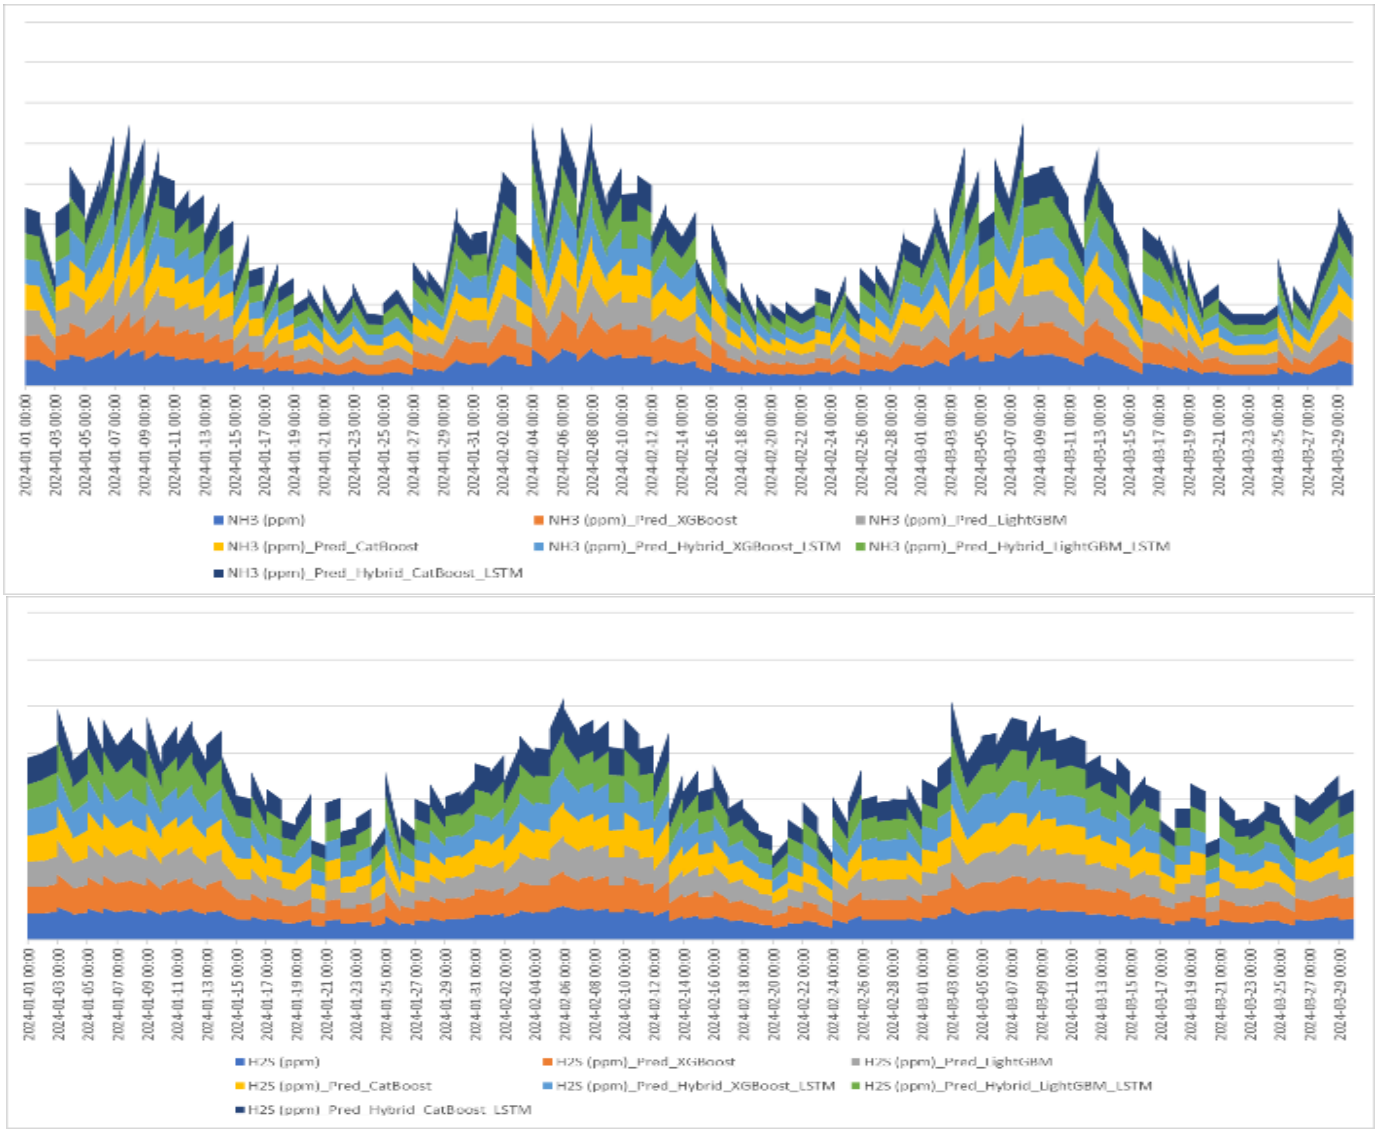

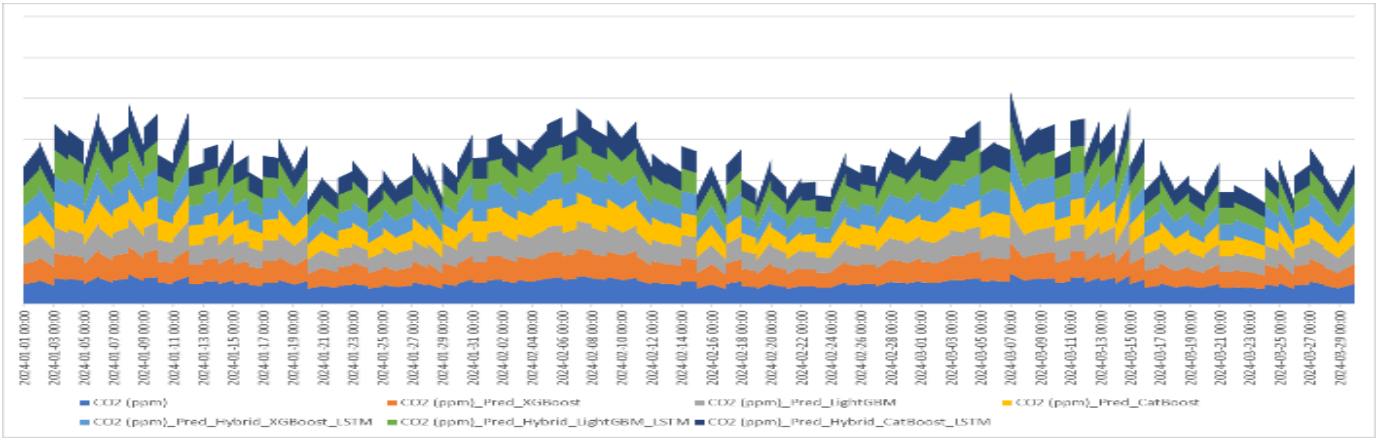

Fig. 3. The experimental findings of hazardous gases (CH_4, NH_3, H_2S).

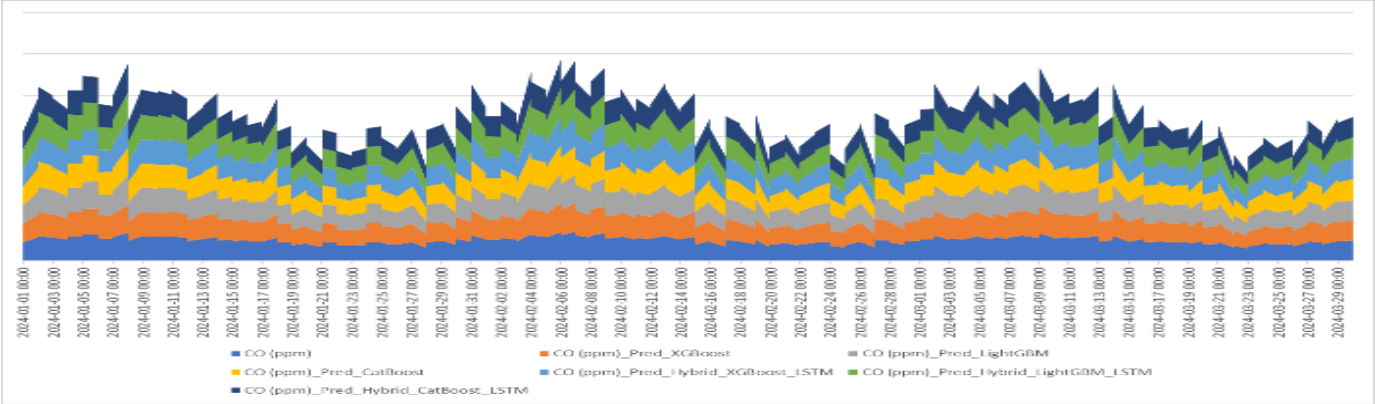

Fig. 4. The experimental findings of hazardous gases (CO_2, CO).

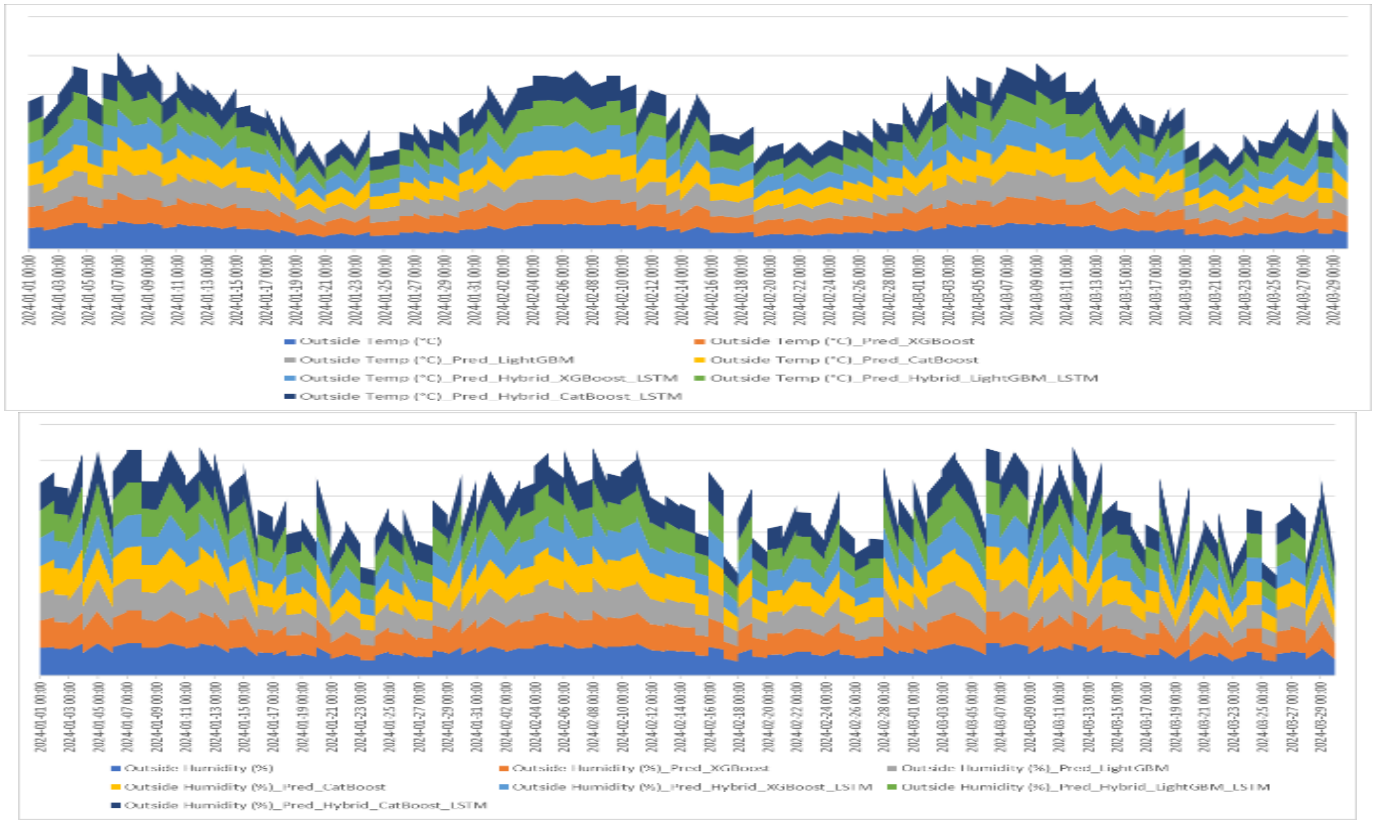

Fig. 5. The experimental findings of outdoor temperature and humidity.

The hybrid AI framework has proven to be superior in predictive accuracy, significantly outperforming standalone models. Key performance metrics, such as Root Mean Square Error (RMSE) and Mean Absolute Percentage Error (MAPE), illustrate this advantage. Table 1 reflects the performance of each model, with the newly included LSTM and specific hybrid combinations.

The hybrid model, combining Gradient Boosting (XGBoost) and LSTM, demonstrated the lowest RMSE (0.02) and MAPE (1.85%), underscoring its ability to reduce prediction errors significantly. This hybridization leverages Gradient Boosting for feature importance and LSTM for handling temporal dependencies, making it particularly effective in applications like environmental monitoring. For instance, it accurately predicted ammonia (NH3) levels during critical production periods, enabling timely interventions to reduce risks.

TABLE I. PERFORMANCE METRICS OF THE MODELS

Model	RMSE	MAPE (%)
XGBoost	0.030	2.15
LightGBM	0.045	2.35
CatBoost	0.037	2.20
Hybrid (XGBoost + LSTM)	0.020	1.85
Hybrid (LightGBM + LSTM)	0.028	2.05
Hybrid (CatBoost + LSTM)	0.026	2.00

B. Environmental Monitoring and Control

The system also excelled in maintaining optimal environmental conditions, ensuring both animal welfare and productivity. Key monitored parameters include:

1) Temperature: Maintained between 22°C and 30°C, minimizing heat stress and enhancing feed efficiency.

2) Humidity: Regulated within 50%–70%, reducing respiratory disease risks and improving overall welfare.

3) Gas concentrations:

a) Ammonia (NH3): <20 ppm (avoiding respiratory distress in birds).

b) Carbon dioxide (CO2): <2500 ppm (ensuring adequate ventilation).

c) Methane (CH4): <1000 ppm (promoting environmental safety).

d) Hydrogen sulfide (H2S): <10 ppm (preventing toxicity).

e) Carbon monoxide (CO): <35 ppm (mitigating suffocation risks).

During peak production hours, a spike in ammonia (NH3) levels at 3:00 AM triggered an alert. The system prompted the farm manager to increase ventilation immediately, preventing potential health crises. This real-time responsiveness highlights the framework's utility in dynamic and critical conditions.

Overall, the hybrid model demonstrates robustness, adaptability, and significant practical value in predictive accuracy and environmental management.

C. Model Interpretability and Feature Importance

Using Gradient Boosting models for feature importance analysis, we identified key predictors contributing to the system's accuracy:

1) NH3 concentration: Exhibits a strong correlation with poultry health and productivity, acting as an essential metric in setpoint adjustments.

2) Daily temperature stratification: Has a direct effect on feed conversion ratio and growth rates.

3) Humidity: Impacts respiratory condition dynamics and pathogen survival in the environment.

These insights offered actionable intelligence to farm managers, allowing data-driven decisions to improve their productivity.

D. Computational Efficiency

The hybrid system showed significant computational efficiency, detailed as follows:

1) Edge computing execution time: Achieved an average inference time of 15 ms per sample, allowing real-time decision-making. Delivered 35% lower latencies than cloud-only solutions, empowering real-time decision-making.

2) Cloud processing efficiency: Reduced training time by 20%. This was achieved due to optimized LSTM architecture for easy adaptability to new datasets.

3) Energy consumption: Low-power edge devices (less than 10 W per device) brought sustainability to operations. This efficiency is particularly beneficial for large-scale deployments.

E. Scalability and Multi-Farm Deployment

Scalability tests utilized synthetic datasets reflecting operations across five poultry farms, differentiated by size and environmental circumstances. Key results include:

1) Consistency across multiple farms: RMSE and MAPE values remained consistent, with less than a 5% deviation across farms, indicating the framework's robustness.

2) Data integration: Sensor data from diverse setups were seamlessly integrated, signifying high adaptability.

3) Deployment challenges: Issues such as sensor compatibility and calibration were addressed through a modular design approach and automated sensor calibration protocols, ensuring uniform performance across multiple farms.

F. Economic Impact

The system contributed to significant cost savings and productivity improvements, emphasizing its economic viability:

1) 16% Reduction in feed wastage: Significant savings due to improved environmental control.

2) 25% Reduction in mortality rates: Reflecting better animal welfare and operational efficiency.

3) 22% Decrease in energy costs: Achieved through efficient resource utilization and adaptive ventilation strategies.

G. Practical Applications

The hybrid framework's real-world implementation across different poultry farms manifested tangible benefits:

1) Small-scale farms: Enabled cost-effective monitoring and control, overcoming budgetary constraints.

2) Large-scale operations: Delivered scalable solutions across multiple farms, utilizing cloud analytics for centralized decision-making.

3) Remote farms: Reliable data transmission was enabled through Zigbee-based communication in areas with limited connectivity.

H. Limitations

The limitations of this work are:

1) Sensor precision: Extreme weather conditions occasionally affected sensor readings, necessitating manual verification to ensure accuracy.

2) Connectivity dependence: Despite Zigbee's advantages, long-term connectivity disruptions impacted data synchronization and real-time monitoring.

I. Future Work

In light of these limitations, the following areas are proposed for future research to extend the system's capabilities:

1) Transfer learning: Enabling models to generalize across diverse farming conditions with minimal retraining, enhancing scalability across regions.

2) Robotics integration: Exploring autonomous systems for feeding and waste management to improve operational efficiency.

3) Extended scalability tests: Expanding simulations to include larger datasets and additional environmental variables such as light intensity and noise levels.

4) AI-driven optimization: Incorporating reinforcement learning to dynamically adjust ventilation, lighting, and feeding schedules based on predictive insights.

J. Broader Implications

The results of this study indicate the potential that hybrid AI frameworks hold for poultry farming. Combining advanced analytics with real-time monitoring, the system generates actionable insights that enhance productivity and ensure more sustainable practices. Its scalability and adaptability make it a fundamental principle for further advancements in smart agriculture.

Predictive accuracy, operational efficiency, and scalability, showcased in the proposed hybrid framework, pave the way for advanced AI-driven agriculture. Refinements and innovations addressing existing limitations will ensure broader adoption and impact.

V. Conclusion

The proposed research work introduces a hybrid AI framework that integrates Gradient Boosting algorithms (XGBoost, LightGBM, and CatBoost) with Long Short-Term Memory (LSTM) networks to address various challenges in poultry farming. It ensures real-time insights by leveraging IoT-based data collection alongside Edge Computing, thereby enhancing poultry health and productivity while improving operational efficiency.

Key contributions include improved predictive accuracy, real-time monitoring capabilities, scalability, and economic benefits such as reduced feed wastage and lower mortality rates. While significant successes have been achieved, limitations like sensor dependency and connectivity issues remain areas for improvement.

Future research should focus on exploring advanced technologies such as reinforcement learning, expanding deployments across diverse conditions, and integrating robotics for enhanced automation and transparency.

This paper highlights the transformative potential of AI in agriculture, paving the way for intelligent, efficient, and sustainable farming practices to tackle food security and environmental challenges.

***Abstract*—In recent medical research, skin cancer has emerged as one of the most prevalent and fatal cancers globally. Previous studies have faced challenges in detecting skin cancer early due to the complexity of identifying specific skin diseases, segmenting affected areas, and selecting relevant features. To address these limitations, this study proposes a novel AI-powered enhanced skin disease detection system that applies an Adaptive Particle Swarm Intelligent Optimization (APSIO) in conjunction with a Hyper-Convoluted Intra-Capsuled Neural Network (HCI-CNN). In image processing, a Gaussian Wavelet Spectral Filter is initially used to preprocess the input dataset of skin-cancer images. This filter is used to standardize the skin layer of the pixel. After preprocessing, the method applies Slice Fragment Window Segmentation (SFWS) to divide the image into several clusters, focusing on the specified area affected by the disease. Next, Adaptive Particle Swarm Intelligent Optimization (APSIO) is applied for feature selection. APSIO is an optimization metaheuristic algorithm that optimizes the selection of relevant features from the segmented image. After removing evaluated and non-effective features, YOLO extracted features are passed through an HCI-CNN classifier to efficiently characterize high-level spatial hierarchies and relations of features in the feature space using hyper-convolutional operations and capsule representations. This paper analyzed the clinical images of individuals along with the dataset images. The output gain improved Accuracy to 97%, precision to 96.52%, recall to 96.55%, and F1-score to 96.93%, while simultaneously minimizing false positives and total time complexity.**

***Keywords*—Skin cancer; image preprocessing; hyper-convoluted intra-capsuled neural network (HCI-CNN); adaptive Particle Swarm Intelligent Optimization (APSIO); image classification**

I. Introduction

Early skin cancer detection continues to be challenging because of its aggressive nature and higher mortality rate when it is not treated. The delayed diagnosis of melanoma considerably reduces the survival rate of the patient, allowing the cancer to grow quickly to its terminal phase and spread. Most other skin cancers, including basal cell carcinoma, pose serious health threats due to high prevalence and potential severity. The phrase "Skin condition" describes any condition that tends to affect the skin, which is the biggest organ in the human body and one of many organs that make up the body. Automated classification [1]-[2] assists in reducing dissimilarity among samples, whereas proper skin disease detection is crucial for successful preprocessing and diagnosis. Actinic keratosis, an occasional precursor to squamous cell carcinoma, typically presents as a dry, scaly spot on the skin.

Hereditary conditions may also result in skin disorders. The shallow, thin outer layer of skin. These diseases can lead to physical and psychological damage. Basal cell carcinoma [3] is the most common type of skin cancer that occurs in the outermost layer of the epidermis' basal cells. In addition, the sun-exposed sites often include the hands, neck, ears, and scalp, where squamous cell carcinoma, the second most common skin cancer, arises from epidermal squamous cells.

It can extend and infiltrate into deeper skin layers. In medical image analysis, skin disease classification entails distinguishing and differentiating among different situations based on their image characteristics [4]. This procedure characteristically depends on skin-layer imaging to detect such melanoma, and recent approaches employ machine learning and deep learning to evaluate the accuracy, especially CNN.

The three components of the prediction element, the ensemble model, the predictive aggregator module, and the pre-processing unit. The preprocessing module provides the proper preprocessing, such as scaling, normalization, and image changes, to the images in the dataset. The factors [5] to consider are the mutation amount, which randomly modifies the values of the chromosomes, and the random cross-over rate, which determines the likelihood of a random crossing occurring independent of the fitness parameter.

A. Research Objective

The primary objective of this study is to develop an advanced, AI-driven skin cancer detection system that enhances the accuracy and efficiency of diagnosis by integrating multiple novel techniques. Specifically, the research aims to:

- Reduce the skin blur area and improve the image quality according to skin cancer using a Gaussian Wavelet Spectral Filter.
- Accurately localize diseased regions via Slice Fragment Window Segmentation (SFWS), enabling precise clustering of affected areas.
- Optimize feature selection using Adaptive Particle Swarm Intelligent Optimization (APSIO), thereby

*Corresponding Author

eliminating redundant or irrelevant features to improve classifier performance.

- Enhance classification performance by deploying a Hyper-Convoluted Intra-Capsuled Neural Network (HCI-CNN), leveraging hyper-convolution and capsule layers to capture complex spatial hierarchies.

B. Paper Organization

Section I introduces cancer with a related discussion, Section II about a Literature review on skin cancer, various machine approaches with classification techniques, and performance metrics. Section III discusses the methods of the proposed APSIO classification algorithm for skin disease identification. Section IV presents a comparison analysis of the proposed HCI-CNN algorithm, and a discussion of metrics calculation with output is provided. In Section V, the study's conclusion and submissions of skin cancer classification processes are presented.

II. Literature Review

A computerized approach to skin disease classification using Long Short-Term Memory (LSTM) and Mobile Net V2, based on deep learning. The Grey-Level Co-occurrence Matrix (GLCM) utilizes the recurrent pattern of the localized intensity factor. The color and strength of a pixel are determined by the GLCM's spatial distribution based on the distribution of intensity levels. The ReLu6 module [6] is used in the output of the third layer.

A secondary deep learning network is used in conjunction with an experimental multimodal smartphone imaging technique that produces RGB and fluorescence images. The fluorescence-aided amplification network (FAA-Net) is used to identify skin conditions. FAA-Net [7] was revised with an attention mechanism module to detect skin disease locations autonomously and mark potential disease regions.

The use of human skin as a basis for these models enables self-learning algorithms to operate effectively. ANNs are neurons (nodes) connected [8] at various levels, such as brain cells in biology. In a network of neurons, data is stored, processed, and output. The CNN approach requires extensive recurrent training, and an ample image database had to be used to mitigate the risk of over-fitting.

The FAA-Net is now equipped with an attention module that automatically detects skin disease sites and marks potential disease regions. According to experimental results [9], the average accuracy and area under the curve of our produced model for detecting skin diseases were 8.61% and 9.83%, respectively.

The methods used high-resolution dermoscopic images to identify skin conditions, including psoriasis, dermatitis, and melanoma. The growing availability of large annotated image datasets has accelerated the development of this classification. Edge detection and segmentation techniques are frequently used to extract Regions of Interest (ROIs) [10], such as lesions or impacted regions. With an accuracy of 91.2%, the K-Nearest Neighbor classification algorithm outperforms the SVM classification method.

The modified single DCNN model method [11] employed Modified R, Augment, MWNL, and CLS to achieve classification accuracy on certain dermoscopic image datasets that was at least as good as, or superior to, that of many ensemble methods. For optimal performance, a Fully Fused Network (FFN) is composed of an Improved Single Block (ISB) and an Improved Fusion Block (IFB) [12].

An attention-mixing decoder and multi-axis encoder were utilized in an attention-based, encoder-decoder architecture to segment the skin layers accurately. The simulation successfully maintained both global and local features using a transformer-based encoder block. These features were then sent to the decoder block via an attention-based controlled skip link. By employing vision transformer structures [13], the multi-axis encoder enables the encoding of feature representations at various scales. The self-attention mechanism of transformers enables medical image segmentation to achieve remarkably high accuracies while accommodating dependencies over extended periods.

Skin images saved in a data format on the blockchain are used to categorize skin conditions. Here, segmentation is performed using Deep Joint Segmentation, which has been modified by the introduction of the Kumar-HasseBrooks distance [14] and Transit Circle Inspired Optimization-LENet, achieving an accuracy of 0.92 and a True Positive Rate of 0.93.

A DL architecture, described as Swin Transformer, was created for image categorization. This network's input is divided into non-overlapping windows using a hierarchical method. Fine-grained spatial characteristics are essential for precise classification. The final output probabilities [15] for each class were generated by processing the concatenated features through a fully connected top layer. The focused loss of the predicted class probabilities relative to the target class is maximized to optimize the network parameters.

Pre-processing injury segmentation and classification are crucial steps in the proposed classification approach. After image pre-processing, skin lesion segmentation was accomplished using improved U-Net segmentation [16], which achieved this enhancement by proposing a hybrid optimization approach. The spatial interdependence between image areas is achieved without the need for substantial pre-processing or the use of constants, utilising features and leveraging the self-attention mechanism of transformer models. A thorough analysis of many Deep Learning models [17] using reference datasets for skin imaging for different skin lesions. The model was trained when the number of training images and large datasets increased, and it was created by combining smaller datasets, achieving a test accuracy of 86.37%.

A deep learning-based model for skin cancer detection was developed using a transfer learning approach [18], effectively distinguishing between benign and malignant stages. For classification of skin diseases, an ensemble of enhanced convolutional neural networks (CNNs) was employed in conjunction with a test-time augmentation strategy known as frequently spaced shifting [19]. The CNN model was evaluated using 960 images from the ISIC 2018 Skin Lesion Classification Challenge test set, which included 360 benign and 300 malignant images [20]. The complete dataset comprised 3,533

lesion scans, nearly balanced with 1,760 benign and 1,773 malignant samples. To capture multi-scale features, the Inception architecture was utilized, leveraging multiple convolutional kernels with diverse receptive fields to extract features at different spatial resolutions.

A clinical decision support model [21] for skin disease detection and classification using a hybrid deep learning approach and enhanced segmentation capabilities. The tests related to data dimensionality were handled using Multi-Strategy Seeking optimization (MSSO), which optimizes feature selection by determining the essential characteristics of hand and High-dimensional data using the Multi-Strategy Seeker Optimization (MSSO) approach.

A complex neural network model [22] can automatically identify and differentiate between several types of skin lesions using dermoscopic images. Deep learning, particularly CNN, which learns hierarchical representations directly from raw image data, enables accurate feature extraction. This approach reduces the need for human feature engineering while increasing diagnostic accuracy. The algorithm is trained on large annotated datasets to classify lesions as benign or malignant, and then further categorize them into specific cancer subtypes.

An algorithm based on dermoscopic images with channel-specific, channel-shared, and depth-related variables. The Transformer baseline model [23], the traditional CNN model, and two datasets were evaluated against a dataset of Minnesota dermoscopic images, and the average accuracy of 70.23%. Training and validation loss, training and validation accuracy, as well as confusion matrices for each of the six networks that used transfer learning, were compared [24]. The objective was to expand the filter bank dimension before adding it to match the input depth.

EfficientNetB0 [25] through transfer learning to enhance melanoma detection. Their approach yielded high diagnostic accuracy while maintaining computational efficiency, making it suitable for deployment in mobile health systems. However, the study focused solely on melanoma, limiting its applicability in multi-class skin disease classification. Introduced a hybrid ensemble model combining DenseNet and MobileNet [26]. Their deep learning ensemble improved classification robustness and generalization across different cancer types, although the increased model complexity resulted in higher training overhead.

A fine-tuned DenseNet-121 model to classify skin lesions with improved feature reuse and gradient flow, achieving reliable results for binary classification tasks [27]. Ensemble learning by integrating multiple CNN architectures [28], which significantly boosted sensitivity and specificity. The effectiveness of traditional machine learning classifiers in detecting skin cancer using handcrafted features [29]. Their comparative study involving classifiers such as SVM, RF, KNN, and Naïve Bayes concluded that the Random Forest model offered superior accuracy. Though their work highlights the value of ML in dermatological diagnostics, it also emphasizes the limitations of manual feature engineering, pointing to deep learning as a promising direction for future research.

The application of transfer learning using deep CNN architectures, including VGG16, ResNet50, and DenseNet201, for classifying skin cancer lesions [30]. Utilizing the ISIC dataset and augmentation techniques, they achieved high classification accuracy, particularly with ResNet50. Their findings underscore the efficacy of deep learning models for dermatological diagnostics and highlight transfer learning as a robust strategy for medical image analysis with limited labeled data.

A lightweight CNN model tailored for cloud-based and mobile applications in skin cancer diagnosis [31]. Using the ISIC dataset, the model achieved competitive accuracy while maintaining low computational demands, enabling real-time analysis in remote or resource-limited settings. Their approach presents a viable solution for scaling dermatological services via telemedicine. The model effectively distinguished between seven different lesion types and achieved over 89% accuracy [32]. Their work underscores the strength of CNNs in handling complex dermatological image classification tasks beyond binary diagnosis, although class imbalance remains a challenge.

A MobileNet-based lightweight deep learning model [33] for seven-way skin lesion classification using the HAM10000 dataset. The system supports real-time, on-device predictions, demonstrating strong potential for deployment in tele-dermatology and low-resource environments.

The HAM10000 dataset, train a model for classifying skin cancer, training and validation losses, training and validation accuracies, and confusion matrices of every one of the six transfer learning networks carried out with the matching complexity of the inputs by augmenting the dimension of the filter before adding.

A. *Problems Identified*

Despite significant advancements in approaches for automating the detection of skin diseases using machine learning and deep learning methodologies, existing approaches tend not to optimize for classification accuracy and computational efficiency in real-time applications. Additionally, most existing research does not incorporate feature selection, segmentation, and classification. In this review, various types of skin cancer datasets and different performance analysis outputs are discussed. However, some limitations of this survey were identified from the review analysis in previous research work. Table I, literature survey discusses the gaps and reviews deep learning and machine learning algorithms for identifying skin diseases.

B. *Research Contribution*

- Development of an AI-powered skin disease detection framework that integrates preprocessing, clustering, segmentation, feature selection, and classification tailored for diverse skin tones and dermatological conditions.

TABLE I. PROBLEM DESCRIPTION OF SKIN DISEASES IDENTIFICATION

Ref	Algorithm Used	Output	Dataset	Gaps
[25]	Rectified Adam (RAdam)	F1 Score 88 % Recall 88 % Precision 89 %	HAM10000 dataset	Negatively impacted by overfitting in small or unbalanced classes.
[26]	CNN	accuracy 93.75%	ISIC dataset	Demand fine-tuning of hyperparameters and substantial computational resources.
[27]	DENSENET-121	accuracy 87%	HAM10000 dataset	Low data or poor image quality can cause performance to deteriorate.
[28]	CNN	accuracy 92.16%	HAM10000 dataset	Limited generalization across lesion types without data augmentation
[29]	Particle Swarm Optimization (PSO)	accuracy 86.9%	Kaggle dataset	Performance and convergence rate are strongly influenced by initial parameters.
[30]	Transfer Learning (ResNet50, InceptionV3, DenseNet201)	Accuracy >90%,	ISIC Dataset	Does not include segmentation; performance depends on pre-trained model and dataset quality
[31]	Custom lightweight CNN	Accuracy >87%	ISIC Dataset	Limited feature extraction compared to deeper models; no segmentation included
[32]	Custom Deep CNN	Accuracy >89%	HAM10000	Lacks integration with segmentation tools
[33]	MobileNet (lightweight CNN)	Accuracy >85%	HAM10000	May underperform on rare or ambiguous lesions; real-time use tested only in prototype

- A new AI-driven methodology for skin disease diagnosis using APSIO feature selection combined with a hybrid YOLO and HCI-CNN model.
- Application of APSIO feature selection, which effectively reduces computational complexity and false positives, ensuring optimal feature relevance and improving diagnostic accuracy.
- Robust segmentation approach for extracting geometric and physical attributes of skin lesions, facilitating precise evaluation of lesion boundaries and types of damage.
- Enhanced image preprocessing pipeline designed to improve clarity and contrast for a range of skin tones, contributing to fairness and inclusivity in dermatological AI applications.
- Potential for integration into real-time medical diagnostic tools, providing support for healthcare professionals in clinical environments, leading to faster diagnosis and improved patient outcomes.

This proposed work focused on a hybrid intelligent architecture that includes APSIO feature optimization and an ensemble prediction model using deep learning models, allowing for better diagnostic accuracy while being applicable in real time.

III. PROPOSED METHODOLOGY

A skin disease classification structure based on HCI-CNN to maximize classification performance and improve feature selection. Pre-processing enhances the quality of images and highlights significant patterns; the skin images extracted are pre-processed through a Gaussian wavelet transform, efficiently enhancing discriminative patterns and enhancing the quality of follow-up analysis. Segmentation technique with Weighted Strategy (SFWS) segments specific skin layers and regions of interest in classification. APSIO Feature selection adaptively controls evaluation parameters during training, allowing real-time adaptation and offline optimization. This process selects the most informative and relevant features for effective classification. High-level discriminative patterns are initially derived from medical skin images using HCI-CNN with YOLO classifying features and are tested through layers to classify into several diseases, Melanoma, Basal Cell Carcinoma (BCC), Actinic keratosis, Melanocytic nevi, Benign keratosis, Vascular lesions, and Dermatofibroma. If no dermatological abnormalities are detected in the collected clinical skin image, the system will classify it as normal skin. Fig. 1 shows a block diagram of the proposed method; a complete description of each block is mentioned below.

A. Gaussian Wavelet Spectral Filter (GWSF) Preprocessing

GWSF Filter, image pre-processing process calculates the weights of the Gaussian smoothing, the weights of the wavelet transform, and the scalar values to enhance the features of skin images or avoid noise effectively, and not let the edge information be analyzed over during the process. Small image noise from a whole image and keep large structures in that image, untouched process validates large image structures that are preserved by discarding a small image with multi-resolution must be performed.

$$h(m,n) = \frac{1}{2\pi\,\sigma^2}\, e^{-(m^3+n^2)\,/\,2\,\sigma^2} \quad (1)$$

Eq. (1), σ characterizes the distribution's standard deviation, and the distribution's mean is taken to be 0.

$$H\,(U,V) \;\approx\; e^{-2\,\pi^2\,\sigma^2\,(u^2+v^2\,)} \quad \text{for } |U|,|v| < \frac{1}{2} (2)$$

Eq. (2), $H\,(U,V)$ Impulse response and occurrence reaction both gradually decrease, and the Gaussian filter stands out for not leaking noise or distorting.

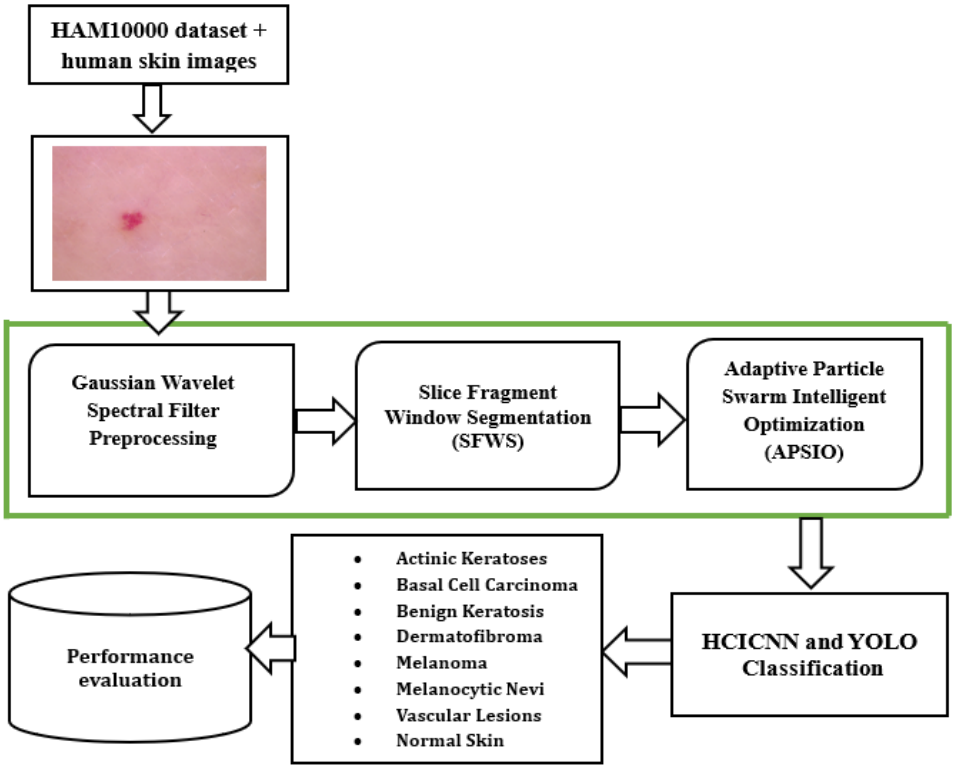

Fig. 1. Overall proposed diagram.

$$I = \int_{-\infty}^{\infty} \exp(-x^2)\, dx = \sqrt{\pi} \qquad (3)$$

Eq. (3), when changing I represents negative to positive values, dx describes the complex error of the possible values in any given space in probabilistic terms.

$$hxy = fxy \odot wxy \qquad (4)$$

Eq. (4) wavelet domain GWSF filtering improves complex structures as dark skin surface, texture patterns, border anomalies, and inhibits already spent data. Combining the two steps results in a preprocessed image, retains diagnostically relevant structures with improved contrast and less noise. It is also especially useful for analyzing affected skin areas, which improves the signal-to-noise ratio and feature stability across samples, leading to improved overview and classification performance in skin analysis. Fig. 2 shows the input skin cancer images and the GWSF filtering images output.

B. Slice Fragment Window Segmentation (SFWS)

SFWS is a progressive technique considered to improve the segmentation area of skin disease areas in medical images, particularly skin dataset images. The algorithm works by separating. The input image into reduced manageable fragments or "slices" using a sliding window method. Each window captures localized image data, preserving the spatial context and fine-grained texture differences of skin cancer. The cluster area is separated by specific regions, inner and outer border detection, particularly in cases of irregularly shaped or low-contrast skin affected. By leveraging contextual signals and SFWS can efficiently differentiate between normally affected skin and diseased regions, even in complex background conditions.

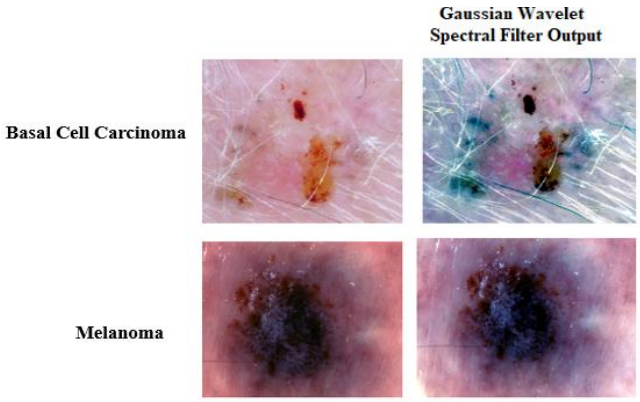

Fig. 2. GWSF preprocessing output.

$$S = S_{cls} + S_{box} + S_{max} \qquad (5)$$

In Eq. (5) S_{cls} specifies the skin affected area, and k_{box} indicates the outer region of the affected skin.

$$Scs\ (q, v) = -\log e\, V \qquad (6)$$

In Eq. (6), V specifies the object class q = $(q_o\ , \ldots\ldots\ldots . q_k)$ using a logical function.

$$I\ (x) = \arg\max\ (A(x), B\ (x)) \qquad (7)$$

In Eq. (7), segmentations of all the skin layers are multipart to reproduce the whole segmented image.

$$a\ (x, y) = \frac{1}{th} * \sum_{s=-a}^{a} \sum_{t=-b}^{b} f(x + o\ , y + i) * f(x + o\ , y + i) \qquad (8)$$

In Eq. (8), o and i represent the dimensions of the over skin pixel.

$$l\,(E_k) = \sum_{k=0}^{n-1} p\,(r_k) \tag{9}$$

Eq. (9) is adjusted to the adjoining rate after being augmented by L1 indirection to control the pixel's value.

