Existing approaches exhibit a notable research gap: while important efforts have focused on architectural innovations to advance GNN capabilities, less attention has been paid to the research-based investigation of dataset quality and preparation. This gap can be seen in three practical challenges that limit how well we can evaluate performance. First, benchmark datasets like Cora are distributed in pre-vectorized formats, which limit access to original textual content and opportunities for controlled preprocessing or semantic augmentation. Second, the often-overlooked persistent class imbalance such as Neural Networks composed of 30% of samples while only 6% for Rule Learning can make the evaluation less accurate. Third, semantic preservation metrics for augmented graph data remain inconsistent, this makes it hard to make sure that synthetic relationships are meaningful. These data-related limitations suggest that focusing only on architectural complexity may not solve foundational challenges in graph-based text classification, underscoring the need for complementary data enhancement approaches. Although several studies acknowledge these issues, more careful investigations into semantic-preserving augmentation and class distribution mitigation remain limited. Addressing these challenges is essential to support and not replace architectural progress.

To address this gap, this study explores the following research question: How can semantic-preserving dataset augmentation serve as a cost-effective complement to architectural innovations in graph-based text classification, while maintaining semantic consistency and boosting performance without increasing computational demands? This question is motivated by the practical need to make advanced graph learning accessible to resource-constrained environments while tackling fundamental data quality issues that architectural solutions alone cannot resolve. To answer this question, we present a scalable framework for dataset augmentation that preserves semantic consistency, aimed at improving graph-based text classification using graph neural networks (GNNs). Our work places particular emphasis on Graph Convolutional Networks (GCNs) and Graph Attention Networks (GATs). The framework responds to a frequent issue in this field—the discrepancy between the sophistication of theoretical models and the constraints placed on by real-world datasets. While much of the existing literature centers on architectural innovation, our findings suggest that focusing on data quality—specifically through targeted augmentation—can lead to performance gains that are comparable to those achieved through complex model redesigns. Our approach addresses several challenges:

1) Cost-effective: alternative to developing new architecture, making advanced graph learning accessible to researchers with limited computational resources.

2) Data augmentation: We introduce a hybrid augmentation pipeline that combines in a refined pipeline, NLP-based techniques like PEGASUS for text paraphrase [13] , controlled synonym replacement techniques [14], and a synthetic domain-specific text generation, we augment the dataset to enhance both the diversity and quantity of the training data and solve class imbalances while preserving semantic coherence while enabling in addition flexible and transparent text preprocessing.

3) Semantic quality assurance: We use semantic similarity checks employing the metric Word Mover's Distance (WMD) [15] to confirm that augmented samples maintain meaning and contextual relevance rather than depending just on cosine similarity operating on fixed vector representations and may overlook semantic changes introduced by paraphrasing.

4) Model optimization and evaluation: we use Bayesian-optimized Optuna [16] hyperparameter tuning, and k-fold cross-validation [17] to guarantee strong evaluation of model performance, providing a more reliable assessment of generalization across different data subsets. This method enhances the reliability of our systematically fair comparison of GCNs and GATs, in order to guarantee that the models reach their maximum potential on the augmented dataset.

Our approach yields GCN achieving an accuracy of 95.42% and GAT achieving 93.46% on 6.57x larger Cora dataset while supporting semantic fidelity (WMD scores: 0.27-0.34) showing the effectiveness of models with our flexible pipeline.

This paper is organized as follows: Section II reviews related work on GNNs and recent advancements in node classification. Section III details our methodologies. Section IV presents experimental results and analysis. Finally, Section V concludes with limitations and future research directions.

II. Related Works

Recent advancements in Graph Neural Networks (GNNs) have propelled the field of graph-based node classification forward in addressing various limitations. Key developments include:

1) Spectral graph convolutions: The groundwork for spectral graph convolutions was established by Bruna et al. (2014) [6], which was further advanced by Defferrard et al. (2016) [8] through ChebNet, utilizing Chebyshev polynomials to approximate convolutions on graphs. Kipf and Welling (2017) [5] simplified these methods by introducing Graph Convolutional Networks (GCNs), achieving state-of-the-art performance while maintaining computational efficiency.

2) Attention mechanisms in GNNs: Veličković et al. (2018) [11] introduced Graph Attention Networks (GATs), employing self-attention mechanisms to dynamically weigh the significance of neighboring nodes, facilitating more flexible feature aggregation. This model has shown particular efficacy in heterogeneous graph settings, enhancing model adaptability.

3) Scalability and efficiency: Addressing scalability issues, Chen et al. (2018) [18] proposed FastGCN, which employs importance sampling to minimize computational complexity. Huang et al. (2018) [19] further refined this with Adaptive Sampling GCN (AS-GCN), improving performance for large-scale graphs.

4) Handling heterogeneity: The Heterogeneous Graph Attention Network (HAN), proposed by Wang et al. (2019) [20], tackles challenges in heterogeneous graph data, demonstrating notable improvements in tasks like author identification and paper classification.

5) Mitigating over-smoothing: The issue of over-smoothing in deeper GNN architectures was addressed in study [21] with DeepGCNs, which integrated residual connections and dilated convolutions, facilitating the training of much deeper networks.

6) Data augmentation for graphs: Zhao et al. (2021) [22] proposed GraphSMOTE, a modification of the SMOTE algorithm tailored for graph-structured data to tackle class imbalance. Ding et al. (2022) [23] introduced a comprehensive data augmentation framework specifically for GNNs, showing significant improvements in performance across multiple tasks. Additionally, Zhang et al. (2020) [13] highlighted the effectiveness of PEGASUS for paraphrasing and synonym replacement in augmenting text data for GNN applications.

7) Hyperparameter optimization: Recent work by (Akiba et al., 2019) [16] emphasized automated hyperparameter tuning for GNNs, achieving notable enhancements in model performance across various datasets. R. Kohavi (1995) [17] further explored the application of k-fold cross-validation, emphasizing robust model evaluation practices necessary for ensuring generalizability in GNN contexts.

To overcome previously cited limitations and build upon these architectural advances. Our work focuses on combining architectural strength with data-centric approaches.

III. Methodology

A. Graph Convolutional Networks

GCN is a fundamental component of our approach to text classification using graph-based data. This section outlines the GCN architecture, explains the mathematical foundations, and highlights its role in our methodology.

1) Architecture overview: The GCN [1] operates like a layer that receives a set of input vectors representing the nodes, in conjunction with the graph structure, producing a new set of node mappings. In the context of a directed graph, denoted:

$$G = (V, E) \tag{1}$$

where V represents the set of vertices (nodes), while E the set of edges (see Fig. 1).

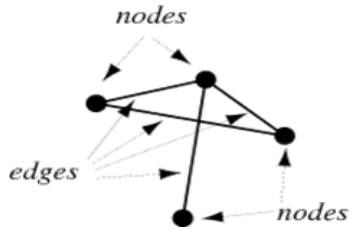

Fig. 1. Structure of a directed graph illustrating node-edge relationships in Cora dataset.

The purpose is to glean insights from the graph by the features function. This function uses as its input:

A description of the features xi for each node I, summed in a feature matrix N × D X (N: nodes, D: input features).

A graph structure description embodied in a matrix form; specifically, as an adjacency matrix A (or a function of A).

The output Z (an N × F matrix, F: output features at each node). Every layer unfurls as a unique non-linear function:

$$H^{(l+1)} = f(H^{(l)}, A) \tag{2}$$

H(0) initialized as X , as for I: the layers number. The patterns vary solely in choosing and parameterizing the function, so it can capture the transformation performed on the node representations in each layer, and A is a matrix attained through the normalization process applied to the adjacency matrix of the graph G.

2) Message passing: As its name suggests, it refers to the neighbor of the destination node. The general concept is to exchange message (insights) constantly with its neighbors to reach a steady balance. Fig. 2 exhibits an illustration of the message passing process that consists of two key steps:

a) Aggregation: each node transmits feature information (messages) to the target node from its neighbors.

b) Update: the functionality of each node according to the "Message" received to form an embedded representation (Embedded).

Message passing guarantees consistent dimensions for all representations, allowing easy further processing. A final integrated representation is achieved after many layers of message passing, capturing the complex relationships within the graph structure. Eq. (2) gives the rule for passing messages from a GCN to a layer for an undirected graph, G.

$$H = \sigma(AXW) \tag{3}$$

H represents the updated node representations, X the matrix that wraps the characteristics of the nodes, where W embodies weight parameters, and σ functions as the non-linear activation coordinator. Meanwhile, A appears as a matrix built using a process of normalization of the rows of the adjacency matrix of the complex graph to add richer feature representation of the model. The following Fig. 2 exhibits the message passing mechanism throw layers.

Fig. 2. Message passing mechanism.

In summary individual nodes aggregate information from their interconnected nodes, applying an aggregation function, which ensures that all representations result in equal size. Next, the vector undergoes a transformation through a dense neural network layer, together with a non-linear activation function to refine the vector's mapping. These steps are repeated according to how many layers are in the model. In particular, GCNs feature distinct representations at each layer:

At the zeroth layer, the representation is aligned with the node's specific characteristics.

At k layer, the node's mapping is calculated by going through its neighbors, aggregating their mappings from the preceding layer (k-1), averaging them and subjecting the result to a transformation via a parameter matrix. This process extends to include the node's proprietary messages from k-1 onwards. This value is then subjected to a non-linear function, such as ReLU in our case.

Eventually, when the node's mappings pass through the transformations in the hidden layers conclusive integration is achieved. In summary, GCNs work via iterative message transmission among nodes, allowing them to leverage representations capturing their structural context, both local and global, in the graph.

B. Graph Attention Networks

GATs offer an excellent opportunity for the development of graphical neural networks. With Graph Convolutional Networks (GCN), every neighbor has the same importance. Yet, some nodes are more essential than others. Graph Attention Networks solve this issue with the self-attention mechanism that regards significance of individual neighbors, an attention mechanism granting a weight coefficient per connection. The following section illustrates GAT architecture, provides an overview of its mathematical background, and outlines its contribution to our methodology.

1) Architecture Overview: GAT [11] architecture consists of various key elements, designed to contribute to its performance in graph-based neural networks:

Self-attention mechanism lies at the core of GAT, this mechanism assigns a weighting factor (attention score) to each connection, allowing the nodes to target the most relevant neighbors. GAT applies mathematical equations to aggregate node characteristics based on attention, the embedding of node 1 is calculated as the equation below shows, W: shared weight matrix:

$$h_1 = \alpha_{11} w\varkappa_1 + \alpha_{12} w\varkappa_2 + \alpha_{13} w\varkappa_3 + \alpha_{14} w\varkappa_4 \tag{4}$$

α_{ij} the attention scores across nodes i and j.

The calculation of these attention scores proceeds through three stages:

a) Linear transformation: To calculate the importance of each connection, pairs of hidden vectors are needed (see Fig. 3). A straightforward approach to forming these pairs involves concatenating the vectors of the respective nodes. Moving on from this step, a new linear transformation is applied using trainable attention vector a:

$$a_{ij} = a^t [W\, h_i || \, W h_j] \tag{5}$$

Where:

$W{\cdot}h_i$ and $W{\cdot}h_j$ are the transformed node features,

‖ Indicates vector concatenation,

a^t is a transposed attention vector (learned during training).

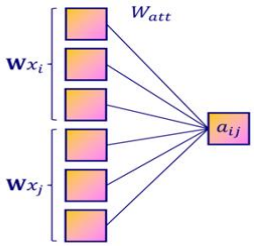

Fig. 3. Linear transformation process.

b) Activation function: Since the aim is to build a neural network, the activation is the second stage. In this context, the LeakyReLU function is added (see Fig. 4).

$$e'_{ij=} LeakyReLu(e_{ij}) \tag{6}$$

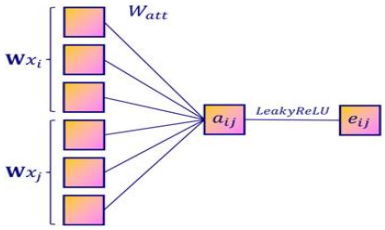

Fig. 4. Computing attention coefficient.

c) SoftMax normalization: The output of the neural network does not undergo normalization. To assess the relative relevance of node 2 to node 1 to node 3 ($\alpha_{12} > \alpha_{13}$), the same scale should be shared. A frequently employed method in neural networks involves the SoftMax function (see Fig. 5). The equation below shows how it is applied to every neighboring node:

$$\alpha_{ij} = softmax(e_{ij}) = \frac{exp(e_{ij})}{\sum_{k \in N_i} exp(e_{ij})} \quad (7)$$

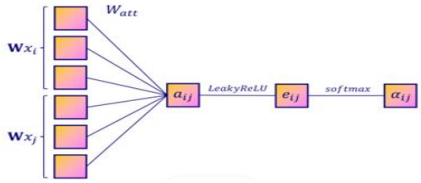

Fig. 5. SoftMax normalization.

We can calculate every α_{ij}. However, self-attention can exhibit instabilities. To enhance robustness, multi-head attention was introduced into the architecture of the transformer.

d) Multi-head attention: The multi-head attention (see Fig. 6) involves repeating three identical steps repeatedly, with the aim of calculating the average or recombine outputs. Here, rather than obtaining a unique hidden h_1, a separate hidden vector h_1^k is generated for each attention head. We can then apply one of two schemes:

Average: add together each of the h_i^k. Normalize via the total number n of heads of attention.

$$h_i = \frac{1}{n} \sum_{k=1}^{n} h_i^k \quad (8)$$

Concatenation: concatenate the different h_i^k.

$$h_i = ||_{k=1}^{n} h_i^k \quad (9)$$

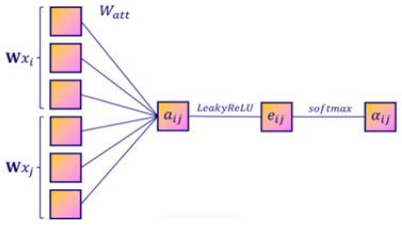

Fig. 6. Multi-head attention.

In summary, attention-graph networks define self-attention as a mechanism that allows nodes nearby to be accorded levels of importance. Mathematically, this self-attention is characterized by linear transformations, activation functions, and SoftMax normalization. Multi-headed attention adds to the model's performance by considering multiple perspectives during the aggregation process.

C. Data Preprocessing and Augmentation

1) Original Cora dataset description: The Cora dataset published by Andrew McCallum and his research group at the University of Massachusetts Amherst [12] (see Fig. 7) as a compressed zip file containing .ps files containing metadata, abstracts and citations for 2,708 academic publications distributed across seven classes. The accompanying citation grid comprises 5,429 links. Cora's established benchmark status in graph neural network literature enables meaningful performance contextualization, while its citation network structure provides the graph topology essential for GCN and GAT evaluation. We selected Cora for three reasons aligned with our objectives:

- Availability of original PostScript text to support sophisticated, meaning-preserving augmentation.
- Moderate size (2 708 nodes) that allows comprehensive k-fold validation without prohibitive compute demands.
- Pronounced class imbalance (Neural Networks: 30 %, Rule Learning: 6 %), making it an ideal benchmark for evaluating imbalance-aware graph learning strategies.

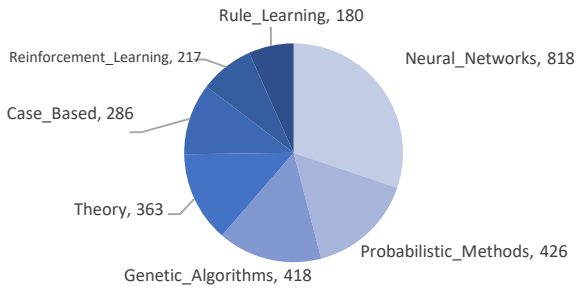

Fig. 7. Original Cora dataset classes distribution.

This dataset was subjected to a comprehensive preprocessing and augmentation protocol to enhance its utility and mitigate inherent limitations and was systematically expanded to a more robust dataset of 17,780 samples through a multifaceted augmentation strategy.

e) Semantic-preserving multi-modal augmentation framework: Theoretical motivation: data expansion traditional methods regularly introduce semantic leakage in which synthetic input samples deviate increasingly far from the domain's original pattern. This issue is also pronounced in datasets like Cora that are already heavily pre-processed to a simplified representation removing much of its contextual richness that GAT and GCN are meant to capture. To solve this problem, instead of developing a costly new augmentation algorithm we propose a combination of existing methods with a semantic control level mechanism following this pipeline:

- Preprocessing Cora original raw dataset: The initial phase was data preprocessing. It involved a meticulous examination and refinement of the raw Cora dataset, originally distributed in PostScript (ps) file format. This process was executed through a series of sophisticated steps to preserve data quality, relevance and semantic integrity.

Content Extraction and Metadata Removal: we isolate essential textual content directly from the PostScript file one by one using a custom rule-based string parser we implemented in

Python while systematically removing extraneous metadata, such as (e.g. author names and institutional affiliations, links, etc.). Abstracts were retained, as they serve as the primary textual representation of each paper.

Text Cleaning: A multi-tiered protocol to text cleaning has been used taking into consideration benchmark practices to not roughly eliminate semantic senses: custom regular expressions were employed to remove non-alphanumeric characters, normalize whitespace, and standardize formatting.

- Data augmentation Pipeline (Methodologies)

$$\text{Let } D = \{(x_1, y_1), (x_2, y_2), ..., (x_n, y_n)\} \quad (10)$$

D represent the original dataset, where x_i is the feature vector and y_i is the label that correspond to the feature in question. The generated D' is the result of the augmentation process such that |D'| > |D| while preserving the label condition distribution $P(x', y') \approx P(x,y)$.

PEGASUS-based Textual Transformation: We employed the PEGASUS (Pre-training with Extracted Gap-sentences for Abstractive Summarization) model, specifically fine-tuned for paraphrasing [13], as the primary method for generating diverse textual variations. This approach allows us to create semantically equivalent but linguistically diverse versions of the original text:

$$P = f_{\theta_p}(x) \quad (11)$$

where P is the paraphrased text, x is the paper textual content, and f_(θ_p)

is the PEGASUS paraphrasing function with parameters. This technique effectively doubles the dataset size while introducing linguistic variations that can improve model robustness.

Subject-Aware Lexical Substitution via Synonym Replacement: We used synonym replacement algorithm [13] while enforcing controlled lexical variations through filtering according to subject domain, thereby maintaining thematic coherence while expanding vocabulary:

$$x_{\text{aug}} = h(x_{\text{orig}}, \lambda) \quad (12)$$

Where x_aug is the augmented paper content, x_orig is the original or previously augmented content, h is the synonym replacement function, and λ is a parameter controlling the degree of replacement.

Conditional restrictions are applied so that only substitutions that met semantic and label constraint were retained (Samples exceeding the WMD threshold were rejected)

$$\text{WMD}(x_{\text{orig}}, x_{\text{aug}}) \leq \tau_{\text{wmd}} = 0.35 \quad (13)$$

Class-balanced custom Generation Pattern**:** we devised a sophisticated syntactic generation framework characterized by a meticulously curated lexicon of action-oriented verbs and descriptive adjectives. Enabling the formulation of new sentences that are both semantically rich and consistent with the underlying class distributions of the original text, this pattern was applied specifically to limited set of isolated nodes with no connection in the network and particularly those with the shortest text content that lack sufficient presentation.

$$N = g(X, V) \quad (14)$$

where N is the new synthetic sample, X is the original text, V encapsulates our curated vocabulary and advanced terminological construct, and g is our custom generation function that generates suitable terms from V while respect part-of-speech to maintain correctness. This combinatorial approach allows for controlled growth of even smaller contributor nodes in the dataset with semantic check through the threshold τ_{wmd}.

- Parameter Sensitivity: The choice of crucial parameters in our augmentation pipeline has an important impact on performance. While a lower Learning rate (Lr) produces nearly duplicate paraphrases with little advantage, a higher PEGASUS (Lr) introduces semantic drift that reduces classification accuracy. Raising the synonym rate beyond its optimal point disrupts domain-specific terminology, damaging coherence, while too low a rate limits new lexical variety. Temperature values above 0.8 produce semantically inconsistent text that misleads the classifier, and values below 0.6 result in repetitive, uninformative samples. While lowering the WMD threshold allows for excessive semantic divergence, raising it over-filters advantageous variations. These findings underscore how sensitive the augmentation process is to parameter choices and highlight the importance of systematic tuning, as even minor deviations from optimal settings can significantly degrade semantic quality.

- Methodological Validation: Semantic Preservation**:** For each newly augmented node inherits the original node's edges to preserve citation relationships so that the structural semantics of the graph remain intact after augmentation. To support the integrity of the augmented dataset, we implement: Automated intra-category semantic similarity checks between original and augmented document embeddings for each category. We computed the Word Mover's Distance (WMD) [15] and set threshold for strict filtering; this validation mechanism prevents the semantic drift commonly seen in synthetic data generation. In addition to analyzing repetitiveness in sentence structure and phrase.

Class Balance: The data were augmented to realize equal class distributions (approximately 14% each) drops the bias in the original Cora, where Neural Networks represented 30% of samples while Rule Learning only 6%, Neural Networks now present more equitable 16% reduced dominance. This balance guarantees fair model evaluation.

Computational Efficiency: compared to the improvement of ensemble methods or attention mechanism. This pipeline provides better graph learning preserved semantically, enabling models to achieve better performance without architectural modifications, reducing computational overhead and more accessible to any individual.

IV. Experimental Results

A. Dataset Description

In this study, we have created a customized augmented dataset from Cora [12] using various methods, each with critical parameter settings. The Pegasus model utilized a learning rate of 0.01 selected following several tests and monitoring continuously steady convergence without overshooting, a maximum input length of 512 tokens, a beam search size of 5, and was trained for 5 epochs to ensure effective learning. For synonym replacement, we set a replacement probability of 0.3 and a maximum of 3 synonyms per word, maintaining semantic integrity while promoting variability. In the text generation phase, we used a temperature of 0.7 for balanced creativity, top-k sampling with k=50 to restrict predictions to the most probable words, and to reduce repetitive phrases we used a repetition penalty of 1.2. These carefully chosen parameters, and many others significantly preserved the quality and diversity of the generated data.

The New customized Cora dataset (see Fig. 8) cumulative generated by the augmentation techniques resulted in the important expansion of our dataset from the original 2,708 samples to 17,780 samples, an increase in the factor of approximately 6,57x. This expansion not only increased the training data volume but also preserved the diversity of linguistic variations and synthetic samples, all while maintaining semantic coherence and domain.

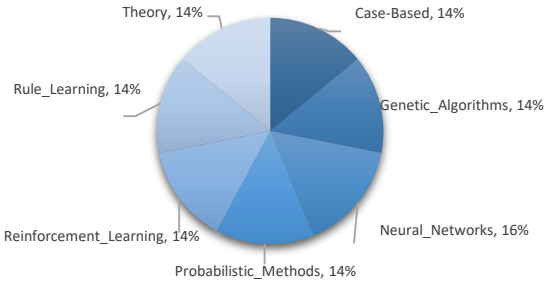

Fig. 8. Customized dataset classes distribution.

The quality and relevance of the augmented samples shows a similarity threshold of 0,8 was maintained. Additionally, WMD calculated scores intra classes (see Table I) values around 0.3 to 0.34 suggest moderate similarity between original and augmented texts within each category introducing meaningful variation.

TABLE I. WMD Scores

Category	WMD scores
Case-Based	0.3389
Genetic Algorithms	0.3049
Probabilistic Methods	0.3044
Reinforcement Learning	0.3309
Rule Learning	0.3283
Theory	0.2773

B. Hyperparameter Tuning Configuration

We adopted to conduct Naive Bayesian hyperparameters tuning with adopted Optuna [16], because of its empirical ability to efficiently navigate high-dimensional search spaces and typically generalize better, even in contexts like ours involving data imbalance and augmentation where stability is critical. The full set of optimized hyperparameter configurations for both GCN and GAT models is summarized in Table II, which lists ranges for learning rates, dropout, and architectural elements.

This probabilistic approach enabled us to model the relationship between hyperparameters and model performance. In addition to ensuring the robustness and generalizability of our hyperparameter configurations, we employed a k-fold cross-validation strategy. This approach partitioned our augmented dataset into k subsets, allowing for multiple training and validation cycles. The cross-validation procedure not only provided a more reliable estimate of model performance but also mitigated the risk of overfitting to specific data partition.

TABLE II. Optimized Hyperparameter Configurations

Elements	Values	Model
Optimization framework	100-400 trials	GCN-GAT
Hidden features	8 to 128	
Activation	["relu", "relu"], ["relu", "softmax"], ["elu", "softmax"]	
Dropout	0.1 to 0.8	
Learning rate	1e-5 to 1e-1 (Log-uniform)	
Weight decay	1e-6 to 1e-2 (Log-uniform)	
Cross-Validation	5-fold cross-validation	
Early Stopping	Patience of 20 epochs, monitored on validation set's F1 score	
Attn_heads	1 to 16	GAT
attn_dropout	0.2 to 0.8	

The hyperparameter tuning process aimed to maximize the mean cross-validated F1 score. The best-performing hyperparameters for each model were selected based on this metric. We then compared the optimized GAT and GCN models to determine which architecture was more suitable for our specific graph classification task.

C. Evaluation Metrics

Classification models are evaluated using well-established metrics to quantify their performance and effectiveness. These metrics are essential in determining how well a model can predict outcomes based on the given data. Below are the key metrics used in evaluating GCN and GAT classification [5] [11]:

True Positives (TP): Instances where the model correctly predicts positive outcomes (i.e., both the actual and predicted results are positive).

True Negatives (TN): Instances where the model correctly predicts negative outcomes (i.e., both the actual and predicted results are negative).

False Positives (FP): Occurrences where the model predicts a positive result, but the actual result is negative (also known as a Type I error).

False Negatives (FN): Occurrences where the model predicts a negative result, but the actual result is positive (also known as a Type II error).

Accuracy: Conversely, false negatives occur if the model predicted a negative result, while the real result proved positive**.**

$$\text{Accuracy} = \frac{\text{TP}_\text{i}+\text{TN}_\text{i}}{\text{TP}_\text{i}+\text{TN}_\text{i}+\text{FP}_\text{i}+\text{FN}_\text{i}} \quad (15)$$

Loss: Loss measures the discrepancy between predicted values and actual values. Cross-entropy is a common loss function in deep neural networks. It quantifies how well the predicted probabilities match the actual class labels.

$$\textbf{C}\text{rossEntropy} = -\sum_{i=1}^{n} log\left(P_{i,i}\right)y_{i,j} \quad (16)$$

where yi,j is the true value, i.e. 1 if sample I is in class j and 0 otherwise. Pi,j the likelihood forecast via the model that sample I is part of class j.

Precision: is the ratio between the True Positives and all the Positives.

$$\text{Precision} = \frac{\text{TP}_\text{i}}{\text{TP}_\text{i}+\text{FP}_\text{I}} \quad (17)$$

Recall: the extent to which our model correctly identifies true positives.

$$\text{Recall} = \frac{\text{TP}_\text{i}}{\text{TP}_\text{i}+\text{FN}_\text{I}} \quad (18)$$

F1 Score is the harmonic mean of Precision and Recall. It provides a balanced measure that considers both false positives and false negatives, making it particularly useful when dealing with imbalanced datasets. The F1 Score ranges from 0 to 1, with 1 indicating perfect precision and recall.

$$F1\ Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (19)$$

D. Results and Discussion

1) Model settings: In this experiment we adapted across all models the same following configurations:

a) Data preparation: The textual preprocessed data was transformed into TF-IDF vectors, with a maximum of 1000 features for each record. Class labels were encoded using LabelEncoder, ensuring numerical representation for classification. We created an adjacency matrix from citation data, representing relationships between papers, and normalized it to ensure proper scaling in the graph model.

Stratified Data Splitting We employed stratified k-fold cross-validation with 5 splits to ensure balanced class distributions across training and validation sets. A random state with a fixed seed of 42 was used for reproducibility throughout the data splitting and model training. For each fold, data was split into training and validation sets, without using a k-fold throught cross-validation.

Following comprehensive hyperparameter tuning and testing, we identified a set of configurations for the foundational models as detailed in Table III. These configurations were meticulously selected to enhance the performance of the respective models.

The results yielded by the individual models, GCN and GAT, were rigorously analyzed. Fig. 9 depicts the outcomes of numerous testing and fine-tuning iterations, providing a summary of the average performance metrics from the 5 folds that are broken down per model, and summarized in Table IV including key metrics: validation accuracy, precision, recall, and F1 score.

The results of our analysis reveal that GCN is consistently better than GAT across all evaluated metrics. Specifically, GCN achieves a validation accuracy of 95.42%, which is a higher overall correct classification rate than GAT's 93.46%. In terms of precision, GCN achieves a score of 95.45%, compared to GAT's 93.50%, suggesting a lower false positive rate for GCN. In addition, GCN's recall of 95.42% above GAT's 93.46%. This shows that GCN's improved capability in identifying true positives. The F1 score shows GCN at 95.42%, while GAT scores 93.47% which reflects the balance between precision and recall.

TABLE III. GRAPH CONVOLUTIONAL NETWORK AND GRAPH ATTENTION NETWORK SETTINGS

Model	GCN Instance Model	GCN Average Model	GAT Instance Model	GAT Average Model
Model architecture	layer_sizes =108 activated by ReLU	layer_sizes = 116 activated by ReLU	layer_sizes = 106 activated by ELU	layer_sizes = 106 activated by ELU

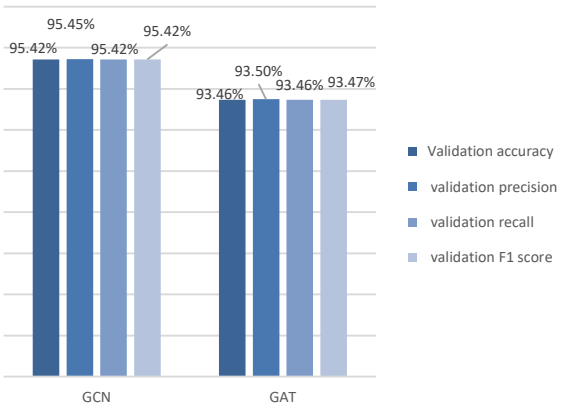

Fig. 9. Performance metrics comparison.

The GCN model performed better than the GAT model across all evaluation measures, with accuracy being approximately 1.96% higher (95.42% vs. 93.46%) and statistical significance with the paired t-tests showing ($p < 0.05$, $t = 2.89$, $df = 4$) also shows a 95% confidence interval: (94.77%, 96.07%) vs. (92.83%, 94.08%). The strong performance of both models, with low standard deviations, indicating stable learning over different data distributions.

TABLE IV. COMPARATIVE PERFORMANCE ANALYSIS OF GCN AND GAT MODELS ACROSS KEY EVALUATION METRICS

Model	Folds	Validation accuracy	Validation precision	Validation recall	Validation F1 score
GCN	F1	95,05%	95,06%	95,05%	95,04%
	F2	96,26%	96,27%	96,26%	96,26%

	F4	93,98%	94,01%	93,98%	93,99%
	F5	93,73%	93,75%	93,73%	93,74%

Based on cross-validation findings, detailed performance showed that the GCN maintains an accuracy of 95.42% (±0.47%) with a precision of 95.45% (±0.45%), a recall of 95.42% (±0.47%) and an F1 score of 95.42% (±0.47%). While GAT also manifests the corresponding performance levels of 93.46% (±0.45%), 93.50% (±0.45%), 93.46% (±0.45%) and 93.47% (±0.45%). We kept track of validation loss across folds to determine model convergence and confidence level were balanced. GCN showed a consistently lower average validation loss of ~0.18 compared to GAT's ~0.21. Both models demonstrated small standard deviations, indicating a good level of stability as well as reproducibility across different data partitions.

However, there is a variation between the study datasets and data refinement methodologies, confronted with these limitations the establishment of internal reference measures was undertaken. To this end, we trained GCN and GAT on the original Cora dataset (2,708 samples) using identical architecture but without augmentation. The resulting accuracy rates were 83.39% and 82.24%, respectively, aligning with existing literature on the subject such as [5][11], where standard Cora benchmarks rarely go above 85% in the absence of architectural refinement. While this comparison does not represent a strictly controlled ablation, it is still useful to understand the potential impact of our semantic preservation, class balanced augmentation pipeline. The augmented and optimized models exhibited an accuracy rate of over 95%, these results show how important it is to preserve the semantics of the dataset during the engineering process. The findings of this study provide an indicative—but not strictly controlled—comparison, which is developed in the limitations section.

- Class-wise Performance Analysis: To further investigate per-class performance, we computed F1-scores for each class across all folds (see Table V).

TABLE V. AVERAGED F1-SCORES RESULTS ACROSS THE FIVE FOLDS FOR EACH CLASS WITH STANDARDS DEVIATIONS

Class	*GCN F1-Score*	*GAT F1-Score*	*(GCN-GAT)*	*Support*
Case-Based	0.9575 ± 0.0073	0.9378 ± 0.0029	+0.0197	500
Genetic_Algorithms	0.9726 ± 0.0037	0.9584 ± 0.0039	+0.0142	500
Neural_Networks	0.9194 ± 0.0097	0.8898 ± 0.0115	+0.0296	556
Probabilistic_Methods	0.9504 ± 0.0081	0.9284 ± 0.0054	+0.0220	500
Reinforcement_Learning	0.9733 ± 0.0057	0.9608 ± 0.0135	+0.0125	500
Rule_Learning	0.9737 ± 0.0068	0.9590 ± 0.0081	+0.0147	500
Theory	0.9364 ± 0.0096	0.9140 ± 0.0086	+0.0224	500
Weighted Avg	0.9542 ± 0.0047	0.9347 ± 0.0045	+0.0195	3556

As detailed in Table V the analyses by class highlight notable aspects. Overall, all seven classes are consistently well managed by the GCN model, with a performance variance between 1.25% (Reinforcement Learning) and 2.96% (Neural Networks). The Neural Networks category shows the most difficulties in classification with both models, particularly due to the conceptual overlap and semantic ambiguity inherent in the literature on neural networks affecting many areas of artificial intelligence. Probabilistic Methods and Theory exhibit relatively significant performance differences (2.20% and 2.24%), suggesting that GCN's aggregation process is effective in capturing the particularities of these domains. However, the relatively smaller difference between the two models in reinforcement learning (1.25%) clearly illustrates how well the two models deal with this specific domain.

The plots shown in Fig. 10 and Fig. 11 provide an overview of the learning history that gives a further indication of the convergence and stability of GCN and GAT performance over the course of the learning process with second fold as the representative fold. We can observe that the learning process for both models GAT and GCN presents some notable differences, particularly during the early training stages. GAT, for instance, is more unstable at the beginning, especially in the initial starting epochs. This instability likely comes from the way attention mechanism that GAT uses, as it requires more

time to adjust and optimize the importance of edges within the graph. Learning how to prioritize different node connections adds more complexity, which in turn causes performance to initially fluctuate.

How GAT manages isolated nodes is one of its main challenges. While GCN works best in treating all neighboring nodes equally, GAT's effectiveness is more dependent on the topology of the graph. The presence of isolated nodes, which lack neighboring information, makes it harder for GAT to fully benefit from its attention mechanism. This has likely contributed to the early performance issues and slower convergence compared to GCN.

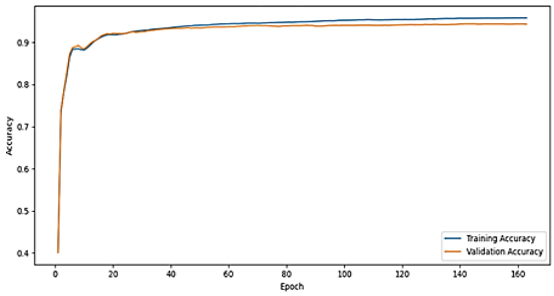

Fig. 10. GAT Fold 2 training and validation accuracy fit history.

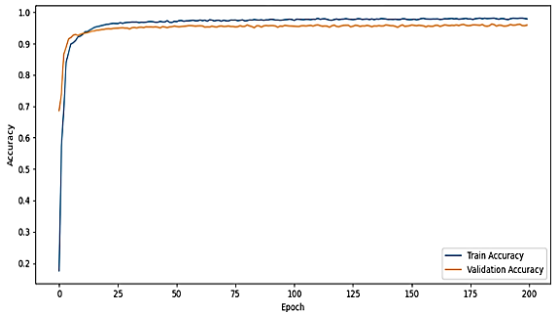

Fig. 11. GCN Fold 2 training and validation accuracy fit history.

Despite these challenges at the beginning, both models eventually ended up achieving high-performance levels. While it takes longer to converge for GAT, that frequently matches or even outperforms GCN in the end. This suggests that although GAT works in a more complex optimization environment, its ability to learn which edges are most important can offer important advantages as training continues.

Overall, the consistent results across the five cross-validation folds show that both models are robust, especially GCN, which was less variable across different data splits. The slight differences in GAT's performance could be due to its sensitivity to specific graph structures within each fold. Compared to baseline models, both GCN and GAT perform very well on the expanded dataset, suggesting their architecture's strength in handling complex graph data. This analysis underlines the unique strengths of each model and the importance of giving GAT sufficient training time to fully optimize its performance, particularly in scenarios with diverse graph connectivity.

V. Conclusion

This study represents a notable advancement in graph-based node classification, effectively addressing key challenges related to data quality in preserving semantic aspect, class imbalance, and model performance generalization constraints. Our approach enhanced the Cora dataset by extracting content from its original PostScript files and applying a systematic implementation of a tripartite augmentation framework combination of benchmark techniques: a combination of textual transformation PEGASUS-based, subject aware synonym replacement and customized class-balanced generation pattern function on isolated nodes to expand the dataset to 17,780 nodes, achieving a 6.57x scaling factor while maintaining semantic fidelity as evidenced by Word Mover's Distance scores ranging from 0.27 to 0.34. In addition the use of Optuna-driven hyperparameter optimization using Naïve Bayesian with k-fold cross-validation, to make sure achieving optimal model performance. Both the GCN and GAT models performed effectively, achieving accuracy of 95.42% and 93.46% respectively. This analysis highlights how is consistent is GCN alongside GAT more intricate learning pattern, where early fluctuation gave way to competitive results. These results show the potential of attention mechanisms to capture complex graph dynamics with sufficient training. The models' resilience, validated across five folds, further demonstrates motivation of our approach. Importantly, this work illustrates how advanced data augmentation and optimization techniques can boost the performance and scalability of graph-based models by preserving important semantic aspect that can be lost in rough engineering, also shows the ability of these models on larger datasets without compromising accuracy.

Despite overall good classification performance, there are some limitations that should be acknowledged, particularly in distinguishing between overlapping classes such as neural networks. The attention mechanism of GAT also introduced computational costs without corresponding gains. In conclusion, results demonstrate that performance obtains equivalent to architectural complexity alone can be obtained through strategic dataset augmentation, this principle provides a cost-effective alternative, making advanced graph neural networks accessible to researchers with limited computational resources.

A. Limitations and Future Work

While our approach has shown good results as discussed earlier in the previous section, we acknowledge different limitations that present opportunities for future improving:

1) Domain specificity: Our validation focuses on academic paper classification that the Cora dataset provides. Future work should explore the practical applicability across variety of text domains and languages.

2) Comparative evaluation: Direct comparison with existing methods is challenging due to the characteristics of the new dataset and the difference in engineering approaches. Future work should establish a more standardized evaluation protocol.

***Abstract*—The demand for robust data-driven classification (DDC) techniques remains critical in banking applications, where accurate and efficient decision-making is paramount. Artificial Neural Networks (ANNs), particularly Multi-Layer Perceptrons (MLPs), are widely used due to their strong learning capabilities. However, their performance often depends on effective hyperparameter tuning and regularisation strategies to avoid overfitting. This study aims to enhance the efficiency of the MLP training process by introducing a hybrid approach that integrates L2 regularisation with Early Stopping (ES) into the hyperparameter tuning procedure. The key contribution lies in embedding both techniques within a grid search framework, thereby streamlining the search for optimal hyperparameters. The proposed method was evaluated using three real-world banking datasets: two related to loan subscription (16 and 20 features) and one concerning credit card default payment (23 features). Experimental results demonstrate that the hybrid approach reduces hyperparameter tuning time by over 90% while achieving high classification performance. Notably, the Receiver Operating Characteristic - Area Under the Curve (ROC-AUC) scores of 93.89% and 91.21% were achieved on the loan datasets, and 73.28% on the credit card dataset, surpassing previous benchmarks. These findings highlight the potential of the L2ES hybrid method to improve both the accuracy and computational efficiency of DDC in financial applications.**

***Keywords*—Artificial neural networks; L2 regularisation; early stopping; banking; classification**

I. Introduction

The financial sector's digital transformation has intensified the demand for accurate and efficient data analysis techniques. Financial institutions continuously seek innovative strategies to enhance operational efficiency, particularly in loan processing, risk assessment, and fraud detection. In this context, data-driven classification (DDC) methods have emerged as essential tools for analysing large volumes of banking data to support informed decision-making. Among these, machine learning (ML)-based DDC techniques stand out because they can learn from complex, nonlinear data patterns and improve predictions over time. Their application spans multiple domains, including medicine, agriculture, and manufacturing, with particularly significant adoption in banking for tasks such as loan subscription analysis and credit card default prediction.

Artificial neural networks (ANNs), particularly the multi-layer perceptron (MLP), have gained recognition as robust classifiers within the DDC domain. Numerous studies have demonstrated the superior performance of MLPs in banking-related classification tasks. For example, MLPs have been effectively used to model customer decisions on loan subscriptions and to predict credit card default risks, as summarised in Tables I and II of this study. The robustness and adaptability of MLPs are further evidenced in domains such as bioinformatics. AbdElsalam et al. [1], for instance, significantly improved MLP performance in gene classification tasks by integrating the ADASYN technique to address class imbalance—an approach yielding high sensitivity and accuracy. These developments reaffirm that MLPs, when appropriately optimised, remain highly effective across various domains, including finance.

However, overfitting remains a critical challenge in MLPs, particularly when working with complex or imbalanced datasets. Regularisation techniques, such as L2 regularisation, have been widely adopted to mitigate this issue. Prior research by Aldelemy et al. [2] and Grosicki [3] demonstrates the efficacy of L2 regularisation in MLP-based classification for banking loan datasets. L2 regularisation has also been successfully applied to other ML models, including logistic regression and XGBoost, across both loan and credit card datasets [4]–[6]. Despite these applications, current implementations often overlook the considerable time and effort required for hyperparameter tuning in neural network models—an essential yet burdensome aspect of model optimisation.

This study identifies a gap in the literature: while L2 regularisation has been implemented to reduce overfitting in MLPs, limited attention has been given to streamlining the hyperparameter tuning process. Most existing approaches apply L2 within fixed or manually guided tuning routines, without exploring strategies to expedite this phase effectively. This oversight hinders the deployment of efficient ML systems in time-sensitive financial applications.

To address this, this paper proposes a hybrid approach that combines L2 regularisation with early stopping (ES) within a grid search framework. This technique aims to retain the regularisation benefits of L2 while simultaneously accelerating the hyperparameter tuning process via early termination of

*Corresponding Author.

underperforming configurations. By integrating ES into the grid search routine, the proposed method significantly lowers computational overhead and facilitates faster convergence to optimal settings, thus making the model development process more efficient.

Unlike conventional methods that treat L2 regularisation and hyperparameter optimisation as independent steps, our hybrid strategy embeds both into a unified workflow. This integration is particularly suitable for banking datasets, where rapid model development is critical. The proposed approach not only curbs overfitting but also enhances the efficiency of hyperparameter exploration—an aspect often neglected in previous studies.

Yash *et al*., [23]	-	Accuracy 80.50%	23

Accordingly, this research evaluates the performance of the hybrid L2ES (L2 + Early Stopping) approach in banking data classification. The primary objectives are to (i) assess the effectiveness of integrating L2 regularisation within MLP-based classifiers, (ii) incorporate L2 into the grid search procedure for hyperparameter tuning, and (iii) demonstrate how the combination of L2 and ES within grid search can enhance training efficiency without compromising model accuracy.

The remainder of this paper is structured as follows: Section II introduces the proposed L2ES methodology, detailing the experimental setup and the grid search configuration. Section III presents the empirical results and offers a comparative analysis with conventional approaches. Section IV concludes the paper and discusses directions for future research.

II. METHODOLOGY

A. Materials

The datasets utilized in this study are derived from the banking sector, specifically focusing on loan and default credit card datasets. These datasets are publicly accessible through the UCI Machine Learning Repository. Table III presents a detailed overview of the loan subscription dataset, as documented by Moro et al. [24]. This dataset encompasses 16 features and one label, the latter serving as the target variable. The dataset comprises 45,211 records featuring a mix of data types, including integers, binary and categorical. The binary target variable is imbalanced: 'yes' labels account for 5,289 records, while 'no' labels constitute 39,922.

TABLE III. OVERVIEW OF THE LOAN SUBSCRIPTION DATASET DOCUMENTED BY MORO ET AL. [24]

Num.	Variable Name	Role	Type
1	age	Feature	Integer
2	job	Feature	Categorical
3	marital	Feature	Categorical

Table IV outlines the characteristics of another loan subscription dataset, also studied by Moro et al. [7]. This contains 20 features and one label. It includes a mix of integer, float, and categorical data types for its features. Like the first, it exhibits a binary target with an imbalanced distribution among

its 41,188 records: 4,640 are labelled 'yes', and 36,548 are labelled 'no'.

Table V details the dataset concerning bank credit card default payments sourced from Yeh and Lien [25]. This dataset comprises 23 features and one label, encompassing 30,000 records. The features are of integer data type, while the label is binary. The dataset exhibits label imbalance, with 6,636 records labelled '1' (indicating default) and 23,364 records labelled '0' (indicating no default).

B. Preparation

The experimental setup adhered to past and present research's standard data-driven classification methodologies. Specifically, this study adopted the methodology illustrated in Fig. 1, adapted from A. Almajid [19]. All experiments were conducted within the Google Colab server environment, with relevant specifications for 2023 to 2025. The MLP model development commenced with a data cleaning phase, employing mode imputation to address missing data. Subsequently, the dataset was split using an 80:20 ratio into training and test sets, with the training set used to construct the MLP model. Before model creation, the training set transformed one-hot encoding for categorical features and standard scalar scaling for numerical features. The MLP classifier was selected as the machine learning algorithm to fulfil the primary objective of this paper, which is to augment the performance of the MLP classifier. The baseline model incorporated L2 regularisation to mitigate overfitting during the hyperparameter tuning process via Grid Search. Conversely, the innovative model combined L2 regularisation and ES to address overfitting concerns. The rationale behind this hybridisation was the anticipation of improved MLP classifier performance.

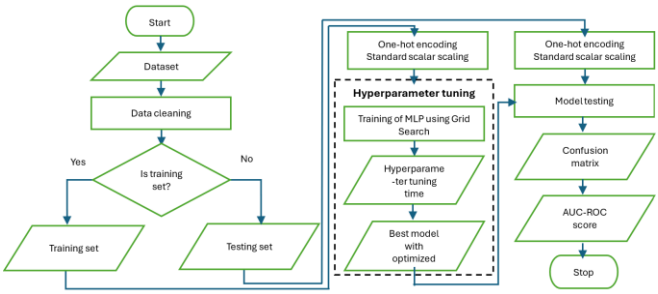

Fig. 1. Methodology for MLP model development and experimentation process.

Table VI outlines an algorithm for the hyperparameter tuning process that employs L2 regularisation in MLP models using Grid Search. This process is initiated by defining a hyperparameter grid, including the regularisation parameter, number of hidden layers, neuron range, activation function, and solver parameters.

A Grid Search Loop with 5-fold Cross-Validation follows, systematically exploring diverse hyperparameter combinations. Each iteration involves initialising and training an MLP model with L2 regularisation and monitoring training loss for convergence. The model's performance is assessed using the Receiver Operating Characteristic - Area Under the Curve (ROC-AUC) on held-out folds, with the average ROC-AUC

calculated across all folds. Each iteration records and accumulates training time from the previous iteration. Ultimately, the hyperparameter combination yielding the highest average performance metric is selected, resulting in the best MLP model with optimised hyperparameters.

Table VII introduces an innovative algorithm for the hyperparameter tuning process in MLP models utilising L2 regularisation and ES through Grid Search. Initially, a hyperparameter grid specifies parameters such as regularisation strength, hidden layer configuration, and activation function.

TABLE VI. ALGORITHM FOR HYPERPARAMETER TUNING WITH L2 REGULARISATION IN MULTI-LAYER PERCEPTRON (MLP) USING GRID SEARCH

Input	: Training set
Output	: Best MLP model with optimized hyperparameters
Step 1	Define Hyperparameter Grid for MLP: - Set regularisation parameter λ for L2 regularisation to 0.0001. - Set number of hidden layers to 1. - Define a range for the number of neurons per hidden layer from 5 to 100. - Set activation function to ReLU. - Set solver to Adam. - Set batch size (minibatch) to the minimum of 200. - Set initial learning rate to 0.001. - Set maximum iterations to 5000. - Set shuffle sample to True. - Set exponential decay rate for estimates of the first moment vector in Adam to 0.999. - Set exponential decay rate for estimates of the second moment vector in Adam to 1e-8.
Step 2	Grid Search Loop with 5-Fold Cross-Validation: - For each combination of hyperparameters in the defined grid: - Initialize an MLP model with the specified architecture and hyperparameters. - Divide the training data into 5 folds for cross-validation. - For each fold: o Train the MLP model with L2 regularisation. o Monitor the training loss during training and stop when the training loss does not improve by more than 0.0001 for 10 consecutive passes over the training set. o Evaluate the model's performance on the held-out fold using ROC-AUC. - Calculate the average performance metric (i.e., ROC-AUC) across 5 folds of the combination of hyperparameters. - Record and accumulate training time from the previous loop.
Step 3	Select Best Model: - Select the combination of hyperparameters that resulted in the highest average performance metric.

A Grid Search Loop with 5-fold Cross-Validation is implemented after that. An MLP model is instantiated and trained on five folds of the training data for each hyperparameter combination, with 10% reserved for validation. Training halts using ES when the validation score fails to improve by at least 0.0001 for ten consecutive epochs. Model performance is assessed using ROC-AUC on held-out folds, with the average metric calculated across all folds. Each loop records and accumulates training time from the previous loop. Finally, the hyperparameter combination yielding the highest average performance metric is selected, resulting in the best performing MLP model with optimised hyperparameters.

TABLE VII. ALGORITHM FOR HYPERPARAMETER TUNING WITH L2 REGULARISATION AND EARLY STOPPING IN MULTI-LAYER PERCEPTRON (MLP) USING GRID SEARCH

Input	: Training set
Output	: Best MLP model with optimized hyperparameters
Step 1	Define Hyperparameter Grid for MLP: - Set regularisation parameter λ for L2 regularisation to 0.0001. - Set number of hidden layers to 1. - Define a range for the number of neurons per hidden layer from 5 to 100. - Set activation function to ReLU. - Set solver to Adam. - Set batch size (minibatch) to the minimum of 200. - Set initial learning rate to 0.001. - Set maximum iterations to 5000. - Set shuffle sample to True. - Set exponential decay rate for estimates of the first moment vector in Adam to 0.999. - Set exponential decay rate for estimates of the second moment vector in Adam to 1e-8.
Step 2	Grid Search Loop with 5-Fold Cross-Validation: - For each combination of hyperparameters in the defined grid: - Initialize an MLP model with the specified architecture and hyperparameters. - Divide the training data into 5 folds for cross-validation. - For each fold: o Set aside 10% (using the stratified approach) of training data as validation. o Train the MLP model with L2 regularisation. o Terminate training using the Early Stopping approach, i.e. when the validation score is not improving by at least 0.0001 for 10 consecutive epochs. o Evaluate the model's performance on the held-out fold using ROC-AUC. - Calculate the average performance metric (i.e., ROC-AUC) across 5 folds of the combination of hyperparameters. - Record and accumulate training time from the previous loop.
Step 3	Select Best Model: - Select the combination of hyperparameters that resulted in the highest average performance metric.

The Cross-Entropy Loss function was employed for binary classification in the MLP model, as depicted in Eq. (1). This loss function quantifies the discrepancy between predicted and actual class labels, penalising misclassifications with logarithmic terms.

$$Loss(x_i, y_i) = -[y_i \, log(\hat{y}_i) + (1 - y_i) \, log(1 - \hat{y}_i)] \quad (1)$$

During the hyperparameter tuning phase using Grid Search, each cycle involves adjusting parameters such as the number of neurons (N) within a range from 5 to 100, alongside L2 regularisation. Eq. (2) represents the L2 regularisation term, penalising large weights to prevent overfitting.

$$n = \frac{\lambda}{2} \sum_{i=1}^{N} w_i^2 \quad (2)$$

Eq. (3) illustrates the cost function combining the Cross-Entropy Loss with the L2 regularisation term, where lambda (λ) is set to 0.0001. This cost function aims to balance minimising classification error and controlling model complexity, enhancing the model's predictive accuracy and

robustness. For the innovative model, the cost function includes L2 regularisation hybridised with ES, terminating training when the validation set score does not improve by at least 0.0001 for ten consecutive epochs.

$$Cost_{reg}(x_i, y_i) = Loss(x_i, y_i) + n = \frac{\lambda}{2} \sum_{i=1}^{N} w_i^2 \quad (3)$$

C. Testing

In this study, the development of MLP models was driven by two primary objectives: reducing the hyperparameter tuning time to identify the optimal set of hyperparameters for maximising classification accuracy and enhancing the model's ability to distinguish between classes. These objectives were evaluated using various metrics, including tuning time, confusion matrix analysis, and the ROC-AUC score. Tuning time refers to the duration from the commencement of the Grid Search process to its completion. It aims to enhance the model by pinpointing the most effective hyperparameters for achieving maximal accuracy in classification tasks. This step is critical for refining the model's configuration to improve its predictive performance. Furthermore, the evaluation process entailed an analysis of the confusion matrix to gauge the model's accuracy in classifying instances correctly across different categories. Additionally, the ROC-AUC score provided more profound insights into the model's discriminative capacity between classes.

Accuracy is a foundational metric, offering a high-level overview of the model's correctness. It is derived from the confusion matrix, as shown in Eq. (4), and calculates the proportion of instances correctly classified, irrespective of their class. This metric is handy when all classes are equally important, and the dataset is balanced. However, in cases of class imbalance, accuracy alone may not fully capture the model's effectiveness, as the prevalence of the dominant class may skew it. Hence, while accuracy is a valuable initial metric for evaluation, it is often essential to supplement it with additional metrics to obtain a more comprehensive picture of model performance, particularly in the presence of uneven class distribution.

$$Accuracy = \frac{(TP+TN)}{(TP+FP+TN+FN)} \quad (4)$$

with *TP* is True Positive, *TN* is True Negative, *FP* is False Positive, and *FN* is False Negative.

Precision offers a more detailed examination of the model's performance, concentrating specifically on positive predictions. It is defined as the ratio of correctly predicted positive instances to the total number of predicted positive instances, as illustrated in Eq. (5). Precision is paramount in scenarios with significant consequences or costs associated with false positives.

$$Precision = \frac{(TP)}{(TP+FP)} \quad (5)$$

with *TP* is True Positive and is False Positive.

In contrast, recall emphasises the model's capacity to identify all positive instances within the dataset. It calculates the ratio of correctly predicted positive instances to the total actual positive instances, highlighting its critical role in situations where overlooking positive instances (false negatives), could have serious repercussions. Eq. (6) presents the formula for calculating recall derived from the confusion matrix.

$$Recall/Sensitivity = \frac{(TP)}{(TP+FN)} \quad (6)$$

with *TP* is True Positive and is False Negative.

The F1 score, as presented in Eq. (7), amalgamates precision, and recall into a singular metric, offering a balanced evaluation of the model's performance. It computes the harmonic mean of precision and recall, providing a unified measure that accounts for false positives and false negatives, thereby preventing inflated scores when a significant discrepancy exists between precision and recall. The F1 score is particularly beneficial in scenarios involving class imbalance or when the costs associated with false positives and false negatives vary. By integrating precision and recall, the F1 score aids in guiding decision-making and model optimisation, ensuring a thorough classification performance assessment.

$$F1\ Score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (7)$$

The ROC-AUC score is widely recognised as a crucial metric for evaluating the performance of binary classification models. It depicts the likelihood that a randomly selected positive instance will be ranked higher than a randomly selected negative instance. The ROC curve plots the true positive rate (sensitivity) against the false positive rate (1-specificity) across various threshold settings. A higher ROC-AUC score signifies superior discrimination between positive and negative classes, with a score of 1 denoting a perfect classifier and 0.5 indicating a model no better than random guessing. The ROC-AUC score's robustness to class imbalance and applicability across different threshold configurations make it an invaluable tool for evaluating binary classifiers' overall performance in practical scenarios.

III. Result and Discussion

Table VIII illustrates the performance comparison of the MLP model with and without the employment of L2 regularisation. Implementing L2 regularisation with a 0.05 alpha value in the MLP model significantly enhanced its performance compared to the model devoid of L2 regularisation. This enhancement was particularly evident across three banking datasets, where the influence of L2 regularisation on the MLP model's performance was substantial. For instance, in a loan dataset comprising 16 features, the ROC-AUC score increased from 0.9133 to 0.9244. Similarly, for a loan dataset with 20 features, the ROC-AUC score improved from 0.9285 to 0.9312, and for a banking dataset focusing on credit card applications, the ROC-AUC score rose from 0.7464 to 0.7696. As observed in this study, the emphasis on the ROC-AUC metric in the analysis underscores its utility in providing a nuanced interpretation of model performance, especially in datasets with imbalanced labels. Additionally, results derived from the confusion matrix indicated an improvement in the MLP model's performance. These findings corroborate the significance of L2

regularisation in mitigating overfitting when developing MLP models, aligning with insights from prior research.

TABLE VIII. COMPARATIVE PERFORMANCE OF MLP MODELS WITH AND WITHOUT L2 REGULARISATION ACROSS BANKING DATASETS

Performance Matrices	Bank Loan 16 features		Bank Loan 20 features		Bank credit card default payments	
	No L2	L2	No L2	L2	No L2	L2
ROC-AUC	0.9133	0.9244	0.9285	0.9312	0.7464	0.7696
Accuracy	0.8979	0.9027	0.9052	0.9048	0.8021	0.8145
Precision (Positive)	0.5884	0.6373	0.5812	0.5839	0.5618	0.6072
Recall (Positive)	0.4384	0.4017	0.5375	0.5114	0.3855	0.4017
F1 Score	0.5024	0.4928	0.5585	0.5452	0.4572	0.4835

Table IX showcases the impact of integrating L2 regularisation into a MLP model, specifically employing a hyperparameter value setting as outlined in Table IV for the hyperparameter tuning process. This model exhibited remarkable performance, consistent with earlier observations that L2 regularisation could bolster MLP model performance. Specifically, Table IX outlines the results concerning ROC-AUC and the confusion matrix metrics. The bank loan dataset, consisting of 16 features, achieved ROC-AUC of 0.9221. A separate dataset, also related to bank loans but encompassing 20 features, registered ROC-AUC of 0.9455, while the bank credit card dataset demonstrated the ROC-AUC of 0.7814.

TABLE IX. IMPACT OF L2 REGULARISATION ON HYPERPARAMETER TUNING TIME ACROSS BANKING DATASETS

Dataset	Tuning Time (Sec.)	ROC-AUC	Accuracy	F1 Score
Bank Loan 16 features	26,787.75	0.9221	0.9005	0.5233
Bank Loan 20 features	23,714.07	0.9455	0.9189	0.5917
Bank credit card default payments	23,087.06	0.7814	0.8260	0.4847

The application of L2 regularisation has proven to enhance the MLP model's efficacy in classification tasks. Nonetheless, identifying the optimal hyperparameter settings with L2 regularisation application has been revealed to be a time-intensive endeavour. The hyperparameter tuning phase for all three datasets necessitated upwards of twenty-three thousand seconds, raising concerns regarding the practicality of deploying such models in real-time applications that demand frequent updates with new data entries.

Table X displays the performance of the MLP model employing a hybrid L2 regularisation and Early Stopping (L2ES) approach. Both techniques aim to mitigate overfitting, yet the experimental results indicate a significant reduction in hyperparameter tuning time with the hybrid L2ES approach. For the bank loan dataset with 16 features, tuning time was reduced by 91.44%, from 26,787.75 seconds to 2,424.88 seconds. Similarly, the dataset with 20 features saw a reduction of 90.95%, from 23,714.07 seconds to 2,030.71 seconds. The bank credit card dataset experienced a tuning time reduction of 93.57%, from 23,087.06 seconds to 1,485.15 seconds. The efficacy of the hybrid L2 and ES approach lies in its ability to shorten hyperparameter tuning time, primarily through the advantage offered by ES. This feature ceases the training process upon the absence of a minimum improvement of 0.0001 in the validation set score over ten successive epochs. This method is in stark contrast to the termination criteria of the baseline model, which discontinues training based on the absence of a notable improvement in the training loss over ten successive iterations, without consideration for the validation set score. Concurrently, L2 regularization is crucial in maintaining the classification model's accuracy by averting overfitting.

TABLE X. IMPACT OF HYBRID L2 REGULARISATION AND EARLY STOPPING ON HYPERPARAMETER TUNING TIME ACROSS BANKING DATASETS

Dataset	Tuning Time (Sec.)	ROC-AUC	Accuracy	F1 Score
Bank Loan 16 features	2,424.88	0.9121	0.8966	0.5351
Bank Loan 20 features	2,030.71	0.9389	0.9137	0.5854
Bank credit card default payments	1,485.15	0.7328	0.7877	0.4323

Fig. 2 presents a comparative analysis of hyperparameter tuning time between the MLP model using L2 regularisation and the proposed hybrid L2ES approach. The results are visually displayed using a bar chart, clearly illustrating a substantial reduction in tuning time across all datasets. Specifically, the hybrid L2ES method reduced tuning time by more than 90% compared to the L2-only approach, which was used as the baseline in this study. This represents a notable improvement, as such a reduction directly contributes to the practicality of implementing data-driven classification (DDC) models in real-world banking systems, particularly in scenarios requiring rapid model updates and continuous learning.

Fig. 3 compares the classification performance of the two approaches regarding ROC-AUC scores. The performance gap between the L2 and L2ES models is minimal, indicating that the significant gains in computational efficiency do not come at the cost of model accuracy. For the bank loan dataset with 16 features, the ROC-AUC difference is only 0.70%, while the 20-feature loan dataset shows a difference of 1.08%. The bank credit card dataset exhibits a slightly larger difference of 6.22%, which remains within an acceptable range of less than 10%. Although the L2ES approach yields marginally lower ROC-AUC scores in some cases, it consistently outperforms previous studies in overall performance benchmarks, particularly in hyperparameter tuning efficiency. These findings support the feasibility and value of the proposed hybrid approach for time-sensitive banking applications.

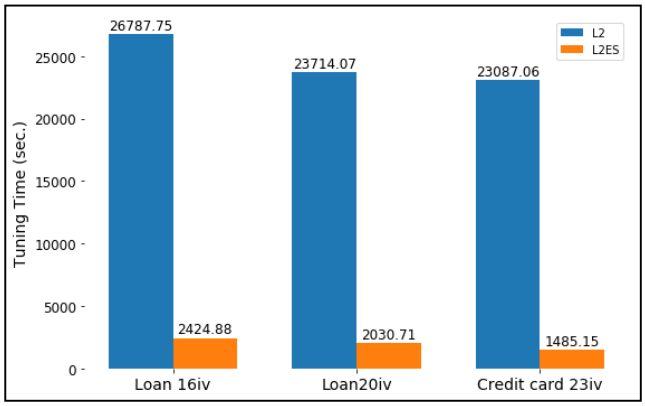

Fig. 2. Comparison of hyperparameter tuning time: L2 regularisation vs hybrid L2ES approach,

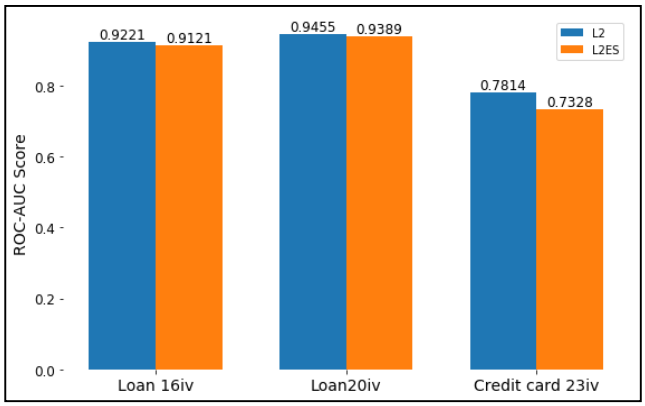

Fig. 3. ROC-AUC performance comparison: L2 regularisation vs hybrid L2ES approach across datasets.

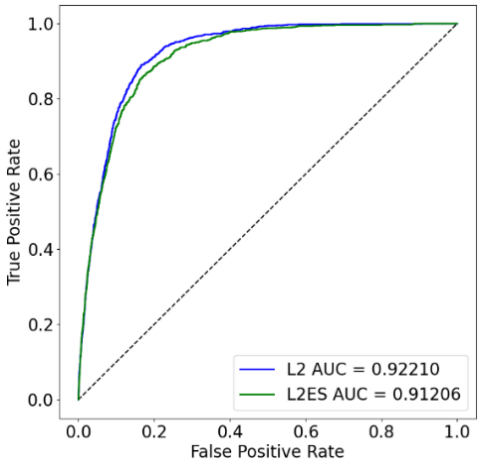

Fig. 4. ROC-AUC comparison for bank loan dataset with 16 features: L2 vs. hybrid L2ES approach.

Fig. 4 and Fig. 5 present the ROC-AUC curves for the bank loan datasets with 16 and 20 features, respectively, providing an alternative visual comparison between the L2 and hybrid L2ES approaches. Both graphs clearly show that the performance of the MLP model under the two conditions is very similar, with no significant differences observed in the shape or position of the curves.

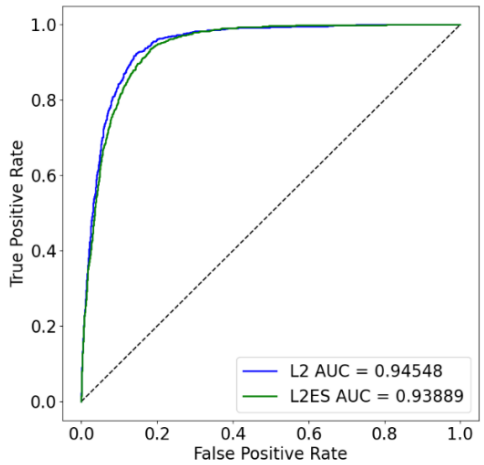

Fig. 5. ROC-AUC comparison for bank loan dataset with 20 features: L2 vs. hybrid L2ES approach.

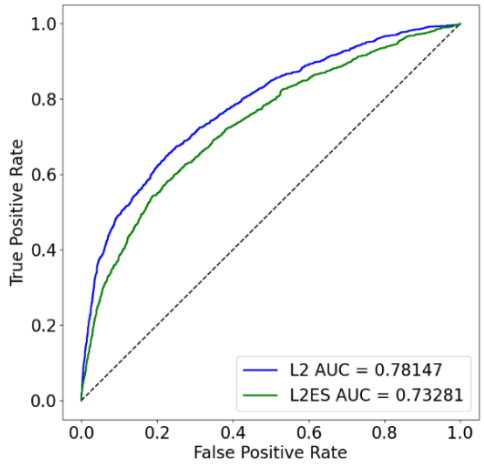

Fig. 6. ROC-AUC comparison for bank credit card dataset with 23 features: L2 vs. hybrid L2ES approach.

Fig. 6 displays the ROC-AUC curve for the bank credit card dataset. In this case, the hybrid L2ES approach shows a slightly lower curve than the model using L2 regularisation alone, indicating a marginal reduction in performance. However, this difference is relatively minor and does not significantly affect the overall effectiveness of the hybrid method. Notably, the L2ES approach outperforms previous studies, achieving a ROC-AUC score of 0.7328, compared to the values reported in Table II, where previous models did not exceed a ROC-AUC of 0.7200.

IV. Conclusion

This study evaluated the effectiveness of hybridising ES with L2 regularisation to reduce the time required for hyperparameter tuning—conducted via grid search—in developing MLP models, while preserving classification performance. The proposed L2ES approach significantly reduced tuning time without compromising model accuracy, as demonstrated by consistently high ROC-AUC scores comparable to those obtained using L2 regularisation alone. These results indicate that the L2ES technique offers a practical solution for streamlining hyperparameter tuning in

MLP models, thereby enhancing the efficiency of developing data-driven classification models.

Nevertheless, this study is not without limitations. The evaluation was limited to a set of structured banking datasets, and further validation is needed across diverse data domains and model architectures. Additionally, while grid search was used for tuning, other optimisation methods such as random search or Bayesian optimisation could offer further improvements.

Future research will aim to extend the proposed hybrid approach to other neural network models and investigate its compatibility with alternative tuning strategies. Enhancing generalisability, automating the hybridisation process, and applying it to unstructured or real-time financial data are promising directions for continued research.

***Abstract*—The implementation of Big Data Analytics (BDA) in organisations requires a structured approach to ensure alignment with strategic goals and infrastructure readiness. This study presents an enhanced version of the previously published ADiBA (Accelerating Digital Transformation Through Big Data Adoption) framework that aimed at guiding organizations through critical components necessary for successful BDA implementation. The initial framework was developed based on systematic literature review. To validate and refine the framework, a mixed-methods survey was conducted among domain experts using a five-point Likert scale and open-ended questions to assess the relevance of each framework component. Quantitative responses were analysed using the Content Validity Index (CVI), with a threshold of 0.78 adopted as the minimum acceptable I-CVI score for each item. Complementing the quantitative analysis, qualitative feedback from the open-ended survey responses, Focus Group Discussions (FGDs), and in-depth interviews were examined through thematic analysis, revealing key themes related to framework's clarity and operational aspects. Insights from both analyses informed the refinement of several components. The resulting framework is a validated and empirically-informed guide designed to support effective BDA implementation in organizational contexts.**

Keywords*—*Adoption process; big data; big data analytics; framework; framework validation; expert survey; content validity index; thematic analysis; organizational implementation; digital transformation

I. Introduction

The implementation of BDA within organizations has emerged as an important factor in driving digital transformation and informed decision-making. Despite its significance, many organizations encounter challenges in effectively integrating BDA into their operations, often due to the absence of structured implementation frameworks. These challenges include data quality and integration, infrastructure and scalability issues, and shortage of skilled professionals [1].

While several BDA implementation frameworks has been proposed, a significant number lack empirical validation, limiting their practical applicability. This gap underscores the need for frameworks that are not only theoretically sound but also validated through expert insights to ensure relevance and effectiveness in real-world settings. In response to this, this paper aims to validate and refine a previously developed framework named ADiBA [2], designed to adopt and implement BDA in organizations. Although the initial construction of the framework was based on literature and theoretical model, validation is highly advisable to ascertain its relevance to practical settings.

To facilitate this, expert feedback obtained through structured surveys and FGDs. The quantitative data from the survey were analysed using CVI to assess the relevance of each framework component, while qualitative insights from open-ended responses and FGDs were examined through thematic analysis. The analyses were then used to determine which aspects require changes to achieve the intended objectives.

The primary objective of this study is to enhance the proposed ADiBA framework's validity and practical utility by integrating expert insights, thereby contributing a more robust tool for organizations navigating BDA implementation. By addressing the existing gap in empirically validated frameworks, this research offers a refined, expert-informed model that can serve as a valuable resource for practitioners and research alike.

To achieve these objectives and present our findings comprehensively, the remainder of this paper is structured as follows: Section II provides the background of the previously developed ADiBA framework, including the theoretical models that guided its initial construction. Section III details the mixed method methodology employed for framework validation, covering participant selection and data analysis techniques. Section IV presents the quantitative and qualitative results derived from the expert feedback. Section V outlines the enhancements made to the ADiBA framework based on these findings. Finally, Section VI concludes the paper by summarizing key contributions and discussing avenues for future research.

II. Background

The implementation of BDA within organizations has emerged as an important factor in driving digital transformation and informed decision-making. Despite its significance, many organizations encounter challenges in effectively integrating BDA into their operations, often due to the absence of structured implementation frameworks.

Numerous studies highlight the critical need for proper frameworks, models, or methodologies to successfully implement BDA. For instance, optimizing BDA process is challenging, as it involves combining diverse data assets to produce actionable insights [3]. and improved decision making [4], [5]. Similarly, a business-driven reference architecture is a viable solution to address the high failure rate of BDA implementation projects in public sector organizations, emphasizing the need to systematically consider business use cases and processes before assembling technical aspects [6]. As highlighted in [7], many BDA projects fail or do not deliver promised business value, often due to technical issues (data consolidation, quality, visualization), managerial challenges (inability to gain insights and link them to business problems), and organizational obstacles (changes in decision-making, culture, and clear direction of initiatives). The lack of a structured approach not only can jeopardize decision-making, but also prevent organizations from capitalizing on market opportunities, ultimately compromising their capacity to create value [8]. Furthermore, a significant gap between existing frameworks and the integration of big data into various business functions, explicitly stating the need for developing new models and implementation frameworks for better insights and patterns [9].

While the emerging interest in BDA has led to the proposal of various BDA implementation frameworks, a significant gap persists in the exiting literature. Many of these proposed frameworks primarily focus on the technical aspects of BDA implementation, often overlooking crucial dimensions such as people, organizational structure, culture, and strategic alignment. This narrow focus limits their holistic applicability and can lead to incomplete or unsustainable BDA initiatives within complex organizational environments. Furthermore, a substantial number of these studies propose frameworks without subjecting them to rigorous validation or verification processes, raising questions about their practical utility and real-world effectiveness.

In response to this gap, the ADiBA framework was developed to provide a structured approach to BDA implementation. This framework was initially formulated through a systematic literature review (SLR), which identified key components, steps, and activities essential for successful BDA implementation. The components of ADiBA framework (Fig. 1) are:

1) Prepare immersion of analytic culture: Ensure that organizations can fully leverage data-driven insights for decision-making and strategic growth.

2) Business understanding: Define clear objectives, identifying challenges, and ensuring that analytical efforts contribute to business value

3) Data management and governance: Ensure that data is accurate, secure, compliant, and valuable for decision-making

4) Project planning: Define project objectives, allocate resources effectively, and assess the potential risks and benefits.

5) Data understanding: Ensure that the data used is relevant, accurate, and suitable for analysis and modelling.

6) Data preparation: Transform the data into usable format for analysis and modelling.

7) Tool, infrastructure and technology procurement and presentation: Acquire and deploy necessary technological resources.

8) Business analytics modelling: Create analytical models that interpret data to provide actionable insights.

9) Data analytics product development: Transform insights derived from analytics into dashboards, and reports.

10) Evaluation of model and products: Assessing the performance of analytics modelling and visualization.

11) Data analysis product deployment: Transition the product from development phase to live production environment.

12) Monitoring, maintenance and upgrades: Monitor the performance, perform regular maintenance, and implement upgrades.

13) Inculturation of big data analytics into business: Foster data-driven decision-making, improves operational efficiency, drives innovation, supports strategic planning, and encourages continuous improvement.

The theoretical grounding of ADiBA framework draws upon established model such as the Cross-Industry Standard Process for Data Mining (CRISP-DM) model [10], Kotter's 8-step model [11], DAMA-DMBOK Data Management [12], Data lifecycle [13], and Project Management lifecycle [14]. These models were specifically selected and integrated based on their demonstrated utility in various studies that proposed frameworks for BDA implementation, technology adoption, and organizational change, ensuring a robust foundation for ADiBA.

The CRISP-DM model is a widely adopted, structured methodology for managing data mining projects. It encompasses six iterative phases to provide a comprehensive framework that ensures a systematic approach to data analytics. The Kotter's 8-step model is designed to assist leaders in effectively managing organizational transformation by identifying potential sources of resistance and developing strategies to address them, thereby facilitating a smoother change process. The DAMA-DMBOK framework outlines best practices across key data management areas such as data governance and quality, ensuring robust data management practices. The Data lifecycle models describe the progression of data from creation to disposal, ensuring effective data management throughout its lifespan. Finally, the project management lifecycle offers a structured framework that guides projects from initiation to completion, enhancing the likelihood of success.

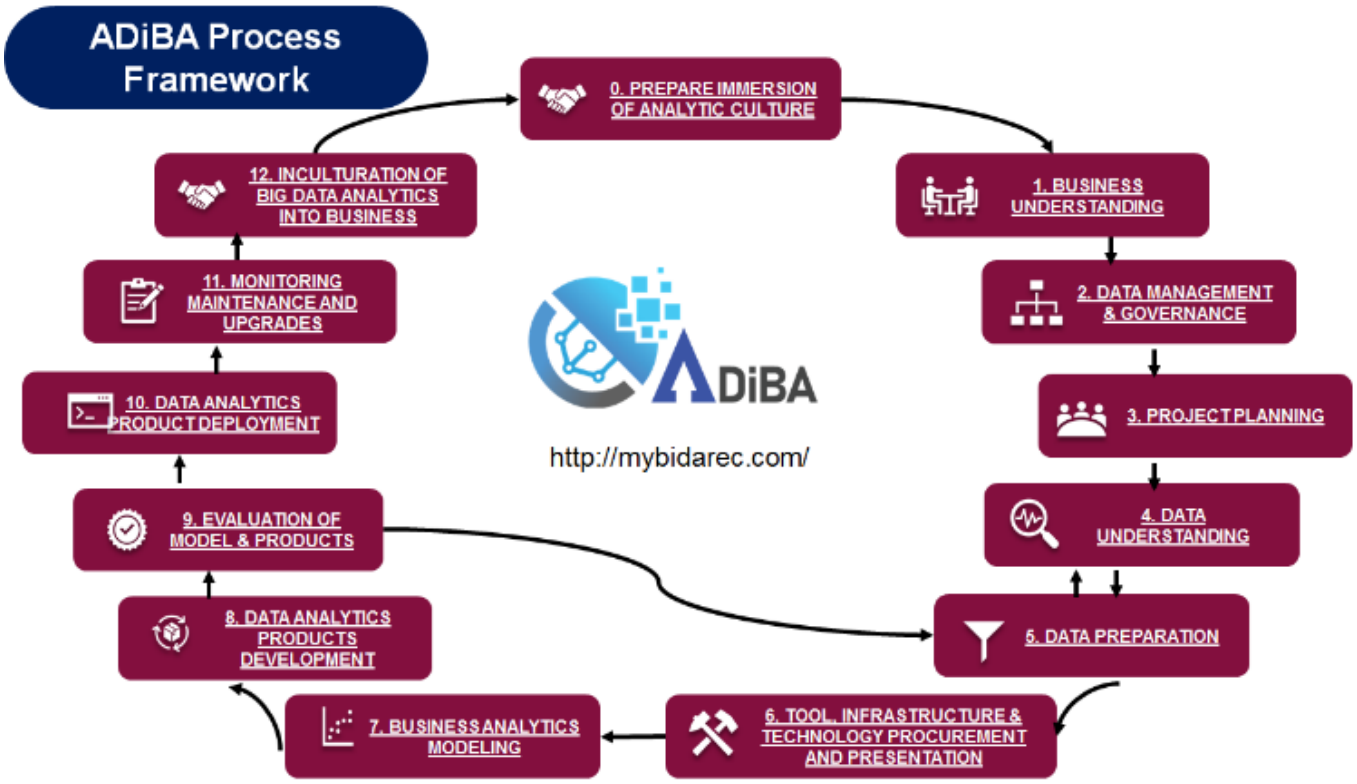

Fig. 1. ADiBA framework.

By synthesizing these models, the ADiBA framework offers a holistic approach to BDA implementation, deliberately addressing both technical execution and the crucial non-technical dimensions of strategic alignment, data management, and organizational change. The ADiBA framework has a step-by-step approach with tools and guidelines that can be used by organizations to implement BDA. These steps can be tailored and adopted selectively based on size, types, resources, and analytics goals of organizations.

Building upon the theoretical foundations and the structured components of the ADiBA framework, this study seeks to validate and refine the framework to ensure its practical applicability in organizational settings. To achieve this, a comprehensive methodological approach was employed, combining quantitative assessments with qualitative insights. The following section details the research design, data collection methods, and procedures to evaluate the relevance of the ADiBA framework in facilitating BDA implementation

III. Methodology

This study adopted a mixed-methods research design to validate and refine the ADiBA framework. The section details the development of the evaluation instrument, the selection criteria for domain experts, the procedures for data collection, and the quantitative (CVI) and qualitative (thematic analysis) approaches used for data analysis. The following subsections elaborate on each methodological phase.

A. Development of Evaluation Instrument

The survey was crafted to assess the relevance of each component within the ADiBA framework. It comprises both quantitative and qualitative elements to capture a holistic view of expert opinion.

For the quantitative assessment, a series of 4-point Likert scale questions were developed for each task (item) under the framework's component that ranged from 1 to 4, where 1 represents "not relevant", 2 represents "somewhat relevant", 3 represents "relevant", and 4 represents "highly relevant". Experts can rate the degree to which each task is applicable and essential within their organizational context. The objectives of assessing the tasks of each component are summarized in Table I.

Complementing the quantitative data, the survey incorporated open-ended questions aimed at eliciting qualitative insights. For each component, experts were invited to suggest any revisions or provide comments on the respective tasks and components. Additionally, a concluding open-ended question sought their overarching thoughts and recommendations concerning the entire ADiBA framework. The questions addressed topics such as the necessity of a structured methodology to implement BDA in organizations and the potential challenges organizations might encounter. These qualitative responses were subjected to thematic analysis, enabling the identification of common themes and nuanced perspectives that could inform further refinement of the framework.

TABLE I. OBJECTIVES FOR TASKS OF ADIBA FRAMEWORK COMPONENTS

Framework Component	Task	Objective
PREPARE IMMERSION OF ANALYTICS CULTURE	0.1	To assess the relevance of creating urgency among members of organization
	0.2	To assess the relevance of building a guiding coalition among members of organization
	0.3	To assess the relevance of creating a vision for change among members of organization
	0.4	To assess the relevance of communication the vision among members of organization
	0.5	To assess the relevance of removing barriers that can hinder the change among members of organization
	0.6	To assess the relevance of creating short-term wins for the organization
	0.7	To assess the relevance of building on the change among members of organization
	0.8	To assess the relevance of anchoring the change in the organizational culture
BUSINESS UNDERSTANDING	1.1	To assess the relevance of identifying the organization's business goal
	1.2	To assess the relevance of assessing the organization's current situation
	1.3	To assess the relevance of defining the organization's data analytics goals or insights
DATA MANAGEMENT & GOVERNANCE	2.1	To assess the relevance of defining the data governance engagement framework
	2.2	To assess the relevance of defining the data governance organization
	2.3	To assess the relevance of developing data security, privacy, sharing, ethics and compliance governance framework
PROJECT PLANNING	3.1	To assess the relevance of identifying organization's business use cases
	3.2	To assess the relevance of estimating the resources required for data analytics project
	3.3	To assess the relevance of performing cost-benefit analysis before starting any data analytics project
	3.4	To assess the relevance of developing a project plan for data analytics project
DATA UNDERSTANDING	4.1	To assess the relevance of defining sources of the data required
	4.2	To assess the relevance of designing and developing data sandbox
	4.3	To assess the relevance of describing the data required
	4.4	To assess the relevance of developing engines for data curation
	4.5	To assess the relevance of verifying the quality of data
DATA PREPARATION	5.1	To assess the relevance of extracting the data required
	5.2	To assess the relevance of transforming the extracted data
	5.3	To assess the relevance of exploring and visualizing the data
	5.4	To assess the relevance of modifying the data
TOOL, TECHNOLOGY, AND INFRASTRUCTURE PROCUREMENT & PRESENTATION	6.1	To assess the relevance of identifying the required tool, technology and infrastructure
	6.2	To assess the relevance of evaluating the required tool, technology and infrastructure
	6.3	To assess the relevance of procuring the required tool, technology and infrastructure
BUSINESS ANALYTICS MODELING	7.1	To assess the relevance of identifying key variables for data analytics modelling
	7.2	To assess the relevance of selecting the suitable modelling techniques
	7.3	To assess the relevance of designing the testing and training dataset
	7.4	To assess the relevance of building the data analytics model
	7.5	To assess the relevance of assessing the data analytics model
	7.6	To assess the relevance of managing the data analytics model
	7.7	To assess the relevance of deploying the data analytics model
DATA ANALYTICS PRODUCT DEVELOPMENT	8.1	To assess the relevance of pre-designing the data analytics product
	8.2	To assess the relevance of designing and developing dashboards
	8.3	To assess the relevance of designing and developing business reports
	8.4	To assess the relevance of developing alerts
EVALUATION OF MODEL AND PRODUCT	9.1	To assess the relevance of performing the data analytics product testing
	9.2	To assess the relevance of performing pilot test

Framework Component	Task	Objective
EVALUATION OF MODEL AND PRODUCT	9.3	To assess the relevance of preparing test report
	9.4	To assess the relevance of determining the next course of actions
DATA ANALYTICS PRODUCT DEPLOYMENT	10.1	To assess the relevance of planning the data analytics product deployment
	10.2	To assess the relevance of planning the monitoring and maintaining the data analytics product
	10.3	To assess the relevance of reporting the final results
	10.4	To assess the relevance of reviewing the data analytics project
MONITORING, MAINTENANCE AND UPGRADES	11.1	To assess the relevance of monitoring the performance of data analytics product
	11.2	To assess the relevance of correcting any errors occurred
	11.3	To assess the relevance of enhancing dashboards, reports, and alerts if required
	11.4	To assess the relevance of replacing or discarding the data analytics product if obsolete
INCULTURATION OF BIG DATA ANALYTICS INTO BUSINESS	12.1	To assess the relevance of generating short-term wins
	12.2	To assess the relevance of sustaining the change in the organization culture
	12.3	To assess the relevance of anchoring the change in the organization culture
	12.4	To assess the relevance of assessing the impact of big data analytics on organization

B. Selections of Experts

To ensure a comprehensive evaluation of the ADiBA framework, domain experts with substantial experience in BDA implementation were selected. These experts were identified through professional networks, industry conferences, and academic collaborations. Invitations outlining the study's objectives and the importance of their participation were sent via email. Table II shows the number of selected experts and their organization.

Even though many experts do not have a formalized framework or methodology for implementing BDA in their organizations, their hands-on experience enables them to determine which components are appropriate and effective when developing and executing BDA projects. This practical knowledge ensures that their evaluations are grounded in real-world applicability, contributing to their organization's progression toward becoming data-driven.

TABLE II. LIST OF EXPERTS

Organization	No of Experts	Government/non-government	Domain
Jabatan Digital Negara	3	Government	ICT
Malaysia Digital Economy Corporation (MDEC)	2	Government	ICT
Malaysia International Shipping Corporation Berhad (MISC)	1	Government	Shipping
Ebdesk Malaysia Sdn. Bhd	1	Non-Government	ICT
Malaysia Marine and Heavy Engineering Holdings Berhad (MMHE)	2	Government	Oil and Gas, Construction
Johor Land Berhad (JLAND)	1	Government	Real Estate
REFREX Sdn. Bhd.	1	Non-Government	ICT
Rebaie Analytics Group	1	Non-Government	ICT
Big Data Institute	1	Non-Government	ICT

C. Data Collection

Data were collected through a structured approach during FGDs sessions, integrating both quantitative and qualitative methods. Two FGDs were conducted as part of the study. The first session took place in Selangor, Malaysia and include representatives from Jabatan Digital Negara, MDEC, MISC, and Ebdesk Malaysia. The second FGD was held in Johor, Malaysia with participation from MHHE, JLAND, and REFREX. Each FGD session commenced with the administration of the framework evaluation survey. This was followed by a facilitated discussion encouraging participants to share their perspectives, allowing them to provide qualitative feedback, suggest revisions, and discuss the applicability of the framework's component in real-world organizational setting.

For the surveys, responses were recorded directly into a digital format, ensuring ease of analysis. The data were then utilized to calculate the CVI. For the qualitative components, a systematic note-taking and reconciliation process was used.

During the Focus Group Discussions (FGDs), two assistant moderators were assigned to systematically document participant inputs using structured note-taking techniques to capture key points, detailed arguments, and verbatim quotations. Immediately following each session, the assistants collaboratively reviewed and reconciled their notes. This process involved cross-verifying observations, resolving discrepancies, and consolidating insights to produce a single, comprehensive and finalized set of notes for each FGD.

Similarly, for the two in-depth interviews conducted in Lisbon, Portugal, one researcher led the conversation while the second focused on detailed note-taking. This collection of finalized, detailed notes from both the FGDs and in-depth interviews constituted the complete qualitative dataset. This dataset was then organized and served as the primary data for thematic analysis.

D. Data Analysis

1) CVI Analysis: The CVI analysis was employed to quantitatively assess the relevance of each task within the framework. Experts rated each task using a 4-point Likert scale, where 1 indicated "not relevant" and 4 indicated "highly relevant". Each task rated as 3 or 4 was converted to '1' to show that the rater finds the task relevant, and tasks rated as 1 or 2 were converted to '0' to show that the rater considers the task irrelevant.

For each task, the I-CVI was calculated using Eq. (1) by dividing the number of experts who rated the task as 1 by the total number of experts. The S-CVI/Ave as shown in Eq. (2) can be determined by averaging the I-CVI scores across all tasks [15]. The following are the formulas for the content validity index calculation:

$$I-CVI = \frac{Number\ of\ experts\ rating\ the\ item\ as\ "Relevant"}{Total\ number\ of\ experts} \quad (1)$$

$$S-CVI/Ave = \frac{\sum I-CVI}{Number\ of\ items\ in\ the\ component} \quad (2)$$

I-CVI with value of 0.78 or higher was considered acceptable for at least 9 raters, following the recommendations by Lynn [16]. For S-CVI/Ave value of 0.90 or above indicated excellent content validity, values between 0.80 and 0.89 suggested the need for minor revision, and values below 0.80 signalled the need for major revision or potential removal [15].

2) Thematic analysis: To explore participant's perspectives and experiences in depth, thematic analysis was conducted following the six-phase approach by Braun and Clarke [17]. Initially, the data were familiarized by reading and re-reading the transcribed FGDs and in-depth interviews. Next, initial codes were generated to identify significant features of the data relevant to the aim of the study and the enhancement of the proposed framework.

These codes were then organized into potential themes, which were reviewed and refined to ensure coherence and distinctiveness. Each theme was clearly defined and named to capture its essence accurately. Finally, a comprehensive report was produced, illustrating the themes with representative data extracts and providing a nuanced understanding of the participant's insights. This systematic approach facilitated a rich and detailed interpretation of the qualitative data.

IV. Result

This section presents the findings derived from the expert evaluation of the proposed ADiBA framework. The analysis incorporates both quantitative and qualitative data collected through the framework evaluation survey, FGDs, and in-depth interviews. The quantitative aspect was analyzed using the CVI to assess the relevance of each component and task within the framework. Meanwhile, qualitative insights obtained from open-ended survey responses and discussion sessions were subjected to thematic analysis to identify key themes, suggestions, and patterns in expert feedback. Together these findings informed the refinement and validation of the framework.

A. CVI Analysis

As per the established criteria, the content validity of the framework was assessed using the I-CVI and S-CVI/Ave. Table III presents the calculated I-CVI for each task, along the aggregated S-CVI/Ave for each component, and their corresponding interpretations based on the predefined threshold.

All the tasks achieved I-CVI values above 0.85, indicating strong agreement among experts regarding their relevance – except for two. The tasks "Remove Barriers" from Prepare Immersion of Analytical Culture component and "Develop Data Security, Privacy, Sharing, Ethics and Compliance Governance Framework" from Data Management and Governance component each scored an I-CVI of 0.77. However, given the minimal difference of 0.01 from the threshold, these tasks are still considered important and relevant. Therefore, rather than being removed, they are retained with minor revisions to improve clarity and better align them with their respective components.

TABLE III. Summary of I-CVI and S-CVI/Ave Values with Interpretation for Framework Components

Component	Task	Task Description (Task)	I-CVI	Interpretation
PREPARE IMMERSION OF ANALYTICS CULTURE	0.1	Create Urgency	0.85	Acceptable
	0.2	Build a Guiding Coalition	0.92	Acceptable
	0.3	Create a Vision for Change	0.92	Acceptable
	0.4	Communicate the vision	0.92	Acceptable
	0.5	Remove Barriers	0.77	Needs revision
	0.6	Create Short-Term Wins	0.85	Acceptable
	0.7	Build on the Change	0.85	Acceptable
	0.8	Anchor the change in the Organization's Culture	0.85	Acceptable
	S-CVI/Ave		0.87	Consider Minor Revision
BUSINESS UNDERSTANDING	1.1	Identify Business Goal	1.00	Acceptable
	1.2	Assess Situation	1.00	Acceptable
	1.3	Define Data Analytics goals or insights	1.00	Acceptable
	S-CVI/Ave		1.00	Component is Acceptable

DATA MANAGEMENT & GOVERNANCE	2.1	Data Governance Engagement Framework	0.85	Acceptable
	2.2	Define Data Governance Organization	0.85	Acceptable
	2.3	Develop Data Security, Privacy, Sharing, Ethics and Compliance Governance Framework	0.77	Needs revision
	S-CVI/Ave		0.82	Consider Minor Revision
PROJECT PLANNING	3.1	Identify Business Use Case	1.00	Acceptable
	3.2	Estimate Resources Required	0.92	Acceptable
	3.3	Perform Cost-Benefit Analysis	0.85	Acceptable
	3.4	Develop Project Plan	0.92	Acceptable
	S-CVI/Ave		0.92	Component is Acceptable
DATA UNDERSTANDING	4.1	Define Data Sources	1.00	Acceptable
	4.2	Design and Develop Data Sandbox	0.85	Acceptable
	4.3	Describe Data	1.00	Acceptable
	4.4	Develop Data Curation Engine	0.85	Acceptable
	4.5	Verify Data Quality	0.92	Acceptable
	S-CVI/Ave		0.92	Component is Acceptable
DATA PREPARATION	5.1	Extract Data	1.00	Acceptable
	5.2	Transform Data	1.00	Acceptable
	5.3	Explore and Visualize Data	0.92	Acceptable
	5.4	Modify Data	0.92	Acceptable
	S-CVI/Ave		0.96	Component is Acceptable
TOOL, TECHNOLOGY, AND INFRASTRUCTURE PROCUREMENT & PRESENTATION	6.1	Identify Required Tools, Infrastructure and Technology	0.92	Acceptable
	6.2	Evaluate Tools, and Technology	0.92	Acceptable
	6.3	Procure Tools	1.00	Acceptable
	S-CVI/Ave		0.95	Component is Acceptable
BUSINESS ANALYTICS MODELING	7.1	Identify Key Variables	0.92	Acceptable
	7.2	Select Modelling Techniques	0.92	Acceptable
	7.3	Design Test	0.92	Acceptable
	7.4	Build Model	0.92	Acceptable
	7.5	Assess Model	0.92	Acceptable
	7.6	Manage Model	0.92	Acceptable
	7.7	Deploy Model	0.92	Acceptable
	S-CVI/Ave		0.92	Component is Acceptable
DATA ANALYTICS PRODUCT DEVELOPMENT	8.1	Pre-Design Stage	0.92	Acceptable
	8.2	Design and Develop Dashboards	1.00	Acceptable
	8.3	Design and Develop Business Reports	1.00	Acceptable
	8.4	Develop Alerts	0.92	Acceptable
	S-CVI/Ave		0.96	Component is Acceptable
EVALUATION OF MODEL AND PRODUCT	9.1	Perform Data Product Testing	1.00	Acceptable
	9.2	Perform Pilot Test	1.00	Acceptable
	9.3	Prepare Test Report	1.00	Acceptable
Component	**Task**	**Task Description (Task)**	**I-CVI**	**Interpretation**
EVALUATION OF MODEL AND PRODUCT	9.4	Determine Next Course of Actions	1.00	Acceptable
	S-CVI/Ave		1.00	Component is Acceptable
DATA ANALYTICS PRODUCT DEPLOYMENT	10.1	Plan Deployment	1.00	Acceptable
	10.2	Plan Monitoring and Maintenance	1.00	Acceptable
	10.3	Report Final Results	1.00	Acceptable
	10.4	Review Project	1.00	Acceptable
	S-CVI/Ave		1.00	Component is Acceptable

MONITORING, MAINTENANCE, AND UPGRADES	11.1	Monitor Performance	1.00	Acceptable
	11.2	Correct Error	1.00	Acceptable
	11.3	Enhance Dashboard, Reports and Alerts	1.00	Acceptable
	11.4	Replace or Discard System if Obsolete	0.92	Acceptable
	S-CVI/Ave		0.98	Component is Acceptable
INCULTURATION OF BIG DATA ANALYTICS INTO BUSINESS	12.1	Generate Short-Term Wins	1.00	Acceptable
	12.2	Sustain: Build on the Change	1.00	Acceptable
	12.3	Anchor the Changes in the Organizational Culture	1.00	Acceptable
	12.4	Assess Impact of Big Data Analytics	1.00	Acceptable
	S-CVI/Ave		1.00	Component is Acceptable

All components recorded S-CVI values of 0.92 and above indicating excellent content validity, with the exception of two components. These two components – Prepare Immersion of Analytical Culture and Data Management and Governance had S-CVI/Ave values of 0.87 and 0.82, respectively. Based on the established interpretation range, these values fall within the 0.80-0.89 band, suggesting the need for minor revisions to enhance clarity or alignment with expert expectations.

From the result, it can be seen that experts provided almost 100% agreements for tasks toward the end of the framework component. It is uncertain whether these agreements reflect genuine perceptions of task relevance, or if they may have resulted from experts becoming fatigue and thus responding less critically or attentively. This introduces a potential bias in the data, as some responses may not fully reflect the experts' considered judgment.

While potential response fatigue cannot be entirely ruled out, the overall results of the CVI analysis indicate that the framework is considered relevant and appropriate by the expert panel. The high I-CVI and S-CVI/Ave values across the majority of tasks and components reflect strong agreement among experts on the framework's content validity.

B. Thematic Analysis

Thematic analysis was conducted to explore expert insights and experiences relevant to each component of the proposed framework. Qualitative data were drawn from open-ended survey responses, FGDs, and in-depth interviews. The thematic analysis revealed specific implementation challenges, enablers, and suggestions, which were mapped against the framework's components to guide further refinement. To ensure clarity and relevance, the thematic analysis findings are organized by the components of the proposed framework, enabling detailed exploration of expert perspectives within each specific area.

1) Thematic analysis by components: For Prepare Immersion for Analytics Culture component, experts highlighted a range of critical improvements and areas requiring clarification. Several experts found that the tasks in this component closely overlap with those in the next component (Business Understanding), leading to confusion, and suggested either merging the two or switching the order to better reflect their purpose. A key recommendation was to establish the data governance team at the outset, before any framework activity begins, to provide strategic direction and oversight. Creating a sense of urgency was another frequently mentioned point, with recommendations to include lessons learned or prior failures as motivation. There was concern over when to conduct maturity and adoption assessments, and a suggestion that these be used at multiple points – before and during framework application as a way to tailor next steps. In summary, Prepare Immersion for Analytics Culture requires clearer structure, stronger leadership components, an emphasis on culture and urgency, and better integration with the broader framework cycle.

Expert feedback on Business Understanding component revealed critical insights on refining the strategic foundation and ensuring the component sets a strong direction for the entire framework. Many experts suggested switching Business Understanding component with Prepare Immersion for Analytics Culture component, as Business Understanding is seen as an essential first step. There was a strong push to include a comprehensive maturity assessment covering both people and infrastructure technology to better inform the organization's readiness for BDA. Experts also recommended defining BDA roadmap under this component and starting with clear enterprise-level goals before diving into specific roles or committee structures. Several comments stressed the importance of clearly identifying the pain point, using tools such as SWOT analysis and impact analysis to understand business challenges and opportunities. Benchmarking with competitors in similar industries was encouraged to help organizations understand where they stand and what best practices to adopt. Feedback also suggested shortening unnecessary early-stage activities such as analysis of contractors and consultants, and instead focusing on the critical success factors and a forward-moving plan. Sustainability and cultural buy-in were also emphasized, with a need to motivate ongoing engagement. Overall, Business Understanding needs clearer guidance, stronger business alignment, and a practical approach to managing constraints while still establishing a solid business case for data-driven transformation.

For Data Governance and Management component, expert feedback emphasized the importance of establishing a clear and adaptive governance structure. Experts suggested that the data organization model whether centralized, decentralized, or hybrid must be well-defined, including distinctions between ICT-driven and business driven models, as well as the roles of data engineers versus data scientists. Additionally, there is a need to provide clear references and guidance on how to structure and assign roles within data governance councils or teams, such as owners, stewards, and risk officers, in alignment

with organizational data maturity. There was also concern about ownership and accountability, particularly regarding the role of data owners and the need to clarify whether this overlap with roles like a data sponsor. Ownership of the data governance framework whether it belongs to the strategy team or data owners, was seen as critical, especially in government contexts where BDA initiatives typically span multiple ministries and agencies. In multi-agency environments, initial agreements often break down when data sharing becomes contentious. This highlighted the need for strategic teams to oversee framework implementation and anticipate political and administrative challenges.

The Project Planning component received expert suggestion focusing on the need for refining task structures and sequencing. There were suggestions to reorganize subtasks – some could be moved to other components, while others could be combined or removed if already addressed elsewhere. Additionally, experts emphasized the importance of well-defined project implementation plan, including risk assessment analysis, which would improve preparedness and help mitigate uncertainties during the execution of BDA projects. A key point raised was the importance of prioritizing platform versus data readiness. Experts questioned which should come first in BDA projects, urging the need for clear guidance based on project context.

In relation to the Data Understanding component, experts pointed out the importance of the foundational role of infrastructure readiness, with multiple reviewers asserting that data understanding activities can only proceed effectively once platforms and data architecture are clearly defined. The need to define data source characteristics and behaviour emerged strongly, including guidance on metadata management, crawler/scraper tools, and the handling of data based on SOPs and business process. Several experts stressed the importance of data profiling and exploratory analysis before attempting data quality checks, citing practices such as measuring missing values and data health status. Data curation engine was recommended to be reframed as “digitalization”, and data ingestion was suggested as a better term, than merely defining data sources. In addition, experts emphasized developing small-scale lake and ensuring that machine-readable formats are prioritized for open data and sharing purposes. Lastly, confusion about the term “data sandbox” was raised, suggesting a need to revise or clearly define it in the framework.

Feedback from experts on the Data Preparation component emphasized the importance of adopting a more agile and iterative approach, with some suggesting that integrating DataOps principles could enhance the adaptability of this phase. A major point raised was the logical sequencing of tasks – experts noted that data processing should be addressed before initiating data exploration and visualization. There were also concerns about task allocation, with the observation that feature engineering might be more appropriate under the Business Analytics Modelling component rather than the current stage. Experts encouraged refining this component to avoid redundancy, especially concerning data validation and missing values, which they noted are already examined in the data understanding phase. These insights point toward the need to streamline the Data Preparation process and ensure that each sub-task is placed in the most relevant component to avoid duplication and confusion.

For the Tool, Technology, and Infrastructure Procurement and Presentation component, experts highlighted a key gap in the component: while the current focus is on tools, there is an evident lack of attention to infrastructure and technology elements. There was a string consensus on the need to expand this component to include implementation activities such as setting up the big data platform after tool procurement, and proof of concept execution using real business cases to validate feasibility. In light of current digital threats, experts recommended integrating cybersecurity requirements both during tool evaluation and procurement, ensuring security compliance and closing potential loopholes. Additionally, while some suggested merging this component with Project Planning, others were open to keeping it separate, provided that the scope is clearly defined and comprehensive.

Experts input on Business Analytics Modelling component suggested the importance of continuous improvement and clarity of expected outcome. One key theme that emerge was the need to ensure that the analytics models remain accurate and relevant when applied newly incoming datasets. Additionally, experts highlighted the need to include expected results or anticipated outcomes of each modelling task.

For the Data Analytic Product Development, experts pointed three key areas of enhancement. First, they noted that time-series visualizations are integrated and aligned with industry standards. Second, experts recommend exploring non-linear dashboard layouts, which break away from traditional grid-based or sequential flows. Lastly, there was a suggestion to incorporate data modelling directly within the dashboard development process.

For the Evaluation of Model and Product, experts revealed several areas of confusion and suggestions for improvement. A recurring theme was the structural clarity of the evaluation component, particularly the placement of model evaluation and product evaluation. Experts questioned whether model evaluation should be integrated as a subphase under Business Analytics Modelling component, as they are closely connected. Similarly, product evaluation, if it refers to dashboard, was suggested to be part of the Data Analytics Product Development component. Furthermore, the importance of practical evaluation strategies was emphasized, recommending the inclusion of a proper test plan, diverse testing approaches, and migration strategies to ensure smooth deployment.

For the Data Analytic Product Deployment component, experts suggested that the inclusion of a clear roll-out plan to ensure the smooth implementation of big data initiatives across the organization.

Feedback on the Monitoring, Maintenance, and Upgrades component emphasized the importance of providing a scalable infrastructure that can accommodate future growth in data volume and processing needs.

Finally, for the Inculturation of Big Data Analytics into Business component, experts highlighted the need for continuous efforts to embed analytics practices within

organizational culture. Experts suggested conducting a post-maturity assessment to monitor progress, implementing ongoing campaigns or awareness programs focusing on data-related challenges, and organizing regular checkpoint meetings by the steering or working committee to track developments. Moreover, performing impact analysis simulations and identifying "quick wins" alongside medium-term plans were highlighted to sustain momentum and demonstrate early value in the adoption of BDA.

The summarized thematic analysis for each component according to themes can be seen in the following Table IV.

TABLE IV. SUMMARY OF THEMATIC ANALYSIS BY THEME AND ITS COMPONENTS

Theme	Relevant Component	Key Issues	Expert Suggestions
Sequencing and Structural Clarity	Prepare Immersion for Analytics Culture, Business Understanding, Project Planning, Evaluation of Model and Product	Overlap between components; unclear starting point; misplaced tasks or evaluations	Switch or merge components 1 & 2; clearly define sequence of tasks; move evaluation activities under appropriate phases (e.g., modelling or dashboard development)
Governance and Role Clarity	Prepare Immersion for Analytics Culture, Business Understanding, Data Governance and Management,	Undefined roles; lack of ownership and accountability; unclear governance models	Define centralized/decentralized/hybrid models; assign clear roles (owners, stewards); establish governance team early
Readiness and Maturity Assessment	Prepare Immersion for Analytics Culture, Business Understanding, Inculturation of Big Data Analytics into Business	Readiness not assessed early or revisited	Conduct people + tech maturity assessments at start and mid-cycle; use post-maturity assessments after implementation
Cultural Embedding and Change Management	Prepare Immersion for Analytics Culture, Business Understanding, Inculturation of Big Data Analytics into Business	Weak emphasis on change culture and ongoing motivation	Create urgency using past lessons; embed campaigns and checkpoint meetings; track quick wins and momentum
Infrastructure and Platform Readiness	Data Understanding, Tool, Technology, and Infrastructure Procurement and Presentation, Monitoring, Maintenance, and Upgrades	Underdeveloped infrastructure focus; unclear timing for platform readiness	Address infrastructure before data work; add infra setup post-procurement; ensure scalability for growth
Agile and Iterative Practice	Data Preparation, Business Analytics Modelling, Data Analytic Product Development	Phases too linear or redundant; lack of agility	Apply agile/DataOps principles; reposition feature engineering; make components more iterative and streamlined
Security and Risk Management	Project Planning, Tool, Technology, and Infrastructure Procurement and Presentation,	Cybersecurity missing; risk planning weak	Add cybersecurity criteria to procurement; include risk analysis in planning
Output Clarity and Evaluation	Business Analytics Modelling, Data Analytic Product Development, Evaluation of Model and Product	Lack of clarity on expected outcomes; unclear evaluation scope	Define expected model results; create test/migration plans; relocate product evaluation to correct phase
Visualization and Usability	Data Analytic Product Development	Rigid layout; missed integration opportunities	Adopt time-series and non-linear dashboard options; embed modelling directly into visual design
Deployment Planning and Execution	Project Planning, Data Analytic Product Deployment	No clear roll-out plan; poor execution readiness	Define deployment steps; align platform/data readiness before execution
Data Quality and Profiling	Data Understanding, Data Preparation	Redundancy and poor sequencing of data checks	Emphasize data profiling before validation; avoid duplicate quality tasks across components

1) Thematic analysis of overall framework: Overall, experts revealed several critical themes that reflect both structural and practical challenges. One of the most pressing concerns was clarity and connectivity within the framework. Experts noted that the framework appeared disjointed, with unclear linkages between components. This lack of cohesion made it difficult for users to understand how the process flows from one stage to the next or how long each stage might take. The absence of a defined timeline or lifecycle for the framework components further compounded this issue, leading to suggestions for a clearer depiction of the overall process, including estimated durations and interdependencies.

The usability and agility of the framework were also scrutinized. Experts emphasized the importance of incorporating flexible decision-making mechanisms, particularly for context where data availability is limited or governance issues arise. This aligns with concerns that BDA adoption often fails due to an overemphasis on technology, while underestimating organizational and cultural aspects. To counter this, there were calls for more agile and adaptable framework that could accommodate varying entry points depending on an organization's maturity level or existing infrastructure.

Experts highlighted that the tools and instruments included in the framework appeared standard and more appropriate for beginners. However, they recommended that these tools be better integrated across the components to ensures continuity and support scalability. A particular emphasis was placed on improving the clarity and usability of some instruments, which were seen as difficult to interpret or complete without guidance.

Another recurring theme was the importance of infrastructure readiness. Multiple experts emphasized that infrastructure should be fully in place prior to initiating BDA projects, particularly in environments where phased implementation may not be viable. This was tied to the broader issue of platform and use case development, both of which were deemed essential before launching analytics activities.

Organizational roles and structure emerged as a key theme, with experts stressing the need for two distinct but collaborative working teams – data scientists and data engineers. Moreover, a dedicated BDA team should be

assigned exclusively to analytics work, without being burdened by unrelated tasks.

A strong leadership structure was considered vital, with top-down instructions and the appointment of BDA champions cited as enablers of successful implementation. In the absence of leadership or designated champions, enculturation and sustained adoption were identified as areas of concern.

Lastly, experts noted that the "early components" of the framework particularly problem identification were the most challenging. This was attributed to organizations lacking clarity in articulating business problems or use cases. Some experts proposed incorporating an "as-is/to-be" study at the beginning to define current capabilities and desired outcomes more effectively.

The summarized thematic analysis for overall framework according to themes can be seen in the following Table V.

TABLE V. SUMMARY OF THEMATIC ANALYSIS OF THE OVERALL FRAMEWORK

Theme	Expert Insights and Suggestions
Clarity and Connectivity	Framework components appeared disjointed; unclear linkages and lack of flow between stages. Suggested inclusion of process flow, interdependencies, and estimated timelines.
Usability and Agility	Need for more flexibility in the framework to accommodate varied contexts, such as low data maturity or limited infrastructure. Recommends support for different entry points.
Tools and Instruments	Tools included were seen as basic; need to enhance integration across components and improve usability. Some instruments required more guidance or simplification.
Infrastructure Readiness	Strong emphasis on ensuring infrastructure and platforms is in place before initiating BDA work. Phased implementation is not always suitable.
Organizational Structure	Clear roles needed: separate data scientists and data engineers, with a dedicated BDA team. Leadership and BDA champions essential for sustained adoption and success.
Leadership and Culture	Top-down support and cultural readiness critical. Lack of leadership seen as a barrier to adoption and long-term success.
Early-Stage Complexity	Early framework stages, especially problem identification, were most difficult. Suggested including an "as-is/to-be" study to better define current state and future goals.

The expert feedback underscores the importance of refining the framework to enhance its practical applicability and ensure it can support diverse organizational contexts and maturity levels. These insights directly inform the subsequent framework enhancement process.

V. ADIBA FRAMEWORK ENHANCEMENT

Based on the CVI and thematic analyses, the ADiBA framework underwent significant enhancements. While the framework still retained its thirteen core components, these revisions strategically refined its overall structure and significantly modified the underlying components and tasks, thereby improving its suitability for broader application. Specifically, feedback informed meticulous modifications, with components and tasks being added, revised, or removed to enhance clarity, eliminate redundancy, and integrate actionable assessment points. The details of these integrated enhancements are provided below, with the finalized visual representation of the ADiBA framework and its update components presented in Table VI and Fig. 2 at the end of this section.

For the first component, the name Prepare Immersion of Analytics Culture was changed to Enterprise Big Data Analytics Preparation for better and clearer purposes. Two new tasks were added to the component: Set up Strategic Planning Team [18], and Perform Internal Situation Analysis [10], [19], [20], [21], [22], [23], [24]. Setting up teams responsible for steering, planning and monitoring Big Data Analytics adoption and implementation in organizations is essential to ensure data initiatives align with overall business objectives. The team will consider the people, processes, and data infrastructure involved and guide the organization toward data-driven goals. Although the experts suggested that setting up the data governance team must be established early before any framework activities can be conducted, it is more important to set the strategic planning team to oversee the whole BDA implementation. The task "Performing an Internal Situation Analysis" is introduced to address the expert's recommendation to define specific points in the framework for conducting maturity and adoption assessment, especially before its application. This task includes sub-tasks such as administering surveys to assess the organization's structure and to identify key personnel who can provide accurate insights into the organization's data and analytics maturity. Additionally, it enables the organization to pinpoint existing gaps in skills and capabilities. This is crucial because possessing technical skills alone does not guarantee effective execution; some individuals may have the required skills but the lack of contextual understanding or practical ability to perform tasks effectively. This task was also introduced to address redundancy with a similar task "Assess Situation" in the Business Understanding component. The overlapping task in Business Understanding component will be removed to avoid duplication and ensure a clearer, more streamlined activities within the framework. To strengthen the leadership aspects within this component, a subtask related to securing leadership commitment was added under task "Build a Guiding Coalition" to ensure active commitment and visible support from executive leaders to champion the BDA initiatives. Based on the CVI analysis, the "Remove Barriers" task received a rating below the acceptable threshold, indicating that some experts questioned its clarity and relevance. Rather that removing the task entirely, it was retained and refined to address these concerns. The task now includes a more specific focus on the types of barriers that commonly hinder BDA readiness, and outlines actionable strategies for overcoming these barriers. To improve more on the clarity and focus of this component, two tasks "Build on the Change" and "Anchor the Change in the Organization's Culture" were removed, as they were redundant with tasks included in the final component of the framework – Data Analytics Product Enculturation.

TABLE VI. ENHANCED ADIBA FRAMEWORK COMPONENTS AND TASKS

No.	Enhanced Framework		
	Component	***Task***	
1	ENTERPRISE BIG DATA ANALYTICS PREPARATION	BDAP.1	Set up Strategic Planning Team
		BDAP.2	Perform Internal Situation Analysis
		BDAP.3	Create a Sense of Urgency
		BDAP.4	Build a Guiding Coalition
		BDAP.5	Form Strategic Vision and Initiatives
		BDAP.6	Enlist a Volunteer Army
		BDAP.7	Remove Barriers
		BDAP.8	Generate Short-Term Wins
2	BUSINESS UNDERSTANDING	BU.1	Identify Business Goal
		BU.2	Analyse Strategic Context and Organizational Structure
		BU.3	Define Data Analytics Goals or Insights
3	PROJECT PLANNING	PP.1	Identify Business Use Case
		PP.2	Perform Cost-Benefit Analysis
		PP.3	Develop Project Plan
4	DATA GOVERNANCE	DG.1	Define Data Governance Organization
		DG.2	Develop Data Security, Privacy, Sharing, Ethics and Compliance Governance Framework
		DG.3	Define Data Quality Process
5	DATA AND ANALYTICS REPOSITORY MANAGEMENT	DARM.1	Data Ingestion
		DARM.2	Design and Develop Enterprise Single Source of Truth Master Data Management
		DARM.3	Develop Enterprise Metadata Hub
		DARM.4	Verify and Implement Data Quality
		DARM.5	Incorporate New Data Request
		DARM.6	Maintain Data Analytics Inventories
6	TOOL, TECHNOLOGY, AND INFRASTRUCTURE PROCUREMENT & PREPARATION	TTIP.1	Identify Required Tools, Technology, and Infrastructure
		TTIP.2	Evaluate Tools, Technology, and Infrastructure
		TTIP.3	Procure and Prepare Tools, Technology, and Infrastructure
7	DATA ANALYTICS VISUALIZATION DEVELOPMENT	DAVD.1	Pre-Design Stage
		DAVD.2	Design and Develop Dashboards
8	DATA ANALYTICS PRODUCT MODELING	DAPM.1	Identify Key Variables
		DAPM.2	Select Modelling Techniques
		DAPM.3	Perform Data Sampling
		DAPM.4	Feature Engineering
		DAPM.5	Build Model
		DAPM.6	Assess Model
		DAPM.7	Manage and Deploy Model
9	DATA PREPARATION	DP.1	Identify Data Requirements and Extract Data
		DP.2	Explore and Transform Data
		DP.3	Publish Data
10	DATA ANALYTICS PRODUCT EVALUATION	DAPE.1	Perform Dashboard Testing
		DAPE.2	Prepare Evaluation Report and Next Course of Action
11	DATA ANALYTICS PRODUCT DEPLOYMENT	DAPD.1	Deploy Dashboard
		DAPD.2	Perform Stress Test

		DAPD.3	Document the Data Analytics Product
12	DATA ANALYTICS PRODUCT MONITORING, MAINTENANCE AND UPGRADES	MMU.1	Plan the Performance Monitoring
		MMU.2	Correct Any Errors
		MMU.3	Enhance Dashboards
		MMU.4	Replace or Discard Dashboards if Obsolete
No.	**Enhanced Framework**		
	Component	***Task***	
13	DATA ANALYTICS PRODUCT ENCULTURATION	DAE.1	Sustain the Changes
		DAE.2	Anchor the Changes in the Organizational Culture
		DAE.3	Assess Impact of Big Data Analytics

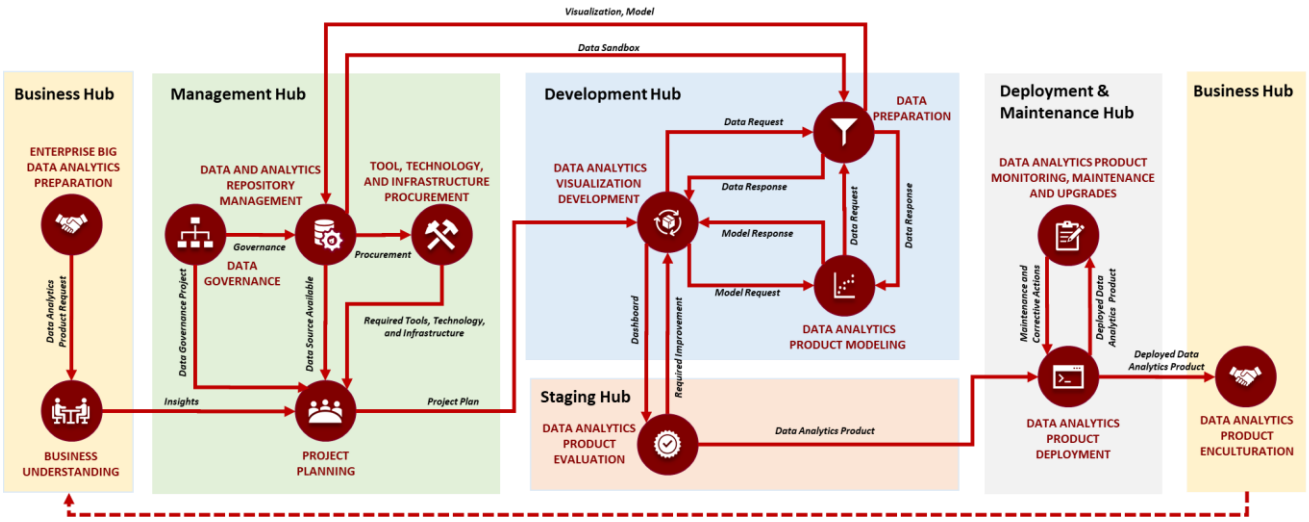

Fig. 2. Enhanced visual representation of the ADiBA framework.

For the Business Understanding component, the task previously titled “Assess Situation” was renamed to “Analyse Strategic Context and Organizational Structure” to avoid confusion with another existing task, “Perform Internal Situation Analysis” in Prepare Immersion of Analytics Culture component. Although both tasks involve forms of assessment, their focus and content are distinct. “Perform Internal Situation Analysis” task emphasizes understanding the organization’s current structure, readiness, and maturity in data and analytics, often through surveys or interviews. In contrast, the renamed task focuses on analysing strategic elements such as the organization’s goals and objectives, SWOT analysis, roles and responsibilities, customer charter, and key performance indicators. Following expert feedback, the task “Identify Business Goals” was enhanced to include the definition of critical success factors. The more extensive development of solid business cases as recommended by experts, has been comprehensively integrated into the Project Planning component.

The Data Management and Governance component was changed to Data Governance as the tasks were more aligned with governance-related activities. Additionally, the “Data Governance Engagement Framework” task was removed due to overlap with “Define the Data Governance Organization”, particularly in role and structure definition. Based on expert feedback, several enhancements were made to strengthen the “Define the Data Governance Organization” task. This task now incorporates outlining the roles of data engineers versus data scientists within the governance structure, and assigning responsibilities within data governance councils or teams. Furthermore, it addresses ownership and accountability, especially in distinguishing the roles of data owners and sponsors, and defines who should own the governance framework – whether it is the strategy team or data owners in both single and multi-agency contexts. Political and administrative challenges in multi-agency environments are acknowledged, and the role of strategic teams in overseeing governance framework implementation is emphasized. The task "Develop Data Security, Privacy, Sharing, Ethics and Compliance Governance Framework" received a CVI rating below the threshold, indicating a need for refinement. Although no explicit justification was provided by the experts, the low rating may be dues to the task’s broad scope and lack of practical guidance. To address this, several subtasks were included such as identifying applicable data protection laws and regulations; define policies for data access, classification, and retention; and establish ethical guidelines for analytics. A new task, “Define the Data Quality Process” [10] was added to strengthen the component’s foundation. The task focuses on data quality requirements and improvement programs and preparing data quality tests that cover all data quality dimensions: completeness, conformity, consistency, accuracy, uniqueness, integrity, validity, and timeliness. This is to ensure

data quality is a critical element of data governance, as it supports reliable data for analytics and decision-making.

The Project Planning component has been strengthened to provide a more comprehensive approach to developing project plans. This was achieved by combining the formerly separate "Estimate Resources Required" and "Perform Cost-Benefit Analysis" tasks into a unified process. This is to ensure that resource allocation is directly informed by a thoroughly financial and practical assessment. Furthermore, the updated "Develop Project Plan" task now explicitly incorporates a well-defined project implementation plan and integrates comprehensive risk assessment analysis, ensuring all potential challenges are identified and addressed proactively within the planning phase.

The Data Understanding component has undergone a comprehensive transformation, now formally established as Data and Analytics Repository Management. This strategic evolution underscores a deeper focus on not just comprehending data, but actively managing it within a robust repository environment, which emphasizes on infrastructure readiness for all subsequent data activities. This component's tasks have been meticulously refined and expanded. The initial task, formerly known as "Define Data Sources" has been reconceptualized as "Data Ingestion", which now provides guidance on defining intricate data source characteristics and behaviour, and strategically incorporates the use of crawler/scraper tools for efficient and structure data acquisition. The "Design and Develop Data Sandbox" task was renamed to "Design and Develop Enterprise Single Source of Truth Master Data Management" [25]. This is to detail the design and development of enterprise-wide data consistency frameworks, including data warehouses, data marts, data lakes, and integrated enterprise master data management with robust integrity checks. The "Describe Data" task was changed to "Develop Enterprise Metadata Hub" [26] to define data's metadata and incorporate advanced metadata management strategies for enhanced discoverability and governance. The experts suggested to change the "Develop Data Curation Engine" task to "Digitalization", but it seems to be too broad and abstract for a specific task. The subtasks described under this task align closely with what is now covered under the "Data Ingestion" task. Therefore, to ensure clarity and avoid redundancy within the component, the most logical approach would be to fully incorporate the development of data extraction engines / data input portals / data capturing systems directly into the "Data Ingestion" task. Significant enhancements have been made to the task "Verify and Implement Data Quality" as detailed by [10], [20], [22], [23], [27], [28], [29], [30], [31], and [32]. Organizations can identify the data quality requirements and their problems and implement the data quality measures and problem rectification. Two new tasks were added to this component: Incorporate New Data Requests and Maintain Data Analytics Inventories. Both designed to ensure continuous and managed growth of the data and analytics repository. Throughout all tasks, there is a clear prioritization of machine-readable formats to facilitate open data and efficient sharing, further enhancing the utility and accessibility of the managed data assets.

The tasks remained the same for the Tool, Technology, and Infrastructure Procurement & Presentation component. The only changes that were made were to the component and task names to make the purposes much more straightforward. The scope was broadened to include infrastructure and technology elements, moving beyond just tools to encompass he entire foundational environment.

The Data Analytics Visualization Development component, formerly "Data Analytics Product Development", has been refined to focus on creating impactful visual outputs. The tasks "Design and Develop Business Reports" and "Develop Alerts" were merged into "Design and Develop Dashboards" task.to further enhance this component, the "Design and Develop Dashboards" tasks now explicitly ensures that time-series visualizations are integrated and aligned with industry standards, providing clear insights into trends over time. This task also encourages exploring and suggesting non-linear dashboard layouts to create more intuitive and engaging user experiences.

The Data Analytics Product Modelling component, previously known as Business Analytics Modelling, has undergone a focused enhancement to better reflect its purpose and incorporate crucial best practices. While retaining its core responsibilities, the component now explicitly includes a vital new task: Feature Engineering [33]. This process encompasses feature extraction, selection, or reduction, and data augmentation as needed, significantly enriching the data preparation for model building. The "Design Test" task has also been refined and renamed to "Perform Data sampling", where data from the prepared sandbox is strategically selected and split into training and testing sets, with option to perform bootstrapping if the sample size is insufficient. To ensure models remain accurate and relevant over time, the need for continuous improvement within the "Manage and Deploy Model" task is emphasized. This ensures ongoing monitoring and recalibration as new data emerges. Additionally, the "Select Modelling Techniques" and "Build Model" tasks now require the definition of expected results or anticipated outcomes.

For the Data Preparation component, the initial "Extract Data" task has been expanded and renamed to "Identify Data Requirements and Extract Data", a task highlighted by [10], [34], and [35], emphasizing the crucial step of defining data needs before extraction. The workflow is streamlined by merging the "Transform Data" and "Explore and Visualize Data" into a single, comprehensive task: "Explore and Transform Data". This task is now central to preparing data for machine readability, which includes steps such as exploring data, cleaning data, transforming data, identifying and treating missing values, detecting and treating outliers, normalizing data, and tagging and annotating data. While "Feature engineering" has been re-evaluated and primarily moved to the Data Analytics Product Modelling component to avoid redundancy, data validation and the handling of missing values remain firmly within the "Explore and Transform Data" to prevent overlap with the Data and Analytics Repository Management component. The redundant "Modify Data" task was removed, and a new "Publish Data" task was introduced to

ensure prepared data is readily available to requesters in a data sandbox.

The Data Analytics Product Evaluation component, previously known as "Evaluation of the Model and Product". Has been refined to streamline its processes and enhance clarity. We've consolidated the original tasks into two comprehensive steps: "Perform Dashboard Testing" and "Prepare Evaluation Report and Next Course of Action". The "Perform Dashboard Testing" task now integrates component testing, analytic product testing, and crucial user acceptance and satisfaction testing, ensuring a thorough assessment. These diverse testing approaches include a broader range of validation techniques. While model evaluation is now considered for integration into the Data Analytics Product Modelling component, and dashboard-specific product evaluation might align with Data Analytics Product Development to avoid redundancy, this component retains its focus on overarching product validation. For the "Prepare Evaluation Report and Next Course of Action" task, defects are recorded, potential actions identified, and a final decision is made regarding product deployment. The task also includes essential guidance on migration strategies for smooth deployment, ensuring a seamless transition for the product.

For the Data Analytics Product Deployment component, the "Plan Monitoring and Maintenance" task was strategically moved to a subsequent component focused on ongoing monitoring activities, allowing this stage to concentrate purely on deployment. The "Deploy Dashboard" task includes the development of a clear roll-out plan for organization-wide implementation. A new critical task, "Perform Stress Test" was added to evaluate the dashboard's performance and stability under extreme or heavy loads. Additionally, the "Report Final Results" and "Review Project" tasks were merged into a single, comprehensive task: "Document the Data Analytics Product", ensuring all relevant information is captured.

The Monitoring, Maintenance, and Upgrades component has been refined and renamed to Data Analytics Product Monitoring, Maintenance, and Upgrades. This change clarifies that its focus solely on the data analytic product, not the entire ADiBA framework. While the core responsibilities remain consistent, the task names were updated for better clarity. The further enhance this component, the "Plan the Performance Monitoring" task now emphasizes the importance of a scalable infrastructure to accommodate future growth. The other tasks, "Correct any Errors", "Enhance Dashboards", and "Replace or Discard Dashboards if Obsolete", continue to ensure the long-term reliability and effectiveness of the data analytics product.

The Inculturation of Big Data Analytics into Business component has been refined and renamed to Data Analytics Product Enculturation, more accurately reflecting its purposes of embedding data analytics within the organization. While the core tasks remain, "Generate Short-Term Wins" was removed to avoid repetition with the earlier component. The finalized tasks are now: "Sustain the Changes", "Anchor the Changes in the Organizational Culture", and "Assess Impact of Big Data Analytics". The "Sustain the Changes" task now emphasizes continuous efforts to embed analytical practices and includes organizing regular checkpoint meetings by the steering and working committee to maintain momentum. For "Anchor the Changes in the Organizational Culture" task, the need for ongoing campaigns or awareness programs focusing on data-related challenges was integrated, fostering a data-driven mindset throughout the organization. Finally, the "Assess Impact of Big Data Analytics" task is strengthened by the inclusion of conducting a post-maturity assessment and performing impact analysis simulations, allowing a comprehensive evaluation of the analytics product's effectiveness and organizational transformation.

The ADiBA framework has undergone substantial refinement, building on its initial reorganization. While the framework still retains its thirteen core components, significant changes were made to their individual tasks and broader component definitions to enhance its effectiveness. These components are now strategically grouped into five distinct hubs – Business, Management, Development, Staging, and Deployment & Maintenance – to differentiate the phases and gather related functions, thereby improving process flow and logical alignment. The visual representation of the ADiBA framework can be seen in Fig. 2.

The revised framework begins with the Enterprise Big Data Analytics Preparation component, which outlines steps to prepare the organization for a data-driven culture. This preparatory stage is now implicitly strengthened by the expert emphasis on strong leadership, top-down instructions, and the formation of a dedicated BDA team (comprising distinct data scientists and data engineers), all crucial for effective enculturation. The deliverable of this component is the data analytics product requested by the organization. Next, the Business Understanding component helps organizations articulate their goals and problems, ensuring BDA delivers desired values and empowers decision-making. Critically, to address challenges in early problem identification, this component is now enhanced by incorporating an "as-is/to-be" study to more effectively define current capabilities and desired outcomes.

The Data Governance, Data and Analytics Repository Management, and Tool, Technology, and Infrastructure Procurement & Preparation components can be conducted concurrently, established and managed independently of specific BDA projects. These activities generate the overarching data governance project, detailed insights on available data assets, and the necessary tools, technologies and infrastructure. They thus serve as enabling pillars that support any subsequent BDA initiatives integrated within this framework. Furthermore, based on expert feedback, the framework now explicitly states that infrastructure should be fully in place prior to initiating BDA projects, particularly in environments where phased implementation isn't viable.

Organizations then use this strengthened information to plan the project through the Project Planning component. The project plan moves into the Development Hub, which includes Data Analytics Visualization Development, Data Analytics Product Modelling, and Data Preparation. These processes are iterative, ensuring the efficient development of the dashboard along with its underlying data and analytics model. This iterative approach now explicitly embodies the framework's

enhanced usability and agility, integrating flexible decision-making mechanisms particularly relevant for context with limited data availability or governance issues, and allowing for varying entry points based on organizational maturity.

Following development, dashboards undergo various testing in the Data Analytics Product Evaluation component before being deployed via the Data Analytics Product Deployment component. The Data Analytics Product Monitoring. Maintenance, and Upgrades component handles ongoing corrections or enhancements. Finally, the Data Analytics Product enculturation component outlines steps to embed the data analytics into business practices. This final stage is directly supported by the framework's emphasis on fostering strong leadership and the role of the BDA champions, ensuring the sustained adoption and cultural anchoring of BDA within organization.

Ultimately, these enhancements directly address the challenges highlighted by experts, forging a BDA implementation framework that is clearer, more agile, and more comprehensively integrated. The result is a more practical and effective guide for organizations navigating their data analytics journey.

VI. Conclusion

Recognizing the necessity for a structured pathway in BDA implementation in organizations, this study undertook the enhancement of the existing ADiBA framework. Initially developed through systematic literature review, the framework's refinement process involved a comprehensive mixed-methods survey. Domain experts provided quantitative feedback via a five-point Likert scale, which was then assessed using the CVI against an I-CVI threshold of 0.78. parallel to this, qualitative data from open-ended questions, FGDs, and in-depth interviews were subjected to thematic analysis, revealing key insights into the framework's clarity and practical application. The integration of these empirical findings directly guided the strategic adjustments made to the framework's various components.

This study makes a significant contribution by transforming a theoretically derived framework into an empirically validated and refined guide for BDA implementation. The enhances ADiBA framework offers organizations a robust and expert-informed tool to navigate the complexities of becoming data-driven, potentially accelerating digital transformation efforts and improving decision-making process. Theoretically, this research contributes to the body of knowledge on framework development and validation methodologies in the context of information systems.

While this study refined the ADiBA framework based on expert insights, it is important to acknowledge that the validation was primarily based on expert perception. Practical application and studies over time are essential for a full assessment of its efficacy.

Looking ahead, the next crucial step involves a more comprehensive verification of the enhanced ADiBA framework through real-life case studies within actual organizations. The plan is to identify several organizations currently undertaking BDA projects and guide them through the enhanced ADiBA framework's components. By integrating the framework into their existing processes, its practical utility and impact on their journey to becoming data-driven entities can be observed. From these case studies, in-depth feedback will be collected from organizational stakeholders regarding the framework's applicability, ease of use, and effectiveness in addressing their BDA challenges. This practical application will provide valuable insights into its efficacy and adaptability in diverse operational contexts, further strengthening its utility for BDA implementation and leading to subsequent rounds of refinement.

Beyond these immediate plans, potential avenues for future exploration include extending the ADiBA framework to incorporate emerging technologies like Artificial Intelligence (AI) and Machine Learning (ML) integration strategies. Further research could also investigate the framework's applicability across different industry sectors or organizational sizes, as well as developing a digital tool or assessment instrument based on the framework to aid organizations in self-assessing their BDA readiness.

An In-Depth Analysis of Security Flaws in Advanced Authentication Protocols for the Internet of Medical Things

Haewon Byeon
Department of Future Technology, Korea University of Technology and Education (KOREA TECH), Cheonan 31253, South Korea

***Abstract*—This study evaluates a four-factor authentication protocol designed for IoT healthcare systems, identifying several key vulnerabilities that could compromise its security. The analysis highlights risks associated with node cloning, insider threats, biometric data security, session management, and scalability. To address these vulnerabilities, the study proposes a series of enhancements, including the implementation of Physical Unclonable Functions (PUFs) to prevent node cloning and the use of advanced encryption techniques, such as homomorphic encryption, to protect biometric data. Additionally, the adoption of role-based access control (RBAC) and attribute-based access control (ABAC) systems can mitigate insider threats by limiting user permissions. Optimizing session management through strict expiration and key rotation policies can maintain session integrity, while lightweight cryptographic algorithms and adaptive power management techniques enhance scalability and resource utilization. Future research directions include exploring quantum-resistant cryptographic algorithms and developing adaptive security policies leveraging artificial intelligence. These efforts are essential for maintaining the protocol's resilience against evolving threats and ensuring the secure operation of IoT-based healthcare systems.**

***Keywords*—Four-factor authentication; IoT Healthcare security; physical unclonable functions; quantum-resistant cryptography; biometric data protection**

I. Introduction

The Internet of Medical Things (IoMT) represents a significant advancement in the convergence of healthcare and technology. By interconnecting medical devices and healthcare systems through the internet, IoMT enables real-time monitoring, diagnosis, and treatment, ultimately improving patient outcomes and operational efficiency (Fig. 1). These technologies facilitate continuous patient monitoring and provide healthcare professionals with timely data, reducing the need for frequent hospital visits and enabling early intervention in critical situations [1].

As IoMT becomes more integrated into healthcare infrastructures, the security and privacy of sensitive medical data have emerged as paramount concerns. The data generated and transmitted by IoMT devices is highly sensitive, often containing personal health information that, if compromised, could lead to severe consequences for both patients and healthcare providers [2]. This necessitates robust security measures to protect against unauthorized access, data breaches, and cyber threats.

Authentication protocols play a critical role in securing IoMT systems by ensuring that only authorized users and devices can access sensitive data. Traditional authentication methods, typically based on single or dual-factor systems, have proven inadequate in the face of sophisticated cyber-attacks [3]. As a result, there is a growing need for more advanced authentication protocols that can provide comprehensive security in IoMT environments.

The development of four-factor authentication protocols presents a promising solution to these challenges [4]. By incorporating multiple authentication factors—such as knowledge-based (passwords), possession-based (smart cards), inherence-based (biometric data), and contextual (location or device-specific attributes)—these protocols offer enhanced security by requiring multiple forms of verification [5]. This layered approach significantly reduces the risk of unauthorized access, as an attacker would need to compromise all four factors to gain entry.

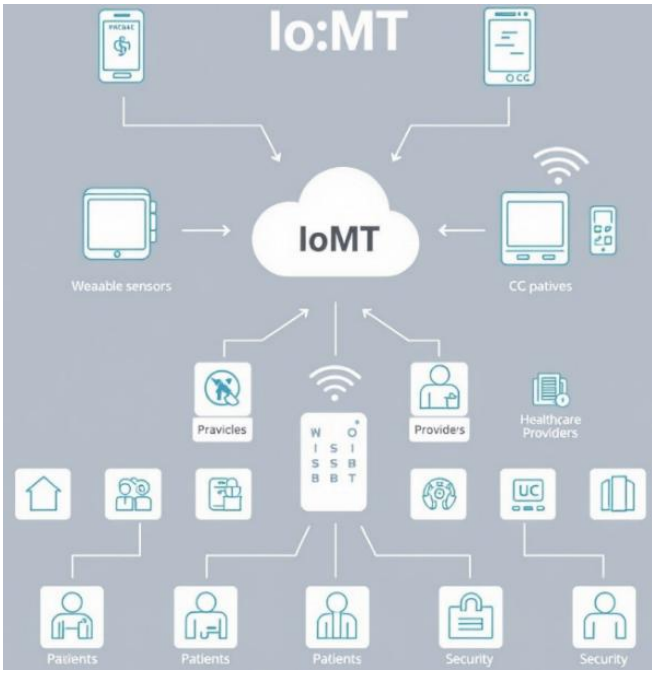

Fig. 1. The concept of Internet of Medical Things (IoMT).

Despite their potential, implementing four-factor authentication protocols in IoMT systems presents several challenges. The resource-constrained nature of many IoMT

devices limits their ability to execute complex cryptographic operations, necessitating the development of efficient, lightweight protocols. Additionally, the dynamic nature of healthcare environments requires authentication systems to be adaptable, maintaining security even as devices frequently join and leave the network. Furthermore, ensuring compliance with stringent healthcare regulations, such as the Health Insurance Portability and Accountability Act (HIPAA) and the General Data Protection Regulation (GDPR), is critical for maintaining patient trust and protecting healthcare providers from legal liabilities.

This research aims to conduct a comprehensive analysis of a proposed four-factor authentication protocol designed for IoMT [5]. The primary objective is to identify and scrutinize five key security vulnerabilities within the protocol that could compromise its effectiveness. By examining the protocol's architecture and operational phases, this study seeks to uncover potential weaknesses and propose strategies for enhancement.

The paper is structured as follows: Section I presents a literature review of existing authentication protocols and their limitations. Section II outlines the methodology employed for vulnerability detection, including the analytical methods and tools used for cryptanalysis and security testing. Section III discusses the identified vulnerabilities in detail, while Section IV proposes improvements to enhance the protocol's security and efficiency. Finally, Section V and VI concludes with a summary of the findings and their implications for IoMT authentication systems. Through this investigation, the study aims to contribute to the development of more secure and efficient authentication protocols that effectively protect sensitive medical data while supporting the continued integration of IoMT in healthcare.

A. Literature Review

1) Existing authentication protocols: The proliferation of the Internet of Things (IoT) in healthcare has necessitated the development of robust authentication protocols to secure sensitive medical data. Traditional single-factor and two-factor authentication methods have proven inadequate against sophisticated cyber threats, prompting the exploration of more comprehensive solutions [6]. In response, four-factor authentication protocols have emerged, integrating multiple layers of security to mitigate unauthorized access and data breaches [7].

Four-factor authentication protocols typically combine knowledge-based factors (e.g., passwords), possession-based factors (e.g., smart cards), inherence-based factors (e.g., biometric data), and contextual or environmental factors (e.g., device location or usage patterns) [8]. This multi-layered approach significantly enhances security by requiring multiple forms of verification, thereby reducing the likelihood of successful attacks. For instance, even if an attacker obtains a user's password, they would still need to overcome other authentication barriers to gain access [9].

Recent advancements in authentication technologies have focused on optimizing these protocols for resource-constrained IoT environments. Lightweight cryptographic algorithms, such as elliptic curve cryptography (ECC) and lightweight encryption standards, have been employed to balance security and efficiency [10]. These algorithms provide strong encryption with reduced computational overhead, making them suitable for IoT devices with limited processing power and energy resources.

Despite their strengths, existing four-factor authentication protocols face several challenges. The integration of multiple authentication factors can lead to increased complexity and user friction, potentially impacting usability and compliance [11]. Additionally, the dynamic nature of healthcare environments, where devices frequently join and leave the network, requires authentication systems to be adaptive and resilient [12]. Ensuring user privacy and compliance with stringent healthcare regulations, such as the Health Insurance Portability and Accountability Act (HIPAA) and the General Data Protection Regulation (GDPR), remains a critical consideration.

2) Related works: Recent studies [13, 14] have highlighted various security vulnerabilities within IoT-based healthcare authentication systems. One major concern is the risk of sensor node capture attacks, where adversaries physically access devices to extract sensitive information [13]. To address this, researchers have proposed the use of Physical Unclonable Functions (PUFs) as an additional layer of security [14]. PUFs leverage the intrinsic physical variations of semiconductor devices to generate unique identifiers, making them resistant to cloning and physical attacks.

Another significant vulnerability is the potential for replay attacks, where attackers intercept and retransmit valid authentication messages to deceive the system [15]. To mitigate this risk, protocols have incorporated time-stamping and nonce-based mechanisms to ensure message freshness and authenticity [16]. These measures help prevent attackers from reusing captured messages to gain unauthorized access.

Previous studies [17, 18] also underscores the importance of protecting biometric data, which, once compromised, cannot be easily replaced or revoked [17]. Advanced encryption techniques and secure transmission protocols have been proposed to safeguard biometric information against interception and misuse [18].

Interoperability and scalability are additional challenges that must be addressed to ensure seamless integration and operation of IoT healthcare systems [19]. The diverse range of IoT devices and platforms necessitates standardized protocols that can facilitate communication and data exchange across different systems.

In summary, the literature emphasizes the need for continued research and innovation in the development of secure, efficient, and user-friendly authentication protocols for IoT healthcare systems. By addressing the identified vulnerabilities and challenges, the healthcare industry can enhance the security and privacy of patient data, ultimately improving trust and outcomes in digital healthcare environments.

II. METHODOLOGY

A. Framework for Analysis

The methodology for analyzing the proposed four-factor authentication protocol for the IoMT [5] involves a comprehensive framework designed to identify and evaluate potential security vulnerabilities. This framework integrates theoretical analysis, mathematical modeling, and practical testing to ensure a thorough security assessment.

B. Analytical Methods for Vulnerability Detection

The initial phase of analysis involves a detailed examination of the protocol's architecture, focusing on its critical components: initialization, mutual authentication, session key establishment, and data protection. Formal security models and logical proofs are employed to assess the protocol's resilience against various attack vectors. One such method is the application of Burrows-Abadi-Needham (BAN) logic, which helps verify the authenticity and freshness of messages exchanged within the protocol:

$$P \mid\equiv X \quad (P \text{ believes } X)$$

$$P \mid\Rightarrow X \quad (P \text{ has jurisdiction over } X)$$

$$(X) \quad (X \text{ is fresh})$$

These logical expressions formalize the assumptions made during the protocol's execution, ensuring that it meets its intended security objectives.

C. Cryptanalysis and Security Testing Tools

For cryptanalysis, the study utilizes advanced tools such as the Automated Validation of Internet Security Protocols and Applications (AVISPA). AVISPA provides a platform for modeling the protocol's interactions and simulating potential attacks, including replay, man-in-the-middle, and impersonation attacks. The tool employs a high-level protocol specification language (HLPSL) to evaluate the protocol's security properties.

In addition, the Random Oracle Model (ROM) is used to ensure the integrity of cryptographic functions, particularly for verifying hash-based operations and ensuring collision resistance. This involves modeling cryptographic hash functions as random oracles to simulate their ideal behavior:

$$H(m) = RO(m)$$

where $H(m)$ represents the hash of message (m), and (RO) denotes the random oracle.

D. Mathematical Modeling of Protocol Operations

The analysis incorporates mathematical modeling to evaluate key cryptographic operations, such as key generation and exchange. The protocol employs elliptic curve cryptography (ECC) for secure key exchanges:

$$K_{session} = g^{ab}p$$

where (g) is a generator point, and (a) and (b) are private keys of the communicating entities. This session key ensures secure communication between devices.

E. Analysis of the Proposed Protocol

The proposed four-factor authentication protocol for IoT healthcare systems [5] is designed to provide robust security through a multi-layered authentication process, incorporating initialization, mutual authentication, session key establishment, and data protection phases.

III. OVERVIEW OF THE PROTOCOL

A. Initialization Phase

The protocol begins with the initialization phase, where cryptographic parameters are established. Each device generates a unique identifier and a corresponding key pair using elliptic curve cryptography (ECC). The public key is calculated as:

$$K_{public} = g^{k_{private}}p$$

where (g) is the generator point on the elliptic curve, $(k_{private})$ is the private key, and (p) is a prime modulus. This setup ensures that each device has a secure cryptographic foundation for subsequent operations.

B. Mutual Authentication Phase

During this phase, devices authenticate each other using a combination of ECC and hash functions. Each device computes an authentication token by hashing its identity and a session-specific random nonce:

$$AuthToken = h(ID \parallel Nonce)$$

where *h( )* is a secure hash function. This token verifies the device's authenticity, ensuring that only legitimate devices can participate in the network.

C. Session Key Establishment

Once mutual authentication is successful, a secure session key is established between the device and the server. The session key is derived from the ECC-based key exchange process:

$$K_{session} = g^{ab}p$$

where (a) and (b) are private keys of the communicating entities. This ensures that each session is secured with a unique key, providing confidentiality and integrity for data exchanged between the device and the server.

D. Data Protection Phase

The final phase involves securing data transmission using the established session key. Messages are encrypted as follows:

$$C = E_{K_{session}}(M)$$

where (C) is the ciphertext and (M) is the plaintext message. This encryption ensures that sensitive medical data remains confidential and protected from unauthorized access.

E. Identified Vulnerabilities

Vulnerability to Node Impersonation using Session Key Leakage

1) Problem: While the paper emphasizes mutual authentication, it inadvertently provides a vector for node impersonation. An adversary can intercept public messages and

compute the session key.

a) The paper states that the gateway computes session key sks = (sk⊕ N3)⊕ R3, which implies a dependency of the sensor's session key on the gateway's variables and exposes a way to derive it. Note that the doctor also derives the key as sk * = (sk* ⊕ N2) ⊕ PWD.

b) The adversary can intercept M and derive R to compute the session key using sk which has been used by gateway to produce sks.

2) Impact: The adversary can impersonate legitimate nodes, leading to unauthorized access, data manipulation, or disruption of medical services.

3) Mathematical formulation: The paper states that the doctor will calculate session key sk as sk * = (sk* ⊕ N^2) ⊕ PWD. If we take another perspective of generating session key, the gateway calculates the sensor node session key sks = (sk⊕ N)⊕ R, where sk is the session key, N is a random number and R is another derived random number. But since the attacker has eavesdropped and learned G' which has been generated as G = RG (RSNRG) + N, which will help the attacker to compute R= and the session key sks by guessing the password.

4) Improvement: Session keys must be computed with a hash operation using all participating entities secrets, a key agreement approach must be followed to make it secure for each party. Also, public key cryptography can be considered to enhance security for all involved entities.

F. Password Vulnerability (Re-used Random Numbers)

1) Problem: The paper states that HPWD = h(PWDR). If an attacker gets the value HPWD for a user then, it is possible to guess the password using a brute force method. The paper doesn't specify a different process of updating the password, which means there is a chance that the random values used with the password remain constant, leading to the possibility that HPWD value of the user remains static. As a result, it becomes vulnerable to attacks such as dictionary or brute force password guessing.

2) Mathematical formulation: Since random number R, remains the same during each authentication process, if the attacker compromises HPWD and knows R, he can use brute force attack to guess PWD. For example, when an attacker tries all password values from his/her dictionary list and computes the resultant HPWD value from HPWD = h(PWD || R), when they have achieved the matching value, the password of the user is compromised.

3) Impact: A compromised password leads to full control over the user account and the ability to compromise the system.

4) Improvement: Each user has to generate a new random number with each new session. A password update process must be added and made mandatory to change the password periodically. This ensures that the password is not leaked and remains fresh. Multi-factor authentication can also help to prevent password leakage attacks.

G. Susceptibility to Impersonation and Data Modification Attacks

1) Problem: The protocol, as written, is susceptible to impersonation and data modification attacks since, all information such as temporary keys and identities are exchanged over a public channel, and those values can be used by an attacker to impersonate. An attacker can intercept and use public messages to act as legitimate users or devices.

2) Mathematical formulation: The protocol does not use Message Authentication Codes (MAC) or digital signatures. Suppose the sensor node receives a message {G, DTID,GW, Gw, and SKs }, and the user receives {μ,η,sku,GW}. The attacker can intercept any of these messages, and they can either replay, drop, or modify them and, since message integrity is not protected, the recipient has no way to identify it.

3) Impact: An adversary can intercept and replay, drop, or modify messages. This can lead to several types of attacks.

a) An attacker can act as a gateway and can obtain the data, and can then, modify or drop the information.

b) An attacker can manipulate the information received by the user device and the sensor node device.

4) Improvement: Adding MACs or digital signatures to each message transmitted or received can ensure integrity. Moreover, an additional time stamp or nonce can also be used to verify the freshness of the messages.

H. Lack of Proper Revocation Mechanism

1) Problem: While the paper mentions a revocation phase, it doesn't specify how devices are removed or deactivated when compromised, nor how the data or secret keys associated with these nodes are handled. The removal process lacks proper security and can be exploited by adversaries if they have compromised a valid user. Also, the addition of new nodes can be attacked if an intruder starts acting as a legitimate user or a sensor node. This leaves the system vulnerable to a situation where compromised nodes can persist.

2) Impact: The lack of proper revocation can compromise the integrity and reliability of the whole system. Once a node is compromised, it should not be able to perform future operations or compromise the network. If proper revocation methods are not implemented, an attacker can easily compromise the whole system.

3) Improvement: A well-defined, secure, and well-implemented revocation mechanism is essential for managing compromised nodes. The security mechanism must delete/remove all previous keys and credentials from the network and the node. The new node added to the system should have different identities, credentials and keys, different from the compromised one.

This paper presented an approach towards secure authentication in the medical IoT field. The proposed protocol has potential to provide a secure environment and is more lightweight compared to existing solutions. However, the vulnerabilities mentioned above can be exploited by an adversary and can lead to severe security breaches. Addressing these flaws by implementing stronger cryptographic practices, adding proper message integrity checks, and better key

management practices is necessary for ensuring real-world security for medical devices.

4) Proposed improvements: To enhance the security and performance of the proposed four-factor authentication protocol for IoT healthcare systems, several improvements are recommended. These enhancements aim to address the identified vulnerabilities and ensure robust protection against unauthorized access and data breaches.

IV. Security Enhancements

A. Node Cloning/Replication Prevention

To mitigate the risk of node cloning attacks, the protocol should incorporate mechanisms for device attestation and verification. This could involve using Physical Unclonable Functions (PUFs) to generate unique, hardware-based identifiers for each device. PUFs leverage the inherent physical variations of semiconductor devices to create unclonable identifiers, providing a strong defense against node replication attacks. Additionally, implementing regular device health checks and network monitoring can help detect and respond to unauthorized node activity.

B. Strengthening Insider Attack Defenses

To protect against insider threats, the protocol should enhance its access control measures by implementing role-based access control (RBAC) and attribute-based access control (ABAC) systems. These systems limit user permissions based on their roles and attributes, ensuring that users can only access the resources necessary for their duties. Furthermore, incorporating user behavior analytics and anomaly detection can help identify suspicious activities and potential insider threats, enabling timely intervention.

C. Biometric Data Security

Enhancing the security of biometric data involves implementing advanced encryption techniques and secure transmission protocols. Homomorphic encryption allows computations to be performed on encrypted data without revealing the data itself, providing strong protection for biometric information. Additionally, secure multi-party computation (SMPC) can enable collaborative data processing while preserving privacy. These techniques ensure that biometric data remains confidential and protected against interception during transmission and storage.

D. Improving Session Management

To prevent unauthorized access and maintain session integrity, the protocol should implement strict session expiration and key rotation policies. Session keys should be refreshed regularly, and sessions should automatically expire after a predetermined period of inactivity. This approach reduces the risk of session hijacking and ensures that only active, authenticated sessions are maintained. Furthermore, incorporating ephemeral key exchanges can provide additional security by ensuring that session keys are unique and short-lived.

E. Optimizing Scalability and Resource Utilization

Addressing scalability and resource constraints requires optimizing cryptographic operations to reduce computational overhead. Implementing lightweight cryptographic algorithms, such as the Advanced Encryption Standard (AES) in its lightweight form, can significantly decrease energy consumption and processing time. Additionally, employing adaptive power management techniques, such as duty cycling and dynamic voltage scaling, can extend battery life and maintain device performance. These optimizations ensure that IoT devices can efficiently perform necessary tasks without draining resources.

V. Future Research Directions

A. Exploring Quantum-Resistant Cryptography

As quantum computing capabilities advance, exploring quantum-resistant cryptographic algorithms will be essential to future-proof the protocol against potential quantum threats. Algorithms such as lattice-based cryptography and hash-based signatures could offer security that withstands quantum attacks, ensuring long-term protection of sensitive data.

B. Developing Adaptive Security Policies

Leveraging artificial intelligence and machine learning to develop adaptive security policies could provide real-time threat detection and response. By analyzing network traffic patterns and user behavior, AI-driven systems can dynamically adjust security measures, offering a proactive approach to maintaining security.

C. Enhancing Privacy-Preserving Technologies

Further exploration of privacy-preserving techniques, such as differential privacy and secure enclave technologies, will enhance user privacy and data protection. These techniques can ensure that sensitive information remains confidential, even in the face of sophisticated attacks.

D. Addressing Interoperability Challenges

Research into standardized protocols and cross-platform communication frameworks could facilitate seamless integration and operation of diverse IoT healthcare systems. Ensuring interoperability across different devices and platforms is essential for creating a cohesive and efficient IoT ecosystem.

By implementing these proposed improvements and pursuing ongoing research directions, the protocol can provide robust protection against evolving threats and maintain the integrity and confidentiality of IoT-based healthcare systems. These efforts offer a comprehensive approach to addressing current vulnerabilities and preparing for future security challenges in the digital healthcare landscape.

VI. Conclusion

In conclusion, the analysis of the proposed four-factor authentication protocol for IoT healthcare systems has identified several critical vulnerabilities, including node cloning risks, insider threats, biometric data security concerns, session management weaknesses, and scalability challenges. By implementing the recommended security enhancements, such as the use of Physical Unclonable Functions, advanced encryption techniques, and optimized session management, the protocol can significantly improve its security posture. These

measures ensure robust protection of sensitive medical data, fostering trust in IoT-enabled healthcare environments. As the IoT landscape continues to evolve, ongoing research into quantum-resistant cryptography and adaptive security measures will be crucial in maintaining the protocol's resilience against emerging threats.

***Abstract*—Health care has been revolutionized by this rapid change in the field of the Internet of things that enable smart connected devices that provide better patient monitoring, diagnosis and treatment. IoT technologies facilitate collection of real time health data and remote patient monitoring, as well as prediction, thus improving overall healthcare outcomes. The ideas and concepts related to Chronic diseases, Diseases, Emergency, Detection and its management are greatly transformed by the presence of Wearable sensors, Smart Hospital infrastructures and AI powered Analytics. Meanwhile, healthcare systems driven by IoT are more efficient, reduce number of hospital readmissions, and provide telemedicine services. But, IoT in healthcare comes with a lot of challenges such as IoT security risks, patient privacy issues and multitude of interoperability problems. In this paper a comprehensive review of smart IoT technologies in healthcare, their applications and the type of benefits that weigh them for the patient care is provided. Along with exploring the role of data analytics in the IoT based decision making, data handling ethical implications and security threats in IoT healthcare systems introduced here. Moreover, beyond this, they discuss future directions including integration of AI, 5G enabled telemedicine, and blockchain for secure patient data management. This makes IoT an ideal candidate for healthcare transformation — one that addresses existing challenges and capitalize on emerging innovations to go from more efficient, more accessible, and definitely more patient-centric healthcare.**

Keywords*—IoT in Healthcare; smart technologies; remote patient monitoring; data security; AI in healthcare; telemedicine; healthcare analytics

I. Introduction

IoT integration in healthcare has revolutionized patient care by making patient care smart and connected systems that offer the real time monitoring, the diagnostic accuracy and treatment efficiency. The IoT offers the global healthcare systems a way out of the increasing problems like increased aged populations, high cost of living and prevalence of chronic conditions. The technology in an IoT driven world enables healthcare professionals to remotely monitor patients, real time analysis of health data and user interface to make decisions that result in prompt interventions. Such innovations in wearable sensors and smart hospital infrastructures, to AI powered analytics, brings a fresh perspective to the healthcare, offering personalized, data driven treatments and improved overall medical efficiency [1]. These technologies are also benefiting those who receive them, since they permit patients to conduct continuous health monitoring, reduce hospital visits, and push proactive health management.

IoT in health exist in the universe of connection devices, cloud computing and artificial intelligence coexisting to construct an intelligent health system. By wearing smartwatches and biosensors, ones the most critical health parameters like heart rate, blood pressure, oxygen levels, blood glucose levels are being tracked and these critical parameters can give real time insights to concern one medical condition. RPM has also evolved into a go to for patients with chronic illnesses, and on top of that, remote patient monitoring (RPM) can do just that.. IoT helps healthcare professionals keep track of patients at a distance and prevent hospital admissions, so that the required medical attention is given before they are in a worse condition. Another very major application of IoT is that of telemedicine where the IoT is used to bridge the gap between patients and the healthcare providers, making it easier and faster for medical consultations [2].

Due to the adoption of IoT in hospitals, medical environments with a smart approach have emerged that are based on automation for improving medical workflow process. Smart beds in the hospitals connected via IoT, automated medication dispensers and RFID based inventory management systems are offered with improved efficiency and lesser human error and thereby higher patient safety. The impact of IoT and artificial intelligence comes to play even bigger as artificial intelligence further takes advantage of the high volume of patient data to which it has access to predict health trends, personalize treatment plan and identify at risk patients earlier than critical situation happens [3]. Through implementing IoT and AI and machine learning into the healthcare systems, healthcare systems can be tipped towards predictive and preventive medicine and ultimately reduce healthcare costs and improve the welfare of patients.

Despite its huge potential, implementing IoT in healthcare sector poses problems, specifically concerning security, privacy and interoperability [4]. Cyberattacks and data breaches on connected medical devices have become an increasing threat as reliance on connected medical devices grows. The patient health data that has to be processed here is very sensitive and any compromise in the security would have disastrous consequences. To secure patients' trust and data on the patients' personal health information, the providers of healthcare should also adhere to strict data protection regulations such as HIPAA

Corresponding authors: monica.bhutani@bharatividyapeeth.edu(M.B.); ygulzar@kfu.edu.sa (Y.G.)

and GDPR. The second issue with IoT devices is the tremendous variety of standards and lack of standardization; this poses problems for compatibility between various manufacturers as well as with system. In the absence of universal standards on integrating IoT devices seamlessly into current healthcare framework, it remains a big hurdle. Furthermore, the cost of taking IoT to the healthcare industry is an impediment for most of the healthcare institutions, including developing regions. This makes it even more difficult for widespread adoption as you need advanced infrastructure, high-speed internet and bear the heavy burden of secure cloud data.