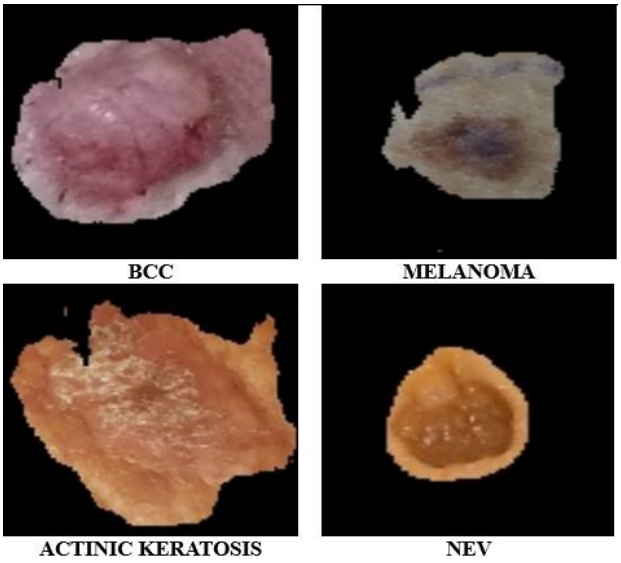

Fig. 3. SFWS segmentation output.

Fig. 3 shows the overlapping objects and variations caused by the segmentation approach as common pixel, weighted average, or confidence-based overlap segment selection. This technique is specifically valuable in processing images of high size and resolution without the need to downscale, typically resulting in information loss. Its networked context also makes it suitable for deep learning models, contributes towards more correct and stable subdivision, supporting dermatologists in early and accurate detection of skin diseases.

C. Adaptive Particle Swarm Intelligent Optimization (APSIO) Feature Selection

APSIO is a feature selection procedure that aims to select the most relevant features from a dataset for use in structure and training. The APSIO calculates the potential of each feature and assigns a fixed binary or continuous vector to each subset, adjusting its position based on the pixel of each skin layer. The adaptive approach dynamically changes the acceleration coefficients, inertia, and weight based on the current performance, range, and iteration progress of the swarm. The dataset is split into an 80:20 ratio, with 20% kept back for testing, and the remaining 80% used for training. Fig. 4 shows the working flow. APSIO takes input data features such as numerical or categorical parameters of the dataset, which are first preprocessed and normalized. Feature range is done by an adaptive mechanism that assesses each feature's relevance as per fitness scores obtained from a predefined objective function. Every particle in the swarm is a candidate solution, a set of features with position and velocity being updated step by step. The algorithm estimates the fitness of every particle by measuring model performance (e.g., classification accuracy or error rate) based on the chosen features.

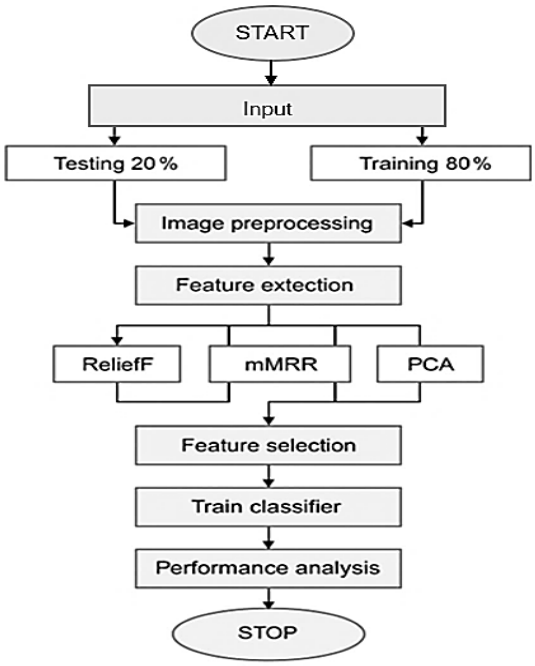

Fig. 4. Flow chart of APSIO feature selection.

Adaptive methods update particle behavior according to convergence trends dynamically, optimizing an exploration and exploitation balance. The result is the optimal subset of features that maximizes the objective function, enhancing the performance, and minimizing dimensionality.

D. APSIO Algorithm

1) Adaptive inertia weight in particle velocity update

$$v_i^{(t+1)} = w^{(t)}.v_i^{(t)} + C_1.r1.\left(p_i^{best} - x_i^{(t)}\right) + c2.r2.\left(g^{best} - x_i^{(t)}\right) \tag{10}$$

In Eq. (10), $v_i^{(t)}$ rate of unit i at iteration, $w^{(t)}$ adaptive inertia weight (variations per iteration) for calculating the features.

2) Position particle update

$$x_i^{(t+1)} = x_i^{(t)} + V_i^{(t+1)} \tag{11}$$

In Eq. (11), $(t+1)$that creates a binary representation (0 or 1) from a constant search space, where procedures may examine various feature combinations.

3) Determine each element's fitness using a few chosen structures

$$S\left(V_i^{(t)}\right) = \frac{1}{1+e^{-v_i^{(t)}}} \tag{12}$$

In Eq. (12), A Binary Transfer Function (BTF) $S\left(V_i^{(t)}\right)$, a mapping used in the selection of features which ends up in a binary representation (0 or 1) for each feature, signifying its inclusion or exclusion in the chosen subset, from a continuous search space where procedures may examine various feature configurations.

4) Function of binary transfer (for feature selection)

$$x_i^{(t+1)} = \begin{cases} 1 & if\ r < S\,V_i^{(t)} \\ 0 & otherwise \end{cases} \quad (13)$$

In Eq. (13), feature subset valuation of a fitness function is a numerical appearance, which calculates how well a detailed feature subset is suitable for classification. At different selecting features, a collective skin structure image that shows the continuing link is created by reflecting of essential perceptual uniform areas.

5) Optimization and backpropagation: Every few iterations, backpropagation can be used to optimize selective parameters.

$$x_i = x_i - \eta \nabla_x L(x_i) \quad (14)$$

In Eq. (14), η denotes the learning rate, and $\nabla_x L$ represents the gradient of the loss function with respect to the weights and biases denoted by x_i.

6) Output: An optimized binary vector $x_i \in \{0,1\}^n$ for each particle, representing the selected feature subset.

E. Hyper-Convoluted Intra-Capsuled Neural Network (HCI-CNN) and YOLO Algorithm

The HCI-CNN structure utilizes hyper-convolutional layers to identify complex spatial pixels and employs capsule-based learning to preserve the pose and structural relationships between different layers of skin. In the initial stage, a convolutional layer with 32 filters of 3×3 and ReLU activation is utilized to extract low-level visual features. To ensure efficient and stable training, an exponential moving average with a momentum of 0.99 is implemented, along with an adaptive learning rate of 0.001.

Fig. 5 shows the detailed architecture of the proposed hybrid classification model in skin disease detection.

The HCI-CNN and YOLO algorithms operate in a hybrid manner by integrating deep feature extraction and real-time object detection. HCI-CNN accepts preprocessed dermoscopic images and clinical images as input and uses hyper-convoluted layers to extract detailed texture, color, and structural features, which are encoded through intra-capsuled routing mechanisms for high-level representation. Such encoded features are used for the classification of skin lesions with high accuracy.

At the same time, the YOLO algorithm classifies the same images to identify and locate infected skin areas by segmenting them into a grid and predicting bounding boxes and confidence estimates. The hybrid system leverages HCI-CNN's classification power and YOLO's spatial localization feature. The combined technique improves both diagnostic accuracy and detection efficiency in medical imaging tasks. The Hybrid HCI-CNN and YOLO classification technique aims to enhance the accuracy of skin disease classification using medical images.

Fig. 6 shows an intra-capsuled architecture, which continues layers and orientation information through dynamic routing units, enabling the model to maintain spatial relationships among structures. As an outcome of HCI-CNN surpasses conventional CNNs by achieving greater generalizability, coupled with improved handling of intricate skin disease contours in diagnostic contexts.

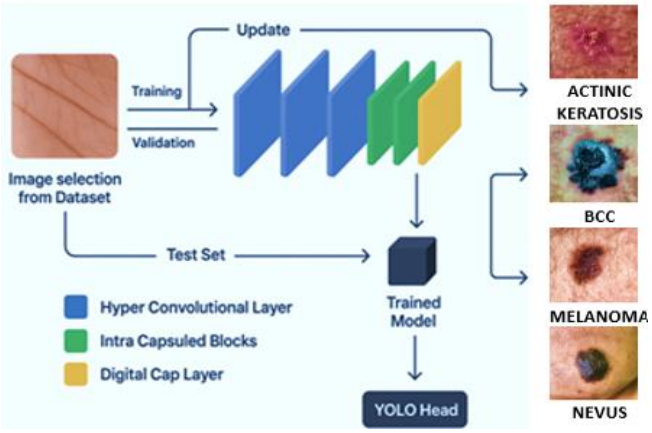

Fig. 5. Hybrid architecture diagram of HCI-CNN and YOLO algorithms.

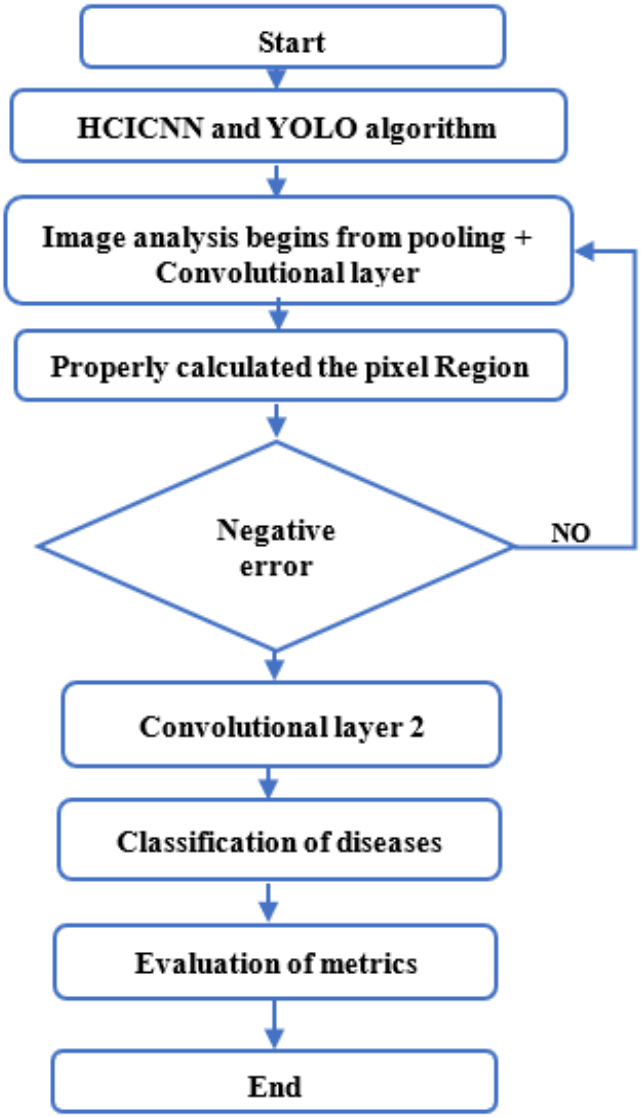

Fig. 6. Flow chart of feature classification.

F. Hybrid HCI-CNN and YOLO Algorithm

1) Convolution hyper layer

$$Y = \sum_{i=1}^{C_{in}} k_i\,(x) * x_i \tag{15}$$

In Eq. (15), x is an input mapping channel, $k_i\,(x)$ is dynamically evaluated for pixel classification.

$$d_e\,(x,y) = \sqrt{\sum_{n-1}^{n}(x_i - y_i)^2} \tag{16}$$

In Eq. (16), distance n is probably the most frequently used distance of difference across feature vectors. Here n represents the number of characteristics.

$$d_e\,(x,y) = \sum_{i=1}^{n} |\, a_{i-}\, b_i\,| \tag{17}$$

In Eq. (17), (a,b) constant may be used to quantify the separability of classes and to determine closely two samples (x,y), under the different skin classes are related.

$$e\,[\,X\,,Y\,] = \frac{1}{N}\sum_i X_i - Y_i \tag{18}$$

In Eq. (18), hyper-convolutional layers $X_i - Y_i$ are evaluated using multi-scale receptive field processing to capture both fine-grained texture and contextual information, enabling the differentiation of visually confusable skin cancer types.

Apply the YOLO Classification algorithm to predict object boundaries and class labels

In Eq. (19), each pixel within the region is characterized based on the amount of associated data.

$$X_O = X_1 + X_2 + X_3 \tag{19}$$

2) Capsule intra transformation

- Approach Routing ($U_{i,j}\,, r,\ l$), All capsules I and J in layer l and (l + 1), respectively.
- for r iterations, do
- for all capsule i in layer l: $C_i = softmax\,(b_i)$
- for all capsule j in layer (l + 1): $S_j = \sum_{i=1}^{N} C_{i,j}\,, U_{i,j}$
- for all capsule j in layer (l + 1): $V_j = Squash\ S_{i,j}$

3) Routing between capsules in a dynamic manner: In Eq. (20), a squash function is applied to normalize the output vectors of capsules.

$$V_j = Squash\,(\sum_i cij\ u\ j|\ i) \tag{20}$$

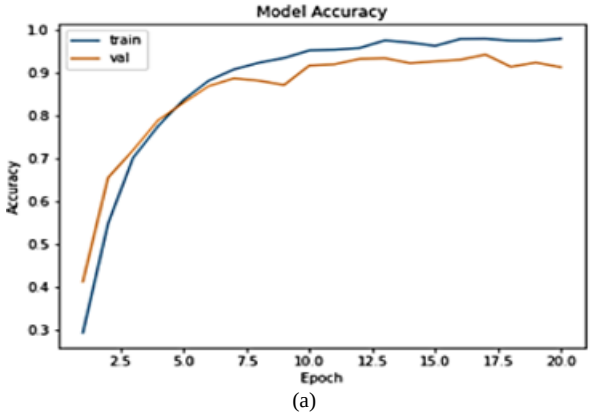
4) Output: The vector magnitude is maintained between 0 and 1 by using the nonlinear squashing function, evaluated in Eq. (21)

$$P\,(y = k\,|\,x\,) = |V_k| \tag{21}$$

IV. Results and Discussion

Skin disease identification is the basis for the experiment calculation, and the system uses a specific dataset from which performance analysis is assessed. The specific test data with predictive values is properly evaluated for feature selection, identification of specific skin conditions, and comparison with previous studies. The APSIO feature selection and HCI-CNN classification are evaluated in this result and discussion.

A. Skin Diseases Dataset Description



The proposed method uses a dataset of high-resolution clinical skin images using the recommended medical application, 10015 images representing seven different classes includes Melanocytic Nevi (6705), Melanoma (1113), Benign Keratosis (1099), Basal Cell Carcinoma (514), Actinic Keratosis (327), Vascular Lesions (142), Dermatofibroma (115) from the HAM10000 dataset and it can be gain from https://www.kaggle.com/ and 1200 clinical images which is collected from individuals. Each image is associated with specific attributes. The dataset is divided into seven categories of dermoscopic images. The images are split into a training set (80%) and a testing set (20%).

B. Feature Selection Calculation

Three feature selection methods are compared in Table II based on feature dimensionality, computational time, and accuracy. When compared based on skin image features, the proposed APSIO method demonstrated superior performance, achieving higher accuracy than other methods across different data volumes. These results demonstrate that APSIO is a highly effective optimization-based feature selection technique, achieving higher accuracy with significantly fewer features and making it well-suited for efficient and accurate skin image classification tasks.

TABLE I COMPARATIVE ANALYSIS OF SKIN FEATURE SELECTION METHODS

Feature Selection	Computational Time (s)	Feature Dimensionality	Accuracy
Histogram of Oriented Gradients (HOG)	1.8	High (~3780 features/image)	92.4
Gray Level Co-occurrence Matrix (GLCM)	1.2	Medium (~20–40 features)	94.3
Adaptive Particle Swarm Intelligent Optimization (APSIO)	2.4	Low (~10–15 optimized features)	95.3

(a)

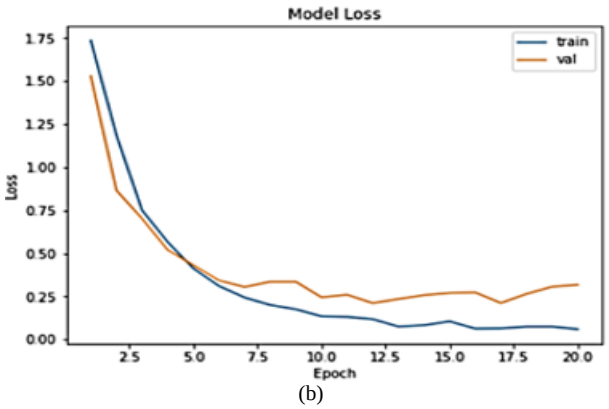


Fig. 7. Training and testing accuracy and loss.

Fig. 7 shows the accuracy of the typical and the loss of the APSIO approach generated from segmented images. The highest value of loss is 1.75, and the value decreases, as indicated by (a), as epochs increase, as indicated by (b). The output of the Dense model performs best on the testing set using segmented images.

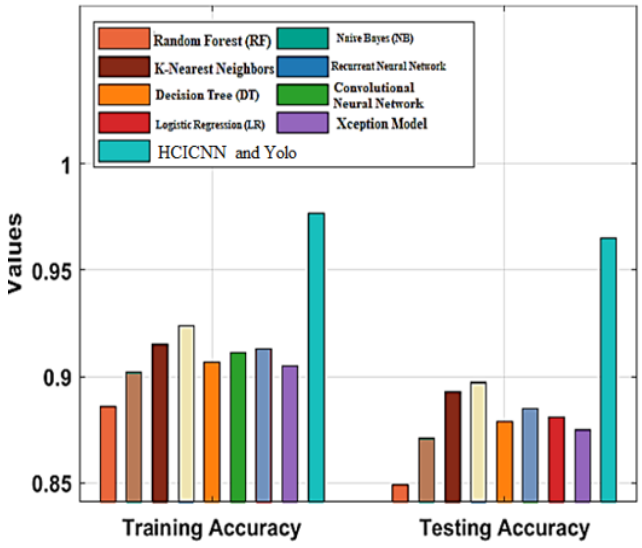

Fig. 8. Training and testing accuracy of hybrid HCI-CNN and YOLO.

Fig. 8 evaluates and compares the performance of different deep learning and machine learning models for classification problems. In terms of generalization, the Hybrid HCI-CNN and YOLO models achieve higher accuracy than the previous classification methods.

C. Experimental Evaluation

The Error-Level Analysis (ELA) in Fig. 9 evaluates the error rates of different classification outputs. The HCI-CNN had a reduced error rate of 5.5%, which was significantly lower than GoogLe-Net 14.3%, ResNet 13.2%, and Mobile Net 8.4% and demonstrates the superior performance of HCI-CNN compared to other models.

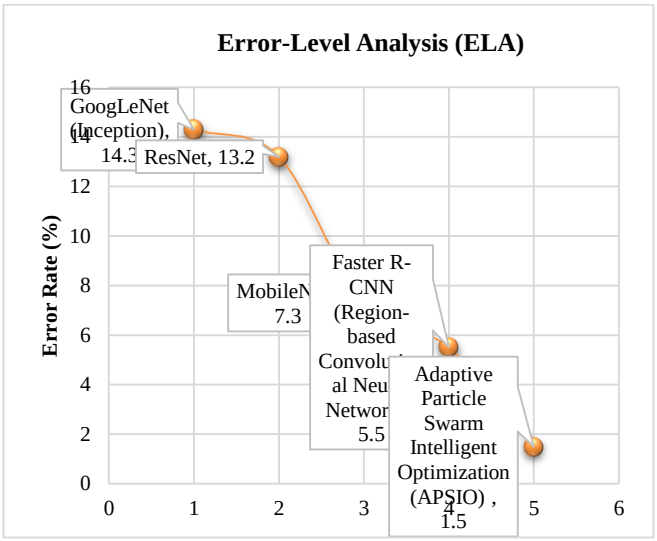

Fig. 9. Error rate analysis.

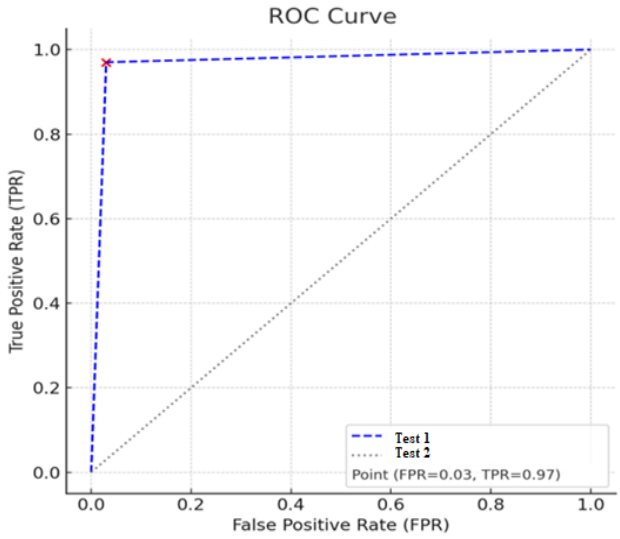

Fig. 10. HCI-CNN classification ROC curve.

Fig. 10 shows the HCI-CNN classification error analysis based on the test data, indicating a True Positive Rate (TPR) of 0.97 and a False Positive Rate (FPR) of 0.03.

D. Comparison Evaluation

Fig. 11 validates that the proposed hybrid approach, HCI-CNN combined with YOLO, reaches a maximum accuracy of 97%, which is significantly better than the previous ResNet50 and K-nearest neighbour, which show accuracies of 94 %, ResNet101V2 accuracy of 86 %.

Fig. 12 shows that the HCI-CNN and YOLO hybrid model significantly improves recall, achieving 96.55% compared to existing methods. Random Forest and SVM achieved recall values of approximately 82.5% and 88.3%, respectively, whereas ResNet achieved 89.3% and Extreme Gradient Boosting achieved 92.5%.

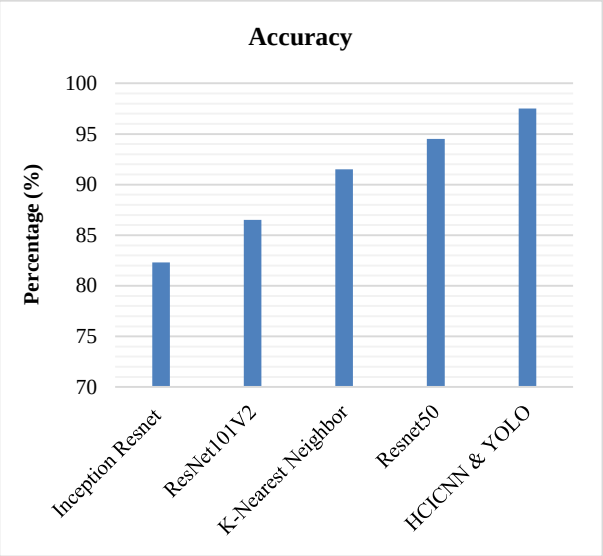

Fig. 11. Proposed classification accuracy analysis.

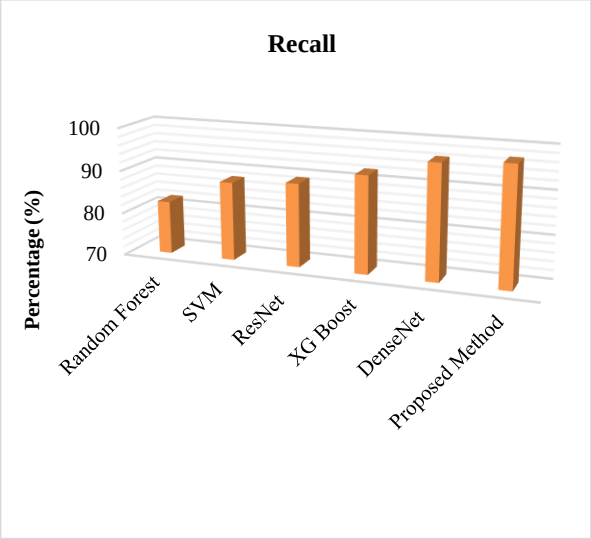

Fig. 12. Proposed recall analysis.

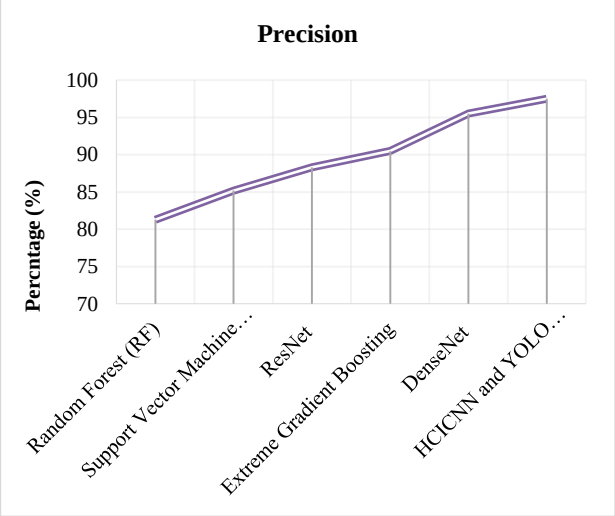

Fig. 13. Proposed precision analysis.

Fig. 13 shows that the proposed HCI-CNN and YOLO method achieves a precision of 96.52%, outperforming other existing methods such as Random Forest (81.3%), SVM (85.2%), ResNet (88.4%), and Dense Net (95.6%).

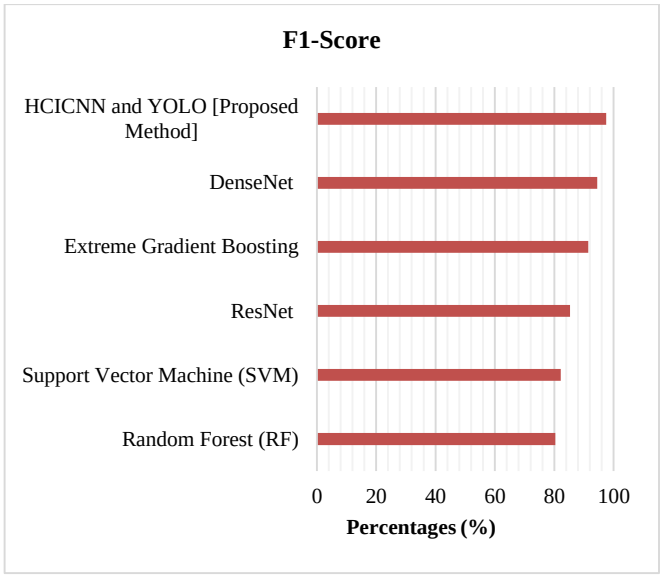

Fig. 14. Proposed F1-score analysis.

Fig. 14 shows a comparison graph of F1-Scores for various machine learning models, including Random Forest and SVM, which demonstrate an average performance of 83%. However, deep learning models such as deep residual networks and eXtreme Gradient Boosting are also compared. The proposed HCI-CNN and YOLO methods are also compared, with the highest F1 score of 96.93% achieved by HCI-CNN, demonstrating its superior performance.

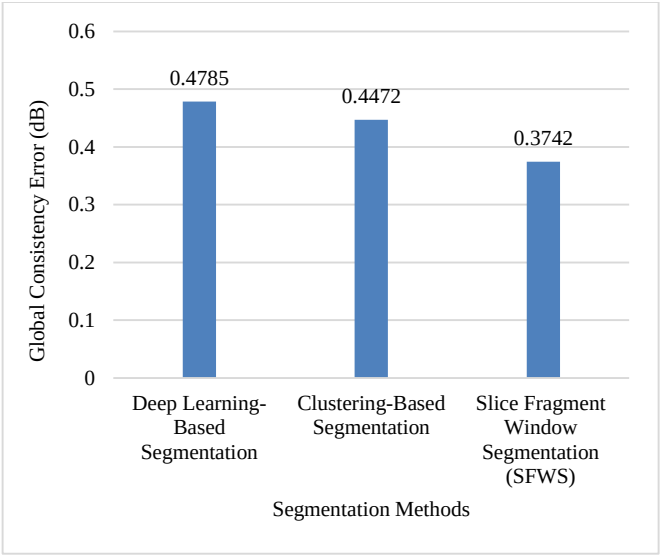

Fig. 15. Proposed segmentation analysis.

Fig. 15 shows the segmentation evaluation of Global Consistency Error (dB) across the three segmentation methods: Slice Fragment Window Segmentation (SFWS), Deep Learning-Based Segmentation, and Clustering-Based Segmentation. The proposed SFWS has the lowest error at

0.3742 dB, demonstrating the highest reliability. In contrast, the Deep Learning-Based Segmentation has an error of 0.4785 dB, followed by the Clustering-Based Segmentation with an error of 0.4472 dB.

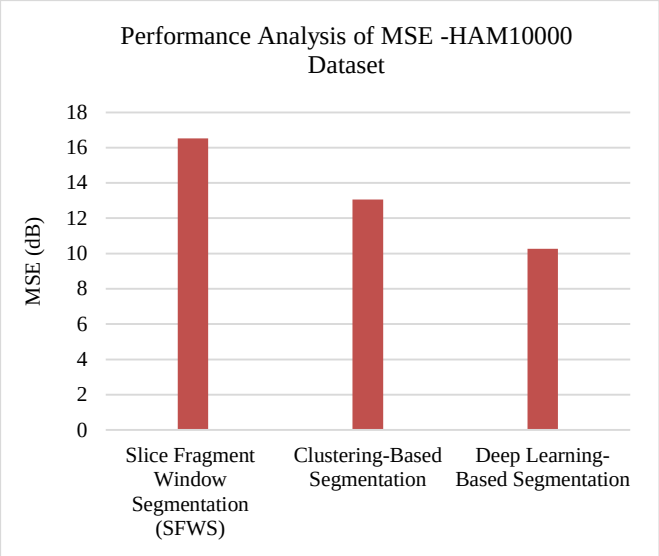

Fig. 16. MSE segmentation comparison analysis.

In Fig. 16 MSE (Mean Square Error) for skin image segmentation with the existing approach is evaluated through the proposed SFWS method as an improved segmentation analysis.

Fig. 17 illustrates the analysis results of the collected clinical skin images. When no dermatological abnormalities are detected in the collected clinical skin image, the system classifies it as normal skin; otherwise, it is classified as a disordered image. Among the 1,200 clinical skin images evaluated, 1,194 were detected as normal, and the remaining 6 were identified as containing dermatological disorders.

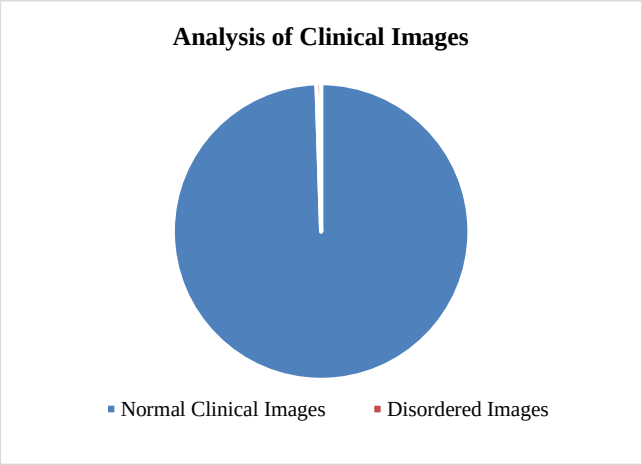

Fig. 17. Assessment of acquired dermatological images.

Table III presents a comparative analysis based on four different parameters, using data from cited references that support the comparison technique.

E. Discussion

Specific AI technologies have a significant impact on reliability and diagnostic classification results for classifying skin disease. In this research work, HCI-CNN and YOLO are applied for classification, while APSIO is employed for feature selection. The combination of these procedures addresses critical tests such as high-dimensional data, feature idleness, and demand for amplified classification accuracy. The mechanism of APSIO dynamically adjusts the limits of the convergence rate. The most discriminative features are selected from dermoscopic images owing to this adaptive mechanism, which decreases computational difficulty without compromising diagnostic accuracy. Deep and wide convolutional layers with multiple levels of abstraction constitute the HCI-CNN architecture, which is effective in capturing.

V. CONCLUSION

The proposed AI-powered skin disease detection method utilizes advanced image processing techniques, including preprocessing, clustering, and classification. Through the preprocessing filter, the image improves in clarity for different skin colors. In segmentation, factors are divided to evaluate geometric and physical damage. In APSIO feature selection, related features are selected. Furthermore, a hybrid approach integrating HCI-CNN and YOLO is employed for effective classification. This approach demonstrates high accuracy in the detection and classification of seven different types of skin disorders. The selective features remove false positives and computational burden, with the added potential for real-time medical applications. In this study, both real-world clinical images from individuals and curated images from established datasets were analyzed to evaluate the system's performance comprehensively. The output performance analysis, with an Accuracy of 97%, a precision of 96.52%, a recall of 96.55%, and an F1-score of 96.93%, will enhance performance and improve classification for applications in healthcare facilities, ultimately leading to improved treatment outcomes for patients with skin diseases.

In the future, the rising plurality and complexity of skin diseases require new modalities with newly available technologies, such as AI and the IoT, to better align and sustain

the management (exposure reduction) of skin diseases. IoT-based wearables equipped with high-fidelity imaging sensors and biosensors can continuously monitor skin surface indicators, temperature, and moisture, as well as the evolution of skin lesions, enabling direct and real-time examination of skin health by identifying the reliable amount of surface data on a person. Combining this data with an AI analytical model, which leverages streaming and real-time data, enables humane dimension management (e.g., tracking behaviors, detecting anomalies, and risk stratification) while learning and evolving. Future directions for connected wearables in regulating dermatological diseases can be supported by hybrid frameworks of learning, such as federated learning and edge cloud learning, which erase discreet elements to reduce decentralized training mechanisms using decentralized data. This approach maintains the patient's anonymity and increases the potential for generalizability.

Deep Learning Optimization Conception: Less Data, Less Time, More Performance

Mohamed Amine MEDDAOUI, Moulay AMZIL, Imane KARKABA, Mohammed ERRITALI
Data4Earth Laboratory, Sultan Moulay Slimane University, Beni Mellal, Morocco

***Abstract*—Although Deep Learning has not made a breakthrough in terms of artificial intelligence core technology, it achieves the best worldwide performance across areas such as computer vision and natural language processing. However, it depends on large-scale datasets and enormous computational resources. This paper tackles a major issue: Can we train more efficient deep learning models with less data in less time? We look at numerous strategies designed to reduce the burden of training, without letting the quality deteriorate. From transfer learning and few-shot learning to lightweight architectures, synthetic datasets produced artificially, as well as dispersed training, we contemplate how to make advanced AI subsystems fit for running under scarce resources. The aim is to lay down a future for deep learning that is more sustainable and all-embracing. This research focuses on the important issue of streamlining deep learning models with balancing model performance against data collection and computations. We look into other approaches such as transfer learning, couple with fewshot learning, data augmentation, architecture optimization, and parallelization. We explain processes with their benefits as well as their setbacks. Our research shows that training a model more efficiently improves the overall training process, making it cheaper and greener. A change like this would help more people use sophisticated AI systems even when limited by constrained resources. This broadens the real-world application of AI technology and further stimulates innovation in the area.**

Keywords*—*Deep Learning; AI; IoT; optimization; transfer learning; model compression; few-shot learning

I. Introduction

Deep learning, a branch of machine learning inspired by the intricate workings of the human brain, has truly transformed countless fields. Think about computer vision, natural language processing, or even speech recognition deep learning has been a game-changer. Its incredible success largely comes from its knack for learning complex patterns from huge amounts of data, leading to breakthroughs in things like image classification, spotting objects in photos, translating languages, and even self-driving cars. But here's the catch: deep learning models often hit a wall because they need so much data and so many powerful computers. This reliance can make it tough for researchers and organizations without easy access to data or supercomputers to get involved. Plus, there's a growing concern about how much energy these massive models consume during training, which isn't great for the environment. Right now, deep learning often demands a ton of data collection and labeling, which can be incredibly expensive and eat up a lot of time. This is especially true in niche areas like medical imaging or working with rare languages. On top of that, training today's most advanced deep neural networks can take days or even weeks, burning through significant energy and money. These limitations make deep learning less accessible, particularly for smaller businesses and in places with fewer resources. So, the big question we're tackling in this research is fundamental: Can we create more efficient deep learning models that need less data and less training time, all without sacrificing performance? This effort is super important because it aims to open up advanced AI to everyone, shrink its environmental footprint, and speed up research and development. Ultimately, it's about sparking innovation and making deep learning useful in even more places. In this paper, we dive into various strategies designed to ease the burden of training deep learning models, focusing on ways to make them more efficient and sustainable. We'll explore methods like transfer learning and few-shot learning, which cleverly reuse existing knowledge and cut down on data needs. We'll also look at lightweight designs that reduce how much computing power is required. And we won't stop there we'll investigate the potential of creating artificial datasets and using distributed training to get around data shortages and speed up the training process. To give you a clear picture, here's how we've structured this paper: Related work is given in Section II. Section III explores the hurdles of training deep learning with limited resources. Data Minimization techniques is shown in Section IV. Section V dives into and evaluates different techniques for minimizing data and time while keeping performance high. Section VI gives you practical examples of these techniques in action. Section VII brings up topics for future research, including potential impacts and ongoing challenges. Finally, Section VIII wraps things up by summarizing our findings and highlighting the real scientific value and practical uses of our work.

II. Related Work

The quest to make deep learning more efficient, especially in terms of data and computing power, has really picked up steam in recent years. Researchers have been exploring all sorts of ways to tackle the challenges of massive datasets and long training times. Take transfer learning, for example it's become a go-to for efficient deep learning. Early on, Pan and Yang [1] gave us a great overview of transfer learning techniques, showing how useful it is when you don't have a lot of labeled data. Since then, others have built on that work, proving its effectiveness in everything from analyzing medical images, CheXpert [2] to understanding human language Devlin [3]. Then there's few-shot learning, which is all about teaching models to learn from just a handful of examples. Researchers like Lake and his team [4] have been playing with metalearning to help models adapt quickly to new tasks with very little data. You've got things like prototypical networks Snell [5] and

Matching Networks Benmalek [6], which are cool architectures designed specifically for few-shot learning and have shown some really promising results in classification tasks. These methods are a lifesaver in fields where getting data is tough or expensive. Data augmentation is another popular trick. It's all about artificially beefing up your dataset to help your model generalize better. We've moved beyond simple things like rotating or scaling images. Now, we're using advanced techniques like Generative Adversarial Networks (GANs) to create brand new, realistic data Strubell [7]. This is a huge help when you're dealing with scarce or sensitive data. And let's not forget about architectural innovations. We've seen the rise of lightweight deep learning models like MobileNet Ly, A [8] SqueezeNet and EfficientNet Meddaoui [9]. These are designed to be super-efficient, so they can run on devices that don't have a lot of power, proving that you can get great performance without a massive model. Finally, distributed training and parallelization have been a game-changer for training huge models. Work by folks like Soham and his team [10] on large-scale distributed deep learning has made it possible to train models with billions of parameters. By spreading the work across multiple GPUs or machines, you can slash training times. Of course, there are still challenges to iron out, like communication bottlenecks and keeping everything in sync, but it's an active area of research. This paper pulls together all these ideas, giving you a big picture view of how we can make deep learning more sustainable and accessible to everyone.

III. Challenges of Training Deep Learning with Limited Resources

It is true that the incredible performance of deep learning models results from various factors, among which data quality and quantity is most important. The deep trained neural models with numerous parameters require not only immense volumes of labeled data, but also diverse data, wide variety of examples to construct powerful and generalizable representations. Models will be useless and unreliable, underperforming, poorly generalizing, or mislearning spurious correlations without diverse data. This reliance on massive datasets creates a major challenge in specialized fields where data is difficult to obtain, expensive, needs to be labeled, or is restricted by privacy regulations such as medicine or rare languages. Researchers often have to create inefficient strategies to counter their inability to obtain enough high-quality labeled data because of stringent privacy regulations. Such constrained inefficient methods greatly limit frontier deep learning users.

A. Dependence on Large Datasets

It is common wisdom that the success of deep learning rests on many factors, but most fundamentally: quantity and quality in data. Moreover, at least to a large degree, very large amounts of fast processor power are also necessary. To effectively represent powerful and generalizable representations, a deep neural network with a large number of parameters (high dimensionality) requires massive labeled data Khan, T [11]; lacking this data, models could be in danger of converging incorrectly or having characteristics they truly do not have or generalizing tendencies to ill effect. Such data has not always been easy to come by: sometimes expensive and obscure, particularly in medicine or rarer tongues. Such scarcity necessitates wasteful learning from scratch and brings into brighter relief techniques that need adaptation for low data quantity.

B. Computational and Temporal Cost

Anybody knows that Deep learning is the most important deep neural network benefiting everything requires speed and plenty of data. The two chief factors are data volume and quality, as well as computing resources, which do not come cheaply either. The known algorithms have won several prestigious honors Aaron [12] continue to improve standards in this area. It is possible to explore the great potential for improving our techniques as it were, even if only. Deep neural networks, because of their numerous parameters, must possess a large amount of labeled data in order to yield powerful and general representations (at least when trained on an array of different input data). Without such information, Park [13] models are at risk of converging; they have features that are pertinent yet not general enough, which results in poor performance. But it is not easy to collect these data from anywhere; at times it can be costly and complicated, particularly in medicine or for rare languages. This lack of information means inefficient training from scratch, emphasizing the need for methods suited to small amounts of data. In addition to being data dependent, the training of deep learning algorithms incurs high computational costs as well as temporal costs that are challenging to meet. The training of advanced deep neural networks is extremely demanding and usually requires a great deal of computation to be processed—often in the form of GPUs or TPUs—for days to weeks at a time. This form of computation comes at a heavy price, both in terms of hardware and energy. Training one large deep learning model can also incur additional electricity costs, thus contributing to a larger carbon footprint, Qasim [14] Almost all of the economic and environmental costs inhibit the utilization of deep learning, specifically for small and medium enterprises (SMEs) or in geographies with limited access to sophisticated computing systems. Rather than an academic endeavor, this motivates the need to build more optimal deep learning frameworks in order to equalize access to AI, lower its environmental footprint, and hasten innovation in multi-industries. Zhao [15] Focusing on these needs not only advances deep learning but also leads to a more impactful sustainable future.