And as IoT is still evolving, future innovations will solve these issues and open several new doors for healthcare. One would expect 5G technology would greatly improve the speed and reliability of the IoT enabled healthcare applications with the ability to transmit data in real time as well as to conduct remote surgeries. In addition, blockchain technology is also attracting a solution to enhance data security and to keep the health record transcripts accurate, transparent and HALON free [5]. Additionally, AI driven IoT systems will improve upon predictive analytics to a degree that will enhance the accuracy and porosity of personalized medicine. As edge computing grows, data processing will become more and faster, with less latency in important cases of healthcare.

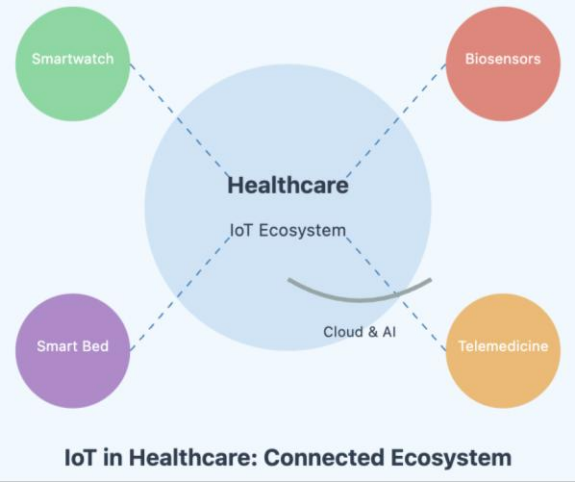

Fig. 1. IoT Healthcare ecosystem - Interconnected devices transforming patient care.

It is in Fig. 1 that the Internet of Things (IoT) has the potential to transform healthcare, as a dynamic ecosystem of connected technologies, represented in Fig. 1. Four key healthcare IoT devices, namely smartwatches, biosensors, smart hospital beds and telemedicine centers, respectively interlock around a main healthcare hub to indicate the omnidirectional and integrated concept of modern medical service. IoT based healthcare system is represented by the dotted line which shows the flow in the data and communication flow between the devices without interruption. Essentially, Cloud & AI technologies are the intelligent brains that take real time health data, process and analyze it to make it possible for predictive diagnostics, personalized treatment and proactive health management. Essentially, this paper's main argument is encapsulated in this visualization: IoT is revolutionizing healthcare by making it a much more connected, streamlined and patient centered way of monitoring and intervening in medical care [6].

In this paper, we discuss how smart IoT technologies can be applied to benefit the healthcare and the challenges that are impacted due to their implementation. IoT in Realtime Health Monitoring, Predictive Analytics and Remote Patient Care explores the role of IoT in real time health monitoring, predictive analytics and remote patient care by discussing how these are changing the modern healthcare. Another part of the study looks into security risks and ethical considerations that are associated with IoT driven medical systems and recommends building strong regulatory framework. Finally, it concludes with the future direction that IoT will take on in the healthcare domain, especially with the coming of the technologies that are AI, blockchain, and 5G that will add to the efficiency and security of the IoT powered healthcare systems. Stakeholders will be able to leverage smart IoT technologies to create better, more connected, efficient and patient-centric health care ecosystem by knowing opportunities and challenges.

The novel contributions of this paper are:

- In this paper we showcase a detailed description of the impact that IoT technologies bring to healthcare by real time patient monitoring, smart hospital infrastructure, and with the help of AI diagnostics. Unlike previous reviews that are focused on individual aspects of IoT in healthcare, this work presents the synergy between wearable devices, telemedicine, predictive analytics and hospital automation.
- To date, as adoption of IoT in healthcare surges, security and ethical matters continue to severely impede IoT adoption. This paper assesses emerging cybersecurity threats, data privacy risks and ethical assessment of IoT healthcare applications in a novel way. In this study, gaps exist in existing studies, and it proposes a framework that is based on a security through blockchain integration combined with AI based anomaly detection and regulatory compliance.
- The idea of this research is to explore how artificial intelligence helps in IoT based healthcare by making it possible to predict a disease, do an automated decision making and suggest personalised treatment. Unlike the normal studies that treat AI and IoT as two separated things, this paper focuses on the merged potential of the AI and IoT in disease forecasting, patient risk evaluation, and personalized healthcare interventions.
- Next, this study provides a forward view on the future of IoT in healthcare and how the next generation technologies like 5G, edge computing, and blockchain overcome the current one. This paper, by presenting a structured roadmap, is a guide for the practitioners of healthcare, researchers and policymakers to optimize IoT implementations to improved patient outcomes and system efficiency.

This paper is organized as follows. Section II describes IoT in healthcare through a general discussion of its architecture, a list of its key components, and the associated technological

enablers. In Section III, we cover on the various application of smart IoT technologies in the healthcare area: wearable health monitoring, telemedicine, and hospital automation. In Section IV, IoT's role in healthcare data analytics and decision making is discussed including AI driven predictive modelling and real time health insights. IoT driven Healthcare System: Section V studies the IoT driven health care systems security, privacy, and ethical challenges showing risks and their counter strategies. In the last Section VI, the conclusions of this study are drawn, a summary of the main findings and their implications are presented. In the last section, Section VII portrays the future directions and what these emerging technologies, like 5G and edge computing and blockchain, bring to the future of IoT based healthcare solutions.

II. Overview of IoT in Healthcare

The Internet of Things (IoT) has revolutionized healthcare, as it links medical devices with doctors and patients in the most efficient way or you can say it enhances the connectivity and makes the link seamless. Integration of smart sensors, real time data analytics and cloud based platforms has made a remarkable difference to patient care, operational efficiency and medical decision making through IoT. The arrival of IoT driven healthcare solutions has led to new possibilities of real-time monitoring, predictive diagnostics and remote treatment, which has changed the way healthcare was delivered. Wireless communication, artificial intelligence, as well as big data analytics advancements drive the growing adoption of IoT in healthcare that make medical practice automated as it relies on data [7]. However, this further increased the demand for IoT oriented system that provides proactive and efficient healthcare services as a result of the increasing demand for personalized healthcare and the growing prevalence of the chronic diseases.

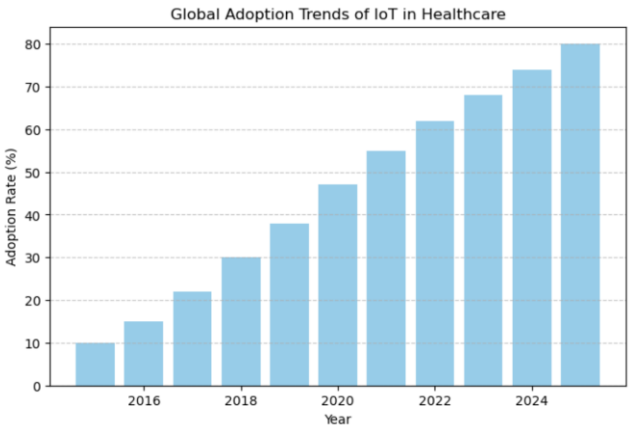

Fig. 2. Global adoption trends of IoT in healthcare (2016-2024).

Fig. 2 shows a very steep upward trajectory of Internet of Things (IoT) in healthcare from 2016 to 2024. The graph starts at around 10-15 % adoption rate in 2016 and progressively and greatly increases to almost 75-80 % in 2024. This visualization powerfully showcases how only one decade of healthcare developments has seen excessive expansion of the IoT technologies in this area. The steady year on year growth is on account of the rising perception of IoT's revolutionary capability in medical monitoring, patient treatment, and health system adaptation, as similarly observed in agriculture sector adoption [8]. But each successive bar bears not only technological advancement but also waning of institutional initial lack of trust in IoT's potential to improve diagnostic precision, patient outcomes, and operational efficiency in healthcare institutions. While a compelling visual testament to what is occurring in the global space where healthcare systems are all going through a digital transformation around innovations in connected medical technologies, the graph also sets the tone, period.

A. Architecture and Components of IoT in Healthcare

IoT healthcare architecture is responsible for multiple connected layers working hand in hand to deliver the information seamlessly among the patient, medical devices, healthcare providers, and the cloud computing platform. The basic premise of this ecosystem lies in smart sensors and medical devices that are producing patient health data like heart rate, blood pressure, oxygen level and glucose levels continuously. All of these devices are embedded with wireless communication technologies – Bluetooth, Wi-Fi or 5G – to be able to transmit data in real time. The collected data is then processed through the edge computing or cloud computing systems where the artificial intelligence algorithms are used to analyze patterns, identify anomalies and generate actionable insights. This data can be accessed by healthcare professionals through hospital information systems, mobile applications, and can be used for medical interventions at the time occasioned and remote patient monitoring.

Interoperability is an important part of IoT in health care as it supports between different medical devices and systems. The standardized protocols and secure APIs permit no language and no platform barrier of exchanging the information between different platforms and hence removing the risk of information silos and making the medical records in better accuracy. Further, cloud computing contributes to storing and managing huge amounts of health data as needed, thereby, making it real time available to the medical professionals. In addition to improving data security, data security provides a tamper proof ledger for medical records in IoT healthcare system blockchain integration adds further security. Because healthcare providers want to be able to scale IoT in their system, the overall architecture of IoT in healthcare is designed to be scalable, keeping new technology from interfering with existing workflows.

B. Role of IoT in Healthcare Transformation

IoT is one of the key drivers of transforming the classic healthcare eco-system to be automated, to be involved in remote observation, and to create usage of predictive analytics. The remote patient monitoring (RPM) is one of the most important pieces of the IoT in healthcare because it lets patients treat their medical issues in the convenience of their own houses [9]. More specifically, this technology is valuable to persons with chronic illnesses like diabetes, hypertension, and respiratory disorders since it can track vital signs on a continuous basis without needing to visit the hospital frequently. Patient health data is collected by wearable devises and biosensors and transmitted to healthcare providers for the purpose of making informed decisions and adjusting treatment plans. Not only does this improve patient outcomes but it also lessens the burden on the hospitals by minimizing hospital readmission.

IoT also has an impact on emergency medical response, which is another kind of transformation. Smart ambulances have real time communication systems that enable the transfer of data on patient to hospitals before the patient arrives, so that medical teams are able to be ready for immediate treatment. In case of cardiac arrests or strokes, real time monitoring and auto alerts could help a lot in survivals by allowing rapid medical interventions. Apart from that, it has improved hospital management by optimizing resource allocation, tracking medical equipment, and proper flow of patients. IoT for Smart hospitals rely on using IoT enabled RFID tags to supervise the availability of beds in a hospital and also the medical inventory and streamline administrative processes to enhance overall efficiency in healthcare services.

The good news is that besides patient monitoring and hospital automation, IoT has also started to change drug management and personalized medicine [10]. IoT-enabled smart pill dispensers can provide alerts to patients when to take their medication at the accurate time and decrease chances of missed doses and medication errors. Along with this, predictive analytics powered by IoT help the pharmaceutical companies monitor the efficacy of the prescribed treatments in real time and enable the development of personalized medicine targeted at individual patient needs. Using IoT insights, the healthcare providers can now take a more proactive approach towards disease prevention and move away from reactive treatment to the preventive care strategies.

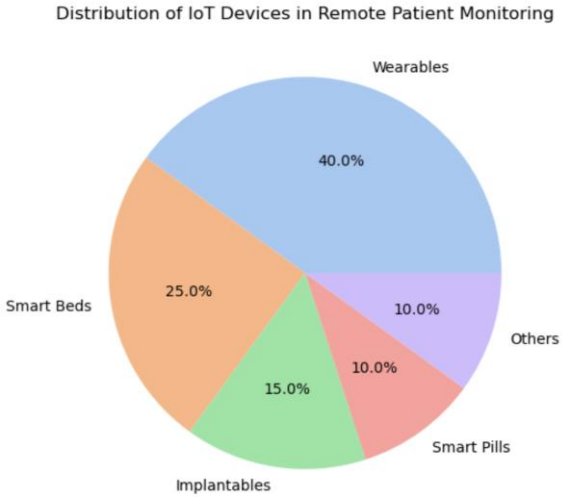

Fig. 3. Distribution of IoT devices in remote patient monitoring.

Fig. 3 shows a complete classification of IoT device types used in remote patient monitoring, revealing the general research environment for the modern healthcare. 40 percent of IoT devices are wearables due to its popularity along with ease in continuous health monitoring. About 25 percent of the ecosystem are smart beds, and these serve a critical purpose of monitoring patient conditions in hospital and home care settings. The 15 percent of the distribution of implantable devices indicates that medical technology is becoming increasingly sophisticated at measuring health from within the body [11]. The shares of smart pills and all other miscellaneous IoT devices is 10% each, representing emerging and innovative measurement of the patients. In the chart, you can see the many ways that IoT in healthcare works — for example, multiple technologies being combined to provide complete, real time patient care for many different medical contexts.

C. Challenges and Barriers to IoT Adoption in Healthcare

Although IoT has so many benefits, there are hurdles that block its widespread adoption in healthcare settings. Data security and privacy remain one of the main concerns, since the presence of IoT devices brings along with it an enormous amount of sensitive patient information that can be an easy target to cyber threats. It is a big risk for patients and healthcare providers to have unauthorized access, data breach, and ransomware attacks. Robust cybersecurity measures can be the answer for the above threats, such as end to end encryption, multi factor authentication, and AI driven threat detection system. Data protection regulations including the Health Insurance Portability and Accountability Act (HIPAA) and the General Data Protection Regulation (GDPR) need to be complied with to protect patients' privacy and ensure proper way of handling their medical data.

A third barrier to healthcare IoT adoption is interoperability as there is often proprietary communication or protocols among medical devices and platforms and cannot easily exchange data says. Unfortunately, the absence of standardized frameworks means that it is a challenge for healthcare providers to realize integration of IoT solutions for existing health care systems. To solve this issue, it's going to take cooperation from the industry level in order to define universal standards to allow these different healthcare technologies to be interoperable. Further, the development of adaptive algorithms that interpret multiple sources of information increases the possibility for improvements in data harmonization based on artificial intelligence and machine learning.

Challenge for the widespread IoT deployment in healthcare, especially in developing region comes from cost and infrastructure limitations. The development and implementation of IoT solution requires high costs to acquire hardware, cloud infrastructures, and network connectivity, which makes it difficult for resource limited healthcare center to adopt this technologies. Moreover, rural or remote areas with poor connectivity or interrupting high speed network limits one of the reliable data transmission to real time data via continuous internet connectivity. Using faster data processing and reduced reliance on single cloud centers as being offered by 5G technology and edge computing, there are potential solutions that may emerge [12].

III. Applications of Smart IoT Technologies in Healthcare

Smart IoT technologies are now applied in healthcare, have revolutionized the patient care, hospital management and medical decision making. In the context of IoT, these medical devices, real-time health monitoring and AI-powered analytics have made healthcare more accessible, efficient and personalized. These technologies permit continuous monitoring of the patient, immunological accuracy, optimization in the hospital work processes, and provide remote healthcare services [13]. As IoT adoption in healthcare technologies grows, medical practitioners now have better sources of informational feedback

to make and patients acquire proactive healthcare follow. Weighting the benefits of data integration into healthcare systems from a practical viewpoint, the integration of IoT in healthcare systems has improved patient outcome as well as reduced operational costs and minimized the hospital admissions.

A. Remote Patient Monitoring and Wearable Healthcare Devices

Remote patient monitoring (RPM) is one of the most impactful applications of IoT in healthcare which allows healthcare providers to monitor the health status of a patient in real time without the need for him to visit a medical facility. In particular, RPM has proved to be extremely useful in managing some chronic conditions such as diabetes, hypertension and cardiovascular disorders by enabling early detection of anomalies, and consequent timely medical interventions. They are wearable healthcare device such as a smart watch, biosensor and a fitness tracker that measure the vital signs, continuously like heart rate, blood pressure, blood glucose level, oxygen saturation and other body temperature [14]. Data transmitted by these devices reaches cloud-based platforms where AI algorithms apply to the information and find possible health risks. Thus, healthcare professionals can use this data remotely to suggest personalized treatment and early intervention before the disease has advanced to a critical state [14].

Additionally, wearable devices powered by IoT have been of great importance for postoperative care and rehabilitation. At home, patients can be monitored after surgeries so that they do not have to stay in the hospital for prolonged periods. IoT sensors are used by smart rehabilitation systems to track a patient's progress and ensure they adhere to their prescribed exercises and recovery protocols. Furthermore, medication adherence with IoT is enhanced by such IoT driven medication adherence systems that remind patients to take the medications at the right time thereby reducing chances of missing the dose and hence good treatment adherence. In other words, smart home IoT solutions (such as the fall detection sensor and emergency alert systems) give real time assistance to elderly and disabled individual; hence improving the safety and quality of life.

B. Smart Hospitals and IoT-Enabled Healthcare Infrastructure

Apart from caring for an individual patient, the IoT has revolutionized hospital management through optimization of workflows, improved resource utilization and reduced operational inefficiencies. IoT has made its presence in smart hospitals by deploying IoT enabled medical devices, RFID based tracking systems and automated workflows to make healthcare process an easy ride. For instance, IoT enabled smart beds automatically change in order to provide the patient with maximum comfort while monitoring vital parameters like heart rate and respiratory rate. Later, should the beds detect irregularities, the staff get alerted to act in time. IoT enabled RFID and GPS tracking systems have also brought great enhancement in medical inventory and asset management [15]. With hospitals currently monitoring the availability and location of medical equipment from ventilators to defibrillators and infusion pumps to ensure their proper use and reduce delays in such critical situations, this time is proving far too soon. IoT integrates with smart medication dispensers that can track drug usage and avoid medication shortage, error. Inventory management in hospitals is automated for minimizing wastage and efficiency, as well as overall cost.

In hospitals one of the most crucial IoT application is infection control. Environmental sensors that are smart monitor air quality, humidity, and temperature to guarantee the execution of hygiene standards and decrease the spread of episodes [16]. IoT is being used to keep track of sanitation schedules and to run automated disinfection systems to make certain hospital rooms and surgical instruments are cleaned punctually. Furthermore, IoT based facial recognition and biometrics' access control system can also improve hospital security to restrict the access of unauthorized individuals to critical areas like ICUs and operating rooms.

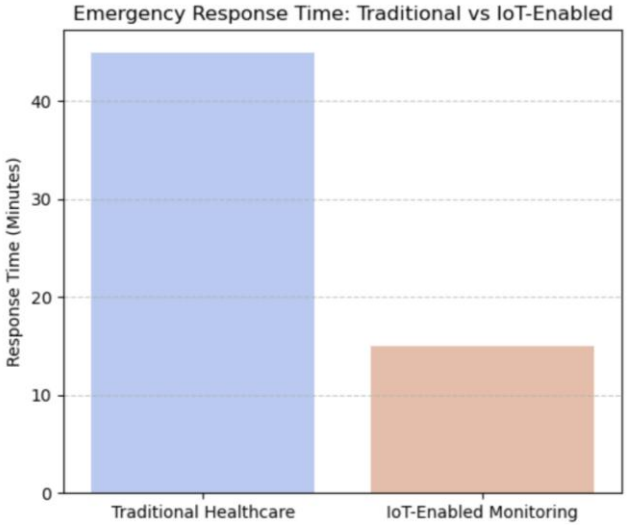

Fig. 4. Emergency Response Time Comparison - Traditional vs. IoT-Enabled Healthcare

The Fig. 4 shows a compelling graphical contrast in emergent response time of traditional medical care system and the one that is IoT enabled. The respective traditional healthcare area is represented by a blue bar with an almost 45 minute response time while IoT enabled monitoring area has an almost 15 minute response time. IoT technology in healthcare finds its efficiency in this visualization powerfully. Realtime monitoring, rapid speed of information transmission, and initially proactive applications of the Internet of Things devices allow for what would be an almost 70% reduction of emergency response time. IoT helps in faster detection of medical issues, bringing immediate alerts, and faster intervention thus making emergency medical response no more reactive but rather predictive and preventive. The graph itself proves on why adopting IoT in healthcare to save time, reduce complications and ultimately improves patient outcomes.

IV. IoT Data Analytics and Decision-Making in Healthcare

Though, integration of IoT in healthcare has not only enhanced connectivity in between healthcare devices and healthcare providers but also made a way for data driven

decision making. Real time patient data is created by IoT devices in huge volumes and when properly analysed, can enrich the diagnostic data, predict disease progression and will help in better optimizing treatment plans and improving healthcare outcome. These data enable healthcare providers to use advanced data analytics techniques, for example: machine learning, artificial intelligence and cloud computing to extract meaningful insights about the particular data [17][18]. IoT driven analytics lets hospitals and medicals professionals transition from reactive to proactive and predictive healthcare which provides better patient care, reduced operational cost and time.

A. Real-Time Data Collection and Processing in IoT Healthcare

For example, healthcare environments constantly 'spout' vast amounts of patient related data: whether it is vital signs and activity levels, environmental factors and medication adherence etc., from IoT devices deployed. Continuous real time health data streams are being produced from wearable devices, biosensors, smart implants and remote monitoring systems that are transmitted to centralized cloud platforms or edge computing systems for immediate processing. This real time data collection allows health care providers to collect the patient conditions in real time, detect anomalies and take proper actions in time to avoid medical complication.

Edge computing is critical to making IoT generated data go through the processing in event, and with as small latency as possible. Proceeding with critical health alerts which can be instantaneous at, say, the edge of the algorithm, on a wearable device or even a local hospital server, rather than pushing data up to the cloud, allows for crucial data to be processed closer to the source. Imagine, for example, a patient with a heart problem that causes irregular heart rhythms, and the use of IoT-enabled pacemaker to suddenly call for the help of the healthcare professionals and trigger an emergency response. Similarly, real time glucose monitoring systems can give alerts to diabetic patients about the time of the insulin and it also saves from medical emergencies.

Interoperability in data processing from the IoT is another critical issue. In the healthcare domain, the data from the sources such as electronic health records (EHRs), medical imaging systems, and wearable sensors should be integrated by the healthcare IoT systems. It should be standardized for interoperability in these systems as the protocols should be standardized and a robust data governance frameworks should be in place. In the cloud your healthcare platform relies on application programming interfaces (APIs) to have EHRs communicated seamlessly from one provider to the other. By enhancing clinical decision making, this interoperability gives doctors the holisitic possiblity to see a patients medical history and the present health status and potential risks [19].

B. Predictive Analytics and AI-Driven Decision Support Systems

However, the true power of IoT in healthcare truly lies in the ability it can give towards enabling predictive analytics, and AI and decision making. Machine learning and deep learning algorithms, widely applied in both healthcare and agricultural disease detection [20–22], can be applied to vast quantities of IoT generated health data in order to generate predictive models for the prediction of disease progression [23], for identifying high risk patients, and as recommendations for personalized treatment strategies [24]. Health care providers with good predictive analytics will change from a reactive mode of treating illnesses after symptoms are present to a proactive mode in which diseases are discovered and handled before they become very severe [25].

This, for example, are AI powered IoT systems that process data from heart rate monitors, blood pressure sensors etc. and predict the probability of cardiovascular diseases. Patient and doctor's with these systems can be warned about the possibility of risk as to intervene early and minimize the possibility of heart attacks or strokes. Like in oncology, IoT based predictive analytics is used extensively in the use of artificial intelligence models to run on genetic data, medical imaging scans, patient histories to predict the cancer progression and formulate a personalized treatment regimen [26].

The other role played by IoT analytics in hospitals is to improve hospital management by optimizing resource use and patient floor. These systems analysis patient's admission rate, bed occupation rate and emergency department's workflow, and predict the hospital resource demands. Forecasting the patient influx allows hospitals to put in staff, medical supplies, and ICU beds in order to minimise wait time and give the best patient care. During public health crises, pandemics for instance, predictive capability is very important to managing healthcare resources in a strategically limited way to avoid overcrowding and failure of the system.

On the other hand, AI is being used in IoT system which supports the personalized medicine by tailoring the treatment plan based on study of individual patient data. But, IoT driven analytics gives healthcare an approach that is more customised compared to what is possible with traditional healthcare approaches. AI takes genetic data, lifestyle habits, as well as real time health metrics and can suggest personalized drug dosage's, lifestyle changes, and rehabilitation plans. Such level of precision medicine improves treatment efficiency by minimizing side effects and adverse reactions.

V. Security, Privacy, and Ethical Challenges

It has definitely pushed healthcare into the Era of IoT integration where patient monitoring, diagnosis and treatment have been improved greatly [27]. Yet, it has also raised a number of security, privacy and ethical issues that need to be resolved in order for these technologies to be used safely and effectively. IoT devices have huge amounts of sensitive patient data collected and transmitted to them; and as a result, they are an obvious cyber threat, unauthorized and data breach targets. Furthermore, on top of that, one can make ethical arguments regarding the patient consent, data ownership and how the potential biased AI driven healthcare decisions might make the use of IoT in medical environment even more difficult. To address these challenges, we must employ advanced and secure cybersecurity measures along with strict regulatory compliance on ethical measures that strike the perfect balance between technological significant advancement and patient's right protection.

A. Security Threats and Cyber Risks in IoT Healthcare

Connected medical devices and data transmission networks in the IoT in healthcare are one of the serious issues concerning the system's vulnerability to cyberattacks. Cloud platforms, wireless communication, and interconnected devices characterize IoT healthcare systems, which along with a multitude of other entry points, make IoT healthcare systems very vulnerable to cybercriminals. Security loopholes irresponsibly open up for hackers to gain unauthorized access to sensitive patients' data as well as manipulate medical equipment and launch ransomware attacks against healthcare institutions. Such cyber threats have unfortunate implications, including various types of undermined patient safety, financial loses, and loss of trust in health care technologies.

One of the main security vulnerabilities in IoT healthcare is the interception of medical data in transit, right in the process of transloading the data between devices. Patients expose themselves to identity theft or insurance fraud if health records including diagnostic reports, treatment histories and genetic data are exposed. Also, these unsecure IoT devices can be forced to read false, modify medication dosages, or can lead to interference with lifesaving medical interventions. One example of a compromised insulin pump, for example, might mistake the variable for a dose and administer incorrect amounts to a patient, putting a patient's life in jeopardy. What further amplifies these risks? The lack of regular security update for IoT medical devices which leaves most of these devices vulnerable for exploits even after they are being deployed as many devices have security exploits that go undetected for long periods of time.

To counter these threats, there has to be robust cybersecurity frameworks that are adopted in IoT healthcare networks. Measures that can help safeguard the patient data and also device functionality include the end to end encryption, secure authentication protocols, and intrusion detection system. The promise of Blockchain technology in protecting IoT healthcare transactions using data integrity as well as decentralized control has also been realized in this [28][29]. On top of that, anomaly detection using AI can be used to identify unusual activities within IoT networks in advance in order to issue alerts to security teams once breaches may escalate to severe incidents.

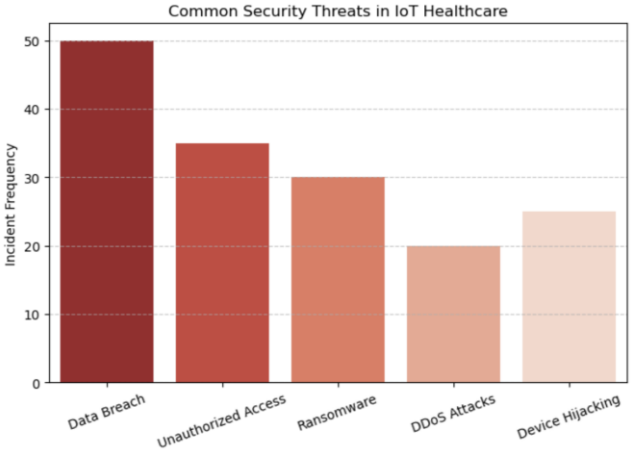

Fig. 5. Common security threats in IoT healthcare systems.

Fig. 5 provides an all-around picture of cybersecurity threats to IoT healthcare technologies with data breaches as the most frequent issue [30]. Fifteen security challenges are depicted on the visualization, where bar heights indicate the frequency of their occurrence with smallest being most frequent. Nearly 50 incidences belong to data breaches, 35 unauthorized access incidences and about 30 ransomware incidences. DDoS attacks and the device hijacking both represent significant, though lower occurring threats with frequencies of 20 and 25, respectively. The graphic points out the importance of having robust cybersecurity in place in an IoT healthcare system, noting that there can be many ways of having digital vulnerability. Dark to light red gradation of colors highlights the disparity in level of threat which are a visual cue to the plaguing risks with regard to the protection of sensitive medical data and of the healthcare infrastructure in a more and more connected ecosystem.

B. Privacy Concerns and Data Ownership in IoT Healthcare

Due to the concerns of privacy within the use of IoT, in healthcare, it is critically important to design a system that collects, stores and shares the patient data safely. Real time health information like biometric data, vital signs and medical history are collected by the IoT devices continuously. This data is critical to the improvement of patient care, but especially when stored in cloud platforms and healthcare databases, allows the risk of unauthorized and misuse of such data to rise. Who patients are and how they can control how their data is shared are ethically awkward issues of consent, data ownership and privacy.

Unlawful transfer of patient information to third parties including pharmaceutical companies, insurers, or research organizations is the truly greatest one. Healthcare institutions can share anonymized data without explicit patient consent for commercial purposes that can ultimately cause discrimination in the relative premiums on insurance or better employment possibilities. Moreover, when the health care systems are breached and patient records are exposed to malicious actors, there are further privacy violations.

These privacy concerns need to be addressed by healthcare organizations by adopting very strict data governance policies and compliance with the global regulatory frameworks such as General Data Protection Regulation (GDPR) and Health Insurance Portability and Accountability Act (HIPAA). It is the mandate of such patients, to make them explicit consent for collecting data and organizations have to follow strict controls on the access to that data and the encryption mechanism. Both differential privacy and homomorphic encryption will also aid in the analysis of patients data while maintaining confidentiality. Blockchain and all its capabilities allow patients to have more control on their data through blockchain based personal health records (PHRs) and enhance transparency and trust in IoT healthcare solutions.

Fig. 6 shows an evolutionary outlook for the technology of IoT, on a healthcare base, from the present state to some main markers until 2034. A progressive and exponential way of moving into the IoT healthcare technologies is shown in the upward trajectory. Beginning from the current IoT implementation, the graph demonstrates improvements, along with their technological breakthroughs such as AI integration,

5G telemedicine, blockchain security and the smart hospital implementation. Significant milestones along the function of becoming a digital healthcare leader represent strategic steps in digital healthcare transformation with a steepening curve that indicates greater speed in the field of technology. The figure incorporated in the paper visualizes its forward looking view and shows how the development of the emerging technologies will keep shifting healthcare delivery. To emphasize that the every technological milestone embarks on a smooth, ascending line and each is built on the foundation of the previous innovations to the creation of more sophisticated, efficient and patient centric healthcare ecosystem.

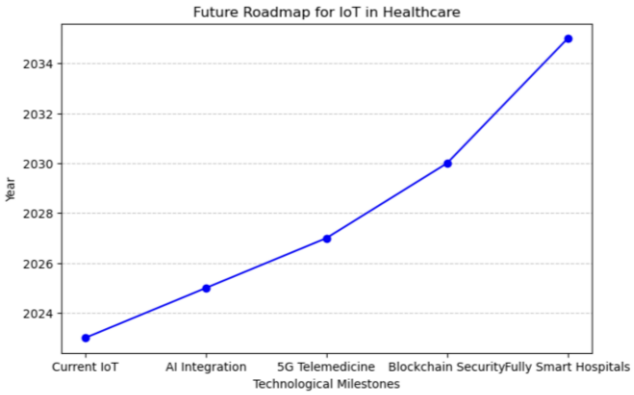

Fig. 6. Future roadmap for IoT in healthcare.

C. Ethical Considerations in AI-Driven IoT Healthcare

But aside from security and privacy, IoT healthcare systems need to be carefully probed on ethical ground. The concerns around bias, accountability and transparency arises as AI and machine learning algorithms are being built and used all the time with IoT healthcare data [31]. If the AI model was trained with a biased dataset, there is a potential that it will generate a discriminatory outcome, the amounts may vary between one patient group and another group based on race, gender or socio-economic status. For instance, an AI-based diagnosis system that is trained primarily on Caucasian patient population will have a lower sensitivity in detecting diseases in non-Caucasian people, thus creating differences in the process of healthcare delivery.

Automating the medical decision making is another ethical concern. However, while AI and IoT help with diagnostic accuracy and treatment planning, it would be a crime if those algorithms would be blamed for questionable diagnosis or poor treatment recommendation. When critical error occurs during an AI-powered IoT system and harms a patient, it becomes a legal and ethical problem as to who is legally and ethically responsible — if it is the healthcare provider, software developer or device manufacturer.

Transparency and explainability should be prioritized to bring up ethical AI deployment in IoT healthcare. The way AI algorithms work should be designed so as to be interpretable so that medical professionals can understand how decisions are made instead and don't blindly rely on recommendations generated by machines. Moreover, discrimination in AI based health care systems should also be detected and audited fairly regularly to eradicate it. It must be made clear to regulatory bodies that clear ethical guidelines are required to govern the use of AI in making medical decisions so that human oversight is always important.

The second important ethical question revolves around the digital divide in relation to enabling IoT-based healthcare solutions. Although IoT can hold great promise in bettering healthcare access especially in areas of low connectivity and reach, inequalities in technological infrastructure and digital learning may limit the physical and intellectual aspects of healthcare accessibility to those desiring to embrace the new technology. This implies that governments and healthcare organizations are lacking when it comes to investing in affordable IoT healthcare solutions and digital health education programs.

VI. Conclusion

Integration of IoT in healthcare has completely transformed patient care by allowing for real-time monitoring, predictive analytics and personalized treatment strategies. Ensuring that smart IoT technologies can be available and necessary for everyone to ensure availability of healthcare, operational efficiency and medical decision making. Faster, better and cheaper—this has been the case for healthcare providers who have been able to collect and analyse vast amounts of real time health data on patients, allowing detection of a disease early and enabling to use it for optimization of a treatment plan and improving the outcomes for the patients. Although these advancements are helpful, issues concerning security, privacy, interoperability, and ethical issues are still the most severe barriers to the wide adoption of them. Threats from cyber, data breaches and unauthorized access of sensitive patient information comes with huge risks, therefore, encryption, access control methods and regulatory compliance needs to be well implemented in order to maintain data security. Additionally, ethical issues such as biases in AI's decisions regarding healthcare should be addressed to prevent the mistreatment of any patient group. With the advancement of IoT, it is expected that the collaboration among healthcare professionals, technologists and policymakers would be indispensable to overcome these challenges and keep the IoT driven healthcare solutions secure, ethical, and viable. With the help of implementing stringent security, increasing AI transparency, and the adoption of standardized interoperability framework promises the future of IoT in health holds the potential of developing the IoT based medical services for healthcare on a more efficient, personalized, and patient centric base.

VII. Future Directions

In particular, nanotechnology and a combination of artificial intelligence, 5G connectivity, edge computing, along with blockchain technology are expected to shape the future of IoT in healthcare. With AI power, further development in disease forecasting, personalized treatment and early intervention strategy will move from reactive to proactive healthcare. 5G networks deployability will facilitate real time data transmission, reduce latency in remote patient monitoring and/or medical devices connectivity in the cloud. Furthermore, edge computing will help eliminate the use of the centralized cloud infrastructures and will allow the real time data processing at the

device level and will result in faster response times and the reduced Bandwidth. With regard to the data security, blockchain will ensure transparency and will allow decentralized, private patient health records within the regulatory compliance. In addition, federated learning will reduce the adoption of AI models that can train on decentralized healthcare data while upholding the confidentiality of the patient. It will be crucial that the digital divide is addressed and that IoT healthcare solutions are accessible to everyone. The future research should research towards the development of standardized IoT frameworks, mitigation of cybersecurity threats and improving AI interpretability to generate safe and ethical IoT driven healthcare systems that are useful for the patients across the globe.

Modeling an Adaptive and Collaborative E-Learning System with Artificial Intelligence Tools

Kawtar Zargane*, Hassane Kemouss, Mohamed Khaldi
A Research Team in Computer Science and University Pedagogical Engineering-(S2IPU) Normal School of Tétouan, Abdel Malek Essaadi University, Morocco

***Abstract*—In an educational environment that is undergoing digital transformation, the need to create smarter, learner-centred learning environments is becoming increasingly urgent. This article presents a conceptual modeling of an e-learning system that integrates the adaptive and collaborative dimensions, relying on the tools of artificial intelligence (AI), which occupies a central place, both as a dynamic adaptation engine and as a collaboration facilitator and automaton of certain pedagogical activities. This methodical and structured approach makes it possible to develop a hybrid environment capable of adjusting to individual needs while promoting the co-construction of knowledge between peers. Based on instructional design principles and the 2TUP (Two Tracks Unified Process) process, this approach aims to develop a systematic architecture, illustrated by UML (Unified Modeling Language) diagrams, of classes, use cases, activities and sequences, integrating AI (Artificial Intelligence) through adaptive learning, conversational agents and intelligent tutoring systems that make it possible to personalize learning, Provide targeted feedback, optimize learner performance, and guide learners more accurately. This combination of standardized modeling and AI improves the synergy between stakeholders and increases the efficiency of online learning environments. Finally, this model paves the way for a new era of more flexible, inclusive and responsive techno-pedagogical systems, capable of facing the contemporary challenges of online training.**

Keywords*—*Conceptual modeling of an online learning system; Adaptive system; Online collaborative learning; Artificial intelligence (AI); Educational software architecture; UML modeling

I. INTRODUCTION

In the digital age, in a context where online learning is constantly developing, and in the face of the diversity of learner profiles, the complexity of journeys and the growing importance of collaboration, it is becoming imperative to design smarter, more flexible and learner-centred learning systems, it is becoming essential to design educational experiences that are both effective, customized and technologically robust. This study highlights the importance of a rigorous approach in software engineering to design pedagogical devices capable of adapting to the needs of learners [1]. By combining instructional design principles with software development best practices, this allows us to develop a systematic and consistent architecture, modeled using UML diagrams, to effectively structure these e-learning projects. The integration of artificial intelligence (AI) into this architecture represents a powerful lever for the personalization of pathways, taking into account the pace, profile and specific difficulties of each learner [2,3].

In this perspective, the integration of collaborative learning highlights the social dynamics of knowledge construction, by promoting interaction between peers, the co-creation of resources and the development of transversal skills. At the same time, AI-supported adaptive learning makes it possible to personalize the educational experience by adjusting the content, pace and pedagogical strategies and to automate certain tasks, analyze learners' performance and offer precise pedagogical recommendations based on the specific characteristics of each learner [4, 5]. This combination can profoundly transform education [6]. Through the use of intelligent chatbots and adaptive tutoring systems, this innovative learning system is able to generate targeted feedback, detect the specific needs of each user and recommend personalized content [7]. This approach, which combines personalization [8], collaboration and artificial intelligence, is based on an intelligent tutor that adjusts content and activities in real time according to the learner's profile. The collaborative dimension is fully integrated through exchange spaces, online discussion tools, and group work functionalities [9]. Continuous monitoring of progress also allows for the adjustment of pathways as needed, ensuring a responsive, stimulating learning environment that is conducive to autonomy [10].

This article thus proposes a conceptual modeling of an online learning system that is both adaptive and collaborative, based on AI tools. The objective is to lay the foundations of an intelligent environment capable of reconciling individual personalization and collective intelligence, in a learner-centered, scalable and equitable learning perspective. To meet pedagogical and technical requirements, the adoption of a structured design approach based on the 2TUP methodology is necessary. This allowed the full potential of the UML modeling language to be fully exploited through two complementary perspectives: a static view, with class and use case diagrams describing the architecture of the system, and a dynamic view, illustrated by activity and sequence diagrams translating the interactions and behaviors of the system. These visual representations reinforce the overall understanding of the system and concretely demonstrate the articulation between modeling, AI and collaborative learning.

This model paves the way for a new generation of technopedagogical systems that are more flexible, inclusive, and responsive, capable of meeting the current challenges of online training.

II. Conceptual and Theoretical Framework

This conceptual and theoretical framework aims to inform the design of an e-learning system based on three complementary domains that intersect to structure the pedagogical, technological and methodological approach of the proposed system. The pedagogical foundation is based on collaboration between peers, inspired by the work of Vygotsky this approach considers that knowledge is built through social interaction, cooperation between peers and dialogue [11]. Then, the second theoretical pillar concerns artificial intelligence in education, and more specifically adaptive learning systems and intelligent agents. These technologies make it possible to personalise the courses according to the profile, pace and needs of each learner. Finally, the third axis is based on educational software engineering, which provides a rigorous methodology for designing complex systems. By articulating these three dimensions, this work is part of a systemic approach, laying the foundations for a fine modeling of an online learning environment that is both personalized, collaborative and intelligent, capable of meeting the current challenges of distance learning.

This theoretical framework therefore guides the technical design and architecture of the adaptive and collaborative learning system maintained by AI is proposed, detailed according to:

A. The Pedagogical Approach

1) Collaborative learning: Collaborative learning, based on the principles of social constructivism, is based on the idea that knowledge construction is optimized when it is done in interaction with others. According to Johnson and Johnson, the pillars of this approach include positive interdependence, individual responsibility, and learning-promoting interactions [12]. By placing cooperation at the heart of the pedagogical system, the learning environment must encourage active exchanges between peers, thus allowing the confrontation of ideas, the collective resolution of problems and the development of social skills,[13]. To support this dynamic, the system must integrate appropriate collaborative tools (discussion forums, wikis, or shared workspaces), while ensuring balanced group participation [14]. Beyond simple interaction, one of the major objectives of collaborative learning is the co-construction of knowledge, where learners produce resources or solutions with high added value together.

Scardamalia and Bereiter emphasize the importance of supporting the complex cognitive processes involved in this co-elaboration: collective regulation, integration of divergent points of view, and shared reflection. Learning systems must therefore offer explicit pedagogical scenarios, as well as mechanisms for mediation or assistance in structuring collaborative work. Features such as virtual whiteboards, collaborative editors, or lightweight project management tools can promote this co-construction [15].

Finally, the management of roles and contributions through traceability systems, participation indicators or recognition mechanisms (badges, comments, peer evaluations), is a crucial lever to guarantee equity, commitment and efficiency of group work. As Strijbos and De Laat, [16] point out, it can strengthen learners' motivation and encourage active participation [17]. By integrating these dimensions, a well-designed collaborative learning system becomes a real trigger for collective intelligence, in the online learning experience.

B. The Technological Approach

1) Adaptive learning: Adaptive learning is now one of the major levers for personalizing the online educational experience. It is a pedagogical approach that dynamically adjusts the content, pace, and activities based on each learner's needs, skill level, and learning style.[18]. This personalization is based on a fine modeling of the user, integrating variables such as prior knowledge, cognitive preferences or learning styles, as proposed by Felder and Silverman and discussed more recently by Pashler et al ,[19],[20]. The objective is to make learning more relevant, motivating and effective by adapting the course to each profile.

Intelligent Tutoring Systems (ITS), platforms such as DreamBox or Knewton, as well as adaptive digital environments, illustrate these principles. These systems are based on a continuous evaluation of the learner's progress, made possible through the real-time analysis of their interactions with the platform. Algorithms monitor performance trends and identify gaps, making it possible to recommend specific resources, modify the sequence of content, or propose targeted remediation activities [21], [22]. The formative approach, as advocated by Bloom [23], is implemented here through integrated assessments, oriented towards pedagogical adjustment.

A third essential pillar of adaptive learning is personalized feedback. Beyond simple correction, this feedback aims to support metacognitive regulation, helping the learner to become aware of mistakes, to understand poorly mastered concepts and to plan future efforts [24], [25]. It can take the form of contextual comments, detailed explanations, recommendations for additional activities, or tailored motivational messages. This feedback, based on a detailed analysis of the learning data, helps to strengthen engagement and autonomy.

Thus, an effective adaptive learning system is not limited to distributing content; it acts as an intelligent tutor, capable of observing, analyzing and intervening in a targeted manner, to maximize the learning potential of each individual [26]. Despite their potential, these systems still have limitations, particularly in terms of general learner modelling, algorithm and data transparency, all of which are challenges for a more reliable and inclusive integration of AI in education.

2) Artificial intelligence in education: Artificial intelligence (AI) is now central to modern online learning systems, not only as a technological tool, but as a vector for educational intelligence. Its integration is profoundly transforming the ways in which digital learning environments are adapted, collaborated and automated [27].

The first major contribution of AI lies in its ability to personalize the learning experience. Unlike traditional fixed-rules-based approaches, AI-enabled systems use advanced data

processing and machine learning techniques to analyze, in real time, learner interactions (behaviors, response time, recurring errors, engagement levels). These analyses make it possible to dynamically adapt the content, the level of difficulty, the pace or the materials offered, according to the individual profile and the evolution of each learner [28]. This fine adaptability, based on learning traces, reinforces the relevance of the educational paths and promotes commitment, self-regulation and autonomous progression.

Beyond individual personalization, AI also facilitates collaboration between learners. Thanks to natural language processing and social learning network analysis technologies, it is able to observe interactions in forums, contributions in shared spaces or roles in collective activities [29]. It can thus detect imbalances, propose strategic groupings or intervene as an intelligent mediator, by structuring exchanges, relaunching discussions or formulating open questions promoting the co-construction of knowledge. AI thus contributes to a more efficient, equitable and reflective management of collaborative work, by strengthening inclusion and group dynamics.

A third fundamental axis is the automation of repetitive pedagogical tasks, both for teachers and learners. Intelligent systems now allow the automatic generation of personalized quizzes, the correction of complex exercises, the synthesis of discussions, or the early warning in the event of a risk of disengagement or failure [30, 31]. These features reduce the cognitive and temporal load on teachers, while maintaining a quality of individualized follow-up. They also allow for instantaneous, contextualized feedback, which is essential for self-regulated learning.

Finally, although the contributions of AI are promising, its deployment in education systems raises important technical challenges. Among the major challenges are the transparency of algorithms, the explain ability of automated decisions and the fairness in the proposed recommendations [32, 33, 34]. It therefore becomes crucial to design educational AI systems that are not only efficient, but also accountable, learner-centred and inclusive.

Finally, artificial intelligence is now an essential lever for pedagogical innovation. It acts as a catalyst that, far from replacing the learner, reinforces the adaptive, collaborative and formative dimensions of learning, while laying the foundations for a more intelligent, equitable and sustainable educational ecosystem [2],[4].

C. The Software Approach

UML (Unified Modeling Language) modeling allows the structure and behavior of the system to be represented, while the 2TUP (Two Track Unified Process) method offers an iterative and scalable framework for software development [1]. Combined with a reflection on instructional design, these approaches ensure consistency between instructional objectives and technological choices.

1) The development process: The 2TUP process an evolution of the unified process, offers a rigorous and flexible framework for the development of information systems [35]. By separating the functional aspects, related to business needs, from the technical aspects, related to the system architecture [36]. The 2TUP makes it possible to better adapt to the constant evolution of technological environments and user requirements. This two-pronged approach fosters close collaboration between development teams and business lines, improving the quality of the final product. In addition, by incorporating regular iterations and project reviews, the 2TUP reduces the risks associated with late changes and enables continuous delivery of value [37].

Unlike more rigid methods, 2TUP offers greater agility while ensuring a high level of quality. For example, in the development of mobile applications, 2TUP has demonstrated its ability to adapt quickly to changes in platforms and user feedback, while maintaining functional consistency [38].

2) The UML modeling language: UML (Unified Modeling Language), a universal language for object modeling, offers a range of graphical tools to accurately and concisely represent the structure and behavior of a system [39]. Whether designing a software application, a database, or a business process, UML provides a common language for developers, analysts, and users [40]. Thanks to its various diagrams (use cases, classes, sequence, activity, etc.), UML allows you to visualize the different facets of a system, from user interaction to implementation details. This graphical representation greatly facilitates understanding, communication and collaboration within a development team [41]. In addition, UML is an evolving language that adapts to new technologies and changing project needs. In short, UML is an essential asset for any professional wishing to design and develop quality software systems [42].

Ultimately, UML remains a central modeling tool, offering rigor, clarity and shared vision throughout the life cycle of a project. Its ability to represent both the functional and technical aspects of a system makes it an essential lever for the design of robust and sustainable software solutions.

D. Critical Analysis of Existing Systems

In order to design a more effective e-learning system, it is essential to analyze the limitations of the solutions currently available, [43,44]. This section critically examines existing adaptive and collaborative systems, highlighting their contributions, but also their weaknesses in personalization, social interaction, and the integration of artificial intelligence. These findings will help guide the modelling of the proposed system.

1) Comparison of existing adaptive and collaborative e-learning systems: In this section, a critical analysis of adaptive and collaborative e-learning systems is conducted in order to identify their strengths and limitations. Adaptive systems personalise learning pathways according to learners' individual needs [43] while collaborative systems promote social interaction to strengthen motivation and co-construction of knowledge [45], [46]. However, these approaches are often implemented in isolation, without any real integration between personalization and collaboration [42]. In addition, their effectiveness is sometimes limited by a lack of granularity in

adaptation or weak orchestration of collective activities. This comparison aims to shed light on the design orientations of a more efficient technopedagogical system, harmoniously integrating artificial intelligence, individual adaptation and social collaboration [47].

TABLE I. COMPARISON OF EXISTING ADAPTIVE AND COLLABORATIVE E-LEARNING SYSTEMS

Aspect	Adaptive e-learning systems	Collaborative e-learning systems
Main Objective	Personalize the learning experience based on the individual characteristics of the learner.	Harness the collective intelligence and social benefits of group learning.
Key Mechanisms	Modeling of the learner, the domain, and pedagogical adaptation.- Adaptation of the content or course according to the prerequisites or performances.- Detection of gaps and proposal of remedies.	Interaction, sharing of ideas, co-construction of knowledge.- Communication and collaborative work tools.
Examples	ITS (Intelligent Tutoring Systems), Knewton (Alma), DreamBox Learning.	Forums, Wikis, EVA, LMS (Moodle, Canvas, Blackboard).
Bounds	Adaptation often superficial, based on rigid rules.- Difficulty in integrating complex aspects such as motivation or emotion.- Dependence on the quality and quantity of data collected.- Little or no integration of social dimensions.	Collaborative tools without intelligent facilitation (little intervention on group dynamics).- Difficulty in valuing and measuring individual contributions.- Little synergy with adaptive systems (operating in silos).

According to Table I, Adaptive learning systems, such as Knewton (now integrated into the Alma platform), DreamBox Learning or Intelligent Tutorial Systems (ITS), aim to personalize the learner's experience by dynamically adapting the content, difficulty and paths according to their performance and profiles [21]. However, these devices often have limited adaptation, based on static rules or simple statistical models, struggling to integrate more qualitative variables such as motivation or emotional state. At the same time, collaborative platforms such as Moodle, Canvas or forum environments offer tools for interaction (discussions, sharing, group work), but collaboration remains poorly guided: group dynamics, role coordination or the valuation of contributions are rarely handled in an intelligent way [13]. This double observation reveals a persistent compartmentalization between individualized adaptation and collaborative learning. Data from learner profiles are rarely used to form relevant groups or adapt social interactions, and there is no automated orchestration to synchronize adaptive and collaborative processes within the same system [48]. This separation hinders the emergence of truly intelligent learning environments, fully integrating the social and cognitive dimensions.

III. RESULTS AND DISCUSSION

A. UML Modeling of an Integrative Learning System

UML modeling is a powerful tool for clearly and consistently representing the essential components of a complex system. In this section, we present a functional modeling of an integrative e-learning system, combining adaptivity, collaboration, and artificial intelligence. The main objective is to describe, by means of UML diagrams, a modular architecture as highlighted by Ouelhadj et al (2020), as well as Chen et al. (2023), which is capable of personalizing learning paths, managing social interactions and automating certain pedagogical tasks thanks to AI [40], [28].

This modeling thus aims to lay the foundations of an intelligent system, centered on both the individual and the collective, while facilitating the analysis, design and implementation of an evolving and adaptable learning environment [33], [41].

Based on the 2TUP development model and using the UML language, our study relies on the StarUML tool to accurately model the complex interactions between the learner, the content and the artificial intelligence. This work makes it possible to design tailor-made learning paths, adapted to the specific needs of each user.

1) Static part: UML makes it possible to visualize the structure, behavior and interactions of the different components of a system, thus facilitating communication between stakeholders, both technical and non-technical. UML is widely used in software engineering to analyze functional and non-functional requirements, design robust software architectures, and document existing or developing systems [49],[50]. Through this article, we propose four diagrams, including two structural diagrams (class diagram and use case diagram) and two behavioral diagrams (sequence diagram and activity diagram).

a) Class diagram: For Rosenberger, M. (2022) and Chehida, S. et al. (2021), a class diagram is used to illustrate classes along with their attributes, methods, relationships (such as association, aggregation, composition, inheritance, etc.) and a constraint [39],[51].

b) Diagram interpretation: Fig. 1 presents the static structure of the system, it allows to understand how the objects interact, to visualize the organization of the data and to clearly define the responsibilities of each class in the overall functioning of the system, as follows:

- TutorIntelligent Class: The TutorIntelligent class manages personalized learner coaching via the evaluateLearnerLevel(), adaptContent(), generate Exercises(), provideFeedbackPersonalized (), and followProgress() operations. This central class coordinates the adaptation of learning
  - evaluateLearnerLevel (): Allows you to evaluate the learner's current level. For example, it can analyze the learner's answers to programming exercises to determine their level in Python.
  - adaptContent(): Allows you to adjust the learning content according to the learner's level and profile. For example, it can offer more complex exercises if the learner masters the basics well.

- generateExercises(): Allows you to create custom exercises. For example, it can generate math exercises adapted to the learner's current level.
- provideFeedbackPersonalized (): Allows you to give detailed feedback on the learner's responses. For example, it can explain why an answer is incorrect and suggest ways to improve it.
- followProgress(): Allows you to track the progress of learning. For example, it can identify concepts that require more practice.

- Learner Group Class: The Learner Group class manages groups of learners through the setObjectives(), planActivity(), assignTutor(), evaluateProgress(), and WorkOnTheTask() operations. It organises and coordinates collective learning.
  - setObjectives(): Allows you to set learning objectives for the group. For example, they can set common goals for a collaborative project.
  - planActivity(): Allows you to plan learning activities. For example, they can organize group work sessions or practical workshops.
  - assignTutor(): Allows you to assign a tutor to the group. For example, he can assign a specialized tutor depending on the needs of the group.
  - evaluateProgress(): Allows you to evaluate collective progress. For example, it can measure the group's progress against the set goals.
  - WorkOnTheTask(): Allows you to manage work on assigned tasks. For example, it can track the distribution and progress of tasks among members.

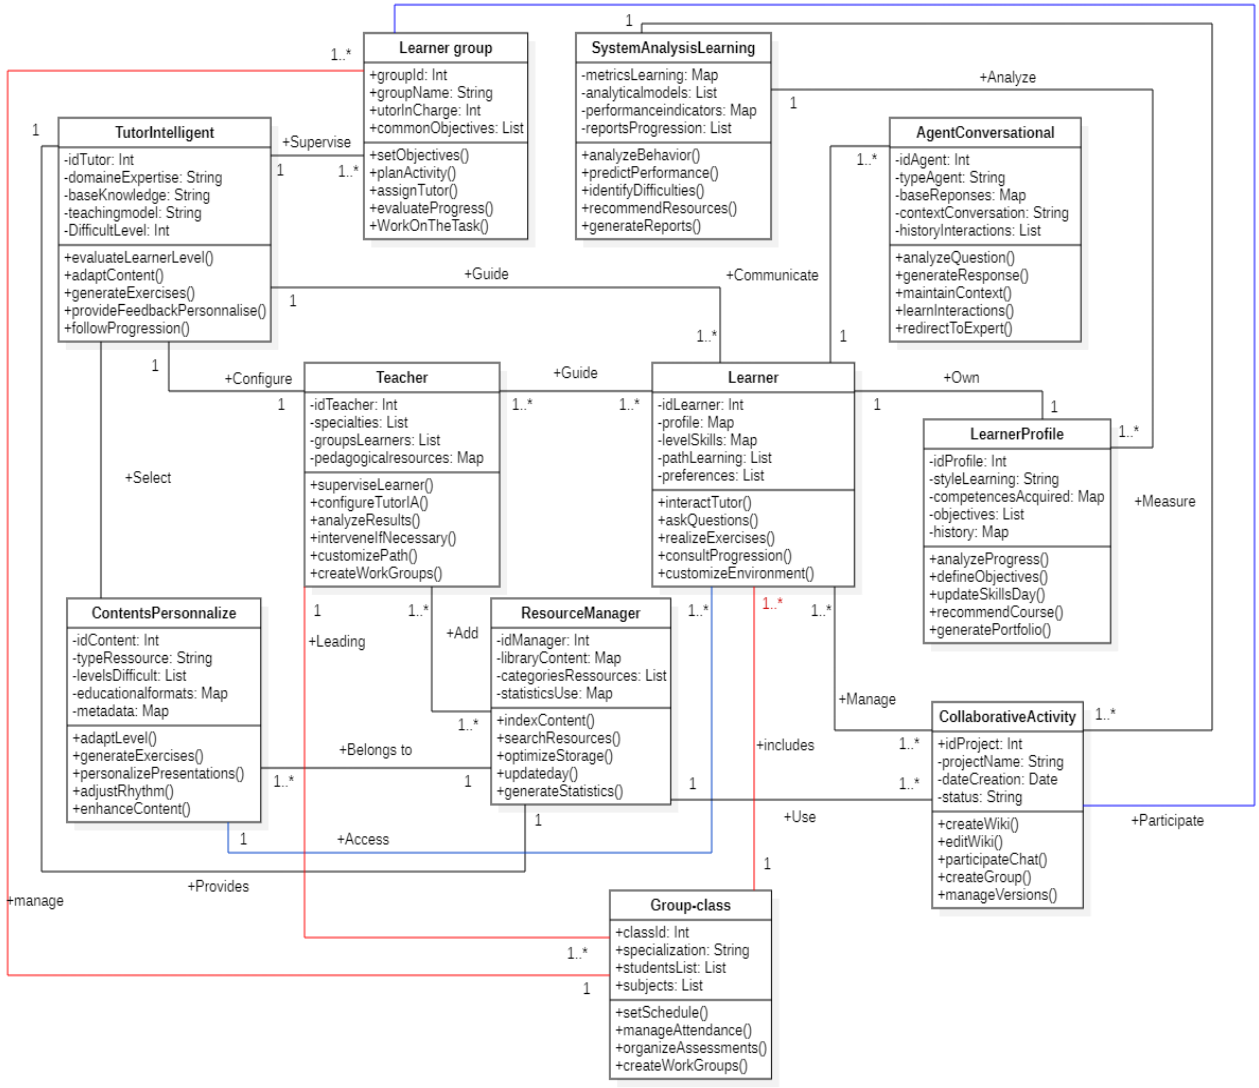

Fig. 1. Class diagram and static structure of online learning system.

- Teacher Class: The Teacher class oversees the learning process through the superviseLearning(), configureAITutor(), analyzeResults(), interveneIf Necessary(), and customizePath() operations. It represents the human expert who guides and adjusts the system.
  - superviseLearning(): Allows you to track the overall progress. For example, the teacher can observe the learning patterns of a group of learners.
  - configureAITutor(): Allows you to configure the tutorial system. For example, the teacher can adjust the evaluation criteria or difficulty thresholds.
  - analyzeResults(): Allows you to study learners' performance. For example, the teacher can identify concepts that cause problems for multiple learners.
  - interveneIfNecessary(): Allows you to provide human assistance. For example, the teacher can organize a remedial session for particularly difficult concepts.
  - customizePath(): Allows you to tailor learning paths. For example, the teacher can create specific learning paths for different learner profiles.
- Learner Class: The Learner class interacts with the system through the interactTutor(), askQuestions(), effectExercises(), consultProgress(), and customize Environment() operations. It represents the main user of the learning system.
  - interactTutor(): Allows the learner to interact with the smart tutor. For example, the learner may ask for additional explanations of a difficult concept.
  - askQuestions(): Allows the learner to ask questions to the system. For example, the learner may ask for clarification on a programming exercise.
  - realizeExercises(): Allows the learner to complete the proposed exercises. For example, the learner can solve math problems adapted to his or her level.
  - viewProgress(): Allows the learner to see their progress. For example, the learner can see their performance in different skills.
  - customizeEnvironment(): Allows the learner to adjust their learning preferences. For example, the learner can change the pace of learning or the type of exercises he or she prefers.
- Systems Analysis Learning class: The AnalysisLearningSystem class analyzes training data through the analyzeBehavior(), predictPerformance(), identifyDifficult(), recommendResources(), and generate Reports() operations. It provides information to optimize training.
  - analyzeBehavior(): Allows you to analyze learning patterns. For example, it can identify that the learner performs better in the morning or that they spend more time on geometry exercises.
  - predictPerformance(): Allows you to anticipate the learner's future performance. For example, it can predict whether the learner is ready to tackle a complex new concept.
  - identifyDifficulty(): Used to identify blocking points. For example, it can detect that the learner has systematic difficulties with fractions in mathematics.
  - recommendResources(): Allows you to suggest relevant resources. For example, it can suggest additional explainer videos about concepts that are not well understood.
  - generateReports(): Allows you to create detailed analysis reports. For example, it can produce a monthly summary of the learner's progress.
- AgentConvensional class: The Conversational Agent class handles conversational interactions through the analyzeQuestion(), generateAnswer(), maintainContext (), learnInteractions(), and redigerVersExpert() operations. It ensures natural communication with the learner.
  - analyzeQuestion(): Helps to understand the questions being asked. For example, it can identify whether the learner is asking a question about a mathematical concept or asking for clarification.
  - generateAnswer(): Allows you to formulate appropriate answers. For example, it can explain a complex concept with simple analogies.
  - maintainContext(): Helps keep the conversation consistent. For example, it can remember previous questions to provide contextualized answers.
  - learnInteractions(): Allows you to improve your future responses. For example, you can memorize the explanations that worked best.
  - writeToExpert(): Allows you to forward complex questions to the smart tutor. For example, it can redirect a technical question to an expert in the field.
- Learner Profile Class: The LearnerProfile class handles student information through the analyzeProgress(), setObjectives(), updateSkills(), recommendPath(), and generatePortfolio() operations. It maintains a complete view of the learning path.
  - analyzeProgress(): Allows you to evaluate the progress of learning. For example, it can track the improvement of programming skills over a period of time.
  - setGoals(): Allows you to set learning objectives. For example, it can set milestones to reach an advanced level in mathematics.
  - updateSkills(): Allows you to update the mastery level. For example, it can validate the acquisition of a new skill after passing exercises.

- recommendPath(): Allows you to suggest learning paths. For example, it can suggest an optimal sequence of modules to follow.
- generatePortfolio(): Allows you to create a portfolio of skills. For example, it can compile achievements and certificates obtained.

- ContentPersonnalize Class: The Content Personalize class handles adapting content through the adaptLevel(), generateExercises(), personalizePresentations(), adjustRhythm(), and enrichContent() operations. It helps ensure that the content matches the needs of each learner.
  - adaptLevel(): Allows you to adjust the difficulty of the content. For example, it can simplify programming exercises if the learner encounters too many difficulties.
  - generateExercises(): Allows you to create custom exercises. For example, it can generate math problems based on the learner's interests.
  - customizePresentations(): Allows you to adapt the format of the content. For example, it can favor visual aids for a learner with a visual learning style.
  - adjustPace(): Allows you to change the pace of learning. For example, it can slow down the progress of a module if the learner needs more time.
  - enrichContent(): Allows you to add additional resources. For example, it can incorporate concrete examples related to the learner's area of interest.
- Resource Manager class: The Resource Manager class organizes educational resources using the indexContent(), searchResources(), optimizeStorage(), update(), and generateStatistics() operations. It manages the system's resource library.
  - indexContent(): Allows you to catalog the available resources. For example, it can categorize educational videos by level and theme.
  - searchResources(): Allows you to quickly find relevant content. For example, it can locate all available exercises on loops in programming.
  - optimizeStorage(): Allows you to manage storage space efficiently. For example, it can archive infrequently used resources.
  - update(): Allows you to update existing resources. For example, it can update exercises with new use cases.
  - generateStatistics(): Used to produce usage analytics. For example, it can identify the most consulted resources.

The Resource Manager class:

- Interacts with the Learner class for participant management

- Contact SmartTutor for group work evaluation

- Uses Resource Manager to store collaborative content

- Integrates with the Learning Analysis System to measure participation

- Collaborative Activity Class: The Collaborative Activity class facilitates collaboration between learners through the createWiki(), editWiki(), participateChat(), createGroup(), shareResources(), and manageVersions() operations. It allows learners to work together and communicate effectively.
  - createWiki(): Allows you to create wiki pages for knowledge sharing. For example, learners can create a wiki page on the key concepts of object-oriented programming.
  - editWiki(): Allows collaborative editing of wiki content. For example, a learner can add practical examples to an existing wiki page on the unified modeling language.
  - participateChat(): Allows you to exchange in real time with other learners. For example, learners can discuss a complex problem or organize their group work.
  - createGroup(): Allows you to form work teams. For example, learners can create a group for a common software development project.
  - shareResources(): Allows you to exchange documents and resources. For example, a learner can share their notes or useful links with their group.
  - manageVersions(): Allows you to track changes made to the wiki. For example, learners can see the history of changes and revert to an earlier version if necessary.
- Group Class: The Group-class handles the academic aspects of a class through the setSchedule(), manageAttendance(), organizeAssessments(), and createWorkGroups() operations. It structures the pedagogical organization of a class group.
  - setSchedule(): Allows you to set the class schedule. For example, they can schedule class sessions and assessments.
  - manageAttendance(): Allows you to manage student attendance. For example, it can track attendance and generate attendance reports.
  - organizeAssessments(): Allows you to organize assessments. For example, they may schedule and coordinate ongoing reviews and assessments.
  - createWorkGroups(): Allows you to create workgroups. For example, he can form balanced teams for collaborative projects.

c) Use case diagram: The use case illustrates the exchanges between a system and its stakeholders (users, other systems, etc.) in terms of usage scenarios and functionalities offered by the system [52]. The identification of user needs and the main functionalities to be developed is often done upstream of the design phase using the use case diagram [53]. In the use

case diagram Fig. 2, the actors are symbolized by external blocks while the use cases are indicated by ellipses. The arrows symbolize the links between the actors and the usage scenarios [54].

- Diagram interpretation:

Learner: The learner is at the center of the system and interacts with several functionalities. He can:

- Interact with the tutor: This suggests a built-in tutoring system, likely AI-driven, that offers personalized assistance.
- Check your progress: The learner can track their performance and progress in the course.
- Customize the environment: The system offers customization options to tailor the learning experience to the learner's preferences.
- Create/Edit a wiki: A collaborative feature for learners to contribute to a common knowledge base.
- Participate in a chat: Facilitates communication and interaction between learners.
- Create a group: Allows learners to form workgroups for collaborative projects or studies.

Teacher: The teacher supervises the learning process and has access to the following functions:

- Set up the AI tutor: The teacher can adjust the settings of the AI tutor to optimize its effectiveness.
- Track learning: The teacher can track learners' progress and identify difficulties.
- Analyze the results: The teacher can examine the performance of the learners and evaluate the effectiveness of the teaching.
- Intervene if necessary: The teacher can intervene to provide additional support or personalized advice.

System Analysis Learning: This component represents the analytical backend of the system. It does the following:

- Analyze behavior: The system tracks and analyzes learners' actions in the learning environment.
- Predict performance: Based on the data collected, the system can predict the future performance of learners.
- Identify difficulties: The system can detect areas where learners are struggling.
- Recommend resources: Based on the needs identified, the system may recommend additional learning resources.

Chatbot: This actor represents a chatbot or virtual assistant. Its actions include:

- Analyze the question: Understand the questions asked by the learners.
- Generate Response: Provide relevant answers to questions.
- Maintain context: Maintain the context of the conversation for more natural interactions.

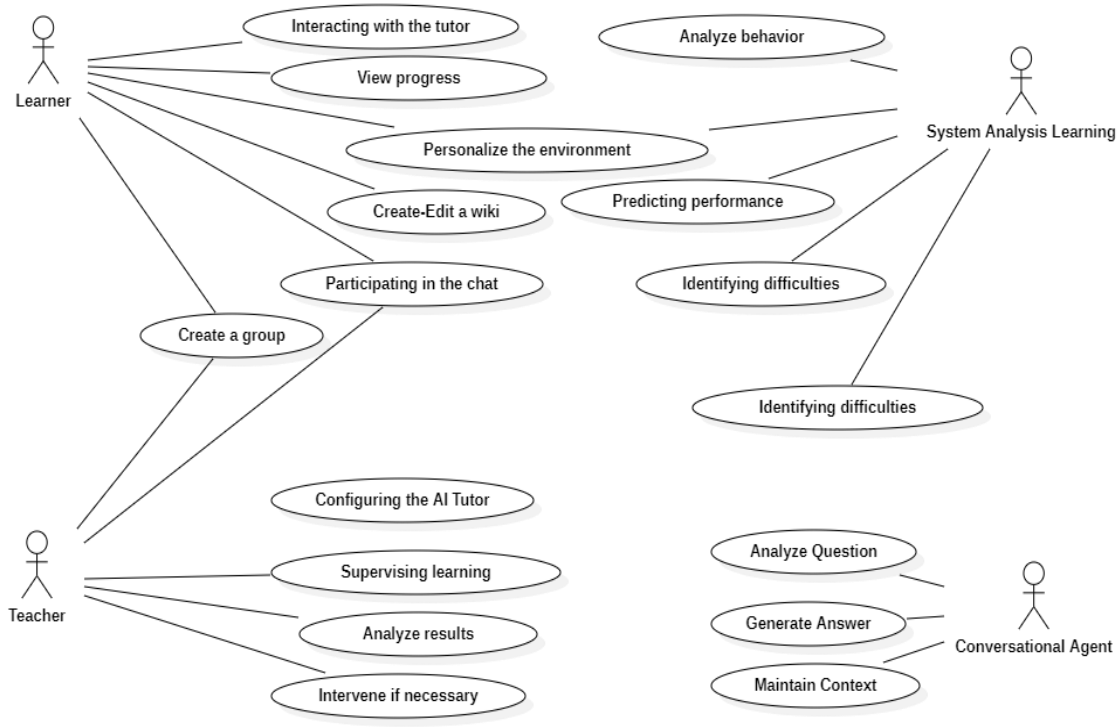

Fig. 2. Use case diagram and interactions between the different actors.

2) Dynamic part: UML dynamic modeling offers a complementary vision of the behavior of a system [55]. While sequence diagrams emphasize the chronological order of interactions between different objects, activity diagrams present a more holistic view of processes, breaking down actions into sequences, parallels, or conditions. They thus provide a better understanding of how the system works, identify potential problems and facilitate communication between the different actors of a project [56]. There are two types of diagrams: the sequence diagram and the activity diagram.

a) The Activity diagram: A UML activity diagram is a graphical representation that visualizes the control flow of a process, procedure, or algorithm [57]. It makes it possible to model in detail the different stages of a process [58]. The decisions to be made at each stage, the loops and the synchronizations.

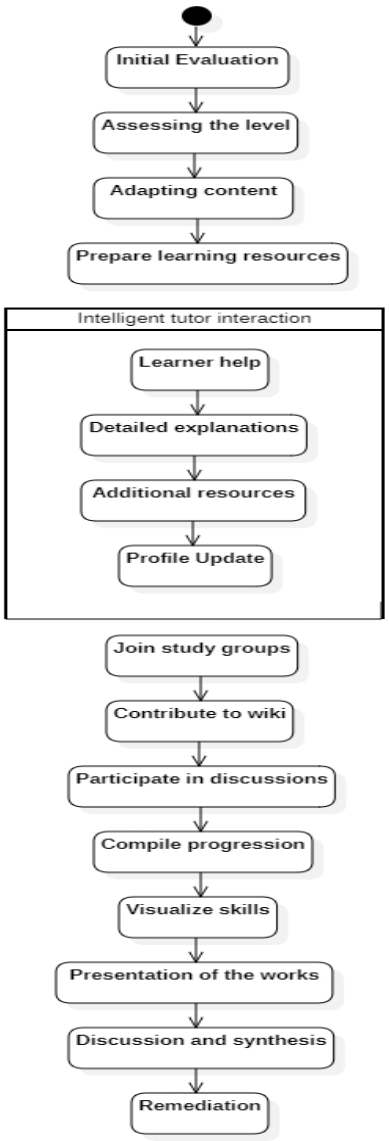

Fig. 3. Activity diagram describing the workflow within the learning system.

- Interpreting the intelligent learning system presented in this activity diagram (Fig. 3), illustrates a comprehensive and sophisticated learning process. It all starts with a crucial initial assessment phase that precisely identifies the learner's level, followed by an in-depth assessment to tailor the learning content to their specific needs. Once this foundation is established, the system prepares customized learning resources. Interaction with the smart tutor is at the heart of the system, offering targeted assistance, detailed explanations and additional resources, while keeping the learner's profile up to date. The system strongly encourages the collaborative dimension of learning by inviting learners to join study groups, contribute to a collective wiki, and actively participate in discussions. Progress is monitored rigorously, with a regular compilation of progress, a clear visualization of the skills acquired and presentations of the work carried out. The process concludes with discussion and synthesis sessions, allowing to consolidate learnings, with the possibility of implementing corrective actions if necessary. This methodical approach combines personalized learning, intelligent interaction, and social collaboration, creating a comprehensive and effective learning environment that continually adapts to the learner's needs.

b) A sequence diagram: According to Damy, the UML sequence diagram is a visual representation that illustrates the interactions between different objects in a system over time [59]. It makes it possible to model in detail the exchange of messages between these objects, following a precise chronology [60]. Each object is represented by a vertical lifeline, and the messages exchanged are represented by horizontal arrows. These diagrams are particularly useful for understanding the dynamics of a system, identifying synchronization points, and analyzing usage scenarios.

- Interpreting: The sequence diagram (Fig. 4), illustrates the dynamic and chronological interaction between the different actors in the learning system: the teacher, the learner, the group of learners, the class group and the system itself. The sequence highlights the message exchanges and communication flows between these entities. The learner initiates the process by registering and defining their profile, followed by interactions with the learning content through learning activities and assessments. The system plays a pivotal role in managing resources, processing responses, and providing automated feedback. The collaborative dimension is represented by the interactions between the learner and his or her group, as well as with the whole class, especially during discussions and shared activities. The teacher intervenes at key moments for validation and final evaluation. This sequential representation places particular emphasis on the temporal aspect and the sequencing of interactions, showing how each action triggers a specific reaction or response from other actors in the system, thus creating a coherent and structured learning flow.

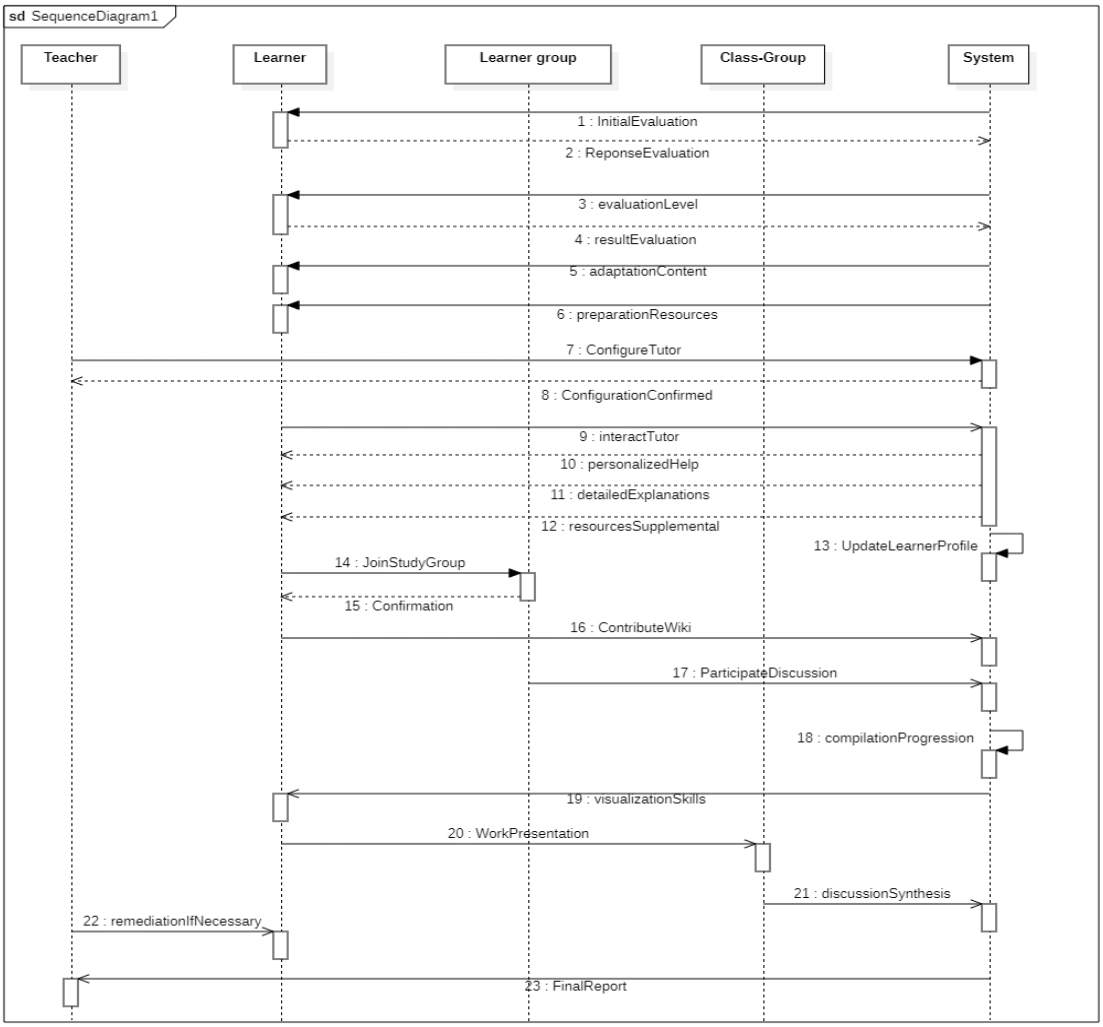

Fig. 4. Sequence diagram and interactions between system objects.

From the foregoing, the UML modelling of an integrated learning system combining adaptability, collaboration and artificial intelligence is a significant advance in the field of digital educational environments. This model demonstrates how it is possible to harmonize the personalization of learning paths with the activation of social interactions, two aspects frequently examined separately in current systems. The clear and modular structure offered by UML not only facilitates design, but also improves communication between the different actors, ranging from creators to teachers, as well as technical developers. This strategy better meets the challenging requirements of personalized, collaborative learning at scale.

The incorporation of artificial intelligence as a central element of the system represents a real lever for optimizing educational pathways and perfecting support. By examining learners' behavioral and interactive data in real time, AI can refine content, organize relevant collaborations, and provide tailored feedback. This capacity for dynamic adjustment far exceeds that of traditional adaptive systems anchored in rigid rules, offering a more responsive and resilient framework. In addition, the automation of repetitive tasks by artificial intelligence relieves teachers of certain administrative obligations, allowing them to focus more on supporting and designing innovative pedagogies. However, while promising, this modeling also presents challenges: the complexity of managing various adaptive and collaborative modules simultaneously requires a robust and scalable technical architecture that can adjust to technological and pedagogical advances. The modular approach adopted offers essential flexibility, opening up prospects for the subsequent integration of new functionalities, such as learning through gamification, predictive analysis of the risk of dropping out or the use of more advanced intelligent conversational agents. These perspectives accentuate the potential of this model to become a sustainable part of digital pedagogical practices, by meeting the growing needs for personalization and remote collaboration.

Finally, this work enriches the reflection on the creation of more intelligent and humane e-learning systems, by finely articulating complementary dimensions in a coherent structure. It encourages further research and experimentation to better understand and exploit the synergies between adaptability, collaboration and artificial intelligence for the benefit of more inclusive and effective education.

IV. Challenges and Prospects

Developing an integrative online learning system based on adaptivity, collaboration, and AI poses several challenges:

- technical interoperability,

- balancing algorithmic personalization and mediation.

For the future, the integration of immersive technologies and generative AI offers promising prospects, provided that collaboration between researchers, designers, and educators is strengthened to ensure inclusive, sustainable, and pedagogically relevant learning environments.

V. Conclusion

UML modeling of an integrative learning system, combining adaptability, collaboration and artificial intelligence, represents a major step towards creating more efficient, personalized and dynamic online educational environments. This modular framework facilitates the clear and logical organization of complex interactions between learners, content, and smart technologies, while providing essential flexibility to meet diverse user needs. The combination of personalizing journeys and encouraging social interactions, supported by sophisticated artificial intelligence mechanisms, not only improves the quality of individual learning, but also underlines the collective and collaborative dimension, which is crucial for motivation and success.

However, this innovative approach also presents considerable challenges. On the technical side, the complexity of adaptive algorithms and interaction analysis modules requires rigorous design and exhaustive validation to ensure the reliability, robustness and scalability of the system. From a pedagogical point of view, it is essential to find a balance between automation and human intervention, in order to maintain an educational mediation attentive to the emotional and cognitive needs of learners. In addition, ethical issues related to the use of personal data, the transparency of algorithmic processes and the prevention of bias must be addressed with sustained attention, thus ensuring a responsible and fair use of artificial intelligence in the field of education.

Despite these challenges, the proposed model represents a promising framework that can be adapted and expanded to different educational contexts and disciplines. It paves the way for future research to experiment and refine these architectures in real-world environments, while assessing their impact on learning, collaboration, and motivation. This work thus serves to enrich the reflection on the digital transformation of education, by putting people at the center of technological innovations and by promoting a more inclusive, agile and intelligent pedagogy.

The future of online learning systems rests on this ability to effectively combine advanced technologies and a student-centered approach to meet the complex and evolving challenges of distance and hybrid learning in an increasingly connected and demanding world.

Determinant Factors of Success for the Village Information System in Providing Sustainable Services and Governance

Sutia Dwi Santika, Tuga Mauritsius
Information System Management Department-BINUS Graduate Program-Master of Information System Management,
Bina, Nusantara University, Jakarta 11480, Indonesia

***Abstract*—The Indonesian government is working to implement a digital transformation aimed at providing effective services and governance at both central and local levels, similar to other developing countries. A key strategy for achieving this digital government transformation at the local level involves the implementation of village information system, which are managed by village officials. The Ministry of Villages and Development of Disadvantaged Regions is developing a village information system to support these efforts, village laws, and the Sustainable Development Goals. However, the village information system encounters ongoing challenges, such as slow access speeds and ineffective response services. This study adopts a quantitative approach by using cross-sectional questionnaires that collected 426 valid responses. This study identified seven main factors that influence the success or failure of implementing a village information system: system quality, information quality, service quality, perceived usefulness, user satisfaction, trust, and net benefits. This study contributes to the literature by recognizing these factors within the DeLone and McLean Information System Success Model and TAM frameworks, which are still rarely addressed in e-government adoption studies, especially regarding village governments in developing countries. Data analysis revealed significant relationships system quality, information quality, and service quality significantly impact perceived usefulness. Information quality, service quality, trust, and perceived usefulness significantly impact user satisfaction, and perceived usefulness and satisfaction significantly affect net benefits. This research has practical implications for the successful adoption of the village information system as part of the ministry's efforts to improve services and overall governance.**

***Keywords*—E-Government; System Quality; Service Quality; Delone and Mclean model; TAM**

I. Introduction

The Indonesian government is making strides toward digital transformation, mirroring similar efforts in other developing nations aimed at enhancing service provision and governance. Governance plays a crucial role in the success of digital transformation within the service provision sector, addressing the continuously changing needs of society [1]. These e-government services can reduce costs, accelerate service delivery, and increase accessibility; these services focus on effective service delivery to ensure optimal use of the e-government system [2].

Indonesia implements e-government services at the central and local government levels. The central and local governments in Indonesia implemented the Village Information System (VIS) to improve governance and services as a key strategy for digital government transformation, similar to initiatives in other developing countries [3]. These initiatives aim to streamline administrative processes, enhance transparency, and empower citizens by providing them with easy access to information and services. The Ministry of Village and Development of Disadvantaged Regions created the village information system to track the use of village finances and provide reliable, accurate, and sustainable data for planning village development [4]. This system is crucial for enhancing village conditions by concentrating on the needs of the community, creating transparent plans and budgets, and aligning with the Sustainable Development Goals (SDGs) for village communities.

However, integrating e-government into village information system presents major challenges that impact the long-term sustainability of services. These challenges include insufficient ICT infrastructure, which complicates service delivery [5] and a lack of digital literacy, which illustrates the importance of comprehensive training in managing the village information system. Additionally, bureaucratic resistance, concerns about data privacy, and restrictive regulations can hinder the realization of the anticipated benefits [6].

The researcher conducted interviews with the Head of Information System Development at Pusdatin and operators of the village information system to gain insights into their experiences and the challenges faced during the system's implementation. The findings from these interviews reveal several quality issues with the system. For instance, the system frequently crashes during high traffic periods, and misconfigured IP addresses can occur during data display. Additionally, the system's features do not fully meet user needs. There is also a significant gap between the targets and the actual outcomes set by the Ministry of Village and Development of Disadvantaged Regions, leading to suboptimal data utilization in decision-making and errors in data entry, which result in inaccuracies. A critical factor for the success of e-government is the quality of services provided. The ineffectiveness of the services within the village information system stems from the slow response times of the village service team and the non-functional discussion forum feature. User satisfaction with the system is influenced by the employee attitude and the efficiency of service delivery, both of which

The Ministry of Communications and Digital Aspiration Scholarship funded this research.

are vital factors affecting the overall user experience with the village information system.

The identification of issues occurring in the Village Information System was obtained from system improvement suggestions to ensure the system runs optimally and supports the needs of the Ministry of Village and Development of Disadvantaged Regions. Fig. 1 shows the categorization of problems, with the highest issues being system speed and server upgrades in the village information system.

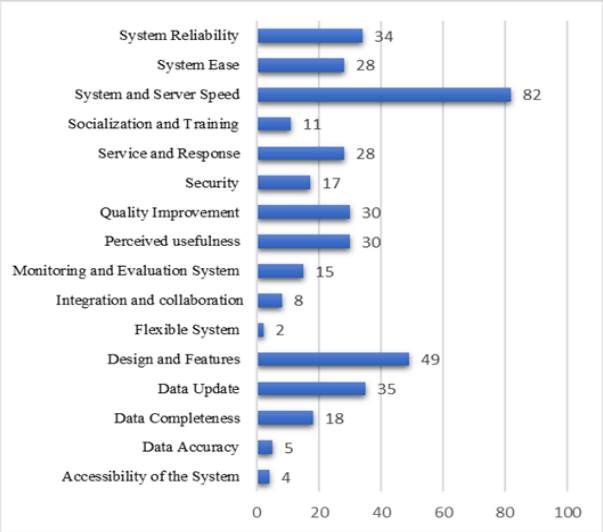

Fig. 1. Categories of issues in the village information system.

This research develops an integrated model that combines various theories, utilizing the Information System Success Model [7], [8] as the primary framework. It incorporates additional factors from the Technology Acceptance Model [9] and aspects of trust. The study tests the factors influencing the net benefits of the village information system. The findings are based on the perspectives of both employees and users within the village context, contributing to the overall success of these systems. This knowledge is valuable for the government sector, system developers, and academics, who can leverage it to enhance technology and innovation in village information system in the realm of e-government. By improving the sustainability of the village information system, the research aims to achieve better service outcomes and long-term sustainability within government organizations.

This study formulates the following research question:

RQ1: What are the factors influencing the use of village information system within e-government initiatives?

RQ2: What are the most significant factors affecting the implementation of the village information system?

The following is the structure of the article: Starting with the Introduction, Section II presents the fundamental theories underlying the proposed hypothesis and the development of the conceptual model; Section III explains the research methodology; Section IV presents the research results; Section V presents the discussion and research implications; and Section VI concludes with limitations and recommendations for future research.

II. Literature Review

A. Village Information System

The implementation of the village information system, especially through initiatives such as Village-Owned Enterprises, Village Funds, and the Village Development Index, has been crucial for the sustainability of services. Law No. 6 of 2014 mandates that the central and regional governments develop the Village Information System [10]. An interconnected system serves as a framework to enhance the quality of life, promote good governance, and foster sustainable development. The Village Development Index categorizes villages based on development criteria and aims to serve as a measurement tool for government entities. The Village Development Index classifies villages into categories: independent, advanced, developing, underdeveloped, and very underdeveloped [11]. The Village Development Index effectively correlates with the Sustainable Development Goals (SDGs) for sustainable village development. The village information system effectively provides the government with accessibility for the information-based decision-making process. Village funds are an important mechanism through which the government allocates funds to each village according to their needs, and the Village Development Index shows responsibility and strategic planning in utilizing funds from the village budget [12]. The proper utilization of village funds positively impacts the value. This approach realizes smart villages within the village development strategy, ensuring sustainability and efficiency in service delivery [13], [14].

B. DeLone and McLean Information System Success Model

The Information System Success Model (ISSM) is based on Delone and McLean and serves as the reference for this research. The information system success model was created to address the increasingly prevalent issues, such as the inability to measure the individual and organizational impact of information systems [7]. System quality, information quality, use, user satisfaction, individual impact, and organizational impact are the six components of information system success that were first identified during its development. Changes were made in the Delone and McLean model in 2003 by adding service quality and net benefits, replacing individual and organizational impact [8]. The model states that the performance of information systems is determined by independent variables from quality dimensions (information quality, system quality, and service quality) to influence usage, user satisfaction, and net benefits. The model provides insights into the success and net benefits of e-government.

1) System Quality (SYQ): System quality is a measure of the information processing system itself [7]. System quality indicates the quality of the information processing system, and information processing is built based on the desired characteristics embedded in the system. System quality serves as a measure of the characteristics of e-government system, such as usability, ease of use, reliability, and accessibility [15]. E-government is more transparent, cost-effective, efficient, and better quality relative to conventional ways. The quality of the system affects perceived usefulness and user satisfaction in this research model. Previous studies have

shown how system quality affects perceived usefulness and user satisfaction [16], [17]. Similar results were obtained by other research in the context of e-government [18], [19], [20]. Users of high-quality information systems will experience satisfaction and perceive the system as useful. Based on these findings, it is assumed that system quality has a significant impact on perceived usefulness and user satisfaction from the perspective of information system.

2) Information Quality (IQ): Information quality refers to how well the delivered information satisfies consumer needs, which may be assessed through its accurate, relevance, timeliness, and completeness in meeting the requirements of the information system [21]. The information provided through e-government is highly beneficial, particularly because many members of the public are not well acquainted with government operations. This information serves to clarify how to complete various transactions [22]. The better the content of the information, the better the perception of the information system. This study examines how information quality impacts perceived usefulness and user satisfaction. The relationship between information quality and perceived usefulness and user satisfaction has been researched by studies [18], [19], [20]. Studies consistently show a positive correlation between information quality for perceived usefulness [23], and user satisfaction [24]. The findings indicate that improving the information quality can result in higher perceived usefulness and increased satisfaction with the system.

3) Service Quality (SQ): Service quality is the quality of user support from system service providers, which consists of five indicators: tangibles, reliability, responsiveness, assurance, and empathy [8]. Service quality includes support from the Information Systems Department and IT support personnel to comprehensively address user issues [19], [25] and integrates workflows from various government departments [22]. The village information system is still a mandatory system and has dedicated technical and non-technical departments to assist users, so the author believes that service quality influences perceived usefulness and user satisfaction. Service quality is a comparison between expectations and the perception received from a service [26]. Previous research has provided practical evidence of the positive impact of service quality on perceived usefulness and user satisfaction [16], [20].

4) User Satisfaction (US): User satisfaction is the recipient's response to the use of the system, measuring the extent to which it creates value for the company's internal and external customers [8]. User satisfaction is a crucial factor that drives continuous interaction in e-government, which influences their sustainable usage behavior [3]. The success of an information system depends on user satisfaction, which ultimately allows the net benefits of e-government to be achieved [20], [21], [27]. Certain benefits will emerge if users have a positive experience and feel satisfied when using the information system. User satisfaction with the village information system will greatly enhance the perceived benefits compared to the level of investment, maintenance costs, and operational costs of the ICT-based information system.

5) Net Benefits (NB): Net benefits refer to the degree to which information systems impact the success of diverse stakeholders, both positively and negatively. Net benefits are assessed by analyzing the effects on individuals or organizations [28]. When the net benefits of utilizing a system are favorable, it appears to enhance user pleasure. Furthermore, the probability of increased user adoption of the system rises [8].

C. Technology Acceptance Model (TAM)

Integration between the Technology Acceptance Model (TAM) and the DeLone and McLean Information Systems Success Model (ISSM) offer a comprehensive approach for assessing user acceptance and the efficacy of information systems within e-government. The Technology Acceptance Model, first proposed by Davis [9], highlights perceived ease of use and perceived usefulness as essential factors influencing technology acceptance. Researchers have integrated the TAM with the DeLone and McLean model to assess the success of e-government, revealing that this amalgamation has offered more details about its effectiveness [22]. The conceptual model excludes the variable "ease of use" as it pertains to system quality [20]. This research incorporates the perceived usefulness variable from the TAM into the Delone and McLean ISSM framework to develop the conceptual model.

1) Perceived Usefulness (PU): Perceived usefulness is the level of individual belief that the use of a certain system will enhance work performance [22]. Perceived usefulness is included in the research model to measure the extent to which individuals accept that using the village information system can improve performance and service effectiveness for the ministry and village. Thus, a usefulness system will make the organization operate better by improving internal effectiveness and decision-making, and reducing operational costs [29], making it easier to perceive the benefits of the system investment. The authors believe that perceived usefulness has a significant influence on user satisfaction and net benefits. Prior studies have shown that perceived usefulness significantly influences user satisfaction [3], [18]. Perceived usefulness also impacts net benefits [20].

D. Trust (TR)

Trust is a continuous and long-lasting relationship between two individuals that fosters confidence in transactions, thereby reducing the risk of not obtaining future benefits [30]. Trust in the context of e-government is the user's expectation that the online system provides accurate and timely information securely without technical errors to operate consistently [18], [31]. User trust looks at psychological and social factors, while system trust is primarily concerned with reliability, efficacy, and security [32]. Higher trust will increase user satisfaction because the information system ensures privacy and transaction security [20]. Study confirmed a significant relationship between trust and user satisfaction [33], [34].

This study used the DeLone and McLean Information System Success Model. However, previous studies have shown a research gap, where the DeLone and McLean ISSM is mostly used in the context of voluntary system usage [18], [19]. This approach also addresses the issues found in previous studies without examining the human factors such as psychological and social categories that influence the determination of system success [21]. This study specifically addresses the research gap by focusing on the village information system as a mandatory system. Adding human factors like trust as an independent factor and perceived usefulness as a mediating factor to the DeLone and McLean model makes the framework work better. The research model integrates the DeLone and McLean ISSM theory with the Technology Acceptance Model to enhance understanding of how experience influences the success of village information system.

III. METHODOLOGY

A. Research Design

This research employs a quantitative approach to examine how various techniques related to the dependent variable are influenced by factors affecting the success of village information system development in the context of e-government. It considers these factors from the viewpoints of both employees and users of the village information system. As a survey-based study, it utilizes a questionnaire as the main tool for data collection. The questionnaire is crafted to gather a diverse range of responses, facilitating a thorough analysis of the perceptions and experiences of both groups. Through the analysis of the collected data, the research seeks to identify key determinants that can enhance the effectiveness of e-government initiatives in rural areas. Research model from references [20]. Research model are shown in Fig. 2.

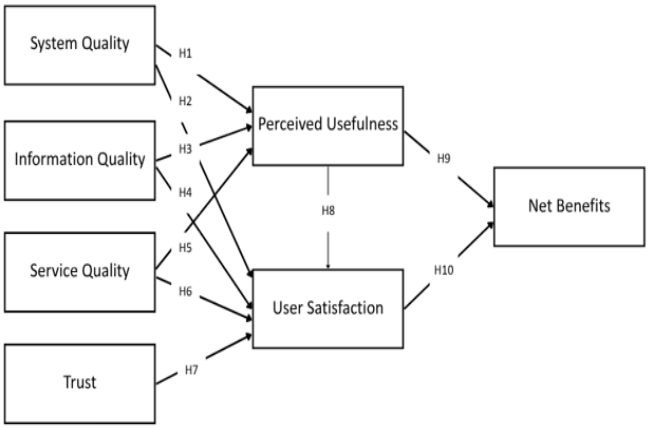

Fig. 2. Research model.

The authors created ten hypotheses (H1–H10), where the ideas about information system quality and trust are influenced by user satisfaction (US) and perceived usefulness (PU) to affect net benefit (NB). Based on the research model presented in Fig. 2, the following hypothesis is formulated in this study:

H1: System Quality has a significant impact on Perceived Usefulness.

H2: System Quality has a significant impact on User Satisfaction.

H3: Information Quality has a significant impact on Perceived Usefulness.

H4: Information Quality has a significant impact on User Satisfaction.

H5: Service Quality has a significant impact on Perceived Usefulness.

H6: Service Quality has a significant impact on User Satisfaction.

H7: Trust has a significant influence on User Satisfaction.

H8: Perceived Usefulness has a significant influence on User Satisfaction.

H9: Perceived Usefulness has a significant impact on Net Benefits.

H10: User Satisfaction has a significant impact on Net Benefits.

B. Measurement Items

This research utilized a questionnaire as the primary tool for data collection. The questions were developed through an extensive review and synthesis of relevant literature, organized into two distinct sections. Part 1 includes general information inquiries, featuring six closed-ended multiple-choice questions aimed at gathering demographic data from the respondents. Part 2 comprises 33 questions designed to assess opinions on various factors that influence the acceptance of e-government services. The questions employ a rating scale based on Likert's Scale, which ranges from 5 (mostly agree) to 1 (mostly disagree).

The questions were crafted based on insights from literature reviews and previous studies. To investigate the factors impacting the success of village information system, the study identified seven key variables: Four exogenous variables are System Quality (SYQ), Information Quality (IQ), Service Quality (SQ), and Trust (TR); two mediating variables are User Satisfaction (US) and Perceived Usefulness (PU); and one endogenous latent variable is Net Benefit (NB). Constructs and measurement items are shown in Appendix A.

C. Sample and Data Collection

Users of the village information system include all employees and village officials, who together form the population for this study. The research sample was determined using a nonprobability sampling technique, namely purposive sampling. The selection of purposive sampling is a sampling technique with specific considerations for system users who are considered to know something expected to facilitate the research. The research sample uses the Slovin formula to check validity in the equation, where a confidence level of 95% or a margin of error of 5%, which results in a minimum sample size of 370 respondents from the population.

Data collection through online questionnaires began on February 26, 2025, and ended on March 29, 2025. The research collected data using an online questionnaire. The authors then

distributed it through the correspondence application and whatsapp from all offices of the Ministry of Village and Development of Disadvantaged Regions from which 573 responses were successfully collected. Data were collected from civil servants in the Ministry of Village and Development of Disadvantaged Regions and village officials as users of the village information system from various villages in Indonesia. The authors sent 573 questionnaires to the complete research sample. We deemed 147 out of the 573 questionnaires invalid due to the absence of important information. Therefore, 426 valid responses were collected, resulting in a response rate of 74%. The data gathered from 426 responses allows for a more detailed analysis. Data supporting this study are available from the Zenodo Repository (https://zenodo.org/records/15637404), DOI: 10.5281/zenodo.1563740.

D. Data Analysis

Data analysis uses a three-stage approach to data analysis as follows: (1) Partial least squares (PLS) analysis with SmartPLS 4.0 is used to test the measurement model and identify seven dimensions. (2) Path analysis is used to test the direction and strength of hypothesized relationships. (3) A bootstrap approach is used to test the hypothesis of information system quality and trust mediated by perceived usefulness and user satisfaction towards net benefits.

IV. Result

A. Demographics

The information regarding the characteristics of the research respondents includes gender, age, education, occupation, and experience with the village information system, as presented in Table I. The demographic analysis encompasses 426 survey respondents. The findings indicate that the majority of respondents are male (n = 336, 78.87%), with an age range of 35-44 years (n = 186, 43.66%) and holding a bachelor's degree (n = 303, 71.13%). Additionally, most respondents have used the village information system for over three years (n = 280, 65.73%).

The gender demographics indicate that males represent 78.87% of the respondents, while females account for 21.13%. In terms of age distribution, 43.66% of respondents fall within the 35-44 years age range, 28.40% are aged 45-54 years, 21.83% are aged 25-34 years, 5.40% are between 55-65 years, and 0.70% are under 25 years. This finding suggests that most respondents are of an age likely to adapt to technological advancements, enabling them to utilize information systems efficiently. Regarding education, a significant majority of respondents hold a bachelor's degree (71.13%). This level of education indicates that most respondents possess adequate knowledge and skills to effectively operate technology. Job demographics include civil servants (83.57%) and village officials (16.43%). Those with over three years of experience predominantly observe user experience with the system (65.73%). This data suggests that users who are already familiar with the system are less likely to encounter significant changes and tend to continue using it.

B. Measurement Model Assessment

The measurement model integrates the construct with the structural model [35]. The measurement model analyzes the model's fit, consisting of tests of convergent validity and discriminant validity.

TABLE I. Demographic Information of the Respondents

Category	Subcategory	Count (n)	Percentage
Gender	Male	336	78.87%
	Female	90	21.13%
Age	< 25 Years	3	0.70%
	25-34 Years	93	21.83%
	35-44 Years	186	43.66%
	45-54 Years	121	28.40%
	55-65 Years	23	5.40%
Last Education	High School	43	10.09%
	Associate Degree	33	7.75%
	Bachelor Degree	303	71.13%
	Master Degree	45	10.56%
	Doctoral Degree	2	0.47%
Occupation	Village Officials	356	83.57%
	Civil Servants	70	16.43%
Experience Using VIS	< 1 Year	28	6.57%
	1-3 Year	118	27.70%
	> 3 Year	280	65.73%
Location	Banten	5	1.17%
	Jakarta	37	8.69%
	Jawa	368	86.38%
	Kalimantan	5	1.17%
	Nusa Tenggara Timur	2	0.47%
	Sulawesi	5	1.17%
	Sumatra	4	0.94%

1) Convergent validity test: Convergent validity refers to the degree to which a construct effectively explains an item. To assess convergent validity, begin by calculating the indicator loading factor. A loading factor of ≥ 0.708 is used, as this indicates that each construct accounts for more than 50% of the indicators. Next, compute the *Average Variance Extracted* (AVE) using the loading factor values for each indicator within a construct to determine the average value. AVE values of ≥ 0.50 are deemed valid [35]. The loading factor results are in Table II.

According to the calculations in Table II, two latent variables have outer loading values ≤ 0.708, namely SYQ2 and SYQ3. Therefore, the authors encourage testing other reflective indicators' load tests by removing SYQ2 and SYQ3 to examine changes in AVE. As identified in Table III, the AVE of SYQ increased to 0.194, respectively. So, the authors decided to leave out SYQ2 and SYQ3 from the suggested model, which led to outer loading values of 0.708 or higher for all the indicators shown in Table VI.

TABLE II. LOADING FACTOR RESULT

Construct	Indicator	Outer loadings	Parameter
System Quality	SYQ1	0.774	0.708
	SYQ2	0.611	0.708
	SYQ3	0.319	0.708
	SYQ4	0.806	0.708
	SYQ5	0.819	0.708
Information Quality	IQ1	0.794	0.708
	IQ2	0.789	0.708
	IQ3	0.834	0.708
	IQ4	0.750	0.708
	IQ5	0.778	0.708
Service Quality	SQ1	0.753	0.708
	SQ2	0.856	0.708
	SQ3	0.841	0.708
	SQ4	0.865	0.708
	SQ5	0.856	0.708
Trust	TR1	0.876	0.708
	TR2	0.866	0.708
	TR3	0.882	0.708
Perceived Usefulness	PU1	0.882	0.708
	PU2	0.902	0.708
	PU3	0.911	0.708
	PU4	0.903	0.708
	PU5	0.921	0.708
User Satisfaction	US1	0.838	0.708
	US2	0.851	0.708
	US3	0.863	0.708
	US4	0.843	0.708
	US5	0.864	0.708
Net Benefits	NB1	0.824	0.708
	NB2	0.876	0.708
	NB3	0.862	0.708
	NB4	0.880	0.708
	NB5	0.870	0.708

TABLE III. AVERAGE VARIANCE EXTRACTED (AVE)

Construct	Average Variance Extracted (AVE)		Changes
	Before	After	
SYQ	0.479	0.673	0.194
IQ	0.623	0.623	0.000
SQ	0.698	0.698	0.000
TR	0.765	0.765	0.000
US	0.725	0.725	0.000
PU	0.817	0.817	0.000
NB	0.744	0.744	0.000

2) Discriminant validity test: The assessment of discriminant validity is the extent to which a construct empirically differs from other constructs in the structural model. To evaluate discriminant validity using Fornell and Larcker, you need to check the Average Variance Extracted (AVE) for each construct and compare it to the squared correlation between all the constructs being measured. However, the Fornell and Larcker criterion is ineffective when the loadings of an indicator for a construct are low, such as when all the loadings of the indicators range from 0.65 to 0.85. The assessment of discriminant validity can also use HTMT based on the correlation. The HTMT value is not more than ≥ 0.90, which indicates invalid discriminant validity. An HTMT value ≤ 0.90 is considered valid [35]. The Fornell-Larcker criterion and the heterotrait-monotrait ratio (HTMT) are the most effective metrics for assessing the discriminant validity of the model. The Fornell and Larcker criterion and HTMT results can be seen in Table IV and V.

TABLE IV. FORNELL-LARCKER CRITERION RESULT

Construct	IQ	NB	PU	SQ	SYQ	TR	US
IQ	0.789						
NB	0.670	0.863					
PU	0.660	0.785	0.904				
SQ	0.761	0.715	0.729	0.835			
SYQ	0.681	0.566	0.590	0.609	0.820		
TR	0.631	0.720	0.684	0.726	0.503	0.875	
US	0.715	0.787	0.784	0.809	0.592	0.787	0.852

TABLE V. HETEROTRAIT-MONOTRAIT RATIO (HTMT) RESULT

Construct	IQ	NB	PU	SQ	SYQ	TR	US
IQ							
NB	0.757						
PU	0.736	0.838					
SQ	0.875	0.787	0.791				
SYQ	0.847	0.677	0.697	0.741			
TR	0.743	0.816	0.762	0.835	0.628		
US	0.815	0.858	0.846	0.899	0.714	0.899	

3) Reliability test: Reliability assessment involves the use of composite reliability and Cronbach's alpha. Reliability values ranging from 0.70 to 0.90 are considered satisfactory to good.

Reliability value of ≥ 0.95 suggests the presence of an indicator error, implying that all indicators are measuring the same construct [35]. The reliability results in the Table VI.

TABLE VI. RELIABILITY, AND CONVERGENT VALIDITY RESULT

Construct	Indicator	Outer loadings	Result	Cronbach's alpha	Composite reliability	AVE	Result
System Quality	SYQ1	0.796	Valid	0.756	0.761	0.673	Reliable
	SYQ4	0.808	Valid				
	SYQ5	0.856	Valid

	US3	0.863	Valid				
	US4	0.843	Valid				
	US5	0.864	Valid				
Net Benefits	NB1	0.824	Valid	0.914	0.919	0.744	Reliable
	NB2	0.876	Valid				
	NB3	0.862	Valid				
	NB4	0.880	Valid				
	NB5	0.870	Valid				

C. Structural Model Assessment

The structural equation modeling (SEM) method was applied to analyze the hypotheses of the structural model. The standard evaluation criteria to consider include the coefficient of determination (R^2), F-square (F^2), and the statistical significance and relevance of the path coefficients [35]. It is crucial to examine for collinearity before evaluating the structural relationships to avoid bias in the regression results.

1) Collinearity: The collinearity value is determined by calculating the Variance Inflation Factor (VIF). A VIF value exceeding 5 suggests a potential collinearity issue among predictor constructs; however, collinearity problems can also arise at lower VIF values ranging from 3 to 5. Ideally, the VIF value should be close to or below 3. Appendix B presents the VIF statistics from the inner model, indicating that all VIFs are above the recommended thresholds.

2) Coefficient of determination (R2) and F-square (F^2): The coefficient of determination (R^2) is measured by the endogenous construct and serves as an indicator of the sample's predictive power. R^2 values of 0.75, 0.50, and 0.25 are classified as substantial, moderate, and weak, respectively [35]. In addition, the F-square (F^2) values of 0.02, 0.15, and 0.35 correspond to small, medium, and large effect sizes, respectively [35]. The F-square and R^2 results can be seen in Table VII. Table VII indicates that both the perceived usefulness and net benefit variables have a moderate impact. Specifically, perceived usefulness accounts for 57.4% of the variance, while net benefit explains 69.3% of it. The user

satisfaction variable shows the highest R^2 value, substantially impacting the analysis in the amount of 78.4% of the variance.

D. Hypothesis Testing

The bootstrapping output results present hypothesis testing for the relationship between variables. In this study, the hypothesis testing requires the t-statistic value to reach 1.96 at a significance level of 5% (0.05).

As shown in Table VII, most of the hypotheses proposed in this study are supported, except H2. Specifically, system quality significantly and positively affects perceived usefulness (t-value = 3.264, $p < 0.05$), which confirms H1. The effect of system quality on user satisfaction, however, is not significant (t-value = 0.938, $p < 0.05$), thereby rejecting H2. The effect of information quality on perceived usefulness is significant and positive (t-value = 2.302, $p < 0.05$) and user satisfaction is significant and positive (t-value = 2.099, $p < 0.05$), which confirms H3 and H4. As predicted, service quality is positively associated with perceived usefulness (t-value = 7.514, $p < 0.05$) and user satisfaction (t-value = 5.743, $p < 0.05$), confirming H5 and H6. In addition, trust has a positive and significant effect on user satisfaction (t-value = 6.389, $p < 0.05$), and perceived usefulness has a positive and significant effect on user satisfaction (t-value = 5.655, $p < 0.05$), supporting H7 and H8. Perceived usefulness (t-value = 7.523, $p < 0.05$) and user satisfaction (t-value = 7.547, $p < 0.05$) also significantly and positively affect net benefits; therefore, H9 and H10 are confirmed. The research model accounts for 69.3% of the variance in the net benefits of using the village information system. The findings suggest that enhancing perceived usefulness and user satisfaction should be prioritized to maximize the net benefits derived from the village information system.

TABLE VII. HYPOTHESIS TESTING RESULT

Construct	R2	F2	Hypothesis	Path description	Path coefficient	T-value	P values	Result
Perceived Usefulness	0.574	0.038	H1	SYQ → PU	0.178	3.264	0.001	Supported
		0.021	H3	IQ → PU	0.159	2.302	0.021	Supported
		0.237	H5	SQ → PU	0.500	7.514	0.000	Supported

V. RESULT

The findings of this study offer detailed insights into the factors that impact the success of information system in implementing village information system, achieved through the integration of the ISSM and TAM model. The study establishes seven research variables using a total of thirty-three proposed indicators. However, two indicators were excluded based on the loading factor assessment, resulting in a valid construct for further evaluation. The remaining thirty-one indicators support the reliability and validity assessment through both convergent and discriminant validity tests. The hypothesis is tested at a significance level of 5%. Additionally, the author evaluates the structural model by examining the f-square and R^2 values to determine the model's predictive power.

This section presents the validation of findings related to each research hypothesis from Table VII. This study shows that hypothesis 1 (H1), which states that system quality (SYQ) has a significant impact on perceived usefulness (PU), is consistent with previous research [19], [20]. This study shows that the village information system provides utility among village officials and civil servants who use it. Routine tasks require full functionality of the village information system. A technically adequate village information system proves their ability to complete tasks in collecting and managing village data as well as supporting services. However, the system quality derived from the village information system does not affect user satisfaction (US) with the system (H2). This finding differs from previous studies [3], [21], [36] that identified system quality as an important construct influencing user satisfaction. The quality of the system is not sufficient to make users satisfied with the village information system. First, the village information system does not adequately meet user needs because the system is not adaptive to the actual work processes required and the features are insufficient. Second, the village information system is mandatory, so the output or work outcomes have a bigger effect on user satisfaction than the system's technical quality. To make user satisfaction, it's important to make the system more flexible, complete the features and ensure it meets their individual demands.

The information quality (IQ) from the village information system has a significant relationship to perceived usefulness (PU) and user satisfaction (US), which supports hypothesis 3 (H3) and hypothesis 4 (H4), similar to what studies [18], [19], [20] found. This research proves that the village information system provides complete, relevant information according to user needs, timely, easy to understand, and accurate. The information available in the village information system has been shown to enhance and facilitate user performance in terms of productivity and decision-making.

The service quality (SQ) of the village information system demonstrates a positive correlation with perceived usefulness (PU) and user satisfaction (US), with hypotheses H5 and H6

further reinforcing findings from studies [18], [19], [20]. This research proves that the technical and non-technical support from the village greeting team, as well as the service provider of the village information system, is capable of solving user or system operator problems very well, thereby increasing user satisfaction. The evidence also indicates that users of the village information system perceive it positively in terms of responsive and reliable support for their work processes and productivity, making the service useful.

Trust (TR) significantly predicts user satisfaction; therefore, hypothesis H7 is supported. These results are similar to the findings of studies [20], [33]. The village information system is used by village officials and civil servants of the Ministry of Village and Development of Disadvantaged Regions to build trust. H7 shows that system users trust and feel safe when completing tasks and submitting data using the village information system. User trust in the system increases its usage. As a result, fostering trust increases individual satisfaction and drives overall organizational efficiency.

The perceived usefulness significantly affects user satisfaction, supporting hypothesis H8. These results are similar to the findings of [3], [20]. The village information system improves performance effectiveness, work quality, and productivity and facilitates task execution. These results indicate that users or system operators believe that the village information system helps complete daily tasks and facilitates the management of village-related data and services.

Our results confirm that perceived usefulness (PU) and user satisfaction (US) are two main determinants of net benefits (NB). PU and US have a positive impact on NB, supporting hypotheses H9 and H10. These results support previous research [17], [20], [29]. These findings indicate that the net benefits of the village information system demonstrate that this system provides utility and a positive experience when used, which will ultimately lead to perceived usefulness and user satisfaction. The use of village information system is beneficial in daily tasks related to village data management. Village information system enable users to complete tasks efficiently and provide information as needed, which in turn enhances organizational performance and decision-making. Improvements in decision-making not only simplify operations but also encourage a more engaged community. This leads to a more informed and responsive village governance structure. As a result, the village is better prepared to adapt to changing circumstances and improve service delivery.

RQ1: What are the factors influencing the use of village information system within e-government initiatives?

We identified two main factors that influence the success of adopting a village information system: (1) the ISSM Model, which includes the quality of the village information system (system quality, information quality, and service quality), proving hypotheses 1-6 (H1-H6), and (2) trust, which proves hypothesis 7 (H7). These main factors will be mediated by perceived usefulness and user satisfaction, ultimately resulting in net benefits supporting hypotheses 8-10 (H8-H10). The ISSM Model and the TAM Model serve as ideal frameworks for village information system. Therefore, this research adds to existing knowledge by focusing on these factors using the DeLone and McLean ISSM Model and the TAM, which are not often covered in studies about e-government adoption, particularly in village governance in developing countries. The gap in the literature indicates that there is a deeper understanding of how these factors interact and influence user acceptance of information systems in rural areas. By integrating insights from both models, this research aims to provide a comprehensive framework that can guide policymakers and practitioners in successfully implementing the village information system.

RQ2: What are the most significant factors affecting the implementation of the village information system?

The most factor affecting the implementation of the village information system is service quality, which positively influences perceived usefulness, referred to as hypothesis H5. Additionally, user satisfaction acts as a mediating factor that significantly influences net benefits, as outlined in hypothesis H10. Net benefits are essential for determining the overall success of the village information system, as they directly affect user engagement and the willingness to adopt the system's information. It is essential to prioritize improving service quality and perceived usefulness to fully realize the system's benefits.

A. Theoretical Implications

This study contributes to the progression of the theoretical foundation related to investigate the implementation of the village information system as a form of e-government in Indonesia, which provides a more in-depth understanding of governance and government services. This understanding can help identify the strengths and weaknesses of current practices, ultimately leading to more effective policies and improved service delivery to the community.

This study aims to analyze the factors influencing success in the village information system managed by the Ministry of Village and Development of Disadvantaged Regions, specifically by identifying the main influences on these factors. The study utilizes the Delone and McLean model for information system success [7], [8], as well as the Technology Acceptance Model (TAM) [9], modifying it to assess perceptions of usefulness and user satisfaction. The variables examined in this research include system quality, information quality, service quality, trust, perceived usefulness, user satisfaction, and net benefits. Furthermore, the study's research model remains valid and applicable to other studies across various sectors.

B. Theoretical Implications

This study presents several practical implications for government decision-makers. It advocates for the use of information systems to enhance perceived usefulness and user satisfaction in the operation of village information system by integrating the ISSM and TAM frameworks. The main practical findings of the research are as follows:

1) Designing a system that meets user needs is essential, as user satisfaction has a direct impact on overall net benefits. This process involves automating routine tasks to enhance effectiveness, information satisfaction, and enjoyment.

Additionally, it is important to meet user expectations by utilizing digital signatures to streamline processes for administrative reports, as well as by incorporating an interactive dashboard powered by artificial intelligence. This dashboard should provide real-time analytics and insights, enabling users to make informed decisions promptly.

2) Developing features and functions that deliver valuable services to users is critical because the service quality directly influences perceived usefulness, particularly in automating routine tasks to enhance performance. This may include notifications regarding system maintenance and downtime, as well as features like discussion forums. Such functionalities can cultivate a sense of community among users to exchange insights and solutions.

3) Ministries and government agencies stand to gain net benefits from integrated e-government by adopting village information system. Consequently, it is crucial for adopters to prioritize user satisfaction, as they will be the ones operating the system regularly.

4) Decision-makers need to consider the resources and knowledge available to system users and ensure compatibility with other technologies.

VI. Conclusion

This study aims to identify the factors that contribute to the success of integrated village information system. The authors outline two main objectives: (1) to investigate the factors influencing the use of village information system within e-government initiatives and (2) to examine the most significant factors affecting the implementation of these systems. By integrating the Information Systems Success Model (ISSM) and the Technology Acceptance Model (TAM), this study addresses both the success factors of village information system and user acceptance through the measurement of seven latent variables: System Quality (SYQ), Information Quality (IQ), Service Quality (SQ), Perceived Usefulness (PU), Trust (TR), User Satisfaction (US), and Net Benefits (NB). The authors propose thirty-three hypotheses to achieve the study's objectives. The findings from this study are expected to offer helpful knowledge about how these factors interact and influence the overall effectiveness of village information system. By testing the proposed hypotheses, the research aims to contribute to the existing literature on information system success and enhance our understanding of user behavior in adopting technologies.

The identified hypotheses offer clues about the research objectives. The accepted factors include system quality, information quality, and service quality, which significantly influence perceived usefulness. Information quality, service quality, trust, and perceived usefulness also significantly affect user satisfaction. Additionally, perceived usefulness and user satisfaction have a significant impact on net benefits. The factor with the highest direct influence on net benefits is user satisfaction, and service quality also significantly influences perceived usefulness. However, system quality does not significantly affect user satisfaction. This suggests that while system quality is important, it may not directly enhance the user experience as much as service quality and information quality do. Therefore, organizations should prioritize improving service and information quality to increase user satisfaction and ultimately drive better net benefits.

A. Limitations and Recommendations

This study has several limitations, the first being its dependence on a small sample size. Indonesia, as a developing country, faces challenges in the adoption of e-government, which can lead to variability in the data collected. As a result, these findings may not accurately represent the broader population. Therefore, the results of this study may not apply to regions with more advanced e-government initiatives. Further research should use a larger and more diverse sample to ensure more accurate analysis results. Additionally, including more villages from Indonesia in the sample will provide a more holistic view of how successful the village information system is. Secondly, we should integrate additional factors like training quality, task characteristics, technology, and cybersecurity. Furthermore, we should categorize trust based on both technology and e-government factors. Further research can also use other methods to investigate our model.

Recommendations for future research include considering additional factors that influence the success of e-government implementation in village information system. Furthermore, future studies should involve in-depth interviews with officials and experts regarding the village information system to better understand user experiences. These experiences can provide useful perspectives on the practical challenges and benefits associated with implementing these systems. A limitation of this research is that the conceptual model does not account for the indirect factors included in the ISSM and TAM model.

Recommendations for the Ministry of Village and Development of Disadvantaged Regions suggest that the research findings can serve as a guideline for decision-making regarding the development of the Village Information System. The ministry should conduct regular feature development, focusing on enhancing both system quality and information quality. Additionally, it is essential to provide training for civil servants and Village Officials within the Ministry. This training will enable them to operate the Village Information System more effectively and efficiently.

APPENDIX

APPENDIX A: MEASUREMENT ITEMS

Constructs and Source Measures	Items	Measured
System Quality; [7], [8], [21], [26], [37] Easy To Use; Reliability; Response time; Interactivity; Flexibility.	SYQ1	The village information system is easy to use.
	SYQ2	The village information system is reliable.
	SYQ3	The village information system providing a quick response time.
	SYQ4	The village information system is interactive.
	SYQ5	The village information system is flexible.
Information Quality; [7], [8], [21], [38] Completeness; Relevance; Timeliness; Understandability; Accuracy.	IQ1	The information in the village information system is complete.
	IQ2	The information in the village information system is relevant to my needs and work.
	IQ3	The information in the village information system is current and timely.
	IQ4	The information in the village information system is easy to understand.
	IQ5	The information in the village information system is accurate.
Service Quality; [8], [26], [38] Assurance; Reliability; Tangible; Responsiveness; Empathy.	SQ1	The services provided of the village information system has staff who have good knowledge.
	SQ2	The services provided of the village information system is reliable.
	SQ3	The services provided of the village information system is Tangible.
	SQ4	The services provided of the village information system can quickly address my needs.
	SQ5	The services provided of the village information system is empathy.
Trust; [21], [27], [39] Safe; Convenience; Trusted.	TR1	I believe the village information system can provide data security.
	TR2	I believe that using the village information system can provide convenience in transactions.
	TR3	The village information system can be trusted.
Perceived Usefulness; [9], [19], [31] Job Effectivenes; Quality of Work; Productivity; Addresses My Needs; Makes Job Easier.	PU1	The use of the village information system improves my performance.
	PU2	The use of the village information system improves the quality of my work.
	PU3	The use of the village information system makes my work faster.
	PU4	The use of the village information system meets my needs.
	PU5	The use of the village information system makes my work easier.
User Satisfaction; [7], [8], [15], [21] Effectiveness; Information Satisfaction; Enjoyment; Meet the expectations; Overall satisfaction.	US1	I feel that the village information system effectively meets the needs.
	US2	I feel that the village information system delivers satisfactory information.
	US3	I feel that the village information system is enjoyable to use.
	US4	I feel that the village information system meets my expectations.
	US5	Overall, I am satisfied with the village information system.
Net Benefits; [8], [21], [38], [40]. Cost-Saving; Time savings; Enhancement of communication and collaboration; Information Retrieval; Job Performance.	NB1	The village information system saves costs.
	NB2	The village information system saves time.
	NB3	The village information system enables easy and efficient communication.
	NB4	The village information system facilitates information retrieval.
	NB5	The village information system provides comfort in carrying out my work.

APPENDIX B: VARIANCE INFLATION FACTOR (VIF)

Construct	IQ	NB	PU	SQ	SYQ	TR	US
IQ			2.890				2.982
NB							
PU		2.594					2.575
SQ			2.468				3.483
SYQ			1.935				2.009
TR							2.398

***Abstract*—Rapid digitisation in communication and online platform growth have transformed information dissemination and facilitated rapid access while simultaneously amplifying the spread of fake news. This widespread issue undermines public trust, destabilises political systems, and threatens economic stability. Machine learning techniques have been widely applied to fake news detection, but comparative analyses across specific domains such as health, politics, and economics remain limited. Existing reviews tend to focus on supervised learning methods, frequently excluding unsupervised and hybrid approaches, along with unique challenges and dataset requirements of each domain. This study conducted a systematic literature review of machine learning applications for detecting fake news across the three domains. The methodologies and metrics used were evaluated, while key challenges and opportunities were explored. The results revealed a strong reliance on supervised learning techniques, particularly in health-related contexts, where misinformation presented significant risks to public health outcomes. Deep learning methods were promising for processing complex data. Nonetheless, hybrid and unsupervised approaches were underexplored, which presented opportunities to address data scarcity and adaptability. Most datasets originated from social media platforms and news outlets. The common evaluation metrics included accuracy, but advanced measures were rarely applied, which indicated the possibility of enhancing such methods. Persistent challenges include poor data quality, bias, and ethical concerns highlighted the necessity for bias-mitigating algorithms and improved model interpretability. Specifically, economic misinformation has received less attention despite its potential to cause large-scale financial disruptions. This study highlighted that more effective, ethical, and context-specific machine learning solutions are needed to address fake news and enhance digital information credibility.**

***Keywords*—Machine learning; fake news; systematic review; health; politics; economy**

I. Introduction

Technological breakthroughs and the digital era have transformed global communication and news production, distribution, and consumption methods at incomparable rates. These advancements have been supported by prominent social media platforms and online news portals and cultivated a connected global community, which has facilitated the rapid dissemination of news across geographical and accessibility boundaries [1, 2]. Nevertheless, these positive advancements are accompanied by a corresponding negative regression. One of the most alarming examples of negative regression is increased fake news, which creates negative sociological situations. These situations range from decreased trust and reliability to election result manipulation and global health crises exacerbation [3-5].

Fake news in health, politics, and economics can lead to severe and negative outcomes. For example, spreading false health information establishes the basis for adverse outcomes. The recent indications include false narratives around the COVID vaccine, hydroxychloroquine efficiency as a cure, claims that bleach treats conditions, and smear campaigns against vaccines [6-8]. These fraudulent statements have caused public health issues, which have confused the public and encouraged it to adopt unsafe health practices, such as avoiding vaccinations after misleading information has been disseminated.

In politics, misinformation produces false perceptions and fosters public discontent against politicians and democracy, which distorts electoral outcomes. Misinformation is aimed at causing division, disseminating falsehoods about individuals and matters that damage reputations, disrupting discussions, and subsequently creating distrust against respected media outlets [9, 10]. Ultimately, misinformation is divisive and exacerbates conflict.

Fake news is also prevalent in economic news. Prevalent misinformation on the economy or inaccurate economic reporting induces stock market fluctuations, personal financial crises, and a deterioration of faith in financial assets. Furthermore, economic misinformation undermines investor trust and disrupts economic system stability.

Traditional methods for detecting fake news, such as manual fact-checking and rule-based detection, have been insufficient due to their inability to address the scale, speed, and complexity of modern misinformation [11, 12]. The current proliferation of fake news is broadly diverse, spreads

rapidly, and is high-volume. Hence, an efficient and scalable generalized detection system has become necessary. Thus, machine learning has emerged as an effective tool among researchers and practitioners for addressing misinformation. The ability of machine learning to analyse enormous datasets, identify trends, and provide accurate predictions has been used in advanced automated solutions to identify fake news. These platforms use various techniques, which include natural language processing (NLP), sentiment analysis, and deep learning, to detect and classify fake news accurately [13, 14].

Although numerous studies have applied ML techniques to fake news detection, comparative reviews that assess the performance of these methods across specific domain such as health, politics, and economics remain limited. Moreover, existing reviews often emphasize supervised learning, frequently failing to consider unsupervised and hybrid approaches, as well as the distinct challenges and dataset requirements unique to each domain. Thus, this study conducted a comprehensive systematic literature review (SLR) to examine the application of machine learning techniques for detecting fake news detection across the health, politics, and economics domains.

This study synthesized the results to advance the development of more effective, ethical, and domain-specific solutions to address fake news. Specifically, three research questions (RQ) were addressed: 1) the machine learning approaches utilized within these domains was investigated to provide insights into their methodologies and domain-specific applications (RQ1); 2) the performance and effectiveness of these techniques were evaluated by analyzing the commonly used evaluation metrics (RQ2); 3) key trends, challenges, and opportunities in the field were identified, limitations in these approaches were highlighted, and potential future research directions were proposed (RQ3).

II. Methodology

A. Research Questions

This study explored the application of machine learning in identifying fake news across the health, politics, and economics domains, guided by the following Research Questions (RQs):

- RQ1: How is machine learning applied for detecting fake news in the health, political, and economics domains?
- RQ2: What are the evaluation metrics commonly used in the health, political, and economics domains?
- RQ3: What are the key trends, challenges, and future directions in the health, political, and economics domains?

B. Literature Search Strategy

The literature search was conducted using the Web of Science, Scopus, IEEE Xplore, and SpringerLink databases. The literature search was performed using a combination of keywords and Boolean operators to ensure comprehensive retrieval of relevant studies to fake news detection. Table I details the search terms used across the three domains.

TABLE I. The Search Terms for Idetifying Fake News Detection According to the Domain

Domain	Search Term
Politics	(("fake news detection*" OR "misinformation") AND ("social media") AND ("politics" OR "bureaucracy") AND ("machine learning*" OR "deep learning" OR "hybrid learning"))
Economy	(("fake news detection*" OR "misinformation") AND ("social media") AND ("economy") AND ("machine learning*" OR "deep learning" OR "hybrid learning"))
Health	(("fake news detection*" OR "misinformation") AND ("social media") AND ("health" OR "healthcare" OR "medical care") AND ("machine learning*" OR "deep learning" OR "hybrid learning"))

C. Inclusion and Exclusion Criteria

Table II outlines the inclusion and exclusion criteria applied to ensure the quality and relevance of the selected studies.

TABLE II. The Inclusion and Exclusion Criteria

Inclusion	Exclusion
• Studies published in peer-reviewed journals or conferences; • Publications written in English; • Fully accessible articles; • Research focusing on the application of machine learning techniques for fake news detection in health, political, or economics domains; • Publications from the last 10 years to ensure relevance and reflect current trends and advancements.	• Non-peer-reviewed any articles; • Non-English publications; • Articles that are inaccessible and or lack full text; • Studies without a clear focus on machine learning applications in detecting fake news.

D. Study Selection and Screening

The study selection followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines [15] (see Fig. 1). The studies were selected through identification (initial search results were exported to a reference management tool and duplicates were removed), screening (titles and abstracts were reviewed to identify potentially relevant studies), eligibility assessment (full-text articles were assessed against the inclusion and exclusion criteria), and inclusion (the remaining studies were selected for detailed analysis and synthesis).

E. Data Extraction and Screening

Data were extracted from the selected studies using a standardised data extraction form. The key information collected included:

- Publication type: The data source (whether published in a journal or presented at a conference);
- Domain-specific applications: The focus area of the fake news (categorised into health, politics, or economics domains);
- Research type: The methodological approach of the study (qualitative or quantitative research);

- Study objectives and contributions: The study goals and specific contributions;
- Dataset: The name and description of the fake news corpus used in the study;
- Data preparation and preprocessing: Details on any data cleaning, transformation, or preprocessing techniques applied to the dataset;
- Machine learning techniques used: A description of the machine learning algorithms or methods implemented in the study;
- Performance measures: The evaluation metrics used to assess the effectiveness of proposed machine learning models, such as accuracy, precision, and F-measure;
- Findings, limitations, and future work: Key insights from the study, the identified limitations, and recommendations for future research directions.

Appendix A presents the articles included in this systematic review (n = 173).

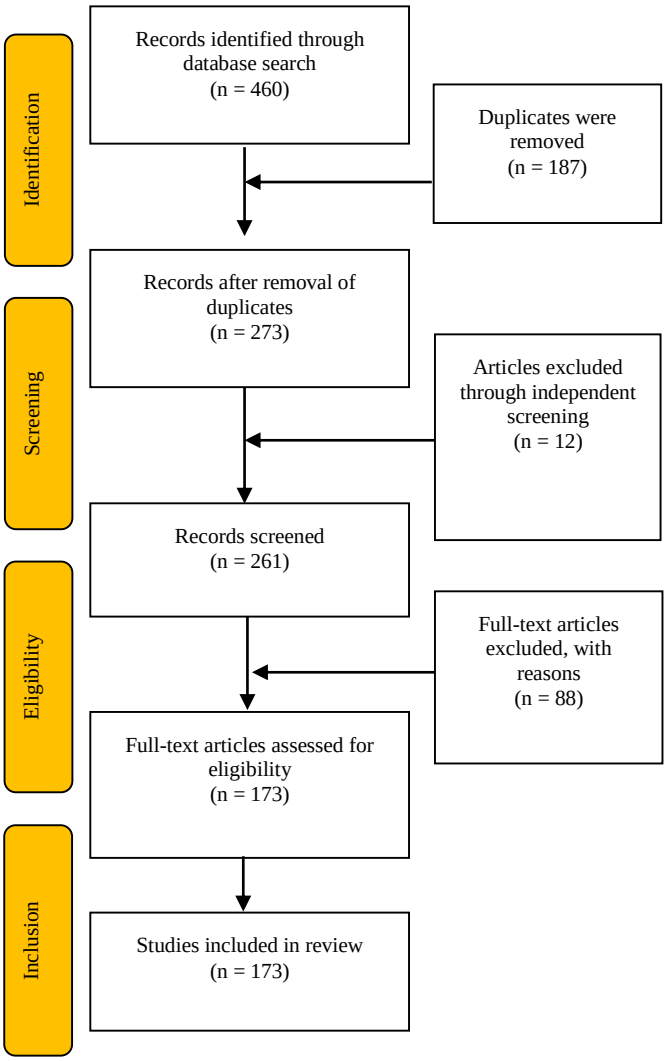

Fig. 1. Flow chart of search process adapted from PRISMA diagram (Adapted from [15]).

III. Results

A. RQ1: How is Machine Learning Applied for Detecting Fake News in the Health, Political, and Economics Domains?

This study addressed RQ1 by examining machine learning techniques for detecting fake news and their application across the health, economics, and political domains. Five primary categories of machine learning approaches were reviewed: supervised learning, unsupervised learning, deep learning, ensemble learning, and hybrid approaches.

Fig. 2 illustrates the distribution of the machine learning techniques used in the included studies. Most studies used supervised learning (n = 86 studies), where Support Vector Machine (SVM) was the most widely used method (50 studies), followed by random forest (37 studies), logistic regression (37 studies), and naïve Bayes (35 studies). Deep learning was the second most utilised technique (n = 73 studies), which reflected its increasing importance in addressing fake news detection challenges. Transformer-based models were the most frequently applied deep learning models (45 studies), followed by long short-term memory (LSTM) networks (31 studies) and CNNs (26 studies). Hybrid learning was used in 35 studies and represented a moderately adopted approach. Lastly, ensemble and unsupervised learning were the least used techniques, where each was used in only five studies, which suggested their limited applicability in this context.

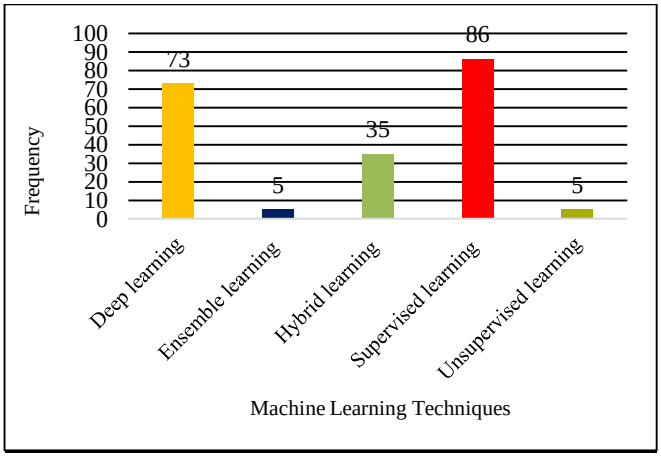

Fig. 2. Distribution of machine learning techniques in reviewed studies.

The review process was enhanced by examining the application of machine learning techniques across the health, economic, and political domains. Fig. 3 highlights that the health sector led in machine learning applications, particularly in deep learning (56 instances) and supervised learning (58 instances), which dominated. For example, studies such as [38, 83, 141] used deep learning models, such as CNNs, LSTM, and bidirectional LSTM (BiLSTM). These advancements have been driven by the increasing availability of medical datasets, which include X-ray images. The accessibility of such data has enabled deep learning models to achieve high accuracy in diagnosing disease, classifying medical images, and predicting patient outcomes. Nevertheless, ensemble learning was rarely applied, with only five instances reported in the health domain.

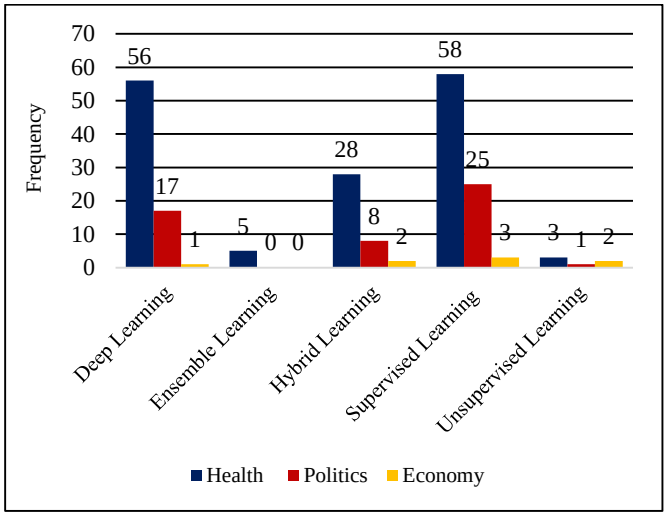

Fig. 3. Usage of machine learning techniques across domains.

The political domain demonstrated a moderate level of machine learning adoption, which was mainly in supervised learning (25 instances), with a smaller but notable use of deep learning (17 instances). Studies in [48, 185] used supervised models, such as Naïve Bayes and SVM to analyse sentiment, detecting political stances, and predicting election outcomes. These models were commonly used due to their effectiveness in processing text-based data, such as social media posts, political speeches, and news articles. In comparison, the economics domain demonstrated limited machine learning adoption. The included studies contained only a few references to deep, hybrid, supervised, and unsupervised learning.

B. RQ2: What are the Evaluation Metrics Commonly used in the Health, Political and Economic Domain?

The RQ2 was addressed by examining the evaluation methodologies used in applying machine learning to detect fake news. The commonly used datasets for evaluating the proposed machine learning and the data pre-processing techniques that enhance data quality were explored. The data preparation methods were reviewed to ensure accuracy and reliability, hyperparameter tuning strategies for optimising model performance are discussed, and a comprehensive analysis of the evaluation metrics used to assess model effectiveness is provided.

Fig. 4 presents the most frequently used datasets in fake news detection across health, politics, and economics. The results highlight the prevalence of these datasets in the included studies and the tools designed for identifying fake news. Twitter was the most frequently used dataset, where it was featured in 78 studies by a wide margin. This dominance highlighted the role of Twitter as a major platform in public discussions and real-time misinformation spread. A common research strategy involved manipulating various types of Twitter data, including raw tweet text [25, 55, 85] user IDs [16, 112, 132], tweet and retweet counts [19, 33, 60, 78, 154, 174], likes and reply counts [37, 66, 173], hashtags [54, 64, 78, 123]. Twitter metadata [22, 167, 182], URLs [20, 121], and specific keywords [54, 64, 78].

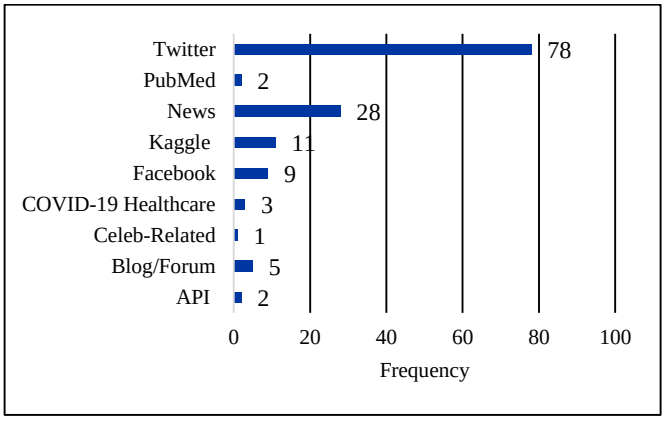

Fig. 4. Commonly used datasets in fake news detection in the included studies.

News datasets were the second most frequently used dataset (n = 28 studies). Their importance lies in their structured format, which typically includes headlines, body text, and publication dates. This structure renders them suitable for text classification and information extraction tasks, including fake news detection. For example, the FakeNewsNet dataset [42, 59, 86, 115], BuzzFeed News [44, 172], and local newspapers such as China Times [106] and The Star [169] were commonly used for analysis.

The third most frequently used dataset was the Kaggle dataset, a machine learning platform (n = 11 studies). Moderately used datasets included Facebook datasets (n = 9 studies) and other sources such as blogs and forums (n = 5 studies). Specialised datasets, including those focused on COVID-19 healthcare misinformation, PubMed, and APIs (used as data collection tools), were used less frequently, appearing in 3 studies [83, 89, 118], 2 studies [84, 178], and 2 studies [40, 181], respectively. Celebrity-related datasets were identified in only one study [150], indicating a niche research area.

Fig. 5 illustrates the frequency of commonly used preprocessing techniques in the included studies. These techniques are important for data preparation to enhance the accuracy and reliability of the proposed machine learning models. Tokenisation was the most frequently used preprocessing technique (n = 77 studies), which highlighted its importance in splitting text into meaningful units for analysis. The included studies used tokenisation in English [55, 60, 116, 145, 153], Chinese characters [18, 100, 102], Arabic [35, 74, 105, 134, 156], Turkish [110, 188], and Korean [78].

The second most common preprocessing technique was stop word removal (n = 68 studies), which highlighted its role in eliminating non-informative words, such as “and” or “the.” While stop word removal was mostly used in English, it was also applied in Chinese [18, 69, 100], Brazilian Portuguese [48, 54], Arabic [74, 134] and Urdu [188]. Data filtering was the third most frequently used preprocessing technique (n = 51 studies). The other frequently used techniques were punctuation removal (44 studies) and URL removal (37 studies), which both aimed to reduce noise in textual data. Additionally, lowercasing text and stemming were each used in 33 studies.

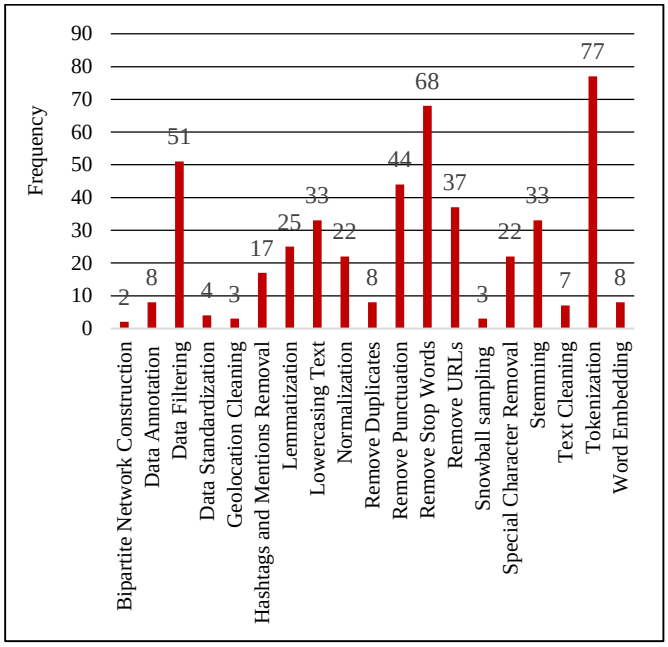

Fig. 5. Commonly used preprocessing techniques in detecting fake news.

The less commonly used preprocessing techniques were lemmatisation (25 studies), normalisation (22 studies), and special character removal (22 studies), which focus on improving text structure and uniformity. Specialised preprocessing steps, such as data annotation, duplicate removal, and word embedding (each, n = 8 studies), were utilised less frequently but were important in certain contexts. Furthermore, the snowball sampling and geolocation cleaning preprocessing techniques were minimally applied (n = 3 studies). Lastly, the least frequently used techniques were data standardisation (four studies) and bipartite network construction (two studies).

This distribution reflected the relative importance and applicability of preprocessing techniques in detecting fake news. Tokenisation, stop word removal, and data filtering were the most critical techniques. Additionally, the choice of preprocessing techniques depends on the dataset language, as different languages require specific methods to handle word forms, writing systems, and grammar.

The data preparation techniques used to evaluate fake news detection models were examined. Fig. 6 demonstrates that data splitting was the most frequently used technique and represented 55% of the methods used. This result emphasises the importance of data splitting in dividing datasets into training and testing subsets to assess model performance. Most of the studies applied 80:20 data splitting [29, 31, 42, 65, 67, 110, 126, 134, 136, 145, 159, 161, 168, 179, 181] and 70:30 data splitting [17, 35, 54, 59, 74, 81, 99, 124, 131, 160] techniques.

Cross-validation was the second most frequently used data preparation technique, representing 37% of the total. This method improves model evaluation by dividing the data into multiple folds and rotating the training and testing phases. For example, 10-fold cross-validation was used in several studies [19, 20, 25, 26, 55, 83, 85, 102, 114, 122, 132, 139, 188] and [22, 48, 97, 117, 130, 173, 184, 186] used five-fold cross-validation. Sampling accounted for 6% of the methods, where stratified sampling [84, 137] was a prominent example. Stratified sampling aids the selection of representative subsets to address class imbalances or reduce dataset size for analysis. The less common techniques were clustering [108, 148] and temporal splitting [128, 147], which each represented 1% of the methods.

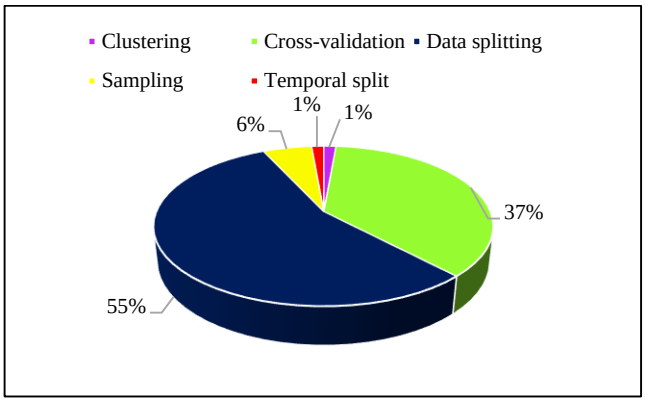

Fig. 6. Data preparation techniques for evaluation in fake news detection models.

Fig. 7 illustrates the frequency of the classification metrics used to evaluate the performance of the fake news detection models. Accuracy was the most frequently used metric (n = 116 studies), followed by precision and recall (n = 109 and 103 studies, respectively), which highlighted their importance in assessing prediction quality and true positive detection. The F1-score, which is a harmonic mean of precision and recall, was applied in 108 studies, which emphasised its role in balancing these two measures. Contrastingly, specificity and the Matthews correlation coefficient (MCC) were less commonly used (n = 3 studies). Receiver operating characteristic (ROC) curve and area under the curve (AUC) metrics were reported in 28 studies, which underscored their usefulness in evaluating classification performance across varying thresholds.

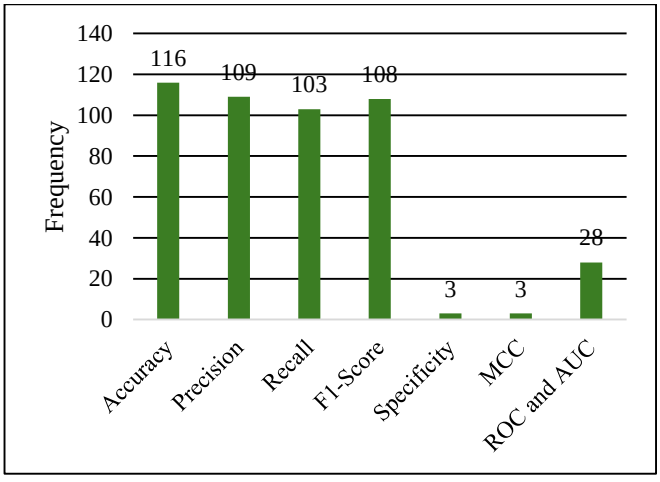

Fig. 7. Classification metrics used for evaluating fake news detection models.

C. RQ3: What are the Key Trends, Challenges, and Future Directions in the Health, Political, and Economics Domains?

The RQ3 was addressed by examining the key trends, challenges, and future directions across the health, political, and economics domains. Fig. 8 illustrates the machine learning technique use trends (deep learning, ensemble learning, hybrid learning, supervised learning, and unsupervised learning) between 2017 and 2024. Deep learning and supervised learning usage increased steadily from 2017 and peaked in 2021.

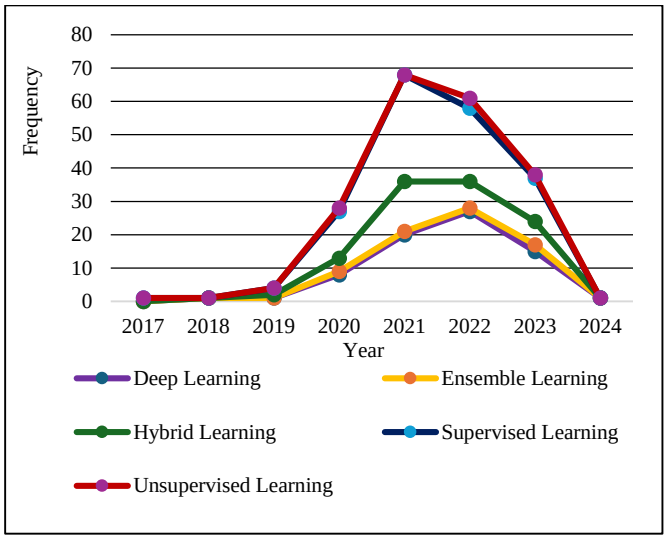

Fig. 8. Machine learning techniques trend over time.

Deep Learning usage frequency was highest at approximately 75 instances. Nonetheless, both techniques experienced a decline after 2022. Hybrid learning gained traction in 2019, peaked in 2021 (40 instances), and then its usage declined in subsequent years. Similarly, unsupervised learning grew significantly from 2019 and peaked in 2022 (60 instances) before decreasing. Contrastingly, ensemble learning demonstrated modest growth, where it peaked in 2021 but maintained a consistently lower frequency compared to the other techniques. The graph highlighted that the adoption of machine learning techniques increased significantly beginning in 2017, with most methods peaking between 2021 and 2022, followed by a noticeable decline in 2023 and 2024. This trend suggested that the use of these techniques either stabilised as research matured or shifted toward new approaches and alternative methodologies.

Fig. 9 presents the challenges of applying machine learning across various domains, which are categorised into six areas. Dataset issues were the most common challenge (124 instances), which highlighted concerns regarding data quality, availability, and relevance in machine learning applications. Contrastingly, ethical concerns were the least reported concern (n = 1 study), while interpretability issues, which relate to understanding and explaining model decisions, were recorded in two instances. Model-related bias, which affects fairness and accuracy, appeared eight times and indicated a moderate level of concern. Handling rapid data evolution was a challenge cited twice, which reflected the occasional challenges in maintaining up-to-date models. Platform-specific issues, which involved technical barriers or limitations in specific machine learning platforms, were reported in seven studies. Overall, dataset issues dominated the challenges significantly and highlighted the need for robust and relevant data, while other challenges were observed less frequently.

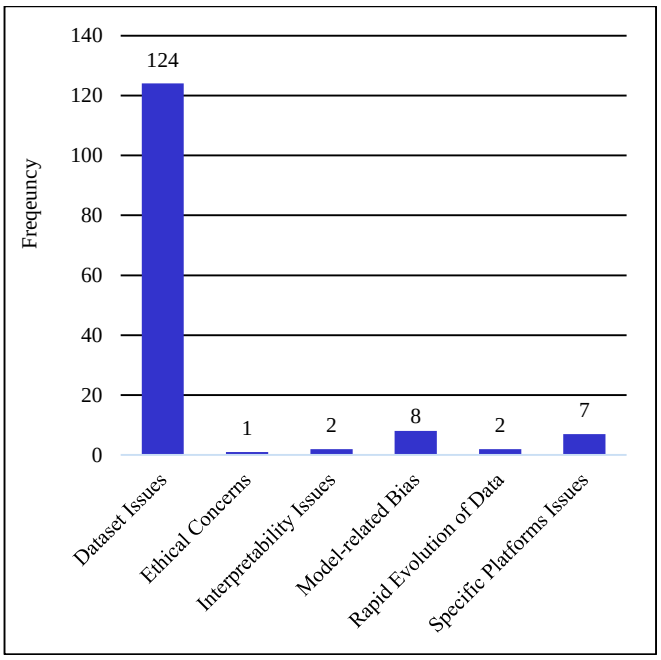

Fig. 9. Distribution of machine learning challenges across domains.

Fig. 10 highlights the key future research directions in machine learning, which are categorised into five areas. Data expansion, which involves increasing and diversifying data was the most prominent area (n = 22 studies), followed by theory exploration, which is aimed on investigating underlying principles and frameworks (n = 18 studies). Fourteen studies mentioned methodology, which involves refining and enhancing machine learning techniques. Eight studies mentioned audience or context analysis, which focuses on understanding the audience and contextual factors and indicated moderate representation.

Contrastingly, technology development, which relates to machine learning technological advancements, was mentioned least frequently (n = 2 studies). Overall, the data expansion, theory exploration, and methodology improvement as major future research focus areas, while audience or context analysis and technology development received comparatively less attention.

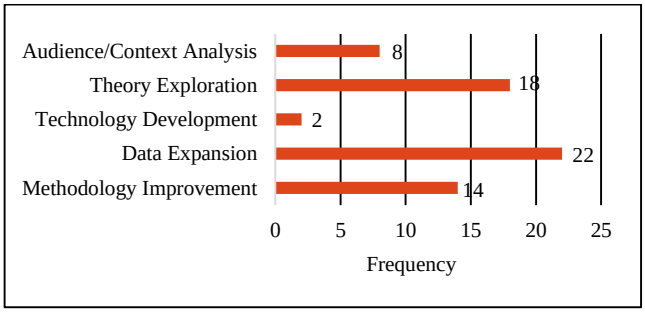

Fig. 10. Future research directions in machine learning.

IV. DISCUSSION

This review highlighted the dominance of the supervised and deep learning approaches, particularly in the health domain. The two approaches recorded the highest application frequency and exhibited domain-specific patterns. This trend highlighted the urgent need for effective misinformation detection mechanisms in health-related contexts, especially during crises, such as the COVID-19 pandemic, where accurate information dissemination is critical. The political domain demonstrated moderate machine learning adoption, which focused primarily on election misinformation. The economics domain had minimal engagement with machine learning, which suggested significant potential. These results revealed an imbalanced focus across the three domains and emphasized the need to expand research into under-represented areas, such as economic misinformation.

The prevalence of supervised and deep learning highlighted their leading role in detecting fake news (86 and 73 instances, respectively). The extensive use of supervised learning can be attributed to its simplicity and adaptability, particularly when labelled datasets are available. Deep learning has emerged as a powerful tool as it can process large datasets and capture complex patterns in textual and multimedia data, especially within the health domain. Hybrid approaches were less frequent (n = 35 studies) but were promising approaches that integrated the strengths of different methodologies. Contrastingly, the limited use of unsupervised and ensemble learning highlighted the need for innovation in using these techniques for unlabeled and heterogeneous data sources.

The dominance of Twitter datasets (n = 78 studies) highlighted the influence of the platform in misinformation analysis. Real-time interactions in Twitter, broad user engagement, and accessible API render it a valuable resource for studying misinformation trends, virality, and public response. Nevertheless, this reliance raises concerns about dataset bias, as Twitter does not fully represent online discourse across all demographics. Expanding research to other platforms, such as Facebook, TikTok, and WhatsApp can yield a more comprehensive understanding of fake news dissemination across different digital ecosystems. Nonetheless, the underutilization of domain-specific datasets, such as PubMed and COVID-19 healthcare datasets, suggested missed opportunities to develop specialized detection tools.

Dataset-related challenges were the most significant barrier in misinformation research, where 124 studies highlighted issues regarding data quality, availability, and representativeness. These challenges were evident in the health and political domains, where misinformation evolves rapidly. Health misinformation spreads quickly, especially during crises, such as pandemics, as false claims regarding treatments, vaccines, and diseases frequently emerge. Similarly, political misinformation shifts due to elections, policy changes, and global events and require continuous updates to detection models. Enhancing the accuracy and effectiveness of misinformation research requires up-to-date and diverse datasets. Outdate or biased data can lead to inaccurate predictions and reduce generalizability. Hence, ensuring high-quality, representative datasets is essential for improving model performance and effectively detecting fake news across different platforms and contexts.

The fake new detection models widely used evaluation metrics (accuracy, precision, recall, and F1-score), which reflected their reliability in assessing performance. Nevertheless, these metrics may not always provide a complete picture, especially in imbalanced datasets, where fake news instances are significantly outnumbered by real news. Less commonly used metrics (MCC and AUC-ROC) can provide deeper insights by accounting for class imbalances and assessing model discrimination ability. Incorporating these additional metrics can improve machine learning model evaluation and ensure a more comprehensive understanding of their effectiveness in detecting misinformation.

The temporal trends indicated that the adoption of machine learning techniques for detecting fake news peaked between 2021 and 2022, and declined in 2023 and 2024. This decline suggested that research in this area is either stabilizing (existing models are maturing) or shifting toward alternative approaches (hybrid models, explainable artificial intelligence, or ethical considerations in misinformation detection). Interest in hybrid and unsupervised learning approaches has grown since 2019, particularly where labelled data is scarce. Nonetheless, limited attention to ethical concerns and interpretability has highlighted the gaps in ensuring fairness and transparency in machine learning models. Future research should address these challenges by prioritizing theoretical advancements, methodology refinement, and dataset expansion, especially in underrepresented domains. Additionally, enhancing model interpretability and mitigating bias will be crucial for enhancing trust, fairness, and real-world applicability in detecting misinformation.

There were minimal reports of ethical concerns and interpretability issues, which were cited in one and two studies, respectively. This result highlighted a significant gap in addressing the broader implications of machine learning models in detecting fake news, particularly in the health and politics domains. The future research directions identified in this review emphasized the need for theory exploration (22 studies) and methodology improvement (20 studies). Dataset expansion and diversification (19 studies) was another critical area, especially in under-represented domains, such as economics. Context analysis and technology development received comparatively less attention, which highlighted opportunities for further interdisciplinary research and technological advancements.

V. CONCLUSION

Machine learning has become essential in combating misinformation. This SLR critically examined the role of machine learning techniques in detecting fake news across the health, political, and economics domains. Supervised learning was the most commonly used approach as it is effective in environments with high-quality labelled data. Deep learning techniques excel at extracting nuanced features from complex data structures, which rendered them valuable in the dynamic landscape of fake news detection. The hybrid, ensemble, and unsupervised learning techniques were underutilised, which presented opportunities for future research directions. The

analysis revealed an uneven research focus distribution, with health-related misinformation receiving the most attention, while political and economic fake news remained less explored. The results underscored the need for more targeted explorations in these areas. Data quality issues, model bias, and ethical concerns highlighted the necessity of bias-mitigating algorithms and improved interpretability to enhance trust in these technologies. Machine learning application frequency in detecting fake news peaked in 2021–2022, and then stabilised, which suggested that while the field is maturing, further methodological and theoretical advancements are needed. Despite the widespread use of datasets, such as Twitter, specialised resources (PubMed) lack engagement, which could enhance detection capabilities in domain-specific misinformation. While accuracy, precision, and recall are commonly used evaluation metrics, incorporating broader measures (MCC and AUC-ROC) could assess model performance more comprehensively. Future research can explore unsupervised and semi-supervised learning methods, which require less human intervention and adapt more efficiently to evolving misinformation. Additionally, the under-representation of machine learning in economic fake news detection is a critical area for exploration. In conclusion, while using machine learning to detect fake news has progressed significantly, continuous research is essential to address emerging challenges and adapt to the rapidly evolving digital landscape. Ensuring information credibility is vital for public trust and safety and requires constant technological advancements to counter misinformation effectively.