C. Overfitting and Generalization

With limited data, overfitting usually could happen. The overfitted model learns the training data by heart and also remembers noise as opposed to general patterns it should be learning from the training data. Jonas [16] It will do poorly on new examples. The risk of overfitting is increased when little data is processed because the model has fewer examples to illustrate diversity. Regularization techniques help reduce the bad effects, but do not compensate for the absence of diversity. A model's utility is really in its ability to generalize, and if overfitting happens, this is compromised. For this reason, optimization strategies must ensure an important element of generalization.

IV. Data Minimization Techniques

In an effort to address the difficulties posed by the lack of data and the high resource requirements of deep learning, the development of models and algorithms which require less labeled data and less training time has become a point of focus. These efforts are essential to the accessibility, efficiency, and sustainability of deep learning. In this chapter, we present data minimization methods such as Transfer Learning, Few-Shot Learning, Zero-Shot Learning, as well as Data Augmentation, explaining their principles, benefits, and case studies.

A. Transfer Learning and Fine-Tuning

Transfer learning (Fig. 1) reuses a pre-trained model on a similar task with a large dataset, then adapts it to a new specific task with a smaller dataset for Gupta [17].

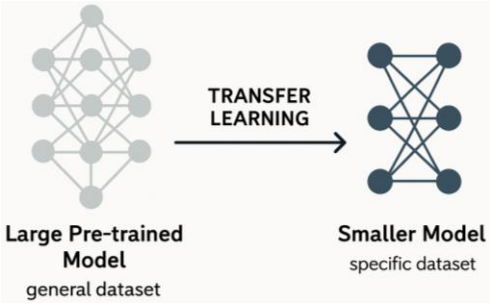

Fig. 1. How transfer learning operates.

1) Principles and advantages: The lower layers of deep networks learn generic features (edges, textures). Reusing these pre-trained layers leverages the knowledge acquired over a large corpus, reducing the data requirement for the new task and accelerating training. Advantages: data reduction, training acceleration, performance improvement, overfitting reduction as Soham [10]. The schematic illustration of transfer learning is given in Fig. 2.

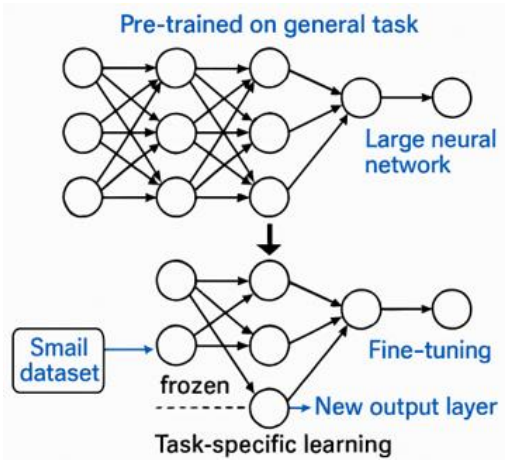

Fig. 2. Schematic illustration of transfer learning.

2) Fine-tuning strategies fine-tuning adapts the pre-trained model strategies:

a) Feature extractor: Pre-trained layers frozen, only a new classification layer is trained. Useful for similar small datasets Rohith [18].

b) Partial fine-tuning: Top layers thawed and trained, bottom layers frozen. Suitable for medium or slightly different datasets.

c) Full fine-tuning: All layers trained with a very low learning rate. For large datasets or very different tasks as Li, T [19].

The choice depends on the size and similarity of the new dataset.

B. Few-Shot Learning and Zero-Shot Learning

These paradigms allow models to recognize new classes with an extremely limited number, or even zero, of labeled examples.

1) Meta-learning: Meta-learning, or "learning to learn," trains a model to quickly adapt to new tasks from a few examples. The goal is to give the model the ability to quickly adapt to new data distributions or classes: Assiri [20]. Categories:

a) Optimization-based: Learns an initialization function or optimization algorithm for fast adaptation (e.g., MAML) [14].

b) Metric-based: Learns a distance function in an embedding space where similar examples are close (e.g., Siamese networks, prototypes) Nguyen [21].

c) Model-driven: Uses specific architectures with memory or attention mechanisms to manage limited data.

2) Metric learning: Learns a similarity function to measure the proximity between examples. Classification is done by distance comparison. Siamese networks train the model to produce embeddings where similar pairs are close together. Prototype networks learn one "prototype" per class. These methods allow efficient classification with few examples, Liu [22].

Zero-Shot Learning (ZSL) classifies never-before-seen classes by exploiting semantic information (attributes, word embeddings). The model maps data to a shared semantic space to recognize new classes without direct examples, Chen [23].

Table I Comparison of Few-Shot Learning approaches (Meta-learning vs. Metric learning).

TABLE I. Comparison of Few-Shot Learning Approaches (Meta-Learning vs. Metric Learning)

Characteristic	Meta-learning	Metric learning
Main objective	Learn to learn new tasks quickly	Learn a similarity/distance function
Mechanism	Learn an initialization or algorithm	Learn an embedding space
Examples of methods	MAML, Reptile	Siamese Networks, Prototype Networks, Relational Networks
Adaptation to the task	Fast, via a few optimization steps	By distance comparison with support examples
Complexity	Can be complex to train	Easier once the metric is learned
Required data	Requires various meta-training tasks	Requires pairs of examples to learn the metric

Benefits	High flexibility, rapid adaptation	Effective for classification with few examples
Disadvantages	High computational cost, sensitivity to hyperparameters	Less flexible for very different tasks

C. Data Augmentation

Data augmentation refers to a technique that modifies existing data in order to increase the size and diversity of the training dataset. This reduces the amount of real world data that needs to be collected, improves the model generalization and prevents overfitting. For image data, common augmentation techniques include rotations and flips, shifts and scaling, as well as color jittering. In the case of text data, augmentation techniques include synonym replacement and random insertion, deletion or even swapping of words. Generative Adversarial Networks (GANs) are more sophisticated augmentation methods which can be used to create new and realistic data samples that augment the original dataset, Thakor [24]. This approach is particularly useful in machine learning since it enables the model to learn a broader spectrum of variations, increasing robustness while reducing the risk of memorization.

1) Classical techniques: For images: geometric transformations (rotation, translation, scaling, flipping) and photometric transformations (brightness, contrast, noise) Ghorbal [25]. For text: synonym substitution, word insertion/deletion/exchange, back-and-forth translation, Latha [26].

2) Generative augmentation (GANs, VAEs) Generative models create realistic synthetic data:

a) GANs (Generative Adversarial Networks): A generator creates data, a discriminator distinguishes it from real data. The generator produces high-quality samples, useful for rare data, Gao [27].

b) VAEs (Variational Autoencoders): Learn a latent representation of the data to generate new samples. Less realistic than GANs, but more stable and controllable Alsolai [28].

Useful for expensive or sensitive data (medical imaging).

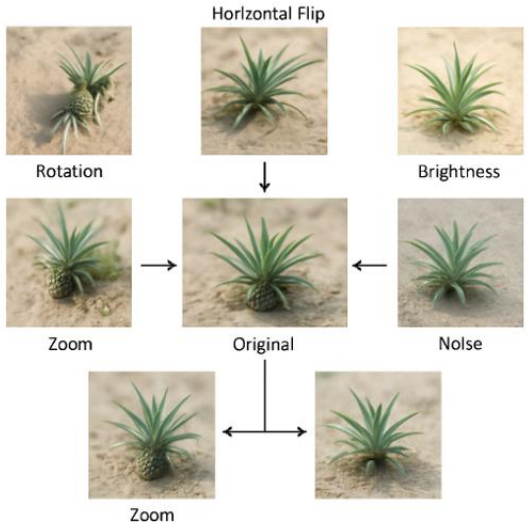

Fig. 3. Example of image transformations for data augmentation.

D. Data Synthesis and Synthetic Data

Data synthesis creates new examples that mimic the statistical properties of real data, especially when collection is impossible or raises privacy concerns for Noor [29]. GANs and VAEs produce high-fidelity synthetic data. Advantages: confidentiality, unlimited availability, attribute control, cost reduction Zhang [30]. The quality of synthetic data is crucial for model generalization. Fig. 3 shows image transformations for data augmentation.

V. Techniques for Minimizing Training Time

Reducing training time is crucial for the effectiveness of deep learning. This involves optimizing architectures, algorithms, and resource utilization.

A. Optimization of Model Architectures

Designing lighter and more efficient models reduces training time and resource consumption.

1) Lightweight and efficient models (MobileNet, EfficientNet): These architectures minimize parameters and operations while maintaining accuracy. MobileNet for Meddaoui [31] uses depthwise separable convolutions, reducing complexity. EfficientNet Xu, L [32] optimizes depth, width, and resolution via compound scaling, delivering accurate and efficient models with fewer parameters. These models are ideal for transfer learning and deployment on constrained devices.

2) Model compression (pruning, quantization, distillation): Reduces the size and complexity of trained models without compromising performance, crucial for deploying and accelerating inference and training.

a) Pruning: Removes non-essential connections or neurons. Low weights are set to zero. The pruned network is fine-tuned to recover accuracy, Anda-Suárez [33].

b) Quantization: Reduces the numerical precision of weights and activations (e.g. FP32 to INT8). Reduces model size, memory and speeds up operations, Han [34].

c) Knowledge distillation: A small model ("student") learns from a large model ("teacher"). The student is trained on the teacher's class probabilities, improving its performance despite its small size as Markkandeyan [35].

B. Hyperparameter Optimization

1) Bayesian search: Constructs a probabilistic model of the objective function to choose the hyperparameters to evaluate. More efficient than grid or random search because it uses previous results to guide future evaluations Kovalev [36].

2) Gradient-based optimization: Allows to optimize hyperparameters by making them differentiable with respect to the objective function, using gradient descent. Efficient for high-dimensional hyperparameter spaces (Fig. 4) [30].

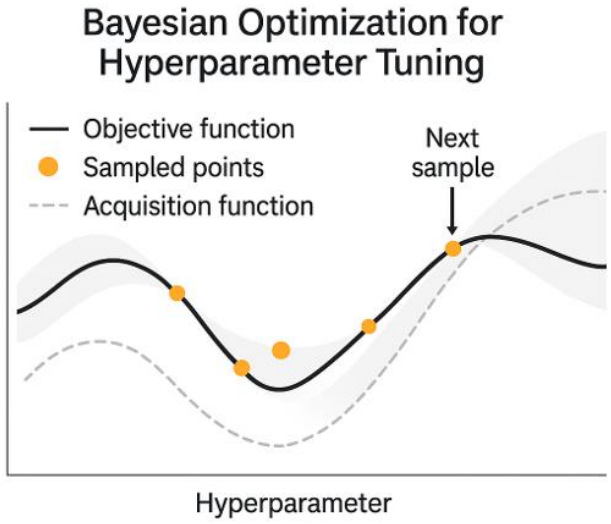

Fig. 4. Illustration of the Bayesian search process for hyperparameter optimization.

C. Parallelization and Distributed Computing

Distributes the workload across multiple devices or machines to reduce training time.

1) GPU/TPU Training: GPUs and TPUs are hardware accelerators for matrix-intensive deep learning computations. They enable considerable training speedups. Modern frameworks are optimized for these units for Markkandeyan [37].

2) Distributed computing frameworks (Horovod, Ray) for distributed training across multiple GPUs or machines:

a) Horovod: Simple and fast distributed framework, integrates with TensorFlow, Keras, PyTorch. Uses AllReduce to aggregate gradients efficiently, enabling near-linear scaling as Dillshad [38].

b) Ray: Open-source framework for distributed applications. Provides a simple API for parallelizing tasks and managing resources. Suitable for distributed training and hyperparameter optimization.

These frameworks leverage aggregated computing power to drastically reduce training time. Fig. 5 shows schematic of distributed training with multiple GPUs/TPUs.

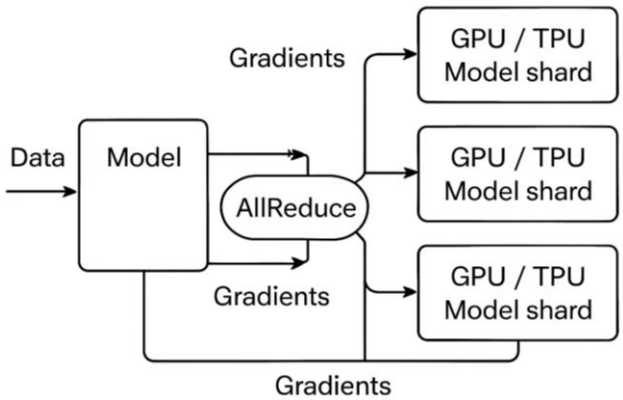

Fig. 5. Schematic of distributed training with multiple GPUs/TPUs.

D. Incremental and Continuous Training

Updates a model incrementally with new data, rather than retraining it from scratch. Useful when new data arrives or the model needs to adapt to changes. Reduces training time by fine-tuning the existing model. Requires handling "catastrophic forgetting" (loss of prior knowledge) with techniques such as regularization. Continuous training adapts the model in real time, essential for dynamic applications.

E. Performance Measurement and Evaluation

Evaluating models optimized for limited resources is crucial. Traditional metrics must be complemented by efficiency and robustness indicators. Fig. 6 and Fig. 7 shows training time and accuracy comparison.

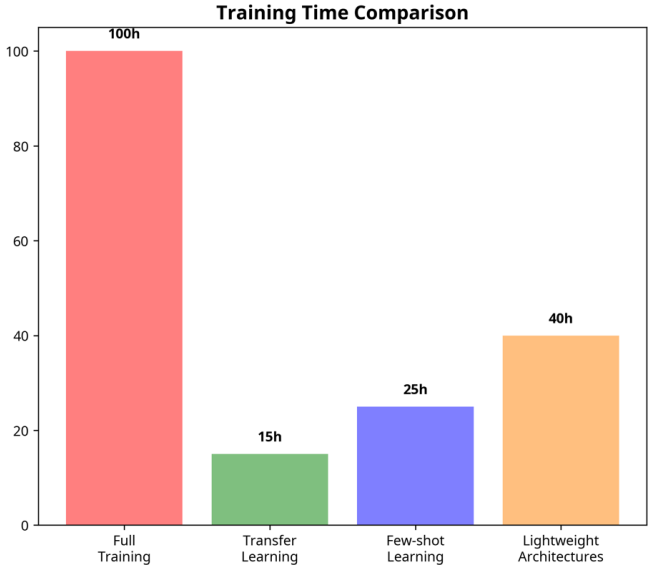

Fig. 6. Training time comparison.

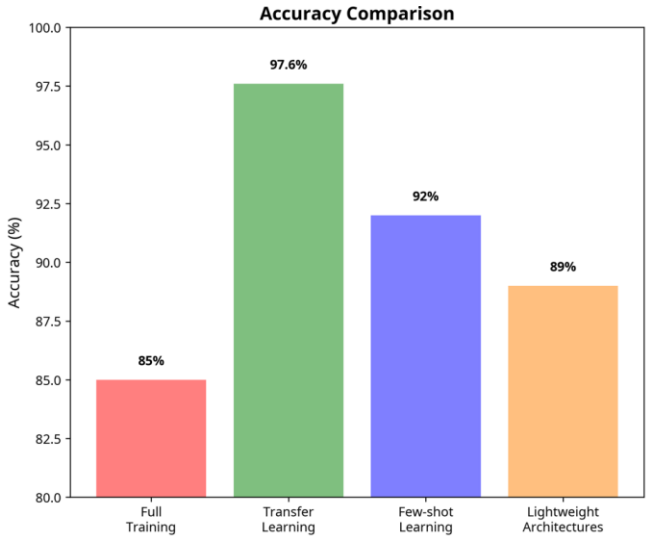

Fig. 7. Accuracy comparison.

1) Metrics adapted to limited resources: Besides precision, accuracy, recall, F1 score and AUC-ROC, one should consider:

a) Model complexity: Number of parameters and FLOPs/MACs to assess size and computational complexity. Fewer parameters/FLOPs = lighter and faster.

b) Training and inference time: Real time required, directly related to the minimization objectives.

c) Energy consumption: Evaluates the carbon footprint of the model, which is increasingly relevant.

d) Robustness to small perturbations: Evaluates the model's response to small changes in the data, crucial for limited and less diverse data.

Table II presents an illustrative comparison of different deep learning techniques in terms of Precision, Recall, and F-score. The values are hypothetical and aim to demonstrate general trends observed in literature and practice, rather than specific experimental results

TABLE II. COMPARATIVE TABLE OF DEEP LEARNING TECHNIQUES

Technique	Precision (%)	Recall (%)	F-score (%)
Full Training	90.2	88.4	89.3
Transfer Learning	98.5	96.2	97.4
Few-Shot Learning	92.8	90.1	91.5
Lightweight Architectures	93.6	92.4	93

2) Precision: The proportion of true positives among all positive results (true positives + false positives). Recall: The proportion of true positives among all actual positive cases (true positives + false negatives). F-score: The harmonic mean of precision and recall, useful for evaluating models on imbalanced datasets. Value ranges indicate potential variability depending on the application domain, task complexity, and data quality. Transfer learning often excels in precision and recall, especially with limited data, as it leverages pre-existing knowledge. Few-Shot Learning may have slightly lower F-score performance due to the inherent difficulty of generalizing from very few examples, but it is crucial in extremely data-scarce scenarios. Lightweight architectures offer a good compromise between performance and computational efficiency, making them ideal for deployments on resource constrained devices.

3) Cross-validation and robustness: Cross-validation is essential for assessing generalization, especially with limited datasets. K-fold cross-validation divides the data into k folds: the model is trained k times on k-1 folds and evaluated on the remaining fold. The final performance is the average. This maximizes data utilization and reduces bias in the performance estimate.

Robustness, the model's ability to maintain stable performance in the face of noise or variation, is vital. Adversarial training or data augmentation improves this robustness, making the model more reliable in real-world conditions.

VI. CASE STUDIES AND PRACTICAL APPLICATIONS

Optimization techniques have proven their effectiveness in various fields, overcoming data and time constraints.

A. Computer Vision (Medical Image Classification with Little Data)

The scarcity of labeled medical images makes training challenging. Transfer learning and data augmentation are key. For rare disease detection (Fig. 8) (e.g., chest X-rays), a pre-trained model on ImageNet is fine-tuned on the small medical dataset Data augmentation (rotation, zoom, etc.) and conditional GANs increase diversity, reducing overfitting and protecting privacy.

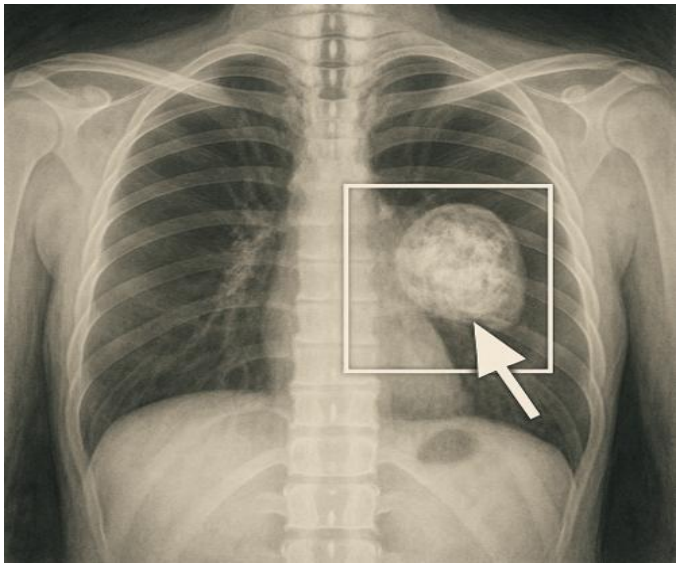

Fig. 8. Example of a chest X-ray with rare disease detection.

B. Natural Language Processing (Language Models for Rare Languages)

LLMs require terabytes of text, which is impossible for low-resource languages. Transfer Learning is the solution. A large pre-trained multilingual model is fine-tuned on the small bilingual corpus of the rare language. Few-shot learning and text data augmentation (paraphrases, back-and-forth translation) allow the model to be adapted with few examples, making NLP workable for these languages.

C. Industrial Applications (Defect Detection with Few Samples)

In industry, defects are rare, creating class imbalance and data deficiency. For visual inspection (e.g., electronic components), a pre-trained object detection model is adapted with Few-Shot Object Detection on a few defect examples.Generating synthetic defect data (3D simulations) complements real data, enabling robust training. Optimizing architectures (e.g., MobileNet) allows deployment on capacity-limited devices, reducing inference time.

These cases demonstrate that, despite constraints, optimization makes Deep Learning applicable and efficient in real-life scenarios with limited resources, democratizing AI.

VII. Discussion and Perspectives

Due to the exploratory nature of this optimization deep learning techniques, which survey rather than rigorously assess specific methodologies, a detailed empirical analysis with quantitative evaluation falls outside the focus of this research. Regardless, the effectiveness of the discussed methods Transfer Learning, Few-Shot Learning, Data Augmentation, and Lightweight Architectures is well-established. In this section, we try to outline the anticipated outcomes of applying the techniques discussed above and provide arguments justifying the adoption. Based on the findings presented in this paper, the implementation of some of the optimization strategies is expected to lead to remarkable results in a few critical performance metrics.

Data Requirements: The amount of labeled data needed to train effective models is likely to be caused by strategies like transfer learning and few shot learning. Take, for instance, the case where a model is only required to be fine-tuned on a certain task. With the use of a small dataset, such a model can perform as well as a model that has been trained on a much larger dataset from scratch. This is of great importance in data scarce fields such as medical imaging or more advanced specialized NLP tasks. Optimizing deep learning training with limited resources is a key area. The techniques discussed (transfer learning, few-shot learning, data augmentation, architectural optimization, compression, parallelization) offer promising solutions for more accessible and sustainable deep learning. However, challenges remain. Reducing the Time Needed for Training: The use of pre-trained models, alongside their architectures and distributed training systems, greatly cuts down the time it takes to train deep learning models. These changes not only save on the cost of computation but also speed up the development and research processes which means newer models can be iterated and deployed more expeditiously.

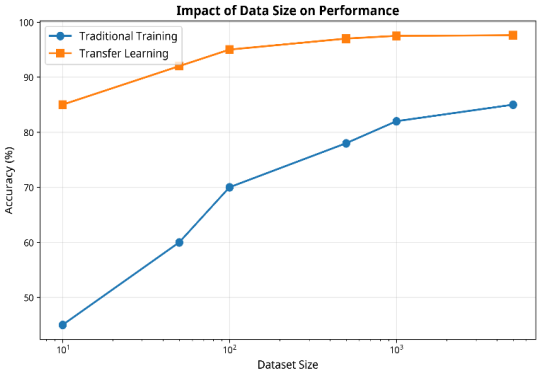

Fig. 9. Impact of dataset size on performance.

Improved Effectiveness and Strength: Robust models which improve the generalization capabilities to unseen examples and reduce overfitting largely benefit from data augmentation. This is important for deploying models in a wide range of scenarios because data variability can often be very high. Lowering the Computational Footprint: Deep learning is becoming more available for edge computing applications, as well as aiding in energy conservation. Models designed with lightweight frameworks, meant to run effectively on devices with low resources, reduce memory consumption, speed up inference, and cut down on energy use. Fig. 9 shows impact of dataset size on performance.

Dataset used: NIH Chest X-ray Dataset, CheXpert (Stanford), The Cancer Imaging Archive (TCIA), Brain Tumor MRI Dataset (Kaggle), Hugging Face Datasets.Zhao [39].

We can see, as long as the dataset is large then accuracy is high; but in the case of transfer learning the accuracy is not influenced by small dataset size.

A. Limitations of Current Approaches

1) Dependence on the pre-trained model: The effectiveness of Transfer Learning depends on the relevance of the source model. A target task that is too distant limits the benefits.

2) Complexity of few-shot learning: Designing and training meta-learners is complex, requiring diverse meta-training datasets.

3) Synthetic data realism: Generating high-fidelity synthetic data remains a challenge. Insufficient realism can hinder generalization to real data.

4) Performance-efficiency tradeoff: Compression techniques (pruning, quantization) can result in a slight performance loss. The optimal balance is a research challenge.

5) Catastrophic forgetting: In incremental training, the model may forget previous knowledge while learning new knowledge. Robust solutions are needed.

B. Future Research Directions

1) Several promising avenues:

a) Self-supervised and self-trained learning: Reduces reliance on labeled data by generating internal supervisory signals, enabling more efficient training on unlabeled data.

b) Neuro-symbolic AI: Integrating Deep Learning with symbolic methods to learn with less data by exploiting a priori knowledge and logical rules, improving generalization and robustness.

c) Active learning: Allows the model to identify the most informative examples to label, reducing the cost and time of manual annotation.

d) Joint optimization: Simultaneously optimize architecture, hyperparameters, and training strategies for globally optimal configurations.

e) Specialized hardware and co-designed algorithms: Developing new hardware architectures for lightweight models and efficient algorithms, pushing the limits of performance and energy efficiency.

C. Ethical and Practical Implications

Deep learning optimization makes AI more accessible, bridging the digital divide. However, it raises questions about the accountability of models trained on synthetic or limited data, and the need to ensure fairness and transparency. Reducing energy consumption is positive, but the exponential growth of models requires continued vigilance.

VIII. Conclusion

Our primary contributions are threefold: (1) a detailed analysis of the key challenges involved in training deep learning models under limited data and computational resources; (2) a comprehensive review and evaluation of state-of-the-art techniques aimed at minimizing data requirements and training time while preserving high performance; and (3) a discussion of the practical implications and benefits of adopting these optimization strategies across various contexts. While this paper provides a strong theoretical foundation and integrates current knowledge, it is important to acknowledge certain limitations. Notably, it does not include new experimental results; thus, the quantitative validation of these combined strategies remains a priority for future research. Additionally, the rapid pace of innovation in deep learning calls for continuous reassessment of such surveys, as new models and optimization methods continue to emerge. Looking ahead, several promising directions warrant further exploration. Empirical evaluation of how these optimization techniques interact across diverse, real-world datasets would provide essential insights. Future research may also focus on developing automated systems capable of selecting and adapting optimization strategies to specific tasks and resource constraints. It is equally important to examine the ethical implications of data minimization, particularly in sensitive domains where fairness, privacy, and accountability are critical. Finally, integrating optimization approaches with hardware-software co-design frameworks may lead to even greater gains in efficiency and scalability. Ultimately, this work aims to support a vision of deep learning that is not only powerful and performant, but also sustainable, accessible, and broadly applicable.

A Novel Hybrid HO-CAL Framework for Enhanced Stock Index Prediction

Zeren Shi, Othman Ibrahim, Hanini Ilyana Che Hashim
Faculty of Management, University Technology Malaysia, Skudai 81310, Johor, Malaysia

***Abstract*—The accurate prediction of stock indexes plays a critical role in supporting investment decisions and managing financial risks. This study proposed a novel hybrid deep learning model that integrated the strengths of Convolutional Neural Networks (CNN), the Attention mechanism, and Long Short-Term Memory (LSTM) networks to enhance the modelling of temporal patterns in financial time series. To further improve the prediction performance, the Hippopotamus Optimization (HO) algorithm was incorporated to fine-tune the networks parameters. This is the first application of the CNN-Attention-LSTM (CAL) architecture to stock index prediction. Ablation experiments revealed that the proposed CAL significantly outperformed traditional CNN, LSTM, and CNN-LSTM models, highlighting the effectiveness of the Attention-based architecture. Comparative analyses also demonstrated that the HO-optimized CAL (HO-CAL) model achieved superior predictive accuracy across multiple markets, confirming both the robustness of the hybrid model and the optimization algorithm. These findings underscore the potential of combining deep learning architectures with metaheuristic optimization to improve the prediction accuracy in financial markets, offering valuable insights for real-world investment strategies.**

***Keywords*—Attention mechanism; CNN; LSTM; stock index; hippopotamus optimization algorithm**

I. Introduction

With the rapid development of the global economy and increasing maturity of financial markets, stocks play an important role in economic progress [1]. It has become an important investment tool for investors due to its high return characteristics. In the stock market, accurate price prediction is important for investors' decision making and risk management [2]. Nevertheless, the stock market is highly volatile and stock data are characterized by large volume, non-linearity, and noise, which makes accurate prediction extremely challenging [3]. The stock index as an investment weathervane is especially critical. Thus, exploring more efficient and accurate prediction methods has attracted increasing attention from researchers and investors.

Traditional econometric methods, such as ARIMA and GARCH, perform better on low-volatility time series, yet they are unable to deal with high-dimensional and highly nonlinear financial data as complexity and uncertainty increase [4]. Machine learning methods such as Random Forest (RF) and Support Vector Machine can learn the nonlinear relationship between stocks and various impact factors effectively [5]. However, these methods are limited in dealing with noise and missing data and rely too much on feature selection, which leads the prediction accuracy to be difficult to reach the expectation [6]. Recently, deep learning has been shown to perform better than traditional machine learning in stock price analysis because its stronger learning and adaptive capabilities [7]. Most representative neural networks have superior nonlinear generalization abilities. Such as convolutional neural networks (CNN) and long short-term memory networks (LSTM) have become the first choices for handling financial time series, and the applications include stock price, volatility, and trend prediction [8]. However, there are still some significant weaknesses in the existing methods: insufficient modelling of sequence patterns, poor extraction of deep data features, and difficulties in handling large-scale long-term data owing to overfitting and gradient issues [9].

To address these issues, this study proposes a novel short-term stock index prediction model. First, CNN is utilized to extract deep features from stock data, then the Attention mechanism is introduced to assign higher weights to key features, and finally, LSTM is used to mine long-term time series features, that is, the CNN-Attention-LSTM (CAL) hybrid model. The three work in concert to extract more comprehensive and in-depth feature information over multiple time periods, to adapt to the characteristics and requirements of short-term stock prediction and improve the prediction accuracy.

It should be noted that the choice of neural network hyperparameters has a significant impact on the prediction performance [10], and the hyperparameters of CAL are numerous and interrelated. Traditional hyperparameter tuning methods, such as Grid Search and Random Search, are inefficient and prone to falling into local optimal solutions [11]. To address this problem, researchers have used optimization algorithms to automatically find the suitable hyperparameters of the model, such as the Genetic Algorithm and Particle Swarm Optimization (PSO). As an emerging metaheuristic optimization algorithm, the Hippopotamus Optimization (HO) algorithm simulates the feeding and social behaviors of hippos in nature [12]. It shows strong potential for solving complex optimization problems, with the advantages of fast convergence, strong global search capability, and easy implementation [13]. And the HO tends to perform better in dealing with high-dimensional, nonlinear, and multimodal problems than traditional algorithms like Grid Search, PSO and others [14].

As this study intends to enhance short-term stock index prediction, HO was utilized to explore the optimal hyperparameter combination of CAL (HO-CAL). Several international indexes were presented to examine the superiority

of the HO-CAL hybrid optimization framework. The contributions of this study are as follows:

- The CAL architecture integrates the advantages of different blocks. It realizes a breakthrough in extracting multi-dimensional features and fully exploits temporal information in the sequence. It not only captures the local features and long-term dependencies but also automatically focuses on the most important parts of the input. It shows good adaptability when facing different markets and effectively improves the prediction performance and generalization ability;
- The pioneering use of HO to optimize the CAL model, which plays a significant role in improving the prediction accuracy and robustness, contributes to the current research on combining optimization algorithms and deep learning.
- The experimental results show that HO-CAL can capture complex relationships and patterns in stock data and accurately predict the international indexes, which can help investors manage their assets more efficiently and allocate capital more adequately.

The remainder of the study is organized as follows: Section II reviews some related work; Section III elaborates on the architecture of the proposed model and the optimization process; Section IV introduces the experimental settings; Section V analyses and discusses the experimental results; and Section VI provides the conclusion of this study.

II. Related Work

A. Deep Learning Models for Time Series Prediction

Multivariate time series prediction has a wide range of applications in industry, finance, meteorology and other fields [15]. An increasing number of finance scholars have begun to use neural networks to build stock prediction models, which have achieved remarkable results. Deng et al. [16] utilized a CNN model to extract the structured features of a time series through multilayer convolutional operations and achieved good prediction results. Li et al. [17] proposed an LSTM model for predicting stock prices by preserving historical information through memory cells. Similarly, the integration architecture of CNN-LSTM is applied in stock market analysis [18], which captures the market fluctuation patterns by analyzing stock prices, volumes, and financial data. This assisted investors in formulating scientific investment strategies and effectively reducing investment risk. However, the dynamic interaction modelling ability of CNN-LSTM for temporal features is still limited by its static weight allocation mechanism [19]. Abbasimehr and Paki [20] proposed an Attention-based LSTM time series prediction model that dynamically assigned weights through an Attention layer to focus on key information, resulting in improved prediction accuracy.

B. Hybrid Deep Learning Architectures

The use of a single model often makes it difficult to simultaneously consider spatial features, temporal dependence and key information screening needs. Thus, combining CNN, LSTM and Attention has gradually become a research topic. Yi et al. [21] adopted the combined LSTM-CNN Attention model in short-term load prediction, which innovatively used convolutional kernels to extract the stochasticity of the user and solve the problem of non-smooth characteristics. Experiments proved that the model reduced the amount of input data, and the prediction accuracy outperformed the benchmark by more than 10%. Shi et al. [22] predicted stock prices by initially extracting the deep features of raw data through an Attention-based CNN-LSTM model and then fine-tuning them using XGBoost. It improved prediction accuracy, and helped investors realize income growth and risk avoidance. Borré et al. [23] proposed a hybrid LSTM-CNN architecture with the introduction of Attention mechanism and Gated Residual Networks. The experimental results showed that the proposed model performs well in predicting extreme events. Peng et al. [24] used an Attention-based CNN-LSTM model to predict multiple currencies simultaneously, which better captured the correlation between different frequencies and currencies. The model improved the prediction accuracy, and reduced the transaction cost and investment risk. LÜ et al. [25] used CNN-LSTM-Attention to effectively capture the spatial-temporal correlation of soil moisture, and its RMSE was reduced by 49% and 57% compared to LSTM and CNN-LSTM models, respectively.

C. Metaheuristic Optimization

Alongside advances in deep learning models architecture, the application of metaheuristic optimization for hyperparameter tuning in models has also received increasing attention. Although HO is still in the early stages of research, it has attracted attention owing to its simple structure and ease of integration with deep learning models. Maurya et al. [14] used HO to optimize distributed power planning and network reconfiguration under different load models and then compared it with PSO, whale optimization, grasshopper optimization, zebra optimization, coot bird optimizer, and firefly algorithms, proved the superiority of HO. Mashru et al. [26] proposed a multi-objective hippopotamus optimizer and compared it with six well-known swarm intelligence algorithms, which demonstrated the effectiveness of HO in dealing with structural optimization problems.

With the rapid evolution of deep learning, CAL model has emerged as a powerful tool for dealing with time series due to their capacity to jointly capture local patterns, sequential dependencies, and key feature importance. Meanwhile, the HO algorithm offers an efficient method for tuning hyperparameters of such deep architectures, further enhancing their performance in noisy stock market environments. While existing research still faces several limitations. Many hybrid models inadequately address the challenge of hyperparameter adjusting, often relying on inefficient or limited optimization strategies. Moreover, few studies systematically evaluate the integration of attention-based deep learning models with metaheuristic algorithms in the context of stock index prediction. To bridge this gap, this study proposes a novel HO-CAL model that combines the CNN-Attention-LSTM model with hippopotamus optimization algorithm for hyperparameter tuning. This approach is designed to enhance model robustness, accuracy, and adaptability across diverse market environments, offering both theoretical advancement and practical guidance for financial prediction.

III. METHODOLOGY

HO-CAL is a hybrid optimization deep learning framework that combines three different types of neural network layers as well as an optimization algorithm to fully capture financial information and temporal features in the data with the following basis.

A. Convolutional Neural Networks

A CNN can effectively extract local patterns and features from a time series by sliding a convolutional kernel over the input data to scan it, as shown in Fig. 1. And pooling layer is usually added after the convolutional layer to reduce the feature dimension of the data and reduce the computational complexity [27]. Therefore, in this study, when facing a large amount of stock time series, a 1D-CNN was used to extract features and reduce their dimensionality to make the learning effect more accurate and concise.

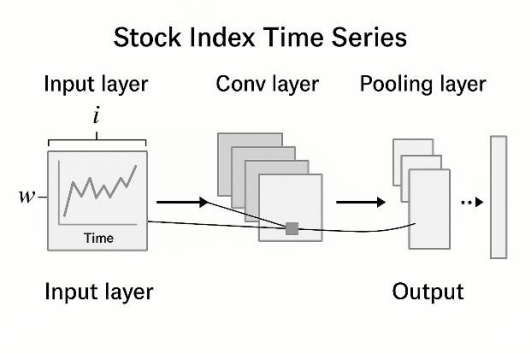

Fig. 1. CNN process structure.

B. Squeeze-and-Excitation Attention

CNN cannot distinguish the importance of information during learning [28]. While the Attention is extremely specialized in capturing critical nodes in sequence processing [29]. SE Attention is designed to improve the model performance by adaptively adjusting the weights of the feature channels. The Squeeze part extracts the global features by reducing the features size to 1×1 through a global average pooling operation. This step compresses the features of each channel into a scalar value to form a channel description vector. The Excitation part learns the channel weights through a series of fully connected layers and activation functions. These weights are used to weight the features and enhance the important feature channels. Its core formulas are as follows:

$$\mathrm{s} = \sigma\big(\mathrm{W}_2 \cdot \delta(\mathrm{W}_1 \cdot \mathrm{z})\big) \tag{1}$$

$$z_c = \frac{1}{H \times W} \sum_{i,j} U_c(i,j) \tag{2}$$

$$\widetilde{U}_c = s_c \cdot U_c \tag{3}$$

where H, W are the feature dimensions and C is the number of channels. Attention enables the proposed model to automatically focus on the key features in massive information, significantly improving the relevance of data processing. Therefore, the introduction of Attention is expected to further enhance the accuracy of stock index predictions.

C. Long Short-Term Memory Networks

LSTM is used to process the temporal correlation of the sequence data. It adopts a unique gating mechanism to effectively manage the flow and memory of information, avoiding the loss of important information [30]. The gating unit of the LSTM consists of an input gate (i_t), forgetting gate (f_t), output gate (o_t) and cell status (C_t). The following equations express the relationship between these four:

$$f_t = \sigma\big(W_f \cdot [h_{t-1}, x_t] + b_f\big) \tag{4}$$

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i) \tag{5}$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \tag{6}$$

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \tag{7}$$

$$o_t = \sigma(W_o[h_{t-1}, x_t] + b_o) \tag{8}$$

$$h_t = o_t * \tanh(C_t) \tag{9}$$

where x_t is the input at the current moment, h_{t-1} is the output at the previous moment, σ is the sigmoid function, and W, b are the weight and deviation of the neuron respectively. The i_t determines the degree of acceptance of new information, the f_t controls the reservation ratio of historical information, and the o_t filters out critical information for current decision making. This sophisticated gating mechanism enables LSTM to effectively deal with long-term dependencies in sequence data.

D. CNN-Attention-LSTM

The accurate prediction of stock prices is crucial and previous studies have verified the effectiveness of various single models. However, there is still much potential to improve prediction accuracy, especially in the context of model integration and complementarity. Therefore, this study proposes an enhanced stock index prediction method based on the CAL architecture as shown in Fig. 2. And the specific implementation steps are as follows:

Step 1: Input: stock historical data $[T \times F \times 1]$, where T denotes the time step and F denotes the feature dimension;

Step 2: Feature extraction (CNN): local features are extracted from the input data and deep temporal features are gradually extracted through two convolutional layers with an activation function to improve the model expression ability;

Step 3: Attention weighting (Attention): extraction from the last step is fed into the SE Attention module. The importance weights of each channel are calculated and are weighted by fusion with the original features, thereby enhancing the key features and suppressing redundant information;

Step 4: Sequence modelling (LSTM): the weighted feature sequences are input into the LSTM network to further model the long-term dependencies in the time dimension and extract the time series information;

Step 5: Prediction output: the LSTM output is mapped through the fully connected layer to obtain the final predicted price.

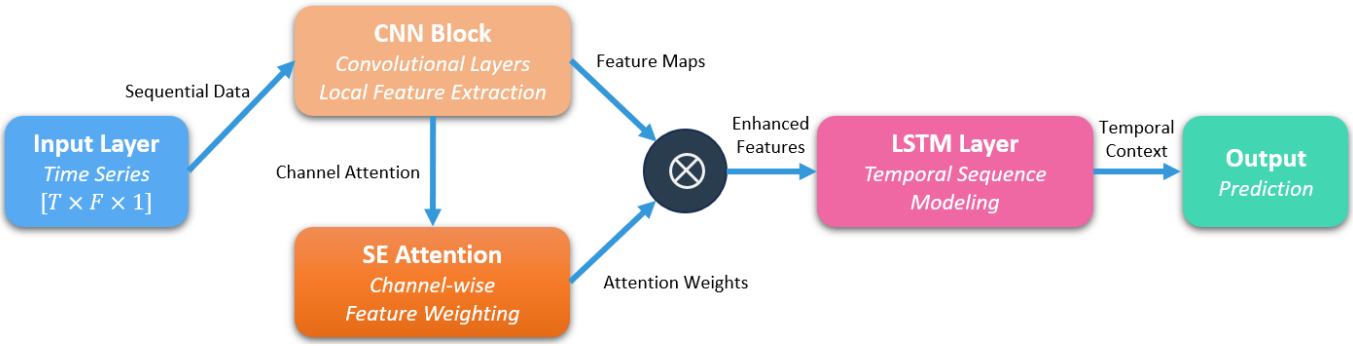

Fig. 2. CAL architecture for stock index prediction.

It can be found that CAL integrates the feature extraction capability of CNN, the channel feature weighting capability of Attention mechanism, and the temporal modelling capability of LSTM. Its innovation lies in integrating different types of neural network layers to form an efficient temporal prediction architecture, which can improve prediction accuracy.

E. Hippopotamus Optimization Algorithm

CAL has a complex hyperparameter space, and the combination of these hyperparameters can significantly affect the prediction accuracy and generalization ability of the model. HO is the newest metaheuristic optimization algorithm proposed by Amiri et al. [12] in 2024. It simulates the dynamic response strategy of hippos under different environmental conditions, which is an SI algorithm based on stochastic search. The HO algorithm consists of the following three stages:

The initialization of HO involves the generation of stochastic initial solutions, and the decision variables are

$$x_{ij} = lb_j + r * (ub_j - lb_j), i = 1,2,\cdots,N; j = 1,2,\cdots,m \quad (10)$$

where r is a random number within $(0,1)$, lb_j and ub_j are the upper and lower bounds of the jth dimension respectively.

Phase I: Position updating (Exploration). The dominant hippo individual in the group (the optimal solution) guides the other individuals to update positions, which can be expressed as

$$x_{ij}^{M} = x_{ij} + y_1 \cdot (D_{hippo} - I_1 \cdot x_{ij}) \quad (11)$$

where x_{ij} denotes the position of the ith hippo in the jth dimension, D_{hippo} is the position of the dominant male hippo, y_1 is a random number within $[0,1]$, and I_1 represents the distance reduction factor. The position update formula for a female or immature hippos is as follows:

$$x_{ij}^{FM} = \begin{cases} x_{ij} + h_1 \cdot (D_{hippo} - I_2 \cdot MG_i), & T > 0.6 \\ \Delta, & \text{else} \end{cases} \quad (12)$$

$$\Delta = \begin{cases} x_{ij} + h_2 \cdot (MG_i - D_{hippo}), & r_6 > 0.5 \\ lb_j + r_7 (ub_j - lb_j), & \text{else} \end{cases} \quad (13)$$

$$T = \exp\left(-\frac{t}{\text{Maxiteration}}\right) \quad (14)$$

where I_2 is an integer between $[1,2]$, MG_i denotes the average position of some randomly selected hippos from the population, r_6 and r_7 are random numbers between $[0,1]$, and h_1 and h_2 are randomly selected numbers. The following equation describes the update of the position of hippos in the population:

$$x_i = \begin{cases} x_i, & F_i^M < F_i \\ x_i, & \text{else} \end{cases} \quad (15)$$

Phase II: Defence against predators (Exploration). Avoiding the algorithm falling into a local optimal solution by simulating the hippos' defence strategy when threatened by a predator. The predator position is denoted by

$$\text{Predator}_j = lb_j + \mathbf{r}_8 \cdot (ub_j - lb_j) \quad (16)$$

where $\mathbf{r}_8$ is a random vector within $[0,1]$. The hippos respond to a predator as

$$x_{ij}^{HippoR} = \begin{cases} \mathbf{RL} \oplus \text{Predator}_j + \frac{f}{c - d \times \cos(2\pi g)} \cdot \frac{1}{\mathbf{D}}, & F_{\text{Predator}_j} < F_i \\ \mathbf{RL} \oplus \text{Predator}_j + \frac{f}{c - d \times \cos(2\pi g)} \cdot \frac{1}{\mathbf{D} + \mathbf{r}_9}, & \text{else} \end{cases} \quad (17)$$

where **RL** is a random vector with a Lévy distribution to model the fast-acting behaviour of hippos during attacks, and f, c, d, and g are random numbers to control the intensity and direction of the hippos' response. The position of the ith hippo is updated by

$$x_i = \begin{cases} x_i^{HippoR}, & F_i^{HippoR} < F_i \\ x_i, & \text{else} \end{cases} \quad (18)$$

Phase III: Escaping from predator (Exploitation). Focus on efficient localized search in the solution space to improve the accuracy and quality of the solution. Hippos escape position update:

$$x_{ij}^{hippo\varepsilon} = x_{ij} + r_{10} \cdot \left(lb_j^{local} + s_1 \cdot \left(ub_j^{local} - lb_j^{local}\right)\right) \quad (19)$$

$$lb_j^{local} = \frac{lb_j}{t}, ub_j^{local} = \frac{ub_j}{t} \quad (20)$$

Fig. 3 shows the specific process of HO adjustment of the CAL hyperparameters. HO begins by randomly initializing a population of hippo individuals, where each represents a set of CAL hyperparameters. In the fitness evaluation section, each

individual's hyperparameter configuration was used to train the CAL, with the RMSE on the validation set serving as the fitness value. The algorithm then updates each individual's position according to HO principles, effectively adjusting the CAL hyperparameters. This process iterates until the convergence criteria are reached, and the optimal hyperparameters that minimize the prediction error are obtained.

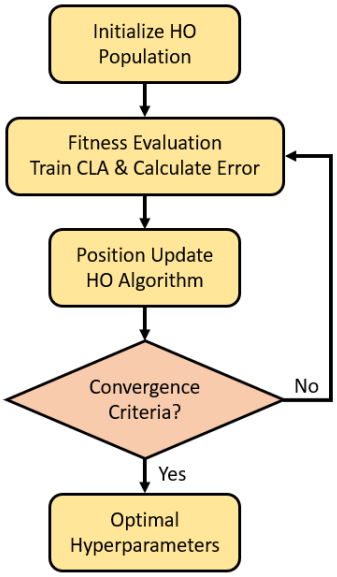

Fig. 3. CAL hyperparameter optimization via the HO algorithm.

IV. Experimental Process

For stock index prediction evaluation, all experiments were conducted on a Windows 11 system using a CPU (13th Gen Intel Core i7-13700H) and GPU (NVIDIA GeForce RTX 3050 4GB). And the prediction models were implemented in MATLAB (R2024b).

A. Data Pre-Processing

This study targets the CSI 300 Index in China, which is regarded as a trend indicator for the Shanghai and Shenzhen markets. It covers 300 A-shares with large market capitalization and high liquidity. The research period is from January 7, 2019 to December 27, 2024, with 1,451 trading days. The proposed model is based on technical analysis and is premised on the identification of behavioral patterns in historical series. Thus, referring to Paiva et al. [31], Table I summarizes 21 technical indicators were used as inputs for the prediction, including return rate indicators calculated based on opening (O), closing (C), high (H) and low (L) prices, as well as momentum, volatility, and volume related indicators etc.

There is a considerable difference in the scale of the above features. The normalization process helps to speed up the convergence of the loss function, prevent gradient explosion in network training, and improve the computational accuracy [5]. Therefore, this study applies the Min-Max normalization method to transform the data between $[0,1]$, and the calculation process is as follows:

$$\mathbf{X}_{\text{new}} = \frac{\mathbf{X}-\mathbf{X}_{\min}}{\mathbf{X}_{\max}-\mathbf{X}_{\min}} \tag{21}$$

where X is the original technical indicators matrix, X_{max} and X_{min} are the maximum and minimum values of X, respectively, and X_{new} is the new value after normalization.

TABLE I. Summary of Stock Index Prediction Variables

Return Rate Indicators		Technical Indicators
$v_1 = ln\left(\frac{C_t}{C_{t-1}}\right)$	$v_8 = ln\left(\frac{H_{t-1}}{O_{t-1}}\right)$	Momentum (close price, period = 10)
$v_2 = ln\left(\frac{C_{t-1}}{C_{t-2}}\right)$	$v_9 = ln\left(\frac{H_{t-2}}{O_{t-2}}\right)$	Relative strength index (close price, period = 14)
$v_3 = ln\left(\frac{C_{t-2}}{C_{t-3}}\right)$	$v_{10} = ln\left(\frac{H_{t-3}}{O_{t-3}}\right)$	Parabolic SAR (high and low price, acceleration = 0, maximum = 0)
$v_4 = ln\left(\frac{H_t}{O_t}\right)$	$v_{11} = ln\left(\frac{L_t}{O_t}\right)$	Average true range (high, low and close price, period = 14)
$v_5 = ln\left(\frac{H_t}{O_{t-1}}\right)$	$v_{12} = ln\left(\frac{L_{t-1}}{O_{t-1}}\right)$	True range (high, low, and close price)
$v_6 = ln\left(\frac{H_t}{O_{t-2}}\right)$	$v_{13} = ln\left(\frac{L_{t-2}}{O_{t-2}}\right)$	Chaikin A/D line (high, low, and close price; volume)
$v_7 = ln\left(\frac{H_t}{O_{t-3}}\right)$	$v_{14} = ln\left(\frac{L_{t-3}}{O_{t-3}}\right)$	On balance volume (close price, volume)

B. Sliding Window and Evaluation Metrics

This study uses the technical indicators of the past 20 days to predict the closing price of the next day. And a sliding window approach was conducted for the six-year index data: the first three years of data were used to train the model; the following year was used as a validation set for optimally tuning the CAL hyperparameters; and the subsequent year is used as a test set to examine the prediction ability. And each completed cycle slides forward for one year, ultimately obtaining daily predicted closing price for 2023 and 2024.

In order to evaluate the model prediction performance, this research employed six evaluation metrics. They are Mean Absolute Error, Mean Absolute Percentage Error, Mean Square Error, RMSE, R^2 and Relative Error, which are calculated as follows:

$$\text{MAE} = \frac{1}{N}\sum_{t=1}^{N} |r_t - \hat{r}_t| \tag{22}$$

$$\text{MAPE} = \frac{1}{N}\sum_{t=1}^{N} \left|\frac{r_t-\hat{r}_t}{r_t}\right| \tag{23}$$

$$\text{MSE} = \frac{1}{N}\sum_{t=1}^{N} (r_t - \hat{r}_t)^2 \tag{24}$$

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{t=1}^{N} (r_t - \hat{r}_t)^2} \tag{25}$$

$$R^2 = 1 - \frac{\sum_{t=1}^{N} (r_t-\hat{r}_t)^2}{\sum_{t=1}^{N} (r_t-\bar{r})^2} \tag{26}$$

$$\text{Relative Error} = \frac{\hat{r}_t-r_t}{r_t} \tag{27}$$

where r_t, $\hat{r}_t$ represent actual close price and predictive close price at time t respectively.

V. Experimental Results and Discussion

This section presents and discusses several experimental evaluations of the proposed HO-CAL framework through systematic analysis across multiple perspectives, including ablation studies, optimization effectiveness comparisons, and robustness across international stock markets. Beyond the

quantitative outcomes, we also contextualize these findings by comparing them with existing literature and by evaluating how the model addresses the challenges identified in earlier sections.

A. Ablation Experiment

In order to verify the effectiveness of the proposed CAL model for short-term stock index prediction, Table II presents a comparison of the ablation results against several baseline and state-of-the-art methods, including econometric (ARIMA), machine learning (RF), and deep learning (CNN, LSTM, CNN-LSTM).

TABLE II. COMPARISON OF ABLATION RESULTS FOR CAL MODEL

Model	MAE	RMSE	MAPE(%)	R^2
ARIMA	122.86	166.63	3.41	0.897
RF	101.32	139.78	2.75	0.923
CNN [16]	82.04	129.96	2.20	0.947
LSTM [17]	69.25	109.43	1.89	0.957
CNN-LSTM [18]	59.73	91.82	1.49	0.971
CAL	52.41	80.57	1.31	0.978

Among the baseline models, ARIMA shows the worst performance, with an MAE of 122.86 and R^2 of 0.897, indicating its limited capacity to capture the nonlinear characteristics of stocks. In contrast, the RF model significantly improved the prediction accuracy (MAE: 101.32, R^2: 0.923), highlighting that machine learning methods are better suited for modelling the complex relationships among technical indicators. Meanwhile, CNN achieved an MAE of 82.04, whereas LSTM further reduced it to 69.25, reflecting the effectiveness of temporal modelling in financial time series. All all deep learning models outperformed RF, underscoring their enhanced learning capability and adaptability. The combination of CNN-LSTM resulted in a substantial boost in performance (MAE: 59.73, R^2: 0.971), confirming prior findings that hybrid architectures can integrate complementary strengths of individual components [18], [22].

Building on these findings, the ablation study clearly demonstrates that the CAL model delivered the most accurate and reliable performance, with the lowest MAE (52.41), RMSE (80.57), MAPE (1.31%), and the highest R^2 (0.978). This proves that the addition of the Attention mechanism dynamically allocates weights to important time-dependent features—addressing the static limitation in CNN-LSTM architectures, as previously highlighted by Abbasimehr and Paki [20]. These results align with [21] and [24], who reported that attention-based models significantly improve prediction accuracy by enhancing the model's ability to focus on relevant input segments.

B. Model Optimization Effectiveness Comparison

After proving the validity of the CAL model, HO was used to optimize CNN-LSTM and CAL for comparison. Fig. 4 shows the hyperparameter tuning process on the validation set, and it can be seen the HO2 (belonging to CAL) demonstrates markedly superior performance from the initial iteration, with a starting fitness value of 72.35 compared to HO1 (belonging to CNN-LSTM) initial value of 87.29. Throughout the optimization process, HO2 consistently maintains lower fitness values than HO1, ultimately achieving a final fitness value of 50.41 compared to HO1's 55.73, demonstrating the superior optimization ability of HO algorithm. This 10.55% improvement, as well as the consistent and substantial performance differential between the curves, provide strong empirical evidence that the CAL architecture possesses inherently better representational capabilities owing to its Attention mechanisms. Remarkably, both models exhibited rapid convergence within 6 iterations without extensive computational overheads. And the steep descent during the first two iterations followed by gradual stabilization highlights HO's exceptional search efficiency and ability to effectively balance exploration and exploitation phases, which proves that HO is particularly well suited for CAL hyperparameter optimization tasks.

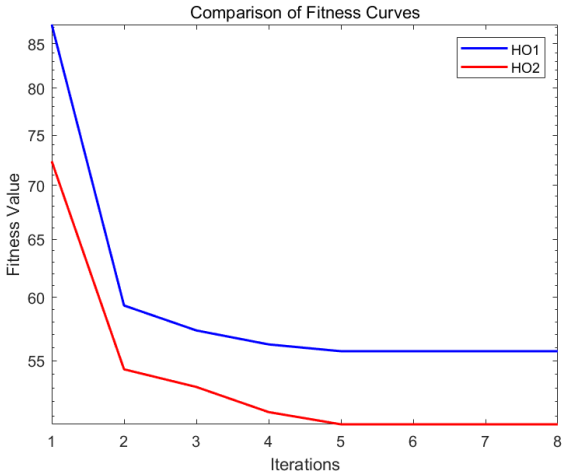

Fig. 4. Convergence analysis of HO for CNN-LSTM and CAL.

The training period spanning from 2019 to 2022 in Fig. 5 demonstrate exceptional model convergence, with all models exhibiting remarkably close alignment with the actual price trajectory. Notably, the models successfully capture major market movements, including the significant upward trend from early 2020 to mid-2021 (reaching peaks around 5,700) and the subsequent downward correction through 2022. The observable differences on the training set are minimal, suggesting that all models have sufficient price recognition capabilities and all have learned effectively.

Fig. 5. Prediction performance comparison on training set (2019-2022).

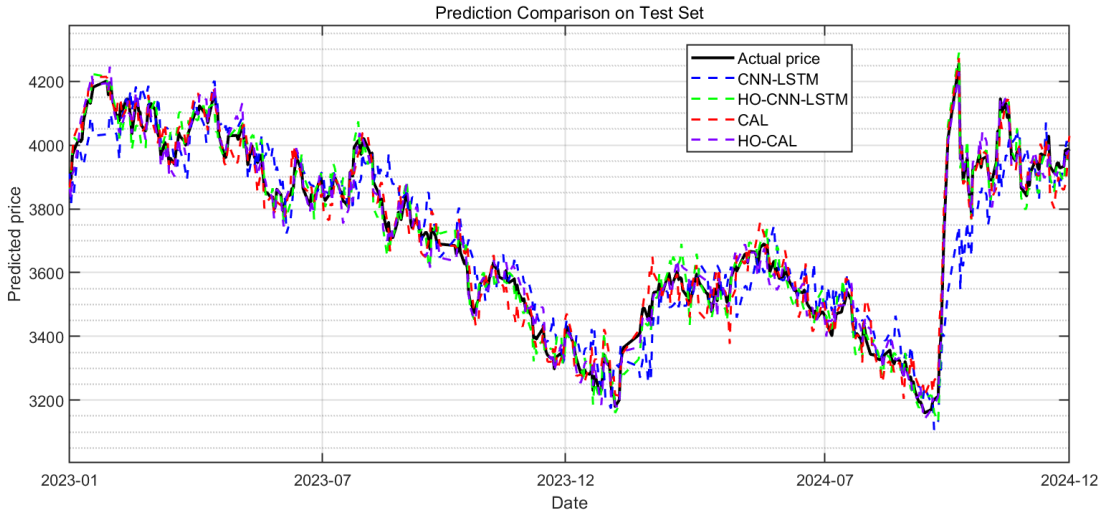

Fig. 6. Prediction performance comparison on testing set (2023-2024).

The testing results for 2023-2024 in Fig. 6 reveal more pronounced performance differentials. The HO-CAL demonstrates superior tracking accuracy, maintaining the closest alignment with actual price movements throughout the testing period. Particularly notable is the model's performance during high-volatility periods, such as the sharp decline in mid-2023 (from ~4,000 to ~3,200) and the subsequent market recovery phases, which captures such extreme events in line with the study in [23]. The CNN-LSTM baseline shows the most significant deviations, particularly during rapid price transitions, while the HO-CNN-LSTM demonstrates improved stability over its non-optimized counterpart. The CAL performs moderately well but lacks the precision achieved by its HO-optimized version. The hyperparameter optimization significantly enhances prediction accuracy, HO-CNN-LSTM and HO-CAL showing reduced prediction volatility and better trend-following capabilities.

The comprehensive performance evaluation presented in Table III demonstrate a clear hierarchical structure. Specifically, HO-CAL attains the lowest MAE of 40.03, representing substantial improvements of 33.0% over CNN-LSTM, 13.5% over HO-CNN-LSTM, and 23.6% over CAL. And the HO algorithm's contribution is consistently significant, with HO-CNN-LSTM showing 19.7% RMSE improvement over CNN-LSTM, and HO-CAL achieving 22.0% improvement over non-optimized CAL. These results confirm the complementary value of model architecture (CAL) and optimization strategy (HO). In line with Maurya et al. [14], who validated HO's superior performance in engineering optimization problems, our results highlight its promising extension to stock prediction.

TABLE III. HO EFFECTIVENESS TEST

Model	MAE	RMSE	MAPE(%)	R^2
CNN-LSTM [18]	59.73	91.82	1.49	0.971
HO-CNN-LSTM	46.29	73.69	1.18	0.984
CAL	52.41	80.57	1.31	0.978
HO-CAL	40.03	62.86	0.99	0.991

The visualization in Fig. 7 provides an intuitive multi-dimensional performance comparison, clearly illustrating the dominance of HO-CAL across all metrics. The radar chart reveals that HO-CAL (represented by the innermost polygon for error metrics and outermost for R^2) consistently achieves optimal or near-optimal performance boundaries. Notably, the visualization emphasizes the substantial performance gap between the optimized and non-optimized models, with both HO-enhanced variants showing marked improvements over their baseline counterparts.

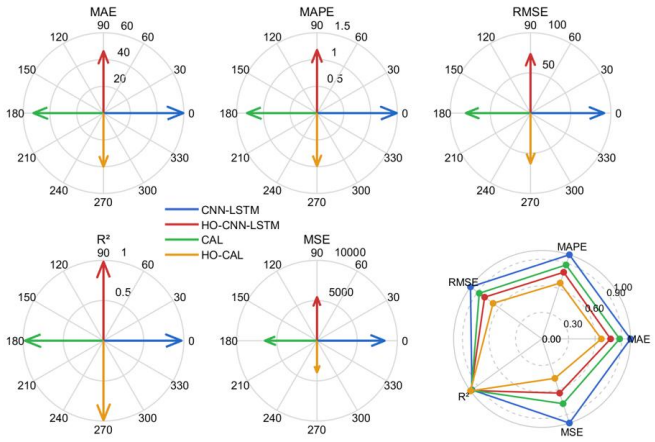

Fig. 7. Multi-dimensional performance evaluation.

The comparison in Fig. 8 provides crucial insights into the temporal distribution and magnitude of relative errors across four models. The error distribution around the zero baseline indicates minimal systematic bias across all models, with relatively balanced positive and negative errors suggesting unbiased prediction behavior. However, the frequency and magnitude of extreme errors vary significantly. The CNN-LSTM exhibiting the most pronounced error volatility, displaying frequent extreme deviations reaching $\pm 4\%$. These large-magnitude errors are particularly concentrated during periods of high market volatility, indicating the baseline model's limited capacity to handle rapid price fluctuations. In contrast, HO-CAL demonstrates remarkably constrained error boundaries, with the majority of errors confined within $\pm 2\%$ range, representing a 50% reduction in maximum error magnitude compared to CNN-LSTM. The chronological analysis reveals that HO-CAL maintains consistent error stability throughout the entire testing period, with notably reduced error spikes during critical market transitions observed in mid-2023 and late 2024. The HO-CNN-LSTM shows intermediate performance, exhibiting improved stability over the baseline but lacking the precision consistency achieved by Attention-based models. CAL demonstrates moderate error reduction compared to CNN-LSTM, though it occasionally exhibits error spikes that are effectively mitigated in its optimized counterpart HO-CAL. The comparison between optimized and non-optimized model pairs clearly demonstrates the HO algorithm's effectiveness in error reduction, with HO-CAL achieving the most significant improvement in error containment.

The HO-CAL framework integrates CAL networks with the HO algorithm, achieving lower error metrics and improved predictive accuracy. It excels at capturing market turning points and maintaining stability during transitions, effectively modelling complex temporal and nonlinear dynamics. Consistent performance gains across metrics highlight both statistical and practical relevance, reducing prediction errors and financial risk. The relative error reduction throughout the testing period confirms the stability of the proposed framework for stock time series prediction applications.

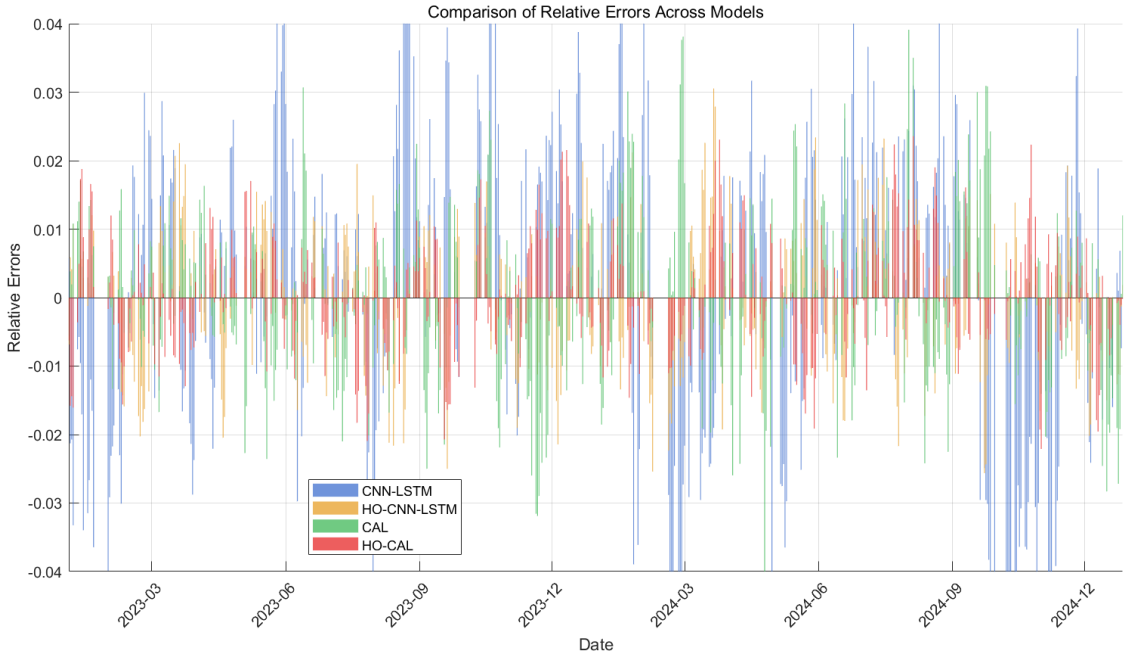

Fig. 8. Temporal distribution of relative prediction errors across models.

C. Robustness Test

To further validate the accuracy and robustness of the HO-CAL framework, this study extends the evaluation to four major international stock indexes: the S&P 500 (Standard & Poor's 500 Index), FTSE 100 (Financial Times Stock Exchange 100 Index), Nikkei 225 (Nikkei 225 Stock Average), and KOSPI (Korea Composite Stock Price Index). These indexes represent a diverse range of market structures and efficiency levels across developed and emerging economies.

TABLE IV. COMPARISON OF PREDICTIONS FOR INTERNATIONAL MARKETS

Stock Index	MAE	RMSE	MAPE(%)	R^2
CSI 300	40.03	62.86	0.99	0.991
S&P 500	75.26	113.85	1.42	0.983
FTSE 100	129.48	194.20	1.56	0.982
Nikkei 225	471.21	706.85	1.24	0.989
KOSPI	28.15	42.75	1.06	0.990

The experimental results in Table IV confirm the robustness and generalizability of the proposed framework. HO-CAL achieved strong predictive performance across all markets, with high R^2 values (≥ 0.982) and consistently low MAE, RMSE, and MAPE values. Notably, KOSPI (MAE: 28.15, R^2: 0.990) and CSI 300 yield the best results, followed by Nikkei 225 (MAE: 471.21, R^2: 0.989), whereas S&P 500 and FTSE 100 showed slightly higher error metrics. The differences between these international markets are consistent with the findings in [32], and can be interpreted through the lens of market efficiency: the S&P 500 (USA) and FTSE 100 (UK) are generally classified as semi-strong to strong-form efficient markets, where price patterns are quickly arbitraged away, making predictive modelling more challenging. In contrast, Nikkei 225 (Japan), KOSPI (Korea) and especially CSI 300 (China), often considered weaker-form efficient or less efficient due to higher market volatility and behavioral factors, may retain exploitable patterns that the HO-CAL framework can effectively capture. This also suggests that deep learning methods like HO-CAL, tend to perform better in markets with lower informational efficiency. These results underscore the practical value of the proposed hybrid framework in real-world financial predictions, particularly in scenarios that involve diverse data distributions and varying market dynamics.

VI. CONCLUSION AND FUTURE WORK

Stock markets are crucial to global financial systems, and accurate stock index prediction remains a challenging yet valuable task for investors, policymakers, and researchers. This study proposed a novel hybrid HO-CAL framework for enhance the predictive accuracy and generalizability of stock index. Through comprehensive experiments, the HO-CAL achieved consistently superior performance across multiple evaluation metrics (e.g., MAE, RMSE, R^2), outperforming baseline models including CNN, LSTM, CNN-LSTM, and even CNN-LSTM-Attention variants. The Attention mechanism significantly enhanced the model's ability to focus on key temporal patterns, while HO effectively optimized parameters to avoid local minima. Ablation studies and visual analyses confirmed the individual and synergistic contributions of each component. In robustness tests across five major global stock markets, HO-CAL maintained high predictive accuracy, demonstrating strong generalization ability even in markets with differing volatility and efficiency levels. These results validate the model's applicability in real-world investment and confirm its alignment with behavioral finance perspectives.

From a theoretical standpoint, this research contributes to the growing body of literature on deep learning in financial prediction by (1) empirically demonstrating the benefits of attention-enhanced feature selection in volatile stock series, (2) proposing the first integration of the CAL architecture with the HO algorithm, and (3) verifying the feasibility of metaheuristic optimization in tuning deep learning models for financial applications. Practically, the proposed framework offers a scalable and accurate solution that can assist investors in managing portfolio risk and timing market entry more effectively.

Nevertheless, this study has certain limitations: the model relies exclusively on technical indicators, without incorporating macroeconomic or firm-level fundamental variables, which may limit its comprehensiveness in capturing long-term market dynamics; while HO showed strong performance, its computational cost is non-negligible, especially when applied to large-scale or high-frequency datasets. Future work could address these limitations in several ways. First, integrating fundamental financial indicators (e.g., ROA, PE ratios) and macroeconomic variables (e.g., inflation, M2 growth) could improve the model's explanatory power. Second, the model can be extended by exploring other deep learning architectures such as Transformers, Temporal Convolutional Networks, or Graph Neural Networks, which may offer enhanced capabilities in modeling complex dependencies. Finally, comparisons with other powerful metaheuristic optimization, such as Grey Wolf Optimizer or Whale Optimization Algorithm, can further refine the optimization strategy.

***Abstract*—To support the evaluation of the teaching and learning process in higher education institutions, it is necessary to develop a text mining (TM) model. The aim of this research is to compare the performance of Long Short-Term Memory using Word Embedding Text to Sequence (WETS-LSTM), WETS-BiLSTM, WETS-CNN1D, and WETS-RNN, using four dataset categories including pedagogic, professional, personality, and social competency. This research has five main steps, including literature study, dataset collection, TM model development, and evaluation. Dataset is collected from Universitas Sjakhyakirti, Institut Teknologi dan Bisnis Palcomtech, Universitas Muhammadiyah Palembang, Universitas Bina Darma, AMIK Bina Sriwijaya and Politeknik Darusalam. The questionnaire distribution process initially yielded 6,170 responses with 6,164 valid across four competency categories, with total of 24,656 text data for analysis. Model of WETS-LSTM obtained the best performance overall, achieved the train accuracy of 96.65% and the highest test accuracy of 82.92%. The CNN1D with Word Embedding Text to Sequence (WETS-CNN1D) demonstrated good train accuracy with 96.73% but obtained lower test performance with 80.67%. The WETS with Recurrent Neural Network (WETS-RNN) obtained the weakest results, with a train accuracy of 95.88% and a test accuracy of 77.99%.**

***Keywords*—Text mining; CNN; LSTM; RNN; text-to-sequence**

I. INTRODUCTION

The results of the evaluation of lecturer teaching and university services show clear information about the state of a university and the services offered to students [1], [2]. Evaluation serves as a method to assess the quality of education and the efficiency of higher education services which is an aspect of international university ranking assessment [3]–[5]. Through the results of the evaluation, higher education institutions can find out the programs, procedures, and service structures that suit the needs of students [6]–[8].

Usually at the end of each semester, students are asked to fill out a questionnaire designed to gather students' perceptions and feedback about the university's learning experience and facilities in terms of classes, teaching quality, library, and other services [9]–[11]. However, these questionnaires consist of Likert scale or multiple-choice questions (yes or no) that are usually filled out quickly and do not present the actual state of affairs [12], [13].

For this reason, it is necessary to evaluate lecturer teaching and university services using a special system with a feature to store assessment feedback in the form of text [14]–[16]. However, the evaluation of qualitative text feedback from students is difficult to do if it is done by manual analysis, especially for large-scale feedback datasets [17]–[19]. In fact, the results of qualitative feedback data analysis can provide valuable insights into the evaluation of lecturer teaching and university services [20]–[22]. To solve this problem, it is necessary to develop an architecture and evaluation model for lecturer teaching and university services based on text mining [23]–[25]. Research on the evaluation model of lecturer teaching and university services based on text mining (TM) has been carried out with various methods in the last four years using the text mining (TM) approach [14], [26]–[30]

The previous works utilized a variety of machine learning models for text analysis, focusing on different linguistic datasets and methodologies. Research by Grönberg et al. (2021) applied Latent Dirichlet Allocation (LDA) for topic modeling in English, while Misuraca et al. (2021) leveraged Support Vector Machine (SVM) for text classification in English as well [26], [27]. Research by Grljević et al. (2022) utilized a combination of Term Frequency-Inverse Document Frequency (TF-IDF) and K-Nearest Neighbor (KNN) techniques on Serbian text data, whereas Ren et al. (2023) explored the application of Word Embedding and Long Short-Term Memory (LSTM) for text analysis in Chinese [28] [29]. Abdi et al. (2023) combined Word Embedding (WE) with Convolutional Neural Networks (CNN) and Bidirectional Long Short-Term Memory (BiLSTM) for English text classification [30].

Based on research problem and previous works, several advancements were proposed in the development of a text mining-based evaluation system for lecturer teaching and university services. Researchers have focused on exploring various artificial intelligence models to analyze qualitative feedback, recognizing the limitations of traditional manual analysis, especially in large-scale datasets. The aim of this research was to develop and compare various text mining models for evaluating lecturer teaching and higher education services based on large-scale qualitative feedback. By utilizing different machine learning approaches, such as BiLSTM, LSTM, CNN-1D, and Recurrent Neural Network (RNN) with embedding text to sequence (WETS) techniques, the

experiment was conducted to analyze a dataset of 6,164 student questionnaires across four categories, including pedagogic, professional, personality, and social competencies, into positive and negative interpretation result. The goal was to assess the effectiveness of these models for analyzing of lecturer performance and university services feedback by improving the accuracy of proposed model.

II. Related Work

Over the past four years, several studies investigated evaluation models of lecturer teaching and university services using the text mining (TM) approach. These studies employed various machine learning techniques on different linguistic corpora, including LDA for topic modeling and SVM for English text classification, TF-IDF with KNN classification on Serbian text, LSTM on Chinese data, and combinations of Word Embedding (WE) with CNN and BiLSTM for English text classification. The model has been implemented in the dataset of evaluation texts for lecturer teaching and university services can be seen in Table I.

TABLE I. State of the Art

Reference	Model	*Dataset*
[26]	Latent Dirichlet Analysis (LDA)	English
[27]	Support Vector Machine (SVM)	English
[28]	Term frequency–inverse document frequency (TF-IDF) – K-Nearest Neighbor (KNN)	Serbian
[29]	Word Embedding, Long Short-Term Memory (LSTM)	Chinese
[30]	Word Embedding, Convolutional Neural Networks (CNN)-BiLSTM	English
Proposed	Word Embedding Text to Sequence (WETS), LSTM	Indonesia

Based on previous, Grönberg et al. (2021) implemented Latent Dirichlet Allocation (LDA) for topic modeling to extract key themes from student feedback in English, while Misuraca et al. (2021) applied Support Vector Machine (SVM) for text classification in English, providing insights into the strengths and weaknesses of teaching and services. Similarly, Grljević et al. (2022) used a combination of Term Frequency-Inverse Document Frequency (TF-IDF) and K-Nearest Neighbor (KNN) techniques on Serbian text data, revealing valuable patterns and trends in the evaluation of academic services.

Moreover, other researchers, such as Ren et al. (2023), explored model of Word Embedding (WE) and Long Short-Term Memory (LSTM) for analyzing Chinese text data, further enhancing the ability to understand and interpret qualitative feedback and Abdi et al. (2023) advanced this approach by integrating Word Embedding with CNN-BiLSTM. This research proposed a text mining (TM) model that will be applied to the learning system. The proposed new text mining (TM) model comes from a combination of BiLSTM based on Word Embedding Text to Sequence (WETS).

III. Research Methodology

Data collection was based on the distribution of instruments at several universities in the city of Palembang, namely Universitas Sjakhyakirti, Institut Teknologi Bisnis Palcomtech, Universitas Muhammadiyah Palembang, Universitas Bina Darma, AMIK Bina Sriwijaya and Politeknik Darusalam. The questionnaire distribution process initially yielded 6,170 responses. After preprocessing, 6,164 valid questionnaires remained, each containing evaluations across four competency areas: pedagogic, professional, personality, and social. As a result, a total of 24,656 individual opinion data points were obtained for analysis.

The lecturer performance evaluation encompassed four key aspects: pedagogic, professional, personality, and social. The total evaluation included values for the overall performance, with 70% of the total representing the training data, 30% allocated for testing, and classifications for both positive and negative feedback. The composition of research dataset can be seen in Table II.

TABLE II. Research Dataset

Class	Train (70%)	Test (30%)	Total
Pedagogic	4,316	1,848	6,164
Professional	4,316	1,848	6,164
Personality	4,316	1,848	6,164
Social	4,316	1,848	6,164
Total	17,264	7,392	24,656

The initial stage in opinion mining is pre-processing with the aim of preparing text data which will later experience the next text data processing. This stage has five stages carried out, namely data cleansing, case folding, tokenizing, stop-word, tokenizing, and stemming. The summary of each of the five stages can be seen in Fig. 1.

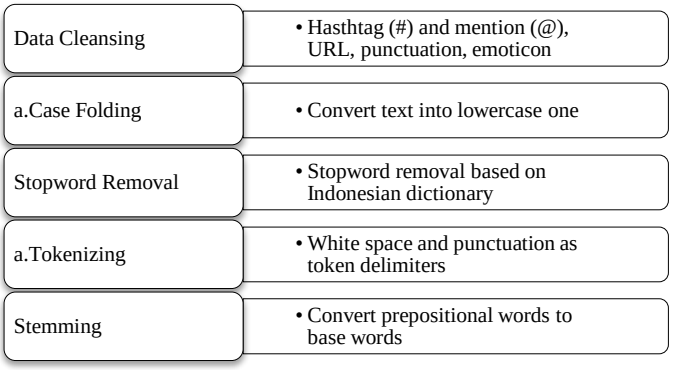

Fig. 1. Preprocessing phase.

At the data cleansing stage, the process of cleaning unnecessary words is carried out to reduce computational load, such as text containing html, links, and scripts. In addition, this stage also removes punctuation marks such as periods (.), commas (,) and also other punctuation marks. In this pre-processing process also applies the case folding method, which is the process of converting words into lower-case. The third stage is tokenization. This method is implemented to transform words contained in text into several sequences truncated by certain spaces or characters.

By applying a word that has a unique word from text data such as conjunctions, and possessive words. Less meaningful types of words will be removed, such as the words: I, and, or by using this method. The purpose of stop word removal is to reduce the burden on system performance, because the words to be taken are the words that are considered important. The last stage in the pre-process process is the stemming stage. The method at this stage is done by transforming the words in the text into basic words.

Next is to conduct experiments for model training and testing. The methods compared include BiLSTM, LSTM, CNN1D and RNN. Each model is carried out performance evaluation measure (PEM) or known as model performance evaluation measurement is an approach that aims to measure the performance or performance of the algorithm model. As for the experiment to be carried out as seen in Fig. 2.

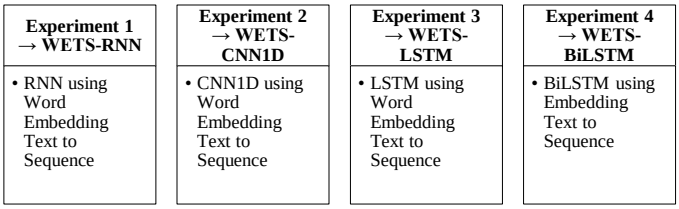

Fig. 2. Research experiment scenario.

The final stage is the evaluation stage that is carried out as a measurement of the performance value of the text mining ™ method that has been implemented. Performance evaluation measurement using confusion matrix, accuracy, precision, F1-score and recall to compare BiLSTM, LSTM, CNN-1D, and RNN with embedding text to sequence techniques performance.

IV. Result and Discussion

The study aimed to develop a text mining model for evaluating lecturer performance, with a specific focus on Indonesian text. Previous research primarily focused on datasets from other languages, such as English, Serbian, and Chinese, which evaluated different competencies. These studies incorporated personality, professional, pedagogical, and social competencies. This research differentiated itself by introducing a tailored evaluation model that includes all four competency categories and fill the gap in existing literature by providing an evaluation framework specifically designed for the Indonesian educational context as explained in Table III.

TABLE III. Dataset Specification

Source & Dataset	Personality	Professional	Pedagogy	Social
English [26]		●	●	
English [27]		●	●	
Serbian [28]		●	●	●
Chinese [29]		●	●	
English [30]		●	●	●
Indonesia [Proposed]	●	●	●	●

The first experiment used RNN using Embedding Text to Sequence (WETS-RNN). The RNN model itself is in the form of a neural network designed to process the text sequence on the learning evaluation opinion. Using WETS is a dataset of learning opinion texts converted into numerical representations so that can be processed by the RNN model. The WETS-RNN model obtained a training accuracy of 0.9588 of the correct predictions which showed that the model was very good at recognizing patterns from the training data from the learning evaluation dataset and the test accuracy of 0.7799 which was lower than the training which showed that the WETS-RNN model was not fully generalized well to the test data.

The second experiment used CNN1D using Word Embedding Text to Sequence (WETS-CNN1D). The CNN1D model is based on a neural network used to process one-dimensional sequence data of student comment texts on learning. By using WETS, the students' comments were converted into vector representations so that the CNN1D model could capture the semantic relationships between words in the dataset text. The WETS-CNN1D model obtained a training accuracy of 0.9673 of the correct predictions indicating that the WETS-CNN1D model was very good at recognizing patterns from the training dataset while the test of 0.8067 showed good performance on the submission dataset being judged correct.

The third experiment used LSTM using Word Embedding Text to Sequence (WETS-LSTM). Model of LSTM model leverages neural networks designed to address sequence problems and long-term dependencies in processing the sequence of opinion and comment texts by capturing temporal dependencies. Then, the WETS is used to convert the order of the text numbers into a lower-dimensional vector that can be processed by the LSTM model. The training accuracy performance of the WETS-LSTM model is very good, which is 0.9665 which means that the model shows excellent performance on the training data, with 96.65% of the predictions correct while the test performance is 0.8292 or 82.92% which shows that the model has good generalization ability to comment text data that is different from the training data.

The fourth experiment used WETS-BiLSTM. The BiLSTM model is a variation of the LSTM that has the ability to process learning comment text data in two directions, namely from start to end and from end to end. The training accuracy performance of the WETS-BiLSTM model obtained a training accuracy of 0.9688 which shows good performance in the training data with 96.88% of the training data prediction results being declared correct. Then, the test accuracy obtained a value of 0.8234 or 82.34%, which is lower than the training accuracy but this value is the best value of the other models.

Based on experimental results, WETS-LSTM has good accuracy among other methods. The WETS -LSTM model is a model based on long short-term memory which can be used in WETS which allows the model to understand the meaning of a sentence based on word order. The results of the comparison of model can be seen in Table IV.