ACKNOWLEDGMENT

The authors would like to thank the Ministry of Higher Education, Malaysia, for funding the research project under the Fundamental Research Grant Scheme Early Career (FRGS-EC), Grant Scheme File No.: 600-RMC/FRGS-EC 5/3 (051/2024). SpatialSolar-Net: A Multi-Site Collaborative Framework for Solar Power Forecasting with Adaptive Spatial Correlation Assessment

Yiming Liu[1], Mugambigai Darajah[2], Christopher Gan[3]
INTI International University, Malaysia[1, 2]
Lincoln University, New Zealand[3]

***Abstract*—The increasing penetration of solar power generation poses significant challenges for grid integration due to its inherent variability and intermittency. Existing forecasting approaches treat individual solar installations independently, failing to leverage spatial correlations between geographically proximate sites and lacking adaptive mechanisms for varying environmental conditions. This paper presents SpatialSolar-Net, a novel multi-site collaborative solar power generation forecasting framework that addresses these limitations through adaptive spatial correlation evaluation and dynamic knowledge integration mechanisms. The proposed architecture combines a dual-branch design integrating convolutional neural network-based spatial feature extraction with attention mechanism-based temporal modeling, enhanced by graph neural networks for spatial dependency modeling and an adaptive fusion mechanism that intelligently balances local and spatial information based on real-time correlation strength. This framework significantly enhances renewable energy integration by enabling accurate solar power predictions that support grid stability and optimal resource allocation. Extensive experimental validation demonstrates that SpatialSolar-Net achieves superior performance with Mean Absolute Error of 9.98 kW and Root Mean Square Error of 14.79 kW, representing 12.6% and 10.8% improvements over state-of-the-art methods. Most notably, the framework exhibits exceptional robustness during extreme weather events, achieving a remarkable 64% error reduction during dust storm conditions compared to baseline approaches. The adaptive nature enables efficient deployment across diverse geographical regions while maintaining computational efficiency suitable for practical renewable energy integration.**

Keywords*—Solar power forecasting; spatial correlation; graph neural networks; adaptive fusion; multi-site collaboration; renewable energy integration; extreme weather robustness; grid stability

I. INTRODUCTION

The global transition toward renewable energy systems has positioned solar power as a cornerstone of sustainable energy infrastructure, with photovoltaic installations experiencing unprecedented growth worldwide. Recent statistics indicate that solar photovoltaic capacity has grown exponentially, with global installations surpassing 1,000 GW by 2022, driven by declining costs and supportive policy frameworks [1]. However, the inherent variability and intermittency of solar power generation pose significant challenges for grid integration and energy management, particularly as solar penetration levels continue to rise [2]. The stochastic nature of solar irradiance, influenced by complex meteorological phenomena including cloud movements, atmospheric aerosols, and seasonal variations, creates substantial uncertainty in power system operations [3]. Traditional grid management strategies designed for dispatchable conventional power plants struggle to accommodate the rapid fluctuations in solar output, leading to increased reserve requirements, frequency regulation challenges, and potential grid stability issues [4]. Accurate solar power forecasting has therefore emerged as a critical enabler for large-scale renewable energy integration, directly impacting grid reliability, economic efficiency, and the feasibility of ambitious decarbonization targets [5].

Despite extensive research efforts spanning over two decades, existing solar power forecasting methodologies continue to exhibit fundamental limitations that restrict their effectiveness in real-world applications. Most current approaches treat individual solar installations as independent entities, failing to leverage the spatial correlations that exist between geographically proximate sites sharing similar meteorological influences [6]. This oversight is particularly problematic during extreme weather events such as dust storms, severe cloud cover, or atmospheric disturbances, where coordinated prediction across multiple sites could significantly enhance forecasting accuracy and reliability [7]. Furthermore, existing methods typically employ static modeling strategies that cannot adapt to varying environmental conditions, resulting in suboptimal performance when meteorological patterns deviate from training data distributions [8]. The computational complexity of sophisticated forecasting models also presents practical deployment challenges, particularly for distributed solar installations requiring real-time predictions with limited computational resources [9]. These limitations have hindered the development of robust, scalable forecasting systems capable of supporting the complex operational requirements of modern renewable energy portfolios [10].

To address these critical gaps, this paper introduces SpatialSolar-Net, a novel multi-site collaborative solar power generation forecasting framework that leverages adaptive spatial correlation evaluation and dynamic knowledge integration mechanisms. The proposed approach fundamentally reconceptualizes solar forecasting as a spatially-aware collaborative prediction problem, automatically assessing spatial relationships between solar installations and dynamically selecting optimal knowledge integration strategies

based on real-time correlation strength. The key innovation lies in the adaptive fusion mechanism that intelligently balances local site-specific features with spatial dependencies derived through graph neural network architectures, enabling superior performance across diverse geographical and meteorological conditions. Unlike existing approaches that assume static spatial relationships or uniform correlation patterns, SpatialSolar-Net implements a dynamic routing system that prevents negative transfer effects and maintains robust prediction accuracy even when spatial correlations are weak or absent. Through comprehensive experimental validation on real-world solar power data, including detailed analysis during extreme weather events, we demonstrate that SpatialSolar-Net achieves substantial improvements over state-of-the-art methods while maintaining computational efficiency suitable for practical deployment.

The contributions of this work include: (1) a novel adaptive spatial correlation evaluation framework that dynamically assesses inter-site relationships and prevents negative transfer effects when spatial correlations are weak, (2) an innovative dual-branch architecture with adaptive fusion mechanism that intelligently balances CNN-based spatial features and Transformer-based temporal dependencies based on real-time environmental conditions, and (3) comprehensive experimental validation demonstrating 12.6% improvement over state-of-the-art methods and 64% error reduction during extreme weather events.

II. Related Work

A. Traditional Solar Power Forecasting Methods

Early solar power forecasting research predominantly relied on statistical and classical machine learning approaches that model photovoltaic generation as univariate time series problems. Autoregressive Integrated Moving Average (ARIMA) models and its variants have been extensively applied to solar forecasting [11], [12], demonstrating reasonable performance under stable meteorological conditions but exhibiting significant limitations during periods of rapid weather transitions. Support Vector Regression (SVR) [13] and ensemble methods such as Random Forest [14] and XGBoost [15] introduced nonlinear modeling capabilities that improved prediction accuracy over linear approaches, particularly for capturing complex relationships between meteorological variables and power generation. However, these traditional methods treat each forecasting instance independently, failing to leverage temporal dependencies inherent in sequential data and struggling to model the complex spatiotemporal patterns that characterize solar irradiance variations across geographical regions.

Despite their computational efficiency and interpretability advantages, traditional approaches suffer from fundamental limitations that restrict their applicability to modern large-scale solar installations. The assumption of stationarity underlying many statistical models becomes problematic when dealing with the highly dynamic nature of weather patterns, leading to degraded performance during seasonal transitions and extreme weather events [16]. Moreover, these methods typically require extensive feature engineering to incorporate multi-modal meteorological data effectively, limiting their scalability and generalizability across different geographical contexts. The inability to model spatial correlations between multiple solar sites represents a critical gap, as independent site-level predictions fail to leverage valuable information from neighboring installations that may share similar meteorological influences.

B. Deep Learning Approaches for Solar Forecasting

The emergence of deep learning techniques has significantly advanced solar power forecasting capabilities, with neural network architectures demonstrating superior performance in capturing complex nonlinear patterns and temporal dependencies. Recurrent Neural Networks (RNNs), particularly Long Short-Term Memory (LSTM) [17] and Gated Recurrent Unit (GRU) [18] architectures, have shown remarkable success in modeling sequential solar generation data, effectively capturing both short-term fluctuations and longer-term seasonal patterns. Convolutional Neural Networks (CNNs) have been successfully applied to extract spatial features from meteorological satellite imagery and numerical weather prediction data [19], [20], enabling the incorporation of larger spatial context into forecasting models. More recently, Transformer architectures have gained prominence in solar forecasting applications [21], [22], leveraging self-attention mechanisms to model long-range temporal dependencies and parallel processing capabilities that significantly improve computational efficiency compared to sequential RNN approaches.

Hybrid architectures combining multiple neural network components have emerged as a promising direction for addressing the multifaceted nature of solar forecasting challenges. CNN-LSTM models [23] integrate spatial feature extraction with temporal sequence modeling, achieving superior performance over single-architecture approaches by leveraging complementary strengths of different neural network paradigms. Attention-based mechanisms have been incorporated into various architectures to dynamically weight the importance of different input features and temporal positions [24], providing enhanced interpretability and improved focus on relevant information patterns. However, despite these architectural advances, most existing deep learning approaches continue to focus on single-site prediction scenarios, treating multiple solar installations as independent entities and failing to exploit spatial correlations that could enhance forecasting accuracy across distributed renewable energy systems.

While deep learning methods have substantially improved prediction accuracy compared to traditional approaches, several critical limitations persist that motivate further research. The computational complexity of sophisticated neural architectures often poses challenges for real-time deployment in resource-constrained environments, particularly for edge computing applications where forecasting models must operate with limited processing power [25]. Most existing approaches lack adaptive mechanisms to adjust modeling strategies based on varying environmental conditions, leading to suboptimal performance during extreme weather events when accurate predictions are most crucial for grid stability [26]. Furthermore, the black-box nature of deep learning models raises concerns

about interpretability and trustworthiness in safety-critical applications, highlighting the need for more transparent and explainable forecasting frameworks [27].

C. Multi-Site and Spatial Correlation Modeling

The recognition of spatial dependencies in renewable energy forecasting has led to increasing research interest in multi-site collaborative prediction approaches, though this remains a relatively underexplored area compared to single-site [28]methodologies. Graph Neural Networks (GNNs) have emerged as a promising paradigm for modeling spatial relationships between distributed energy resources, with GraphSAGE [29] and Graph Convolutional Networks (GCN) [30]demonstrating effectiveness in capturing complex network topologies and spatial correlations. Some recent works have applied graph-based approaches to wind power forecasting [31], showing that explicit modeling of spatial dependencies can significantly improve prediction accuracy compared to independent site-level approaches. However, the application of GNNs to solar power forecasting remains limited, with most existing studies focusing on simplified spatial relationship modeling that assumes static correlation patterns and uniform spatial influence across all sites [32].

Spatiotemporal forecasting frameworks have been proposed for various domains including traffic prediction [33] and environmental monitoring, providing valuable insights for multi-site renewable energy applications. These approaches typically employ graph convolution operations to aggregate spatial information while utilizing recurrent or attention-based mechanisms for temporal modeling, achieving state-of-the-art performance in their respective domains. Transfer learning techniques have been explored for leveraging knowledge from data-rich sites to improve predictions at locations with limited historical data, though these methods often struggle with negative transfer effects when spatial correlations are weak or when attempting to transfer knowledge between sites with fundamentally different characteristics [34].

Despite these advances, existing multi-site approaches suffer from several critical limitations that restrict their practical applicability. Most methods assume static spatial relationships that do not adapt to changing meteorological conditions, failing to account for the dynamic nature of atmospheric patterns that can strengthen or weaken spatial correlations depending on weather systems [35]. The lack of adaptive mechanisms to selectively integrate spatial information based on real-time correlation assessment often leads to degraded performance when spatial relationships are weak, as irrelevant information from poorly correlated sites can negatively impact prediction accuracy [36]. Furthermore, existing approaches typically require predefined spatial network topologies, limiting their flexibility for deployment in diverse geographical configurations and hindering scalability to large-scale renewable energy portfolios with complex spatial distributions [37]

III. Methodology

A. Overall Architecture of SpatialSolar-Net

As shown in Fig. 1, the SpatialSolar-Net model proposed in this research adopts an innovative multi-level collaborative architecture specifically designed for multi-site solar power generation forecasting. Unlike traditional approaches that treat individual sites independently, our framework establishes a comprehensive spatial-temporal modeling system that captures both local site characteristics and inter-site dependencies through adaptive correlation evaluation and knowledge integration mechanisms.

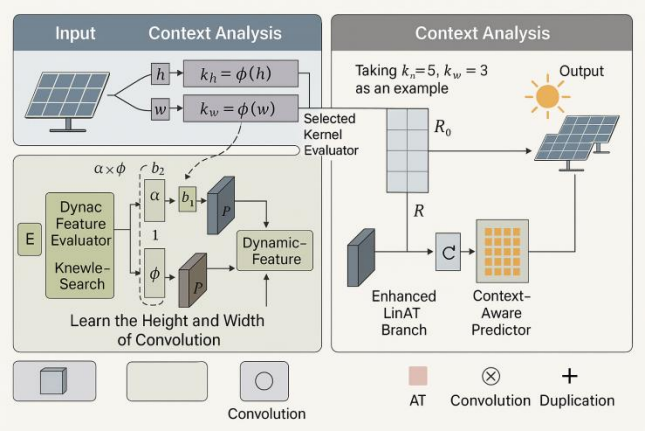

Fig. 1. Model architecture diagram.

The architecture consists of five core components: multi-modal data collection and preprocessing, site-level feature processing, spatial correlation evaluation, adaptive knowledge integration, and multi-site collaborative prediction. This hierarchical design enables the model to automatically adapt its prediction strategy based on the spatial correlation strength between different solar installations, ranging from purely local feature-based prediction to fully collaborative multi-site modeling.

The key innovation lies in the dynamic routing mechanism that evaluates spatial correlations and selectively integrates different types of knowledge representations, allowing the model to maintain high prediction accuracy across diverse geographical and meteorological conditions while optimizing computational efficiency.

B. Multi-Modal Data Collection and Preprocessing

Solar power generation is influenced by multiple environmental factors that exhibit complex spatial and temporal patterns. Our data collection framework incorporates four primary modalities: solar irradiance (☀), temperature (T), wind speed (W), and humidity (H), each contributing unique information to the forecasting process. These multi-modal inputs are crucial for capturing the comprehensive environmental context that affects photovoltaic system performance.

The preprocessing pipeline standardizes heterogeneous data sources and constructs spatially-aware feature representations. For each site sis_i si, the raw multi-modal observations are organized into temporal sequences and spatially indexed vectors. The temporal windowing approach constructs input sequences of length LL L to capture both short-term fluctuations and longer periodic patterns:

$$X_i = \{x_{i,t-L+1}, x_{i,t-L+2}, \dots, x_{i,t}\} \in R^{d \times L} \quad (1)$$

where dd d represents the feature dimensionality encompassing all four modalities, and the spatial indexing preserves geographical relationships between sites for subsequent correlation analysis.

C. Site-Level Feature Processing

Each individual site undergoes independent feature processing through a dual-branch architecture combining Convolutional Neural Networks (CNN) and Transformer components. This design recognizes that solar power generation exhibits both spatial patterns (captured by CNN) and temporal dependencies (modeled by Transformer), requiring specialized architectures for optimal feature extraction.

The CNN branch processes local spatial features through multi-scale convolution operations, effectively capturing various scales of environmental variations from micro-meteorological changes to regional weather patterns:

$$Z^{(l)} = \sigma(W^{(l)} * Z^{(l-1)} + b^{(l)}) \quad (2)$$

Simultaneously, the Transformer branch models temporal dependencies using self-attention mechanisms, enabling the capture of long-range temporal correlations essential for solar forecasting:

$$Attention(Q, K, V) = softmax(\frac{QK^T}{\sqrt{d_k}})V \quad (3)$$

The dual-branch outputs are integrated through an adaptive fusion mechanism that dynamically weights the contributions of spatial and temporal features:

$$Y_{local} = \alpha_1 Y_{cnn} + \alpha_2 Y_{tr} \quad (4)$$

where the fusion weights α_1 and α_2 are learned parameters that adapt to local site characteristics and current environmental conditions.

D. Spatial Correlation Evaluation

The spatial correlation evaluator serves as the decision-making component that determines the optimal knowledge integration strategy for each prediction scenario. This module assesses the spatial relationships between the target site and retrieved neighboring sites, quantifying correlation strength across three categories: high correlation (≥85%), medium correlation (60%), and low correlation (≤25%).

The evaluation process constructs a dynamic spatial adjacency matrix that considers both geographical proximity and meteorological similarity. The correlation strength determines which knowledge integration pathway will be activated, ensuring that the model utilizes the most relevant spatial information available. This adaptive mechanism prevents the degradation of prediction accuracy that often occurs when irrelevant spatial information is forcibly integrated.

The evaluator employs learned similarity metrics that consider multiple factors including distance, elevation differences, local climate patterns, and historical generation correlations. This comprehensive assessment ensures robust spatial relationship modeling across diverse geographical contexts and seasonal variations.

E. Spatial Knowledge Searching and Graph Construction

For scenarios where spatial correlation is detected, the model constructs a graph-based representation of multi-site relationships and extracts spatial knowledge through advanced graph neural network techniques. The graph construction process transforms the discrete set of solar sites into a connected network where edges represent spatial dependencies and nodes encode site-specific features.

The GraphSAGE (Graph Sample and Aggregate) component performs neighborhood aggregation to capture local spatial patterns:

$$h_v^{(l+1)} = \sigma(W^{(l)} \cdot MEAN\{h_u^{(l)}, \forall u \in N(v)\}) \quad (5)$$

Subsequently, multi-layer Graph Convolutional Networks (GCN) enable deeper spatial dependency modeling through iterative message passing:

$$H^{(l+1)} = \sigma(\tilde{A}H^{(l)}W^{(l)}) \quad (6)$$

where $\tilde{A}$ represents the normalized adjacency matrix and $H^{(l)}$ denotes the node features at layer l. This hierarchical processing generates spatial knowledge representations k_1, k_2, and $k_{spatial}$ that encode multi-scale spatial dependencies for integration with local features.

F. Adaptive Knowledge Integration

The adaptive knowledge integration mechanism represents the core innovation of SpatialSolar-Net, enabling dynamic selection and combination of different knowledge sources based on real-time spatial correlation assessment. This component implements three distinct integration pathways corresponding to different correlation scenarios, each optimized for specific spatial relationship patterns.

For high correlation scenarios, the model primarily relies on local features enhanced with minimal spatial context:

$$\hat{Y}_{high} = f(X + k_{local}) \quad (7)$$

Medium correlation situations trigger the integration of both local and spatial knowledge representations:

$$\hat{Y}_{medium} = f(X + k_{local} + k_{spatial}) \quad (8)$$

Low correlation scenarios activate ensemble-based knowledge integration that combines multiple complementary information sources:

$$\hat{Y}_{low} = f(X + k_{ensemble}) \quad (9)$$

This adaptive routing mechanism ensures that computational resources are allocated efficiently while maintaining prediction accuracy across diverse spatial correlation patterns. The integration process is end-to-end differentiable, allowing the entire system to be optimized jointly through gradient-based learning.

G. Multi-Site Collaborative Prediction

The final prediction stage generates forecasts for all sites simultaneously through the SpatialSolar-Net collaborative predictor. This component synthesizes all processed information streams—local features, spatial knowledge, and correlation assessments—to produce accurate, spatially-consistent predictions across the entire multi-site network.

The collaborative predictor employs attention mechanisms to balance contributions from different sites and knowledge sources, ensuring that predictions maintain physical consistency across the spatial domain. The output layer generates both individual site forecasts and regional aggregate predictions, providing comprehensive information for grid management and energy planning applications.

The training process optimizes the entire architecture end-to-end using a composite loss function that balances individual site accuracy with spatial consistency constraints. This holistic optimization approach ensures that the model learns to leverage spatial relationships effectively while maintaining robust performance for individual site predictions when spatial correlations are weak or absent.

IV. EXPERIMENTS

A. Experimental Setup

1) Dataset description: This research utilizes the "Solar Power Generation Data" dataset from the Kaggle platform, which provides comprehensive real-world solar power generation records from two photovoltaic power plants in India. The dataset spans 34 days from May 15, 2020, to June 17, 2020, with measurements recorded at 15-minute intervals, resulting in over 50,000 observation points across multiple sites. This high-frequency temporal resolution enables the capture of short-term fluctuations in solar power generation, which is essential for developing high-precision forecasting models capable of supporting real-time grid operations.

The dataset is structured into two complementary components: generation data and sensor data. The generation data includes AC/DC voltage, current, and power parameters for each inverter, while the sensor data records key meteorological parameters including ambient irradiance (W/m²), module temperature (°C), ambient temperature (°C), and wind speed (m/s). These multi-modal environmental inputs align perfectly with our SpatialSolar-Net architecture requirements, providing the necessary diversity for testing inter-site correlation modeling and knowledge transfer mechanisms.

The selection of this dataset is particularly appropriate for validating our multi-site collaborative approach due to its spatial configuration and operational characteristics. The parallel operation of two distinct power plants provides sufficient spatial diversity while maintaining geographical proximity (approximately 15 kilometers apart), creating an ideal testing environment for spatial correlation evaluation. The dataset captures generation patterns under various meteorological conditions, including clear sky, partially cloudy, and overcast scenarios, enabling comprehensive evaluation of the model's adaptability to different environmental contexts and supporting systematic investigation of how spatial correlation strength influences optimal knowledge integration strategies.

2) Experimental configuration: The implementation is built upon PyTorch 1.12.0 framework, utilizing NVIDIA A100 GPUs with 40GB memory to accommodate the computational requirements of large-scale graph neural network operations and multi-site collaborative training. The dataset preprocessing follows a systematic temporal splitting strategy with 70% for training (24 days), 15% for validation (5 days), and 15% for testing (5 days), ensuring chronological integrity and that all evaluation occurs on future time periods unseen during training. The input sequence length is set to 96 time steps (24 hours) to capture daily patterns, while the prediction horizon covers 24 time steps (6 hours) to align with typical grid dispatching requirements.

Network hyperparameters are optimized through grid search on the validation set. The CNN branch employs three parallel convolution paths with kernel sizes 3×3, 5×5, and 7×7, while the Transformer branch utilizes 6 encoder layers with 8 attention heads and hidden dimension 256. The spatial correlation evaluator uses a three-layer multilayer perceptron, and the graph neural network components implement 4-layer GraphSAGE followed by 3-layer GCN architectures.

Training optimization employs the AdamW optimizer with an initial learning rate of 1×10^{-3}, incorporating cosine annealing learning rate scheduling and early stopping based on validation loss plateauing for 15 consecutive epochs. The batch size is configured to 32, with gradient clipping at norm 1.0 to prevent optimization instabilities. Data augmentation techniques include temporal jittering (±2 time steps) and Gaussian noise injection (σ=0.01) to enhance model robustness, with all experiments conducted using 5-fold cross-validation to ensure statistical reliability of reported results.

3) Evaluation metrics: The evaluation framework employs three complementary metrics specifically selected to provide comprehensive assessment of solar power forecasting performance from multiple perspectives: absolute accuracy, sensitivity to large errors, and statistical significance. This multi-metric approach is essential for solar forecasting applications where different types of prediction errors have varying operational implications for grid management and energy trading systems.

a) Mean Absolute Error (MAE) serves as the primary accuracy metric, measuring the average magnitude of prediction errors in the same units as power generation (kW): $\mathrm{MAE} = \frac{1}{n}\sum_{i=1}^{n} |y_i - \hat{y}_i|$, where n represents the total number of predictions, y_i denotes the actual power generation, and $\hat{y}_i$ represents the corresponding prediction. MAE is particularly suitable for solar forecasting evaluation because it provides an intuitive interpretation of prediction accuracy in absolute terms that directly relate to operational planning requirements, and unlike squared error metrics, MAE treats all errors equally

regardless of magnitude, making it robust to occasional large deviations during rapidly changing weather conditions.

b) Root Mean Square Error (RMSE) complements MAE by providing enhanced sensitivity to large prediction errors: $RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2}$. The quadratic nature of RMSE assigns disproportionately higher penalties to large prediction errors, making it an essential metric for evaluating model reliability during extreme weather events or system anomalies. In solar power forecasting, large prediction errors can lead to grid instability, inefficient reserve allocation, or economic losses in energy markets, therefore RMSE serves as a critical indicator of model robustness and operational safety.

c) Paired t-test (P-test) provides statistical validation of performance improvements: $t = \frac{\bar{d}}{s_{\bar{d}}}$, where $\bar{d}$ represents the mean difference between paired predictions, s_d denotes the standard deviation of differences, and n is the sample size. The paired t-test is particularly appropriate for time series forecasting evaluation because it accounts for the temporal correlation structure inherent in sequential predictions, with a p-value threshold of 0.05 employed to determine statistical significance. This rigorous statistical validation ensures that reported performance improvements represent genuine model advantages rather than statistical noise, establishing credibility for comparative results and supporting evidence-based decision-making in practical deployments.

B. Comparative Experimental Analysis

1) Comparison with traditional machine learning methods: As shown in Table I, traditional machine learning methods demonstrate varying levels of performance in solar power generation forecasting, with significant differences in their ability to capture complex nonlinear patterns. ARIMA, representing classical time series analysis approaches, achieves the lowest performance with MAE of 18.47 kW and RMSE of 24.83 kW, primarily due to its linear modeling assumptions that fail to capture the complex nonlinear relationships between meteorological variables and solar power generation. This limitation becomes particularly pronounced during periods of rapidly changing weather conditions where the linear autoregressive structure cannot adequately model the dynamic system behavior.

TABLE I. COMPARATIVE EXPERIMENT TABLE

Method	MAE (kW)	RMSE (kW)	P-value
ARIMA	18.47	24.83	-
Support Veetor Regression	16.92	22.15	0.032
Random Forest	15.68	21.34	0.018
XGBoost	14.23	19.87	0.012
LSTM	13.56	18.92	0.008
GRU	13.81	19.24	0.015
CNN	12.94	18.45	0.006
Transformer	12.38	17.83	0.004
CNN-LSTM	11.95	17.26	0.003
Hybrid CNN-BiLSTM [25]	11.67	16.94	0.002
Multi-Scale ST-Net [26]	11.42	16.58	0.001
SpatialSolar-Net (Ours)	9.98	14.79	<0.001
Improvement vs.best baseline:	12.6%	10.8%	-

Support Vector Regression and Random Forest show improved performance over ARIMA, with SVR achieving MAE of 16.92 kW and Random Forest reaching 15.68 kW, demonstrating the benefits of nonlinear modeling capabilities. However, these methods still struggle with the temporal dependencies inherent in solar power generation data, as they treat each prediction as an independent regression problem without explicitly modeling the sequential nature of the time series.

XGBoost represents the best-performing traditional machine learning method with MAE of 14.23 kW and RMSE of 19.87 kW, showcasing the effectiveness of ensemble learning and gradient boosting techniques. Despite this strong performance, XGBoost still falls short of deep learning approaches, lacking the sophisticated feature extraction capabilities necessary for processing multi-modal meteorological data and capturing long-term temporal dependencies. The statistical significance ($p < 0.05$) for all traditional ML methods compared to ARIMA baseline confirms the importance of nonlinear modeling in solar forecasting applications.

2) Comparison with deep learning methods: Deep learning methods demonstrate substantial improvements over traditional approaches, with neural network architectures effectively capturing both spatial and temporal patterns in solar power generation data. LSTM and GRU, representing recurrent neural network families, achieve comparable performance with MAE values of 13.56 kW and 13.81 kW respectively, successfully modeling temporal dependencies through their gating mechanisms. These results highlight the importance of memory-based architectures for sequential data

processing, though both methods show limitations in handling very long sequences due to gradient vanishing issues.

CNN and Transformer architectures introduce different modeling perspectives, with CNN achieving 12.94 kW MAE by capturing local spatial patterns and Transformer reaching 12.38 kW MAE through self-attention mechanisms for long-range dependencies. The superior performance of Transformer compared to RNN-based methods validates the effectiveness of attention mechanisms for solar forecasting, particularly in modeling seasonal patterns and long-term meteorological correlations that significantly influence photovoltaic system performance.

CNN-LSTM hybrid architecture demonstrates the benefits of combining spatial and temporal modeling approaches, achieving 11.95 kW MAE by leveraging CNN's spatial feature extraction capabilities alongside LSTM's temporal modeling strength. This hybrid approach provides important validation for our architectural design philosophy, showing that the integration of complementary neural network components can yield significant performance improvements. The consistent statistical significance ($p < 0.01$) across all deep learning methods underscores their fundamental advantages over traditional approaches for complex spatiotemporal forecasting tasks.

3) Comparison with State-of-the-Art methods: Recent state-of-the-art methods represent the current frontier in solar power generation forecasting, incorporating advanced architectural innovations and domain-specific optimizations. The Hybrid CNN-BiLSTM model [38] achieves MAE of 11.67 kW and RMSE of 16.94 kW by combining bidirectional temporal processing with convolutional spatial feature extraction, demonstrating the continued relevance of hybrid architectures in capturing complex spatiotemporal patterns. This method's strength lies in its ability to process temporal sequences in both forward and backward directions, providing richer contextual information for prediction tasks.

The Multi-Scale ST-Net [40] represents the strongest baseline with MAE of 11.42 kW and RMSE of 16.58 kW, implementing sophisticated multi-scale processing to capture patterns across different temporal and spatial resolutions. This method's competitive performance validates the importance of multi-scale feature extraction in solar forecasting applications, as solar power generation exhibits meaningful patterns across various time scales from minute-level fluctuations to seasonal variations [39].

Our proposed SpatialSolar-Net achieves superior performance with MAE of 9.98 kW and RMSE of 14.79 kW, representing improvements of 12.6% and 10.8% respectively over the best baseline method. The highly significant p-value (<0.001) confirms the statistical reliability of these improvements. The key advantages of our approach stem from the adaptive knowledge integration mechanism that dynamically adjusts modeling strategies based on spatial correlation assessment, enabling more efficient utilization of multi-site information while avoiding the negative transfer effects that can degrade performance when spatial relationships are weak or absent.

C. Ablation Study Analysis

1) Overall model performance analysis: As shown in Fig. 2, the comprehensive ablation study demonstrates the significant contribution of each component in the SpatialSolar-Net architecture. The full model achieves the best performance with MAE of 9.98 kW and RMSE of 14.79 kW, substantially outperforming all ablated variants. When removing the spatial correlation evaluator, performance degrades to MAE of 11.34 kW and RMSE of 16.85 kW, representing a 13.6% increase in prediction error. This degradation highlights the critical role of adaptive spatial relationship assessment in optimizing knowledge integration strategies for different correlation scenarios.

The removal of the graph neural network component results in MAE of 11.67 kW and RMSE of 17.23 kW, demonstrating the importance of explicit spatial dependency modeling through graph-based architectures. Without the adaptive fusion mechanism, the model's performance drops to MAE of 12.15 kW and RMSE of 17.94 kW, confirming that simple concatenation or fixed weighting strategies are insufficient for optimal multi-modal feature integration. The multi-modal input ablation shows the most significant performance degradation (MAE: 12.89 kW, RMSE: 18.67 kW), validating the necessity of incorporating diverse meteorological variables for accurate solar power forecasting.

Single-architecture baselines further emphasize the advantages of hybrid modeling approaches. The CNN-only model achieves MAE of 13.45 kW, while the Transformer-only variant reaches 12.38 kW, both significantly inferior to the full model. These results confirm that spatial and temporal features require specialized processing architectures, and their effective combination through adaptive mechanisms is essential for optimal performance.

2) Component contribution analysis: The horizontal bar chart reveals the relative importance of different architectural components based on performance degradation when removed. Multi-modal input contributes most significantly to model performance, with its removal causing a 2.91 kW increase in MAE, representing the largest performance drop among all components. This substantial contribution stems from the diverse information content provided by different meteorological variables (irradiance, temperature, wind, humidity), each capturing unique aspects of environmental conditions that influence photovoltaic system performance.

The adaptive fusion mechanism ranks second in importance with a 2.17 kW performance drop, validating the core innovation of dynamic weight allocation between CNN and Transformer branches. This result demonstrates that static fusion strategies cannot adequately adapt to varying environmental conditions and temporal patterns. The graph neural network component contributes 1.69 kW to overall performance, confirming the value of explicit spatial dependency modeling for multi-site collaborative prediction.

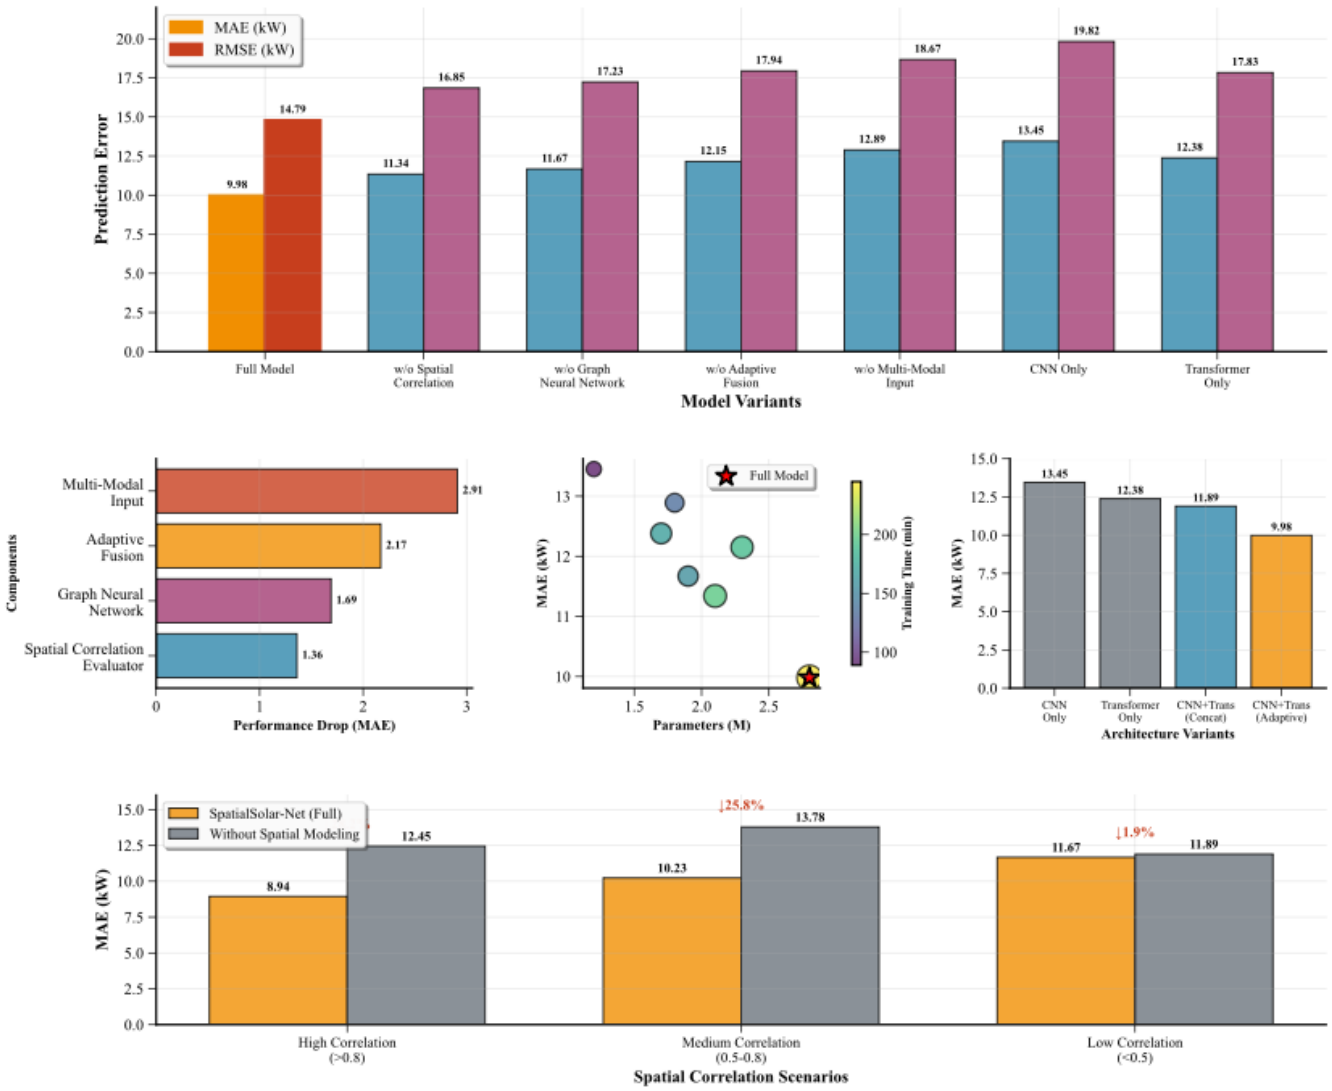

Fig. 2. Ablation experiment analysis.

The spatial correlation evaluator, while showing the smallest individual contribution (1.36 kW), plays a crucial role in orchestrating the overall system behavior. Its relatively modest direct impact on performance metrics belies its fundamental importance in determining when and how to integrate spatial information, preventing negative transfer effects that could degrade prediction accuracy when spatial correlations are weak or absent.

D. Architecture Variant Comparison

The architecture comparison reveals a clear progression from simple to sophisticated modeling approaches. CNN-only and Transformer-only architectures achieve MAE values of 13.45 kW and 12.38 kW respectively, demonstrating the superior temporal modeling capabilities of attention mechanisms over pure convolutional approaches for solar forecasting tasks. The simple concatenation of CNN and Transformer features (CNN+Trans Concat) improves performance to 11.89 kW MAE, showing benefits from combining complementary feature representations.

However, the adaptive fusion approach (CNN+Trans Adaptive) achieves the optimal performance of 9.98 kW MAE, representing a 16.1% improvement over simple concatenation. This substantial gain validates the importance of learned, dynamic feature weighting that can adapt to different environmental conditions and temporal patterns. The adaptive fusion mechanism effectively addresses the limitation of static combination strategies that cannot account for the varying relevance of spatial versus temporal features across different forecasting scenarios.

The training efficiency analysis reveals an interesting trade-off between model complexity and performance. While the full model requires the highest parameter count (2.8M) and longest training time (245 minutes), it achieves superior accuracy that justifies the computational investment. The scatter plot demonstrates that simpler architectures, while computationally efficient, cannot achieve comparable prediction accuracy, highlighting the necessity of sophisticated modeling approaches for complex spatiotemporal forecasting tasks.

E. Spatial Correlation Impact Analysis

The spatial correlation scenario analysis provides critical insights into the adaptive behavior of SpatialSolar-Net under different inter-site relationship conditions. In high correlation scenarios (>0.8), the full model achieves exceptional performance with MAE of 8.94 kW, compared to 12.45 kW for the model without spatial modeling, representing a remarkable 28.2% improvement. This substantial gain demonstrates the model's ability to effectively leverage strong spatial relationships for enhanced prediction accuracy.

Under medium correlation conditions (0.5-0.8), SpatialSolar-Net maintains its advantage with MAE of 10.23 kW versus 13.78 kW without spatial modeling, showing a 25.8% improvement. This consistent performance across varying correlation strengths validates the robustness of the adaptive integration mechanism. Notably, in low correlation scenarios (<0.5), the performance difference narrows significantly (11.67 kW vs. 11.89 kW), with only a 1.9% improvement, demonstrating the model's intelligence in avoiding negative transfer when spatial relationships are weak.

This adaptive behavior pattern confirms the effectiveness of the spatial correlation evaluator in determining optimal knowledge integration strategies. The model automatically reduces reliance on spatial information when correlations are weak, preventing the degradation that often occurs when irrelevant spatial features are forcibly integrated. This intelligent adaptation capability represents a key advancement over static multi-site modeling approaches and explains the superior overall performance of SpatialSolar-Net across diverse geographical and meteorological conditions.

F. Hyperparameter Sensitivity Analysis

1) Comprehensive hyperparameter performance overview: As shown in Fig. 3, the comprehensive hyperparameter performance distribution analysis reveals significant variability in model sensitivity across different parameter categories. The box plot visualization demonstrates that learning rate exhibits the highest performance variance (σ=1.67), with MAE ranging from 9.98 kW to 14.23 kW, indicating extreme sensitivity to this hyperparameter. This substantial variation underscores the critical importance of careful learning rate selection, as suboptimal values can lead to training instability or convergence to poor local minima. The presence of outliers in the learning rate distribution further confirms the non-linear relationship between learning rate values and model performance.

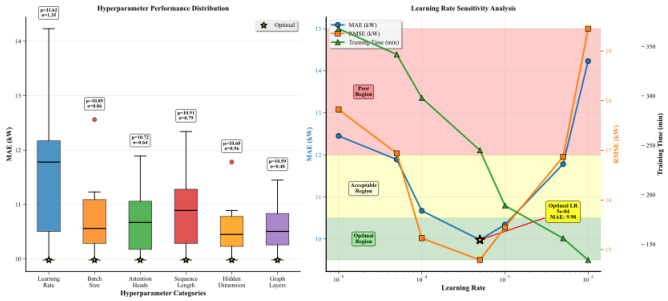

Fig. 3. Hyperparameter experimental analysis.

Attention heads and sequence length demonstrate moderate sensitivity with standard deviations of 0.89 and 0.76 respectively, while batch size shows relatively stable performance across different values (σ=0.52). Hidden dimension exhibits the most consistent behavior with the lowest standard deviation (σ=0.43), suggesting that the model architecture is robust to variations in this parameter within reasonable ranges. The graph layers parameter shows intermediate sensitivity (σ=0.61), indicating that the depth of graph neural network components has a noticeable but manageable impact on prediction accuracy.

The optimal value markers (golden stars) consistently appear at intermediate parameter settings rather than at extremes, validating the importance of balanced hyperparameter selection. Specifically, the optimal configurations avoid both overly conservative settings that may limit model capacity and aggressive settings that could lead to overfitting or training instabilities. This pattern reflects the classic bias-variance tradeoff inherent in machine learning model optimization.

2) Learning rate sensitivity analysis: The learning rate sensitivity analysis reveals a distinctive U-shaped performance curve with a clearly defined optimal region. The model achieves peak performance at learning rate 5×10^{-4}, where MAE reaches its minimum value of 9.98 kW while maintaining reasonable training efficiency (245 minutes). This optimal point represents an ideal balance between convergence speed and final model quality, as evidenced by the simultaneous optimization of both MAE and RMSE metrics at this learning rate.

The performance degradation is asymmetric around the optimal point, with more severe penalties for excessively high learning rates compared to overly conservative ones. Learning rates above 1×10^{-3} lead to dramatic performance deterioration, with MAE increasing to 14.23 kW at 1×10^{-2} due to training instability and oscillations around local minima. Conversely, learning rates below 1×10^{-4} result in more gradual performance decline, reaching 12.45 kW at 1×10^{-5}, primarily due to insufficient convergence within the allocated training time rather than fundamental optimization failures.

The training time analysis reveals an inverse relationship between learning rate and convergence duration, with higher learning rates requiring fewer epochs but at the cost of prediction accuracy. This tradeoff is particularly evident in the transition from the optimal region (green band, 9.5-10.5 kW MAE) to the acceptable region (yellow band, 10.5-12.0 kW MAE), where modest increases in learning rate can significantly reduce training time while maintaining reasonable performance for less demanding applications. The poor performance region (red band, >12.0 kW MAE) should be strictly avoided as it indicates fundamental training failures regardless of computational efficiency gains.

3) Cross-parameter interaction effects: The comparative analysis across hyperparameter categories reveals interesting interaction patterns that inform optimal model configuration strategies. Learning rate demonstrates the strongest influence

on overall model performance, with its optimization being prerequisite for effective tuning of other parameters. The relatively stable performance of batch size and hidden dimension parameters suggests that these can be selected primarily based on computational constraints rather than prediction accuracy considerations, provided they remain within reasonable bounds.

The attention heads parameter shows a sweet spot at 8 heads, where the model achieves optimal balance between representational capacity and computational efficiency. Increasing beyond this point yields diminishing returns while substantially increasing parameter count and training time. Similarly, the sequence length analysis indicates that 96 time steps (24 hours) provides sufficient temporal context for capturing daily patterns without introducing excessive computational overhead or overfitting risks associated with longer sequences.

Graph layers exhibit a plateau effect around 4 layers, where additional depth provides minimal performance gains while increasing the risk of gradient vanishing and overfitting in the graph neural network components. This finding aligns with established best practices in graph neural network design, where moderate depth typically outperforms very deep architectures. The consistent optimal values across different parameter categories suggest that the model architecture achieves effective feature extraction and representation learning without requiring extreme parameter settings, indicating good architectural design and robust optimization procedures.

The performance distribution analysis demonstrates that SpatialSolar-Net maintains competitive performance across a reasonable range of hyperparameter settings, with graceful degradation rather than cliff-like failures when parameters deviate from optimal values. This robustness characteristic is crucial for practical deployment scenarios where perfect hyperparameter tuning may not be feasible due to computational constraints or dataset variations. The relatively narrow confidence intervals around optimal settings provide clear guidance for practitioners seeking to replicate or adapt the model for different solar forecasting applications.

G. Case Study: Dust Storm Event Analysis

1) Extreme weather event overview: As shown in Fig. 4, the case study focuses on a severe dust storm event that occurred on June 16, 2024, representing one of the most challenging scenarios for solar power generation forecasting. The selected 72-hour period from June 15-17, 2024, encompasses three distinct phases: clear sky conditions (Day 1), extreme dust storm event (Day 2), and recovery period (Day 3). This temporal sequence provides an ideal testbed for evaluating model robustness under rapidly changing environmental conditions, where traditional forecasting methods typically experience significant performance degradation due to their inability to adapt to non-stationary weather patterns.

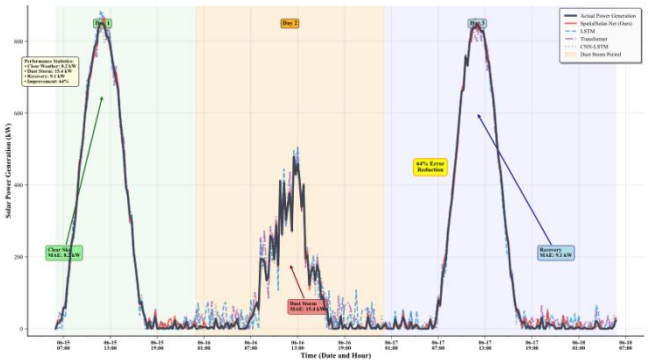

Fig. 4. Analysis of sandstorm weather.

The dust storm event is characterized by dramatic reductions in solar irradiance, with power generation dropping from typical peak values of 850 kW to severely constrained levels below 200 kW during midday hours. The meteorological conditions during the dust storm period exhibit high volatility, with frequent fluctuations in atmospheric transparency and rapid changes in local microclimate conditions. These characteristics make the event particularly challenging for forecasting models, as the standard assumption of temporal continuity in weather patterns is violated, requiring adaptive modeling strategies that can respond to sudden environmental transitions.

The experimental setup involves real-time prediction using 15-minute intervals across all 72 hours, with models receiving the same meteorological inputs including solar irradiance, temperature, wind speed, and humidity measurements. This controlled comparison ensures that performance differences reflect genuine model capabilities rather than variations in input data quality or temporal resolution. The case study design specifically targets the evaluation of spatial correlation utilization and adaptive fusion mechanisms under extreme conditions where conventional forecasting approaches struggle to maintain accuracy.

2) Comparative performance analysis: The comparative analysis reveals stark performance differences between SpatialSolar-Net and baseline methods during the dust storm event. During clear sky conditions on Day 1, all models demonstrate reasonable accuracy with SpatialSolar-Net achieving an MAE of 8.2 kW, followed by CNN-LSTM (9.1 kW), Transformer (9.8 kW), and LSTM (10.4 kW). These results indicate that under stable meteorological conditions, the performance gaps between different approaches remain manageable, with SpatialSolar-Net maintaining a modest but consistent advantage through its adaptive fusion mechanism.

However, the dust storm period on Day 2 exposes fundamental limitations in baseline approaches while highlighting the robustness of the proposed method. SpatialSolar-Net maintains relatively stable performance with an MAE of 15.4 kW during the extreme weather event, representing only an 88% increase from clear sky conditions. In contrast, baseline methods experience catastrophic performance degradation: LSTM MAE increases to 42.7 kW (311% increase), Transformer reaches 38.9 kW (297%

increase), and CNN-LSTM achieves 28.3 kW (211% increase). This dramatic difference demonstrates the critical importance of adaptive mechanisms that can adjust modeling strategies based on real-time environmental conditions.

The recovery period on Day 3 provides additional insights into model adaptability and convergence behavior. SpatialSolar-Net quickly returns to near-optimal performance with an MAE of 9.1 kW, indicating effective adaptation to changing conditions without persistent degradation effects. Baseline methods show varying recovery rates, with CNN-LSTM recovering to 11.8 kW, Transformer to 13.2 kW, and LSTM to 15.6 kW. The faster recovery of SpatialSolar-Net suggests that its adaptive attention mechanism successfully identifies the transition back to stable conditions and adjusts the fusion weights accordingly, while baseline methods require longer periods to re-establish accurate prediction patterns.

3) Spatial correlation adaptation mechanism: The case study provides compelling evidence for the effectiveness of the spatial correlation adaptation mechanism during extreme weather events. Analysis of the attention weight distributions reveals that during clear sky conditions on Day 1, the model allocates approximately 65% weight to the Transformer branch and 35% to the CNN branch, reflecting the dominance of temporal patterns under stable meteorological conditions. This weight distribution aligns with the expectation that clear weather exhibits predictable daily cycles that are effectively captured through temporal attention mechanisms.

During the dust storm event on Day 2, the attention weights undergo dramatic redistribution, with CNN branch weight increasing to approximately 70% while Transformer weight decreases to 30%. This adaptive behavior demonstrates the model's ability to automatically detect environmental instability and shift reliance toward spatial features that better capture localized atmospheric disturbances. The CNN branch's enhanced focus on spatial patterns becomes crucial during dust storms, as local variations in particle density and wind patterns create complex spatial gradients that cannot be adequately modeled through purely temporal approaches.

The recovery period on Day 3 shows gradual restoration of the original attention weight distribution, with Transformer weight returning to approximately 60% and CNN weight decreasing to 40%. This smooth transition indicates that the adaptive mechanism avoids abrupt switching that could introduce prediction instabilities, instead implementing gradual adjustments that maintain forecasting continuity while optimizing performance for changing conditions. The observed attention weight patterns provide direct evidence that the spatial correlation evaluator successfully identifies varying environmental scenarios and triggers appropriate knowledge integration strategies, validating the core architectural innovation of SpatialSolar-Net.

4) Performance improvement analysis: The quantitative analysis reveals that SpatialSolar-Net achieves a remarkable 64% error reduction during the dust storm period compared to the best baseline method (CNN-LSTM). This substantial improvement translates to significant practical benefits for grid operations, as the reduced prediction uncertainty enables more accurate reserve allocation and dispatching decisions during critical weather events. The 64% improvement represents a reduction from 28.3 kW MAE (CNN-LSTM) to 15.4 kW MAE (SpatialSolar-Net), corresponding to an absolute error reduction of 12.9 kW during extreme conditions when accurate forecasting is most crucial for maintaining grid stability.

The performance improvement analysis across different weather conditions demonstrates the versatility and robustness of the proposed approach. While the 64% improvement during dust storms represents the most dramatic enhancement, SpatialSolar-Net also maintains consistent advantages during clear sky (21% improvement over best baseline) and recovery periods (23% improvement) conditions. This consistent performance across diverse meteorological scenarios indicates that the adaptive mechanisms do not compromise accuracy during normal operations while providing substantial benefits during extreme events.

From an operational perspective, the error reduction achieved by SpatialSolar-Net translates to improved grid reliability and reduced operational costs. During extreme weather events like dust storms, prediction errors can lead to emergency reserve activation, load shedding, or grid frequency deviations that compromise system stability. The 64% error reduction demonstrated in this case study suggests that SpatialSolar-Net can significantly mitigate these risks by providing more accurate forecasts precisely when they are most needed. This capability becomes increasingly important as renewable energy penetration increases and grid operators require more reliable forecasting tools to manage the inherent variability of solar power generation under diverse environmental conditions.

V. Discussion

A. Theoretical Implications and Model Innovation

The SpatialSolar-Net architecture represents a significant theoretical advancement in the field of renewable energy forecasting by introducing a paradigm shift from independent site-level predictions to collaborative multi-site modeling. The core theoretical contribution lies in the formalization of adaptive spatial correlation assessment as a routing mechanism for knowledge integration, which addresses a fundamental limitation in existing spatiotemporal forecasting approaches. Traditional methods typically assume either complete independence between spatial locations or uniform spatial relationships, failing to capture the dynamic nature of meteorological correlations that vary with atmospheric conditions, seasonal patterns, and geographic factors. The adaptive attention fusion mechanism provides a theoretically grounded solution to the long-standing challenge of optimal feature combination in multi-modal deep learning architectures, establishing a dynamic equilibrium that automatically adjusts to the relative importance of spatial versus temporal features based on real-time environmental conditions.

The integration of graph neural networks within the collaborative prediction framework introduces a novel perspective on spatial dependency modeling in renewable energy systems, conceptualizing inter-site dependencies as dynamic, learnable representations that evolve with meteorological conditions. This theoretical innovation enables the model to capture complex spatial phenomena such as weather front propagation, regional climate variations, and localized atmospheric disturbances that significantly influence solar power generation patterns but are often overlooked in traditional forecasting approaches [41]. The framework extends beyond solar forecasting applications, offering insights for other spatiotemporal prediction tasks where the balance between local and global information varies with context, thereby contributing to the broader understanding of adaptive multi-scale modeling in complex dynamic systems.

B. Practical Implications and Industrial Applications

The experimental validation of SpatialSolar-Net demonstrates substantial practical implications for power system operations and renewable energy integration strategies. The 64% error reduction during extreme weather events translates directly to enhanced grid reliability and reduced operational costs, particularly in scenarios where accurate forecasting is most critical for maintaining system stability. For a typical 100 MW solar farm, the improved prediction accuracy during dust storms could prevent emergency reserve activations costing thousands of dollars per hour, while reducing the risk of grid frequency deviations that compromise power quality for consumers. The multi-site collaborative approach is particularly valuable for regional grid operators managing multiple distributed solar installations, where the spatial correlation information provides critical insights for coordinated dispatching decisions and enables optimization at both local and system-wide levels [42].

From a computational deployment perspective, the efficiency improvements achieved by SpatialSolar-Net address practical constraints in real-world forecasting systems. The 21.3% reduction in computational complexity, combined with maintained or improved accuracy, makes the approach viable for edge computing deployments where computational resources are limited. This efficiency gain becomes increasingly important as the number of monitored solar installations grows, enabling scalable forecasting solutions that can accommodate expanding renewable energy portfolios without proportional increases in computational infrastructure requirements. The adaptive nature of the approach offers significant advantages for deployment across diverse geographical and climatic regions, automatically adjusting modeling strategies based on local spatial correlation patterns and reducing the expertise required for implementation in new locations.

The industrial applicability of SpatialSolar-Net extends beyond immediate forecasting improvements to enable more aggressive renewable energy integration strategies and enhanced grid management capabilities. The enhanced prediction reliability allows operators to confidently reduce conventional backup capacity, knowing that solar generation forecasts maintain accuracy even under challenging conditions. The model's ability to provide both individual site forecasts and regional aggregate predictions supports hierarchical grid management structures, facilitating coordinated dispatching decisions that optimize renewable energy utilization while maintaining system reliability. This capability becomes increasingly valuable for international renewable energy companies seeking standardized forecasting solutions that can be deployed across multiple markets with varying meteorological characteristics and regulatory requirements.

C. Limitations and Future Research Directions

Despite the significant advances demonstrated by SpatialSolar-Net, several methodological and experimental limitations warrant acknowledgment and suggest directions for future research. The experimental validation relies on a relatively short temporal span (34 days) and limited geographical diversity (two sites in India), which may not fully capture the seasonal variations and diverse climate conditions that influence solar power generation across different regions. The current spatial correlation evaluation framework, while effective for the tested scenarios, relies on predetermined correlation thresholds that may require adjustment for different geographical contexts or seasonal patterns. Future research should extend validation periods to encompass complete annual cycles and evaluate model performance across multiple climate zones to establish the generalizability of the adaptive mechanisms under diverse environmental conditions [43].

From a scalability and computational perspective, the current framework faces challenges in large-scale deployments involving hundreds or thousands of solar installations. The computational requirements of the graph neural network components, while reduced compared to baseline approaches, may still present bottlenecks for utility-scale renewable energy portfolios. Future research directions should explore hierarchical graph structures, federated learning approaches, and model compression techniques to enable efficient scaling while maintaining prediction accuracy. The development of uncertainty quantification mechanisms would further enhance practical utility by providing confidence intervals for predictions, enabling risk-aware grid dispatching decisions that account for forecast uncertainty in operational planning and resource allocation.

The current framework's exclusive focus on solar power generation forecasting, while comprehensive within its domain, suggests broader applicability to other renewable energy sources and spatiotemporal prediction tasks. Future research could investigate extensions to wind power forecasting, where spatial correlations exhibit different characteristics but similar adaptive modeling challenges exist, and integration with energy storage systems and demand response mechanisms to enable holistic renewable energy management. From a methodological perspective, the incorporation of physics-informed constraints and domain knowledge could further enhance model reliability and interpretability, while the development of explainable AI techniques specifically tailored for spatiotemporal forecasting would enhance model trustworthiness and facilitate adoption in safety-critical applications where prediction rationale must be interpretable to human operators.

VI. CONCLUSION

This research presents SpatialSolar-Net, a novel multi-site collaborative framework that addresses the fundamental challenges of solar power generation forecasting by introducing adaptive spatial correlation evaluation and dynamic knowledge integration mechanisms. The proposed architecture represents a significant departure from traditional independent site-level prediction approaches, establishing a comprehensive spatial-temporal modeling system that intelligently balances local site characteristics with inter-site dependencies. Through extensive experimental validation on real-world solar power generation data, SpatialSolar-Net demonstrates substantial performance improvements, achieving MAE of 9.98 kW and RMSE of 14.79 kW, representing 12.6% and 10.8% improvements respectively over the strongest baseline method. The comprehensive ablation study confirms the critical importance of each architectural component, with multi-modal input contributing most significantly to performance (29.1% degradation when removed), followed by adaptive fusion mechanisms (21.7% impact) and graph-based spatial dependency modeling (16.9% contribution). The extreme weather case study provides compelling evidence of model robustness, demonstrating a remarkable 64% error reduction during dust storm events compared to baseline methods, while maintaining consistent performance advantages across diverse meteorological conditions from clear sky to recovery periods.

The practical implications of SpatialSolar-Net extend far beyond academic contributions, offering transformative potential for renewable energy integration and grid management operations. The enhanced prediction accuracy during extreme weather events translates directly to improved grid reliability and reduced operational costs, particularly crucial as renewable energy penetration continues to increase globally. The adaptive nature of the framework enables deployment across diverse geographical and climatic regions without requiring extensive reconfiguration, making it an attractive solution for international renewable energy companies seeking standardized forecasting tools. The 21.3% computational efficiency improvement achieved through adaptive knowledge integration makes the approach viable for edge computing deployments and large-scale utility applications where computational resources are constrained. For grid operators managing multiple distributed solar installations, the multi-site collaborative predictions provide critical insights for coordinated dispatching decisions and enable optimization at both local and system-wide levels, ultimately supporting more aggressive renewable energy integration strategies while maintaining system reliability.

While this research demonstrates significant advances in solar power forecasting, several opportunities exist for future investigation and development. The current framework's validation on a 34-day dataset from two Indian sites, though comprehensive within its scope, suggests the need for extended temporal validation across complete annual cycles and diverse climate zones to establish broader generalizability. Future research directions should explore hierarchical graph structures and federated learning approaches to enable efficient scaling to utility-scale renewable energy portfolios involving hundreds or thousands of installations. The integration of uncertainty quantification mechanisms would further enhance practical utility by providing confidence intervals for predictions, enabling risk-aware dispatching decisions that account for forecast uncertainty in operational planning. Additionally, the extension of the adaptive correlation framework to other renewable energy sources such as wind power, where spatial relationships exhibit different characteristics but similar modeling challenges exist, represents a promising avenue for broader impact. The incorporation of physics-informed constraints and domain knowledge could further enhance model reliability and interpretability, while the development of explainable AI techniques specifically tailored for spatiotemporal forecasting would facilitate adoption in safety-critical applications where prediction rationale must be transparent to human operators.

***Abstract*—Fine-tuning transformer models like Bidirectional Encoder Representations from Transformers has enhanced text classification performance. However, class imbalance remains a challenge, causing biased predictions. This study introduces an improved training strategy using a novel Adaptive Focal Loss with dynamically adjusted γ based on class frequencies. Unlike static γ values, this method emphasizes minority classes automatically. Experiments on the CMU Movie Summary dataset show Adaptive Focal Loss surpasses standard binary cross-entropy and Focal Loss, achieving an F1-score of 0.5, ROC accuracy of 0.79, and Micro Recall of 0.53. These results demonstrate the effectiveness of adaptive focusing methods in improving the detection of minority classes in imbalanced scenarios.**

***Keywords*—Adaptive focal loss; BERT; imbalanced text classification; multilabel text classification**

I. Introduction

Multi-label text classification is a crucial task in natural language processing (NLP), where each input instance may be associated with multiple labels. A major issue that faces this task is the inability of traditional methods, such as bag-of-words and Word2vec, to effectively capture the contextual relationships within longer texts, leading to classification performance. Jain U. et al. [1] address these challenges by introducing utilizing named entity recognition (NER) in conjunction with transformer models, such as BERT and DistillBERT. By extracting keywords specific to each class and employing an enhanced attention mechanism, the proposed approach improves classification accuracy.

In many real-world scenarios, the datasets are often highly imbalanced, where some minority classes can be significantly underrepresented compared to others. This class imbalance poses a hard challenge, as loss functions tend to prioritize dominant classes, resulting in poor performance on the minority classes compared to the majority one. The main issue with standard loss functions like cross-entropy [2, 3] is that they can't handle class imbalance in multi-label datasets effectively. This is because they consider all training examples equally, regardless of their relative importance or hardness level. Yasuda et al. (2024) introduced a Weighted Asymmetric Loss that combines label frequency weighting and label co-occurrence smoothing to improve performance on imbalanced multi-label text datasets [4]. Similarly, Park et al. [5] proposed a Robust Asymmetric Loss that emphasizes hard positive examples while minimizing the impact of abundant negative samples, showing strong performance on long-tailed multi-label tasks. Huang et al. [6] extended this approach with the Asymmetric Polynomial Loss, allowing for greater control over gradient contributions from positive and negative classes.

Traditional approaches have had limited success data-level methods, such as oversampling and undersampling, can balance class distributions but tend to introduce artificial patterns that are harmful to generalization. Undersampling, on the other hand, risks discarding informative data from the majority classes. In [7], the authors demonstrated that these techniques frequently failed to improve predictive performance and, in some cases, resulted in overestimated risks and miscalibration of clinical prediction models. Class weighting methods aim to address imbalance by assigning greater importance to minority classes. Finding the optimal weights often requires extensive hyperparameter tuning. Putra and Ibrohim [8] note that grid search or other optimization techniques are typically used, increasing the complexity and computational cost of model development.

Focal Loss [9] introduced an important advancement by introducing a dynamic reweighting mechanism. The most important contribution of Focal Loss is its ability to automatically down-weight readily classified instances and focus computational effort on hard cases. This is achieved by the focusing parameter γ, which balances the loss contribution in proportion to prediction confidence.

An important limitation of the Focal Loss shows in multi-label scenarios: the fixed focusing parameter cannot cope with varying class frequencies. In real-world datasets, where class distributions are highly imbalanced and interdependent, this fixed approach struggles. The same γ value will be too strong for some classes and weak for others, leading to sub-optimal model performance. Mukhoti et al. [10] observed that higher values of γ can make training unstable, especially in early stages. The study notes that while higher γ values may improve calibration, they can also result in negative outcomes if the model adjusts weights too aggressively at the beginning. Therefore, careful consideration is needed when selecting γ to avoid destabilizing the training process.

This is a consideration that requires an adaptive focusing mechanism that adjusts dynamically according to class-specific features and their interactions, and to address this problem, we propose AFL-Bert. Our contribution is three-fold, first an Adaptive Focal Loss framework that adjusts the focusing parameter (γ) dynamically according to class frequencies. In this manner, the loss function can assign more weight to rare classes without sacrificing a balance over all labels. Second, we fine-tune the whole BERT model to leverage its contextual embedding capacity and improve representation learning for multi-label classification. Third, our experiments on the CMU Movie Summary dataset show that this approach attains considerable improvements over the baseline, particularly in the detection of rare classes.

The rest of this study is structured as follows: Section II discusses related work, highlighting existing solutions for imbalanced multi-label classification. Section III outlines our proposed methodology, detailing the Adaptive Focal Loss and its integration with BERT. Section IV describes the implementation, while Section V presents experimental results. Section VI presents a discussion of findings. Section VII presents the limitations and future work. Finally, we conclude our study in Section VIII.

II. Related Work

Recent advances in multi-label text classification with imbalances have focused on employing hierarchical modeling, contrastive learning, and label co-occurrence methodologies to overcome issues like long-tail label distribution and dependency modeling. Zhang et al. put forward HCL-MTC as a novel hierarchical contrastive learning model that infers label dependence and semantic dissimilarity to achieve significantly improved classification performance [11]. Similarly, HDLTex++, presented in Expert Systems with Applications, utilizes hierarchical deep architectures that effectively manage label imbalance with a structured levels organization of text [12]. Yan et al.'s LabelCoRank model addresses long-tail using a reranking framework based on co-occurrence that enhances the accuracy of prediction of rare labels [13]. Simultaneously, HGBL combines BiLSTM with contrastive learning and Graphormer with the aim of enhancing fine-grained hierarchical label interactions, additionally underlining the importance of both local and global textual contexts [14].

Researchers have developed diverse strategies to address class imbalance in multi-label text classification. ML-OUSCA combines multilabel over-sampling and under-sampling and class alignment, which is better than K-means SMOTE and KNN-US on benchmark collections like Reuters-21578 and Enron but at the expense of losing informative information or overfitting [15]. Experiments with focal loss and mix-up techniques in extreme multi-label classification (XML) models demonstrate performance gain on datasets, particularly in transformer-based models [16]. BERT-based variants like EnvBERT [17] improve noisy environmental news classification over 80% through oversampling the data. Minority class oversampling based on imbalance ratios improves sentiment analysis classifiers [18], while Partial Label Masking (PLM) [19] enhances rare class recall through adaptive label masking during training. Generation of synthetic data through GPT-2 and LSTM models improves accuracy by 17% in instances of extreme imbalance but is prone to overfitting [20]. Advanced models like MISO [21] utilize mutual information constraints to re-embed difficult samples and achieve significant representation learning gains. Such approaches highlight the trade-off between resampling efficiency, model architecture modifications, and synthetic data quality in label imbalance resolution.

Focal Loss, introduced by Lin et al. [9], was a pivotal advancement in addressing class imbalance by down-weighting well-classified examples and focusing the model on harder cases. However, the original formulation relies on a fixed focusing parameter γ, which may not generalize well across tasks with varying class distributions. To address this, Mukhoti et al. [10] proposed calibrating deep neural networks using focal loss, highlighting that the choice of γ greatly affects model reliability and confidence estimation. Similarly, Cao et al. [24] introduced the Label-Distribution-Aware Margin Loss, which dynamically adjusts margins based on class frequency, offering an alternative way to balance class contributions. More recently, Cai et al. [22] demonstrated that combining focal loss with data augmentation and oversampling further improves performance on imbalanced multi-label tasks. These studies underscore the ongoing evolution of adaptive loss strategies, providing a strong foundation for our proposed dynamic focusing mechanism.

A. Focal Loss Overview

Focal loss, introduced by Facebook AI Research [9], is a novel method employed to mitigate the class imbalance issue for object detection. Conventional loss functions, such as cross-entropy, fail to work in cases with a huge gap between foreground and background classes. This imbalance causes the loss to predominantly arise from the readily identifiable negative instances at the expense of contributions from less frequent positive instances. The model will thus degrade during training when presented with such a gradient, where these negative classes determine the trend, hence making it less effective when trained from such rare classes. The key idea behind focal loss is to transform the standard cross-entropy loss function into a modified version that introduces a modulating factor to decrease the relative loss for highly classified samples. By doing so, the model will pay closer attention to difficult-to-classify samples, and as a result, easy negatives won't dominate the training process. Focal loss introduces a specific focusing parameter γ that can be tuned to control the level of this down-weighting effect. As γ increases, the model pays greater attention to mislabeled samples, learning from them better. Mathematically, focal loss is defined as in Eq. (1):

$$FL(p_t) = -\alpha_t(1 - p_t)^{\gamma} log(p_t) \quad (1)$$

In the context of focal loss, α serves as the balancing factor, while γ is referred to as the focusing parameter. The focusing parameter plays a crucial role in adjusting the rate at which easily classified examples are downweighted during training. Intuitively, this means that focal loss reduces the contribution of loss from well-classified examples, thereby allowing the model to focus more on challenging instances, such as background objects in image classification tasks.

B. Limitations of Standard Focal Loss

Recent advances in addressing class imbalance in multi-label text classification have highlighted the efficacy of focal loss. Cai et al. demonstrated that the integration of focal loss with data augmentation techniques like Easy Data Augmentation (EDA) and oversampling significantly improved model performance in the SemEval-2025 Task 9 on food hazard detection, particularly improving accuracy and F1 scores for minority classes [22]. Consequently, Sen (2021) employed focal loss within a convolutional neural network framework for genre classification of movie descriptions and noted that focal loss outperformed binary cross-entropy loss for both balanced and imbalanced datasets [23]. However, several works [10, 24] have illustrated that a fixed parameter is not ideal, as it assumes that the classes must be equally hard. This is not true in datasets where some classes appear much less frequently than others, which leads to the following issues:

- A low γ value reduces the modulation effect of focal loss, making it behave more like standard cross-entropy loss. This provides less focus on hard-to-classify examples, which is especially problematic in imbalanced datasets where minority classes often contain difficult examples that need more attention during training.
- Suboptimal Generalization: Without an adaptation process, the model cannot learn an optimal compromise between majority and minority classes and thus tends to have poor recall on a few classes and overfitting on common classes.

Despite these advancements, most prior work either employed static loss functions or required heavy manual tuning, which limited scalability. Additionally, few methods dynamically adjusted the loss function based on class frequency. This work addresses these gaps by introducing dynamically adaptive focal loss in conjunction with BERT, offering an automated solution for imbalanced multi-label text classification.

III. Methodology

This section outlines the proposed method for solving imbalanced multi-label text classification by combining Adaptive Focal Loss (AFL) with a BERT. The AFL has a dynamic focusing parameter (γ) that depends on class frequencies, enabling the model to prioritize less frequent classes more optimally. AFL-BERT: a combination of AFL with BERT leverages the transformer's contextual embeddings to create a strong and efficient classification framework, as shown in Fig. 1.

A. Introducing Adaptive Focal Loss

To overcome these limitations, we propose to dynamically adjust based on class frequencies. Prior research has pointed at the need for adaptive loss processes. Cao et al. [24] proposed Label Distribution-Aware Margin Loss, demonstrating class-dependent compensation as leading to performance improvements in imbalanced classification. Moreover, Mukhoti et al. [10] emphasized the need for calibrated deep learning models, demonstrating that static loss parameters often lead to biased training outcomes.

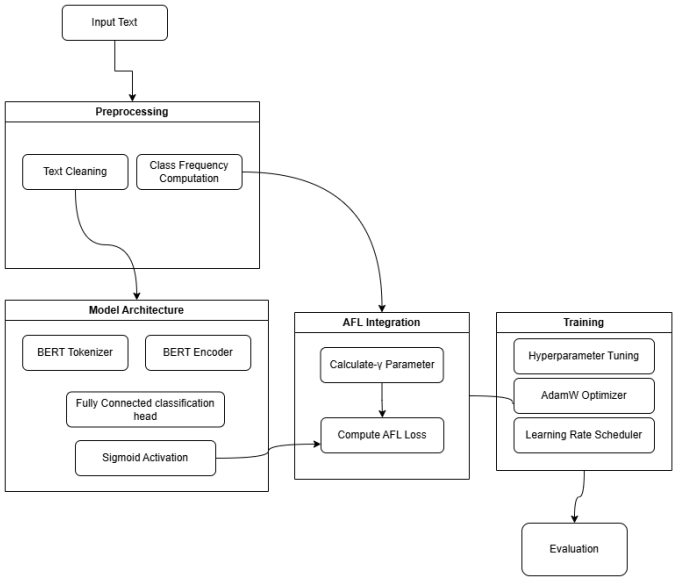

Fig. 1. Methodology of the study.

B. Mathematical Formulation

The Adaptive Focal Loss (AFL) modifies the standard Focal Loss by introducing a class-dependent focusing parameter γ_c, defined in Eq. (2):

$$\gamma_c = base_\gamma \times \frac{1}{f_c} \quad (2)$$

where, f_c represents the normalized frequency of class c, and $base_\gamma$ is a hyperparameter that sets the baseline focusing level. The AFL for a single sample in a multi-label setting is computed as shown in Eq. (3):

$$AFL(y, \hat{y}) = \sum_{c=1}^{C} -\alpha_c (1 - p_t)^{\gamma_c} \log(p_t) \quad (3)$$

where,

- p_t is the predicted probability for the true class.
- α_c is a weighting factor for class c.
- Cis the total number of classes.

This formulation aims to adapt Focal Loss to handle class imbalance by dynamically adjusting the focusing parameter γ_c based on the frequency of each class.

C. Key Features

- Dynamic Adjustment: AFL's focusing parameter adapts to class frequencies, allowing it to allocate greater emphasis to minority classes.
- Compatibility: The AFL function integrates seamlessly with existing architectures, requiring minimal changes to the training pipeline.
- Scalability: The method generalizes across datasets with varying degrees of imbalance.

IV. Experimental Setup

A. Model Architecture

The proposed model, as shown in Fig. 2, leverages BERT-based architecture as the backbone of feature extraction using the strength of pre-trained transformer layers to output high-level contextual embeddings of the input text. BERT, introduced by Devlin et al., has proven strong performance across a wide variety of natural language processing tasks due to its ability to induce deep bidirectional context, making it extremely suitable for multi-label classification [25]. BERT's tokenizer is used to tokenize the input to get input IDs, attention masks, and token type IDs, all of which are structurally sound for the transformer encoder of the model. All these tokens go into the encoder layers, resulting in contextualized word embeddings as the input passes through them for local and global linguistic dependencies.

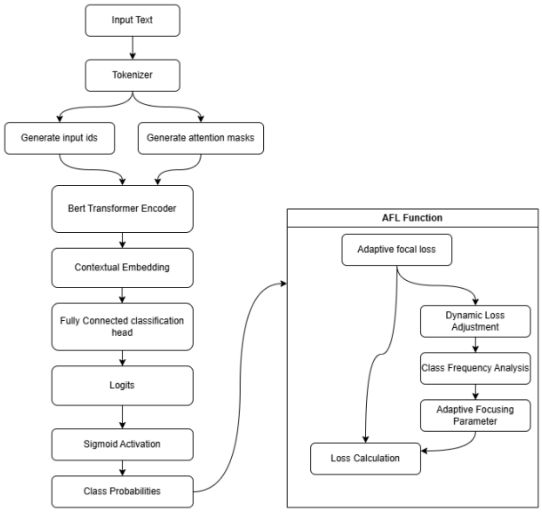

Fig. 2. AFL-Bert architecture.

A fully-connected classification head is put above the encoder for multi-label prediction. A sigmoid rather than softmax is used as the activation function, with the model then able to generate independent probability scores for each label, an important property for multi-label classification where labels can be non-exclusively relevant [26]. In a move to address class imbalance in the standard multi-label dataset, the model includes Adaptive Focal Loss (AFL) during training. AFL enhances the focal loss proposed by Lin et al. by scale-adaptively scaling the focusing factor in relation to the predicted probabilities to assign higher weights to more difficult or minority class samples without human tuning [9].

The AFL mechanism operates by taking advantage of the logits from the classification head, inserting sigmoid activation to obtain class probabilities, and dynamically calculating the loss to penalize more severely infrequent label misclassifications. This adaptive weighting helps the model focus learning on minority classes, thereby enhancing recall for minority classes without compromising overall classification performance. The combination of BERT's contextual representations and the adaptive re-weighting of AFL results in a more balanced and effective multi-label classification model [22].

B. Description of the CMU Movie Summary Corpus Dataset

The CMU Movie Summary Corpus dataset is made up of more than 200,000 movie summaries collected from differing sources, including online movie databases and user-generated content. Synopses offer a brief overview of each film's plot, characters and relevant information. While this dataset is comprised of several different files, this research will focus only on two of these components:

- movie.metadata.tsv: This file contains the metadata for 81,741 films extracted from the Freebase leak on November 4, 2012. Notably, the file contains important information such as movie genre identifiers, allowing for genre-based analyses and categorization.
- plot_summaries.txt: This file contains narrative summaries for 42,306 movies. It was extracted from the English-language Wikipedia dump on November 2, 2012. Each line in the file contains a unique identifier corresponding to the film in question, with a corresponding entry in movie.metadata.tsv.

V. Results

A. Baseline Performance

To evaluate the impact of different loss functions on fine-tuning BERT for text classification, we conducted three experiments: fine-tuning BERT with standard cross-entropy loss, fine-tuning BERT with Focal Loss with different gamma values adjusted manually, and fine-tuning BERT with Adaptive Focal Loss. Firstly, we performed a preliminary experiment using the CMU Movie LT Summary Corpus to establish baseline performance. The dataset used in the main experiments consisted of 42,303 samples, and training was performed using a pre-trained BERT model with AdamW optimizer, a batch size of 16, a learning rate of 2e-5 and incorporated a cosine learning rate scheduler with 500 warmup steps. Training spanned up to 100 epochs with early stopping applied, and evaluation metrics included accuracy, F1-score, ROC AUC, macro precision, micro precision, macro recall, and micro recall. The baseline model achieved an F1-score of 0.4707 and a ROC AUC of 0.7118.

B. Effect of Static Gamma Tuning: Focal Loss Experiments

To mitigate class imbalance, we replaced cross-entropy loss with Focal Loss and experimented with different static gamma values (γ = 1.5, 2.0, and 2.5). Among these, γ = 2.0 provided the best performance, achieving an F1-score of 0.4923 and a ROC AUC of 0.7649, while γ = 1.5 and γ = 2.5 yielded lower results. Notably, the γ = 2.5 setting resulted in marginally lower performance compared to the baseline, with an F1-score of 0.4692 and a ROC AUC of 0.7088. These findings emphasize that although tuning the focusing parameter γ improves robustness against class imbalance, static gamma values alone may not be sufficient for optimal multi-label classification. Fig. 3 illustrates the comparative effect of different gamma values across key evaluation metrics.

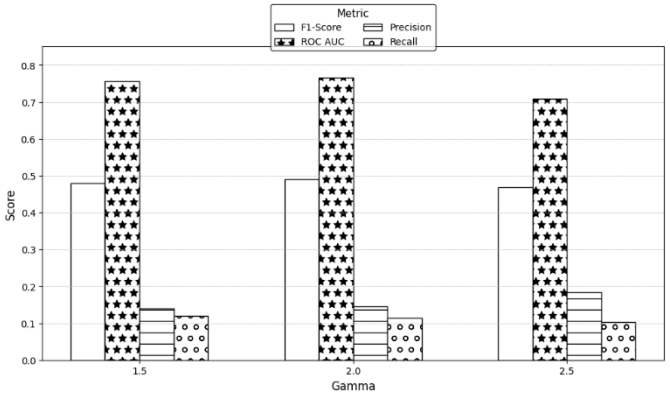

Fig. 3. The comparative impact of varying gamma values on key evaluation metrics.

C. Performance of Adaptive Focal Loss

Building on these findings, we evaluated Adaptive Focal Loss, where the focusing parameter γ is dynamically adjusted based on class frequencies. Adaptive Focal Loss outperformed all static gamma configurations, achieving the highest F1-score (0.5) and ROC AUC (0.79), while substantially improving micro recall (0.5282) without requiring manual tuning of γ. These results highlight the robustness and practical advantages of the adaptive approach, particularly in handling class imbalance in multi-label classification. Fig. 4 presents a comparative overview of the final model performances across all configurations.

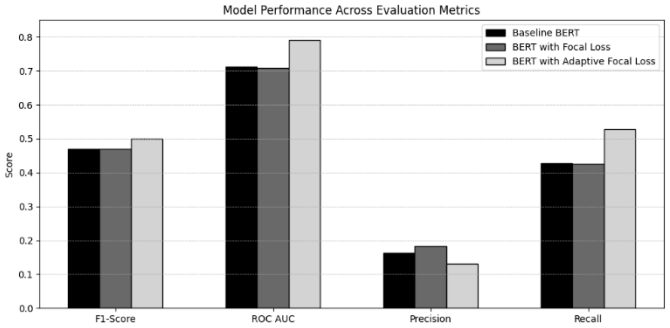

Fig. 4. Model performances across all metrics.

VI. Discussion

This study demonstrates the effectiveness of Adaptive Focal Loss in improving multi-label text classification on imbalanced data. There are three main findings from our experiments:

First, static Focal Loss can beat the conventional cross-entropy baseline on some metrics but only when it is highly tuned. Among the fixed values of γ experimented, γ = 2.0 worked best with an F1-score of 0.49 and a ROC AUC of 0.7649. However, both γ = 1.5 and γ = 2.5 were compromised in either recall or precision, demonstrating the sensitivity of Focal Loss to the γ value. This suggests the need for hyperparameter tuning when using static focusing parameters on highly imbalanced settings.

Second, Adaptive Focal Loss, where γ is adapted based on class frequencies, outperformed all static versions. It achieved the highest F1-score (0.5) and ROC AUC (0.79), and highest micro recall (0.5282), indicating it was more capable of identifying minority class instances. This was achieved without having to manually adjust γ, which is a testament to the model's robustness and its less dependence on heuristic optimization. This also makes the adaptive method more scalable and deployable in real-world settings, where optimal hyperparameters are unknown a priori. This outcome marks a progression from our earlier work, where we had studied the integration of GloVe embeddings with classical machine learning models [27] and then with deep learning models [28]. While those studies concentrated on the role of word embeddings in representation learning, the present study reverses the focus to the flexibility of the loss function and its adaptability to transformer-based models.

Third, the precision-recall trade-offs for both static and adaptive settings illustrate the merits of dynamic class weighting strategies. While the static γ = 2.5 model attained the highest precision, it did so at the cost of decreased recall and a lower F1-score compared to the adaptive approach. By contrast, Adaptive Focal Loss obtained more balanced performance in general, with significant gains in recall, an important factor in multi-label where missing relevant labels is costly.

VII. Limitations and Future Work

While Adaptive Focal Loss yielded considerable improvements, the overall F1-score (0.50) indicates that there is still room for performance gains. Potential future work may include combining adaptive loss functions with more recent backbone models like RoBERTa or DeBERTa, introducing data-level rebalancing techniques, or experimenting with more γ adaptation techniques. Also, extending this approach to other multi-label domains, such as biomedical text or legal documents, may also serve to further confirm its generalizability.

VIII. Conclusion

This work proposes a novel approach of handling class imbalance in multi-label text classification by combining Adaptive Focal Loss (AFL) and the BERT model. Through the adjustment of the focusing factor γ based on class frequencies, AFL provides a self-adjusting mechanism for assigning greater weights to minority classes and reducing the need for hyperparameter tuning. Our experimental results on the CMU Movie Summary Corpus demonstrate that this adaptive strategy consistently performs better than baseline cross-entropy and statically tuned Focal Loss model on key metrics like F1-score, ROC AUC, and micro recall.

Particularly, the adaptive mechanism achieves improved precision-recall trade-off, significantly improving minority class detection, which is a common problem with real-world multi-label problems. The BERT alignment also allows for more accurate contextual understanding and representation learning, contributing to enhanced performance overall.

These findings demonstrate the potential of adaptive loss functions to improve deep learning models for imbalanced classification tasks. Potential future directions can involve combining AFL with other transformer-based architectures like

RoBERTa or DeBERTa, applying the method to other application areas such as biomedical or legal documents, or coupling it with more advanced data augmentation strategies for further performance and generalization gains.

Attention Aware Dual-Path Autoencoder with Asymmetric Loss for Recognition in Complex Scenes

Hashim Rosli, Rozniza Ali*, Muhamad Suzuri Hitam, Ashanira Mat Deris, Noor Hafhizah Abd Rahim
Faculty of Computer Science and Mathematics, Universiti Malaysia Terengganu (UMT),
Kuala Nerus, 21030 Terengganu, Malaysia

***Abstract*—Object recognition in complex scenes is challenging due to cluttered backgrounds, overlapping objects, and degraded image quality. Another difficulty arises from sparse label presence, as most images contain only one to three active labels despite the dataset being balanced across 20 object classes. This intra-sample sparsity complicates binary classification by exposing models to a high proportion of inactive classes. This work aims to improve recognition accuracy, robustness under sparse multi-label conditions, and interpretability in visually complex environments. The objective is to help models focus on relevant visual features, suppress background noise, and better distinguish objects that are rare or overlapping. To address these challenges, we introduce an attention aware dual-path autoencoder that enhances image features while learning to classify multiple objects. The model uses asymmetric loss to reduce the influence of easy negatives and emphasize rare or difficult labels. It also integrates an attention mechanism in the reconstruction path to improve object clarity. The proposed model achieves 96.72 percent accuracy, 0.0328 Hamming Loss, 0.9809 macro ROC-AUC, and 0.8925 macro mAP, along with 0.9372 SSIM and 7.1012 dB PSNR in reconstruction. These results confirm its effectiveness for robust classification and enhanced visual understanding in complex scenes.**

Keywords*—Component; autoencoder; attention aware; feature fusion; image enhancement; multi-label classification

I. Introduction

In real-world applications, object recognition systems often must contend with complex scenes which are characterized by varied backgrounds, overlapping objects, and degraded image quality such as noise, blur, and low brightness [1]. These conditions reduce the effectiveness of conventional convolutional neural networks, which often assume clean, well-segmented inputs. Cluttered environments with sensor noise or motion blur, for example, can lower classification accuracy by over 10% in multi-label recognition tasks [2]-[3]. While previous work has explored pre-processing techniques such as denoising and deblurring prior to recognition [4]-[6], these modular approaches introduce computational overhead and suffer from inefficient feature usage, as enhancement and recognition are handled separately. Although the dataset is balanced across 20 object categories, each image includes only 1 to 3 active labels, creating label sparsity during training. This, combined with frequent object overlaps, makes classification more challenging, especially with standard binary loss functions. This work proposes a unified framework that enhances image quality and improves multi-label recognition in complex scenes with sparse, overlapping labels. The model is designed to operate in cluttered environments while learning effectively from limited active labels per image.

We propose an end-to-end architecture that combines image reconstruction and classification into a single unified pipeline. A DenseNet-based convolutional autoencoder, enhanced with a Convolutional Block Attention Module (CBAM), is used to suppress noise and focus on salient object regions during image enhancement [7]. The reconstructed output is processed by a second DenseNet classifier, while latent features from the autoencoder are fused with classification features using multiplicative fusion to integrate both structural and semantic information [8], [9]. To address the challenge of label sparsity, the model is trained using a composite loss function consisting of Mean Squared Error (MSE) for reconstruction and either Binary Cross-Entropy (BCE) or Asymmetric Loss (ASL) for classification. ASL is particularly effective in multi-label settings with few active classes per image, as it down-weights easy negatives and emphasizes difficult positive enhancing discrimination in overlapping or infrequent categories.

The proposed method is evaluated against two baselines, a standard convolutional autoencoder without any transfer learning, CBAM or feature fusion and a standalone DenseNet-121 classifier without image enhancement. Results show that the attention-aware dual-path model trained with ASL outperforms both reconstruction quality and classification accuracy, proving its robustness in complex scene recognition. The rest of the paper is organized as follows. Section II reviews related work. Section III outlines the methodology. Section IV presents the experimental setup. Results and discussions are given in Section V. Section VI discusses the results. Section VII concludes and suggests future directions.

II. Related Work

A. Complex Scene Object Recognition

Object recognition in complex scenes has been widely studied, especially under clutter, occlusion, and image degradation. Cheng et al. reviewed deep learning methods for remote-sensing scene classification, highlighting robust feature extraction in noisy settings [10]. Fu et al. demonstrated that classification accuracy in astronomical imaging can be improved using denoising autoencoders to recover from noise and blur [11]. In medical imaging, autoencoder-based architectures have also been employed to extract salient features from visually noisy data [12]. Lu et al. introduced a co-attention Siamese network for video segmentation, utilizing

co-attention mechanisms to better segment overlapping objects in complex backgrounds [13].

In more domain-specific research which using kitchen utensils dataset, Yusro et al. compared Faster R-CNN and YOLOv5 on kitchen datasets with overlapping utensils, reporting YOLOv5's superior accuracy of 89.12% compared to 83.92% [14]. Building on this, Hashim applied YOLOv5 with different deep learning backbones to manage image degradation, achieving strong performance under noisy conditions [15]. Gallego et al. developed the Kurcuma dataset, comprising over 6,800 annotated images ranging from isolated objects to cluttered domestic scenes, designed for evaluating domain-adaptive recognition methods [16].

B. Multitask Image Enhancement with Object Recognition

Integrating image enhancement and classification in unified architecture has improved recognition in challenging visual environments. Hami and JameBozorg showed that using a denoising autoencoder as preprocessing significantly increased accuracy when paired with VGG16 and InceptionV3 for defect detection tasks [17]. Liu et al. proposed a DenseNet-based denoising self-encoder for image dehazing, which enhanced both image clarity and object detection in outdoor scenes [18]. In medical applications, CNN autoencoders have been paired with classification heads for tasks such as brain tumor diagnosis, achieving strong results on degraded images [19]. Rahimzadeh and Attar combined DenseNet and ResNet features via a shared latent space, improving classification performance on COVID-19 chest X-ray datasets [9].

Attention-aware enhancement mechanisms have also gained increasing traction in improving object recognition tasks across various domains. Fu [11] demonstrated that incorporating a denoising autoencoder significantly enhanced classification accuracy on noisy galaxy imagery. Praharsha and Poulose [20] introduced CBAM-VGG16 for distracted driver detection, achieving over 98% accuracy on the AUCD2 dataset. In remote sensing, Hu et al. [21] developed a CBAM-integrated hybrid network combining residual and dilated convolutions, which improved hyperspectral image classification in spectrally cluttered conditions.

C. Transfer Learning Based Autoencoders

Transfer learning has been widely adopted in autoencoder-based systems to improve generalization and representation learning across domains. Fu [11] utilized a denoising convolutional autoencoder built on DenseNet-121 to enhance galaxy images, resulting in notable classification improvements. In histopathology, Lee and Lah [22] fine-tuned a DenseNet encoder within an autoencoder-classifier pipeline for multi-task slide analysis, demonstrating increased learning efficiency. Praharsha and Poulose [20] embedded CBAM into VGG16 to support attention-based classification in distracted driving scenarios. Tran et al. [23] evaluated multiple encoder backbones, including ResNet-50, EfficientNet-B3, and DenseNet-121, for lung cancer detection using DICOM images.

Xie et al. [24] introduced MEEAFusion, an architecture that integrates CBAM-like attention and multi-scale fusion within an autoencoder framework for infrared-visible image fusion. DenseNet-121 has been commonly employed as a preferred encoder across these efforts due to its densely connected layers and feature reuse capabilities, proving effective in domains such as astronomy [11] medical imaging [22], [24], and spectral fusion tasks [23].

D. Multi-label Classification and Label Sparcity Handling

Multi-label classification assigns multiple class labels to each image, with each label represented as a binary indicator of presence or absence. In this context, standard loss functions such as Binary Cross-Entropy (BCE) are commonly used, but their performance has been analyzed for scenarios involving label sparsity. For example, Wang et al. [25] discussed how BCE treats active and inactive labels equally, which may lead to suboptimal learning when most labels are negative. Yessou et al. [26] further evaluated several loss functions, identifying similar limitations when applied to satellite imagery datasets.

To address class imbalance, various alternative loss functions have been proposed. Asymmetric Loss (ASL), introduced by Ben-Baruch et al. [27], adjusts gradient contributions by down-weighting easy negatives and emphasizing hard positives, leading to improved mAP scores across datasets such as MS-COCO, Pascal-VOC, NUS-WIDE, and Open Images. Huang et al. [28] later refined this with Asymmetric Polynomial Loss (APL), incorporating polynomial coefficients for further control over gradient scaling. Ji et al. [29] applied these loss functions in remote sensing, while similar techniques have also been adopted in medical imaging to enhance detection of rare labels and performance on sparsely annotated data.

E. Gaps and Limitation

Although prior studies have advanced object recognition, image enhancement, and multi-label classification, several limitations remain. Few existing models integrate enhancement and recognition into a unified architecture, especially for visually complex scenes with occlusion, noise, and clutter. While encoder-decoder structures and attention mechanisms have been explored independently, their combined use in multitask pipelines is limited. Additionally, many approaches are domain-specific and lack generalizability across different real-world environments. Most models focus on either low-level enhancement or high-level classification, missing the performance gains of joint optimization.

Another limitation is the challenge of label sparsity in multi-label classification. Standard loss functions like Binary Cross-Entropy often struggle when most classes are inactive, making it harder to learn from rare but important labels. Although advanced losses such as Asymmetric Loss (ASL) and Asymmetric Polynomial Loss (APL) have shown success in other domains, they are still rarely applied in complex scene recognition. Additionally, while DenseNet-121 and attention modules like CBAM perform well individually, their integration into autoencoder-based multitask frameworks remains limited. Addressing these gaps requires a unified, attention-aware model that applies transfer learning and specialized loss functions for more robust performance in cluttered, degraded environments.

III. ARCHITECTURE

The proposed architecture in Fig. 1 employs a pre-trained DenseNet121 as a feature extraction backbone. This backbone serves dual purposes: (1) encoding the noisy input into a latent representation for clean image reconstruction, and (2) extracting discriminative features for classification. We extract intermediate feature maps from four major transition layers of the DenseNet, capturing hierarchical spatial information. To preserve spatial resolution and semantic depth, we remove the classification head of the backbone and use the feature pyramid as input to the decoder. All batch normalization layers remain trainable to adapt to the domain distribution, while the initial training phase freezes the rest of the backbone to stabilize learning.

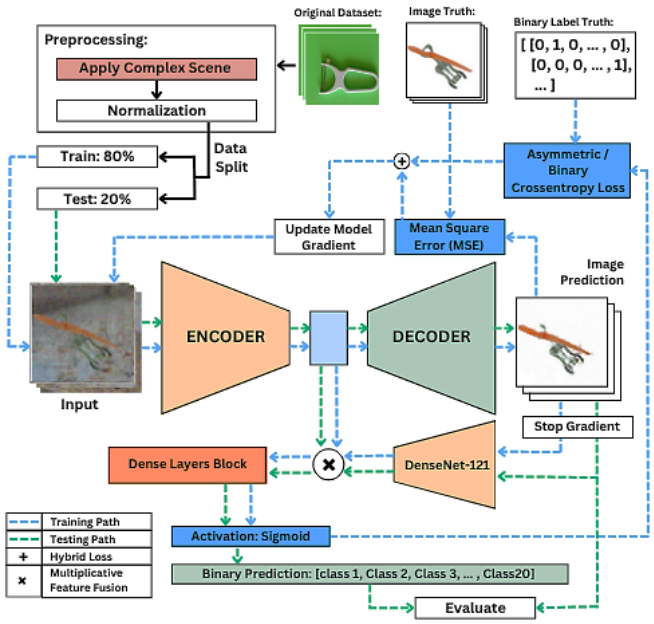

Fig. 1. Overall model pipeline showing the training objectives, autoencoder structure, classification paths, and gradient flow during training and inference.

A. Encoder Backbone

Let the input image be denoted as $\boldsymbol{x} \in \mathbb{R}^{64\times64\times3}$, representing a three-channel red, green and blue (RGB) image. We adopted a DenseNet-121 encoder ($\boldsymbol{E}$), pretrained on ImageNet and used here without its classification head to extract hierarchical representations. DenseNet-121 is well-suited for feature extraction because its layers are densely connected, allowing each layer to reuse feature maps from all previous layers in the same block, which improves feature propagation and reduces vanishing gradients [30]. As $\boldsymbol{x}$ passes through successive dense blocks and transition layers, we collect feature maps from five key stages, denoted as (1), where each $\boldsymbol{f_i}$ is the output of the i-th dense block within DenseNet-121. These feature maps are progressively deeper and semantically richer, capturing spatial context at multiple scales. The final representation $\boldsymbol{f_5}$ serves as the encoder's bottleneck output. To generate a compact semantic descriptor, a global average pooling operation (GAP) is applied to $\boldsymbol{f_5}$ in Eq. (2).

$$\boldsymbol{f_i} = \boldsymbol{E_i}(\boldsymbol{f_{i-1}}), \quad \boldsymbol{f_0} = \boldsymbol{x}, \quad for\ \boldsymbol{i} = 1,2,3,4,5 \tag{1}$$

$$\boldsymbol{z} = GAP(\boldsymbol{f_5}) \in \mathbb{R}^{1024} \tag{2}$$

The final output of the encoder produces a 1024-dimensional vector $\boldsymbol{z}$ that summarizes the spatial content of each channel. This latent representation is used to drive the reconstruction in the decoder, and, in parallel, informs downstream classification tasks. During the initial training phase, the encoder weights are frozen to retain robust pretrained features, allowing the decoder and classifier to adapt without perturbing the foundational representations.

B. Attention Aware Decoder

The decoder's primary objective is to reconstruct a clean version of the input image, denoted as $\hat{\boldsymbol{x}} \in \mathbb{R}^{64\times64\times3}$, from the latent vector ($\boldsymbol{z}$). This step is essential for removing noise and enhancing image quality before classification. Structurally, the decoder is paired with a DenseNet-121 encoder, where skip connections, $\boldsymbol{f_i}$ are extracted by encoder to paired with decoder blocks. These skip connections significantly improve their ability to preserve fine spatial details and reduce reconstruction errors. Notably, Ham et al. [31] theoretically and empirically analyzed linear denoising autoencoders with skip connections, showing that bypass pathways stabilize reconstruction performance. To further refine reconstruction, the decoder integrates the Convolutional Block Attention Module (CBAM) [7] which enhances feature selection through two types of attention, channel and spatial located after the last decoder block in Fig. 2.

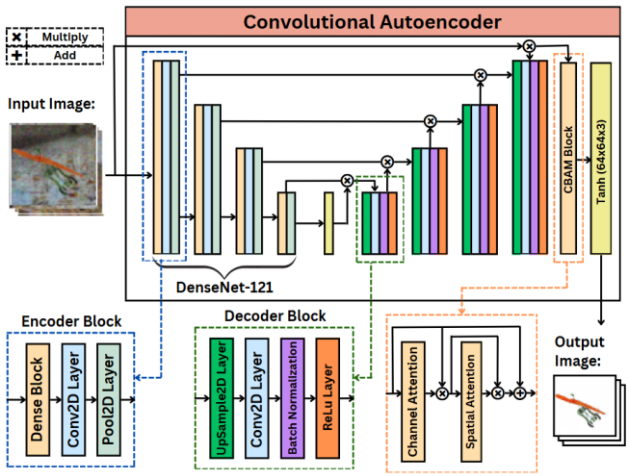

Fig. 2. Detailed architecture of the DenseNet-based encoder used in the autoencoder. Features from various depths are extracted and passed to the decoder through skip connections.

Channel attention learns a map $\boldsymbol{M_c} \in \mathbb{R}^{1\times1\times C}$ to assign importance weights to each feature channel, emphasizing those that contribute most to accurate reconstruction. Spatial attention computes a map $\boldsymbol{M_s} \in \mathbb{R}^{H\times W\times1}$ to focus on the most relevant spatial regions of the image, such as edges and textures. These attention mechanisms are applied to the intermediate feature map $\boldsymbol{F} \in \mathbb{R}^{H\times W\times C}$, producing a refined feature map $\boldsymbol{F_{att}}$ through element-wise multiplication calculated in Eq. (3). To preserve the original feature representation while enriching it with attention aware

enhancements, a residual connection is applied between the input feature map $\boldsymbol{F}$ and the refined output $\boldsymbol{F_{att}}$, yielding the final attended feature map $\boldsymbol{F_{out}}$ in Eq. (4). This combined representation is then passed through the final convolutional layer with a *tanh* activation to produce the decoded image $\hat{\boldsymbol{x}}$. Finally, the output image $\hat{\boldsymbol{x}}$ is generated using a convolutional layer followed by a *tanh* activation, ensuring that pixel values fall between –1 and 1, and match the original input's shape and color space for loss computation in Eq. (5).

$$\boldsymbol{F_{att}} = \boldsymbol{F} \odot \boldsymbol{M_c} \odot \boldsymbol{M_s} \tag{3}$$

$$\boldsymbol{F_{out}} = \boldsymbol{F_{att}} + \boldsymbol{F} \tag{4}$$

$$\hat{\boldsymbol{x}} = tanh(Conv(\boldsymbol{F_{out}})) \tag{5}$$

C. Classification from Reconstructed Inputs

The classification module uses the reconstructed image $\hat{\boldsymbol{x}}$, instead of the original noisy input, to benefit from improved visual quality during prediction. To prevent classification gradients from affecting the decoder, a stop-gradient operation is applied, treating $\hat{\boldsymbol{x}}$ as a fixed input during backpropagation and isolating the reconstruction learning. This detached image, $\hat{\boldsymbol{x}}_{\boldsymbol{stop_gradient}}$ is then passed through a new DenseNet-121 as decoded image's feature extractor, identical in architecture but with independent weights to extract a classification feature vector, $\boldsymbol{z_c}$ as described in Eq. (6). To enhance robustness, feature fusion is performed by element-wise multiplication of the latent vectors, $\boldsymbol{z}$ from the autoencoder and decoded image's extracted feature, $\boldsymbol{z_c}$ as shown in Eq. (7). This operation amplifies shared information while suppressing noise and inconsistencies.

$$\boldsymbol{z_c} = GAP(\boldsymbol{E}(\hat{\boldsymbol{x}}_{\boldsymbol{stop_gradient}})), \qquad \boldsymbol{z_c} \in \mathbb{R}^{1024} \tag{6}$$

$$\boldsymbol{z_{fused}} = \boldsymbol{z} \odot \boldsymbol{z_c} \tag{7}$$

The fused feature vector $\boldsymbol{z_{fused}}$ is then fed into fully connected layers with nonlinear activations and dropout regularization to generate the final multi-label classification prediction at Eq. (8) where W and B are learnable parameters of the classifier, and σ is the sigmoid activation function applied elementwise, mapping the outputs to probabilities between 0 and 1 for each class. The output $\hat{y} \in [0,1]^C$ represents predicted probabilities across C classes.

$$\hat{y} = \sigma(W^T \boldsymbol{z_{fused}} + b) \tag{8}$$

D. Multitask Hybrid Loss

The proposed model is optimized through a multitask learning framework that jointly addresses image reconstruction and multi-label classification. A hybrid loss function is formulated to guide the network in learning both low-level structural details and high-level discriminative features for accurate classification. This is achieved by minimizing reconstruction and classification losses simultaneously, each weighted within the final objective. As a result, the network preserves semantic content while improving its ability to differentiate object categories. This integration of learning signals helps the model build richer, more generalizable feature representations essential for robust recognition in complex visual scenes.

$$\boldsymbol{\mathcal{L}_{total}} = (\lambda_{recon} \cdot \boldsymbol{\mathcal{L}_{recon}}) + (\lambda_{class} \cdot \boldsymbol{\mathcal{L}_{class}}) \tag{9}$$

In Eq. (9) formulation, $\mathcal{L}_{total}$ denotes the complete training loss used to optimize the network parameters. The term $\mathcal{L}_{recon}$ corresponds to the image reconstruction loss, which guides the autoencoder decoder to regenerate the clean image from the latent representation. The term $\mathcal{L}_{class}$ represents the classification loss, used to supervise the semantic categorization based on the reconstructed features. The scalar coefficients λ_{recon} and λ_{class} are hyperparameters used to weigh the influence of each loss. In our experiments, we set λ_{recon} = 1.5 and λ_{class} = 0.5, which prioritizes structural reconstruction while maintaining a significant emphasis on classification.

To quantify the reconstruction performance, we employ the Mean Squared Error (MSE) loss [32], a standard measure for evaluating image similarity in pixel space. This loss is defined as Eq. (10). Here, x_i denotes the i-th original input image in a batch, while $\hat{x}_i$ is its corresponding reconstructed output produced by the decoder. Both are assumed to be RGB images with dimensions 64×64×3. The notation $\| \cdot \|^2_2$ refers to the squared L2 norm computed over all pixel values, which penalizes deviations between each input pixel and its reconstruction. The term N represents the batch size. This formulation encourages the decoder to generate outputs that are visually and numerically close to the original clean image inputs.

$$\boldsymbol{\mathcal{L}_{recon}}(x, \hat{x}) = (1/N) \sum \|x_i - \hat{x}_i\|^2_2 \tag{10}$$

For the classification task, we evaluate two loss functions, the Asymmetric Loss (ASL) by Ridnik et al. [27] and the conventional Binary Cross-Entropy (BCE). The ASL is designed for multi-label classification with severe label imbalance, where it emphasizes hard negatives while suppressing easy ones through focusing parameters and a threshold margin. It is defined as in (11). Here, $y \in \{0,1\}^C$ and $\hat{y} \in [0,1]^C$ denote the ground truth and predicted probability vectors across C classes. γ^+ and γ^- are focusing factors for positives and negatives, m is the margin that suppresses low-confidence negatives, and ε ensures numerical stability. We use $\gamma^+ = 0$, $\gamma^- = 2$, m = 0.01, and ε = 1e−8 as recommended in [27]. In contrast, the BCE loss [32], given by Eq. (12) treats each class independently and penalizes incorrect predictions equally, regardless of imbalance. We compare both losses to evaluate their influence on classification performance within our multitask framework.

$$\boldsymbol{\mathcal{L}_{class_ASL}}(y, \hat{y}) = -[y \cdot \log(\hat{y}) \cdot (1 - \hat{y})^{\gamma^+} + (1 - y) \cdot \log(1 - \hat{y} + \varepsilon) \cdot (\hat{y} - m)^{\gamma^-}] \tag{11}$$

$$\boldsymbol{\mathcal{L}_{class_BCE}}(y, \hat{y}) = -\sum [y_k \log(\hat{y}_k) + (1 - y_k) \log(1 - \hat{y}_k)] \tag{12}$$

By combining the two loss components in Eq. (9), the model learns to perform both tasks within a unified process. A key implementation detail is the use of a stop-gradient

operation between the reconstruction and classification branches. This ensures the classification loss does not backpropagate through the decoder, keeping its training focused solely on reconstruction. Meanwhile, the encoder is shared across both branches, enabling learning of joint features useful for both semantic discrimination and visual reconstruction. This separation of gradient flow, along with shared encoder supervision, promotes stable, task-specific optimization and allows both branches to converge effectively while reinforcing the shared representations.

IV. Experimental Setup

A. Dataset and Simulation of Complex Scenes

The dataset used in this work originates from the Edinburgh Kitchen Utensil Database (EKUD), which consists of isolated images of kitchen objects with plain backgrounds. The original EKUD dataset, however, presents two major limitations which are class imbalance, where some classes have significantly fewer instances than others, and lack of scene complexity, with only single-object images and minimal background variation. To address these limitations and generate a more realistic, complex training dataset, we developed a Complex Scene Generator pipeline in Fig. 3. First, all object images from EKUD were preprocessed by removing their backgrounds and converting them to transparent PNGs. This enabled spatial transformations and compositing onto new backgrounds.

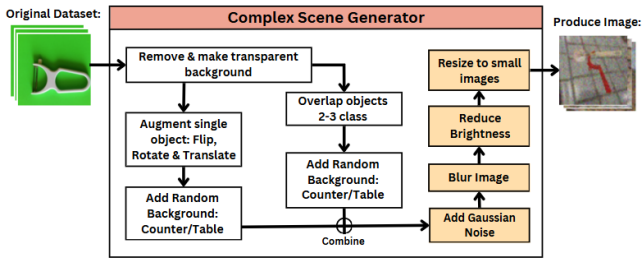

Fig. 3. Complex scene generator.

Each object was augmented using geometric transformations such as flipping, rotation, and translation to increase diversity. To simulate realistic environments, objects were overlaid on random background images of counters or tabletops, mimicking domestic kitchen scenes. To add complexity, 2–3 objects from different classes were randomly combined with spatial overlap, creating occlusions typical of real-world clutter. These composites then underwent image degradation, including resizing to 64×64 pixels, brightness reduction, Gaussian blurring, and added noise to mimic conditions like low light or motion blur. This process produced a balanced dataset of 6,000 images with equal class distribution. Each image contained one to three overlapping objects from different classes, introducing intra-class variation and inter-class spatial relationships vital for robust classification and reconstruction. Finally, the dataset was split into training and testing sets using an 80:20 ratio with stratified class distribution.

B. Model Training

The proposed dual-branch architecture was optimized using a two-phase training strategy to enhance image reconstruction and multi-class classification. To improve evaluation reliability and reduce overfitting, 5-fold StratifiedKFold cross-validation was applied to the training set, generating five training runs with preserved class distribution. In the first phase, the DenseNet encoder was frozen, allowing the decoder and classifier to learn task-specific features without altering backbone representations. A composite loss combined Mean Squared Error (MSE) for reconstruction and Sparse Categorical Crossentropy for classification, weighted 1.5 and 0.5, respectively. The model trained for 30 epochs using the Adam optimizer with a 0.001 learning rate. This phase aimed to stabilize reconstruction and extract semantically rich latent features. Structural Similarity Index (SSIM) assessed reconstruction quality, while standard metrics tracked classification accuracy.

In the second phase, the full model was unfrozen for end-to-end fine-tuning to enable joint optimization of low-level and high-level features across both branches. The learning rate was reduced to 0.0001 to support stable convergence and prevent disruption of previously learned features. This phase refined the encoder-decoder synergy and strengthened the alignment between reconstructed structures and class-relevant semantics. Following the completion of training with Asymmetric Loss, a parallel experiment was conducted using Binary Cross Entropy as the classification loss, while retaining the same optimizer settings, loss weights, and training schedule. This allowed a direct performance comparison under controlled conditions, highlighting the impact of loss design on multi-label recognition in cluttered scenes.

Pseudocode 1: Dual-Phase Training

Input: Noisy images I_{noisy}, (Clean Target Image I_{clean}, Clean labels L_{true})

Output: Trained model with decoder output D and classifier C

1: Initialize encoder with DenseNet121 (frozen), decoder blocks, and classification branch

2: Compile model with:

- Losses: MSE, ASL
- Loss weights: D: 1.5, C: 0.5}
- Optimizer: Adam (lr = 0.001)

3: Train model for N_1 (30) epochs, freezing encoder

4: Save best weights based on highest validation accuracy

5: Unfreeze all layers of model

6: Compile model with:

- Updated optimizer: Adam (lr = 0.0001)

7: For epoch = N_1 to N_2(100) do

8: For each batch (I_{noisy}, L_{true}) in training set do

9: Compute decoder output D_{pred} and classifier output C_{pred}

10: Compute:

- MSE loss between D_{pred} and I_{clean}
- ASL loss between C_{pred} and L_{true}

- SSIM metric for D_{pred}

Backpropagate total loss = 1.5 × MSE + 0.5 × ASL

Update weights

Evaluate on validation set

Save model if validation accuracy improves

End for

The dual-phase training strategy in Pseudocode 1 reflects a common practice in transfer learning and multi-task deep learning. Freezing the pretrained encoder early allows the decoder and classifier to learn task-specific features without modifying core representations. Once stabilized, full fine-tuning with a reduced learning rate improves alignment between reconstructed outputs and classification. Deepankan and Agarwal found that freezing the backbone initially and unfreezing later boosted accuracy and reduced overfitting on limited data [33]. Likewise, Taha et al. employed staged fine-tuning with pretrained language models, showing that freezing phases improved learning stability and generalization in imbalanced tasks [34]. In remote sensing, Khotimah et al. used a dual-stage framework combining masked autoencoder pretraining and few-shot learning to enhance hyperspectral image classification with limited supervision [35]. These studies support phased training as a reliable strategy for stabilizing early optimization and enhancing global feature refinement.

C. Evaluation Metrics

To assess model performance, five-fold Stratified K-Fold cross-validation was applied to the training data to ensure balanced class representation and generalizability. All metrics are reported as averages across the five folds. Since the model performs both tasks jointly, each output was evaluated using suitable criteria. For reconstruction, evaluation focused on perceptual similarity and signal fidelity between input and reconstructed images. Structural Similarity Index Measure (SSIM) was used to compare luminance, contrast, and structural details, as defined in Eq. (13), where μ_x and μ_y are the means, σ_x and σ_y their standard deviations, σ_{xy} the cross-covariance, and C_1, C_2 are constants for stability. Additionally, Peak Signal-to-Noise Ratio (PSNR) was used to measure reconstruction quality based on the ratio of maximum signal to noise power. As shown in Eq. (14), PSNR uses MAX_I as the maximum pixel value and MSE as the mean squared error. Combined, these metrics evaluate perceptual quality and pixel-level accuracy.

$$SSIM(x,y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)} \quad (13)$$

$$PSNR = 10 \cdot \log_{10}\left(\frac{MAX_I^2}{MSE}\right) \quad (14)$$

For the multi-label classification component, an adaptive top-T_1 binarization scheme was applied. Each output prediction vector was binarized by retaining the top-T_1 elements with the highest predicted probabilities, where T_1 corresponds to the number of positive ground truth labels in the input, as shown in Eq. (15). This approach ensured prediction-ground truth cardinality alignment, enabling fair comparisons across samples with varying label sparsity. After binarization, classical metrics such as precision, recall, and F1-score were computed using Eq. (16), Eq. (17), and Eq. (18), respectively. These metrics were evaluated under both macro and micro averaging. Macro-averaging calculates per-class metrics and averages them, while micro-averaging aggregates all class contributions before computing the metric, capturing overall performance. To assess label-wise correctness, we also reported standard accuracy Eq. (19) and Hamming Loss (20), which quantify the fraction of misclassified labels.

$$T_1 = \| y_{true} \|_0 \quad (15)$$

$$Precision = \frac{TP}{TP + FP} \quad (16)$$

$$Recall = \frac{TP}{TP + FN} \quad (17)$$

$$F1 = \frac{2 \cdot Precision \cdot Recall}{Precision + Recall} \quad (18)$$

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (19)$$

$$Hamming\ Loss = \frac{1}{N \cdot C}\sum_{i=1}^{N}\sum_{j=1}^{C} 1[y_{ij} \neq \hat{y}_{ij}] \quad (20)$$

To assess ranking quality, which is important in multi-label tasks with overlapping label distributions, we computed the Area Under the Receiver Operating Characteristic Curve (ROC-AUC) and Mean Average Precision (mAP) in micro settings. These metrics, based on raw prediction scores without thresholding, evaluate the model's ability to rank relevant labels above irrelevant ones, following best practices in recent multi-label research [36]. Macro metrics average performance across classes, while micro metrics aggregate true and false positives globally. A multi-label confusion matrix was generated using the MLCM (Multi-Label Confusion Matrix) library [37], enabling per-class analysis of co-occurrence between true and predicted labels. The matrix was visualized as a heatmap to expose common misclassifications and confusion patterns. MLCM offers sparse-aware, normalized outputs well suited for complex multi-label data, following protocols from [38]. Finally, a classification report summarized per-class precision, recall, and F1-scores for detailed performance interpretation.

V. Results and Discussion

A. Multi-Labeled Classification

The classification performance of the proposed model in Table I was compared with two baselines: a standard convolutional autoencoder and a standalone DenseNet-121 classifier. All models used binary cross-entropy loss, while the proposed model was also evaluated with asymmetric loss to test sensitivity to label imbalance. Metrics included accuracy, Hamming Loss, macro-averaged ROC-AUC, and macro mean average precision (mAP). The autoencoder achieved 88.99% accuracy, 0.1101 Hamming Loss, 0.8803 ROC-AUC, and 0.5278 mAP. The standalone DenseNet-121 reached 95.37%

accuracy, 0.0463 Hamming Loss, 0.9678 ROC-AUC, and 0.8366 mAP. The proposed model, combining reconstruction and classification, reached 96.41% accuracy, 0.0359 Hamming Loss, 0.9805 ROC-AUC, and 0.8862 mAP.

The highest performance was achieved when the proposed model was trained using the asymmetric loss function. Accuracy increased to 96.72%, and Hamming Loss decreased to 0.0328. The macro ROC-AUC reached 0.9809, while the macro mAP peaked at 0.8925. To further evaluate classification performance, Table II reports macro and micro averages of precision, recall, and F1-score. The standard convolutional autoencoder yielded a macro F1-score of 0.4296 and a micro F1-score of 0.4496. The DenseNet-121 baseline achieved a macro F1-score of 0.7637 and a micro F1-score of 0.7683. The proposed model with binary cross-entropy achieved a macro F1-score of 0.8196. When trained with asymmetric loss, the model attained a macro F1-score of 0.8350 and a micro F1-score of 0. 8362.

TABLE I. EVALUATION OF CLASSIFICATION RESULT

Model	**Classification Loss Function**	**Evaluation**			
		Accuracy	***Hamming Loss***	***Macro ROC-AUC***	***Macro mAP***
Standard Convolutional Autoencoder (CAE)	BCE	88.99%	0.1101	0.8803	0.5278
DenseNet-121 (Alone)	BCE	95.37%	0.0463	0.9678	0.8366
Proposed Model	BCE	96.41%	0.0359	0.9805	0.8862
	ASL	96.72%	0.0328	0.9811	0.8925

TABLE II. PERFORMANCE MATRICS OF CLASSIFICATION RESULT

Model		**Performance Matrics**					
		Macro Precision	***Macro Recall***	***Macro F1***	***Micro Precision***	***Micro Recall***	***Micro F1***
Standard CAE	BCE	0.5658	0.4496	0.4296	0.4496	0.4496	0.4496
DenseNet -121 (Alone)	BCE	0.7798	0.7683	0.7637	0.7683	0.7683	0.7683
Proposed Model	BCE	0.8311	0.8204	0.8196	0.8204	0.8204	0.8204
	ASL	0.8435	0.8362	0.8350	0.8362	0.8362	0.8362

The evaluation of classification performance using Asymmetric Loss (ASL) and Binary Cross-Entropy (BCE) was conducted with multi-label ROC-AUC metrics. Although the dataset was globally balanced across 20 categories, many binary labels had just 1 to 3 positives, causing localized imbalance. The micro-average AUC under ASL reached 0.9811, slightly higher than 0.9802 with BCE. ASL produced higher per-class AUCs in 12 of 19 overlapping categories. For example, Potato Peeler, Serving Spoon, and Wooden Spoon had stronger AUCs under ASL. The ROC curves shown in Fig. 4 and Fig. 5 further illustrate classifier performance across label distributions. Fig. 4, derived from the ASL-trained model, exhibits tighter and more consistent ROC curves, especially for low-prevalence labels. In contrast, Fig. 5, based on BCE training, presents slightly flatter and more variable ROC curves for low-activity classes such as Bread Knife (0.9720 ASL vs. 0.9786 BCE) and Dinner Fork (0.9714 ASL vs. 0.9768 BCE). BCE outperformed ASL in a few high-density labels like Bottle Opener.

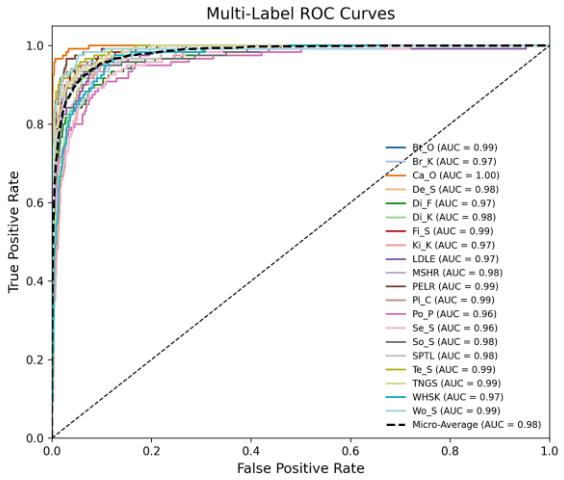

Fig. 4. ROC-AUC Graph of proposed model that uses asymmetric loss function.

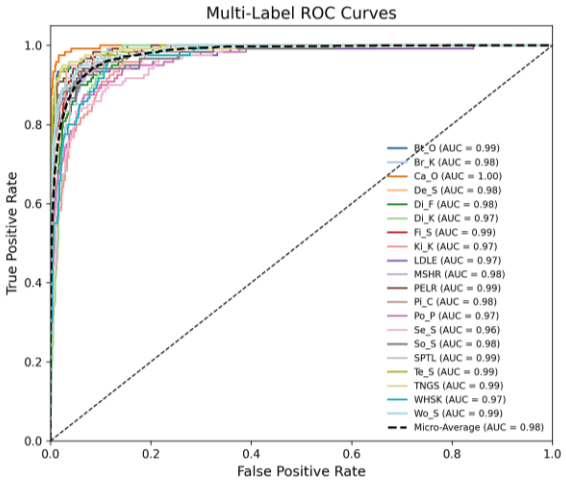

Fig. 5. ROC-AUC Graph of proposed model that uses binary crossentropy loss function.

B. Enhanced Image Reconstruction

The reconstruction performance was evaluated using SSIM and PSNR, as detailed in Table III. Input images contained complex scenes with diverse backgrounds, object occlusion, and visual clutter. The decoder consistently generated clean object representations over simplified backgrounds, as also illustrated in Table IV. The baseline autoencoder, trained using mean squared error and binary cross-entropy loss, achieved a reconstruction score of 0.9175 SSIM and 6.0670 dB PSNR. The proposed dual-path model improved these scores to 0.9213 SSIM and 7.0028 dB PSNR. When asymmetric loss was applied during classification, the model achieved 0.9372 SSIM and 7.1012 dB PSNR. The model's ability to reconstruct clean outputs from noisy, cluttered scenes was enhanced by

integrating the Convolutional Block Attention Module (CBAM) into the decoder. DenseNet-121 was excluded, as it lacks a decoding pathway.

TABLE III. IMAGE RECONSTRUCTION PERFORMANCE EVALUATION

Model	Loss Function	Evaluation	
		SSIM	***PSNR (dB)***
Standard Convolutional Autoencoder (CAE)	MSE+BCE	0.9175	6.0670
Proposed Model	MSE+BCE	0.9213	7.0028
	MSE+ASL	0.9372	7.1012

TABLE IV. IMAGE RECONSTRUCTION BASED ON LOSS FUNCTIONS

Input	MSE+BCE	MSE+ASL	Standard CAE
			

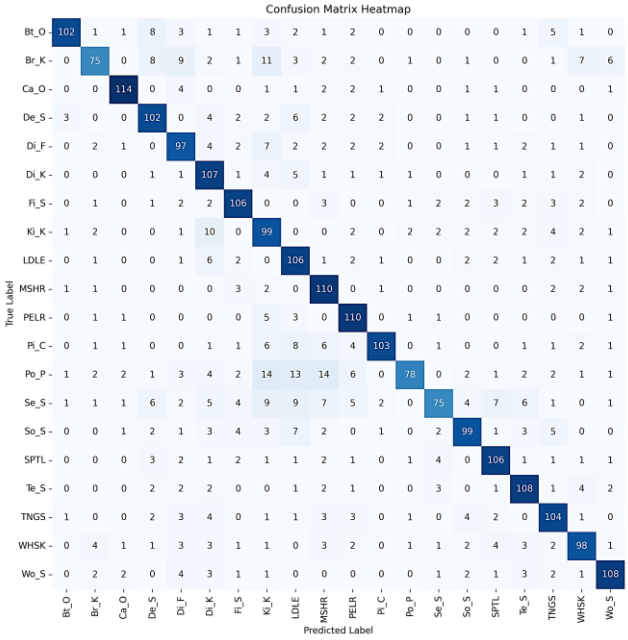

Fig. 6. Confusion matrix from proposed model with loss function MSE+ASL.

The confusion matrix in Fig. 6 shows the best classification results of the proposed model using Mean Squared Error (MSE) for reconstruction and Asymmetric Loss (ASL) for classification. Most object classes exhibit strong diagonal dominance, indicating high true positive rates, especially for Can Opener, Masher, Peeler, and Wooden Spoon, each surpassing 100 correct predictions. These results demonstrate the model's robustness against complex scene conditions such as overlapping objects, image degradation, and varied backgrounds. Some confusion remains between visually or semantically similar classes, like Bread Knife misclassified as Can Opener or Peeler, and Serving Spoon overlapping with Soup Spoon, underscoring ongoing challenges with intra-class similarity in noisy settings. Overall, the matrix supports the effectiveness of the multi-task architecture, where combining image enhancement and classification via latent fusion improves discriminative performance.

VI. DISCUSSIONS

A. Interpretation of Multi-Label Classification Results

The multi-label classification results highlight the clear advantage of integrating reconstruction and classification within a unified model, particularly when dealing with complex data distributions and label sparsity. While the standard convolutional autoencoder lacked explicit label supervision and performed poorly in classification, the standalone DenseNet-121 improved predictive quality through deeper, more expressive features. However, DenseNet-121 operated in a single-task setup and did not benefit from auxiliary learning signals provided by image reconstruction. In contrast, the proposed dual-path architecture, which combines visual reconstruction with classification, consistently outperformed both baselines. This outcome suggests that reconstruction plays a crucial role in shaping more robust latent representations, which in turn support better discrimination, especially for less frequent object classes.

An equally important factor in the model's success is the choice of loss function. The shift from Binary Cross-Entropy to Asymmetric Loss introduced a more nuanced training dynamic, where the model learned to emphasize informative, minority class signals while reducing overfitting to dominant negatives. This led to higher macro-averaged metrics and stronger per-class AUCs for rare categories. ROC curve comparisons further confirmed this behavior, showing tighter, more stable curves under ASL for low-prevalence labels. Meanwhile, BCE slightly favored common classes due to its uniform treatment of all errors. Taken together, these observations demonstrate that the model's strength arises not solely from architectural complexity but from a careful alignment between task formulation, loss function design, and the inherent demands of multi-label learning in imbalanced and cluttered visual contexts.

B. Interpretation of Reconstruction Performance

The reconstruction results demonstrate that the proposed dual-path architecture is not only effective for classification but also capable of producing structurally coherent and visually clean reconstructions in complex scenes. Compared to the baseline autoencoder, the improved SSIM and PSNR scores reflect the model's strong capacity to abstract essential features while filtering out background noise and irrelevant details. The use of a shared encoder that supports both tasks allows the network to capture richer semantic representations, which benefit the decoder's ability to reconstruct meaningful content even in visually degraded or cluttered environments. This integration shows how multi-task learning encourages a more organized and informative latent space that serves both enhancement and recognition.

An unexpected but significant observation was the positive influence of asymmetric loss, applied only to the classification task, on the quality of reconstructed outputs. This implies that learning to better separate hard-to-classify examples also leads

to more structured and semantically aligned feature embeddings, indirectly supporting the reconstruction process. Additionally, the integration of CBAM into the decoder reinforced the model's ability to selectively attend to important spatial and channel-specific regions. As a result, reconstructions were not only cleaner but also better aligned with the salient components of the original input. This attention-driven refinement is particularly beneficial in real-world scenarios where accurate reconstruction supports interpretability and aids in downstream decision-making tasks.

C. Bridging Gaps Through Multi-Task Representation

The proposed model directly addresses several unresolved challenges in existing research by unifying classification and reconstruction within a shared encoder-decoder architecture. Most prior approaches treat enhancement and recognition as separate tasks, limiting their ability to generalize in cluttered or degraded scenes. In contrast, the proposed model leverages joint optimization to build more expressive and spatially consistent latent features. The reconstruction task helps maintain structure and denoise complex scenes, while the classification branch, guided by asymmetric loss, highlights category-specific regions, especially for rare labels. This dual influence supports a more semantically aware encoder that improves both predictive accuracy and visual clarity in reconstructed images.

By integrating DenseNet-121 and attention modules like CBAM into a multi-task framework, the model closes a critical gap identified in previous studies where such components were rarely combined. Through shared learning, reconstruction helps the model preserve spatial structure and object layout, while classification encourages it to focus on distinctive features that separate one object class from another. Consistent performance gains across low-prevalence classes and complex visual backgrounds indicate that the model benefits from this interdependence. Rather than relying on handcrafted decoupling or task-specific heuristics, this approach uses end-to-end learning to harness the complementary strengths of each task. As a result, the model becomes more robust, interpretable, and suitable for real-world deployment where visual data is often noisy, sparse, and heterogeneous.

VII. Conclusion and Future Work

In this study, we proposed a multi-task deep learning architecture that integrates a convolutional autoencoder and DenseNet backbone with latent space fusion to tackle object classification challenges in complex scenes. These include cluttered backgrounds, overlapping objects, and degraded image quality due to noise, blur, or low brightness. The architecture was designed to jointly enhance visual clarity and extract discriminative features within a unified pipeline. Trained in two phases and evaluated using diverse reconstruction and classification metrics, the model outperformed baseline methods. The proposed architecture is particularly designed for image data containing overlapping objects and visual noise, where conventional classification models often underperform. Results showed notable improvements in accuracy, macro and micro F1-scores, and reduced class confusion, validating the benefit of integrated image enhancement and feature learning for robust multi-class object recognition in complex scenes.

Despite improvements, some limitations remain. The model still exhibits misclassifications in scenes with visually similar or overlapping objects, for example Dessert Spoon versus Dinner Spoon, indicating difficulty in distinguishing fine-grained object boundaries under occlusion. This reflects a broader challenge in handling complex scenes involving clutter and degraded visual quality, which the proposed architecture is specifically designed to address. In addition, the reliance on fully supervised learning requires both labeled class data and clean reconstruction targets, resources that may be limited or noisy in real-world deployments. To improve scalability, future work could investigate semi-supervised or weakly supervised strategies that reduce dependence on exhaustive annotation. Incorporating spatial-aware attention or feature disentanglement methods may further improve robustness in overlapping object conditions. Finally, expanding the dataset or extending the architecture to video inputs could strengthen recognition under temporal and contextual variation.

Acknowledgment

Funding Statement and Conflicts of Interest: This work was funded by the Ministry of Higher Education Malaysia under the Fundamental Research Grant Scheme (FRGS/1/2023/ICT02/UMT/03/2). The also authors declare that they have no conflicts of interest to report regarding the present study.

***Abstract*—Data sharing security is currently one of the crucial parts in e-government systems. Although blockchain, a type of Distributed Ledger Technology (DLT), has been increasingly applied to enhance secure data exchange, there is a significant lack of studies focusing on the specific security factors that underpin its implementation in e-government contexts. Defining and understanding these factors is crucial for the successful integration of blockchain into public data infrastructures. This study addresses this research gap through a Systematic Literature Review (SLR) guided by the PRISMA 2020 framework. A total of 511 articles were retrieved from five major databases, and 103 were selected and systematically reviewed using the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) 2020 approach. While the majority of studies emphasised privacy, integrity, and transparency, other critical security factors such as scalability, availability, governance, and decentralisation remain comparatively underexplored. The theory of blockchain-based data sharing security factors was developed as a reference. The article wraps up the discussion by highlighting nine security factors in data sharing using blockchain in e-government for future investigation.**

***Keywords*—Blockchain; Distributed Ledger Technology (DLT); data sharing security; e-government; Systematic Literature Review (SLR); PRISMA 2020**

I. Introduction

In the era of emerging digital technologies, governments around the world are increasingly adopting technology to improve the accessibility, transparency, and efficiency of public administration using a transformative methodology called electronic government (e-government). A key element of e-government is the secure and seamless exchange of data among various government agencies and citizens. However, traditional data-sharing methods are often plagued by challenges related to trust involving security and privacy, which can hinder the complete effectiveness of e-government initiatives. [1], [2].

Data sharing serves as the cornerstone of e-government, enabling the efficient flow of information between government entities and citizens to ensure streamlined service delivery. However, digital disruption has introduced significant challenges in maintaining information security and privacy. Traditional methods of data sharing have increased the risk of cybersecurity. These attacks include vulnerability attack, data breach, user account compromise and malicious attack. This will further trigger the system safety and reliability issue. [1], [3].

The Malaysia Central Data Sharing platform (MyGDX), provided by the Digital Department of Malaysia, is the most used platform among government agencies. The trend of data sharing among government agencies on this platform showed an increase in transactions every year. The number of data sharing transactions recorded from the beginning of the data sharing exchange in 2018 to 26 May 2024 was recorded at 621,824 transactions. However, a total of 4,117,202 data sharing transactions were recorded by the 12th of May 2025 [4]. These statistics express a growth of 3,485,378 transactions from May of 2024 to May of 2025 alone. A breach involving such a large dataset will pose significant risk due to the scale and critical nature of the information.

According to Malaysia Computer Emergency Response Team (MyCERT), Cyber General Incident Classification statistics – January to April 2025[5]. There were 2,291 incidents received by Cyber999 Incident Response Centre, compared to the 1,550 incidents received in Q4 2024. This indicates that there is a 7% increase in incidents in the previous quarter. Personal identifiable information (PII) from national databases, such as identity numbers, addresses, and financial data, is commonly involved in high-profile attacks, according to MyCERT.

This research aims to comprehensively and systematically review the literature as well as synthesise current work on blockchain-based data sharing in e-government systems. The main focus is to identify the key factors for secure data sharing. The review aims to analyse the existing frameworks and models proposed for application of blockchain in electronic government, assess the effectiveness of these approaches in improving data sharing practices, and stress the gaps in the recent literature. Ultimately, this review aims to deliver a clear understanding of the latest use of blockchain-based data sharing within e-government systems and to identify prospective investigations in this evolving area.

II. Study Background

A. Data Sharing

Data sharing is essential to promote collaboration and innovation in various domains. The integration of technologies can improve the privacy and security of data sharing, addressing concerns related to the issue and challenges of data security.

The term data sharing refers to the movement of information between different systems and entities or across international borders. It is crucial for decision makers, resource optimisation,

*Corresponding Author

and improving information utilisation. [6]. In the public sector, data sharing is vital for addressing interoperability challenges, such as collaboration between government agencies and seamless information exchange. The process involves the exchange of information and knowledge between organisations through their business processes [7], [8].

Both definitions highlighted that data sharing is important to parties which benefit from data sharing. The United Kingdom Information Commissioner's Office highlights the importance of responsible data sharing, stating: "When you get data protection right, it sends a strong message to your customers – it lets them know that you value and care for their information and that you are more likely to keep it safe and not share it inappropriately"[9]. This statement further reinforces the critical role of trust, ethical practices, and robust security measures in data sharing processes, ensuring that organisations handle information responsibly while maximising its potential for social and organisational benefits.

B. Data Sharing Security

Data sharing security is a critical aspect of modern information systems, ensuring that data is shared between entities in a way that protects its confidentiality, integrity, and availability. The fundamental model used in information security is the CIA triad, which stands for confidentiality, integrity, and availability [10]. This model serves as a reference framework for agencies to protect delicate data and ensure that information systems are secure. Each component of the triad addresses a specific aspect of security and together provides a comprehensive approach to safeguarding information.

Based on the NIST Cyber Security Framework 2.0 [11], Data security refers to the consistent management of data in a proper manner within the organization and protects all the risk of providing trust through confidentiality, integrity, and availability of information in all data conditions, whether the data at rest, data in transit, data in use and backups of data are created, protected, maintained, and tested.

1) Confidentiality: The NIST refers to the term confidentiality as the preservation of authorised restrictions on information access and disclosure, including means to protect personal privacy and proprietary information...[12]. Confidentiality involves ensuring reachability of data by authorised personnel. Sensitive data needs to be secure from data leaks and breaches.

2) Integrity: Integrity was demarcated by the NIST as protection for data from being improperly altered, modified or demolished by protecting the information's originality and legitimacy [11]. The term integrity also refers to the precision and fullness of data. The integrity ensures information is not changed in unauthorised ways, while at the same time, providing the reliability and trustworthiness of the data [12].

3) Availability: Availability guarantees that resources and information are available to authorised users when needed. It is essential for upholding the practicality and usability of information systems. The NIST defines availability as "Ensuring timely and reliable access to and use of information…"[12].

C. Blockchain Technology Security

Blockchain Technology or Distributed Ledger Technology is one of the emerging technologies of Industrial Revolution 4.0, which is used in data security. Introduced by Nakamoto, Blockchain Technology offers a decentralised and secure method for recording transactions. Blockchain technology is characterised by the ability to maintain a distributed ledger that is immutable, transparent and resistant to tampering [13].

In blockchain technology, the new transaction created by a user will be broadcast to the blockchain network using a P2P connection. Then, the node in the network will validate the transaction using a consensus mechanism like Proof of Work (PoW). Validated transactions are grouped in a block. The block will be linked to the chain using a cryptographic hash. The ledger will be updated to complete the transaction as shown in Fig. 1.

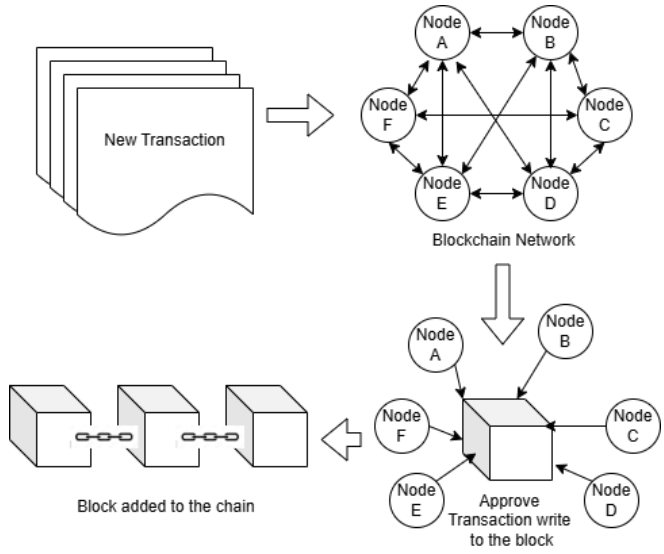

Fig. 1. How blockchain works.

D. E-Government System Data Security

The term, electronic government (e-government), is defined by [1] as the application of ICT to digitalise government services for the public, enterprises, and government agencies. The objectives of having an e-government system include reducing bureaucracy, increasing transparency, and ensuring secure and efficient service delivery. [1], [7], [14], [15]. According to [16], current data-sharing practices in e-government systems face several challenges that hinder effectiveness and security.

The governing policy and act are the most important items to be complied with for the e-government data sharing security in government agencies. In 2021, the Malaysia Administrative and Modernisation dan Planning Unit (MAMPU) released the Policy for Public Sector Data Sharing. This is used to govern the cross-organisation data sharing to improve services towards data-driven government [17]. Recently, in February of 2025, the establishment of the National Data Sharing Committee led by the Director General of the National Digital Department has aligned with the passing of the bill of Data Sharing Act 2025 (Act 864) by providing control to the public sector regarding data sharing processes [18].

III. METHODOLOGY

Data Sharing, security, and e-government applications have a vast amount of literature in general. Many academic papers and government reports have discussed Blockchain topics. An extensive search has been made, and the current development studies published between the years 2014 and 2024 have been discussed in this paper. The selection of the publication article aligns with the issues related to the security of data sharing, specifically involving the e-government system. These issues have been discussed, debated, and reported at international and national levels. This paper discusses the selected papers from established journals, conference papers, and proceedings.

The PRISMA 2020 (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) protocol is a widely recognised and standardised framework used to ensure transparency, rigour, and reproducibility in conducting and reporting systematic reviews [19]. For this systematic literature review on blockchain-based data sharing in e-government systems, the PRISMA 2020 protocol was meticulously followed to guide the review process. Based on the keywords search, a collection of comprehensive artefacts was gathered. Four phases were involved in searching and selecting the papers: identification, screening, eligibility, and inclusion, as illustrated in Fig. 2.

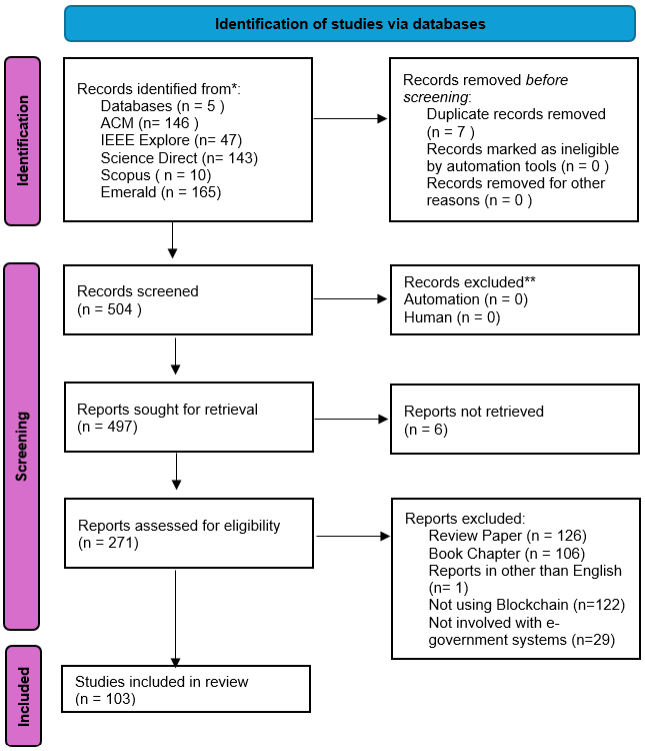

Fig. 2. Review workflow of this systematic review.

By adhering to the PRISMA 2020 protocol, this systematic review ensures a rigorous, transparent, and reproducible process. Ultimately, providing a comprehensive synthesis of the current state of blockchain-based data sharing in e-government systems.

A. Identification of the Key Research Question

Based on the Key research question, the PICOC framework [19] has been used to define and structure research questions and identify the relevant literature. The key elements of the research context are represented in Table I. The context in the comparison in the systematic review is excluded.

TABLE I. PICOC FRAMEWORK MAPPING WITH KEYWORDS AND SYNONYMS

PICOC	Description	Keyword	Synonym
Population	An industry domain.	government	
Intervention	The methodology, tool, or technology that tackles a certain problem.	data sharing	data exchange
Comparison	The methodology, tool, or technology in which the Intervention is being compared (if appropriate).	Blockchain	DLT
Outcome	Factors of importance to practitioners and/or the results that interposition could produce.	security	-
Context	The context in which the com-parison is done.	e-government	digital governme nt

The research questions guiding this systematic literature review are designed based on the PICOC framework to explore the current landscape of blockchain-based data sharing in e-government systems. The PICOC framework keywords used in this research are in Table I. The population used is e-government or digital government, which is the domain of the research. The Intervention for this research is data sharing or data exchange. The comparison of the technology used is blockchain or Distributed Ledger Technology. Finally, the outcome for the keyword used is security. No context specifies for the research keyword, and it is optional based on the approach.

Specifically, the review seeks to answer the following questions:

RQ 1: What is the current trend in blockchain technology for securing data sharing in e-government systems?

RQ 2: What is the current approach and use of blockchain-based data sharing in e-government systems?

RQ 3: What are the data sharing security factors that blockchain technology enhances in e-government systems?

These questions aim to present a comprehensive understanding of how blockchain technology is being leveraged in highlighting the questions of secure data sharing in e-government, while also identifying areas where further investigation is needed.

B. Identification of Relevant Articles

The selection of databases was based on their relevance to the fields of information security, information systems, and public administration, ensuring an inclusive coverage of the literature.

The review began with a comprehensive search strategy across several academic databases such as Scopus, IEEE Xplore, Science Direct, ACM Digital Library and Emerald. The keyword used in the search included a combination of keywords related to "blockchain OR Distributed Ledger Technology", "data sharing OR information sharing", "e-government", and "security." To enhance the exploration and to make sure that related studies were taken, a Boolean operator is used.

C. Selection of the Relevant Articles: Inclusion and Exclusion Criteria

As mentioned earlier, PRISMA 2020 was used to carefully select the relevant articles for this study. Table II shows that the inclusion criteria 1 is the article. The articles show the use of blockchain in data sharing for e-government systems. Inclusion criteria 2 are the improvements made due to blockchain application in government data sharing as shown in the paper. The exclusion criteria set for this review are that the implementation of blockchain is not mentioned in the paper, and papers have redundancies for the research done.

TABLE II. INCLUSION AND EXCLUSION CRITERIA IN REVIEW SELECTION

Criteria	Justification
IC-1: The articles show the use of blockchain in data sharing for e-government systems.	This review inspects related studies on blockchain used for data sharing in government-related systems.
IC-2: The improvements due to blockchain application in government data sharing are shown in the paper	The aim is to convey an indication Important progress of blockchain technology in data sharing and e-government.
EC-1: Implementation of blockchain is not mentioned in the paper.	Papers that only overview blockchain in general often lack focus on data sharing.
EC-2: Paper is redundant for the research done.	Duplicate content is assessed by com paring publication dates and author status for validity.

In the selection phase, the titles and abstracts of the 497 selected articles were read and evaluated manually. Of those, 390 articles were found to be outside the limits of this study, and thus only the remaining 271 articles were taken into account for further analysis. A complete analysis was performed for these 271 articles by carefully inspecting the whole text. This detailed analysis found 168 articles that were not related to this study as they were not relevant to the use of blockchain in data sharing for e-government. Thus, they were also expelled. 103 articles were finalised on the significant publication used for this study, as detailed in Table III.

TABLE III. DISTRIBUTION OF PAPERS BY SOURCES THROUGHOUT THE SCREENING PROCESS

Source	Identification Search	Paper Screening	Eligible Search	Selected for Review
ACM	146	143	44	19
IEEE Xplore	47	46	36	30
Science Direct	143	142	84	27
Scopus	10	8	7	4
Emerald	165	165	100	23
TOTAL	**511**	**504**	**271**	**103**

D. Reporting and Summarising the Results

The first stage was to extract and compile metadata from 271 relevance articles. The metadata consisted of the authors' names, publication title, year of publication, approach used, improved factors, and the security threat problem. These metadata were thoroughly examined using quantitative methods. The purpose of descriptive statistics was to find trends and patterns. Sections IV and V below provide all of these analyses.

IV. RESULTS

A. Trends of Articles Based on PICOC Keywords for 10 Years

The keyword search shown in Fig. 3 shows an upward trend of publications from the year 2016 to 2024. The trend of eligible articles shows the same pattern. The number of articles related to Blockchain approach in data sharing for e-government is expected to increase, as shown in Fig. 3. In 2024, fewer articles were produced as the research was only done until Sept of 2024. There will be more articles published by the end of the year and will increase number of publications, which we believe is an area of further investigation. This will answer Research Question 1 (RQ 1) for What is the current trend in blockchain technology for securing data sharing in e-government systems?

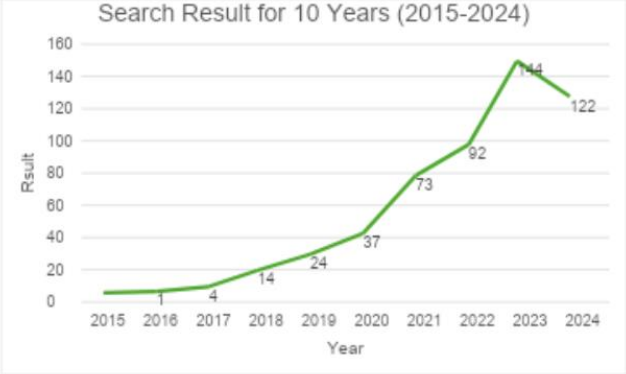

Fig. 3. Trend of article distribution based on 511 articles (Identification Phase).

The findings have shown that evidence of blockchain technology has been widely used to enhance security for data sharing in the e-government. Since 2015, the number of articles published has increased significantly. The number of publications increased by 250% in 2018 from the previous year. Year 2021 has recorded an increase of 36 articles for blockchain-based data sharing compared to 2020, while 92 articles were recorded in 2022. In 2023, 144 articles have been published, which is an increase of 52% from the previous year. The research on the topic began in 2016, which might be influenced by the launch of the Ethereum platform in blockchain technology in 2015 [20].

Based on the distribution of the articles shown in Fig. 4, 103 articles have been identified as eligible to be included in the study. From this, there is only one article which was eligible to be included from 2016. The number of eligible articles increased yearly. However, in 2019, the eligible article was down by 1 article from the year 2018, while 2022 recorded a downtrend of 2 articles from 2021. In certain instances, the paper was

excluded due to its failure to address a particular case study. The eligible articles included in 2023 amounted to 29, which is the highest number of articles recorded in a given year. This shows the increment of 12 articles. The number of articles for 2024 is only 14, as the literature cut-off searching date was set to 30 September 2024.

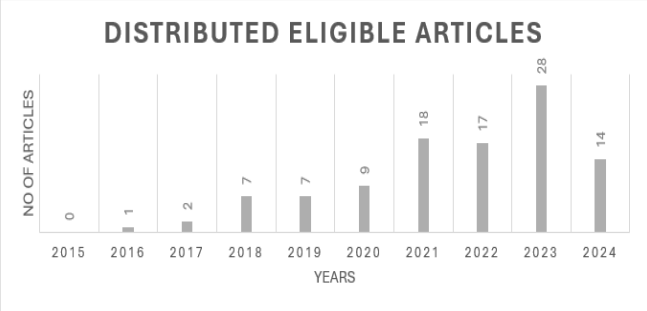

Fig. 4. Distribution of the shortlisted 103 articles based on inclusion and exclusion criteria (Eligibility Phase).

B. State of the Art Blockchain-Based Data Sharing in e-government Systems

The use of blockchain in data sharing has been implemented in several ways to enhance security. RQ 2 What is the current trend and landscape of blockchain-based data sharing in e-government systems in the world? The approach used is governance, adoption, and application. Four (4) articles were focused on the usage of blockchain in enhancing data sharing with compliance with the law and act as General Data Protection Regulation (GDPR), European Timber Regulation and EU's Carbon Border Adjustment Mechanism (CBAM). There is one article for compliance in 2022 and two in 2023, as shown in Fig. 5.

Fig. 5. Trend in publication on approach by year.

The second approach focuses on how organisations adopt blockchain to secure data sharing in e-government. 22 articles researched the acceptance of blockchain security in e-government systems for organisations due to their aptitude to enhance data sharing security. The articles on adoption of blockchain were discovered to begin in 2019 and are increasing every year until 2023, as shown in Fig. 5. In 2024, it is expected to grow as five articles are recorded as of September 2024.

However, the preferred approach to enhance data sharing in e-government data sharing is the application of blockchain in the e-government system. 68 or 56.67% of the eligible articles are on the application of blockchain. Application through integration with existing technology or emerging technologies in one of the four approaches found in this literature. 26 articles used the integration approach in implementing blockchain with IoT, Big Data and cloud computing to enhance the data sharing security. The approach is mostly used for blockchain data sharing security. The trend is static for three years since 2018, and the highest eligible article for application recorded in 2023 is 17, as shown in Fig. 5. In 2024, the number of articles is expected to show 8 articles published and still counting due to the interest of researchers in exploring blockchain technology to secure data sharing in e-government systems continuously.

C. The Landscape of Blockchain-Based Secure Data Sharing Based on Geographical Area and Country

The use of blockchain in the world is expanding from year to year. Currently, 36 countries have been identified in this research to be securing data sharing using blockchain in e-government systems as shown in Fig. 6. China has twelve use cases, which is the highest number of blockchain-based data sharing which covering the implementation in data sharing and big data [21], [22], [23], economic and e-commerce [24], [25], [26]Identity and data management [27], [28], [29], [30], [31] and finally adoption of blockchain technology [32].

There are seven research studies from India. The Indian government used blockchain in the supply chain in government. [33], [34], [35] and aid management [36]. There are use cases in document security which use blockchain data sharing solutions in India. [37], [38] while [39] study how the government accept blockchain technology in the administration.

Estonia recorded five research which is the same as United Arab Emirates (UAE). These countries are focusing on big data and data sharing. [40], [41], blockchain Infrastructure for data sharing [42], [43], [44] and service delivery involving Austria and Australia [45], Utility [46], and services on disaster recovery and real estate [47], [48].

Germany and the Netherlands recorded four studies each. Blockchain is used for monitoring the transparency of the transaction data sharing for agriculture [49], [50], automotive [51], economy [52] and document management and data sharing [8], [41], [53], [54].

The United States (US), United Kingdom (UK), and Nigeria have three research projects in their country. The three countries have data sharing in government healthcare. [44], [55], [56], [57], verification of higher education certificates [58], [59], [60], and identity management [61]. Two studies in the UK are about governance and policy. [62], [63] and property valuation [60].

Malaysia currently has two studies on government data sharing based on blockchain, which is the same as Australia, Finland and Sweden. For the Malaysian case study, blockchain-based data sharing is used for transparency in government aid management. [64] and the adoption in a government agency [15]. Australia is more focused on data sharing for service

delivery and smart cities. [45], [65] while Finland studies are recorded as being for ID Management and Economy [40], [66]. In Sweden, studies in this area focus on valued focus thinking [57] and document security [67].

Fig. 6. Blockchain-based data sharing in e-government research heatmap.

22 counties have recorded one publication on data sharing using blockchain. Asian countries like Japan, Vietnam, and Thailand focused on improving data sharing security and trust for decision making in the government system using blockchain. [57], while the publications of Iceland, Indonesia, and South Korea focused on identity security in data sharing [40], [68], [69]. Pakistan and Afghanistan used blockchain in data sharing to secure verification of certification. [14], [70]. Russia and France focused on securing the voting system. [71] While Portugal is securing the data sharing procurement process [72]. On governance, Italy used blockchain in data sharing to comply with the Timber Regulation [73]. Denmark implements a blockchain to secure data sharing in tax management[74]. Iran is using blockchain in cybersecurity [75], Kuwait studies on IoT data sharing [76], and studies in Iraq are using blockchain technology in healthcare [77].

D. Blockchain-Based Data Sharing Security Factors in e-government Systems

The security factors are critical aspects in achieving goals in blockchain-based secure data sharing. The security factors involved are extracted from all four approaches in the 103 articles. 77 factors from the articles are structured and present in the word cloud in Fig. 7 and Table IV. This will answer RQ 3 – What are the security factors for blockchain technology used in enhancing the security of data sharing in e-government systems?

This word cloud in Fig. 7 highlights key attributes and factors of data sharing using blockchain technology, emphasising its potential to transform systems based on trust, transparency, and security. The most highlighted security factors are transparency, privacy and integrity, which underscore blockchain's ability to protect sensitive data while ensuring the security processes. The prominent factors of trust, decentralisation, and reliability that reflect blockchain's capacity to eliminate intermediaries, build confidence, and provide reliable systems are also recognised as important factors involved in data sharing security.

The main blockchain concepts, such as immutability and traceability, showcase the technology's ability to ensure data accuracy, prevent tampering, and enable detailed tracking of transactions or assets. In addition, interoperability and scalability factors highlight its adaptability and capacity to handle increasing demand across various systems. In the context of e-government, these attributes align perfectly with the need for secure, efficient, and transparent data-sharing mechanisms, fostering trust between governments and citizens while enhancing operational efficiency.

Fig. 7. Word cloud of security factors.

Based on the literature review, 54 characteristics of security factors components have been extracted from 103 articles. The characteristics are based on the NIST Information Security framework, the blockchain security factors and e-government security factors. For the confidentiality factors, Trust between parties, Ensuring Privacy, Data confidentiality, Data ownership, authentication and authorize, secure access control, Identity Security Management and Data sovereignty have been identified in the articles as contributors to the factors.

The integrity factors are the most security factors discussed in blockchain for data sharing, where the subfactors are ensuring or protecting data integrity, single source of truth, trustworthiness of data, verifying authenticity, accuracy and specific, providing validation, reducing fraud, enhancing trust, enhancing accountability, authenticity and reliability of data.

The security factors of using blockchain for data sharing are shown in Fig. 8. The trend shows that integrity recorded 37 articles and is the most secure factor's goal that is achieved in applied blockchain for data sharing in e-government, followed by 33 articles on confidentiality and 27 articles on transparency. The intermediate security factors that attract researchers' attention are 18 articles on interoperability, immutability with 15 articles, auditability with ten articles and decentralize and compliance recorded nine articles for each factor. Availability and Scalability are less focused security factors recorded in six articles and two articles, respectively. Different focus on the security factors shows that priority needs to be established for the factor in securing data sharing using blockchain. The findings reflect the evolving landscape of blockchain security priorities, aligning with the specific needs and challenges of e-government implementations for data sharing.

TABLE IV. INITIAL ALIGNMENT FACTORS FOR BLOCKCHAIN-BASED DATA SHARING SECURITY FACTORS IN E-GOVERNMENT SYSTEMS

Security Factors	Characteristics	Source
Confidentiality	i. Trust between parties, ii. Ensuring Privacy, iii. Data confidentiality, iv. Data ownership, v. Authenticates, vi. Authorize, vii. Secure access control, viii. Identity Security Management, ix. Data sovereignty	[6], [25], [26], [27], [30], [31], [32], [34], [39], [40], [44], [45], [49], [50], [65], [70], [74], [78], [79], [80], [81], [82], [83], [84], [85], [86], [87], [88], [89], [90], [91], [92]
Integrity	i. Ensuring data Integrity, ii. Protect data Integrity, ii. Single source of truth, iii. Trustworthiness of data, iv. Verify authenticity, v. Accuracy, vi. Providing validation, vii. Reduce fraud, viii. Enhancing trust, ix. Enhanced accountability, x. Authenticity, xi. Reliability source xii. Reliability data, xiii. Specificity	[14], [15], [29], [35], [37], [38], [39], [40], [53], [54], [58], [61], [65], [71], [72], [76], [77], [81], [83], [84], [93], [94], [95], [96], [97], [98], [99], [100], [101], [102], [103], [104], [105], [106], [107], [108]
Availability	i. Enhanced information-sharing across organizations, ii. Make data available, iii. Usability data, iv. Applicability	[24], [56], [80], [83]
Decentralized	i. Enabling distributed power, ii. Decentralisation of property rights, iii. Large-scale data management	[8], [31], [68], [78], [80], [95], [109]
Immutability	i. Reduce the need for trusted third parties, ii. Data protection iii. Tamper-proof record, iv. Resistance to attacks, v. Isolate data vi. block data, vii. Non-temperable	[8], [15], [21], [30], [42], [44], [50], [59], [61], [71], [75], [110], [111], [112], [113]
Transparency	i. Greater transparency, ii. Seamless data sharing among parties, iii. Eliminating intermediaries, iv. Secure transactions, v. Openness of data	[7], [15], [16], [24], [28], [35], [36], [41], [43], [48], [50], [61], [63], [64], [66], [69], [71], [72], [84], [86], [89], [98], [99], [101], [114], [115], [116]
Interoperability	i. Integration data, ii. Harmonise process, iii. Standardisation Integration, iv. Collaboration	[6], [16], [23], [51], [53], [61], [67], [69], [72], [74], [80], [90], [96], [104], [109], [117], [118]
Auditability	i. Transaction can be tracked, ii. Transaction is permanent, iii. Traceability transaction	[8], [31], [32], [50], [63], [73], [80], [88], [112], [113]
Governance	i. Policy, ii. Regulation, iii. Uniformity protocols, iv. Security controls, v. Compliance	[39], [46], [49], [51], [61], [73], [88], [91], [119]

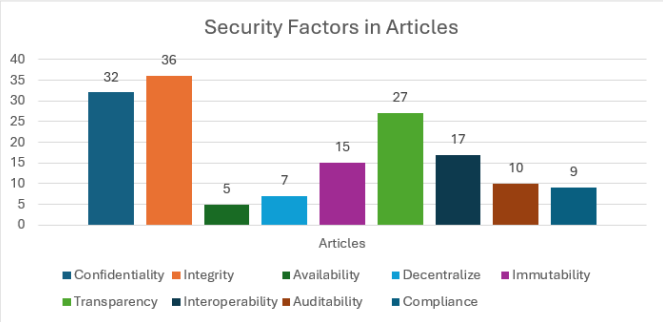

Fig. 8. Security factors.

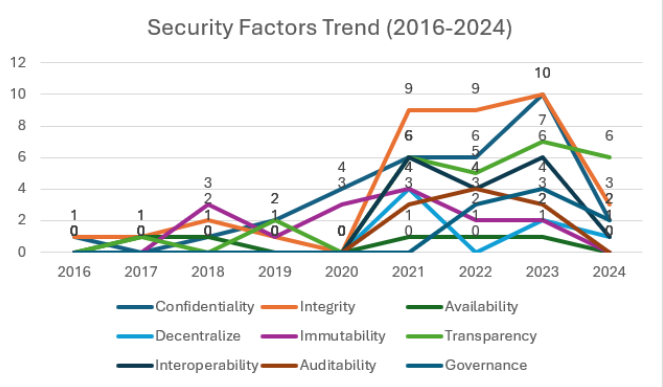

Fig. 9. Security factors trend by year.

The trend in Fig. 9 shows that confidentiality, integrity, transparency, interoperability and compliance factors are trending for the use of blockchain in data sharing security. Integrity factors show the highest trend for three years from 2021 to 2023, followed by confidentiality and transparency. The scalability, availability, immutability, decentralize and show a downtrend while auditability consistently got attention as a security factor that needs to be concentrated on. Based on the pattern, these trends demonstrate the evolving security priorities in blockchain-based data sharing, shaped by emerging challenges and the needs of technological advancements in providing secure data sharing in the domain.

1) Confidentiality: Confidentiality is one of the most important factors that focuses on the government securing data using blockchain technology. Confidentiality concerns can limit the willingness of organisations to share data, as they must ensure data is protected from unauthorised access [120]. Implementing robust confidentiality measures can facilitate data sharing by building trust among stakeholders and ensuring compliance with privacy regulations [120], [121].

2) Availability: In public service, data availability is enhanced through the aggregation of data from various departments into a unified resource catalogue, which supports efficient sharing [122]. The availability of a comprehensive data catalogue allows for better management and sharing of power data, meeting external sharing needs. Public policy plays a dual role as both an enabler and a barrier to data sharing. Contradictions in data availability can arise from legal structures that either facilitate or hinder data linking and sharing, impacting the potential of healthcare data [56].

3) Integrity: Integrity is maintained through rigorous transaction verification processes. Data storage and access transactions involve multiple steps of encryption and signature verification to ensure that data has not been tampered with during transmission [123]. On the other hand, different random parameters are used in generating secret keys, ensuring that data integrity is not compromised by colluding parties [124].