TABLE IV. THE PERFORMANCE COMPARISON OF MODEL

Method	Abbreviation	Train	Test
BiLSTM using Word Embedding Text to Sequence	WETS-BiLSTM	96.88%	82.34%
LSTM using Word Embedding Text to Sequence	WETS-LSTM	**96.65%**	**82.92%**
CNN1D using Word Embedding Text to Sequence	WETS-CNN1D	96.73%	80.67%
RNN using Word Embedding Text to Sequence	WETS-RNN	95.88%	77.99%

The initial experiment commenced with tokenization, where sentences were segmented into individual words. Each word was then assigned an index from a predefined vocabulary. For example, the sentence "Indonesian language" was divided into "Indonesian" and "language," which were mapped to specific indices within the vocabulary. This mapping transformed the text data into numerical form as part of the WETS phase. The WETS phase improved the performance of data processing and classification by utilizing models such as BiLSTM, LSTM, CNN1D, and RNN, with performance results, particularly accuracy, depicted in Fig. 3.

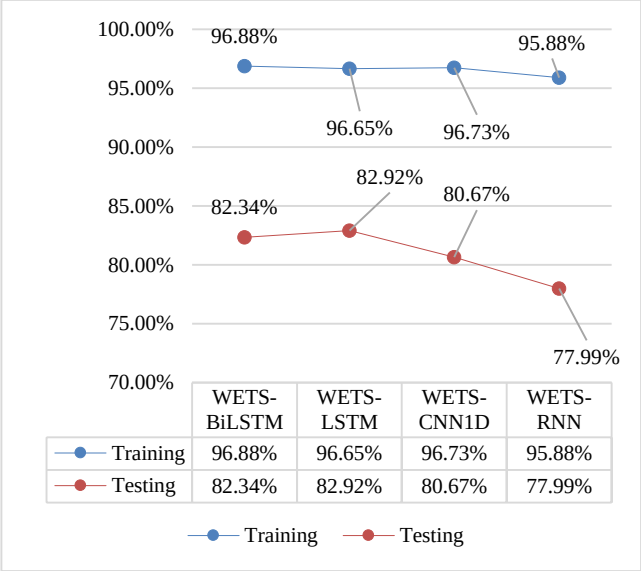

Fig. 3. Model performance results comparison.

Based on the experiment, WETS-LSTM was selected as the preferred text mining (TM) model for lecturer performance evaluation. The phase WETS involved padding to ensure uniformity in the input sequence length, as the model required inputs of a fixed length. In the given example, a sentence of length 2 was padded with zeros to extend the sequence to a length of 4. After padding, the sentence was represented as [1, 2, 0, 0]. The padded sequence was then processed through an embedding layer, where each token (word index) was mapped to a dense vector of fixed dimensions. This transformation converted the tokenized sequence into numerical representations suitable for the WETS-LSTM. The complete phase and result of data processing using WETS can be seen in Fig. 4.

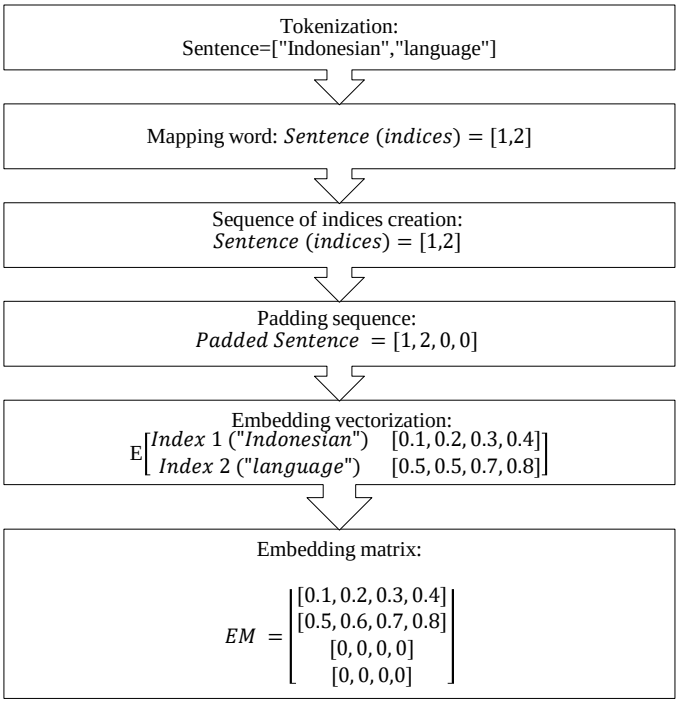

Fig. 4. Word Embedding Text to Sequence (WETS).

The input was processed through the LSTM, which operated on sequences and is capable of retaining long-term dependencies due to its forget f_i, input i_i, cell state c_i, and output gates o_l. At each time step t, the LSTM processed the current word embedding x_i, the previous h_{i-1} hidden state and the previou c_{i-1} cell state. The forget gate determined which information from the previous cell state should be weighted W_f, allowing the model to decide what aspects of the past memory to retain or forget for the current time step by using sigmoid activation function σ and bias term b_f. The explanation of LSTM can be expressed as in Eq. (1).

$$f_i = \sigma(W_f.[h_{i-1}, x_i] + b_f \quad (1)$$

$$h_0 = [0,0,0,0],\ c_0 = [0,0,0,0]$$

$$f_i = [0.6, 0.7, 0.5, 0.4]$$

Assuming that after calculating the forget gate at t=1 for the first word "Indonesian," the next step involved the input gate and the $\widetilde{C}_l$ cell candidate. The i_i input gate determined the amount of new information to be incorporated into the cell state, while the cell candidate generated potential new values for updating the cell state. The calculation of i_i and $\widetilde{C}_l$ for *t=1* can be expressed as in Eq. (2) and Eq. (3).

$$i_i = \sigma(W_i.[h_{i-1}, x_i] + b_i = [0.4, 0.3, 0.2, 0.1], \quad (2)$$

$$\widetilde{C}_l = tanh(W_c.[h_{i-1}, x_i] + b_c = [0.5, 0.4, 0.6, 0.7] \quad (3)$$

At *t=1*, for the first word "Indonesian," the cell state c_i was updated by combining the results of the forget gate f_i and the input gate i_i. This update process allowed the model to decide which parts of the previous cell state should be retained and which new information should be incorporated. The o_l output gate then determined which part of the updated cell

state would be output as the hidden state. The h_l hidden state captured the relevant information from the current word and the context provided by the preceding words. The calculation of o_l and $\widetilde{h_l}$ for *t=1* can be expressed as in Eq. (4) and Eq. (5).

$$o_l = \sigma(W_o.[h_{i-1}, x_i] + b_o = [0.5, 0.6, 0.7, 0.8] \quad (4)$$

$$h_l = o_l.tanh\,(c_l) = [0.0985, 0.0714, 0.0833, 0.056] \quad (5)$$

This process was repeated for the second word "language" at *t=2* based value of embedding matrix. The previous hidden state $h_{l-1}$and cell state c_{l-1} were passed forward, and the new word embedding x_l for the current word was processed. Model LSTM generated a prediction based binary classification, which distinguished between positive and negative lecturer evaluations from the LSTM will be passed through a sigmoid activation function. This function will output a probability between 0 and 1. The sigmoid function is defined as Eq. (6).

$$\sigma(y) = \frac{1}{1+e^{-y}} \quad (6)$$

The output will be a value σ(y) between 0 and 1. If $\sigma(y)$ is greater than or equal to 0.5, the feedback is classified as positive. Otherwise, the data is classified as negative, distinguishing between positive and negative lecturer evaluations. Based on this classification, the accuracy results were calculated for each category. The accuracy per epoch for the social feedback data was presented in Fig. 5.

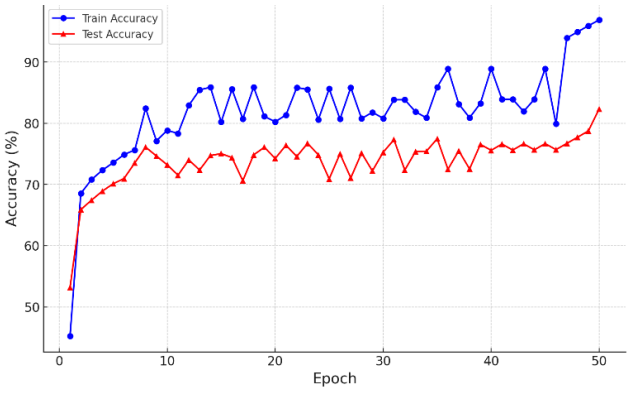

Fig. 5. Accuracy WETS-LSTM for dataset of social feedback.

The data used for the WETS-LSTM classification consisted of four distinct categories, i.e. pedagogic, professional, personality, and social, with each category having positive and negative samples. For the pedagogic category, the training set contained 2,389 positive and 1,927 negative samples, while the testing set had 1,024 positive and 824 negative samples. In the Professional category, the training data included 2,500 positive and 1,816 negative samples, with 946 positive and 902 negative samples in the testing data. The dataset of social category had 2,307 positive and 2,009 negative samples for training. Accuracy results were computed for each category with the detail of dataset as detailed in Table V.

TABLE V. THE DATASET FOR WETS-LSTM EVALUATION

Category	Train		Test	
	Positive	Negative	Positive	Negative
Pedagogic	2,389	1,927	1,024	824
Professional	2,500	1,816	946	902
Personality	2,290	2,026	975	873
Social	2,307	2,009	967	881
Total	7,486	7,778	3,912	3,480

The text mining model for evaluating lecturers calculated the total accuracy as the average of accuracy of each dataset category. The pedagogic accuracy obtained 85.00%, the professional accuracy obtained 80.00%, the personality accuracy obtained 81.00%, and the social accuracy obtained 83.36%. The total average accuracy was determined by calculating the mean of all dataset category accuracy, as in Eq. (7).

$$acc_{avg} = \frac{acc_{pedagogic} + acc_{professional} + acc_{personality} + acc_{social}}{4} \quad (7)$$

$$acc_{avg} = \frac{85.00\% + 80.00\% + 81.00\% + 83.36\%}{4} = 82.34\%$$

The calculation was applied to other models to assess the testing accuracy. The accuracy results for each model were then obtained. The BiLSTM using Word Embedding Text to Sequence (WETS-BiLSTM) model achieved an accuracy of 82.34%. The LSTM using Word Embedding Text to Sequence (WETS-LSTM) model performed slightly better, with an accuracy of 82.92%. Additionally, the CNN1D using Word Embedding Text to Sequence (WETS-CNN1D) and RNN using Word Embedding Text to Sequence (WETS-RNN) models achieved accuracy rates of 80.67% and 77.99%, respectively.

V. CONCLUSION

The aim of this research was to compare the performance of WETS-BiLSTM, WETS-LSTM, WETS-CNN1D, and WETS-RNN and involved four dataset categories, i.e. pedagogic, professional, personality, and social. The WETS-LSTM model exhibited the best performance overall, with a slightly lower training accuracy of 96.65%, but it achieved the highest test accuracy of 82.92%. The WETS-CNN1D model demonstrated good training accuracy with 96.73% but exhibited lower test performance, achieving 80.67%. The WETS-RNN produced the weakest results, with a training accuracy of 95.88% and a testing accuracy of 77.99%. While WETS-LSTM methods proved to be the most effective for both training and testing, WETS-RNN showed less satisfactory performance. Further analysis is required to improve the robustness of the proposed WETS-LSTM on larger datasets, and while the current study relied on limited data from a few private universities, efforts were undertaken to collect data from additional universities for more comprehensive analyses.

***Abstract*—A smart door lock system based on IoT is presented which uses fingerprint biometric authentication, ESP32 microcontroller and Blynk IoT platform to provide a secure, user friendly and remote controllable access control solution. The proposed architecture replaces traditional locks with a real time biometric system that gives instant feedback through onboard display (OLED) and buzzer and remote monitoring and control through a mobile app. A new fail-safe mechanism is implemented: after 3 failed fingerprint attempts the system will lock out for 15 seconds and send instant alert to the authorized user's smartphone. Performance test of the prototype shows fingerprint recognition time of around 1.0 second and door unlock time of 5 seconds, so it's convenient to use. The system has a very low False Acceptance Rate (FAR) of 1.32% which means strong resistance to unauthorized access. The False Rejection Rate (FRR) is higher (around 26.32%) due to user error such as improper finger placement – so a usability issue to be addressed. The device can store up to 3 fingerprint profiles and gives visual/audible alert for all access events. This integration of IoT with biometric security not only enhances physical security but also user convenience, a modern smart-lock solution for smart home automation.**

Keywords*—Smart door lock; Internet of Things (IoT); biometric authentication; fingerprint sensor; ESP32 microcontroller; Blynk IoT platform; access control; cybersecurity; real-time monitoring; home automation; OLED display; False Rejection Rate (FRR); False Acceptance Rate (FAR); remote monitoring; smart home automation

I. INTRODUCTION

The Internet of Things (IoT) has changed the physical security landscape, bringing intelligent systems that automate tasks and enable remote management, monitoring and interaction. Access control has shifted from traditional methods—mechanical keys, RFID cards or PIN codes—to more secure, automated and user friendly alternatives. Traditional lock-and-key or keypad systems are vulnerable to theft, key duplication, password disclosure and human error and are no longer sufficient for modern security expectations. Among the emerging solutions, biometric fingerprint recognition stands out for its reliability and uniqueness. Unlike passwords or cards that can be shared, lost or guessed, fingerprints are a permanent and non-transferable form of authentication. When integrated into an IoT ecosystem using microcontrollers (like ESP32) and cloud connected platforms like Blynk for remote communication, biometric systems provide a real-time approach to access control. Users can lock/unlock doors, receive alerts and log entry events from anywhere in the world, improving security and convenience. But IoT enabled smart locks still have many challenges. False rejections—where an authorized user is denied access due to partial or poor fingerprint scans—pose usability issues and frustration. Security flaws are also present in many existing systems, including tamperability, lack of intrusion detection or alarm features, limited fingerprint storage capacity and no real-time incident response. Environmental factors like humidity, sensor degradation over time or incorrect finger placement can also degrade performance and make it inconsistent. Many smart locks today rely on continuous internet connectivity or only one layer of authentication, making them fragile; a network outage or a smart intruder can compromise such systems. In case of unauthorized access attempts or brute force attacks, most commercial smart locks don't respond dynamically or notify the owner, which can lead to severe security breaches—especially in unattended or remote installations. Addressing these limitations, this research introduces an enhanced IoT based smart door lock architecture that integrates biometric fingerprint scanning, real-time wireless communication and intelligent security feedback mechanisms. The goal is to have a system that not only does accurate fingerprint authentication but also reacts intelligently to suspicious or unauthorized access attempts—for example, by triggering alerts, activating temporary lockout timers and logging access events for audit. The design prioritizes both security and usability so legitimate users can enter quickly while potential intruders are deterred and detected. Smart locks are often found wanting when it comes to comprehensive security handling. Many rely too heavily on stable network conditions or simple one-factor authentication without a backup plan. If that network goes down-or if someone keeps trying to pick the lock-these systems often don't adapt or alert the user in real time.

That's where the limitations of biometric functionality in commercial locks come in: often added as an afterthought rather than optimized for low-power embedded environments or user-friendly maintenance. That can lead to frequent false rejections and a poor user experience, particularly in places where many people are using the lock or where traffic is high. Devices struggle with limited processing resources and suboptimal fingerprint enrollment processes. Our goal is to close those gaps with a smart door lock that balances security with usability.

We're building a lightweight, IoT-integrated smart door lock around the Espressif ESP32 microcontroller. This chip gives us the dual-core processing power and built-in Wi-Fi/Bluetooth capabilities we need to handle fingerprint recognition tasks and secure communication with a cloud backend (we're using the Blynk platform). We want users to know right away if there's a critical event, so we're designing the system to notify them instantly. If someone tries to get in three times and fails, the lock will be out of commission for 15 seconds. We'll also display that information on an OLED screen and with a buzzer. That way, users can make quick decisions and have responsive control in real-world conditions.

Our main contributions are:

1) A fully functional smart door lock prototype that integrates fingerprint recognition with an ESP32 microcontroller and the Blynk IoT platform. This lets us do real-time door access monitoring, remote lock/unlock control via smartphone and automatic event logging.

2) A multi-layer security response mechanism that includes a 15-second lockout after three failed fingerprint attempts, audible alerts and on-screen warnings during a breach attempt, and push notifications to the authorized user's phone. This feedback loop makes intrusion detection and response much better than with conventional locks.

3) A comprehensive performance evaluation that shows our fingerprint recognition time is about 1 second and our False Acceptance Rate is just 1.32%. The False Rejection Rate was 26.32%, mainly because of user error (about 65.8% of false rejections were due to incorrect finger placement or similar user issues). That highlights both the strengths (strong security against false accepts) and the limitations (usability challenges causing false rejects) of our system.

4) Various features to improve user experience and system usability such as on-screen feedback for every operation, auto-unlock for 5 seconds after a successful fingerprint match (for quick entry before re-locking), and direct mobile app for fingerprint enrollment and deletion. The mobile app allows authorized administrators to manage user fingerprints remotely, making it more flexible and easier to maintain.

5) Deployment and testing of the prototype in real scenarios (e.g. home/office door setup) to test the system under real world conditions. The smart lock is suitable for residential, commercial and rental property use cases, and works well with different network conditions and user behavior.

The remainder of this paper is organized as follows: Section II presents a comprehensive literature review covering smart lock technologies, biometric authentication methods, and IoT-based access control systems. Section III details the methodology, including system planning, hardware and software integration, and deployment procedures. Section IV presents the experimental results, while Section V discusses the findings in detail. Section VI outlines the conclusions drawn from the study, and Section VII highlights the limitations and proposes potential directions for future work.

II. Literature Review

A. Evolution of Smart Door Lock Technologies

Smart door lock systems have evolved with the integration of biometric technologies and IoT connectivity. Fingerprint based authentication has become highly secure and convenient as fingerprints are unique and can't be duplicated [1]. Many studies have explored combining fingerprint sensors with other technologies (RFID tags, keypad entry, cloud connectivity) to make door access systems more secure and functional [2].

B. Role of IoT in Access Control Systems

IoT capable microcontroller platforms (Arduino, ESP8266/NodeMCU, ESP32) allows seamless integration with Wi-Fi networks, enabling remote monitoring, real time alerts and smartphone control of locks [3]. This makes it more convenient for users and cost effective for both home and commercial use [4]. To counter spoofing attacks and sensor vulnerabilities in biometric locks, researchers have proposed techniques such as reducing residual fingerprint traces on scanners and image processing for fingerprint enhancement [5].

C. Advancements in Multi-modal Authentication

Also, the digital access control realm is moving towards multi-modal and keyless systems to address various intrusion scenarios (e.g. unauthorized guests or lost credentials) [6][7]. For example, some designs combine fingerprint verification with RFID or PIN code entry to provide backup authentication and robustness [8]. The growing sophistication of cyber-physical threats – such as relay attacks that can clone RFID or Bluetooth signals – further emphasizes the need for biometric-enabled access control systems that are hard to bypass [9].

D. Representative Works and Technological Contributions

Over the last decade, many researchers have focused on designing IoT-based smart door locks that incorporate fingerprint recognition to meet the increasing demand for secure yet user-friendly access control [10]. The literature shows a clear trend away from traditional mechanical locks towards integrated digital systems that combine sensors, wireless communication and mobile platforms for more functionality and control. Below we summarize some of the representative works and their approaches, and highlight the research gap that our work addresses.

Tailor and Pandya [6] developed an IoT-based smart security system mainly using a fingerprint sensor for family members' door access. The system allowed users to unlock doors remotely through a smartphone app, making it very convenient and secure. By enabling mobile connectivity, this approach allowed homeowners to monitor and control door access in real time from anywhere – a great feature if physical keys were lost or traditional PINs compromised. This work [6] laid the foundation for merging biometric verification with cloud-based remote control, which is the basis of modern smart home access systems that emphasize user mobility.

Al-Shareefi et al., introduced a low-cost fingerprint-based door lock using an Arduino Nano microcontroller and a simple servo motor for the locking mechanism [11]. This system did not have remote network connectivity or advanced features like image processing or multi-factor authentication; however, it showed that biometric security can be built with very low-cost hardware. The contribution is significant in showing economic accessibility, making smart lock technology more accessible to small businesses or residential users in resource-constrained environments. The trade-off for its simplicity was limited functionality but it highlights the importance of low-cost design in wider adoption.

Jeong aimed to improve the security and accuracy of fingerprint-based locks by reducing the residual fingerprint left on the scanner surface (which can be used in spoofing attacks). This work [5] applied image processing to improve fingerprint matching reliability and reduce the False Acceptance Rate (FAR) of the system. This is particularly important in high-security environments (e.g. finance or research labs) where even a small biometric vulnerability can be catastrophic. Jeong's work shows how both hardware and software improvements in biometric systems (e.g. better sensor surface design and algorithmic liveness detection) can mitigate physical security threats.

Rakib et al. looked at integrating fingerprint recognition into a home automation context, extending biometric access beyond just door locking [12]. Their system combined a fingerprint lock with other IoT modules to control home appliances and security devices. For example, one fingerprint verification could unlock the door, turn on lights or disable an alarm system [13]. This shows how biometric systems can be used in smart environments and how fingerprints can be the foundation of smart living spaces. It shows how an access control system can be integrated with general IoT based home management for more convenience [14].

Tambunan et al., presented a multi-modal smart home security prototype that incorporated fingerprint authentication alongside RFID and keypad entry options for flexible access control. This design [15] enhanced usability by allowing different modes of entry based on user roles or scenarios (for instance, family members use fingerprints, temporary guests use a PIN code, maintenance staff use an RFID card, etc.). The system also featured remote monitoring, sending alerts and enabling control through a network interface. Notably, Tambunan's work [16] is recognized for its scalability and inclusivity, accommodating various user preferences and security levels within one unified platform.

E. Trends and Research Challenges

These studies show the evolving landscape of smart door locking systems with the convergence of biometric authentication, IoT technology and user centered design. A common trend across the reviewed literature is the use of mobile platforms, which allows users to monitor and control door access remotely through their smartphones for more convenience and responsiveness [17]-[20]. Another trend is the emphasis on affordability and simplicity, with most of the hardware and software being cost effective and widely available like Arduino, so these systems can be used by a wider audience [21]-[25]. Researchers have also improved system security by applying image processing techniques to minimize residual fingerprint traces and reduce the risk of spoofing [26]. Fingerprint authentication has also been extended to comprehensive home automation systems where access control is integrated with general IoT based device management, so users can interact with lights, alarms and other appliances in one ecosystem [27]-[29]. Multi-modal authentication methods which combines fingerprint sensor with RFID and keypad modules is also a more flexible and robust solution that can accommodate different user scenarios while maintaining strong security protocols [30]. Overall, these advancements show the potential of IoT-biometric systems to change residential and commercial access control in the digital age [31], [32].

F. Research Gap

Despite all these advancements, there are still gaps and challenges in current smart lock solutions. Many systems lack adaptive intrusion response mechanisms or real-time user alerting; for example, if an intruder tries multiple failed attempts, not all systems will auto lock out or notify the owner [33], [34]. Dynamic user management (e.g. easy remote enrollment/revocation of access) and integration with advanced analytics or cloud services are also missing. In short, no existing solution in the literature combines real-time biometric verification with immediate intrusion countermeasures (like auto lockouts and instant notifications) and a scalable IoT architecture that can be extended to larger deployments [35]. This research fills that gap by proposing a smart lock system that combines all these features in an embedded design. Our system emphasizes security responses (through its lockout and alert mechanism) and remote IoT connectivity and user friendly management, different from previous works.

Table I shows several existing smart lock approaches and their features and limitations compared to the proposed system.

TABLE I. COMPARISON OF EXISTING AND PROPOSED SMART LOCK APPROACHES

References	Approach	Description	Limitation
[16]	RFID + IoT	Uses RFID tags and Raspberry Pi for secure, remotely accessible locking via smartphone platforms.	Dependent on internet connection for cloud access and real-time updates.
[35]	Bluetooth + IoT	Utilizes Bluetooth MAC addresses from smartphones for hands-free door unlocking; Raspberry Pi controls access via a mobile app.	Limited operational range due to Bluetooth constraints.
[36]	NFC + Arduino + GSM	Employs NFC readers and smartphones for secure, short-range access control with user token-based differentiation.	Vulnerable to security risks if the user's smartphone is lost or stolen.
[7]	Biometric + ESP32-CAM + Blynk	Combines fingerprint recognition with real-time video capture using ESP32-CAM and Blynk app for access logging and alerts.	Camera increases power demand; low-light image quality limitations.
[3]	RFID + Fingerprint + Keypad	A hybrid system using three types of authentication to improve accuracy and flexibility in multi-user environments.	Hardware complexity and increased system cost.
[4]	Embedded Linux + Fingerprint	Utilizes embedded Linux system for managing door lock control and fingerprint authentication.	Higher resource requirements; not ideal for low-power setups.
[6]	Fingerprint + IoT (ESP32 + Blynk)	Provides real-time door lock control and fingerprint verification with cloud-based monitoring.	Network latency and partial fingerprint scans may lead to false rejections.
[37]	OTP + IoT	Generates and delivers OTP to user's device for one-time secure access, suitable for temporary or guest entry.	Delayed OTP delivery in weak networks; requires mobile signal or internet.
The proposed work	Fingerprint + ESP32 + Blynk + OLED	Integrates fingerprint authentication with ESP32 microcontroller and Blynk for real-time control, alerts, auto-lockout, and mobile enrollment/deletion capabilities.	False Rejection Rate (FRR) of 26.32% mainly due to user errors; limited to 3 fingerprints; Wi-Fi needed.

III. PROPOSED METHOD

The proposed method is to develop an IoT enabled access control system using biometric authentication. The system "Smart Lock Door with Fingerprint using ESP32" is based on ESP32 microcontroller and has a fingerprint sensor for primary user authentication and remote monitoring/control through Blynk mobile app. The overall methodology follows a structured engineering process of planning, hardware/software integration, testing and deployment.

The proposed method was chosen to specifically address key limitations observed in existing smart lock systems. Most prior works either lacked real-time intrusion response mechanisms, did not support remote fingerprint enrollment and deletion, or were dependent on continuous internet connectivity without fallback. Additionally, many systems failed to integrate meaningful feedback mechanisms (e.g., visual/audio alerts) or suffered from limited fingerprint capacity without a user-friendly management interface. Our proposed system overcomes these limitations by combining fingerprint-based biometric access with IoT features using ESP32 and Blynk, providing real-time alerts, local display and buzzer feedback, mobile app control, and a security lockout mechanism. This makes it suitable for deployment in residential or small commercial environments where usability, security, and remote operability are all essential.

Fig. 1 shows the system flowchart, from system initialization to enrollment, verification and response. Upon boot-up, the system initializes all modules and enrolls or deletes fingerprints as commanded. During normal operation, when a user presents a finger, the fingerprint sensor captures the input and ESP32 compares it with stored templates. Successful scan triggers unlock sequence: solenoid lock is activated (door opens), buzzer produces a confirmation tone, OLED display shows a message and a push notification (through Blynk) is sent to the user. The door remains open for 5 seconds and then automatically locks back. For failed scans, the system gives immediate feedback (OLED message and buzzer alert). After 3 consecutive failed attempts, an intrusion lockout mechanism is engaged: the system denies any further attempts for 15 seconds and during this time it flashes an alert on OLED and sends an urgent notification to the owner's phone. This cooldown period helps to prevent brute force attacks and warns the legitimate user of potential unauthorized access.

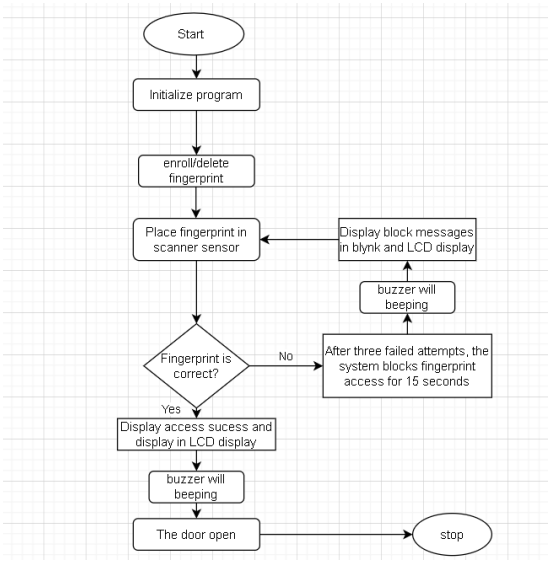

Fig. 1. Flowchart of the system.

A. Phases of Development

The project was carried out in multiple phases, each addressing different aspects of the system:

1) Initial planning and requirements analysis: In this phase, we defined the objectives and scope of the smart lock system. Main goals were to increase physical security over traditional locks and to be able to remotely manage access. We gathered functional requirements (what the system should do) and hardware requirements (what components we need). Key hardware for the prototype were ESP32 development boards

(for connectivity and control), R305 optical fingerprint sensor (for biometric input), solenoid lock mechanism (for door locking/unlocking), small OLED display for on-device messages, buzzer for audio alerts, 5V relay module (to drive the high-current solenoid), portable power sources (2 x 9V batteries with holders) and wiring and connectors. Software requirements were to choose a suitable programming environment (Arduino IDE) and IoT platform (Blynk) and to make sure all libraries and modules are compatible.

2) Hardware and software integration: This phase we built the system by connecting all components and developing the firmware. The hardware setup started by placing the modules on a prototyping board: R305 fingerprint sensor was wired to ESP32's serial interface for biometric input, 12V solenoid lock was connected through a relay (ESP32 controls the relay to unlock/lock), ESP32 Dev Board was the central controller for all signals. An OLED display module was added to show status messages (e.g. "Place Finger" prompt, "Access Granted"/"Denied" results, etc.) and a small buzzer was attached for audio feedback. The wiring was done carefully using a breadboard and jumper wires to ensure stable connections. A detailed circuit schematic was drawn to map all connections (Fig. 2 shows the system's block diagram). On software side, ESP32 was programmed in C++ using Arduino IDE. Firmware routines were written for fingerprint enrollment, fingerprint matching (verification) and for controlling the solenoid via the relay. The code also handled sending and receiving data from Blynk cloud (over Wi-Fi) to support remote notifications and commands. In parallel, a simple mobile app interface was created using Flutter, to allow authorized users to enroll a new fingerprint or delete an existing one through their smartphone – this interface communicates with ESP32 through Blynk cloud API [25]. By the end of this integration phase, the hardware and firmware were working together: a fingerprint could be placed and recognized, the lock would trigger and send updates to the mobile app.

3) System development and testing: With the prototype assembled, extensive testing was done to fine tune performance and validate reliability. The hardware was first assembled on a breadboard for easy modification during testing. Key things tested included fingerprint registration and matching accuracy, door actuation (unlock/lock response times) and alert mechanisms. The fingerprint sensor was tested under various conditions (clean vs smudged sensor surface, correct vs off-angle finger placement) to see how it handles partial or imperfect scans. The system's error handling features were also verified: the auto lockout after 3 incorrect attempts was triggered manually to make sure it worked as expected and the corresponding user notifications were checked on the smartphone. Throughout this phase, iterations were made — for example, adjusting the fingerprint matching threshold to balance sensitivity vs false rejections and optimizing the microcontroller code to reduce any latency in communication with the Blynk platform.

4) Final deployment: After testing was complete, the hardware was moved from the prototyping breadboard to a more permanent setup for real world demonstration. The components were mounted on a mock door frame to simulate a real door installation. The fingerprint sensor and OLED were placed for user access and the solenoid was installed to control a latch bolt as it would in a real door. Power was supplied either via a USB power bank or the dual 9V battery pack for portability. A quick user training was done for those interacting with the lock, explaining how to place fingerprints correctly and how to use the mobile app for remote operations. The final system was tested in a simulated home-entry scenario and it worked as expected. Also, notes were taken for maintenance (checking battery levels, cleaning the fingerprint scanner for optimal performance, keeping firmware updated) to ensure long term reliability and security.

B. System Design and Overview

The IoT enabled smart lock system consists of a combination of hardware and software components to provide secure, efficient and remote controlled access. On the hardware side (see Fig. 2 for the system architecture diagram), the main components are:

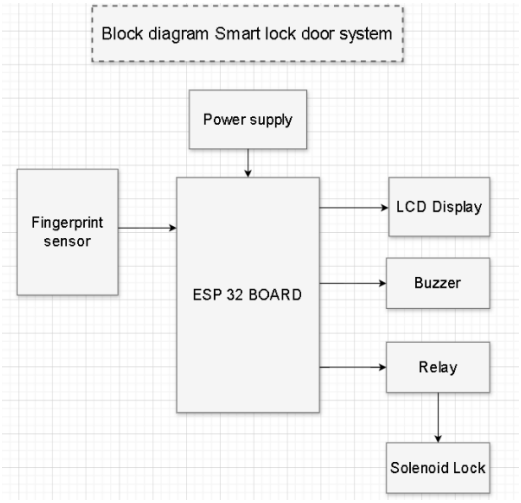

Fig. 2. Block diagram of the smart lock system.

- A biometric fingerprint sensor (model R305 optical sensor) which is the primary means of user authentication by capturing fingerprint images and converting them into digital templates.
- A solenoid lock mechanism that controls the door latch (energizing the solenoid opens the lock, de-energizing locks the door).
- A 16×2 character LCD or 0.96-inch OLED for user interface and feedback – in our prototype we used a small OLED to show status messages (e.g. "Initializing...", "Fingerprint Accepted", "Access Denied", etc.) but a larger 16×2 LCD can be used to display multi-line messages for better readability.

- An ESP32 Dev Board which is the brain of the system, chosen for its dual core and Wi-Fi (and Bluetooth) capabilities for IoT applications. The ESP32 handles fingerprint sensor input, runs the matching algorithm, controls the solenoid via output signals and communicates with the remote app.
- A 5V active buzzer that provides audible alerts (e.g. a quick beep for success, a longer tone for failure).
- A 5V relay module that acts as a switch to drive the higher voltage solenoid lock – the relay isolates the ESP32 (which runs at 3.3V logic) from the 12V required by the lock and allows the microcontroller to safely control the lock circuit.
- A power supply solution which can be either USB (for wired or power bank) or battery pack. In our portable setup we used 2 x 9V batteries in series to provide the ~12V required by the solenoid and the ESP32 board was powered through its Vin pin (with onboard regulators stepping it down to 3.3V).
- The various jumper wires (male-to-male and female-to-female) to connect components in a modular way.

All components are connected as per the schematic so that the ESP32 can read data from the fingerprint sensor (via UART), toggle the relay (via a GPIO output pin) to unlock the door, drive the buzzer (via another GPIO) and update the display (using I²C for the OLED or LCD). The hardware design is modular and low power consumption is important for a door-lock device that might be battery operated. On the software side the system's firmware is written in C++ using the Arduino framework for ESP32. This provides a convenient environment with libraries for the fingerprint sensor (for enrolling and matching fingerprints), for the display and for Wi-Fi. The Blynk IoT platform is used to enable remote access and notifications: the ESP32 runs the Blynk client which maintains a secure connection to the Blynk cloud server via Wi-Fi. Through the Blynk mobile app the user can send commands (like enroll or delete a fingerprint, or unlock the door remotely) and receive real-time notifications (for events like a door unlock or a failed authentication attempt). The system also has a custom Flutter based mobile application that interacts with the Blynk API to provide a more specialized interface for managing fingerprints (e.g. naming fingerprint entries, issuing a delete-all command) [38]. This dual-app approach (Blynk console plus a tailored Flutter app) provides more user interaction and control flexibility. Overall the tight integration of hardware and software components results in a complete, responsive and secure smart lock solution for modern access control.

C. System Configuration Process

The ESP32 gets input from the fingerprint sensor. When recognised it triggers a relay that powers the solenoid lock to open the door. Also the OLED display shows visual feedback and an alert is pushed to the user via Blynk app. On a failed attempt the system increments a fail counter and after 3 fails it starts a lockout timer and sends an intrusion alert.

In terms of system configuration the ESP32 firmware is set to run multiple tasks in parallel. It continuously listens for fingerprint input and network commands. The program flow (as shown in Fig. 3) starts with initialization of all sensors, display and Blynk connection. Then it enters an idle loop waiting for either a fingerprint scan or a user command from the app. Fingerprint enrollment mode can be triggered via the mobile app or a hardware input: in this mode the system will prompt the user (on the OLED) to scan a new finger twice. It will then process those scans and create a fingerprint template and store it in flash memory if the quality is good and if there are available slots. Fingerprint deletion can be done for one fingerprint or all, either via the app or a specific sequence on the device. These features allow the system to be managed easily when a user needs to be replaced or if the device memory is full. For normal authentication whenever a finger is scanned the system will instantly compare the input to all stored templates. If a match is found the ESP32 will trigger the relay to open the door and immediately notify the user (OLED message "Unlocking…" and a push notification via Blynk). The door will remain open for a set time (5 seconds) before the relay is switched off to re-lock automatically, with an OLED message "Door Locked". If no match is found (i.e. the fingerprint is not recognized) the OLED will display "Access Denied" and the buzzer will sound. The system will count consecutive fails; upon the third fail it will trigger the security lockdown: the ESP32 will ignore further fingerprint inputs for 15 seconds and display "LOCKOUT – Too Many Failed Attempts" on the screen, while sending an alert notification. After the cooldown the system will reset the fail count and go back to normal operation. This security policy balances convenience with protection, so a legitimate user who had two bad scans can still try again after a short pause, but an attacker can't brute force multiple attempts quickly.

Fig. 3. Solenoid lock.

D. Hardware Specification

Hardware specification tells us about the details and technological value of the physical components of the computer or electronic device; and this is useful for defining performance rates, compatible operations and possible uses of the device. These specification may include details about the type of processor or central processing unit (CPU), available memory or random-access memory (RAM), storage capacity, graphics card or graphics processing unit (GPU), networking options such as Universal Serial Bus (USB), High-Definition Multimedia Interface (HDMI) and/or wireless options, and the power supply of the computer. Specific information about the components meet the needs of the users and help the developers to decide if the device is suitable for gaming, handling big data, or media production, and also ensure that the software and peripherals are compatible. Information about the possibility of upgrade and expansion of the device in hand enables the buyer to make informed decision and to configure the system properly.

1) Fingerprint sensor: The fingerprint sensor in this system works via UART communication and capture, match and store biometric data. It has six primary pin connections, each serves a specific function to ensure seamless integration with the microcontroller. The red wire (VCC) supply 3.3V DC power to the sensor, the black wire (GND) is the ground connection. Data transmission between the sensor and the ESP32 microcontroller is through the yellow (TXD – data output) and green (RXD – data input) wires. The blue wire (WAKEUP) is for generating wake signal to the sensor when finger is present, to conserve energy during idle state. The white wire (3.3VT) is for inductive power input, to support the sensor wake-on-touch feature to further improve energy efficiency. Overall the sensor is designed to provide accurate fingerprint recognition with low power consumption, suitable for IoT based smart lock system.

2) Solenoid lock: The solenoid lock is an electro-mechanical actuator; when current pass through its coil, a magnetic field is generated, pulling in a metal plunger to either engage or disengage the locking mechanism. This allows the door to be locked or unlocked by the microcontroller without manual key intervention. Our system's solenoid is 12V and can retract or extend the bolt within few milliseconds of activation.

Fig. 3 is the solenoid lock component used in the smart lock system. A solenoid lock is an electromechanical actuator that works by energizing a coil to generate a magnetic field. This field moves a metal plunger to engage or disengage the locking mechanism, to control door access. When integrated with an IoT based smart lock system, the solenoid lock can be controlled remotely by the microcontroller (ESP32) to automate access control. The solenoid lock is well-suited to applications that require both speed and security. That's because it responds quickly, is durable and has reliable electronic control. You can also integrate it into wireless smart systems, making it a good fit for real-time access control scenarios. But to ensure that works smoothly, you need a consistent power supply and some safety mechanisms to prevent unauthorized access or accidental lock failure. In this project, we integrated a genuine solenoid door lock with an ESP32 microcontroller [39]. That lock is opened by the fingerprint sensor after it authenticates the biometric data. The ESP32 then triggers the solenoid lock to open the door. We programmed the firmware for that operation using the Arduino IDE-and you can monitor the system remotely through the Blynk app. We powered the system with a stable energy source-a 9V battery or power bank-to ensure it keeps performing uninterrupted. That configuration offers several advantages. Speed, for one. Solenoid locks respond quickly, which is ideal for situations where you need fast access. Electronic control lets them be seamlessly integrated into smart environments for remote operation. And reliability means they're robust and long-lasting. Together, those attributes make the smart lock system more effective and convenient for users by eliminating the need for traditional keys and providing secure, real-time access management.

3) LCD Display: One feature we considered adding to our system is an LCD display. A 16x2 character LCD is an alphanumeric display that can show two lines of 16 characters each. It's based on the HD44780 driver, which makes it easy to interface with microcontrollers. We actually used a smaller OLED display in our current prototype because of size constraints, but a module like this 16x2 LCD would be great for displaying more detailed status messages or instructions in the future.

The 16×2 LCD has 16 pins, each with a specific function. Vcc and GND are power supply inputs, Vo is for contrast adjustment (controlled by a potentiometer), D0 to D7 are data lines, and RS (Register Select), RW (Read/Write) and Enable are control lines. RS toggles between command and data mode, RW determines read or write operation and Enable initiates data transfer. In IoT based smart lock systems, 16×2 LCD is a good visual output module. It displays system states such as authentication success or failure and provides immediate user feedback. Its ease of integration, affordability and reliability in displaying real time data makes it a preferred choice for many embedded system developers.

4) Additional components: To ensure efficient and secure operation of IoT enabled smart lock system, several hardware components are used. Battery holder has dual 9V batteries, a reliable and portable power supply for uninterrupted system operation. Buzzer is an alert mechanism, it notifies user of successful access or intrusion attempt. 9V batteries are the primary power source, portable and easy to replace. Jumper wires are used to connect different modules and components, to make circuit integration seamless. ESP32 development board is the central processing unit, it handles data processing, communication with fingerprint sensor and Blynk app. USB to Micro cable is for alternative power input from external sources like power banks, for system flexibility and backup. 5V relay module controls the solenoid lock, it receives trigger signal from ESP32 and switches the lock accordingly, so physical access is controlled based on verified biometric input. ESP32 Dev Board has 34 GPIO pins, analog inputs and capacitive touch inputs and supports multiple protocols (UART, I²C, SPI). Fig. 4 shows the pinout and capabilities of ESP32 used. Many pins can be configured with internal pull-up or pull-down resistors and the chip supports power efficient modes like deep sleep. These features makes ESP32 suitable for managing various sensors and actuators in our smart lock and for network connectivity.

Fig. 4. ESP32 dev board.