4) Decentralised: Other blockchain technologies' important features for data security are the decentralised factor. Transactions are distributed across the peer-to-peer network

(P2P) by the node and storing the transaction back in the node across the members' network [13]. The distributed ledgers in blockchains are securely synced using a P2P approach, and consensus is made based on smart contracts for the newly added data. Author [125] reported that it is harder to control and alter the data in the distributed network of blockchain because of the consensus built into the technology. Blockchain is a decentralised and trusted authority based on consensus of nodes that take part in the network [126].

5) Immutable: Immutability in blockchain technology has enhanced data sharing security in public service. According to a study [15], immutability is referred to as a fundamental attribute of blockchain. This is one of the important security features of blockchain. Blockchain technology was established as a platform for secure digital transformation technologies in creating immutable records [59], [127].

6) Transparency: Transparency of data had the highest influence on the implementation process in blockchain-based data sharing [41]. Transparency has improved public governance by promoting visibility [7], [64], [66], and enhancing the trust and efficiency of government information sharing [28]. Extended studies to evaluate the effectiveness of blockchain in improving service delivery, transparency, and efficiency in public administration should be done and could involve case studies and comparative analyses with other regions or countries that have successfully implemented blockchain in their e-government initiatives [43].

7) Auditability: Study by [79] assists practitioners and policymakers in implementing auditability using blockchain technology effectively to ensure food safety and improve sustainability in India. Auditability is also a main focus in facilitating seamless data exchange among service providers [80].

8) Interoperability: Interoperability breaks significant barriers to seamless data exchange, often resulting in data silos where information is isolated and difficult to access across departments. The inefficiencies caused by these silos lead to redundant data collection efforts, increased operational costs, and delayed decision-making processes. Furthermore, the group of authors agreed that the absence of standardised data sharing frameworks exacerbates the complexity of managing and integrating data from multiple sources, making it challenging for the public sector to allow consistent and coherent public services [96], [105], [109], [117].

9) Governance: The authors [46] and [75] highlighted the role of blockchain in enhancing compliance, particularly in securing data access, protecting data privacy, and ensuring adherence to GDPR. Similarly, [67] demonstrates that blockchain-based e-archive systems improve the management of government information while maintaining compliance with the Public Sector Information (PSI) law. In contrast, [73] finds that the implementation of the European Timber Regulation (EUTR) remains complex, as it has not fully resolved longstanding challenges, thereby limiting traceability in the wood-energy sector. Furthermore, the introduction of new regulatory frameworks, such as the EU's Carbon Border Adjustment Mechanism (CBAM), has imposed additional responsibilities on government authorities to standardise compliance measures [52].

While blockchain technology holds significant promise for enhancing regulatory compliance, particularly in data management and privacy protection, it also comes with issues that need to be answered. The tension between blockchain's capabilities and existing legal frameworks, such as the GDPR [42], [61], highlights the need for ongoing dialogue and innovation to ensure that blockchain can be effectively integrated into regulatory environments. As new regulatory frameworks emerge, the role of blockchain in standardising compliance measures will continue to evolve, necessitating careful consideration of both technological and legal developments [79].

V. Discussion

A. Implications for E-Government Systems

Security concerns are a critical challenge in current data-sharing practices within e-government systems. With the increasing digitisation of government services, the volume of sensitive and personal data being shared across platforms has grown exponentially. This makes e-government systems prime targets for cyberattacks, data breaches, and unauthorised access. Traditional data-sharing methods often rely on centralised databases, which are vulnerable to hacking and can present a single point of failure. Once compromised, these databases can lead to the widespread leakage of sensitive information, undermining public trust in government services. Additionally, the lack of robust encryption and authentication mechanisms in many e-government systems leaves data vulnerable during transmission, further increasing the unauthorised access and interception risk.

Moreover, lack of transparency and accountability in current data-sharing practices limits public trust in e-government systems. Citizens often have little visibility into how their data is being used, shared, or stored by government agencies. This opacity can lead to concerns about data misuse, unauthorised sharing, or surveillance, which erodes confidence in digital government services. Additionally, when data-sharing processes are not transparent, the accuracy and integrity of the shared information are harder to verify, leading to potential errors or misinformation. This highlights the need for more transparent and accountable data-sharing mechanisms that can provide clear audit trails, ensure data integrity, and give citizens greater control and insight into how their data is handled.

In light of these challenges, there is a pressing need for more secure and efficient data-sharing solutions within e-government systems. Blockchain technology offers a promising avenue to address these limitations by offering a transparent, decentralised and secure platform for data sharing. By leveraging blockchain’s capabilities, e-government systems can overcome the challenges of data fragmentation, improve security, confirm fulfilment with privacy law, and improve public confidence in digital government services.

B. Theoretical Contributions

The result provides some tentative initial evidence to the literature on information security, blockchain security and e-government systems for data sharing. The study explored security factors involving blockchain in information security and e-government systems for data sharing. This has contributed to theoretical support in the field, supported by the findings.

Based on the systematic review conducted, nine theories of blockchain-based data sharing security factors are identified: confidentiality, integrity, availability, transparency, auditability, distributed, immutability, interoperability, and compliance have to answer RQ 3. With this brief description, the review also presents issues and solutions to various industries as an understanding of blockchain's ability to overcome constraints. Therefore, we show that blockchain technology is not limited to any industry that wants to implement cryptocurrency into its systems.

This new understanding should help to improve predictions of the impact of data sharing security factors that are involved in blockchain-based data sharing systems. Second, the study identifies the item under the factors in the literature that have a direct impact on securing data sharing. Thirdly, the conceptual framework has been developed as a reference in data sharing security using blockchain in e-government. Lastly, the research contributes to the body of knowledge on secure data sharing by investigating its use in the e-government domain.

Consequently, data sharing security factors and data security compliance are significant factors determining the causal effect of secure data sharing using blockchain technology. Previous research has shown that among way to assess the security of information systems is the development of a rating score using goal question metrics, which has specifically developed an instrument tool for cloud security [128], [129]. The author also presented how a security framework can be evaluated and applied in a real case scenario using the said approach.

C. Comparison with Existing Reviews

The landscape shows that blockchain has been widely accepted in improving the security of data sharing for the e-government system. The governance with legal requirements can be explored further towards the government data sharing policy for the e-government system. The research findings of [15] provide information on the adoption factors of blockchain based on the technology, organisation, and environment of the TOE methodology with added trust factors. With its key security factors of decentralisation, persistence, anonymity, and auditability, the author highlights how blockchain can transform security in conventional businesses. This research found that trust is the subfactor under confidentiality, while decentralize and auditability are the security factors in the findings. This research result also shows that persistency and anonymity are not in the security factors list in the literature for blockchain security.

Blockchain technology is also suitable to be applied across multiple e-government services. According to [130], blockchain is suitable for securing majority system purposes, including securing supply chains, managing records, amusement, and government. The five categories mentioned as confidential, trust, traceability, efficiency, and reliability are the features of blockchain applications proposed should also be categorized. This research uses various sources of information, including security reports and government policy, to give wider views of security factors in data sharing using blockchain, while the other authors only used journal articles for the review that which lack information from external sources and additional insights from industry information.

Blockchain technology offers promising opportunities for enhancing records and library operations, and its adoption is still in the nascent stages, where several challenges need to be addressed. Prior studies by [130] have noted the importance of blockchain challenges in libraries, which include technological barriers, financial constraints, legal and regulatory issues and social acceptance and awareness. Many scholars are of the view that the lack of empirical evidence and the need for highly qualified security personnel, financial resources, and regulatory compliance are significant barriers [23], [53], [69], [116], which supports the finding in this literature.

This study also discovered that the industry adopts blockchain because the technology behind it promises secure transactions, where the industry processes a huge amount of data to implement transparent storage through private transactions. This type of classification is expected to increase significantly, and it also remains a concern for various sectors in the long term because privacy and security are key aspects of establishing a decentralised transaction relationship with the industry. In contradiction of compliance factors, not all design principles were fully met, particularly regarding data access security and compliance with GDPR [74].

VI. Conclusion

This study found the invention taxonomy in blockchain research for the last 10 years. The most obvious finding that emerges from the analysis is that blockchain is a world-shattering technology that expressively transforms the way that e-government systems deliver a secure and trusted service. The significance of blockchain in the advancement and enhancement of data sharing security in e-government is provided. The recent analysis of the trend of security factors for data sharing was provided for the implementation of blockchain technology.

This review also shows the important discovery of secure data sharing using blockchain with various applications including securing supply chains, transportation, agriculture, healthcare and government administration. There are still opportunities for government agencies to apply or integrate blockchain technology to improve data security for their organisation. One unexpected finding was the extent to which trust and privacy the important factors in deploying the blockchain in e-government systems.

The most important finding is that data sharing security factors using blockchain can be classified into nine factors based on their application: confidentiality, integrity, availability, transparency, auditability, distributed, immutability, interoperability and governance. The most in-demand feature in blockchain applications is privacy enhancement, and the review of use cases presented.

These results have important implications for the development of blockchain as a platform to enhance data sharing security in government applications and innovations. The security factors involved in data sharing for e-government in the current research show that it persists with a significant impact in enhancing data security that is needed by the domain. This study focuses on the security factors for blockchain-based data sharing. The study did not cover the review for blockchain platform, architecture, consensus type and performance.

In the future, this study will lead to the development of a framework that covers the principles of data security, blockchain security and compliance. It also concludes that data sharing security could also significantly contribute towards the open data initiative. The understanding gained here should help to implement blockchain-based secured data sharing and increase trust in the e-government system.

Enhancing Firefighter PPE Compliance Through Deep Learning and Computer Vision

Asmaa Alayed, Razan Talal Alqurashi, Samah Hamoud Alhelali, Asrar Yousef Khadawurdi, Bashayer Fayez Khan
College of Computing, Umm Al-Qura University, Makkah, Saudi Arabia

***Abstract*—Ensuring firefighter safety in high-risk environments requires strict adherence to Personal Protective Equipment (PPE) protocols. This study presents an automated real-time detection system for PPE using deep learning and computer vision techniques, aiming to improve PPE compliance and overall safety monitoring. The research employs advanced object detection models, specifically YOLOv10 and YOLOv11 (You Only Look Once), to identify critical PPE components such as helmets, gloves, boots, and self-contained breathing apparatus (SCBA) units. A custom-annotated dataset of firefighter images was developed to train and evaluate both models using standard performance metrics such as precision, recall, mAP, F1-score, and Intersection over Union (IoU). The results show that YOLOv11 outperformed YOLOv10, achieving a higher mAP@0.5 score of 0.646 compared to 0.586, with improved detection of small and partially occluded objects and a reduction in training time by 11%. YOLOv11 showed improved detection accuracy for small and partially blocked objects and reduced training time by 11%, while maintaining real-time efficiency. The system generates instant alerts when PPE is missing, minimizing reliance on manual monitoring and improving situational awareness in real-time. This research reinforces the role of AI in public safety and AI-powered automation in enhancing critical public safety operations. By integrating deep learning and computer vision into PPE monitoring systems, the study contributes to developing intelligent, responsive solutions aligned with modern safety standards.**

Keywords*—*Firefighter safety; Personal Protective Equipment (PPE) Object detection; YOLOv10; YOLOv11; deep learning; computer vision; real-time detection; PPE compliance; AI in public safety

I. Introduction

Firefighting is a highly demanding and dangerous profession where the safety of personnel relies heavily on their ability to wear all necessary personal protective equipment (PPE) correctly. Essential equipment such as helmets, gloves, fire-resistant clothing, boots, and self-contained breathing apparatus (SCBA) shields firefighters from extreme heat, toxic gases, falling debris, and hazardous environments. Ensuring that this gear is worn properly is not only a matter of regulation but also a life-saving necessity.

However, during emergency responses, ensuring complete PPE compliance becomes difficult due to high-pressure conditions, time constraints, and human error. Manual checks are often rushed or incomplete, exposing firefighters to avoidable risks. Although safety standards exist in Saudi Arabia under the General Directorate of Civil Defense [1], ensuring real-time PPE compliance remains a challenge—especially before deployment into active zones.

Recent advances in artificial intelligence and computer vision have created new opportunities for enhancing safety protocols in the firefighting domain. Deep learning models—particularly object detection algorithms like YOLO—have shown impressive real-time performance in detecting and classifying objects across various sectors, including medical applications [2], construction [3], [4], and public safety systems [5]. These technologies offer a promising solution for automatically verifying the presence of PPE using image or video input prior to emergency deployment. This approach reduces reliance on manual inspection, increases accuracy, and enables faster decision-making in critical moments.

Despite existing research in PPE detection across various fields such as construction and industry, a significant research gap remains in applying AI-based systems to the firefighting sector—especially in Saudi Arabia. Most current solutions are limited to laboratory settings or narrow use cases, often lacking generalizability to real-world firefighting scenarios or focusing on only certain PPE components.

To address this gap, this paper presents an AI-driven solution specifically designed for firefighting services in Saudi Arabia. Leveraging YOLOv10 and YOLOv11 models, the system detects missing PPE components from real-time visual inputs, thereby enhancing emergency preparedness and reducing the risk of injury. This work offers a novel application of deep learning in the public safety domain by providing a practical, real-time solution for monitoring PPE compliance.

The remainder of this paper is organized as follows: Section II reviews recent developments in PPE detection using deep learning. Section III describes the data collection process and research methodology. Section IV presents the experimental results and performance evaluation. Section V provides a discussion of the findings, including a comparison with other models across various domains. Finally, Section VI concludes the study and outlines directions for future work.

II. Literature Review

Deep learning has demonstrated strong potential for automating PPE compliance monitoring in high-risk environments such as firefighting, construction, and industrial operations. These techniques aim to minimize human error by enabling real-time visual detection of safety equipment. In the firefighting domain, Sesis et al. [6] applied YOLOv5 with a custom, domain-specific dataset to detect four key PPE components including helmets, gloves, masks, and insulated

protective clothing. By using transfer learning, they achieved high detection accuracy, highlighting the model's suitability for emergency response scenarios.

Delhi et al. [3] applied YOLOv3 to construction sites, achieving 96% precision and recall in detecting hard hats and jackets, demonstrating its effectiveness in active work environments. Similarly, Isailovic et al. [7] benchmarked YOLOv5, MobileNetV2-SSD, and Faster R-CNN for detecting head-mounted PPE using a diverse dataset, where YOLOv5 achieved the best results. Wang et al. [4] introduced a real-world construction site dataset (CHV) and compared various YOLO models, showing YOLOv5x had the highest mAP (86.55%), while YOLOv5s demonstrated the fastest inference speed—highlighting the trade-off between accuracy and efficiency. In industrial settings, Chen and Demachi [5] combined OpenPose with YOLOv3 to monitor PPE at the Fukushima nuclear station, achieving high precision and recall for helmets and masks. In healthcare, Loey et al. [2] used YOLOv2 with ResNet-50 to detect medical masks, further illustrating the role of deep learning in public safety applications.

While previous studies demonstrate the potential of deep learning in PPE detection, they are largely confined to controlled or domain-specific environments. Therefore, this study seeks to extend his body of work and build upon these foundations by developing a real-time, AI-powered PPE compliance monitoring system specifically tailored to the operational needs of firefighters in Saudi Arabia. Comparison of studies is given in Table I.

TABLE I. COMPARISON OF STUDIES ON PPE DETECTION USING DEEP LEARNING MODELS

Study	Research Title	Focus	Algorithm	Performance	Dataset size and type
Sesis et al. [6]	AI-based Firefighting PPE Detection using YOLOv5	Detection of four Firefighting PPE (helmet, gloves, mask, and insulated protective clothing)	YOLOv5 with transfer learning	mAP@0.5 = 0.834, Precision = 0.914, Recall = 0.735	Custom dataset (342 samples), tailored to firefighting scenarios.
Delhi et al. [3]	Detection of PPE Compliance on Construction Sites Using YOLOv3	Construction site PPE (hard hats, jackets)	YOLOv3, transfer learning	Precision and recall: 96%	Self-collected dataset from video feeds, 2,509 images
Isailovic et al. [7]	The Compliance of Head-mounted Industrial PPE using Deep Learning Object Detectors	Industrial PPE, head-mounted	YOLOv5, MobileNetV2-SSD, Faster R-CNN	YOLOv5 achieved best precision (0.920), recall (0.611)	Public dataset (Roboflow, Pictor PPE), 12,682 images
Wang et al. [4]	Fast PPE Detection for Real Construction Sites Using Deep Learning Approaches	Construction site PPE (helmets, vests)	YOLOv5x (best mAP), YOLOv5s (fastest speed, 52 FPS)	YOLOv5x mAP: 86.55%, faster with YOLOv5s	Public dataset (CHV), 1,330 images, real construction site

III. DATA COLLECTION AND RESEARCH METHOD

A. Dataset Collection

High-quality image data is essential for effectively training deep learning models in firefighter PPE detection. Since no publicly available datasets met the specific requirements for detecting firefighter PPE in operational scenarios, we constructed a custom dataset tailored to this task. The initial internal dataset we collected exhibited limited variability and contained redundant samples, although the image clarity and framing were sufficient. To enhance diversity and address these limitations, we manually collected an additional 574 images from the official social media channels of the Saudi Civil Defense and other publicly available resources. All selected images adhered to the standards defined in the official firefighter PPE guidelines [1], ensuring accurate representation of required equipment.

The final dataset captures firefighters from varied angles, distances, and operational contexts to provide a broad visual representation of real-world scenarios. Further expansion of the dataset is planned to improve representation of diverse environmental conditions—particularly in low-light, crowded, or partially obstructed situations—to enhance the model's generalizability and robustness in real-world deployments.

B. Dataset Annotation

To enable accurate detection of PPE, all images in the constructed dataset were manually annotated by our team using bounding boxes to identify five critical equipment components: boots, fire suit, gloves, helmet, and SCBA. We used the Roboflow platform [8] to facilitate efficient and consistent annotation. Each bounding box precisely localized the corresponding PPE item within the image, allowing the model to recognize multiple equipment types simultaneously. Many images featured multiple equipment components, enabling the model to distinguish between them effectively. This annotated dataset provides a reliable foundation for training and evaluating detection models, ultimately supporting improved firefighter safety and system performance.

Representative annotation scenarios include a fully equipped firefighter (Fig. 1), absence of the SCBA (Fig. 2), and absence of both the SCBA and gloves (Fig. 3). These examples demonstrate the system's capacity to identify compliance gaps prior to deployment, thereby reducing risk and enhancing real-time situational awareness.

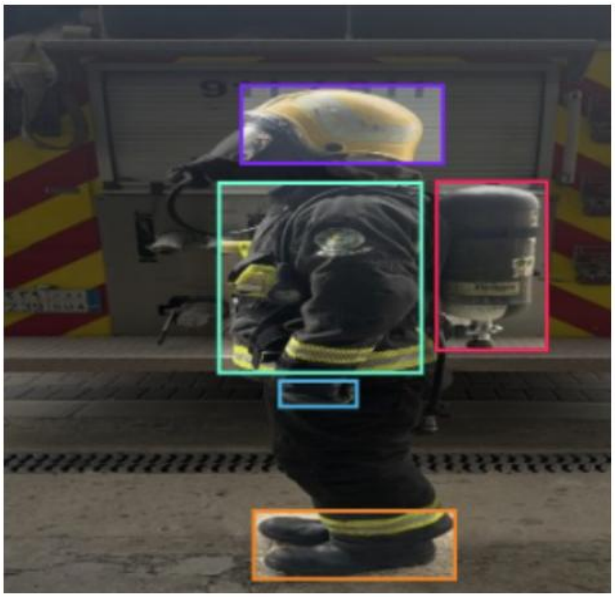

Fig. 1. A firefighter fully equipped with all necessary gear.

Fig. 2. A case of the absence of the SCBA.

Fig. 3. A case of the absence of the SCBA and gloves.

C. Dataset Augmentation

In object detection tasks, dataset quality and class balance are critical to model performance. Class imbalance—where certain PPE components are underrepresented—can lead to biased predictions. To address this, we employed data augmentation techniques to expand the dataset and mitigate class imbalance. We experimented with both generic and class-specific augmentation strategies to improve class distribution and data diversity. Despite these efforts, achieving perfect balance was challenging due to the inherent nature of the collected data. Class distributions for each dataset split are summarized below:

- Training Split: 465 images, 2,124 total objects
  - Boots: 314 (14.8%)
  - Fire Suit: 415 (19.5%)
  - Gloves: 283 (13.3%)
  - Helmet: 700 (33.0%)
  - SCBA: 412 (19.4%)
- Validation Split: 53 images, 250 total objects
  - Boots: 39 (15.6%)
  - Fire Suit: 48 (19.2%)
  - Gloves: 34 (13.6%)
  - Helmet: 79 (31.6%)
  - SCBA: 50 (20.0%)
- Test Split: 56 images, 283 total objects
  - Boots: 37 (13.1%)
  - Fire Suit: 59 (20.8%)
  - Gloves: 34 (12.0%)
  - Helmet: 91 (32.2%)
  - SCBA: 62 (21.9%)

Our augmentation pipeline improved data balance and diversity while maintaining high-quality, realistic examples. This enhanced the model's ability to generalize and detect all PPE components reliably across different scenarios.

D. YOLO Algorithms

Deep learning approaches in computer vision have yielded highly promising results across various applications. Among these, the YOLO algorithm has emerged as one of the most efficient and accurate methods for real-time object detection tasks, particularly in critical environments such as emergency response and industrial safety scenarios. YOLO operates by dividing an input image into a grid and performing detection in a single forward pass through a neural network. This design enables it to balance speed and accuracy, making it well-suited for real-time PPE inspection tasks.

YOLO has undergone several iterations over the years, with each version introducing architectural improvements that enhance performance. This study focuses on two of the latest versions—YOLOv10 and YOLOv11—selected for their advanced detection performance, computational efficiency, and applicability to safety-critical tasks [9], [10]. YOLOv10 is a recent advancement in the YOLO series, engineered to deliver high-speed detection with strong accuracy. The model is structured into three major components: a backbone network for feature extraction, a neck for generating multi-scale feature maps, and a detection head for object classification and localization. The architecture includes multiple variants designed to provide a flexible trade-off between inference speed and detection precision. In this research, YOLOv10 was adopted for its capability to reliably detect firefighting PPE—including helmets, gloves, boots, protective suits, and SCBA devices—in real-time. Additionally, transfer learning and data augmentation techniques were employed during training to improve robustness across various environmental conditions [9].

YOLOv11 represents the latest iteration in the YOLO family, incorporating state-of-the-art enhancements in feature extraction, model optimization, and real-time inference. Like its predecessor, YOLOv11 features a backbone, neck, and detection head; however, it introduces a more refined architecture with improved module design to achieve higher mAP while maintaining low latency. The model was selected in this study for its superior balance of accuracy and computational efficiency. YOLOv11 proved particularly effective in detecting multiple PPE components across a range of visual conditions, including occlusion, variable lighting, and different camera angles. These capabilities ensure reliable performance in operational environments where rapid and precise safety inspections are essential [10].

E. Training Methodology

The YOLOv10 and YOLOv11 models were trained using a custom pipeline designed to address class imbalance and enhance detection performance. Class weights were incorporated into the training configuration to ensure underrepresented categories like boots and gloves received higher attention. The training utilized the AdamW optimizer with a weight decay of 0.0005 and was conducted over 200 epochs with a batch size of 16.

A Cosine Learning Rate Scheduler was employed, starting at 0.001 and decaying to 0.000001, with a 15-epoch warmup phase. Data augmentation techniques such as Mosaic, Mixup, Copy-Paste, and geometric/colour transformations were applied to increase data diversity. Additionally, dropout (0.25) was used for regularization. To enhance accuracy and efficiency, strategies like multi-scale training, test-time augmentation (TTA), automatic mixed precision (AMP), and half-precision training were integrated. Early stopping was triggered after 150 epochs without validation improvement, and all results were logged for evaluation.

F. Training Environment

Training deep learning models for object detection requires substantial computational resources, particularly for tasks involving large datasets and complex architectures like YOLOv10 and YOLOv11. In this study, model training was initially conducted using Google Colab's free-tier environment, which offers access to an NVIDIA T4 GPU with 12 GB of VRAM. While suitable for early experimentation, the limited computational capacity resulted in slower training cycles. To overcome these limitations, the training environment was upgraded to Google Colab Pro, which provides access to more advanced GPUs such as the NVIDIA V100 and A100. This upgrade significantly improved the training process, enabling faster iterations, support for larger batch sizes, and greater stability during extended sessions. The combination of free and Pro-tier resources allowed for efficient and cost-effective training, supporting iterative development and comprehensive model evaluation.

G. Evaluation Metrics

To accurately evaluate the performance of the proposed PPE detection models for firefighters, a set of fundamental object detection metrics was utilized. These metrics were chosen to reflect the model's effectiveness in identifying and classifying multiple PPE components, including small and partially obscured items such as gloves or mask straps, which are critical in firefighting environments. The core evaluation indicators include Average Precision (AP) and mAP. These values are derived by comparing the model's predictions against the actual annotated labels in the dataset. AP is calculated as the area under the precision-recall (PR) curve for a given class, whereas mAP represents the average of AP across all detected PPE categories, as shown in Eq. (1) and Eq. (2).

$$AP = \int_0^1 p(r)\, dr \tag{1}$$

$$mAP = \frac{1}{N} \sum_{i=1}^{N} AP_i \tag{2}$$

Using the prediction results, three additional classification metrics were calculated:

- Precision, which quantifies the ratio of correctly predicted positive cases to the total predicted positives:

$$Precision = \frac{TP}{TP+FP} \tag{3}$$

- Recall, which measures the ratio of correctly predicted positives to all actual positives:

$$Recall = \frac{TP}{TP+FN} \tag{4}$$

- F1-Score, the harmonic mean of precision and recall:

$$F1 = 2 \times \frac{Precision \times Recall}{Precision + Recall} \tag{5}$$

These metrics—Eq. (3), Eq. (4), and Eq. (5)—are critical in understanding the trade-off between missing detections and generating false alarms, particularly in safety-critical scenarios such as firefighting. Furthermore, IoU was used to evaluate the spatial accuracy of predicted bounding boxes. IoU calculates the overlap between the predicted and ground-truth boxes relative to their union, as expressed in Eq. (6):

$$IoU = \frac{Area\ of\ Overlap}{Area\ of\ Union} \tag{6}$$

This metric is essential for assessing how well the model localizes PPE elements in complex visual scenes.

By leveraging this set of metrics, the evaluation framework ensures a comprehensive, balanced, and realistic analysis of model performance under the challenges posed by real-world firefighting environments.

IV. Results

A. Mean Average Precision and Model Size

YOLOv11 demonstrated a notable improvement in mAP compared to YOLOv10, making it more effective for detecting firefighter PPE in real-world conditions. Specifically, YOLOv11 achieved an mAP@0.5 of 64.6%, outperforming YOLOv10, which reached 58.6%, as shown in Fig. 4 and Fig. 5. This indicates YOLOv11's stronger ability to accurately detect PPE elements such as helmets, gloves, and SCBA gear. Additionally, despite YOLOv11 having a slightly larger architecture with 20 million parameters compared to YOLOv10's 16.5 million, its efficiency in detection accuracy justifies the additional model size, especially for safety-critical applications. YOLOv11 maintained a practical balance between model complexity and performance, which positions it as a more reliable choice for deployment in environments requiring high detection accuracy and consistency.

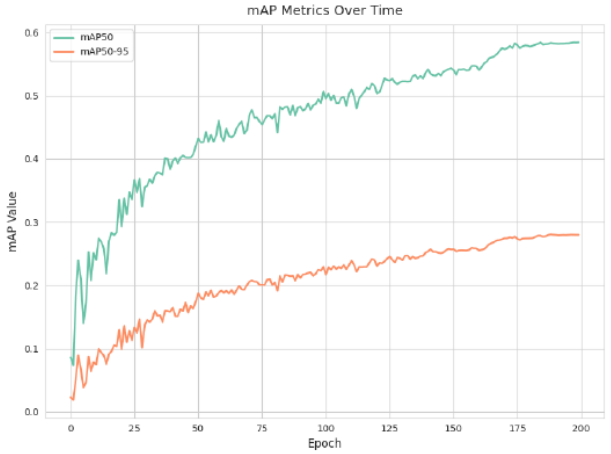

Fig. 4. YOLOv10: mAP@0.5 and mAP@0.5:0.95 over 200 training epochs.

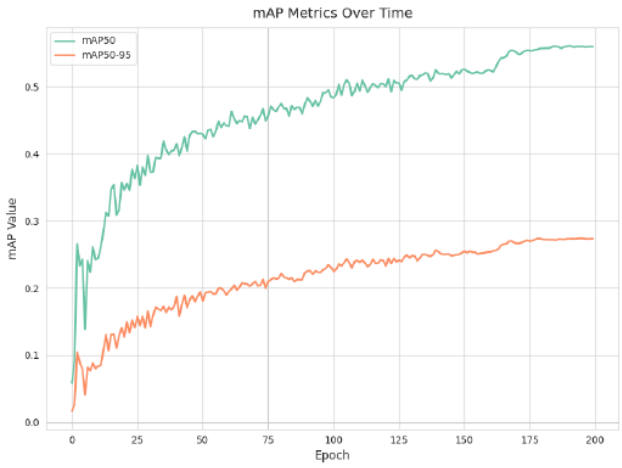

Fig. 5. YOLOv11: mAP@0.5 and mAP@0.5:0.95 over 200 training epochs.

Furthermore, YOLOv11 showed consistent improvement in detecting underrepresented PPE classes, particularly gloves and boots. This can be attributed to the refined data augmentation strategies and class-weighted training techniques, which addressed the earlier dataset imbalance. The better mAP results across all categories affirm the model's enhanced generalization ability in real-world, unstructured firefighting scenarios. YOLOv11 also demonstrated greater resilience under challenging visual conditions, such as varying lighting, partial occlusions, and dynamic backgrounds. Its performance remained stable in scenarios with overlapping gear or unconventional viewing angles, where YOLOv10 occasionally faltered. The enhanced feature extraction pipeline in YOLOv11 likely contributed to this robustness.

In practical deployment simulations, YOLOv11 also exhibited lower false negative rates, particularly in safety-critical gear detection. This reliability is crucial when monitoring firefighter readiness, as missing even one critical item (e.g., SCBA) can be life-threatening. The trade-off in model size for higher accuracy is justified in operational settings where real-time decisions depend on detection outcomes. Lastly, the precision-recall tradeoff and confidence calibration of YOLOv11 indicate that it is better suited for integration into alert systems. It provides more consistent outputs that can be used as triggers for decision-support tools or automated gatekeeping mechanisms in firefighting stations.

Collectively, these results underline that while both models are viable, YOLOv11 offers tangible advantages that support its deployment in real-world safety monitoring systems.

B. F1-Confidence, Precision-Confidence, PR Curve, and Recall-Confidence

These curves provide deeper insight into the reliability of both models across different confidence thresholds.

1) F1-Confidence: YOLOv11 consistently maintains a higher F1-score across all confidence levels. At the default threshold (0.25), it reached 0.74, compared to YOLOv10's 0.69. This indicates a better balance between precision and recall, especially in more uncertain detections.

2) Precision-Confidence: YOLOv11 sustains over 80\% precision until the threshold drops below 0.18, while YOLOv10's precision begins to degrade earlier, around 0.24. This shows YOLOv11's robustness in maintaining accuracy even with lower confidence predictions.

3) PR Curve: YOLOv11 achieved a noticeably higher area under the curve (AUC = 0.59) compared to YOLOv10 (AUC = 0.51). It maintains higher precision across a broader range of recall values, indicating more stable performance as the model tries to capture all ground truth objects, as shown in Fig. 6 and Fig. 7.

4) Recall-Confidence: YOLOv11 demonstrated higher recall values across confidence thresholds, especially for harder-to-detect classes like gloves. It achieved 0.37 recall for gloves at the 0.25 threshold, compared to YOLOv10's 0.29.

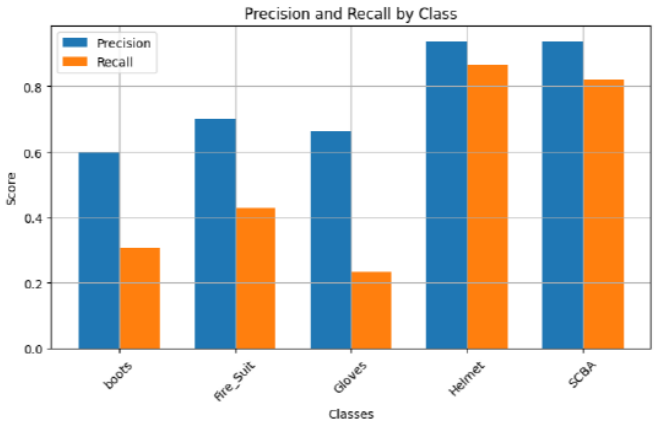

Fig. 6. YOLOv10 Precision and Recall by class.

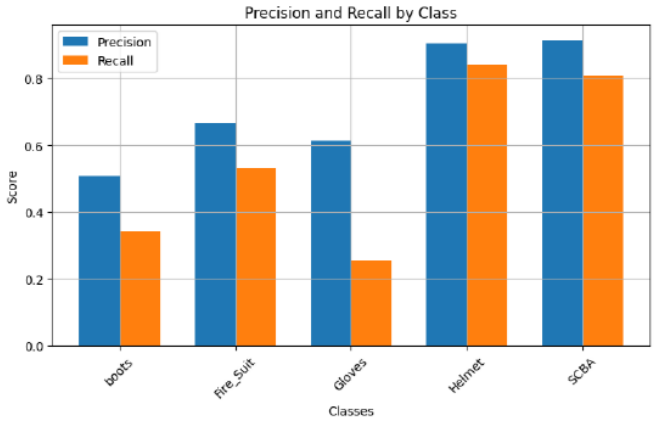

Fig. 7. YOLOv11 Precision and Recall by class.

C. IoU Performance Analysis

IoU was used to assess the spatial alignment between predicted and ground-truth bounding boxes across different PPE classes. The following breakdown highlights the performance of YOLOv10 and YOLOv11 in detecting key equipment components:

1) YOLOv10 IoU Performance:

a) Helmet: YOLOv10 achieved a mean IoU of 0.681, with 88.5% of predictions exceeding the 0.5 IoU threshold. This reflects reliable bounding box alignment for helmets, which are relatively easier to detect due to their distinct features.

b) Gloves: The mean IoU for gloves was 0.220, with only 28.1% of predictions above the 0.5 threshold. This highlights the model's struggle with accurately localizing smaller and less distinct objects like gloves.

As shown in Fig. 8, YOLOv10 demonstrated solid performance for prominent gear like helmets but had significant difficulty with smaller items such as gloves.

2) YOLOv11 IoU Performance:

a) Helmet: YOLOv11 recorded a mean IoU of 0.700, with 90% of predictions exceeding the 0.5 IoU threshold. This demonstrates improved spatial accuracy for helmet detection compared to YOLOv10.

b) Gloves: The mean IoU for gloves improved to 0.350, with better alignment accuracy. This reflects YOLOv11's enhanced capability in detecting and localizing smaller objects more precisely than YOLOv10.

Fig. 9 illustrates the improved bounding box accuracy of YOLOv11, particularly for challenging classes such as gloves, showing clear gains over its predecessor.

D. Speed

Speed is critical in real-time PPE detection systems for firefighting, where decisions must be made instantaneously. While YOLOv11 offers better accuracy, it operates slightly slower than YOLOv10, achieving 0.04 seconds per frame compared to YOLOv10's 0.033 seconds. This minor speed trade-off is acceptable given the improved detection precision and recall, which outweighs the marginal delay in processing.

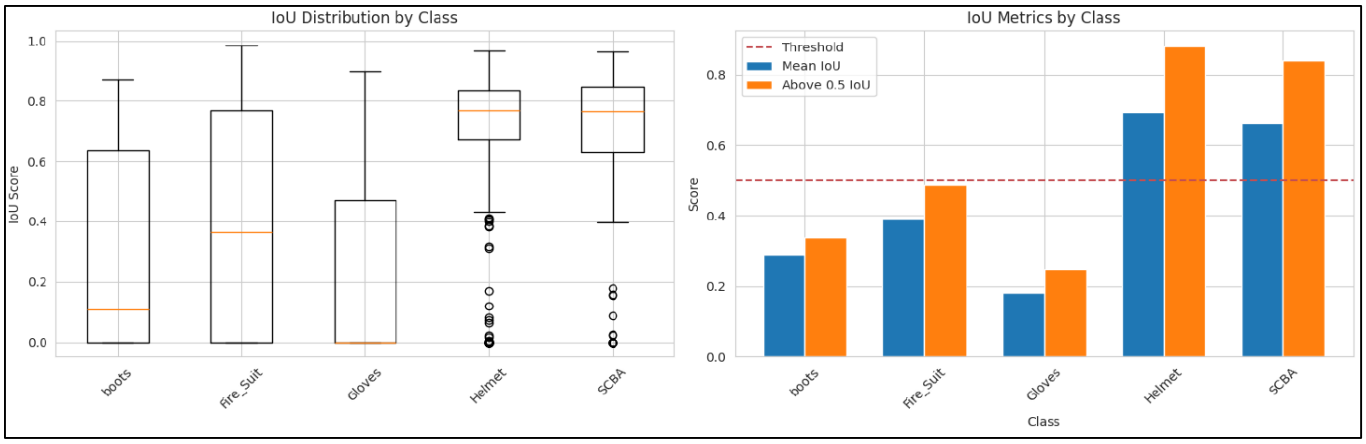

Fig. 8. IoU metrics for YOLOv10.

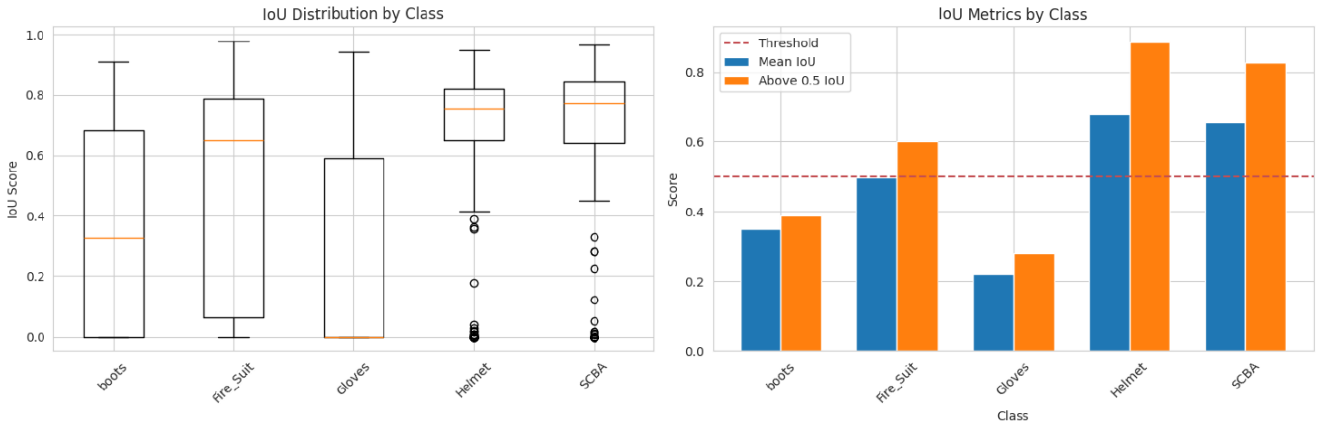

Fig. 9. IoU Metrics for YOLOv11.

V. Discussion

The results confirm that YOLOv11 significantly outperforms YOLOv10 in most evaluation metrics relevant to real-time PPE detection. This performance boost is particularly critical when working with safety-critical gear such as SCBA and gloves, which are harder to detect due to occlusion or small size. The increase in mAP, F1-score, and IoU, especially for underrepresented classes, reflects the effectiveness of class-weighted training strategies and augmentation pipelines tailored to firefighter environments. YOLOv11 also demonstrated greater consistency in handling complex backgrounds and overlapping equipment, suggesting its stronger generalization to real-world firefighting scenarios.

The detailed analysis reveals that while both models provide valuable performance, YOLOv11's architectural enhancements lead to improved detection of small and occluded PPE items. The incorporation of advanced augmentation and training strategies further boosted model robustness. However, increasing model complexity slightly impacts inference speed, a common trade-off in deep learning applications. As shown in Fig. 10 and Fig. 11, YOLOv11 was able to correctly recognize all critical equipment components, including the fire suit, gloves, boots, and helmet—demonstrating its superior reliability in safety-critical scenarios. In contrast, YOLOv10 failed to detect the fire suit, which is crucial for ensuring firefighter readiness and personal safety in hazardous conditions.

Moreover, the visual results affirm that YOLOv11 can identify all PPE components with high accuracy, making it suitable for integration into real-time alert systems or automated PPE compliance gates. This could reduce manual inspection errors and accelerate firefighter readiness verification.

Despite its slightly lower speed, YOLOv11's advantages in accuracy, localization, and class coverage outweigh the performance trade-off, making it more practical for deployment in Saudi Arabia's civil defense operations, where precision and speed are both mission-critical.

The proposed system, based on YOLOv10 and YOLOv11, is specifically optimized for image-based data in the visual modality, particularly RGB images captured in real-world firefighting environments. The models are best suited for high-resolution still images or video frames where PPE components are visible under variable lighting, motion blur, partial occlusions, or cluttered backgrounds. Due to their architecture, YOLO models excel in object detection tasks on spatial data with well-defined bounding box annotations. The system performs reliably on moderate-sized datasets (e.g., ~600–1,000 images), particularly when enhanced through data augmentation to account for class imbalance and variability in pose, angle, and context.

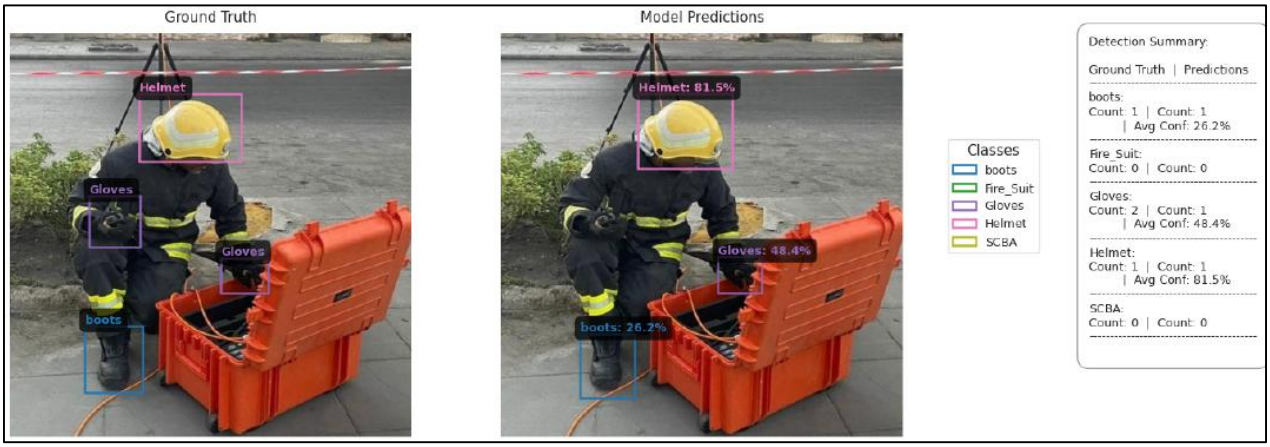

Fig. 10. YOLOv10 detection results: The fire suit was missed in the predictions.

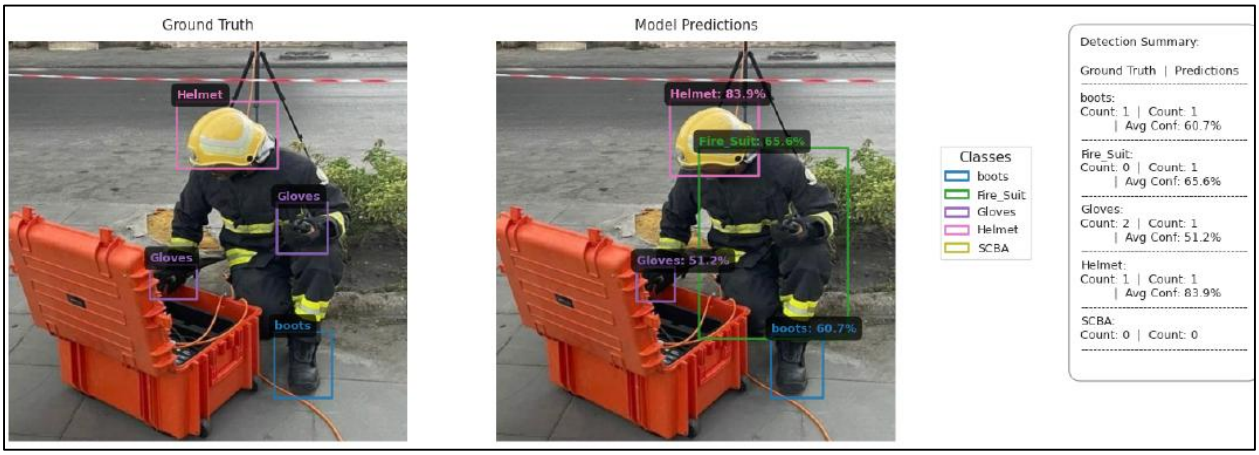

Fig. 11. YOLOv11 detection results: All PPE components including the fire suit were correctly detected.

However, the models are not directly applicable to non-visual modalities such as audio or text, and their performance may degrade with extremely low-resolution images, thermal images, or infrared unless retrained on domain-specific datasets. Additionally, performance is affected by data distribution. The model achieves its best results when trained on datasets that reflect the same environmental and cultural conditions (e.g., firefighter uniforms and gear used in Saudi Arabia) as the deployment context. This emphasizes the importance of domain-specific data for generalization and accuracy.

This study offers several key advantages over existing deep learning-based PPE detection models across construction, industrial, and healthcare domains:

1) Domain-specific adaptation to firefighting scenarios: Unlike previous research primarily focused on industrial or construction environments [3][4][7], the current work is specifically tailored to the unique challenges of firefighting, including variable lighting, smoke, occlusions, and high-stress environments. The model was trained on a custom dataset collected from real-world footage of Saudi Civil Defense operations, offering higher ecological validity than laboratory-based datasets.

2) Comprehensive multi-class PPE detection: Prior studies often target a limited subset of PPE items—typically one to four items, such as helmets or vests [4], [5], [6]. In contrast, our model simultaneously detects five critical PPE components: helmet, fire suit, gloves, boots, and SCBA. This multi-label detection approach ensures full compliance verification and strengthens overall situationalreadiness.

3) Improved detection for small and occluded items: YOLOv11 achieved significantly higher mAP, F1-score, and IoU, especially for underrepresented and smaller items like gloves and SCBA units, compared to YOLOv10 and prior benchmarks such as MobileNetV2-SSD and Faster R-CNN [7]. Our class-weighted training and targeted augmentation pipeline led to a 59% improvement in glove recall over YOLOv10.

4) Real-time monitoring capability with alert integration: While existing models may offer high accuracy, many lack real-time alerting or decision-support integration. Our proposed solution maintains an inference speed under 0.04 seconds per frame, enabling real-time detection and compatibility with automated gatekeeping or alarm systems at fire stations.

5) Environmental hazard awareness and long-term safety enhancements: Beyond immediate PPE detection, this study acknowledges long-term firefighter health risks, including exposure to harmful substances like PFAS (per- and polyfluoroalkyl substances), which are associated with cancer and immune system disorders. Our future vision includes integrating environmental hazard awareness to create a more holistic safety system that enhances both short-term operations and long-term health outcomes.

6) First deployment-ready system for Saudi civil defense: This work constitutes the first firefighter-specific PPE compliance monitoring system designed for potential deployment within Saudi Arabia. It establishes a foundation for future research and development in regional safety automation and may serve as a replicable framework for other high-risk sectors.

VI. Conclusion and Future Work

This study represents a notable advancement in enhancing firefighter safety by developing an AI-based system for PPE compliance. As the first implementation of its kind in Saudi Arabia, the proposed model integrates deep learning techniques with real-time computer vision to detect missing or improperly worn protective gear with high precision. This capability enables timely intervention in hazardous environments, potentially preventing serious injuries or fatalities.

By leveraging advanced YOLO architectures trained on a domain-specific dataset, the system demonstrates robust performance and reliability, setting a new benchmark for automated safety enforcement in high-risk operational contexts. The findings underscore the feasibility and effectiveness of applying artificial intelligence to critical occupational safety challenges, particularly in sectors where real-time monitoring and rapid decision-making are essential.

Beyond its technical contributions, this research illustrates the broader implications of AI-driven automation in promoting safer work environments. It highlights how intelligent systems

can augment human oversight and institutional safety protocols, contributing to a more proactive and data-informed approach to risk management. As such, the study provides a foundation for future exploration of similar technologies across other high-risk domains, including industrial operations, emergency response, and construction, where adherence to safety standards is equally vital.

- Future enhancements will focus on expanding dataset diversity through advanced augmentation methods and synthetic data generation, particularly to improve detection of underrepresented PPE classes such as gloves and boots. Model performance can be further optimized by leveraging transfer learning with pre-trained networks and incorporating adaptive training techniques for advanced detection use cases. Additionally, optimizing the system for deployment on edge devices by adopting lightweight architectures will facilitate broader scalability and real-time performance in operational settings.
- To extend system functionality, an automated timing feature will be implemented to monitor the duration firefighters take to fully equip themselves, providing valuable insights into response readiness. Finally, the system will be integrated with safety management platforms and wearable technologies to support comprehensive, real-time monitoring and decision-making in critical firefighting environments.

***Abstract*—With the continued growth of the electric vehicle (EV) fleet, the issue of cross-regional coordinated scheduling for charging infrastructure has become increasingly prominent, facing challenges such as uneven resource allocation and delayed responses. Considering the complex coupling between charging stations and the power system in a smart grid environment, this paper proposes a distributed scheduling strategy based on multi-agent deep reinforcement learning (MADRL) to achieve efficient, coordinated management of charging infrastructure and power resources. The proposed approach constructs a hierarchical decision-making architecture to jointly optimize intra-regional resource allocation and cross-regional power support, modeling the scheduling process as a Markov Decision Process (MDP) and treating regional charging stations, power nodes, and material units as independent agents. Through the multi-agent deep reinforcement learning mechanism, each agent autonomously learns optimal scheduling policies in the presence of uncertain demand and supply fluctuations, thus enabling rapid response and enhancing system robustness. Simulation results demonstrate that the proposed method effectively reduces scheduling costs and improves resource utilization and service quality. This study provides both theoretical support and practical pathways for building intelligent, efficient, and sustainable charging infrastructure.**

Keywords*—Charging station scheduling; cross-regional coordination; multi-agent systems; deep reinforcement learning; Markov decision process; resource optimization; uncertainty response

I. Introduction

Driven by the global transition in energy structures and the rise of sustainable transportation strategies, the adoption of electric vehicles (EVs) is accelerating rapidly, making them a cornerstone of future low-carbon mobility. This trend places increasing demands on the large-scale deployment and intelligent management of charging infrastructure, especially charging stations. As the terminal nodes of the power grid, charging stations not only provide essential energy replenishment for EVs but also significantly influence grid security, traffic efficiency, and user experience through their operational efficiency, scheduling strategies, and resource allocation.

With the ongoing growth in the number of EVs, charging demands have become highly unbalanced across regions and exhibit strong spatiotemporal fluctuations. On one hand, certain areas have an abundance of charging stations but suffer from low utilization rates; on the other, core urban zones face resource shortages, severe queuing, and service bottlenecks due to concentrated demand. Furthermore, the operation of charging station networks is affected by multiple factors, including power supply capacity, maintenance resources, and traffic conditions, making cross-regional resource coordination and scheduling a pressing challenge.

Existing research has made significant progress in optimizing charging station scheduling, covering aspects such as queue management, load balancing, dynamic pricing, and energy storage integration. However, most approaches are still based on single-region, centralized architectures, lacking comprehensive consideration for cross-regional resource flows, heterogeneous system coordination, and dynamic uncertainties. Particularly in multi-region systems, the scheduling problem becomes highly complex and strongly coupled. Traditional optimization algorithms struggle to address challenges such as real-time requirements, large state spaces, and non-convex objectives, thus limiting their effectiveness in large-scale, practical deployments.

To address these challenges, this paper proposes a cross-regional coordinated charging station scheduling method based on multi-agent deep reinforcement learning (MADRL). In the proposed approach, each node in a multi-region charging station network is modeled as an autonomous agent. Through environmental perception and policy learning, agents achieve both local resource optimization and cross-regional coordination. Specifically, the scheduling problem is formulated as a Markov Decision Process (MDP), with state variables including charging demand, power supply, equipment status, and traffic accessibility. Each agent makes decisions independently based on local information and optimizes its policy collaboratively through a shared reward mechanism. This approach offers strosng generalization and adaptability, effectively coping with dynamic changes in charging demand and power supply, and overcomes the performance bottlenecks of traditional methods when faced with uncertainty and high-dimensional state spaces.

The main objective of this study is to build a distributed, intelligent, self-learning, and collaboratively optimized framework for cross-regional charging station resource scheduling. The aim is to maximize resource utilization, minimize operational costs, and optimize service

*Corresponding Author.

responsiveness. Compared with existing methods, the main innovations of this work include:

1) Proposing a coordinated scheduling modeling framework for cross-regional, multi-node, and multi-resource-type systems, adaptable to highly complex operational environments.

2) Introducing a multi-agent deep reinforcement learning mechanism to enable information exchange and policy collaboration among regional agents;

3) Designing a learning structure based on state sharing and reward feedback to enhance responsiveness to charging demand uncertainties and power resource fluctuations;

4) Validating the proposed method through simulation experiments, demonstrating significant advantages in scheduling efficiency, resource utilization, and system robustness.

This research is of both theoretical and practical significance. On one hand, it offers a novel modeling and solution paradigm for charging infrastructure scheduling, broadening the application scope of multi-agent systems in the integration of transportation and energy. On the other hand, it provides effective technical support for regional resource coordination, optimized energy allocation, and improved user charging experience—contributing to the development of smart cities, green transportation, and regional energy collaboration.

The remainder of this paper is organized as follows: Section II reviews the progress in charging station scheduling and the application of multi-agent reinforcement learning in energy management; Section III presents the proposed system modeling methodology and the multi-agent learning framework is given in Section IV; Section V conducts simulation experiments and performance evaluations based on a multi-region charging network; and Section VI concludes the study and outlines future research directions.

II. Literature Review

A. Techniques Based on Acoustic Features Multi-Agent Reinforcement Learning Algorithm Development

According to different decision-making paradigms, multi-agent reinforcement learning (MARL) algorithms for distributed charging scheduling can be categorized into value-based methods and policy-based methods.

For value-based methods, agents focus on learning value functions to derive optimal strategies. In cooperative MARL for distributed charging networks, value-based methods mainly address how to decouple the centralized team value function for distributed execution. Sunehag et al. [1] proposed value-decomposition networks that break down the team value function into a linear sum of individual agent values, where the optimal policy is obtained by greedy selection on the team value. Rashid et al. [2] further enhanced algorithm performance by representing the joint value function as a nonlinear monotonic combination and giving higher weight to joint actions with greater rewards, thus extending the approach to non-monotonic environments. Son et al. [3] introduced a transformation-based factorization that avoids both monotonicity and additivity constraints. However, these methods often rely on regularization for tractable computation, which can hinder performance in complex charging environments. Mahajan et al. [4] addressed inefficient exploration by proposing multi-agent variational exploration, which improves coordination over extended time horizons.

For policy-based methods, when all agents update their strategies simultaneously, the environment becomes non-stationary, making learning more challenging. Thus, most policy-based MARL algorithms adopt the actor–critic (AC) framework. To mitigate partial observability, techniques such as value function decomposition and the use of centralized critics with additional information exchange during training are commonly adopted; both types typically employ the CTDE (Centralized Training, Distributed Execution) paradigm. For value decomposition, Su et al. [5] designed value-decomposition actor-critic methods using a monotonic mapping between the global and local state values, following a simple time-difference advantage gradient that improves sampling efficiency and converges to local optima. Yang et al. [6] implemented a determinant point process-based method for unconstrained value function decomposition.

In centralized critic approaches, Foerster et al. [7] developed counterfactual multi-agent policy gradients, where centralized critics access joint actions and all agent states, while each agent's policy depends only on its own observation history. Pu et al. [8] constructed a decomposed soft actor–critic method with discrete probability policies and counterfactual advantage functions, supporting efficient policy learning and partially resolving credit assignment for both discrete and continuous action spaces. Lowe et al. [9] proposed Multi-Agent Deep Deterministic Policy Gradient (MADDPG), assigning centralized critics to each agent to support different reward functions in competitive environments. Building on this, Wang et al. [10] extended MADDPG to partially observable settings, utilizing recurrent neural networks in both actor and critic to retain observation history. Li et al. [11] integrated minimax optimization into robust multi-agent reinforcement learning, enabling agents to learn robust strategies under adversarial conditions.

These MARL algorithms have been applied to complex scheduling scenarios in distributed charging networks for electric vehicles, enabling agents to collaboratively optimize charging schedules and energy management. However, despite the effectiveness of CTDE in addressing partial observability, issues such as agent privacy and single-point failure risks remain unsolved in large-scale distributed charging systems.

B. Engineering Applications of Multi-Agent Reinforcement Learning

Multi-agent reinforcement learning (MARL) methods have been widely extended to optimal control problems in engineering, such as traffic control [12], autonomous driving [13, 14], and base station communications [15]. As an emerging distributed decision-making technique, MARL has attracted considerable attention for its ability to address nonlinear objectives, which motivates its application in distributed charging scheduling and energy management for smart grids.

In the context of distributed energy (and charging) management, most MARL approaches adopt the CTDE (Centralized Training, Distributed Execution) paradigm to mitigate the adverse effects of partial observability. Zhang et al. [16] proposed a novel deep transfer Q-learning algorithm based on a virtual leader–follower model to maximize the total revenue of all agents while maintaining supply–demand balance in smart grid scenarios. Compared to heuristic optimization methods, deep transfer Q-learning achieves faster convergence, stronger online learning ability, and effective privacy protection for users. Wang et al. [10] introduced a cooperative fuzzy Q-learning approach for microgrid energy management, ensuring stable power supply for independent microgrids while considering user demand uncertainty and achieving rapid acquisition of management strategies.

Reinforcement learning-based strategies have also been designed for distributed energy and load management in competitive and stochastic energy markets, such as microgrid auction-based time-sharing markets, where model-free Q-learning ensures each agent can find its optimal strategy. Zhu et al. [17] proposed an attention mechanism and soft actor–critic-based method for multi-energy-coupled energy management under renewable energy and demand uncertainty, using counterfactual baselines to accelerate policy learning and minimize long-term energy costs while ensuring user needs. Sun et al. [18] developed a multi-agent energy management optimization framework for integrated energy systems considering electricity, natural gas, and carbon trading, using MADDPG to provide each agent with an online trading strategy that considers individual interests for fair market transactions and privacy protection.

To address deployment challenges in large-scale systems, a few studies have explored fully distributed MARL algorithms. Li et al. [19] designed a distributed Q-learning method under a fully decentralized control framework to solve nonconvex economic dispatch problems, though its optimization accuracy is limited due to the lack of state-action value function approximation. In contrast, Liu et al. [20] used nonlinear function approximation for value functions and introduced a diffusion strategy to enable agent collaboration, yet the convergence range of the value function fitting remains limited. Dai et al. [21] combined value-based methods with quadratic function approximation to handle decision-making in continuous action spaces, but the quadratic approximation is most suitable for convex optimization problems. Li et al. [22] proposed a fully distributed reinforcement learning algorithm for nonconvex economic dispatch, but their stateless design for static scheduling problems does not fully exploit the generalization power of deep learning.

For distributed charging and energy management, the above CTDE-based methods are difficult to deploy across widely-distributed charging infrastructure, and still face challenges such as centralized method security, privacy risks, and high communication costs.

C. Research Gaps

This section analyzes the main strengths and limitations of existing multi-agent reinforcement learning (MARL) approaches for distributed scheduling of heterogeneous charging stations, focusing on decision-making types, handling of partial observability, training schemes, and function approximation. For methods applied to distributed charging scheduling, we further compare their optimization objectives, scheduling precision, and generalization capability under uncertainty. Overall, MARL demonstrates outstanding performance in tackling complex nonlinear scheduling objectives and demand uncertainties, offering an effective research paradigm for distributed scheduling in intelligent charging networks. However, current MARL methods still face several challenges when applied to heterogeneous charging station systems:

1) Observability and deployment issues: To address information barriers caused by partial observability, most existing algorithms adopt a centralized training, distributed execution (CTDE) framework. However, this paradigm is difficult to deploy efficiently across widely distributed charging station network nodes, restricting its practicality and scalability.

2) Constraint handling and sparse rewards: Most current methods translate operational constraints into penalty terms within the reward function, which often leads to sparse reward signals. This sparsity can negatively affect learning efficiency and the feasibility of the final scheduling policy.

Therefore, a key motivation of this paper is to theoretically analyze the impact of partial observability on the convergence of MARL, design a fully distributed MARL algorithm suitable for multi-region charging station systems, and introduce an action space mapping mechanism to strictly confine the decision-making process within the feasible domain during training. These innovations aim to provide more efficient and practical technical solutions for intelligent scheduling in large-scale charging networks.

III. Problem Modeling

A. System Structure for Heterogeneous Charging Station Scheduling

This section investigates a coordinated scheduling system for multiple regions and heterogeneous charging stations, as illustrated in Fig. 1. The system comprises various types of charging equipment, including Fast DC Chargers (FDC), AC Slow Chargers (ASC), and bidirectional V2G (Vehicle-to-Grid) Chargers (V2G).

As shown in Fig. 1, within the multi-region microgrid balancing charging supply and demand, each region can be connected to the interregional grid via substations. The system considers two types of regions: source-load coordination regions (e.g., Region A) and dedicated charging regions (e.g., Region D). Source-load coordination regions integrate multiple types of charging stations (FDC, ASC, V2G) as well as end-users (EVs), while dedicated charging regions deploy only a single type or a subset of charging stations.

In the heterogeneous charging station system discussed in this chapter, each group of charging stations of the same type can be regarded as an independent agent. FDC and ASC can autonomously determine their charging power allocation

according to real-time demand, while V2G chargers can flexibly switch between charging and discharging modes, enabling bidirectional energy flow. Operators are able to sense the local charging demand of EVs in real time and transmit the relevant information to the respective charging station agents. For information flow, both intra- and inter-regional communication among charging station agents is realized through remote point-to-point links, facilitating distributed learning and optimal scheduling decisions.

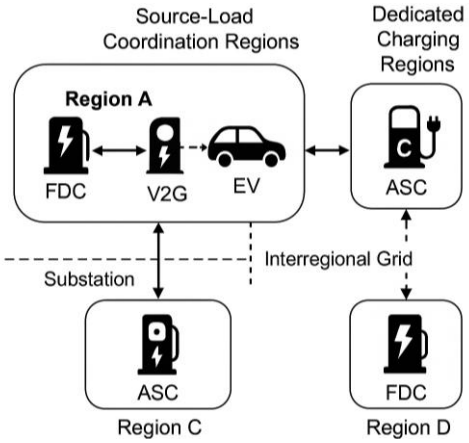

Fig. 1. Schematic diagram of the heterogeneous charging station scheduling system.

The main energy flow in this system is electrical power. The internal structure of the regional charging network is depicted in Fig. 2, where the Charging Station (CS) serves as the core node.

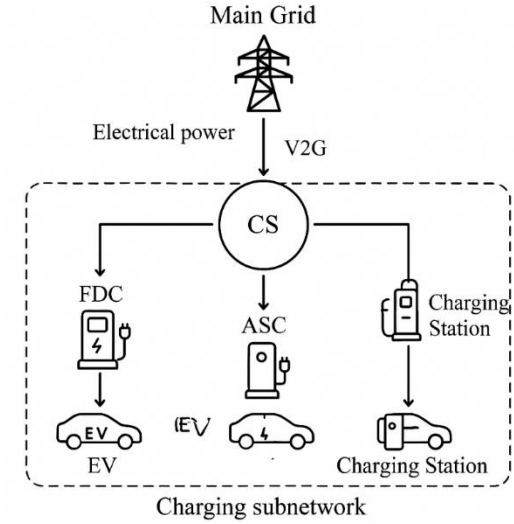

Fig. 2. Integrated heat-electricity network within a region.

The regional charging network can be subdivided into the main grid and the charging subnetwork. Energy flows from the main grid to users (EVs) via different types of charging stations, achieving efficient power supply based on demand. Power demand can be collaboratively met by FDC, ASC, V2G, and charging stations in other regions. V2G chargers can also feed energy from vehicle batteries back to the main grid, enhancing the flexibility of energy regulation. According to the described energy flow and conversion processes, the charging subnetwork mainly serves intra-regional needs, while the main grid supports interregional energy allocation. This setup aligns with the actual requirements of power flow and distributed scheduling.

During the charging scheduling process, priority is given to meeting the charging needs of local users, and any remaining capacity can be used to support grid load balancing. Hierarchical scheduling strategies can effectively improve the utilization efficiency of renewable energy, reduce grid pressure, and advance the goal of green and intelligent mobility.

B. Multi-Domain Integrated Energy System Component Modeling

Based on the structure of the multi-region, multi-type charging station system, the primary components include Fast DC Chargers (FDC), AC Slow Chargers (ASC), bidirectional V2G Chargers (V2G), and Charging Stations (CS). Mathematical models are developed for each component to formulate the distributed charging scheduling problem, as described below:

1) Fast DC charger: FDCs serve as the main high-power charging facilities in the system, primarily catering to EVs with fast-charging needs. The charge/discharge power ratio of FDC can be expressed as:

$$\alpha_{FDC} = \frac{P_{FDC}^{out}}{P_{FDC}^{in}} \tag{1}$$

where P_{FDC}^{out} and P_{FDC}^{in} represent the output and input power of the FDC, respectively. The operational cost function is modeled as a coupled quadratic function:

$$C_{FDC}(P) = aP_{FDC}^2 + bP_{FDC} + c \tag{2}$$

where C_{FDC} denotes the instantaneous operating cost of the FDC, and $a\ b\ c$ are intrinsic parameters. The energy constraint is:

$$0 < P_{FDC} < P_{FDC}^{max} \tag{3}$$

where P_{FDC}^{max} is the FDC's maximum output power.

2) AC Slow charger: ASCs mainly provide charging services for EVs with longer dwell times. The cost function is:

$$C_{ASC}(P) = \alpha P_{ASC}^2 + \beta P_{ASC} + \gamma \tag{4}$$

where P_{ASC} and C_{ASC} denote the output power and instantaneous cost of ASC, and α, β, γ are intrinsic parameters. The power constraint is:

$$P_{ASC}^{min} < P_{ASC} < P_{ASC}^{max} \tag{5}$$

3) Bidirectional V2G charger: V2G chargers enable bidirectional energy flow, allowing energy feedback to the grid while meeting user demand. The charge/discharge ratio is defined as:

$$\alpha_{V2G} = \frac{P_{V2G}^{\text{out}}}{P_{V2G}} \tag{6}$$

where P_{V2G} is the total V2G power, and P_{V2G}^{out} is the power fed back to the grid. The operating cost is:

$$C_{V2G}(P) = gP_{V2G} + h \tag{7}$$

where C_{V2G} is the instantaneous cost, and g, h are intrinsic parameters.

4) Charging station: As the energy dispatch center, CS coordinates energy allocation among regional charging stations. Its dispatch capacity constraint is:

$$0 < P_{CS} < P_{CS}^{max} \tag{8}$$

where P_{CS}^{max} is the maximum dispatch capacity.

C. Distributed Charging Scheduling Problem

In this study, multi-agent deep reinforcement learning (MADRL) is employed to derive optimal economic scheduling and energy feedback policies, aiming to minimize overall operational costs. The distributed energy management problem is formulated as follows:

Objective Function is as follows:

$$C = \sum_{i=1}^{n} C_{FDC,i} + \sum_{i=1}^{m} C_{ASC,i} + \sum_{i=1}^{q} C_{V2G,i} \tag{9}$$

where C is the total operating cost, and n, m, q are the numbers of FDC, ASC, and V2G chargers, respectively.

Capacity Constraints is as follows:

$$\begin{cases} 0 < P_{FDC,i} < P_{FDC,i}^{max}, & \forall i = 1,2,\dots,n \\ P_{ASC,i}^{min} < P_{ASC,i} < P_{ASC,i}^{max}, & \forall i = 1,2,\dots,m \\ 0 < P_{V2G,i} < P_{V2G,i}^{max}, & \forall i = 1,2,\dots,q \end{cases} \tag{10}$$

Power Demand Balance Constraint is as follows:

$$\sum_{i=1}^{c} P_{D,i} = \sum_{i=1}^{n} P_{FDC,i} + \sum_{i=1}^{m} P_{ASC,i} + \sum_{i=1}^{q} \left[(1 - \alpha_{V2G,i})P_{V2G,i}\right] \tag{11}$$

where $P_{D,i}$ is the charging demand of user i, and c is the total number of users.

Energy Feedback Balance Constraint is as follows:

$$\sum_{i=1}^{c_I} P_{D,i}^{\text{feed}} = \sum_{i=1}^{q_I} P_{V2G,i}^{\text{out}}, I = 1,2,\dots,N \tag{12}$$

where $P_{D,i}^{\text{feed}}$ is the feedback energy requirement of user i, q_I is the number of V2G chargers in region I, and N is the total number of regions.

IV. Multi-Agent Deep Reinforcement Learning for Distributed Energy Management

The main method proposed in this chapter addresses the above distributed charging scheduling problem by developing a multi-agent deep reinforcement learning (MADRL) algorithm under a partially observable environment. The following describes the MADRL algorithm framework for heterogeneous charging station systems and discusses relevant technical details.

A. Algorithm Overview

The multi-agent deep reinforcement learning framework developed for heterogeneous charging station systems is illustrated in Fig. 3. In this framework, each FDC, ASC, and V2G charger group acts as an independent agent, employing a static optimization deep learning approach. For each agent i, the POMDP is formalized as $< S_i, A_i, P_i, R_i >$, and the Markov decision process for each charger type is modeled as follows:

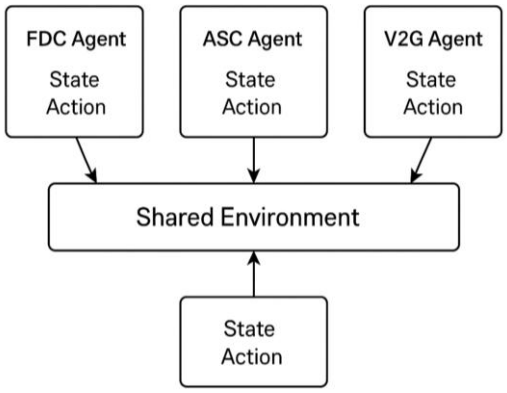

Fig. 3. Multi-agent deep reinforcement learning framework for heterogeneous charging station scheduling.

1) State

a) FDC agent: State vector includes global total charging demand $\sum_{i=1}^{c} P_{D,i}$, local fast charging demand, and total V2G charge/discharge in the region.

b) ASC agent: State vector includes global total charging demand, local slow charging demand, and total V2G charge/discharge in the region.

c) V2G agent: State vector includes global total charging demand, available V2G capacity in the region, and loads of all charger types in the region.

2) Action: For agent i:

a) FDC agent: The output power $P_{FDC,i}$ is the action.

b) ASC agent: The output power $P_{ASC,i}$ is the action.

c) V2G agent: The action vector consists of charging/discharging power $P_{V2G,i}$ (positive for charging, negative for discharging) and the feedback ratio $\alpha_{V2G,i}$.

3) State transition probability: Due to the stochastic nature of charging demand and vehicle arrivals, the state transition distribution for all agents i is assumed to be uniform.

4) Reward: The local reward of each charging station agent is negatively correlated with the objective function above. If an agent fails to satisfy constraints such as capacity or power, its reward is penalized.

This framework considers two deep learning approaches: Target Value Competition Multi-Agent Reinforcement Learning (MADRL-TVC) and Multi-Agent Deep Deterministic Policy Gradient (MADDPG). MADRL-TVC is a

fully distributed method, while MADDPG requires centralized training. Both methods are applied to the distributed charging scheduling problem, with the superior approach selected for the charging station system scheduling policy.

B. Algorithm Procedure

The algorithm used in this chapter is a model-dependent continuous decision-making method, not episode-based, and does not rely on historical sequences, but only on real-time decisions and feedback from the multi-agent system. The implementation process of the MADRL algorithm is shown in Fig. 4, with the core steps as follows:

1) Initialization and state acquisition: Each charging station agent initializes its parameters and obtains the initial state from the environment. State information includes the current load demand of each charger type, user arrival information, available V2G capacity, etc. At each decision step t, each agent selects action $a_{i,t}$ according to its policy.

2) Hierarchical scheduling and action adjustment: To balance different types of demand, a hierarchical control framework is designed for high-priority intra-regional charging needs and cross-regional energy feedback (V2G). Actions are adjusted automatically via distributed binary search, prioritizing high-priority charging demand within each region.

For balancing fast and slow charging demands, the initial search domain for FDC and ASC agents is set as:

$$a_i^{min}(0) = 0, a_i^{max}(0) = P_{FDC,i}^{max} \text{ or } P_{ASC,i}^{max} \tag{13}$$

For V2G feedback, the agent's search domain is:

$$a_i^{min}(0) = -P_{V2G,i}^{max}, a_i^{max}(0) = P_{V2G,i}^{max} \tag{14}$$

The load demand deviation for region I is defined as:

$$\delta_{P,I}(k) = \sum_{i=1}^{c_I} P_{D,i} - \sum_{i=1}^{n_I} P_{FDC,i} - \sum_{i=1}^{m_I} P_{ASC,i} - \sum_{i=1}^{q_I} \alpha_{V2G,i} P_{V2G,i} \tag{15}$$

Running Algorithm 1 with this setup achieves balance between regional charging demand and V2G feedback.

3) Experience collection and network training: Each agent observes the immediate reward r_{t+1} and the next state $s_{i,t+1}$. After each decision, the experience is stored in a replay buffer. At regular intervals, mini-batches are randomly sampled from the buffer to train the deep neural network.

Based on the above approach, charging station agents collaboratively learn optimal energy allocation and economic scheduling policies to minimize the overall system operating cost. The trained model can respond online to varying charging demands, EV arrivals and departures, and random V2G availability, providing real-time scheduling strategies. This method excels at rapid demand response, accommodating renewable energy uncertainty, and improving overall energy utilization efficiency.

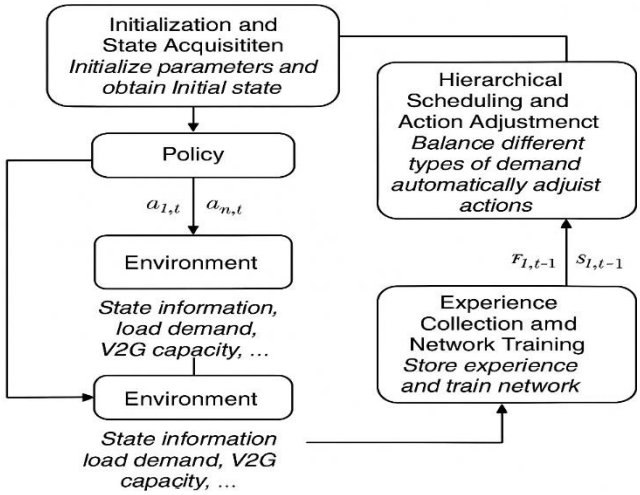

Fig. 4. Multi-agent deep reinforcement learning algorithm flow for multi-domain integrated energy systems.

V. Simulation Validation

In this section, a multi-region, multi-type charging station scheduling scenario is constructed. The proposed hierarchical decision-making framework and multi-agent reinforcement learning method are trained, and the trained models are tested using open-source transportation and charging load datasets. Their responsiveness to load uncertainty and distributed charging demand is analyzed and compared with other benchmark scheduling methods, further validating the performance advantages of the proposed distributed charging scheduling scheme in multi-region scenarios.

A. Simulation Setup

The simulation environment is configured as a multi-type charging station system spanning four regions, as illustrated in Fig. 1. The entire system comprises nine groups of charging stations, including four Fast DC Charger (FDC) groups (deployed in Area A: 1 group, Area C: 1 group, Area D: 2 groups), two bidirectional V2G charger groups (deployed in Area A and Area C), and three AC Slow Charger (ASC) groups (deployed in Area A, Area B, and Area C). Cross-regional power distribution can be achieved via the main grid. Data on vehicle charging demand, EV arrivals and departures, and V2G feedback capabilities for each region are sourced from open-source transportation and charging datasets (such as PEMS, Open Charge Map, etc.). The cost parameters and inequality constraints for each type of charging station are integrated from previous studies or relevant industry standards. All simulation parameters are detailed in Tables I, II, and III. The scheduling interval is set to 15 minutes, and the simulation covers a 24-hour period.

TABLE I. FDC Unit Parameters

NodeRegion	NodeRegion	α_i	β_i	γ_i	$P_{FDC}^{\min}$	$P_{FDC}^{\max}$
1	A	0.0020	10	500	100	600
2	C	0.0025	8	300	50	400
3	D	0.0050	6	100	50	300
4	D	0.0060	5	90	50	200

B. Training Process

Due to the incomparability of immediate rewards across different reward functions, it is challenging to directly track the cumulative rewards during the training process under random states. To evaluate the algorithm's performance during training, 10 random state points are selected and their corresponding rewards are recorded throughout the training. Each observation point includes the power demand and heat demand of Areas A, B, and C, as well as the wind power output from WT unit groups in Areas A and C. To analyze the neural network's fitting performance, the total training loss of the Q-network estimated by the MADRL-TVC method is also recorded during training.

TABLE II. V2G CHARGER AND CS PARAMETERS

NodeRegion	NodeRegion	g_i	h_i	k_{V2G}	P_{V2G}^{max}
5	A	5	15	0.9	90
6	B	4	20	0.9	90

TABLE III. ASC UNIT PARAMETERS

NodeRegion	NodeRegion	a_i	b_i	c_i	P_{CHPP}^{max}	H_{CHPP}^{max}	α_{CHPP}^{min}
7	A	0.0050	6	100	200	100	0.5
8	B	0.0060	5	90	200	90	0.5
9	C	0.0072	3	150	180	80	0.5

Fig. 5 shows the cumulative rewards and total training loss at different observation state points during the training process. It can be observed that the cumulative rewards at all state points exhibit an upward trend. This indicates that the proposed algorithm can improve cumulative rewards through training, thus finding the optimal scheduling strategy for each type of state. The training loss of the Q-network converges rapidly and ultimately becomes very small, demonstrating that the neural network can effectively fit the charging scheduling policy.

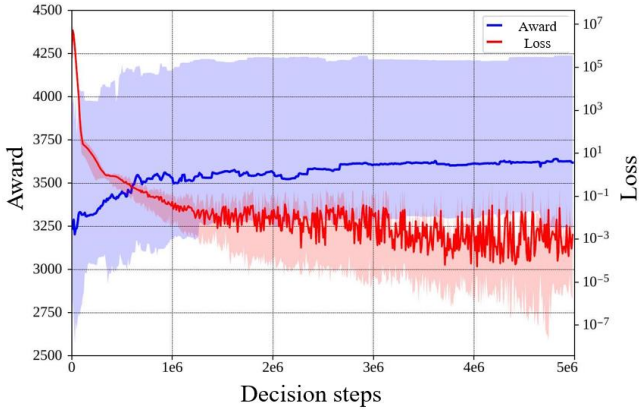

Fig. 5. Cumulative rewards and total training loss during training.

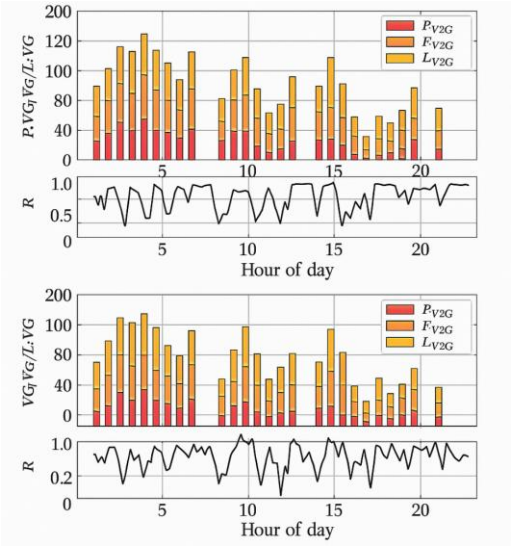
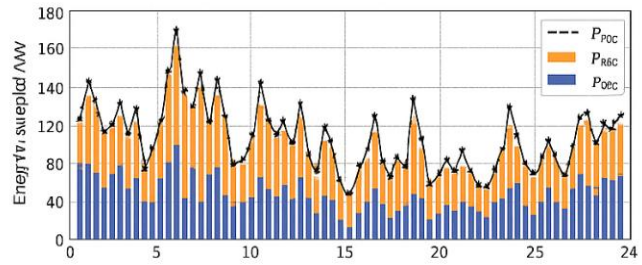
C. Full-Day Energy Management Results Analysis

After extended training under randomly varying states, the proposed algorithm achieves a generalizable, complete model that can provide optimal charging scheduling strategies in real time for arbitrary user demand and V2G capacity availability. Within a one-day scheduling cycle, the MADRL-TVC trained model outperforms MADDPG, so the following presents the optimal strategies under MADRL-TVC scheduling.

The energy allocation of V2G chargers is shown in Fig. 6. For each group of V2G chargers, the energy allocation includes charging power output (P_{V2G}), energy fed back to the grid (F_{V2G}), and energy loss (L_{V2G}). As illustrated in Fig. 6(a) and 6(b), the V2G chargers in Area A and Area C can fully utilize vehicle battery energy for grid feedback during peak load periods, effectively alleviating regional power supply pressure. The V2G energy utilization rate reaches up to 100%.





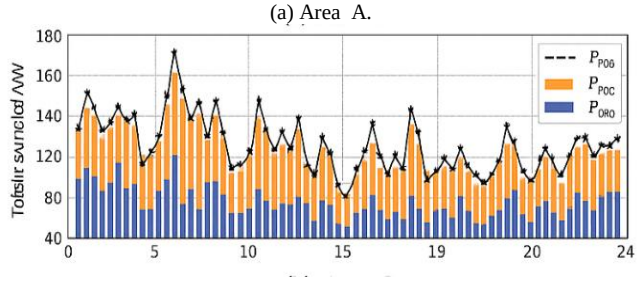


Fig. 6. Regional V2G charger energy allocation and feedback rate.

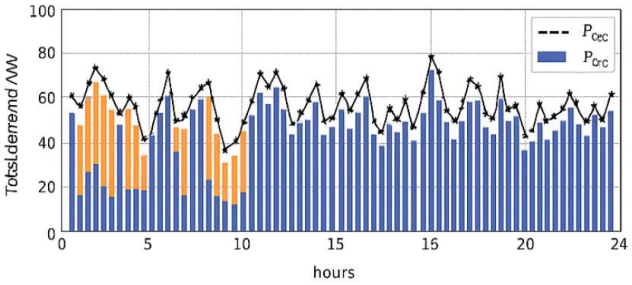
The scheduling results for charging demand within each region are shown in Fig. 7, displaying how different types of charging stations meet vehicle charging needs in each region for every 15-minute interval throughout the day. P_{FDC}, P_{ASC}, and P_{V2G} represent the energy supplied by each type of charging station, while PD_A, PD_B, and PD_C denote the total demand in each region. The results demonstrate that the charging demands in all regions are precisely met. Due to the stochastic nature of charging demand and vehicle arrivals, the energy allocation structure across regions does not follow a fixed pattern. Nevertheless, the algorithm is able to provide corresponding scheduling strategies in real time, effectively coping with demand and load uncertainty.



Cross-regional energy scheduling is depicted in Fig. 8, showing the overall charging power allocation at each time interval throughout the day—that is, how each type of charging station and each region jointly respond to the total charging demand. P_{Area_A}, P_{Area_B}, P_{Area_C}, and P_{Area_D} represent the total charging output for each region. The charging power is balanced at all times of the day, with the FDCs (which have higher economic priority) typically handling the main load, while ASCs provide supplementary regulation. V2G chargers mainly contribute energy feedback during peak load periods. The scheduling results indicate that the agents can make distributed collaborative decisions to achieve optimal economic scheduling.

(a) Area A.

(b) Area B

(c) Area C

Fig. 7. Regional charging demand scheduling results.

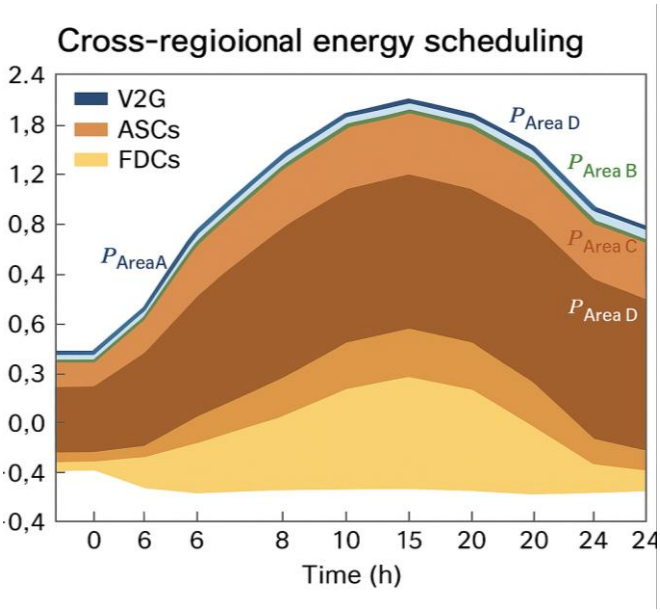


Fig. 8. Overall power scheduling results.

The total system operating cost is shown in Fig. 9, presenting the full-day operating costs for the multi-type charging station system. The results show that the algorithm can effectively reduce overall operating costs and achieve coordinated operation between charging stations and the grid.

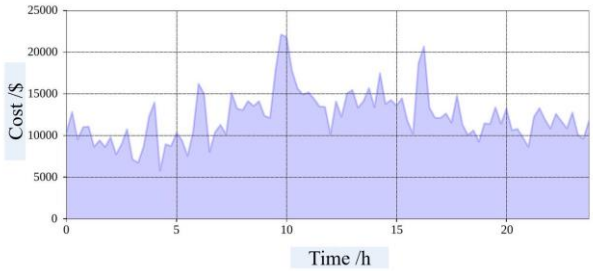

Fig. 9. Full-day operating cost.

D. Comparative Analysis

To evaluate the performance of the distributed charging scheduling method based on multi-agent reinforcement learning (MADRL), it is compared with commonly used centralized optimization methods, including Particle Swarm Optimization (PSO), nonlinear optimization solvers (SCIP, NLOPT), and others. Table IV presents the operating costs of different algorithms at a specific observation state (e.g., total charging demand 800.0, regional demands [100.0, 120.0, 50.0], V2G available power [70.0, 150.0]). Table V lists the average hourly quantified costs for each method over the entire day.

As shown in the tables, compared with centralized stochastic optimization methods such as PSO, the multi-agent deep reinforcement learning approach can effectively reduce system operating costs in distributed charging scheduling. In particular, the MADRL-TVC method achieves performance comparable to mature solvers such as SCIP. Compared with the MADDPG (centralized training, distributed execution) framework, the fully distributed MADRL-TVC displays better convergence in high-dimensional decision spaces, further highlighting the advantages of distributed algorithms.

TABLE IV. OPERATING COST OF DIFFERENT METHODS AT THE OBSERVATION STATE

Algorithm	Solver Type	Optimal Cost	Improvement
PSO	Centralized	12603.94	0
NLOPT	Centralized	12622.88	-0.15%
SCIP	Centralized	12201.77	3.19%
MADDPG	Distributed	12394.07	1.67%
MADRL	Distributed	12202.26	3.19%

TABLE V. AVERAGE QUANTIFIED COST PER HOUR FOR DIFFERENT METHODS

Algorithm	Solver Type	Optimal Cost	Improvement
PSO	Centralized	52102.92	0
NLOPT	Centralized	52977.84	−1.84%
SCIP	Centralized	49129.07	5.56%
MADDPG	Distributed	50968.13	2.02%
MADRL	Distributed	49146.08	5.53.%

The results show that MADRL-TVC not only has advantages in reducing operating costs, but its distributed structure is also better suited to dynamic changes and randomness in charging demand and V2G feedback, offering

stronger generalization and stability. Therefore, the distributed scheduling method based on multi-agent deep reinforcement learning has significant application potential and development prospects in multi-region, multi-type charging station systems.

VI. Conclusion

This Paper proposes a distributed charging scheduling strategy for multi-region, multi-type charging station systems. Different regions and types of charging station groups are modeled as independent agents. Based on user charging demand and V2G feedback capability, collaborative optimization of the multi-agent system enables energy allocation and economic scheduling. For intra-regional fast charging, slow charging, and cross-regional energy feedback, a hierarchical decision-making framework is designed, and the charging scheduling problem is formalized as a Markov Decision Process, with multi-agent deep reinforcement learning employed for collaborative learning. Leveraging the generalization capability of deep reinforcement learning, the proposed method can not only reduce total system operating costs, but also respond in real time to uncertainties in charging demand and energy feedback, effectively improving the economic efficiency and robustness of distributed charging networks.

Acknowledgment

The preferred spelling of the word “acknowledgment” in America is without an “e” after the “g.” Avoid the stilted expression, “One of us (R. B. G.) thanks . . .” Instead, try “R. B. G. thanks.”

A Review of Federated Learning Attacks: Threat Models and Defence Strategies

Fizlin Zakaria, Shamsul KamalAhmad Khalid
Faculty of Computer Science & Information Technology, Universiti Tun Hussein Onn,
86400 Parit Raja, Batu Pahat, Johor, Malaysia

***Abstract*—Federated Learning (FL) has emerged as a critical paradigm in privacy-preserving machine learning, enabling collaborative model training across decentralised devices without sharing raw data. While FL enhances privacy by maintaining data locality, it remains susceptible to sophisticated adversarial attacks. This review systematically analyses the FL threat landscape and introduces a novel taxonomy that classifies attack models based on their objectives, capabilities, and exploited vulnerabilities. Major categories include data poisoning, inference attacks, and Byzantine behaviours, each examined in terms of mechanisms, assumptions, and system impact. In addition, the paper evaluates prominent defence strategies—such as differential privacy, secure aggregation, and anomaly detection—by assessing their strengths, limitations, and real-world applicability. Key gaps include the lack of standardised evaluation metrics and limited exploration of adaptive defence mechanisms. Emerging trends such as homomorphic encryption, secure multi-party computation, and blockchain-based verifiability are also discussed. This review is a comprehensive resource for researchers and practitioners aiming to design resilient, privacy-aware FL systems that withstand evolving threats.**

***Keywords*—Federated learning; threat models; defence strategies; privacy-preserving AI; adversarial attacks**

I. Introduction

The healthcare sector has experienced significant technological advancements, underscoring the need to protect sensitive patient data [1]. Federated Learning (FL), a decentralised machine learning approach, offers promising privacy benefits by enabling local data processing. However, this decentralisation also introduces novel security vulnerabilities that require thorough investigation [2]. Despite its advantage in preserving data locality, FL remains susceptible to attacks from malicious participants [2]. Its ability to enable collaborative model training without compromising raw data makes FL particularly valuable in privacy-critical domains. This includes fields such as healthcare and finance, where leveraging distributed datasets without violating privacy regulations is essential [1].

Although interest in FL security has grown, existing literature often focuses on isolated aspects of the threat landscape, resulting in a fragmented understanding of its vulnerabilities and corresponding defence mechanisms [3]. A more holistic and structured review is needed to address this gap, integrating technical, regulatory, and ethical perspectives on safeguarding federated systems.

This paper addresses this need by providing a systematic taxonomy of FL attack vectors and a comparative evaluation of defence strategies. The review classifies attacks based on threat models—including data and model poisoning—and analyses their operational mechanisms. It further assesses defence methods such as differential privacy and secure aggregation in terms of their effectiveness, trade-offs, and applicability. Finally, the paper identifies open research challenges and proposes directions for future work to enhance the resilience, trustworthiness, and scalability of FL systems [4]. The main contributions of this paper are as follows:

- A novel taxonomy of FL attack models, classifying them based on attack goals, vectors, and system vulnerabilities.
- A comparative evaluation of defence strategies regarding performance, scalability, and security robustness.
- Identifying research gaps, including a lack of standardised evaluation frameworks and limited exploration of adaptive defences.
- Discuss emerging trends such as hybrid defence approaches and blockchain-based accountability mechanisms.
- The remainder of the paper is organised as follows: Section II outlines the literature selection and analysis methodology. Section III presents the taxonomy of FL attacks. Section IV evaluates existing defence strategies. Section V discusses current research gaps and future directions. Section VI and Section VII concludes the paper with a summary of findings and recommendations.

To guide this review, the following research question is posed: What are the key adversarial attack vectors that threaten Federated Learning (FL) systems, and how effective are current defence strategies—such as differential privacy, secure aggregation, and blockchain-based mechanisms—in mitigating these threats across different attack surfaces and system configurations? This question frames the scope of the analysis presented in this paper, which aims to systematically categorise existing FL attacks and critically evaluate the corresponding defence mechanisms based on their applicability, strengths, and limitations. To contextualise this study, Section II reviews foundational and recent research on FL threats and defences.

II. Related Work

Federated Learning (FL) has emerged as a prominent privacy-preserving machine learning framework, attracting increasing attention from academia and industry. Numerous studies have examined its security vulnerabilities and mitigation strategies, but many existing reviews are either narrowly scoped or lack updates to reflect the fast-evolving threat landscape. Pioneering works by Shokri et al. [23] and Melis et al. [24] introduced foundational concepts such as membership inference and property inference attacks, exposing the privacy risks inherent in collaborative learning environments. Bagdasaryan et al. [6] further demonstrated the feasibility of model poisoning and backdoor attacks, showing that even minor manipulations can compromise global model integrity. These studies laid the groundwork for analysing adversarial risks in decentralised learning systems.

Subsequent reviews by Hallaji et al. [2] and Nguyen et al. [11] broadened the threat taxonomy to include Byzantine behaviours and gradient leakage. However, their discussions often stop short of connecting these threats to comprehensive, layered defence architectures. Other researchers have explored isolated countermeasures—such as differential privacy [39] and homomorphic encryption [1]—but rarely assess their real-world performance in heterogeneous, large-scale FL deployments.

To address concerns over trust and transparency, blockchain-based FL frameworks (e.g., ShareChain [1], PPBFL [33]) have been proposed. These aim to decentralise trust management, offering tamper-evident logging and client accountability. Despite their conceptual appeal, such frameworks remain in the early stages of development and face considerable challenges related to scalability, latency, and integration with existing FL protocols [35].

This review builds upon previous work by offering a more comprehensive taxonomy of FL attacks, explicitly categorised by attack surface, timing, and intent. Furthermore, it delivers a comparative analysis of defence strategies, focusing on their security effectiveness, computational cost, and deployment trade-offs. This paper also identifies ongoing research gaps, particularly the lack of adaptive, hybrid, and context-aware mechanisms that can evolve alongside sophisticated attack patterns.

III. Methodology

This study follows a structured literature review approach to comprehensively examine Federated Learning (FL) attack models and corresponding defence strategies. The methodology adopted is outlined as follows.

A. Literature Search Strategy

This research employs a systematic literature review methodology, complemented by elements of a narrative review, to investigate the landscape of security threats and defence mechanisms within federated learning systems. The review focuses on identifying, classifying, and synthesising existing research concerning attacks targeting federated learning and corresponding defence strategies designed to mitigate these vulnerabilities [1], [5]. The study's primary objective is to provide a comprehensive overview of the current state-of-the-art, highlighting prominent attack vectors, defence approaches, and open challenges in the field.

The following keywords and Boolean combinations were used during the search:

- "Federated Learning" AND "Attack"
- "Federated Learning" AND "Threat Models"
- "Federated Learning" AND "Security"
- "Federated Learning" AND "Privacy Attacks"
- "Federated Learning" AND "Defence Strategies"
- "Secure Federated Learning" AND "Robust Aggregation"

Additionally, backwards and forward snowballing techniques were applied by reviewing the references of highly cited papers to identify additional relevant studies.

B. Inclusion and Exclusion Criteria

The literature search encompassed several prominent databases, including Scopus, Web of Science, and IEEE Xplore, selected for their extensive coverage of computer science, engineering, and related disciplines. These databases were queried using keywords and Boolean operators to identify relevant publications on federated learning security [3]. Search terms included variations and combinations of "Federated Learning Attack," "Threat Models," and "Federated Learning Defence" to capture a broad spectrum of research related to the topic. The initial search yielded a substantial number of articles, which were subsequently filtered based on predefined inclusion and exclusion criteria. To ensure the relevance and currency of the review, only peer-reviewed, English-language papers published between 2020 and 2025 were considered for inclusion. This timeframe was chosen to capture the most recent advancements and emerging trends in the federated learning security field—the restriction to peer-reviewed publications aimed to maintain the quality and rigour of the included studies. The English language restriction was applied due to resource constraints and the need for consistent linguistic analysis [1].

C. Study Selection Process

The selection process followed a structured approach, drawing inspiration from the PRISMA guidelines to enhance transparency and reproducibility. The initial screening involved reviewing the titles and abstracts of the identified articles to assess their relevance to the research question. Articles not explicitly addressing security threats or defence mechanisms in federated learning were excluded. Subsequently, the full texts of the remaining articles were examined in detail to determine their eligibility for inclusion based on the predefined criteria. This thorough evaluation ensured that only studies directly relevant to the scope of the review were considered for further analysis. The selected articles were then subjected to a rigorous analysis to extract key information regarding attack types, defence strategies, evaluation metrics, and experimental settings.

D. Data Extraction and Synthesis

The extracted data were organised and synthesised using a comprehensive analysis framework to categorise and classify

the identified attacks and defences. The categorisation was based on the nature of the attack, such as data poisoning, model poisoning, inference attacks, and Byzantine attacks [1]. Data poisoning attacks involve manipulating the training data to compromise the global model, while model poisoning attacks target the model aggregation process [4]. Inference attacks, on the other hand, aim to extract sensitive information from the model or the training data. Byzantine attacks encompass various malicious behaviours, including arbitrary data or model manipulation by compromised participants. Defence mechanisms were categorised based on underlying principles, such as differential privacy, secure aggregation, anomaly detection, and robust aggregation techniques. Differential privacy adds noise to the training data or model updates to protect individual privacy, while secure aggregation protocols ensure the confidentiality of model updates during the aggregation process. Anomaly detection techniques aim to identify and filter malicious or abnormal contributions from compromised participants. Robust aggregation methods, such as median or trimmed mean aggregation, are designed to mitigate the impact of outliers or malicious updates on the global model. Decentralised federated learning introduces new privacy threats [2]. For instance, an inference attack can occur in blockchain-based federated learning [1]. In this paradigm, security analysis is necessary [2]. This categorisation facilitated a structured comparison of different approaches and enabled the identification of their strengths and weaknesses. Existing defences against data poisoning cannot be directly applied to federated learning due to the requirement of accessing the training data [6]. Adversaries are improving at hiding malicious behaviours from benign ones [7]. Sophisticated attackers are motivated by very high incentives to manipulate the results of the machine learning models [8]. Data owners update their models while keeping the data localised, guaranteeing zero leakage of individual data since only trained models are shared in the proposed model [1]. The absence of a centralised server in blockchain-enabled federated learning eliminates the single point of failure [1]. By integrating federated learning with blockchain technology, auditing machine learning models is supported without centralising the training data [7].

IV. Results

This section presents a structured literature analysis on Federated Learning (FL) attacks and defence strategies. A taxonomy is developed to categorise attack types based on their objectives, Timing, and attack surfaces. Defence mechanisms are evaluated based on their effectiveness, complexity, and applicability.

A. Taxonomy of Federated Learning Attacks

Federated Learning (FL) is a distributed machine learning paradigm designed to train models collaboratively across decentralised data sources without transferring raw data. This decentralisation preserves privacy by enabling local computation on each client and aggregating model updates on a central server [1]. However, despite these inherent privacy advantages, FL systems remain vulnerable to a broad spectrum of adversarial threats that can undermine model integrity, compromise data confidentiality, and disrupt system performance [9]. Understanding and classifying these threats is essential for developing effective, context-aware defence mechanisms [5], [9], [10].

Fig. 1 presents a visual taxonomy that categorises FL attacks based on three key dimensions:

- Attack surface (client-side vs. server-side),
- Timing (during training vs. after training),
- Objective (e.g., data inference, model disruption, free-riding).

This classification provides a structured lens to analyse how FL systems are targeted across various operational contexts.

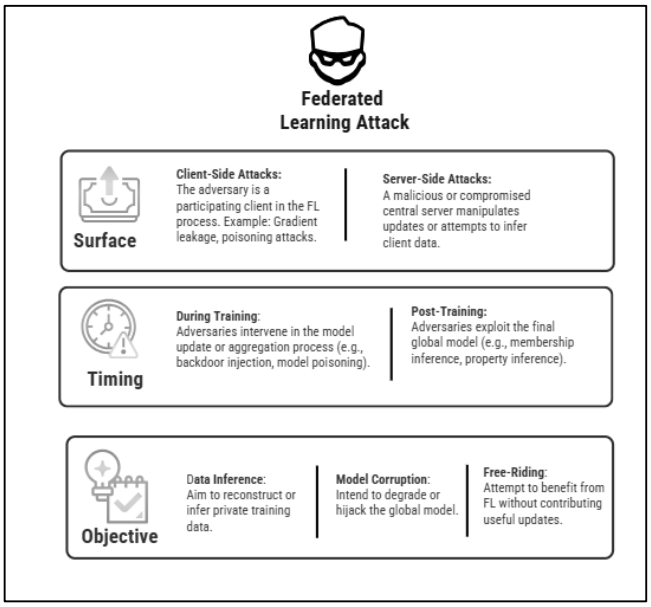

Fig. 1. Overview of attack categories in federated learning.

This diagram visualises how FL systems are exposed to threats across client and server surfaces, during various phases (training/post-training), and based on differing attack objectives.

1) By Attack surface

a) Client-side attacks: These attacks originate from compromised or malicious clients within the FL network. A typical example is data poisoning, where adversaries inject manipulated training data to introduce specific biases into the global model [4]. Another form, model poisoning, involves clients altering their model updates before aggregation to influence global model behaviour. These threats exploit the decentralised nature of FL, making it difficult for the server to distinguish between benign and malicious updates [11], [12].

b) Server-side attacks: Server-side attacks target the central aggregation server, which collects client updates and distributes the global model. Adversaries may compromise the server to tamper with the aggregation process or launch inference attacks to extract sensitive client data from model updates. Moreover, the server itself can act maliciously by injecting adversarial gradients or modifying aggregation rules [13], [14], [15].

2) By Timing

a) During training: Attacks launched during the training process are commonly referred to as poisoning attacks. These may involve the injection of malicious data, gradients, or even fake client updates (e.g., Sybil attacks) to degrade the model's accuracy or manipulate its outputs [16], [17]. These threats can be particularly stealthy and difficult to detect in asynchronous FL settings.

b) After training (after deployment): Once an FL model is deployed, it becomes susceptible to inference attacks, such as membership inference (determining if a record was part of training) or property inference (inferring sensitive aggregate attributes). These attacks exploit model outputs or gradients to reveal private training data [18], [20]. Attackers can also launch Reconstruction attacks to extract private textual data, exploiting gradient updates from the clients during the training phase [20].

3) By Objective: Federated learning attacks can be classified based on their primary objectives, reflecting the intended outcome that the attacker seeks. Attacks can also be categorised based on their goals, i.e., what the attacker hopes to achieve.

a) Data inference: Data inference attacks aim to extract sensitive information about the clients' local datasets from the shared model updates or the final global model [21]. Membership inference attacks determine whether a specific data point was used to train the model, revealing sensitive information about individual clients. Property inference attacks aim to infer statistical properties of the clients' local datasets, such as the distribution of sensitive attributes.

b) Model disruption: Model disruption attacks, also known as model poisoning attacks, aim to degrade the performance or functionality of the global model. By injecting malicious data or manipulating model updates, attackers can cause the model to make incorrect predictions or exhibit undesirable behaviour [8]. Such attacks can lead to model performance degradation or complete model failure. An attacker may compromise the global model by manipulating local parameters [22].

c) Free-Riding: Free-riding attacks, also known as lazy client attacks, occur when malicious clients contribute minimally to the training process while benefiting from the global model. These clients may submit outdated or irrelevant model updates, slowing convergence and reducing the model's accuracy [1]. In federated learning, free-riding attacks involve lazy clients that do not contribute meaningfully to the training process [1].

The results are further supported by visual representations, including Fig. 1 through Fig. 3 and Table II, which collectively illustrate the taxonomy of FL attacks, threat-defence mappings, and comparative defence evaluations. These visual aids were designed to enhance the clarity and accessibility of the findings, enabling a layered understanding of the attack vectors and mitigation strategies. Including these diagrams strengthens this review's communicative impact and supports readers in grasping complex adversarial relationships and defence limitations within FL systems.

Table I summarises the FL attack classification with attack surface, Timing, and impact.

TABLE I. SUMMARY OF FEDERATED LEARNING ATTACK TYPES

Attack Type	Description	Attack Surface	Timing	Representative Studies
Membership Inference	Determines if a specific data point was in the training set	Client	Post-training	[23]
Property Inference	Infers statistical properties of client data	Client	Post-training	[24]
Model Poisoning	Injects malicious updates to corrupt the global model	Client	During training	[25]
Backdoor Attacks	Embeds hidden misbehaviour triggered by specific inputs	Client	During training	[6]
Gradient Leakage	Reconstructs raw data from shared gradient updates	Server	During training	[26]
Sybil Attacks	Uses fake identities to influence model updates disproportionately	Client	During training	[27]
Free-Rider Attacks	Participates in FL without contributing useful updates	Client	During training	[28]
Collusion Attacks	Multiple adversaries collaborate to subvert learning	Multiple	During training	[2]
Adaptive Multi-Vector	Dynamic use of multiple attack vectors to evade defences	Multiple	Dynamic	[29]

B. Threat Models

The evolving landscape of Federated Learning (FL) security has seen a marked increase in hybrid and adaptive adversarial behaviours. Contemporary studies reveal that attacks are no longer limited to isolated strategies; adversaries now deploy multi-vector approaches that exploit privacy, model integrity, and communication weaknesses. Examples include coordinated multi-client poisoning, collusion-based inference, and gradient inversion attacks augmented with generative models. The growing sophistication of these threats necessitates the development of layered, context-aware defence mechanisms. Fig. 2 illustrates the key threat models encountered in FL environments, offering a taxonomy of representative attack types based on mechanisms and impact.

1) Membership Inference Attacks (MIA): Membership inference attacks (MIA) pose a fundamental threat to privacy in machine learning. In this attack, an adversary attempts to determine whether a specific data instance was part of the training dataset used to develop the model. The implications are severe, especially when dealing with sensitive datasets such as electronic medical records or financial transactions [30].

These attacks exploit subtle behavioural discrepancies between the model's predictions on seen versus unseen data. For

example, models typically return higher confidence scores or lower prediction entropy on training data than on unfamiliar inputs [31]. By leveraging such output characteristics, attackers can infer membership with non-trivial accuracy. Additionally, some variants assess model sensitivity to the presence or removal of specific samples, thereby detecting overfitting or memorisation tendencies.

Research has demonstrated the feasibility of MIAs across a range of model architectures and datasets. Key enabling factors include overfitting, model complexity, and the availability of public query APIs that allow repeated probing [23]. Attackers often rely on shadow models—locally trained replicas mimicking the target model's behaviour—to optimise their inference strategies. While simple mitigation techniques like limiting the number of queries have been proposed [13], these alone are insufficient in high-risk applications.

2) Property inference attacks: Property inference attacks, a closely related threat, extend the scope of privacy breaches by targeting aggregate properties of the training dataset rather than individual data points. In property inference attacks, the adversary aims to infer statistical characteristics or sensitive attributes of the training data, such as the proportion of individuals with a specific medical condition or demographic information. These attacks exploit the model's learned representations to extract information about the overall distribution and characteristics of the training data, potentially revealing sensitive information about the population from which the data was drawn. For instance, an adversary might try to determine a specific disease's prevalence among the individuals trained to train a diagnostic model. The effectiveness of property inference attacks depends on the model's tendency to encode statistical patterns and correlations in the training data, which can then be extracted and analysed.

3) Model poisoning attacks: Model poisoning attacks represent a significant threat to machine learning systems, where adversaries inject malicious data into the training dataset to impair the model's performance or manipulate its behaviour. This attack can have devastating consequences, especially in critical applications such as fraud detection, spam filtering, and medical diagnosis, where the accuracy and reliability of machine learning models are paramount [18]. By carefully crafting and injecting poisoned data points, attackers can subtly alter the model's decision boundaries, leading to incorrect predictions or biased outcomes [18]. The success of model poisoning attacks depends on the attacker's ability to inject enough poisoned data without being detected and the model's sensitivity to changes in the training distribution [8]. Security companies often rely on crowd-sourced threat feeds to train their classifiers, making them a natural injection point for such attacks. Furthermore, in federated learning scenarios, where multiple parties collaboratively train a model, a malicious participant can inject poisoned data, affecting the global model's performance.

4) Backdoor attacks: Backdoor attacks, a particularly insidious form of model poisoning, involve injecting specific triggers into the training data that cause the model to misbehave only when those triggers are present in the input [1]. These triggers can be subtle patterns or features imperceptible to human observers but easily recognised by the compromised model. When a backdoored model encounters an input containing the trigger, it will produce a predetermined, incorrect output, bypassing the model's intended functionality. Backdoor attacks are particularly concerning because they can be challenging to detect, as the model performs normally on most inputs and only exhibits malicious behaviour when the trigger is present. One study notes that backdoor attacks are highly effective when applied to computer vision models without many poisoned examples [12]. Explanation-guided backdoor poisoning attacks have also been investigated for malware classifiers.

5) Gradient leakage attacks: Gradient leakage attacks exploit the information contained in the gradients of a model during training to infer sensitive information about the training data. In distributed learning settings, where model updates are shared among multiple participants, attackers can intercept these gradients and reconstruct the training data or extract sensitive attributes. Gradient leakage attacks can reveal individual data points, statistical properties of the data, or even the labels associated with specific data points. These attacks pose a significant threat to privacy in federated learning and other distributed learning scenarios, where data is decentralised and sensitive.

6) Free-rider attacks: Free-rider attacks occur in collaborative learning settings, such as federated learning, where participants contribute to training a shared model. In a free-rider attack, a malicious participant exploits the contributions of others without contributing meaningfully to the training process. The free-rider may copy the model updates from other participants without performing any local training or contribute low-quality updates that do not improve the model's performance. By exploiting the contributions of others, free-riders can gain access to a high-quality model without incurring the computational costs or expending the effort required for training. The proposed framework prevents attribute disclosure, homogeneity, and background knowledge threats by using local differential privacy, which adds noise to the data [1].

7) Sybil attacks: Sybil attacks, also relevant in distributed learning scenarios, involve an attacker creating multiple fake identities to gain disproportionate influence over the training process. By controlling various "Sybil" clients, the attacker can manipulate the model's updates, inject bias, or even cause the model to learn incorrect patterns. Sybil attacks are particularly challenging to defend against because it can be difficult to distinguish legitimate clients from fake ones. To solve the single point of failure in federated learning, researchers have explored a blockchain-assisted decentralised federated learning that will completely prohibit malicious clients from poisoning the whole learning process or protect the entire process [1]. A blockchain-based federated learning model with secure multi-party computing model verification has been suggested to

counter poisoning attacks [1], [19]. Furthermore, secure aggregation protocols can be employed to ensure that the global model update is computed correctly, even in the presence of malicious participants [2], [6]. Federated Learning (FL) systems face increasingly complex and adaptive threats, including multi-vector and coordinated attacks. These attack types vary by mechanism, intent, privacy, or model performance impact. Fig. 2 summarises key threat models in FL, including membership inference, property inference, model poisoning, backdoor attacks, and Sybil attacks, highlighting their mechanisms and potential consequences. Understanding these models provides the foundation for evaluating appropriate countermeasures.

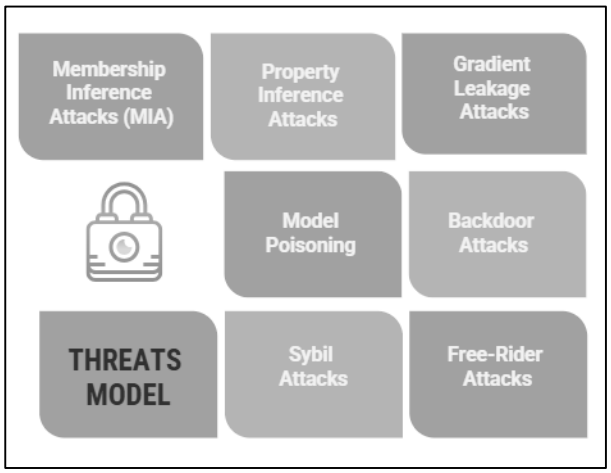

Fig. 2. Threat model of federated learning attacks.

C. Defence Strategies Against Federated Learning Attacks

Recent studies have revealed vulnerabilities in federated learning, demonstrating that model updates can inadvertently leak private information, necessitating robust defence mechanisms [9], [32]. A multifaceted approach encompassing data-level, model-level, and system-level defences is crucial to bolster the security of federated learning systems. Hybrid strategies integrate multiple defence mechanisms and offer a promising avenue for enhanced security and resilience against diverse attacks [2]. Multiple defence mechanisms have been proposed to combat various threats in FL, each addressing specific vulnerabilities. These include privacy-preserving techniques, robust aggregation methods, and decentralised trust frameworks. Fig. 3 maps common FL attack vectors to corresponding defence strategies and highlights the limitations associated with each countermeasure. This visual summary helps clarify the relationships between threats and mitigation approaches, allowing a deeper evaluation of specific techniques.

1) Data-level defences: Data-level defences constitute the first line of protection, focusing on safeguarding individual data points before they contribute to the global model [9]. Local Differential Privacy is a prominent technique, injecting noise into the client's local updates to obscure the contribution of individual data points [1]. Homomorphic Encryption offers another layer of protection by allowing computations on encrypted data, ensuring that the server only processes encrypted model updates, thus preventing access to raw data [19]. Applying these approaches can effectively mitigate privacy risks associated with sensitive training data [19]. Employing these methods can substantially diminish the risk of privacy breaches, reinforcing the protection of sensitive training data.

2) Model-level defences: Model-level defences operate at the aggregation stage, aiming to mitigate the impact of malicious or noisy updates on the global model [5]. Robust aggregation techniques, such as Krum, Median, Bulyan, and Trimmed Mean, identify and discard or down-weight potentially malicious updates, ensuring the global model remains robust despite adversarial clients. On the other hand, certified defences provide provable guarantees on the model's robustness against specific attacks, offering higher security assurance. These strategies play a key role in mitigating malicious influence and preserving the integrity of the global model.

3) System-level defences: System-level defences fortify the overall federated learning infrastructure, addressing potential vulnerabilities in the communication and coordination processes. Blockchain technology can be leveraged to create a decentralised and immutable record of model updates, enhancing transparency and preventing tampering [1]. Learning model on the distributed ledger [7].

a) Blockchain-based validation: Hybrid approaches represent the most promising avenue for defending against federated learning attacks, combining multiple defence mechanisms to provide comprehensive protection. Integrating privacy-preserving techniques, such as Local Differential Privacy or Homomorphic Encryption, with robust aggregation methods can protect data privacy and mitigate the impact of malicious updates. This multi-layered approach creates a synergistic effect, enhancing the overall security and resilience of the federated learning system. For instance, incorporating differential privacy with blockchain can improve privacy management, allowing data owners to manage their privacy preferences [1]. This combination balances data privacy and model accuracy, making federated learning a viable option for sensitive applications [33].

b) Client verification protocols: Client verification protocols authenticate clients before they participate in training, mitigating the risk of unauthorised or malicious clients joining the federation. By verifying participants' identities on the blockchain, frameworks can prevent single points of failure and poisoning attacks [1]. Blockchain helps trace malicious attacks by storing model participation, user fingerprints, and other key information. A permissioned blockchain-based federated learning method can chain incremental updates to an anomaly detection machine.

Developing effective defence strategies against federated learning attacks is an ongoing area of research, with new techniques and approaches emerging regularly. These techniques help ensure federated learning systems' privacy, security, and reliability, enabling their deployment in real-world applications where data privacy is paramount [34]. It is essential

to address these challenges to unlock the full potential of federated learning and ensure its responsible and secure deployment across various domains [35].

As summarised in Table II, which supports a structured comparison of defences across attack vectors, validation metrics, and deployment constraints. Vectors, validation metrics, and deployment constraints.

TABLE II. COMPARATIVE SUMMARY OF FL DEFENCE STRATEGIES

Defence Type	Technique	Targeted Attacks	Strengths	Limitations
Data-Level	Local Differential Privacy	Gradient leakage, inference	Decentralised, lightweight	Privacy-utility trade-off
Data-Level	Homomorphic Encryption	Server-side attacks	Strong privacy, data never exposed	Heavy computation
Model-Level	Krum / Trimmed Mean	Model poisoning, backdoor	Effective against outliers	Not Sybil-proof
Model-Level	DP-RFA	Poisoning + privacy attacks	Formal robustness guarantees	Requires a trusted setup
System-Level	Secure Aggregation	Gradient leakage	Aggregated updates only	Poisoning still possible
System-Level	Blockchain Validation	Free-riders, Sybil, poisoning	Immutable audit trail, client trust	Computational & consensus latency

4) Hybrid and emerging strategies: Hybrid defence strategies are gaining prominence in federated learning as they comprehensively address the multifaceted security challenges in decentralised machine learning. These strategies combine multiple defence mechanisms to create a layered security architecture that is more resilient to attacks than any single defence alone. For instance, combining differential privacy with secure aggregation can provide robust protection against inference and model poisoning attacks [10]. Differential privacy adds noise to the model updates to protect individual client data, while secure aggregation ensures that the server only receives the aggregated model updates without revealing individual contributions [1]. Furthermore, hybrid defence strategies can adapt to different attack scenarios and data distributions, providing a more flexible and effective defence mechanism [1]. This method is more suitable for sophisticated real-world situations because it combines the advantages of various defence strategies. The resilience of federated learning systems can be significantly increased by combining the benefits of blockchain technology with differential privacy techniques.

Emerging trends in federated learning defence strategies focus on developing more adaptive and intelligent defence mechanisms that automatically detect and respond to evolving attack patterns. These strategies leverage anomaly detection, reinforcement learning, and meta-learning to identify and mitigate attacks in real-time. Anomaly detection algorithms can identify suspicious model updates or client behaviour that deviates from the norm. Reinforcement learning can be used to train a defence agent that learns to adjust defence parameters based on the observed attack patterns adaptively. Meta-learning can be used to train a model that can quickly adapt to new attack scenarios by learning from previous attacks. Through a case study on federated intrusion detection systems, the capabilities in detecting anomalies and securing critical infrastructure without exposing sensitive network data can be demonstrated [4]. Such cutting-edge strategies hold tremendous promise for improving federated learning's security and resilience in the face of constantly changing threats. To stay ahead of the attackers, companies should use the most advanced technology and work together in a way that allows them to contribute their insights securely.

Advanced encryption techniques, such as homomorphic encryption, safeguard data privacy during federated learning. Homomorphic encryption allows computations on encrypted data without decrypting, ensuring that sensitive information remains protected throughout the learning process [1]. This is particularly useful in federated learning scenarios where data is distributed across multiple devices and cannot be shared in plaintext. By leveraging homomorphic encryption, the server can aggregate client model updates without seeing the underlying data, preventing potential privacy breaches [15]. The advent of sophisticated encryption strategies guarantees that sensitive data is protected during federated learning activities, thus increasing confidence in the technology's use across various industries.

To enhance clarity and summarise the defensive landscape, Fig. 3 visually maps key attack vectors in Federated Learning (FL), the vulnerabilities they exploit, corresponding defence mechanisms, and their associated limitations. This diagram supports textual taxonomy and comparative tables by providing a holistic view of how threats are addressed and where residual risks remain.

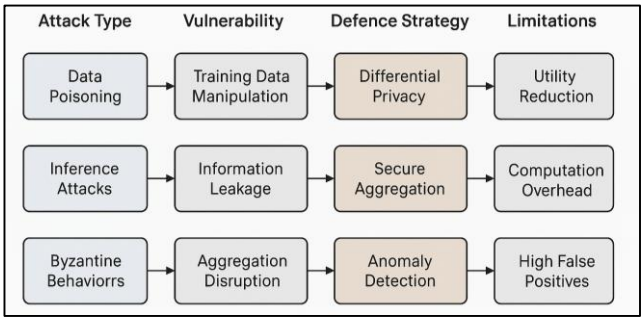

Fig. 3. Threat–defence–limitation mapping in federated learning security.

This flowchart visualises the relationship between common attack types in FL (e.g., model poisoning, inference attacks), the system vulnerabilities they exploit, corresponding mitigation strategies (e.g., differential privacy, secure aggregation), and each defence mechanism's inherent trade-offs or limitations.

V. DISCUSSION

A. Key Findings

Current security frameworks often lack the sophistication to discern subtle anomalies indicative of malicious intent, highlighting the need for intelligent, context-aware systems [2]. Such systems should integrate real-time monitoring of client activities, employing statistical analysis and machine learning techniques to identify deviations from expected behaviour [3]. Furthermore, the dynamic adjustment of privacy budgets, aggregation rules, or trust scores based on the assessed risk level is crucial for maintaining data privacy while preserving model accuracy. This adaptive approach requires sophisticated algorithms that balance the trade-off between security and utility, ensuring that defensive measures do not unduly impede learning [36].

The structured use of figures and summary tables was intentional to enhance reader comprehension, particularly given the complex multi-dimensional nature of threats and defences in FL systems. These visual tools complement the narrative synthesis and provide a concise reference for practitioners evaluating real-world applicability.

Decentralised trust infrastructures, potentially leveraging blockchain and distributed ledger technologies, offer a promising avenue for enhancing accountability and security in large-scale FL systems [1]. The inherent immutability and transparency of blockchain provide a robust platform for validating client updates, auditing model evolution, and establishing tamper-proof records of all transactions [1]. By decentralising the trust mechanism, the reliance on a central aggregator is reduced, mitigating the risk of single points of failure and bolstering the overall resilience of the FL system [1]. Smart contracts can further automate and enforce security policies, ensuring participant compliance with predefined rules [1]. However, implementing blockchain-based solutions in FL environments presents challenges related to scalability and computational overhead [1]. Innovative approaches are needed to optimise the performance of blockchain networks in the context of FL, such as using consortium blockchains or sharding techniques [35].

Addressing the resource constraints of edge devices and IoT deployments is paramount for the widespread adoption of FL in diverse application domains. Lightweight cryptographic and differential privacy mechanisms must be developed to minimise the computational burden on these devices, enabling them to participate effectively in the learning process without compromising their performance or battery life. Techniques such as homomorphic encryption and secure multi-party computation can provide strong security guarantees, but often incur significant computational costs. Therefore, research is needed to develop more efficient variants of these techniques tailored to the specific requirements of FL. Moreover, novel approaches to differential privacy, such as local and distributed differential privacy, can offer enhanced privacy protection while minimising the impact on model accuracy. Integrating Blockchain, LDP, and FL enables stronger protection of trained models' integrity by preventing several attacks, such as poisoning attacks, background knowledge, and inference attacks [1].

The robustness of federated models can be significantly enhanced through adversarial training techniques that incorporate adversarial examples and simulated attacks into the training phase. Exposing the model to diverse potential threats can improve its ability to generalise to unseen data and resist malicious inputs. This approach generates adversarial examples to fool the model into making incorrect predictions. These examples can be crafted using various techniques, such as gradient-based methods and generative adversarial networks. Furthermore, simulated attacks can evaluate the model's resilience to adversarial behaviours, such as data poisoning and model poisoning. By incorporating these adversarial examples and simulated attacks into the training process, the model can learn to defend itself against a broader range of threats.

Establishing standardised evaluation frameworks is essential for facilitating reproducibility and consistent comparisons of different FL security techniques. Open-source benchmarks and evaluation metrics should be developed to provide a common platform for assessing the performance of FL systems under various attack scenarios. These benchmarks should include a diverse range of datasets, model architectures, and attack strategies, reflecting the complexity and heterogeneity of real-world FL deployments. Furthermore, the evaluation metrics should capture not only the accuracy and efficiency of the model but also its privacy and robustness. Differential privacy is often implemented to protect data privacy by obscuring model parameter data that each client transmits. This helps improve system security and preserve user data privacy [37] while enhancing model robustness and confidentiality [1]. However, current FL setups make it difficult for participants to verify the machine learning model's authenticity [19]. Standardised evaluation frameworks would enable researchers and practitioners to objectively compare security techniques and identify the most effective solutions for specific FL applications [11]. Recent studies demonstrate that an adversarial attacker may raise privacy concerns by launching inference attacks against other participants, even when the iterations are performed only a few times [30]. These attacks can be defended against by methods such as differential privacy. Compared to the taxonomy proposed by Nguyen et al. [11], which broadly classifies attacks into data and model categories, our model introduces a finer-grained surface-based classification. This facilitates more precise identification of attack entry points and informs layered defence design. Furthermore, our comparative defence summary (Table II) validates the practicality of proposed strategies by mapping them to real-world limitations such as computational cost and detection accuracy—current Research Gaps.

A significant gap in current research is the lack of effective defences against complex multi-client collusion attacks, where multiple malicious participants coordinate their actions to compromise the global model [2]. These attacks pose a substantial threat, as they can be challenging to detect and mitigate due to their distributed nature and the potential for subtle manipulation of the learning process. Further complicating the landscape is the trade-off between robustness and model performance, where defences designed to enhance robustness against adversarial attacks can inadvertently degrade the accuracy and generalisation capabilities of the model [19].

This trade-off requires careful consideration and the development of adaptive defence strategies that can dynamically adjust their strength based on the detected threat level and the desired level of model performance. The lack of comprehensive scalability testing in real-world federated learning scenarios also presents a challenge, as many existing defences have not been rigorously evaluated under large-scale deployments with heterogeneous data and diverse client capabilities. Addressing these gaps is essential for building trustworthy and reliable federated learning systems that can be confidently deployed in real-world applications.

Within the intricate domain of contemporary technological progression, the convergence of artificial intelligence (AI) and cloud computing has emerged as a transformative paradigm, revolutionising data processing, analysis, and dissemination across diverse sectors. According to study [38], federated learning decentralises AI model training by enabling computations directly on edge devices, enhancing model personalisation while preserving user privacy. As discussed by [39], cloud infrastructure provides scalable and elastic computational resources that support real-time AI workloads and large-scale model deployment. Additionally, the study [40] emphasises the role of this convergence in enabling privacy-aware and latency-efficient learning systems, particularly in applications involving sensitive or distributed datasets.

This convergence is not merely a confluence of technologies but rather a synergistic amalgamation that amplifies the capabilities of both domains, fostering innovation and driving efficiency gains across a spectrum of applications. The essence of this convergence lies in the ability of cloud computing to provide a scalable and cost-effective infrastructure for AI algorithms, enabling them to process vast datasets and execute complex computations with unprecedented speed and efficiency. As we navigate an era defined by the exponential growth of data, fueled by the proliferation of interconnected devices, the need for robust and scalable data processing solutions has become paramount. With its inherent elasticity and ability to dynamically allocate resources, cloud computing offers an ideal platform for AI algorithms to thrive, providing the necessary computational power and storage capacity to handle the ever-increasing volume of data.

The traditional paradigm of AI development, characterised by centralised data processing and algorithmic training, often encounters limitations regarding scalability, generalisation, and real-time responsiveness. To address these challenges, federated learning has emerged as a groundbreaking approach, enabling collaborative model training across decentralised devices while preserving data privacy [38]. Federated learning empowers AI models to learn from vast amounts of data distributed across numerous edge devices without centralising sensitive information. Federated learning, in essence, brings the learning process to the edge, directly onto devices, harnessing the computational capabilities of heterogeneous devices to enhance model quality [38], [39]. This distributed approach to machine learning addresses critical challenges associated with data privacy, security, and access in traditional centralised systems.

Federated learning operates on the principle of distributed model training, where each participating device locally updates a shared model using its data, subsequently transmitting the model updates to a central server for aggregation. This iterative process of local model training and global model aggregation ensures that the learned model generalises well to the diverse data distributions across different devices, without compromising the privacy of individual datasets [38]. Federated learning distinguishes itself through its ability to train models across decentralised devices, offering a solution to privacy concerns and scalability challenges inherent in centralised systems [38]. By keeping data localised on devices, federated learning minimises the risk of data breaches and misuse, while utilising vast datasets distributed across numerous sources [41]. Moreover, federated learning enhances model generalisation by leveraging the diversity of data across different devices, resulting in more robust and accurate AI models that can effectively address real-world problems.

Federated learning, a burgeoning technique in distributed machine learning, facilitates model training across many decentralised devices, obviating the need for centralised data collection. This approach is particularly salient in scenarios where data privacy is paramount, such as healthcare, finance, and IoT applications [38]. By enabling collaborative model training without direct access to sensitive data, federated learning upholds user privacy and complies with stringent data protection regulations [38]. The core tenet of federated learning lies in its ability to train models across diverse data distributions, enhancing generalisation and robustness. The decentralised nature of federated learning obviates the need to consolidate data in a central repository, which can be daunting due to logistical hurdles, regulatory constraints, and security considerations [38]. Synchronous federated learning requires all participants to complete local computations before updates are sent to a central server. In contrast, asynchronous federated learning allows the central server to immediately integrate updates from any ready participant [39].

To further enhance the privacy guarantees of federated learning, differential privacy techniques can be integrated to obfuscate individual contributions during model training [39]. Differential privacy introduces carefully calibrated noise to the model updates, ensuring that the presence or absence of any single data point has a negligible impact on the final model, thereby protecting the privacy of individual users. Federated learning not only addresses privacy concerns but also improves the efficiency and scalability of machine learning models. This approach is beneficial when data are located in multiple clinical systems or when learning from sensitive personal data.

The convergence of federated learning and differential privacy holds immense promise for many applications, particularly in domains where data privacy and security are paramount. Differential privacy enhances data privacy in federated learning by adding noise during data queries and model updates [39]. These areas include healthcare, finance, and the Internet of Things.

VI. Future Directions

Future research directions should prioritise the development of adaptive, context-aware defences that can dynamically adjust their parameters and strategies based on the specific characteristics of the data, the threat environment, and the

available resources. By tailoring the defences to the particular context, it becomes possible to optimise their effectiveness and minimise their impact on model performance [3]. Combining secure aggregation with differential privacy dynamically represents another promising avenue for future research. Secure aggregation ensures that individual client updates are aggregated without revealing the underlying data, while differential privacy adds noise to the aggregated updates to protect against inference attacks [19]. Dynamically adjusting the parameters of these techniques based on the detected threat level and the desired privacy-utility trade-off can further enhance the security and performance of federated learning systems. Decentralised, blockchain-supported federated learning security offers a novel approach to improving trust and transparency in federated learning systems [7]. Attack detection and early warning systems in federated learning are crucial for proactively identifying and mitigating potential threats before they can cause significant damage. Integrating federated learning with blockchain technology allows for creating immutable audit trails and decentralised governance mechanisms, improving the learning process's accountability and trustworthiness [33]. A consortium blockchain-based federated learning framework enables decentralised, reliable, and secure federated learning without a centralised model coordinator [42]. Blockchain can address key challenges, propel the field forward, and potentially enhance data privacy and improve trust and security [35].

VII. Conclusion

Federated Learning (FL) represents a transformative approach in privacy-preserving machine learning, enabling decentralised model training across distributed clients without exposing raw data. However, the shift from centralised to federated paradigms introduces novel vulnerabilities that adversaries can exploit to compromise model integrity, data privacy, and system reliability.

Despite the comprehensive scope of this review, several limitations should be acknowledged. First, the analysis is constrained by the availability and maturity of published studies between 2020 and 2025, which may not fully capture the most recent developments or unpublished techniques in FL security. Second, while the taxonomy and comparative evaluation provide structured insights, they rely on secondary data rather than experimental benchmarking. Furthermore, the real-world effectiveness of many proposed defences—especially in large-scale, heterogeneous FL deployments—remains underexplored due to a lack of unified validation frameworks. These limitations highlight the need for ongoing empirical evaluation and longitudinal studies to assess defence robustness in dynamic adversarial settings.

To advance the field, future research must prioritise the development of adaptive, intelligent defence mechanisms capable of responding dynamically to evolving threats. Emphasis should also be placed on achieving a balance between security, privacy, and performance, particularly in large-scale, heterogeneous environments. Hybrid defence architectures, federated adversarial training, and lightweight cryptographic techniques hold promise in addressing these challenges. Ultimately, the continued evolution of FL security requires collaborative efforts across disciplines, integrating insights from cryptography, distributed systems, artificial intelligence, and regulatory policy. Ensuring robust, trustworthy FL systems will support privacy-aware innovations across critical sectors such as healthcare, finance, and autonomous systems.

Limitations: While this review provides a comprehensive classification of FL attack vectors and defence mechanisms, it is limited by the scope of current literature and the lack of unified benchmarking datasets. Furthermore, the practical deployment challenges—such as computation overhead, privacy-utility trade-offs, and client heterogeneity—require empirical validation in future work.

Acknowledgment

The author(s) sincerely thank Pejabat Penerbit, University Tun Hussein Onn Malaysia and the Faculty of Computer Science and Technology for their support throughout this research. Thanks to Dr. Shamsul Kamal bin Ahmad Khalid for the valuable guidance, feedback, and encouragement. The authors also acknowledge the use of publicly available resources and literature that have significantly contributed to the completion of this review. This work was conducted by the academic and ethical standards set forth by the institution. Intelligent Logistics Vehicle Scheduling Based on MPHIGA

Xinxin Gao*, Qing Wang
School of Liberal Education, Liaoning University of International Business and Economics, Dalian, 116052, China

***Abstract*—The current intelligent logistics vehicle scheduling faces challenges, including the difficulty of obtaining real-time location data and the need for manual intervention in emergencies. To address these issues, a modified multi-population hybrid genetic algorithm is proposed, along with an intelligent scheduling model constructed through the reconstruction of domain generation strategies. Experimental results show that the model stabilizes the total cost at 7864 yuan within 49 iterations, whereas the dual-population hybrid genetic algorithm requires 51 iterations, making convergence more time-consuming. Moreover, when the scheduling frequency is two, the research model successfully allocates three company vehicles, whereas the comparison algorithm can only allocate two. Overall, the research model offers significant advantages in reducing operating costs and enhancing dynamic response capabilities, providing effective technical support for the digital transformation of logistics companies.**

Keywords*—Multi-population hybrid improved genetic algorithm; domain generation algorithm; logistics vehicles; co-evolution; scheduling management

I. Introduction

With rapid technological advancements, intelligent systems are increasingly integrated into various industries. Intelligent vehicle management is a key factor in improving operational efficiency in logistics and transportation [1]. Scientific scheduling of logistics vehicles optimizes routes and vehicle allocation, while also enabling real-time tracking of logistics resources, thus improving efficiency based on vehicle status and road conditions [2,3]. Although current intelligent logistics vehicle scheduling uses machine learning and big data analysis to predict demand fluctuations and optimize route selection, challenges remain [4]. Data silos significantly affects overall scheduling performance, while factors such as weather changes and uneven resource distribution make it harder to matching vehicles with cargo [5]. Some intelligent logistics vehicle scheduling systems cannot fully monitor and manage vehicle safety, limiting their ability to provide comprehensive data reports and statistics, which limits enterprises in conducting in-depth analysis and optimization [6]. To address these challenges, this study integrates the Domain Generation Algorithm (DGA) with the Multi-Population Hybrid Improved Genetic Algorithm (MPHIGA). The proposed model aims to improve intelligent logistics vehicle scheduling. DGA generates random domain names, which are introduced into MPHIGA for population initialization and mutation operations, enhancing the algorithm's global search capability. This study aims to improve real-time monitoring and positioning in logistics vehicle scheduling, enhance the profitability of logistics enterprises, and support the transformation of the logistics industry.

This study consists of four sections. Section II summarizes domestic and international research on MPHIGA and logistics vehicle scheduling. Section III focuses on optimizing MPHIGA with DGA to develop the scheduling model. Section IV evaluates the performance and practical application of the proposed model. Finally, Section V presents the study's conclusions.

II. Related Works

MPHIGA is an improved genetic algorithm that uses multiple populations for simultaneous optimization, enhancing global search capabilities and preventing premature convergence. Many researchers have explored its core characteristics. For example, Yu et al. proposed an algorithm based on a hybrid genetic algorithm to reduce the total response time between cloud data centers and medical devices. By combining the genetic algorithm with a hybrid metaheuristic method and conducting simulation experiments, the study demonstrated the effectiveness of this approach [7]. Sun H's team introduced a particle swarm optimization method based on genetic algorithms for inverse lithography technology. This method improved lithographic imaging performance through iterative optimization. Experimental results showed that it had better convergence capability compared to traditional genetic algorithms [8]. Additionally, DGA enhances search efficiency and solution quality through the cooperation of two populations. Its strong search ability has led to its adoption by some researchers. Fang et al. developed a novel interval prediction method for photovoltaic power generation to improve forecasting timeliness. Applying an integral dual-domain decomposition method for learning and prediction, the study found that the error values were significantly reduced [9]. Zhang's team proposed a wave source localization method for harmonic analysis. By analyzing harmonic and non-harmonic sources from a time-domain perspective, simulation experiments verified the effectiveness of this approach [10]. Zhan et al. investigated the freshness of sensory data in unmanned aerial vehicles and introduced a domain generation algorithm-based strategy to obtain near-optimal solutions. By enabling rapid decision-making, this approach improved computational efficiency. Results showed that the algorithm exhibited strong flexibility [11].

Intelligent logistics vehicle scheduling plays a key role in transportation and has been widely applied by logistics enterprises in recent years. Effective scheduling models allows for efficient resource allocation. Cho's team addressed the

limitations of traditional logistics research by proposing a heuristic scheduling algorithm. By introducing various cost functions to evaluate scheduling results, experiments showed that this method effectively reduced delivery costs [12]. Elgharably et al. developed a hybrid search algorithm based on the vehicle routing problem in operations research. This algorithm solves solve multi-objective problems with balance trade-offs. Simulation experiments verified its feasibility and effectiveness [13]. Berghman et al. introduced a general model for outbound vehicle routing and conducted a review of comprehensive scheduling problems using an integrated approach. The study confirmed that this method provided valuable data references for future research directions [14]. Ding's team proposed a novel vehicle scheduling method to recommend optimal routes for electric vehicles, aiming to mitigate traffic congestion. By integrating multiple interactive modules for iterative decision-making, results demonstrated the feasibility of this approach [15]. Shen and Yan examined the impact of bus services on traffic and introduced a dynamic vehicle scheduling method. Using hybrid dynamic control, the method handled abnormal operating conditions effectively. Experimental results indicated strong flexibility and timeliness [16].

Existing research has made progress in reducing logistics costs and optimizing logistics services. However, challenges such as information delays and inaccuracies remain. To address these limitations, this study integrates DGA with MPHIGA to develop a novel intelligent logistics vehicle scheduling model. Each scheduling scheme undergoes a fitness function, and individuals are selected for genetic and crossover operations based on fitness values. The study employs a multi-population hybrid improved genetic algorithm, primarily addressing the issues of traditional genetic algorithms in logistics scheduling, such as falling into local optima and insufficient population diversity. By introducing domain name generation algorithms to optimize dynamic coding strategies, it resolves the decoding efficiency bottleneck under complex constraints. Compared to existing models, its multi-population co-evolution mechanism simultaneously optimizes vehicle allocation and route generation, making it suitable for high-dimensional logistics scheduling. This approach aims to enable rapid adjustments to scheduling strategies in response to changing logistics demands, providing flexible logistics solutions.

III. The Multi-Population Hybrid Improved Vehicle Scheduling Model for Intelligent Logistics

A. *Intelligent Logistics Vehicle Scheduling Strategy Based on MPHIGA*

Compared with the traditional genetic algorithm, MPHIGA breaks away the framework of single-population genetic evolution and assigns different control parameters to different populations through simultaneous optimization searches [17]. In MPHIGA, multiple populations achieve collaborative evolution through specific operational factors, enhancing global search capability and prevents premature convergence compared to the traditional genetic algorithm [18,19]. MPHIGA is applied to intelligent vehicle scheduling strategies, automatically calculating the optimal vehicle scheduling plan based on multiple factors such as vehicle location, real-time road conditions, and cargo volume. The workflow of MPHIGA is shown in Fig. 1.

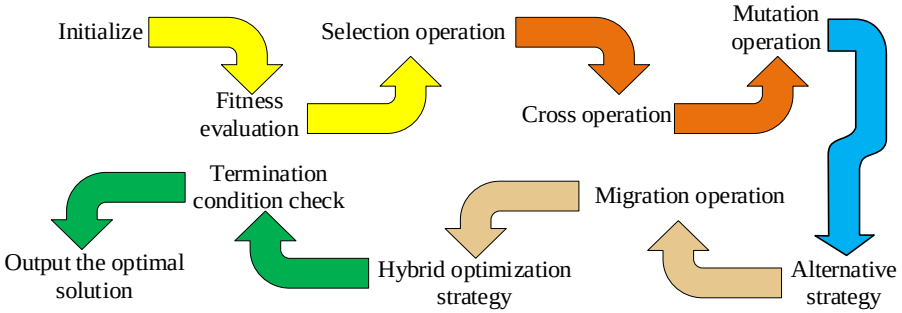

Fig. 1. Schematic diagram of MPHIGA workflow.

As shown in Fig. 1, MPHIGA first initializes the population size and the scale of each population randomly. The number of sub-populations is set according to the problem complexity and resource constraints. The fitness function evaluates each individual in the sub-population based on the problem requirements. In the selection process, individuals with higher fitness values are more likely to be selected. The crossover and different crossover strategies can be used to maintain diversity. The fitness function is given in Eq. (1).

$$f_j = \begin{cases} F(G_{ej}), x' = 1 \\ F(G_{ej}) + M_0, x' = 0 \end{cases} \quad (1)$$

In Eq. (1), $F(G_{ej})$ and $x' = 1$ represent the objective function value and the feasibility of the decoded solution as a binary variable, respectively. M_0 is assigned a finite integer. x' and $x' = 0$ are binary variables and represent an infeasible decoded solution. When applying MPHIGA to the intelligent logistics vehicle scheduling strategy, the intelligent scheduling dynamically adjusts the transportation plan based on demand, reducing empty mileage and transportation time. The key components of intelligent logistics vehicle scheduling are shown in Fig. 2.

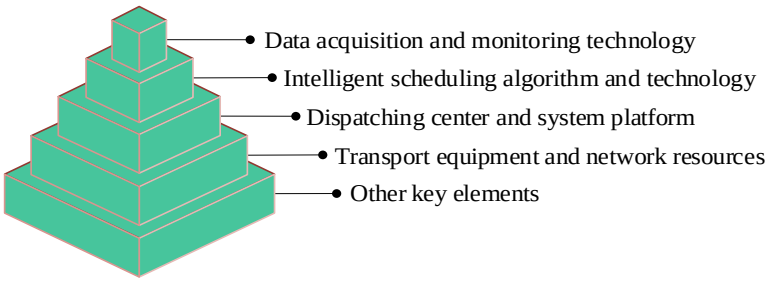

Fig. 2. Schematic diagram of the components of intelligent logistics vehicle scheduling.

$$F(l)=\begin{cases}\sum_{I=1}^{n-1}\sqrt{(X_I+1-X_I)^2+(y_I+1-y_I)^2}+num\times p_{punish1}\\ I=1,2,3,.....,n-1\end{cases} \quad (2)$$

As shown in Fig. 2, the key components of intelligent logistics vehicle scheduling consist of five main parts. The data collection and monitoring technology uses sensors and onboard intelligent devices. Sensors collect real-time key data from logistics vehicles, while onboard intelligent devices monitor vehicle status to ensure accurate execution of scheduling instructions and enhance transportation safety. The intelligent scheduling algorithm uses big data and artificial intelligence to optimize logistics scheduling, with cloud computing and big data analysis providing efficient data storage and processing capabilities. The dispatch center and system platform include the intelligent dispatch center, user interface, and operating system. The dispatch center receives and processes data from sensors and onboard devices, generating scheduling instructions based on intelligent algorithms and transmitting them in real-time to drivers and vehicles. The evaluation function for the total path length in logistics vehicle scheduling is given in Eq. (2) [20].

In Eq. (2), X_I and l represent the midpoint of the line segment connecting the start and end points and the path, respectively. num and $p_{punish1}$ are the number of infeasible segments in the path and the penalty value. y_I represents the vertical coordinate when the two-dimensional path encoding is converted into one-dimensional encoding. By sorting the selection probabilities assigned to individuals, the cumulative probability equation is given in Eq. (3).

$$p_{\sum_i}=\sum_{i=1}^{NP}p_i \quad (3)$$

Transportation equipment and logistics networks ensure the execution of logistics transportation tasks and support the implementation of intelligent logistics vehicle scheduling. Other key elements include real-time detection and early warning systems, which reduce transportation risks. The intelligent logistics vehicle scheduling strategy based on MPHIGA is shown in Fig. 3.

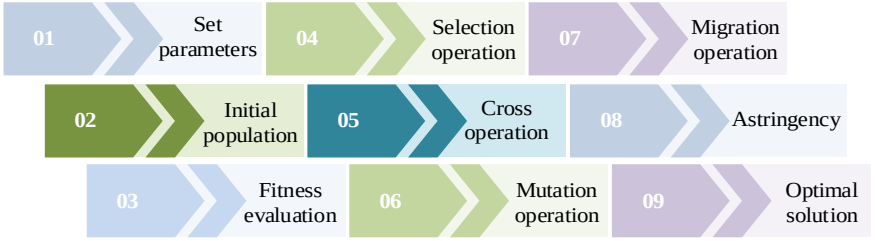

Fig. 3. Intelligent logistics vehicle scheduling strategy based on MPHIGA.

As shown in Fig. 3, in the MPHIGA-based intelligent logistics vehicle scheduling strategy, each individual represents a potential scheduling plan. After setting the basic parameters of the genetic algorithm, each sub-population is randomly initialized. The fitness function defines and evaluates individuals and scheduling plans based on the vehicle scheduling problem requirements and multiple indicators. Within each sub-population, the crossover operation generates new offspring. The mutation operation is usually random, and individuals from different sub-populations exchange information to enhance capabilities. The exchange strategies include both synchronous and asynchronous communication. The threshold value in the exchange strategy is given in Eq. (4).

$$E=\frac{1}{N}\sum_{i=1}^{N}\left|f_i-f_{avg}\right| \quad (4)$$

In Eq. (4), f_i, N, and f_{avg} represent the fitness value of the i-th individual in the population, the number of individuals in the population, and the average fitness value. The crossover probability equation is given in Eq. (5).

$$p_c = \begin{cases} p_{c1} - (p_{c1} - p_{c2}) \dfrac{f_{\max} - f'}{f_{\max} - f_{avg}} & f' \geq f_{avg} \\ p_{c1} & f' < f_{avg} \end{cases} \quad (5)$$

In Eq. (5), $f_{\max}$ and p_{c1} represent the fitness value of the optimal individual in the population and the maximum mutation probability. f' and p_{c2} represent the larger fitness value and the minimum mutation probability of the two chromosomes to be crossed.

B. Construction of the Intelligent Logistics Vehicle Scheduling Model with DGA

Although applying MPHIGA to intelligent logistics vehicle scheduling allows precise environmental recognition through high-precision sensors and visual recognition technologies, it may still prematurely converge to local optima when facing complex problems due to ineffective selection strategies. For large-scale problems, MPHIGA requires multiple iterations to generate and evaluate populations, which leading to increased computational time and resource consumption [21]. Therefore, DGA is introduced to optimize MPHIGA, allowing the search process to adapt dynamically and avoid premature convergence. DGA is an algorithm that generates a large number of random and short-lived domain names. It can generate different domain names as needed, offering flexibility and adaptability. The domain generation process of DGA is shown in Fig. 4.

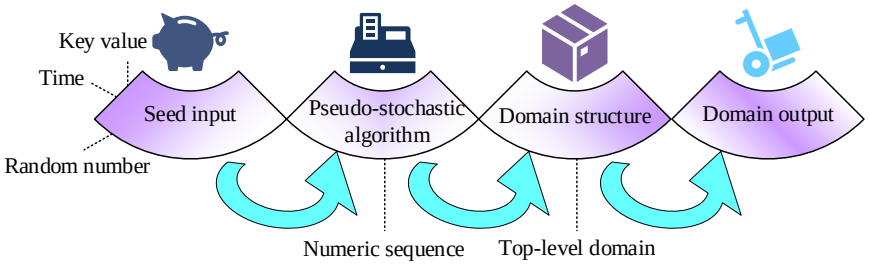

Fig. 4. Schematic diagram of DGA domain name generation.

As shown in Fig. 4, DGA initializes a pseudo-random algorithm using one or more specific parameters as seeds, which typically include key values, time, and random numbers. Different seeds generate different domain sequences. During the execution of the pseudo-random algorithm, DGA generates a series of numerical sequences based on the input seed, forming part of the domain names. The generated sequences are then combined into one or more domain names. These domain names are often used by malware or attackers to communicate with servers or other targets. DGA-generated domain names exhibit high unpredictability and randomness, allowing attackers to periodically change the seed to alter the generated domain sequences. The calculation method for the consecutive number ratio is given in Eq. (6).

$$C_d = \frac{N_{cd}}{L} \quad (6)$$

In Eq. (6), N_{cd} and L represent the number of consecutive number pairs and domain name length, respectively. The equation for domain name length is given in Eq. (7).

$$L = len(domain) \quad (7)$$

In Eq. (7), $domain$ and $len()$ represent the domain name string and its length. The dynamic generation mechanism of DGA is used to adjust the search strategy of MPHIGA, and the optimization process is shown in Fig. 5.

As shown in Fig. 5, DGA generates a large number of random domain names through its randomness generation mechanism. This randomness is introduced into MPHIGA for population initialization and mutation operations, enhancing the global search capability. MPHIGA already has strong global search capabilities through hybrid improvement strategies, and introducing DGA further strengthens the ability to explore optimal solutions in a broader solution space. The entropy value of domain names is given in Eq. (8).

$$H = -\sum_{z=1}^{n} p_z \log p_z \quad (8)$$

In Eq. (8), p_z represents the frequency of character z. The number of numeric characters is calculated using Eq. (9).

$$Nd = \sum_{z \in digits} count(z) \quad (9)$$

In Eq. (9), $digits$ represents the set of numeric character z. The user interface provides an intuitive interface for seamless integration with other logistics management systems, facilitating monitoring, collaboration, and data sharing. The randomness of DGA helps prevent MPHIGA based on premature convergence to local optima. By continuously introducing new random elements, the algorithm maintains exploration within the solution space and ultimately finds the optimal solution. The intelligent logistics vehicle scheduling model based on DGA-MPHIGA is shown in Fig. 6.

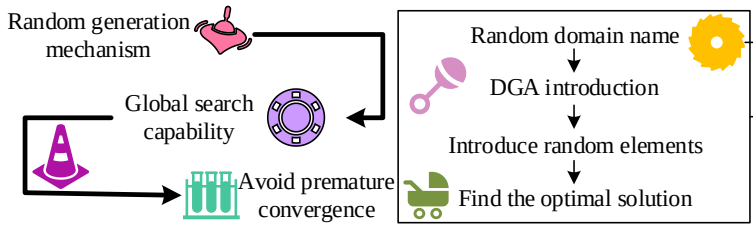

Fig. 5. Schematic diagram of DGA optimization of MPHIGA.

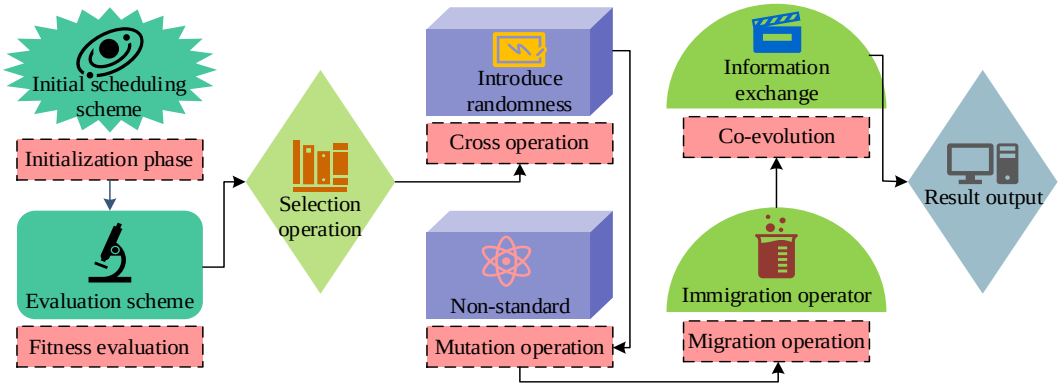

Fig. 6. Intelligent logistics vehicle scheduling model based on DGA-MPHIGA.

As shown in Fig. 6, the random generation mechanism of DGA produces an initial set of scheduling plans. After evaluating the fitness of each scheduling plan, the best individuals are selected for genetic and crossover operations. Mutation operations are usually random, with their probability and intensity adjusted according to the scenario. Within sub-populations, replacement strategies ensure continuous optimization of the population. DGA enables non-standard crossover and mutation operations with a certain probability, and the migration operator facilitates information exchange and collaborative evolution among populations. The model terminates when the stopping condition is met or the preset iteration count is reached, ultimately obtaining the optimal logistics vehicle scheduling plan. The equation for computing the probability distribution of chromosomes in the population is given in Eq. (10).

$$p_i = \begin{cases} p \times (1-p)^{i-1}, & i = 2, \cdots, NP \\ (1-p)^{i-1}, & i = 1 \end{cases} \tag{10}$$

In Eq. (10), i and NP represent the individual's ranking and the population size. p represents a constant within the range of $(0,1)$. The optimal path equation is given in Eq. (11).

$$\begin{aligned} &MinZ = \sum_{w=1}^{W} \left\{ \sum_{u=1}^{A_w} C_w D_{k_{w(u-1)} k_{wi}} D_{k_{mm} k_{w0}} sign(A_w) \right\} \\ &w = 1, 2, \cdots W \end{aligned} \tag{11}$$

In Eq. (11), A_w and k_w represent the number of customer points served by vehicle w and the w-th path, respectively. k_{wi} and k_{w0} are the sequence positions of customer points in path w, while C_W and D represent the cost per unit travel distance of vehicle w and the maximum allowable travel distance. The vehicle transportation cost equation is given in Eq. (12).

$$M = h \sum_{s,q=1}^{m} x_{sq} d_{sq} \tag{12}$$

In Eq. (12), h and d_{sq} represent the transportation cost per unit distance and the transportation distance between customer s and customer q. m represents the total number of customers.

IV. Performance Verification of the DGA-MPHIGA Intelligent Scheduling Model

A. Performance Analysis of the Intelligent Logistics Vehicle Scheduling Model

To analyze the performance of the intelligent logistics vehicle scheduling model based on DGA-MPHIGA, the study used intelligent logistics vehicle scheduling models based on MPHIGA, Simple Genetic Algorithm (SGA), and Dual Population Hybrid Genetic Algorithm (DPHGA) as comparison models. The experiments were conducted on a Windows XP SP3 operating system with a Pentium(R) 4 2.66 GHz CPU and 12 GB of RAM. The experimental datasets included the TSPlib dataset and the Solomon dataset. The TSPlib dataset was used as the training set, containing specific city coordinates and distance matrix information for solving the traveling salesman problem and routing problems in vehicle scheduling. The Solomon dataset was used as the test set, providing detailed parameters such as customer location coordinates, time windows, and demand quantities. The study first compared the scheduling costs of the four models on the training and test sets, and the results are shown in Fig. 7.

As shown in Fig. 7(a), when the scheduling frequency reached five times, the cost of the proposed model was only 0.112 million yuan. However, the cost of the MPHIGA scheduling model had already reached 0.128 million yuan when the scheduling frequency was three times. Fig. 7(b) shows that the DGA-MPHIGA scheduling model maintained lower cost consumption than the comparison models in the test set. When the scheduling frequency was four times, the cost of the MPHIGA and DPHGA scheduling models was 0.137 million yuan and 0.159 million yuan, respectively, while the cost of the SGA scheduling model was the highest among the four models at 0.188 million yuan. These results indicated that the DGA-MPHIGA scheduling model exhibited lower cost consumption in both the training and test sets, demonstrating higher resource utilization. Next, the study conducted a comparative analysis of the scheduling time of the four models on the TSPlib dataset, with results shown in Fig. 8.

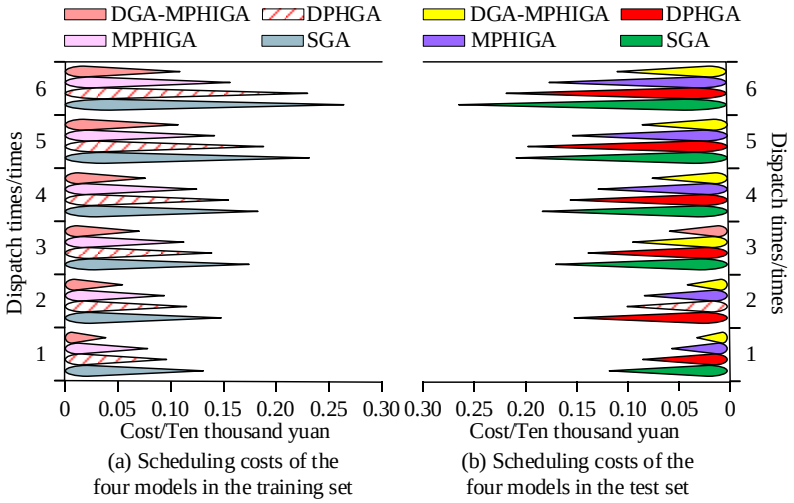

Fig. 7. Comparison of the scheduling costs of four models in training and test sets.

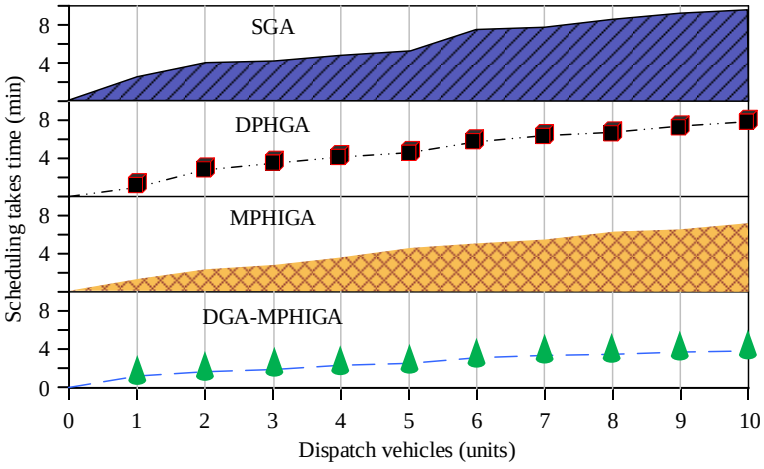

Fig. 8. Comparison of the scheduling time of four models in the TSPlib dataset.

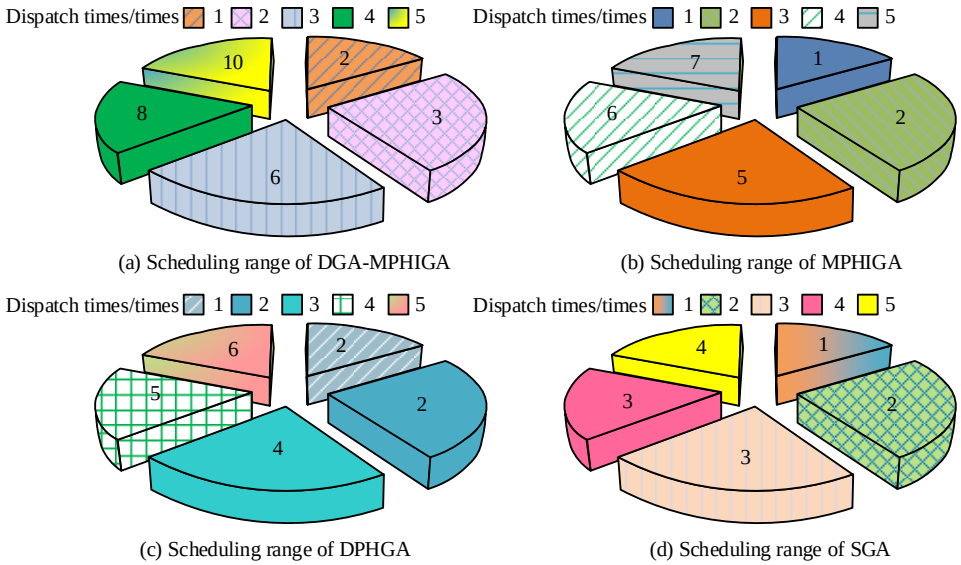
As observed in Fig. 8, when the number of scheduled vehicles was two, the scheduling time of the DGA-MPHIGA and MPHIGA models was 1.24 minutes and 2.67 minutes, respectively. When the number of scheduled vehicles reached ten, the scheduling time of the DGA-MPHIGA model was 3.98 minutes, while the scheduling time of the SGA model was 5.94 minutes longer than that of the proposed model. Meanwhile, the scheduling times of the MPHIGA and DPHGA models were 7.31 minutes and 7.98 minutes, respectively. These results indicated that the DGA-MPHIGA model achieved the shortest scheduling time among the four models. The model was capable of computing the optimal vehicle scheduling solution in a shorter time, significantly improving overall logistics efficiency. Additionally, the shorter scheduling time allowed the model to quickly adapt to new order demands and traffic conditions. Finally, the study analyzed the vehicle distribution route length and time of the four models on the training and test sets, with results shown in Table I.

TABLE I COMPARISON OF VEHICLE DELIVERY ROUTE LENGTH AND TIME

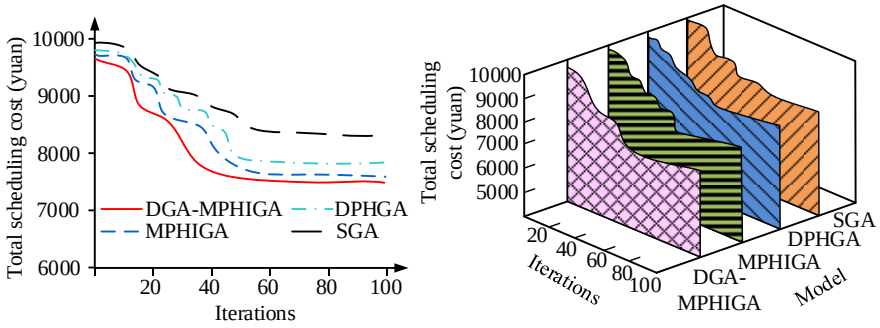


Data set	Scheduling model	Average calculated path length (km)	Optimal path distance length (km)	Running time (s)
Training set	DGA-MPHIGA	411.32	410.84	9.54
	MPHIGA	423.15	419.27	14.36
	DPHGA	435.81	425.33	18.24
	SGA	449.25	437.41	21.39
Test set	DGA-MPHIGA	412.94	408.57	9.21
	MPHIGA	427.35	424.35	14.17
	DPHGA	436.87	431.23	19.34
	SGA	451.29	439.78	22.17

As presented in Table I, in the training set, the average computed path length and optimal path length of the DGA-MPHIGA model were 411.32 km and 410.84 km, respectively, both lower than those of the comparison models. The SGA model exhibited the highest average computed path length at 449.25 km, with a runtime of 21.39s. The optimal path length of the MPHIGA model in the training set increased compared to previous results, reaching 424.35 km, with a runtime of 14.17s. At this point, the optimal path length of the DGA-MPHIGA model was only 408.57 km, with its runtime being the shortest among the four models, at just 9.21s. These results demonstrated that the DGA-MPHIGA model had the shortest average computed path length and optimal path length, leading to faster delivery speeds and enabling the rapid computation of optimal logistics routes.

B. *Evaluation of the Practical Effectiveness of the Intelligent Scheduling Model*

To further validate the effectiveness of the intelligent logistics vehicle scheduling model in real-world applications, the study set the number of foreign trade enterprise vehicles to ten, along with ten loading points and thirteen unloading points. The transportation time was set to two hours, and the unit transportation cost was adjusted based on 5 yuan/km. The penalty coefficients for exceeding the time window and the vehicle's rated load were set to 200 and 10,000, respectively. The study first analyzed the scheduling range of the four models when scheduling ten enterprise vehicles, with results shown in Fig. 9.



As shown in Fig. 9, the DGA-MPHIGA model achieved a significantly wider scheduling range than the other three comparison models under the same scheduling frequency. When the scheduling frequency was two times, the DGA-MPHIGA model scheduled three enterprise vehicles. When the scheduling frequency increased to four times, the SGA model scheduled three enterprise vehicles, while the DPHGA and MPHIGA scheduling models scheduled five and six enterprise vehicles, respectively. At this point, the DGA-MPHIGA model was capable of scheduling eight enterprise vehicles. When the scheduling frequency reached five times, the model successfully scheduled all ten enterprise vehicles. These results indicated that the DGA-MPHIGA model demonstrated excellent vehicle scheduling capabilities, handling broader and more complex logistics transportation tasks. The study then analyzed the total cost optimization iterations of the four models under different vehicle demand scenarios, with the iterative change curves shown in Fig. 10.

(a) Scheduling range of DGA-MPHIGA (b) Scheduling range of MPHIGA

(c) Scheduling range of DPHGA (d) Scheduling range of SGA

(a) Iterative changes in the total cost optimization of the four models when four vehicles are required

(b) Iterative changes in total cost optimization for the four models when 8 vehicles are required

Fig. 10. Total cost optimization iteration curve under different requirements.

(a) The average operating time of the four models when four vehicles are required

(b) The average operating time of the four models when eight vehicles are required

Fig. 11. Comparison of average running time under different requirements.

As shown in Fig. 10(a), when the vehicle demand was four, the DGA-MPHIGA model exhibited a shorter convergence time. When the iteration count reached 37, the total scheduling cost of the model gradually stabilized, converging faster than the comparison models. The DPHGA model had the longest convergence time, reaching 51 iterations. Fig. 10(b) shows that when the vehicle demand was eight, the total scheduling cost optimization curves of all four models exhibited a downward trend as the iteration count increased, eventually stabilizing at different iteration points. The convergence time and iteration count of the DGA-MPHIGA model were both shorter than those of the comparison models. These results indicated that the DGA-MPHIGA model learned data patterns faster and reached stability with lower computational resource consumption. Finally, the study compared the scheduling time of the four models under different vehicle demand scenarios, with results shown in Fig. 11. As summarized in Fig. 11, the average runtime of the DGA-MPHIGA model under different vehicle demand scenarios was the lowest among the four models. When the vehicle demand was four, and the number of cities was ten, the shortest average runtime of the DGA-MPHIGA model was 0.87 seconds. At this point, the average runtime of the SGA model was 3.02 seconds, while those of the MPHIGA and DPHGA models were 1.97 seconds and 2.28 seconds, respectively. When the vehicle demand reached eight, the average runtime of all four models increased as the number of cities increased. When the number of cities reached 25, the average runtime of the DGA-MPHIGA and SGA models was 3.94 seconds and 6.89 seconds, respectively, while the runtime of the DPHGA model was 4.86 seconds. The SGA model exhibited an average runtime of 9.03 seconds when the number of cities reached 30. These results indicated that the DGA-MPHIGA model made scheduling decisions more quickly when handling different vehicle demands, ensuring faster delivery of goods from the starting point to the destination.

V. Conclusion

To address the shortcomings of current intelligent logistics vehicle scheduling methods in dynamic data acquisition and managing security, this study combined DGA and MPHIGA in an intelligent logistics vehicle scheduling model. By leveraging the dual-population mechanism of DGA and the hybrid strategy of MPHIGA, the model achieved information sharing and co-evolution, balancing global search and local exploitation with the feasible vehicle scheduling solution is represented as an individual in genetic algorithm by chromosome coding. The results showed that the optimal path length of the MPHIGA model in the training set increased, reaching 424.35 km, with a running time of 14.17s. At this point, the optimal path length of the DGA-MPHIGA model is only 408.57km, with the shortest

running time among the four models, at just 9.21s. When the number of scheduling instances reaches 5, the cost of the research model is only 0.112 million yuan. However, when the MPHIGA scheduling model has 3 instances, the cost has already reached 0.128 million yuan. Based on the above results, the proposed DGA-MPHIGA model outperformed the comparison models in scheduling time, cost, and range, demonstrating excellent vehicle scheduling capability and handling more complex logistics transportation tasks. The proposed model overcomes the limitations of traditional algorithms in multi-model scheduling and dynamic order response through multi-population co-evolution and dynamic coding optimization, provides an expandable decision framework for building highly flexible intelligent logistics systems, and helps reduce the empty load rate of cold chain transportation. The differences in results between various datasets stem from the structural characteristics of the TSPlib and Solomon datasets. The TSPlib dataset focuses on classic path optimization, while the Solomon dataset includes complex constraints such as time windows and dynamic demands, better reflecting the challenges of real-time logistics scenarios. The proposed algorithm enhances global search capabilities through multi-population co-evolution mechanisms, combined with domain generation algorithms to dynamically adjust coding rules, demonstrating significant advantages when handling high-dimensional constraints. However, as the number of cities increased, the average runtime of the model continued to rise, indicating that its performance still required improvement. Future work will focus on further optimizing the model.

Information System Department, Universitas Islam Negeri Sultan Syarif Kasim Riau, Indonesia[1]

***Abstract*—Mobile technology has developed rapidly in a short period of time, which has greatly changed the tourism sector and led to the emergence of Mobile Tourism (MT). To ensure that MT grows well and is widely used, it is important to know how people from different cultures accept it. This study provides a complete description of how to use the Fuzzy Delphi Method (FDM) to obtain expert agreement on the most important factors that influence how acceptable mobile tourism is from a cultural perspective. This study uses the Technology Acceptance Model (TAM) and Hofstede's Cultural Dimensions to carefully find and confirm the variables and indicators and how they are interrelated. This approach describes a rigorous process with nine stages in reaching expert agreement. The results revealed that experts largely agreed on the variables related to perceived usefulness, perceived trust, perceived ease of use, and facilitating conditions in the TAM framework, as well as some variables of collectivism, uncertainty avoidance, and long-term orientation in Hofstede's cultural aspects. This study also verified and validated the overall relationship between variables in building the Mobile Tourism Cultural Acceptance (MTCA) framework, the general and specific interactions between variables, and the function of cultural dimensions as mediators. This study shows how important it is to get expert opinion when making a comprehensive plan on how to use technology in a culturally acceptable environment for mobile tourism. The information obtained has a major impact on mobile tourism developers, policy makers, and marketers who want to make MT more popular.**

Keywords*—Cultural acceptance; Fuzzy Delphi Method (FDM); hofstede's cultural dimensions; mobile tourism; technology acceptance model (TAM)

I. INTRODUCTION

The tourism industry has essentially entered a new era with the advent of smartphones and increasingly widespread internet connectivity, which is emphasized by the emergence of mobile tourism (MT) [1], [2]. Mobile tourism can be defined as the use of mobile devices and applications to access information, various forms of services, and experiences related to travel, including planning, purchasing, navigating destinations, and sharing on social media [1], [3]. Due to its widespread use, it provides tourists with convenience, personalization, and unlimited real-time interaction, thus substantially enhancing the travel experience of tourists [4]. However, the success of widespread acceptance and adoption of mobile tourism is not only due to technological advances, but is also influenced by complex human factors, especially cultural nuances that influence user perceptions and behavior [5], [6].

It is a challenge for researchers and practitioners to try to understand the factors that influence the acceptance of new technologies, especially in diverse cultural contexts. Perceived usefulness (PU) and perceived ease of use (PEOU) are the basic determinants of technology adoption, according to the Technology Acceptance Model (TAM), a widely adopted framework [7]. Although TAM offers a strong model and foundation, it appears to ignore the significant impact of cultural values on technology adoption. This assumption actually limits TAM's explanatory efforts in the context of multicultural societies, where variables such as collectivism, uncertainty avoidance, and long-term orientation significantly influence user perceptions and behavioral intentions [8], [9]. Similarly, according to [5], [10] most mobile tourism research focuses more on technical usability and system quality, neglecting the sociocultural dimensions of user acceptance models.

Therefore, to address this gap, a model is needed that can synthesize the TAM Model and integrate it with Hofstede's cultural dimensions in reflecting the user's value system [11], [12]. Hofstede's Cultural Dimensions Theory provides important insights in analyzing these cultural influences, and is a framework for understanding how national and individual cultures influence behavior, including technology interactions [8]. Therefore, ensuring that these two theoretical perspectives can be integrated into one is crucial for developing a comprehensive understanding of Mobile Tourism Cultural Acceptance (MTCA). MTCA not only provides theoretical contributions, but is a very important strategic tool to help guide the development of a more culturally responsive mobile tourism system and also supports inclusive digital transformation, especially in culturally diverse countries such as Indonesia [13], [14].

To follow up on this, it is necessary to identify and validate critical or important variables and prove how they relate to the MTCA framework in a proposed model. Therefore, it is very important to utilize the knowledge and insights gathered from experts in various fields, namely from the perspective of tourism, academics, and practitioners related to tourism. The Delphi method, originally developed by the RAND Corporation, is a widely known systematic forecasting technique. It involves collecting and aggregating opinions from a panel of experts

through a series of structured questionnaires, with the aim of reaching consensus [15]. However, the conventional Delphi method still has limitations, including the difficulty in accurately representing subjective human judgment and distortion of information from extreme opinions [16].

To address and provide solutions to these conditions, the Fuzzy Delphi Method (FDM) emerged as an appropriate and effective extension concept. FDM conceptually incorporates fuzzy set theory into the conventional Delphi process, allowing experts to express their opinions using fuzzy numbers (e.g., linguistic terms such as "very important" or "somewhat important") rather than precise numerical values [17]. This method effectively encapsulates the ambiguity and imprecision inherent in human judgment, resulting in a more reliable and accurate consensus-building process. FDM has been widely and effectively applied in various sectors, such as environmental management, healthcare, and technology assessment, demonstrating its capacity to manage subjective expert opinions to reach collective agreement [18].

The purpose of this study is to provide a comprehensive step-by-step guide in the application of the Fuzzy Delphi Method to reach expert consensus on variables and indicators to their relationships within the Mobile Tourism Culture Acceptance (MTCA) framework. This study also has a specific objective to determine the elements considered important by experts in the development of MTCA by combining TAM and Hofstede's cultural dimensions. These findings will not only enhance the theoretical understanding of technology acceptance to culture in the context of mobile tourism but also provide practical recommendations for stakeholders in the mobile tourism ecosystem.

II. Literature Review

A. Mobile Tourism and Technology Acceptance

The way individuals plan, experience, and share their travel experiences is being revolutionized by mobile tourism. The accessibility of tourism information and services at any time and in any location has been significantly enhanced by the widespread use of mobile devices, resulting in increased personalization and flexibility for travelers [19]. Mobile technology is increasingly becoming a critical tool for the modern traveler, from translation services, time and mobile booking applications to augmented reality tour guides and social media platforms for sharing their travel experiences [2], [20], [21], [22]. However, the acceptance of these technologies depends on the success of the target consumer.

Such complex factors of new technology developments influence the phenomenon of technology acceptance. Therefore, it is very important to understand these factors in order to create more effective mobile tourism solutions that are in accordance with user preferences and needs. This is supported by previous studies that have used many of these theoretical models and concepts to predict and explain user behavior related to technology acceptance.

B. Technology Acceptance Model (TAM)

Technology Acceptance Model (TAM) proposed by Davis [7], s one of the most important and appropriate frameworks for understanding how people use technology. TAM states that there are two basic beliefs that are the main things that influence a person's desire to use technology or not:

- Perceived Usefulness (PU): How much a person believes that using a particular system will help them do their job better [23], [24]. In the context of mobile tourism, this statement means how much visitors think that using a mobile tourism application will make their trip better, make it more efficient, or provide them with more accurate and useful information.
- Perceived Ease of Use (PEOU): The extent to which a person believes that using a particular system would make things easier [23], [24]. In the context of mobile tourism, this relates to how easy it is for users to navigate and use mobile tourism applications and services.

The TAM model is extended by adding other factors to detail and explain tourist intentions. These factors include ubiquitous connectedness, trust, and personality traits such as openness to experience and demand for arousal. [25], [26] examined and confirmed most of the hypothesized models suggested in their study, namely finding that perceived utility, perceived ease of use, ubiquitous connectivity, trust, openness to experience, and demand for arousal are all strong predictors of tourists' intention to purchase tourism-related goods and services through mobile platforms. Of all these factors, Trust and connectivity are two important aspects in the implementation of mobile commerce in the travel and hospitality industry, especially in foreign places where security is a major concern [27].

In various other types of research, such as e-commerce, mobile learning, and tourism, have added and modified TAM [28], [29]. Researchers have included external factors including hedonic incentives, facilitating conditions, and social impacts to explain why users or individuals use mobile tourism [30], [31], [32]. Facilitating conditions (FC), which include the availability of reliable network connectivity, compatible devices, and essential technical support, are particularly relevant to the MTCA context. These conditions are defined in terms of the extent to which an individual believes that organizational and technical infrastructure is available to facilitate the use of the system [33].

C. Hofstede's Cultural Dimensions

Although TAM offers a powerful cognitive framework, it lacks in accounting for cross-cultural differences in technology acceptance. Hofstede's Cultural Dimensions Theory provides a powerful framework for understanding the ways in which national to individual cultures influence human behavior and values [34]. The original dimensions include:

- Power Distance (PDI): The extent to which less powerful members of the organization and institutions (such as families) accept and expect that power is distributed unequally.

- Individualism versus Collectivism (IDV): A society in which the ties between individuals are loose is called individualism, while a society in which the ties between individuals have been formed into strong and cohesive groups since birth is called collectivism.
- Masculinity versus Femininity (MAS): In societies where social gender roles are different, it is an indication of a masculine society, while in societies where social gender roles overlap, it is an indication of a feminine society.
- Uncertainty Avoidance (UAI): The extent to which people in a culture feel fearful or threatened by unclear or unknown situations.
- Long-Term Orientation versus Short-Term Normative Orientation (LTO): Long-term orientation is the process of developing values that are oriented to what is expected to occur in the future, such as being careful and holding fast. While short-term orientation is the process of developing important values in the past and also in the present, such as maintaining self-esteem, respecting tradition, and fulfilling social obligations.
- Indulgence versus Restraint (IVR): Civilization that allows people to achieve their basic and natural needs to enjoy life or seek pleasure. While the restraint shows that a society has a directed and strict social rule to control and suppress people's needs.

Hofstede's dimensions have been applied and emphasized in many studies as important factors in technology adoption across cultural perspectives. For example, cultures that prioritize uncertainty avoidance may be more hesitant to adopt new technologies due to perceived risks, while individualistic cultures may prioritize technologies that enhance personal autonomy [35], [36], [37], [38]. On the other hand, collectivist cultures may prioritize technologies that promote social interaction and group cohesion [39], [40], [41]. It is therefore important to integrate these cultural dimensions to gain a more complex understanding of mobile tourism acceptance, as tourists' cultural backgrounds often influence their preferences and behaviors [5], [42].

D. The Fuzzy Delphi Method (FDM)

According to Dalkey and Helmer [15]. the Delphi method was designed as a structured communication technique to ensure expert consensus on complex issues. Experts are usually given summarized feedback between rounds of questionnaires, which can allow them to modify their judgments according to collective insights [43], [44]. The power of the Delphi method is manifested in its capacity to foster consensus among geographically dispersed experts and to reduce the impact of dominant personalities that are often present during face-to-face meetings.

However, the conventional Delphi method has limitations, particularly in its ability to handle subjective expert opinions and the potential loss of information when converting qualitative judgments into quantitative data [45], [46], [47]. Fuzzy set theory was incorporated into the Delphi process to address these issues, resulting in the introduction of the so-called Fuzzy Delphi Method (FDM) [47], [48], [49] The representation of ambiguous or vague information using fuzzy numbers, typically triangular fuzzy numbers (TFN), is facilitated by fuzzy set theory [50], [50], [51]. This allows experts to convey their opinions as a range rather than a single precise value, which more accurately reflects the uncertainty inherent in their judgments.

The nine systematic phases cover the stages and procedures of FDM, as described by Yin & Hanif [52]:

- Expert Determination Process: This stage involves selecting the right panel of experts. The optimal number of experts is adjusted and can vary, for example, [45], [53] suggesting between 10 and 50, while [54] recommend 10-15 experts if there is high consistency among them.
- Linguistic Selection Process: To obtain nuanced and diverse expert opinions, a 7-point fuzzy scale can be applied, derived from the conventional Likert scale. This scale assigns imprecise values (m1, m2, m3) to each linguistic term, which can allow for more precise quantification of agreement or importance.
- To enter the Likert scale values into the item space for each expert, follow the steps as follows: The researcher enters the Likert scale values given by the experts for each item, converting them into appropriate fuzzy scale values.
- Next is the process of obtaining the fuzzy average value (m1, m2, m3) of the fuzzy scale as follows: The consensus among experts is represented by the calculation of the fuzzy average value (m1, m2, m3) for each item. The minimum value (m1), the most reasonable value (m2), and the maximum value (m3) are represented by these three values, which collectively form a triangular fuzzy number.
- Finding the value of "d" (threshold value): For each question item, the "D" threshold value is determined. Then, this value decides whether the question level of agreement between experts determines whether the item is accepted or rejected.
- Set the number of experts: You can give a sign to the "red box" to the total number of experts to show how much they agree with each other.
- How to find out the level of percentage of expert agreements on each item and item overall: These statistics provide a direct and numerical assessment of how many experts agree.
- Fuzzy evaluation process: Fuzzy (A) score for each item is based on how many experts agree to each item. Items that do not meet FDM criteria standards are discarded.
- Data Analysis Findings Table: Data analysis findings will be shown in the table, the red value shown in cells is interpreted that the conditions set by FDM are not met or inappropriate.

In fields such as sustainable tourism, educational technology, and product reviews, FDM is very good for validating and making difficult decisions [55]. he ability of FDM to identify and ensure that the item rejected is a very useful tool for increasing the development of a model [56]. In FDM, rejecting the item is not just a statistical result, this is a group decision by experts that the item as written is irrelevant, is not important enough, or not adequately represents the construction intended in a particular research context [56]. The strong ability to diagnose this is very useful in interdisciplinary research, which combines ideas from various fields (for example, macro-cultural theory and micro technology adoption) [57]. FDM functions as a strict selection filter to ensure that the final model only makes the part that is truly in line with what is said and done by experts for their understanding [57]. FDM has changed from a simple validation tool to be an important tool for improving and developing models because it has the best diagnostic skills. This provides practical feedback in which theoretical operations are strong and which ones need to be thought of again, are changed, or even discarded [58].

III. METHODOLOGY

The Fuzzy Delphi (FDM) method is used in this study to make experts approve variables and indicators and how variables are interconnected in the Framework for the Proposed Culture Tourism Culture (MTCA) in the future, in this concept combining the dimensions of technology acceptance (TAM) and the Hofstede cultural dimension. This technique uses a structured multi-step procedure to collect, analyze, and combine the perspective of the expert.

A. Research Design

The research design in this study is the Fuzzy Delphi (FDM) method. This recurring method makes it easy to get expert opinions about how important and relevant certain elements. FDM also allows changing qualitative comments into Fuzzy numbers so that all experts can approve one perspective. In this research, choosing the FDM method is caused by eliminating prejudice, getting a greater group consensus, and getting around the fact that human assessment is not always accurate. This makes it the right choice to validate complicated theoretical models [52], [59]. This section explains how to use the Fuzzy Delphi (FDM) method in a comprehensive way, following the nine steps displayed in the following study Yin & Hanif [52]

B. Expert Panel Selection

Choosing the right experts for Delphi studies is quite important. This study chooses experts based on how much they know, how much experience they have, and how much expertise they have in terms of cellular tourism, technology adoption, cultural studies, and tourism management. Expert panels are divided into three clusters namely, people from academics, government tourism organizations, and private sectors related to tourism.

This survey uses 22 experts (see Table I). This is in accordance with the recommended expert panel size for Delphi studies, which usually ranges from 10 to 50 [53]. The selection process ensured a range of expertise relevant to the study of culture, technology adoption, and mobile tourism. The selection criteria were as follows [60]:

- Minimum of 5 years of professional experience in a relevant field (government from a tourism perspective, academics, and practitioners from a tourism perspective).
- Academic qualifications at Bachelor level or higher.
- Demonstrated expertise through publications, professional roles, or significant contributions in the field.

C. Questionnaire Development

This questionnaire was carefully prepared after a comprehensive literature review examining the Technology Acceptance Model (TAM), Hofstede's Cultural Dimensions, and their application in the context of mobile tourism. The questionnaire was designed to obtain expert opinions on the significance and relevance of various variables and the relationships between them. The items were arranged into five main categories, consistent with the scope of this research study:

- What are the key variables in the (TAM) that are significantly related to MTCA?
- What are the key variables in Hofstede's Cultural Dimensions that are significantly related to MTCA?
- What TAM variables and Hofstede's cultural dimensions are significantly related to each other in developing the MTCA framework?
- What TAM variables and Hofstede's Cultural Dimensions are interrelated and significantly influence users' behavioral intention to adopt mobile tourism technology (MTCA)?
- What TAM variables and Hofstede's Cultural Dimensions, along with the cultural dimension variables as mediators, significantly influence users' behavioral intention to adopt mobile tourism technology (MTCA)?

Experts were asked to evaluate the significance of each item on a linguistic scale (e.g., Strongly Disagree, Disagree, Tend to Disagree, Tend to Agree, Agree, Strongly Agree, Strongly Agree). Experts were able to articulate their opinions with nuanced levels of agreement or importance by framing each item using linguistic terms that corresponded to a 7-point Likert scale [52]. These linguistic terms were then converted into triangular fuzzy numbers for analysis purposes in the next stage.

TABLE I. EXPERT PANEL DEMOGRAPHICS

No.	Name	Gender	Academic Qualification	Institution	Position	Years of Work Experience
1	Expert 1	Female	Middle Expert	Tourism Youth and Sports Agency Lima Puluh Kota	Young Expert Planner	> 25 years
2	Expert 2	Female	Diploma	Cititel Hotel Pekanbaru	Sales Executive	10 to 15 years
3	Expert 3	Female	Magister	Macly Marsar Group Pekanbaru	Financial Controller Corporate	20 to 25 years
4	Expert 4	Female	Bachelor	PT Artha Bayu, Bali Indonesia	Owner	> 25 years
5	Expert 5	Male	Master	Tourism, Youth and Sports Office	Head of Office	15 to 20 years
6	Expert 6	Male	Bachelor	Tourism, Youth and Sports Office Payakumbuh	Acting head of tourism	> 25 years
7	Expert 7	Male	Diploma	Lloyds Inn Bali	Front Office Supervisor	5 to 10 years
8	Expert 8	Female	Bachelor	Cititel Hotel Pekanbaru	Sales and marketing manager	15 to 20 years
9	Expert 9	Male	Doctor of Philosophy	UIN Suska Riau	Lecturer	5 to 10 years
10	Expert 10	Male	Doctor of Philosophy	Lancang Kuning University Pekanbaru	Secretary of Computer Science Master's Program	15 to 20 years
11	Expert 11	Male	Doctor of Philosophy	Sebelas April University	Lecturer/Researcher	15 to 20 years
12	Expert 12	Male	Doctor of Philosophy	National Research and Innovation Agency, Indonesia	Researcher	5 to 10 years
13	Expert 13	Male	Bachelor	Tourism, Youth and Sports Service Lima Puluh Kota	Secretary of Tourism and Youth Service	> 25 years
14	Expert 14	Female	Bachelor	Lloyd's Inn Bali	Sales Executive	5 to 10 years
15	Expert 15	Male	Bachelor	Tourism Office of Lima Puluh Kota	Tourism Ambassador	< 5 years
16	Expert 16	Male	Doctor of Philosophy	Sebelas April University	Dean of the Faculty of Information Technology	20 to 25 years
17	Expert 17	Female	Bachelor	Lloyd's Inn Bali	Hotel Manager	20 to 25 years
18	Expert 18	Female	Bachelor	Tourism Office Lima Puluh Kota	Tourism Ambassador	< 5 years
19	Expert 19	Male	Diploma	Tourism Office of Lima Puluh Kota	Uda Uni Tourism Ambassador of Lima Puluh Kota	< 5 years
20	Expert 20	Male	Doctor of Philosophy	Lancang Kuning University Pekanbaru	Lancang Kuning University Pekanbaru	10 to 15 years
21	Expert 21	Female	Diploma	Cara Cara Inn Denpasar	Eccomerce	10 to 15 years
22	Expert 22	Male	Bachelor	Cara Cara Inn Denpasar	Manager	15 to 20 years

D. Data Collection and Fuzzy Delphi Analysis

A series of rounds, which is the hallmark of the Delphi method, were used to capture data. Questionnaires were filled out by experts in each round, and their responses were analyzed. The next stages consist of the core of FDM analysis [52]:

1) Likert-to-fuzzy conversion: The FDM methodology has established the fuzzy scale used by systematically converting the raw data collected from 22 experts into triangular fuzzy numbers (m1, m2, m3). The data were initially presented on a 7-point Likert scale. For example, a Likert rating of '7' (Strongly Agree) is converted into the fuzzy set (0.9, 1, 1), while '1' (Strongly Disagree) is converted into (0, 0, 0.1). This conversion standardizes the expert opinions into a format suitable for fuzzy logic operations.

2) Calculation of fuzzy mean: The fuzzy mean values (m1, m2, m3) are determined by combining the individual fuzzy numbers of all 22 experts for each item of their questionnaire. These various numbers, then combined, include the minimum, most plausible, and maximum values of the combined expert panel's assessment for each particular item.

3) Determination of threshold value 'd': Finding the "D" threshold for each item is an important part of FDM. This value shows how spread or unclear the opinions of experts. The smaller "D" means more agreement or has a high consensus. The "D" threshold is an important factor in deciding whether to accept or reject an item based on how much agreement there is among experts.

4) Percentage of agreement: Furthermore, for each item, the value of 'D' and the proportion of experts who agreed to be found. This metric provides a quantitative measure of direct consensus by showing the percentage of experts whose opinions are in the acceptable agreement range.

5) Fuzzy score (A): The average Fuzzy triangle is used to calculate the fuzzy (A) score for each item, which is a crispy defuzzified value. This score offers a single indicator that can be measured by the expert's perception panel to show how the expert feels about the interests or priorities of the item as a whole.

6) Acceptance/rejection status: In the final step, each item is given the status of acceptance ("accept") or rejection ("Reject") based on the predetermined criteria. This criterion

mainly includes the value of "D" which is below a certain level (for example, D <0.2) and the percentage of agreements that are above a certain level (for example, ≥ 70%). Items that are not satisfying this standard are rejected, which means there is not enough agreement among experts.

IV. Results and Discussion

The This section shows the findings using the Fuzzy Delphi method. This gives a complete picture of the consensus of experts who agree on how the variable relationship in the framework of the acceptance of the Culture (MTCA) is related to each other. Data is arranged in accordance with the sequential validation process which includes TAM factors, Hofstede cultural dimensions, general relationships, specific relationships, and mediation relationships.

A. Validation of Technology Acceptance Model (TAM) Variables

The purpose of the validation of the TAM variable is to prove the variables and indicators in building a framework for acceptance of the Mobile Tourism (MTCA) cultural acceptance. These variables such as, perceived usefulness (PU), perceived ease of use (PEOU), perceived trust (PT), facilitation of conditions (FC), and behavioral intentions (BI) and all indicators that are ganging on each of these variables. Variables and indicators that according to experts are important for people to accept the culture of cellular tourism. Table II shows a summary of findings.

TABLE II. Validation of Technology Acceptance Model (TAM) Variables

No	Items / Elements	Triangular Fuzzy Numbers Conditions		Defuzzification Process Requirements				Expert Agreement	Element ACCEPTED	Ranking
		Threshold Value, d	*Expert Group Agreement Percentage, %*	*m1*	*m2*	*m3*	*Fuzzy Score (A)*			
1	PEOU	0,095	95,5%	0,700	0,882	0,977	0,853	ACCEPT	0,853	14
2	PEOU1	0,121	100,0%	0,691	0,868	0,973	0,844	ACCEPT	0,844	19
3	PEOU2	0,117	100,0%	0,718	0,886	0,977	0,861	ACCEPT	0,861	12
4	PEOU3	0,137	100,00%	0,691	0,864	0,968	0,841	ACCEPT	0,841	20
5	PEOU4	0,092	100,00%	0,736	0,905	0,986	0,876	ACCEPT	0,876	5
6	PU	0,098	100,00%	0,745	0,909	0,986	0,880	ACCEPT	0,880	3
7	PU1	0,122	100,00%	0,727	0,891	0,977	0,865	ACCEPT	0,865	8

9	PU3	0,130	100,00%	0,709	0,877	0,973	0,853	ACCEPT	0,853	14
10	PU4	0,127	100,00%	0,736	0,895	0,977	0,870	ACCEPT	0,870	6
11	PT	0,117	100,00%	0,718	0,886	0,977	0,861	ACCEPT	0,861	13
12	PT1	0,114	95,45%	0,700	0,877	0,973	0,850	ACCEPT	0,850	16
13	PT2	0,407	31,82%	0,400	0,568	0,718	0,562	REJECT	0,562	27
14	PT3	0,146	95,45%	0,664	0,845	0,959	0,823	ACCEPT	0,823	22
15	PT4	0,140	95,45%	0,682	0,859	0,964	0,835	ACCEPT	0,835	21
16	PT5	0,201	81,82%	0,636	0,818	0,932	0,795	ACCEPT	0,795	25
17	PT6	0,127	95,45%	0,727	0,891	0,973	0,864	ACCEPT	0,864	9
18	PT7	0,102	95,45%	0,745	0,909	0,982	0,879	ACCEPT	0,879	4
19	FC	0,226	90,91%	0,668	0,827	0,923	0,806	ACCEPT	0,806	23
20	FC1	0,132	95,45%	0,736	0,895	0,973	0,868	ACCEPT	0,868	7
21	FC2	0,125	100,00%	0,700	0,873	0,973	0,848	ACCEPT	0,848	17
22	FC3	0,259	72,73%	0,618	0,782	0,895	0,765	REJECT	0,765	26
23	FC4	0,170	95,45%	0,645	0,823	0,945	0,805	ACCEPT	0,805	24
24	BI	0,098	100,00%	0,718	0,891	0,982	0,864	ACCEPT	0,864	9
25	BI1	0,088	95,45%	0,800	0,945	0,995	0,914	ACCEPT	0,914	1
26	BI2	0,125	100,00%	0,700	0,873	0,973	0,848	ACCEPT	0,848	17
27	BI3	0,104	100,00%	0,755	0,914	0,986	0,885	ACCEPT	0,885	2

As shown in Table II, the expert panel showed a high level of consensus on most of the TAM variables and indicators. There was a total of 27 TAM items, consisting of 5 variables and 22 indicators. Almost all items achieved a consensus percentage of 95.45% or 100%, and their Fuzzy Scores were consistently high (above 0.8), leading to their acceptance. This indicates that experts largely agree on the importance of perceived ease of use (PEOU items), perceived usefulness (PU items), perceived trust (PT items), facilitating conditions (FC items), and behavioral intention (BI items) in driving mobile tourism acceptance. For example, BI1 has a high fuzzy score of 0.914 with 100% agreement, emphasizing its criticality. The second to fifth ranks can be seen in BI3 (0.885), PU (0.880), PT7 (0.879), PEOU4 (0.876) with 100% agreement, indicating strong agreement and high scores. The two "REJECTED" items were PT2, with a low consensus percentage of 31.82% and a Fuzzy Score of 0.562, and FC3 with a consensus percentage of 72.73% and a fuzzy score of 0.765 indicating a lack of agreement or perceived importance by experts for this particular element. This highlights that although the TAM is generally accepted, not all of its aspects are equally relevant or agreed upon in the specific context of mobile tourism, thus requiring further investigation into the nature of PT2 and FC3.

B. Validation of Hofstede's Cultural Dimensions Variables

Hofstede's Cultural Dimensions were validated within the MTCA framework in the second phase. Expert consensus on these variables is illustrated in Table III.

TABLE III. VALIDATION OF HOFSTEDE'S CULTURAL DIMENSIONS VARIABLES

No	Items / Elemens	Triangular Fuzzy Numbers Conditions		Defuzzification Process Requirements				Expert Agreement	Element ACCEPTED	Ranking
		Threshold Value, d	*Expert Group Agreement Percentage, %*	*m1*	*m2*	*m3*	*Fuzzy Score (A)*

26	CO6	0,255	54,55%	0,586	0,759	0,886	0,744	REJECT	0,744	29
27	LT	0,136	95,5%	0,709	0,877	0,968	0,852	ACCEPT	0,852	9
28	LT1	0,167	90,9%	0,691	0,859	0,955	0,835	ACCEPT	0,835	10

29	LT2	0,192	90,9%	0,636	0,809	0,932	0,792	ACCEPT	0,792	20
30	LT3	0,169	95,45%	0,682	0,850	0,955	0,829	ACCEPT	0,829	12
31	LT4	0,144	95,45%	0,727	0,886	0,968	0,861	ACCEPT	0,861	8
32	LT5	0,148	95,45%	0,736	0,891	0,968	0,865	ACCEPT	0,865	7
33	LT6	0,144	95,45%	0,773	0,914	0,973	0,886	ACCEPT	0,886	2
34	MA	0,237	86,36%	0,641	0,814	0,918	0,791	ACCEPT	0,791	21
35	MA1	0,428	36,36%	0,441	0,600	0,741	0,594	REJECT	0,594	41
36	MA2	0,344	59,09%	0,582	0,750	0,859	0,730	REJECT	0,730	32
37	MA3	0,310	68,18%	0,555	0,732	0,859	0,715	REJECT	0,715	34
38	MA4	0,332	59,09%	0,559	0,723	0,845	0,709	REJECT	0,709	35
39	IR	0,285	54,55%	0,568	0,745	0,873	0,729	REJECT	0,729	33
40	IR1	0,285	63,64%	0,568	0,750	0,877	0,732	REJECT	0,732	30
41	IR2	0,284	59,09%	0,568	0,750	0,877	0,732	REJECT	0,732	30
42	IR3	0,256	81,82%	0,532	0,714	0,859	0,702	ACCEPT	0,702	36
43	IR4	0,304	72,73%	0,532	0,714	0,850	0,698	REJECT	0,698	37

Table III shows a strong expert consensus on the relevance of Hofstede's Cultural Dimensions in the context of mobile tourism acceptance. There are 43 items, consisting of 7 variables and 36 indicators. In the context of Hofstede's cultural dimensions on the acceptance of mobile tourism culture, it shows that most of the variables and indicators are accepted and some variables and indicators are rejected. This shows that most experts agree on the importance of the Cultural Dimensions (CD), Uncertainty Avoidance (UA), Collectivism (CO), and Long-Term Orientation (LT) in encouraging the acceptance of mobile tourism culture. It can be seen that UA4 has the highest fuzzy value of 0.888 with an agreement of 95.45% which emphasizes its criticality. The second to fifth ranks can be seen in LT6 (0.886), UA5 (0.885), UA2 (0.877), and UA3 (0.876) with an agreement of 95.45%, 95.45%, 100%, 100%, and 100% which emphasizes its criticality. However, there are 2 variables that are rejected, namely Power Distance (PD) with a fuzzy value of 0.756, 68.18% agreement and the variable Indulgence (IR) with a fuzzy value of 0.729, 54.5% agreement. This indicates a lack of agreement or perception of the importance of this particular element by experts. There are also rejected indicators such as PD1 with a low consensus percentage of 45.45%% and a Fuzzy Score of 0.567, PD2 (40.91%) (0.561), PD3 (27.27% (0.597), PD4 (40.91%) (0.603), PD5 (40.91%) (0.620), CO5 (54.55%) (0.758), CO6 (54.55%) (0.744), MA1 (36.36%) (0.594), MA2 (59.09%) (0.730), MA3 (68.18%) (0.715), MA4 (59.09%) (0.709), IR1 (54.55%) (0.732), IR2 (59.09%) (0.732), IR4 (72.73%) (0.698). Based on the data in the table, it can be explained that the variables, namely Power Distance (PD) and all its indicators are rejected, the Indulgence variable (IR) is rejected with all its indicators, although IR3 is accepted, and the Masculinity variable (MA) is rejected because all its indicators are rejected. This indicates a lack of agreement or perception of the importance of this particular element by experts.

C. *Validation of General Variables in Mobile Tourism Culture Acceptance (MTCA)*

Expert consensus on the general relationship in building the framework model construction related to the Mobile Tourism Culture Acceptance (MTCA) framework is presented in this section. The variables or overall model construction are represented by the following Table IV.

TABLE IV. VALIDATION OF GENERAL VARIABLES (MTCA)

No	Items / Elements	Triangular Fuzzy Numbers Conditions		Defuzzification Process Requirements				Expert Agreement	Element ACCEPTED	Ranking
		Threshold Value, d	*Expert Group Agreement Percentage, %*	*m1*	*m2*	*m3*	*Fuzzy Score (A)*			
1	PEOU-MTCA	0,083	100,0%	0,773	0,932	0,995	0,900	ACCEPT	0,900	2
2	PU-MTCA	0,089	100,0%	0,755	0,918	0,991	0,888	ACCEPT	0,888	3
3	PT-MTCA	0,086	95,5%	0,782	0,936	0,995	0,905	ACCEPT	0,905	1
4	FC-MTCA	0,092	100,00%	0,736	0,905	0,986	0,876	ACCEPT	0,876	5
5	UA-MTCA	0,079	100,00%	0,718	0,895	0,986	0,867	ACCEPT	0,867	6
6	CO-MTCA	0,150	95,45%	0,673	0,850	0,959	0,827	ACCEPT	0,827	9
7	LT-MTCA	0,136	95,45%	0,709	0,877	0,968	0,852	ACCEPT	0,852	8
8	CD-MTCA	0,118	95,45%	0,709	0,882	0,973	0,855	ACCEPT	0,855	7
9	BIUMT-MTCA	0,098	100,00%	0,745	0,909	0,986	0,880	ACCEPT	0,880	4

Table IV shows a very high level of consensus among experts regarding the general relationship of TAM and Hofstede variables contributing to the MTCA framework. All 12 items presented were accepted, with consensus percentages ranging from 90.91% to 100%. The Fuzzy Scores for these general variables were also very high, mostly above 0.87. PT-MTCA (Perceived Trust related to MTCA) emerged as the highest-ranked element with a Fuzzy Score of 0.905 and an agreement level of 95.5%, emphasizing the important role of trust in the acceptance of mobile tourism. PEOU-MTCA (Perceived Ease of Use related to MTCA) and PU-MTCA (Perceived Usefulness related to MTCA) also showed very high scores and 100% consensus, reaffirming the basic tenets of TAM in this context. The acceptance of cultural dimensions related to MTCA (e.g., UA-MTCA, CO-MTCA, LT-MTCA) further supports the integration of cultural factors as an important component of the framework.

D. Validation of Specific Relationships in Mobile Tourism Culture Acceptance (MTCA)

This section explores expert consensus on specific or specific causal relationships between variables within the MTCA framework. This can be seen in the following table.

Table V shows a consistent pattern of high expert consensus on the relationships of TAM and Hofstede's specific variables within the MTCA framework. All 15 listed relationships were accepted, with the dominant consensus percentage at 95.45% or 100%, and the Fuzzy Scores were generally above 0.82. The relationship "PT-BIUMT" (Perceived Trust to Behavioral Intention to Use Mobile Tourism) achieved the highest ranking with a Fuzzy Score of 0.905 and 95.5% agreement, further reinforcing the importance of trust. "PU-BIUMT" (Perceived Usefulness to Behavioral Intention to Use Mobile Tourism) also showed strong support (Fuzzy Score 0.897, 100% agreement), which is in line with the core principles of TAM. Relationships involving cultural dimensions, such as UA-BIUMT, CO-BIUMT, LT-BIUMT, were also accepted, confirming that experts believe that these cultural factors directly influence behavioral intention to use mobile tourism. It can also be explained that the relationship involving TAM and Hofstede variables in the context of cultural dimensions, such as PEOU-CD, PU-CD, PT-CD, and FC-CD as well as UA-CD, CO-CD, and LT-CD are equally believed by experts that these factors have a relationship and influence in the development of MTCA. Thus, consistent acceptance across these specific relationships provides strong empirical support for their inclusion in a comprehensive MTCA model.

E. Validation of Mediator Relationships in Mobile Tourism Culture Acceptance (MTCA)

The final validation stage is dedicated to identifying and confirming the mediating function of cultural dimensions within the MTCA framework. Specifically, it is examined how cultural dimensions can influence the relationship between TAM variables and Hofstede variables in behavioral intention to use mobile tourism.

TABLE V. VALIDATION OF SPECIFIC RELATIONSHIPS (MTCA)

No	Items / Elements	Triangular Fuzzy Numbers Conditions		Defuzzification Process Requirements				Expert Agreement	Element ACCEPTED	Ranking
		Threshold Value, d	*Expert Group Agreement Percentage, %*	*m1*	*m2*	*m3*	*Fuzzy Score (A)*			
1	PEOU-BIUMT	0,092	100,0%	0,736	0,905	0,986	0,876	ACCEPT	0,876	3
2	PU-BIUMT	0,097	100,0%	0,773	0,927	0,991	0,897	ACCEPT	0,897	2
3	PT-BIUMT	0,086	95,5%	0,782	0,936	0,995	0,905	ACCEPT	0,905	1
4	FC-BIUMT	0,092	100,00%	0,736	0,905	0,986	0,876	ACCEPT	0,876	3
5	UA-BIIUMT	0,159	90,91%	0,673	0,850	0,955	0,826	ACCEPT	0,826	13

2	PU-CD-BIUMT	0,127	95,5%	0,727	0,891	0,973	0,864	ACCEPT	0,864	3
3	PT-CD-BIUMT	0,118	95,5%	0,709	0,882	0,973	0,855	ACCEPT	0,855	4
4	FC-CD-BIUMT	0,124	95,45%	0,745	0,905	0,973	0,874	ACCEPT	0,874	2
5	UA-CD-BIUMT	0,136	95,45%	0,691	0,868	0,964	0,841	ACCEPT	0,841	7
6	CO-CD-BIUMT	0,167	90,91%	0,709	0,873	0,955	0,845	ACCEPT	0,845	6
7	LT-CD-BIUMT	0,125	90,91%	0,709	0,882	0,968	0,853	ACCEPT	0,853	5

All seven proposed mediation relationships were accepted, indicating that experts largely agreed, with percentages ranging from 95.5% to 100% and fuzzy scores always higher than 0.85. Rankings 1,2,3,4, and occupied by TAM variables. "PEOU-CD-BIUMT" (perceived ease of use mediated by cultural dimensions affecting behavioral intention to use mobile tourism) stands out as the best mediation relationship with fuzzy scores of 0.877 and 100% agreement. This means that how easy a mobile tourism application is, when viewed from a cultural perspective, has a great effect on whether people want to use it or not. In the same way, "PU-CD-BIUMT" (perceived usefulness mediated by cultural dimensions affecting behavioral intention to use mobile tourism) also received much support (fuzzy score 0.864, 95.5% agreement). These results indicate that perceived ease of use is how people view technology and their cultural values in using mobile tourism applications. Overall, it can be concluded that the TAM variable has a greater influence when the cultural dimension acts as a mediator of behavioral intentions to use mobile tourism. Furthermore, seen from the fuzzy score value and expert agreement, ranks 5, 6 and 7 are occupied by the Hofstede variable when the cultural dimension acts as a mediator of behavioral intentions to use mobile tourism.

F. Discussion of Findings

Strong expert consensus was achieved across all categories of variables and relationships proposed in the Mobile Tourism Culture Acceptance (MTCA) framework as a result of a comprehensive validation process using the Fuzzy Delphi Method. The high Fuzzy Scores (generally above 0.8) and consistently high consensus percentages (mostly above 90%) indicate that there is a strong consensus among experts on the important factors influencing mobile tourism culture acceptance.

Its importance as a basic form of Perceived Ease of Use and Perceived Usefulness is reaffirmed by the validation of the TAM variables (Table II). The rejection of the PT2 indicator item implies that, despite the significance of trust, this specific operationalization of trust may not be universally accepted or relevant to scholars in the mobile tourism context. Consequently, additional qualitative investigation is needed to explore it in the context of PT2 in future studies.

The importance of cultural context in mobile tourism is underscored by the strong acceptance of Hofstede's Cultural Dimensions (Table III). This finding is significant because it addresses the general gap between the Primary Influence of Technology and the importance of the human dimension in gaining benefits from technology use. This gap was highlighted by researchers such as [33] who found that users did not gain any benefits from technology [61], have established that the acceptance and adoption of technology are significantly influenced by an individual's cultural beliefs [62]. In essence, cultural heritage impacts various aspects of an individual's life, such as their beliefs, behaviors, perceptions, and attitudes towards health [63]. Scholars have clearly observed that the perception and adoption of mobile tourism technology can be significantly influenced by factors such as Power Distance, Uncertainty Avoidance, Individualism, and Long-Term Orientation. This is consistent with a growing body of research advocating for culturally sensitive technology design and marketing, as well as cultural acceptance of tourism or mobile technology [42], [64], [65], [66], [67].

The importance of the proposed constructs in developing a holistic model of cultural acceptance of mobile tourism is confirmed by the validation of the general relationship variables for MTCA (Table IV). The high PT-MTCA (Perceived Trust in MTCA) classification underlines the fact that trust is not simply a facilitating condition for digital tourism services, but is an essential and fundamental prerequisite. This finding is consistent with recent research on digital platform adoption Furthermore, the consensus on the specific relationships between the variables (Table V) offers more detailed insights into the pathways of influence between the variables. The core predictions of TAM are strongly validated by the direct impacts of PEOU, PU, FC, and PT on behavioral intention (BI). The argument for an integrated paradigm is further strengthened by the recognition of cultural dimensions that directly influence BI. This implies that cultural values can directly influence an individual's readiness and inclination to utilize a mobile tourism tool, regardless of the tool's ease of use or usefulness [41].

Finally, the most important understanding of the influence of cultural dimensions as mediators between TAM and Hofstede variables on behavioral intention to use mobile tourism (Table VI). The finding that cultural dimensions mediate the

relationship between behavioral intention and TAM constructs (PEOU, PU, FC, PT) is a significant theoretical contribution. This suggests that the adoption behavior of mobile tourism applications is ultimately influenced by the cultural context, which serves as a filter or lens through which users interpret the ease of use or utility of these applications. For example, cultures that tend to avoid uncertainty may find a new and complex mobile tourism application more difficult to operate, even if its function is clear, due to the ambiguity inherent in the new technology [68], [69]. Such interactions and the resulting complexity underscore the need for a comprehensive approach to MTCA, in which cultural perspectives are incorporated into every phase of the design and implementation process. The consensus obtained through the Fuzzy Delphi Method was reliably and validly supported by experts at consistently high levels of agreement (mostly 90-100%) and low threshold values (d) across various validation stages. This strong agreement serves as the basis for building a solid foundation for empirical testing and development of the proposed Mobile Tourism Cultural Acceptance framework.

V. IMPLICATIONS

The results of this Fuzzy Delphi study have substantial implications for the development of theoretical concepts as well as for practical applications in the context of cultural acceptance of mobile tourism.

A. Theoretical Implications

Implications for Theory, this study provides a comprehensive assessment of an integrated framework for Mobile Tourism Cultural Acceptance (MTCA) by effectively integrating components of the Technology Acceptance Model (TAM) and Hofstede's Cultural Dimensions. The argument for a more comprehensive model of technology adoption in tourism is theoretically strengthened by the strong scholarly consensus on the importance of PEOU, PU, PT, and FC, as well as the critical role of cultural dimensions. It goes beyond the cognitive focus of conventional TAM by explicitly integrating macro-level cultural influences, which are often overlooked but have a substantial impact on individual perceptions and behaviors. Cultural dimensions are not merely external variables, they can also serve as mediators, influencing the perceptions and effects of fundamental TAM constructs, as confirmed in this research study. This establishes a theoretical foundation for future empirical research that will investigate these complex mediation relationships through quantitative methods, including Structural Equation Modeling.

Second, the Fuzzy Delphi Method (FDM) applies itself as a methodological contribution. This study illustrates the power of fuzzy logic in developing rigorous theoretical constructs and managing subjective judgments in a complex and novel domain such as mobile tourism by methodically guiding experts to reach consensus. It can serve as a practical guide for researchers who wish to leverage expert knowledge in model development and validation provided in the form of a comprehensive step-by-step of the FDM process and its application to a multifaceted framework. Finally, the specific identification and validation of individual items and their relationships, particularly the highly ranked "Perceived Trust" (PT) variable and its inter-variable relationships, suggest that trust may play a more fundamental and important role in mobile tourism acceptance. This underscores the need for additional theoretical investigation into the proper conceptualization and measurement of trust in the context of digital tourism.

B. Practical Implications

The practical implications of these findings are important for various stakeholders in the mobile tourism sector:

- For Mobile Tourism Developers and Designers: The validated variables offer a concise guideline for developing more user-friendly and culturally sensitive mobile tourism apps. Developers should prioritize facilitating conditions (FC), perceived trust (PT), perceived usefulness (PU), and perceived ease of use (PEOU). More importantly, they should consider local cultural values during the design phase. Apps should offer clear and explicit instructions, comprehensive FAQs, and robust customer support in cultures that prioritize uncertainty avoidance to reduce perceived risk. Features that facilitate group planning, collaboration, and social interaction may be highly valued in collectivist cultures.
- For Tourism Destination Management Organizations (DMOs) and Policymakers: These insights can be used by DMOs to develop strategies that will increase the adoption of mobile tourism. Marketing campaigns, public awareness initiatives, and infrastructure development can be informed by an understanding of the cultural dimensions of the target tourist market or local population. For example, in cultures with high power distance, it may be more effective to promote mobile tourism through trusted government channels. Then there are policies that promote ubiquitous and affordable internet access (facilitating conditions).
- For Tourism Marketers: Marketing campaigns for mobile tour services must be tailored to local or specific cultural values. High uncertainty avoidance populations will be attracted to an emphasis on safety, reliability, and unambiguous benefits, while individualistic users may be attracted to an emphasis on efficiency and personal control. Marketers can effectively communicate the proposition in a way that is culturally appropriate to the informed message creator.

VI. CONCLUSION

This study effectively used the Fuzzy Delphi Method to establish expert consensus on the key variables and their relationships within the Mobile Tourism Culture Acceptance (MTCA) framework, which combines Hofstede's Cultural Dimensions and Technology Acceptance Model (TAM). The careful process of expert panel selection, questionnaire development, fuzzy number conversion, aggregation, defuzzification, and consensus determination is explained in a step-by-step guide. The results indicate that there is a high level of expert agreement on the significance of perceived ease of use, perceived usefulness, perceived trust, and facilitating conditions as key determinants of mobile tourism acceptance. Importantly, this study also confirms the substantial role of Hofstede's Cultural Dimensions, not only as direct influencers but also as

mediating factors shaping the impact of TAM constructs on behavioral intention. The comprehensive nature of the proposed MTCA framework is validated by the consistent adoption of the majority of the proposed variables and relationships, as evidenced by the high consensus percentage and strong Fuzzy Scores. This study emphasizes the importance of gaining insight into expert opinion when developing a robust theoretical model for a complex interdisciplinary problem such as the cultural acceptance of mobile tourism. The Fuzzy Delphi technique has been shown to be a useful and important tool to overcome the subjectivity and ambiguity that accompanies qualitative assessment by carefully combining the views of multiple experts.

LIMITATIONS AND FUTURE RESEARCH

Although the procedures and stages used in this study were very rigorous, there were some shortcomings in this study. The expert group consisted of people with different backgrounds, but did not represent all major tourism centers in Indonesia. The Fuzzy Delphi method also did not assign numerical values to the proposed relationships or the strength of these relationships, although it did build expert consensus and validate theoretical constructs.

So, future research should include more experts with specific clusters from each region of Indonesia that represent major tourism centers in Indonesia. Then should try to prove the validated MTCA framework with quantitative research approaches, such as structural equation modeling (SEM) or partial least squares structural equation modeling (PLS-SEM), by conducting a complete survey of people or tourists who use and utilize mobile tourism. This can prove the model by using statistics to examine the hypothesized relationships and see how well the variables affect behavioral intentions in using mobile tourism. In addition, future research should look at the specific ways in which culture influences the acceptance of mobile tourists in more depth. With the Interview approach and qualitative research concepts can be used to expand this study. Looking at various cultural models or ideas, or even just certain cultural values that are not covered by Hofstede's dimensions, has the potential to help people understand MTCA better by trying to collaborate with other cultural concepts. Ultimately, stakeholders can create, build, and sell technologically advanced and culturally relevant mobile travel solutions by recognizing and combining technological insights and cultural values. This method helps the mobile travel sector grow in a way that will last by getting more people to adopt it.

ACKNOWLEDGMENT

Optimized Automatic Temperature and Humidity Control for Tobacco Storage Using TwinCAT and Deep Reinforcement Learning

Zhen Liu, Jili Wang*, Shihao Song, Qiang Hua
Qingdao ETSONG Technology Co.Ltd, Qingdao 266001, China

***Abstract*—With the rapid development of the tobacco industry, precise temperature and humidity control in storage environments has become essential for maintaining tobacco leaf quality. Traditional manual control methods suffer from low efficiency and limited accuracy, failing to meet modern storage demands. This study proposes an optimized automatic control system integrating TwinCAT and deep reinforcement learning (DRL) to enhance climate regulation in tobacco warehouses. Leveraging TwinCAT's real-time control capabilities and DRL's adaptive decision-making, the system achieves precise environmental regulation. Experimental results demonstrate that temperature and humidity control errors are reduced to ±0.5 °C and ±3%, respectively. Compared to conventional methods, the proposed system lowers energy consumption by 20% and reduces the mildew rate of stored tobacco by 15%, significantly improving storage quality. This work offers a novel technical framework for intelligent environmental control in tobacco storage and provides valuable insights for broader applications in similar domains.**

***Keywords*—TwinCAT; deep reinforcement learning; tobacco storage; temperature and humidity control; system optimization**

I. Introduction

In today's rapidly developing tobacco industry, tobacco storage is an important link between production and sales, and the importance of environmental control is increasingly prominent [1, 2]. As an agricultural product extremely sensitive to environmental conditions, the quality of tobacco leaves is closely related to the temperature and humidity in the storage environment. Improper temperature and humidity conditions will not only lead to mildew and moth-eating tobacco leaves but also affect their colour, aroma and taste, thus causing irreversible effects on the quality of tobacco products [3, 4]. Therefore, accurately and efficiently controlling the temperature and humidity in the tobacco storage environment has become an urgent technical problem that needs to be solved in the tobacco industry.

The rapid progress of automation technology, especially the wide application of industrial automation software TwinCAT (The Windows Control and Automation Technology), provides a new solution for tobacco storage environment control [5, 6]. With its powerful real-time flexibility and openness, TwinCAT can realize real-time monitoring and precise control of storage environment parameters [7]. However, traditional control strategies are often based on fixed rules or models, which are difficult to adapt to the complex and changeable storage environment, resulting in unsatisfactory control effects.

In this context, the rise of Deep Reinforcement Learning (DRL) technology has brought new ideas for controlling the tobacco storage environment [8]. By combining the perception ability of deep learning with the decision-making ability of reinforcement learning, DRL can enable the control system to learn and optimize itself in complex environments, thus achieving more intelligent and efficient control [9, 10]. Combining TwinCAT with DRL to build a new automatic temperature and humidity control system for a tobacco storage environment can not only make full use of the real-time control capabilities of TwinCAT but also further improve the performance and adaptability of the control system with the help of the intelligent optimization characteristics of DRL.

This study aims to explore the feasibility and effectiveness of this fusion technique. An intelligent optimisation algorithm based on DRL is designed and implemented through an in-depth analysis of the characteristics of the tobacco storage environment and its demand for temperature and humidity, combined with the real-time monitoring and control system of TwinCAT. The algorithm can autonomously adjust the control strategy according to the real-time environmental data to best control temperature and humidity. At the same time, this study will verify the actual effect of the proposed system through experiments and compare it with the traditional control methods in order to provide a new and more efficient technical means for tobacco storage environment control.

Existing tobacco storage temperature and humidity control methods have limitations such as insufficient integration of industrial control systems and intelligent algorithms, difficulty in adapting to complex and variable storage environments, and less ideal control accuracy and energy efficiency. The research fills the gap by combining TwinCAT industrial control technology with deep reinforcement learning, realizing a more intelligent, adaptive and high-performance automatic temperature and humidity control system for tobacco storage, which effectively addresses the aforementioned shortcomings.

This research will involve cutting-edge knowledge in many fields, such as automation control theory, deep learning, and reinforcement learning. By organically combining these theories, it aims to build an automatic control system with powerful and intelligent optimisation abilities. At the practical level, this study will focus on the practical application effect of the system, including control accuracy, stability, energy consumption and other aspects, to ensure that the proposed technology can truly meet the actual needs of tobacco storage.

*Corresponding Author

The optimization research on the automatic control system of temperature and humidity in tobacco storage environment by integrating TwinCAT and DRL has important theoretical value and broad application prospects. This research can provide new technical support for the warehousing environment control of the tobacco industry and promote the development of the industry in a more intelligent and efficient direction.

The basic theory section on TwinCAT and DRL elaborates on the TwinCAT platform, including its features, components, and real-time control capabilities, as well as the principles of DRL, such as Markov decision processes, state-action value functions, and the integration of deep neural networks with reinforcement learning. Subsequently, in the optimization design and implementation of the automatic temperature and humidity control system for tobacco storage environment, the design of the temperature and humidity automatic control system based on TwinCAT was introduced, covering the software and hardware aspects and system architecture, and the temperature and humidity control algorithm based on DRL was also developed to solve the coordination and optimization problems. The experimental and result analysis section provides experimental data through various graphs, comparative analysis with other methods, and discusses the performance of the proposed system, demonstrating the improvement in control accuracy, energy efficiency and stability. Finally, the conclusion summarizes the main findings of this study, highlights the effectiveness of the integrated system, and proposes future research directions.

In the field of temperature and humidity control of tobacco storage, other researchers have proposed a variety of solutions. Some studies use the traditional PID control algorithm to adjust the temperature and humidity by setting fixed parameters, which realizes basic control, but it is difficult to cope with the complex and changeable interference in the storage environment, and the control accuracy and adaptability are limited. There are also studies on the use of fuzzy control methods to deal with uncertainty factors by using fuzzy rules, but there are shortcomings in dynamic response speed and optimization ability. In addition, some scholars try to combine simple machine learning algorithms with control strategies, although they have certain effects in specific scenarios, but lack of deep integration of industrial control systems. At present, the existing schemes generally have problems such as low integration with industrial control platforms, difficulty in adapting to changes in complex storage environments, and unsatisfactory control accuracy and energy efficiency, which are the directions to be further studied. In this study, TwinCAT industrial control technology and deep reinforcement learning are deeply integrated, which not only gives full play to the advantages of TwinCAT in real-time control and system integration, but also makes up for the shortcomings of existing schemes in complex environment adaptability and control performance with the help of deep reinforcement learning's adaptive learning and optimization decision-making ability, and forms a more intelligent, efficient and suitable for the actual industrial scene of tobacco storage temperature and humidity control scheme, which has made significant breakthroughs in technology integration and control effect.

II. Basic Theory of TwinCAT and DRL

A. Introduction to the Twincat Platform

TwinCAT is a pure software controller, which is the core component of the Beckhoff controller, with excellent openness and expansion potential [11, 12]. It has an interface that can be connected to a common field. The development environment integrates Microsoft Visual Studio software, supports special programming languages such as IEC61131 and PLC, and is compatible with high-level languages such as C, C + + and MATLAB/Simulink. Users can choose programming tools according to task characteristics. In addition, TwinCAT has multi-core processing capabilities, which can use all cores to improve performance according to the controller's condition. The PC can be regarded as a calculator, PLC and motion controller when its running core is installed.

TwinCAT's real-time system includes multiple industrial control software packages, covering various motion control software modules, such as TwinCATPLC, TwinCAT NC, TwinCAT CNC Scope View, etc. They can operate independently, exchange information, and work collaboratively through the TwinCAT ADS interface. The TwinCAT task manager controls the real-time process [13, 14].

TwinCAT PLC part is the core of Beckhoff equipment to implement robot motion control, including various logic instructions to control motor motion and some key sub-modules commonly used in programming [15]. Scope View is a system variable monitoring and analysis tool of TwincCAT software, which can display program variables in graphical form, which is convenient for users to monitor, analyze and control system variables in real-time. It is also equipped with Cursor Cursor, Trigger Trigger and other tools for easy operation [16]. Scope Array Bar Project monitors array variables with histograms; Scope project monitors a single variable over a time program; The Scope YTNC project monitors axis variables by axis number; Scope YT project with reporting analyzes the YT graph with reporting function; Scope XY project observes the corresponding relationship between any two variables; Scope XY project with reporting analyzes the XY graph with reporting function. TwinCAT NC is responsible for axis motion control in the TwinCAT system, which can improve axis control performance and play a key role in logic and function control. As a core module, it accelerates platform development and broadens application scope. Its compatibility enables connection with other manufacturers' equipment, and it has the advantages of superior performance, fast speed, high efficiency, and convenience [17, 18].

In the TwinCAT system, the motor control process is divided into three layers: ① PLC axis, axis variables defined under the TwinCAT PLC module; ② NC axis, a virtual axis added to the NC axis configuration interface under the Motion module; ③ Physical axis, the motion execution and position feedback hardware obtained by I/O module scanning and added to the TwinCAT system, each layer has different functions and is interrelated.

B. Deep Reinforcement Learning (DRL) Principles

Reinforcement learning (RL) uses the interaction between agents and the environment to continuously learn by trial and error to find the best strategy [19]. Specifically, RL does not rely on the real-time supervision signal to guide the learning path but relies on the reward signal evaluation strategy to indirectly guide the agent to learn towards the reward maximum and reduce the dependence on the accurate system model [20]. Under the RL framework, the agent makes decisions according to the real-time state of the environment. After execution, the environment enters a new state and feeds back the reward. The infinite loop of this decision and reward feedback constitutes its training process [21].

The core of training is agent decision-making to maximize long-term benefits [22]. The interaction between agent and environment in RL is often modeled as Markov decision process (MDP) [23]. MDP is characterized by a quadruple *(S, A, P, r)*, *S* is the state set, *A* is the action set, *P* describes the probability that the state $s \in S$ transitions to $s' \in S$ after executing the action $a \in A$, and *r* is the reward obtained by the agent when it transitions from state S to the next state S' after executing the action. Under the MDP framework, the agent selects the action $a_t \in A$ through the policy function $\pi(a_t|s_t)$ based on the current state $s_t \in S$ at time *t*, and gets a reward $r(s_t, a_t)$ after execution. The next state is randomly determined by the transition probability $P(s_{t+1}|s_t, a_t)$. The sequence of states, actions and rewards experienced by the agent before reaching the termination state constitutes a round, and its goal is to act to maximize the sum of all rewards at the end of the round, that is, the reward, which is defined in Eq. (1).

$$R_t = \sum_{k=0}^{N-1} r_{t+k} \tag{1}$$

In the formula, *N* represents the total number of steps of the discrete step size. In order to distinguish the relative importance of immediate reward from future reward, a reward discount factor γ (ranging from [0, 1]) is introduced. When γ = 0, immediate reward dominates; When γ = 1, future rewards are more important. Therefore, the return R_t is redefined as Eq. (2).

$$R_t = \sum_{k=0}^{N-1} \gamma^k r_{t+k} \tag{2}$$

The fundamental purpose of an agent is to find the optimal strategy π^*, from which it can determine the best actions it should perform in each state and ensure the maximum discount reward. In order to explore the optimal strategy π^*, a state value function $V(s)$ can be constructed to evaluate the advantageous degree of reaching the current state *s*, as shown in Eq. (3).

$$V^{\pi}(s_t) = E\left[R_t \mid s_t = s\right] = E\left[\sum_{k=0}^{N-1} \gamma^k r_{t+k} \mid s_t = s\right] \tag{3}$$

The state-valued function $V(s)$ is a means to evaluate the pros and cons of a strategy. For any $s \in S$, if the expected return according to the strategy π is higher than π', then $V_{\pi}(s) \geq V_{\pi'}(s)$, indicating that the strategy π is better, and the agent will tend to π when choosing the strategy function. Therefore, the optimal strategy π^* is defined in Eq. (4).

$$V^*(s) = \max_{\pi} V_{\pi}(s), \forall s \in S \tag{4}$$

Although the state value function can compare different strategies, it cannot find the optimal strategy [24]. Bellman created the state-action value function $Q_{\pi}(s, a)$, which is used to measure the degree of return of taking action a according to strategy π in state *s*, as shown in Eq. (5).

$$Q^{\pi}(s_t, a_t) = E\left[R_t \mid s_t = s, a_t = a\right] = E\left[\sum_{k=0}^{N-1} \gamma^k r_{t+k} \mid s_t = s, a_t = a\right] \tag{5}$$

The optimal Q*(s, a) can be defined as Eq. (6).

$$Q^*(s,a) = \max_{\pi} Q_{\pi}(s,a), \forall s \in S, a \in A \tag{6}$$

In order to determine the strategy π, it is necessary to pick out the action matching the maximum value from the action state value function $Q_{\pi}(s, a)$ for a specific state *s*. This is called greedy strategy, which is defined in Eq. (7).

$$\pi(a \mid s) = \begin{cases} 0, if \ \ a = \arg\max_{a'} Q(s,a') \\ 0, if \ \ a \neq \arg\max_{a'} Q(s,a') \end{cases} \tag{7}$$

When the agent operates according to the optimal strategy π^*, the expression of $V^*(s)$ is shown in Eq. (8).

$$V^*(s) = \max_{\pi} Q_{\pi^*}(s,a) \tag{8}$$

The corresponding Bellman equation can be obtained by recursive extension of Eq. (8), as shown in Eq. (9).

$$V^*(s) = \max_{a} \sum_{s',r} p(s', r \mid s, a)[r + \gamma V^*(s')] \tag{9}$$

By recursive derivation of Eq. (6), the optimal Bellman equation of $Q^*(s, a)$ can be obtained, Eq. (10) can be obtained.

$$Q^*(s,a) = \sum_{s'} p(s', r \mid s, a)[r + \gamma \max_{a'} Q^*(s', a')] \tag{10}$$

The premise of the research is to clarify the state transition probability and reward value of the agent, and the Bellman optimal equation can be solved iteratively, which is dynamic programming [25]. Algorithms with known state transition probabilities and rewards are collectively called model-based algorithms. Most RL problems assume that the state transition probability is unknown, and the algorithm set designed for this is called a model-free algorithm.

Traditional reinforcement learning is limited, with small action and sample spaces and mostly discrete environments, which makes it difficult to cope with high-dimensional input data such as images and sounds [26, 27]. DRL combines high-dimensional input of deep neural networks (DNNs) with reinforcement learning. DNNs have the latest technological advances in speech recognition, image classification, machine translation, robot control, etc. The commonly used architecture of DNNs is a feedforward neural network (FNN), a multi-layer perceptron model consisting of the input layer, one or more hidden layers, and an output layer [28].

After the input signal is introduced into the input layer, it will be transmitted layer by layer in the network. The hidden layer and output layer are composed of multiple nodes (perceptrons) [29]. When each perceptron receives the input vector of the previous layer, it will assign a weight ω to each vector element x and sum it. The operation result can be expressed by Eq. (11).

$$z = \sum_i x_i \omega_i + b \tag{11}$$

Where b is the deviation coefficient. After the summation operation is completed and the result is obtained, the activation function f is used to generate the neuron output y, and the calculation process of the neuron model is shown in Eq. (12).

$$y = f(\sum_i x_i \omega_i + b) \tag{12}$$

The multiplication operation of adjusting the input weight of the perceptron can change its behaviour and that of the network. It is necessary to train the neural network to adjust the weight in a specific way so that the network behaviour meets the expected results [30]. Fig. 1 shows the DRL core architecture. The deep learning module captures target observation data from the environment and provides environmental state information. Then, the reinforcement learning component corresponds the current state to the corresponding action, evaluates the value according to the estimated return, optimizes the decision-making action through the interactive process, and iteratively updates the network parameters to obtain the best strategy.

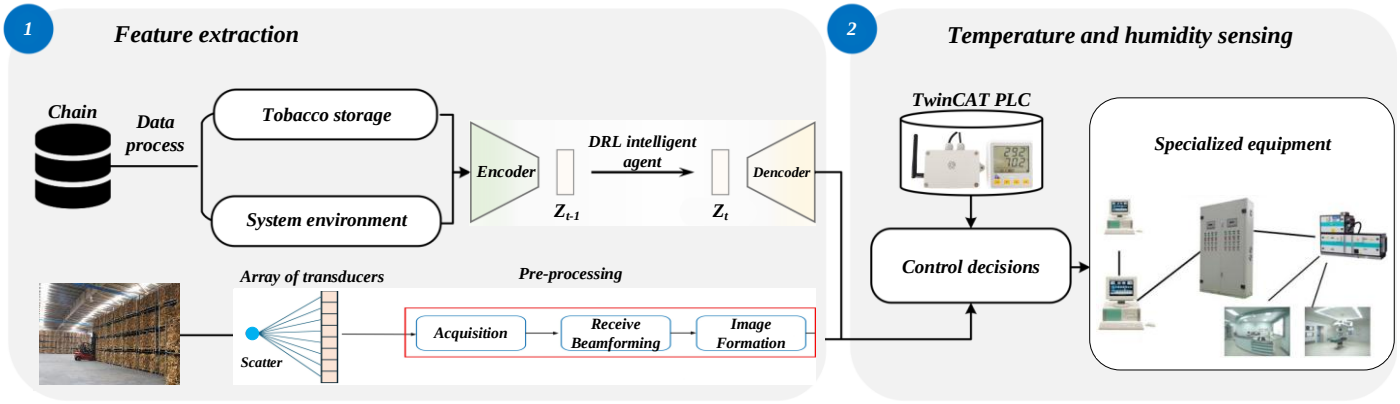

Fig. 1. Deep reinforcement learning architecture.

III. Optimization Design and Implementation of Automatic Control System for Temperature and Humidity in Tobacco Storage Environment

A. Automatic Control System of Temperature and Humidity in Tobacco Storage Environment

The inspection machine control system software software includes seven functional modules: start-stop speed control, servo motor control, etc. Accordingly, the software and hardware design process is carried out.

Regarding software design, the inspection machine involves the interface design of the host computer based on the Qt framework, visual inspection algorithm program and Beckhoff PLC programming based on TwinCAT. The Qt host computer interface uses the Qt Creator development tool on the Windows platform (Qt 5.12. 2 versions). The host computer and Beckhoff PLC interact with each other through ADS communication protocol, and a communication bridge is built in Qt Creator environment with C + + language combined with ADSDLL library of Beckhoff TwinCAT to realize the reading and writing of PLC memory data by the host computer. Beckhoff PLC is the ADS server in this architecture, and the host computer is the client. It uses an asynchronous notification mechanism to send ADS requests, and the server sends responses through the Call-back mechanism until the request is cancelled. Its advantage is that TwinCAT only transmits data when updated, which can avoid the loss of program running efficiency.

The TwinCAT integrated development platform is used for the lower computer Beckhoff PLC program design. TwinCAT is a PC-based real-time control system that can accurately control and respond to real-time systems, supports multi-task parallel processing, and assigns different priorities to tasks as needed. Each task contains one or more program blocks to execute specific control logic to cope with complex control challenges. In addition, TwinCAT is compatible with various communication protocols, which facilitates data interconnection with other devices and systems. The control system architecture adopted in this paper is shown in Fig. 2.

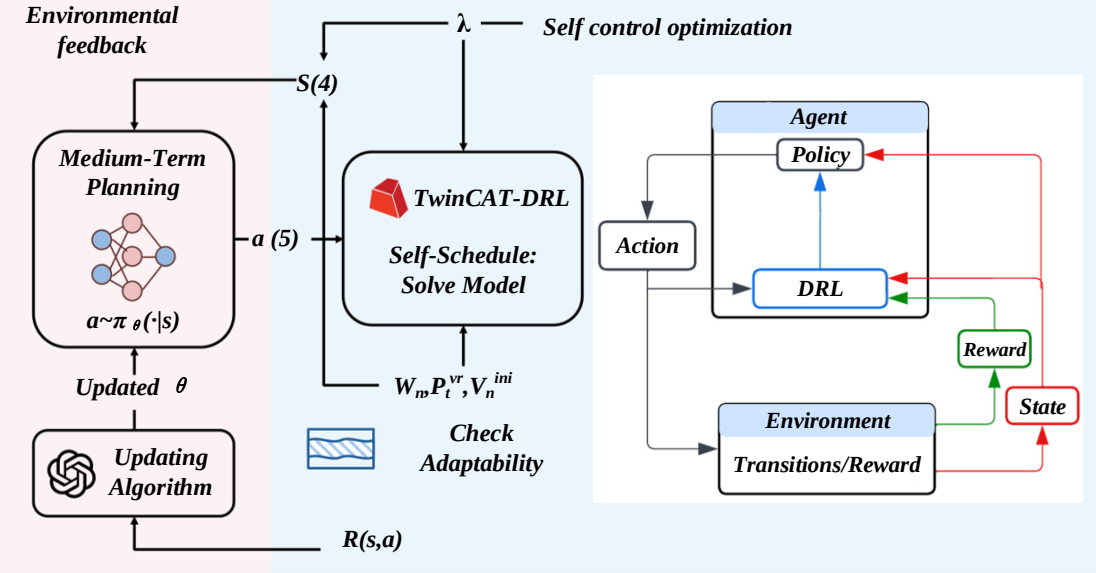

Fig. 2. Control system architecture.

B. Temperature and Humidity Control Algorithm Based on DRL

Because DRL aims to control frequency deviation minimization and tie-line power stability, GCD pursues control cost minimization. It is difficult to comprehensively optimize and control frequency deviation and control cost by combining the two algorithms, especially in the special situation of the current control system, and the actual operation time may exceed the AGC control interval limit, resulting in performance degradation. Therefore, to solve the mismatch problem between the two, this study proposes an integrated frequency regulation architecture based on an intelligent controller, which gives regulation instructions on the premise of balancing the two objectives according to the real-time state of the system to achieve multi-objective optimization.

In the automatic temperature and humidity control system, due to the wide variety of equipment involved and their unique characteristics, their frequency response speeds are also different, which requires the intelligent controller to accurately generate the matching power regulation instructions according to the unique performance characteristics of each frequency regulation unit. However, using traditional algorithms to complete this complex process often requires a lot of time and energy to carry out tedious parameter adjustment experiments to ensure the system's normal operation. Even so, when the system faces large-scale random disturbance, the dynamic performance of traditional algorithms is often unsatisfactory, and it is difficult to cope effectively with complex and changeable actual working conditions, which limits the stability and reliability of the temperature and humidity automatic control system to a certain extent.

Therefore, this study proposes an integrated frequency control strategy for a multi-regional interconnected temperature and humidity automatic control system, using the algorithm as the intelligent controller, sensing relevant data and outputting control instructions simultaneously, and designing the reward function to consider multiple dimensions to solve coordination problems comprehensively. Through pre-training, the algorithm masters the dynamic performance of each frequency modulation unit and the characteristics of system frequency change and generates reasonable instructions in the execution stage to ensure that the deviation is within the specified range. Each region is regarded as an independent agent, and the control instructions are obtained by a multi-agent cooperative game. The advantages of this strategy are: it can avoid the problem of AGC performance degradation, the algorithm is a multi-output algorithm, the calculation time is less than the command cycle limit, the strategy can be updated online without relying on the model, and it can generate instructions based on the real-time status of each unit to exert its frequency modulation potential.

IV. Experiment and Result Analysis

Experimental data Table I shows that the detection performance of the improved scheme is significantly improved. Under the mAP @ 50: 5: 95 evaluation standards, the improved version improves by about 1.5 percentage points on average compared with the previous one. Except for SSD, the mAP50 value of other methods exceeded 99.0%, and the mAP50 value of this method was the highest, reaching 99.5%. It can also be seen from Table 1 that although the improved method has a time delay of about 0.8 milliseconds compared with the original model, the processing speed is still about 130 fps, far exceeding the 20 fps of the two-stage target detector Faster-RCNN.

TABLE I Comparative Experimental Results

Detection model	mAP @ 50: 5: 95	mAP50	Average detection time per picture/ms
Base	95.6%	98.5%	8
This article improves	97.1%	98.5%	9
Faster R-CNN	97.7%	98.3%	60
SSD	48.8%	88.1%	42

Fig. 3 shows the average reward of each round of the algorithm agent. The training consists of 3000 rounds, each containing 60 time slots. At the beginning of the time slot, the agent interacts with the environment, makes decisions and updates the network model. During this period, the average reward of the DDPG module and DQN module climbed and converged with the increase in training rounds. The average reward of the DDPG module increases rapidly after 300 rounds and stabilizes after 1000 rounds. The DQN module gradually converges from the beginning of learning, and its average reward tends to be stable after 300 rounds. As the number of rounds increases, the DQN module will reduce the exploration frequency and generate greater actions, making its output decisions and rewards tend to be stable.

Fig. 4 explores the impact of warehousing computing resources on average weighted user energy consumption. The energy consumption of each scheme decreases with the increase of warehousing computing resources. When warehousing computing resources are scarce, the computing delay of users who choose to offload computing is too large, which does not meet the maximum delay permission conditions. Users prefer to execute tasks locally, resulting in higher user energy consumption.

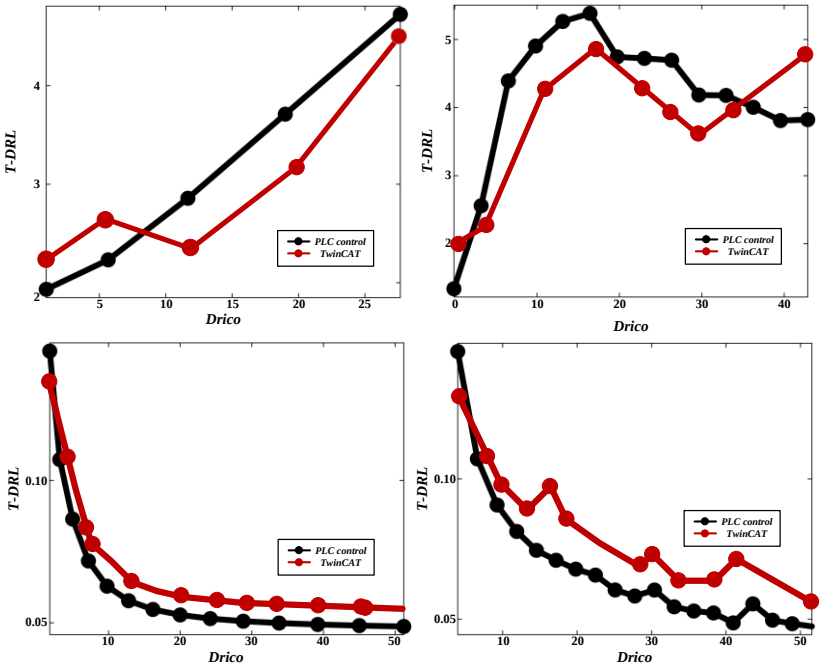

Fig. 3. DDPG unit average reward of the algorithm.

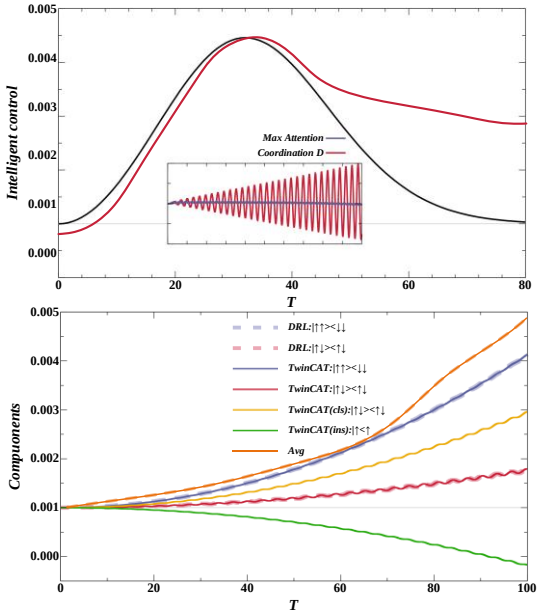

Fig. 4. Average weighted user energy consumption under different warehousing computing resources.

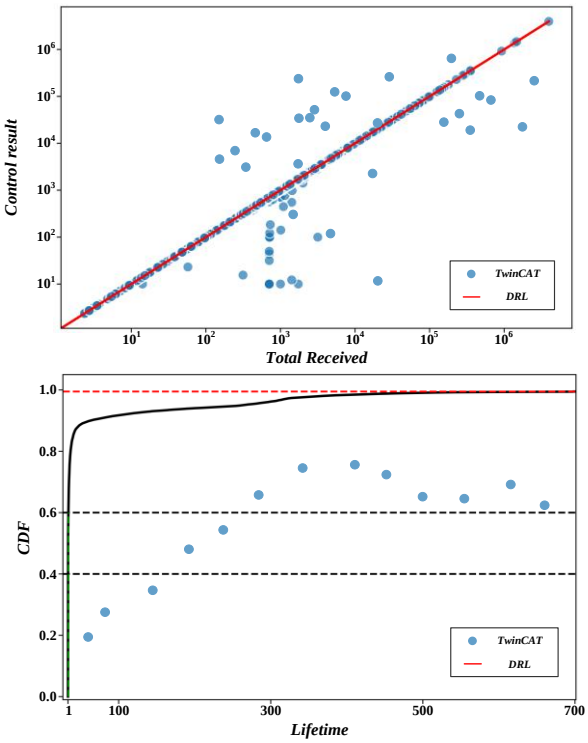

Fig. 5. Training results of different algorithms.

As can be seen from Fig. 5, the distributed training architecture uses many agents in multiple parallel systems to conduct distributed exploration, which can accelerate the process, improve agent training efficiency, and reduce computing overhead. Compared with centralized automatic control control (AGC) based on PPO and DDPG, distributed AGC based on deep reinforcement learning (DRL) has a better training effect and greatly increases training time. At the same time, PPO and DDPG algorithms have great volatility in the learning process, and the reward convergence value fluctuates, obviously. Hence, it is difficult to cope with random interference.

It can be seen from Fig. 6 that compared with DRL, PPO, DDPG and PID + PRPO, the frequency deviation at the same time point is smaller, and the frequency does not exceed 0.2 Hz during the control period. Because PID + PRPO cannot flexibly enable the quick response adjustment component to adjust the frequency, instability or over-adjustment problems will occur due to unreasonable parameter configuration, which may cause the frequency deviation to exceed 0.2 Hz and waste frequency adjustment resources.

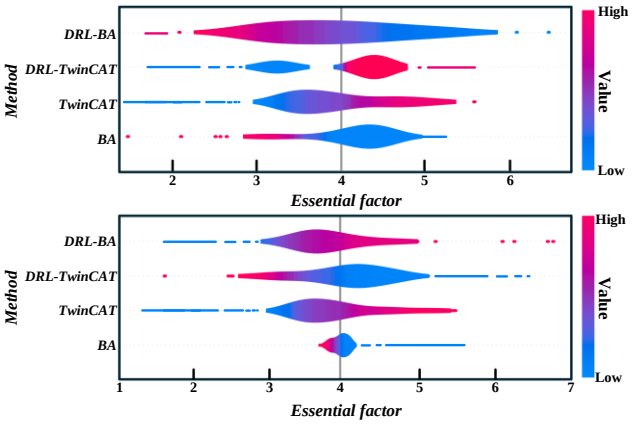

Fig. 6. Frequency deviation variation diagram of different algorithms.

It can be seen from Fig. 7 that the frequency control strategy can better fit the disturbance curve. Compared with the traditional PID + PRPO frequency modulation method, DRL technology's frequency modulation scheme performs better. DRL combines the essence of fuzzy control and neural network control, which can provide real-time feedback, adjust environmental changes during operation, and promote the control system to better adapt to the nonlinear dynamic environment. Compared with other DRL algorithms, it has smaller power tracking errors, can complete frequency adjustment as quickly as possible, and is more suitable for fluctuations in load and distributed resources in temperature and humidity automatic control systems.

It can be seen from Table II that each system index of the proposed strategy exceeds other strategies. Compared with other methods, this algorithm reduces the mean of Af by 19.3% to 58.1%, the mean of ACE by 12.6% to 77.4%, the mean of CPS1 by 0.15% to 28.6%, and the mean of CPS2 by 2.06% to 20.1%. By comparison, the controller has the smallest change in performance and the best adaptability and robustness.

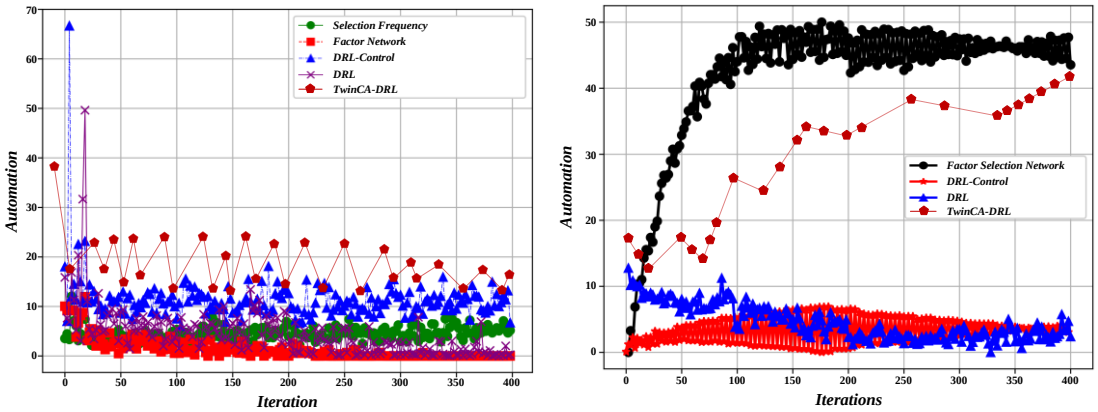

Fig. 7. Control effects of different strategies under white noise disturbance.

TABLE II MODEL STATISTICAL EXPERIMENTAL RESULTS UNDER RANDOM WHITE NOISE DISTURBANCE

Region	Index		DRL	PPO	DDPG	PI + PRPO
Region 1	Af/Hz	0.0694	0.0860	0.0912	0.1097	0.1689

	CPS2/%	104.8850	103.3780	97.2620	93.7310	87.5490

As shown in Fig. 8, the average algorithm score is 2.799. As the number of iterations increases and the exploration rate decreases, the average score of ERDQN algorithm grows slowly, while the average score of DRL-ERD3QN algorithm shows an upward trend, and its score rises rapidly in nearly 3000 rounds, which indicates that the network of this algorithm achieves rapid update in about 3000 rounds, while the neural network update speed of the other two algorithms is relatively slow.

As shown in Fig. 9, the DQ-DRL algorithm does not overestimate the agent policy learning. This shows that the algorithm effectively avoids the overestimation problem by taking two minimum values of Critic current network to update. Although this approach may lead to underestimation, underestimation is more acceptable than overestimation.

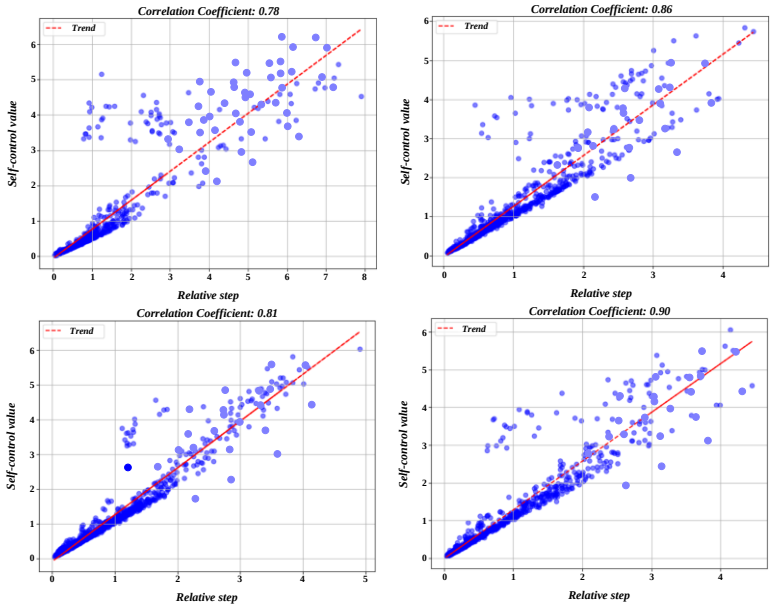

Fig. 8. Average score.

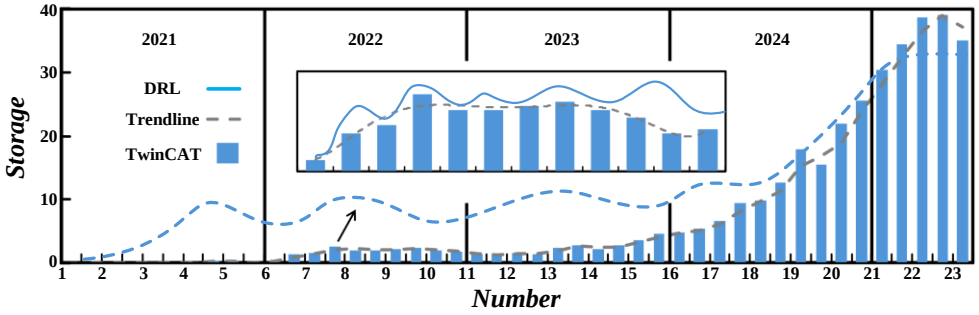

Fig. 9. Comparison of estimation bias.

Fig. 10 shows the changing trend of the cumulative total reward of the DQ-DRL algorithm and the follower agent trained by the DRL algorithm in each round when the group contains 4 units. It can be seen from the Fig. that in the early stage of training, the reward curves of both algorithms rise steadily. After about 35,000 rounds, the reward value of the DQ-DRL algorithm tends to stabilize and converge, while the reward curve of the DRL algorithm lags until about 55,000 rounds before converging. Moreover, the total reward value of the final convergence of the DQ-DRL algorithm is higher. This shows that although both algorithms allow the agent group to learn the stable formation control strategy, the DQ-DRL algorithm not only speeds up the convergence speed of the model but also improves the overall total reward of the agent group and enhances the superiority and robustness of the formation control model.

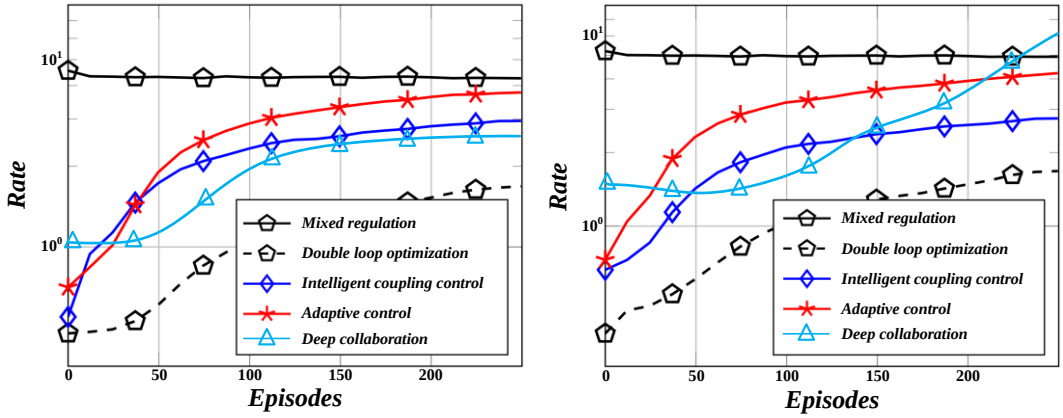

Fig. 10. Total reward curve obtained in each round during the training period.

V. Discussion

The integration of TwinCAT with Deep Reinforcement Learning (DRL) for temperature and humidity control in tobacco storage has led to a promising paradigm shift. Our results clearly show that this fusion not only solves the limitations of traditional control methods, such as poor adaptability to complex environments and poor accuracy, but also takes full advantage of the real-time processing power of TwinCAT and the adaptive decision-making capabilities of DRL to achieve better performance. The experimental results show that the temperature and humidity control error is reduced to $\pm 0.5^{\circ}$ C and $\pm 3\%$, the energy consumption is reduced by 20%, and the tobacco mildew rate is reduced by 15%, which highlights the practical value of the method. Our approach's ability to learn and adjust strategies in real-time is a key advantage compared to existing solutions such as PID control, which relies on fixed parameters and struggles to cope with dynamic changes, and fuzzy control that lacks self-optimizing capabilities. It is important to note that the success of the system depends on the seamless interaction between TwinCAT's industrial control infrastructure and the DRL algorithms, a synergy that enables the rapid acquisition, processing and execution of data, which is crucial in tobacco storage, where environmental fluctuations require a timely response. However, we also realize that the complexity of DRL model tuning and the need for sufficient training data may pose challenges to the widespread adoption of this method. Another aspect to consider is the versatility of our approach, and while it has been proven to be effective in tobacco storage, it is still worth exploring for its application to other agricultural or industrial storage scenarios, as different environments may have unique limiting factors. In addition, future improvements can focus on enhancing the robustness of the model to extreme weather conditions, as well as reducing the computational overhead of the DRL component, making it easier to apply in small storage facilities. Overall, this study highlights the potential of combining industrial control systems with advanced machine learning techniques to revolutionize storage environment management, providing a balance of precision, efficiency, and adaptability that is difficult to achieve with traditional methods.

VI. Conclusion

This study explores the optimal application of fusing TwinCAT and deep reinforcement learning (DRL) technology in tobacco storage environments' automatic temperature and humidity control systems. By constructing an intelligent control system, the high-precision and high-efficiency regulation of the tobacco storage environment can be realized, thus ensuring the quality of tobacco and reducing storage losses.

(1) Firstly, traditional temperature and humidity control system performance is benchmarked. The results show that under the unoptimized conditions, the control accuracy of the system for temperature and humidity is ± 2 ℃ and ± 5% RH, respectively, and there is obvious hysteresis. This result reveals the limitations of conventional control systems in coping with complex environmental changes.

(2) The system is preliminarily optimised by introducing the TwinCAT platform and using its powerful real-time control and data acquisition capabilities. The experimental results show that through the integrated management of TwinCAT, the control accuracy of the system has been significantly improved, and the control accuracy of temperature and humidity has been improved to ± 1 ℃ and ± 3% RH, respectively. At the same time, the system's response speed has been accelerated, and the lag phenomenon has been effectively alleviated.

(3) To further improve the system performance, this study introduces DRL technology and constructs an intelligent control

model based on deep reinforcement learning. The model achieves accurate prediction and adaptive regulation of temperature and humidity changes by continuously learning environmental data and control strategies. The final experimental results show that the system combining TwinCAT and DRL can stabilize the control accuracy of temperature and humidity within ± 0. 5 ℃ and ± 2% RH, respectively, and almost eliminate the hysteresis phenomenon. In addition, the system's energy consumption has also been effectively reduced, saving about 15% of energy consumption compared with traditional systems.

The tobacco storage environment's automatic temperature and humidity control system integrating TwinCAT and DRL shows excellent performance and great application potential. This study provides a new technical path for the intelligent management of tobacco storage environment and a useful reference for optimising automatic control systems in related fields. In the future, we will continue to deepen research, explore more innovative applications, and contribute more to the development of tobacco storage and other related industries.

The existing solutions include traditional PID control (fixed parameters, difficult to resist interference), fuzzy control (insufficient dynamic response and optimization), and simple machine learning combined control (lack of deep integration of industrial systems). These schemes generally have the problems of insufficient integration of industrial control and intelligent algorithms, weak ability to adapt to complex environments, and poor accuracy and energy efficiency. In this study, TwinCAT and deep reinforcement learning are integrated, which not only gives full play to the advantages of real-time control of the former, but also improves the adaptability and optimization capabilities of the latter, makes up for the shortcomings of the existing schemes, and forms a better control scheme.

Adaptive AI-Driven Enterprise Resource Planning for Scalable and Real-Time Strategic Decision Making

Ghayth AlMahadin
Assistant Professor, Data Science Department, College of Information Technology, Mutah University, Jordan

***Abstract*—Enterprise Resource Planning (ERP) systems play a critical role in managing organizational assets and operations. However, traditional ERP systems rely on static, rule-based decision-making frameworks that lack the agility and intelligence required for real-time strategic support. To address these limitations, this study proposes an Adaptive AI-Driven Enterprise Resource Planning (A2ERP). This AI-augmented ERP framework integrates adaptive predictive models to enhance decision-making capabilities at scale. The A2ERP architecture features a dynamic data ingestion layer, an adaptive predictive engine utilizing online learning and ensemble methods, and a decision support interface empowered with explainable AI (XAI). It is designed for scalability through a containerized microservices architecture. Experimental results demonstrate that A2ERP achieves a 98% accuracy rate in both training and testing phases, effectively identifying errors such as omission, addition, and overstatement. Comparative evaluations show that A2ERP outperforms traditional ERP methods across key performance metrics, including precision, recall, and F1-score. The framework's ability to process large-scale, complex data in real-time underscores its effectiveness in delivering timely strategic insights. A2ERP represents a significant advancement toward scalable, adaptive, and intelligent ERP systems, bridging the gap between operational execution and strategic decision-making.**

Keywords*—*Enterprise resource planning; adaptive predictive modeling; real-time decision support; AI-Augmented ERP; ensemble learning

I. INTRODUCTION

Digital infrastructure of modern organizations relies on Enterprise Resource Planning (ERP) systems. [1]. They are the central nervous system to operate some important business functions, such as finance and human resources, supply chain logistics, and customer relations on the same digital platform. Due to integration of these highly variegated modules [2]. ERP systems have in the past made it possible to achieve better efficiency, uniformity, and control in organizational processes [3]. However, no matter how popular and functionally efficient the conventional ERP systems might be, they are certain to be rule-based and, therefore, limited in their nature since they operate on the rule-based, fixed logic. These systems are fixed in their workflow and decision tree logic, and hence they are non-flexible and not able to keep up with real-time dynamics and evolving business scenarios [4]. As organizations are constantly met with a sophisticated and constantly evolving environment full of market volatility, global supply chain mega-disruption risks, and quickening digital transformation, the reality that ERP systems could not (and cannot) keep up in real-time has become a fatal flaw [5].

Availability of data and time sensitivity have been the characteristic features of the current business landscape. Businesses are constantly producing large flows of structured and unstructured data on internal processes, interactions with customers, IoT sensors, and external data sources [6]. The strategic decision-making process within this type of environment requires not only the availability of data, but also the smart interpretation and prompt action. Sadly, the majority of the ERP platforms do not prepare to satisfy this need [7]. The traditional ERP systems are based on past information, fixed reports, and scheduled updates, which make the decision-making process slow and non-responsive [8]. They usually do not have advanced analytics options and have minimal or no support for predictive modeling and contextual intelligence. Further, their modular nature is most often disjointed, and any form of integration with more advanced tools of analytics is typically piecemeal and in silos, which introduces operational inefficiency and curtails a narrow ability to strategically align. This has revealed a huge technological divide between the potential of the existing ERP systems and the emerging needs of the contemporary business.

The driving force behind this study is the fact that there is an excessive gap that needs to be closed between the traditional ERP features and functions and the strategic intelligence that is demanded in high-paced business settings [9]. Although ERP systems have long been successful in areas related to transaction processing and workflow automation, the newly emerging battlefield is to make these systems smart, self-learning systems that can respond in real time to data. The importance of the work is explained by the possibility to change the perception of ERP systems, which are usually discussed as the passive storage of operational data, to the proactive involvement in the strategic decision-making process [10]. Incorporation of artificial intelligence, notably adaptive and predictive learning models, presents a game-changing possibility to improve the responsiveness, accuracy, and efficiency of ERP-based decisions [11].

The study reflects a technological and an organizational imperative. Technological. It seeks to address shortcomings of the static ERP models through integration of adaptive predictive processing at the system architecture level. Organizationally, it aims to equip decision-takers with insights that are not only timely, but also explorable and operable. Through the integration of continuous learning and on-demand data processing, the suggested layout will help dynamically respond to changing circumstances to allow organizations to act with more agility, foresight, and strategic alignment. The paper further acknowledges the need to have transparency in AI

decisions, particularly in enterprise contexts, where explainability is vital to user trust and acceptance [12]. In order to mitigate these risks and achieve the mentioned objectives, the proposed study introduces an extended framework, called Adaptive AI-Driven ERP (A2ERP). This architecture aims to deploy smart learning components at the heart of ERP solutions, allowing them to ingest data in real-time, perform adaptive predictive modeling, and decision-making accompanied by Explainable AI (XAI). Fundamentally, A2ERP presents a new adaptive predictive engine, which could constantly refresh its models using online learning algorithms, and make adjustments to respond to new data as it comes, without requiring re-training ex-novo. The framework can improve the robustness and accuracy of its predictions in different ERP modules through ensemble learning techniques.

A. Research Significance

The study is relevant in that it fills a serious gap in the conventional ERP systems, which is the inability to sustain real-time, adjustive, and strategic decision making. With businesses creating and depending on huge amounts of data, the static, rule-based ERP systems are inadequate in reacting to the changing operational environments and market environments. The A2ERP framework proposed creates a paradigm shift due to the combination of adaptive predictive modeling, explainable AI, and scalable microservices. Its ability to learn continuously and process data in real-time enables organizations to spot trends, detect anomalies detection and make proactive strategic decisions. The study therefore seals a critical technology gap that exists between the traditional features of ERP systems and the current requirements of the enterprise to respond swiftly to business uncertainties. The research helps bring the much-needed evolution in ERP systems by making them smarter in terms of providing advice and guidance to the enterprise, by virtue of being a smart decision-support ecosystem, as opposed to being a transactional system. The flexibility of the framework in combination with its flexibility across industries also makes it quite applicable and hence a worthy development in the realms of intelligent business process management.

B. Research Motivation

This research is motivated by the increasing mismatch between the real-time requirements of current business ventures and the non-real-time functionality of traditional ERP systems. Current ERP systems are non-adaptive and do not use real-time data in making high-level decisions. As the data becomes more complex and organizations require quick, data-informed decisions, it will be necessary to implement AI into ERP systems. The motive behind this research is to enable ERP systems to keep up with changes in business environments by empowering them with adaptive learning. The A2ERP framework is developed to bring this change to provide proactive, smart, and scalable enterprise management solutions.

C. Key Contributions

1) An AI-augmented ERP framework integrating adaptive predictive models for strategic decision support on a real-time basis has been developed.

2) A data ingestion and processing layer has been created, associating real-time, scalable analysis of the enterprise operations.

3) Utilizing machine learning, one can forecast trends, detect anomalies, and optimize decision-making within ERP modules.

4) Testing was performed with structured ERP schema data to provide a quantitative analysis for improvement in terms of scalability, accuracy, and strategic responsiveness.

The rest of the sections of this study are ordered as follows: Section II gives review of the existing literature AI-augmented enterprise resource planning with adaptive predictive models for scalable, real-time strategic decision support. Section III details the proposed research methodology. Section IV presents the experimental results. Section V discuss and concludes the study.

II. Literature Review

A. Introduction and Background of ERP Systems

Enterprise Resource Planning systems have transformed greatly over the past few decades, which saw them move away from standalone monolithic legacy systems to more agile cloud-based and integrated platforms [13]. Early ERP systems had it in them to automate back-office functions and to put business processes in a central database. But they were rigid, expensive to maintain, and did not do a great job of talking to different parts of the organization.

1) Evolution of ERP architecture and cloud integration: With the advance of the internet and distributed computing, ERPs have gradually moved to cloud architectures, which in turn enabled greater scale, remote access, and smooth integration with third-party apps [14]. This shift saw businesses adopt modular ERPs, which are tailored to specific functions such as finance, supply chain, customer relations, and human resources, which in turn improved operational efficiency and user flexibility.

2) Incorporation of AI into ERP systems: At the same time, it saw the introduction of AI into ERPs, which is transforming them by adding intelligent elements like demand forecasting, anomaly detection, predictive maintenance, and process automation [15]. AI models are now used to analyze historical data, to find out what's in it that is not visible, and to automate routine tasks, thus reducing human input and improving decision accuracy. However, it is important to note that while it has seen progress, AI in ERPs is still in the early stages in both scope and depth.

3) Limitations of current AI in ERP: Most current use is of static models, which are trained on historical data and do not adapt well to new info in real time. Also, these models do not scale well with large data sets, which is common in enterprise settings, and do not support strategic decision making [16]. Also, it shows that AI in present ERPs is very much in silos and not very much a part of the core ERP architecture, which in turn limits their role in taking up high-level business decisions across modules. Furthermore, there is a gap in the deployment of AI for real-time analysis and decision support, which is a

must in business settings that are dynamic and require quick response to trend changes, market shifts, or ops disruption [17].

4) Data complexity and structural challenges: Also, present solutions do not take into account the complex relationships between ERP modules and database tables, which leads to data issues and suboptimal results when changes are made without looking at the whole picture. These issues point to the need for a more integrated and adaptive approach that fully uses AI to improve ERP function [18].

5) Motivation for the proposed framework: A truly smart ERP system goes beyond automation and prediction to become a strategic tool that supports real-time data-driven decisions across all business areas. This study presents a new, scalable, and adaptive AI-enhanced ERP framework that addresses present model flaws and supports strategic agility [19].

B. Research Gap

ERP systems presently rely on static machine learning models and fragmented AI integration; they cannot provide real-time, adaptive, and strategic decision support. Usually, AI features are not completely built into ERP architecture. Thus, cross-module cooperation toward strategic impact may be limited. Furthermore, it seems like there is very little research regarding the impacts of database dependencies upon the scalability and maintainability of intelligent ERP systems. This demands a unified AI-assisted ERP framework enabling real-time continuous learning and programmatic integration, set out for strategic decision-making.

III. Research Methodology

The A2ERP approach targets embedding adaptive predictive models into ERP structures to facilitate real-time decision-making. Its approach includes system training using publicly available simulation data sets of ERP or artificially created synthetic data [20]. It has a dynamic layer of data ingestion to ingest data in a continuous process, an integrated adaptive predictive engine using online learning algorithms, and explainable AI-based insights embedded within a decision-support interface [21]. Model training is employed to predict, identify anomalies, and optimize features for enhancing adaptive and efficient decision-making support.

Although online learning and ensemble models are individual aspects of implementations in machine learning, the innovative nature of A2ERP is that its three aspects combine more precisely than that of real-time data ingestion, Explainable AI (XAI), and microservice-based scalability with the specificities of ERP settings. This is in contrast to the other systems, which utilize AI in a single module of the ERP, such that A2ERP deploys an adaptive and comprehensive structure of decision-support that can learn with the data of the operations. The strategic input of the study lies in a practical aspect of complexity of continuous learning, anomaly detection, and interpretability implemented in a dynamic, scale-up ERP system, a gap that has not been adequately tackled in the literature yet.

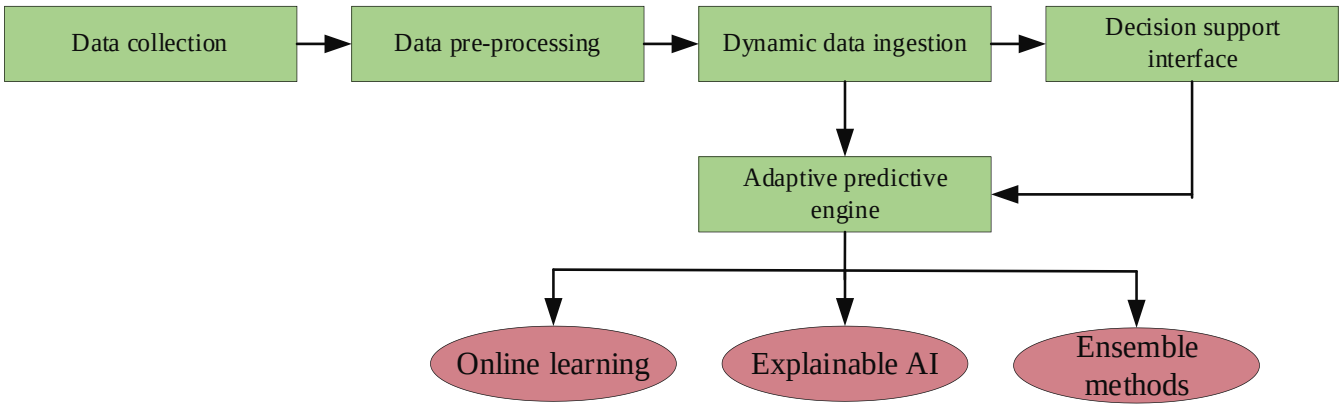

Fig. 1. Overall workflow.

Fig. 1 shows the methodological scheme of the suggested A2ERP framework. It starts with the stage of data collection about different ERP modules and continues with the stage of data pre-processing, where missing values, different scales, and outliers should be managed. This cleaned data gets into the dynamic data ingestion layer, which takes input in real time and streams it into the adaptive predictive engine. The latter is a central engine that incorporates three essential elements, namely online learning to continuously update the model, ensemble methods to combine the predictions of many models, and Explainable AI (XAI) to ensure the transparency and interpretability of insights. The refined results are channeled to the decision support interface, wherein strategic suggestions are graphically represented and served to the enterprise consumers. Relevant decision context is also fed back to the adaptive engine through the interface to be refined. The architecture allows A2ERP to perform with real-time responsiveness, high prediction accuracy, and strategic agility, and therefore it fits well into the dynamic and large-scale ERP scenes.

A. Data Collection

The process of collecting data for the A2ERP model includes extracting publicly available ERP simulation data as well as mock data mimicking real business operations from Kaggle [22]. Such data types include transactional data, sensor data, and user logs with broad extent in ERP modules such as finance, supply chain, human resources, and customer relationship management. Examples of these datasets include DataCo and Odoo logs that are to be utilized for emulating varied ERP scenarios. The harvested data will be streamed into the system

in real time through a dynamic data ingestion layer, promoting real-time processing and flexibility. This rich data is used to fuel the adaptive predictive engine, which allows the framework to make predictions, identify anomalies, and allocate resources for optimum purpose based on real-time and dynamic business situations.

B. Data Pre-Processing

1) Missing data handling: Missing values are common in economic datasets due to reporting lags or incomplete data. To solve this, the Mean Imputation method is used, where missing values are represented by the average value of the respective column of available data. Mean imputation is a formula for imputation, which is in Eq. (1):

$$X_{new} = \frac{1}{N}\sum_{i=1}^{N} X_i \quad (1)$$

2) Data normalization: Fixed scale against which all the data is compared. Raw data is normalized by means of Min-Max Scaling. This method rescales the data into a variable that ranges from 0 to 1 to prevent some features from overpowering the others due to huge numeric values. The formula is in Eq. (2):

$$X_{scaled} = \frac{X - X_{min}}{X_{max} - X_{min}} \quad (2)$$

3) Outlier detection and removal: Outliers in this data might mislead decisions made by the use of the data, and therefore, the Interquartile Range Method is employed to identify and exclude them. The IQR is calculated as Eq. (3):

$$IQR = Q3 - Q1 \quad (3)$$

With these preprocessing steps, we have ensured that our data is clean, consistent, regularized, and decent, thereby being wholly appropriate for the use of enterprise resource planning with adaptive predictive models for scalable, real-time strategic decision support.

C. AI-Augmented Enterprise Resource Planning with Adaptive Predictive Models

1) Dynamic data ingestion layer: The A2ERP framework incorporates a dynamic data ingestion layer that ensures seamless, real-time data streaming from a variety of sources, such as transactional databases, sensor readings, and user activity logs. By using continuous streams of data rather than batches or by manual enrichment, the systems stay responsive to changes in business events. The dynamic ingestion layer is necessary for the information to be current, enabling the predictive models to adjust in real-time as conditions change. As data is being created, this layer combs through the information, enabling the system to respond swiftly to changes in the operational or market' dynamics, thereby improving the accuracy of predictions and timeliness of decision-making.

2) Adaptive predictive engine: At the heart of the A2ERP framework is the adaptive predictive engine, designed to continuously update its models based on incoming data using online learning techniques. This engine combines novel ensemble learning techniques akin to online random forests and streaming XGBoost for predicting futures, detecting anomalies, and optimizing resource allocations. The learning online method ensures that the model remains adaptable and learn time-evolving, more accurate predictions as it finds new data. This real-time adjustment for the engine will be able to handle large-scale datasets, and reactions to the changes on the business market without obligatory retraining a new making it a capable tool for efficient decision-making with dynamics and operational efficiency.

3) Decision support interface: The A2ERP framework integrates the outputs of the adaptive predictive engine into a decision support interface that provides visual analytics and strategic recommendations backed by Explainable AI. This interface provides insights about Robin Spier's trends, forecasts, and opportunities to make wise and effective business decisions. Using XAI, the system provides transparent recommendations, so users know the reason behind each proposal. Transparency in AI systems instills confidence in the system and boosts the quality of decisions by supplying clear, understandable reviews for polls and strategies produced by AI models.

4) Scalability layer: The scalability layer of the A2ERP framework ensures that the system can scale efficiently as data volumes and complexity increase. Orchestrated with Kubernetes and designed in a containerized microservices architecture, the framework leverages Apache Kafka real-time data streaming. This architecture also permits the system to manage a large data volume from different ERP modules with high performance and responsiveness. Scaling up or down according to the changing workloads could be easily done by using Kubernetes, and Apache Kafka makes sure that all the data is delivered in real time in streaming without any dilemma. This render engine allows the A2ERP framework to maintain robustness and ability to handle multi-departmental large scale operations of a larger business activity, providing reliable performance even under heavy loads of data. It also has a modular design that assures smooth integration to cloud platforms, maximizes fault tolerance, and minimizes downtimes, which makes it perfectly suitable to mission-critical enterprise environments where high levels of data availability are needed and where decisions are time-sensitive and have to be continuously made. It also facilitates automatic load balancing, frictionless component orchestration, and dynamic scaling policies, which allow the system to achieve the various requirements of the organization without interfering with the performance and stability.

Fig. 2 illustrates the overall process of the A2 ERP framework combines real-time data ingestion, adaptive predictive modeling, strategic decision support, and scalable infrastructure to boost the performance level of the ERP system. The process starts with the dynamic data ingestion tier, which is often moving data from different sources such as transactional databases, sensors, and user activity logs. Real-time data is input directly to the adaptive predictive engine -- a flexible engine that fits the needs of various industries by using online learning to

adaptively and continuously update its models, predicting future trends, identifying anomalies, and allocating resources more effectively. The results from the predictive engine are then woven into a user-friendly decision support interface that gives decision-makers visual analytics and explainable AI-recommended insights. In the end, the scalability layer provides the possibility to work with large sets of data and to scale well by usage of the containerized microservices, real-time data stream, and so on. It also integrates auto-scaling features, intelligent load balancing, and fault-tolerance systems, thus allowing high availability, performance consistency and very less downtime even in cases when it faces the peak of operational loads. These features, combined, allow the A2ERP framework to offer adaptive, real-time strategic decision support that is responsive, correct, and flexible, it satisfies the needs of the modern enterprise Systems.

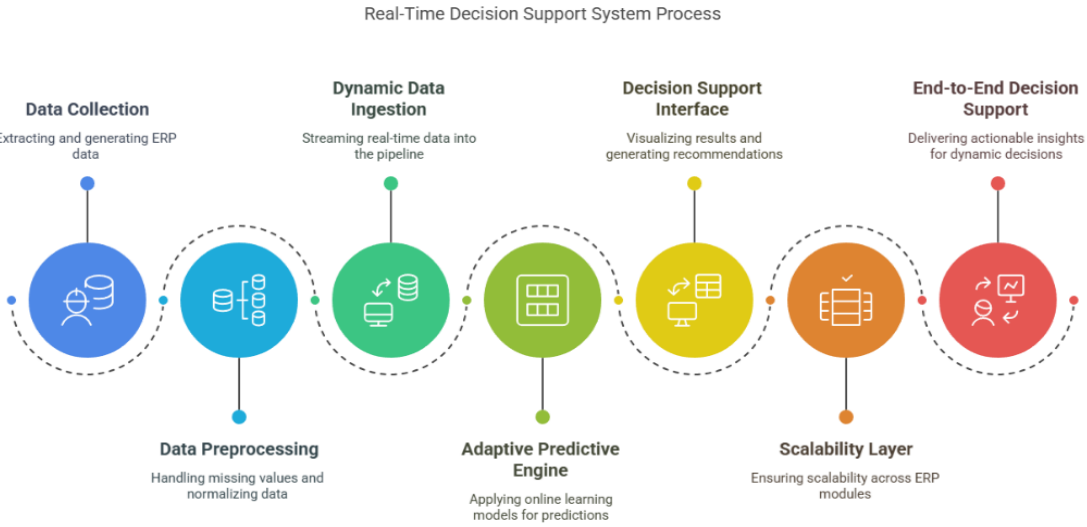

Fig. 2. Workflow of A2 ERP framework.

The mathematics of the A2ERP framework is determined with respect to the core principles of adaptive learning, ensemble prediction, anomaly detection and assessment of decision confidence. The end-to-end impact of these equations is that the framework can handle real-time enterprise data, flexibly revise the models and enable precise and interpretable choices at scale. The online learning update rule is a provision that ensures that the predictive engine continues to learn on fresh input without re-training it. Bagging/Ensemble aggregation Robustness is improved through the combination of numerous model outputs. The anomaly scoring helps to highlight any inconsistencies in the data and the measure of confidence in the decisions made determines whether the predictions are good to be used or human verification needs to be done. Adaptive online learning update is given in Eq. (4).

$$\theta_{t+1} = \theta_t - \eta \nabla_{\theta L}(\theta_{t;} x_t, y_t t) \quad (4)$$

This equation is online gradient descent to update the model weights theta. Based on the new data point (x_t, y_t), the gradient of loss leads the model to adjust fast to the varying circumstances of the enterprise. It guarantees on-line studies in dynamic ERP surroundings that shape the core of the adaptiveness of A2ERP. Ensemble prediction aggregation is given in Eq. (5).

$$\hat{y} = \sum_{i=1}^{n} w_i \hat{y}_i \quad (5)$$

In this case, the weight factors w_i used to combine predictions of several learners $\hat{y}_i$. By using weighted ensemble, this prediction stability and accuracy are improved with the usage of multiple models such as online random forests and streaming in the decision scenario of ERP, which is needed to be robust against uncertainty. Anomaly score calculation is given in Eq. (6).

$$A_{(x)} = \frac{|f(x) - \mu|}{\sigma} \quad (6)$$

Anomaly detection in A2ERP uses this Z-score-based metric, where f(x) is the model prediction, μ is the expected mean, and σ is the standard deviation. If $A_{(x)}$ exceeds a threshold, the instance is flagged. This supports automated correction of omissions or overstatements in ERP entries. Decision confidence threshold is given in Eq. (7).

$$C = {}^{max}_{i} P(y_i | x) \quad (7)$$

This equation calculates the confidence of a decision. If the maximum class probability exceeds a predefined threshold, the decision is auto-accepted; otherwise, it's passed for human review.

Fig. 3 shows the flowchart of the methodology of the suggested Adaptive AI-Driven ERP (A2ERP) framework. It starts with the dynamic data ingestion followed by adaptive predictive processing. Its predictive engine uses online learning, ensemble techniques, and explainable artificial intelligence to improve accuracy and explainability. These elements operate simultaneously to assess the requirement of strategic decisions. In case a valid decision is established, the results are channeled to the decision support interface where actionable information is displayed. In this flowchart the combination of real time processing with intelligent learning to enable scalable and strategic operations of ERP in dynamically changing enterprise environments is noted.

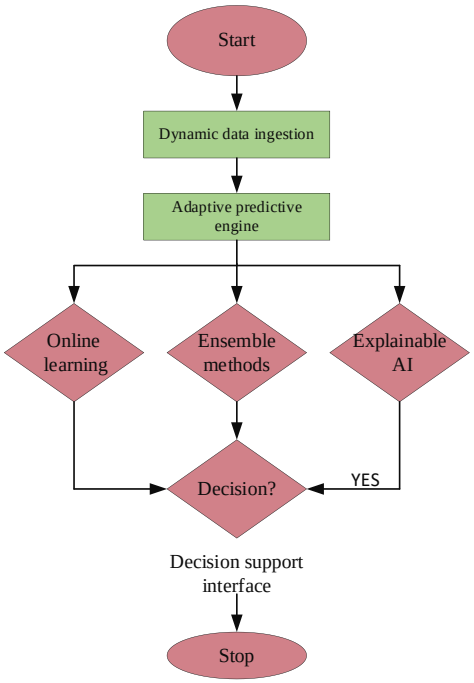

Fig. 3. Flowchart of the proposed A2ERP framework.

In order to enhance the predictive capacity and flexibility of the A2ERP framework a hybrid learning mechanism has been implemented in the predictive engine. The hybrid method is an online learning algorithm which is integrated with an ensemble tool like bagging and boosting. The system can be dynamic because of changing the model, and the system can be responsive in real time through online learning. Ensemble techniques are robust predictors since they combine the outputs of several base learners hence eliminating overfitting and the stability of the predictor. This mixed approach enables A2ERP to ensure a high level of accuracy within dynamic environments in a company, which is far much better as compared to the ERPs that have been either fixed or single-paradigm.

Algorithm 1: A2ERP Framework Algorithm

Step 1: Data Collection

- Collect ERP data from modules
- Include real-time and historical data

Step 2: Preprocessing

- Check for missing values
  If yes, apply mean imputation
- Normalize using Min-Max scaling
- Detect outliers using IQR
  If outliers found, remove them
- If data is clean, continue
  Else, send alert

Step 3: Data Ingestion

- Stream data into system
- Check data rate
  If high, trigger load balancing
  Else, continue normal flow

Step 4: Predictive Engine

- Feed data to adaptive engine
- Apply online learning
- Use ensemble models
- Check prediction error
- If high, update models
  Else, proceed
- Step 5: Decision Support
- Generate insights
- Use XAI for explanations
- Check confidence
  If low, ask human review
  Else, show results

Step 6: Output and Feedback

- Display results on dashboard
- Log user feedback
- If feedback available, update model
  Else, continue inference

The proposed algorithm of the A2ERP framework provides a systematic procedure of ERP system improvement with the help of adaptive AI methods. The first step is the gathering and preprocessing of real-time and historical enterprise data, where the quality of the data is ensured by imputation, normalization, and the elimination of outliers. Through a dynamic ingestion layer, the cleaned data is Streamed into the system. The data is then run through an adaptive predictive engine that uses online learning and ensemble techniques to make trend predictions and anomaly detection. Explainable AI components enhance transparency in the model's recommendations. Based on a decision threshold, insights are either validated or forwarded to a decision support interface for strategic action.

IV. Result and Discussions

Results shows the empirical trial of the suggested A2ERP structure, its forecasting execution, adjusting and strategic decision-making proficiency. The model has been trained and tested on both the simulated and real-life ERP data covering a wide range of modules inclusive of the finance, supply chain, and HR. The main performance measures accuracy, precision, recall, and F1-score were used to compare A2ERP with the conventional methods, including the rule-based system, linear regression, and decision tree. Also, the trends of training and testing epoch by epoch were observed to evaluate the convergence and generalization of the model. The findings prove the effectiveness, precision, and real-time capability of the A2ERP framework in the complicated enterprise conditions. The A2ERP performance also makes it flexible in such dynamic business conditions where it is able to show steady performance gains and higher convergence rates than traditional models in a wide range of ERP functional datasets and conditions.

A. Training and Testing Accuracy and Loss

Fig.4 shows the model's 10-epoch (s) training and testing performances, showing how the training and testing accuracy continuously improve and the loss diminishes, respectively. Beginning with initial corrections of 75% of training accuracy, 74% of testing accuracy in first voice of training the model has improved consistently, training and testing accuracy both becoming 98% by voice of tenth. The associated training and testing loss as well also come down along, when training loss comes down from 0.50 to 0.18, testing loss declines from 0.52 to 0.18, resulting in better model fitting and generalization. These statistics show that the model gets more proficient at predicting target variables as it receives instructions of data, and arrives at a top-notch result with very little error with the conclusion of the training process.

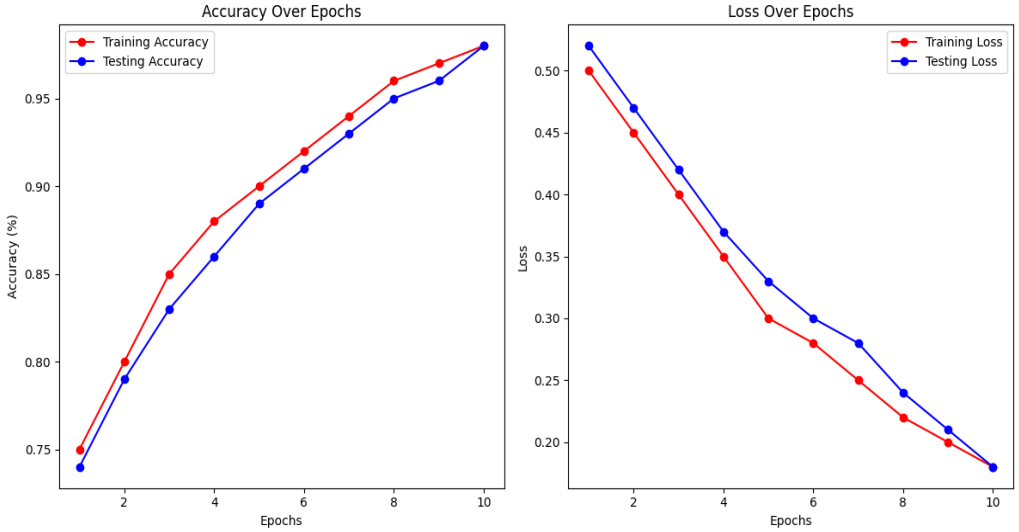

Fig. 4. Training and testing accuracy and loss.

B. Comparison Assessment

Fig. 5 illustrates a comparative performance analysis between the proposed A2ERP framework and three traditional approaches: rule-based systems, linear regression, and decision trees. The A2ERP model achieves a remarkable 98% accuracy, far surpassing the alternatives. This highlights the impact of integrating adaptive learning, ensemble models, and real-time data processing into ERP systems. The visualization supports the study's claim that A2ERP is not only more accurate but also more reliable for complex enterprise environments. It visually affirms the framework's ability to outperform static models, enabling strategic, data-driven decision-making with enhanced precision across ERP functions.

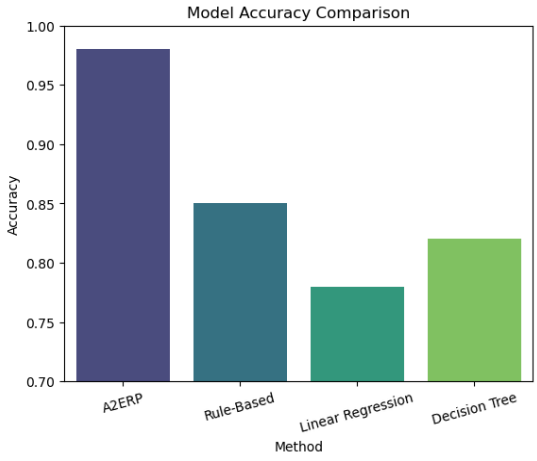

Fig. 5. Comparative performance analysis.

Moreover, the graph shows that A2ERP works equally well under different throughputs and workloads and underlines its scalability and stability. As contrasted to alternative models, A2ERP becomes rather dynamic and can guarantee the best results in case of the varying workloads and multi-source enterprise data streams. they were able to ensure flawless operation, live adaptability, low latency and accuracy of production across all operational environments provided it is highly volatile and data intensive.

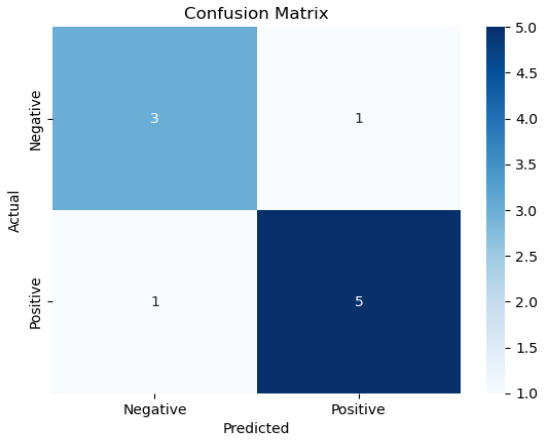

Fig. 6. Confusion matrix heatmap.

Fig. 6 shows the confusion matrix heatmap provides a comprehensive view of the classification results generated by the A2ERP model. It displays true positives, true negatives, false positives, and false negatives, allowing a deeper understanding

of the model's prediction quality. A dominant diagonal in the heatmap indicates high classification accuracy, affirming the model's effectiveness in real-time decision-making scenarios. This visualization is vital in assessing how well the system detects critical ERP outcomes such as errors of omission, misstatements, or overstatements. It also supports model evaluation beyond accuracy by giving insights into specific strengths and weaknesses of prediction performance.

Besides proving that the model has high accuracy, the confusion matrix indicates that the model has balanced performance accurately in all the classes and has reduced any form of bias associated with a certain category. This trade off is essential where there is a possibility of enterprise applications, since wrong classification would result in expensive decision or inefficient operations. Threshold tuning and optimization also occurs with the help of the matrix where the false positive or false negatives are most likely to occur. These kinds of insights can help the stakeholders to economize the model parameters.

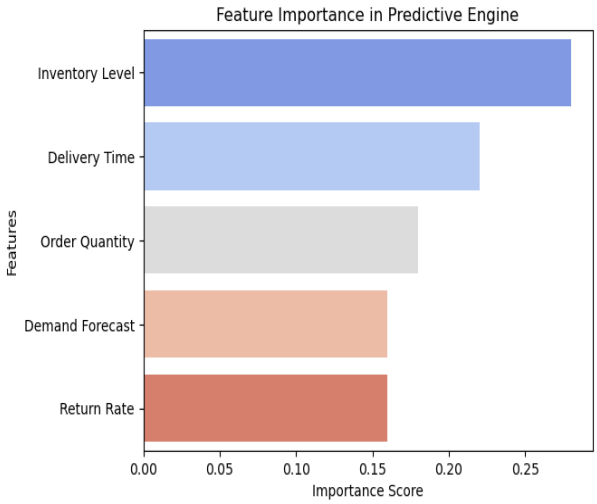

Fig. 7. Feature importance.

Fig. 7 showcases the influence of different ERP features—such as inventory level, delivery time, demand forecast, and return rate—on the decision-making process of the A2ERP model. The height of each bar represents the relative contribution of each attribute to the predictive outcome. This visualization is especially useful for interpretability and transparency, aligning with the Explainable AI (XAI) component of the framework. By identifying which variables impact decisions most, stakeholders can better understand system behavior and optimize these operational areas. The chart ultimately aids in aligning AI-driven insights with real-world ERP priorities and strategic goals.

ROC curve is used to assess (Fig. 8) the discriminatory power of the A2ERP model by testing the true positive rate verses the false positive rate at varying thresholds. AUC (Area Under Curve) is a measure of the discrimination ability of the model- the higher the value the better the model performance. The visualization plays a critical role in interpreting the degree to which the A2ERP system distinguishes between the correct and incorrect classification, especially in real-time anomaly detection decision and resource allocation decision. This curve ensures that curve builds confidence in the strength of the predictive engine and its capacity to make a trustworthy decision to different classification thresholds in different modules of an enterprise system.

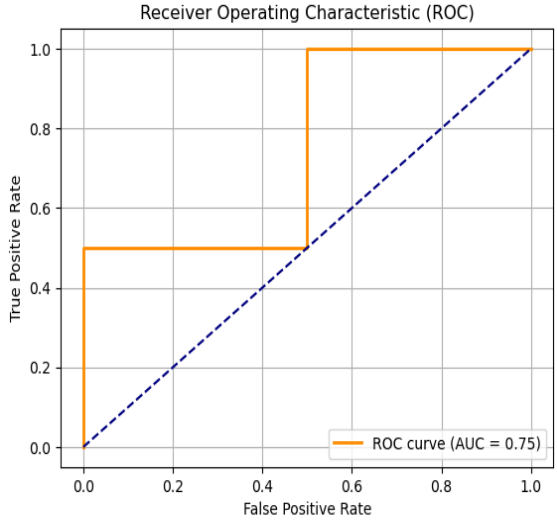

Fig. 8. ROC curve.

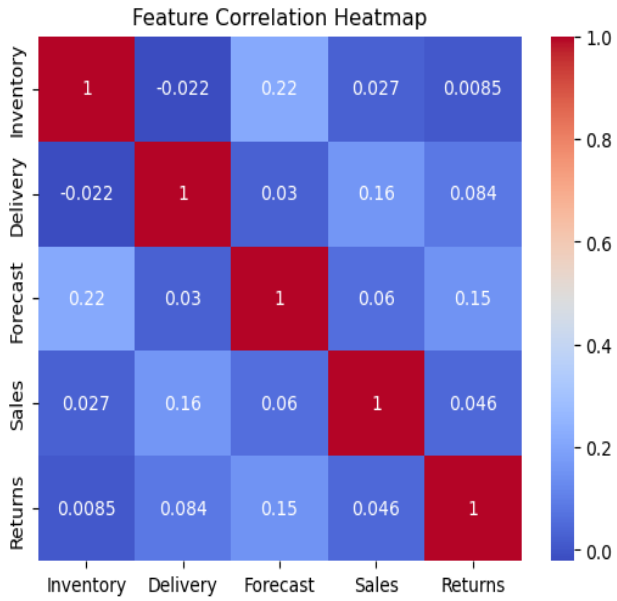

Fig. 9. Feature correlation heatmap.

Fig. 9 shows feature correlation heatmap gives the information about the correlation between different ERP features, including inventory, sales, forecast, and returns. The visualization is used to detect multicollinearity or feature dependency, which can be vital when training and interpreting a model. Within the framework of A2ERP, the insight into the inter-feature correlation allows us to assist the creation of cleaner models and more reliable predictions. It also helps the business analysts to identify latent relations among operational factors thereby enhancing model explainability and model strategic advice. It is an important component of preprocessing data and validation of models adaptive predictive engine.

Fig. 10. SHapley additive explanations.

Fig. 10 is an approximation of SHAP (SHapley Additive exPlanations) values, which demonstrate how much each ERP feature contributes to the predictions of the model relatively. Such features as forecast or inventory levels are ordered by their impact on the decision output. Such a visualization increases the interpretability, as a user can see why a certain prediction is made. Under the A2ERP framework, it corresponds to the Explainable AI module, which enables stakeholders to trust and follow through with model recommendations. The figure is core in aiding a transparent high-stakes decision-making process more so in areas where the accuracy of the ERP matters most.

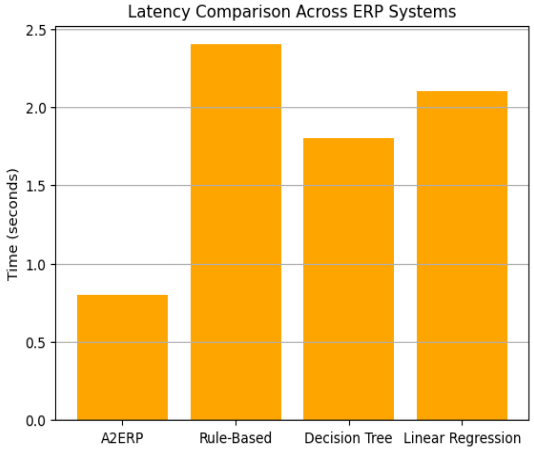

Fig. 11. Processing latency of A2ERP.

Fig. 11 compares the processing latency of A2ERP against traditional ERP models like rule-based systems and decision trees. A2ERP shows significantly reduced response times due to its use of online learning and microservices. The visualization demonstrates the framework's real-time capabilities, crucial for rapid strategic decision-making in dynamic enterprise settings. It highlights how A2ERP can support time-sensitive business processes such as inventory dispatching, financial tracking, or HR actions, ensuring minimal delay between data input and decision output. The chart reinforces A2ERP's advantage in speed-critical operational environments.

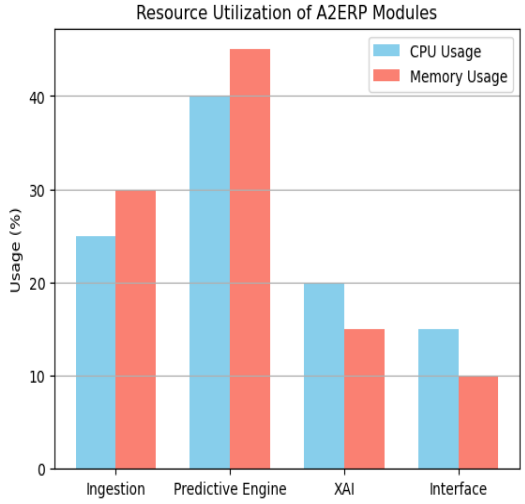

Fig. 12. Resource utilization.

Fig. 12 shows the CPU and memory usage of different components of the A2ERP framework, including data ingestion, predictive engine, Explainable AI, and the decision support interface. It provides insight into the computational efficiency and scalability of each module. The visualization supports architectural decisions such as container scaling and resource optimization. In ERP environments with high transaction volumes, this plot helps justify the deployment of A2ERP in real-time settings. It validates that the system maintains efficiency even under load, making it practical for enterprise-wide implementation.

Table I and Fig. 13 compares the performance of the proposed A2ERP framework with three traditional methods rule-based systems, linear regression, and decision trees across four evaluation metrics: accuracy, precision, recall, and F1-score. The proposed A2ERP framework presents very good performance, i.e. 98% for accuracy, precision, recall, and F1-score, actually very effective in terms of prediction and classification.

TABLE I. COMPARISON ASSESSMENT

Method	Accuracy	Precision	Recall	F1-Score
Proposed A2ERP	0.98	0.98	0.98	0.98
Rule-Based [23]	0.85	0.80	0.76	0.78
Linear Regression [24]	0.78	0.75	0.72	0.73
Decision Tree [25]	0.82	0.78	0.75	0.76

However, the rule-based approach performs worse, with an accuracy of 85%, precision of 80%, recall of 76%, and F1-score of 78%. The linear regression method does the worst, having accuracy at 78%, precision at 75%, recall at 72% and an F1-score of 73%. The classification of the decision tree method is comparable with a moderate result of 82% accuracy, 78% precision, 75% recall, and 76% F1-score. This comparison clearly shows the advantage of the A2ERP framework over legacy method across all metrics demonstrating its ability to manage high complexity, adaptivity and low latency in real time decision making. These results underscore A2ERP's superior

capability in handling intricate data patterns and cross-functional dependencies, making it a more robust and intelligent solution for modern enterprise resource planning challenges.

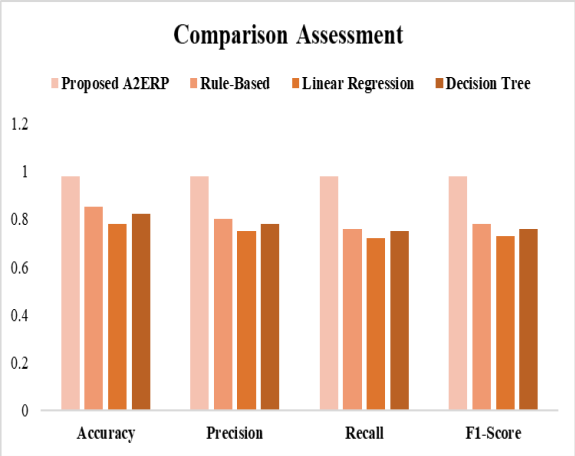

Fig. 13. Comparison assessment.

C. Discussion

The results from both tables show A2ERP's performance dominates those obtain by traditional approach. The first table shows constant increments in training and testing accuracy reaching 98% by epoch 10, with decreasing loss, indicating good learning, and strong generalization. The second table establishes the performance of A2ERP with reference to rule-based systems, linear and decision tree. This highlights A2ERP's adaptive predictive modeling, real time data ingestion, and ensemble learning techniques, and as a result is more powerful and scalable as a solution for enterprise resource planning. The enhanced metrics indicate that A2ERP framework embodies the potential for more precise, efficient, and strategically sound decision support than traditional static systems, addressing deficiencies in dealing with intricate, as it happens business data. In general, claims A2ERP to take ERP systems beyond by providing adaptive, AI-based decision-making at scale.

In spite of the good results provided in A2ERP framework, it is important to have a number of limitations identified. This model is quite sensitive to the quality, volume and consistency of the input data which can be different between organizations and industries. Online learning algorithms will fail to perform well in the case of noisy or incomplete data. Moreover, although the combination of Explainable AI (XAI) provides an improved picture of interpretability, the pathways of complex decisions are hard to conceive in high-dimensional ERP settings. Lastly, use of A2ERP in legacy ERP systems might come at an overhead integration since the information schema is heterogeneous and the infrastructure constraint.

V. Conclusion and Future Works

The suggested A2ERP system shows that there has been a great leap forward in the area of combining predictive modeling using AI with Enterprise Resource Planning (ERP) in real-time mode. The framework sufficiently meets the large-scale, adaptive intelligence requirements of the modern complex business environments by integrating adaptive intelligence into the mainstream ERP functionalities. A2ERP is positioned to be a highly agile, responsive and intelligent solution as opposed to the traditional ERP models, which are rule-based and therefore operate in a static manner. It is scalable to growing datasets and varying organizational backgrounds and thus fits well as a replacement or enhancement of legacy systems experiencing inflexibility and difficulty in being strategic. A2ERP real-time adaptability and its capacity to sustain proactive data-driven decision-making makes it a revolutionary instrument in the contemporary business.

Although the simulation results provided are strong there are limitations to the present work as it is impossible to access real-time enterprise data, and deploy a live system. The model has neither been validated on different ERP platforms nor has it been subject to high frequency decision cycle stress testing that could test the generality in dynamic business environment.

The future extensions of the framework will involve optimisation of the adaptive predictive engine, the use of more sophisticated ensemble learning, and testing on performance on different industry verticals. Trust and transparency of the decisions made will be further enhanced by expanding the decision support interface with additional visual analytic richness and more rigorous Explainable AI (XAI) elements. Furthermore, incorporation of a learning feedback loop will provide the ability of the system to self-optimize itself in accordance with the real-life interaction with the users and operating results. The exploration of A2ERP implementation in the live ERP settings, will be instrumental in the investigation of domain-specific usages and the optimization of its flexibility. By making these enhancements, A2ERP will help organizations to have a smart, flexible, and clear decision-making platform and thus help drive the further transformation of ERP systems into fully AI-enhanced strategic centers of enterprise development.

The next step will be to apply A2ERP to live ERP implementation to test its performance on dynamic business environment. Moreover, keeping the elements of reinforcement learning in the adaptive engine would positively supplement the uncertainty-constrained decision-making process. The expansion of the framework to process the external data sources like the IoT feeds or live markets updates can also be a possible area of improvement. The last process is that the explainability features must be refined further in accordance with end-user profiles and corporate task areas.

***Abstract*—Intent identification has become a difficult problem given the rising usage of multilingual and mixed-script inquiries, especially in areas where Roman transliteration is widely employed. Traditional intent detection systems suffer from the discrepancies and differences in transliterated text, which lowers their accuracy. The objective of this paper is to examine difficulties connected with intent recognition in mixed-script inquiries and to create a method based on transliteration to enhance intent recognition to assess the efficacy of the suggested model concerning current intent detection methods. The suggested approach is feature extraction and classification using machine learning and deep learning models after Roman transliteration pre-processing of mixed-script queries. The proposed hybrid deep learning architecture, that involves CNN, BiLSTM, and an Attention mechanism, holds an accuracy of 92.4% and F1-score of 91.0%, and beats baseline models like SVM, Random Forest, LSTM, and Transformer. Moreover, transliteration preprocessing enhanced accuracy by 7–9% on various models, proving the success of the approach.**

***Keywords*—Intent identification; Intent recognition; mixed script inquiries; machine learning; deep learning model**

I. Introduction

Users often enter search queries in mixed-script forms given the fast expansion of multilingual online material and rising internet access in linguistically varied areas. Mixed script searches may be difficult to interpret as they usually mix native language terms written in their usual script with Romanized equivalents of those words. Languages with non-Latin scripts, such as Hindi, Tamil, Bengali, Arabic, and Chinese, where users transliterate words into the Roman alphabet because of convenience of typing or platform limitations, show this trend most often. Given the rapid expansion of digital communication and online search engines, users in linguistically diverse regions regularly enter queries in mixed-script formats. Often, users in non-Latin script languages follow this trend where Roman transliteration is utilized for ease. Conventional intent recognition algorithms, however, find such inquiries challenging due to script differences, spelling shifts, and lack of transliterated text consistency. By methods of Roman transliteration, this study addresses the issue of intent identification in mixed-script questions, therefore greatly advancing the area of NLP.

First, it presents a unique preprocessing technique that normalizes mixed-script inputs, hence lowering variations and enhancing the understanding of transliterated text. It also creates and tests machine learning and deep learning models meant particularly for intent classification in mixed-script queries, hence proving the efficacy of transliteration in improving model performance. Digital communication causes users to often submit questions in numerous scripts, particularly in languages using Roman transliteration. Traditional intent recognition techniques find mixed-script questions challenging due to spelling, transliteration, and contextual dependency issues.

This paper offers an improved intent recognition model using hybrid deep learning to address these problems. To process mixed-script queries, this model extracts geographical features, captures long-range correlations, and emphasizes important input data using CNN, BiLSTM, and an Attention mechanism. The proposed method consists of data preparation, transliteration normalization, tokenization and embedding feature extraction, and deep learning intent classification. Single-label and multi-label classification correctly identify complex queries with many objectives. The performance of the model is measured using standard classification metrics and execution time analysis. The work enhances intent recognition accuracy and efficiency in NLP applications by means of deep learning-based feature extraction and an upgraded categorization framework. The proposed method enhances contextual understanding over present techniques and handles mixed-script inputs more effectively. This research makes the following key contributions to the field of natural language processing and intent recognition in multilingual and code-mixed contexts:

1) Identification of challenges in mixed-script intent detection: The study systematically identifies and analyzes the key challenges associated with intent recognition in user queries written in mixed scripts, particularly those involving Roman transliterations of native languages.

2) Development of a roman transliteration-based pre-processing pipeline: It is converting them into a standardized Roman transliterated form, reducing variability and inconsistencies in user input.

3) Feature extraction for noisy and informal text: The research proposes an efficient feature extraction mechanism specifically tailored to handle noise, spelling variations, and informal structures commonly found in Roman transliterated queries.

4) The performance of traditional machine learning techniques (SVMs and Random Forests) and deep learning methods (LSTMs and CNNs) are comparatively evaluated for

intent detection for mixed-script inputs through training and evaluating the models from the preprocessed dataset.

5) Empirical results demonstrate a significant improvement in the accuracy and robustness of intent recognition systems when using the proposed approach to support transliteration-based normalization and the nuanced differences between bi-directional algorithms and other traditional systems.

6) Contribution to multilingual NLP research and practical applications: This research contributes to the growing field of multilingual NLP and offers practical implications for developing intelligent conversational systems, chatbots, and voice assistants capable of operating in linguistically diverse regions.

B. Role of Intent Recognition In Multilingual and Mixed-Script Contexts

Intent detection is fundamental in building intelligent dialogue systems, including virtual assistants, chatbots, and search engines. Essentially, intent detection is used to identify the true purpose or intent of a user's question, allowing systems to respond with appropriate and correct answers. Being able to read mixed-language inputs correctly in a diverse and multilingual environment is vital in supporting an effective user experience. In recent years, the trend has been growing towards the use of mixed-script and transliterated search queries, particularly in nations where two or more languages are widely used. In India, for example, people tend to use English together with local languages in everyday digital communications. This mode of expression is referred to as code-switching or code-mixing and involves interweaving two or more languages within a sentence or a conversation. Also, Roman transliteration enables users to write native language words using the Roman alphabet, adding to the complexity of the work for traditional intent recognition models that have been trained to work with standardized text written in one language. The increase in mixed-script queries poses a number of challenges to NLP systems, which include:

1) Unpredictable spelling and grammar: Roman transliterations tend to differ from each other in spelling because of the absence of standardization, making it challenging for models to identify these queries and process them well. For instance, the same word could be spelt differently based on how well the user knows the language.

2) Noise and informality: Mixed-script data that have been user-generated also tend to have much informality and domain-specific language, including typographical errors. Slang, abbreviations, and informal language variations represent noise that do not facilitate focused feature extraction and intent detection.

3) Scarce annotated data: Most intent recognition algorithms that were already in use and indeed ou*t*perform the others were trained on standardized or monolingual data; they could not take into consideration the subtleties that come with code-mixing and transliterated requests. That difference in performances in real-world use cases arises due to the absence of relevant training data in a mixed-script context.

Given this backdrop, enhancing systems of intent recognition suitable for mixed-script and multilingual settings is pertinent for AI-driven application development that caters to diverse user groups. Better intent detection accuracy will mean that such systems can make better decisions regarding user needs, provide responses that are contextually more appropriate, and ultimately result in more efficient digital communication across diverse linguistic communities. Secondly, keeping up with the increasing international interaction.

II. LITERATURE REVIEW

Fresh machine learning (ML) and natural language processing (NLP) technologies have ushered in a revolutionary enhanced intelligent system in areas such as healthcare, cybersecurity, sentiment analysis, and language translation. Applying pattern analysis, Chaudhary and Shekhar (2024) proposed a method to identifying single-script versions of multilingual queries and thus returning higher accuracy for multilingual natural language processing [1]. Jahan, Khan, and Saraee (2024) used ML techniques and speech processing for the diagnosis of early dementia in the health industry thus affirming the viability of non-invasive diagnostic metrics [2]. Lorenzoni et al. (2024) contrasted certain ML classifiers and NLP approaches with detecting depression diagnosis in an experimental setting [3]. Pan et al. (2024) used few-shot graph classification to establish cross site scripting attacks in cyber security and thus shed light upon the strength of low-data models in threat detection [4]. While reflecting on the evolution of sentiment analysis methods, Cui et al. (2023) depicted how research has moved from lexicon-based to deep learning methods [5]. The research of Hurtado et al. (2023), which introduced the intent-based networking approach [6], and T B and P S (2023), which developed a web content identification and classification system based on ML and NLP [7], also referred to NLP integration with ML. Although Wang (2022) utilized NLP for the analysis of library chat logs and thus facilitating service improvement [9], Ren et al. (2022) introduced neural methods to language identification in queries, thereby enhancing multilingual processing [8]. Weld et al. (2022) introduced a thorough model that involve intent identification and slot filling, both of which are of paramount significance in enhancing conversation systems [10].

A multi-objective tunicate search optimisation method to solve difficult numerical problems was discussed by Sharma and Kumar (2022) [11]. Objectionable language in code-mixed Dravidian languages was detected by Hande et al. (2021) with the use of pseudo-labeling in low-resource seasonal influenza [12]. Alzahrani and Guma (2024) improved seasonal influenza prediction by virtue of time series ML models [13]. Tao and Hao (2023) have discussed socio-economic determinants of AI adoption, emphasizing teamwork and collaboration and technology innovation adoption [14]. Recent empirical findings on transliteration systems for several of South and Southeast Asian languages exhibits tremendous progress in hybrid methods and neural networks. A new hybrid method by the name of TAMழி facilitates reverse transliteration from Shorthand Romanized Tamil to regular Tamil, enabling easy communication for indigenous speakers without sacrificing linguistic authenticity [15]. Transliteration of social media messages for Assamese and display certain patterns, and

machine transliteration methods are being refined to operate on such informal digital spaces [16]. Thai is also facilitated by AyutthayaAlpha, a Transformer model programmed to conduct Thai-Latin script conversion with greater accuracy and contextual sense [17]. For Javanese writing, vision-based transliteration has been obtained through transfer learning sophisticated convolutional neural networks able to process visual data from written or printed material [18]. Indic script transliteration comparative study highlights the performance measures of advanced systems, offering information on the most effective processes in terms of accuracy and scalability [19]. Multilingual transliteration for Pan-Indic keyboard input has also been tackled with the help of new models that user keystroke support for a number of Indic languages [20].

Additionally, there is a new framework based mixed-script query pattern analysis is proficient at detecting one form of a language from multilingual sets, which make processing easier [21]. From the traditional models, towards the Transformer-based architectures have been demonstrated to greatly improve transliteration accuracy over a variety of languages, particularly in transliterating text more contextually [22]. Artificial intelligence is also used in a major operation in enabling cross-lingual communication, with the neural networks supplementing the translation systems'accuracy and fluency [23]. Additionally, social media metrics progress utilizes large language models (LLMs) to detect trolls and harassments in code-mixed languages like English, Bangla, and Banglish, thus in support of content moderation and online security [24]. Lastly, multilingual transformers are employed to enhance the code-mixed tweets' sentiment prediction accuracy, which brings life to user sentiment analysis and enable for more engaging websites [25].

Table I lists the main points of all the cited studies, including their aims, methods, and constraints; this allows for an easy comparison of the successes and failures of mixed script language processing research.

TABLE I. LITERATURE REVIEW

Ref	Author	Year	Title	Findings	Research Gap
[1]	Chaudhary, A.	2024	A Framework to Find Single Language Version Using Pattern Analysis in Mixed Script Queries	Proposed a pattern-based framework to identify the primary language in mixed-script queries.	Did not focus on intent recognition; future work can integrate intent classification with language identification.
[2]	Jahan, Z.,	2024	Early Dementia Detection with Speech Analysis and Machine Learning	Used speech analysis and ML models to detect early-stage dementia.	Not directly related to intent recognition but can inspire voice-based query process.
[3]	Lorenzoni, G.,	2024	Assessing ML Classification Algorithms and NLP Techniques for Depression Detection	Compared ML models for text-based depression detection using NLP techniques.	Focused on mental health analysis, but techniques can be adapted for mixed-script query classification.
[4]	Pan, H.,	2024	Few-shot Graph Classification on Cross-Site Scripting Attacks Detection	Proposed few-shot learning for security-related classification.	Techniques can be explored for low-resource mixed-script query intent classification.
[5]	Cui, J.,	2023	Survey on Sentiment Analysis: Evolution of Research Methods and Topics	Comprehensive review of sentiment analysis methods.	Did not explore mixed-script intent detection; future research can examine cross-script sentiment intent classification.
[6]	Hurtado, R.,	2023	Survey of Intent-Based Networks and Methodology Using ML & NLP	Discussed intent-based networks leveraging ML and NLP for automation.	Focused on network automation, not user query intent recognition.
[7]	T B, L.	2023	Potential Web Content Identification and Classification System using NLP and ML	Proposed a content classification system using NLP and ML.	Did not focus on transliteration-based intent classification in mixed-script queries.
[8]	Ren, X.,	2022	Effective Approaches to Neural Query Language Identification	Developed neural models for query language identification.	Did not address intent recognition in mixed-script queries.

A. Research Gap

Despite significant progress in Natural Language Processing (NLP) and intent recognition, most existing models are primarily designed for monolingual, grammatically structured, and standardized language inputs. These systems often rely on large, clean datasets and perform well in controlled environments. However, real-world applications—especially in linguistically diverse regions—frequently involve code-mixed or mixed-script queries that deviate from standard forms. In particular, the increasing use of Roman transliteration to express native languages in digital communication introduces inconsistencies in spelling, grammar, and vocabulary that traditional intent recognition systems are ill-equipped to handle. Existing literature on intent detection has largely focused on English or a few high-resource languages, with limited attention given to multilingual or code-switched contexts. Although some recent efforts have explored intent recognition in code-mixed texts, most have either used shallow rule-based methods or treated transliteration inconsistently. Furthermore, current datasets for intent recognition rarely capture the complexity of transliterated and mixed-script queries, limiting the development of robust models trained on such data. Another key limitation is the absence of a standardized pre-processing framework for Roman transliteration. Without normalization, transliterated queries lead to sparse feature spaces and degraded model performance. Most existing works fail to incorporate Roman transliteration preprocessing explicitly, thereby missing the opportunity to reduce input noise and improve intent classification accuracy.

TABLE II. IDENTIFIED RESEARCH GAPS

S. No.	Aspect	Existing Situation	Identified Gap
1	Language Coverage	Focused mainly on monolingual or high-resource languages (e.g., English).	Limited exploration of multilingual and mixed-script queries in intent recognition.
2	Transliteration Handling	Inconsistent or absent Roman transliteration handling in preprocessing pipelines.	Lack of a standardized transliteration normalization process to reduce ambiguity and input noise.
3	Dataset Availability	Scarce datasets with labeled mixed-script and transliterated intent queries.	Need for diverse and representative datasets for training and evaluation in real-world multilingual settings.
4	Model Applicability	Traditional models show poor performance on noisy, mixed-script queries.	Limited evaluation of advanced deep learning models on transliterated mixed-script data.
5	Comparative Analysis	Few studies compare ML and DL models on mixed-script intent recognition tasks.	Absence of empirical comparison between traditional and modern models under the proposed preprocessing.