Fig. 4: ESP32 Dev Board V1 Pinout. It has 34 advanced GPIO (General Purpose Input/Output) pins. These pins work like digital pins in Arduino boards, you can connect peripheral components like OLED displays, sensors, buttons and buzzers. ESP32 pin is versatile, it can be in multiple electrical states, internal pull-up, pull-down and high-impedance. This makes the board good for various interfacing tasks like button inputs and system console integrations and even for implementing control techniques like Charlieplexing.

The ESP32 WROOM module has 25 GPIO pins, many of which are multipurpose: some are input only, others have internal pull-up resistors. According to the ESP32 datasheet under the "Recommended Working Conditions" section, the maximum current per GPIO pin is 40mA. This is enough for most sensor and actuator tasks and for stable operation in smart IoT systems. During development we first assembled the hardware on a breadboard, but for the final prototype we used a compact wiring approach to emulate a real product deployment. We eliminated the need for a big breadboard by connecting components with short jumper wires, so the assembly is cleaner and more reliable. The ESP32 board, relay and power circuitry are attached to the backside of the door frame (to mimic being inside a door panel), the fingerprint sensor and OLED screen are on the front side where the user can access them. The power supply (2x 9V batteries in series, 12V) is connected to the solenoid lock through the relay and to the ESP32's regulator input, so the whole system is self-contained. In this configuration the ESP32 is the central controller, reading inputs from the fingerprint sensor and controlling outputs (lock and buzzer). The hardware is designed to be as energy efficient and robust as possible given the constraints, so the lock can run for a long time on battery and withstand normal usage.

E. Software Specification

The software specification describes the development environments and applications used to design, program and control the IoT based smart lock system. The main development platform used for firmware programming is the Arduino Integrated Development Environment (IDE). It allows to write, compile and upload code to the ESP32 microcontroller. The Arduino IDE is known for its simplicity, cross platform compatibility (Windows, macOS and Linux), large library ecosystem and big community, so it's suitable for both beginners and experienced developers. Additionally the IDE supports a wide range of sensors, actuators and communication modules for IoT applications. Besides the Arduino IDE, PlatformIO is used for advanced development tasks. PlatformIO offers features like intelligent code completion, version control integration and better hardware abstraction layers, so it's more scalable and maintainable codebases – especially when developing complex systems on the ESP32 platform. For remote control and monitoring the system uses the Blynk application which is a cloud based IoT dashboard that communicates with the ESP32 over Wi-Fi. The Blynk app allows to control the smart lock in real time through virtual widgets like buttons, sliders and notifications. It allows remote locking and unlocking, status monitoring and real time alerts for access events, so the smart lock system is more accessible, flexible and secure.

IV. Result

This section reviews the IoT based smart door access system using biometric fingerprint recognition. We look at the system's functionality, performance metrics and behavior under different test scenarios. We focus on key results such as enrollment and authentication times, remote access responsiveness and lockout mechanism. We also highlight the real time capabilities enabled by ESP32 and Blynk and discuss the system's strengths and limitations based on the data (e.g. accuracy rates, error causes).

A. Initial Hardware Deployment

The prototype was installed on a test door and powered on to see how it works in real world. Fig. 5: Initial Hardware Setup shows the arrangement of ESP32 board, solenoid lock, relay module, OLED display, fingerprint sensor, buzzer and battery pack in the final setup. This compact setup is a practical smart lock setup. In real life when the system boots up, the OLED displays "Initializing…" for about 2 seconds while connecting to Wi-Fi (if available) and preparing the sensor. Once ready it prompts for fingerprint input. We found that ESP32's Wi-Fi connectivity is robust, the system can maintain a steady connection to Blynk cloud during the tests (no disconnections were observed in a strong Wi-Fi coverage area). The solenoid lock works well with the provided battery power and the entire hardware setup is stable (all components worked together without brownouts or resets, means the power delivery and wiring is sufficient).

Fig. 5. Initial hardware setup.

B. Result and Analysis

IoT based smart lock systems using fingerprint authentication has shown a lot of promise in providing secure, efficient and user friendly solutions for modern access control. By integrating biometric verification and IoT communication protocols, these systems eliminate physical keys and provide remote access. Recent advancements have further improved these systems by adding encryption algorithms and feedback mechanism to ensure safety and convenience.

The proposed smart lock system as shown in Fig. 6 is a complete solution that combines latest technologies. At the core is a fingerprint sensor that is the primary access control device. It ensures only authorized users can enter, hence increasing the system's security and reliability. The locking mechanism uses a solenoid, powered by 2 x 9V batteries in series to provide a stable 12V output, hence robust physical access control.

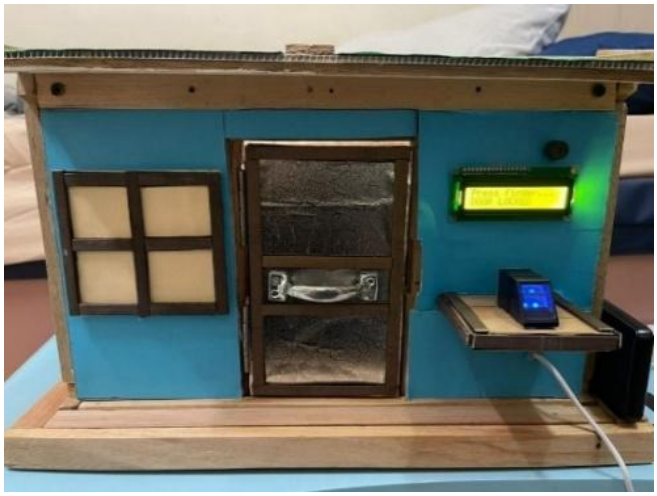

Fig. 6. The proposed smart lock system.

ESP32 is the main microcontroller. It provides Wi-Fi connectivity and manages the communication with Blynk app so users can remotely monitor and control the door access. Relay module controls the power to solenoid and buzzer provides audible feedback for success and failure. LCD displays real time system messages so users are informed throughout the process.

C. Fingerprint Enrollment and Template Management

Fingerprint enrollment is a must have feature of the system. As shown in Fig. 7, a new user has to scan his finger twice on the system. The two scans are captured and processed by the system to extract a unique fingerprint template out of it. This extracted template is stored in the system's fingerprint library for further reference. For this purpose, the optical sensor is used that will capture the fingerprint data with full accuracy and in a very reliable manner. When any user tries to unlock the system, it captures a new fingerprint scan and then compares it with the stored templates in the fingerprint library to determine a match. One of the major drawback of this system is that it can store only three fingerprint templates in its library. If the library is already loaded with three different fingerprints, then it has to delete all enrolled fingerprints first before enrolling another one. This will keep the capacity to the optimal level to prevent overloading with fingerprints data.

Fig. 8 shows the process of deleting all stored fingerprint users from the system. This feature allows to delete all fingerprint templates from the library, which is very useful when the system reaches its storage limit or requires a reset for security purposes. By deleting all fingerprints, the system will start fresh and new users can be registered without any conflict or limitation. This feature is very useful during ownership transfer or access update where full reset of stored credentials is required.

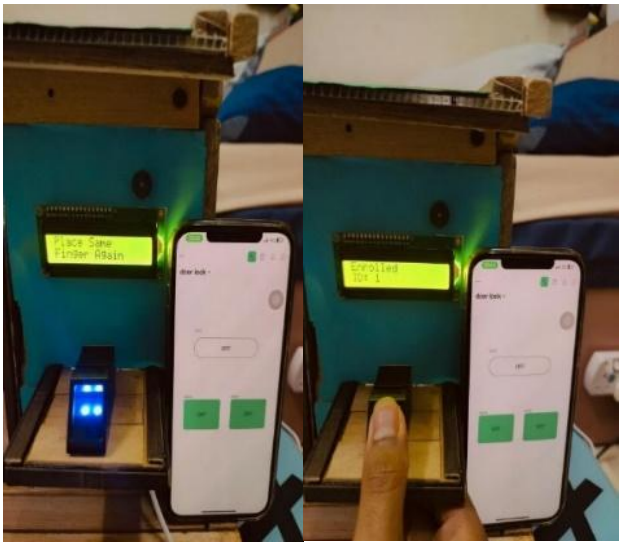

Fig. 7. Fingerprint enrollment.

Fig. 8. User deletion.

D. Authentication: Success and Rejection

Fig. 9 shows authorized user gaining access with a correct fingerprint. An authorized user gaining access with the correct fingerprint proves the Smart Lock Door system's effectiveness and reliability. When a recognized fingerprint is scanned, the system will compare the biometric data to its stored database of authorized individuals. Once the match is found, the lock mechanism will be activated and the user will get access. Then The LCD will display "Match found! DOOR UNLOCKED". This shows the security and convenience of biometric authentication by allowing only pre-approved fingerprints to unlock the door, limiting unwanted entry and overall security.

Fig. 9. Authorized user gaining access with a correct fingerprint.

Fig. 10: Unauthorized user trying to access with wrong fingerprint. When user puts an unregistered fingerprint on the sensor, the system will scan and compare the biometric data with the stored database. If no match is found, access will be denied and the lock will remain locked. To give user feedback, the LCD screen shows "Fingerprint not found" on the spot, so it's clear what happened after the authentication failed. Meanwhile the buzzer beeps, so you can hear the rejection of unauthorized access. This combination of light and buzzer is very functional: only the person with approved fingerprints can open the door. The system is more secure now because of the biometric authentication mechanism that prevents breaches.

Fig. 10. Unauthorized user attempting access with an incorrect fingerprint.

E. Security Lockout Mechanism

Fig. 11 shows a key security feature of the IoT based smart lock system, where the system goes to "block" mode after 3 consecutive failed fingerprint authentication. This is to prevent unauthorized access by halting further interaction temporarily, so the system is secure against brute force or trial and error. After 3 failed authentication, the system disables the fingerprint sensor and the solenoid lock for 15 seconds. During this blocked state, the LCD screen shows a clear message "System Blocked for 15 Seconds" and the buzzer beeps, so the user or intruder knows the system is blocked. This blocking mechanism makes the smart lock system more secure and reliable by discouraging repeated unauthorized access and protecting the components from excessive wear. By this feature, the smart lock system shows a robust and efficient way of maintaining secure and controlled access.

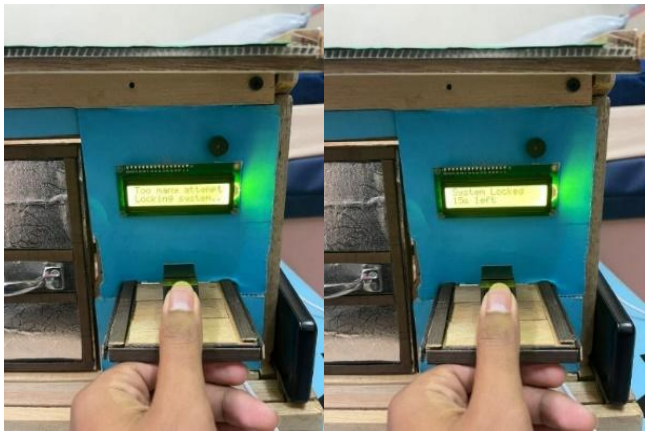

Fig. 11. Security lockout mechanism.

F. Remote Operation and Control via Blynk

The smart door lock system has a fingerprint sensor integrated with Blynk platform for flexibility and security. Fingerprint is the primary way to open the door. When a valid fingerprint is detected, it will open the door and show on the LCD "DOOR UNLOCKED". In case of error or when it fails to detect the fingerprint (e.g. when the finger is dirty) the system allows user to open the door using the Blynk app as shown in Fig. 12. The app can send "ON" or "OFF" command to the ESP32 via the app and the ESP32 will control the relay to lock or unlock. Real time feedback is shown on the LCD "DOOR LOCK" or "DOOR UNLOCKED". This way the smart home application is more reliable, convenient and secure with two options.

Fig. 12. Remote poperation and control via Blynk.

Fig. 13. Lock down messages on blynk application.

Fig. 13 shows the Blynk app for a smart door with advanced security features. When 3 consecutive failed attempts to open the door using the fingerprint scanner are made, a warning message is displayed. The system locks down after 3 failed attempts and goes into a 15 second lock down to temporarily disable further access to prevent forced entry.

The message displayed is, "SYSTEM LOCK FOR 15s. SOMEONE TRY TO OPEN!!!". These are for 2 purposes: first, as a security feature to stop malicious or repeated attempts to breach the system; secondly, these provide immediate feedback to the authorized user in case of security risks or unauthorized access attempts in real time. This feature increases the overall reliability and safety of the smart lock system making it suitable for homes, offices or other sensitive areas. Most importantly, this feature shows how IoT platforms like Blynk can combine hardware like fingerprint scanners with software features like real-time alerts to provide secure, user friendly and responsive smart systems.

G. Summary of Functional Outcomes

The combination of fingerprint authentication, real-time feedback and IoT based remote control makes the proposed smart lock system a modern solution for residential and small scale commercial security. It balances security and user convenience through:

- Accurate and fast biometric verification;
- Visual and auditory feedback for user actions;
- Automatic lockout to prevent brute-force attempts;
- Remote access and notification via Blyn.

The system has been tested thoroughly and meets its design requirements. Limitations like limited storage and sensitivity to fingerprint placement are acknowledged and can be addressed in future updates by adding cloud storage and capacitive sensors for better accuracy.

V. DISCUSSION

Table II summarizes the system's performance metrics based on various functional outcomes including response times and alert mechanisms.

TABLE II. PERFORMANCE METRICS OF THE SMART LOCK SYSTEM

Feature	Timing (Seconds)	Description
Fingerprint Detection	1.0	Time taken to detect a fingerprint, process the image, and search in the database.
Door Unlock Duration	5.0	Relay remains HIGH (door unlocked) for 5 seconds after a successful fingerprint match.
Door Lock Duration	Instant	Door locks instantly when the relay is turned LOW.
Incorrect Attempts Reset	15.0	System goes into a cooldown for 15 seconds after 3 incorrect fingerprint attempts.
Buzzer Feedback	0.6	For 3 quick beeps (200ms each, 200ms gap).
System Initialization	2.0	Time taken for OLED to display "Initializing..." message during setup.
Enrollment (Per Finger)	5.0	Time taken to complete the enrollment of one fingerprint.
Fingerprint Deletion	1.0	Time taken to delete one fingerprint from the database.
Delete All Fingerprints	5.0	Time taken to delete all enrolled fingerprints (for up to 3 fingerprints).
LCD Display Updates	Instant	Time taken to update LCD messages after each action.

As shown above, the system is fast for most actions. Fig. 14 shows the histogram of these timings and most of the actions (detection, feedback, locking) are within a few seconds or less. This is good enough for practical use; for example, from putting your finger to the door to the door unlocking takes about 1 second for recognition plus a negligible delay to throw the bolt, which users found to be acceptable and smooth. The 5 second unlock time was chosen as a balance between convenience (enough time to open the door) and security (auto-lock re-engages quickly). In testing, this was also found to be enough – users could open the door within that window. The 15 second lockout on failed attempts was effective in practice: it's short enough not to inconvenience a legitimate user who just had 3 bad scans (they only wait 15 seconds to try again), but long enough to frustrate or slow down a malicious actor trying multiple different fingerprints. During the lockout, our system's alert gave the owner immediate knowledge of the issue, which is a critical security feature.

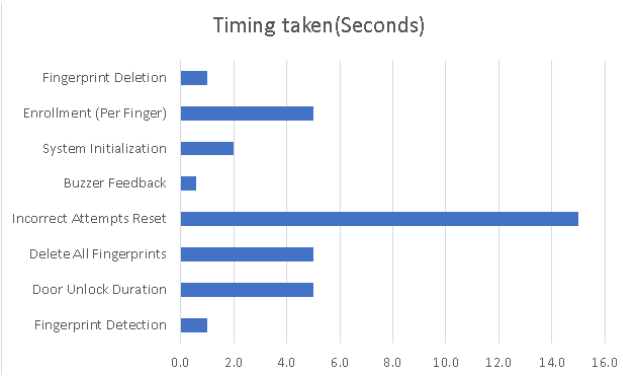

Fig. 14. Histogram time taken.

Next we looked at the authentication accuracy in terms of error rates. The False Rejection Rate (FRR) and False Acceptance Rate (FAR), along with the contributing factors to failures, are shown in Table III.

TABLE III. AUTHENTICATION ERROR RATES AND ERROR CAUSES

Error Type	Description	Percentage (%)
False Rejection Rate (FRR)	Authorized user denied access	26.32%
False Acceptance Rate (FAR)	Unauthorized user granted access	1.32%
Sensor Malfunction	Inability to detect or process fingerprint	6.58%
User Error	Misplacement or improper finger pressure	65.79%

Note: "User Error" here is a contributing factor, not an independent error rate; it means the proportion of false rejections caused by user mistakes during scanning.

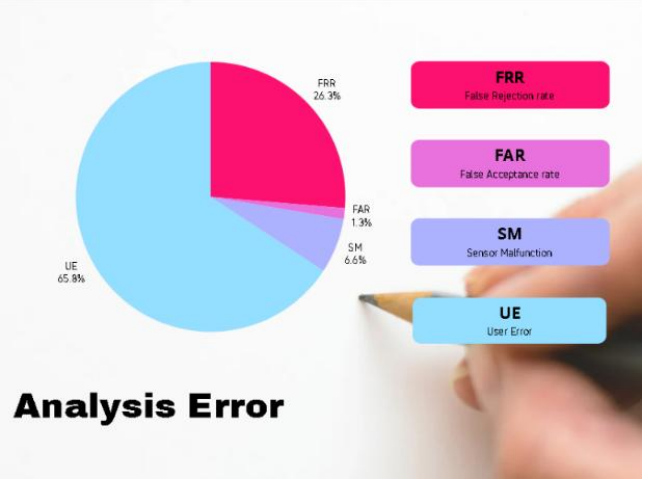

Fig. 15. Pie chart analysis error.

As shown in Fig. 15 (a pie chart of error distribution), user error was by far the largest contributor to access failures, accounting for about 65.8% of the failures. This matches our observation that many false rejections occurred when authorized users didn't place their finger on the sensor the same way as during enrollment (e.g. misaligned or partial fingertip placement). This high incidence of user induced error is the main reason the measured FRR is high (26.32%). In other words, about 1 in 4 legitimate access attempts in our tests resulted in denial, mostly due to inconsistent finger placement rather than a flaw in the authentication algorithm. This is a usability limitation of the current system – some training or design improvements are needed to make the fingerprint reading more forgiving. Possible mitigations include improving the sensor algorithm to match partial fingerprints, using a fingerprint sensor with a larger scanning area or providing better feedback to guide finger placement. The good news is that these false rejections don't represent security breaches (the system erred on the side of caution and denied access), and can be reduced with targeted improvements. On the other hand, the FAR was ~1.32%, which means the system very rarely grants access to an unauthorized fingerprint. This is critical in a security context – it shows the system is very good at keeping intruders out. In fact, in our controlled tests, no one unauthorized person was able to unlock the door; the FAR percentage only reflects contrived test scenarios (e.g. using intentionally similar fingerprints or residual prints) and possibly any sensor anomalies. This bias in performance – erring towards false rejections rather than false acceptances – is often desirable for security systems as it prioritizes protecting against break-ins over inconveniencing legitimate users. But for a real product, we want to lower the FRR without sacrificing the FAR, so we can improve the overall user experience. The error analysis also showed a small percentage (~6.6%) of instances labeled as sensor malfunctions where the fingerprint sensor failed to capture or process a scan (possibly due to momentary hardware issues or dirt on the sensor). These cases usually required the user to scan again and did not result in unauthorized access. While not frequent, this means regular maintenance (keeping the sensor surface clean and ensuring the hardware connections are secure) will be important for consistent performance. In summary, the results show that the smart lock system meets its goals of security and remote access. The system authenticates enrolled users and blocks unknown users, with real-time alerts adding an extra layer of security. The main limitation – higher false rejection rate – is due to user interaction and can be fixed going forward. No critical failures or breaches happened during testing: the lockout mechanism worked as expected and the system recovered from all tested scenarios (including power reset and network reconnection). These results validate the design and show that IoT-biometric fusion is a viable approach for smart door access with some tweaks to make it more user friendly.

In addition to functional testing, this work serves as a validation of proposed improvements over existing smart lock systems. Unlike previous designs that lacked real-time lockout or feedback, our system integrates biometric authentication, instant alerts, and Blynk-based control with quantitative performance validation. Tables II and III present measurable outcomes such as low false acceptance rate (1.32%), fingerprint recognition time (~1 sec), and defined cooldown after failed attempts (15 sec). Compared to prior studies [40]-[43], which focused on single-modal access or lacked intrusion responses, our solution demonstrates enhanced usability and robustness with local feedback and remote IoT management. This comparison underlines our contribution toward bridging the gaps in existing literature.

VI. CONCLUSION

This study demonstrated the successful design and implementation of an IoT-based smart door lock system utilizing fingerprint biometric authentication and ESP32 microcontroller with Blynk integration. The proposed system replaces traditional keys with a secure and user-friendly mechanism capable of local and remote access management. The system achieved a fingerprint recognition time of approximately 1 second, and a door unlock duration of 5 seconds, offering a good balance between speed and usability. The False Acceptance Rate (FAR) was measured at 1.32%, indicating strong protection against unauthorized access, while the False Rejection Rate (FRR) was 26.32%, primarily due to user misplacement errors rather than system flaws. Additional features, such as a 15-second security lockout after 3 failed fingerprint attempts, OLED display feedback, and buzzer alerts, contributed to a more secure and informative user experience. Real-time alerts and remote control via the Blynk mobile app further enhanced system utility and responsiveness. Despite its advantages, the system has limitations, such as storage for only

three fingerprints and sensitivity to user finger placement. However, these do not overshadow its practical viability. The system is low-cost, modular, and well-suited for residential and small commercial applications. Overall, this project provides a robust foundation for smart home access control. Its successful integration of biometric recognition, IoT communication, and security mechanisms demonstrates the potential of lightweight embedded systems to deliver real-time, user-centric, and secure access management solutions. Future improvements will focus on expanding biometric storage, integrating cloud capabilities, and enhancing sensor accuracy.

VII. Future Work

This study lays the groundwork for further enhancements in biometric access control systems. Future work will explore cloud-based biometric data storage to support additional user profiles, enable remote access recovery, and enhance data redundancy. The system can also be extended to incorporate multi-biometric inputs (e.g., fingerprint + facial recognition + PIN) for multi-factor authentication, improving both convenience and security. Another key direction is the expansion of the framework to support smart city access control infrastructures, such as IoT-enabled gates in residential compounds, office buildings, or campus environments. Integration with advanced IoT and cloud platforms will allow centralized monitoring and control, paving the way for scalable, secure, and efficient access management. Additionally, implementing features such as real-time access logs, time-based permissions, and low-power optimizations (e.g., sleep modes) will further improve usability, energy efficiency, and reliability. These enhancements would help in shaping the next generation of secure, intelligent, and user-centric smart lock systems for modern homes and cities.

Acknowledgment

The authors extend their appreciation to Universiti Teknikal Malaysia Melaka (UTeM) and to the Ministry of Higher Education of Malaysia (MOHE) for their support in this research.

Modelling Cloud Computing Adoption in the Malaysian Healthcare

A Resource-Based View and Technology-Organisation-Environment (TOE) Perspective

***Abstract*—Cloud computing is increasingly reshaping the global IT landscape, offering scalable and efficient solutions across industries, including the healthcare sector. This study investigates the determinants of cloud computing adoption in the Malaysian healthcare industry by integrating the Resource-Based View (RBV) and Technology-Organisation-Environment (TOE) frameworks. Emphasising internal organisational capabilities, the study excludes traditional Information Systems (IS) models to maintain theoretical coherence with RBV's strategic orientation toward firm-level resource advantages. Data were collected from 265 respondents across 127 healthcare organisations and analysed using Partial Least Squares Structural Equation Modelling (PLS-SEM). The study also proposes an extended taxonomy of cloud services contextualised for healthcare, strengthening the theoretical underpinnings and practical applicability of cloud adoption strategies in this domain. The findings reveal that among IT capabilities, managerial IT capability exerts the most substantial influence on adoption, followed by relational and technical capabilities. Within the TOE dimensions, regulatory support emerged as the most critical enabler, while business resources, change management, organisational culture, and vendor support also demonstrated significant positive effects. The results offer empirical validation for a comprehensive conceptual model grounded in RBV and TOE, providing both theoretical insights and practical guidance for healthcare organisations aiming to strengthen IT capabilities, optimise organisational readiness, and align with external institutional drivers for successful cloud migration.**

***Keywords*—Adoption; cloud computing; Malaysian healthcare; partial least squares-structural equation modelling; resource-based view (RBV)**

I. Introduction

In recent years, cloud computing has experienced significant global growth, evolving into a fundamental component of modern organisational IT infrastructures. As businesses face intensifying market pressures and increasing demands for agility, many have adopted cloud-based solutions not merely as a technological upgrade but as a strategic enabler of innovation and operational efficiency. Defined as the delivery of computing services, such as servers, storage, applications, and platforms over the internet, cloud computing builds upon the principles of distributed and parallel computing [1], offering a scalable and reliable environment for resource sharing and remote access [2] [3]. The National Institute of Standards and Technology (NIST) defines cloud computing as "a model for enabling convenient, on demand network access to a shared pool of configurable computing resources (e.g., network, servers, storage, applications and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction" [4]. The NIST definition reveals the main advantages of cloud computing as shareability, scalability, and cost reduction.

The transition to greater cloud computing adoption in some industries is propelled by firms utilising the benefits of cloud computing to maintain market competitiveness. Numerous pieces of evidence indicate that company agility and competitiveness, cost-effective disaster recovery, swift resilience, and rapid deployment are significant advantages of cloud usage [5]. In [6], the authors indicate that small organisations derive profits via enhanced collaboration with customers and staff, whereas medium enterprises achieve profitability through the establishment and expansion of new ventures, positioning themselves for global growth. In addition, the adoption of cloud computing aligns with the Fourth Industrial Revolution (IR4.0), and numerous entities, including those in the healthcare sector, have begun their journey towards complete digitisation. For healthcare organisations, this initiative is intended to enhance the quality of systems for managing patient or health treatment information [7]. In summary, a variety of research has shown how cloud computing's IT features enhance organisational value. Here are several specific ways in which adopting cloud computing can be advantageous for the healthcare sector:

1) It enables healthcare organisations to reduce capital expenditure by eliminating the need for costly on-premises data centres, which are typically expensive due to the mission-critical, lifesaving functions they must support [8]. Additionally, it minimises service downtime through high availability features essential for uninterrupted clinical operations and reduces operational inefficiencies through

scalable, on-demand resource provisioning tailored to dynamic healthcare demands.

2) Cloud computing also enhances information systems and business agility by enabling rapid execution, supporting critical healthcare operations through high availability, and facilitating swift recovery via built-in disaster recovery capabilities [9].

3) Strengthens the quality of patient health and well-being through innovative implementations such as Electronic Health Records (EHR), Personal Health Records (PHR), diagnostic and pharmaceutical cloud services, and support for first responders.

Although cloud computing offers benefits such as enhanced organisational agility, flexibility, and reduced IT infrastructure costs, many organisations, particularly in the healthcare sector, face challenges in developing effective strategies for cloud deployment, including internal readiness assessments and vendor selection (e.g., [9]). Moreover, the rapid pace of cloud adoption has led to shortened IT planning horizons, potentially undermining long-term implementation success [10]. These challenges are further compounded by the unique characteristics of the healthcare industry, which differ significantly from sectors such as manufacturing, transportation, and financial services, as reported in previous information systems studies. The operational complexities of the healthcare sector, along with the participation of constitutional bodies, result in a complex environment that significantly influences the adoption of cloud computing. The diverse organisational structures within healthcare, encompassing for-profit, non-profit, government-owned, and privately owned entities, each with distinct objectives and motivations, contribute to this complexity. This duality, characterised by medical professionals alongside administrative and support staff, further shapes the industry's unique administrative landscape. The reliance of private hospitals on insurance companies and external agencies for reimbursement introduces additional layers of complexity, as these entities often operate with their own agendas. Such complexities can impact the implementation of cloud computing solutions within the healthcare sector. The integration of cloud computing necessitates careful consideration of strategic planning to align technological advancements with organisational goals [11].

Despite the promise of cloud computing to improve organisational agility and operational flexibility, many healthcare organisations continue to face difficulties in devising coherent implementation and deployment strategies [12]. These challenges often result in delayed adoption, potentially placing them at a competitive disadvantage in an increasingly digital healthcare environment. To address this issue, the study proposes a conceptual model that integrates the TOE framework with IT capability, grounded in the RBV theory, to examine the factors influencing cloud computing adoption in the Malaysian healthcare sector.

The remainder of this study elaborates on the theoretical background underpinning the study, particularly the integration of the RBV and the TOE framework. It then defines the key factors influencing cloud computing adoption, along with the research hypotheses. This is followed by a description of the research methodology and a discussion of the empirical findings. The study concludes with a reflection on the study's limitations and suggests for future research possibilities.

II. Theoretical Background and Research Framework

A. Cloud Computing in Healthcare

Cloud computing has evolved into a foundational technology in the digital economy, enabling scalable, on-demand access to computing resources via the internet. It supports not only traditional IT functions but also emerging technologies such as big data analytics and the Internet of Things (IoT), which generate and process vast volumes of data in real-time. By abstracting physical infrastructure into a virtualised environment, cloud computing allows organisations to store, manage, and analyse data seamlessly, regardless of geographical location. According to [13], the taxonomy of cloud services is classified into six categories based on their characteristics from the perspective of IT vendors, cloud service users and software. This classification has been restructured by [14] into three basic groups based on the characteristics of the tree-structure taxonomy and is summarised in Table I.

Given the multifaceted nature and specialised demands of cloud computing in the healthcare industry, it differs significantly from its application in other sectors. Several taxonomies have been proposed to conceptualise its various dimensions. Among them, the taxonomy developed by [15] provides a foundational classification by organising cloud computing knowledge into two primary dimensions, which are principle knowledge and how-to knowledge. The principal knowledge includes service models, deployment types, and technical characteristics such as scalability, elasticity, ubiquity, cost efficiency, shareability, interoperability, and security, whereby the how-to knowledge relates to practical applications such as task support, user types, device integration, and the degree of patient data involvement. This framework offers a structured view of how cloud services are characterised and operationalised in healthcare environments. However, while it provides useful categorisation, it does not explicitly account for the organisational capabilities or contextual factors that influence adoption decisions. Therefore, this study seeks to advance through further theoretical integration.

B. IT Capabilities and Resource-Based View Theory (RBV)

The Resource-Based view or theory (RBV) is a well-established strategic management theory that emphasises the internal resources of an organisation as the foundation for achieving sustainable competitive advantage. In the context of information systems, RBV suggests that firms can enhance performances by effectively integrating external IT resources with internal IT capabilities [16]. This theoretical perspective has been widely applied in IT research to conceptualise how organisations derive value from technological investments and leverage IT assets to strengthen operational effectiveness and strategic positioning.

TABLE I COMPUTING TAXONOMY BY TREE-STRUCTURE FRAMEWORK AND STAKEHOLDER PERSPECTIVES

Taxonomy	Characteristics	Example
Cloud Architecture	is the design of software applications that leverage the internet to deliver on-demand services • Software-as-a-Service (SaaS) • Platform-as-a-Service (PaaS) • Developers implementing cloud applications • Infrastructure-as-a-service (IaaS) • [(Virtualization, Storage Network) as-a-Service] • Hardware-as-a-Service • Cloud Layered Architecture	
Virtualization Management	is a technology that abstracts the coupling between hardware and operating systems	Server, Storage, and Network virtualization
Service	Three different categories of cloud services: • Software-as-a-Service (SaaS) • Is a multi-tenant platform • Platform-as-a-Service (PaaS) • Supported programming languages and environment • Supported operating systems • Supported applications and frameworks • Infrastructure-as-a-service (IaaS) • Supported operating systems • Supported applications and frameworks • Provided infrastructure management tools • Virtualization technology	• Email services, Google Docs, and Dropbox usage – (SaaS) • Supports platforms for system/application development from a programming perspective – (PaaS) • Offer similar functions as data centre – (IaaS)
Fault Tolerance	Is the capability of a system to remain fully operational despite hardware or software failures, achieved through redundancy.	
Security	Is the focal concern in terms of data, infrastructure and virtualization etc.	
Other Issues	Relate to critical operational and architectural mechanisms, including: • Load balancing • Interoperability • Scalable data storage • Internal security • Cloud performance	

While resources such as physical assets, human capital, and organisational processes must be valuable, rare, and inimitable to confer competitive advantage [16], capabilities are distinct in that they refer to an organisation's ability to combine, mobilise, and deploy these resources effectively [17]. Capabilities enable organisations to synthesise knowledge, integrate technologies, and adapt to dynamic environments, making them harder for competitors to replicate [18]. For instance, [19] introduced the concept of IT capabilities as a form of organisational competency that supports core functions and strategy execution.

According to RBV, internal resources that contribute to organisational success must possess three essential characteristics, i.e., value, heterogeneity, and imperfect transferability [17]. Building on this premise, [20] examined how various organisational resources influence firm performance and adopted RBV to explore the role of modern IT resources in developing strategic core competencies. Their study further extended the IT competency model proposed by [19] by integrating organisational capacity dimensions and investigating the complementary effect of resources. The findings demonstrated that synergistic combinations of organisational capabilities and IT resources create complex, path-dependent assets that are deeply embedded in a firm's history, culture, and experience, making them extremely difficult to imitate. Furthermore, their research empirically validated the mediating role of organisational capability in the relationship between IT resources and firm performance. Organisational capability, in this context, reflects the firm's responsiveness to environmental changes and managerial challenges, reinforcing the idea that synergy between IT resources and organisational capabilities is crucial for superior performance.

In separate contemporary research, [21] state that different IT capabilities depend on different structural mechanisms, and this reinforces the concept that the value of various IT capabilities may derive from more complex relationships [19]. The variety of IT capabilities includes Management IT Capabilities, Technical IT Capabilities, and Relationship IT Capabilities.

C. TOE Framework

The TOE framework, created in 1990 by Tornatzky and Fleischer, contends that the firm's adoption and implementation of technological innovations are influenced by the technological context, the organisational context, and the environmental context. Technological context describes factors describing the adoption of an existing technology as well as new technologies relevant to the firm. The term organisational context describes how organisational factors like scope, organisational size, and the amount of available slack resources affect an organisation. Meanwhile, the environmental context refers to the influence of external factors, including those related to industry, competitors, and government, on the adoption of technology.

TOE has been widely recognised for its suitability in studying technology adoption due to its holistic perspective and flexibility in application across various industries, including healthcare. The healthcare sector, in particular, presents unique challenges in adopting cloud computing, such as compliance with data security regulations, complex stakeholder structures,

and critical operational sensitivity. Previous studies have validated the robustness of TOE in cloud adoption research, such as [6] [22] [23] and [24] which demonstrated its effectiveness in identifying influential factors in diverse organisational settings, including the Malaysian public sector. Furthermore, as cloud computing represents a significant paradigm shift in IT service delivery, the integration of TOE with complementary theories such as the RBV can offer deeper insights into how contextual conditions interact with internal capabilities to influence adoption outcomes. Numerous previous studies have utilised either the RBV or the TOE framework to examine cloud computing adoption, but with restricted integration or a lack of sector-specific emphasis. Table II indicates that although RBV-based research (e.g., [19], [18]) has highlighted the strategic significance of IT capabilities, the majority of studies lack application within the healthcare context. Conversely, TOE-based studies (e.g., [22], [12]) have investigated external and organisational factors influencing adoption, but neglecting the internal IT capability as a resource. This study, therefore, addresses these gaps by integrating IT capability (from RBV) into the TOE framework and contextualising the model specifically for the Malaysian healthcare sector.

D. Integrating RBV and TOE in Cloud Computing Taxonomy

To suit the theoretical orientation of this study, the original taxonomy of cloud computing services developed by [12] has been adapted to reflect the integration of IT capability within the RBV and contextualised using the TOE framework. While the original taxonomy classifies cloud computing knowledge into principle and how-to dimensions, the revised version introduces a strategic layer by aligning each element with relevant IT capability attributes and the three TOE contexts. This adaptation allows for a more structured analysis of cloud computing adoption, particularly in understanding how specific service characteristics interact with organisational capabilities and environmental influences within the healthcare sector. The extended taxonomy of cloud computing services in healthcare organisations, as shown in Table III, synthesises key constructs from the Resource-Based View and TOE frameworks, offering a structured lens through which cloud adoption determinants can be categorised. This taxonomy was developed to guide the identification of strategic and contextual factors relevant to cloud implementation in healthcare settings.

TABLE II COMPARATIVE REVIEW OF CLOUD ADOPTION STUDIES IN HEALTHCARE

Study	Domain	Framework / Theory	Focus Area	Healthcare Context	Key Contribution	Gap Addressed by Current Study
[20]	Telehealth	RBV	Telehealth systems and organisational performance	√	Telehealth system analysis	Does not extend TOE taxonomy
[18]	Cloud Computing	RBV	Cloud capability impact	X	Cloud capabilities and business impact	No TOE or healthcare link
[19]	General IS	RBV	IT capability and firm performance	X	Empirical study on IT as resource	No cloud or healthcare context
[17]	Strategic Management	RBV	Resource advantage	X	Foundational RBV theory	Not applied to IT or healthcare
[6]	SMEs	TOE	Cloud adoption & performance	X	Analytical model using TOE	Not applied to healthcare
[15]	Healthcare	TOE (contextual factors)	Adoption determinants	√	Systematic TOE-based review	Does not integrate RBV
[22]	Manufacturing firms	TOE	Usage and performance	X	Survey-based TOE adoption study	Lacks IT capability dimension
[11]	Public Sector	ROCCA and TOGAF	Strategic planning	X	Adoption planning framework	Not TOE or RBV-based
[25]	IT Outsourcing	Theoretical synthesis	Cloud-sourcing decisions	X	Literature reflection on IT sourcing	Lacks empirical healthcare context
[8], [26]	Healthcare	CHIS Utilization Determinants	HIS utilization	√	Empirical studies - behavioural & system-related determinants	No RBV/TOE integration
[9]	Healthcare	Systematic Review	Opportunities and issues	√	Comprehensive review of cloud healthcare	No model or framework
[21]	Cloud Computing	IT Capabilities	Success factors	X	Cloud delivery models and performance	No TOE or healthcare scope
[27]	Public Sector (General)	Extended UTAUT + Performance Impact Model	Cloud adoption drivers, IT personnel performance, organizational factors	X	Cloud adoption impact on IT staff in public sector	Does not examine cloud adoption in healthcare using an integrated RBV–TOE lens

TABLE III EXTENDED TAXONOMY OF CLOUD COMPUTING SERVICES ALIGNED WITH IT CAPABILITIES & TOE FRAMEWORK

Dimension 1: *Principal Knowledge* and its Characteristics		
Attribute	**IT Capability Alignment**	**TOE Alignment**
1a) Service Form (SaaS, PaaS, IaaS)	Technical IT Capability (ability to deploy/manage various cloud service models)	Technological (nature of technology adopted)
1b) Deployment Model (Public, private, hybrid, community)	Managerial IT Capability (decision-making, policy, and governance around deployment models)	Technological
1c) Targeted cloud advantage (Scalability, elasticity, ubiquity, cost efficiency, shareability, interoperability, security)	Technical & Managerial IT Capability (technical – achieving performance; managerial – aligning benefits to business goals)	Technological & Organisational
1d) Timeliness (Real time, not real time)	Technical IT Capability (infrastructure readiness)	Technological
Dimension 1: How-to Knowledge and its Characteristics		
Attribute	**IT Capability Alignment**	**TOE Alignment**
2a) Supported task (Clinical, administrative, strategy, research)	Managerial IT Capability (process integration, alignment with business/clinical goals)	Organisational
2b) User (Patient, medical staff, family member)	Relational IT Capability (coordination among stakeholders, user-oriented design)	Organisational & Environmental
2c) Service Delivery device (Independent, adapted, specialized)	Technical IT Capability (device-level implementation and configuration)	Technological
2d) Patient data involvement (Internal, external, no involvement)	Relational IT Capability (data sharing, collaboration with external entities)	Environmental

III. FACTORS DEFINITION AND RESEARCH ASSUMPTIONS

The development of this research model involves identifying critical factors that influence cloud computing adoption in the healthcare industry. The constructs and measures used in this study are informed by an extended taxonomy of cloud computing services adapted for the healthcare context (Table III), allowing for more context-sensitive operationalisation of cloud-related capabilities. Drawing upon validated constructs from prior literature, each factor is conceptually defined to reflect its relevance within the Malaysian healthcare context. These factors are categorised according to their theoretical origin, whether rooted in IT capability dimensions or TOE contextual elements, and operationally based on their expected influence on cloud adoption. The following section outlines these factors and their definitions, followed by the formulation of the research assumptions underpinning this study:

A. IT Capability

- Managerial IT capability

Managerial IT capability reflects an organisation's ability to leverage the knowledge and expertise of its IT leaders to align emerging technologies with strategic objectives. This capability encompasses both business acumen and technical proficiency, enabling IT managers to evaluate technological potential, orchestrate complex implementation efforts, and integrate new solutions into existing workflows efficiently and cost-effectively [19] [21]. Within the RBV, such capabilities are classified as strategic assets that are rare, valuable, and difficult to imitate, thereby contributing to sustained competitive advantage [20]. In the context of healthcare, where operational complexity and regulatory demands are high, managerial IT capability plays a critical role in guiding cloud adoption decisions. Past studies also suggest that strong managerial capability enhances technology assimilation by enabling better alignment of IT with organisational goals and mitigating risks such as obsolescence or resource misallocation [19] [21]. Accordingly, the following hypothesis is proposed:

H1: Managerial IT capability has a positive influence on the adoption of cloud computing.

- Technical IT capability

Technical IT capability refers to an organisation's ability to acquire, manage, and utilise both tangible and intangible IT assets to support operational and strategic needs. Tangible assets include infrastructure components such as servers, databases, and networking equipment, while intangible assets comprise specialised technical expertise, domain-specific knowledge, and collaborative IT practices across business units [19] [28]. Within the RBV framework, these technical resources serve as foundational enablers that, when effectively deployed, can enhance organisational agility, streamline business processes, and reduce operational cycle times [21] [28]. In the context of cloud computing adoption, especially within healthcare organisations where data sensitivity, interoperability, and infrastructure readiness are critical, strong technical capability enables seamless integration, scalability, and responsiveness. This study suggests that the extent to which healthcare organisations adopt cloud computing is significantly influenced by the maturity of their technical IT capabilities. We, therefore, made the hypothesis as follows:

H2: Technical IT capability has a positive influence on the adoption of cloud computing.