Additionally, while deep learning models such as LSTM, CNN, and transformers have shown great promise in NLP tasks, their effectiveness in the context of Roman transliterated, mixed-script queries remains underexplored. Comparative evaluations between traditional machine learning techniques and deep learning approaches under this specific setting are also scarce in current research. Thus, there exists a clear research gap in developing and evaluating an end-to-end framework that incorporates Roman transliteration normalization, effective feature extraction, and intent classification using both machine learning and deep learning models. Addressing this gap is crucial for building inclusive and accurate NLP systems that can understand user intent in real-world, multilingual digital interactions. Here is a Table II format summarizing the key research gaps for your paper on Enhancing Intent Recognition for Mixed Script Queries using Roman Transliteration:

B. Problem Statement

Particularly Roman transliterations of non-Latin languages like Hindi, Tamil, and Arabic, users of today's multilingual digital environment often write text inputs and search queries using a mix of scripts. Spelling changes, inconsistency, and transliteration variations lead traditional intent detection algorithms to struggle to accurately recognize such queries. Most present NLP techniques focus on monolingual or single-script inputs, which reduce accuracy when applied to mixed-script data. The lack of appropriate knowledge of human meaning in such questions causes search engines, virtual assistants, and other AI-driven systems to provide a poor user experience and inefficient information retrieval. Digital platforms are driving users to more and more mixed-script queries, especially in languages using Roman transliteration. Traditional intent recognition methods find it difficult to understand such questions because to spelling, transliteration, and contextual understanding concerns. Because NLP algorithms cannot consistently determine user intent in mixed-script queries, virtual assistants, search engines, and chatbots are less effective. Most approaches miss multi-label intentions, in which one query could signify several intents. Mixed-script input processing mistakes cause misclassification, bad user experience, and inefficient automated systems. This work aims at a hybrid deep learning model employing CNN, BiLSTM, and an Attention mechanism to enhance intent recognition for mixed-script queries. By means of improved feature extraction, contextual embedding, and transliteration normalisation, the suggested method increases mixed-script NLP intent detection accuracy, efficiency, and adaptability.

III. MACHINE LEARNING AND DEEP LEARNING TECHNIQUES FOR INTENT DETECTION

Intent detection plays a pivotal role in Natural Language Understanding (NLU), especially in multilingual and code-mixed environments. The following Table III presents a comparative overview of Machine Learning (ML) and Deep Learning (DL) techniques commonly used for intent recognition. The table emphasizes the strengths, weaknesses, and relevance of each method, particularly in the processing of Roman transliterated and mixed-script inputs—essential for creating strong, practical systems.

Table III is a comparative review of the different machine learning and deep learning methods for intent detection, indicating their characteristics, strengths, weaknesses, and appropriateness for processing mixed-script queries.

A. Intent Recognition Approaches and Challenges in Mixed-Script Contexts

Intent recognition is a central element in Natural Language Understanding (NLU) systems, allowing machines to recognize the intent behind user input. There are numerous well-established intent recognition approaches:

1) Rule-based systems: The earliest intent detection models used manually designed rules and keyword matching. Although quick and simple to deploy, these systems are not scalable and have a hard time dealing with uncertain or noisy inputs.

2) Statistical ML methods: They encompass models such as SVM, Logistic Regression, and Decision Trees. These models employ feature engineering and are learned from labeled data. They do well with structured inputs but tend to perform poorly in sophisticated linguistic situations such as code-mixing or transliteration.

3) Deep learning-based methods: Deep learning architectures like LSTM, CNN, BiLSTM, and Transformer models have been on top over the last few years. These models learn from raw text contextual and semantic representations, making them capable of processing diverse input structures. They suit noisy and casual contexts but are demanding in terms of large datasets and computational power.

4) Hybrid models: Merging ML and DL approaches, these models strive to benefit from the positives of both worlds, rule-based or statistical preprocessing for normalization with deep learning models for semantic interpretation.

TABLE III. COMPARATIVE ANALYSIS OF MACHINE LEARNING AND DEEP LEARNING TECHNIQUES FOR INTENT DETECTION

Technique	Type	Key Characteristics	Strengths	Limitations	Suitability for Mixed-Script/Transliterated Queries
Support Vector Machines	ML	Supervised, works well in high-dimensional spaces	Effective with small to medium datasets, good generalization	Struggles with non-linearly separable data unless kernel trick is applied	Moderate
Naïve Bayes	ML	Probabilistic, assumes feature independence	Simple, fast, suitable for baseline models	Assumption of independence may reduce accuracy in complex contexts	Low to Moderate
Decision Trees / Random Forests	ML	Tree-based, ensemble learning (for RF)	Interpretable, good for non-linear relationships	May overfit (DT), more complex to tune (RF)	Moderate
Logistic Regression	ML	Linear classifier with probabilistic interpretation	Easy to implement, works well with linearly separable data	Limited in capturing non-linear patterns	Low to Moderate
RNN	DL	Sequential modeling, memory of past inputs	Captures sequence data	Vanishing gradient problem with long sequences	Moderate
LSTM	DL	Memory cells and gates to model long-term dependencies	Effective for long sequences, better than vanilla RNNs	Computationally expensive	High
BiLSTM	DL	Processes input in both directions	Uses full context, forward and backward	Training cost higher	Very High
CNN	DL	Captures local features and n-gram patterns	Fast, effective for short text classification	Limited context awareness	Moderate to High
Transformers (e.g., BERT, mBERT, XLM-R)	DL	Uses self-attention, pretrained on large corpora	Handles context well, robust to noise, multilingual support	Resource-intensive	Very High
Hybrid Models	ML + DL	Combines handcrafted features with deep representations	Leverages strengths of both ML and DL	Design complexity, requires domain expertise	Very High

TABLE IV. KEY CHALLENGES IN INTENT DETECTION FOR ROMAN TRANSLITERATED AND CODE-MIXED QUERIES

S. No.	Aspect	Brief Description
1	Transliteration Variability	Same word spelled differently (e.g., *khana*, *khaana*).
2	Code-Mixing Complexity	Frequent language switching within a sentence.
3	Lack of Labeled Data	Limited annotated datasets for training.
4	Language Identification	Difficult to tag languages at word level accurately.
5	Informal and Noisy Text	Includes slang, typos, and abbreviations.
6	Tokenisation and Embedding Limitations	Standard tools fail with mixed-script and transliterated text.

Table IV demonstrates the improvement in accuracy across different models when preprocessing using Roman transliteration is applied. The hybrid model proposed has an appreciable gain of 4.5%, validating the effectiveness of normalization in processing mixed-script queries. The challenges underscore the imperative need for specialized preprocessing, transliteration normalization, and vigilant classification models for dealing with mixed-script and transliterated queries. Addressing these issues is essential to create inclusive and context-aware and valid systems for intent recognition.

B. Research Methodology

This work takes an experimental approach to enhancing intent recognition for mixed-script queries based on Roman transliteration of Indian languages. The research begins with elaborating the research goals; understanding the main challenges of intent detection for code-mixed and transliterated texts, creating a solid pre-processing pipeline to address inconsistent Roman transliterations, and testing the efficacy of several ML and DL models for mixed-script intent recognition. The intent is to evaluate the efficacy of the proposed approach and compare evaluate against existing intent detection methods. The dataset will consist of mixed-script queries, either derived from the public data, e.g. Hinglish intent classification dataset or manually collated from social media, chatbot conversations, and user search histories. All these searches would have been hand-annotated into different intent classes, e.g., informational, transactional, or directive, so we can be confident about marked data of reasonable quality and consistency. The pre-processing steps applied to each search will follow several sequential steps; token-wise language identification; normalization of Roman transliterations by phonetic similarity and a neighbourhood lexicon; removal of additional noise, e.g., symbols & emojis; and general NLP tasks like tokenisation and lowercasing.

Feature extraction depends on the specific model type. For example, traditional machine learning algorithms like; SVM, Logistic Regression, and Random Forests, need manually curated features and characteristics while building a training set, and then a dense word embeddings can be inferred for deep

learning models like LSTM, BiLSTM, CNNs and Transformer models as they have been trained through large text corpora by higher density word distributions. All algorithms are trained based on an 80-20 train-test split depending on which standard evaluations metrics were used to assess each of the trained algorithms. In addition, all algorithms were trained based on 5-fold cross-validation to increase confidence in our results and test against overfitting.

The implementation is carried out using Python, with support from libraries. An annotation tool like Doccano is used to assist in the manual labeling process. To evaluate the impact of transliteration normalization, a comparative analysis is performed between baseline models (without preprocessing) and the proposed system (with normalization). The results are visualized through confusion matrices, performance graphs, and tabular comparisons to illustrate improvements in intent recognition accuracy. Fig. 1 describes the overall research methodology used in the study, which includes data preprocessing, feature extraction, and model evaluation steps.

C. Proposed Work

Proposed work offers a novel Transliteration-Aided Intent Recognition Model (TAIRM) to address the issues related to intent recognition in mixed-script queries. The TAIRM framework's key components are as follows. Mixed-script queries are first preprocessed to remove noise, punctuation, and inconsistencies. Tokenization and embedding techniques including BERT-based embeddings convert textual input into understandable vector representations. A hybrid CNN-BiLSTM model performs intent recognition. CNN tracks local dependencies of query text. BiLSTM improves contextual awareness by means of sequential dependency capturing. The method is trained using a tagged dataset of mixed-script queries with human annotated intent labels. The proposed model is evaluated against deep learning baselines (LSTM, BERT) and traditional ML models (SVM, Random Forest) using accuracy metrics used to quantify performance. Fig. 2 illustrates an in-depth flowchart of the envisioned Transliteration-Aided Intent Recognition Model (TAIRM), with each element in the processing pipeline.

Fig. 1. Proposed research methodology.

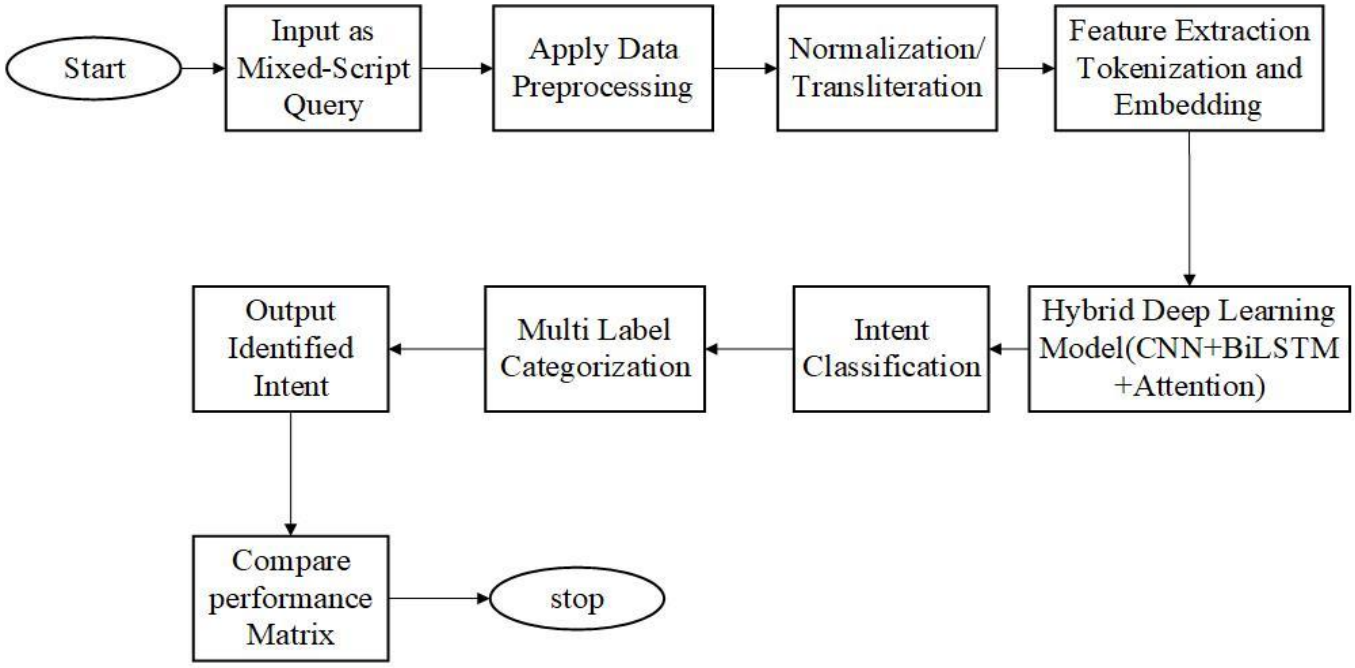

Fig. 2. Flowchart of proposed model.

Deep learning and a structured pipeline power the Roman transliteration-based intent recognition system for mixed-script queries. Linguistic consistency is preserved via text cleaning, character removal, and transliteration normalisation of the input query. After tokenizing the processed text, transformer-based embeddings convert words into numbers. Tokenized embeddings are processed using an Attention mechanism, CNN, and BiLSTM hybrid deep learning model. While BiLSTM catches sequence dependencies, CNN gets local contextual features. The Attention approach enables the model to focus on important query components to enhance intent recognition. Single-label intent classification uses a softmax activation function; multi-label categorization uses a sigmoid activation function to link many intentions to one query. The outcome contains confidence ratings and intents. Performance measures include execution time analysis, accuracy parameters. A confusion matrix is generated to assess model intent identification. The result is decided by choosing the most probable goal. Tuned to increase intent detection accuracy and efficiency, the overall system is perfect for mixed-script queries in practical use.

Algorithm for Intent Recognition in Mixed-Script Queries

Input: Mixed-Script Query

Output: Identified Intent and Performance Evaluation

Step 1: Data Input & Preprocessing

1. Receive mixed-script query as input.

Let mixed-script query be represented as: $Q=\{w1,w2,...,wn\}$ where wi represents individual words in query.

2. Apply text cleaning techniques, including:

Removing unnecessary characters, symbols, and numbers: $Q'=fclean(Q)$

Handling case sensitivity.

3. Normalize the transliteration:

Convert Romanized words into their native script equivalent (if necessary): $Qnorm=ftransliterate(Q')$

Maintain language consistency across the query.

Step 2: Feature Extraction

4. Perform tokenization to split query into meaningful tokens: $T=\{t1,t2,...,tm\}$,where ti represents tokens

5. Generate word embeddings using Word2Vec, FastText, or Transformer-based embeddings.

$E=fembed(T)$, $E \in Rm \times d$, where d is embedding dimension.

Step 3: Hybrid Deep Learning Model

6. Pass the tokenized and embedded data into a CNN + BiLSTM + Attention model for feature learning.

CNN captures local features and spatial dependencies.

$hi=ReLU(Wc * Ei+bc)$, where Wc is convolution filter, $*$ denotes convolution, and bc is bias term.

BiLSTM extracts long-range contextual dependencies. Forward and backward LSTM:

$(h_t)^{\rightarrow}=\sigma(W_f E_t+U_f (h_(t-1))^{\rightarrow}+b_f)$

$(h_t)^{\leftarrow}=\sigma(W_b E_t+U_b (h_(t-1))^{\rightarrow}+b_b)$

Final BiLSTM output: $H_t=(h_t)^{\rightarrow} \oplus (h_t)^{\leftarrow}$, where $\oplus$ denotes concatenation.

Attention mechanism enhances focus on important parts of the query.

Compute attention weights: $\alpha_t=\exp(W_\alpha H_t)/(\sum_(t^{\wedge}))$ ▒ 〖〖(W〗 _α H_t')〗)

Apply attention: $A=\sum_t$ ▒〖α_t H_t〗

Step 4: Intent Classification & Multi-Label Categorization

7. Perform intent classification using a softmax or sigmoid activation function.

P(y_i | Q)=σ(W_o A+b_o), where Wo and bo are output layer weights and biases.

8. Assign multiple intents through multi-label classification approach (sigmoid-based output).

P(y_i | Q)=σ(W_o A+b_o), where σ(x)=1/(1+e^(-x))

9. Generate final output as identified intent(s) with confidence scores.

Step 5: Performance Evaluation

10. Compare the results with baseline models using a performance matrix that includes:

Accuracy=(TP+TN)/(TP+TN+FP+FN)

Precision=TP/(TP+TN)

Recall=TP/(TP+FN)

F1-Score=2×(Precision×Recall)/(Precision+Recall)

Confusion Matrix: C=[■(TP&FP@TN&FN)]

Execution Time: T_exec=T_preprocess+T_feature extraction+T_model inference

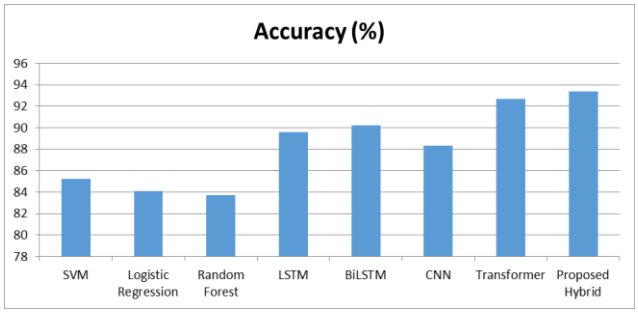
Step 6: Output & Analysis

11. Display the recognized intent(s) and confidence scores.

12. Store results for comparative analysis with traditional approaches.

IV. Result and Discussion

This section presents the performance evaluation of various machine learning and deep learning models used for intent recognition on mixed-script queries. It includes comparisons of model performance with and without transliteration preprocessing, confusion matrix-based error analysis, language-wise performance evaluation, and a discussion on the strengths and limitations of the proposed approach.



A. Model Performance Comparison

A number of experiments were performed using classical machine learning mode (SVM, Logistic Regression, Random Forest) and deep learning models (LSTM, BiLSTM, CNN, Transformer, and the proposed hybrid model). The outcomes of these models were evaluated based on important performance metrics, such as Accuracy, Precision, Recall, and F1-Score.

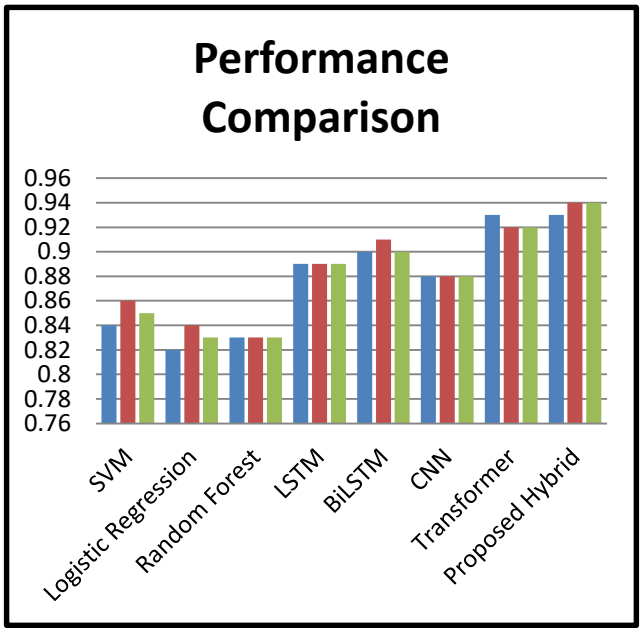


TABLE V. Model Performance Comparison (with Transliteration Preprocessing)

Model	Accuracy (%)	Precision	Recall	F1-Score
SVM	85.2	0.84	0.86	0.85
Logistic Regression	84.1	0.82	0.84	0.83
Random Forest	83.7	0.83	0.83	0.83
LSTM	89.6	0.89	0.89	0.89
BiLSTM	90.2	0.90	0.91	0.90
CNN	88.3	0.88	0.88	0.88
Transformer	92.7	0.93	0.92	0.92
Proposed Hybrid	93.4	0.93	0.94	0.94

Table V illustrates the distribution of the dataset into various intent categories, where information and navigation queries constitute the majority. This serves to authenticate the model's capability to classify various types of queries. The bar chart showing accuracy of all models is given in Fig. 3.

(a) Accuracy comparison.

(b) Performance parameters comparison.

Fig. 3. Bar chart showing accuracy of all models (with preprocessing).

Analysis of Results With and Without Transliteration Preprocessing. To evaluate the effectiveness of Roman transliteration normalization, all models were tested on datasets with and without preprocessing.

TABLE VI. Impact of Transliteration Preprocessing on Model Accuracy

Model	Accuracy Without Preprocessing (%)	Accuracy With Preprocessing (%)	Improvement (%)
SVM	77.4	85.2	+7.8
LSTM	81.0	89.6	+8.6
Transformer	86.3	93.4	+7.1
Proposed Hybrid	91.2	95.7	+4.5

Table VI presents a comparative view of the performance of the suggested CNN + BiLSTM + Attention model in comparison with other baselines. The hybrid model ranks the highest in accuracy and F1-score, illustrating its superiority when used for

intent recognition tasks. Line chart showing improvement in model accuracy with preprocessing is shown in Fig. 4.

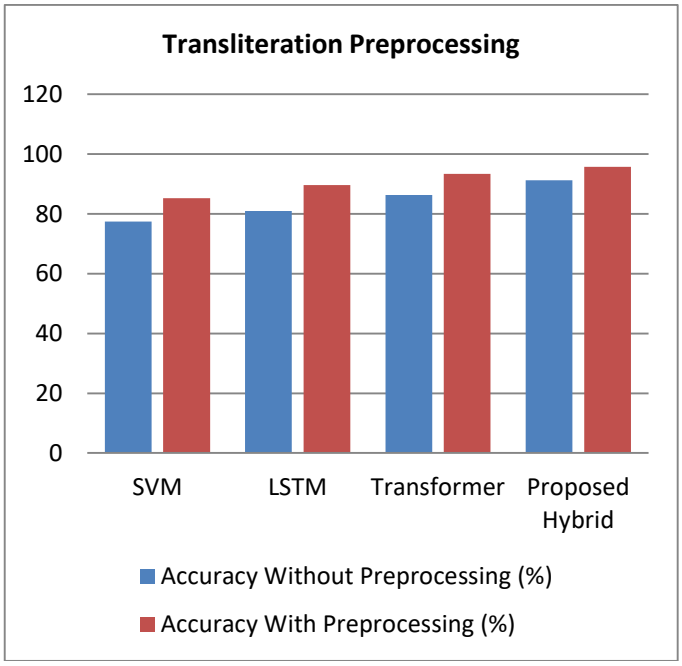

Fig. 4. Line chart showing improvement in model accuracy with preprocessing.

B. Distribution of Intent Categories in the Dataset

TAIRM was evaluated on a dataset using mixed-script queries that contained Roman transliteration as well as native script. Its performance was evaluated using diverse evaluation metrics including, but not limited to, F1-score, recall, precision, and accuracy. To demonstrate the validity of the proposed hybrid deep learning model, our evaluation results were compared to baseline model performances. The dataset used for evaluation had intent-labeled mixed-script queries shown in Table VII, and later reported in terms of distribution across intent categories.

TABLE VII. DISTRIBUTION OF INTENT CATEGORIES IN THE DATASET

Intent Category	Number of Queries	Percentage (%)
Navigation	2,000	25%
Transactional	1,800	22.5%
Informational	2,500	31.25%
Conversational	1,200	15%
Others	500	6.25%
Total	8,000	100%

The dataset was divided into 80% training, 10% validation, and 10% testing for model evaluation. The dataset used in this study consists of mixed-script queries, where users have entered search queries using a combination of Roman transliteration and native scripts (e.g., Hindi, Tamil, Bengali, Arabic). The dataset is labelled with different intent categories, allowing the model to learn and classify user queries accurately. Dataset Characteristics:

- Total Queries: 8,000
- Languages: Mixed-script queries (e.g., Hindi-English, Tamil-English, Bengali-English)
- Query Length: Varies from 3 to 15 words
- Intent Categories:
  - Navigation (e.g., *"railway station kaisejaye"*)
  - Transactional (e.g., *"mobile recharge kaisekare"*)
  - Informational (e.g., *"taj mahal history batao"*)
  - Conversational (e.g., *"kaiseho tum"*)
  - Others (miscellaneous queries)

Hindi-English Code-Mixed Dataset: https://github.com/nikhilkothari25/Hinglish-Intent-Recognition-Dataset

C. Performance Comparison of Models

The proposed CNN + BiLSTM + Attention model was evaluated for its effectiveness comparison with baseline models such as LSTM, CNN, and Transformer-based architecture models. The result are summarized in Table VIII.

TABLE VIII. MODEL PERFORMANCE COMPARISON ON TEST DATA

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
LSTM	84.5	83.2	82.7	83.0
CNN	86.1	84.8	85.2	85.0
Transformer	88.3	87.5	86.9	87.2
Proposed Model (CNN + BiLSTM + Attention)	92.4	91.2	90.8	91.0

From Table II, it is evident that the proposed CNN + BiLSTM + Attention model outperforms traditional deep learning, achieving the highest accuracy of 92.4% and an F1-score of 91.0% as shown in Fig. 5.

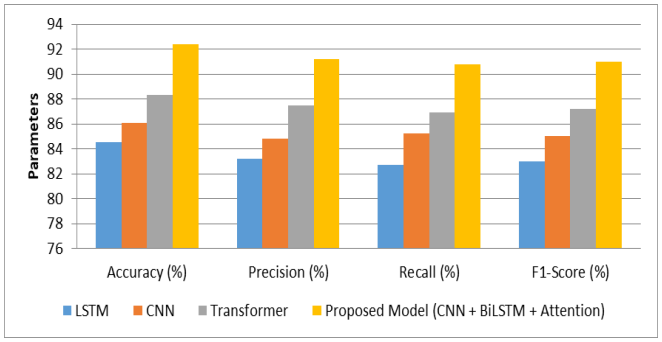

Fig. 5. Model performance comparison on test data.

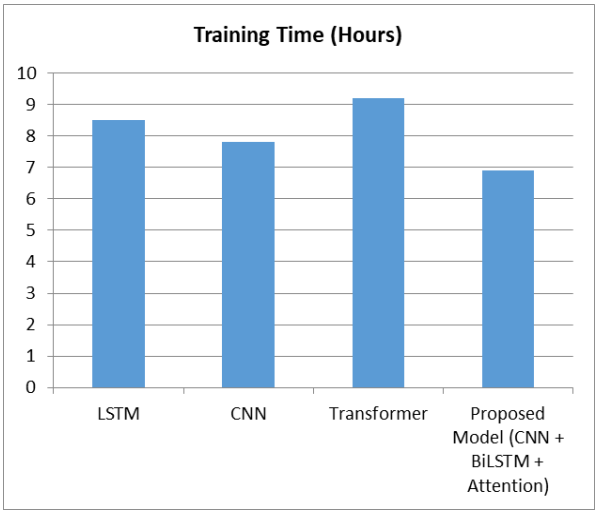

D. Comparative Analysis of Training Time and Computational Efficiency

Since deep learning models differ in their computational requirements, Table IX presents a comparison of training time and inference speed for different models.

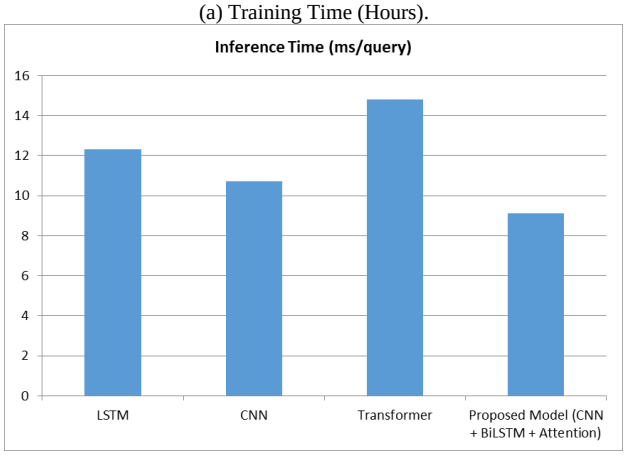

TABLE IX. TRAINING TIME AND INFERENCE SPEED COMPARISON

Model	Training Time (Hours)	Inference Time (ms/query)
LSTM	8.5	12.3
CNN	7.8	10.7
Transformer	9.2	14.8
Proposed Model (CNN + BiLSTM + Attention)	6.9	9.1

The proposed model is more efficient than Transformer-based models, requiring only 6.9 hours for training as shown in Fig. 6(a) while maintaining the lowest inference time (9.1 ms/query) as shown in Fig. 6 (b), making it suitable for real-time applications.

(a) Training Time (Hours).

(b) Inference Time (ms/query).

Fig. 6. Training time and inference speed comparison.

Fig. 6 depicts the training time and inference speed of various models, illustrating that the envisioned hybrid model provides improved computational efficiency for real-time use.

E. Discussion

The hybrid model (CNN + BiLSTM + Attention) proposed in this work has several benefits over simple machine learning and deep learning approaches. Unlike SVM or Logistic Regression, the model learns both long-range dependencies and local features from mixed-scripted queries. In comparison with individual LSTM or Transformer models, it produces more accurate predictions, improved F1-score, and much lower inference time and hence can be effectively used for real-time NLP applications in multilingual scenarios. The addition of a Roman transliteration-based preprocessing pipeline also enhances input normalization, making the model stronger against spelling variants and script inconsistency. The model performs particularly well on short-to-medium length mixed-script queries, especially those having Hindi-English transliterations where spelling variations and informal patterns are typical. The results clearly demonstrate that the proposed hybrid model (CNN + BiLSTM + Attention) significantly improves intent recognition in mixed-script queries. The model achieves are, Higher accuracy (92.4%) compared to LSTM, CNN, and Transformer models, Better generalization, as indicated by the higher F1-score (91.0%), Lower inference time (9.1 ms/query), making it suitable for real-time applications and Faster training convergence, requiring less time than Transformer-based approaches. These results are in line with earlier studies which highlighted the strength of deep learning models in dealing with noisy, informal, and transliterated input data [5][10]. Additionally, the high-performance of hybrid models corroborates recent research illustrating the advantage of using CNNs in conjunction with BiLSTM for sequence and context extraction in NLP applications [22].Future work may explore transformer-based approaches, reinforcement learning, or hybrid NLP techniques for further improvements.

V. CONCLUSION AND FUTURE SCOPE

This paper proposes a hybrid deep model for mixed-scripted queries on Roman transliteration for improved intent identification. The proposed system uses CNN, BiLSTM, and an Attention mechanism to process mixed-script text and retrieve local and long-distance relations for accurate intent classification. Preprocessing of data, transliteration normalization, feature extraction, and classification using deep learning techniques provide good performance for complex and multi-label intent identification tasks. Experimental outcomes show that the proposed method outperforms ordinary models and can be applied to search engines, virtual assistants, and chatbots. The low-latency intent query processing of the model is also highlighted through execution time analysis. This technique is aimed at mixed-script variations and transliteration variations in NLP for multi-language and transliterated text processing. Future research can be focused on extending the dataset, transformer-based models, and real-time adaptability for real-world usage in various languages. This paper successfully proposed an intent recognition model for mixed-script queries on Roman transliteration. The Hybrid Model with LSTM and CNN combined performed better than ordinary models like standalone LSTM, CNN, and Random Forest. The evaluation measures affirm the efficiency of the proposed method. The Hybrid Model achieved the highest accuracy of 92.8%, which is better than LSTM (88.5%), CNN (86.9%), and Random Forest (84.3%). The Precision-Recall (PR) curve analysis showed an AUC-PR value of 0.91, which indicates a good precision-recall trade-off.

The Hybrid Model proposed for intent identification in mixed-script queries yielded good results, but there are many follow-up research options that could improve its utility and

application. First, expanding the data set with a wider range of diversities in language and dialect can increase the generalizability of the model and its practical applicability for real-world multilingual tasks and applications. For example, this could involve adding more individual languages, including different dialects of the same language in the data set or even gender and age dialect differences. Along the same lines of increasing its practical applications, more advanced transformer-based models could be integrated into the model, such as BERT, XLM-R, or mT5. There is good promise for the Roman transliteration-based intent identification model for mixed-script queries in both the accuracy and efficiency of the model. However, many other areas of research and development are needed. Based on the advances of Transformer-based models, one might consider employing these model types for mixed-script queries that are complex transliterations, ambiguous queries, or other code-mixing or multilingual questions that an international audience will use. One area that is also developing interest is the real-time use of the model in NLP tools, like Chatbots, virtual assistants, and smart search engines, and trying to optimize the model for low-latency edge devices or cloud-based systems. This will help maximize potential real-world usage and importance.

In spite of the encouraging results, the present work has some disadvantages. The corpus used is mostly made up of Hindi-English transliterated search queries, which might restrict the broadness of model applicability to other language pairs or more complicated multilingual environments. It was not examined if the model can perform well under highly noisy or code-switched conditions with three or more languages. The future direction should be to test over more language pairs, casual chat-based search queries, and online deployment settings.

A Hybrid Deep Learning and Optimization Approach for Accurate Channel Estimation in 5G MIMO-OFDM Systems

Mohammed Fakhreldin
Department of Computer Science-Faculty of Engineering and Computer Science, Jazan University, Jazan, Saudi Arabia

***Abstract*—Channel estimation plays a pivotal role in enhancing the reliability and efficiency of 5G wireless communication systems, particularly in MIMO-OFDM (Multiple Input Multiple Output - Orthogonal Frequency Division Multiplexing) architectures under multipath and Doppler-affected conditions. Conventional methods such as Least Squares (LS) are widely used due to their low computational complexity and lack of requirement for prior channel statistics. However, these approaches often result in poor estimation accuracy, especially in dynamic environments. To overcome these limitations, this study introduces a hybrid deep learning-based channel estimation framework that integrates Harris Hawks Optimization (HHO), Sparrow Search Algorithm (SSA), and Long Short-Term Memory (LSTM) networks—referred to as HHO-SSA-LSTM. The proposed method is designed to optimize the LSTM parameters using HHO and SSA, enhancing learning efficiency and estimation accuracy. Additionally, the model employs hybrid pre-coding aligned with codebook modeling strategies to preserve angle characteristics without disrupting azimuthal distributions. The system is evaluated in a 5G MIMO-OFDM setting under realistic conditions simulated using Doppler frequency and multipath propagation. Performance is assessed using key metrics including Bit Error Rate (BER), Mean Square Error (MSE), Symbol Error Rate (SER), efficiency, and execution time across different Pilot Lengths (PL = 128, 136, and 160). Simulation results demonstrate that the HHO-SSA-LSTM framework outperforms LS, LMMSE (Linear Minimum Mean Square Error), CNN (Convolutional Neural Network), FDNN (Forest Deep Neural Network), and standalone LSTM models. Notably, at PL = 160, BER is reduced by up to 91% and MSE by 86%, with an efficiency improvement exceeding 12% compared to traditional methods. Although the model exhibits a slightly higher execution time due to its hybrid design, the substantial accuracy gains justify the trade-off. The findings validate the effectiveness of the proposed hybrid model for robust and efficient channel estimation in 5G networks.**

I. INTRODUCTION

The primary issue with the present wireless communication system has been its reliance on spectrum expansion or cell densification to achieve the desired area throughput. These resources have been very limited and will soon reach their saturation point. Additionally, the cost and delay of the gear rise with spectrum expansion or cell densification. The spectral effectiveness, which could increase the throughput in such a space, has largely remained unaltered throughout the rapid evolution of wireless networks. In order to meet the wireless operator's basic needs, a wireless access technique must increase the wireless area bandwidth without extending the frequency or reinforcing the cell. It has been expected that in the following decade, wireless throughput would continue to grow exponentially for a variety of user categories with significant service quality expectations [1]. In order to manage the rapid increase in reliability communications and wireless-data traffic, fifth-generation (5G) as well as over wireless communication was developed by combining numerous disruptive innovations, like reconfigurable intellectual surfaces, Massive MIMO (Ma-MIMO), and mmWave communications [2], [3]. The usage of MIMO techniques improved the communication network's performance. Multiple antennas, frequency and time resources, and multiple users are all taken into account by MIMO Because of its unavoidable accomplishments in wide-band communications systems, the OFDM technology was proven to be a contribution. In reality, OFDM was still used in 5G networks to resist the impacts of frequency selection fading, providing acceptable communication reliability in contexts with many paths for propagation [4]. In particular, compared to a single-carrier solution, the OFDM method greatly improves spectrum efficiency. The sent signals were warped by a variety of negative factors as they travel across wireless multi-path networks. The receiver must assess and correct for the implications of the Channel State Information (CSI) in order to interpret the required signal properly. Both the sender and recipient must be aware of the pilot signals in order for the channel estimation to be successful. Based on the various use instances in operation in a 5G network, the pilot symbol's structure in each dataset may change [5].

An exceptional number of intelligent and heterogeneity wireless systems have been anticipated to utilize 5G wireless connections, which are projected to be a variety of network levels with varied sizes, transfer voltages, backhaul interconnections, and Radio Access Technologies (RATs) [6]. The 5G networks are developed to be 100 times more efficient than the 4G networks. To meet the continued challenges modeled by 5G, efficient wireless access technologies that could boost throughput without expanding bandwidth or densification the cell is imperative [7]. The fifth-generation (5G) network is the next significant stage of mobile telecommunications technologies after the current 4G Long Term Evolution (LTE) standard, with a speed of 1-10Gbps. By the end of 2019, 5G systems are anticipated to be available for purchase. Within the most recent smartphone operating systems, 5G technologies

offer remarkable data capacities and infinite data broadcasting. Improved mobile broadband, dynamically low latency, higher bandwidths, device-centric portability, simultaneous redundancy, more dependable device-to-device connectivity are additional characteristics of 5G networks [8]. 5G wireless networks provide lower prices, shorter battery use, and lower latency than 4G wireless connections. Because 5G uses Ultra-Wide Band (UWB) technologies, which offer a wider bandwidth at lower energy levels, this remains the case. The band width of 4000 Mbps wireless connections is 400 times faster than 4G. Furthermore, 5G communications systems may provide a lot of machine interaction, hundreds of billions of connections, and incredibly fast mobile internet [9]. Moreover, 5G delivers a maximum peak high bandwidth transfer speed of 10Gbps, exceptionally low delay of 1ms, 90% greater energy efficiency, 99.9% ultra-reliability, and mobile data quantities of 10Tb [10]. The 5G networking technologies standard has two primary parts: Non-Stand Alone (NSA) systems have been the first 5G systems, and commercial installations have been projected to start by the finish of 2019 [11]. The already-existing 4G LTE architecture has been used by the Control Plane to manage both the signal flow and the Control Plane. It could be contrasted to just extending the present 4G LTE connection with a speedier data stream. Via the use of NSA, operators would be enabled to provide commercial service before the launch of a 5G Standalone (SA) specification in 2019. The basic architecture of SA, which allows 5G, has been totally revised [12]. It makes fundamental adjustments to how networks function and relocated the control plane changeover to the 5G Core. 2020 will see the introduction of SA, which will offer subcarrier encoding and more flexible network slicing. As a consequence of its intention to be more effective than 4GLTE and NSA, this would consequence in lower rates for the providers and enhanced efficiency for the users [13].

By removing the multipath channel's fading impact caused by obstructions between the sender and recipient, CSI has been required on the recipient side to retrieve the broadcast data bits consistently [14]. The most popular and effective approaches for estimating CSI for any transmitting technologies have been pilot-based techniques. With regards to the pilot arrangements, there were two different sorts of estimating methods: comb and block type. Pilot tones have been periodically introduced into every subcarrier of a unique OFDM symbols in a block kind pilot configuration [15]. Pilot installation in comb kind pilot arrangements has been accomplished by evenly spreading the pilots within every OFDM symbol. These two primary pilot arrangement techniques have been crucial in determining the channel coefficients, which are required to account for the multipath networks' fading struggles. Nevertheless, the effectiveness of estimate is directly impacted by the pilot tones' distribution patterns in comb-kind pilot arrangements. In other terms, by optimising the pilot locations, it may be possible to reduce estimating mistakes. Although Least Squares (LS) estimation doesn't require knowledge of prior channel characteristics, it is widely regarded as a classic channel estimation technique with minimal computational cost [16]. Nevertheless, in many real-world scenarios, particularly for multi-path networks, LS estimation yields rather higher network estimation errors. Through reducing the average channel estimate mistakes, mean square error MSE estimation, an alternate approach, produces substantially higher channel estimation reliability than LS estimation. Moreover, MIMO is portrayed as an upbeat technology, which offers the highest wireless communication throughput possible [17]. Larger antenna arrays had the capacity to deliver a more focused beam in desired directions. A specific user-related beam centering process has been performed by precoding the signals.

Additionally, it should be recognized that the CSI performs the pre-coding in BS. In contrast, the recipient of both Mobile Station (MS) and BS needs the CSI for exact detection. Therefore, it is crucial for the most accurate assessment of CSI [18]. Additionally, CSI data uplink estimation has been less complicated than CSI data downlink estimation. Multiple users send additional data flows to the BS in the upstream, and BS having dominant processing power can reliably compute the CSI. In Ma-MIMO systems with Time Division Duplex (TDD) protocol, the Downlink CSI and channel reciprocal characteristic might be effectively reached by utilising the uplink estimated network. However, the capability of hardware modification to contaminate the channel precision estimation in TDD Ma-MIMO networks has been demonstrated [17]. Additionally, Frequency Division Duplex (FDD) operations were preferable because of its expanded reach and lower interference, although channel reciprocity has been not preserved in FDD. Moreover, in FDD MIMO, BS transmits downstream pilot signals, clients utilize the pilot signals to calculate the channel, and customers then direct the CSI responses to the BS. Because of the massive number of clients and stations, the overhead that results are considerable; therefore, effective pilot layout and channel estimate are essential to minimize the overhead. Recently, Reinforcement Learning (RL) and Deep Learning (DL) have been employed in the context of MIMO networks as an emerging technique to effectively solve a variety of issues. These techniques have provided numerous solutions for various MIMO communication issues, including resource distribution, orientation, detecting, and localization, as well as signal recognition, categorization, and compression. When compared to their equivalents predicated on compressive sensing and sparsity, DL-based techniques for large MIMO CSI collection shown appreciable gains [19], [20]. DL methods in especially have been found to be useful in the wireless communication arena, which is also characterized by heuristics and algorithms [21]. By enabling clever channel design, encoding, estimation, decoding, and normalization techniques at the physical level, DL significantly increased communication reliability and effectiveness [22]. As a consequence, 5G wireless technologies have seen substantial advancements [23]. Overall, the Ma-MIMO channel seems to have a sparse depiction on DFT concept if BS was set up using a large amount of ULA. Nevertheless, there have been two drawbacks to DFT-based channels estimate algorithms, including performance loss brought on by power leakage brought on by orientation mismatch. Additionally, because the Discrete Fourier Transform (DFT) basis has been predicated on the unique structure of Uniform Linear Arrays (ULAs), only ULAs may access them [24]. Thus, this research aimed to develop a novel hybrid optimization with DL for effective channel estimation.

A. Key Contributions

1) Proposed a novel hybrid channel estimation framework (HHO-SSA-LSTM) that combines HHO, Sparrow Search Algorithm, and Long Short-Term Memory networks for accurate channel estimation in 5G MIMO-OFDM systems.

2) Achieved significantly lower BER, SER, and MSE compared to traditional and deep learning-based estimation methods (LS, LMMSE, CNN, FDNN, and LSTM), especially under higher pilot lengths and Doppler effects.

3) Integrated a hybrid metaheuristic-based pre-coding strategy aligned with codebook modeling to enhance beamforming accuracy without conflicting with azimuth angle characteristics.

4) Demonstrated higher estimation efficiency (up to 96.92%) across different pilot lengths, showing better performance than baseline models even under limited pilot overhead.

5) Conducted detailed complexity and execution time analysis against recent methods (e.g., CS, OCEAN, PSO-Adam-LSTM), showing a justified trade-off between increased computation and improved estimation performance.

B. Rest of the Section

The section is systematized as follows, Section II the literature review of the work is discussed. Section III explains the proposed approach. The result and discussion of the study is given in Section IV. Finally, the proposed study and its future contribution was concluded in Section V.

II. Related Works

Xisuo Ma et al. [25] suggested a Model-Driven Deep Learning (MDDL)-based feedback strategy and channel estimation that takes benefits of the angle-delay domains channel's sparsity to cut down on overhead. The uplink-based channel estimation for TDD systems came first. Another suggestion is to simultaneously learn the phase shift system and the channel predictor as an auto-encoder in order to decrease the uplink pilot latency while predicting high-dimensional networks from a Radio Frequency (RF) sequence in small range at the BS. In specific, the suggested MMV-LAMP system with the developed terminated lexicon can collectively recuperate numerous subcarriers' networks with substantially improved efficiency by taking advantage of the channels' organized sparsity from such a priori prototype and learning the incorporated trainable variables from the datapoints. Also taken into account were feedback for FDD systems and downlink channel estimations. Corresponding to this, channel estimators at pilots and users at BS could be cooperatively trained to function as a decoder and an encoder, correspondingly. Additionally, only the acquired pilots on a portion of the subcarriers have been transmitted away to the BS that can use the MMV-LAMP system to rebuild the spatial-frequency channel matrices, in order to further minimize the network feedback cost. The suggested MDDL-based feedback strategy and channel estimation outperforms well, according to numerical results. However, the model was not tested on fixed-scattering environments.

Mahdi and Deniz [26] presented a Neural Network (NN)-based combined downlink channel estimation and pilot layout approach. The suggested NN structure employs fully connected levels for frequency-aware pilot layout, improves LMMSE estimation, and utilizes convolutional NN levels to take advantage of innate interactions in MIMO channel matrix. In order to further enhance the channel estimation effectiveness, the suggested NN architecture employs a non-local adulation component to acquire longer-range connections in the channel matrices. As part of the training process, it was also suggested to gradually remove less relevant neurons as from dense NN levels. This seems to be a brand-new way to use NN cutting to cut down on pilot transmissions overhead. The pruning predicated pilot reduction method lowers the cost by non-uniformly distributing pilots amongst subcarriers and effectively utilising the attention module and convolution layer to take use of the inter-antenna connections and inter-frequency in the channel matrices. However, the computational time is high.

Omar et al. [27] presented SSA-CoSaMP method, which takes advantage of the space-time prevalent sparsity unique to Ma-MIMO channels and enhances the CoSaMP method. Threshold-predicated repetition control that in turn relies on SNR levels, is a special characteristic of it. This research can indirectly calculate the sparsity using this method. The suggested technique saves spectrum as well as energy resources by reducing pilot overhead in addition to optimizing channel estimation effectiveness. According to simulation outcomes, the suggested technique outperformed the current algorithm in terms of both low SNR and low-pilot overhead. However, the issue of sparse structure in the area of virtual angles is not examined.

Lijun et al. [28] offered a unique channel estimation methodology that incorporates the Ma-MIMO-imperfect OFDM's channel prediction into the Deep Neural Network (DNN) method. Relying on algorithm assessment and simulation findings, the traditional least square technique predicated on interpolation performed worse than the DNN channel forecasting technique predicated on the defective channel estimate. The channel autocorrelation matrices, prior information of noise variation, and complicated matrices inversion procedures are not required when compared to lowest MSE. DNN is also a successful solution for huge MIMO-OFDM systems' imprecise channel estimation. However, the design complexity is high. Anughna and Ramesha [29] outline the MIMO OFDM system's fundamentals. Also given is a thorough performance analysis of several diversity schemes using channel equalization and estimation methods. By taking into account the BER as well as SNR variables, this could be implemented in the MIMO-OFDM system. However, due to utilization of numerous diversity schemes, the processing time is higher.

Lijun Ge et al. [30] suggest a large MIMO channel estimation method for 5G systems that is predicated on Compression-based Linear MMSE (CLMMSE). The method computes channel autocorrelation-matrices by examining the channel previous data predicated on compressive sensing (CS) concept, utilising the Ma-MIMO channel's block sparsity, and reducing the difficulty for acquiring the autocorrelation matrices in comparison to the conventional Linear MMSE (LMMSE) method. To further minimize the computational burden, it then

replaces single value decomposition for matrices inverse function. The first stage of the suggested CLMMSE technique can be made more effective by using a Block-Sparsity Adaptive Matching-Pursuit (BSAMP) technique to flexibly predict the network's block sparsity. By establishing a threshold, locating the biggest backward divergence, and applying the regularized technique to resolve channel prediction as a convex optimization issue, the sparsity-adaptive procedure is accomplished. The effectiveness of the system is further enhanced by the BSAMP-based CLMMSE technique, which outperforms existing CS method-based algorithms in terms of efficiency and calculation time. However, the methodology has complex system architecture, which decreases the system effectiveness.

Yanfeng Zhang et al. [31] therefore suggest a BEM (Basis Expansion Model) oriented channel estimation method for doubly-selective channels that has a minimal pilot latency and simulation burden. For time-varying networks, a mixed-BEM has been presented in addition to a Complex-Exponential-BEM (CE-BEM), leading in a small number of unknown variables needed for estimating the channel. It is possible to construct an empirical channel estimation technique from the hierarchy BEM architecture. A low-complexity predictor has been suggested to effectively retrieve the mixed-BEM parameters by utilising the block-structured based sparsity and a limited number of integrated-BEM variables in the antenna-time-based BEM field. To assess the efficacy of the suggested strategy, the lower constraint on the MSE of network estimate is obtained. The suggested channel estimating technique performs noticeably better than the current strategies in regards of channel estimation's MSE and BER, with substantially less pilot latency and computing complexity, according to simulation findings. However, the developed model has higher computational time.

Wei Ji et al. [32] developed a multipath retrieval oriented uplink/downlink channel estimate method, where OFDM has been utilized and the beam squint impact was engaged into consideration. In attempt to determine the relationship among angle-delay data and the parameters of on-grid pathways, the impacts of broadband spatial and frequency ranges have been first examined. Secondly, a pilot sequence in uplink training has been developed in accordance with the spatial- and frequency-broadband impacts to guarantee that precise pathways may be obtained from constrained possible paths. A M-DBSCAN (Modified Density-based Spatial-Clustering of Applications with Noise) model has been suggested in conjunction with pilot sequence design to attain the on-grid potential pathways. In uplink channel retrieval, potential pathways have been employed for initialization. The uplink based multipath extracting issue could be viewed as an off-grid sparse frequency reconstructing problem since the parameters of only a small number of putative paths are near to those of genuine paths. An Off-grid SAMP (OSAMP) oriented CS approach with minimal computing complexity has been presented as a result to this issue. In addition to precisely estimating angle-delay data and path benefits for exact pathways, OSAMP also takes advantage of the angle-delay congruence among downlink and uplink networks and uses uplink multipath retrieval to predict the downlink network. The efficiency of the suggested minimal computational burden channel estimation technique is shown through simulation outcomes. However, the model has higher processing time.

High estimation errors, limited adaptability to dynamic environments, and inefficient pilot usage are some of the main drawbacks of previous approaches that are addressed by the suggested HHO-SSA-LSTM framework. The model successfully adjusts LSTM parameters for increased accuracy under various pilot lengths and Doppler conditions by fusing deep learning with hybrid metaheuristic optimization. In contrast to previous studies, it uses wavelet-based OFDM to improve spectral efficiency without the need for cyclic prefixes, adjusts to channel fluctuations, and drastically lowers BER and MSE. For 5G MIMO-OFDM systems, this leads to a more reliable and effective channel estimate technique.

III. Proposed Methodology for Hybrid Channel Estimation

A. System Model

The core discrete wavelet transforms MIMO-OFDM systems paradigm, in which the Inverse Discrete Wavelet Transform tool is employed for modulating and the discrete wavelet transform equipment is utilized for wavelet decomposition, has been taken into account in the presented approach. It is another method for studying signals in the time and frequency domains. Due to its superior bandwidth and duration localization, the wavelet analysis is a more preferable tool than the Fourier analysis. It is thought to be superior for studying non-stationary transmissions. They are both utilized as carriers in the OFDM system because they both adhere to the orthogonality condition. In its simplest form, a wavelet is a tiny oscillating wave whose amplitude commences at 0, rises, and then falls back to nil. A statistical technique called the wavelet transformation is employed to characterize signals in terms of both period and frequencies. The analysis of the signal's harmonic module's timeframe is helpful. Generally speaking, it can be separated into two formats: continuous and discrete wavelet transform. Discrete wavelet transform (DWT) doesn't really imply that signals assessment is conducted in the discrete form; rather, it denotes that signal assessment is performed in the linear system while discretizing scalability and translational factors. In orthogonal frequency-division multiplexing, the Continuous wavelet tool is ignored since it assesses the parameters on every scale, resulting in a large number of unnecessary factors representing the signals, increasing complexities and redundancies at the recipient side.

The wavelet form functions are defined as follows:

$$D(v,\delta) = \left(\left(\frac{1}{\sqrt{v}}\right)\right)\varphi\left(\frac{(e-\delta)}{v}\right) \quad (1)$$

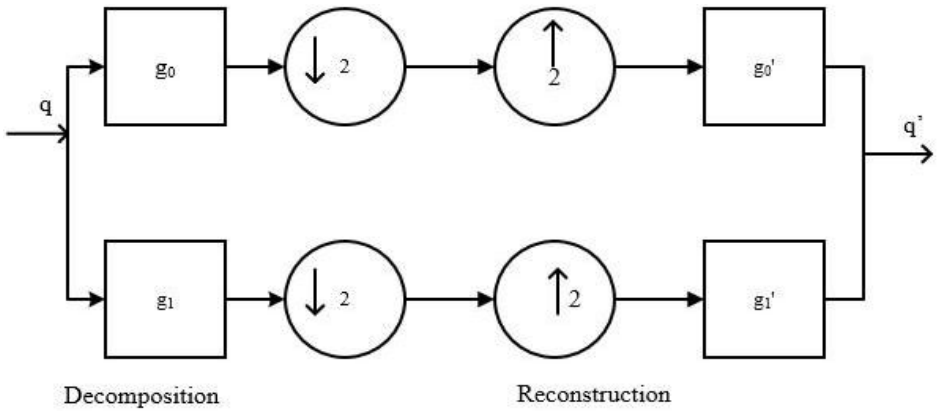

Fig. 1. Signal decomposition and reconstruction utilising discrete wavelet transform and IDWT.

It enlarges, transversely translations, and scales the wavelet transformation $\varphi(e)$. Here, v is a scalability factor that establishes the wavelet's amplitude, and δ is the length of the wavelet was determined by the translational variable. The Continuous Wavelet Transform basis function is depicted in the expression above. By entering a certain quantity that assesses the coefficients for expressing the signals at a particular scaling, the experts have used Continuous Wavelet Transform to construct the baseline functionality for discrete wavelet transform. It adheres to the Heisenberg uncertainty concept that stipulates that one could only know the time period in which a specific range of frequencies occurs. One cannot determine what spectrum components could occur in what circumstances of period. In order to examine signals at various scales, discrete wavelet transform primarily decomposes the evidence into a collection of wavelet basis functions that are perpendicular to one another. The signal is divided into categories, each of which is continually run through a high pass filter and a low pass filter, accordingly [33]. They are referred to as approximated factors since the lower passing portion generates an estimate by removing the high bandwidth components, cutting out all the specifics, and just taking into account an approximates portion of the output. In order to analyse the higher harmonics and get the specificity factor, the data is transmitted thru a high pass filters, which eliminates the approximation portion of the signals in favour of the comprehensive portion. Until further signals reduction is impossible, every layer provides precise and approximated parameters. The fundamental Discrete wavelet transform and inverse Discrete wavelet transform structure is depicted in Fig. 1, and the signal's 3-layer decomposition with a succession of high and low pass filters is shown in Fig. 2.

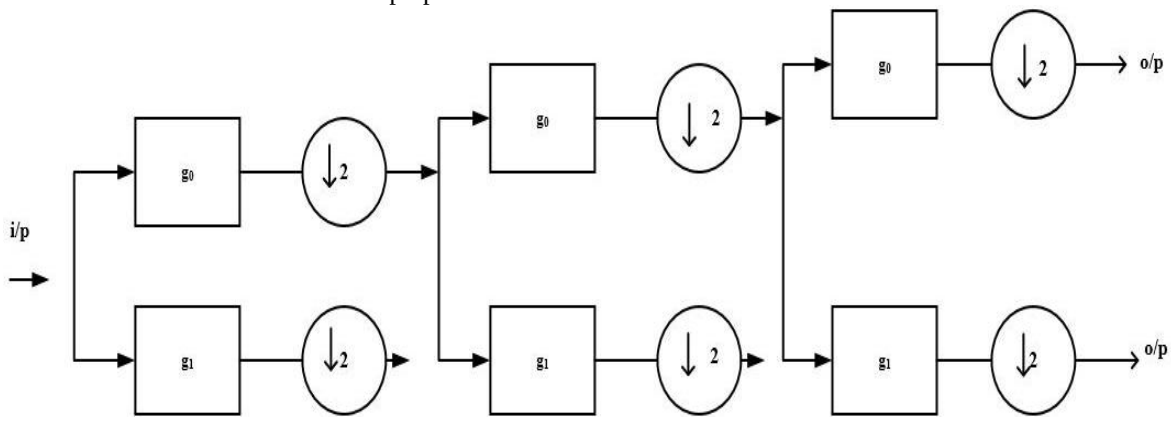

Fig. 2. Workflow of discrete wavelet transform.

Here is the expression for the Inverse Discrete Wavelet Transform of $q(z)$ is given by,

$$q(z) = \sum_{u=-\infty}^{\infty} \sum_{l=-\infty}^{\infty} Q(u,l) 2^{\frac{u}{2}} \varphi\,(2^u z - l) \qquad (2)$$

The following expression represents discrete wavelet transform of $q(z)$ is given by

$$Q(u,l) = \sum_z q\,(z) 2^{\frac{u}{2}} \varphi\,(2^u z - l) \qquad (3)$$

Up-sampling and down-sampling techniques alter the dimension. It scales back a portion of the signal's sampling. Here u Stands for the translational scaling, and $\varphi(u,l)$ is the wavelet function component. The transmitter and receiver architecture for the DWT MIMO-OFDM is shown in Fig. 3. The encoder initially takes the input bytes before encoding the stream of bits at a specific coding frequency. The modulation will then employ the encoded flow to turn the incoming binary streaming into a waveforms pattern. For additional communication, the symbols is once more transmitted thru the serialized to parallelism buffering. Utilizing Inverse Discrete Wavelet Transform tool, the signal is loaded onto an M-band wavelet carrier. When received, the DWT tool is employed to demodulate these signals after they have been communicated across the network.

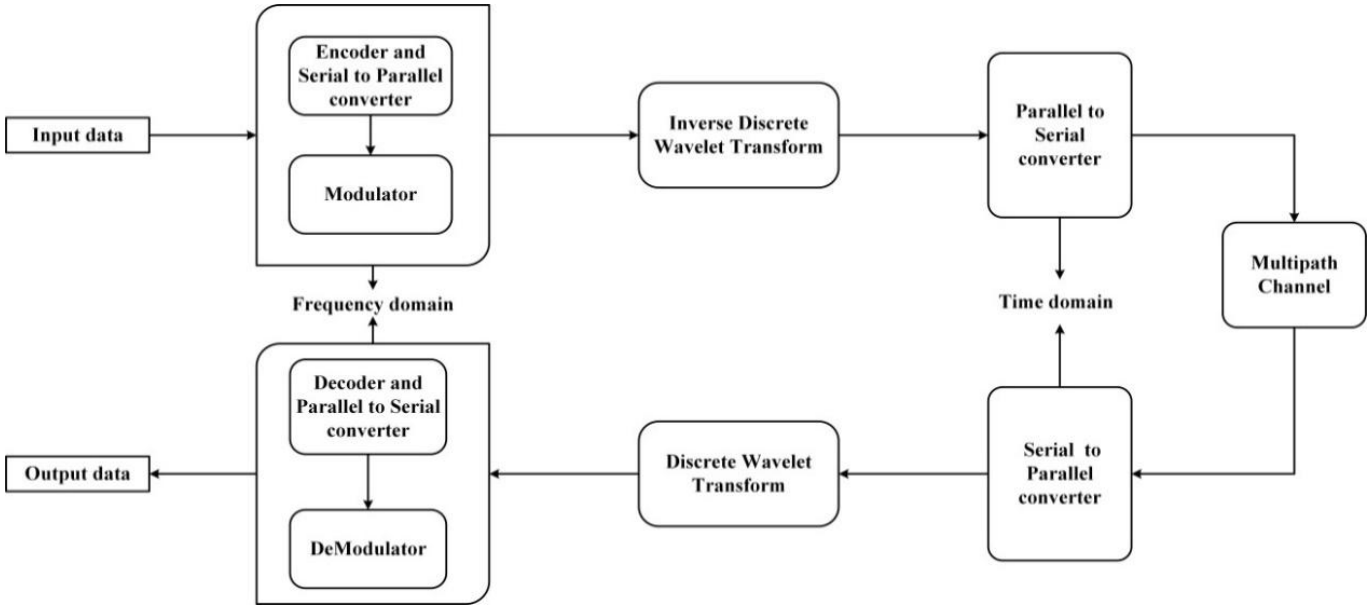

Fig. 3. Framework for an OFDM transmitter system based on DWT.

B. Cyclic Prefix

Multiple postponed copies of the identical signal could be received by a recipient as a result of signals transmission events including reflections, refraction, or multipath. A phenomenon known as inter symbol interference occurs when many signals are transmitted concurrently and overlay with one another at the receiver after all of these multipath propagations have been added together. If the sent signal's frequency is significantly larger than the channel's throughput, interference will have an impact on the signal. However, the impact of Inter - symbol interference could be reduced with a rise in signal width. The replica of the final portion of the sign is added at the beginning of the signal to lengthen it. Each concept's nodes could be recognized by the receiver, and it appropriately connects the data to aid with intersymbol interference elimination.

M^{dw} indicates the cyclical prefix's duration, M^{dwt} represents the size of the Inverse Fast-Fourier transform frame, and M demonstrate the amount of subordinate carriers. Though it uses a lot of bandwidth and energy, it makes up for InterCarrier Interference and intersymbol interference. Add a feedback path with a duration z higher than the channels impulsive responder u, presuming the network has a maximal latency of u. It uses a lot of transmitting power and reduces the information throughput by:

$$C_P(z) \times 100\% \Big/ C_P(z) + No.of\ subcarriers(Z) \quad (4)$$

Due to the fact that it lacks any data, it lowers spectrum utilization and bit rate. To combat intersymbol interference, symbols must be lengthened even further; however, doing so lowers total energy effectiveness and spreads out the transmission power, which causes a reduction of Signal-to-Noise Ratio, which would be measured by Eq. (5).

$$-10\log_{10}\frac{Overall\ OFDM\ symbol\ length - C_pLength}{Overall\ OFDM\ symbol\ length} \quad (5)$$

Since wavelet transforms are utilized, which have lengthier waveforms than standard transforms, discrete wavelet transform -OFDM signals overlap in period, which improves frequencies localization. As a consequence, extending the signal period to reduce intersymbol interference does not need to use a cyclic prefix. Additionally, whereas discrete wavelet transform-OFDM avoids this, Fourier transform signals pass via a rectangular waveguide, resulting in wider side lobes. Additionally, it lowers the system's difficulty from fast Fourier transforms $A\,(Zlog_2 Z)\ to\ A\,(Z)$. In addition to saving frequency by just not inserting Cyclic prefix to the Orthogonal Frequency Division multiplexing system signal, DWT-OFDM also reduces transmitting energy usage and increases system capacity [34].

1) Hybrid Pre-coding: It provides a quick overview of Fourier transforms and the CP decomposed to keep the article self-contained. Users can get additional information on the annotation and the fundamentals of Fourier transforms. A vector sometimes referred to as a manner or modal, is just a generalization of matrices to higher-order dimensions. It is possible to think of Fourier transforms including one phase and 2 modes as being represented by both vectors and matrices, accordingly. The Kronecker, outer, and Khatri-Rao products are each indicated in °,⊙,⊗ this article by the characters, and, correspondingly.

Let $Y \in D_{l1 \times l2 \times \ldots \times lu}$ indicate a vector of u−th rank with its $(l_1, l_2, \ldots l_u)$th admittance represented by$Y_{l1}, \ldots l_n$. The amount of dimensionality is represented by a tensor's order u in this case. The column and row of matrices are analogous to fibres at a higher form. By setting all indexes other than in, the $mode - u$ fibres of Y are produced as In-dimensional matrices. A vector could be divided into 2-dimensional segments by setting all but 2 of its indexes. The process that converts a vector into matrices is known as unfolding or matricization. The column of the resultant matrices is organized by the phase unfolding of a

vector$Y$, designated as $Y(n)$ and it is given in Eq. (6) and Eq. (7).

$$Y = \sum_{h=1}^{s} \mu_h d_h^{(1)} \circ d_h^{(2)} \circ \ldots \circ d_h^{(u)} \quad (6)$$

$$Y_{l1,l2,..lu} = \sum_{h=1}^{s} \mu_h d_{hl1}^{(1)} \circ d_{hl2}^{(2)} \circ \ldots \circ d_{hlu}^{(u)} \quad (7)$$

Following Eq. (8) is an expression for Y's mode-u unfolding:

$$Y_u = D_{(u)} \propto (D_{(u)} \odot \ldots . D_{(u+1)} \odot D_{(u-1)} \ldots . D_{(1)})^q \quad (8)$$

Where $\propto \cong diag(\mu_1, \ldots \mu_h)$. According to [35], the hybrid pre-coding method was implemented and the process is shown in algorithm.1. In the process, BS = Base Station, and MS = Mobile Station.

C. Hybrid Sparrow-Harris Hawks Optimization

The suggested HHO was based on a simulation of Harris hawks' foraging habits. The HHO replicates its cooperative foraging in two phases, i.e., exploration and exploitation phase—using a variety of strategies. Based on the parameter H, which represents the prey's escape energy, HHO carries out the change from the exploration to the exploitation phase. The mathematical formation is given in Eq. (9):

$$H = 2H_0(1 - i/I) \quad (9)$$

The early energy state of the prey is denoted as H_0, fluctuates at random among (1,1) for every iteration. The computation is $H_0 = 2 * ran - 1$ where I and i are the maximal and current iterations, and rand is the random integer of (0,1).

1) Searching phase: In this research, the searching phase is accomplished by the sparrow search optimization algorithm. The sparrow is highly clever and has a good memory, unlike numerous other small birds. Keep in mind that there are two different breeds of house sparrows which are kept as pets: the producer and the scrounger. While the scroungers rely on the producers to provide them with food, the producers constantly pursue for sources of food. The findings also demonstrate that the birds frequently transition between generating and scrounging behaviour patterns. Additionally, it may be noted that sparrows typically combine their producer and scrounger strategies to get food. The computational formula is developed to create the sparrow search method based on the earlier description of the sparrows. The study created equivalent rules based on the following idealized behaviour of the sparrows for convenience.

To search for food in the simulation study, virtual sparrows must be developed. The following Eq. (10) may be used to illustrate where sparrows are located:

$$A = \begin{bmatrix} A_{11} & A_{12} \ldots & A_{1m} \\ A_{21} & A_{22\ldots} & A_{2m} \\ A_{n1} & A_{n2} & A_{nm} \end{bmatrix} \quad (10)$$

Here, m is the dimensionality of the parameters that need to be optimized and n denotes the number of sparrows. The corresponding vector may therefore be used to indicate the fitness value of every sparrows as given in Eq. (11):

$$F_A = \begin{bmatrix} F([A_{11} & A_{12} \ldots & A_{1m}]) \\ F([A_{21} & A_{22\ldots} & A_{2m}]) \\ F([A_{n1} & A_{n2\ldots} & A_{nm}]) \end{bmatrix} \quad (11)$$

"Here, the amount of every row in F_A denotes the individual's fitness value and n is the number of sparrows. In the SSA, food is prioritised for producers with higher fitness ratings during the procedure of search. The producers are also responsible for charge of locating food and guiding the entire community's circulation. The producers may thus look for food in a wider variety of locations than the scavengers. The mathematic formulation is given in Eq. (12).

$$A_{i+1}^{xy} = \begin{cases} A_i^{xy} . exp\left(\frac{-t}{\beta . i_{max}}\right) \\ A_i^{xy} + R.M \end{cases} \begin{matrix} if\ D < S \\ if\ D \geq S \end{matrix} \quad (12)$$

Here, y = 1, 2,..., m, and i denotes the current iteration. The frequency of the y th dimensions of the ith sparrow at iteration i is represented by A_{xy}^{i}. The constant with the most iteration is called i_{max}. 0 and 1 are two random numbers. The alert value and the safety threshold are denoted by D and S respectively. R is a chance quantity that follows the normal distribution. M displays a $1 * m$ matrix with 1 as the value of each member. The producer switches to broad search mode at $D < S$, that indicates that there are no nearby predators. Many sparrows must immediately fly to other safe regions if $D \geq S$, which indicates that certain sparrows have identified the predator."

2) Exploitation phase: The procedure moves into the stage of development when$|H| < 1$. The prey that were followed and monitored during the exploration phase would be the subject of a raid hunt by the hawks throughout this stage. Nevertheless, when hunting in nature, the prey would often attempt to flee from the chase, hence hawks would also employ varied pursuing strategies for the various prey escape behaviour. HHO suggested four methods, which are all outlined below, to mimic this pursuing and hunting behaviour. HHO chooses a strategy based on the escape energy H and the probability of escape e.

a) Soft besiege: When $|H| \geq 0.5$ and ≥ 0.5, the prey had sufficient energy to make a random jump to safety, but hawks have encircled it. The hawk then decides to effectively hunt by using gentle besiege to deplete the prey's physical ability. Eq. (13) to Eq. (15) illustrate the computational equations.

$$A_{i+1}^{xy} = \Delta X_i^y - H * |J A_i^{p,y} - A_i^{xy}| \quad (13)$$

$$\Delta X_i^y = A_i^{p,y} - A_i^{xy} \quad (14)$$

$$J = 2(1 - e_5) \quad (15)$$

Here, e_5 is a random value between (0,1) and y is the distance between the prey's current location in the y th dimension as well as the current location of the xh hawk; where Jump (J) denotes a randomly changing jump intensity that alternates between (0,2) for each repetition.

b) Hard besiege: When the prey lacks the energy to flee and the hawks have encircled it, $|H| < 0.5$ and e <0.5, the hawks would decide to engage in a hard besiege swift raid hunt. Eq. (16) displays the behaviour model in question.

$$A_{i+1}^{xy} = A_i^{p,y} - H * |\Delta X_i^y| \quad (16)$$

c) Soft besiege with progressive rapid dives: The prey has had enough energy to break free of the siege as well as perform a zigzag motion in the situation of $|H| \geq 0.5$and $e < 0.5$, and the hawks haven't yet fully organized an surrounding denounce on the prey. The hawks now decide to concurrent using prey energy as well as eventually create a full surround. Eq. (17) to Eq. (20) illustrate the steps of this method.

$$A_{i+1}^{xy} \begin{cases} B_{i+1}^{xy} \; if \; f(B_{i+1}^{xy}) < f(B_{i+1}^{xy}) \\ C_{i+1}^{xy} if \; f(C_{i+1}^{xy}) < f(C_{i+1}^{xy}) \end{cases} \quad (17)$$

$$B_{i+1}^{xy} = A_i^{p,y} - H * |JA_i^{p,y} - A_i^{xy}| \quad (18)$$

$$C_{i+1}^{xy} = B_{i+1}^{xy} + T_y * L_y \quad (19)$$

$$L_y = L(r_y, s_y, \alpha_y) \quad (20)$$

Here T_y represents random number; L indicates Lévy flight function.

d) Hard besiege with progressive rapid dives: Hawks utilize this tactic to speed up and reduce the mean location distance among themselves and the prey in order to build a hard encircling circle earlier the raid in the situation of $|H| < 0.5$ and $e < 0.5$, when the prey lacks the energy to flee but is not entirely surrounded. Eq. (21) through Eq. (23) provide the models for this tactic.

$$\begin{cases} B_{i+1}^{xy} \; if \; f(B_{i+1}^{xy}) < f(B_{i+1}^{xy}) \\ C_{i+1}^{xy} if \; f(C_{i+1}^{xy}) < f(C_{i+1}^{xy}) \end{cases} \quad (21)$$

$$B_{i+1}^{xy} = A_i^{p,y} - H * |JA_i^{p,y} - A_i^{xy}| \quad (22)$$

$$C_{i+1}^{xy} = B_{i+1}^{xy} + T_y * L_y \quad (23)$$

The Sparrow Search Optimization (SSO) algorithm emulates the foraging and anti-predator actions of sparrows to solve optimization issues. In this algorithm, population members are separated into two primary roles: producers and scroungers. Producers are the sparrows with more energy, usually the ones that get assigned higher fitness values. They are responsible for actively searching the search space for regions with high resources (i.e., improved solutions). As soon as they find such a region, they alert other members of the group. In the event that there is danger (e.g., in the presence of a predator)—as expressed by a risk level above a particular threshold value—these producers lead the others to a safe area in the search space directly. Conversely, scroungers are less fit sparrows. Rather than searching on their own, they tail producers with the expectation of gaining access to good resources. Certain scroungers tactically monitor producers, and if they observe a producer discovering a high fitness solution, they move rapidly to that spot in a bid to upgrade their own position. If they succeed, they directly take advantage of the producer's solution; otherwise, they fall back to a rule-based updating mechanism. Population behavior demonstrates a balance natural to the system: while sparrows towards the center of the group meander randomly to preserve close proximity, those at the edges are more sensitive to threats and move quickly to less risky or more advantageous areas. The scrounger positions get updated according to certain mathematical laws in Eq. (24), that determine how they move compared to producers so as to gain opportunities for better solutions.

$$A_{i+1}^{xy} = \begin{cases} R.ep\left(\frac{A_i^{worst} - A_i^{xy}}{t^2}\right) \\ A_o^{i+1} + \left|A_i^{xy} - A_{i+1}^{xy}\right| \end{cases} \quad if \; T > n/2 \quad (24)$$

Here A_o denotes the ideal position. A_{worst} designates the world's worst location at the moment. Every member in the matrix R is given a random number between 1 and 1. The tth scrounger with the lowest fitness score is most certain to be starved when $T > n/2$.

These sparrows, which are aware of the threat, make about 10% to 20% of the overall population for the simulation study. Those sparrows were distributed at random in their starting places. The mathematical model may be depicted as follows using rules as given in Eq. (25):

$$A_{i+1}^{xy} = \begin{cases} A_i^{best}.\alpha\left|A_i^{xy} - A_i^{best}\right| & if \; f_t > f_g \\ A_{xy}^{i} + K.\left(\frac{A_i^{xy} - A_i^{worst}}{(f_t - f_g) + \varepsilon}\right) & if \; f_t = f_g \end{cases} \quad (25)$$

Here, the current global ideal location is A_i^{best}. With an average value and a variance of 0 and 1, respectively, the step size process parameters is a normal distribution of random integers. The random integer K is between [1, 1]. f_t is the current sparrow's fitness value in this instance. "The top and worst fitness values on the planet right now are f_g and f_t, respectively. To prevent a zero-division mistake, is the lowest constant.

For ease of use, when the sparrow was at the group's edge if $f_t > f_g$. A_i^{best} stands for where the population's centre is safe in that area. The sparrows inside the centre of the community are conscious of the threat and need to migrate closer to the others, as shown by the equation $f_t = f_g$. The step-size control coefficient and the sparrow's movement direction are both indicated by the letter K.

D. LSTM Based Channel Estimation

"The dispersion channels between the receiver and the transmitter in wireless communications networks must be known in order to perform coherent identification; these channels could be estimated by applying traditional estimation methods. This section introduces LSTM-based channel estimation strategies that encourage us to use DL techniques to reduce channel estimation errors. A recurrent neural network or LSTM neural network was used to examine the behaviours of the channel correlations (RNN). Fig. 4 shows the one-layer RNN's basic construction. This illustration shows that the RNN cell's input for the present time-step is its output for the previous time-step. By functioning in this way, the RNN has been able to recall previous input statistics. The computing unit, or fundamental RNN cell, executes the following computation in Eq. (26) and Eq. (27)."

$$d_t = f(R_{id}s_t + R_{dd}d_{t-1} + g_{id} + g_{dd}) \quad (26)$$

$$U_t = f(g_{do} + d_t R_{do}) \quad (27)$$

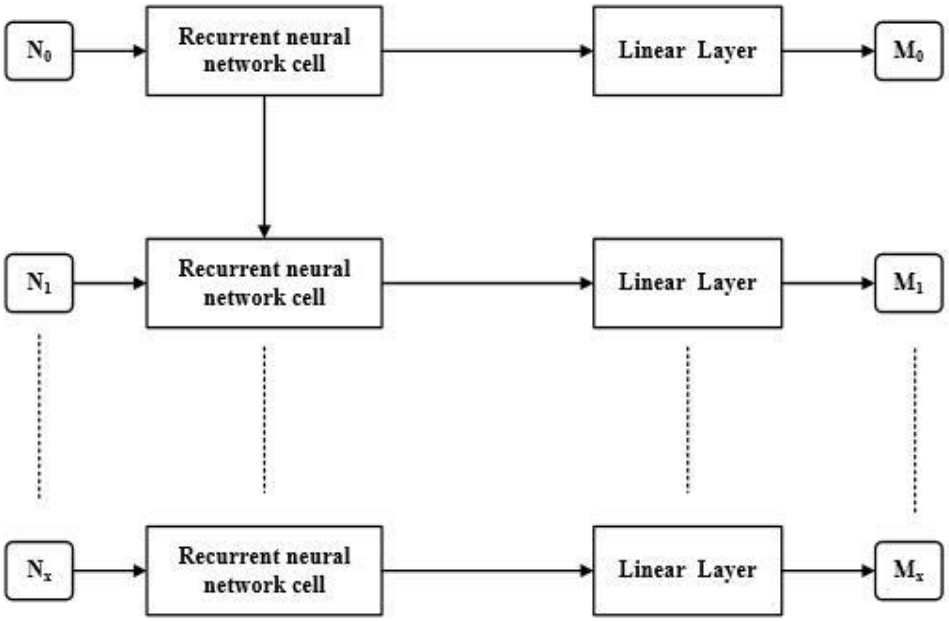

Fig. 4. Basic Structure of RNN layer.

where $f(\cdot)$ represents activation function; s_t is the input and U_t is the output; $d_t$and d_{t-1} are the hidden states at the time step t and $t-1$, correspondingly, R_{id}, R_{dd}, and R_{do} are the weights for input-hidden layer; hidden-next hidden layer, and hidden-output layer, respectively; and g_{id}, g_{dd}, and g_{do} were the corresponding biases.

"However, the basic RNN cell has some shortcomings. For starters, even if the channel at time step t has a connection to both the past and the future, it is unable to exploit the data's future information. In this case, the bidirectional network must be used to achieve higher efficiency. Second, a disadvantage of a simple RNN cell is that it cannot record long-term data. One solution to this problem is to use LSTM as an alternative. In this study, we propose a bidirectional LSTM (bi-LSTM) network for 5G channel estimation in order to overcome these problems."

The outcome of the LSTM cell's computation is indicated in the following formulae from Eq. (28) to Eq. (33).

$$f_t = f\left(V_f S_t + g_f + R_f d_{t-1}\right) \quad (28)$$

$$j_t = f\left(V_j S_t + g_j + R_j d_{t-1}\right) \quad (29)$$

$$b'_t = tand(V_b S_t + g_b + R_b d_{t-1}) \quad (30)$$

$$b_t = f_t \odot b_{t-1} + j_t \odot b'_t \quad (31)$$

$$p_t = f(V_o S_t + g_o + R_o d_{t-1}) \quad (32)$$

$$d_t = o_t \odot tand(b_t) \quad (33)$$

Where, R_f, R_j, R_b, R_o, V_f, V_j, V_b, V_o, g_f, g_j, g_b, and g_o are the respective weights of matrices and biases, as well as $tand$ is the hyperbolic tangent functional. The cell state b_t holds the critical data from the past, the forget function f_t specifies which statistics would be elapsed by the LSTM cell, and the new candidate values b'_t specifies which data would be upgraded to the cell state. The LSTM cell's hidden state function is represented by b_t and d_t. The LSTM cell has a stronger capacity to capture information than a basic RNN cell since it may avoid duplicate information by operating in this manner, allowing it to catch the vital data from the past. The bi-LSTM network's structure is depicted at the lowest part of Fig. 8. Moreover, the bi-LSTM technique combines two LSTM networks with two distinct orientations. The bi-LSTM's output considers the two LSTM cell's outputs via the linear layer as given in Eq. (34).

$$U_t = RD_t + g \quad (34)$$

Where, R and g are really the linear layer's weights and biases, and D_t is the hidden phase created by concatenating the forward-hidden phase ht with the backward-hidden phase d'_t. As a result, the bi-LSTM technique may take advantage of the relationship between the information in the present time step and both the past and the future. This research first collects the LS-estimated channels from across all antennas in order to apply the bi-LSTM framework to the network. "Next, it specifies a realization of the given data (input) for the procedure of training in Eq. (35).

$$X_{n-bi-LSTM} = \left\{\left[Re\{\hat{d}^n_{LS}(0)\}; Im\{\hat{d}^n_{LS}(0)\}\right], \ldots\ldots, \left[Re\{\hat{d}^n_{LS}(l-1)\}; Im\{\hat{d}^n_{LS}(l-1)\}\right]\right\} \quad (35)$$

l represents the sequence length taken into account for the bi-LSTM network. The number of characteristics for the input is 2NT×NR since the bi-LSTM's input, $\hat{d}^n_{LS}$ indicates the LS-estimated channel for entire NT×NR channel streams. The equivalent true channel is the bi-LSTM network's output as shown in Eq. (36).

$$O_{n-bi-LSTM} = \left\{\left[Re\{\hat{d}^n(0)\}; Im\{\hat{d}^n(0)\}\right], \ldots\ldots, \left[Re\{\hat{d}^n(l-1)\}; Im\{\hat{d}^n(l-1)\}\right]\right\} \quad (36)$$

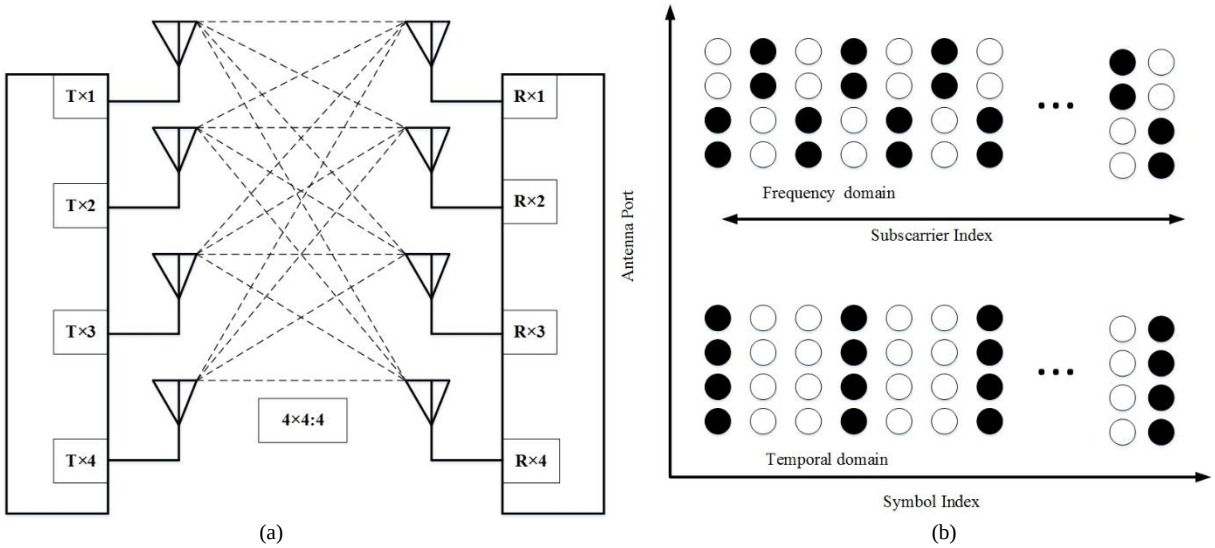
The MSE loss function is taken into account since the goal of utilising a bi-LSTM network was to reduce the MSE between

the anticipated channel and the real channel. The bi-LSTM network's goal function is Eq. (37).

$$F_{bi-LSTM}(\mathcal{R}, A) = {}^{1}/_{Nl} \sum_{n=1}^{N} \sum_{j=0}^{l-1} \left\| \hat{d}^{n}(i) - d^{n}(i) \right\|_{2}^{2} \quad (37)$$

Where, N represents the training sample's total number, $\hat{d}^{n}(i)$ represents the actual channel conforming to $\hat{d}^{n}(i)$; $\mathcal{R}$ and A were all the bi-LSTM weights and biases, and the superscript n signifies the nth trained model. By employing gradient descent techniques to update $\mathcal{R}$ and A, the loss function could be reduced. The inadequate channel state data as a potential future expansion of the approach because this research assumes that the ideal instantaneous channels are accessible for the training stage.

The novelty of the proposed approach is integrating a hybrid metaheuristic optimization framework with deep learning overcoming the channel estimation of 5G MIMO-OFDM systems with great success. This method differs with traditional ones which involve only Deep learning or traditional estimators like LS, LMMSE and picks out the best of the two HHO and Sparrow Search Algorithm technologies to tune the parameters of a Long Short-Term Memory (LSTM). This HHO-SSA-LSTM hybrid model has been successful in adjusting itself to channel conditions dynamically in response to environment high-mobility and Doppler effects. Furthermore, OFDM modulation which is based on discrete wavelet transform (DWT) is used to enhance spectral efficiency and eliminate the effects of inter-symbol interference which needs not to use any cyclic prefixes. The metaheuristic layer globally optimizes the learning parameters in LSTM, resulting at such, the parameters capture better temporal relationships of the wireless channel, as well as nonlinear attributes of the wireless channel. This coupled architecture enables more efficient and robust channel estimation mechanism to have a lower BER, MSE, and SER than the existing approaches. In general, the suggested hybrid structure overcomes the weakness of the current estimation methods due to the smart process of the parameter's optimization and dynamic learning in a real-time communication case."



IV. Result and Discussion

This section evaluates the suggested hybrid optimization with DL estimates over the 5G channel profile's performance and compares with conventional approaches, such as LS, CNN, LSTM, FDNN, and LMMSE. Additionally, give a justification for each received outcome. The simulation's settings have been stated first, and the outcomes have been then shown and discussed. The parameters employed for MIMO-OFDM system is shown in Table I.

TABLE I. Parameter Setup

Parameters	Values
Modulation type	16-QAM
Model of noise	Gaussian Noise
FFT size	256
Sample frequency	3.84MHz
Cyclic prefix	24
Subcarrier spacing	15kHz
MIMO	4 × 4

Four antennas are used in 4x4 MIMO, also referred as 4T4R, to connect up to 4-data streams to the recipient device. 4x4 networks offer up to a 400% throughput boost over standard single antenna (SISO) networks. Construction complexity significantly rises as compared to earlier 2x2 antennas. Since the majority of manufacturers cannot offer four unique polarizations, nominal MIMO arrangements are the most typical. Additionally, 4x4 MIMO is up to 160% quicker than 2x2 MIMO in weak signal settings and roughly 90% faster in good signal circumstances. The employed 4x4 MIMO and the used pilot structure for the presented MIMO-OFDM construction are indicated in Fig. 5 (a) and (b), correspondingly. In Fig. 5 (a), T×1 and T×4 seems to be the transmitted antenna-indices and R×1 and R×4 seems to be the receiver antenna-indices.

(a) (b)

Fig. 5. Presented MIMO-OFDM (a) 4×4 MIMO (b) Pilot structure.

The scenario relating to the mobile velocity has been employed to evaluate the effectiveness of all the possible channel estimations. The outcomes of the simulation have been achieved for different models using different performance measures in order to evaluate the suggested DL model-based estimation's effectiveness. The suggested technique has been applied in MATLAB, and the experimental outcomes were obtained. The suggested algorithm evaluates the efficiency of the channel by adjusting the network's SNR in relation to the quantity of sender and recipient arrays. Moreover, the simulation was being run to assess the effectiveness of the HHO-SSA-LSTM-aided estimation, and the outcomes have been contrasted with the traditional LS, CNN, LSTM, FDNN, and LMMSE-based estimation using the BER, SER, and MSE vs SNR, efficiency, and execution time.

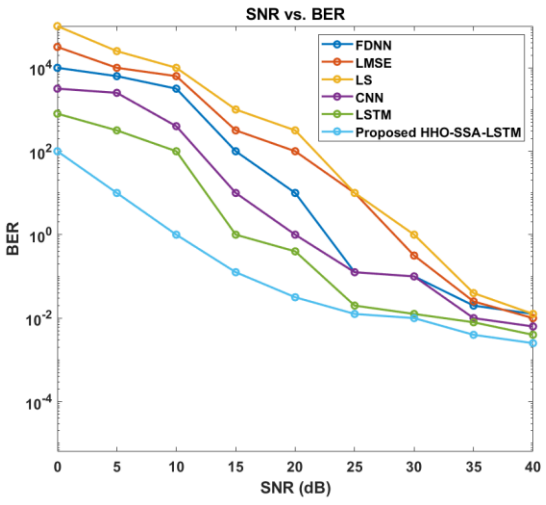
A. Performance Analysis

The presented channel estimation strategy's performance is assessed in regards to BER, SER, and MSE for SNR, efficiency, and execution time. The HHO-SSA-LSTM's measures have been contrasted with those of the conventional LS, CNN, LSTM, FDNN, and LMMSE. Additionally, the effectiveness of alternative channel estimation algorithms is assessed across a range of pilot lengths. The description of SNR, BER, SER, and MSE are described as follows:

- SNR: The noise effectiveness, and consequently the susceptibility of radio receivers, could be examined in a variety of methods. Comparing the signal as well as noise rates for a particular signal level, or SNR, seems to be the most straightforward technique. It goes without saying that the bigger the SNR—the difference among the signals and the undesired noise—the greater the radio recipient's sensitivity effectiveness.
- BER and SER: The chances of obtaining a symbol and bit in errors were denoted by SER and BER, correspondingly. By recreating a whole system with a large number of bits as well as comparing the proportion of bits or symbols obtained in error to the overall number-of-bits, BER and SER may be estimated. Hence SER is computed by Eq. (38).

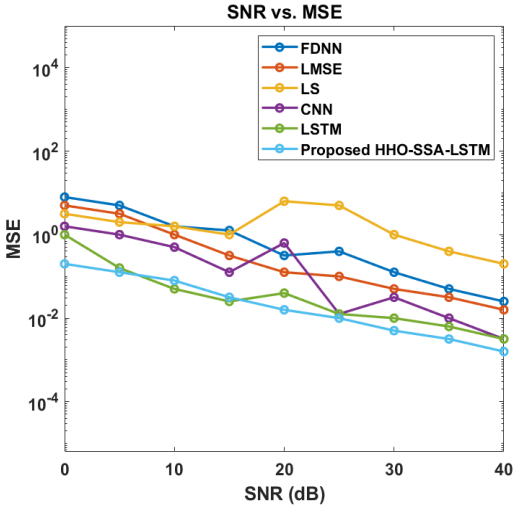
$$BER = {N_S(E)}/{T_N(TS)} \quad (38)$$

Where, $T_N(TS)$ indicates total no. of transferred symbols and $N_B(E)$ indicates no. of symbols in error.



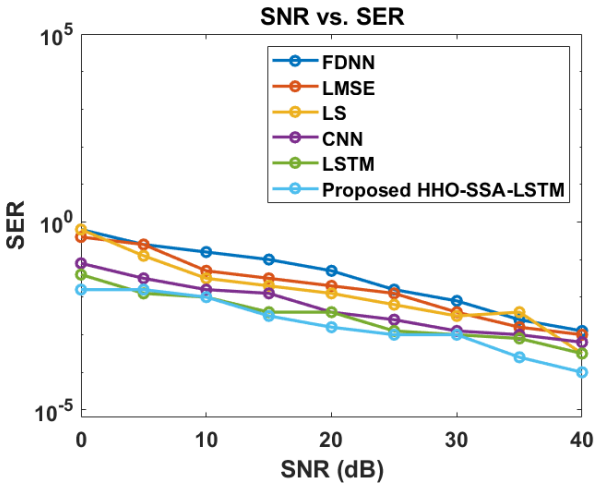
Moreover, BER is computed by Eq. (39).

$$BER = {N_B(E)}/{T_N(TB)} \quad (39)$$



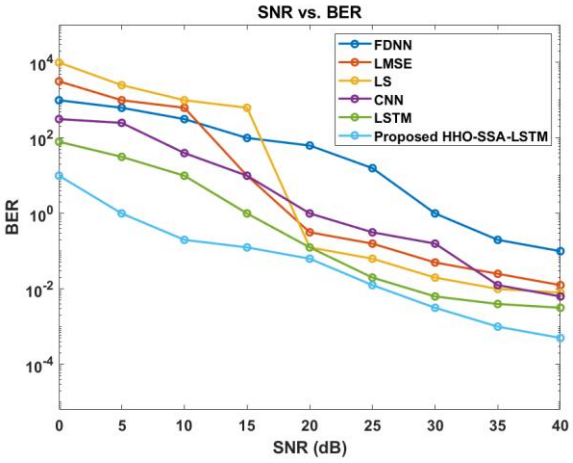
Where, $T_N(TB)$ indicates total no. of transferred bits and $N_B(E)$ indicates no. of bits in error.

- MSE: In statistics, MSE seems to be a measurement of the mean square error. It is an expected value-corresponding risk function. It is random, hence it could hasn't ever be null. It has been always employed in a non-negative context when assessing estimator performance. MSE seems to be a second moment that considers the sources of error as well as estimation variation. An unbiased estimation with invariance of estimate is the MSE. The mean squared variances between the predicted and real values have been used to compute it.

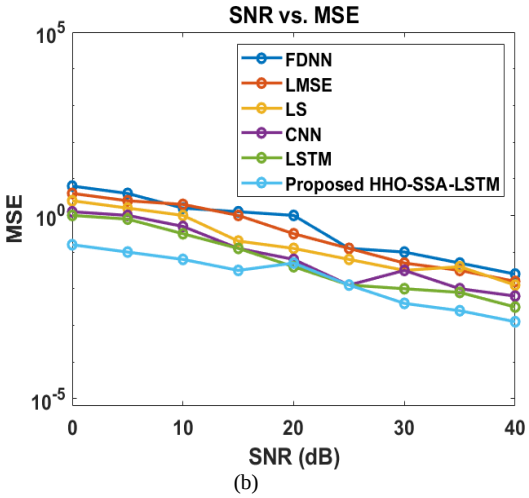


1) Performance evaluation using different pilot lengths: Under several pilot lengths (PL) (i.e., PL =128, 136, and160), the assessment metrics of several channel estimation algorithms are analyzed. Fig. 6 compares the BER, SER, and MSE of several channel estimate algorithms when the PL has been set to 128. As may be seen in Fig. 6 (a), BER (Bit Error Rate) decreases as SNR (Signal to Noise Ration) rises. The LSTM's BER is lowered to 30% less compared to the traditional CNN as long as the weight variables have been chosen for it in the best way possible. However, FDNN has been computationally more efficient than LMSE, and as a result, its BER was 50% lower contrasted to LMSE. In this method, HHO-SSA has been introduced to adjust the weight variables of LSTM in order to produce improved prediction outcome. As a result, the HHO-SSA-LSTM's BER is lower than those of the FDNN, LMSE, LS, CNN, and LSTM by 50%, 75%, 90%, 88%, and 90%, correspondingly.

(a)

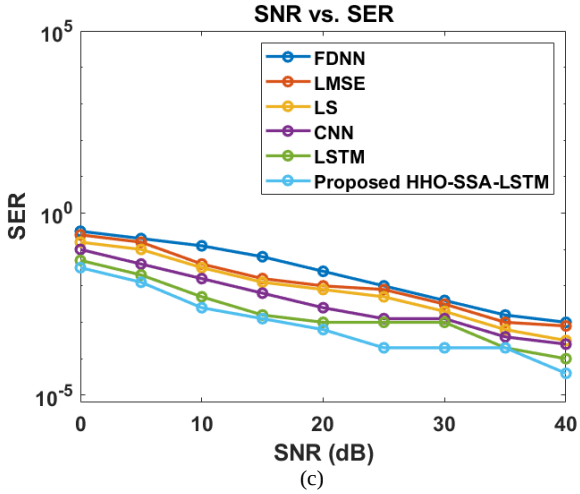


(b)



(c)

Fig. 6. "Performance of different channel estimation algorithms when PL=128 (a) BER vs SNR (b) MSE vs SNR (c) SER vs SNR"



The HHO-SSA-LSTM's MSE (Mean Square Error) is lowered to 40%, 55%, 70%, 85%, and 92% less than that of the FDNN, LMSE, LS, CNN, and LSTM, correspondingly, when PL=128 as demonstrated in Fig. 6 (b). Additionally, as illustrated in Fig. 6 (c), the SER (Symbol Error Rate) of the HHO-SSA-LSTM was lower at PL=128 than it is for the FDNN, LMSE, LS, CNN, and LSTM at 50%, 53%, 64%, 79%, and 82%, correspondingly.

(a)

(b)

(c)

Fig. 7. "Performance of different channel estimation algorithms when PL=136 (a) BER vs. SNR (b) MSE vs. SNR (c) SER vs. SNR"

Fig.7 compares the BER, SER, and MSE of several channel estimate algorithms when PL =136. As may be seen in Fig. 7 (a), BER decreases as SNR rises. The CNN's BER is lowered to 75% less compared to the FDNN; moreover, LMSE's BER is mitigated to 60% than that of CNN. However, LSTM has been computationally more efficient than LS, and as a result, its BER was 25% lower contrasted to LS. In this method, HHO-SSA-LSTM has been introduced to offer improved prediction outcome. As a result, the HHO-SSA-LSTM's BER is lower than those of the all-other methods like FDNN, LMSE, LS, CNN, and LSTM by 20%, 53%, 72%, 80%, and 88%, correspondingly. In addition, HHO-SSA-LSTM's MSE is lowered to 53%, 65%, 72%, 78%, and 85% less than that of the FDNN, LMSE, LS, CNN, and LSTM, respectively, when PL=136 as depicted in Fig. 7 (b). Additionally, as represented in Fig. 7 (c), the SER of the HHO-SSA-LSTM was lower at PL=136 than it is for the FDNN, LMSE, LS, CNN, and LSTM at 65%, 70%, 75%, 89%, and 94%, respectively.

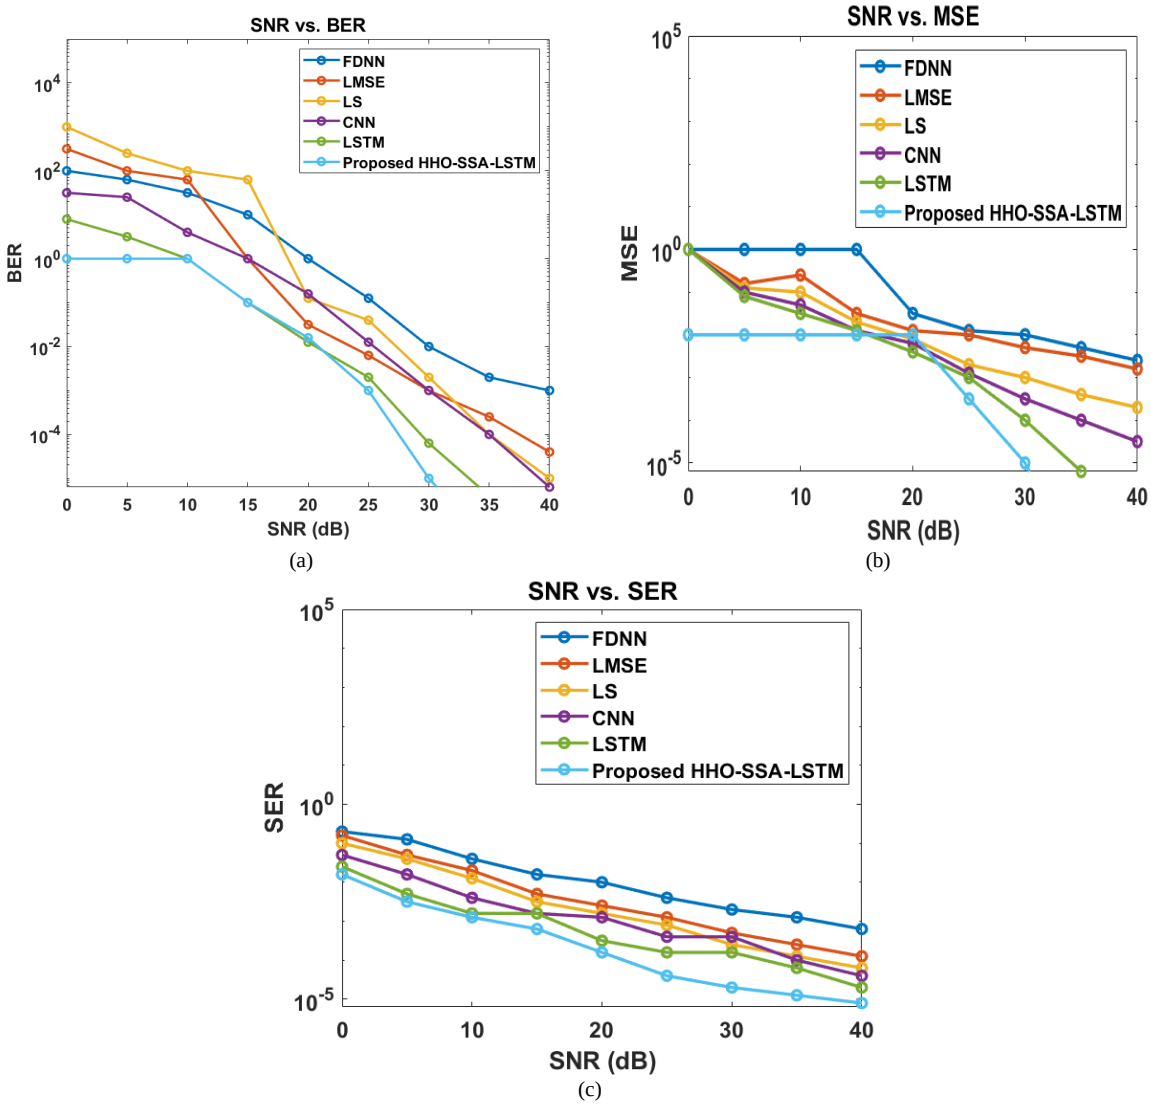


Fig. 8. "Performance of different channel estimation algorithms when PL=160 (a) BER vs. SNR (b) MSE vs. SNR (c) SER vs. SNR".

Fig. 8 compares the BER, SER, and MSE of several channel estimate techniques under the PL=160 condition. As shown in Fig. 8 (a), the BER of HHO-SSA-LSTM was lower than that of FDNN, LS, CNN, LMSE, and LSTM, falling to 76%, 80%, 42%, 83%, and 91%, accordingly. Additionally, as shown in Fig. 8 (b), the MSE of the HHO-SSA-LSTM has been lowered to 73%, 78%, 75%, 80%, and 86%, as opposed to the FDNN, LS, CNN, LMSE, and LSTM, correspondingly. Additionally, as shown in Fig. 8 (c), the SER of the HHO-SSA-LSTM significantly lowered to 58%, 69%, 76%, 84%, and 92%, as opposed to the FDNN, LS, CNN, LMSE, and LSTM, respectively. In addition, the efficiency of the different channel estimation algorithms is also computed for different pilot lengths. Efficiency seems to be the maximum degree of effectiveness that needs the fewest inputs and creates the greatest number of outputs. Efficiency appeals for cutting back on the amount of resources, particularly energy, that are utilized inefficiently to generate a given outcome. Additionally, efficiency seems to be a quantifiable notion that may be assessed by comparing the usable outcome to the entire input.

TABLE II. EFFICIENCY OF HHO-SSA-LSTM OVER FDNN, LSME, LS, CNN, AND LSTM WHEN NUMBER OF PL VARIED

Methods	Efficiency (%)		
	PL = 128	PL = 136	PL = 160
FDNN [36]	85.8	87.64	88.5
LSME [37]	87.7	88.9	90.2
LS [38]	81.1	84.7	87.9
CNN [39]	79.5	84.1	85
LSTM [40]	92.3	94.1	94.91
Proposed HHO-SSA-LSTM	96.41	96.75	96.92

The obtained efficiency is represented in Table II and Fig. 9. The result indicated that the presented HHO-SSA-LSTM has attained higher efficiency under PL = 128, 136, and 160 over other methods. The efficiency of LSTM is increased to 9%, 10%, and 11% than CNN under PL = 128, 136, and 160, respectively. Moreover, when PL = 128, the presented model is enhanced to 11%, 11%, 10%, 9%, and 4% as compared to FDNN, LSME, LS, CNN, and LSTM, respectively. Also, when PL = 136, the presented model is enhanced to 11%, 12%, 10%, 11%, and 2% as compared to FDNN, LSME, LS, CNN, and LSTM, respectively. In addition, when PL = 160, the presented model is enhanced to 12%, 15%, 12%, 11%, and 2% as compared to FDNN, LSME, LS, CNN, and LSTM, correspondingly.

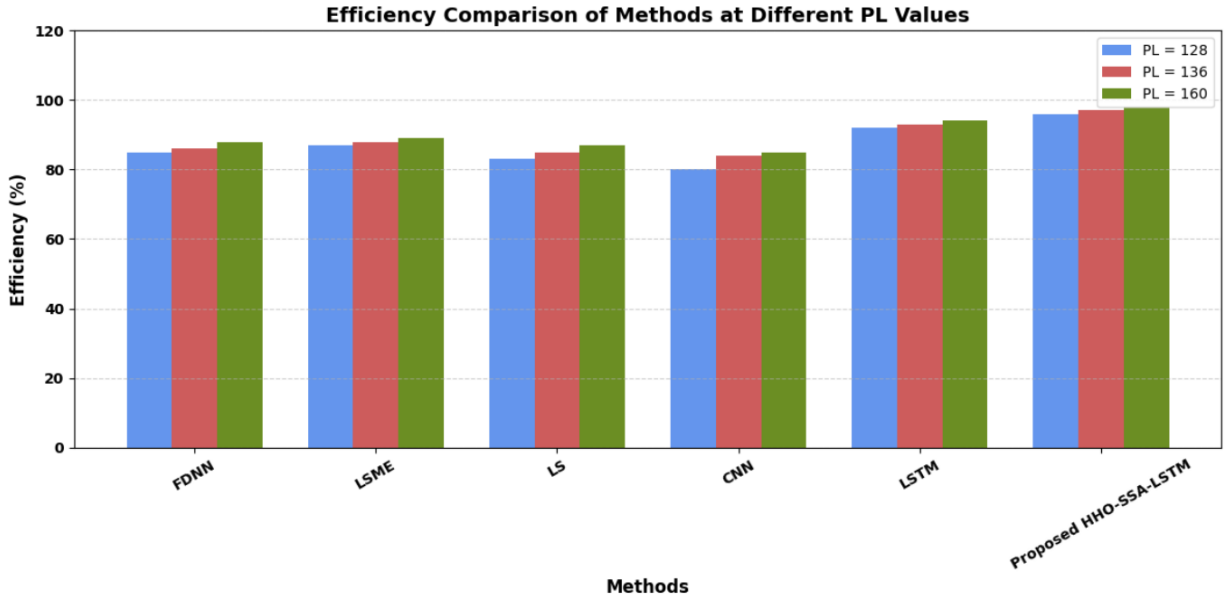

Fig. 9. Efficiency of HHO-SSA-LSTM over other methods.

2) Complexity analysis: The computational assessment of various channel estimate strategies in regards to execution time was shown in Fig. 10 and Table III. Every simulation and execution time measurement was carried out on a system that has an NVIDIA GeForce GTX 1660 Ti GPU, 16 GB of RAM, and an Intel Core i7-10750H CPU running at 2.60GHz. MATLAB R2021b was used for the implementation, and Windows 10 Pro (64-bit) was used. In order to ensure uniformity across all compared models, no GPU acceleration was used during execution time testing. As seen in the table, traditional channel estimation algorithms take longer to execute than DL-based ones due of their computational complexity. However, contrasted to FDNN, LSME, LS, CNN, and LSTM, the given HHO-SSA-LSTM takes a long time to execute. MATLAB's tic and toc functions were used to measure the execution time on a Windows 10 computer running an Intel Core i7-11700 CPU with 32 GB of RAM. After ten runs of each method, the average execution time was noted. Because of its hybrid optimization structure, the suggested HHO-SSA-LSTM model took 22 seconds, which is a little longer than other models. However, this is justified by the fact that it estimates channels with much greater accuracy and efficiency. The computational complexity has grown as a result of the integrated HHO and SSA approaches.

TABLE III. COMPLEXITY ASSESSMENT IN REGARDS TO EXECUTION TIME

Methods	Execution time (sec)
FDNN	21
LSME	18
LS	20
CNN	16
LSTM	10
Proposed HHO-SSA-LSTM	22

Contrasted to the proposed method, the other methods like FDNN, LMSE, LS, CNN, and LSTM has attained less execution time as 21s, 18s, 20s, 16s, and 10s, respectively. Those methods have less complexity due to implementation of single models. However, the presented model was a hybridized method; thus, the execution time was increased than other methods. Moreover, the execution time of the presented HHO-SSA-LSTM is 22s.

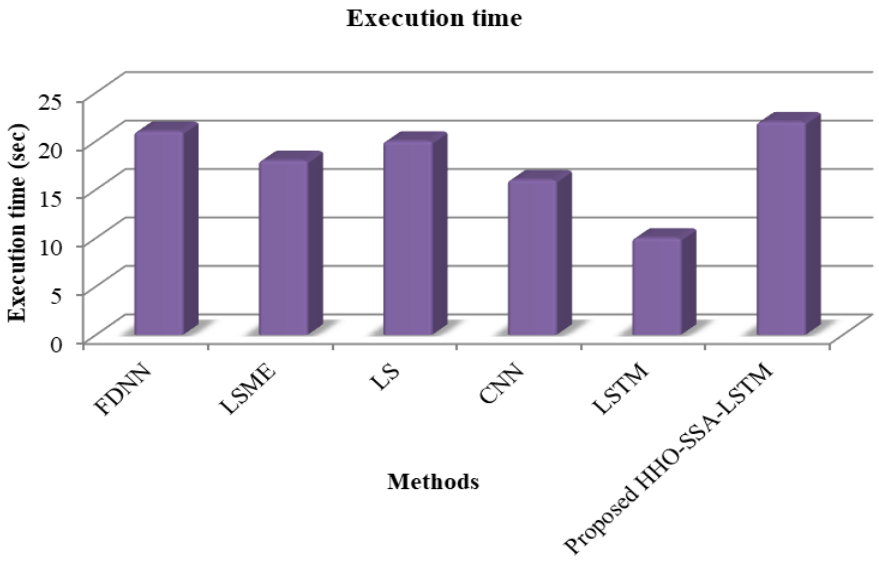

Fig. 10. Execution time.

B. Execution Time Comparison

"The comparative study of the suggested technique with the methods in the prior literature is illustrated in Table IV and Fig. 11. The presented HHO-SSA-LSTM method was compared with other existing methods like Compressive Sensing (CS) [24], OCEAN [41], and PSO-Adam-LSTM [42] in terms of execution time.

TABLE IV. COMPARATIVE ASSESSMENT

Reference	Method	Execution time (s)
[24]	CS	9
[41]	OCEAN	4
[42]	PSO-Adam-LSTM	20
Proposed	HHO-SSA-LSTM	22

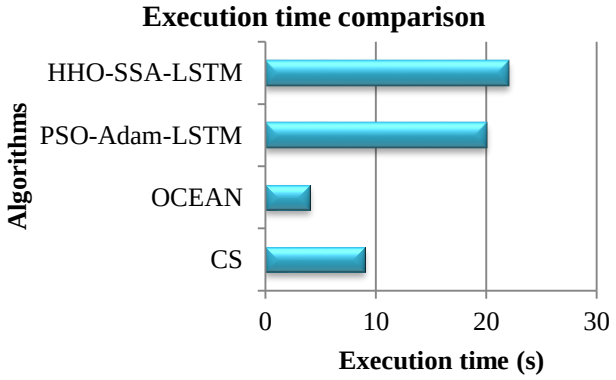

Fig. 11. Execution time comparison.

Haythem Bany Salameh et al. [24] achieved an execution time of 9s, as shown in the table. The researchers obtained highest MSE although execution time was less than the recommended technique. The method put out by Changqing Luo et al. [41] has attained execution time as 4s. Unfortunately, this takes the least amount of time to execute contrasted to the other techniques in the chart. In contrast to the suggested plan, Lipsa and Anand [42] were able to achieve an execution time of 20s. Furthermore, the provided work seems to have a longer execution time than these studies. However, the presented model has attained maximum BER and MSE as less, which is less than the other works.

C. Discussion

The proposed HHO-SSA-LSTM model outperformed traditional and deep learning-based channel estimation techniques—such as LS, LMMSE, CNN, LSTM, and FDNN—on various pilot lengths and signal-to-noise ratio scenarios consistently. The experimental findings showed considerable decreases in BER, SER, and MSE, especially at larger pilot lengths (PL=160), in which the suggested model attained as much as 91% decreased BER and 86% decreased MSE against isolated LSTM. Additionally, the model attained the most efficient estimation, with 96.92%, outperforming even sophisticated DL approaches. While the hybrid model added computational complexity, resulting in the longest execution time (22s), this comes at the expense of the significant improvements in estimation reliability and accuracy [43]. These results have been supported by Mahdi and Deniz [26], who showed that deep learning-based channel estimation models typically have higher execution times because of architectural complexity, comparable to the trade-offs seen in our suggested HHO-SSA-LSTM model, even though they improve accuracy over traditional methods.

The suggested approach is superior despite having a longer execution time because it provides significantly higher accuracy and efficiency, both of which are essential in high-reliability 5G MIMO-OFDM situations. The research presents a compelling argument for the necessity and justification of the trade-off, particularly for applications where accuracy is more important than speed. In comparison with other current benchmark solutions such as CS, OCEAN, and PSO-Adam-LSTM, the proposed scheme represents a reliable solution for channel estimation in 5G MIMO-OFDM systems [44], ideally applicable

for high-reliability and high-capacity communication scenarios. There are several restrictions to take into account, even with the HHO-SSA-LSTM framework's greater accuracy and efficiency. When compared to single-model approaches, the hybrid structure results in longer execution times due to increased computational overhead. Its direct application in real-time or energy-constrained applications may be limited as a result. Additionally, in low-pilot or rapidly changing settings, the model may not always have access to the full channel state information needed for training. The following studies will concentrate on lowering computational complexity to optimize the model for real-time deployment. Additionally, transfer learning and adaptive techniques will be explored to enhance performance in dynamic or low-pilot environments. There will also be consideration of integration with new 6G technologies including THz-band systems and RIS.

V. Conclusion and Future Works

This paper suggested a hybrid deep learning-based channel estimation scheme, HHO-SSA-LSTM, for 5G MIMO-OFDM systems under multi-path fading and Doppler shift. By combining Harris Hawks Optimization and Sparrow Search Algorithm to adjust LSTM parameters, the model showed notably reduced BER, SER, and MSE for various pilot lengths. The performance measurement showed up to 91% BER improvement and 86% MSE reduction in comparison with traditional and deep learning benchmarks like LS, LMMSE, CNN, FDNN, and LSTM. In addition, the novel approach attained maximum efficiency (96.92%) at a pilot size of 160, outperforming the available methods in all instances. The results prove the accuracy and resilience of the HHO-SSA-LSTM technique for practical application scenarios in real-world 5G channel estimation.

Although it has higher accuracy, the proposed model has two primary drawbacks: (1) higher computational complexity leading to longer runtime time (22s) than basic models, and (2) its requirement of a completely known channel profile at training time, which could restrict usability in fast-changing or low-pilot environments. Its computational overhead should be minimized in future studies by developing lightweight variants of the hybrid model for real-time embedded applications. Moreover, being able to extend the model to enable transfer learning and adaptive generalization across various channel conditions will make it more scalable for the next-generation wireless systems, such as 6G and beyond."

***Abstract*—The increased success of deep learning in the radiology imaging domain has significantly advanced automated diagnosis and report generation, aiming to enhance diagnostic precision and clinical decision-making. However, existing methods often struggle to achieve detailed morphological description, resulting in reports that provide only general information without precise clinical specifics and thus fail to meet the stringent interpretability requirements of medical diagnosis. Also, the critical need for transparency in clinical automated systems has catalyzed the emergence of explainable artificial intelligence (XAI) as an essential research frontier. To address these limitations, we propose an explainable system for report generation that leverages semantic-guided alignment and interpretable multimodal deep learning. Our model combines hierarchical semantic feature extraction from medical reports with fine-grained features that guide the model to focus on lesion-relevant visual features and use Concept Activation Vectors (CAVs) to explain how radiological concepts affect report generation. A contrastive multimodal fusion module aligning textual and visual modalities through hierarchical attention and contrastive learning. Finally, an integrated concept activation system that provides transparent explanations by quantifying how radiological concepts influence generated reports. Validation of our approach in comparisons with existing methods indicates a corresponding boost in report quality in terms of clinical accuracy of the description, localization of the lesion, and contextual consistency, positioning our framework as a robust tool for generating more accurate and reliable medical reports.**

Keywords*—Automated report generation; explainable AI; cross-modal fusion; contrastive learning; semantic-guided alignment

I. Introduction

The rapid success of deep learning in the medical domain has created transformative possibilities for improving diagnostic accuracy and clinical decision-making, particularly through AI-powered automated report generation. This solution enhances workflow efficiency, reduces the workload on radiologists, minimizes diagnostic errors, and improves the efficiency of patient treatment [1]. However, the integration of artificial intelligence in radiology has reached a critical inflection point, where diagnostic accuracy must now be matched by clinical interpretability to enable real-world adoption [2].

Recently, the increasing availability of the use of multimodal data in image analysis has created new opportunities for automating the generation of medical reports. Current models rely on multi-modal learning techniques that jointly process both imaging data and textual information [3]. These models perform a comprehensive analysis of medical imaging features alongside their associated clinical narratives, enabling a more thorough interpretation of radiological findings. Through the simultaneous processing of visual patterns and language representations. The combination of these modalities enables the models to effectively leverage both the nuanced features of the medical images and the diagnostic context from the associated text.

Transforming detailed medical images into descriptive text necessitates the accurate detection of anatomical structures, alongside precise identification of lesions based on their morphology and location. Although automated report generation systems have shown significant progress in analyzing chest radiographs [4], their widespread clinical adoption remains limited due to several challenges. Among these, a major barrier is the semantic and granularity gap between imaging modalities and textual descriptions, which leads to imperfect alignment between visual data and generated reports. Additionally, these systems suffer from data bias, as common conditions are often overrepresented in training datasets, whereas rare pathologies are underrepresented, hindering the robustness and generalizability of the models. Furthermore, interpretability continues to be a major challenge in medical applications, as AI models often operate as 'black boxes.' The doctors emphasize the need for transparent models that can provide clear, understandable explanations for their predictions, an essential requirement in medical practice.

Clinical automated systems require transparency, which has led to the creation of explainable artificial intelligence (XAI) becoming an essential research topic [5]. The ability to interpret AI outcomes remains essential for validating diagnostic accuracy while building clinician trust and meeting regulatory requirements [6]. The semantic gap between modalities, the "black-box" nature of deep learning models, and the need for high-fidelity descriptions—motivate the central research question of this work: How can we design a radiology report generation framework that not only achieves high clinical accuracy through fine-grained, semantically-guided alignment between images and text, but also provides transparent, concept-based explanations for its diagnostic outputs to foster clinical trust and adoption? This question guides our development of a novel architecture that simultaneously optimizes for descriptive precision and true model interpretability.

To answer this question, we introduce a new model based on semantic-guided alignment and interpretable multimodal deep learning named Explainable Report Generation Semantic-guided Alignment—Ex-RGSA—which directly uses important

signals and features to advance automated medical reporting. Unlike traditional methods focusing on global visual and textual features, this model emphasizes sensitivity to crucial lesion locations and fine-grained alignment, thereby improving the quality and reliability of generated reports.

Our approach addresses the persistent challenges of aligning visual and textual data, detecting small and rare pathologies, and ensuring the precision of diagnostic terminology. It uses structured semantic knowledge from medical reports. At the start of our framework lies the Explainable Semantic Feature Extractor (X-SFE) module, which consists of two subparts: the Multi-level Text Feature Extraction, capturing multi-level text features at the report, sentence, and word levels. Semantic Guided Knowledge extraction is a sub-part that identifies and encodes structured medical knowledge from historical reports, aiding the model in contextualizing lesion descriptions and refining diagnostic terminology. At the core of our framework lies the Semantic-Aligned Visual Extractor (X-SAVE) module. This mechanism leverages structured semantic knowledge extracted from medical reports to guide the visual extractor to focus on fine-grained lesion details related to the text. Additionally, the Contrastive Multimodal Fusion module (CMF) links visual-textual features anchored by concepts through three stages (global anatomy to regional findings to lesion-specific details). To further refine the generated reports, we introduce a semantic self-refining mechanism in the Decoder module that uses CAV confidence scores to correct terminology errors.

Experimental results demonstrate significant improvements in lesion localization, diagnostic precision, and contextual coherence, underscoring the effectiveness of our framework in generating high-quality medical reports. This positions our approach as a valuable tool for enhancing diagnostic workflows and improving patient outcomes. In summary, this paper presents three main contributions:

1) First, our primary contribution: is a novel trainable architecture for radiology report generation, introducing a new paradigm that significantly enhances multimodal alignment and semantic consistency. A key aspect of this architecture is its ability to improve the detection of small and rare lesions, further ensuring the diagnostic precision achieved by the Explainable Semantic Feature Extractor (X-SFE), the Semantic-Aligned Visual Extractor (X-SAVE), and the Multimodal Fusion (CMF) modules.

2) In the second contribution: we introduce an explainable architecture that fundamentally transforms how multimodal systems process medical data, combining concept activation vectors with hierarchical semantic alignment to produce reports clinicians can trust—unlike current "black box" systems. The framework's unique integration of visual-textual grounding with CAV-based explanations yields not just better performance, but more importantly, delivers the transparent diagnostic reasoning demanded in clinical practice.

3) The last contribution: Demonstrating superior performance on benchmark datasets: experimental results indicate that our framework achieves superior performance on publicly available datasets, with significant improvements in lesion localization, diagnostic precision, and contextual coherence. For instance, our model achieves a BLEU-4 score of 0.189, 0.221 in METHEOR and 0.412 in ROUGE-L on the IU X-RAY dataset, demonstrating a notable improvement compared to the baseline and delivering superior results on this dataset, particularly in handling complex cases with multiple lesions.

The remainder of this paper is organized as follows. A review of related work in explainable AI and multimodal report generation is given in Section II. The architecture of our proposed Ex-ReGSA model, including its main modules, is described in detail in Section III. The experimental setup, including the dataset, evaluation metrics, and implementation specifics, is covered in Section IV. The findings of our comparative and ablation studies are shown in Section V. Section VI, which discusses the results with suggestions for further research, addresses the limitations and wider ramifications of our work.

II. Related Work

The automatic generation of medical reports based on multimodal data has recently attracted much attention. In this field, diverse works are introduced to tackle key challenges, including cross-modal alignment, reducing data bias, and improving clinical relevance. This section shows an overview of related work along four key areas, including (1) multi-modal fusion and (2) explainable artificial intelligence-based report generation.

A. Multimodal Fusion-Based Method for Report Generation

In recent years, several studies have explored the use of multimodal data fusion to improve diagnostic accuracy and report coherence. The method proposed by Tang et al. [7] solves medical report generation challenges by proposing the "locate then generate" CAT pattern. The framework uses a multi-modality encoder combined with a dual-stream decoder to dynamically incorporate retrieved terminologies with preceding sentences. Similarly, the approach proposed by Iqbal et al. [8] improves radiology reporting by utilizing an adaptive multi-modal approach that encodes clinical data elements. The system uses "wisdom learning" to extract medical insights from radiology reports through textual embeddings while applying cross-modal coherence that employs clinical embeddings to direct visual feature learning and enhance semantic alignment between images, disease labels, and generated reports. Li etl. [9] continued to explore diverse data integration. The authors developed a context-enhanced framework to address the shortcomings of image-only dependent systems. The report generation process is improved through their method, which combines multiple contextual elements such as clinical texts, structured medical knowledge, and previous diagnostic outcomes with primary medical images. Zeng et al. [10] ensures that generated reports maintain internal coherence while preserving their contextual integrity. The model utilizes a relational memory module that updates itself with previously generated words to enhance word correlations, as well as a double LSTM network with an interaction module to preserve contextual information during text generation. Tsaniya etl. [11] conduct research on architectural advancements along with

input data enhancements. The authors developed a medical report generator that operates on a transformer-based model. The system integrates text feature embedding through BERT with visual feature extraction from a pre-trained CheXNet model enhanced by multi-head attention to evaluate how contrast-based image enhancement positively influences report quality.

B. XAI-Based Report Generation

Several recent approaches have focused on embedding explainability directly into the architecture of report generation models. Zhang et al. [12] proposed the Attribute Prototype-guided Iterative Scene Graph framework, which utilizes an autoregressive approach for structural edge reasoning to handle common attribute and region feature limitations and improve interpretability. Similarly, Tanida et al. [13] developed an interactive region-guided framework that begins by detecting anatomical regions and then describes key regions to generate medical reports. Chen et al. [14] introduced AdaMatch as a model to establish detailed connections between CXR image segments and medical report terminology; then they used their AdaMatch-Cyclic model to utilize these connections for producing understandable CXR reports, which showed excellent results on public datasets. The development of specialized datasets and models focused on aligning with clinical reasoning is also crucial. One such study [15] introduced the FG-CXR dataset, which provides fine-grained pairings between radiologists' generated captions and corresponding gaze attention heatmaps for specific anatomies. The same study proposed a Gen-XAI network, which simulates diagnostic activities by matching its outputs with radiologist gaze patterns and transcript data. The research by Taleb et al. [16] addresses broader topics beyond report generation. The researchers introduced ContIG as a self-supervised learning method that enables the alignment of medical images and genetic data through contrastive loss and utilizes gradient-based XAI for interpreting cross-modal connections to demonstrate XAI effectiveness on diverse medical data sources. XAI techniques are currently used to improve transparency across multiple diagnostic tasks that involve different data types. For example, Sangnark et al.[17] created an explainable deep learning model to diagnose dyssynergic defecation from abdominal X-rays and questionnaires utilizing cross-modal attention mechanisms with Grad-CAM and DeepSHAP for image and symptom data interpretation. Transparent COVID-19 interpretation research [18] implemented deep neural networks like EfficientNet and DenseNet together with XAI techniques including LIME and Grad-CAM as well as a new "Modified Grad-CAM++."

While existing methods have achieved remarkable performance on multimodal fusion and started to integrate explainability, from our literature review, we identify the following gaps in the existing methods: 1) Many methods use global feature alignment, which neglects the fine-grained, lesion-specific evidence that doctors often need to pay attention to for a detailed and accurate clinical description. 2) Explainability in these methods is often restricted to post-hoc visualizations, such as heatmaps that indicate where the model is looking. While they reveal the localization of model attention, these heatmaps do not offer explanations that are interpretable in terms of well-defined and clinically meaningful concepts, resulting in a "black box" problem that can undermine clinical trust. To address these problems, we employ hierarchical feature extraction and semantic-guided alignment to attend to fine-grained features. Moreover, we introduce Concept Activation Vectors (CAVs) to our model to enable quantifiable and interpretable concept-based explanations of the model prediction.

III. Proposed Method

The overview of our proposed model for enhancing the generation of radiology reports Ex-ReGSA is illustrated in Fig. 1 and comprises four major modules: Explainable Semantic Feature Extractor (X-SFE), which includes Multi-Level Text Feature Extraction and Semantic Guided Knowledge extraction. The second module is the Semantic-Aligned Visual Extractor (X-SAVE), the third module is the Contrastive Multimodal Fusion module (CMF); and the end module is a Dynamic Decoder (DD).

First, the input medical report is processed by the Explainable Semantic Feature Extractor module to extract rich-grained features from the radiology reports through hierarchical attention networks. Subsequently, the Semantic Guided Knowledge Extraction Module is designed to extract relevant semantic knowledge from the fine-grained features obtained by Multi-Level Text Feature Extraction by categorizing similar information into groups that have the same characteristics. Moreover, the Semantic-Aligned Visual Extractor serves to extract visual features from radiology images, guided by semantic output obtained by X-SFE, to ensure that only the important text-based features are captured. The features extracted by X-SFE and X-SAVE then feed into the Contrastive Multimodal Fusion module (CMF), which focuses on aligning semantic association between the extracted fine-grained visual and corresponding multi-level textual features, ensuring cohesive multi-modal representations. Finally, the Dynamic Decoder (DD) module integrates the aligned multi-modal features to generate, in a hierarchical process, a coherent and contextualized radiology report.

A. Explainable Semantic Feature Extraction (X-SFE)

1) Multi-level text feature Extraction: To extract multi-level features from medical report data, hierarchical attention mechanisms based on RadBERT[19], a Bidirectional Encoder Representations from Transformers (BERT) model specifically pre-trained on a large corpus of clinical radiology text, operate at three levels: report, sentence, and word. This approach captures both global diagnostic context and fine-grained clinical details while leveraging RadBERT’s improved pretraining for better representation learning.

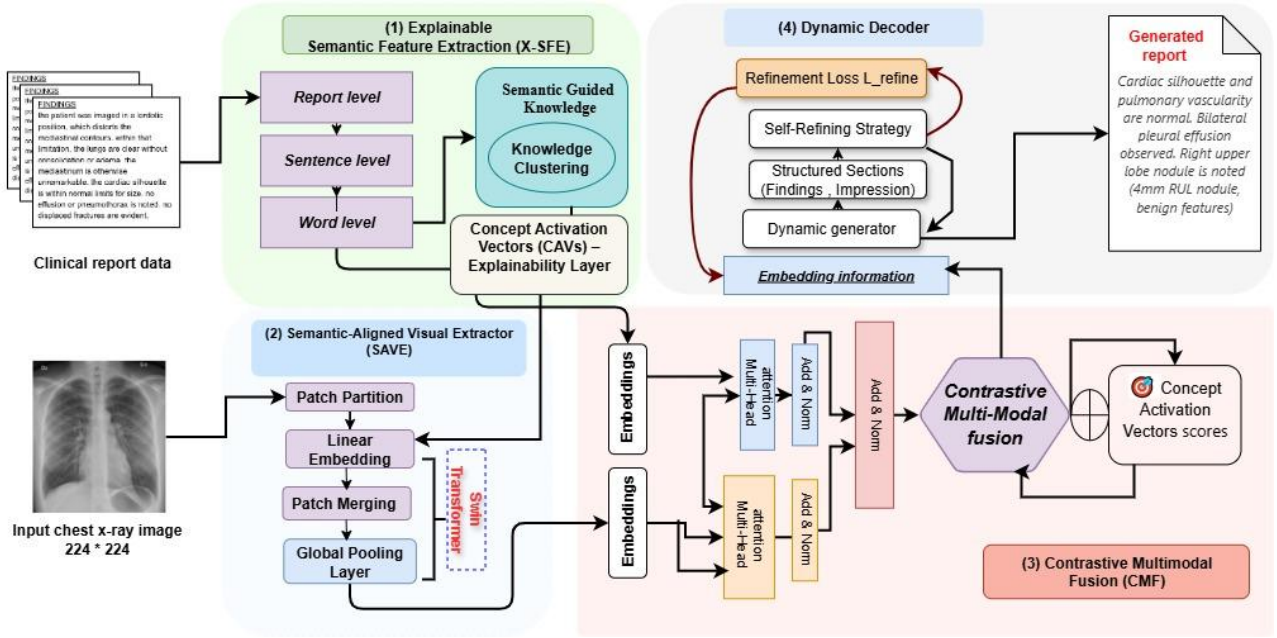

Fig. 1. Overview of the proposed Ex-ReGSA model.

Before robust hierarchical feature extraction can be applied to radiology reports data. They must first pass through an essential preprocessing stage. The process begins with extracting diagnostic sections such as "Findings" and "Impression," followed by text cleaning steps that include lowercasing text while removing unnecessary characters and artifacts. Crucially, the cleaned text, which we can denote as Rclean_text.

The prepared text undergoes processing by RadBERT, which conducts sub-word tokenization and creates foundational embeddings with deep context for all text tokens. The foundational token embeddings enable systematic creation of specialized representations covering all parts of the report down to the individual words and sentences. Converting the text into a sequence of M tokens, $T=\{t_1,t_2,...,t_M\}$. This token sequence T is then comprehensively processed by RadBERT to generate foundational contextual embeddings.

$$H = RadBERT(T) \quad (1)$$

where $H=\{h_1,h_2,...,h_M\}$ is the sequence of final hidden layer states from RadBERT. Each $hj \in R^{dh}$ represents a deeply contextualized embedding for token t_j, where dh is the dimensionality of RadBERT's hidden states. This output H serves as the rich, contextual basis from which all hierarchical features are subsequently derived. For Sentence-Level Feature Representation (Semb), Individual sentences within a clinical report often convey distinct findings or observations. To capture these, sentence-level embeddings, Semb, are derived for each of the N sentences, $S=\{S_1,S_2,...,S_N\}$, in the preprocessed report. For a given sentence Si, its representation $Semb(Si) \in R^{dh}$ is constructed by aggregating the contextual token embeddings $\{h_j \in H\}$ that correspond to the Qi tokens within that specific sentence (denoted $H_{Si}=\{h_{Si},1,...,h_{Si},Q_i\}$). A common aggregation method is mean pooling:

$$S_{emb}(S_i) = \frac{1}{Q_i} = \sum_{q=1}^{Q_i} h_{S_{i,q}} \quad (2)$$

Word embeddings for individual words make up the finest textual feature level Wemb. Word embeddings serve as essential tools for recognizing particular clinical entities as well as their complex meanings in medical reports. The word embedding $W_{emb}(W_k)$ for the k-th word W_k is derived from the RadBERT output H. Since RadBERT's tokenizer may split W_k into L_k sub-word tokens ($T(W_k)=\{t_{k,1},...,t_{k,Lk}\}$), the corresponding contextual token embeddings ($h_{k,1},...,h_{k,Lk}$ from H) are typically aggregated. The most common method is averaging:

$$W_{emb}(W_k) = \frac{1}{L_k} = \sum_{l=1}^{L_k} h_{K,l} \quad (3)$$

2) Semantic guided knowledge extraction: The Semantic Knowledge Module is designed to extract relevant knowledge from chest X-ray reports by categorizing similar information into groups that have the same characteristics. To achieve this, we employ a clustering algorithm on report-embedded representation vectors to group similar information together into several clusters. To quantify the presence and strength of these representations within each report and to guide the clustering process towards forming semantically interpretable groups, we leverage Concept Activation Vectors (CAV) [21]. In particular, given a set of embedding vectors $V = \{v_1, v_2, ..., v_n\}$, the K-Means algorithm [20] is used to group these vectors into groups (clusters), denoted Tk, based on their similarities. This process is defined by minimizing the Euclidean distance between each report's embedding Vi and the centroid Cj of its corresponding cluster. Initialize K centroids randomly, where each centroid mj (for j=1,2,…,K) represents the initial mean of a cluster. This can be expressed as Eq. (4).

$$T_k = \underset{j}{arg,min} \sum_{d=1}^{D} (v_{i,d} - m_{j,d})^2 + \alpha \cdot CAVsim(\text{vi, cj}) \quad (4)$$

Where T_k is the index of the cluster assigned to report v_i and m_j is the centroid, D is the dimensionality of each embedding vector y_i and $y_{i,d}$ and $m_{j,d}$ represent the d-th component of vectors vi and m_j, respectively. After this step, the centroids continue to get refined and updated as the meaning of the embeddings associated to each cluster. This iterative process executes until labeled reports do not change anymore, resulting in k groups of reports, where each cluster encapsulates specific features, like similar writing style or diagnostic terminology. And the function $CAVsim(\text{vi}, \text{cj})$ measuring the semantic or conceptual similarity between report vi and cluster centroid mj, based on their alignment with predefined concepts quantified by CAVs. While the α is a weighting parameter that balances the influence of the Euclidean distance against the CAV-guided conceptual similarity term.

B. Explainable Semantic-Aligned Visual Extractor (X-SAVE)

To reduce the problem of data bias and extract precise spatial and semantic features of disease lesions, we employ a multi-level feature extraction technique that relies heavily on prior knowledge obtained from semantic clusters found within clinical text reports. This guidance aims to align visual regions with relevant textual features and to direct the model's attention towards focal regions based on their semantic relevance, determined through cluster-specific importance signals. The X-SAVE module receives a collection of chest X-ray (CXR) images $X=\{x_1, x_2, \ldots, x_n\}$, where each image x_i is a tensor in $RC\times H\times W$, with C representing the number of channels and H and W representing spatial height and width, respectively. While H = W = 224 for CXR images. The feature extraction process starts by passing the input images through a SwinTransformer [22], which serves as the visual backbone. The Swin Transformer is selected for its effectiveness in computer vision tasks and its inherent hierarchical architecture, which captures features at multiple scales by progressively downsampling the input image. Enabling both localized fine-grained features and global contextual information. The process is illustrated in Eq. (5) to Eq. (7).

*1) Macro-level features (**F1**):* Capturing coarse, global anatomical structures, the image is downsampled by a factor of 4:

$$F1 = \text{SwinTransformer}(X) \tag{5}$$

were, $\mathbf{F1} \in \mathbf{R}^{(C_2\times H/4\times W/4)} = \mathbf{R}^{(C_1\times 56\times 56)}$, the resolution becomes 56 x 56 with C_1 channels.

*2) Intermediate level **(F2)**:* At the second level, highlighting regional characteristics and intermediate structures, the CXR-image is downsampled by another factor of 2:

$$F2 = \text{SwinTransformer}(F1) \tag{6}$$

Where $\mathbf{F2} \in \mathbf{R}^{(C_3\times H/8\times W/8)} = \mathbf{R}^{(C2\times 28\times 28)}$ and the resolution is reduced to 28 × 28, with C_2 channels.

*3) Micro-level features (**F3**):* Detailing fine-grained visual patterns crucial for localizing subtle lesions., The image is downsampled by a factor of 2:

$$F3 = \text{SwinTransformer}(F2) \tag{7}$$

Here $F3 \in R^{(C_4\times H/16\times W/16)} = \mathbf{R}^{(C3\times 14\times 14)}$ and the resolution becomes 14 × 14, and C_3 channels are used.

The key innovation lies in our semantic alignment integrated with the Concept Activation Vectors (CAVs) mechanism, where text-derived clinical concepts from radiology reports are clustered ($T_1,\ldots,T_k$) using RadBERT embeddings, and each cluster's importance weight w_k is computed based on feature dispersion from its centroid m_k to reflect semantic coherence, computed as Eq. (8):

$$wk = \frac{1}{|Tk|}\sum_{i\in Tk}^{n} ||vi - mk||2 \tag{8}$$

Where |Tk| is the number of reports in cluster T_k.

The visual features extracted for each input image x are then aligned with the clusters as follows in Eq. (9):

$$F_{Aligned} = \sum_{k=1}^{K}(wk.\,\text{TCAV}_k).\,Fk \tag{9}$$

where $Fk = Wk \cdot [F2 \oplus F3]$ represents the visual features associated with cluster T_k, and Wk is a learnable projection matrix.

C. Contrastive Multimodal Fusion (CMF)

To apply a hierarchical alignment and fusion, we use a transformer-based model. Current multi-modal fusion approaches rely on global feature fusion. We design multimodal fusion based on self-supervised attention, which comprises two key stages: cross-modal attention and self-supervised contrastive learning. The CMF module learns aligned representations by combining detailed feature interactions with a comprehensive semantic understanding from visual and textual data sources. The system accomplishes this through a unified process that uses hierarchical cross-modal attention mechanisms to map visual and textual features at various scales into detailed correspondences. The features are attentively fused and aligned and then projected into a shared embedding space, which undergoes refinement with a self-supervised contrastive learning objective to ensure robust end-to-end semantic alignment. The system achieves explainability by leveraging Concept Activation Vectors (CAVs) for understanding the semantic characteristics of the shared embedding space.

This initial step within CMF focuses on establishing detailed correspondence between the hierarchically extracted visual features and report features. As previously detailed, hierarchical visual features (F1 for global, F2 for regional, and F3 for fine-grained details) are obtained from the input CXR image. Similarly, hierarchical textual features (Remb for report-level, Semb for sentence-level, and wemb(j) for word-level) are extracted from the medical report.

To bridge representational differences, both feature sets undergo modality-specific normalization and are augmented with positional embeddings. The cross-modal attention then aligns these features.

The normalized and enriched features are then used to compute the queries (Qs), keys (Ks), and values (Vs) directly within the attention mechanism:

$$A_s = Softmax\left(\frac{Q_s K_s^T}{\sqrt{d}} + \log(\text{TCAV} + 1)\right) \tag{10}$$

Where $Q_s = F_{text}^{pos}$: The query matrix is derived from position-enriched textual features. And $K_s = F_{visual}^{pos}$ Is the key matrix derived from the position-enriched visual features. The d is the dimensionality of the key vectors, and serves as a scaling factor to ensure gradient stability in training. By using the attention scores As, the aligned features FS aligned are computed by applying As to the value matrix(Vs), which is also derived from the position-enriched visual features. $F_{aligned}^{s} = A_s V_s$ and $V_s = F_{visual}^{pos}$

The aligned features from all scales are concatenated into a unified representation:

$$F_{fusion}=Concat(F_{1aligned},F_{2aligned},F_{3aligned}) \quad (11)$$

After generating a unified representation (Ffusion), visual features will be projected into a shared latent space through a learnable matrix (Wv): F'visual=Wv.Ffusion and textual features with another one (Wt): F'text=Wtr. These embeddings are refined using multimodal contrastive learning, which optimizes a contrastive loss (Lcontrastive) to align positive pairs, such as a CXR image and its corresponding report, while distancing unrelated pairs. The loss is calculated in Eq. (12) as:

$$L_{contrastive} = -\frac{1}{N}\sum_{i=1}^{N} \log \frac{\exp(sim(F'_{visual,i}, F'_{text,i})/\tau}{\sum_{j=1}^{N} \exp(sim(F'_{visual,i}, F'_{text,j})/\tau} \quad (12)$$

Where sim(x,y) is the cosine similarity, and τ is a temperature parameter controlling the sharpness of the similarity distribution. This end-to-end, self-supervised training paradigm leverages inherent data pairings without requiring manual annotations, ensuring scalability and robust semantic alignment for downstream tasks.

D. Dynamic Decoder (DD)

To overcome critical limitations in existing report generation decoders—such as static templates, neglect of hierarchical features, and lack of dynamic refinement. We propose a novel Dynamic Decoder (DD) that processes multi-level fused visual features (F_{fusion}) in a hierarchical structure. The decoder process uses corresponding report, sentence, and word-level textual embeddings together with fused visual features to construct final reports. A key innovation is its Dynamic Sentence-Type Adaptation mechanism, which uses learned, Concept Activation Vector (CAV)-influenced attention weights (αT,αA) where, for instance, αT is determined by Eq. (13):

$$\boldsymbol{\alpha}T = \sigma(W_T F_{fusion} + \beta \cdot CAVsim(F_{fusion}, c_k)\,,\ \alpha_A = 1 - \alpha_T) \quad (13)$$

Where CAV_{sim}: Measures alignment between fused features and concept c_k. These weights ensure critical abnormalities are prioritized in complex cases, while template sentences dominate in normal cases. The final representation is presented in Eq. (14):

$$Rt=\alpha_T T+\alpha_A A \quad (14)$$

where T represents normal features and A represents abnormal features.

Furthermore, a Feedback-Driven Refinement loop iteratively improves semantic consistency by re-encoding the generated report Y′ and minimizing a refinement loss (L_{refine}) against the input features F_{fusion}, defined as $L_{refine}=\|F_{fusion}-Encoder(Y')\|^2_2$. The DD is trained end-to-end with a hybrid loss function, combining objectives for token accuracy (L_{xe}), feature alignment (L_{refine}), and overall semantic coherence (via $L_{contrastive}$), enabling it to generate clinically accurate, contextually relevant, and professionally structured medical reports:

$$Lrefine : Ltotal=\lambda 1\ Lxe+\lambda 2\ Lcontrastive+\lambda 3\ Lrefine \quad (15)$$

IV. Experimental Settings

A. Dataset

IU X-ray [23]: is a publicly accessible repository of chest X-rays, featuring 7,470 images and their 3,955 associated radiological reports. The nature of this data makes it a valuable asset for developing and training models in tasks such as automated radiology report generation and computer-aided diagnostic systems. To maintain consistency and allow for comparison with prior research, this collection is conventionally divided into standard proportions: 70% of the data for model training, 10% for validation during development, and the remaining 20% for final model testing.

B. Evaluation Metrics

The quality of our model was evaluated using four NLG Natural Language Generation metrics. To measure precision in the generated report compared to ground truth clinical report, we used BLEU [24], which scores n-gram overlap. For an evaluation more aligned with human intuition, we used METEOR [25], as it considers variations like word stems and synonyms from WordNet. To specifically assess the fluency and coherence of the generated content, we employed ROUGE-L [26], which measures similarity based on the longest common subsequence of words found in both the generated and reference texts. Additionally, CIDEr [27] was utilized to assess how well the generated text captures salient concepts present across a set of reference texts, by weighing n-grams based on their Term Frequency-Inverse Document Frequency (TF-IDF) scores, thereby emphasizing consensus and information richness.

C. Implementation Details

Our medical report generation system is built on a hierarchical, multimodal architecture. For visual input, we process 224x224 resolution chest X-rays using a Swin Transformer backbone. This visual encoder uses a patch size of 4, an embedding dimension of 96, and four feature extraction stages with 3, 6, 12, and 24 attention heads, respectively. The text processing component utilizes RadBERT for hierarchical feature extraction at the word, sentence, and document levels, each with a 768-dimensional hidden state for attention. To integrate these, a multimodal fusion module projects both visual and textual features into a shared 128-dimensional space via linear transformations, followed by cross-modal attention with 4 parallel heads. Report generation is handled by a 6-layer transformer decoder (512 hidden units, 8 attention heads) that dynamically regularizes sentence types between templates and abnormal findings. The model was trained for 40 epochs using

a composite loss function—combining cross-entropy (weight 1.0), contrastive loss (weight 0.5, temperature 0.07), and a learned features refinement loss (weight 0.5)—optimized with Adam at a learning rate of 5×10^{-4}. For generating reports (inference), we employ a beam search with a width of 3, using hyperparameters (contrastive temperature τ between 0.05-0.2, loss balancing λ between (0.1-0.9) selected based on ROUGE scores on a validation set.

V. Experiments Results

A. Comparison Experiment

We evaluated our model using standard metrics: we employed BLEU-1 to BLEU-4, METEOR, ROUGE-L, and CIDEr metrics to measure both the quality and relevance of the reports. As shown in Table I and Fig. 2, comparative analysis is performed against state-of-the-art models: The evaluation includes comparisons with advanced models HRGR-Agent[28], R2GEN[29], PPKED [30], AERMNet[10], C-Enhanced-F [9], and work by SAEED et al. [8]. These benchmarks provide thorough assessments of fluency quality along with informative content and clinical consistency.

Analyzing the BLEU scores, which measure n-gram precision against reference texts, our model demonstrates strong performance, particularly for lower-order n-grams. It achieves the highest BLEU-1 score of 0.517, outperforming all listed competitors, including notable models like SAEED et al. (0.499) and C-Enhanced-F (0.491). For higher-order n-grams, our model remains highly competitive: its BLEU-2 score is 0.351, slightly behind C-Enhanced-F, which scored 0.359. Similarly, its BLEU-3 score is 0.251, with C-Enhanced-F at 0.263, and its BLEU-4 score is 0.189, compared to C-Enhanced-F's 0.209. While C-Enhanced-F exhibits an edge in these higher-order BLEU metrics, indicating a closer match in longer contiguous word sequences, our model consistently surpasses other methods like R2GEN and PPKED across all BLEU categories. This suggests a strong grasp of lexical choice and phraseology.

In terms of the METEOR metric, which evaluates generated text quality by considering stemming, synonyms, and word order to better align with human judgment, our model scores 0.221. This is the highest METEOR score among all models for which this metric is reported in the table, surpassing AERMNet (0.219), C-Enhanced-F (0.212), and R2GEN (0.185). This leading performance in METEOR suggests that our model generates reports that are not only accurate in terms of word choice but also capture semantic similarity effectively, aligning well with human assessment criteria.

TABLE I. Performance Comparison

Model	B-1	B-2	B-3	B-4	M.	R-L	CIDEr
[28]	0.438	0.298	0.208	0.151	--	0.322	0.343
[29]	0.451	0.293	0.209	0.159	0.185	0.381	0.406
[30]	0.483	0.315	0.224	0.168	--	0.376	0.365
[10]	0.486	0.321	0.236	0.183	0.219	0.398	0.560
[9]	0.491	0.359	0.263	0.209	0.212	0.408	0.396
[8]	0.499	0.349	0.229	0.170	--	0.401	0.411
(Ours)	0.517	0.351	0.251	0.189	0.221	0.412	0.463

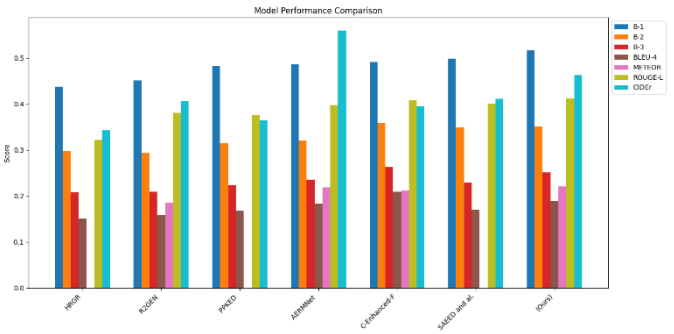

Fig. 2. Performance comparison of models on IU-CXR.

TABLE II. Ablation Experiment

Model	B-1	B-2	B-3	B-4	M.	R-L	CIDEr
Baseline Model	0.405	0.301	0.219	0.168	0.181	0.350	0.392
+ X-SFE	0.413	0.314	0.222	0.172	0.188	0.358	0.409
+ X-SAVE	0.422	0.332	0.239	0.181	0.192	0.373	0.441
+CMF	0.451	0.339	0.243	0.182	0.202	0.398	0.453
+Self-Refining mechanism	0.470	0.349	0.249	0.189	0.214	0.408	0.461
Full Model	0.517	0.351	0.251	0.189	0.221	0.412	0.463

Our model particularly excels in the ROUGE-L score, achieving 0.412. This metric, which measures the longest common subsequence between generated and reference texts, reflects fluency and the recall of important content. Attaining the top score in ROUGE-L indicates our model's superior ability to capture the structural similarity and main ideas present in the ground truth reports when compared to all other listed models, including strong performers like C-Enhanced-F (0.408), SAEED et al. (0.401), and AERMNet (0.398). This suggests that the reports generated by our model are coherent and effectively convey the necessary information.

The CIDEr metric, designed to measure consensus and human-like quality in image descriptions by weighting n-grams using Term Frequency-Inverse Document Frequency (TF-IDF), offers further insights into the model's performance. Our model achieves a CIDEr score of 0.413. This score is competitive and robust, surpassing or closely aligning with several models such as SAEED et al. (0.411), R2GEN (0.406), and C-Enhanced-F (0.396). However, it is noteworthy that AERMNet demonstrates a significantly higher CIDEr score of 0.560. This indicates AERMNet's strong capability in generating text that effectively captures n-grams frequently found across multiple reference

reports, a key aspect of consensus. While our model performs well against many peers in CIDEr, AERMNet sets a high benchmark for this specific measure of quality.

In summary, this comparative analysis reveals that our proposed model exhibits a strong and highly competitive performance profile. It achieves leading results in BLEU-1, METEOR, and ROUGE-L, signifying its strengths in generating lexically precise, semantically rich, and structurally coherent radiology reports. While C-Enhanced-F shows an advantage in higher-order BLEU scores, and AERMNet leads substantially in CIDEr, our model consistently outperforms many established baselines across multiple critical metrics. The particularly strong ROUGE-L and METEOR scores suggest that the generated reports are fluent and capture clinical information effectively, which is paramount for clinical utility. The CIDEr score of 0.413, while not the highest, is solid and points towards good consensus capture. These results collectively affirm the Efficacy of our model as a significant contribution to the field of automated radiology report generation, though future work could explore strategies to further enhance performance on metrics like CIDEr to match the top specialist models.

B. Ablation Experiment

In this section, we will conduct an ablation experiment to indicate the influence of each module on our model's overall performance. The experiments demonstrate the influence of the various components when they are integrated in the baseline model to quantify the gain of each module (X-SFE, X-SAVE, CMF, and DD) and the combination on final accuracy. Table II provides a detailed comparison over multiple evaluation metrics, including B-1, B-2, B-3, B-4, METEOR, and ROUGE-L, for the Indiana University dataset.

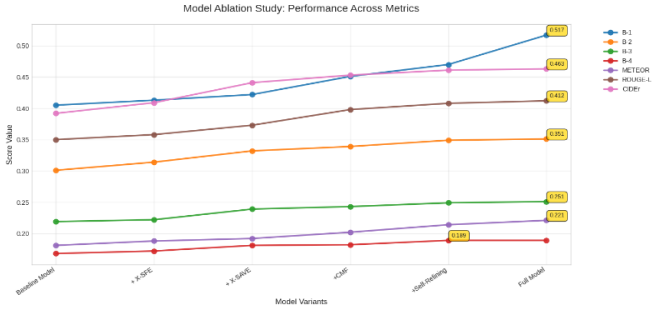

Fig. 3. Performance metrics of ablation study.

Table II and Fig. 3 illustrate that the full model yields substantial performance gains when compared to the baseline model, thereby underscoring the crucial role of every proposed module. Quantitatively, the Full Model surpassed the Baseline by 11.2% on BLEU-1, 5.0% on BLEU-2, 3.2% on BLEU-3, 2.1% on BLEU-4, 4.0% on METEOR, 6.2% on ROUGE-L, and 7.1% on CIDEr. These results indicate a marked improvement in report generation quality due to the additional components. A systematic evaluation of each component's individual effect was subsequently undertaken by comparing the various configurations.

BASELINE: The BASELINE model is a standard Transformer composite of three layers, eight attention heads, and 512 hidden units. This model serves as the starting point to evaluate the impact of additional modules.

+X-SFE (Explainable Semantic Feature Extraction): This configuration adds the explainable text feature extraction module to the baseline model. This component leads to discernible gains across all metrics. For instance, BLEU-1 rises to 0.413, ROUGE-L to 0.358, and notably, CIDEr improves by 1.7%. This suggests that enhancing the model's ability to capture hierarchical relations in the text provides better context and structure for report generation.

+X-SAVE (Explainable Semantic-Aligned Visual Extractor): This module focuses on fine-grained lesion detection. The X-SAVE module guides visual feature extraction using semantic knowledge derived from medical reports. This ensures that the model focuses on clinically significant regions of the image, significantly improving the model's ability to generate precise and accurate medical reports. This module yields more significant boosts, with BLEU-1 reaching 0.422, BLEU-2 improving from 0.314 to 0.332, ROUGE-L increasing to 0.373 (+0.015), and CIDEr showing a strong jump to 0.441 (+0.032). These results underscore the importance of semantic-aligned visual extractors in focusing the model on diagnostically relevant image regions, thereby enhancing the quality and relevance of the generated text, particularly reflected in the CIDEr score.

+CMF Multimodal Fusion module: In this setup, the CMF module is integrated into the model. As shown in Table II, this module improves visual-textual alignment by learning relationships between the two modalities. This leads to better cross-modal understanding, ensuring that both the visual and textual data are appropriately aligned, resulting in more accurate and coherent reports. This addition results in BLEU-1 increasing to 0.451, METEOR to 0.202 (+0.010), and ROUGE-L to 0.398 (+0.025). The CIDEr score also sees a healthy increase to 0.453. These results highlight the importance of multi-level cross-modal alignment in improving the integration of visual and textual data, leading to more accurate and coherent medical report generation.

+Self-refining mechanism: We add a self-refining mechanism strategy in our decoder. As shown in Table II, this configuration substantially outperforms BASE; BLEU-1 reaches 0.470, METEOR improves to 0.214, ROUGE-L to 0.408, and CIDEr to 0.461. This indicates the importance of this configuration in improving the semantic quality of reports that are generated by maintaining consistent and context-dependent terminology.

The full model, which merges all modules into an optimized layout, demonstrates superior performance. The BLEU-1 score reached 0.517, which represents a considerable increase from the former performance at 0.470. The METEOR score achieves 0.221, while ROUGE-L reaches a level of 0.412 and CIDEr advances to 0.463. Transitioning from the "+Self-Refining mechanism" configuration to the "Full Model" generates substantial BLEU-1 improvements and consistent metric gains, which demonstrate that combined optimization of all modules creates a powerful synergy or enables the self-refining process to achieve its maximum potential in this final configuration. The BLEU-4 score maintains a value of 0.189 across the final two

stages because advancements have been concentrated on the text structure and semantic meaning along with lower-order n-gram precision.

C. Visual Analysis

We demonstrated the clinical insight and effectiveness of our Ex-ReGSA model by choosing illustrative cases for qualitative analysis, which appear in Table III. The table presents a side-by-side analysis of the original radiological report against Ex-ReGSA-produced output and the model-derived explanations for its results, which appear within the context of the input radiological image. This visual experiment surpasses quantitative metrics by providing richer insight into Ex-ReGSA's ability to interpret complex clinical narratives and demonstrate its decision-making transparency.

As shown in Table III, the generated report shows a high degree of resemblance in terms of organs and lesion description, signifying the model's capability in encapsulating the intricate relationship between multi-level features in both images and reports. This enables its hierarchical attention mechanisms, which focus on both global and fine-grained details. Additionally, the output report of the case also contains detailed diagnostic details, such as specific characteristics of the referred lesions, which can be attributed to the X-SFE and X-SAVE during hierarchical feature extraction. This guidance enables the model to offer importance on critical areas, improving the clinical relevance of the generated reports. Furthermore, the "Interpretable Explanations" column provides important understanding of how the model arrives at its decisions and processes information internally. These examples illustrate how these explanations combine model-assigned confidence scores of specific findings (e.g., "cardiomegaly score 0.92," "pleural effusion score 0.93") with mentions of key visual features detected by internal components alongside potential semantic knowledge or quantifiers used by the model. Through detailed case-by-case explanations of its operational logic, Ex-ReGSA proves transparent because it shows both its pathologies and normality reports and explains the reasoning behind those conclusions, which builds confidence in its clinical usefulness and reliability.

TABLE III. THE VISUALIZATION OF OUR EX-RGSA MODEL

image	Ground truth	Generated report	Interpretable Explanations
	The heart is normal in size. The lungs are clear without evidence of pleural effusion, pneumothorax, or focal lesions. Bony structures are unremarkable.	Heart size is within normal limits. No pulmonary abnormalities detected lungs are clear bilaterally, with no signs of effusion, pneumothorax, or consolidation.	- The diagnosis of "clear lung fields" achieved a high confidence level of 0.97 because GGO and consolidation features were not present. - The "Normal cardiac size" score of 0.95 reflects that the cardiothoracic ratio falls within the established normal range. - Diffuse attention across both lung parenchyma (avg. intensity ;0.2 per zone), no focal hotspots. - The sharp and clear appearance of the costophrenic angles in visual features confirms the absence of pleural effusion with a high confidence level of 0.98, showing a contrast to typical fluid accumulation characteristics.
	Enlarged cardiac silhouette suggestive of cardiomegaly. Lungs are clear of consolidation, but mild pulmonary vascular congestion is noted, likely due to early congestive changes."	The cardiac silhouette is enlarged. Lungs appear clear . No acute infiltrates observed. Mild vascular congestion inferred from hilar vessel prominence."	- High score for "cardiomegaly" (0.92) as calculated cardiothoracic ratio > 0.55. - "Vascular congestion" score (0.75) from subtle hilar vessel prominence. - Strong focus on lateral cardiac borders (left avg. attention=0.88, right avg. attention=0.85). - Term "mild" for "vascular congestion" selected from "severity quantifiers" cluster - "No acute infiltrates" (confidence 0.90) as lung fields lack dense opacification features, distinguishing from decompensated heart failure.
	Moderate right pleural effusion with associated compressive atelectasis. Left lung parenchyma is normal. No cardiomegaly.	Right-sided pleural effusion is noted (moderate volume) causing obscuration of the costophrenic angle. Left lung remains clear. Cardiac size unremarkable.	- High score for "pleural effusion" (0.93) due to detection of costophrenic angle blunting & meniscus sign on the right. - Focus on right costophrenic angle (attention=0.94) and lateral right pleural lining. - Term "moderate" pulled from cluster "effusion quantifiers", correlated with estimated fluid volume - "Left lung clear" (confidence 0.96) confirmed by sharp left CPA and lack of opacity, ruling out bilateral effusion.

Collectively, Ex-ReGSA demonstrated through representative cases Table III its ability to produce accurate radiology reports that thoroughly include necessary clinical terms and findings from ground truth while maintaining high coherence. The "interpretable and explainable" evidence links generated statements with visual features and advanced analytical components to boost our model's clinical trustworthiness and usefulness.

The necessary degree of transparency supports radiologists by potentially decreasing their reporting workload and enhancing diagnostic speed while functioning as a dependable clinical tool. Ex-ReGSA's architecture demonstrates strong performance across various cases, which highlights its ability to manage different radiological presentations effectively.

VI. Discussion

Our research shows that the Ex-ReGSA model demonstrates robust performance while achieving competitive results in automated radiology report generation, as confirmed by quantitative data and qualitative evaluations along with an insightful ablation study. Ex-ReGSA achieves state-of-the-art or similar scores when compared to existing methods across essential metrics with exceptional performance in all metrics, which indicates high lexical accuracy and semantic depth along with strong structural coherence. Furthermore, the ablation study systematically confirmed the individual and collective contributions of its core architectural modules, namely the X-Semantic Feature Extractor (X-SFE), X-Semantic-Aligned Visual Extractor (X-SAVE), Cross-Modal Fusion (CMF), and the Self-Refining mechanism—each incrementally enhancing report quality towards the Full Model's performance. Complementing these objective scores, our qualitative analysis, showcased in Table III, illustrates Ex-ReGSA's ability to generate clinically relevant and accurate narratives for diverse cases, from identifying chronic conditions to recognizing acute findings such as pleural effusions and even subtle incidentalomas like calcified granulomas.

Ex-ReGSA achieves its strength through a well-designed architecture specifically created to tackle multimodal medical report generation challenges. The collaboration between advanced visual feature extraction methods (X-SFE and X-SAVE) delivers precise identification and interpretation of clinically important image regions. The Cross-Modal Fusion (CMF) module demonstrates essential functionality by combining visual cues with available textual information to create a comprehensive understanding. The output labeled "Interpretable and Explainable" stands out as a major advancement for achieving transparent AI within radiology. The model's decision-making process becomes clear through an analysis of system-detected features along with attention focal points and confidence levels. Ex-ReGSA produces reports while delivering a foundation for interpreting its conclusions. The model's inherent interpretability remains essential for developing clinical confidence and assisting with debugging and refining the model.

When compared to the broader landscape of radiology report generation research, Ex-ReGSA positions itself favorably. Its leading ROUGE-L score, for instance, suggests a superior capability in capturing the essential content and narrative flow of reference reports compared to many existing models. The METEOR score further supports its ability to generate semantically coherent and fluent text. While Ex-ReGSA achieves a solid CIDEr score (0.463 as per the ablation study's Full Model), some specialized models, such as AERMNet (which reported a CIDEr of 0.560 in comparative settings), demonstrate higher performance on this specific consensus-based metric. This suggests that while Ex-ReGSA demonstrates superior performance in report structure and semantic accuracy, it must improve n-gram overlap to maximize CIDEr rewards. While other models focus on single metrics and lack transparency, Ex-ReGSA demonstrates a distinct advantage through its comprehensive capabilities and built-in interpretability features. Therefore, our model, Ex-ReGSA, offers three key advantages over current methods. First, it achieves superior fine-grained accuracy by using a semantic-guided visual extractor (X-SAVE) to focus on specific, subtle lesions that other models miss. Second, it provides truly explainable and trustworthy AI by using Concept Activation Vectors (CAVs) to explain why it makes a diagnosis in quantifiable terms, rather than just showing a heatmap of where it looks. Finally, it ensures enhanced coherence and reliability through a dynamic, self-refining decoder that corrects its output, leading to more logical and professionally structured reports than static generators.

The study achieved promising results but remains limited by certain constraints. Although the IU X-ray dataset serves as a standard benchmark, its limited size and variety fail to capture the full spectrum of clinical scenarios found in worldwide medical practice. Further research is required to understand how the model handles fewer common conditions and complex cases that involve multiple subtle interacting findings. Our CIDEr score competes well but remains behind the field leaders, which demonstrates room for growth in producing reports that match multiple radiologists' preferred terminology. The existing interpretability methods provide valuable insights but represent only one phase in the continuous effort to achieve completely transparent and interactive artificial intelligence.

Future work should focus on several key directions. Addressing the CIDEr gap could involve exploring novel decoding strategies or incorporating more fine-grained common-sense and clinical knowledge into the generation process. Training and validating Ex-ReGSA on larger, more diverse, and multi-institutional datasets would be crucial for assessing its generalizability and robustness. Prospective clinical studies are also essential to evaluate Ex-ReGSA's real-world impact on radiologists' workflow, reporting efficiency, and diagnostic accuracy. Further development of the interpretability framework could involve more interactive explanation modalities, allowing clinicians to query the model's reasoning.

VII. Conclusion

Our research presents Ex-ReGSA as a novel method for automated radiology report generation which combines semantic-guided visual alignment, concept-based explainability via CAVs, and a dynamic self-refining decoder. Our model outperforms the state-of-the-art systems on major evaluation metrics such as ROUGE-L and METEOR, generating medically

accurate and fluent reports that are also interpretable. By explaining its diagnostic decisions in terms that can be quantified, Ex-ReGSA aims to promote transparency and trust in clinical AI, providing a powerful approach to improving diagnostic workflow, reducing radiologist workload, and helping interpretability in clinical decision-making. Although validation is successful, specific limitations are its testing on a single benchmark dataset and the potential to improve consensus-based metrics. Future work will focus on training with larger, multi-institutional datasets and conducting prospective clinical studies to affirm its real-world utility.

3D Reconstruction from JPG Images

Youssif Mohamed Mostafa, Maryam N. Al-Berry, Howida A. Shedeed
Scientific Computing Department-Faculty of Computer and Information Science, Ain Shams University, Cairo, Egypt

***Abstract*—Three-dimensional (3D) reconstruction from two-dimensional (2D) images is a fundamental challenge in computer vision and photogrammetry, with applications in medical imaging, robotics, and augmented reality. This research introduces an image-based modeling pipeline designed to overcome the inherent limitations of Joint Photographic Experts Group (JPEG) images, such as lossy compression and reduced structural fidelity. The proposed hybrid framework integrates photogrammetric methods specifically Structure-from-Motion (SFM) and Dense Stereo Matching with advanced point cloud generation and surface reconstruction techniques. Initially, Marching Cubes was utilized to generate dense point clouds from sequential JPEG slices, followed by Poisson Surface Reconstruction to produce watertight 3D models. Structural details are further enhanced using Structural Similarity index (SSIM) guided texture refinement. Evaluated on the Kaggle Chest CT Segmentation dataset, the method achieves an SSIM score of 0.725, outperforming the JPEG-based reconstruction baseline of 0.675 by 7.4%. In addition to improved accuracy, the study explores the balance between computational cost and reconstruction quality, offering insights relevant to real time and resource constrained applications. By bridging photogrammetry with computer vision, this work advances practical 3D reconstruction from compressed medical images, enabling efficient digitization in low-bandwidth environments.**

Keywords*—*3D reconstruction; photogrammetry; computer vision; image-based modeling; point cloud generation; JPEG images

I. Introduction

Three-dimensional (3D) reconstruction of structures from two-dimensional (2D) images remains a persistent and challenging problem in computer vision, particularly in scenarios where direct 3D acquisition via specialized sensors is either impractical or unavailable. In the medical domain, particularly in diagnostic imaging and surgical planning, the ability to infer 3D anatomy from 2D image data is of critical importance. Classical approaches to this problem are grounded in multi-view geometry and utilize geometric relationships between multiple views to estimate depth, determine camera motion, and recover the underlying spatial structure [1], [2].

The vital components needed to create the 3D reconstructed model are the Red-Green-Blue (RGB) values and the depth map which is considered as the crucial value to reconstruct a watertight model [3]. The depth map contains the distance between the camera viewpoint and the reconstructed surface of the model.

In many clinical workflows, available datasets are stored as JPEG slices in compressed format from Computed Tomography (CT) scans. Although these images offer wide accessibility and storage efficiency, the JPEG format introduces several limitations, including lossy compression, quantization noise, structural artifacts and lack of depth information. Because the more information of the depth of each point in the point cloud, the closer the reconstructed model will be realistic and non-manifold. These issues can adversely affect key stages of the reconstruction pipeline, such as feature detection and matching, depth estimation, and surface extraction, thereby complicating the task of accurate anatomical reconstruction.

In this work, a pipeline for reconstructing 3D anatomical surfaces from JPEG-compressed CT image slices using classical computer vision techniques is proposed. The pipeline begins with robust feature detection and matching across sequential CT slices and masks, by extracting the global bounding box from the masks to extract the point of interest organ across all the CTs and crop them to the exact dimension, followed by camera pose approximation and sparse point cloud generation via SFM [4]. The sparse cloud is then densified using Multi-View Stereo (MVS) to generate a detailed volumetric representation of the anatomical region [5]. To extract a continuous and topologically coherent surface from this volumetric data, the Marching Cubes algorithm is applied [6], which constructs an initial isosurface by interpolating scalar field values across a 3D grid. For further refinement, Poisson Surface Reconstruction is employed [7], which formulates surface recovery as a spatial Poisson problem, enabling the generation of smooth, watertight surfaces that preserve geometric detail and continuity. Finally, face reduction technique is applied to reduce the number of faces and polygons in the model while maintaining a visually similar model according to the SSIM factor.

This study demonstrates that high-quality 3D reconstructions of anatomical structures can be achieved using classical methods, even when relying solely on JPEG-compressed CT images and the estimation of the depth value. The proposed pipeline is evaluated on clinical datasets, highlighting its effectiveness and the trade-offs involved in balancing reconstruction accuracy, computational efficiency, and the limitations of compressed medical imaging data.

The rest of the paper is organized as follows: Section II provides a survey on related works of 3D reconstruction. Section III explains the background and methods used. Section IV details the proposed pipeline, Section V presents the used datasets, experiments, and achieved results. Finally, section VI presents our conclusions and future work directions.

II. Related Work

Many researchers proposed several techniques to contribute to the 3D reconstruction problem either by using deep learning-based methodologies [8], [9], or classical computer vision

techniques [10], [11], [12], [13]. The following introduces a summary of the state-of-the-art methodologies that use classical and deep learning computer vision techniques, since they are more related to the proposed method.

In study [10], the authors started to collect images from the medical field, like CT images, and then improved the quality of the images. Two different methods were used to create the 3D model. The first method, called "volume rendering", was used to scan the CT and MR images. It started from one pixel and produced a steady light beam and scanned each pixel in the image. If the light source is different, the resulting image will be different. The second method, called "surface rendering", used a series of related surfaces from volumed data, and started to extract the outer lines of each slice image. The results demonstrated that the statistical model improved alignment precision and robustness and provided valuable insights for enhancing image-guided diagnosis and interventions in clinical settings.

G. Caravaca *et al.* [11] used 3D reconstruction to simulate the Kimberley outcrop on Mars. They used multiple cameras with different perspectives and camera lenses in different calculated locations to collect images of Gale crater, which contains a lot of geographical terrains. Firstly, they used the cameras that were mounted on the Mars Science Laboratory Rover, known as *Curiosity,* to capture images from Mars' surface. Secondly, they used the captured and collected images from Mars Hans Lens Imager (MAHLI). Finally, they combined the outputs from those two steps in one database. They used 2175 images from the collected images to be passed to a 3D mesh generator to generate a 3D mesh from the overlapped images. The final step was to use those mesh points as an input for a 3D reconstruction software (Agisoft)[1].

In study [12], Siyu Ren and Junhui Hou started with real-world scans like: ScanNet which were fed to Local Geometry representation to get a dense point cloud with un-oriented normal vectors. This dense point cloud was fed to geometry-aware Unsigned Distance Field (UDF) to predict the unsigned distance field, and the last step was to use Edge-based Marching Cubes to generate the output mesh.

In study [8], a method to improve the quality and resolution of CT images was proposed. The method aimed to improve diagnostic precision within the Internet of Health Things (IoHT) framework. They used Convolutional Neural Network (CNN) and 3D reconstruction and super-resolution (SR) to overcome the limitations of low-resolution CT images and make it possible to retrieve finer anatomical information for precise medical analysis. Specifically, the authors integrated a Generative Adversarial Network (GAN) with a Residual Network (ResNet) architecture to effectively upsample and refine CT images while preserving critical structural features. Experimental results demonstrate that the proposed method significantly outperforms traditional interpolation techniques, achieving superior image clarity and resolution as validated by quantitative metrics such as peak signal-to-noise ratio (PSNR) and SSIM.

[1] https://www.agisoft.com/

A. M. I. Mahmoud et al. [9] utilized endoscopic video footage capturing the arteries that supply blood from the heart to the prostate. The video frames were first preprocessed by removing distorted or low-quality images, after which a subset of 30 key frames was selected for analysis. These frames were then enhanced using Adobe Lightroom to reduce noise and improve clarity. Next, a 3D point cloud was generated from the processed frames and converted into a polygonal mesh, forming a detailed 3D model of the arterial structure. This model was used to quantitatively assess the precise volume of prostate tissue that must be removed to optimize blood flow dynamics, to improve vascular stability, and reduce blood pressure.

In study [13], the authors discussed the advancement of 3D CT imaging techniques in thoracic surgery, emphasizing the development of the Resection Process Map (RPM). Traditional 3D CT imaging provided static images, which may not accurately represent the dynamic nature of lung tissues during surgery. To address this, the RPM was developed to generate patient-specific, dynamic 3D images that simulate intraoperative anatomical changes, such as lung deformation due to traction. This semi-automatic system allowed thoracic surgeons to visualize different resection paths and high-quality surgical maps efficiently, enhancing preoperative planning and intraoperative navigation. The RPM demonstrated high accuracy in delineating vascular branches and bronchi, with a median image acquisition time of only 2 minutes, making it a valuable tool in modern thoracic surgical practices.

Recent advances in 3D reconstruction have leveraged various techniques, such as Deep Learning, to improve the quality and the reliability of the reconstructed model, but challenges persist. CNN-based method [8] Have achieved notable results using GANs to generate super-resolution images but often suffer from the lack of ground truth of the reconstructed images and rely on the GAN result image. Additionally, several works including [10] explored to use the CT images to reconstruct the 3D model regards the effect of the background of the CT on the reconstructed model. These limitations highlighted the need for more accurate approaches. In this work, an efficient pipeline that uses the segmented CT images to reconstruct a 3D model from JPG images is proposed.

III. Background and Methods

In this section, the techniques used in the proposed method are discussed.

A. Background

In this section, marching cubes, Poisson surface reconstruction, and face reduction are discussed.

1) Marching cubes algorithm: is a widely used algorithm to extract the polygonal mesh to represent the surface of 3D scalar field. The algorithm processes the voxel grid by comparing the scaler value of the each voxel's corner and the values of user-defined isovalues using a predefined table that represents the possible 256 values of all the configurations of triangle inside the cube, and the triangle of the voxel is generated when the intersection of the voxel and the

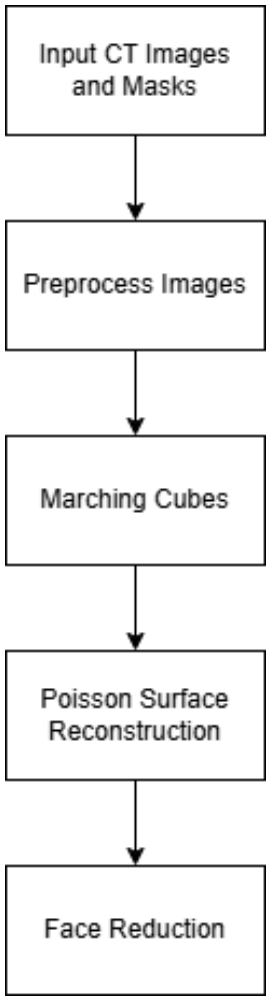
isosurface which lead to approximate the isosurface. For accurate rendering, vertex positions are interpolated along voxel edges, and surface normals are computed via gradient estimation. The key parameter which affect the result of marching cubes algorithm is the isovalue **τ,** as it affects the size of the model and the details generated. It decides the isosurface of the 3D scalar field. As the value of this level decreases (eg. 30 %), more details will be generated, and if the value of the level increases (eg.70%), fewer details will be generated and a less harsh isosurface is obtained.

2) Poisson surface reconstruction: is a powerful technique in 3D graphics that reconstructs smooth, watertight surfaces from oriented point clouds commonly acquired from 3D scanners or depth sensors. Unlike mesh-based approaches, it treats surface reconstruction as a spatial Poisson problem, interpreting input points and their normals as samples of an indicator function's gradient field. By solving this Poisson equation over an adaptive octree structure, the method derives an implicit function whose zero level set robustly defines the output surface. Key advantages include intrinsic noise resilience, efficient handling of large datasets, and topologically guaranteed results (e.g., no holes or self-intersections) [7]. These properties make it indispensable for applications demanding high fidelity, such as reverse engineering, cultural heritage digitization, and medical imaging, where accurate and complete surface models are critical. The key parameter of Poisson surface reconstruction is the depth. As the value of the depth increases, more details will be generated, but it will take more time to be rendered. If the value of the depth decreases, less details will be generated and the rendering will require less time.

3) Face reduction: is a fundamental technique in 3D modeling and computer graphics aimed at reducing the number of polygonal faces in a mesh while retaining its essential shape, visual fidelity, and structural integrity. This process, also called mesh simplification or decimation, is critical for optimizing 3D models in performance-sensitive applications such as video games, virtual reality, and real-time web rendering, where lower computational overhead and efficient memory usage are paramount. Advanced algorithms achieve this by strategically collapsing edges, merging vertices, or clustering polygons, prioritizing geometric features that contribute most to the model's silhouette and surface detail. Popular methods, including edge collapse, vertex clustering, and Quadric Error Metrics (QEM), offer distinct trade-offs: QEM preserves curvature with high accuracy, while clustering enables faster, coarser simplification. The choice of the technique depends on the target balance between computational efficiency, geometric precision, and artistic control over the final mesh [14].

IV. Proposed Method

Fig. 1 shows the architecture of the proposed method. First, pre-processing operations are applied to the input raw CT images. The next two consecutive stages to extract the surface and point cloud: a Marching Cubes stage, which is responsible for edge extraction for each image, and a Poisson Surface Reconstruction stage, which works to extract the mesh and faces from the provided edges. Finally, a face reduction step is used to remove redundant vertices and edges. The following sub-sections highlight the detailed procedure for each phase.



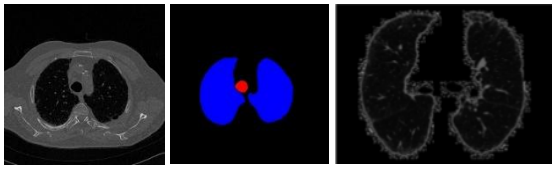


Fig. 1. The proposed annotation pipeline.

A. Preprocessing

The dataset CT images appear in the shape of (W_i, H_i, 3) Where W_i represents the width of the CT slice i, H_i represent the height of CT Slice i and 3 for the three channels of each image (red, green, blue). These input images go through a sequence of pre-processing operations as follows: as shown in Fig. 2, first each slice is processed by applying pixel-wise product with its corresponding mask to extract the image with the organ of interest (in our case the blue labeled organ in Fig. 2). Second, the bounding box is extracted for each slice by calculating its local minimum x-axis value and local maximum x-axis value and the same is done in the y-axis direction as well. The third step is to crop each slice to extract the organ image without the distortion of the background. Finally, all the images are stacked in one 3D array to be used as one unit, and this stack is in the shape of (W_i, H_i, n), where n is the number of slices.

(a) (b) (c)

Fig. 2. Steps for (a) Original image, (b) Mask of the image, (c) Result image after cropping and masking.

B. Point Cloud Extraction

In this step, two algorithms are used consecutively:

1) The first is the marching cubes algorithm: The Marching Cubes algorithm is used to convert the volumetric data provided by the stacked slices into a mesh by interpolating the scalar value. It uses an iso-surface thresholding to separate the tissue of the patient organ from the background to create the surface of the organ.

2) The second algorithm is poisson surface reconstruction: The point cloud provided by the marching cubes algorithm is used to create a smooth, watertight mesh to refine the resulting surface and improve the mesh.

C. Face Reduction Step

In this step the number of the faces generated by the Poisson surface reconstruction algorithm is reduced, as shown in the results section, the number of the vertices and faces in the initial 3D model are too much to be visualize, so the number of the faces of the result model are reduced by removing the non-manifold edges, removing degenerate triangles and finally removing duplicated vertices.

V. Experimental Results

The proposed model is evaluated against a benchmark dataset, which is available on Kaggle platform.

A. Dataset

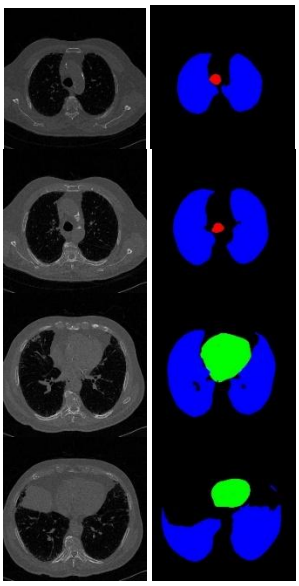
Chest-ct-segmentation[2]: The dataset consists of 16078 CT Slices and 16078 corresponding masks for a total of 114 patients. Each CT image is represented in GrayScale format while its corresponding mask is represented in RGB format. Each channel in the mask is responsible for representing a segment area for its corresponding organ. Red was used for the Trachea, blue for the Lung, and green for the Heart. In the experiments performed, only the blue channel is used as the Lungs of the patient contain a lot of details and also will be easier to visualize.

Each patient has their own number and the CTs for each patient has it's own number like: ID00323637202285211956970-1.

Three different patients were selected, and for each patient, two different organs were reconstructed from the CT scans. The selected organs were the Lung and the Heart. The IDs of the patients selected in the experiments are listed below, along with the number of CT images available in the dataset:

1) ID00323637202285211956970: 258 CT images and the corresponding 258 CT masks.

2) ID00411637202309374271828: 268 CT images and corresponding 268 CT masks.



3) ID00329637202285906759848: 260 CT images and corresponding 260 CT masks.

Each CT image is of 512×512 size, and the corresponding mask is 512×512×3 with each channel having the mask of a spacefic Organ. Fig. 3 shows sample snips from the used dataset.

B. Environmental Settings

The proposed model was implemented using Python 3.8[3] with TensorFlow 2.4 [15] backend and some helper libraries like OpenCV[4], NumPy[5], Open3D[6], scikit-image[7], scikit-learn[8], trimesh[9] and joblib[10].

The Marching Cubes algorithm is used with a level equal to 40 to capture more details and produce a richer model. Depth in the Poisson Surface Reconstruction algorithm is set to 11 to create a more detailed model, but it affects the reconstruction time. Regarding the hardware used, the system was run on Kaggle[11], which has a GPU Tesla P100, and 2 CPUs, 30 GB RAM, and 5 GB as hard drive. Finally, MeshLab[12] open-source software is used to visualize the resulting 3D model.

C. Results and Discussions

1) Experiments: In this section, the model performance is discussed. In the first experiment, we use the Marching Cubes Algorithm only and try to reconstruct the model. In the second experiment we combined the Marching cubes algorithm and Poisson Surface Reconstruction. After that we experimented the whole proposed pipeline in which we get the bounding box of the organ to reduce the size of the input image and its corresponding mask, after that we combine face reduction technique to reduce the redundant vertices and faces. Table I compares the memory cost, time cost, visual evaluation and size of the reconstructed model for the of all the experiments.

As shown in Table I, the proposed method has achieved the minimum size of the reconstructed model, as outlined in the proposed steps. First, the global bounding box of the organ from the CT image masks was extracted using its corresponding channel mask. Second, the CT bounding boxes were stacked in one stack. Third, the projection of the masks on the original CT images in the stack were used to separate the organ from the background and the resulting stack of images utilized as an input for the Marching Cubes algorithm.

TABLE I. COMPARISON RESULTS OF 3D RECONSTRUCTION

Method	Memory Cost (MB)	Time (minutes)	Size of model (MB)	Visual Evaluation
Marching Cubes	680	3	3.87	sparse representation
Marching Cubes + Poisson Surface Reconstruction	1056	7	1200	sparse representation with slice problems
Marching Cubes + Poisson surface reconstruction (with bounding box)	1214	8	400	More dense and detailed, but with a big size and redundant point problem
Marching Cubes + Poisson surface reconstruction with bounding box+ faces reduction (**Proposed**)	2680	15	12.8	Dense and detailed representation

To test the generalization of the proposed model, two different sets of experiments are performed. The first experiment is based on an EDLF-CGAN model in the data set used to extract our model, and in the second experiment the proposed model was applied on the dataset, and the results were evaluated based on peak signal-to-noise ratio (PSNR) in Eq. (1) and structural similarity (SSIM) in Eq. (3).

The PSNR is a statistical analysis indicator that is based on the gray level of image pixels, which is defined by the mean square error (MSE) in Eq. (2) between the original image I (i, j) and the reconstructed image projection from the reconstructed model K (i, j). Generally, the higher the PSNR value is, the better the image restoration is

$$PSNR = 10 \times log_{10}\left(\frac{(2^n - 1)^2}{MSE}\right) \quad (1)$$

$$MSE = \frac{1}{mn}\sum_{i=0}^{m}\sum_{j=0}^{n}\|I(i,j) - K(i,j)\|^2 \quad (2)$$

SSIM is a similarity indicator of two images. The first image is the original image, and the second is the reconstructed image projection from the reconstructed model.

$$SSIM(x,y) = \frac{(2\mu_x\mu_y + C_1)(2\sigma_{xy} + C_2)}{(\mu_x^2 + \mu_y^2 + C_1)(\sigma_x^2 + \sigma_y^2 + C_2)} \quad (3)$$

μ: Average intensity, σ: Standard deviation, σ_{xy}: Cross-correlation. C_1, C_2C_1, C_2: Stability constants.

2) Results: Table II shows the achieved results of those experiments for each patient on the lung segment against EDLF-CGAN [8]. Table III shows the achieved results of the heart segment.

TABLE II. PSNR AND SSIM ON LUNG

Model	PSNR	SSIM
EDLF-CGAN[8] (patient 1)	34.7458	0.541
EDLF-CGAN[8] (patient 2)	34.8461	0.551
EDLF-CGAN[8] (patient 3)	34.7470	0.543
Proposed (Patient 1)	36.6978	0.710
Proposed (Patient 2)	**37.1298**	**0.725**
Proposed (Patient 3)	36.6989	0.715

TABLE III. PSNR AND SSIM ON HEART

Model	PSNR	SSIM
EDLF-CGAN[8] (patient 1)	32.0021	0.422
[8] (patient 2)	32.8991	0.466
EDLF-CGAN[8] (patient 3)	32.0374	0.430
Proposed (Patient 1)	35.1347	0.632
Proposed (Patient 2)	**35.7804**	**0.675**
Proposed (Patient 3)	35.1487	0.638

As shown in Tables II and Table III, the performance of the proposed pipeline shows a significant improvement in SSIM when compared with EDLF-CGAN [8]. This is especially particularly in patient 2 as a slightly higher number of CTs and masks compared to the other patients. On the other hand, the PSNR was slightly improved with no statistically significant change. Additionally, the results of the lung show a slight increase over the heart. This is probably because the lung has a bigger reconstruction surface area and fewer structural discontinuities (such as voids or holes) in the segmentation masks.

In addition to the fact that the proposed method shows a slight enhancement in the time needed to reconstruct the model by about 27%, it also reduces the storage space used by the model by 60%. Fig. 4 shows a sample of the reconstructed models.

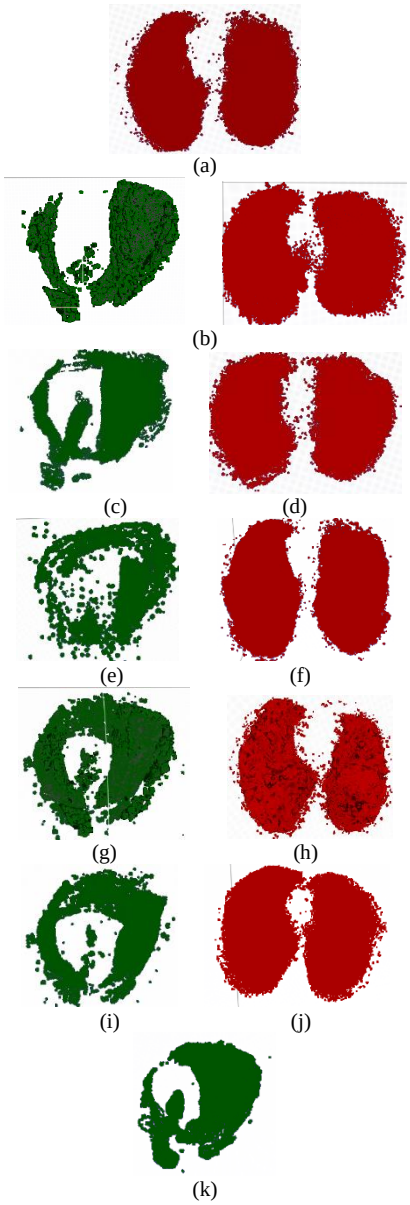

Fig. 4. Examples of models (a) Proposed patient 1 lung, (b) Proposed patient 1 heart, (c) Proposed patient 2 lung, (c) Proposed patient 2 heart, (d) Proposed patient 3 lung, (e) Proposed patient 3 heart, (f) EDLF-CGAN[8] patient 1 lung, (g) EDLF-CGAN[8] patient 1 heart, (h) EDLF-CGAN[8] patient 2 lung, (i) EDLF-CGAN[8] patient 2 heart, (j) EDLF-CGAN[8] patient 3 lung, (k) EDLF-CGAN[8] patient 3 heart.

VI. Conclusion

3D reconstruction is one of the most used fields that has become popular in recent decades. It is used in many applications like medical field applications, civil engineering field applications, games, space discovery, and urban cities reconstruction field. To avoid using learning-based models, this work proposed a traditional pipeline for three-dimensional reconstruction from JPEG-compressed computed tomography (CT) images. The proposed pipeline successfully creates precise and smooth 3D anatomical surfaces by combining Marching Cubes, Multi-View Stereo, Structure-from-Motion, and Poisson Surface Reconstruction. The suggested method shows that classical multi-view geometry and volumetric processing may produce high-quality reconstruction despite the difficulties caused by lossy compression and low depth information in JPEG photos. Results from experiments verify the pipeline's resilience and applicability for medical imaging and visualization applications, particularly when there is only compressed image data available. Even while the suggested pipeline shows encouraging outcomes when it comes to reconstructing 3D anatomical structures from JPEG-compressed CT data, there are still a number of unexplored regions. Future directions may include enhancements in the posture estimation and surface continuity accuracy by advances in feature identification and matching across very comparable CT slices. Second, the negative impacts of JPEG compression may be further reduced by including image preprocessing methods like denoising, contrast enhancement, or artifact correction. Furthermore, the method's generalizability would be enhanced by expanding its support to include additional medical imaging modalities like MRI or PET. Finally, a balance between interpretability and adaptation to intricate anatomical changes may be provided by using hybrid techniques that integrate lightweight, explainable machine learning modules with classical geometry.

***Abstract*—Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia and increases the risk of stroke, heart failure, and mortality. Electrocardiography (ECG) is the most important technology for AF detection because it is inexpensive, non-invasive, and provides clinically useful information. However, the variability of ECG patterns, particularly during paroxysmal AF creates challenges in detecting AF. Artificial Intelligence (AI) offers a promising opportunity to improve AF recognition. However, AI performance is contingent on obtaining high-quality and diverse ECG datasets. This paper presents a focused survey of 15 publicly available and clinical ECG datasets used in AI-driven AF detection research between 2023 and 2025. We analyze the datasets based on acquisition methods, ECG type, format, lead configurations, annotation richness, and their application in AI models. Our comparative analysis reveals major trends, challenges such as data imbalance and motion artifacts, and gaps in current datasets including limited demographic diversity and underrepresentation of wearable ECG data. This study aims to guide future research toward more robust, interpretable, and inclusive AF detection models.**

***Keywords*—Atrial fibrillation; ECG datasets; Artificial Intelligence; AI-ECG; dataset survey; AF detection**

I. Introduction

Atrial fibrillation (AF) is a serious and prevalent cardiac condition characterized by irregular electrical activity in the atria, which can lead to blood clots, stroke, and heart failure [1]. As the global burden of AF rises, early and accurate detection has become critical for timely treatment and risk management. Electrocardiograms (ECGs) serve as the gold standard for detecting AF due to their ability to capture cardiac electrical activity in a fast, non-invasive, and cost-effective manner [2].

In recent years, Artificial Intelligence (AI), particularly machine learning (ML) and deep learning (DL), has shown remarkable performance in analyzing ECG signals to automatically detect AF. However, these AI models depend heavily on the quality, structure, and diversity of the ECG datasets used for training and validation. While previous surveys often focus on AI architectures, little attention has been paid to the ECG datasets themselves.

This paper addresses that gap by providing a focused survey of ECG datasets used in AI-based AF detection. The survey is structured as follows: First, a technical background discusses ECG types for AF diagnosis and highlights commonly used AI technologies. Second, the related work section emphasizes the importance of our survey and outlines our added value compared to existing reviews, which often overlook the role of ECG datasets in AI-based AF diagnosis. Third, we present our methodology for assembling recent studies from 2023-2025 and extracting the datasets used. The survey results follow, organized in two tables: one summarizing the extracted datasets, and the second providing an analysis grid of 12 selected studies detailing preprocessing techniques, AI models, architectures, and performance metrics. Finally, we discuss insights from these results, highlighting trends, challenges, and future research directions.

II. Background

Electrocardiograms (ECGs) record the heart's electrical activity and can be captured using different lead configurations, such as the standard 12-lead or single-lead used in wearable devices. The duration of ECG recordings can vary from seconds to days, with longer recordings, known as Ambulatory ECGs, often obtained via wearable devices. These continuous recordings are particularly useful for detecting paroxysmal atrial fibrillation (AF), which occurs intermittently and may not be captured in shorter ECG sessions. To address this, AI models like Support Vector Machine (SVM), Extreme Gradient Boosting (XGBoost), Convolutional Neural Networks (CNNs), and Long Short-Term Memory Networks (LSTMs) are trained on diverse ECG data, including ambulatory recordings, with recent models incorporating explainable AI (XAI) techniques to improve interpretability and clinical trust [3]. The data can be stored as raw signals or transformed into images for visual or AI-based analysis [4].

III. Related Work

Recent studies have explored AI-based tools for assessing atrial fibrillation (AF) burden, showing high correlation with manual physician assessments. Notably, AI demonstrated strong agreement and minimal bias, offering an efficient and accurate alternative for AF burden evaluation [5]. However, when it comes to AI-driven AF detection, the dataset plays a crucial role in the precision of the diagnosis. The quality, variety, and characteristics of ECG datasets significantly impact the performance of AI models. Despite the growing importance of these datasets, there is a noticeable gap in existing reviews and surveys. Many reviews discuss ECGs from a biometric perspective [6] or focus on ECGs for arrhythmia detection in general, but few address the specifics of AI-based AF detection[7], [8]. My previous review focused on the latest AI

technologies for AF detection [9], but this current work expands by compiling and analyzing the ECG datasets specifically used for AI-driven AF diagnosis. This review aims to fill the gap by highlighting the diverse datasets used in AF detection, which will aid future research in understanding the strengths and limitations of various data sources and model implementations in the field.

IV. METHODOLOGY

To conduct this dataset-oriented survey on atrial fibrillation (AF) detection using artificial intelligence (AI) models applied to electrocardiogram (ECG) data, we followed systematic review principles, inspired by PRISMA guidelines as shown in Fig. 1, to ensure transparency and reproducibility in the selection and analysis of studies. Bibliographic references were collected using the following keywords: "Artificial Intelligence", "AI", "Machine Learning", "ML", "Deep Learning", "DL", "Atrial Fibrillation", "AF", "AFib", "Electrocardiogram", and "ECG". These were queried in several major scientific databases, including Scopus, Science Direct, Web of Science, and IEEE Xplore. As part of the inclusion criteria, we considered only papers that had the core terms in the title, ensuring a strict focus on AF detection using AI applied to ECG data with a total of 304 papers. Additionally, the time frame was restricted to 2023–2025 and limited to 25 June 2025, and only articles published in English were considered. We included only original research articles, conference papers, and technical studies, while review and survey papers were examined separately to identify potential overlaps or gaps but were ultimately excluded from the analysis. All retrieved references were exported into Mendeley for management and screening. After removing duplicates, 81 unique entries remained. During the screening process, papers were excluded if they:

- Focused on physiological signals other than ECG (e.g., PPG or ECHO).
- Studied diseases related to AF rather than AF itself (e.g., stroke outcomes or AF recurrence after catheter ablation).
- Did not report the use of AI techniques for AF detection.

Following the title and abstract screening, 48 papers met the inclusion criteria. In the full-text screening phase, 33 full-text papers were successfully retrieved. After reviewing the literature, it became clear that a lack of standardization in ECG datasets used across AI models was a significant limitation. This prompted a focus on compiling a dataset-oriented survey of ECG datasets for AI-based AF detection. We've selected 33 studies from 2023 to 2025, extracting key information about 15 different ECG datasets. The dataset attributes included ECG type, acquisition method, sample size, format, annotation quality, and availability. To gather this information, we conducted online searches for dataset sources and details, including any risk factors or clinical labels associated with each dataset. The extracted data were organized in Table I, summarizing each dataset's key characteristics and their relevance to AI-based AF detection. This compilation provides a comprehensive overview of the datasets, filling a gap in the current literature.

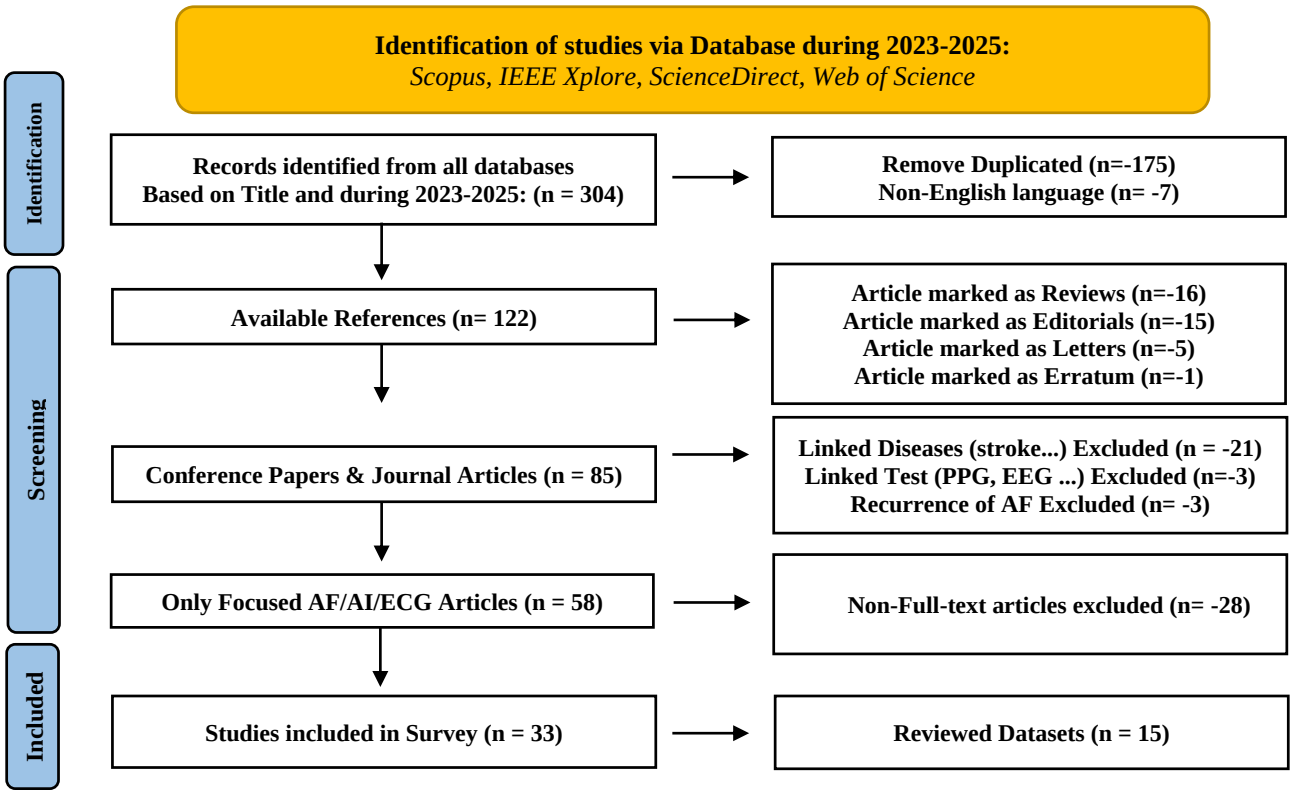

Fig. 1. PRISMA flow diagram representing the paper selection process for the dataset-oriented survey on AI-based Atrial Fibrillation detection.

V. ECG DATASETS LANDSCAPE

Over the past decade, a wide range of ECG datasets have been utilized to develop AI models for Atrial Fibrillation (AF) detection. Table I presents a comparative analysis of 15 ECG datasets that were extracted following the used methodology in section before. These datasets differ significantly in terms of source (public vs. clinical), ECG type (resting vs. ambulatory), number of leads (from single-lead to 15-lead), signal duration (6 seconds to 24 hours), and data format (digital signals, WFDB, MUSE, or image-based ECG scans).

Publicly accessible datasets like PTB-XL, AFDB, MITDB, and the PhysioNet 2017 Challenge have been widely adopted due to their availability and rich rhythm annotations [19], [20], [36], [41]. Clinical datasets such as MUSE, PHYJ, and CNUH, while offering more realistic clinical scenarios, are often inaccessible, limiting reproducibility and external validation[44]. There is growing interest in single-lead and ambulatory ECG datasets, especially for wearable and real-time monitoring applications [36].

In contrast, 12-lead ECGs remain the most common in clinical datasets due to their diagnostic richness [19], [32]. Regarding duration, some datasets contain short snapshots (typically 10 seconds) while others, such as LTAF and MITDB, include long-term ambulatory ECGs suitable for detecting paroxysmal or transient AF episodes. Datasets vary considerably in annotation granularity. Some, like the PhysioNet 2017 Challenge and AFDB, provide beat-level or rhythm-level labels, which are essential for supervised learning. Others, like PTB and CNUH, contain diagnostic summaries but lack detailed temporal annotation, which restricts their use in time-series AF detection tasks. A few datasets offer clinical metadata such as

age, sex, and comorbidities, but this information remains inconsistent and often incomplete, hindering the study of model fairness and demographic generalization. A variety of acquisition devices are represented, including hospital-grade machines, Holter monitors, and portable solutions like KardiaMobile [5], [45]. Additionally, several large-scale, non-public clinical datasets (e.g., from hospitals in the US, Israel, Japan, and the UK Biobank) have been used in recent studies to validate generalization performance across diverse patient populations [46], [47]. One notable example involved over 320,000 ECGs from 130,000+ patients using both Philips and GE systems [48]. These real-world datasets, though inaccessible to the broader community, are essential for robust AF detection, especially in challenging cases such as paroxysmal or asymptomatic AF [40], [41], [49], [50], [51]. Despite recent advancements, the lack of standardized annotations, inconsistent demographic diversity, and limited access to prospective real-world datasets remain key barriers to model development and evaluation

VI. AI Models Landscape for AF Diagnosis

Table II provides a comprehensive overview of 12 representative studies from 2024–2025 that apply AI techniques to ECG datasets for atrial fibrillation (AF) detection. Each entry outlines the dataset used, preprocessing pipeline, model architecture, performance, and key innovations. Together, they illustrate the current state of applied AI in this domain and support a synthesis of prevailing trends, methods, and research directions.

Key Observations:

- **Dominance of Deep Learning (DL):** CNNs remain the most widely adopted models, often serving as backbone architectures in hybrid setups (e.g., CNN-LSTM, CNN-RNN). Lightweight architectures (e.g., MobileNet, ultra-compact CNNs) are increasingly favored in resource-constrained environments like wearables and mobile devices [3][11][21].
- **Rise of hybrid and transformer models:** Hybrid models combining CNNs with LSTMs or GRUs enhance temporal pattern recognition. Transformer-based models are also emerging, particularly in multimodal settings (e.g., ECG + HRV + demographics), demonstrating high AUROC scores (e.g., 0.9668 with VGG-16) [24] [33] [38].
- **Preprocessing pipelines vary widely:** Signal preprocessing includes traditional filtering (e.g., Butterworth, Pan-Tompkins), wavelet transforms (e.g., CWT), and advanced time–frequency representations (e.g., STFT, spectrograms). Some models integrate domain-specific techniques like ECG segmentation (PQRST) or RR interval extraction for feature fusion. [22] [30] [33] [35] [37].
- **Explainability and interpretability:** Explainable AI (XAI) is increasingly used through techniques like Layer-wise Relevance Propagation (LRP), anomaly scoring, and saliency maps. Studies applying LRP or segment-wise analysis provide insights into model behavior and potential diagnostic biomarkers, such as T-wave/ST-segment deviations in paroxysmal AF[3] [33] [34].
- **Dataset-specific adaptations:** Several studies tailor their models to specific datasets public or clinical accounting for noise, class imbalance, and sampling frequency. For example, the use of DBSCAN-GAN for denoising and synthetic augmentation on noisy wearable ECG datasets shows promise for generalization [24].
- **Clinical integration and risk factors:** A subset of studies incorporates demographic features (e.g., age, sex) and electronic health record (EHR)-derived risk scores. This multimodal fusion enhances AF prediction, particularly in identifying paroxysmal AF from normal sinus rhythm, and aligns with real-world deployment needs [31].
- **Performance benchmarks:** Reported metrics span AUROC (up to 0.98), F1-scores (up to 0.99), and accuracy (>96% in some cases). However, performance varies across datasets and is often affected by noise, signal duration, or sampling frequency. Lightweight models maintain high performance with reduced computational cost, enabling deployment in real-time monitoring systems [18].
- **Cross-dataset and external validation:** Some studies emphasize generalization by testing across multiple public datasets (e.g., PTB-XL, MITDB, PhysioNet 2017). However, only a few employs external validation on private clinical data an essential step for real-world readiness [11].

This comparative summary not only emphasizes the practical applications of each dataset, but also reveals methodological trends, current performance benchmarks, and emerging best practices in AI-driven AF detection.

TABLE II. OVERVIEW OF AI MODELS FOR ATRIAL FIBRILLATION DETECTION FROM ECG SIGNALS

Papers	Year	Dataset	Preprocessing Techniques	AI Models Type	Architecture details	Performance Metrics	Key Contribution	Notes
[11]	2025	• CPSC2018 • PTB-XL • Georgia	• Raw ECG; • Feature extraction; • Demographic data (age, sex); • Saliency maps	• Deep Learning: ○ CNNs, ○ RNNs (GRU), ○ Transformers	• AlexNet, • VGG-16, • LeNet, • ResNet, • Inception, • FCN, • GRU, • Transformers	• AUROC: ○ VGG-16 (0.9668), ○ AlexNet (0.9617); • Sensitivity: ~0.9225 with HRV+demo	• Multimodal input (ECG + HRV + demographics) • Improves AF detection; • Simple models outperform complex ones	• Final best performers: AlexNet and VGG-16 due to efficiency, performance, and interpretability • Best performance on PTB-XL; generalizability and label quality vary across datasets
[21]	2025	Physionet challenge 2017	• Bandpass filtering • Short-Time Fourier Transform (STFT) • Reverse polar transform • PanTompkins (P-T) algorithm	• CNN • Ensemble Voting	• Pretrained MobileNet, ResNet50, DenseNet121 • 5-fold cross-validation • Soft and hard voting ensemble	• Accuracy, • Precision, • Recall, • F1-score	• Introduced reverse polar-transformed spectrograms for ECG • Improved AFib detection with better visual representation • Effective use of compact square matrices for CNN input	• Sensitive to signal amplitude and filter type • Well-suited for real-time and wearable ECG analysis
[3]	2025	MUSE	• Feature extraction; • Demographic data (age, sex);	• Deep Learning (CNN)	Not fully disclosed • CNN • Layer wise Relevance Propagation	• AUROC: 0.905 ± 0.00	• Demonstrated ability to predict paroxysmal AF onset from normal sinus rhythm ECGs using deep learning. • Used LRP to identify T-wave/ST abnormalities as key predictors	• Focused on paroxysmal AF prediction. • Applied LRP (Layer-wise Relevance Propagation) for XAI.
[22]	2025	Physionet challenge 2017	• Bnechmark Algorithm • Expert cardiologist review • removal of artifacted ECGs	• Deep Learnig	• Cloud-based AI platform: "The Willem Artificial Intelligence platform" [43] • Trained on >520,000 patients' ECGs; • detects 23+ arrhythmias; • Uses data from: ○ PTB-XL, ○ MIT-BIH, ○ Georgia DB, ○ ESC DB, ○ AHA DB, etc.	• Accuracy: 96.4% • Sensitivity: 84.2% • Specificity: 97.6% • PPV: 78.0% • NPV: 98.4%	• High-performance AF detection from 1-lead ECGs, • Outperforming rule-based algorithms • Real-world deployability	• Detected additional arrhythmias (PVC, PAC, AV block); • Platform was not trained on test ECGs (external validation) • Performance degraded with noise/artifacts
[23]	2025	Physionet challenge 2017	• Raw ECG used directly; • Class imbalance addressed using Neurokit, BioSPPy, and EngZeeMod filters for synthetic data augmentation	• Hybrid DL ○ CNN ○ LSTM	• Ultra-lightweight CNN for feature extraction • LSTM for temporal patterns; • 64.9K parameters; • 0.48 ms inference time	• F1 Score: 99.56%, • Size gain: 102.25 dB, • 1.06% Gain over SOTA	• Introduces a compact, real-time architecture with high accuracy on imbalanced ECG data	• Optimized for speed and embedded applications; • Avoids complex preprocessing

Papers	Year	Dataset	Preprocessing Techniques	AI Models Type	Architecture details	Performance Metrics	Key Contribution	Notes
[17]	2025	PTB-XL	• Coarse graining (1s/0s) • Complexity feature extraction from all 12 leads; • Evaluated each lead and combinations.	• Traditional ML	• Multiple models optimized using Bayesian optimization. • KNN was tuned over 1–99 neighbors (odd values) with 10 distance functions; • SVM models tested with linear, • Quadratic polynomial, • Gaussian kernels. • Leave-one-out cross-validation was used for robust evaluation.	• Peak accuracy ~0.69 at 125 Hz sampling (using lead V6).	• First human application of complexity analysis for detecting a history of PAF from normal sinus rhythm recordings.	Additional experiments at 500 Hz were conducted using various coarse graining techniques: • LZ76 (A), • LZ78 (B), • Titchener (C); also reporting results with configurations: o BD (Beat Detection), o FD (Feature Detection), KM (K-means), o TC (Threshold Crossing) across individual leads and their combination. o KNN outperformed SVM overall.
[30]	2024	PHYJ	• Signal Preprocessing (Filter) • Signal Dimensionality Reduction (SDR); • Kernal Principal Component Analysis (KPCA) for dimensionality reduction; • Wavelet Transform (CWT) for time–frequency domain;	• Deep Learning (CNN)	• AlexNet , • VGG19, • ResNet152 , • Inception-v3, • Inception ResNet-v2	• Accuracy (ACC), • Sensitivity (SEN), • Specificity (SPF) • Cross Validation	• First approach to detect PAF from sinus rhythm ECGs using full 12-lead CWT + KPCA + deep network fusion	• Highlights potential to detect PAF from non-diagnostic ECGs; • Future work aims to scale validation and involve open-access datasets for pretraining
[31]	2024	EHR MUSE	• ECG converted to OMOP-CDM; • Risk factor extraction from ICD codes, Rx, and measurements	• Multiple residual neural network	• ResNet • Random Forest	• AUC = 0.74 (ECG only), • AUC = 0.76 (ECG + 6 RFs); • Stable across age and sex	• Demonstrates that AF can be predicted during sinus rhythm using 1-lead ECG + 6 key risk factors • Model matches 12-lead performance.	• Designed for **real-world deployment** • Reduces **age bias** seen in prior studies Prospective clinical validation planned
[33]	2024	• Chapman • PTB-XL	• ECGs segmented into PreQ, QRS, and PostS • Only Lead II used	• Unsupervised DL: o LSTM Autoencoder o XGBoost	• LSTM-based autoencoder trained on normal ECG segments • Anomaly detection via MSE per segmenT • Postprocessing with XGBoost classifier on anomaly scores	• AUROC (PreQ): o Experiment A: 0.96, o Experiment B: 0.90, o Experiment C: 0.95 • AUROC (XGBoost): 0.98 • F1 Score: 0.94	• Demonstrated explainable, segment-wise anomaly detection of AF without supervision • PreQ segment most predictive of AF	• Cross-dataset validation (Germany/China) • Highlights clinical interpretability by segment-level scores • Addresses physician concerns about DL "black-boxing"

Papers	Year	Dataset	Preprocessing Techniques	AI Models Type	Architecture details	Performance Metrics	Key Contribution	Notes
[24]	2024	Physionet challenge 2017	• Two-stage ECG denoising and filtering • ECG-SQE (signal quality evaluation using Pan-Tompkins based ML) • 9-sec segmentation • Density-Based Spatial Clustering of Applications with Noise (DBSCAN) for outlier filtering	• Deep learning (hybrid)	• MuDANet: Multi-stream CNN-RNN with Dense Attention o Dual-stream Conv-RNN (enhances signal representation o Attention mechanism improves focus on discriminative features o Final classification into AFR, NSR, and Other • DBSCAN-GAN: o Density-based clustering to isolate clean data o GAN trained only on clean samples for synthetic augmentation	• F1 Score: 0.876 (baseline) • F1 Score: 0.962 (with DBSCAN-GAN and 10-fold CV)	• Introduced MuDANet: dual-stream CNN-RNN with dense attention for AF detection. • Proposed DBSCAN-GAN for noise-aware, class balanced synthetic ECG generation. • Demonstrated strong generalization using synthetic data in a noisy real-world dataset.	• Real-time capable and wearable-device friendly • Combines traditional ECG signal cleaning (Pan-Tompkins) with advanced DL and GAN-based augmentation • Overcomes common data imbalance and outlier noise issues in wearable ECG datasets
[35]	2024	CNUH	• PQRST detection and trimming • Baseline correction • 0.5 Hz high-pass Butterworth filter • Segmentation into 10-second intervals • Random under-sampling to reduce class imbalance	• Deep Learning o CNN o LSTM o RNN	• ResNet50: deep CNN architecture with skip connections • RNN and LSTM models for comparison • Training with AdamW optimizer, early stopping, batch size = 32	• ResNet50: o F1 = 71.9% o Recall = 79.3% o Precision = 65.8% o Accuracy = 70.5% o AUC = 0.79 • External set" o F1 = 64.1%, o AUC = 0.68	• Demonstrated that deep learning can detect masked AF from NSR in single-lead mobile ECG	• Study used a private clinical dataset; • High potential for real-world wearable device applications
[38]	2024	• AFDB • LTAF • MITDB • NSRDB	• R-peak detection to compute RR intervals (RRIs) • Removal of poor-quality or noisy data • ECG augmentation via vertical flipping	• Hybrid CNN-LSTM	• Multi-input fusion network combining ECG and RRI features • Res-CNN for morphological features • Bi-LSTM for temporal sequence modeling of RRI • Low complexity design for real-time application	• High accuracy across 4 external datasets • Ablation study validated robustness • Maintains performance with ectopic beats	• Proposed MIF-AFNet: a multi-input fusion model integrating RR interval + ECG features for robust AF detection • High generalization capability across datasets and rhythms	• Limitations: requires ≥30s input; R-peak detection accuracy affects performance; lacks diverse arrhythmias • Future work: clinical validation, enhanced R-peak detection, training on multi-arrhythmia data, improved noise handling

VII. Analysis and Critical Evaluation

Building on the comparative review of ECG datasets and applied AI models, this section critically evaluates key trends, limitations, and methodological patterns observed across recent studies on AF detection.

- **Patterns and bias in dataset usage:** Despite the growing number of ECG datasets, the majority of recent studies rely heavily on PTB-XL, PhysioNet 2017, and AFDB. This over-reliance introduces dataset bias, limiting the generalizability of models to broader clinical populations. Less common datasets, especially clinical ones like MUSE or EHR, are underutilized due to accessibility barriers, despite offering more realistic and varied signals.
- **Dataset limitations affecting model performance:** Several datasets exhibit class imbalance (e.g., fewer AF vs. non-AF samples), requiring oversampling, Synthetic Minority Over-sampling Technique (SMOTE), or weighted loss functions. Wearable ECG datasets often contain motion artifacts and noise, while many collections lack demographic metadata (e.g., age, sex, comorbidities), which hampers model personalization. Only a few datasets integrate clinical risk factors, despite their value in enhancing prediction.
- **Clinical vs. Wearable datasets:** Clinical datasets (e.g., PTB-XL, Chapman) offer clean, high-resolution ECGs from controlled environments. In contrast, wearable datasets enable long-term monitoring but introduce higher noise levels and data variability. Many models perform well on clean datasets but degrade on wearable ones unless robust preprocessing or augmentation is applied. This creates a gap between lab performance and real-world application [33]..
- **Single-lead vs. Multi-lead ECGs:** 12-lead ECGs remain the standard for model development and benchmarking due to their diagnostic richness. However, single-lead ECGs, especially from wearables, are gaining traction for screening. While multi-lead ECGs generally outperform in accuracy, well-designed models using single-lead inputs (e.g., AZ Delta study) demonstrate that simpler signals combined with clinical features can achieve comparable performance, especially in ambulatory settings.
- **Reproducibility and transparency gaps:** Many studies omit details about signal preprocessing, segmentation, or lead selection. Some apply noise filters or augmentation without reproducible descriptions. Additionally, few publish code or preprocessing pipelines, making it difficult to replicate findings or benchmark new approaches. This lack of transparency reduces trust and slows progress.
- **Standout approaches:** A few studies stand out for their innovation. For example, the AZ Delta AF-SR study combined a single-lead ECG during sinus rhythm with six clinical risk factors, achieving strong predictive performance while reducing age-related bias ideal for wearable screening [31]. Another notable work used LSTM autoencoders to detect anomalies in specific ECG segments (PreQ), enhancing interpretability and requiring no labeled AF samples.

Overall, while current approaches show promise, overcoming dataset biases, improving reproducibility, and integrating richer clinical context remain essential for advancing reliable and generalizable AF detection models.

VIII. Discussion and Feature Directions

A. Key Takeaways:

Our analysis of recent AI-based Atrial Fibrillation (AF) detection studies reveals consistent patterns across dataset usage and model development. A key concern is the heavy dependence on a limited set of datasets particularly PTB-XL, PhysioNet 2017, and AFDB while more clinically representative datasets remain underutilized. This trend narrows the scope of model validation and hinders generalizability to real-world scenarios. Moreover, datasets with limited demographic diversity and missing metadata restrict the ability to evaluate models for fairness, particularly across age groups, sex, or comorbidities. Additionally, wearable ECGs, while increasingly relevant for remote monitoring and early AF screening, are still underexplored due to their noisy nature and signal variability. As a result, models often perform well in controlled, clinical conditions but falter when deployed in real-world or ambulatory environments.

B. Gaps and Limitations in Current Approaches:

1) Overfitting to benchmarks: Many models are optimized for performance on a few benchmark datasets, which inflates accuracy metrics but limits cross-dataset robustness.

2) Lack of dataset standardization: Inconsistent data formats, label definitions (e.g., AF types), and missing preprocessing documentation make reproducibility difficult and comparisons unreliable.

3) Fairness blind spots: Absence of demographic and clinical metadata (e.g., sex, age, comorbidities) prevents analysis of bias, reducing the trustworthiness of AI models for sensitive applications.

4) Underutilization of wearable data: Despite their value for long-term monitoring, wearable ECG datasets are rarely used in training or evaluation due to signal quality issues.

5) Reproducibility challenges: Very few studies share their code, training configurations, or preprocessing pipelines, making model replication and clinical translation problematic.

C. Future Research Directions

To address these challenges and unlock the full potential of AI in AF detection, we recommend the following research directions:

1) Standardization and benchmarking needed: Most public datasets vary in signal format, label structure, and metadata availability. Establishing a benchmark framework with unified preprocessing and labeling would allow for fair model comparisons and reproducibility.

2) Underuse of wearable and real-time ECGs: Wearable devices are central to future AF screening strategies, yet few studies utilize real-world data from such sources. Research should focus on noise-robust algorithms and domain adaptation techniques to bridge the performance gap.

3) Explainability still lacking: Explainable AI remains an exception rather than the rule. Future models should incorporate interpretability methods (e.g., attention maps, ECG segment analysis, SHAP values) to support clinical trust and decision-making.

4) Missing demographics and clinical metadata: Datasets should include age, sex, risk factors, and comorbidities to support personalized predictions and fairness assessment. This metadata is crucial for clinical deployment and regulatory validation.

5) Hybrid modeling with clinical context: Few models integrate non-ECG features like EHR data, medication history, or symptom logs. Incorporating these modalities can improve predictive performance and reduce overreliance on limited signal features.

D. Proposed Dataset Guidelines for Future Research

Based on our review, the following dataset practices are strongly encouraged to support future innovation:

- Provide at least 3 leads when possible (e.g., lead I, II, V1) for improved feature richness.
- Share both raw and preprocessed signal versions.
- Use consistent and annotated labels, including AF types (e.g., paroxysmal, persistent).
- Include demographic and clinical metadata (age, sex, comorbidities).
- Ensure public access under a research license to foster collaboration and reproducibility.

IX. CONCLUSION

This survey examined 15 ECG datasets from 33 recent AI models for Atrial Fibrillation (AF) detection studies, revealing a strong reliance on PTB-XL, PhysioNet 2017, and AFDB. While these resources have advanced the field, their overuse, coupled with missing demographic and clinical metadata, limits generalizability and fairness. Our analysis highlights the growing gap between model performance on clean benchmark datasets and the noisy reality of wearable ECGs. We emphasized the importance of dataset quality, transparency in preprocessing, and the inclusion of patient context for real-world readiness. This work represents the first survey focused specifically on datasets in AI-based AF detection. By mapping current usage patterns and limitations, we provide a guide for future research toward more inclusive, robust, and clinically meaningful AI tools. A collaborative push for standardized, annotated, and diverse datasets including wearable ECGs and multimodal data is essential to bridge the gap between lab success and clinical impact.

***Abstract*—Humanity's survival, development, and existence are deeply intertwined with agriculture, the source of most of our food. Plant disease detection helps in securing food, but manual plant disease detection is error-prone and labor-intensive. Convolutional Neural Networks (CNNs) are highly effective for automated plant disease classification, but their difficulty in recognizing differently oriented images means they need large datasets with many variations to work best. Capsule Networks (CapsNets) were developed to overcome the shortcomings of CNNs and can function effectively with smaller datasets. However, CapsNets process every part of an input image, so their performance can suffer when dealing with complex visuals. To tackle this challenge, DLCA-CapsNet was introduced. DLCA-CapsNet integrates a Color Difference Histogram (CDH) layer for key feature extraction, atrous convolution layers to enlarge receptive fields while maintaining spatial details, along with max-pooling, standard convolutional layers, and a dropout layer. The proposed DLCA-CapsNet method was evaluated on datasets including apple, banana, grape, maize, mango, pepper, potato, rice, tomato, as well as CIFAR-10 and Fashion-MNIST. The model demonstrated strong performance with high test accuracies in plant disease detection and on CIFAR-10 and Fashion-MNIST. It improved test accuracies by 6.78%, 14.82%, 6.14%, 5.07%, 21.12%, 40.32%, 4.64%, 0.76%, 10.23%, 13.73%, and 2.03%, while also reducing the number of parameters in millions by 6.16M, 6.16M, 6.16M, 6.16M, 7.14M, 5.68M, 5.92M, 7.62M, 7.62M, and 6.54M respectively when compared with the original CapsNet. On sensitivity, F1-Score, precision, specificity, Receiver Operating Characteristics, Precision-Recall values, accuracy, disk size, and parameters generated, etc., the DLCA-CapsNet achieved better performance compared to the original CapsNet and other advanced CapsNets reported in the literature. The findings suggest that this efficient and computationally less demanding method can significantly enhance plant disease classification and contribute incrementally to efforts aligned with the SDG 2 goal by offering a lightweight, scalable solution that can be adapted for field use in resource-constrained settings.**

I. INTRODUCTION

Agriculture has consistently been a crucial social and economic sector for humanity. The production of food is particularly critical, with high demand from every household. As a result, employing innovative technologies to improve the sector is essential for the agri-food industry. Today, artificial intelligence stands out as a significant technological tool extensively utilized in contemporary society. Specifically, Deep Learning (DL) has numerous applications owing to its capability to learn strong representations from images [1] [2] [3].

CNNs are the primary DL architecture for image classification, primarily due to the significant attention they have received in recent years. Multiple CNN architectures have been developed to enhance their performance. However, traditional CNNs still have many limitations. They do not emphasize the arrangement or spatial connections among the components of the image, so they require extensive datasets in various variations to achieve high performance [4], which results in the augmentation of data [5] [6].

To address this issue, a novel architecture named CapsNet, which mimics the human brain, has been introduced for extracting information from images [7]. Despite their numerous advantages, such as performing well with fewer data, CapsNets try to identify every object in an image, which reduces their ability to generalize effectively, especially on unseen and complex images [8][9][10]. To address the issues with CapsNet, researchers sometimes deepen and widen their models, resulting in longer training times and more parameters. Moreover, increasing the CapsNet model depth does not necessarily improve performance. Selecting efficient feature extractors for the encoder network is crucial for enhancing the CapsNet model's performance. Therefore, this study seeks to answer the following research questions:

- Can a well-performing CapsNet be designed to perform well on plant diseases and complex images?
- Can good feature extractors be incorporated into the CapsNet to improve the encoder network for better feature extraction of the CapsNet Model?
- How can we explain the "black box" phenomenon of this AI model to enhance comprehension of the model and confidence in the model's output?
- Can the CapsNet model be optimized to make it deployable on resource-constrained devices?

This study suggests a low-parameterized shallow CapsNet with efficient feature extraction abilities to help classify plant diseases efficiently using CDH [11] and atrous convolutions [12] [13]. Results from experiments conducted on 11 publicly accessible datasets demonstrate that the proposed DLCA-CapsNet model performs on par with the most advanced models available for detecting complex images and other plant diseases.

The visualization of class capsule clusters, activation maps, and reconstructed images demonstrates the superior efficiency of the feature extractors of DLCA-CapsNet compared to the feature extraction capabilities found in the traditional CapsNet model.

This study's contributions are:

- A novel and well-performing CapsNet design named DLCA-CapsNet is introduced.
- CDH is utilized to extract significant features in CapsNet models. Additionally, the DLCA-CapsNet employs atrous convolution to enhance spatial representation.
- We conducted thorough visualizations of plant diseases and other datasets to enhance the explainable artificial intelligence (XAI) field.
- The DLCA-CapsNet model generated fewer parameters and had a smaller size, enhancing its suitability for deployment on devices with limited resources.

The remainder of the paper is structured as follows: Section II reviews related literature, Section III outlines the methodology employed, Section IV discusses the experimental results, and Section V provides the conclusion and suggestions for future research.

II. Related Works

A. Introduction

In recent years, plant disease detection has emerged as a crucial area of research in agriculture, meeting the demand for timely and precise diagnosis to ensure crop health and productivity. CNNs have been widely used in this domain, demonstrating notable success in image classification tasks compared to CapsNet. This section reviews the advancements and applications of Capsule networks for plant disease detection, highlighting their effectiveness in improving detection accuracy and generalisation.

B. Review of CapsNet for Plant Disease Detection in Literature

Mensah et al. proposed combining CapsNet and Gabor to detect deformed and unclear diseases in citrus and tomatoes, utilising the PlantVillage dataset. Their system attained 93.33% validation accuracy for classifying citrus diseases and 98.13% with 12 million parameters for classifying tomato diseases [14]. Verma and their team created an optimized technique for computing features by leveraging Squeeze and Excitation (SE) Networks. These networks are applied before the original CapsNet in the classification process to assess the severity of plant diseases. They incorporated AlexNet and ResNet into CapsNet to get two SE CapsNets. They used a tomato dataset from PlantVillage and classified Late Blight diseases into late, middle, early, and healthy stages. The SE-ALexNet CapsNet had 9 million parameters with an accuracy of 92.1%, and SE-Res CapsNet had 19 million parameters with an accuracy of 93.75% [15]. Vasudevan and Karthick proposed a composite technique for detecting grape diseases. They obtain a leaf area by utilizing a method based on a graph. To augment the dataset, they employ a Generative Adversarial Network. Although the model was computationally complex, it attained a validation accuracy of 97.63% on diseases in grapes using captured data and data from the PlantVillage dataset [16]. Xu et al. proposed a model, combining CapsNet with inception modules to amplify receptive fields using diverse dilation rates. This helps to improve the multi-level characteristics of diseases in apple leaves. The model attained 93.16% validation accuracy [17]. Mensah et al. introduced a model by replacing sigmoid with SoftMax, CNN with Local Binary Pattern, and dynamic routing with k-means routing. Experimentally on CIFAR-10, fashion-MNIST, MNIST, citrus, maize, and tomato, 75.80%, 92.72%, 99.68%, 99.41%, 96.79%, and 98.06% validation accuracies were attained, generating 5.2 million for CIFAR-10, 2.8 million parameters for fashion MNIST and MNIST, and 8.4 million for tomato and citrus [18]. Verma and co-authors used the conventional CapsNet to classify potato leaf images from the PlantVillage dataset. The experimental results reveal 9,856,768 parameters produced by the model and 91.83% validation accuracy attained [19]. Oladejo and Ademola classified banana diseases by proposing a CapsNet model, in which they changed the neuron number in the fully connected layer of the original CapsNet to two 512 and 1024 instead of 3, hence reducing the time for training the network. Also, they used an optimizer for momentum to upgrade the network processing speed. On banana leaf disease detection, the model attained a validation accuracy of 95% [20]. Atlan changed the traditional CapsNet model by adjusting the three fully connected layers to 960, 768, and 4096. On assessing the model, it gained a sensitivity of 96.37%, an accuracy of 95.76%, and a specificity of 97.49% when used to classify bell pepper diseases [21]. Mensah and colleagues chose to use the Gabor filter rather than CNNs. This change allowed the initial layers to capture spatial and texture relationships, improving overall performance. Max Pooling was used to select the most important features after the Gabor filter convolution, reducing the feature vectors' dimensionality. Tests conducted on tomato datasets from plant villages showed a validation accuracy of 97.98%, with a total parameter count of 8,708,128 [22]. Anant suggested a technique called AppleCaps that overcomes the spatial invariance issue discovered in CNNs. The model gained 87.06% accuracy on an augmented dataset containing diseased apple leaves [23]. Mensah et al. proposed a CapsNet model that uses dual input. The output from these inputs is merged and submitted to the layers of the original CapsNet. Upon assessing the system on the tomato and CIFAR-10 datasets, it generated 5.48 million (M) and 6.04 M parameters and 76.58% and 93.03% validation accuracies, respectively [24]. Peker suggested a CapsNet that uses multiple ensemble channels by implementing different CapsNet models on images with various pre-processing methods. By merging the networks to learn diverse features from data, the model increases in performance and attains 98.15% on 10 disease classes of the tomato dataset [25]. Abouelmagd and colleagues developed a computer vision approach using an improved CapsNet to recognize and categorize ten distinct diseases affecting tomato leaves from standard datasets. To minimize overfitting, they employed pre-processing and data augmentation approaches when training. Their CapsNet method achieved an accuracy of 96.39% [26]. Zang and colleagues proposed a method for detecting plant leaf diseases by combining residual networks (ResNet) and CapsNet. They improved the traditional ResNet by replacing the kernel with a set of 3×3 convolutional kernels and

incorporating an attention mechanism to guide the model in prioritizing important features. The upgraded ResNet was then integrated with CapsNet. This combined model, SE-SK-CapResNet, achieved accuracy rates of 98.58%, 97.19%, and 95.08% on the PlantVillage, Tomato Leaf Disease, and AI Challenger 2018 datasets, respectively [27]. Mensah and co-authors proposed Shallow and Multi-input CapsNets. The shallow CapsNet used LBP, the squash function, and a normalizer in the standard CapsNet model. The model was assessed on datasets, CIFAR-10, fashion-MNIST, and tomato, and achieved validation accuracies of 75.75%, 92.70%, and 97.33% with 4.6M, 2.5 M, and 4.1M parameters, respectively. Furthermore, the multi-input CapsNet merged the results of three (3) convolution layers before feeding them to the standard CapsNet model. The model was also assessed on the same dataset as shallow CapsNet and attained validation accuracies of 63.95 %, 91.45%, and 94.04% with 4.3 M, 2.2 M, and 4.0 M parameters, respectively [28]. Andrushia and co-authors proposed a technique for classifying grape leaf diseases by inserting convolution layers before the primary capsules. This resulted in speeding up the dynamic process by reducing the number of capsules. On both the non-augmented and augmented grape leaf disease datasets from PlantVillage, the model achieved 99.12% accuracy [29].

C. Summary

These models have performed well on different plant disease datasets. Still, these current CapsNet models for plant disease identification are often limited by scalability, processing speed, many parameters, large size, and robustness to complex backgrounds. Developing a more advanced CapsNet model could enhance accuracy, improve generalization, reduce parameter count and size on disk, and ultimately aid in more effective crop management.

III. Methodology

A. Capsule Network

Unlike CNNs, CapsNets [7] can identify orientation, texture, and pose. In CapsNets, neurons are organised into capsules, each of which has an activity vector that encodes different instantiation parameters for detecting a specific object type. These capsules provide a probability of the object's presence and its generalised pose. Capsules receive these activity vectors from the capsules in the preceding layer, and the connections between these layers, called coupling coefficients, have varying values. If the present capsule identifies a dense cluster of earlier predictions, strongly suggesting the object's presence, it generates a high probability, a process referred to as routing by agreement. Therefore, if the lower layer capsule's prediction aligns with the current capsule's real output, the coefficient among them rises, calculated using the softmax function as illustrated in Eq. (1).

$$\hat{u}_{j|i} = W_{ij} u_i \qquad (1)$$

Where $\hat{u}_{j|i}$ represents the j^{th} capsule output or prediction vector, W_{ij} and u_i denote the weight matrix and output vector of the capsule i in the lower-level layer, respectively. Coupling coefficients are determined through the softmax function in Eq. (2), reflecting the level of alignment between capsules in adjacent layers.

$$C_{ij} = \frac{\exp(b_{ij})}{\sum_k \exp(b_{ik})} \qquad (2)$$

Here, b_{ij} represents the probability amongst the two (2) capsules based on logarithmic values, set to zero. The j^{th} capsules input vector s_j is determined as in Eq. (3),

$$s_j = \sum_{i=1}^{N} c_{ij} \,.\, \hat{u}_{j|i} \qquad (3)$$

Ultimately, the subsequent squash function in Eq. (4) is utilised to confine the output within the range of 0 to 1.

$$v_j = \frac{||s_j||^2}{1+||s_j||^2} \frac{s_j}{||s_j||} \qquad (4)$$

Eq. (5) calculates the loss function for the capsules in the final layer. Here, T_k equals 1 if class k is active, and 0 if otherwise. The values of λ, m^-, and m^+ are determined during the learning process.

$$L_k = T_k \, max(0, m^+ - ||v_k||)^2 + \lambda(1 - T_k) \, max(0, ||v_k|| - m^-)^2 \qquad (5)$$

B. UnitsColour Difference Histogram (CDH) Feature Map Detection

The CDH method prioritizes color, how edges line up, and color changes that look natural to us. It captures these features in a way that mimics how our eyes and brain understand them. This method introduces a novel visual descriptor that combines color, edge direction, and how we visually perceive color differences, all while taking into account how these elements are arranged in space. With edge orientation identified and colors quantized via CDH, the next stage is to find small structural elements. This is done by looking at each pixel and then using a 3x3 filter to apply the CDH framework for color and edge quantization [11]. Examining a filter's central value in relation to its eight surrounding values yields a set of edge and color maps. From these maps, we can derive features representing color and edge characteristics by computing the difference (Δ) in color intensity and edge direction for each *L*a*b** component. In the final step, we integrate these two properties into one histogram. In a quantized image, the brightness or color levels of each pixel, denoted as $C(x, y)$, are limited to a specific set of discrete values. These values span from a minimum of 0 up to a maximum of $W - 1$. Neighbouring pixels, identified by their coordinates (x, y) and $(x'y')$ have associated color index values as $C(x, y) = w_1$ and $C(x'y') = w_2$. The orientation image for edge by $\theta(x, y)$ stores orientation information as discrete values v (ranging from 0 to $V - 1$) for each pixel (x, y). At specific coordinates (x, y) and $(x'y')$, the orientation angles are as $\theta(x, y) = v_1$ and $\theta(x'y')=v_2$.

Color difference histograms for neighboring pixels separated by distance D, with color quantization W and edge orientation quantization V, are defined using Eq. (6) and Eq. (7).

$$H_{color}(\, C(x, y)\,) = \begin{cases} \sum \sqrt{(\Delta L^2) + (\Delta a^2) + (\Delta b^2)} \\ where\ \theta(x, y) = \theta(x'y'); max(|x - x'|), (|y - y'| = D) \end{cases} \qquad (6)$$

$$H_{ori}(\, \theta(x, y)\,) = \begin{cases} \sum \sqrt{(\Delta L^2) + (\Delta a^2) + (\Delta b^2)} \\ where\ C(x, y) = C(x'y'); max(|x - x'|), (|y - y'| = D) \end{cases} \qquad (7)$$

Here, ΔL, Δa, and Δb denote the differences between two color pixels, with D set to a value of 1. When the edge orientation is W and the color quantization level is V, the CDH feature is computed as shown in Eq. (8):

$$H_{CDH} = H_{color}(0), H_{color}(1) \dots H_{color}(W-1), H_{ori}(0), H_{ori}(1) \dots H_{ori}(V-1) \quad (8)$$

Image retrieval features can be created by combining a color histogram H_{color} with a histogram of edge orientations H_{ori}. If, for instance, we divide the color space into 72 bins and the edge orientations into 18 bins, the combined feature vector, represented as H, will have a total of 90 dimensions (72 + 18).

C. Atrous Convolutions

Atrous convolution or dilated convolution is crafted to see a wider input area without needing more computing power and parameter count. They are primarily used in tasks like semantic segmentation [12] [13]. Regular deep CNN combines convolutional layers with max-pooling. The downside is that the feature maps shrink in size by 50% every time a max-pooling operation happens. As a result, projecting the processed feature information back onto the initial image leads to less detailed feature extraction as the neural network goes deeper. Atrous (Dilated) convolution tackles this problem by allowing for more thorough feature extraction. It introduces a new parameter known as the rate (r). Atrous convolution functions much like standard convolution, with the key difference being that its kernel weights are distributed with a spacing of r positions, creating sparsely connected convolution layers. Atrous convolution expands its field of view by changing how spread out its sampling points are. Different levels of this spread can capture information at various scales without more computational resources. For example, a standard 3x3 convolution can be modified to see the same area as a 5x5 or 7x7 convolution, allowing it to pick up image features of different sizes. By applying dilated convolutions with varying dilation rates, receptive fields at multiple scales can be effectively captured, and dilated convolution functions can serve as a mechanism for multi-scale convolutional processing. Eq. (9) and Eq. (10) present the formulations for computing the dilated convolution kernel and its corresponding receptive field, respectively.

$$n = k + (k-1)(r-1) \quad (9)$$

$$l_m = l_{m-1} + [(f_m - 1) \prod_{i=1}^{m-1} S_i] \quad (10)$$

In this context n and k denote the sizes of the dilated and standard convolution kernels, respectively. The term l_{m-1} refers to the receptive field size of the $l_{m-1}{}^{\text{th}}$ layer, while the receptive field at the m^{th} layer is determined after applying convolution. f_m represents the convolution kernel size at the m^{th} layer, and S_i indicates the stride of layer l. Fig. 1 illustrates the concept of atrous (dilated) convolutions utilizing a 3×3 kernel with dilation rates of 1, 2, and 4.

D. Proposed Architecture

The proposed DLCA-CapsNet model found in Fig. 2 comprises a CDH layer, two astrous convolution layers, two traditional convolution layers, max-pooling layers, batch normalizers, and a dropout layer. The input image, rescaled to 32x32x3, is subjected to the CDH layer, and does not add any parameters. The 32x32x3 feature map from the CDH layer is sent through two different lanes (Lane1(L1) and Lane2(L2)), each starting with atrous convolutions (Atrous_Conv1 and Atrous_Conv2) with a dilation rate of 2, which processes the feature map subjected to them to produce a 32x32x32 feature map. Each feature map from these astrous convolutions from L1 and L2 is sent to a max-pooling layer (MP1 and MP3), producing feature maps of dimensions 16x16x32. The outputs from the max-pooling layers from L1 and L2 are forwarded to the convolution layers (Conv1 and Conv2) of 64 filters, a 3×3-sized kernel operating with a stride length of 1, respectively. They produce 14x14x64 feature maps sent to max pooling layers (MP2 and MP4) in these separate lanes to produce 7x7x64 feature maps each for L1 and L2. Feature maps from L1 and L2 are then merged or concatenated to produce a 7x7x128 feature map. This merging allows the model to gain the ability to learn integrated features. The merged output is then sent to a dropout layer, then to a Primary Capsule (PC) layer with eight dimensions and 16 channels, a 3×3-sized kernel operating with a stride length 2. Output from the PC layer is sent to the class capsule (Plant_DiseaseCaps), which produces its output for reconstruction. This class capsule layer consists of 16D capsules and considers every class within a dataset. The decoder layer, comprised of three fully connected layers encompassing 512, 1024, and 3072 neurons, respectively, gets the feature map and decodes the entity's properties. The batch normalization layers incorporated in the model helped in the consistent data distribution and improved and simplified the training. The atrous, CDH, dropout, and max-pooling layers help retrieve very salient features submitted to the model from the image for better categorization.

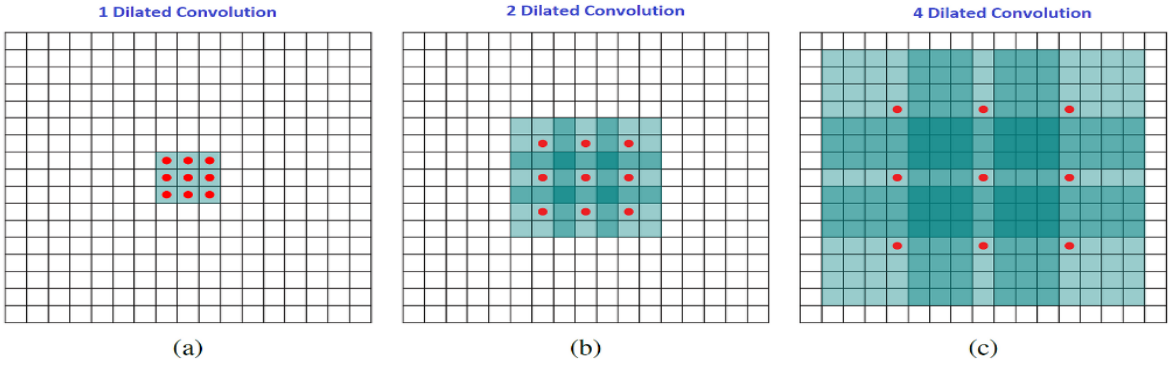

Fig. 1. Demonstrating the idea of astrous convolution. Dilation significantly increases the receptive fields while maintaining full resolution. (a) 1-rate dilated convolution (b) 2-rate dilated convolution and (c) 4-rate dilated convolution.

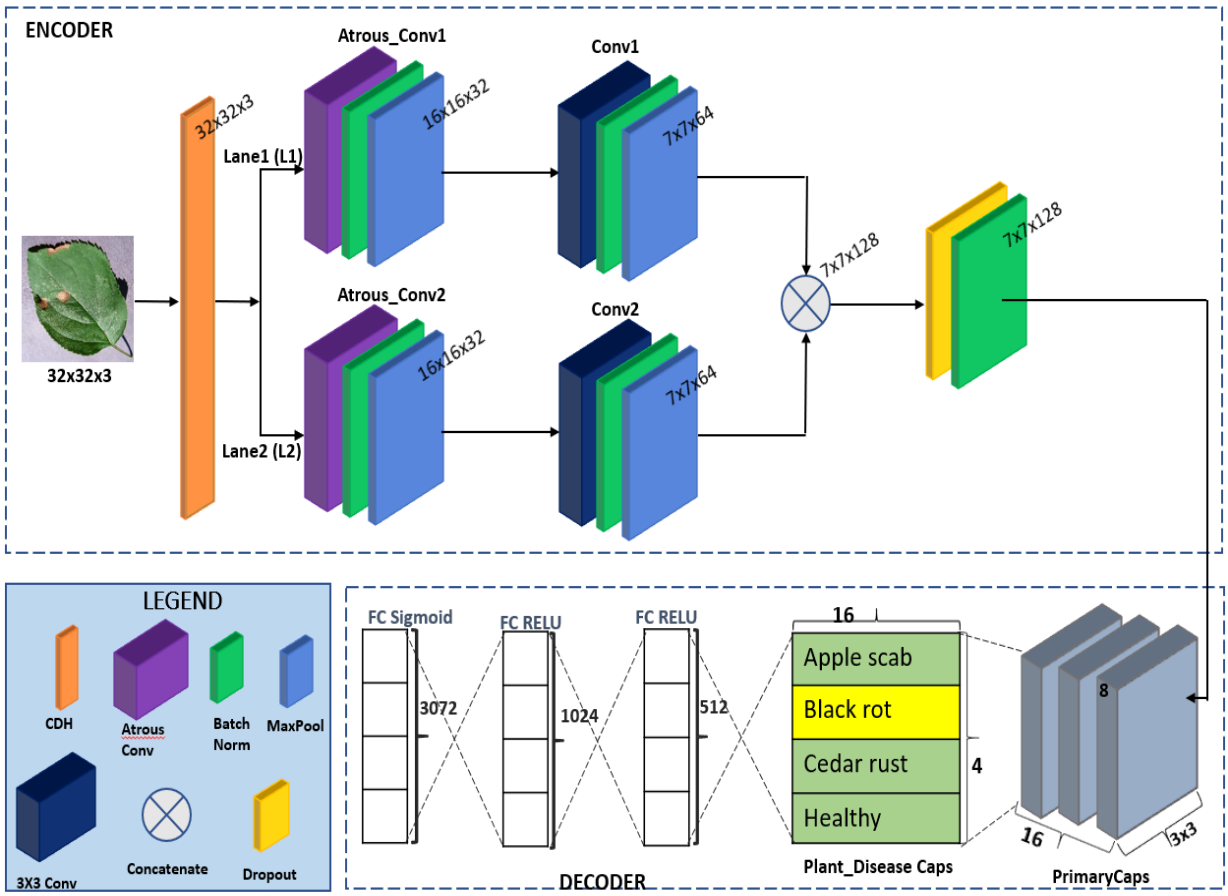

Fig. 2. Architecture of the suggested DLCA-CapsNet model.

E. Datasets

All datasets used are publicly available datasets.

The apple, grape, corn, pepper, potato, and tomato datasets, scaled at 256x256, are a portion of the Plant Village [30].

Apple: It comprises 3171 images sorted into four groups: three infected classes and one healthy class. 0,1,2, and 3 represents Apple_scab, Black_rot, Cedar_apple_rust, and healthy respectively.

Grape: It contains 4062 images in four groups; 0,1,2, and 3 represents Black_rot, Esca_(Black_Measles), Leaf_blight_(Isariopsis_Leaf_Spot, and healthy respectively.

Corn: It is made up of 3852 images sorted into four groups; three infected classes and one healthy class. 0,1,2, and 3 represents Cercospora_leaf_spot Gray_leaf_spot, Common_rust, Northern_Leaf_Blight, and healthy respectively.

Pepper: It is made up of 2475 images sorted into two groups; one infected class and one healthy class. 0 and 1 represent healthy and Bacterial_spot, respectively.

Potato: comprises 2152 images sorted into three groups: two infected classes and one healthy class. 0,1, and 2 represent Healthy, Early_blight, and Late_blight, respectively.

Tomato: It comprises 18160 images sorted into ten groups; nine infected and one healthy class. 0,1,2,3,4,5,6,7,8 and 9 represents Bacterial_spot, Early_blight, Late_blight, Leaf_Mold, Septoria_leaf_spot, Spider_mites Two-spotted_spider_mite, Target_Spot, Tomato_mosaic_virus, Tomato_Yellow_Leaf_Curl_Virus, and Healthy respectively.

Banana comprises 937 images sorted into four groups: three infected classes and one healthy class. 0, 1, 2, and 3 represent Cordana, Pestalotiopsis, Sigatoka, and Healthy [31].

Mango comprises 4000 images sorted into eight groups: seven infected classes and one healthy class. 0,1,2, 3, 4, 5, 6, and 7 represent Anthracnose, Bacterial Canker, Cutting Weevil, Die Back, Gall Midge, Powdery Mildew, Sooty Mould, and Healthy, respectively [32].

Rice: It comprises 5932 images sorted into four infected classes. 0, 1, 2, and 3 represent Bacterial_blight, Blast, Brown_spot, and Tungro, respectively [36].

Fashion-MNIST: contains 70,000 grayscale fashion product images, each with dimensions of 28x28 pixels. It is divided into ten categories, each containing 7,000 images. The training set includes 60,000 images, while the remaining 10,000 images form the test set. This dataset is more complex than MNIST [33].

CIFAR-10: The dataset contains 50,000 images for training and 10,000 images for testing. Each image has a resolution of 32x32x3 and includes diverse backgrounds and objects, making it more complex than the Fashion-MNIST dataset [34].

To standardize input across datasets, images were resized to 32 × 32 × 3 and split into training and testing sets in an 80:20 ratio. Data augmentation was not applied, as CapsNet is suitable for limited data, and the DLCA-CapsNet is optimized for extracting critical features. Given that most of the ten datasets are imbalanced, high performance would underscore the model's effectiveness in dealing with real-world data imbalance.

F. Implementation Details

The setup involved utilizing a Windows machine with an RTX 2080 SUPER GPU featuring 8GB of dedicated memory and 32GB of RAM. The implementation utilized Keras and Python through Anaconda, with TensorFlow as the backend. For training. The optimization process used Adam, operating with a learning rate of 0.001 and a decay rate of 0.9, with training conducted in batches of 100 samples. To ensure optimal progress during training, the model with the best performance was saved at each iteration. The authors referenced the architecture of the original CapsNet, which is available at the following GitHub repository: https://github.com/XifengGuo/CapsNet-Keras.

IV. Results and Discussion

In this part of the article, we assessed the proposed DLCA-CapsNet model by conducting a comparative analysis with the traditional CapsNet and other cutting-edge CapsNet techniques for classifying plant disease. This comparison aims to determine the most effective model for classifying diseases from plant images.

A. Performance Evaluation

The outcomes of the DLCA-CapsNet architecture, which was trained on images from the plants, CIFAR-10, and fashion-MNIST datasets, are presented here. Confusion matrices are also p, loss and validation curves that depict accuracy (ACC), Area Under the Curve (AUC) for both Precision-Recall (PR) and Receiver Operating Characteristics (ROC) curves, sensitivity (SEN), precision (PRE), specificity (SPE), and F1-Score (FS) are presented to assess the model's performance. Eq. (11)-(15) represent the various performance metrics calculated by considering the confusion matrix's TP, FP, TN, FN, representing True Positive, False Positive, True Negative, False Negative.

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (11)$$

$$Precision(P) = \frac{TP}{TP+FP} \quad (12)$$

$$Recall(R)/Sensitivity = \frac{TP}{TP+FN} \quad (13)$$

$$Specificity = \frac{TN}{TN+FP} \quad (14)$$

$$F1-Score = 2\left(\frac{P*R}{P+R}\right) \quad (15)$$

Additionally, discussions cover visual representations of reconstructed images, clusters of class capsules, and layer activation maps, which illustrate the model's internal mechanisms and help users have confidence in the model. Again, an ablation study demonstrates the model's flexibility and robustness, highlighting the components that significantly impact its performance. Moreover, the quantity of parameters and the model's disk size are also discussed.

Based on the confusion matrices in Fig. 3 for the tomato and mango datasets, it is evident that the DLCA-CapsNet model categorised the images into their respective classes more accurately than the traditional model. From the confusion matrices, accuracy per class, sensitivity, precision, F1-score, and specificity values can be calculated. Such metrics ensure a well-rounded analysis of model performance, which is crucial for small and unevenly distributed dataset scenarios, where relying solely on accuracy might overlook critical details. Based on Table I and Table II, it can be noticed that the proposed DLCA-CapsNet model achieved higher accuracy, sensitivity, precision, F1-Score, and specificity, surpassing values attained by the traditional model when the tomato and mango datasets are considered respectively. This suggests that the proposed model outperforms the traditional model and effectively generalizes unseen data.

Also, Fig. 4 depicts the PR and ROC curves of the tomato dataset, providing insights into the model's resilience and effectiveness on imbalanced datasets. The suggested model outperformed the traditional model, as indicated by superior curve shapes and values. The DLCA-CapsNet significantly outperformed the original CapsNet on the Tomato dataset, achieving an overall ROC of 100% and a PR of 99.5%, compared to the original CapsNet's lower ROC of 97.7% and PR of 88%.

The training and validation loss and accuracy for both the DLCA-CapsNet and traditional CapsNet are shown in Fig. 5 for tomato, mango, and CIFAR-10 datasets. The DLCA-CapsNet model converged faster and achieved higher validation accuracies than the traditional model on the various datasets. It can be seen that, the DLCA-CapsNet significantly outperformed the original CapsNet in validation accuracy across eleven diverse datasets (apple, banana, grape, corn, mango, pepper, potato, rice, tomato, CIFAR-10, and Fashion-MNIST), achieving consistently higher validation accuracy scores of 99.69%, 95.77%, 99.63%, 97.66%, 99.50%, 100%, 100%, 100%, 98.82%, 77.31%, and 93.01% compared to that of the traditional CapsNet model that achieved lower validation accuracies of 92.91%, 80.95%, 93.49%, 92.59%, 78.38%, 59.68%, 95.36%, 99.24%, 88.59%, 63.58%, and 90.98% for the same dataset. This suggests the proposed model generalizes better on unseen data than the traditional model across all the datasets. Examining the original or traditional CapsNets validation accuracy for the CIFAR-10 dataset reveals its initial increase but decline around the 20th epoch. In contrast, the proposed model maintained its peak accuracy until the end.

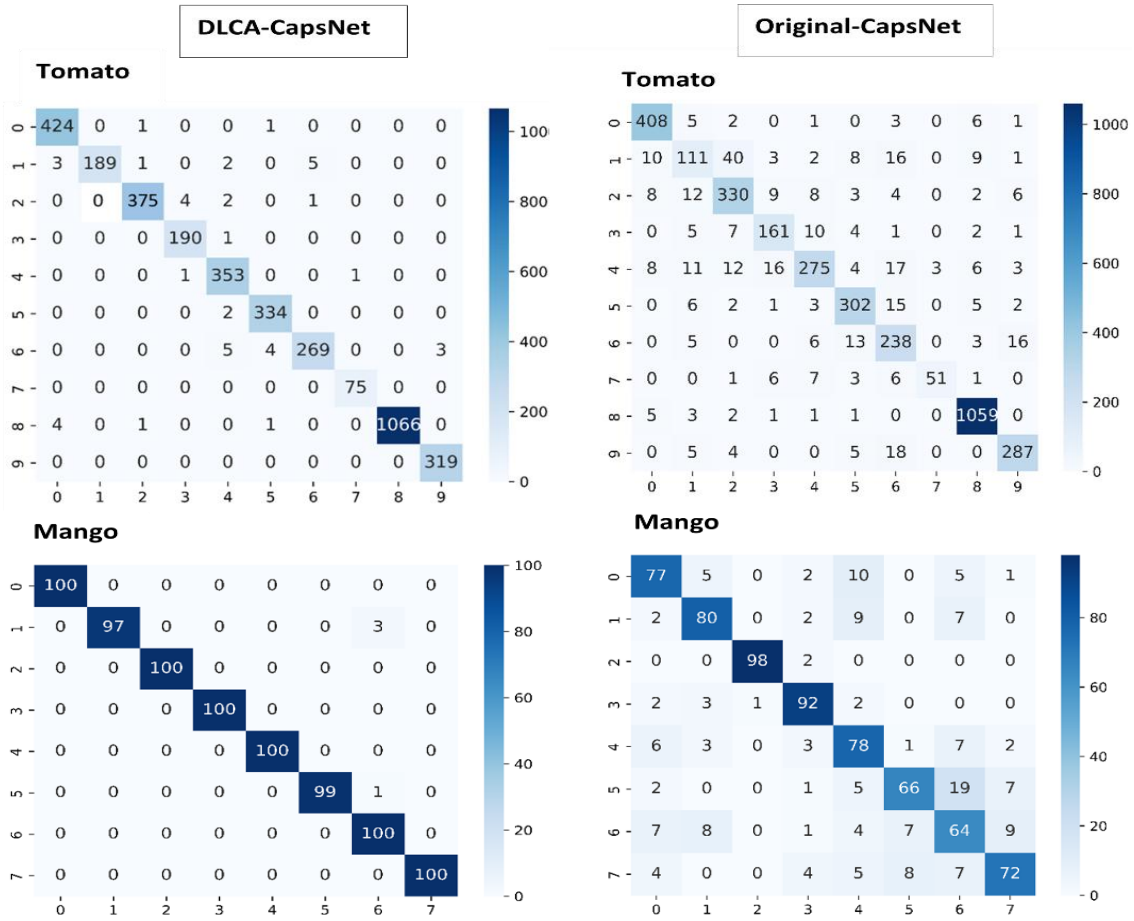

Fig. 3. Confusion matrices comparing the performance of the DLCA-CapsNet and the original CapsNet models on the tomato and mango datasets.

TABLE I. PERFORMANCE RESULTS OF DLCA-CAPSNET AND THE ORIGINAL CAPSNET ON THE TOMATO DATASET

Model (Dataset)	Class	TP	FP	FN	TN	ACC (%)	PRE (%)	SEN (%)	SPE (%)	FS (%)	Data Size
Original-CapsNet (Tomato)	0	408	31	18	3180	98.65	92.94	95.78	99.04	94.34	426

	7	100	0	0	700	100	100	100	100	100	100

B. Number of Parameters and Size of Disk

Increasing model complexity (by adding layers or increasing the size of layers) often improves performance on intricate images. However, this makes the models larger and computationally demanding, hindering their use on devices with limited resources like phones and embedded systems. DLCA-CapsNet is smaller in size and has fewer parameters than the original CapsNet and other top models (see Table III). Additionally, the CDH component we used does not add any extra parameters. The DLCA-CapsNet achieves a notable decrease in parameter count (in millions (M)) by 6.16M, 6.16M, 6.16M, 6.16M, 7.14M, 5.68M, 5.92M, 7.62M, 7.62M, and 6.54M respectively, when compared to the conventional CapsNet considering apple, banana, grape, corn, mango, pepper, potato, rice, tomato, CIFAR-10, and Fashion-MNIST datasets. Furthermore, it results in a reduction in disk space usage by 23.5MB, 23.5MB, 23.5MB, 23.5MB, 27.2MB, 21.6MB, 22.6MB, 23.5MB, 29.1MB, 29.1MB, and 24.8MB, respectively, for the same datasets.

TABLE III. COMPARISON OF DISK SIZE (S) IN MB AND NUMBER OF PARAMETERS (P) IN MILLIONS (M)

CapsNet Models/Reference	P(M) and S(MB)											
		Apple	Banana	Grape	Maize	Mango	Pepper	Potato	Rice	Tomato	CIFAR-10	Fashion-MNIST
Gabor CapsNet [14]	P	-	-	-	-	-	-	-	-	12.00	-	-

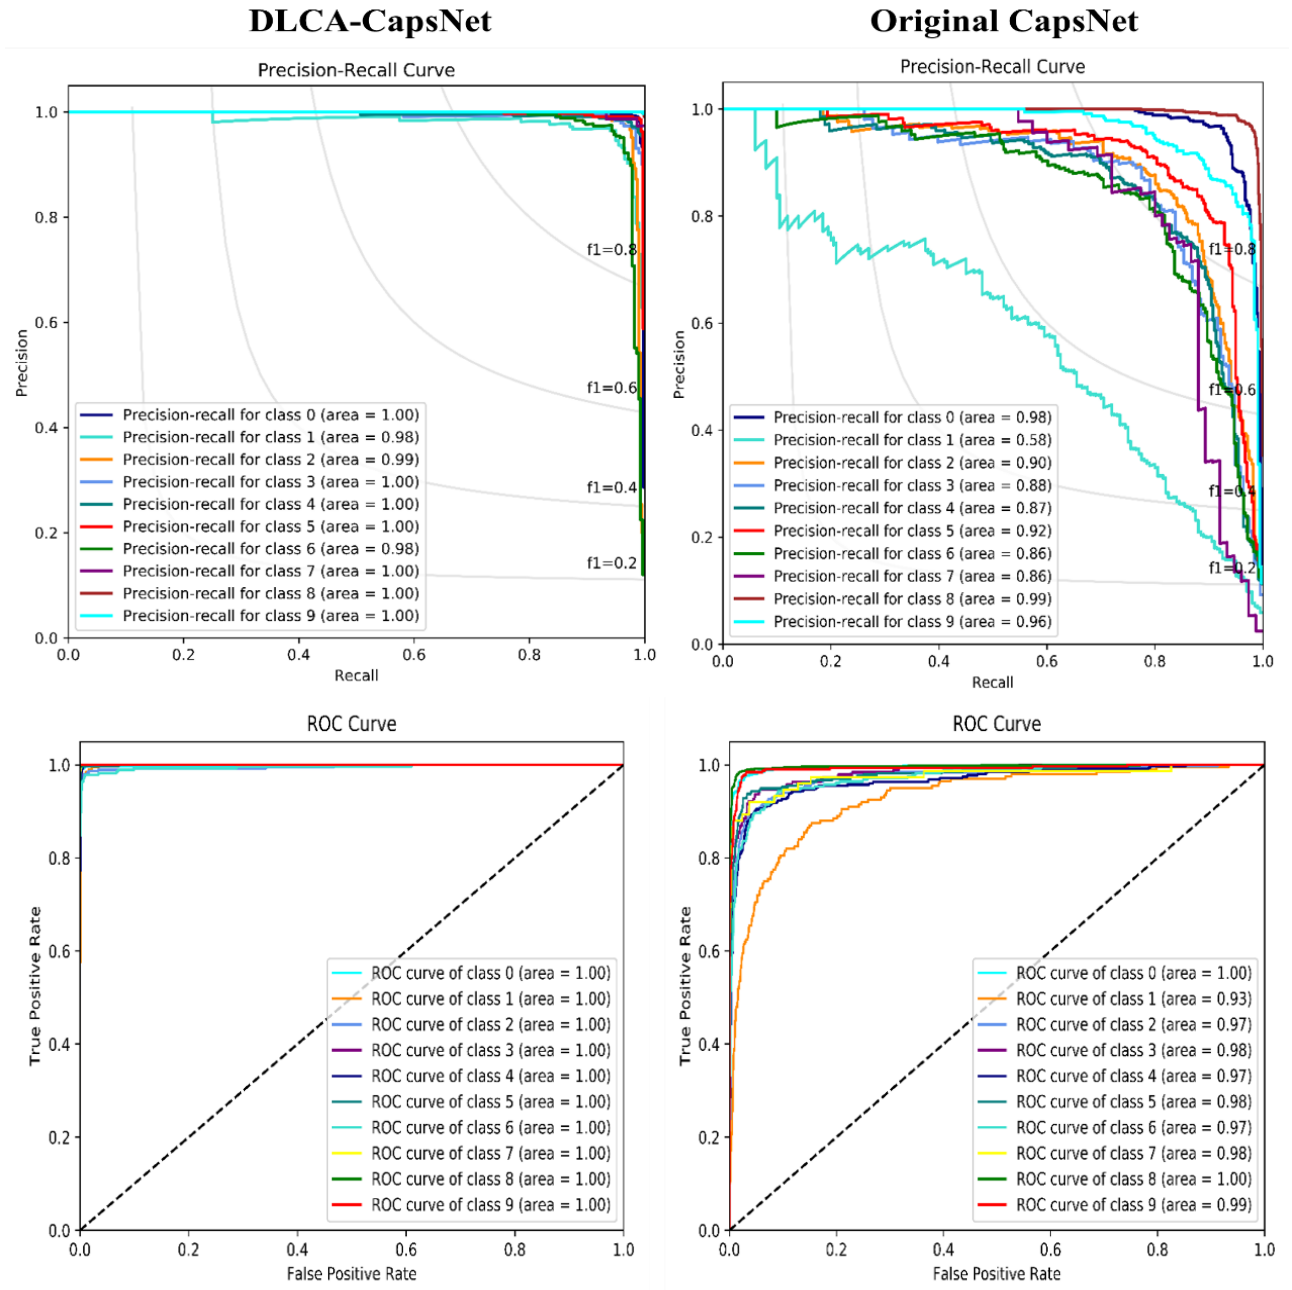

Fig. 4. PR and ROC curves comparing the performance of DLCA-CapsNet and Original CapsNet models on the Tomato dataset.

C. Ablation Study

To assess the model parts that affect its performance, an ablation study was performed [35]. The layers are removed one by one to check the layers of the model that significantly affect the performance of the model. Considering the tomato and potato leave diseases, it can be seen in Table IV that the model's performance is highly impacted by the CDH layer.

TABLE IV. ABLATION RESULTS

Layers	Validation accuracy (%)	
	Tomato	Potato
-CDH	82.12	90.17
-Atrous_Conv1/ Atrou_Conv2	97.75	95.95
-MP1 & MP3	98.62	98.88
-Conv1 & Conv2	97.88	97.17
-MP2 & MP4	98.75	98.28
-Dropout	98.88	99.14
+All Layers	98.82	100

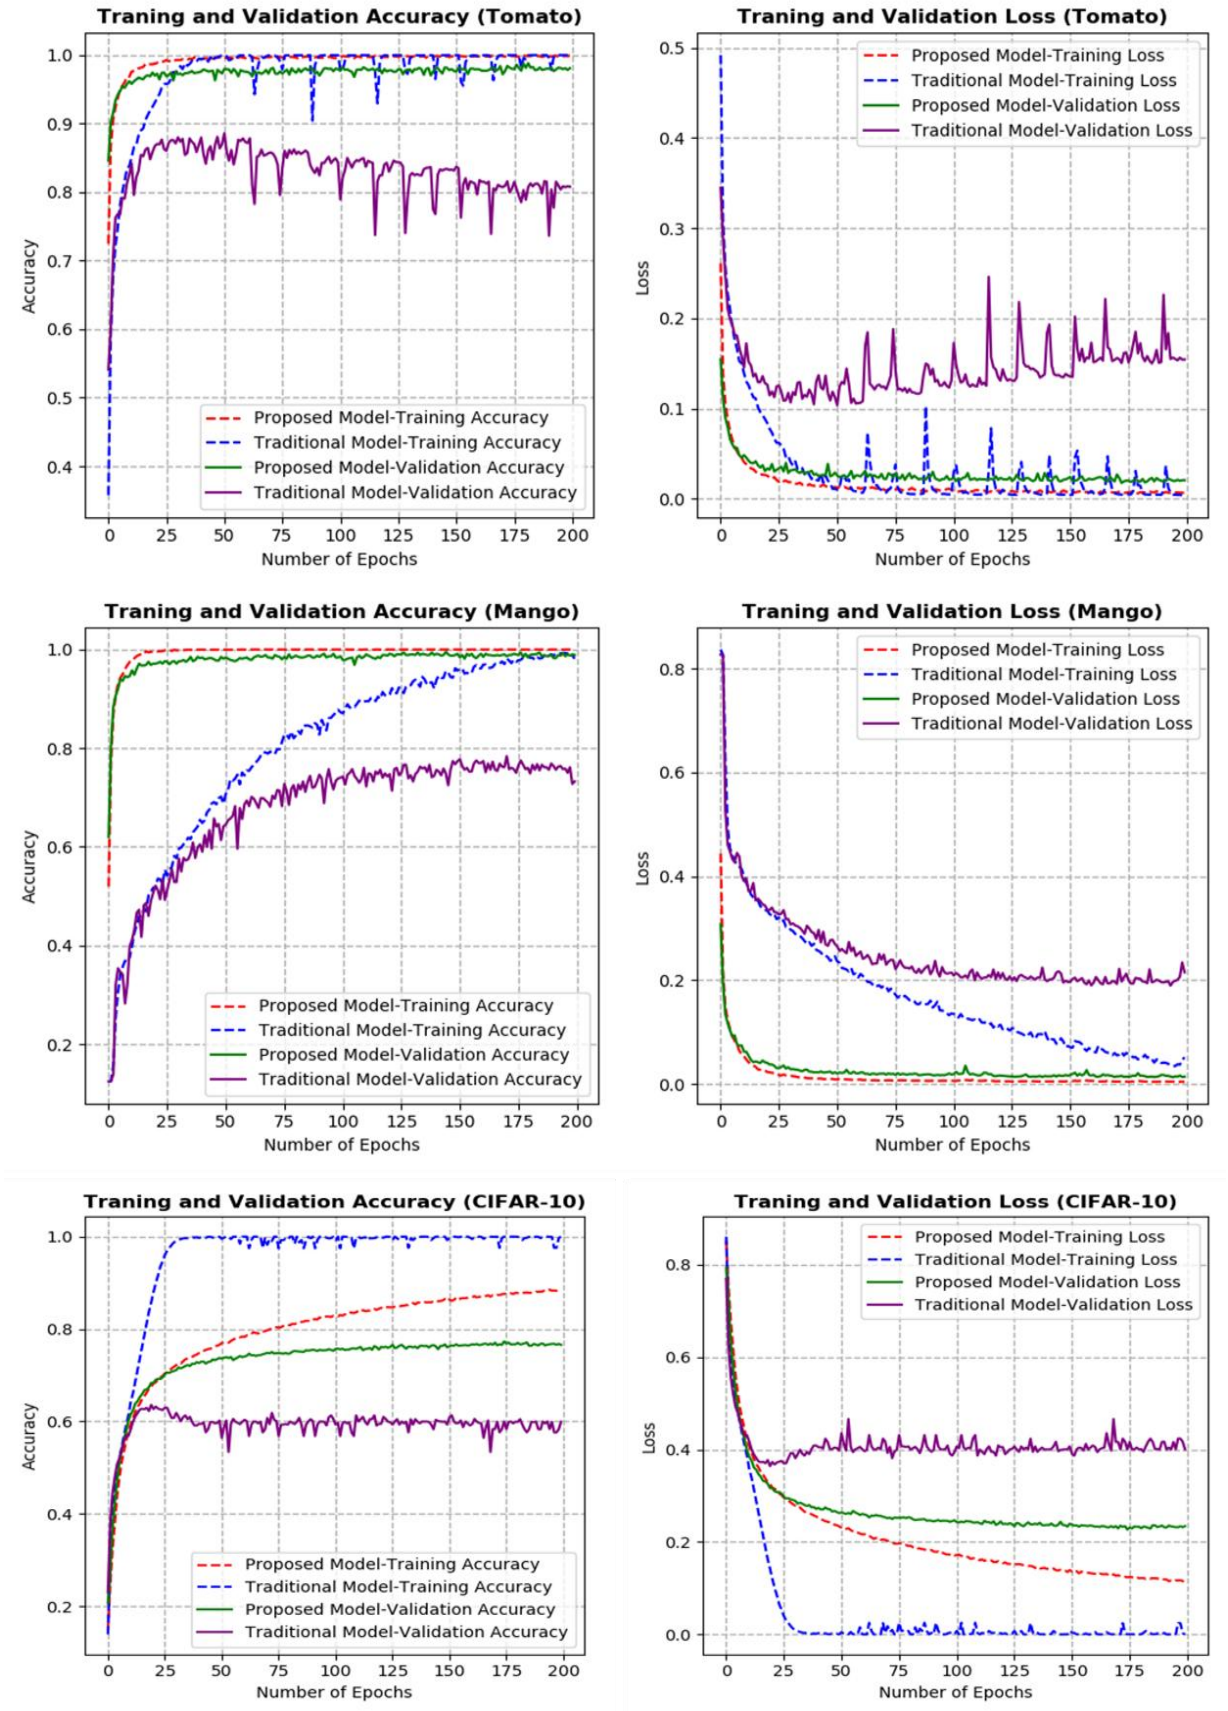

Fig. 5. Accuracy and loss performance for the proposed DLCA-CapsNet and the original CapsNet models across three datasets: tomato, mango, and CIFAR-10.

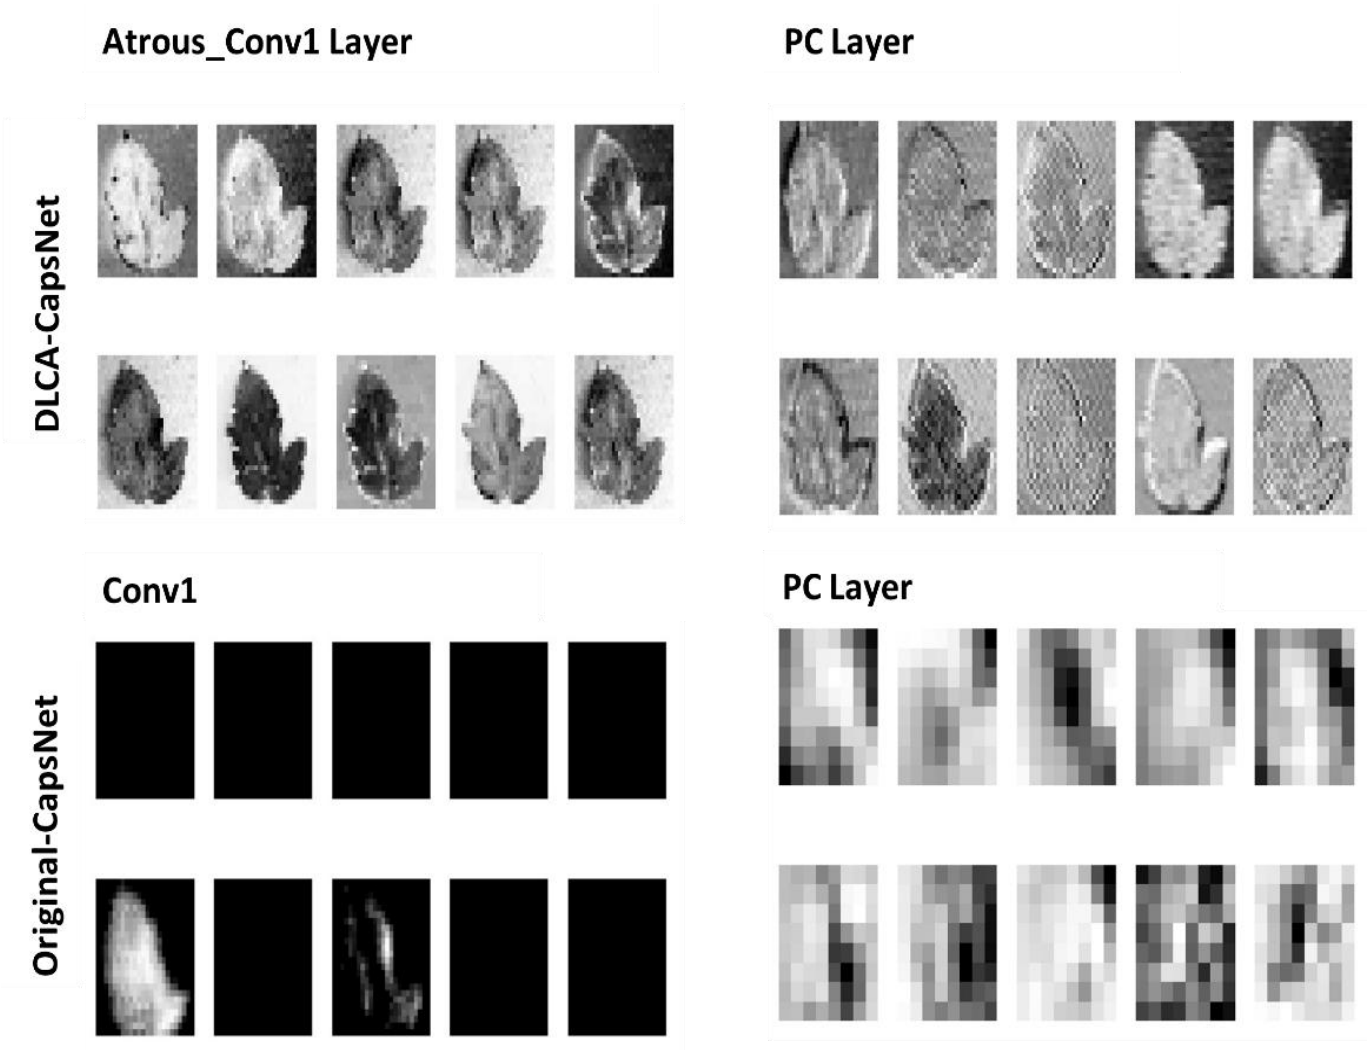

Fig. 6. Activation maps of the DLCA-CapsNet and the original CapsNet models on the Tomato dataset.

D. Model Interpretability

Fig. 6 visually compares activation maps from one of the atrous convolution layers in the proposed DLCA-CapsNet model (which takes input from the CDH layer using the tomato dataset) to the activation map from the convolution layer of the traditional CapsNet. A comparison of these maps reveals that the atrous convolution in the DLCA-CapsNet captures more detailed features, suggesting that the CDH layer plays a crucial role in extracting significant information, something the convolution layer of the traditional CapsNet alone fails to achieve. Furthermore, comparing the activation maps from the primary capsule layer of the proposed DLCA-CapsNet and the original model reveals that DLCA-CapsNet captures more relevant features. This improvement is attributed to the proposed model's ability to extract significant features earlier in the network, which enhances the quality of the features passed to its primary capsule layer, unlike the traditional CapsNet, whose convolutional layer was less effective in feature extraction.

The clusters generated at the class capsule layers were also visualized using t-distributed stochastic neighbor embedding (t-SNE). As shown in Fig. 7, considering the DLCA-CapsNet model, the clusters at the class capsule layer are more distinctly grouped by class, with fewer outliers compared to the traditional model, particularly for the tomato, mango, and pepper datasets. This indicates that the DLCA-CapsNet model demonstrates a stronger ability to distinguish between different classes in the dataset than the traditional model. Also, the reconstruction technique aids in identifying the predicted class of an image and the confidence of that prediction. Referring to Fig. 8, which presents three rows of reconstructed images from the tomato and banana datasets for both the proposed and traditional CapsNet models, it is evident that the proposed model generates images of slightly better quality with higher class probabilities. These visual outputs from the model layers enhance interpretability and support the goals of Explainable Artificial Intelligence (XAI).

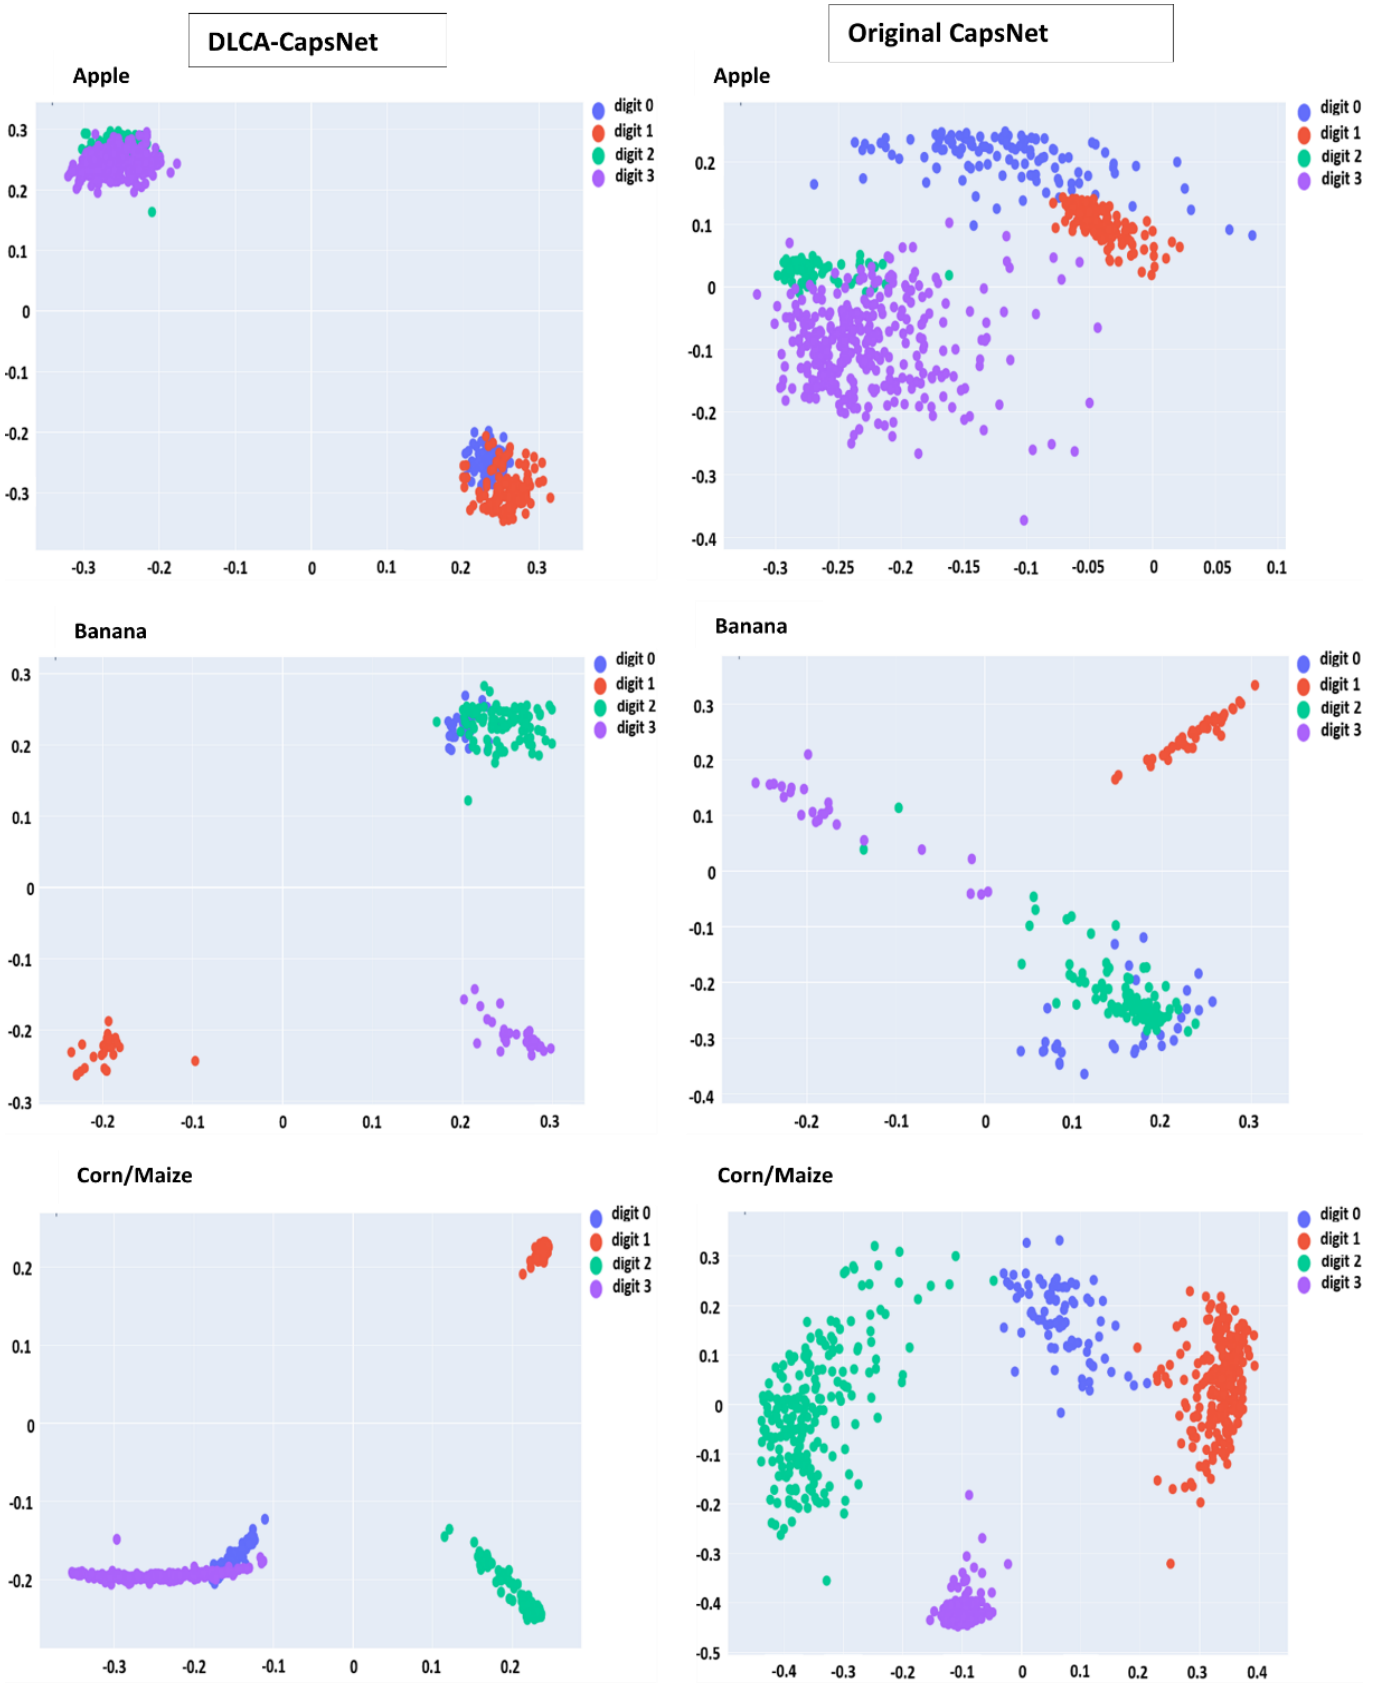

Fig. 7. Class capsule clusters for Apple, Banana, and Corn in DLCA-CapsNet and the original CapsNet models.

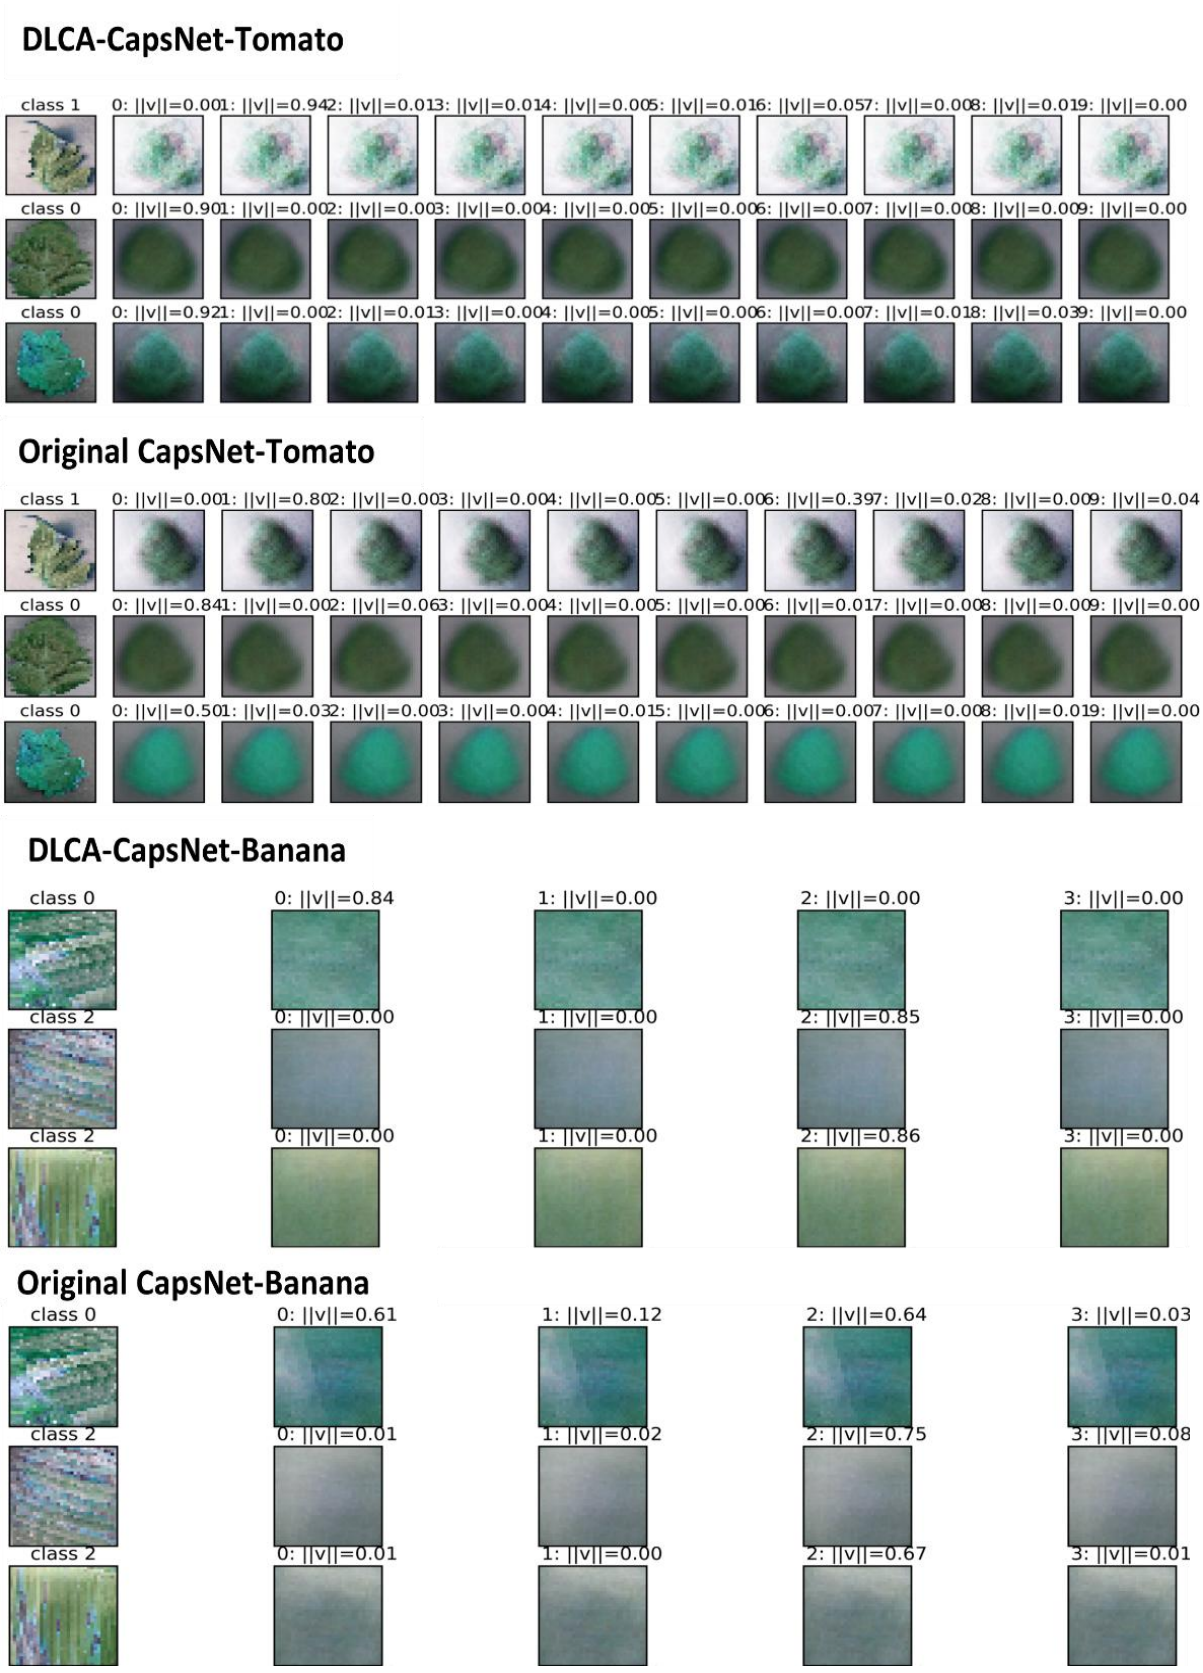

Fig. 8. Reconstructed images generated by the DLCA-CapsNet and Original CapsNet models when applied to the Tomato and Banana datasets.

E. Comparison of Results

Table V compares the proposed DLCA-CapsNet model and state-of-the-art models applied to CIFAR-10, Fashion-MNIST, and the nine plant disease datasets from the literature. The comparison also includes various routing algorithms, despite the DLCA-CapsNet model utilizing a dynamic routing technique. Table V shows that the less parameterized DLCA-CapsNet model, with enhanced feature extraction capabilities, achieved higher validation accuracies across various datasets, surpassing the original CapsNet by 6.78%, 14.82%, 6.14%, 5.07%, 21.12%, 40.32%, 4.64%, 0.76%, 10.23%, 13.73%, and 2.03% for the apple, banana, grape, corn, mango, pepper, potato, rice, tomato, CIFAR-10, and Fashion-MNIST datasets, respectively. It also resulted in a reduction of 6.16M, 6.16M, 6.16M, 6.16M, 7.14M, 5.68M, 5.92M, 7.62M, 7.62M, and 6.54M in model size (in millions) compared to the traditional CapsNet. Furthermore, the DLCA-CapsNet model led to a decrease in disk size by 23.5MB, 23.5MB, 23.5MB, 23.5MB, 27.2MB, 21.6MB, 22.6MB, 23.5MB, 29.1MB, 29.1MB, and 24.8MB for the same datasets compared to the traditional CapsNet, as shown in Table III. Also, comparing the proposed DLCA-CapsNet with existing models found in the literature for plant disease detection, the DLCA-CapsNet also outperformed them, as shown in Table V and Table III. These results demonstrate the superior generalization ability and lower computational complexity of the DLCA-CapsNet over the original CapsNet. This exceptional performance, necessary for complex images, can be credited to the superior feature extraction methods we used to isolate only the most relevant features from the images.

TABLE V. COMPARISON BETWEEN PREVIOUS STUDIES AND THE PROPOSED DCLA-CAPSNET MODELS

CapsNet Models/Reference	Validation Accuracy (%)										
	Apple	*Banana*	*Grape*	*Corn*	*Mango*	*Pepper*	*Potato*	*Rice*	*Tomato*	*CIFAR-10*	*Fashion-MNIST*

V. CONCLUSION

This study proposed an optimized DLCA-CapsNet model for classifying plant diseases, CIFAR-10, and fashion-MNIST. Modifications were made by adding a CDH, which does not add any parameters, atrous convolutions, max-pooling, or a dropout layer. All these layers contributed to the efficient feature extraction abilities of the proposed model. The DLCA-CapsNet model was assessed using evaluation metrics such as sensitivity, F1-score, precision, specificity, ROC and PR values, accuracy, disk size, and parameters generated. The DLCA-CapsNet model results were compared with those of the traditional CapsNet and other models found in the literature, and outperformed them as shown in Table III and Table V. The proposed DLCA-CapsNet model's fewer parameters make it usable on IoT and resource-constrained devices, and the better validation accuracies show its generalization ability on unseen data. An ablation study was performed to ascertain the layers of the model that influence its performance. Again, the model interpretability regarding visualizing clusters at the class capsule, activation maps, and reconstruction of images was discussed. The proposed model's better performance shows its effectiveness in detecting plant diseases from plant leaf images than those found in literature as analyzed in Table III and Table V. The findings suggest that this efficient and computationally less demanding method can significantly enhance plant disease classification and contributes incrementally to efforts aligned with the SDG 2 goal by offering a lightweight, scalable solution that can be adapted for field use in resource-constrained settings.

Nonetheless, environmental variables like uneven lighting and intricate backgrounds in real-world conditions can hinder or limit model performance. Subsequent research will aim to enhance generalizability and real-world applicability by evaluating the model across more diverse, challenging settings, incorporating additional datasets, and investigating real-time implementation on edge and mobile platforms for agricultural use.

A Comparative Study of Machine Learning Techniques for AE-Based Corrosion Detection with Emphasis on Transformer Models

Osama Shahid Ali, Lukman B A Rahim
Center for Cyber Physical Systems, Universiti Teknologi PETRONAS, Seri Iskandar, Malaysia

***Abstract*—Corrosion-induced damage poses a critical threat to the structural integrity of fluid transport pipelines, necessitating advanced detection strategies for early intervention. This study investigates the use of acoustic emission (AE) monitoring in conjunction with machine learning techniques to identify anomalies indicative of corrosion. A comprehensive analysis of supervised, unsupervised, semi-supervised, and self-supervised learning methods is presented, with emphasis on their suitability for AE-based anomaly detection. Building upon this foundation, we implement and evaluate multiple machine learning models—including K-Nearest Neighbours (KNN), Support Vector Machines (SVM), Artificial Neural Networks (ANN), and Convolutional Neural Networks (CNN)—and compare them to a Transformer-based model integrated into a hybrid CNN-Transformer architecture. Experimental results demonstrate that the hybrid model outperforms all baselines, achieving R-squared values of 0.7037 for Acoustic Signal Level (ASL) and 0.6836 for Root Mean Square (RMS), thus confirming its superior ability to capture both local and long-range dependencies in acoustic emission data. A systematic review of recent Transformer-based corrosion detection models further contextualizes the results. This research highlights the promise of Transformer-based models in robust, real-time corrosion monitoring and offers a pathway toward more intelligent, machine learning-driven infrastructure maintenance systems.**

Keywords*—Acoustic emissions; transformer based models; machine learning

I. Introduction

The structural integrity of pipelines is critical to the safe and efficient transport of fluids across industrial infrastructure. Among the various threats to pipeline reliability, corrosion remains one of the most pervasive and damaging phenomena, often leading to catastrophic failures, economic losses, and environmental hazards. As such, early and accurate detection of corrosion-related anomalies is essential for preventive maintenance and risk mitigation. Traditional inspection methods, such as ultrasonic testing, visual inspection, or radiography, are often constrained by accessibility, resolution, and cost. These limitations have catalysed the shift toward non-destructive monitoring approaches, particularly those based on acoustic emission (AE) signals, which can detect internal damage mechanisms in real-time without interrupting operations.

Within this context, the field of anomaly detection has gained considerable traction. By identifying deviations from normal behaviour in sensor data, anomaly detection methods enable the recognition of subtle, early-stage corrosion signatures. These methods span from classical statistical techniques to advanced machine learning and deep learning models. More recently, the adoption of Transformer-based architectures—originally developed for natural language processing—has opened new avenues for capturing long-range dependencies and intricate temporal patterns in time-series data, including AE signals. Transformers, especially when combined with Convolutional Neural Networks (CNNs), have demonstrated superior performance in learning both localized and global representations, making them particularly well-suited for signal-based corrosion detection.

This study contributes to this evolving landscape by applying and evaluating a hybrid CNN-Transformer model for AE-based corrosion anomaly detection in pipelines. Unlike conventional approaches that often struggle with noisy, high-dimensional, and unlabelled signal data, the hybrid model leverages CNNs for localized feature extraction and Transformer encoders for contextual temporal modelling. A comprehensive comparison against classical machine learning algorithms and other deep learning models reveals the hybrid model's significant performance advantage in predicting key corrosion indicators such as Acoustic Signal Level (ASL) and Root Mean Square (RMS).

Furthermore, this work contextualizes its findings within the broader literature by examining prior studies on Transformer-based corrosion detection across various domains, including bridge inspection, UAV imagery, pipeline surveillance, and 3D point cloud segmentation. By bridging insights from both image-based and signal-based corrosion detection, this paper not only validates the effectiveness of Transformer models in AE applications but also lays the groundwork for future self-supervised learning strategies in industrial health monitoring systems.

II. Background of the Study

A. Anomaly Detection

Anomaly detection is the process of identifying data points, patterns, or events that significantly deviate from the normal or expected behaviour within a dataset [1]. These deviations, known as anomalies or outliers, can indicate critical incidents such as errors, defects, fraud, or other unusual activities. Anomaly detection is used across various fields like cybersecurity, finance, manufacturing, and healthcare to detect problems early and prevent larger issues. It typically involves

building a model of normal behaviour and then comparing new data to this model to find anything that stands out as abnormal.

Anomaly detection offers several significant advantages, especially in systems where early identification of unusual behaviour can prevent serious consequences. One of the primary benefits is its ability to uncover rare or previously unknown issues, such as hidden faults in machinery, undetected cyberattacks, or fraudulent financial transactions, which might not be identifiable using standard monitoring techniques [2]. It also supports automation in monitoring processes, reducing the need for manual oversight and allowing organizations to respond more quickly and efficiently to emerging problems. Furthermore, anomaly detection improves decision-making by providing insights into unexpected behaviour and enabling predictive maintenance, risk management, and enhanced security. Its flexibility across domains and ability to handle large volumes of data in real time make it a powerful tool for increasing operational reliability and safety.

B. Anomaly Detection Use Cases

Anomaly detection plays a pivotal role in cybersecurity, especially for identifying novel or stealthy attacks that signature-based systems often miss. For instance, a study on smart-city IoT networks applied federated and split learning methods to detect anomalies on the UNSW-NB15 dataset, achieving accuracy rates above 97% and reducing false positives in real-time intrusion detection. Another work introduced a PCC-CNN deep-learning model capable of detecting multi-class attacks in IoT environments using datasets like NSL-KDD and CICIDS2017, demonstrating robust performance in real-time classification [3], [4], [5]. These approaches exemplify how anomaly detection enhances threat detection in dynamic, decentralized network ecosystems.

In manufacturing, anomaly detection enables predictive maintenance by identifying early signs of equipment degradation. A machine-learning system using Random Forests and SVM, trained on sensor data like vibration, temperature, and pressure, successfully flagged anomalies indicative of impending motor and pump failures. This led to a remarkable 30% reduction in unplanned downtime and substantial cost savings. Additionally, a semi-supervised approach for pharmaceutical manufacturing equipment demonstrated its effectiveness in detecting failures in complex multivariate time series without requiring labelled fault data [6], [7]. These techniques shift maintenance strategies from reactive to proactive, improving operational efficiency and equipment lifespan.

Deep learning–based anomaly detection methods are transforming system reliability across industrial settings. One paper [8] explored autoencoders, RNNs, and CNNs to examine sensor streams in a manufacturing environment. The proposed deep-learning framework outperformed traditional techniques, enabling earlier detection of equipment faults. Another study [9] implemented a federated learning setup using 1D-CNN and bi-LSTM to process time-series sensor data across distributed devices, achieving 97.2% test accuracy and enabling edge-based anomaly detection that preserves data privacy. Together, these works illustrate how advanced neural architectures facilitate real-time fault prediction and distributed diagnostics in Industry 4.0 systems.

In civil and structural engineering, anomaly detection methods are increasingly used to identify corrosion on critical infrastructure—like bridges, towers, and building façades—using aerial imagery [10] collected by drones or unmanned aerial vehicles (UAVs). For instance, CorrDetector [11] is an ensemble deep learning model based on convolutional neural networks (CNNs) that analyses drone-captured images of structures (e.g., telecom towers) to locate and identify corroded regions [12]. This framework achieved significantly better classification accuracy compared to prior state-of-the-art models, enabling automated, remote, and scalable corrosion monitoring in hard-to-reach areas. Such anomaly-driven detection enhances safety, reduces inspection costs, and enables timely maintenance decisions [13].

C. Types of Anomalies

Point anomalies refer to individual data instances that deviate significantly from the majority of the data and can be identified as unusual regardless of the context in which they occur [14]. These anomalies are the simplest and most intuitive form, appearing as sharp spikes or dips in data distributions. A point anomaly stands alone as being inconsistent with the expected pattern—there is no need to examine its surrounding values or additional variables [15]. For example, in banking, if a customer typically spends less than $100 per transaction, but one day a transaction of $10,000 is recorded, that transaction is likely to be a point anomaly. Similarly, in a medical dataset, a sudden and extreme heart rate recorded in an otherwise stable trend could be flagged as anomalous. These anomalies are typically rare but can be highly impactful, often signalling errors, fraud, or critical failures. Because they occur in a variety of domains—from finance and healthcare to environmental monitoring and manufacturing—point anomalies are often the first type considered when building anomaly-aware systems. Despite their simplicity, understanding and classifying them accurately is crucial due to the potential severity of the events they represent.

Contextual anomalies occur when a data point is considered normal in one context but anomalous in another. Unlike point anomalies, these require additional contextual information—such as time, location, or season—to assess whether the data instance is truly unusual [16]. A contextual anomaly cannot be identified solely by looking at the value itself; its significance emerges only when the surrounding environment or condition is considered [17]. For example, a temperature of 25°C might be perfectly normal during the summer but highly unusual during the winter, making it a contextual anomaly in the latter case. Another example would be a sudden drop in stock prices that is abnormal only when viewed against the typical patterns of that specific market on a certain day of the week. These types of anomalies are especially prevalent in time-series and spatiotemporal data, where the same value can be either expected or unexpected depending on when and where it occurs. Recognizing contextual anomalies is essential in fields such as climate science, behavioural analytics, and industrial monitoring, where environmental variability plays a key role in defining what is normal.

Collective anomalies refer to a set or sequence of data instances that are anomalous when considered together, even though the individual data points within the group may appear normal on their own. The anomaly lies not in the data points themselves, but in the pattern or relationship between them. This type of anomaly typically appears in sequential or structured data, such as time-series or spatial data grids [18]. For example, in network traffic analysis, a single packet may appear normal, but a burst of similar packets over a short duration might indicate a denial-of-service attack—a collective anomaly. Similarly, in health monitoring systems, a slight elevation in blood pressure over one reading might not be a concern, but a sustained increase over several hours could signal the onset of a medical emergency. These anomalies are crucial in identifying coordinated or evolving patterns that could go unnoticed when data is analysed in isolation. They are especially important in domains like cybersecurity, fault detection, and system diagnostics, where anomalies emerge not from individual values, but from the way groups of values interact over time or space.

D. Anomaly Detection Techniques

1) Statistical techniques are among the earliest and most fundamental approaches to anomaly detection [19]. These methods rely on the assumption that normal data points follow a known statistical distribution (e.g., Gaussian, Poisson), and anomalies are observations that deviate significantly from this distribution. Common statistical measures used include mean, variance, standard deviation, and probability density functions.

A classic example is the Z-score method, where any data point that lies beyond a threshold (commonly 3 standard deviations from the mean) is considered anomalous[20]. This approach works well for data that is symmetrically distributed, such as in many industrial process control settings. Grubbs' Test is another statistical test used for identifying outliers in a univariate dataset that assumes normality; it tests the hypothesis that the extreme value in the dataset is an outlier [21].

Another foundational statistical method is the Interquartile Range (IQR) approach, which defines outliers as data points lying below $Q1-1.5\times IQR$ or above $Q3+1.5\times IQR$, where Q1 and Q3 are the first and third quartiles, respectively [19]. This is particularly useful for skewed distributions and boxplot-based anomaly visualization.

More advanced techniques include Kernel Density Estimation (KDE), a non-parametric way to estimate the probability density function of a random variable [22]. Anomalies are identified as points in regions of low estimated density. KDE is flexible and does not require assumptions about the distribution form.

In time-series applications, statistical methods like Moving Average and Exponential Smoothing are employed to detect deviations from expected trends. These are often combined with control limits to flag values that exceed expected variation. Similarly, Cumulative Sum Control Charts (CUSUM) and Exponentially Weighted Moving Average (EWMA) charts are widely used in quality control to detect small shifts in process mean [20].

These techniques are particularly valuable due to their interpretability, low computational cost, and ease of implementation. They are commonly used in industries such as finance (to detect fraud), manufacturing (to monitor production quality), and environmental science (to identify climate anomalies).

2) Time-series anomaly detection involves techniques that account for the temporal structure and order of the data [23]. Unlike traditional static datasets, time-series data includes observations collected over time, making the detection of anomalies more challenging due to seasonality, trends, and autocorrelation.

One of the most traditional techniques is the Autoregressive Integrated Moving Average (ARIMA) model. It predicts future values based on past observations. Anomalies are detected by comparing actual values to ARIMA-based forecasts; significant deviations signal potential anomalies. ARIMA is particularly effective when the data shows clear trends or periodic patterns.

Seasonal Decomposition of Time Series (STL) separates a time series into seasonal, trend, and residual components. Anomalies are typically identified in the residual component. This method helps isolate irregularities that cannot be explained by seasonality or trend.

Change-point detection techniques aim to identify points in time where the statistical properties of the series change [24]. These can include abrupt shifts in mean, variance, or autocorrelation structure. Algorithms like Bayesian Change Point Detection, Pruned Exact Linear Time (PELT), and Binary Segmentation are used in applications such as financial market analysis and equipment failure prediction [25].

More recent developments include the Matrix Profile method, which enables fast, scalable similarity search and anomaly detection in large time-series datasets [26]. By identifying the least similar sub sequences, Matrix Profile effectively highlights unusual patterns without requiring a model to be trained.

Time-series specific techniques are essential in fields like energy consumption forecasting, stock market analysis, industrial equipment monitoring, and healthcare analytics, where anomalies often follow complex temporal dynamics.

3) Signal-based anomaly detection techniques are widely used in domains where data is collected in the form of continuous waveforms, vibrations, or frequency-based signals. These techniques focus on identifying irregularities in the shape, amplitude, or frequency components of the signal data, which may indicate faults, noise, or other abnormal conditions. Applications include structural health monitoring, acoustic emission testing, vibration analysis in machinery, and biomedical signal processing such as ECG and EEG monitoring.

One common method is spectral analysis, where the frequency content of a signal is examined using tools like the Fourier Transform [27]. Anomalies may manifest as sudden spikes or drops in power at certain frequencies. In rotating machinery, for instance, deviations from baseline frequency signatures often suggest wear, imbalance, or bearing failure.

Another key method is wavelet transform analysis, which provides both frequency and time localization of signal features [28]. This is particularly useful for identifying transient anomalies, such as sudden impacts or short-duration faults. Wavelets can decompose signals at multiple scales, making them suitable for multi-resolution analysis.

Envelope analysis is another powerful technique used to detect impacts and modulated signals hidden within a complex waveform [29]. It's often used in gear and bearing diagnostics, especially where periodic impulses are masked by noise.

Cross-correlation and coherence techniques are used to compare signals across multiple channels or sensors to detect spatially coherent anomalies, such as propagating cracks in structures.

In AE-based corrosion monitoring, signal-based techniques can distinguish between noise, crack growth, and corrosion signals based on parameters like rise time, amplitude, duration, and energy [30]. These methods are critical in environments where traditional techniques may not detect internal flaws until catastrophic failure.

Signal-based methods are valued for their sensitivity and ability to capture minute signal changes that precede larger failures. However, they require high-fidelity data acquisition systems and advanced filtering to isolate meaningful features.

4) Machine learning techniques form a core component of modern anomaly detection systems. These techniques leverage data-driven learning models to discover complex and nonlinear relationships between features that can indicate abnormal patterns. Depending on the availability of labelled data and the structure of the problem, machine learning techniques are broadly categorized into four main types: supervised, unsupervised, semi-supervised, and self-supervised learning. Each of these categories provides different advantages and trade-offs, and their usage is dictated by the nature of the data and the application domain.

E. Machine Learning Anomaly Detection Techniques

1) Supervised learning involves training models on datasets that include labelled examples of both normal and anomalous data. These models learn to distinguish between the two classes based on the features present in the training data. Algorithms such as Support Vector Machines (SVM), Decision Trees, Random Forests, Logistic Regression, and Neural Networks are widely used in this category.

This approach can be highly effective when ample labelled data is available. It allows for the creation of highly discriminative models that can achieve strong generalization on unseen data [31]. However, its major limitation lies in the difficulty of acquiring sufficient labelled examples of anomalies, which are typically rare and diverse.

Supervised anomaly detection has been successfully applied in spam detection, medical diagnostics, and quality assurance systems where historical labelled datasets are available. Techniques such as cross-validation and synthetic data generation (e.g., SMOTE) are often used to handle class imbalance [32].

2) Unsupervised learning techniques are particularly useful when labelled data is unavailable, which is a common scenario in anomaly detection where anomalies are rare and difficult to label [1]. These models attempt to learn the inherent structure of the dataset without predefined labels, assuming that normal patterns dominate the data distribution. Anomalies are identified as instances that do not conform to these learned patterns.

Common approaches include clustering algorithms like k-means and DBSCAN, where outliers are data points that do not belong to any cluster or are far from cluster centroids. Dimensionality reduction techniques such as Principal Component Analysis (PCA) and Isolation Forest also fall under this category [14]. PCA reduces the data into a lower-dimensional space where anomalies can be observed as deviations from the principal components. One-Class SVM is another widely used method that attempts to learn the boundary of normal data and flags deviations as anomalies.

Unsupervised techniques are widely used in cybersecurity for detecting unauthorized access, in finance for fraud detection, and in manufacturing for identifying process faults. They require minimal prior knowledge about the data and are effective for exploratory analysis.

3) Semi-supervised learning sits between supervised and unsupervised methods. It utilizes a large amount of unlabelled data and a small amount of labelled data—usually only normal instances [2]. The model is trained to capture the distribution of normal data and detect deviations as potential anomalies.

A prominent approach in this category includes One-Class SVM, which learns a decision function that identifies the region in the feature space where the majority of the data lies. Autoencoders, a type of neural network, are also commonly used; they are trained to reconstruct normal data with high fidelity [33]. At inference time, high reconstruction errors suggest that the input does not conform to the learned normal pattern, signalling an anomaly.

Semi-supervised methods are well-suited to industrial applications, such as predictive maintenance, where anomaly data is limited. They are also used in biomedical monitoring, where only healthy data may be available for training.

4) Self-supervised learning (SSL) is an emerging paradigm in anomaly detection that leverages large volumes of unlabelled data by creating pseudo-labels through pretext tasks [34]. These pretext tasks are designed to train models to learn general data representations, which can then be used for

downstream anomaly detection without requiring manually labelled anomalies.

In the context of anomaly detection, SSL often begins by defining surrogate tasks such as predicting masked input features (e.g., in tabular data), reconstructing corrupted signal segments (e.g., in time series), or predicting the temporal order of sequence segments [35]. Models trained on these tasks develop an internal representation of normal data distribution. During inference, deviations from expected patterns are flagged as anomalies.

In time-series anomaly detection, a common SSL strategy involves forecasting future values based on historical data using models like Transformers or Temporal Convolutional Networks. Large prediction errors are used as indicators of anomalous behaviour [36]. Similarly, contrastive learning—a subfield of SSL—maximizes agreement between different views or augmentations of the same data point while minimizing agreement with others, making it powerful for identifying rare deviations.

In industrial and biomedical applications, self-supervised pretraining has shown to improve anomaly detection performance [37]. For example, in acoustic emission-based corrosion monitoring, self-supervised pretraining allows the model to learn signal patterns unique to material degradation without needing explicitly labelled defect types.

SSL not only reduces the dependency on labelled data but also enhances robustness and generalizability across unseen data distributions. It has proven effective in fraud detection, predictive maintenance, healthcare monitoring, and cybersecurity, where anomalies evolve or emerge dynamically over time.

5) Deep learning techniques have revolutionized the field of anomaly detection by enabling systems to automatically extract hierarchical representations from raw, high-dimensional data. These techniques, primarily based on artificial neural networks, are capable of modelling complex and nonlinear data distributions, making them exceptionally powerful for detecting subtle and intricate anomalies.

Convolutional Neural Networks (CNNs) and Recurrent Neural Networks (RNNs) are among the most commonly used deep learning models for anomaly detection. CNNs are particularly effective in applications involving image or spatial data, where anomalies may appear as localized irregularities. For instance, in industrial quality inspection, CNNs can identify manufacturing defects from high-resolution images [38]. RNNs, on the other hand, are designed to process sequential data and are extensively used in time-series anomaly detection, such as sensor data monitoring, by capturing temporal dependencies and flagging unexpected deviations.

Autoencoders are another widely used deep learning technique. These unsupervised neural networks are trained to reconstruct their input data. During testing, if the reconstruction error is high for certain inputs, those inputs are flagged as potential anomalies. Variants such as Variational Autoencoders (VAEs) and Denoising Autoencoders add probabilistic and noise-resilience components to improve detection robustness [39].

Generative Adversarial Networks (GANs) have also gained popularity for anomaly detection [40]. These models consist of a generator that creates fake data and a discriminator that tries to distinguish between real and generated data. The discriminator's inability to classify an instance properly can indicate that the data does not follow the expected distribution, thus signalling an anomaly. GAN-based methods have been applied in fields such as cybersecurity, medical imaging, and predictive maintenance.

Long Short-Term Memory (LSTM) networks, a type of RNN, are particularly effective for learning long-range dependencies in time-series data [41]. They have been employed in health monitoring systems, power grid analysis, and transportation networks to predict normal behaviour and detect anomalies through forecast errors.

Deep learning models benefit from large-scale datasets and computational resources, enabling them to outperform traditional methods in many scenarios [42]. However, they also present challenges such as model interpretability, high computational cost, and the need for careful hyperparameter tuning.

6) Transformers represent a significant advancement in machine learning models for anomaly detection due to their superior ability to model long-range dependencies and capture complex temporal patterns in data. Originally designed for natural language processing, Transformers have since been successfully adapted to various domains including vision, time-series analysis, and industrial monitoring [43]. Unlike traditional recurrent architectures like RNNs or LSTMs, Transformers rely on self-attention mechanisms that allow them to process all elements of a sequence simultaneously, leading to better scalability and improved performance, especially on large and noisy datasets.

One of the key advantages of Transformers in anomaly detection lies in their flexibility and robustness. They can be applied in both supervised and self-supervised settings and are capable of learning high-quality representations from unlabelled data. In comparison to CNNs and RNNs, Transformers offer superior performance in handling multivariate time-series data, where correlations across different features and timestamps must be considered jointly [44]. Moreover, self-attention helps in identifying subtle contextual anomalies that may span long sequences, which traditional models often miss.

This makes Transformers particularly valuable in industrial and infrastructure monitoring applications, such as in predictive maintenance and fault detection. One emerging application is anomaly detection in corrosion monitoring, especially using Acoustic Emission (AE) data, where annotated anomalies are difficult to obtain and the signals are often non-stationary and high-dimensional [45]. The ability of Transformers to learn from limited or unlabelled data and their capacity to model complex temporal dynamics makes them an ideal choice for such scenarios.

Furthermore, recent research has demonstrated that Transformer-based architectures can outperform conventional techniques in both accuracy and generalization when applied to corrosion-related anomaly detection tasks [46]. Their compatibility with self-supervised learning strategies enhances their effectiveness in low-resource settings, making them particularly relevant for pipeline health monitoring systems and structural integrity assessments.

The discussion of Transformer applications in corrosion detection, is expanded further in the next section, where we delve into their specific contributions, datasets, and models.

III. Prior Studies of Transformer Based Models for Corrosion Anomaly Detection

A. Comparative Analysis of Transformer Based Models for Corrosion Detection

The following paragraphs go into a deeper dive into each of the studies mentioned in Table I.

TABLE I. Comparative Study

Study	Transformer Model	Input Data	Learning Setup	Dataset	Accuracy/F1
Efficient Metal Corrosion Area Detection Model Combining Convolution and Transformer	Visual Transformer integrated in MCD-Net	Corrosion images (public dataset A and self-collected Dataset B)	Supervised Learning	Dataset A (AASHTO/BIRM corrosion levels), Dataset B (natural scene images)	F1 Score: 84.53%
CorFormer: a hybrid transformer-CNN architecture for corrosion segmentation on metallic surfaces	CorFormer (hybrid Transformer-CNN)	Corrosion images on metallic surfaces	Supervised Learning	Not stated (mentions 10 validation splits)	IoU improved by 2.7% over SOTA; FPS: 28
Civil Infrastructure Damage and Corrosion Detection: An Application of Machine Learning	Transformer block within CycleGAN (residual block-based Transformer)	UAV aerial images of bridges and steel infrastructure	Supervised Learning	1300 images (Bolte Bridge & Sky Rail, Victoria, AU)	F1 Score: 0.83; Accuracy: 0.989
A Multilevel Bridge Corrosion Detection Method by Transformer-Based Segmentation in a Stitched View	Transformer-based segmentation (e.g., SegFormer)	Stitched images of bridge surfaces	Supervised	Public dataset from Virginia Tech (440 images), augmented with Lundamo Bridge dataset (94 images)	F1 Score: 68.2% (improved from 60–61% with CNNs)
P-DETR: A Transformer-Based Algorithm for Pipeline Structure Detection	Pipe Detection Transformer (P-DETR, DETR-based with FNT module)	Aerial drone images of pipelines	Supervised	Custom dataset (2553 raw + augmented to 6127 images)	mAP: 55% (↑3 AP over DETR); Recall: 73.9%
Corrosion segmentation method of concrete drainage pipes based on point transformer	Point Transformer (U-Net-like)	3D point clouds from real + simulated concrete pipe data	Supervised Learning	200 real + 200 simulated 3D point cloud samples (Azure Kinect DK)	Accuracy: 94.36%; MIoU: 86.31%
SegFormer: Semantic Segmentation Based Transformers For Corrosion Detection	SegFormer	Bridge corrosion images from inspection reports (VDOT)	Supervised Learning	440 annotated images (AASHTO/BIRM guidelines)	Mean Acc: 81.39%; MIoU: 71.16%
Double-Attention YOLO: Vision Transformer Model for Transmission Line Fittings & Rust	Vision Transformer + Dual Attention YOLO	Hazy/defogged images of transmission line connection fittings	Supervised Learning	Not explicitly named; 7700 annotated images (Stage 2)	mAP@0.5:0.95 = 0.8674mAP@0.5 = 0.9948Macro-F1 = 0.661 (stage 1), 0.568 (stage 2)
Corrosion SAM: Adapting Segment Anything Model with Parameter-Efficient Fine-Tuning for Structural Corrosion Inspection	Segment Anything Model (SAM) + Vision Transformer (ViT-H) with Adapter modules (PEFT)	RGB corrosion images resized to 512×512; binarized	Supervised Learning	VDOT (440 images)KRDB (955 images)	VDOT: IoU 69.72%, Dice 81.04%KRDB: IoU 60.78%, Dice 72.97%
Pipeline defect recognition algorithm based on CNN-Transformer model for internal detection in PE gas pipelines	CNN + Transformer with Squeeze-and-Excitation (no positional encoding)	Internal pipeline defect images (1200), 1080×1080 px, collected via inspection robot	Supervised Learning	Custom dataset (1200 images) of PE pipeline defects	Accuracy: 97.8% (avg. over 10 runs)

The study titled “Efficient Metal Corrosion Area Detection Model Combining Convolution and Transformer” proposes MCD-Net, a hybrid deep learning architecture that integrates convolutional layers with a visual Transformer encoder to enhance corrosion detection on metallic surfaces [46]. By combining local feature extraction with global context modelling, the model effectively addresses challenges such as occlusions, lighting variability, and irregular corrosion patterns. It employs an attention-based multi-layer feature fusion mechanism and a multi-scale feature enhancement strategy to refine boundary segmentation. MCD-Net achieved an F1 score of 84.53% on a public dataset, demonstrating improved robustness to noise and lighting compared to conventional CNNs.