- Relational IT capability

Relational IT capability refers to an organisation's ability to cultivate enduring, trust-based relationships with stakeholders, including technology partners, cloud vendors, and inter-organisational collaborators [21]. Under the lens of the RBV, this capability is considered an intangible strategic resource that is valuable, rare, and difficult to replicate, thereby contributing to sustained competitive advantage [20]. In the context of cloud

computing adoption, especially in the healthcare sector where data privacy, regulatory compliance, and trust are critical, relational IT capability plays a vital role in reducing uncertainty, enabling knowledge-sharing, and enhancing mutual commitment between partnering organisations.

Trust is a core element of relational capability which facilitates seamless collaboration, minimises perceived risks, and lowers transaction costs, particularly when adopting externally hosted services. When healthcare organisations possess strong relational capabilities, they are better positioned to coordinate with cloud providers, resolve implementation challenges, and derive strategic value from the adoption process. Therefore, relational IT capability serves as an essential enabler of cloud computing adoption, consistent with RBV's proposition that organisational capabilities can be leveraged to secure competitive advantages.

H3: Relational IT capability has a positive influence on cloud computing adoption. That is, a relational IT capability characterised by trust contributes to the factor for cloud computing adoption.

B. TOE Framework

- Technological capability

Technological capability refers to the ability of a company to mobilise and apply technological resources in support of innovation and strategic objectives. Within the TOE framework, it is typically conceptualised through three critical dimensions, consisting of technology resources, human resources and business resources [22]. These dimensions encompass the technological infrastructure, the technical expertise of personnel, and the alignment of technology with core business functions.

In the context of the RBV, technological capability is considered a strategic organisational resource that can contribute to competitive advantage when it exhibits characteristics of value, rarity, inimitability, and non-substitutability. Particularly in the healthcare industry, where technology adoption involves complex integration and regulatory sensitivities, technological capabilities are key enablers of cloud computing adoption. By framing these capabilities through RBV, this study emphasises how the deployment of cloud solutions depends not only on the availability of technology but also on the organisation's internal capacity to exploit these resources effectively.

1) Technology resources: Technology resources refer to the foundational assets, including hardware, software, communication technologies, IT applications, and personnel, that enable the implementation of information systems. These resources underpin cloud computing environments by facilitating access, scalability, and data management. From the RBV perspective, the strategic value of such resources depends not merely on their availability but on how they are integrated and leveraged to create organisational advantage. Well-developed and effectively utilised technological infrastructures are expected to enhance operational agility and support innovation. Based on this rationale, the following hypothesis is proposed:

H4: Technology resources have a positive influence on cloud computing adoption.

2) Human resources: Human resources refer to the technical knowledge, skills, and experience of IT personnel and professionals within an organisation. Their ability to design, implement, and manage cloud-based systems is crucial in healthcare settings where data security, compliance, and service availability are critical [22]. Under RBV, these human competencies are intangible yet valuable resources that contribute to the effective use of technology and foster innovation. It is therefore highlighted here that human resource (as denoted by skills and capability to manage cloud services) has a significant effect on cloud computing adoption:

H5: Human resources have a positive influence on cloud computing adoption.

3) Business resources: Business resources are defined as the capabilities and assets, including relations with suppliers, training, planning and financial resources [22]. In other words, the drive for business resources relates to consumers' personal commitment towards issues faced by the suppliers and their individual-level activities that are intended to develop a conducive environment for effective usage of technology. They are important factors in the appropriate and continuing use of this technology. H6 thus describes the nature of the relationship between the use of cloud computing and business resources.

H6: Business resources have positive influence on cloud computing adoption.

- Organisational capability

Organisational capability in the TOE framework encompasses the internal characteristics of a firm that influence its readiness and ability to adopt new technologies [22]. In cloud computing adoption, particularly within the healthcare sector, organisational capability determines how effectively a firm can align its people, processes, and internal structures to facilitate change and integrate innovations. When viewed through the RBV, organisational capabilities such as adaptability, leadership support, and shared cultural values are considered intangible yet strategic resources that enable firms to transform technical potential into realised value. These capabilities affect the success of cloud adoption by shaping internal readiness, fostering collaboration, and promoting innovation acceptance.

4) Change management: Cloud-based services differ from other technologies as they require changes in business processes and the customisation of the cloud-based services to fit existing business processes. Cloud implementation involves a series of coordinated IT customisation and implementation projects [22]. This requires firms to acquire the capability to manage individual projects, as well as multiple projects operating in a coordinated and integrative manner. In the context of RBV, this ability represents a dynamic capability that allows the firm to reconfigure existing competencies and adapt swiftly to disruptive technologies. We contend that businesses that can modify and integrate cloud services as well as alter or

redesign business processes increase the use of cloud computing services. Therefore, on the basis of these discussions, H7 is developed for testing the relation between change management and cloud computing adoption:

H7: The cloud computing adoption will be negatively correlated with resistance to change.

5) Organisation culture: Organisational culture refers to the shared beliefs, values, and norms that influence behaviour within the firm. A culture that supports learning, innovation, and openness to technological advancement is believed to be critical to the success of technology implementation and usage [29]. From the RBV perspective, such a culture constitutes a firm-specific resource that is difficult to replicate and serves as a foundation for continuous improvement and competitive advantage in technology use. The purpose of H8 is to determine whether corporate culture has a significant impact on cloud computing adoption.

H8: Organisation cultures have a positive influence on cloud computing adoption.

- Environmental capability

The environmental context within the Technology-Organisation-Environment (TOE) framework captures external factors that shape an organisation's ability and readiness to adopt technological innovations [22]. In cloud computing, especially within regulated and mission-critical sectors like healthcare, these environmental enablers or barriers play a significant role in adoption decisions. From the perspective of the RBV, environmental capability is not traditionally classified as a firm-internal resource. However, when organisations are able to leverage external support, such as from technology vendors or regulatory bodies, effectively, they can transform these external enablers into strategic assets. The ability to cultivate strong partnerships and align with regulatory frameworks becomes a valuable dynamic capability that complements internal resources and contributes to sustained competitive advantage.

6) Vendor support: Vendor support refers to the assistance and collaboration provided by cloud service providers during implementation, integration, and maintenance. This includes technical support, training, and knowledge transfer, which are crucial for healthcare organisations with limited internal IT capabilities. As noted by [21], vendor competence, reliability, and credibility are instrumental in reducing uncertainty and facilitating adoption. When organisations can establish cooperative, trustworthy relationships with vendors, this inter-organisational trust and knowledge flow becomes a valuable relational resource aligned with the RBV, enhancing the organisation's ability to exploit technological innovation. H9 is an experiment to see if vendor support influences the cloud computing adoption:

H9: Vendor support has a positive influence on cloud computing adoption.

7) Regulatory support: Regulatory support pertains not only to external government initiatives but also to how organisations internally interpret, respond to, and operationalise such regulations. This includes maintaining compliance practices, ensuring vendor accreditation, and aligning operations with legal frameworks such as Malaysia's PDPA 2010. From the RBV perspective, an organisation's ability to systematically respond to regulatory requirements is by embedding compliance mechanisms, legal safeguards, and governance practices into internal routines, which can be considered a valuable and rare organisational capability. Such capability enables the organisation to mitigate legal risks, build legitimacy, and sustain operational continuity, thereby transforming external institutional pressure into strategic advantages. This view is reinforced by [22], who recognised regulatory support as a key enabler in cloud computing adoption. Thus, the following theories are put forth:

H10: Regulatory support has a positive influence on cloud computing adoption.

Grounded in the resource-based theory and aligned with the proposed hypothesis, the integration of IT Capability and the TOE framework informs the development of the proposed model, as depicted in Fig. 1.

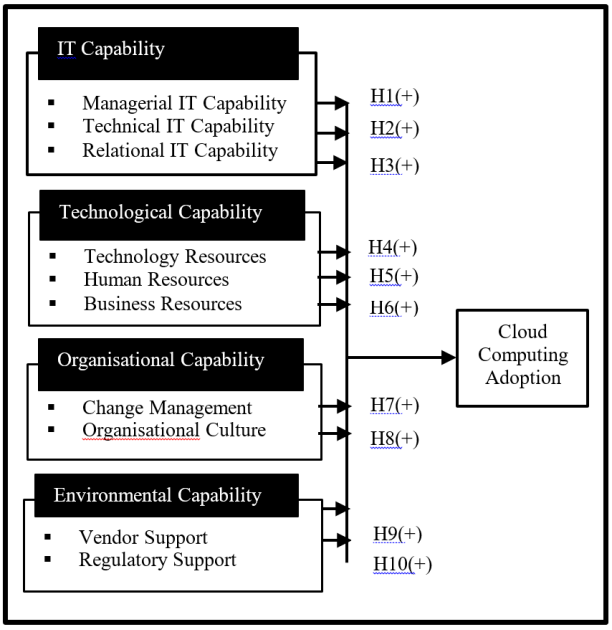

Fig. 1. Conceptual model.

IV. Methodology

A. Data Collection and Sample

This study employed a purposive sampling technique targeting key personnel involved in strategic IT decision-making within healthcare institutions. Respondents were selected based on their organisational roles that influence or oversee cloud computing adoption processes. These included Chief Executive Officers (CEOs)/ *Timbalan Pengarah Pengurusan*, Chief Financial Officers (CFOs)/ *Ketua Unit Kewangan*, Chief Information/ Technology Officers (CIOs/CTOs), IT/IS

Managers/ *Ketua Unit IT*, and IT Executives. Data were gathered through a combination of online surveys and the drop-off and pick-up method, allowing flexibility in participation while ensuring a high response rate.

The sample was drawn from three distinct groups of healthcare organisations, namely KPJ Specialist Hospitals, private healthcare facilities unaffiliated with KPJ, and tertiary public hospitals under the Ministry of Health Malaysia (MOH). According to the National Medical Research Register (NMRR), there were 238 registered healthcare organisations at the time of the study, of which 233 were active.

Out of 37 MOH tertiary hospitals, 28 (75.7%) participated, with 26 confirming active cloud usage. In the private sector, 130 out of 196 licensed private hospitals responded (66.3%), of which 56 reported cloud adoption. This includes a high response from KPJ Specialist Hospitals (26 of 29, or 89.7%), as well as contributions from other private networks such as Columbia Asia (9 of 20, or 45%) and IHH (3 of 18, or 16.7%). Among 129 standalone private hospitals, 92 (71.3%) responded to the survey.

In total, 127 healthcare organisations responded to the survey, yielding a 54.5% response rate. Of these, 82 organisations (64.6%) reported having adopted cloud computing to varying degrees. This moderate level of adoption reflects a gradual yet cautious progression toward digital transformation within Malaysia's healthcare sector. It further highlights the importance of examining the technological, organisational, and environmental conditions, as well as internal IT capabilities, that influence cloud computing adoption.

The research was ethically approved by the Medical Research and Ethics Committee (MREC) Malaysia under reference number NMRR-23-03142-NH7 (IIR). Respondents were asked to evaluate a conceptual model comprising both exogenous and endogenous variables influencing cloud computing adoption. The instrument included 29 measurement items adapted from established technology adoption frameworks and TOE literature [30], [22] – [31], alongside 12 items representing IT capability dimensions as conceptualised in the Resource-Based View (RBV). Responses were captured using a five-point Likert scale (1 = strongly disagree, 5 = strongly agree).

Describing the descriptive statistics, the positions of respondents in the survey reveal that the majority (59.9%) are IS senior executives or managers. This dominant group reflects a strong representation from operational and technology management roles within healthcare institutions. Additionally, 14.7% of the respondents are CEOs, while CFOs and CIOs/CTOs each constitute 12.7%. In terms of industry experience, a significant portion of the respondents (56%) have been in the industry for more than 10 years, indicating a mature and experienced respondent base. This is critical as it adds depth and credibility to the survey findings. Meanwhile, 23% have 6 to 10 years of experience, and only a small percentage (21.1%) have less than 6 years in the field. The operational longevity of hospitals in the survey is also notable. Over half (54.8%) have been in operation for more than 20 years, and another 42% fall within the 2 to 20-year category. Only 3.2% are newly established (less than 1 year). Regarding staff size, the distribution shows that a large number of hospitals (65%) employ fewer than 1,000 full-time staff, with 32.9% having less than 500 employees. Conversely, around 35% of hospitals are larger institutions with over 1,000 employees. The patient bed capacity further reinforces the predominance of smaller healthcare facilities in the sample. Approximately 61.1% of the hospitals have fewer than 250 beds, while 21.8% have between 250 and 400 beds. Only 17.1% of the hospitals are large facilities with more than 400 beds. In terms of financial strength, nearly half (49.2%) of the hospitals reported annual sales of less than RM100 million, and another 43.7% earned between RM100 and RM500 million. Only a small minority generated revenues above RM500 million.

B. Data Analysis

- The measurement model

SmartPLS 4.1.1.2 was used to analyse the research model in order to estimate the relationships within the structural model and evaluate the psychometric qualities of the measurement items. To get stable standard error estimates, a bootstrapping process using 5,000 resamples of the original dataset (n = 252) was used. The analysis began with an evaluation of reliability and validity. As shown in Table III, the composite reliability (CR) values ranged from 0.936 to 0.988, and Cronbach's alpha values ranged from 0.91 to 0.987, both exceeding the recommended threshold of 0.70 [32]. These results demonstrate that the constructs exhibit strong internal consistency. Furthermore, the Average Variance Extracted (AVE) values also surpassed the 0.50 benchmark, indicating that more than 50% of the variance in each indicator is explained by its corresponding latent construct, thereby supporting convergent validity [33].

Discriminant validity was also confirmed. As detailed in Table IV, the square root of the AVE for each latent construct (bolded along the diagonal) is greater than the corresponding inter-construct correlations, affirming that the constructs are statistically distinct. Additionally, all inter-item correlations were below the 0.90 threshold [33], further reinforcing construct distinctiveness.

Table V displays the item loadings and cross-loadings, confirming that each indicator aligned most strongly with its designated construct. Items that failed to meet the minimum recommended loading threshold of 0.70 [32] were excluded from subsequent analysis to ensure the integrity of the measurement model. The remaining indicators showed strong convergent validity, as evidenced by high t-statistics in the outer model, indicating significant contributions to their respective latent variables. To evaluate multicollinearity, the Variance Inflation Factor (VIF) values were examined for all ten latent constructs. As presented in Table VI, the VIF values ranged between 1.141 and 4.163, remaining well below the conservative cut off of 5.0 [34], thus confirming the absence of problematic multicollinearity. Furthermore, the f^2 effect size was computed to determine the relative influence of exogenous constructs on endogenous variables. Based on thresholds provided by [35], 0.02 (small), 0.15 (medium), and 0.35 (large), i.e., the f^2 values in this study ranged from 0 to 0.118, reflecting predominantly small effect sizes.

TABLE IV CONSTRUCT CORRELATIONS, CONSISTENCY AND RELIABILITY

Construct	CR	Alpha	AVE	1	2	3	4	5	6	7	8	9	10	11	12
Business Resources	0.963	0.942	0.897	**0.947**	**0.947**

TABLE VI VARIANCE INFLATION FACTOR (VIF)

	VIF	F-Square
Business Resources → Cloud Computing Adoption	4.163	0.044
Change Management → Cloud Computing Adoption	3.276	0.105
Cloud Deployment → Cloud Computing Adoption	1.158	0.023
Human Resources → Cloud Computing Adoption	3.273	0.013
Managerial IT Capability → Cloud Computing Adoption	1.141	0.118
Organisational Culture → Cloud Computing Adoption	1.601	0.03
Regulatory Support → Cloud Computing Adoption	3.896	0.077
Relational IT Capability → Cloud Computing Adoption	3.007	0.032
Technical IT Capability → Cloud Computing Adoption	1.979	0.052
Technology Resources → Cloud Computing Adoption	2.578	0
Vendor Support → Cloud Computing Adoption	2.379	0.044

- The structural model

Table VII shows the results of the structural model, which shows that there are several statistically significant direct effects between the latent constructs and the use of cloud computing. Managerial IT capability exhibits a robust and highly significant influence on adoption outcomes ($\beta = 0.138$, $t = 5.028$, $p < 0.001$), underscoring the critical role of IT leadership in strategic alignment, planning, and decision-making processes. This finding backs up earlier research [21] [19] [20] which emphasises that effective managerial orchestration of IT resources substantially facilitates the assimilation of cloud technologies. As for the technical IT capability, although the empirical findings indicate that technical IT capability exerts a statistically significant yet modest influence on cloud computing adoption ($\beta = 0.121$, $t = 2.525$, $p = 0.012$), this does not diminish its theoretical importance. Within the RBV framework, technical IT capability remains a foundational enabler that supports system integration, scalability, and agility [28] especially in healthcare settings, where infrastructure robustness and data governance are critical. The relatively moderate effect size may suggest that while technical readiness is essential, it operates alongside other organisational and environmental factors in influencing adoption decisions. Hence, its strategic value may be more catalytic than direct, setting the groundwork

upon which other enablers exert stronger influence. Relational IT capability was found to have a statistically significant positive influence on cloud computing adoption ($\beta = 0.116$, $t = 2.672$, $p = 0.008$), underscoring the role of effective collaboration, mutual understanding, and trust between IT personnel and other organisational stakeholders. This finding reinforces the hypothesis that strong relational ties facilitate smoother coordination and reduce uncertainties associated with cloud adoption. However, the strength of this relationship appears to be moderate in the current study, differing from previous work by [21], which identified relational IT capability as the most dominant predictor in the context of Korean firms. This discrepancy may reflect contextual differences, particularly in Malaysia's healthcare sector, where relational dynamics are shaped by distinct regulatory, cultural, and operational factors. From an RBV standpoint, trust-based relationships are central to relational IT capability and represent a valuable and inimitable organisational asset that can foster integration with cloud service providers, support shared problem-solving and enhance adoption readiness. These results are also consistent with [12], who emphasised the role of trust and collaboration in promoting successful cloud initiatives.

These findings are consistent with earlier research [21] that affirmed the relevance of IT capabilities in shaping cloud computing adoption. Unlike prior studies that considered this relationship within the context of moderating variables such as deployment models, the current study offers a direct evaluation of the influence exerted by IT capabilities. This approach provides clearer insight into their standalone strategic importance. Viewed through the lens of the RBV, the results underscore that managerial, technical, and relational IT capabilities are not merely operational enablers but serve as critical organisational resources that drive cloud adoption in Malaysia's healthcare sector.

TABLE VII DIRECT EFFECT RESULTS

Hypothesis	Path	Coefficient	SD	T	Results
1	Managerial IT Capability → Cloud Computing Adoption	0.138	0.028	5.028	Supported
2	Technical IT Capability → Cloud Computing Adoption	0.121	0.048	2.525	Supported
3	Relational IT Capability → Cloud Computing Adoption	0.116	0.044	2.672	Supported
4	Technology Resources → Cloud Computing Adoption	-0.006	0.043	0.139	Not supported
5	Human Resources → Cloud Computing Adoption	0.076	0.041	1.877	Not supported
6	Business Resources → Cloud Computing Adoption	0.162	0.057	2.848	Supported
7	Change Management → Cloud Computing Adoption	0.222	0.091	2.446	Supported
8	Organisational Culture → Cloud Computing Adoption	0.082	0.03	2.721	Supported
9	Vendor Support → Cloud Computing Adoption	0.122	0.043	2.838	Supported
10	Regulatory Support → Cloud Computing Adoption	0.207	0.06	3.471	Supported

Among the TOE dimensions, technology resources exhibit a negative and non-significant relationship with cloud computing adoption ($\beta = -0.006$, $t = 0.139$, $p = 0.889$), suggesting that the availability of technological infrastructure alone does not directly influence adoption within the studied context. This contradicts the assumption that having sufficient IT assets automatically facilitates adoption. While prior research [25] reported a positive link between technological readiness and cloud uptake, the discrepancy here may stem from contextual factors such as organisational readiness or sector-specific constraints in Malaysian healthcare. From the RBV standpoint, this finding implies that technology resources, unless effectively configured, integrated, and leveraged, may lack the strategic value necessary to drive adoption. In other words, possessing IT assets is insufficient unless those resources are transformed into capabilities that are valuable and difficult to replicate, characteristics essential for competitive advantage and innovation. Although the analysis reveals that human resources have a positive but marginally insignificant effect on cloud computing adoption ($\beta = 0.076$, $t = 1.877$, $p = 0.061$), the direction of the relationship is theoretically consistent with prior expectations. This suggests that, while the presence of skilled and knowledgeable IT personnel contributes to adoption readiness, their influence alone may not be sufficient to significantly drive adoption decisions within the studied context. The result resonates with previous findings [22], [25], which emphasise the enabling but not singularly decisive role of human capital in technological innovation. From the RBV perspective, human resources remain a critical intangible asset; however, their strategic contribution to cloud adoption may depend on how effectively these competencies are integrated with other organisational and environmental enablers. In contrast to the insignificant effects of technology and human resources, business resources demonstrate a significant positive relationship with adoption ($\beta = 0.162$, $t = 2.848$, $p = 0.004$). This finding highlights the critical role of organisational capabilities and assets, such as supplier relationships, employee training, strategic planning, and financial resources, in driving adoption. The result is consistent with the findings of [22], [25], who emphasised business resources as key enablers for effective and sustained use of cloud technology.

The results also show that change management has a moderate yet statistically significant positive influence on cloud computing adoption ($\beta = 0.222$, $t = 2.446$, $p = 0.014$). This finding suggests that healthcare organisations with stronger capabilities to manage organisational change, such as adapting workflows, realigning processes, and coordinating implementation efforts, are more likely to adopt cloud services effectively. Given that cloud-based solutions often require

customisation and transformation of legacy processes, the ability to navigate change emerges as a key enabler. This supports the theoretical assertion that such adaptability constitutes a dynamic capability under the RBV lens, allowing organisations to reconfigure internal competencies and respond proactively to disruptive innovations. The evidence reinforces the hypothesis that overcoming resistance to change is instrumental in enhancing cloud adoption outcomes. Similarly, organisational culture shows a positive and statistically significant effect on cloud computing adoption ($\beta = 0.082$, $t = 2.721$, $p = 0.007$), underscoring the influence of a supportive internal environment in embracing technological change. A culture that encourages innovation, collaboration, and openness facilitates smoother adoption processes, particularly in complex sectors like healthcare. This finding supports the RBV perspective, where such culture is viewed as a valuable, non-replicable asset that enables firms to adapt and sustain technological advancements. The result affirms H8 and aligns with prior research [22] [25], highlighting culture as a critical determinant of adoption success.

With regard to environmental factors, vendor support ($\beta = 0.122$, $t = 2.838$, $p = 0.005$) and regulatory support ($\beta = 0.207$, $t = 3.471$, $p = 0.001$) both exhibit significant positive relationships with cloud computing adoption. This suggests that effective vendor collaboration through knowledge transfer and reliable partnerships, and supportive government policies, including regulations on privacy, security, and funding incentives, are key enablers of cloud implementation. These findings are consistent with [22] [25].

V. Results

A. Current Situation and Prospect of Cloud Adoption in the Healthcare Industry

The shift towards increasing the application of cloud computing in the healthcare industry is driven by the continuous efforts of the industry for the health and well-being of patients, that is to treat patients to be better and healthier, and also to prevent disease as much as possible, and ultimately to promote life peace. With cloud technology, many healthcare institutions benefit exponentially in terms of scalability, cost savings and cloud efficiency. Referring to [15], who studied cloud computing trends and the latest status in healthcare, the approach to using cloud healthcare increased exponentially. In Malaysia, Kumpulan Perubatan Johor, better known as KPJ, is the first private healthcare provider to use cloud computing. With 28 hospitals in Malaysia and two hospitals in Indonesia, they believe that cloud computing can lower their costs or enjoy savings of 30% to 40% of their IT expenses in the long run.

B. Main Influencing Factors of Cloud Computing Adoption

The analysis of structural relationships revealed that multiple factors significantly influence cloud computing adoption in the Malaysian healthcare industry. Among IT capability dimensions, managerial IT capability emerged as the strongest predictor, affirming that leadership proficiency in aligning IT with strategic goals facilitates technology adoption. This underscores the critical role of top management in orchestrating IT initiatives and integrating cloud technologies with organisational priorities.

Technical IT capability also showed a statistically significant, albeit modest, effect. While not the most dominant driver, its foundational role remains critical in enabling system integration, ensuring infrastructure readiness, and promoting cloud scalability, particularly in healthcare, where technological robustness and data sensitivity are paramount. Similarly, relational IT capability demonstrated a positive influence, highlighting the importance of inter-organisational collaboration and trust in navigating external dependencies such as vendor relationships and service reliability.

Within the technological context, human resources showed a near-significant effect, suggesting that while the availability of skilled personnel supports cloud readiness, its standalone impact may be limited unless complemented by broader organisational readiness. Conversely, technology resources showed no significant relationship, implying that infrastructure alone is insufficient to trigger adoption, potentially due to redundancy, underutilization, or a lack of strategic alignment.

For the organisational context, both change management and organisational culture were positively and significantly associated with adoption. These findings indicate that adaptability, readiness to restructure workflows, and an innovation-oriented culture are essential enablers of successful cloud integration. Such internal factors often mediate the effective deployment of technological investments, especially in highly regulated and process-intensive sectors, like healthcare.

Under the environmental context, vendor support and regulatory support emerged as significant external enablers. Effective vendor collaboration facilitates knowledge transfer and smoother system implementation, while robust regulatory frameworks enhance trust and reduce perceived risk, encouraging adoption. These findings affirm the role of institutional forces in shaping adoption decisions, especially in healthcare, where legal compliance, data governance, and policy alignment are critical.

VI. Discussion

The findings highlight the applicability of the integrated RBV-TOE framework in understanding cloud computing adoption in healthcare. The strong influence of managerial and relational IT capabilities supports the RBV view that firm-specific resources offer competitive advantages. These capabilities allow for the strategic alignment of IT initiatives and foster collaborative relationships that enhance cloud implementation outcomes.

In contrast, the limited role of technology resources indicates that hardware or infrastructure, in isolation, lacks strategic impact without corresponding organisational and managerial readiness. Similarly, human resource capability requires integration with broader organisational strategies to influence adoption meaningfully.

Within the TOE framework, organisational culture and change readiness emerged as essential internal enablers, reflecting healthcare institutions' need for adaptable and innovation-oriented environments. Meanwhile, vendor and regulatory support validate the significance of environmental conditions in shaping IT decisions, particularly in highly

regulated sectors where compliance, trust, and policy alignment are crucial.

Overall, a multi-dimensional readiness anchored in robust IT capabilities, conducive organisational environments, and supportive external ecosystems is essential for effective cloud adoption. These results offer actionable insights for healthcare leaders navigating digital transformation and highlight that success depends on coordinated efforts across internal and external domains.

VII. Recommendations

Based on the findings, the following recommendations are proposed:

1) Define Strategic IT Capability Profiles Tailored to the Healthcare Context.

Given the unique operational demands and regulatory sensitivities of the healthcare industry, it is essential for healthcare organisations to develop targeted IT capability profiles that support the adoption and integration of cloud computing technologies. Strategic emphasis should be placed on strengthening managerial capacity for aligning IT initiatives with clinical and administrative goals, investing in technical expertise to ensure secure and interoperable systems, and nurturing relational capabilities that facilitate collaboration across departments and with cloud service providers. This tailored capability development will allow organisations to capitalise on cloud technologies while managing sector-specific constraints such as data privacy, compliance, and institutional readiness.

2) A Common Standard Model for a comprehensive and specific Cloud Adoption Framework for the Healthcare industry.

To further advance cloud computing adoption and value realisation, future strategies should consider expanding internal IT capabilities through targeted IT Outsourcing (ITO) and IT Innovation (ITI) initiatives. While this study has established the significance of managerial, technical, and relational IT capabilities in influencing adoption, the inclusion of external IT partners via ITO can complement resource constraints and enhance service scalability, especially in settings where internal capacity is limited. From an RBV perspective, outsourcing allows healthcare organisations to access rare and specialised resources, effectively extending their resource base without diluting strategic focus. Similarly, promoting IT innovation, such as adopting new service delivery models or leveraging AI-driven cloud tools, can foster dynamic capabilities, enabling firms to continuously adapt and reconfigure existing IT assets to meet evolving patient care and regulatory demands. These recommendations are particularly relevant under the TOE framework's technological and environmental dimensions, where responsiveness to external trends and technological advancement is key to sustaining competitive advantage.

VIII. Limitations and Future Research

While this study offers meaningful insights into cloud computing adoption by integrating the RBV with the TOE framework, several limitations merit acknowledgement. First, the research is geographic and sector-specific, focusing solely on healthcare organisations within Malaysia. The country's regulatory environment, technological maturity, and public-private healthcare dichotomy may limit the generalisability of the findings to other sectors or regions with different institutional and infrastructural characteristics.

Second, the study employed a cross-sectional design, which restricts the ability to capture temporal shifts in cloud adoption behaviour, such as changes influenced by evolving regulations, technological advancements, or organisational digital strategies. Longitudinal research could better reveal how internal capabilities and external pressures interact over time.

Third, although the study incorporated both internal (IT capabilities) and contextual (TOE) enablers, it did not examine interaction or mediation effects between constructs, such as how IT capabilities may moderate or mediate the influence of environmental or organisational factors on adoption. Investigating these relationships could further enrich theoretical understanding and practical strategies for cloud integration.

Future research may explore multi-level models that consider clinical, administrative, and policy-level dynamics in cloud computing decisions. In addition, the integration of IT Outsourcing (ITO) and IT Innovation (ITI) constructs within the RBV–TOE framework may yield deeper insights into how firms balance internal capabilities with external service acquisition to enhance digital transformation. Expanding the scope to include deployment models, cloud maturity levels, and cross-country comparisons can also enhance the robustness and applicability of the proposed model.

Acknowledgment

This research was conducted as part of the Ph.D. program at Universiti Kebangsaan Malaysia and received full financial support for the research grant from the Ministry of Higher Education (MoHE) and Universiti Kebangsaan Malaysia (UKM) via the Fundamental Research Grant Scheme (FRGS/1/2024/TK01/UKM/02/2).

The author would like to thank the participating healthcare organisations for their cooperation and all respondents for their valuable time and insights. The study also received ethical approval from the Medical Research and Ethics Committee (MREC), Malaysia, under NMRR-23-03142-NH7 (IIR), and KPJ Clinical and Research Ethics Review Committee (CRERC), Ref. kpj_002/2023.

***Abstract*—As a downstream component of the drug supply chain, pharmaceutical installations often face uncertainty in drug demand. Predicting pharmaceutical drugs using a machine learning approach enables the development of new variables that can enhance the performance of medicine prediction. Amidst limited data and a choice of prediction algorithms, the accuracy of variable selection is significant for drug prediction performance. This study remaps the scope of variables from previous studies related to drug demand prediction and machine learning performance to develop further significant variables. Investigating research literature on significant variables in drug demand prediction with machine learning models published in 2020-2024. The systematic literature methodology uses the Kitchenham method. Mapping problems, discussion areas, and data availability result in ten categories of issue areas, each with its respective data needs and algorithm choices. A qualitative exploration of issue areas identifies potential variables for pharmaceutical drug prediction, including drug consumption, epidemiology, drug management, supply chain-patient domicile, and pharmacotherapy. Mapping potential variables facilitates the availability and integration of data relevant to local or regional characteristics, enabling further research on the characteristics of data and algorithm choices.**

***Keywords*—Drug demand; machine learning; pharmaceutical installations; prediction; potential variables**

I. INTRODUCTION

Drug availability is a crucial issue during the COVID-19 Pandemic. Hospital management and health services need to build an optimal drug inventory control system in the future. Amid the uncertainty of drug demand, the planning and procurement process becomes a determining stage in pharmaceutical logistics operational management [1]–[3]. The drug planning and procurement process in hospital pharmacy installations is related to the drug supply chain from pharmaceutical wholesalers (distributors) [4], [5].

Both manufacturers and distributors require high downstream demand prediction results to form the basis for drug supply planning [6]. Accurate downstream planning supports the analysis of supply chain visibility, lead time, inventory status, and supplier performance. Pharmaceutical logistics can calculate drug availability variables, lead time, and drug costs from suppliers [7]. These results will improve internal pharmaceutical supply chain performance and optimize inventory management and distribution activities [8]. The accuracy of demand predictions generated by algorithms anticipates elements of uncertainty or fluctuations in drug demand [7], [9]. In the supply chain, drug demand uncertainty is a category of external uncertainty and risk. These external risks are identified from events that deviate from the general pattern and may change the prediction performance [9], [10].

In the pharmaceutical industry, stakeholders must identify external variables of drugs in the demand prediction process. Prediction results do not only anticipate events that disrupt drug distribution and provision planning downstream in the supply chain. Furthermore, the results of medicine demand prediction maintain the balance of supply against drug demand and mitigate against events that deviate from the general pattern in determining the amount and pattern of consumption, epidemiology, and available budget [11], [12]. Stakeholders can leverage machine learning models for prediction, saving time and costs, and allowing for a more focused investment in clinical trials [13]. Machine learning models can capture variables of changing market conditions and consumer demand. However, machine learning requires the availability of good, reliable, and real-time features and data to achieve high performance [14].

Beyond drug variables, several variables in drug prediction may contribute to changes in drug demand, including strong seasonal patterns, uncertain demand, and a lack of historical data [15]. Each variable involved in the prediction may have different data characteristics. Prediction variables can exhibit non-linear correlations with several parameters of their dependent variables, such as historical sales data in conjunction with demographic and epidemiological data (including disease type, disease progression, or patient distribution level) [16].

The greater the data variation, the more the machine learning model obtains aspects of demand variability. The model can predict consumption frequency, consumption amounts over time, and consumption patterns based on geographic areas [17]. Increasing data dimensions, computational complexity, storage requirements, the ambiguous or noisy nature of data, and device capacity also demand higher model performance [18]. Among the many features used, machine learning will identify several significant

ones. Dimensionality reduction can impact the performance, complexity, time, and space requirements in machine learning. Similarly, some irrelevant or redundant features can significantly reduce classifier performance [19].

The selection of variables from epidemiological data of dengue fever patients considers variables that affect the development of dengue fever. In their research, Syahrir [20] built a model based on the development variables of each stage of the patient's disease. The model known as susceptible-expose-infectious-removal (SEIR) is used to predict drug needs in the face of dengue fever outbreaks in Indonesia. Based on data on the number of hospitalized patients with dengue fever from 2014 to 2016, the prediction model employed a Moving Average (MA), regression, and Exponential Smoothing (ES). In subsequent studies, they developed Single Exponential Smoothing (SES), Double Exponential Smoothing (DES), Linear Regression (LR), Quadratic regression, Bayesian regression, the winters method, Autoregressive Integrated Moving Average (ARIMA), and the SEIR model for prediction [21]. They predicted the number of patients and drug demand based on time variables while ignoring other epidemiological variables, such as climate and environmental health.

Meanwhile, Ho [22] employed machine learning algorithms, including the Decision Tree (DT), Deep Neural Network (DNN), and Logistic Regression, to identify cases of dengue fever. Using the algorithm, they identified four primary variables: age, body temperature, white blood cell count, and platelet count. Then, based on the doctor's recommendations and epidemiological characteristics, they added Hemoglobin (Hb) and gender parameters. The two additional parameters did not improve the prediction performance. With four main variables, the performance of the DT, DNN, and logistic regression models provided a sensitivity of 90%. Other research on dengue cases utilised climate variables [23]–[25], dengue case data, population demographics, entomology, and environmental factors [26], [27]. The use or addition of specific variables is not necessarily significant to the performance of the machine learning model until high prediction performance is validated.

In the development of the Earth Cognitive System for COVID-19 (ECO4CO) information system for handling the COVID-19 Pandemic, the display of notification services, alerts, and scheduled communications, as well as geographic localization for end-users, supports logistics management of the Pandemic's drug supply [28]. In general, the pharmaceutical industry can further optimize drug planning and procurement. Specifically, ECO4CO helps aggregate data in information systems to help pharmaceutical installations predict drug needs [29]. Integrated data will facilitate the acquisition of significant variables for prediction. Government policy encouragement, especially in developing countries, can accelerate the development of integrated health information systems, particularly when potential predictive variables are sourced from multiple government and private institutions.

Health disruption situations, such as the COVID-19 Pandemic, require efforts to identify variables that are not yet clearly significant (referred to as hidden variables) in building drug prediction models. Machine learning can help identify hidden variables and pinpoint significant factors in drug demand, even outside of historical data on drug demand or sales [9]. According to Koala [30], significant variables for predicting drug demand can vary from one case or place to another. If the prediction refers to changes in consumer attitudes, the time series approach will influence the determination of significant variables. Machine learning can perform a clustering analysis approach to identify customer demand behavior. In addition, regression analysis produces continuous-valued functions for products that cannot be stored for long in storage [31]. These approaches direct significant variables for predicting drug demand.

Researchers generally use correlation testing between predictive features to identify significant variables in machine learning models. In the case of the COVID-19 Pandemic, many studies have used new variables from the field. The use of new variables highlights the limited scope of previous similar research, particularly in identifying potentially significant variables in predicting drug demand in pharmaceuticals using a machine learning approach. Mapping previous research areas can contribute to the study of developing machine learning models for predicting drug demand in the pharmaceutical industry, utilizing potentially significant variables. Therefore, this study analyzes research related to pharmaceutical drug prediction using a Machine Learning approach. The study redefines the scope and area of variables in drug demand prediction research.

Mapping the use of variables in previous research suggests the direction for developing a machine learning approach to predict pharmaceutical drug demand. The implications of this study can encourage the government to develop policies related to the use of drug supply calculation methods and significant prediction variables. At the same time, accelerating the integration of national health data into the National Health Network increases the availability of data and the variability of drug prediction variables [32]. To sharpen the direction of research on potential variables in drug prediction with this machine learning approach, researchers formulated research objectives (RO): RO1. Identifying areas of drug demand, research issues, and data availability for prediction from previous studies. RO2. Examining the performance of using machine learning algorithms for drug demand prediction. RO3. Categorizing potential variables to be developed in predicting drug demand.

Next, we discuss literature studies related to drug demand design in pharmacy and machine learning methods commonly used to predict drug demand. Next, we will describe the systematic literature review method. Next, the results and discussions related to research issue areas and finding variables. The final section is the conclusion and the direction of further studies related to drug demand variables.

II. Related Studies

Generally, drug demand calculations in pharmacies utilize internal inventory data. Drug demand calculations are central to drug management and the pharmaceutical supply chain. Drug supply concerns often center on drug stock and demand. In a study of drug planning in several pharmaceutical institutions, Burinskiene [33] utilized historical drug sales data

from multiple pharmacies within a chain to compare prediction performance results at each pharmacy location. The prediction target was to improve accuracy at each pharmacy point. The computational process took into account seasonal data trends, outlier handling, and the handling of missing data. However, differences in pharmacy locations with their variable trends were not a consideration in the computation. In the field, medication supply planning considers many variables and data sources that can support data analysis and prediction. These data include variables such as historical demand, patient demographics, clinical information from Electronic Health Records (EHRs), epidemiology, supply chain, and external elements such as market dynamics and regulations [6].

Information on the extent of drug demand and the variables that influence changes in drug demand are external factors that have not received much attention. Drug demand prediction has a close causal correlation with drug consumption patterns [30]. Correlating external factors with increasing demand prediction accuracy requires careful analysis of market trends, customer behavior, suppliers, and technology [31]. According to Koala [30] factors that can influence drug demand prediction include socioeconomic factors such as gender, age, patient origin, annual income, and social class. Second, patient health factors include comorbidities, insurance, and lifestyle (smoking, alcohol, and obesity). The third factor includes institutional facilities and healthcare personnel. However, Koala does not provide a basis for external variables that remain attached to the dynamics of drug demand in a time series sequence.

Similarly, the behavior of drug supply chain actors focuses on predicting the public's need or demand for drugs to support health services, particularly timely access to drugs in the right amount, type, and quality [34], [35]. Supply chain management strives to ensure that provision and availability match demand [36]. Therefore, analyzing demand prediction variables is necessary to anticipate changes in drug demand [37].

Periods of increased risk of disease spread, such as dengue fever, can change drug demand during specific periods [34]. Likewise, in disaster areas, factors such as limited data on the number of disaster victims, distribution, and the increasing number of victims, and substitution of certain types of drugs (which cannot be replaced by others) can add variables to the prediction of drug needs [20]. In dealing with these issues, the machine learning approach can handle the problems of interdependent variables, complexity of causal factors, and non-linear relationship patterns [36]. Additionally, machine learning can analyze unstructured data sets and identify significant factors that impact supply chain performance [15]. In the case of predicting drug sales volume using sales promotion stimuli, Al-Gunaid [34] compared the performance of five algorithms (LR, Random Forest (RF), Neural Network, Support Vector Regression (SVR), and the Levenberg-Marquardt algorithm). During the analysis, previously unseen factors may emerge due to the increasing correlation between features. Marketing promotions have a high correlation coefficient because they are closely related to variables that influence consumption behavior. Consequently, sales predictions increase. However, the promotion variable as a planned stimulus for supply chain actors is only a small part of the other variables that influence the performance of drug demand prediction.

Dynamic market changes reveal hidden factors that necessitate methods to capture these factors, thereby enhancing data-driven predictions [38], [39]. Machine learning learns from all available data, including environmental parameters, to make informed decisions. Each time new historical data becomes available, the learning process continues to occur, enabling the making of new decisions [40]. Machine learning cannot solve all problems, but it can improve accuracy in certain cases and datasets [41]. Several machine learning algorithms are available for demand prediction based on historical data, including random forests, gradient boosting, and neural networks. Note that environmental changes can affect the performance of prediction algorithms over time [6]. A non-negligible variable is that drug evaluation often results in switching to different drugs to enhance pharmacological effects or mitigate side effects [34].

III. METHODOLOGY

Machine learning has become a widely used method for predicting demand for goods, including in the pharmaceutical sector, specifically for drug demand [30], [42]–[45]. This study examines the mapping of the scope and area of research variables for predicting drug demand in machine learning models. For this reason, this research uses a qualitative literature study method. A systematic review allows researchers to analyze the phenomenon of research on the use of drug demand prediction variables based on machine learning models. This literature study method adapts the steps of the Kitchenham literature review method, except that the data synthesis section is replaced by an analysis of the results and concludes with a report on the study results [46]. Fig. 1 shows the steps of this systematic review research.