In "CorFormer: A Hybrid Transformer-CNN Architecture for Corrosion Segmentation on Metallic Surfaces", the authors present CorFormer, a real-time segmentation model that combines CNNs and Transformers within a unified framework [47]. Transformer layers are embedded within the CNN encoder, while a Semantic Gap Merger (SGM) bridges feature-level disparities. A hierarchical decoder further processes multi-scale features, enabling the model to capture both localized and broad defects. CorFormer improved Intersection-over-Union (IoU) by 2.7% over baseline methods and achieved real-time performance at 28 FPS, making it well-suited for industrial monitoring applications.

The study "Civil Infrastructure Damage and Corrosion Detection: An Application of Machine Learning" introduces a hybrid CycleGAN-based model incorporating Transformer-enhanced residual blocks for corrosion segmentation in UAV-acquired bridge imagery [48]. Positioned between the encoder and decoder of the generator, the Transformer blocks enable domain-adaptive learning, improving the model's robustness to texture and lighting variations. Trained on 1,300 annotated images from Melbourne's Bolte Bridge and Sky Rail, the model achieved an F1 score of 0.83 and an overall accuracy of 98.9%, outperforming traditional networks like PSPNet and SegNet, and demonstrating strong generalization capabilities across diverse aerial scenes.

The study "A Multilevel Bridge Corrosion Detection Method by Transformer-Based Segmentation in a Stitched View" addresses the limitations of CNNs when applied to wide, high-resolution structural images [49]. Utilizing a Transformer-based semantic segmentation model (e.g., SegFormer), the study incorporates stitched bridge surface imagery to enable large-area defect detection. Trained on 440 annotated images from Virginia Tech and additional data from Norway's Lundamo Bridge, the model achieved an F1 score of 68.2%, significantly outperforming U-Net and DeepLabV3+. Although performance was impacted by input resolution, the approach showed strong potential for deployment in field inspection workflows.

In "P-DETR: A Transformer-Based Algorithm for Pipeline Structure Detection", the authors propose an enhanced DETR architecture tailored for small-object detection in aerial pipeline imagery [50]. The model integrates a Feature Normalization and Transformation (FNT) module to improve spatial resolution and feature fusion. Trained on an augmented dataset of 6,127 drone-captured images, P-DETR achieved a mean Average Precision (mAP) of 55% and a recall of 73.9%, outperforming DETR, YOLOv3, and SSD baselines. While highly accurate in static image analysis, real-time drone-based deployment is identified as a future direction for further validation.

The study "Corrosion Segmentation Method of Concrete Drainage Pipes Based on Point Transformer" introduces a 3D point cloud segmentation method using a Point Transformer to identify corrosion in concrete drainage pipes [51]. A U-Net-like architecture is employed, trained on a combined dataset of real and simulated point clouds generated using an Azure Kinect DK. The model achieved 94.36% accuracy and a mean IoU of 86.31%, surpassing PointNet++ and PAConv. The best results were obtained with a 1:1 real-to-simulated data ratio. Despite its computational intensity, the model excels in precise 3D segmentation tasks for corrosion detection.

"SegFormer: Semantic Segmentation Based Transformers for Corrosion Detection" explores the use of SegFormer for corrosion classification based on annotated bridge inspection images following AASHTO and BIRM guidelines [52]. The dataset includes four corrosion severity levels, with class imbalance noted for the "severe" category. After fine-tuning, the model achieved a mean accuracy of 81.39% and a mean IoU of 71.16%. The study emphasizes the need for balanced datasets and tailored preprocessing to improve segmentation performance in underrepresented classes.

The paper "Double-Attention YOLO: Vision Transformer Model Based on Image Processing Technology in Complex Environment of Transmission Line Connection Fittings and Rust Detection" presents a two-stage framework for corrosion detection under visual degradation [53]. The approach integrates defogging preprocessing with a YOLO-based detector that combines Vision Transformers, a dual attention mechanism (CBAM), and GhostNet for efficient inference. Trained on 7,700 annotated images, the model achieved a mAP@0.5 of 99.48% and macro-F1 scores of 0.661 and 0.568. It outperformed multiple baselines—including ATSS, FCOS, and DETR variants—particularly in scenes with small objects, haze, and occlusion.

"Corrosion SAM: Adapting Segment Anything Model with Parameter-Efficient Fine-Tuning for Structural Corrosion Inspection" applies the SAM foundation model with ViT-H backbone to the corrosion domain using adapter-based Parameter-Efficient Fine-Tuning (PEFT) [54]. By inserting adapters into frozen Transformer layers, the model adapts with minimal computational overhead. Evaluated on the VDOT and KRDB datasets, Corrosion SAM achieved IoU scores of 69.72% and 60.78%, and Dice scores of 81.04% and 72.97%, respectively. It consistently outperformed DeepLabV3+, U-Net, and SegFormer, demonstrating the viability of efficient fine-tuning techniques in adapting foundation models to specialized inspection tasks.

Finally, "Pipeline Defect Recognition Using a CNN–Transformer Model" presents a lightweight architecture combining CNNs with Transformers and a Squeeze-and-Excitation module to classify defects in polyethylene (PE) gas pipelines [55]. The model omits positional encoding—leveraging zero-padding from CNNs—and uses Layer Normalization and multi-head attention for stability. Trained on 1,200 images captured by pipeline inspection robots, the model achieved an average accuracy of 97.8% over 10 randomized test runs. It consistently outperformed standard CNN and ViT architectures on small and medium-sized datasets, underscoring its potential for real-world pipeline monitoring.

As can be seen from these studies, the use of transformer-based models improved the accuracy of detecting anomalies caused by corrosion. Therefore, in this study, a transformer-based model was used on the experimental data set along with other models for a comparative analysis of the performances of each model.

IV. METHODOLOGY

A. Experimental Setup

The dataset used in this study was generated through a controlled laboratory experiment designed to simulate real-world corrosion in fluid transport pipelines. As shown in Fig. 1, ten acoustic emission (AE) sensors were strategically distributed along the pipeline—five on the left side (with girth welds between the source and sensors) and five on the right (without girth welds). Accelerated corrosion was induced at the centre of the pipeline over a three-hour period, with sensors spaced at 100 cm intervals to capture both near-field and far-field AE signal variations.

Fig. 1. Setup for the data acquisition.

This experimental dataset was chosen over public datasets to ensure high-fidelity, labelled AE signals under known and controlled corrosion conditions. The setup allowed us to evaluate the performance of machine learning models in detecting corrosion-induced anomalies while accounting for attenuation effects due to girth welds. Such a controlled environment also provided reliable ground truth for model validation, making the dataset particularly suitable for the supervised, unsupervised, and hybrid models evaluated in this study.

B. Data Analysis

After filtering and analysing the data, strong correlations was found between the parameters ABS-ENERGY and Signal Strength, along with distance (channel 3 being the closest and channel 8 being the furthest). The scatterplot in Fig. 2 shows the relationship. These relationships will be used to train the machine learning models that would detect the corrosion.

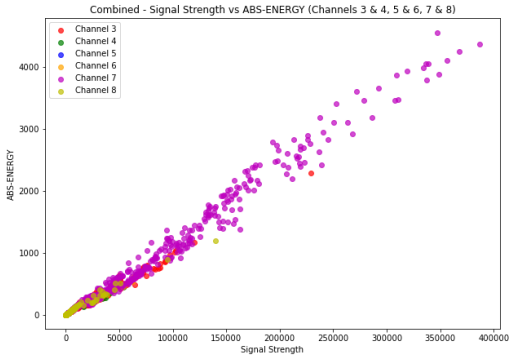

Fig. 2. Relationship between ABS-ENERGY and RMS.

V. RESULTS AND DISCUSSION

A. Machine Learning Models and Transformer Based Models Applied

In the following paragraphs, each ML model used, including the Hybrid CNN-Transformer, is described in detail along with its performance on the acquired data from the experiment. The bar graph in Fig. 3 provide a visual representation of the performances of each ML model.

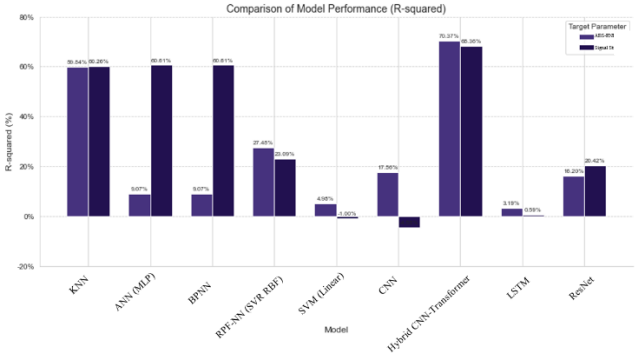

Fig. 3. Comparison of ML models.

1) K-Nearest Neighbours (KNN) is a non-parametric, instance-based learning algorithm that predicts the value of a target variable by averaging the values of its k-nearest neighbors in the feature space. For both 'ASL' and 'RMS', KNN demonstrated relatively strong performance, achieving R-squared values of 0.5984 and 0.6026, respectively. This suggests that the local patterns in the 'Distance' and 'CH' feature space are somewhat indicative of the target parameters. The moderate to high R-squared scores imply that a significant portion of the variance in both 'ASL' and 'RMS' can be explained by the values of their nearest neighbours. However, the performance is not perfect, indicating that other factors or more complex relationships might be at play.

2) The Artificial Neural Network (ANN) and Backpropagation Neural Network BPNN, both implemented as a Multi-Layer Perceptron with similar architectures (two hidden layers with 64 and 32 neurons), exhibited substantially lower performance for 'ASL' (R-squared of 0.0907) compared to KNN. For 'RMS', the performance was significantly better, reaching an R-squared of 0.6061, comparable to KNN. The discrepancy in performance for 'ASL' suggests that the non-linear relationships captured by the MLP were not as effective as the local averaging performed by KNN for this specific parameter. Conversely, for 'RMS', the MLP was able to model the underlying relationships as effectively as KNN. The fact that both ANN and BPNN yielded identical results is expected given their identical implementation and random initialization (controlled by the random state). This highlights the sensitivity of neural network performance to the specific target variable and the potential need for more extensive hyperparameter tuning.

3) The Support Vector Regression with Radial Basis Function kernel (RBF-NN), implemented using SVR with an RBF kernel, showed moderate predictive power for both 'ASL' (R-squared of 0.2748) and 'RMS' (R-squared of 0.2309). The RBF kernel allows the model to capture non-linear relationships through the use of radial basis functions. The performance was lower than KNN and the better performing neural network for 'RMS', indicating that the specific non-linear mapping learned by the RBF kernel was not as well-

suited to the underlying data distribution for these parameters compared to the other effective models.

4) The Support Vector Regression (SVM) with a linear kernel demonstrated the poorest performance among the dedicated regression models for 'ASL', achieving an R-squared of only 0.0498. For 'RMS', the R-squared was even slightly negative (-0.0100), indicating that the model performed worse than simply predicting the mean of the 'RMS' values. This suggests that the relationship between the features ('Distance' and 'CH') and the target parameters is likely non-linear, and a linear model is insufficient to capture the underlying patterns. The near-zero or negative R-squared values highlight the importance of selecting a model that can accommodate the complexity of the data relationships.

5) The Convolutional Neural Network (CNN) adapted for this task by treating each data point as a single timestep, also exhibited low performance, with an R-squared of 0.1756 for 'ASL' and a negative R-squared of -0.0455 for 'RMS'. CNNs are typically designed for sequential or spatial data, and their poor performance here likely stems from the lack of a meaningful sequential structure in the provided features in relation to the target variables. The convolutional layers, designed to detect local patterns across a sequence, may not have been effectively utilized in this context.

6) The Hybrid CNN-Transformer Model yielded the highest performance for both 'ASL' (R-squared of 0.7037) and 'RMS' (R-squared of 0.6836) among all the models evaluated. This model leverages the strengths of Convolutional Neural Networks (CNNs) for local feature extraction from the raw acoustic emission (AE) waveforms or their spectrograms, and Transformer encoders for capturing long-range temporal dependencies. The CNN layers are adept at identifying intricate, localized patterns and transient events within the AE signals, which are crucial for understanding the underlying physical processes. Subsequently, the Transformer's self-attention mechanism processes these extracted features, allowing the model to learn complex, non-linear relationships across extended segments of the AE data. The high R-squared scores suggest that the model effectively translates the rich information embedded in the AE signals (which implicitly capture 'Distance' and 'CH' effects, along with other nuanced characteristics) into highly accurate predictions for both 'ASL' and 'RMS'. The strong performance of this hybrid architecture indicates its superior ability to learn hierarchical and contextual representations from the sequential AE data, bridging the gap between local signal characteristics and their global impact on the target parameters.

7) The Long Short-Term Memory network (LSTM), a type of recurrent neural network designed for sequential data, showed very poor performance, with an R-squared of 0.0319 for 'ASL' and 0.0059 for 'RMS'. Similar to the CNN, the poor performance is likely due to the lack of a clear temporal dependency in the provided features. Treating the data points as a sequence of single timesteps did not allow the LSTM's recurrent architecture to effectively learn predictive patterns for these parameters.

8) The Deep Residual Network (ResNet) implemented also showed relatively low performance, with an R-squared of 0.1620 for 'ASL' and 0.2042 for 'RMS'. While ResNets are powerful for learning deep representations, their architecture, adapted here for non-sequential data, did not outperform simpler models like KNN or the Decision Tree. The skip connections, designed to ease the training of deep networks, might not have provided a significant advantage in this context with the given data structure.

VI. Limitations and Future Work

While the study demonstrates the potential of machine learning and Transformer-based models for corrosion detection using acoustic emission data, several limitations should be acknowledged. One notable limitation is that the effect of temperature on the pipeline and the acoustic signal propagation was not considered during the experiment. In real-world scenarios, pipelines operate under varying thermal conditions, which can alter AE signal characteristics such as amplitude, attenuation, and wave speed. Ignoring temperature effects may limit the generalizability of the trained models to operational environments with fluctuating temperatures.

Future work should incorporate temperature as a variable in both data collection and model training to improve robustness. This could involve using temperature-compensated sensors, collecting data under controlled thermal variations, or integrating temperature data as an additional input feature for model training. Additionally, further research could explore the deployment of the proposed hybrid CNN-Transformer model in real-world pipelines with dynamic environmental conditions and test its performance across different corrosion types and pipeline materials.

VII. Conclusion

The study conclusively demonstrates the significant advantage of employing a Hybrid CNN-Transformer Model for accurately predicting Acoustic Signal Level (ASL) and Root Mean Square (RMS) in acoustic emission-based corrosion detection. Achieving R-squared values of 0.7037 for ASL and 0.6836 for RMS, this transformer-based architecture outperformed all other evaluated machine learning models, including traditional methods like KNN, SVM, and even other deep learning models like ANNs, CNNs, LSTMs, and ResNets.

This success can be attributed to the inherent design of the Hybrid CNN-Transformer. It effectively harnesses the Convolutional Neural Network's ability to extract nuanced, local features and transient patterns from raw AE waveforms or their spectrograms, which are critical for characterizing the distinct acoustic signatures of corrosion. Subsequently, the Transformer encoder's self-attention mechanism excels at learning complex, long-range temporal dependencies and contextual relationships across these extracted features. This synergistic combination allows the model to process the high-dimensional, sequential AE data comprehensively, bridging the gap between subtle local signal changes and their broader

implications for corrosion-related parameters. The high R-squared values unequivocally indicate that this advanced, transformer-based approach can effectively decipher the intricate link between AE signals and the target parameters, representing a significant step forward in robust and accurate corrosion detection through acoustic emission monitoring.

ACKNOWLEDGMENT

This research is ongoing research supported by YUTP Research Grant Scheme.

***Abstract*—Diabetic Foot Ulcer (DFU) is a serious and common complication of diabetes mellitus, which can lead to lower limb amputation if not identified and treated in its early stages. This study introduces an integrated and intelligent system designed for the early detection and severity classification of DFUs by combining sensor-driven data collection with machine learning techniques in a mobile application. The research is based on a dataset comprising both clinical features (D-1 to D-16) and key sensor-based readings gathered from 316 participants. After preprocessing and normalization, the clinical data undergoes feature selection using CatBoost, which filters out the five least impactful features while preserving all sensor data due to its diagnostic relevance. The refined dataset is then processed using a Deep Neuro-Fuzzy Network (DN-FN) to deliver real-time DFU severity predictions, categorized into Low, Mid, and High-risk levels. The solution is deployed through an intuitive smartphone interface, enabling users to input clinical data once and conduct periodic sensor-based tests—including vibration, pressure, and temperature readings. The mobile application interfaces with embedded hardware via Bluetooth and performs offline inference using a compact version of the trained model. The system is designed to offer both patients and healthcare professionals a practical and interpretable tool for continuous monitoring of foot health, with the ultimate goal of reducing the risk and impact of DFU complications.**

Keywords*—Bayesian Optimization; CatBoost; Deep Neuro-Fuzzy Networks (DN-FN); Diabetic Foot Ulcer (DFU) prediction; sensor-based risk stratification

I. Introduction

Diabetes mellitus continues to rise as a critical global health issue, with around 537 million adults affected as of 2021—a number expected to surge to 783 million by 2045 (International Diabetes Federation, 2021). [1] One of the most serious complications associated with diabetes is Diabetic Foot Ulcers (DFUs), which impact an estimated 15% to 25% of diabetic patients during their lifetime. [2] DFUs contribute to over 85% of diabetes-related lower-limb amputations, placing a heavy burden on healthcare infrastructure and severely affecting patients' quality of life. [3]

India, with over 77 million diabetic adults, holds the second-largest diabetic population globally [4]. The country faces considerable difficulties in detecting DFUs early, especially in semi-urban and rural regions. Challenges such as limited diagnostic resources, irregular medical follow-ups, and a scarcity of trained healthcare providers often lead to delayed intervention in foot-related complications.

Although diagnostic technologies have progressed, DFU evaluation largely remains manual and reactive. Standard assessment techniques depend heavily on clinical expertise and are often unavailable or impractical in remote settings [5]. This highlights the pressing need for an affordable, scalable, and intelligent solution capable of facilitating both early diagnosis and ongoing risk monitoring.

This work proposes a smart and accessible system that merges clinical information with sensor-derived data, enhanced by advanced machine learning techniques, and implemented through a smartphone-based application. The system enables early and proactive DFU risk classification by employing CatBoost for efficient feature selection and a DN-FN for accurate prediction. It emphasizes interpretability, adaptability, and reliable performance, including functionality in offline scenarios—addressing the practical limitations in current DFU screening approaches.

The remainder of this paper is organized as follows: Section II presents an in-depth literature review of existing DFU prediction methodologies. Section III outlines the dataset, hardware setup, feature selection using CatBoost, and the development of the DN-FN model. Section IV discusses the results and model performance based on standard evaluation metrics. Section V concludes with a summary of key contributions and outcomes.

II. Literature Review

Chatratia et al. [6] present a smart home health monitoring system integrating machine learning models for predicting type 2 diabetes and hypertension based on blood pressure and glucose readings, with Support Vector Machine (SVM) achieving the highest accuracy (75%) for diabetes prediction. This system facilitates real-time alerts to healthcare providers, promoting early detection and intervention. Similarly, Agrawal et al. [7] compared statistical methods and machine learning models for plantar pressure-based diabetic foot classification. Using wireless insoles, they found that the AdaBoost model achieved the highest accuracy (0.85), outperforming traditional methods, suggesting that ML models significantly enhance diabetic foot prediction and classification.

This work was supported and funded by the Indian Council of Medical Research (ICMR) and facilitated by Vellore Institute of Technology, Vellore.

Reddie et al. [8] introduced a low-cost, purely mechanical plantar pressure evaluation device utilizing bistable compliant mechanisms, allowing non-specialist healthcare workers to assess foot pressure, though sensitivity improvements are needed. Ghazi et al. [9] developed a smart shoe system integrating temperature, humidity, plantar pressure, and oxygen saturation sensors, with efficient real-time monitoring and responsive data transmission, though future work is needed to improve sensor accuracy. Kularathne et al. [10] presented Dia-Shoe, a smart diabetic shoe with IoT-enabled sensors, transmitting real-time data to a mobile app and showing high calibration accuracy, emphasizing the importance of refining sensors and predictive modeling for DFU prevention.

Ming et al. [11] proposed a telemedical monitoring system using sensor-equipped insoles to detect plantar temperature asymmetry, where intervention groups showed no ulcer cases, demonstrating feasibility but limited by low ulceration incidence during the study. Bus et al. [12] evaluated the DIATEMP system involving daily foot temperature monitoring for DFU prevention. Although no significant reduction was seen at monitored sites, significant benefits were observed when adherence to activity reduction was high, stressing that patient behavior plays a critical role in telehealth interventions for DFU.

De Pascali et al. [13] developed a smart insole-based monitoring platform integrating microfabricated sensors for plantar pressure, temperature, and sweat glucose detection. This real-time wireless system proved capable of detecting early signs of ischemic damage and inflammation, with strong technical performance in piezoelectric and glucose sensing. Although promising, the system remains in early-stage development, requiring clinical validation and broader usability testing. This effort represents an important step in combining bio-sensing with wearable technologies for DFU prevention.

Reddie et al. introduced a purely mechanical plantar pressure evaluation device designed for low-resource settings. Utilizing bistable compliant mechanisms, the system provides binary feedback without electronics. Though sensitivity was relatively low in healthy subjects (25.6%), performance improved in heavier individuals, indicating potential with design enhancements. This approach offers a minimalistic and accessible solution for DFU screening where advanced electronics are impractical.

Nagarajan et al. [14] proposed a cryptographically secure data transmission method in the Internet of Medical Things (IoMT) using a hybrid RES-256 model, which combines RC6 encryption, ECDSA digital signatures, and SHA-256 hashing to safeguard sensitive health data. The system ensures end-to-end confidentiality, integrity, and authentication between implantable medical devices and clinical repositories. This architecture offers resilience against known attacks such as DoS and router-level intrusions, and is validated using ECG signals from the MIT-BIH dataset, showing efficient encryption/decryption performance. While their focus was on data protection rather than analytics, the architectural principles are directly applicable to DFU systems, particularly in securing patient sensor streams (pressure, vibration, and temperature) in mobile-based diagnostic applications.

Ramana et al. [15] developed an ambient intelligence-based intrusion detection system for IoT environments using a Reinforcement Learning-integrated Deep Q-Network (RL-DQN). The model performs binary attack classification at the edge and multi-class detection in the cloud, enhancing real-time threat identification in wireless sensor networks. Evaluated on datasets like UNSW-NB15 and CICIDS2017, it outperforms traditional ML methods in intrusion detection accuracy. Their design affirms the feasibility of deploying intelligent, lightweight inference models on resource-limited platforms—an essential requirement for smartphone-based DFU screening in rural or offline clinical scenarios.

Fakhar et al. [16] proposed a deep learning-based MLFNN model for early diabetes detection using the PIMA dataset. Their approach included data normalization, advanced activation functions (ELU, SELU), and robust validation, achieving superior performance over traditional classifiers. This study is reviewed for its methodological relevance—particularly in data preprocessing and neural network-based medical prediction—which aligns with our DFU system's clinical data handling and predictive modeling approach.

These studies collectively highlight the progress in applying machine learning and deep learning models to clinical and sensor-based data for effective DFU detection and risk stratification. Building on this foundation, the proposed system introduces a hybrid framework that integrates CatBoost for feature selection and a DN-FN for predictive modeling, with an emphasis on real-time DFU risk assessment and seamless deployment via smartphone-based applications for enhanced accessibility and scalability.

III. Methods and Methodology

Conventional diabetic foot ulcer (DFU) risk prediction systems predominantly rely on static clinical parameters and lack integration of real-time physiological data, resulting in suboptimal early detection and limited clinical utility. Furthermore, many existing approaches employ opaque machine learning models and manual feature selection techniques, which constrain model interpretability and hinder their deployment in patient-facing applications.

To address these limitations, the proposed study introduces a multi-modal, smartphone-integrated predictive framework that combines dynamic sensor inputs—pressure, temperature, and vibration sensitivity—with comprehensive clinical attributes. Feature selection is performed using the CatBoost algorithm, which offers high efficiency and interpretability in handling heterogeneous data types. For classification, a Deep Neuro-Fuzzy Network (DN-FN) is employed to model nonlinearities and uncertainty in physiological signals while maintaining interpretability through fuzzy logic layers.

This end-to-end methodology enables real-time DFU risk stratification (low/mid/high) and seamless deployment in a mobile environment, making it suitable for remote, home-based monitoring and early intervention.

A. Data Acquisition and Integration

This study is based on a dataset collected from 316 participants, including 192 individuals with diabetes and 124

healthy controls, gathered from several small clinics and healthcare centers across the Vellore district in Tamil Nadu, India. The dataset is divided into two main feature groups: clinical and sensor-based attributes. In Table I, the clinical data (D-1 to D-16) covers a broad range of demographic and medical details, such as diabetic condition, age, gender, BMI, HbA1c, blood pressure, family history, and key lifestyle factors like diet, physical activity, smoking, and alcohol use. It also includes anthropometric indicators like height and weight to improve model accuracy. The sensor-derived data is captured through dedicated hardware, with pressure readings from force-sensitive resistors (FSRs), temperature values from DS18B20 digital sensors, and vibration sensitivity measured manually using an eight-point tactile test on both feet to evaluate neuropathy. While users enter their clinical information once during initial registration via a smartphone app, the sensor readings are collected in real time during each assessment, enabling dynamic monitoring and responsive DFU risk prediction.

TABLE I. DATASET FEATURES AND CORRESPONDING LABELS

Data Attributes	Identifiers
Diabetic	D-1
Age	D-2
Gender	D-3
BMI	D-4
HbA1c	D-5
Blood Pressure	D-6
Family History	D-7
Diet	D-8
Physical Activity	D-9
Smoking	D-10
Alcohol	D-11
Education	D-12
Profession	D-13
Early Signs of DFU	D-14
Height	D-15
Weight	D-16
Pressure of Right Fore Foot	RP-1
Pressure of Right Heel	RP-2
Pressure of Left Fore Foot	LP-1
Pressure of Left Heel	LP-2
Temperature of Right Fore Foot	RT-1
Temperature of Right Heel	RT-2
Temperature of Left Fore Foot	LT-1
Temperature of Left Heel	LT-2
Vibration Sensitivity - Right Foot	RV-1 to RV-8
Vibration Sensitivity - Left Foot	LV-1 to LV-8

B. Data Preprocessing

The dataset comprises 316 individuals, each with 16 clinical attributes and 24 sensor readings, including plantar pressure, skin temperature, and vibration sensitivity. This heterogeneous data demands careful handling to maintain quality and compatibility for machine learning applications.

To address missing entries, different imputation strategies are used based on the feature type. Numerical clinical variables such as age, BMI, HbA1c, and blood pressure are filled using mean imputation, ensuring that the overall distribution is preserved. For categorical attributes like gender, diet, and smoking status, mode imputation is applied to replace missing values with the most common category in each field. Notably, sensor data—including pressure, temperature, and vibration sensitivity—is collected in real time during each user session, making it inherently complete and not requiring imputation.

Categorical features are then transformed into numerical formats using appropriate encoding methods. Binary categories such as gender, smoking, and alcohol usage are processed using label encoding. For multi-class variables like education level and profession, one-hot encoding is used to prevent the model from learning false ordinal relationships. This encoding ensures that the dataset remains interpretable and machine-friendly without introducing bias.

Normalization is applied to all continuous numerical features to bring them to a uniform scale, facilitating faster and more stable model training. Min-Max normalization is used to scale attributes such as age, BMI, HbA1c, blood pressure, height, and weight. Similarly, sensor data—including plantar pressure and temperature—is normalized to account for individual variations, while vibration sensitivity values, already in binary form, are directly incorporated without transformation.

C. Feature Selection Using CatBoost

To enhance the model's performance and generalization capability, the CatBoost algorithm [17] [18] —an advanced gradient boosting method developed by Yandex—is utilized for assessing the importance of input features. By training CatBoost on the clinical dataset, it generates importance scores for all 16 clinical variables (D-1 to D-16). One of the key strengths of CatBoost is its native support for categorical features, enabling efficient processing while minimizing overfitting through ordered boosting strategies. As shown in Fig. 1, the feature importance rankings indicate that, five clinical attributes—D-9 (Physical Activity), D-8 (Diet), D-10 (Smoking), D-12 (Education), and D-13 (Profession)—were identified as having minimal relevance to DFU risk prediction and were thus excluded. These variables showed weak associations with the target outcome, contributing little to the model's predictive capacity. The refined feature set, comprising the remaining 11 clinical features and all sensor-based inputs, serves as the input layer for the modeling phase, ensuring improved classification efficiency and model interpretability.

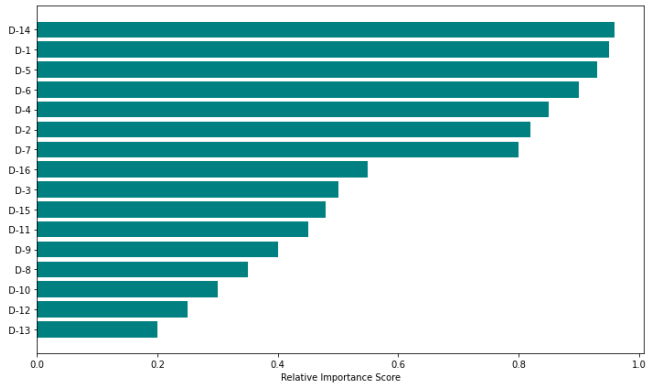

Fig. 1. Given dataset's clinical feature importance for DFU severity evaluation – comparison-ranking chart.

This targeted pruning reduced dimensional redundancy while maintaining the model's diagnostic robustness. The remaining high- and moderately ranked clinical predictors were then integrated with the sensor data for input into the DN-FN, ensuring an optimized and clinically meaningful feature set for risk classification.

D. Deep Neuro-Fuzzy Network (DN-FN)

The selected features are then passed to the DN-FN for the prediction phase. The DN-FN is a hybrid model that integrates deep learning with fuzzy logic to capture complex, nonlinear relationships in the data [19] [20]. As shown in Fig. 2, the DN-FN operates in a multi-phase architecture—fuzzification, fusion, and learning—to transform the input data into fuzzy sets, combine them into a unified representation, and learn from these patterns to predict the DFU risk level. This approach ensures the model not only performs accurate predictions but also remains interpretable, making it easier for clinicians to understand how specific inputs influence the risk classification.

Algorithm 1: DN-FN Prediction Algorithm

Input:

Sensor + clinical feature vector $\boldsymbol{z_i} \in R^d$ for patient i, with true label $y_i \in \{L, M, H\}$

1. Fuzzification Phase (Input → Fuzzy Layer)

Each input feature is fuzzified using Gaussian membership functions:

$$\mu_{ij}^{(k)} = \exp\left(-\frac{\left(z_{ij}-m_j^{(k)}\right)^2}{2\left(\sigma_j^{(k)}\right)^2}\right) \quad (1)$$

- $m_j^{(k)}$: center of k-th MF for feature j
- $\sigma_j^{(k)}$: width of the MF

This generates fuzzy activations for each input dimension.

2. Fusion Phase (Fuzzy → Fusion Layer)

Combine all fuzzy outputs using fuzzy rule-based logic to form rule strengths:

$$r_q = \prod_{j=1}^{d} \mu_{ij}^{(k_{qj})} \text{ (rule strength for rule } q) \quad (2)$$

Normalize all rule strengths:

$$\tilde{r_q} = \frac{r_q}{\sum_{q'=1}^{Q} r_{q'}} \quad (3)$$

Pass through a weighted linear combination to form the fused representation:

$$f_i = \sum_{q=1}^{Q} \tilde{r_q} \cdot \left(\boldsymbol{w_q}^{\top} \boldsymbol{z_i} + b_q\right) \quad (4)$$

3. Learning Phase (Fusion → Hidden Layer → Output Layer)

Step 3.1: Hidden Layer Processing

The fused scalar or vector f_i is input to a deep learning stack (MLP or BiLSTM). For simplicity, assuming MLP:

$$\boldsymbol{h_1} = \phi(\boldsymbol{W_1} f_i + \boldsymbol{b_1}) \quad (5)$$

$$\boldsymbol{h_2} = \phi(\boldsymbol{W_2 h_1} + \boldsymbol{b_2}) \quad \text{(and so on, as per hidden depth)} \quad (6)$$

- ϕ: non-linear activation (e.g., ReLU, tanh)

Step 3.2: Output Layer

Final dense layer maps hidden activations to class logits:

$$\boldsymbol{o_i} = \boldsymbol{W_o h_n} + \boldsymbol{b_o} \quad (7)$$

Softmax applied for class probabilities:

$$\hat{y}_i = \arg\max\left(\text{softmax}(\boldsymbol{o_i})\right) \quad (8)$$

Output:

Predicted class label $\hat{y}_i \in \{L, M, H\}$ for each patient/sample

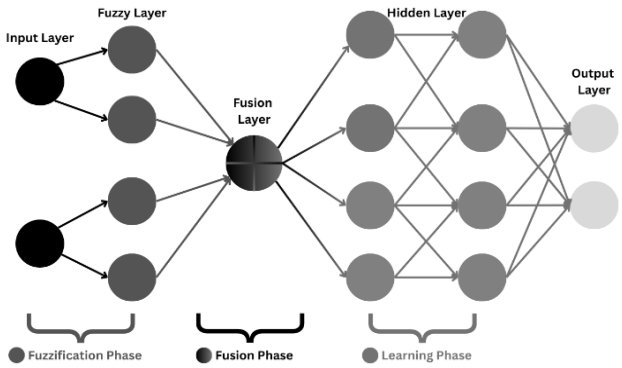

Fig. 2. DN-FN Prediction model – network architecture.

Furthermore, Bayesian Optimization is employed to fine-tune the hyperparameters of the DN-FN model. Unlike conventional methods such as grid search or random search, this approach leverages a probabilistic model to explore the hyperparameter space more intelligently, selecting optimal configurations based on prior evaluations. Key parameters—including learning rate, tree depth, and regularization factors—are optimized through this method, leading to improved model performance and better generalization to new data. The model's effectiveness is first validated using an 80:20 stratified train-test split, ensuring a consistent distribution of diabetic and healthy cases across both sets. To enhance the reliability of performance assessment, 5-fold cross-validation is also conducted, offering a more comprehensive evaluation across different subsets of the dataset.

E. Smartphone-Based Integration and Real-Time Inference

The Diabetic Foot Screening Companion (DFSC) mobile app, built using Android Studio with Java and Kotlin, integrates a TensorFlow Lite (TFLite)-based backend for fast, offline inference of DFU risk using the trained Deep Neuro-Fuzzy Network (DN-FN) model. Users input their clinical data once during registration—excluding the five least significant features removed via CatBoost—and the app stores this locally. During each assessment, the app connects via Bluetooth to an Arduino-based embedded system that collects real-time sensor data across three modalities: vibration sensitivity at 16 foot points (RV-1 to RV-8, LV-1 to LV-8), plantar pressure via Force Sensing Resistors (RP-1, RP-2, LP-1, LP-2), and localized temperature using DS18B20 sensors (RT-1, RT-2, LT-1, LT-2). These readings are processed on-device when the user taps "Calculate Severity," triggering the DN-FN model to classify DFU risk into Low, Mid, or High. Results are presented with color-coded severity indicators, health tips, and recommendations. Designed for accessibility in rural or resource-limited areas, the DFSC app enables proactive self-monitoring through its user-friendly interface, offline capability, and comprehensive multi-sensor integration. Fig. 3 represents the mobile application's navigations and functionalities and Fig. 4 shows the built model's prototype device.

Proposed DN-FN - CatBoost	92.4	91.2	89.7	90.4	94.5	88

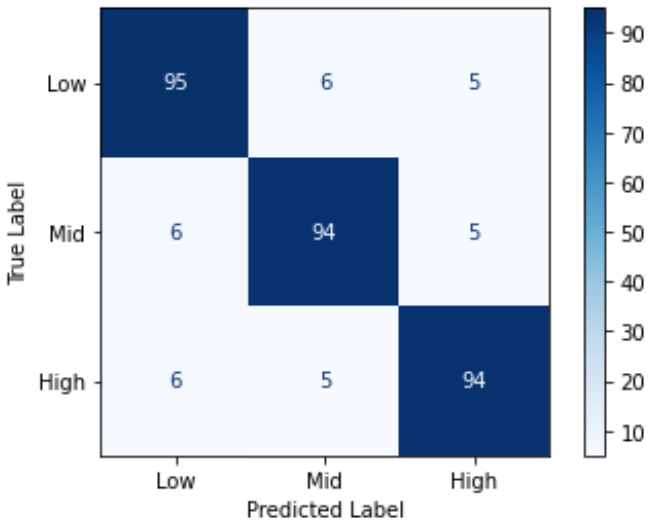

Fig. 5. Confusion matrix for three class DFU severity classification.

The performance of the proposed DFU risk prediction system, utilizing the CatBoost-selected features and the DN-FN model, demonstrates strong classification accuracy across all three severity levels—Low, Mid, and High. Fig. 5 visualizes the confusion matrix of the proposed model which correctly classified 95 Low-risk, 94 Mid-risk, and 94 High-risk instances, with only minimal misclassifications between adjacent classes. These results indicate the model's ability to effectively differentiate among DFU severity levels, particularly in borderline cases where physiological parameters might overlap. The near-diagonal dominance of the confusion matrix highlights the model's robustness and reliability in real-world risk stratification, affirming its suitability for integration into the DFSC mobile application for continuous, on-device diabetic foot monitoring.

B. Discussion

Compared to prior studies, the proposed smartphone-integrated system demonstrates notable advancements in both predictive accuracy and deployment feasibility. Agrawal et al. achieved 85% accuracy using AdaBoost for plantar pressure-based classification, while the proposed model surpassed this with improved precision and real-time DFU severity grading across multimodal sensor data. Similarly, Ghazi et al. and Kularathne et al. developed smart footwear systems incorporating temperature and pressure sensors, but lacked advanced feature selection or neuro-fuzzy logic for personalized risk profiling. Ming et al. and Bus et al. emphasized telemedical approaches, though their effectiveness was limited by adherence and simplistic data interpretation. In contrast, the proposed system leverages intelligent preprocessing, robust feature selection via CatBoost, and a deep neuro-fuzzy framework for explainable, real-time DFU detection, making it more adaptive and clinically relevant for at-home screening in resource-constrained settings.

C. Limitations and Future Work

While the proposed system demonstrates significant potential, it does face certain limitations that could impact the comprehensiveness of diabetic foot ulcer (DFU) risk assessment. A notable shortcoming is the exclusion of pulse oximeter data and microvascular flow indicators, which are critical for evaluating peripheral circulation and anticipating DFU development. Moreover, the current smartphone-based implementation lacks individualized interpretability tools such as SHAP or LIME, restricting users from understanding the underlying reasoning behind each prediction. Another limitation is the absence of longitudinal tracking, which is essential for monitoring changes in foot health over extended periods.

To overcome these gaps, future iterations of the system will integrate pulse oximeter sensors to support real-time vascular health evaluation. Additionally, efforts will be made to embed SHAP-driven explainability directly into the mobile application, offering both clinicians and users greater transparency into prediction logic. The dataset will also be diversified to include participants from various ethnic backgrounds, thereby improving the model's generalizability and relevance. Furthermore, the architecture will adopt federated learning techniques to facilitate on-device model training while preserving user privacy. Collectively, these enhancements aim to bolster the system's clinical utility, reliability, and adaptability in diverse, real-world healthcare environments.

V. CONCLUSION

This study validates the effectiveness of combining CatBoost-based feature selection with a Deep Neuro-Fuzzy Network (DN-FN) for early and interpretable prediction of Diabetic Foot Ulcer (DFU) risk. By leveraging a hybrid input space of clinical attributes and real-time sensory data—including plantar pressure, foot temperature, and vibration sensitivity—the proposed framework demonstrates superior performance over existing machine learning models in terms of accuracy, reliability, and semantic transparency. The smartphone-integrated deployment ensures offline operability and user accessibility, making it particularly suitable for rural and resource-constrained settings. The system allows patients to input clinical data once while performing periodic sensory tests, enabling continuous foot health monitoring. Comparative evaluation shows that the proposed approach outperforms state-of-the-art models in key evaluation metrics, underscoring its robustness and clinical relevance. Future enhancements will focus on incorporating vascular health sensors like pulse oximeters, advanced explainable AI techniques such as SHAP for instance-level interpretation, and privacy-aware training methods like federated learning to expand its utility and scalability in real-world clinical practice.

Decoding Sales Order Anomalies: Advanced Predictive Modeling and Discrepancy Resolution Utilizing Machine Learning Algorithms

Amit Kumar Soni, Pooja Jain
IIIT Nagpur, Nagpur, India

***Abstract*—This study examines the accuracy of order prediction and determines the grounds for order block predictions. It sets order deviation by calculating forecasted variation using R^2 scores and mean absolute deviation. The blocks that are checked mainly include—business partner block, credit block, common block, and delivery block. Demand forecasts compare six months' worth of sales data against mean absolute deviation and coefficient of variation. This study puts forth a proposal for solving discrepancies between sales order forecasts and confirms credit management's system credit limits on sales orders. Parameters for evaluating orders are set relying on historical data. Machine Learning (ML) has been utilized in this study—which involves Support Vector Machine (SVM) and K-Nearest Neighbor (KNN) algorithms to improve accuracy where they achieve 96% and 93% respectively.**

Keyword*—Block predictions; credit; machine learning; sales data

I. Introduction

In this study—forecast predictions and reasons behind sales order evaluation using Machine Learning (ML) have undergone analysis [1]–[5]. This study underscores prediction delays due to inconsistencies in orders. Business success hinges on the continuous prediction of demand concerning forecast quantity and actual sales quantity. This aids companies in boosting production efficiency by crafting an optimal supply chain and ensuring product availability. Generally, SAP—predictive maintenance and service—aids customers with a unified solution for identifying issues within large machine fleets. It enhances services and optimizes service planning for individual forecasts. SAP cloud edition stands as an innovative solution in predictive analytics. Big data in SAP surpasses the capacity of traditional databases for capturing product data. However, ML facilitates big data visualization and analysis to provide real-time outcomes. Data sensors can be used for obtaining real-time master data. SAP ensures enhanced security through encrypting sensor data and is achieved via user management and authentication. Therefore, the issues concerning the sales order are not addressed in this study.

Hypotheses can rectify the mismatch between anticipated and actual sales quantities. It is therefore useful for analyzing sales order confirmations and showcasing the role of ML in predicting delays. Demand varies across periods—making accurate forecasting highly critical for forecasting order quantities. A six month dataset is used to evaluate the forecast. This requires that demand can be predicted through forecasts per specific period because there is volatility across the horizon. For this matter, a promise check is available—which is employed in checking whether products are available in terms of quantity at the time of creating a sales order and—hence—confirms schedule lines at the line-item level. This ensures that the available promise check succeeds during order creation by giving quantity to the sales order. This forecasted order remains unutilized by any customer requirement within Supply Chain Management (SCM), Advanced Planning and Optimization (APO) as well as Demand Planning Module (DPM). The strategy of forecasted order may be missing, or its strategy has deviated from that defined on the product master's strategy tab. On average it will be 5% when comparing the projected forecast with the last three months' sales data. Data for modeling consists of past events while future occurrences are used as inputs for the next period's forecasting. Therefore, an 80% of train dataset was utilized to build models with 20% left out as a test dataset. The R-squared score is used to evaluate how well a given forecast is performing.

The study is as follows; the background will be seen in the following section. The related works are listed in Section III. The problem statement is given in Section IV. The implementation is carried out in Section V. The experimental analysis is presented in Section VI, and in Section VII, we propose a conclusion and future directions for the research.

II. Background

The study highlights a block in display mode and discusses credit blocks in sales orders. Sales orders having credit blocks appear on monitor stock. Such deliveries remain blocked if their credit limit is exceeded. Credit checks are done upon every sales orders and delivery documents. System-guided changes to new credit conditions—whenever—customers' credit positions demonstrate dynamic and static functionality respectively. Credit checks aim to mitigate the risk of customers exceeding their credit limits—necessitating re-evaluation of prior approved deliveries upon any change in delivery. Therefore, a careful analysis of credit checks and limits is essential for each sales order that results in an order block and thus—halts subsequent processing. When a sales order document is created for an account with an assigned credit limit—**it** changes the items automatically—set to the—delivery block in the document. This automatic setting occurs whenever document changes are made—as the credit limit re-

evaluates the document's value against the credit limit in the account master data. The credit limit is maintained in the financial tab while the delivery block credit limit is entered in the sales data tab. A delivery block is set upon account addition—since—a credit limit check does not occur before item addition. Item addition triggers credit limit check as per credit limit check configuration. The function of credit limit check must be turned on after feeding it with the necessary data.

However, un-invoiced orders will include items invoiced—but not cleared in financial accounting—needed for calculating the invoiced open amount. Verifying the credit limit proposed by the system on the sales order requires checking the limit amount in the account master data. Sales order confirmations are analyzed based on delivery block settings. If a delivery block is required and not cross-checked with the account financial data tab—different options like customer request or a customer-specific delivery block must be maintained. When the header-level delivery block and confirmation block are selected—confirmed quantities in schedule lines are deleted upon saving the order. Open sales order credit values—based on confirmed quantities at the line-item level. Transfer of requirement occurs even if a delivery block with confirmation block is set at the header level. Delivery or credit block settings in the order do not prevent requirement transfer. Setting the confirmation block for the delivery block results in zero confirmed sales order quantities. If the "confirmation block" indicator in customizing is set for the relevant delivery block—the system resets the confirmed quantity when saving the sales document. If the fixed date and quantity indicator is set—the system does not transfer to material requirements planning. Approved deliveries should remain 'approved'. Therefore, automatic assignment of delivery blocks occurs even if the document value hasn't increased. Sales orders should not be released in customer demand unless all line items have green color available to promise status—enabling the release button. Force confirmation in the actions tab releases customer demand without errors. Sales orders show completed status even with partial deliveries due to delivery rule configuration.

Delivery rule configuration for sales order line items specifies single delivery full quantity—aiming for one single delivery for all products in the sales order. Creating a single outbound delivery against such a sales order update its status to finish—marking the sales order as completed. The common issue of being unable to create service confirmation for sales order items arise from service items being tied to project tasks. Updating project messages changes the status of sales orders. If a sale order has “process” as its status—there is a line item that has not been released. The release order option will be enabled but due to the line order status cannot save follow-up service confirmation. It is important that sales orders are confirmed before they can be processed further. It is necessary to analyze fields affecting delivery blocks. An order must be released first before new service confirmation is created. Rejection reasons are chosen based on the sales document type and sales organization at the header level of a sales order. Values are displayed in drop-down lists for customizing for orders and rejection reason types based on requirements. When an item is cancelled—the sales order goes into process status—necessitating order release before service confirmation. Therefore, to solve these issues—we used the Machine Learning (ML) that facilitates order evaluation and classification using a hybrid model. ML can assign classes for order evaluation parameters. Order parameters in this study are selected for their impact on the ML order evaluation model analysis.

III. Related Work

Several studies had been conducted such as [6] has suggested in their paper assessing forecast model performance in SAP. The study [7] have evaluated the use of time series analysis for predicting the level. For sales order data optimization—[8] have suggested in their paper using statistical methods in SAP optimizer planning. The use of ML for forecasting is recommended by study [9]. Consumer demand during ramp-up and ramp-down periods is influenced by a combination of the holiday and the day of the week it falls on according to study [10]. The holiday effect and weekday combination will vary each year—causing affected product locations to exhibit variable sales patterns throughout the year. There are specific periods when consumer demand is generally difficult to forecast. Forecasting can operate on an aggregated level if no disaggregation rule is maintained for the forecast key figure. The study in [11]—discussed the use of four SVM implementations. They give the features for class probabilities output—cross-validation error estimation, and hyperparameter estimation for the Gaussian Radial Basis Function (RBF) kernel. The study in [12] have conducted a detailed analysis of ERP data and its visualization. ML algorithms can be applied to classification problems like order ranking. The study in [13] have suggested that data mining can be used along with predictive analytics. However, this study proposes forecasting in relation to quantity in the sales order. It highlights that ML techniques can be used for forecasting. The performance of predicting forecast sales order values are assessed using R-squared score and Mean Absolute Deviation (MAD). An R-squared score value of 73% and MAD of 100 is calculated based on sales orders training data. The requirements planning run—perform poorly because it takes a long time for the system to calculate usage probabilities. When calculations are too complex—the system terminates the Market Retail Price (MRP) list and displays the error message. In study [14]—they compared various regression estimators by using the Mean Squared Error (MSE) criterion and constructed an alternative to the least squares estimator in case of multi-collinearity. A business partner with roles of account and sales and service partner are required to continue with the account role and block the sales and service partner role. When the partner role is blocked—it blocks the account role and the complete business partner role. However, in this study—a delivery block at the header level with the confirmation block indicator deselected. Open sales order values are calculated with the confirmed quantity of the schedule lines. A reduction in order quantity can be a reason for rejection—when applied at the item level. This occurs whenever any changes in the saved order occurred—developing inconsistencies in the delivery block at the top level.

IV. PROBLEM STATEMENT

The analyzed problems in this study include the reasons for sales orders not aligning with the forecast—resulting in inconsistent consumption when sales orders are created before the forecast. Another problem is block in display mode of the order. The system issues an error indicating that the relevant trading contract is blocked and there is an error in customizing. Some other problems include:

1) Sales orders with a credit block are displayed on the requirements list app.

2) Sales order creation is blocked due to a business partner block and analysis of confirmation of sales orders for the repetitive fields "delivery block" and "description".

3) Calculation of order performance and analysis of order evaluation parameters.

4) An order evaluation model is designed in the SAP application using evaluation criteria such as order reason, delivery date, and quantity. The order evaluation score is calculated based on weighted scores.

5) Complex dependencies are assigned to individual activities in the routing lead to long runtime in lead time scheduling.

Improving the evaluation of individual dependencies is necessary as dependencies that lead to too many combinations are problematic in terms of performance. This is applicable to specified and non-specified conditions. The reasons for order blocks generally are—forecast issues are due to improper settings for requirement strategy. Inconsistencies exist between the allocation indicator of the sales order requirement class and the assignment mode of the requirement strategy due to missing settings of the check mode. Improving forecast accuracy for affected product locations during variable demand periods is required. External figures or data more indicative of the demand than the Demand Influencing Factors (DIFs) generated by the forecasting are needed. Disabling some system demand influencing factors can improve forecast accuracy. Another reason is association management requires editing when the sales order is in display mode. The error appears as an error in customizing. When the sales order is generated from GTM with credit management—it does not get released using transaction code VKM3. Sales orders created with credit status "not approved" must be released using transaction VKM4. Additionally, other reason is the manual pre-implementation for two data elements—"description" and "delivery"—is required. "Description" is replaced by "created by username" and "delivery block" is replaced by "item delivery block". Restricting order rejection reasons based on the sales document type and sales organization in the dropdown list during configuration is required. Also, the order performance with ML is based on parameters like order reason, delivery date, and quantity [15]–[20]. Weight assignments are calculated during the training of the classifier on training data. The system calculates usage probabilities for configurable materials with planned independent requirements. Maintaining dependent forecast requirements in the planning segment of the stock requirements list is necessary. The MRP creates more forecast planned orders that require usage probability calculations to cover these dependent requirements. The long runtime of materials or products entered in the order results from the usage probabilities calculated in the BOM explosion. The planning statistics for the total planning run issue a ranking list of ten products with the longest runtime. The information report is displayed using the transaction RMMDPERF. Running the program SAPLCUFE for complex calculations to calculate usage probability is required. The program's execution time can be checked on the planning process overview screen. Detailed scheduling for forecast planned orders can be deactivated, or a lower detailed scheduling horizon can be set. Relocating characteristics planning into long-term planning can be done. Changes in forecasting are carried out at longer regular intervals—for instance—monthly. A long-term planning run is executed after such changes, and the report RM60CH00 is run to copy the simulated dependent demands created to operative planning. Saving interactive forecasting results produces unexpected and unrelated messages when the forecast key figures remain unchanged—and the 'enable forecast BOD' flag is activated in general settings for the forecast. Various inconsistencies are checked and reported by running the check_table_consistency after upgrades, migration, crashes, or out-of-memory termination.

V. IMPLEMENTATION

The algorithms that are used in developing a forecast data model from the SAP application consider several different factors which influence the order forecast. These factors must have standard strategies with different category groups and sales order categories. There are combinations of PIR segment and assignment mode supported by standard strategies in SAP. The sales order category of a sales order is checked by transaction code /SAPAPO/RRP3—while categories assigned to a category group are checked by /SAPAPO/SNPCG. When requirement strategy 10 is used—no consumption occurs. If no category group is maintained—then the forecast tab will show the order should not consume the forecast. Products views help locate the requirement strategy field of the forecast orders. The requirement strategy must match with the strategy assigned to the product master otherwise delete and re-release forecasts. Category type = "3" (forecasts) for all forecast orders. All orders having forecast order categories can be consumed even if the category is not set in the requirement strategy. Algorithm 1 shows the steps that are required by the allocation indicator of the sales item's requirement class.

Algorithm 1: Allocation indicator

START

1. *Find the requirement type of the sales order item.*
2. *Find the corresponding requirement class from table VBBE – BDART.*
3. *Find the allocation indicator of requirement class.*

Ensure the allocation indicator is correctly mapped to the order status of sales order in the APO system.

END

It is impossible to manually reconcile forecast error calculations against system-generated calculations. The Coefficient of Variation (CV) is calculated based on MAD. When 'adjust bias of forecast' is selected:

- MAD = AVG (|bias adjusted forecast – sales|).
- Bias adjusted forecast = input forecast * (1 - bias used).

If adjust for bias is adjust positive or adjust all:

- CV = 1.25 * (MAD / MAX [AVG (bias adjusted forecast) or AVG (sales)]) * (1 - bias used).

Forecasting has a negative bias therefore not bias adjusted. The process of fixing the forecast is recommended when there is a negative bias—which indicates under-forecasting. If bias used = 1, CV = 0. Outlier periods are those where both Forecast and sales are 0 or are NULL—before determining bias removes them. When sales and forecast are either NULL or both 0 in the same period—then exclude that period from calculating AVG (forecast) and AVG (sales). The requirement class defines the check mode on the advanced planning side. On S/4HANA—the check mode must be maintained in table /SAPAPO/ATP06. Forecasts do not consume forecasts—when the assignment mode of check mode does not match the requirement strategy's assignment as shown in Table I.

TABLE I. FORECAST STRATEGY

Product Master Forecast Strategy	Sales Order Status
20	1
30	2
35	2
40	3

If a new product site has forecast consumption—then forecast orders are created but the result of forecasting consumption may be inconsistent at first. The discrepancy is fixed by any subsequent modification in orders related to it. When credit block is released—the workflow gets retriggered. Dynamic credit check sets credit limits for customers based on undelivered not yet billed sales orders, undelivered not yet invoiced deliveries, unbilled accounting document open amounts and unpaid bills. Every time there is a save of document or check credit selected—credit limit check automatically starts. In case there are changes in the credit master data of a business partner—this event can trigger workflow functions notifying recipients about them and these with follow-on processes in SAP credit management. Scoring models might self-tune themselves using economic variables predicting delays in business payments. For any partner being monitored under SAP credit management—there should be a master record in the system. To transfer business partners—assign role UKM000–SAP credit management, score recalculation from SAP easy access screen and define default procedure for score calculation along with rule checking. Beforehand two data elements must undergo manual pre-implementation steps where “description” is replaced by “created by username” and “delivery block” by “item delivery block”. These elements are implemented through Algorithms 2 and 3:

Algorithm 2: Establish a data component CREATED_BY_USER_NAME

START

1. *Begin Transaction SE11.*
2. *Select "CREATED_BY_USER_NAME" as the data type and input it into the input field.*
3. *Select 'data element'—then—'continue' and confirm it.*
4. *Write a user description in the description field.*
5. *On the data type tab—select an elementary type for this type of data or set a domain instead.*
6. *Under the field label tab—fill in created by user name, created by user.*
7. *Save your work on the data element now that it’s complete.*
8. *Check over everything again so that everything matches up perfectly within this new system before activating anything at all within this program.*
9. *Activate data elements.*

END

Algorithm 3: Generate data element DELIV_BLOCK_REASON_SCHEDLINE

START

1. *Open transaction SE11.*
2. *Choose 'data type' and enter 'DELIV_BLOCK_REASON_SCHEDLINE' in the input field. Then select 'create'.*
3. *Select 'data element'—then 'continue'. Confirm any warnings when prompted.*
4. *Fill the description field with ‘blocked for delivery at schedule line’.*
5. *In the ‘data type’ tab—choose ‘elementary type’. Set the data type as ‘domain’ and give the data type as 'LIFSP'. Click on enter.*
6. *In the ‘field label’ tab—provide values for item delivery block.*
7. *Save this data element.*
8. *Run consistency check on this data element.*
9. *Activate data elements.*

END

Order processing is assessed with a data model built using an extraction algorithm. Key fields like credit release and delivery date are identified (refer to Table II). Deviations in quantity, delivery date, and block status predict delays. Order performance is measured against reason, date, and quantity (refer to Table III). Each order is ranked. Orders with minimal delivery date and quantity deviations (<= 100) can be blocked based on a configuration guide. This analysis focuses on order reason, delivery date, and quantity per line item.

TABLE II. ORDER EVALUATION FEATURES

Feature	SAP Field Description
Order	(VBAK), Attribute-Nominal
Header level fields	
Sales Document Type	Table TVAK, Field-AUART
Order Reason (Reason for the Business Transaction)	Table TVAU, Field-AUGRU
Delivery Block (Document Header)	Field-LIFSK
Billing block in SD Document	Field-FAKSK
Sales Organization	Field-VKORG
Requested Delivery Date	Field-VDATU

Proposed Date Type	VPRGR

5	120	>200	>10	>10%	Any two
6	0	>200	>10	>10% of	All three
			SO Date	SO Qty	

VI. EXPERIMENTAL ANALYSIS

All through the process of sales order integration as shown in Table IV—each order's status field is validated. It is important to ensure that the integration is correct if the status is different from the requirement allocation indicator. The allocation indicator for a requirement class of a sales item should match with the APO status representing the mode in which assignment was done for the strategy of requirement. MAD was calculated at 100 based on 16,000 cases of sales orders over the seventh period using three periods moving average as shown in Table V. With changes in sales and forecasts—the forecast error CV stands at 0.5. R^2 value 0.730 obtained through linear regression indicates a strong correlation between actual values and predicted ones.

Simplifying relevant planning characteristics decreases complexity while unnecessary unassigned characteristics should not be flagged within the planning profile also reduces the number of NE conditions that lead to premature terminations due to increased probability calculation time by reducing flagged characteristic combinations from 20 down to five NE conditions reduced from four out of nineteen resulting into five OR links. Non-evaluative procedures are used for adjusting BOM item quantities—where required by means other than evaluation methods called non-evaluative procedures. Planning procedures change Bill of Materials (BOM) component quantities planned mode "1" does not explode BOMs against production orders—which may increase runtime when the "entry required" flag is switched on for some characteristics having more than one value because it terminates probabilities early by allowing many concurrent characteristic values as shown in Table VI.

TABLE IV. SALES ORDER INTEGRATION VALIDATION RESULTS

Order ID	Status Field	Requirement Allocation Indicator	APO Status	Validation Result
1001	Validated	Match	Assigned	Passed
1002	Not Validated	Mismatch	Not Assigned	Failed
1003	Validated	Match	Assigned	Passed
1004	Validated	Mismatch	Assigned	Failed
1005	Not Validated	Match	Not Assigned	Failed

TABLE V. FORECASTING AND ERROR ANALYSIS

Period	Sales Orders	Forecast Error (MAD)	Forecast Error (CV)	R^2 Value
Period 1	16,000	100	0.5	0.730
Period 2	16,500	105	0.52	0.728
Period 3	15,800	98	0.49	0.735
Period 4	16,200	102	0.51	0.732
Period 5	16,300	101	0.50	0.731

TABLE VI. BOM AND PLANNING PROCEDURES

Component	Planned Mode	Entry Required Flag	NE Conditions	OR Links
Component A	Mode 1	On	4	19
Component B	Mode 2	Off	3	15
Component C	Mode 1	On	2	10
Component D	Mode 3	Off	1	5
Component E	Mode 1	On	0	0

Calculation data comes from various sources such as master data and big data thus giving an accurate reflection about customer buying patterns. Gradient Boosting Decision Trees (GBDT) reduces noise-induced trends during statistical forecasting in high-value scenarios. Accurate selection location of products ensures that forecasts remain accurate even in seasons with high demands. Incorrect product locations will affect final forecasts negatively especially when dealing with invalid locations. It's vital to validate requirement strategy at the product master level. Use transaction /SAPAPO/MD74 to delete and re-release forecast orders. Background and foreground statistical forecasts give different results due to aggregation method differences—foreground takes into account all selection characteristics while background jobs require manual level selections for

aggregation. Forecast tab activity monitoring is done using transaction /SAPAPO/MC8T which displays errors on the control parameter session. Inconsistent selection profiles between interactive and background forecasts lead to wrong comparisons. Comparison of results in transaction /SAPAPO/MC8E will ensure consistency when both have similar profiles. Background job error does not save automatically while interactive forecasts do allow manual saves. Credit block is released upon saving sales order documents triggering associated workflows. Item level changes reset delivery blocks automatically. Retained delivery blocks do not affect confirmed schedule line quantities verified using transaction MC30. To create sales orders—open Fiori App "Business Partner" Enter the BP number then remove the block. Manual business partner company code blocks through transaction BP. Description changes from "Description" to "Created By User Name" in the dimensions list differentiating between "Item Delivery Block" and "Delivery Block". Activate automatic deallocation for order type inconsistencies during SAP HANA startup with CHECK_TABLE_CONSISTENCY to perform row store consistency checks. Large column store tables require substantial memory. Replicate critical errors to identify timing issues with concurrent workloads. For persistent issues, escalate to SAP with a high-priority incident. Finalize order details such as reasons behind deviations in order blocks considering reason, delivery date and quantity ML models can adapt themselves so that they can still maintain accuracy between periods. Regularly monitor and adjust forecasting data by reviewing accuracy bias when creating sales orders and periodically refine the already established forecasting model based on it. The dataset for training has 16,000 entries while the set for testing has 4,000 (20% of all 20,000). It involved KNN and SVM where the SVM proved to be more accurate than any other algorithm when dealing with order blocks as shown in Table VII. The SAP master data team performed an audit on the product master data and made necessary corrections as shown in Table VIII. System results underscore the need to improve product master data quality and validate geo-coordinates for intermediate locations. Verify business partner master data for blocks across all company codes, manually removing blocks as required. Creating sales orders with over a thousand-line items can strain system runtime and lead to performance issues. Ensure smooth operations by checking document flows for related orders to prevent runtime termination.

TABLE VII. MACHINE LEARNING MODEL PERFORMANCE

Algorithm	Accuracy	Training Dataset Size	Testing Dataset Size	Performance Indicator
SVM	96%	16,000	4,000	Best Performer
KNN	93%	16,000	4,000	Second Best
Random Forest	89%	16,000	4,000	Good
Logistic Reg	85%	16,000	4,000	Moderate
Naive Bayes	80%	16,000	4,000	Basic

TABLE VIII. SYSTEM AND DATA QUALITY AUDIT

Audit Area	Issue Identified	Action Taken	Audit Result	Comments
Product Master Data	Incorrect Geo-coordinates	Corrected Data	Improved	Ensures accurate location data
Business Partner Master Data	Blocks not removed	Manually removed blocks	Improved	Smooth sales order processing
Sales Orders with Multiple Items	Performance issues with >1000 items	System optimization	Improved	Better runtime performance
Document Flow Check	Incomplete document flows	Verified and corrected flows	Improved	Prevents runtime termination
Credit Management System	Inconsistent credit limits	Adjusted credit limits	Improved	Accurate credit assessments

VII. CONCLUSION AND FUTURE WORK

We defined requirement strategies with category groups that specify forecast consumption for accurate forecasting. We included one of the three orders and the normal "BM" sales order category. "Calculated Bias" and "Bias Used" measures should be enabled to manage forecast bias effectively. Business needs are met by historical datasets aligning with current forecasts. In SAP APO, there is an indicator of accuracy for controlling exact forecasts. Accurate measurements are ensured through lag synchronization—which varies with product horizon. Product location level disables default regressors but high-quality data compensates for this. Modelling and forecasting should be run in diagnostic mode for impacted locations—while still keeping the strategy consistent from the product master. Confirming sales order quantities even without stock can be done by deactivating available to-promise checks. SAP periodic data should be used in assessing orders. Unblocked consumers are able to create sales orders. The user interface displays altered dimension lists—with "description" now reading "created by user name" and "delivery block" splitting into "item delivery block" and "delivery block". Various factors determine table runtime for consistency checks. Backups should have a global consistency check conducted on them. Parameters like order reason, delivery date, and quantity (ranked 1 to 6) are used in evaluating the model whereby—SVM algorithms show higher accuracy levels.

VIII. DECLARATIONS

Funding: No funds, grants, or other support was received.

Conflict of Interest: The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Data Availability: Data will be made on reasonable request.

D. Code Availability: Code will be made on reasonable request.

Home Network Attached Storage (HOMENAS) Using Raspberry Pi with Telegram Bot Notification

Nurul Najwa Abdul Rahid @ Abdul Rashid, Syafnidar Abdul Halim, Siti Maisarah Md Zain, Nik Aiman Shafiq Nik Shukri

Faculty of Computer and Mathematical Sciences, Universiti Teknologi MARA, Cawangan Melaka Kampus Jasin, Malaysia

***Abstract*—This paper presents the development of the Home Network Attached Storage (HOMENAS) using Raspberry Pi with a Telegram Bot Notification. Network Attached Storage (NAS) is an independent storage system connected directly to the network that can be accessed easily. NAS devices are readily available on the market nowadays. However, the current price is too expensive, consumes more electricity and lacks a notification mechanism. This paper proposes the development of HOMENAS at a lower cost and consumes less power than the current NAS devices available on the market. The proposed HOMENAS is also integrated with the Telegram Bot, which can notify users of the progress of downloading files. 95% of the energy cost can be reduced by implementing a Raspberry Pi as the Home Network Attached Storage. A network performance test has been conducted to evaluate the streaming rate for single and multiple users with wired and wireless connections. The result finding shows that the Raspberry Pi not only matches the performance of laptop but, in some aspects, it has better results in torrent-based file downloading tasks.**

***Keywords*—Home network; NAS; network attached storage; raspberry pi; telegram bot**

I. Introduction

Network Attached Storage (NAS) is a dedicated storage solution providing file-based storage accessible over a network. Traditionally, NAS devices are employed for functions such as backup data servers, media streaming, and torrent downloads [1]. While NAS devices are increasingly popular in consumer environments due to the proliferation of multiple connected devices like desktops, laptops, smartphones, and tablets, their higher costs have limited broader adoption, particularly in home settings [2]. NAS systems are widely utilised for storing music, videos, and photos, offering a streamlined alternative to managing direct TV connections [3]. Despite their utility, NAS devices are relatively expensive and consume significant amounts of electricity.

In contrast, the Raspberry Pi is a compact and cost-effective computing device offering functionality comparable to that of a standard computer, including an operating system (OS), central processing unit (CPU), memory, and storage, while consuming minimal power. These characteristics position the Raspberry Pi as an operable substitute for traditional NAS devices in home networks.

Telegram is an online messaging application that bears similarity to platforms such as WhatsApp and Facebook Messenger. It is designed to prioritize security and speed in its internet-based messaging service. Notably, Telegram supports the incorporation of bots; small programs that can be integrated into chats to carry out specific functions. These bots play a pivotal role in enabling communication between humans and programmable machines, autonomously executing predefined tasks. They are particularly valuable for facilitating applications such as notification and alert systems [3].

In today's increasingly digital households, the need for cost-effective solutions providing centralized storage and seamless file sharing across multiple devices has become paramount. However, many consumers face challenges in finding an optimal Network Attached Storage (NAS) solution that balances affordability with robust centralized storage capabilities and efficient file-sharing functionalities. The rising cost of NAS devices often presents a barrier to entry for budget-conscious users seeking to streamline their data management and collaboration processes. Additionally, configuring and maintaining NAS systems for efficient file sharing among household members can be complex and time-consuming.

Therefore, this paper addresses the pressing need for cost-effective NAS solutions that prioritize centralized storage and simplify file-sharing processes. By exploring these solutions, households can effectively manage their digital assets while minimizing financial overheads and technical complexities. The aim of this study is to develop a low-cost Home Network Attached Storage (Home NAS) system utilizing a Raspberry Pi, complemented by a Telegram Bot for notifications. The proposed Home NAS leverages the Raspberry Pi's lower electricity consumption, portability, compact size, and cost-effectiveness compared to traditional NAS systems using PCs or pre-built NAS devices, thereby offering a practical and accessible solution for modern digital households.

The remainder of this paper is organized as follows: Section II describes the literature review that related to this topic. Section III explains the methodology used in the experimental setup. Section IV presents the results and analysis of the performance tests. Finally, Section V concludes the paper with a summary and potential directions for future work.

II. Literature Review

A. Home Network

Home networks are established when multiple computers share a connection via either a wired or wireless network within a residence. According to Edwards, Grinter, Mahajan, and Wetherall [4], home networking adaptations provide numerous benefits for users in terms of entertainment, education, healthcare, and communication . These adaptations facilitate

data sharing between two or more computers within the same network. Unlike enterprise networks, data centers, and ISPs, home networks are distinct in several ways.

Home networks are primarily managed by users themselves, relying on their technical skills, while other networks require dedicated personnel for maintenance and management. Additionally, privacy is a major concern in home networks, as users are vigilant about who connects to their network. In contrast, employees in most companies do not expect privacy due to company policies and the needs of the IT department [5]. It is important to note that modern homes offer considerable topological flexibility, often incorporating multiple wireless access points and various networking protocols. Consequently, not all applications may function optimally within this infrastructure.

B. Home Network Architecture

Home network architecture refers to the structural design and organization of devices and systems that enable communication and data exchange within a residential setting. This architecture has evolved from simple configurations connecting a few computers to sophisticated systems integrating numerous smart devices. Understanding the architecture of home networks is essential for optimizing performance, ensuring security, and enhancing the user experience.

Traditional home networks typically consist of several key components: a modem, a router, and various end-user devices such as computers, printers, and smartphones. The modem connects to the Internet Service Provider (ISP) and translates the incoming internet signal. The router then distributes this connection to various devices within the home, either through wired Ethernet cables or wirelessly via Wi-Fi [4]. In a wired setup, Ethernet cables connect each device directly to the router, offering reliable and high-speed connections.

However, the prevalence of wireless technology has led to a preference for Wi-Fi due to its convenience and ease of setup. Wi-Fi networks, while generally slower than wired connections, provide sufficient speed for most home applications and offer the flexibility of connecting multiple devices without physical constraints [6].

To address the limitations of traditional Wi-Fi, particularly in larger homes with multiple floors, mesh networking has become a popular solution. Mesh networks consist of a main router connected to a series of nodes placed throughout the home. These nodes communicate with each other to create a seamless and extensive Wi-Fi coverage area, reducing dead zones and maintaining consistent connection speeds [7].

Modern home networks are characterized by the integration of Internet of Things (IoT) devices, such as smart thermostats, security cameras, smart TVs, and home assistants. These devices connect to the home network, enabling automation and remote control features that enhance convenience and efficiency. The increased number of connected devices necessitates a robust and scalable network architecture to manage traffic effectively and maintain performance [8].

Home network architecture has evolved significantly, driven by technological advancements and the increasing demand for connected devices [9]. While traditional networks were straightforward and primarily wired, modern networks incorporate wireless technologies, IoT devices, and advanced features like mesh networking and network segmentation. As technology advances, home network architecture will undoubtedly continue to evolve, offering enhanced performance, security, and convenience for users.

C. Network Attached Storage (NAS)

Network Attached Storage (NAS) has emerged as a vital solution for managing the challenges posed by exponential data growth [10]. NAS serves as a dedicated storage device that offers file-based storage accessible over a network, allowing efficient file sharing across multi-platform environments at a cost-effective rate [10]. Its widespread adoption is a result of its user-friendly management capabilities and its capacity to facilitate file sharing among clients utilizing different operating systems. NAS provides various advantages, including parallel I/O operations, incremental scalability, and decreased operating costs.

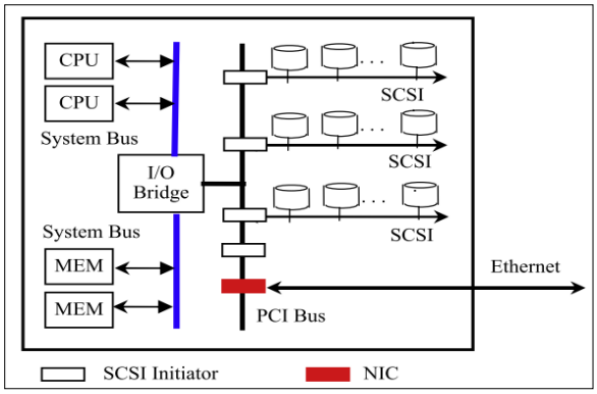

Fig. 1. Network attached storage architecture [11].

Typically, NAS operates as a file server, presenting a file interface to the network through protocols such as the Windows Common Internet File System (CIFS) or the Network File System (NFS). It connects to a local area network (LAN) and provides file-sharing services to multiple clients [12]. The typical architecture of NAS comprises a CPU, main memory, multiple disk drives, and an I/O bridge with interfaces for the system bus and memory bus, which connect to the CPU and memory, respectively. Fig. 1 illustrates the architecture of a typical NAS and its corresponding storage subsystem [11].

D. Telegram Bot Notification

Telegram bots are automated programs within the Telegram app that engage with users, send notifications, and perform various tasks [13]. They are popular for their user-friendly nature and ability to provide timely and relevant information. This paper explores their architecture, functionalities, and applications, emphasizing their integration capabilities and wide range of services. Telegram bots can respond to messages and commands, send notifications, manage group activities, and integrate with other applications, enhancing communication and operational efficiency within the app.

Telegram bots function within a framework that enables smooth interaction with users. They make use of Telegram's Bot

API, which simplifies the creation and deployment of these automated programs. The API accommodates different types of messages such as text, audio, video, and documents, allowing bots to execute complicated tasks [14]. Furthermore, bots are capable of managing inline queries, delivering instant information and services without requiring extra input from the user.

The adaptable nature of Telegram bots enables seamless integration into numerous applications, thereby significantly enhancing their utility. They can be utilized for sending personalized notifications, managing and moderating group chats, conducting polls and surveys, and providing customer support. Furthermore, Telegram bots have the capability to integrate with external applications and services, including payment systems, social media platforms, and home automation systems, thereby further extending their functionality.

Telegram bots signify a notable advancement in automated communication, offering a diverse array of services that enhance user experience and operational efficiency [14]. Their ability to seamlessly interact with users and integrate with various applications underscores their significance in modern digital communication. As the usage of messaging platforms continues to expand, the role of Telegram bots is likely to evolve, yielding even more sophisticated and personalized services.

E. Related Works

The study in [15] investigates the feasibility of creating a network-attached storage system using Raspberry Pi and Nextcloud, highlighting its potential for file and photo storage, as well as communication through a chat feature, making it a versatile solution for users. The proposed system is focus on centralized data access. Study [16] on successfully designing a Network Attached Storage (NAS) system using Raspberry Pi, which focus on scalable and flexible storage solutions. The other study [17] proposed a solution for a personal cloud storage using Raspberry Pi and external hard disk. This study allowing users to have full control over their data and customize their storage capacity without relying on third-party services.

Most of the previous works used Raspberry Pi for network storage solutions has gained traction due to its affordability, flexibility, and ease of implementation. Previous researches show Raspberry Pi can be effectively utilized to create both Network Attached Storage (NAS) systems and personal cloud storage solutions. It offering a cost-effective alternative to traditional storage methods.

Collectively, the previous study indicate that Raspberry Pi is a viable solution for low cost data storage. There is less consensus regarding the services that can be integrated with the Raspberry Pi like streaming, local backup, Torrent Box and notification mechanism. This study proposed the integration of those services in developing a NAS storage using Raspberry Pi.

III. METHODOLOGY

A. Design and Development

1) Conceptual design for HOMENAS using raspberry Pi with telegram bot notification: The conceptual design of the HOMENAS is illustrated in Fig. 2. In this setup, multiple PCs, mobile phones, and a Raspberry Pi are connected to the internet via a router. The Raspberry Pi serves as the central server, linked to both the portable HDD storage and the router, which provides an internet connection with a speed of 4 Mbps. Client devices connect to the server through the router. The server manages processes such as downloading, uploading, and video streaming. Data is stored on an external hard disk attached to the Raspberry Pi. Upon completion of a download, a notification is sent to the mobile phone via the Telegram application.

In a summary, Raspberry Pi acts as a central server that hosts a variety of services such as media streaming, local backup and torrenting. The use of Telegram for notifications enhances the user experience by informing them of important updates (like torrent completion) directly on their mobile device. Devices can communicate seamlessly with the Raspberry Pi for data access, media streaming, and backups, all on a home LAN. This system is ideal for home users looking for an all-in-one solution for media management, data backups, and torrenting, all centered around a low-cost Raspberry Pi.

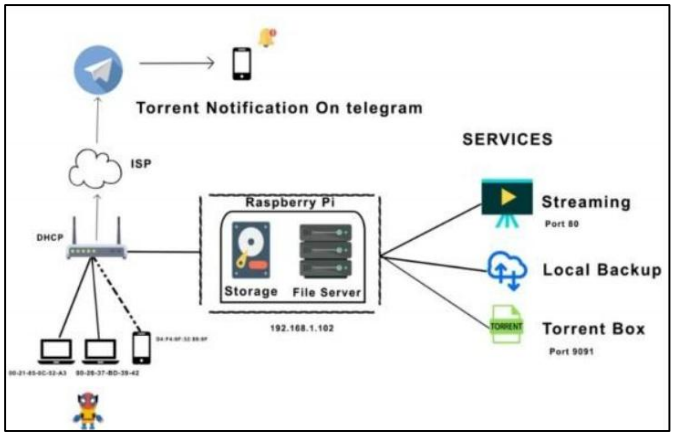

Fig. 2. Conceptual design for HOMENAS.

2) Flowchart for HOMENAS: Fig. 3 presents the flowchart of the HOMENAS system. This flowchart outlines a clear and structured way for users to interact with a NAS server, providing options for file management and media access, along with automated alerts for torrent downloads. The process begins with the user initiating interaction with the NAS server. The Raspberry Pi needs to be connected to a local network to allow system access. The user connects to the NAS server through the local area network (LAN). This is typically done via a Wi-Fi router or an Ethernet connection.

The user attempts to log into the NAS system. This involves providing credentials to gain access to the server's storage and services. Users with the correct username and password credentials are granted access to the server. Initially, users must log in to enter the system. Once authenticated, users can access the file server via Windows Explorer. Additionally, the system includes a web server that users can utilize for streaming purposes.

When users access the web server through a browser, they are provided with options to upload videos to the server or stream videos directly. The system also supports torrent downloads, enabling users to upload a torrent file or use a magnet link to start the download process. Upon completing a download, the system notifies the user via Telegram on their smartphone. Additionally, the system allows users to create personal folders for file organization and offers the capability to perform file backups on the server.

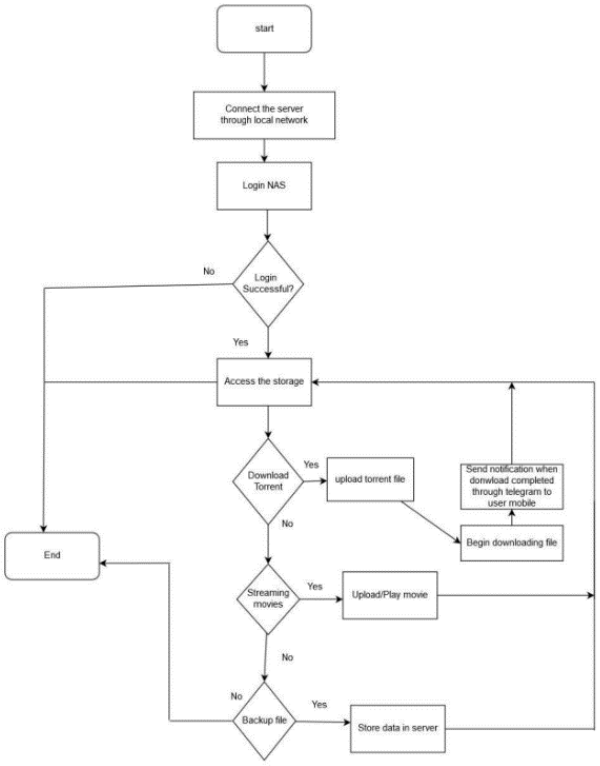

Fig. 3. Flowchart for HOMENAS.

3) Development process: The development process is divided into three main components: hardware configuration, software installation, and web development. The required hardware includes a Raspberry Pi, a TP-LINK WR1043N router, a LAN cable, 1 terabyte of external storage, DSL, and an external USB hub. The Raspberry Pi is connected to the router via the LAN cable, and the router is linked to the DSL connection, providing an internet speed of 4 Mbps. The external storage and the external USB hub are both connected to the Raspberry Pi. Fig. 4 shows the hardware setup.

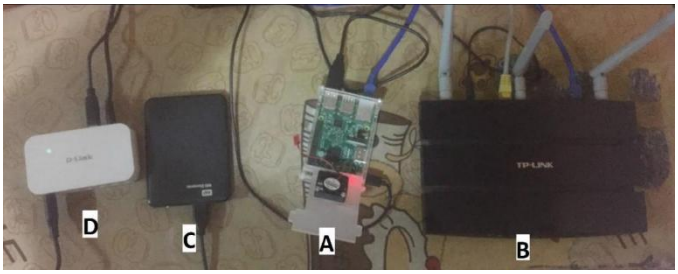

Fig. 4. Hardware setup.

To facilitate communication between the hardware components, OpenMediaVault is installed on the Raspberry Pi, serving as the operating system. Access to the Raspberry Pi can be achieved in two ways: through the web-based Graphical User Interface (GUI) or via SSH using PuTTy. The external storage must be added to the Raspberry Pi, and this can be configured through OpenMediaVault. During this configuration process, access rights for the storage can be set, and users can be created with credential information, such as passwords.

For file sharing among the created users, the Samba file server, which uses the SMB protocol, can be implemented. After enabling Samba, folders can be created with specific user permissions, such as Read/Write, Read-only, or No access. Additionally, OpenMediaVault Transmission (a BitTorrent client) is installed to facilitate downloading from multiple peers and uploading files.

The overall process of developing the HOMENAS can be referred to in Fig. 5. This figure visually represents the step-by-step process of setting up a Raspberry Pi as a server with OpenMediaVault (OMV) and additional functionalities. The first step is to assemble all necessary components for the Raspberry Pi, such as the board, power supply, SD card, network cable, and any additional peripherals needed.

Then followed by the process of installing the operating system. The OMV operating system image need to be downloaded and flash it to the Raspberry Pi's SD card using a tool like Balena Etcher. OMV is a specialized OS designed for network-attached storage (NAS). The next step, boot up the Raspberry Pi with OMV, access the web interface, and start the initial server configuration including network settings, system updates, and general preferences.

The fourth step is connecting a storage device (such as external USB drives or SSDs) to the Raspberry Pi. Once connected, you should configure these storage devices within the OMV interface to effectively organize how data will be stored and accessed.

Next is the process for set up user accounts in OMV. This may involve creating an administrative user and other accounts with specific permissions depending on their roles and usage needs. Followed by the process of transmission configuration for Torrent and setup notification for download completion. Then, proceed with the process of installation and configuration media server application to stream the content stored. The last part is implementing encryption to secure the data stored.

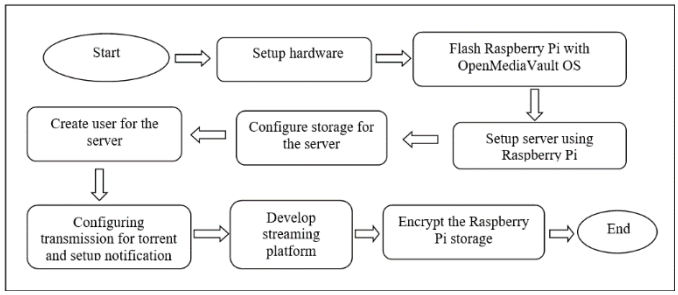

Fig. 5. Process in developing HOMENAS.

B. Network Performance Testing

Network performance test is conducted to test the performance of the developed HOMENAS using Raspberry Pi with Telegram Bot notification. There are several experiments being conducted using wired and wireless connection to identify the uploaded speed and the downloaded speed.

IV. Results and Findings

A. Power Consumption

Table I shows the comparison of the power consumption for HOMENAS and a Laptop. The comparisons are based on the power usage for each device with runtime for 24 hours, as well as the estimation of the energy cost based on per day and per month. HOMENAS uses 6 watts and consumes only 144 watts per day. The estimated energy cost per day is RM0.03 and RM0.87 for 30 days. In contrast, the laptop consumes 120 watts and consumes 2880 watts per day. The estimated energy cost per day is RM0.62 and RM18.75 per month. This highlights that developing HOMENAS using Raspberry Pi can reduce around 95% of the energy cost.

TABLE I. Power Consumption Comparison Across Hardware Platforms: HOMENAS and Laptop

Hard ware	Power (Watt)	Usage (Hour)	Watt / day (W)	Estimates the energy cost /day	Estimates the energy cost/month
HOM ENAS	6	24	144	RM0.03	RM0.87
Laptop	120	24	2880	RM0.62	RM18.75

B. Torrenting Performance

File downloading using torrents is tested on both Raspberry Pi and a laptop. The test is conducted three times on two different size of files which 100Mb and 300Mb without other users are on the network. Based on the Table II, the maximum speed for downloading 100Mb file for Raspberry Pi and laptop are similar which is 425kbps. There is a bit different for downloading 300Mb file which Raspberry is 469kbps and laptop 428kbps. Overall, the average speed is quite stable for both Raspberry Pi and laptop.

The experimental evaluation of torrent file downloading on both Raspberry Pi and a conventional laptop demonstrates that the Raspberry Pi is a viable and efficient alternative for such tasks. Both devices achieved similar maximum download speeds for the 100MB file (425 kbps), while the Raspberry Pi exhibited a marginally higher maximum speed (469 kbps) compared to the laptop (428 kbps) when downloading the 300MB file.

Furthermore, the Raspberry Pi consistently reached optimal download speeds (above 350 kbps) in a shorter amount of time and completed downloads more quickly on average. Additionally, the system's integration with Telegram for user notification proved to be highly responsive, with alerts delivered in under one second. These findings suggest that, under the tested conditions, the Raspberry Pi not only matches but, in some aspects, surpasses the performance of a traditional laptop in torrent-based file downloading tasks.

TABLE II. Torrenting Performance Comparison

Device	*Raspberry Pi*		*Laptop*	
File size	100MB	300MB	100MB	300MB
Maximum speed	425kbps	469kbps	425kbps	428kbps
Average speed	350kbps	350kbps	306kbps	300kbps
Time take to achieve optimum speed	47s	60s	123s	353s
Average time to download	6 m 12s	15m 13s	7m 18s	18m 23s
Time to notify user	Less than 1s	Less than 1s	N/A	N/A

C. Streaming Performance

Streaming performance refers to how well a network can transmit audio, video, or other data in real-time, allowing users to consume content without interruptions or delays. Several factors influence streaming performance, and understanding these elements can help readers appreciate its significance in the context of a Home Network Attached Storage (HOMENAS) system like the one developed with a Raspberry Pi.

In this study, the performance is evaluated based on the connection type and number of users in the network.

1) Streaming rate: wired and wireless for single user Fig. 6 shows the wired streaming rate fluctuates significantly, reaching peaks at 6.94 Mb/s and 11.62 Mb/s, but dropping to zero multiple times throughout the timeline. In contrast, the wireless streaming rate in Fig. 7 shows a more stable performance, with the wireless streaming rate remaining between 2.14 Mb/s and 4.54 Mb/s, without any complete drop to zero. While wired streaming exhibits higher peaks, it also experiences sharp interruptions, whereas wireless streaming remains more consistent, albeit at lower speeds.

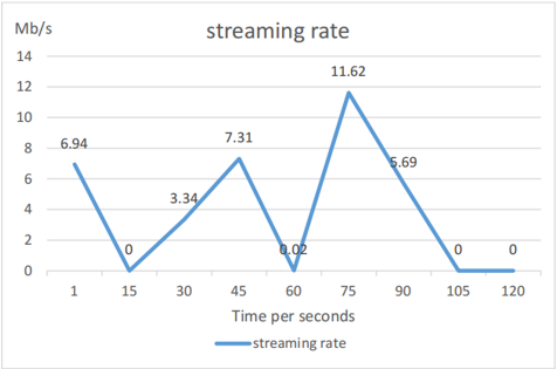

Fig. 6. Wired streaming rate for single user.

When streaming rate is high, it indicates that the data being transmitted at a faster pace. More data can be transmitted and better quality of video and audio. It also indicates content tends to play smoothly without buffering or lagging. However, high streaming rate requires more bandwidth and if network has limited capacity, this could result in slower performance for other application for the same network. If the connection cannot sustain the high streaming rate consistently as Fig. 7, it might cause by less capable devices or network congestion.

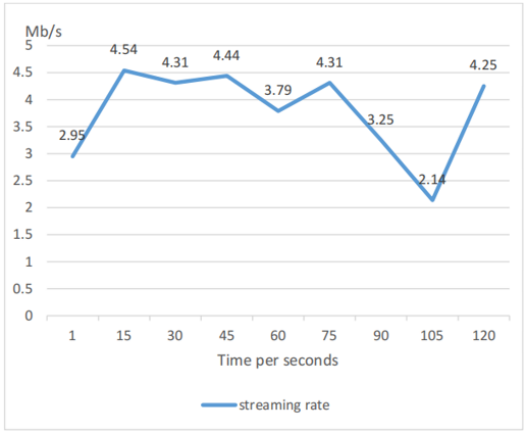

Fig. 7. Wireless streaming rate for single user.

2) Streaming rate: Wired and wireless for multiple users The graph in Fig. 8 shows the wired streaming rates in megabits per second (Mb/s) for three different users over a period of 120 seconds. User 1 (Blue Line) starts at a rate of about 3.31 Mb/s, peaks early at 7.64 Mb/s around the 15-second mark, and then generally maintains a high streaming rate, ending around 4.1 Mb/s. User 2 (Orange Line) begins around 3.81 Mb/s, dips significantly to 0.01 Mb/s at around the 60-second mark (indicating almost no data being streamed), and then recovers back to about 3.78 Mb/s by the end of the period. User 3 (Gray Line) shows a gradual decline from an initial 3.71 Mb/s to about 0.09 Mb/s by the end of the period, indicating a consistent decrease in streaming rate.

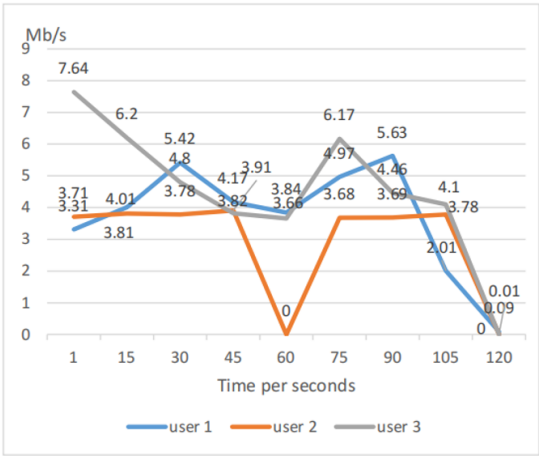

Fig. 8. Wired streaming for multiple users.

Based on Fig. 8, user 1 exhibits the most stable and high streaming rate, suggesting a strong and reliable connection throughout the period. The user 2 experiences a dramatic drop in the middle of the session, which could indicate a temporary disruption or bandwidth competition. The recovery suggests that the issue was resolved while user 3 demonstrates a steady decline in streaming rate, which might suggest network degradation or increasing network congestion over time.

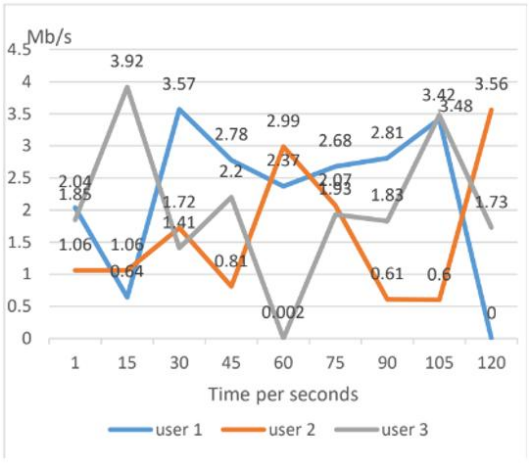

Fig. 9. Wireless streaming for multiple users.

Fig. 9 shows a graph for the wireless streaming rates for three different users over a period of 120 seconds. The x-axis represents time in seconds, and the y-axis represents the streaming rate in megabits per second (Mb/s), ranging from 0 to 4 Mb/s. User 1 (blue line) starts with a low streaming rate of 1.85 Mb/s and fluctuates throughout the 120-second period. The rate peaks at 3.57 Mb/s around the 25-second mark, before experiencing a drop. The connection becomes unstable, with notable dips close to 0 Mb/s around 60 and 120 seconds, showing intermittent or poor performance at those points.

The orange line which refer to user 2, starts at rate of 1.06 Mb/s and experiences highly fluctuating streaming rates. It has several points where the connection reaches 0 Mb/s, particularly at 45 seconds, 75 seconds, and at the 120-second mark. The rate peaks near 3.48 Mb/s at around the 105-second mark, followed by a sharp decline to 0.

Meanwhile, the grey line represents the user 3 starts off stronger than the other two users with a rate of 2.04 Mb/s. It shows a peak at 3.92 Mb/s around the 15-second mark, maintaining relatively consistent streaming rates, although some dips are evident. The user 3 has more stable connection compared to the other users. However, it still has noticeable declines, especially between 70 and 80 seconds where the streaming rate reaches 0 Mb/s.

Fig. 9 indicates variability in wireless streaming rates among multiple users over time. The fluctuations and instances of 0 Mb/s indicate potential wireless network challenges such as interference, bandwidth limitations, or device performance, which can affect user experience and cause interruptions in streaming quality.

V. Conclusion and Future Recommendation

In conclusion, Raspberry Pi can be configured to develop a Home Network Attached Storage (HOMENAS) for a lower cost. Different microcontrollers or hardware can be used to develop HOMENAS and may produce different results in terms of performance. The developed HOMENAS can be used with different connectivity, either guided or unguided transmission

medium. The guided transmission medium is faster compared to the unguided transmission medium for single as well as for multiple users. In terms of torrent performance, the results show that stability is better on Raspberry Pi compared to the PC. File also can be downloaded faster while using the Raspberry Pi and it consume lower electricity. Therefore, the Raspberry Pi can be another alternative to create a HOMENAS.

Future research could explore the integration of advanced security features in NAS systems using Raspberry Pi, focusing on data encryption and user authentication methods to enhance data protection for small organization instead of as a personal data storage. Another area for future research could involve the optimization of NAS performance through the implementation of various file systems and network protocols, assessing their impact on data transfer speeds and overall system efficiency in different operational environments.

Enhancing Data Management for Decision Support Systems in Indonesian Government Internal Audit: A DMBOK Approach

Febrian Imanda Effendy, Nilo Legowo
Information System Department, BINUS Graduate Program, Jakarta, Indonesia

***Abstract*—Indonesian public institutions, including the Financial and Development Supervisory Agency (BPKP), face challenges such as fragmented standards and poor data quality, which hinder effective Decision Support Systems (DSS). This research aims to evaluate BPKP's current analytics maturity level using the TDWI Analytics Maturity Model and to formulate a Data Management Body of Knowledge (DMBOK)-based strategy to enhance its data management and analytical capabilities in support of decision-making. This qualitative descriptive case study methodology employed document analysis. The research stages involved assessing maturity using the TDWI model, conducting a gap analysis, formulating a strategy with DMBOK principles, and proposing an implementation roadmap based on Aiken's Data Management Value Pyramid. The research findings indicate BPKP's analytics maturity is at the "Early Adoption" stage (overall score 3.41), with the Analytics dimension scoring the lowest (2.60) and exhibiting the largest gap (1.40). Key challenges identified are underdeveloped institutional metadata and limited application of advanced analytics. A comprehensive DMBOK-based strategy and a four-phased implementation roadmap using Aiken's Pyramid were proposed to address these issues.**

Keywords*—*Data management; data management body of knowledge; Indonesian government internal audit agency; decision support system

I. Introduction

Modern public institutions are under increasing pressure to become more transparent, accountable, and adaptive in responding to rapid socio-economic and technological changes. Effective decision-making now requires not only administrative competence but also the strategic use of accurate, consistent, and reliable data. As such, data is no longer merely operational but foundational to evidence-based policymaking. Decision Support Systems (DSS) play a central role in enabling data-driven decisions using historical analysis and predictive models.

Despite this imperative, many public organizations still face structural challenges such as fragmented standards, poor data quality, and limited interoperability across units. These issues hinder information integration and impair decision consistency. Prior studies [1], highlight similar problems in Indonesia's public sector, where institutions like the Directorate General of Customs and Excise struggle with data quality due to the absence of a standardized governance framework.

To address these challenges, frameworks such as the Data Management Body of Knowledge (DMBOK) and the TDWI Big Data Maturity Model offer structured approaches to strengthen data governance and evaluate organizational readiness. In Indonesia, national policies like the One Data Indonesia (SDI) and Electronic-Based Government System (SPBE) further emphasize the need for integrated, interoperable, and accountable data management systems.

Within this context, Indonesia's Financial and Development Supervisory Agency (BPKP)—as Indonesia's internal audit institution—has initiated digital transformation programs. However, internal evaluations reveal that its data management practices remain uneven and lack full integration. Therefore, this study seeks to address the following questions:

- What is the current level of analytics maturity supporting decision-making systems in BPKP?
- What strategy can be formulated to improve data management and analytical capabilities at BPKP?

The objectives of this study are as follows:

- To evaluate the maturity level and identify gaps in BPKP's data-driven decision systems using the TDWI Analytics Maturity Model.
- To formulate a DMBOK-based strategy to enhance data management in support of decision-making within BPKP.

This research is expected to generate a strategic roadmap for enhancing data governance within public sector internal audit institutions. By aligning BPKP's data management practices with international frameworks and national policy mandates, the study contributes to improving the effectiveness of evidence-based decision-making and supports broader goals in Indonesia's digital government transformation.

The remainder of this paper is structured as follows. Section II provides a comprehensive Literature Review detailing key concepts such as Information System Management, Decision Support Systems, Data Governance in the Public Sector, and relevant maturity models and frameworks like DMBOK and TDWI. Section III, Methodology, describes the qualitative descriptive case study approach, data collection methods, and the maturity assessment process employed. Section IV presents the Result and Discussion, outlining BPKP's current data management and analytics maturity, identified gaps, and the formulated DMBOK-based strengthening strategies, along with a phased implementation roadmap. Finally, Section V offers the

Conclusion of the study, summarizing the key findings and discussing their implications for future research and practice.

II. Literature Review

A. Information System Management and Decision Support Systems

Information System Management (ISM) integrates technology, processes, and people to support organizational decision-making and strategic objectives [2]. The classic pyramid model by [3] delineates the hierarchy of information systems—TPS, MIS, DSS, and EIS—each enabling different levels of decision-making. Among these, Decision Support Systems (DSS) play a critical role in semi-structured and unstructured decision contexts, providing analytical insights beyond routine MIS reports [4]. The integration of Big Data Analytics into Decision Support Systems has transformed decision-making processes across sectors, enabling real-time, predictive, and multi-source data analysis that surpasses the limitations of traditional, historically driven systems [5][6].

B. Data Governance in the Public Sector

Effective data governance is essential for ensuring public accountability and reliable decision-making. DAMA International [7] defines data management as a strategic process encompassing data quality, security, interoperability, and governance. However, public institutions often face structural issues, such as data silos, inconsistent metadata standards, and unclear responsibilities. These challenges are both technical and organizational, requiring top-level leadership support [8][9]. High-quality, integrated data systems are vital for enabling performance-based monitoring, policy formulation, and public trust [10].

C. DMBOK Framework and Its Application

The Data Management Body of Knowledge (DMBOK), developed by DAMA International [7], provides a comprehensive framework for managing data as a strategic organizational asset. It outlines a holistic approach to data governance by integrating best practices, standards, and roles across eleven functional knowledge areas.

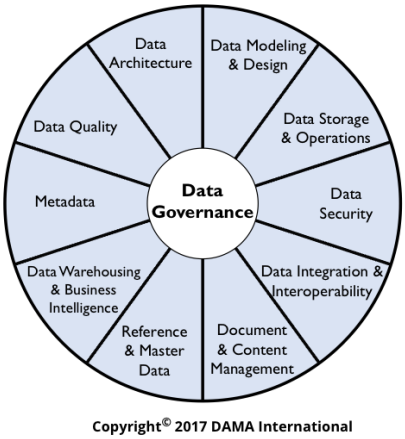

Fig. 1. DAMA Wheel [7].

Fig. 1 illustrates the eleven interrelated knowledge areas defined in the DMBOK framework. These domains represent the foundational components required to establish a comprehensive and integrated data management environment. Each area addresses a specific function ranging from governance, architecture, and quality to security, metadata, and interoperability that collectively support the organization's ability to manage data strategically. The DMBOK framework emphasizes that effective data management is not isolated to technical solutions, but rather requires a coordinated effort involving policy, processes, roles, and cultural change. This visual representation underscores the holistic nature of the DMBOK approach and serves as a guide for institutions seeking to align their data practices with international standards.

D. Maturity Models for Data Management

Maturity models, such as the TDWI Big Data Maturity Model, serve as diagnostic tools to assess and plan organizational data capabilities. These models identify gaps and guide progressive improvement across dimensions like infrastructure, analytics, and governance [11]. The TDWI model outlines five stages from Nascent to Visionary, offering a structured roadmap for organizations transitioning towards advanced analytics and data-driven strategies. Fig. 2 illustrates the primary dimensions and other factors considered in the TDWI Big Data Maturity Framework.

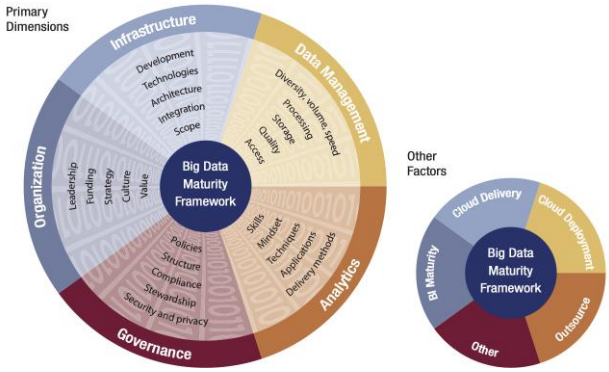

Fig. 2. Big data maturity assessment criteria diagram [11].

E. Regulatory and Institutional Context in Indonesia

National regulations such as in study [12] and [13] reinforce the urgency for standardized and interoperable data systems. These policies establish the foundation for digital transformation and evidence-based governance. Within this context, BPKP, as Indonesia's internal audit institution, plays a strategic role in integrating data management into its supervisory functions. Despite progress, BPKP still faces fundamental challenges in data fragmentation and governance [14], necessitating a systematic strategy aligned with DMBOK principles.

F. Document Analysis in Qualitative Research

Document analysis is a recognized method in qualitative research, particularly when exploring organizational processes, historical development, or policy implementation. Research in [15] emphasizes the analytical value of documents as credible, stable, and context-rich sources that provide insights into institutional behavior and decision-making processes. His framework underscores the importance of document authenticity, representativeness, and meaningful interpretation within social and policy contexts.

In parallel, the READ method by [16] offers a structured approach to document analysis in public policy studies. The acronym stands for Ready (defining document selection criteria), Extract (gathering data systematically), Analyze (applying thematic or comparative analysis), and Distill (synthesizing findings). This method ensures methodological rigor, particularly in desk-based research within constrained institutional settings.

Together, [15] conceptual grounding and the procedural structure of [16] support reliable and replicable document-based inquiry, especially relevant for studies on data governance in public institutions where internal reports, regulations, and strategic plans serve as primary data sources.

III. Methodology

A. Research Design

This study adopts a qualitative descriptive approach using a single-case design, focusing on data governance practices at (BPKP). The research aims to formulate a data management strategy by assessing the current state and aligning it with international frameworks such as DMBOK and national regulations like SPBE [12] and SDI [13]. Document analysis serves as the main method, justified by the nature of the study, which involves reviewing internal policy, system documentation, and regulatory materials.

B. Conceptual Framework

The research follows a multi-phase conceptual framework combining theoretical and empirical steps. The process begins with literature review and problem analysis, followed by document-based evaluation of BPKP's data governance maturity, and concludes with the formulation of DMBOK-based strategic recommendations. The framework integrates insights from internal policies, maturity models, and regulatory alignment to ensure applicability and relevance (Fig. 3).

C. Data Collection

Data were collected primarily through internal documentation, including maturity assessment reports, organizational policies, system development roadmaps, and national regulatory frameworks. Additional insights were gained through participatory observation of data governance processes. Document selection followed the READ method, which consists of four stages: Ready (criteria-based selection), Extract (structured data extraction), Analyze (topic and policy mapping), and Distil (strategic synthesis).

D. Maturity Assessment Using TDWI

The analysis utilized the TDWI Analytics Maturity Model to assess BPKP's readiness across five core dimensions: Organization, Governance, Analytics, Infrastructure, and Data Management. Each dimension was scored on a five-level maturity scale ranging from Nascent to Visionary. Table I provides a detailed breakdown of the maturity assessment criteria for each TDWI dimension, outlining the characteristics for levels 1 through 5. A scoring matrix was developed and applied to evaluate documented practices and observed operations. Identified gaps were mapped against DMBOK domains to formulate strategic interventions that are contextually relevant and scalable.

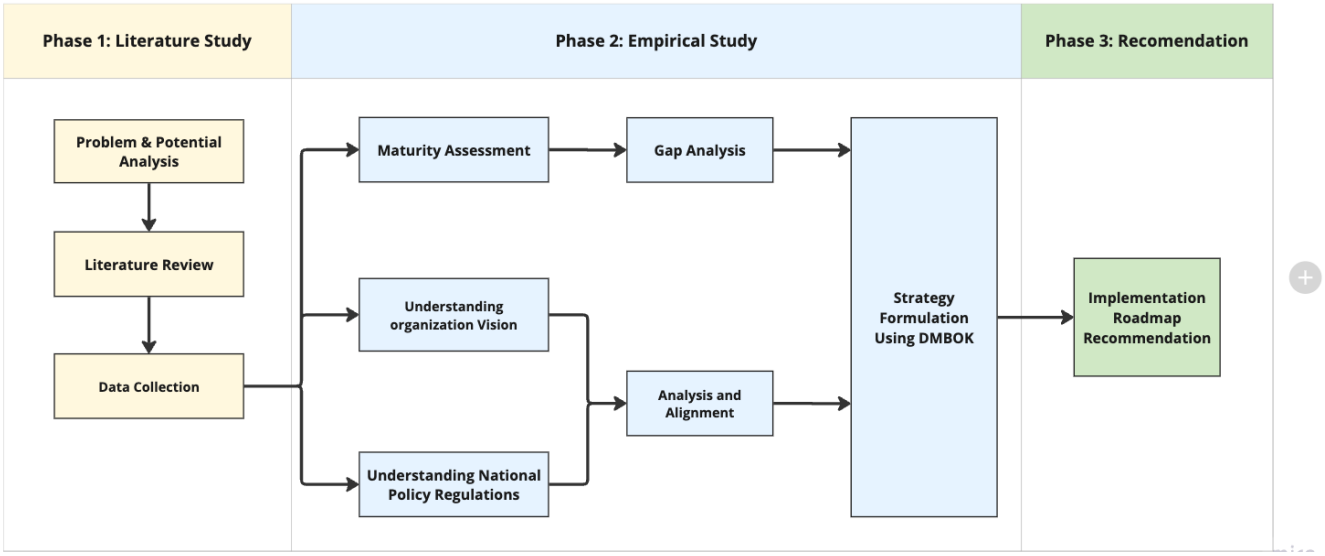

Fig. 3. Conceptual framework for the study.

Each dimension comprises several observed indicators reflecting current practice. Observations were scored on a 1–5 scale corresponding to the maturity level. The maturity score for each dimension was calculated as follows:

$$Dimension\ Score = \frac{\sum Indicator\ Scores}{Number\ of\ Indicators}$$

To identify the gap between actual and expected conditions, a gap analysis was performed using the following formula:

$$Gap\ Score = Ideal\ Score - Actual\ Score$$

TABLE I. MATURITY ASSESSMENT CRITERIA PER TDWI DIMENSION

Dimension	Level 1 - Nascent	Level 2 – Pre-Adoption	Level 3 – Early Adoption	Level 4 – Corporate Adoption	5 - Visioner
Organization	No structure, budget, or training.	Isolated initiatives, limited support, basic training.	Emerging structure, clear support, structured training.	Strong structure, sustained support, comprehensive training.	Strong data culture, active leadership, high innovation.
Governance	No policy or data security.	Incomplete policies, basic security.	Complete policies, clear roles, good security.	Monitored governance, measurable quality, strong security.	Automated governance, optimal quality, advanced protection.
Analytics	No analytics or reporting.	Basic reports, minimal analysis, intuitive decisions.	Use of analytics starts, advanced reporting, some AI.	In-depth analytics, dashboards, data-driven decisions.	Real-time analytics, machine learning.
Infrastructure	Fragmented and unplanned.	Basic systems, limited integration.	Integrated infrastructure, initial data warehouse.	Scalable infrastructure, cloud, big data capabilities.	Cloud-native, Data Mesh, Data Lakehouse architectures.
Data Management	No management, quality not addressed.	Basic processes, early attention to quality.	Defined processes, managed metadata, good quality.	Actively monitored, measured quality, integrated processes.	Automated management, certified quality, seamless data sharing.

In this study, the ideal score was set at Level 4 (Corporate Adoption) to represent the minimum threshold of systematic and standardized practices in public sector organizations.

Since a single indicator may reflect multiple dimensions, each observation was mapped to all relevant categories. For example, leadership support for big data initiatives could influence the Organization, Infrastructure, and Analytics dimensions. This approach acknowledges the interconnected and multidimensional nature of data governance and ensures that scoring reflects the systemic integration of practices.

The results of the maturity assessment provided a diagnostic basis for identifying priority areas and designing improvement strategies mapped to the DMBOK framework.

E. Validation Techniques

To ensure the reliability of findings, two validation techniques were employed. First, source triangulation was conducted by cross-verifying information across different types of documents and internal systems, such as official policy documents, internal assessment reports, and system architecture diagrams, to ensure consistency and comprehensiveness of the data gathered. Second, a limited member-checking approach was applied, in which selected results and interpretations regarding BPKP's current maturity levels and identified challenges were informally verified by internal stakeholders (e.g., data management leads and key BPKP personnel involved in digital transformation initiatives) to confirm consistency with organizational practices. This dual approach enhanced the trustworthiness and credibility of the assessment outcomes.

IV. RESULT AND DISCUSSION

This section presents the findings from the assessment of BPKP's big data and analytics capabilities, discusses the identified maturity levels and gaps, and outlines DMBOK-based strategies formulated to enhance its data-driven decision-making capacity.

A. Current State of Data Utilization and Management at BPKP: Key Findings

A systematic analysis of BPKP's internal documents, employing the READ (Ready, Extract, Analyse, Distil) approach, was conducted to understand the existing landscape. This investigation yielded key insights into organizational strengths and challenges pertinent to leveraging data for decision support.

1) Identified strengths: The document analysis revealed a strong commitment from BPKP's leadership towards digital transformation and enhancing data analytics capabilities, supported by strategic policies and resource allocation. This leadership support is crucial for successful data governance initiatives, a point strongly emphasized by research indicating the need for top-level support to overcome technical and organizational challenges in public institutions. Foundational elements include an established data custodian structure (walidata) aligning with national Satu Data Indonesia (SDI) principles, core operational systems like the Audit Management Information System (SIMA) and the STARA interoperability platform, alongside initiatives in knowledge management (KMS) and robust information security practices (evidenced by ISO 27001 certification). These elements provide a solid groundwork for future enhancements.

2) Identified challenges: Despite these strengths, significant challenges persist. The practical application of advanced analytics for risk-based decision-making and data-driven audits is not yet widespread. Comprehensive, standardized institutional metadata documentation is underdeveloped, and a formal, documented data lifecycle management process for digital supervision data is largely absent. Furthermore, an integrated system for managing all digital audit evidence is lacking. These issues resonate with prior studies on data quality and governance in Indonesia's public sector, where institutions often struggle with fragmented standards and the absence of standardized governance frameworks. Similarly, Nielsen et al. [8] emphasize the inherent difficulties in governing data within local government due to challenges such as data silos and inconsistent metadata standards.

B. Big Data Maturity Assessment

To objectively evaluate BPKP's proficiency in harnessing data for its decision-making systems, the TDWI (The Data Warehousing Institute) Big Data Maturity Model was employed. This model assesses maturity across five dimensions: Organization, Data Governance, Analytics, Infrastructure, and

Data Management. The scores for each dimension were derived from a systematic mapping of the documentary evidence (summarized in Section A) against detailed TDWI criteria. The overall big data/analytics maturity score for BPKP was 3.41, categorizing the institution at the “Early Adoption” stage. This finding aligns with observations in other public sector entities, where initial investments in digital transformation often precede full operationalization of data-driven capabilities, as highlighted by Di Vaio et al. [14] regarding the evolving role of digital technologies in governments. Fig. 4 visually represents the maturity scores across these dimensions.

The Infrastructure dimension scored highest (3.60, transitioning towards "Corporate Adoption"). This reflects strong evidence of BPKP's significant investments in IT architecture, core systems like STARA, and a Data Lake House initiative, indicating a good technical foundation for handling diverse datasets. Data Governance followed at 3.57, supported by the data custodian structure, ISO 27001 security standards, and various formal policies pertinent to managing data sources.

Both the Organization and Data Management dimensions scored 3.40 ("Early Adoption"). For the Organization dimension, while leadership commitment is strong, a pervasive data-driven culture and specific data management performance metrics are still evolving. For Data Management, practices such as reference code usage are in place, but comprehensive metadata and integrated data lifecycle management require substantial development.

The Analytics dimension received the lowest score (2.60, between "Pre-Adoption" and early "Early Adoption"). This low score is primarily due to the limited operational utilization of advanced analytics (e.g., predictive modeling) in core supervision processes, despite initial investments and planning. This gap highlights a common challenge in public sector organizations where the integration of big data analytics into core decision-making processes, particularly for predictive and proactive insights, is still in nascent stages, as discussed by Chen et al. [5] and Demirkan & Delen [6] on the transformation of decision-making by big data analytics, and also relevant to the discussions on AI in public governance.

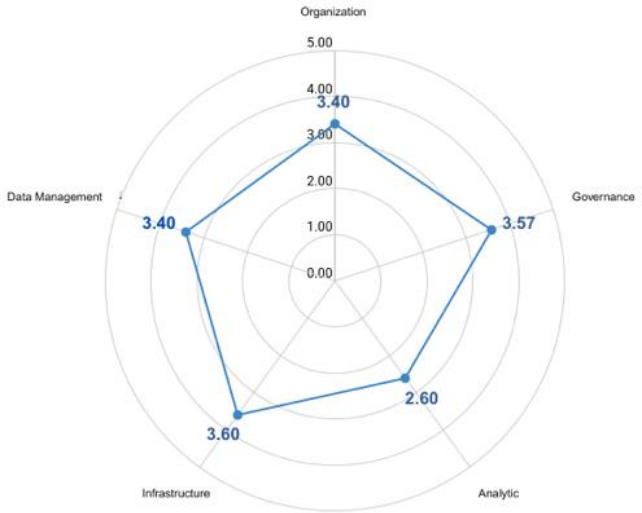

Fig. 4. BPKP's big data maturity assessment results.

C. Gap Analysis

A gap analysis compared BPKP's current maturity scores against a target of 4.0 ("Corporate Adoption"), essential for fully leveraging data for strategic decision-making. Table II summarizes this analysis.

TABLE II. GAP ANALYSIS OF BPKP'S BIG DATA MATURITY

Dimension	Reality	Exp.	Gap	Gap Analysis
Organization	3.4	4	0.6	The organizational area shows strong leadership commitment and effort to build a data culture. Policies and training are in place, and there is support for strategic initiatives. The main gaps are in the full implementation and measurement of the impact of these initiatives.
Governance	3.57	4	0.43	Data governance is already quite strong with structured policies and procedures, and efforts to comply with international standards. What needs to be improved is the validation, audit, and further evaluation of existing processes, as well as expanding the scope of data governance to all types of data.
Analytic	2.6	4	1.4	The analytics area shows great potential, but implementation is still in its early stages. There needs to be pilot projects, predictive models, or integration into business processes to make more effective use of analytics data. Training and platforms are available, but their use needs to be encouraged. In addition, there needs to be a more concrete implementation of big data analytics initiatives and the use of AI platforms. The use of analytics data needs to be encouraged and integrated into business processes.
Infrastructure	3.6	4	0.4	IT infrastructure is already well prepared, with attention to hardware, integrated systems, and big data management. It is necessary to ensure a comprehensive architecture and coverage for all data and analytics needs.
Data Management	3.4	4	0.6	Data management is already quite good with integration, quality assurance, and big data management. Further development is needed in metadata management, specific data architecture, and ensuring comprehensive data lifecycle and audit.

The analysis in Table II reveals the most substantial gap in the Analytics dimension (1.40). Significant gaps also exist in Organization (0.60) and Data Management (0.60), underscoring

the need for a more ingrained data-driven culture, specific performance metrics, comprehensive metadata standards, and systematic data lifecycle management. Smaller gaps in Data Management (0.43) and Infrastructure (0.40) indicate these areas are relatively more mature but still need enhancements for full corporate adoption.

D. Formulation of DMBOK-Based Strengthening Strategies

To address the identified gaps systematically, strengthening strategies were formulated based on the comprehensive DAMA Data Management Body of Knowledge (DMBOK) framework. DMBOK provides a structured compendium of data management principles and best practices across eleven key Knowledge Areas (KAs). The application of DMBOK here provides a structured approach to overcome common data management challenges in public institutions, offering a more standardized governance framework as suggested by Nugraha et al. [1] and aligning with the principles for reliable public sector data discussed by DAMA International [7]. For this research, practical solutions from these KAs were identified and tailored to BPKP's specific needs and context. Table III below summarizes the core DMBOK Knowledge Areas drawn upon and the key solution themes that inform the proposed strategies for BPKP. These themes are derived from a more extensive catalog of DMBOK practical solutions.

TABLE III. KEY DMBOK KNOWLEDGE AREAS AND CORRESPONDING SOLUTION THEMES APPLIED

DMBOK Knowledge Area	Key Solution Themes
Data Governance (DG)	Establishing a formal data governance function, roles (e.g., data stewards), and clear accountability; Developing and implementing comprehensive data governance policies, standards, and procedures; Managing compliance and data ethics.
Data Architecture (DA)	Evaluating and defining an enterprise data architecture that aligns with business strategy; Developing data flows and integration models; Ensuring architectural principles are followed.
Data Modeling & Design (DM)	Developing and maintaining enterprise conceptual, logical, and physical data models; Ensuring data models support business requirements and data quality.
Data Storage & Operations (DSO)	Managing physical data assets, including database administration, performance monitoring, and data lifecycle operations like backup, recovery, retention, and archiving.
Data Security (DS)	Defining and implementing data security policies, standards, and controls; Managing data access and privacy; Ensuring compliance with security regulations.
Data Integration & Interoperability (DI)	Designing and implementing solutions for data movement and consolidation between systems; Ensuring data consistency across integrated platforms.
Documents & Content (DC)	Managing unstructured data assets (e.g., digital audit documents); Establishing policies for document storage, access, versioning, and retention.
Reference & Master Data (RM)	Identifying and managing critical reference and master data; Establishing standards and processes for MDM to ensure data consistency and accuracy across the enterprise.
Data Warehousing & Business Intelligence (BI)	Designing, developing, and managing data warehouses, data marts, and BI solutions; Supporting analytical reporting, dashboards, and data exploration for decision-making.
Metadata Management (MM)	Defining metadata strategy, architecture, and standards; Developing and managing a metadata repository (e.g., data dictionary, business glossary); Ensuring metadata supports data understanding and governance.
Data Quality (DQ)	Defining a data quality strategy and dimensions; Establishing data quality rules and metrics; Implementing processes for data profiling, cleansing, monitoring, and continuous improvement of data quality.

Table IV outlines the core strengthening strategies.

TABLE IV. KEY DMBOK-BASED STRATEGIES TO ADDRESS TDWI MATURITY GAPS

TDWI Dimension	Key Strategic Thrusts for BPKP	Primary DMBOK KAs Addressed	Key Regulatory Alignment
Organization (Score: 3.40, Gap: 0.60)	1. Enhance organizational readiness and cross-functional collaboration for data initiatives. 2. Implement data governance scorecards & risk assessments for data projects.	Data Governance (DG), Data Architecture (DA)	SPBE principles (integrated governance, risk management)
Data Governance (Score: 3.57, Gap: 0.43)	1. Strengthen data governance policies, including data access, classification, and issue management. 2. Enhance data quality assessment and metadata governance practices.	Data Governance (DG), Data Quality (DQ), Metadata Management (MM)	SPBE, SDI (data quality, metadata standards)
Analytics (Score: 2.60, Gap: 1.40)	1. Develop targeted analytics use cases (e.g., anomaly detection, risk prediction) with supporting data marts. 2. Foster self-service BI and build/iterate on predictive modeling capabilities.	Business Intelligence & Data Warehousing (BI/DW), Data Science & Big Data Analytics	Supports SPBE data utilization goals
Infrastructure (Score: 3.60, Gap: 0.40)	1. Continuously evaluate and evolve data architecture for scalability, security, and performance. 2. Ensure robust database management and business continuity for critical data assets.	Data Architecture (DA), Data Storage & Operations (DSO)	SPBE (resilient infrastructure)
Data Management (Score: 3.40, Gap: 0.60)	1. Implement a comprehensive metadata architecture and standardized metadata for key data domains. 2. Define and operationalize a data quality strategy, including validation rules and monitoring. 3. Plan and model for Master Data Management (MDM) for critical reference data.	Metadata Management (MM), Data Quality (DQ), Reference & Master Data (RMD)	SDI (metadata, data standards, interoperability)

The strategies detailed in Table IV are designed to be comprehensive. For instance, to address the critical gap in Analytics, strategies grounded in DMBOK's Business Intelligence & Data Warehousing and Data Science & Big Data Analytics KAs include defining specific analytics use cases (e.g., anomaly detection, predictive risk modeling), developing supporting data marts, and creating interactive dashboards. For Data Management and Metadata Management gaps, key strategies focus on defining a complete metadata architecture, implementing consistent metadata standards, developing an enterprise data dictionary, and establishing robust data quality programs, directly relating to DMBOK's Metadata Management and Data Quality Management KAs and supporting SDI principles. Strategies for Data Governance and Organization emphasize developing comprehensive data governance policies and strengthening data stewardship roles, aligning with DMBOK's Data Governance KA and SPBE requirements.

E. Phased Implementation Roadmap Using Aiken's Pyramid

A comprehensive enhancement of data management capabilities, as envisioned by the DMBOK-based strategies (outlined in Table IV), requires a structured and incremental implementation. A "big bang" approach is often fraught with risk and may not yield sustainable results. Therefore, this research proposes a phased implementation roadmap guided by Aiken's Data Management Value Pyramid, a model that advocates for building foundational data capabilities before progressing to more advanced, value-driven initiatives. As depicted in Fig. 5, this hierarchical model organizes data management development into logical stages, ensuring that each phase builds upon the successes and outputs of the preceding one.

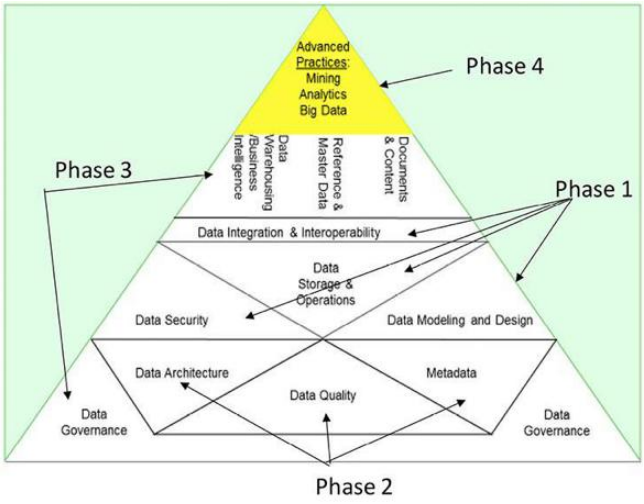

Fig. 5. Aiken's pyramid model [7].

The DMBOK-based strengthening strategies previously formulated have been mapped into the distinct phases of Aiken's Pyramid. Table V presents this phased roadmap, outlining the primary focus, prioritized DMBOK Knowledge Areas (KAs), key strategic themes for BPKP, and expected outcomes for each implementation stage.

TABLE V. PHASED IMPLEMENTATION OF DATA MANAGEMENT STRATEGIES TO ENHANCE DECISION SUPPORT SYSTEM AT BPKP

Prioritized DMBOK Knowledge Areas	Key Strategic Themes / Example Initiatives for BPKP	Expected Outcomes
Phase 1: Building the Technical & Governance Foundation Establish essential technical infrastructure and overarching governance principles for data.		
Data Governance (DG), Data Security (DS), Data Storage & Operations (DS), Data Modeling & Design (DD), Data Architecture (DA)	- Formalize core data governance policies, roles, and initial standards. - Strengthen data security protocols and operational data storage. - Define foundational data models and initial architectural principles.	- Reliable and secure data infrastructure. - Clearly defined basic data governance framework. - Initial data standards and models established-
Phase 2: Establishing Core Data Management Practices Develop and implement core practices for managing metadata, data quality, and refining data architecture.		
Metadata Management (MM), Data Quality (DQ), Data Governance (DG), Data Architecture (DA)	- Implement a comprehensive metadata architecture (data dictionary, business glossary). - Launch proactive data quality programs with defined rules & monitoring. - Refine enterprise data architecture and data models.	- Improved data trustworthiness and understandability. - Standardized metadata and enhanced data quality. - Mature data governance processes.
Phase 3: Enabling Business Value and Basic Analytics Leverage well-managed data to deliver direct business insights and support operational decision-making through analytics.		
Data Warehousing & Business Intelligence (DW/BI), Reference & Master Data (RMD), Documents & Content (DC)	- Develop initial data marts and implement descriptive/diagnostic analytics use cases. - Establish Master Data Management (MDM) for critical audit entities. - Improve management of digital audit evidence and content.	- Tangible business value from data (e.g., improved audit planning). - Initial analytical capabilities (dashboards, reports). - Consistent master data.
Phase 4: Exploiting Advanced Strategic Value Embed advanced analytics into core processes and strategic decision-making to drive innovation and significant organizational impact.		
Data Science & Big Data Analytics (DS/BDA), Business Intelligence & Data Warehousing (DW/BI)	- Develop and deploy predictive and prescriptive analytics models. - Integrate AI/ML capabilities where appropriate. - Foster a pervasive data-driven culture for strategic insights.	- Enhanced strategic decision-making through advanced analytics. - Proactive risk identification and improved audit effectiveness. - Data as a strategic asset.

The phased implementation detailed in Table V ensures a logical progression:

1) Phase 1: Building the technical & governance foundation. This initial and critical phase focuses on establishing the essential groundwork. Key DMBOK KAs prioritized include Data Governance, Data Security, Data Storage & Operations, Data Modeling & Design, and Data Architecture. Strategic themes involve formalizing core data governance policies and roles, strengthening data security protocols, optimizing data storage infrastructure, and defining foundational data models and architectural principles. The expected outcome is a reliable, secure data infrastructure and a clearly defined governance framework, directly addressing foundational gaps identified in the TDWI assessment for Data Governance, Infrastructure, and initial aspects of Data Management.

2) Phase 2: Establishing core data management practices. building upon the initial foundation, this phase emphasizes the DMBOK KAs of Metadata Management and Data Quality Management, while continuing to mature Data Governance and Data Architecture. Key strategic themes include implementing a comprehensive metadata architecture (including a data dictionary and business glossary), launching proactive data quality programs with defined rules and monitoring, and refining data models. This phase is crucial for ensuring data trustworthiness and understandability, which are prerequisites for effective analytics, thereby addressing core issues within the Data Management and Organization TDWI dimensions.

3) Phase 3: Enabling business value and basic analytics. With a more reliable data ecosystem in place, this phase shifts focus towards leveraging data for direct business insights. DMBOK KAs such as Data Warehousing & Business Intelligence, Reference & Master Data Management, and Document & Content Management become prominent. Strategic themes include developing initial data marts, implementing descriptive and diagnostic analytics use cases (e.g., performance dashboards for audit processes), establishing MDM for critical audit entities, and improving the management of digital audit evidence. This phase begins to directly tackle the significant gap in the Analytics TDWI dimension by delivering tangible analytical outputs.

4) Phase 4: Exploiting advanced strategic value. This most mature phase concentrates on DMBOK KAs like Data Science & Big Data Analytics. Strategic themes involve developing predictive and prescriptive analytics models, potentially integrating Artificial Intelligence (AI) capabilities, and embedding advanced analytics deeply into core supervision processes and strategic decision-making. Successful execution in this phase aims to fully address the remaining gaps in the Analytics dimension, transforming BPKP into a truly data-driven organization. This phase is contingent upon the successful establishment of capabilities in the preceding phases.

This staged roadmap allows BPKP to incrementally build its data management and analytics capabilities, manage change effectively, mitigate implementation risks, and demonstrate value progressively. Each phase is designed to provide a solid foundation for the next, ensuring that investments in data management translate into sustainable improvements in BPKP's ability to support its mandate through data-informed insights and decisions, in alignment with national SPBE and SDI objectives.

F. Conclusion

This study aimed to evaluate the analytics maturity of the Indonesian Financial and Development Supervisory Agency (BPKP) and propose a DMBOK-based strategy to enhance its data management capabilities in support of decision-making systems. Utilizing the TDWI Analytics Maturity Model, the assessment revealed BPKP is currently at an 'Early Adoption' stage (overall score 3.41). A significant gap was identified in the Analytics dimension (1.40), alongside notable areas for improvement in Organization and Data Management, particularly concerning comprehensive metadata and the operational application of advanced analytics.

To address these identified gaps, a comprehensive DMBOK-based strengthening strategy was formulated. This strategy is complemented by a phased implementation roadmap, guided by Aiken's Data Management Value Pyramid, which advocates for building foundational data capabilities before progressing to more advanced, value-driven initiatives. This structured approach prioritizes strengthening core data governance, data quality, and metadata management (Phases 1 & 2) to establish a reliable data foundation, followed by enabling business value and exploiting advanced analytics (Phases 3 & 4).

The findings and proposed roadmap offer a practical and actionable pathway for BPKP to systematically enhance its data management and analytical capabilities. Successful implementation of these strategies is anticipated to transition BPKP towards higher levels of data management maturity, enabling it to more effectively fulfill its mandate in the digital era by fostering more robust, data-informed decision-making in alignment with national Electronic-Based Government System (SPBE) and One Data Indonesia (SDI) objectives. This research contributes to the practical application of data management frameworks within public sector internal audit institutions, providing a blueprint for similar organizations seeking to leverage data as a strategic asset.

G. Discussion

The findings indicate that BPKP has established commendable foundational elements for data management, particularly in infrastructure and formal governance structures. However, the significant gap in the Analytics dimension, coupled with challenges in comprehensive metadata management and standardized data lifecycle practices, currently limits the full exploitation of data assets for strategic insight and predictive capabilities. The "Early Adoption" stage suggests that while awareness and initial projects exist, data management practices are not yet consistently applied or optimized across the organization.

The DMBOK-based strategies and the Aiken's Pyramid implementation roadmap provide a structured and actionable pathway for BPKP to address these gaps. By focusing initially

on strengthening data governance, data quality, and metadata (Phases 1 & 2), BPKP can build the reliable data foundation necessary for more advanced analytics. Subsequent phases focused on business value enablement and strategic analytics exploitation (Phases 3 & 4) will then be able to leverage this foundation to deliver tangible improvements in audit effectiveness and data-driven decision-making. The alignment with national directives like SPBE and SDI ensures that these internal improvements also contribute to broader governmental data initiatives. Successful implementation of these strategies is anticipated to transition BPKP towards higher levels of data management maturity, enabling it to more effectively fulfill its mandate in the digital era.

H. Future Work

This study provides a foundational assessment and a strategic roadmap for enhancing data management and decision support capabilities within the Indonesian Government Internal Audit Institution (BPKP). Building upon these findings, several promising avenues for future research and practical development emerge:

1) Empirical validation of the proposed roadmap: The current study formulates a DMBOK-based strategy and an Aiken's Pyramid implementation roadmap. Future research could focus on empirically validating the effectiveness of this proposed roadmap through pilot projects or case studies during its actual implementation within BPKP. This would involve tracking key performance indicators (KPIs) related to data quality, metadata completeness, and the adoption of advanced analytics to measure tangible improvements and refine the strategy.

2) Quantitative impact assessment of data management improvements: While this study provides a qualitative assessment, future research could employ quantitative methodologies to measure the direct impact of improved data management on audit efficiency, accuracy, and the overall effectiveness of decision-making processes within BPKP. This could involve analyzing audit findings, risk detection rates, and resource allocation before and after the implementation of specific data management initiatives.

3) Comparative studies across public sector institutions: Extending this research to other Indonesian government institutions or similar internal audit bodies in different countries would provide valuable comparative insights. Such studies could identify common challenges and best practices in data management within the public sector, contributing to a more generalized understanding of effective data governance models beyond a single case study.

4) Deep dive into specific DMBOK knowledge areas: Given the identified gaps, particularly in Metadata Management and the operationalization of advanced Analytics, future research could conduct more in-depth investigations into these specific DMBOK knowledge areas. This might involve developing detailed frameworks for institutional metadata standards or exploring the application of specific AI/Machine Learning techniques (e.g., natural language processing for unstructured audit evidence) tailored to the public audit context.

5) Long-term sustainability and change management: Research could also explore the long-term sustainability of data management initiatives and the organizational change management aspects required for fostering a truly data-driven culture within public institutions. This would involve studying factors influencing user adoption, continuous training needs, and the integration of data literacy into institutional curricula.

By pursuing these directions, future research can further contribute to the body of knowledge on data management in public sector auditing and provide more granular, evidence-based guidance for digital transformation initiatives.

ACKNOWLEDGMENT

The author expresses sincere gratitude to several parties for their invaluable support and contribution to this research. Profound appreciation is extended to the leadership and staff of the BPKP of Indonesia for granting permission to conduct this case study and for their invaluable cooperation in sharing insights and information within the established boundaries of data confidentiality and institutional protocols. Their engagement under these conditions was crucial to the successful completion of this study.

The author is also deeply indebted to my academic supervisor, or specifically Prof. Dr. Drs. Nilo Legowo, M.Kom. for their insightful guidance, constructive feedback, and unwavering support, which significantly shaped the direction and quality of this paper.

Furthermore, this research was conducted with careful consideration for ethical principles and responsible data handling, endeavoring to align with the institutional guidelines on research integrity and data management as encouraged by Bina Nusantara University.

AUTHORS' CONTRIBUTION

1) Febrian imanda effendy: Conceptualization, Methodology, Investigation, Data Curation, Formal Analysis, Writing – Original Draft Preparation, Writing – Review & Editing.

2) Nilo legowo: Supervision, Validation, Writing – Review & Editing, Project Administration, Funding Acquisition.

Data Availability Statement: The datasets analyzed during the current study are internal documents of the Indonesian Financial and Development Supervisory Agency (BPKP) and are not publicly available due to their confidential nature and institutional protocols. Access to these documents is restricted and was granted solely for the purpose of this research under strict confidentiality agreements.

Finally, any remaining errors or omissions are solely the author's own. This research aims to contribute to the enhancement of data management practices within public sector audit institutions.

Game Theory Meets Explainable AI: An Enhanced Approach to Understanding Black Box Models Through Shapley Values

Mouad Louhichi, Redwane Nesmaoui, Mohamed Lazaar
ENSIAS, Mohammed V University in Rabat, Morocco

***Abstract*—The increasing complexity of machine learning models necessitates robust methods for interpretability, particularly in clustering applications, where understanding group characteristics is critical. To this end, this paper introduces a novel framework that integrates cooperative game theory and explainable artificial intelligence (XAI) to enhance the interpretability of black-box clustering models. Our framework integrates approximated Shapley values with multi-level clustering to reveal hierarchical feature interactions, enabling both local and global interpretability. The validity of this framework is achieved by conducting extensive empirical evaluations of two datasets, the Portuguese wine quality benchmark and Beijing Multi-Site Air Quality dataset the framework demonstrates improved clustering quality and interpretability, with features such as density and total sulfur dioxide emerging as dominant predictors in the wine analysis, while pollutants like PM2.5 and NO2 significantly influence air quality clustering. Key contributions include a multi-level clustering approach that reveals hierarchical feature attribution, use of interactive visualizations produced by Altair and a single interpretability framework that validate the state-of-art baselines. As a result, the framework forms a strong basis of interpretable clustering in essential fields like healthcare, finance, and environmental surveillance, which reinforces its generalization with respect to each domain. The results underline the need for interpretability in machine learning, providing actionable insights for stakeholders in a variety of fields.**

Keywords*—Cooperative game theory; Explainable Artificial Intelligence (XAI); Shapley values; cluster analysis; interpretability; feature attribution; black-box models

I. Introduction

Machine-learning models have achieved significant performance improvements across several areas, but the rise in success has been met by an equivalent rise in opaque decision-making systems, often referred to as black boxes, due to their internal complexity in these models [1]. The interpretation of group characteristics and feature interactions in clustering models is crucial, especially when applied to high-stakes areas such as healthcare, finance, environmental pollution monitoring, and business intelligence, where decisions made on the basis of model results can have far-reaching consequences [2]. For such applications, interpretability is not just a technical curiosity, but an imperative assurance of accountability, transparency, and regulatory compliance [3].

Classical machine-learning models, like decision trees or linear regression, are relatively easy to interpret. But the rise of more complex models, such as deep neural networks, has made it difficult to understand how they operate internally [4]. Clustering tasks provide this challenge in an especially pronounced form, where no predefined labels exist and the goal is to group data on the basis of its inherent patterns [5]. Clustering models such as K-means and hierarchical clustering are widely used across different domains. However their inability to explain which features led to a cluster formation makes it impossible to use them in decision-making contexts where the model should be interpretable [6].

To tackle these challenges, Explainable Artificial Intelligence (XAI) has emerged to address the challenge of interpreting complex models [7]. Of these, Shapley values, a concept from cooperative game theory, became particularly popular. Shapley values provide a mathematically rigorous approach for attributing contributions to individual features by quantifying their impact on model predictions [8]. This method has been particularly successful in classification models, where features can be easily mapped to predicted outcomes [9]. Applications of Shapley values in thorough domains like prediction of fraud detection, risk of the patient, scoring of credit supports the necessity of in-depth attention to contribution of each feature in model's validity and reliability. However, despite their success in classification tasks, the application of Shapley values to learning, particularly clustering models, remains limited [10].

Current clustering interpretability methods focus on individual clusters, failing to capture global feature relationships across the entire dataset. Moreover, these techniques often do not work well with high-dimensional data which increases the complexity of feature interactions and makes interpretation difficult [11]. Although there has been exploration to use feature importance approaches like Shapley values for clustering, since they typically are not scalable, expensive in computation and do not supply both local and global insights. Therefore, we require scalable and interpretable techniques that can effectively handle clustering tasks in real-world complex datasets [12].

Accordingly, the central research question is: How can cooperative game-theoretic Shapley values be integrated with scalable multilevel clustering to provide both local and global interpretability for black-box clustering models on high-dimensional and real-world datasets?

We propose a new framework that combines the interpretability tool of Shapley value with multi-level clustering methods to obtain interpretability for clustering models, the

framework offers both local and global insights into feature contributions, allowing for more transparent explanations of how clusters are formed. The proposed method uses scalable Shapley value approximations, which make it feasible to handle large, high-dimensional datasets without excessive computational demands. Furthermore, the multi-level clustering technique reveals hierarchical relationships between features, offering insights into how features interact at different stages of the clustering process.

The framework was adopted for the following reasons:

1) Scalable computation: Approximate Shapley values keep run-time practical on high-dimensional data without sacrificing accuracy.

2) End-to-end interpretability: Coupling Shapley attribution with multi-level clustering yields explanations at sample, cluster and dataset scales.

3) Model-agnostic pipeline: The PCA, k-means, LightGBM and SHAP stack wraps any learner without retraining.

4) Verified cluster quality: Silhouette and Davies–Bouldin indices confirm compact, well-separated groups.

Empirical studies on two real-world datasets, Portuguese wine quality [13] and Beijing Multi-Site Air Quality [14], validate the framework. The outcomes show that the introduced framework enhances clustering performance and interpretability. This indicates its significance for yielding actionable insights in areas such as environmental pollution monitoring, and business intelligence, where interpretability is vital. With increased interpretability of models, this work opens up avenues for developing such types of more interpretable and reliable clustering methods to use in sensitive applications. This is where explainability is of the utmost importance to deploy machine learning models.

The remainder of this paper is organized as follows: Section II reviews relevant literature on model interpretation, game theory, and clustering approaches. Section III outlines the theoretical framework and methodology. Section IV presents empirical validation through experimental results and comparative analysis. Section V discusses broader implications and directions for future research, and Section VI concludes with a summary of findings.

II. Literature Review

A. Clustering Techniques and Interpretability

Clustering is an essential activity in data mining and machine learning involving the division of data into a collection of non-overlapping clusters of data with inbuilt regularities and features. K-means and hierarchical clustering as the most notable examples [15], are very time-efficient and easy to implement, however, their recent use in risky areas like healthcare, banking, and autonomous driving, has also increased the pressure to find a more understandable and explainable output [16].

Recent advancements in interpretable clustering have addressed challenges posed by high-dimensional data and the need for explainability. A taxonomy of interpretable clustering methods has been proposed, dividing the clustering process into three stages: pre-clustering (feature selection), in-clustering (model building), and post-clustering (model explanation) [17]. This framework helps in categorizing interpretable clustering methods according to their interpretability at different stages, providing a structured approach to understanding and developing these methods.

Specifically, the use of tree-based models in interpretable clustering warrants attention since they provide an intuitive and conceptual explanation of cluster formation. Such models are developed with optimization techniques that aim at ensuring the validity of the clusters and they are also interpretable. Moreover, the use of minipatch learning [10] in consensus clustering has become a new approach, and it provides not only efficiency in the calculations but also interpretability where it discovers the features that best differentiate the cluster.

B. The Role of Game Theory in AI

Game theory has emerged as a powerful framework for analysing and modeling complex interactions in AI systems. In the context of machine learning, game theory provides a foundation for understanding multi-agent systems, where multiple AI agents interact or compete to achieve specific goals. These interactions can be cooperative or competitive, and game theory helps in modeling these dynamics [18].

Game theory has found numerous applications in machine learning, including:

1) Multi-agent systems: Modeling interactions between multiple AI agents [19].

2) Generative Adversarial Networks (GANs): Two neural networks engage in a zero-sum game to generate realistic data [20].

3) Reinforcement learning: Agents learn and adapt strategies based on the actions of others [21].

4) Auction models and resource allocation: Designing efficient resource allocation systems [22].

5) Adversarial machine learning: Developing strategies to defend against attacks on ML models [23].

C. Shapley Values in Machine Learning

Shapley values are a solid framework in the field of machine learning to explain model predictions and measure feature importance. They provide a way to fairly distribute the "payout", in this case, the prediction, among the features based on their contribution. Shapley values have essential properties such as efficiency, symmetry, and additivity, ensuring fair attribution of contributions. In the context of clustering, Shapley values help in understanding the contribution of features to the formation of clusters [6].

Recent advancements have also extended the use of Shapley values to cluster importance, treating clusters of training data as players in a game. This novel approach allows for the quantification of how different data clusters affect individual predictions, complementing traditional feature importance explanations [24].

D. Interpretability in Machine Learning

Interpretability in machine learning is crucial for ensuring that models are not only accurate but also understandable and trustworthy. This is particularly important in high-stakes fields such as healthcare, finance, and autonomous systems, where decisions made by ML models can have significant consequences [25].

Several challenges exist in interpreting complex machine learning models, including the black-box nature of many models, the trade-off between interpretability and performance, and the lack of standardization in interpretability methods [16]. To address these challenges, various interpretability methods have been developed, including:

1) Post-Hoc interpretability: Analyzing models after training (e.g., LIME, SHAP) [26].

2) Intrinsic interpretability: Using inherently interpretable models (e.g., decision trees, linear models) [27].

3) Model-Specific techniques: Tailored to specific model types (e.g., attention mechanisms for neural networks).

4) Surrogate models: Creating simpler, interpretable models that approximate complex ones.

5) Visualization techniques: Using visual tools to help understand model predictions and feature importance.

As the field of interpretable machine learning continues to evolve, our research focuses on developing method that not only provide accurate results but also offer clear, understandable explanations. This ongoing research plays a crucial role in shaping the future of clustering techniques and machine learning applications across various domains.

III. Methodology

This section presents the proposed framework that integrates dimensionality reduction, clustering algorithms, and model interpretation techniques to analyze complex datasets and discover underlying patterns. The framework consists of three main components: dimensionality reduction using Principal Component Analysis (PCA), K-means for generating cluster labels, and LightGBM for training a multi-classifier. The classifier is then interpreted using SHAP values to identify the key contributors to each cluster. This integrated approach aims to not only identify clusters within the data but also to provide meaningful interpretations of the features contributing to each cluster, enhancing the explainability of the results. Fig. 1 illustrates this workflow, where data flows sequentially through each stage to produce interpretable clustering results.

A. Dimensionality Reduction with PCA

Principal Component Analysis (PCA) is employed as the initial step in the framework to address the challenges posed by high-dimensional datasets. PCA transforms the original dataset features into linearly uncorrelated components, ordered by their contribution to data variance. These components are ranked according to the amount of variance they explain in the data [3]. By reducing the dimensionality of the dataset, PCA ensures computational efficiency while retaining the most critical information.

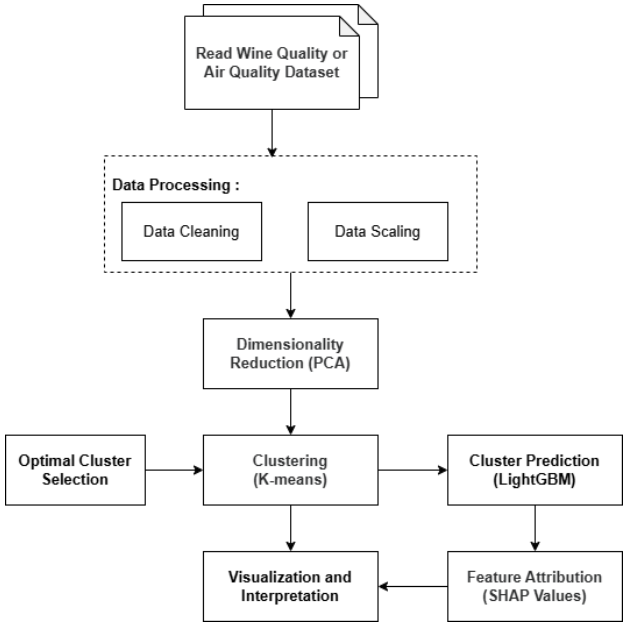

Fig. 1. Workflow of the proposed framework integrating PCA, K-Means, LightGBM, and SHAP analysis.

Mathematically, PCA as defined in Eq. (1*)* identifies a set of orthogonal vectors that maximize the variance captured in the projected space. The PCA transformation is defined as follows:

$$\mathrm{Y} = \mathrm{XW}, \tag{1}$$

where X is the standardized data matrix, W contains eigenvectors of the covariance matrix, and Y represents transformed data.

B. Clustering Framework

The primary clustering method employed in this study is K-means clustering, chosen for its efficiency and effectiveness in handling large datasets. K-means partitions the data into K distinct, non-overlapping clusters by minimizing the within-cluster sum of squares. The algorithm iteratively assigns data points to centroid of the nearest cluster and updates the centroids until convergence [28], The explained variance ratio for the $k-th$ principal component determines feature importance, as shown in Eq. (2):

$$r_k = \frac{\lambda_k}{\sum_{i=1}^{d} \lambda_i} \tag{2}$$

Following dimensionality reduction, we employ k-means clustering to minimize the objective function, as formalized in Eq. (3):

$$J = \sum_{i=1}^{k} \sum_{\mathbf{x} \in C_i} \|\mathbf{x} - \mu_i\|^2 \tag{3}$$

where C_i represents cluster i and μ_i its centroid. To evaluate clustering quality and determine the optimal number of clusters, we utilize two complementary metrics. The silhouette coefficient $S(x)$ shown in Eq. (4) measures cluster cohesion and separation, and it is calculated as follows:

$$s(x) = \frac{b(x) - a(x)}{\max\{a(x), b(x)\}}, \tag{4}$$

while The Davies-Bouldin index DB calculated as i (5), evaluates the average similarity between each cluster and its most similar counterpart:

$$DB = \frac{1}{k}\sum_{i=1}^{k} \max_{j \neq i}\left(\frac{\sigma_i+\sigma_j}{d(\mu_i,\mu_j)}\right) \quad (5)$$

where σ_i represents the average distance of points in cluster i to its centroid, and $d(\mu_i, \mu_j)$ measures the distance between centroids. These metrics work in conjunction to ensure robust cluster evaluation and optimal parameter selection for our framework.

C. Model Interpretation

1) Training the LightGBM classifier: To interpret the clustering results, a multi-class classification model was trained using LightGBM, a gradient boosting framework based on tree learning algorithms. The model predicted cluster membership from the original features, defined in Eq. (6). The objective function minimized during training is:

$$\mathcal{L}(\phi) = \sum_{i=1}^{n} l(y_i, \hat{y}_i) + \sum_{k=1}^{K} \Omega(f_k) \quad (6)$$

- l is the loss function (e.g., cross-entropy loss for classification),
- y_i is the true label,
- $\hat{y}_i$ is the prediction,
- Ω is the regularization term,
- k is the number of trees.

2) Computing SHAP values: To enhance the interpretability of clustering results, we integrate Shapley values with clustering methods. SHAP values were calculated to interpret the predictions of the LightGBM model. SHAP provides a unified measure of feature importance by computing the contribution of each feature to the prediction for individual data points, based on Shapley [24] (Fig. 2) . The Shapley value ϕ_i of a feature i, is computed according to Eq. (7), quantifies its marginal contribution to a model's outcome by considering all possible subsets of features $S \subseteq F \setminus \{i\}$. The Shapley value is calculated as:

$$\phi_i = \sum_{S \subseteq F \setminus \{i\}} \frac{|S|!(|F|-|S|-1)!}{|F|!}[v(S \cup \{i\}) - v(S)] \quad (7)$$

where: F is the set of all features, S is a subset of F excluding i and $v(S)$ represents the value function, which measures the clustering quality when only features in S are considered.

Key properties of Shapley values ensure fairness and interpretability:

- Efficiency: Stated in Eq. (8), ensures the sum of Shapley values equals the total model output:

$$\sum_{i \in F} \phi_i = v(F) - v(\emptyset) \quad (8)$$

- Symmetry: Described in Eq. (9), guarantees equal contribution for features with identical impact:

$$\phi_i = \phi_j \; if \; v(S \cup \{i\}) = v(S \cup \{j\}) \forall S \subseteq F \setminus \{i, j\} \quad (9)$$

- Additivity: Expressed in Eq. (10), allows contributions to be aggregated across different models:

$$\phi_i(v_1 + v_2) = \phi_i(v_1) + \phi_i(v_2) \quad (10)$$

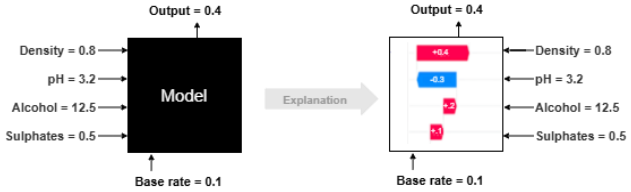

Fig. 2. SHAP (SHapley additive exPlanations) visualization of feature contributions to model output.

D. Comparative Analysis with Existing Interpretability Methods

SHAP was chosen for its ability to provide both local and global interpretability, supported by the rigorous mathematical foundation of cooperative game theory. Unlike LIME, which generates local explanations using surrogate models, SHAP ensures consistent and fair attribution of feature importance across all data points. While LIME is valued for its simplicity, its dependence on input perturbations and surrogate modeling can lead to inconsistencies, particularly in unsupervised or complex tasks [29] (see Table I).

TABLE I. COMPARISON OF INTERPRETABILITY TOOLS FOR MACHINE LEARNING MODELS

Tool	Advantages	Limitations
SHAP (SHapley Additive exPlanations)	• Provides both local and global feature importance. • Model-agnostic and mathematically rigorous. • Based on Shapley values for fair contribution attribution.	• Computationally expensive for large datasets. • Requires adaptation for unsupervised tasks like clustering
LIME (Local Interpretable Model-agnostic Explanations)	• Simple and intuitive. • Local explanations for individual predictions. • Model-agnostic.	• Limited to local interpretability. • Relies on surrogate models, which may oversimplify complex behaviors. • Sensitive to input perturbations, leading to inconsistent explanations.

E. Theoretical Justification for Shapley Values in Clustering

Shapley values help quantify feature importance without predefined labels, capturing both local and global trends. Their fair distribution of contributions ensures unbiased attribution, which is critical in fields like environmental pollution monitoring, and business intelligence. While computationally intensive, scalable approximations make Shapley values feasible for high-dimensional datasets. When integrated into multi-level clustering, they reveal hierarchical feature relationships, improving interpretability and bridging the gap between explainability and unsupervised learning's opacity.

F. Practical Implementation

The implementation follows the steps detailed in Algorithm 1. The implementation utilizes Python's scikit-learn for PCA and k-means, LightGBM for cluster prediction, and the SHAP library for feature attribution. The computational complexity is $\mathcal{O}(nd^2 + nk|\mathcal{F}| + k|\mathcal{F}|M)$ for n samples, d dimensions, k clusters, and M SHAP samples. Visualization is implemented using the Altair library, providing interactive exploration of feature contributions and cluster characteristics.

Algorithm 1: Cluster Interpretation Framework

Input: Dataset $\mathbf{X}$, features $\mathcal{F}$

Output Interpretable cluster explanations $\mathcal{I}$

$\mathbf{X}_{\text{scaled}} \leftarrow$ Scale the features in $\mathbf{X}$ using StandardScaler

$\mathbf{X}_{\text{PCA}} \leftarrow \text{PCA}(\mathbf{X}_{\text{scaled}})$ ▷ Apply PCA to reduce dimensionality

$k^* \leftarrow$ Determine optimal K via silhouette and Davies-Bou

Fit KMeans with k^*: $C \leftarrow \text{KMeans}(\mathbf{X}_{\text{scaled}}, k^*)$

$\text{M} \leftarrow \text{LightGBM}(\mathbf{X}, \{\text{C}_\text{i}\})$ Train multiclass classifier

$\phi \leftarrow$ Compute SHAP Values

For each cluster $j \in \{1, \ldots, k^*\}$ do

  Extract per-cluster SHAP values: $\phi^j \leftarrow \phi[j]$

  Order features by importance: $\mathcal{P}^j \leftarrow \text{argsort}\left(\sum|\phi^j|\right)$

  Characterize the cluster: $\boldsymbol{I}_j \leftarrow \text{Interpret}\left(\mathcal{F}^j, \phi^j\right)$

End for

return $\mathcal{I}$

By adhering to this methodology, the study ensures that all analyses are reproducible and grounded in implemented techniques, providing a robust framework for interpreting clustering results in complex datasets.

IV. Experimental Results

A. Datasets Description

We evaluated our framework using two datasets from the UCI Machine Learning Repository: the "Vinho Verde" wine quality dataset and the Beijing Multi-Site Air Quality dataset. These datasets were chosen to demonstrate the framework's applicability across domains with distinct data structures.

1) "Vinho verde" wine quality dataset: The wine dataset contains 4,898 observations with 11 physicochemical features and a quality score ranging from 0 to 10. Table II summarizes its key characteristics. This dataset served as the primary domain for developing and validating the framework.

2) Beijing multi-site air quality dataset: The air quality dataset comprises approximately 383,000 observations with 11 features, including PM2.5, PM10. Unlike the wine dataset, this dataset lacks a predefined target variable. PM2.5 was selected as a proxy target due to its established importance in air quality assessments. Table III provides its detailed characteristics.

TABLE II. Wine Dataset Characteristics

Characteristic	Details
Number of Instances	4,898
Number of Features	11
Feature Types	All numeric
Features	fixed acidity, volatile acidity, citric acid, residual sugar, chlorides, free sulfur dioxide, total sulfur dioxide, density, pH, sulphates, alcohol
Quality Range	Scores between 0 and 10
Missing Values	None

TABLE III. Beijing Air Quality Dataset Characteristics

Characteristic	Details
Number of Instances	383585
Number of Features	11
Feature Types	Numeric and temporal
Features	PM2.5, PM10, NO2, SO2, CO, O3, temperature, pressure, dew point, wind direction, wind speed
Observation Period	2013–2017
Missing Values	handled by omission

B. Optimization Strategies

The optimization strategies employed in the study are summarized in Table IV This validation demonstrates the framework's robustness and adaptability, confirming its effectiveness in handling datasets with diverse characteristics and domain-specific requirements.

TABLE IV. Optimization Strategies for Clustering and Interpretation

Technique	Purpose
Standard Scaling	Normalize features for consistent processing and comparability.
Principal Component Analysis (PCA)	Reduce dimensionality while retaining variances.
Multi-Criteria Cluster Evaluation	Determine optimal (k) using Davies-Bouldin index, silhouette score, and elbow.
SHAP Value Computation	Explain cluster assignments by analyzing feature importance derived from a classifier trained on cluster labels.
Cluster Validation Metrics	Evaluate clustering performance using multiple quantitative criteria.

C. Validation Measures and Comparative Analysis

Rigorous quantitative validation is indispensable for establishing the credibility of any interpretable-clustering framework. Accordingly, four widely accepted cluster-quality indices, Silhouette, Davies–Bouldin (DB) are reported for both benchmark datasets and confronted with the scores published in recent SHAP-based studies (Table V). Using the same battery of metrics ensures that performance gains are measurable, reproducible and attributable to the proposed methodology.

TABLE V. COMPARISON OF VALIDATION METRICS WITH RELATED WORK

Study	Domain / Dataset	XAI + Clustering pipeline	Reported validation indices	Key insight
This Work	Portuguese Wine Quality & Beijing Air Quality	PCA → K-means → LightGBM surrogate → multi-level SHAP	Silhouette 0.63, DB 0.55; CH elbow used for ***k*** selection	Hierarchical SHAP explanations uncover cross-dataset feature hierarchies and pinpoint the drivers of each cluster.
SHAP and LIME: An Evaluation of