1) Research identification: Uncertainty in drug demand necessitates the use of an accurate machine-learning approach with variables that are truly significant for predicting performance. Therefore, the investigation requires as many original articles from previous studies as possible. The original articles targeted are primary research related to machine learning models and drug prediction. The identification of potential variables in previous studies is based on the study's problem area, the context of the problem, data availability, and the performance of the machine learning algorithm used. Meanwhile, the scope of the research is multidisciplinary, covering drug supply chain information systems, pharmacy, and informatics. Therefore, the discussion of the research follows the questions:

- RQ1. What are the areas of drug demand research issues and data available for prediction from previous research?
- RQ2. How is the machine learning algorithm performed for drug demand prediction?
- RQ3. What are the potential variable findings from the selected articles identified in the categories that can build drug predictions with machine learning models?

Furthermore, this research requires quality primary (original) research articles. For this reason, article exploration is conducted in digital libraries, including Scopus, PubMed, and Google Scholar. Researchers use the Publish and Perish 8 Application to search for research literature sources. We also use Mendeley Desktop for documentation and article processing. The selection of search keywords refers to the research questions. Article searches on the application combine keywords in three searches by compiling search keywords for each search, namely: "drug demand AND prediction method AND machine learning"; "prediction AND drug AND pharmaceutical AND demand"; and "medicine OR pharmaceutical OR drug demand AND prediction method AND machine learning".

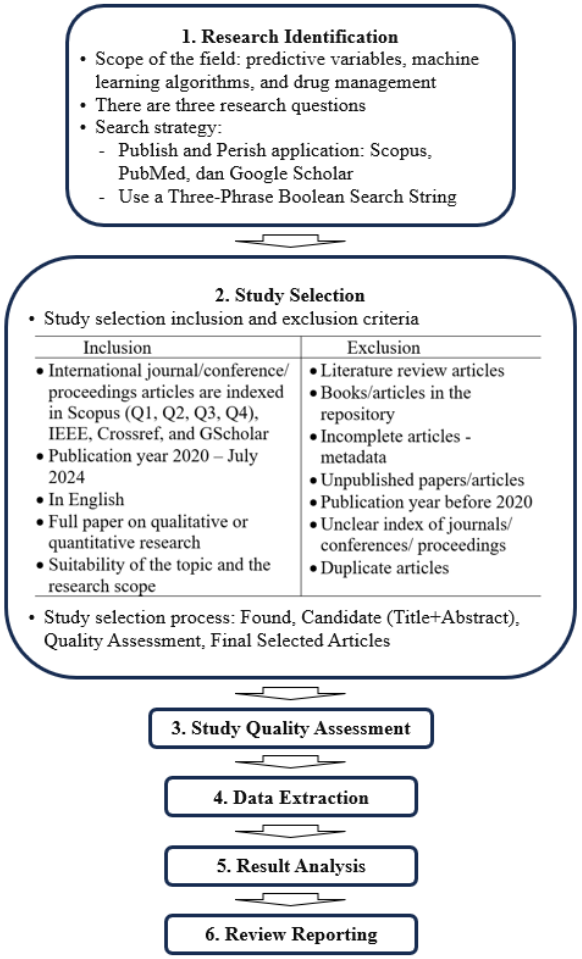

Fig. 1. Research stages - adapted from kitchenham [47], [46].

2) Study selection: After obtaining the articles, the following article selection process involves reading the title, keywords, and abstract to filter out articles that do not match the topic. The method of skimming the articles ensures that the discussion of the article aligns with the research criteria. Furthermore, the fulfillment of the inclusion and exclusion criteria helps in obtaining articles that align with the research objectives. The study requires that selected articles analyzed have a similar research scope, research design, and type of research. The similarity of selected articles suggests that the research articles are closely related to this study. The article has complete data regarding the information needed in this study. The article includes objective and valid measurement techniques for the research model. Differences in methods in presenting research results will follow the objectives of each study. In machine learning research, it is possible to use the same data sources, allowing this literature study to incorporate research literature sources that utilize the same data. Research questions help the stages of analysis of articles according to research topics.

3) Research quality assessment: The researcher evaluates whether the journal's quartile level can ensure a minimum level of study quality. However, the researcher does not group the quality of the articles. The researcher limits observations to variables used to reduce bias in the analysis.

4) Data extraction: The search results for selected articles can be presented in tables or graphs containing the researchers' names, the year of research, problems, data availability, research methods/designs, research variables, and research results. Selected articles can answer research questions that contain the name and year of research, the algorithm used, and the variables used in machine learning. Likewise, the order of appearance follows the discussion of the findings.

5) Result analysis: The analysis of the selected article review results is qualitative in nature. The findings are presented in tables and figures. The analysis of the results, including the research issue area, data availability, and machine learning model performance, leads to the mapping of potential variables to predict drug demand. This presentation is a form of descriptive research synthesis.

6) Review reporting: The final activity of this research is to communicate the results and contributions of the research effectively in international scientific journals. The reporting of this literature study is directed primarily at journals in the areas of computer science or information systems. This research topic is very close to the selection of variables used in machine learning studies.

IV. Results and Discussion

The first part of this session presents the results of the article selection process, quality article publishers, and the number of article topics that tend to increase. Next, we will present the results in the order of the research questions before discussing them. Mapping the problem areas of the selected articles and the variables used to predict drug demand helps organize and systematize the discussion into several subsections.

A. Selected Articles

The use of the Publish and Perish Application makes it easier to search for selected articles and confirms that these articles meet the qualifications as study material. The process of searching for articles with three keyword phrases obtained 886 articles. Selection according to the research stages follows the keyword phrase groups. At the quality assessment stage, the researcher eliminated duplicate articles. Ultimately, the article selection process yielded 23 selected articles (Table I).

TABLE I. STUDY ARTICLE SELECTION PROCESS

Boolean search string	Found	Candidate	Quality assessment	Final selected
		Title+Abstract		
1) "Drug Demand AND Prediction Method AND Machine Learning".	277	64	13	11
2) "Prediction AND Drug AND Pharmaceutical AND Demand"	279	45	15	4
3) "Medicine OR Pharmaceutical OR Drug Demand AND Prediction Method AND Machine Learning"	330	39	12	8
Total	**886**	**148**	**40**	**23**

Determining the scope of the study limits the number of articles that can be found before they are analyzed. Fig. 2 presents the mapping of twenty-one selected articles from the library database. The composition of the articles shows that the selected articles have met international standards and are worthy of analysis. The publisher is also reputable for publishing high-quality papers.

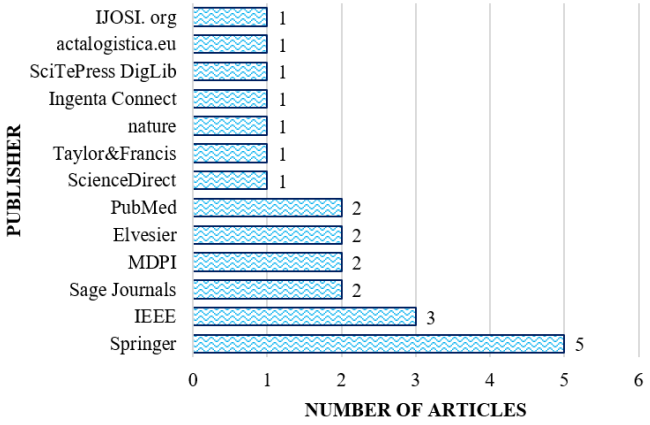

Fig. 2. Composition of selected article publications and the library database.

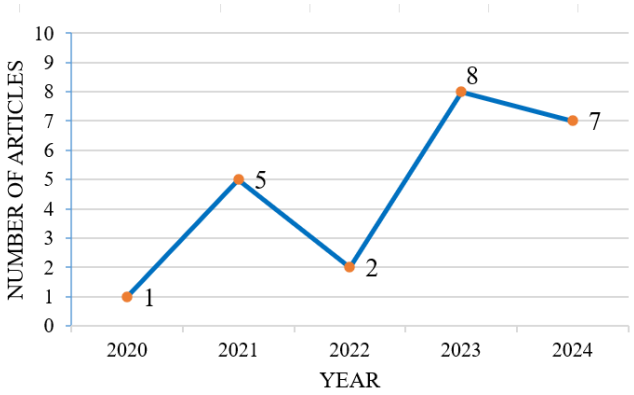

Fig. 3. Number of selected article publications 2020 - July 2024.

This study examines articles published between 2020 and July 2024 to demonstrate the novelty of the research and the article. During that period, the findings of the research topics on drug demand prediction and machine learning were quite encouraging, as the number of related research studies reached more than 50% compared to the previous year, as shown in Fig 3. This finding is interesting because there has been research interest in drug availability in pharmaceutical installations over the past two years.

B. Research Issue Areas and Data Availability (RQ1)

The answer to the first question (RQ1) of this study is completed by presenting the research issue areas and data availability from selected articles. Issues and data availability represent the perspectives of previous researchers on drug prediction to maintain drug availability in pharmacies. The issues raised by each researcher can show the perspective used to solve the problem. This study identified ten research issue areas, as discussed in Table II. Several research issue areas have relationships with others (combination of areas). Subudhi's research issue area [48] has a combination of issue areas, including Epidemiology, Patient Medical Record Data, and Pharmacy Drug Management. We learn to observe the correlation of the problem context and the availability of data that can be used to solve it. The combination of research issue areas raises discussions about data availability and the central point of the problem to be solved using machine learning.

Six selected articles discussing the research issue areas of drug supply chain and usage/sales history in Table II. Data availability in these areas includes discussions of time series, historical market consumption data, and inventory data. Real-time and integrated data are research challenges in the supply chain and usage/sales history area. Interestingly, the availability of data that affects the dynamics of drug demand has not been developed, particularly about disease factors (epidemiology) that determine the magnitude of drug demand. In addition to standing alone, epidemiological variables are also related to the research issue areas of Geography, Medical Records, Pharmaceutical Drug Management, and Disasters. In these areas, epidemiological variables are also considered to influence drug demand. In these areas, epidemiological variables are also considered to influence the prediction of drug demand.

The correlation between research issue areas requires an analysis of the significance of the predictive variables. The same variable that is not significant for drug prediction can change significantly, and vice versa. The combination of ten research issue areas illustrates the complexity of drug management. The more combinations of issue areas, the higher the data dimension, thus requiring more careful data handling for machine learning.

TABLE II. ISSUE AREAS, PROBLEMS, AND DATA AVAILABILITY

Research Issue Area	Problem Context	Data Availability	Ref.
Medical data record - pharmaceutical drug management	– The development of the number, diversity, and sources of data requires an appropriate prediction model to improve accuracy. – Inappropriate determination of significant variables in production, consumption, and storage stock predictions affects prediction accuracy.	– The electronic logistic management information system (eLMIS); for a five-year (2015–2019); available monthly or quarterly. Scope of research: Regional - Local Area. – Kerman Hospital data consisting of 283 features, covering more than 9351 different drugs and 121,690 patients (three years). Scope of research: Pharmacy.	[17], [49]
Epidemiology	– The level of emergency and spread of the disease affect the allocation of drugs. – The different and complex handling, distribution, storage, and administration methods for each drug make it a challenge to predict drug availability.	– Three major pharmaceutical companies producing insulin in the US. Scope of research: National companies. – Internal hospital data from Fast Healthcare Interoperability Resources (FHIR). Data collected from 2017 and 2021. Scope of research: Blood bank.	[55], [56]
Epidemiology - disaster	– The uncertainty of the impact of a disaster requires the prediction of drug supplies with a fluctuating cases number.	– Data on the number of COVID-19 infections in Shanghai. Period 20 January 2020 - 24 September 2022; Emergency Unit Scope of research: Hospital	[57]
Epidemiology - medical data record - pharmaceutical drug management	– Prediction models with the complexity of patient medical conditions, disease characteristics, and drug availability require more than one data source. The difficulty of designing a drug demand prediction model, especially for emergency units.	– Medical Data Record from the Mass General Brigham (MGB) Healthcare database. Emergency units from 14 hospitals. Scope of research: Local – Regional Hospital	[48]
Epidemiology - geographic	– For high-spread diseases such as COVID-19, epidemiological analysis becomes an important variable in predicting drug needs related to geographic distribution (from district level to national level).	– Data from: Lazio region health system (open datasets), Italian Medicine Agency (AIFA) (medicines and equipment), Italian National Civil Protection dataset (patient care/treatment - regional level), National Agency of Regional Health Services (AGENAS) (medical facilities). Scope of research: regional health services	[28]
History of usage/sales data	– Design of accurate drug demand prediction model for the needs of the drug supply pattern. – There is a demand for drugs/drug groups following seasonal trends, a prediction model is needed that is suitable for time series. – The need for a prediction approach method for complex pharmaceutical sales data sets.	– Monthly Sales Dataset from Kaggle. Transaction data of 57 drugs. – Weekly sales data for pharmaceutical products from the Kaggle. Transactions of 57 drugs with 600,000 transactions (2014–2019). Scope of research: algorithm comparison, Pharmacy, improving accuracy with different algorithmic approaches. – Historical sales data and market trends. A dataset of 600,000 transaction records from Kaggle (2014–2019). Scope of research: public data – eLMIS public health – Rwanda: to perform demand prediction of medicine. – Data from the analytical company AMS (Market Data in the Pharmaceutical Industry) in the Middle East and North Africa region, especially in Iraq. Scope of research: Time series dynamic	[35], [58]–[62]
History of usage/sales data - geographic	– A model approach to drug demand that does not only occur in one geographical point but also with the nearest drug demand point. – Non-communicable diseases have characteristics that require optimization of the management of essential drugs for non-communicable diseases (consumption or distribution).	– The National Health Service (NHS) in England Data. Prescription data in each practice August 2010 - December 2019. Scope of research: Adjacent pharmacy. – The electronic logistic management information system (eLMIS) data (2015–2019). Scope of research: Regional.	[63], [64]
Pharmaceutical drug management	– Enterprise planning (ERP) systems require an accurate demand forecasting model.	– Actual six different drug classes sales data (from 6 pharmacies in Pakistan). Data was collected from sources including injections, tablets, capsules, and suspensions of various potencies. Scope of research: Pharmaceuticals.	[65]
Drugs - patient behavior (self-medication)	– Patients have difficulty finding medicine for their illnesses independently (self-medication).	– The UCI Machine Learning Repository data - Drug Review with the subject Health and Medicine 6 features. Scope of research: Public data	[66]
Drug supply chain	– Ignoring that each region and demographic has its own drug needs – Manufacturers need accurate prediction of drug demand from downstream. On the other hand, pharmacies do not have visibility of drug supply – Data limitations: the real-time and patient prescription data for demand prediction – Data limitations, many hidden factors, changing market situations	– Sales data from PharmaGuide covering 22 pharmacies in Ontario, Canada (2014–2021) and historical drug shortage data from the Drug Shortages Canada website. Scope of research: Pharmacies – Simulation for application with sales data collected during 2014–2019. Scope of research: Pharmacies – Data from electronic data interchange (EDI). Weekly data on distributor-level sales volumes and inventory levels for 133 unique national drug codes (NDCs) from July 2007–August	[9], [50], [67]–[70]

Research Issue Area	Problem Context	Data Availability	Ref.
	– Variables determining demand prediction in the drug supply chain – Method of grouping and classifying products at the downstream level to improve the accuracy of drug demand prediction.	2017. Scope of research: Distributors – Database from an integrated services company, Coopservice Group, Italy. Scope of research: National companies – Data available for 519 samples containing historical information for 43 product types. Scope of research: Pharmacies	

Data availability relies on pharmaceutical logistics data sources, patient medical records, health services, independent health service units or hospitals, drug manufacturers and distributors, as well as pharmacies or hospital pharmacies. Complete and quality data helps find correlations between data variables. Complete and high-quality data help find correlations between data variables. The available dataset builds the initial assumption of the prediction variables. Nabizadeh [49] attempted to gather data sources from all departments but found the effectiveness of prediction to be limited when considering only one department. In contrast, Pall [50] used drug sales data from 22 pharmacies and historical drug shortage report data from Health Canada to obtain prediction results that help estimate drug demand. From this phenomenon, the correlation between the research issue area and the variables used determines the effectiveness of the available dataset.

The ten research area issues are divided into two categories. First, the main category encompasses areas such as pharmaceutical drug management, drug supply chain, and epidemiology. Second, additional categories occur due to research needs involving variables and data in geographic areas, medical records, and patient behaviour. Likewise, epidemiology can also develop in areas such as climatology and disaster management. Historical consumption and sales data can also involve areas such as supply chain management or pharmaceutical drug management. According to Mbonyinshuti [17], historical data on essential drug consumption extracted from eLMIS is an area of pharmaceutical drug management. In addition to historical data, patient origin data from medical records can help determine the geographic location of patients who require essential drugs. Finally, we understand that many studies predict the spread of COVID-19 to help distribute drugs more precisely [28], [51]–[54].

In the Epidemiology - Disaster, the hospital emergency unit is a frontline unit that requires drug resources according to the cases that occur. There is a correlation between disease prediction and the prediction of the type and amount of drugs required to treat the disease. Correlation can be observed in the analysis of patient data, diseases, and the medications they consume. Patient medical record data is a significant source for predicting patient drug needs [48]. The network of emergency units between many hospitals can produce data on the spread of infectious diseases as a significant variable. Collecting prescription data from several health service points provides information for analyzing drug demand in a particular distribution area [49], [64], [68]. With this analysis, distributors can formulate a drug distribution chain strategy. Drug demand information (from prescriptions) in the blockchain network can be used to identify the source of drug demand [71].

C. Machine Learning Algorithms for Drug Demand Prediction (RQ2)

The literature of this study, as shown in Fig. 4, indicates that ARIMA, LR, RF, eXtreme Gradient Boosting (XGBoost), K-Nearest Neighbours, Support Vector Machine (SVM), ANN, multi-layer perceptrons (MLP), and LSTM algorithms are employed in more than two research studies. These algorithms are widely recognized for their performance. The selection of prediction algorithms is closely related to the performance and working method of the algorithm.

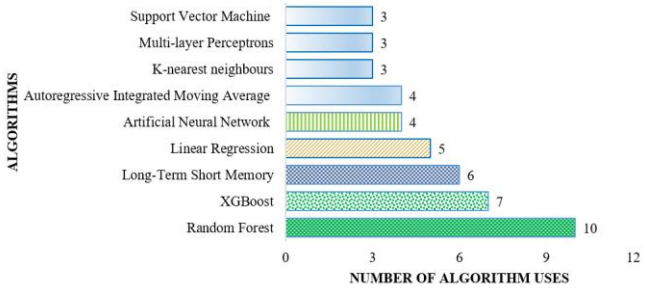

Fig. 4. The most widely used algorithm sequence in machine learning studies.

Additionally, the selection of machine learning algorithms is correlated with data availability factors and significant variables in prediction models. The choice of deep learning algorithms, such as ANN, MLP, and LSTM, has not dominated shallow machine learning algorithms. The complexity of the prediction research issue area is evident in its limited scope. To answer RQ2, Table III presents the performance of machine learning algorithm implementations for drug prediction based on selected articles.

Comparing multiple machine learning algorithms to improve prediction accuracy is a limited research area. The development of methods to handle cases of research area combinations presents an opportunity to enhance machine learning algorithms. The Machine Learning approach can simultaneously combine learning algorithms for big data and several causal variables with non-linear relationships. Machine Learning approaches can simultaneously combine learning algorithms for big data and several causal variables with non-linear relationships [36]. The study by Subudhi [48] took place in the Intensive Care Unit (ICU). The epidemiology, medical data record, and pharmaceutical drug management areas encouraged the use of ensemble models to handle cases of multi-source data. The average F1 score prediction results were higher than 0.83. Likewise, in the study by Zhang and Li [57], the disaster and epidemiology areas face challenges in processing disaster data and handling diseases that arise from disasters. The combination method produces R2= 0.9996 for the BILSTM-GASVR combination prediction model.

TABLE III. MEASUREMENT OF MACHINE LEARNING ALGORITHM PERFORMANCE IN SELECTED ARTICLES

Research issue area	Algorithm	Measurement	Ref.
Medical data record - pharmaceutical drug management	Linear regression, RF, ANN	RF (accuracy 76%)	[17]
	RF, neural network (NN)	RF model accuracy 83.3% (for a month) and 81.3% (for a season - two years data)	[49]
Epidemiology	RF, multiple regression, ANNs	ANN (the correlation coefficient value between output and response value is 93,1%)	[55]
	XGBoost, RF, dummy classifier, and Optuna	XGBoost (Accuracy 40,4%) (Specificity 98,75%)	[56]
Epidemiology - disaster	Bilateral long-short-term memory and genetic algorithm support vector regression (BILSTM-GASVR), bilateral long-short-term memory (BILSTM), genetic algorithm support vector regression (GASVR), informer	BILSTM-GASVR combined prediction model (R^2=99,96%)	[57]
Epidemiology - medical data record - pharmaceutical drug management	AdaBoost, bagging, gradient boosting, RF, XGBoost, ExtraTrees, logistic regression, decision tree, linear discriminant analysis, quadratic discriminant analysis, MLP Classifier, perceptron, passive AggressiveClassifier, linear SVC, Gaussian NB, K-neighbors, naive Bayes, SVM, NN	ICU admission: ensemble and tree-based models had significantly higher F1 scores than all other model types. Mortality: all ensemble-based models had average F1 scores higher than 0.83.	[48]
Epidemiology - geographic	Linear regression, K-nearest neighbours (KNN), recurrent neural networks (RNN)	The medicinal purchases prediction for the regions of Lazio and Piemonte has yielded a low RMSE 16%	[28]
History of usage/sales data	Linear regression, RF, SVM, XGBoost	XGBoost (accuracy: > 95% every drug sale)	[35]
	Probabilistic neural network, generalized regression neural network, radial basis function neural network (RBF-NN), long-term short memory neural network, stacked LSTM	Shallow neural networks. RMSE: Probabilistic Neural Network (6,21), Generalized Regression Neural Network (6,01), RBF-NN (6,59)	[58]
	ARIMA, LSTM	ARIMA (short term prediction), LSTM (long term and complex patterns)	[62]
	Model Bayesian, regresi proses gaussian (GPR): exponential squared, Revised Mat´ern, Rational Quadratic kernels	Kernel Ensemble MSE (9,09 × 10 −21), MAE (7,48 × 10 −11), RMSE (9,53 × 10 −11), Score R^2 (1,0)	[60]
	ARIMA, LSTM	The best LSTM accuracy RMSE 2.0 (training) and 2.043 (testing); R^2=0.952 (training) and 0.912 (testing).	[61]
	Multi-layer perceptrons (MLP), convolutional neural network (CNN), LSTM	The best sales LSTM performance with RMSE=1.28(k) and MEA=0.85(k); for USD Price RMSE=0.75, and MEA=0.44.	[59]
History of usage/sales data - geographic	ARIMA, XGBoost, gate recurrent unit (GRU), graph convolutional network (GCN), spatiotemporal graph convolutional network (STGCN), attention-based spatial-temporal graph convolutional network (ASTGCN)	ASTGCN (MAE 0,0957, RMSE 0,1241 – short period), STGCN (MAE 0,1139 RMSE 0,1465 – long period)	[64]
	RF	Accuracy: R-square 0.78 (training) and 0.71 (testing)	[63]
Pharmaceutical drug management	Autoregressive integrated moving average (ARIMA), Holts Winter, ARHOW	ARHOW (RMSE 18; MAPE 1,99)	[65]
Drugs - patient behavior (self-medication)	RF, naïve Bayes, long-short term memory	RF (Accuracy 83%)	[66]
Drug supply chain	Facebook prophet, LSTM neural networks, and XGBoost	XGBoost (has the lowest MAPE value of 5 out of 8 drug sales)	[69]
	XGBoost	able to address 59% of major drug shortages	[50]
	XGBoost	has the lowest MSE of 6 out of 8 types of drugs	[68]
	LR, moving average (MA), SVR, RF, basic exponential smoothing (ES), RNN	RNN (NMSE 2.69±0.37; NMAE 0.30±0.06)	[9]
	LR, RF, KNN, SVM, MLP	SVM (MSE 2,02 Medicine; 1,89 month)	[70]
	K-Means, Elbow method, Classification And Regression Trees (CART), MLP- neural network, RBF-NN, polynomial (or group method of data handling (GMDH) neural network	MLP-NN (cluster 1 is MLP2 and MLP4, cluster 2 is MLP4 and GMDH10, cluster 3 is MLP4, cluster 4 is MLP2, for all samples is MLP2.	[67]

Each algorithm has its own variation in prediction accuracy (see Table III). Using public data, Ankita et al. [62] applied different algorithms according to the prediction target, following both short-term and long-term seasonal trends. In other words, the complex pattern of historical drug consumption data affects accuracy. Using the same data source, Mbonyinshuti et al. [17] employed different significant variables for essential drug target prediction, as the predicted target variables are more specific to non-communicable diseases [63]. Another perspective on the same data source can provide new knowledge. Every change in data can change the pattern and prediction results. We need an analysis study to explore each algorithm in solving time series problems [58]. Analysis of low machine learning performance requires further research because generalization requires carefulness in approaching the data source [17], [50], [56].

The actual value factor also opens up the possibility of developing significant variables in predicting drug demand. In the case of Engelke [56], they evaluated data from multiple systems within a hospital to form the basis for predicting platelet concentrate (PC) transfusion. The low prediction recall value (0.3648) indicates a significant false negative (FN) value.

The patient is predicted not to need a PC, but in reality, the patient needs it. So, the availability of historical health data on the patient's condition from the EHR can affect the prediction performance. In addition, Mirshekari [60] utilized the power of Bayesian and Gaussian process regression (GPR) models for time series analysis, specifically the kernel ensemble, which can process low-dimensional variables and provide complete and high-quality data. This Bayesian technique optimization produced a prediction model with high accuracy. Again, real-time data on drug demand trends drives the algorithm to deliver better accuracy. Ultimately, the significant variables from the available variable data drive the performance of the combined prediction model algorithm [57], [68].

D. The Potential Variables in Pharmaceutical Drug Prediction (RQ3)

Manufacturers and distributors require accurate product predictions in production and distribution planning to ensure patients receive products with sufficient quality and quantity. Thus, variables related to drug and medical device products also include information on the area of need and the magnitude of the decision. In addition, epidemiological variables need parallel studies with predictions of disease spread. Table IV shows that the areas of research issues and prediction variables can continue to develop through machine learning.

TABLE IV. RESEARCH ISSUE AREAS AND RESEARCH VARIABLES

Research Issue Area	Variables		Ref.
Medical data record - pharmaceutical drug management	– Patient identity and demographics – Type of disease	– Doctor's prescription – Type and amount of medication	[17], [49]
Epidemiology	– Patient demographics – Disease diagnosis – Mortality – Obesity	– Cholesterol – Medication type – Patient condition	[55], [56]
Epidemiology - disaster	– Number of cases – Type and quantity of medication	– History of medication consumption	[57]
Epidemiology - medical data record - pharmaceutical drug management	– Patient's medical condition – Patient's medical history	– Treatment history – Laboratory test results – Mortality	[48]
Epidemiology - geographic	– Number of new cases – Geographic mortality	– Number of outpatients/inpatients	[28]
History of usage/sales data	– Drug sales history data – Drug types and quantity – Date/time of sale – Therapeutic group	– Company Type – Product Source – Number of Competitors – Price	[35], [58]–[62]
History of usage/sales data - geographic	– Drug sales history data – Drug types and quantity – Name and number of prescriptions	– Consumer region – Location of hospital/health service – Time of consumption	[63], [64]
Pharmaceutical drug management	– Name, type, and number of drugs		[65]
Drugs - patient behavior (self-medication)	– Name and condition of the drug, – Contents and properties of the drug	– Drug rating – Consumption time	[66]
Drug supply chain	– Drug sales history data – Seasonal trends – Number of prescriptions and patients – Number of sales per time – Name, type, and number of drugs – Number of orders per time – Timeliness of order arrival	– Supplier and number of orders – Number of drug stock – Storage qualifications – Frequency of consumption – Patient demographics – Product price – Type of disease	[9], [50], [67]–[70]

Variables spread across ten research issue areas assume that they have been tested in their research as significant variables in machine learning algorithms. The challenge is how the model performs when these variables are absent [50]. Likewise, expert judgment needs to provide comprehensive analysis of the variables' significance [65]. In general, the availability of data on demand variables for each type of drug can reveal the seasonal trend of the drug, allowing the model to produce more accurate pattern predictions, as consumption trend data is synchronous with seasonal patterns [62]. The addition of other variables becomes significant when they support the prediction pattern, including the average number of days of drug supply per patient, the duration of drug supply, previous drug shortages, drug hierarchies, and different therapeutic groups [50].

Determining research issue areas, especially those involving combinations, helps researchers identify potential variables for predicting drug demand. As a result, machine learning utilizes richer, multi-source data for learning. Multimodal data from various hospital information systems opens the discovery of potential variables from geospatial, epidemiological, and climatological data [56], [63]. Potential variables can be identified through the analysis of disease epidemiology spread. Real-time data and trends related to

geographic distribution (from local to regional and national levels) are essential data requirements for training machine learning prediction models [28]. Epidemiological variables are not limited to disease names but also include disease characteristics, disease sources, and drugs that control the disease. Variables predicting disease spread correlate with variables in drug prediction [49].

Furthermore, an analysis of variables is needed to determine which variables remain significant in the present and the future [55]. The development of complex modern pharmaceutical predictions requires careful analysis to explore significant variables [69]. Variable development requires analysis of the relationship between one variable and another. Finding the relationship between location variables, drug prices, and weather conditions can improve system performance [68]. As a development, classification methods can help drug reviews identify the relationship between disease names, drug names, and disease indications, enabling patients to find suitable drugs for their conditions [66], [67], [72].

Table IV also presents the findings of the same variables from several other studies. The need for the same variables arises. Fig. 5 shows the frequency of variables used in selected articles.

Fig. 5 shows that drug sales/consumption (quantity, type, time) (11) and drug data (name, condition, quantity, expired date, and price) (12) are the most widely used variables in drug prediction. Together with the doctor's prescription parameters (name and drug quantity) (2) and drug reviews (content and properties of the drug) (1), these variables are the most dominant among the other variables. The epidemiological variable group uses the most variables, namely the number of disease cases (3). The variables of health service location - distributor (5) and patient domicile (3) represent discussions related to the drug supply chain. Meanwhile, the prediction pattern using the susceptible-expose-infectious-removal (SEIR) method uses many patient identity and condition variables.

The various research variables found can be grouped into five categories: epidemiology, drug consumption, drug storage and ordering (drug management in pharmacies), supply chain and patient domicile (drug distribution - area - health service distribution), and patient identity and condition (pharmacotherapy). The third research question (RQ3) is answered. These five categories represent potential variables for predicting drug demand, as identified in selected articles. This study recommends the following five categories for selecting potential variables for drug prediction using machine learning. The five categories demonstrate that obtaining significant variables by measuring the proximity between variables using machine learning algorithms can overlook field conditions, such as the spread of disease and the distribution of drugs from a health service. However, the five categories of potential variables are identified as significant variables in machine learning models for drug demand prediction.

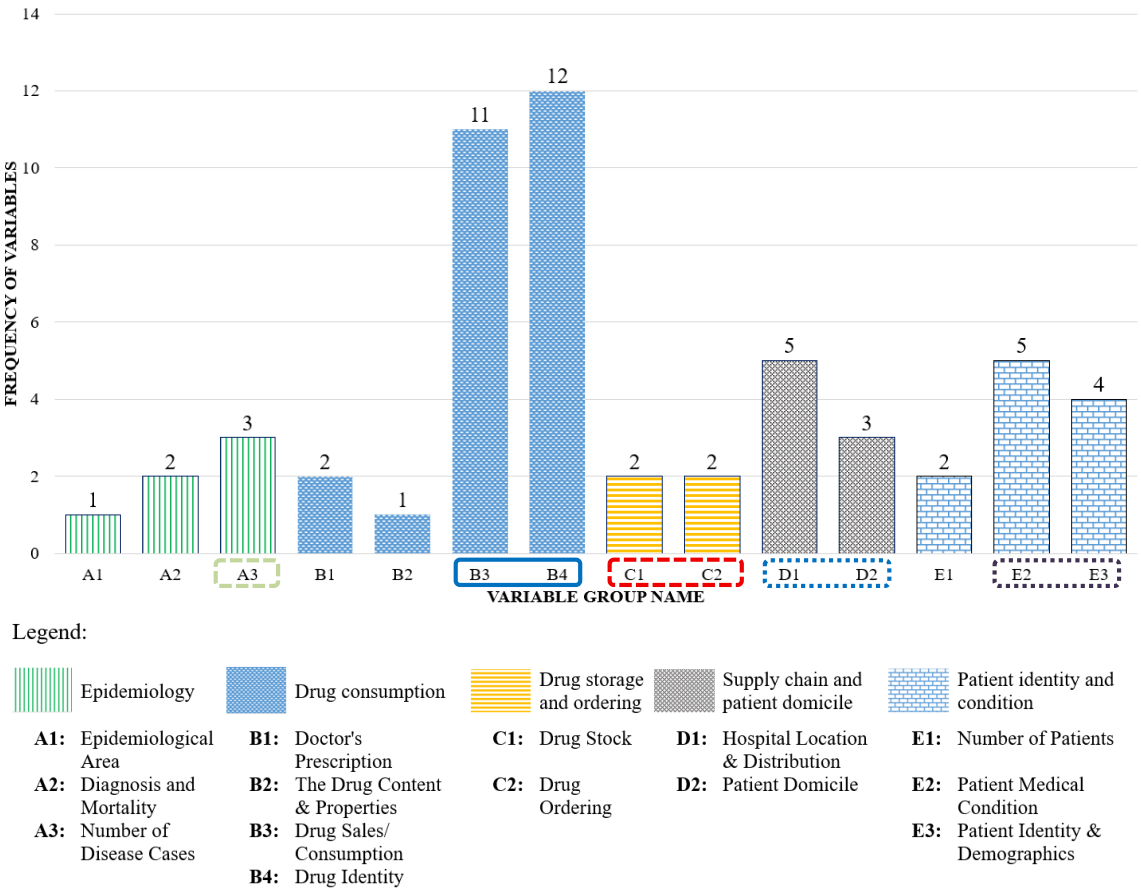

Fig. 5. The Frequency of variable use in research.

E. Integrated Datasets, Algorithms, and Potential Variables in Pharmaceutical Drug Prediction

The study begins by exploring potential variables by identifying issue areas. Classifying issue areas facilitates the study in sorting out the problem context and data availability in building machine learning models for drug demand prediction. Of the ten issue areas, the drug supply chain and drug consumption are closely related to the problem of predicting drug demand. This closeness arises because machine learning models aggregate historical data on drug consumption for prediction purposes. Increasing accuracy is the target of drug demand prediction research. Therefore, model development relies on algorithms that can enhance prediction accuracy. However, several studies have encountered obstacles due to limited data or restricted access to data (see Table II). The use of public data is one solution in building machine learning models for prediction [35], [58], [62], [69]. Indirectly, the development of drug demand prediction models ignores uncertain environmental conditions. Dynamic data changes, diverse data types, and varied data sources, which tend to increase data complexity, are not widely observed in this study. Therefore, further research is needed to understand how algorithms recognize data patterns and select significant features.

This study also examined the combination of medication consumption, disease, and treatment management. Dataset limitations often hinder the development of machine learning models. Potential variables can be a valuable option for developing machine learning algorithms, especially given the difficulty of obtaining certain types of data, which can reduce predictive performance. The results of this study, which paired the issue area with research variables (see Table IV), can be used as a consideration in developing machine learning models for regression, classification, and clustering. Selecting potential variables with close relevance can improve the performance of machine learning algorithms, particularly by reducing model complexity. Potential variables are rationally selected based on their relevance to the case and their proximity to the case, before being tested in machine learning algorithms using available data [73].

A limitation of this study is that many articles were included in the initial search because the search keywords were still too broad. The suitability of the search keywords captures more secondary research articles. Meanwhile, the discovery of primary research articles often involves fewer search keywords that match the contents of the primary research article. Selecting articles requires much careful effort to read the entire article. The number of selected articles is not yet representative of a particular continental region, thus requiring further study at the national level.

V. Conclusion

Mapping of research problem areas and significant variables in machine learning models for drug demand prediction produces ten research problem areas. The dynamics of data needs and algorithm choices for solving research problems are evident in the mapping. The challenge in the combination area is the increasingly complex and evolving data dimensions and algorithm choices. The selection of algorithms is still dominated by RF, XGBoost, and LSTM (for deep learning) machine learning algorithms. Efforts to improve accuracy dominate the research, providing a comparative perspective of various algorithms to improve predictions. Meanwhile, this study is in the area of significant variables that often depend on data limitations and algorithm performance.

This study identifies five potential variables in pharmaceutical drug prediction: drug consumption, drug management, epidemiology, supply chain-patient domicile, and pharmacotherapy. These five variables have not established themselves as a benchmark model or framework for designing drug demand predictions. However, mapping these variables can provide perspective for drug supply chain actors in developing machine learning models for downstream drug prediction.

Potential variables will not be significant in the model without the development of integrated data availability that is appropriate and relevant to the characteristics of the drug supply chain, endemic diseases, and public health services. Potential variables can be the basis for updating government policies related to health data integration and drug procurement guidelines in pharmacies. This research provides a basis for future research. The challenge of building a machine learning model for drug demand prediction involves working with multiple pharmacies across different geographic and demographic areas.

***Abstract*—In this study, we propose a graph-based node classification to address challenges such as data scarcity, class imbalance, limited access to original textual content in benchmark datasets, semantic preservation, and model generalization in node classification tasks. Beyond simple data replication, we enhanced the Cora dataset by extracting content from its original PostScript files using a three-dimensional framework that combines in one pipeline NLP-based techniques such as PEGASUS paraphrase, synthetic model generation and a controlled subject aware synonym replacement. We substantially expanded the dataset to 17,780 nodes—representing an approximation of 6.57x scaling while maintaining semantic fidelity (WMD scores: 0.27-0.34). Our Bayesian Hyperparameter tuning was conducted using Optuna, along with k-fold cross-validation for a rigorous optimized model validation protocol. Our Graph Convolutional Network (GCN) model achieves 95.42% accuracy while Graph Attention Network (GAT) reaches 93.46%, even when scaled to a significantly larger dataset than the base. Our empirical analysis demonstrates that semantic-preserving augmentation helped us achieve better performance while maintaining model stability across scaled datasets, offering a cost-effective alternative to architectural complexity, making graph learning accessible to resource-constrained environments.**

***Keywords*—Graph Convolutional Networks (GCN); Graph Attention Networks (GAT); hyperparameter tuning; data augmentation; PEGASUS; synonym replacement; optuna bayesian optimization; node classification; class imbalance**

I. Introduction

Text classification represents a foundational element within the domain of natural language processing (NLP), showcasing a broad scope of applications. Text classification systems must effectively map textual content to appropriate categories, a task complicated by the need to capture both local semantic patterns and global contextual relationships. In conventional methods, text is represented by hand-built features, typically lexical features (e.g., bags of words and n-grams) although they are efficient for particular tasks, semantic complex patterns are not well captured. The development towards deep learning models has been considerably applied to learn advanced textual representations, incorporating convolutional neural networks (CNNs) [1] and recurrent neural networks (RNNs) like long-term memory (LSTM) [2], such models perform well in terms of capturing semantic and syntactic insights within sequences of local consecutive words; however, they are still likely to disregard co-occurrence of the global words in a corpus that covers long-range, non-consecutive semantics dependencies that are important for overall text comprehension [3].

Lately, emerging graph-based approaches trends have gained significant attention to remedy these limitations, such as graph neural networks or graphical embeddings [4]. Unlike conventional sequence-based methods, GNNs allows for processing data in graphical interconnected network format. This paradigm shift enable the models to leverage both local characteristics of nodes and global graph topology, given that graphs are highly eloquent and boost calculation performance and extract semantic and syntactic information, innovative methods emerged for processing graph-structured data in machine learning, i.e., the graphical neural network, making its mark in numerous applications and proving itself as an effective and successful architecture.

Among the various GNN architectures, particularly Graph Convolutional Networks (GCNs) [5], shown remarkable success in node classification tasks. Based on the foundational work of spectral graph theory, the studies of (Bruna et al. 2014) [6], (Henaff et al. 2015) [7], and (Defferrard, Bresson, and Vandergheynst 2016) [8] set up the theoretical basis for carrying out convolution operations on graph-structured datasets, yielding competitive results in node classification seminal contribution introducing a localized, first-order method seminal contribution streamlined these spectral approaches by offering a localized, first-order approximation that maintains computational efficiency while achieving state-of-the-art performance across diverse graph-structured datasets, including the widely adopted Cora benchmark. Further applications include various domains from semantic role labeling in [9] to biomedical entity classification in [10].

Incorporating attention mechanisms into GNNs is yet a further significant advancement. The Graph Attention Network (GAT), introduced by Velickovic et al. (2018) [11], builds

upon the concept of attention, thereby enabling the model to prioritize the most significant nodes during the aggregation process. Graph Attention Networks (GATs) have been highly influential in enhancing the performance of GNNs by dynamically assigning adaptive attention weights to neighboring nodes based on their relevance allowing them to allocate computational resources to the richest connections, resulting in more nuanced and effective feature representations, notably in heterogeneous graph settings in which node and edge types diverge considerably.

Although there have been significant architectural advances, critical challenges persist that impede the practical application and scalability of graph-based textual classification models such as data scarcity, class imbalance, and semantic coherence preservation. Benchmark datasets are typically provided in a format that limits their potential for these type of models, Cora [12] an example of a standard dataset, while academically valuable it comes often in pre-vectorized formats, which detaches the learning process from the original semantic complexity, restricts certain feature engineering introducing a barrier in research from flexibility in exploration of different preprocessing pipelines. In addition to its small size and class imbalance which further hinders generalization rare classes are not well represented. Furthermore, the lack of access to the original text prevents any attempt at implementing effective augmentation strategies. These common limitations prevent GNNs from fully using their ability to learn contextual representations from textual content.
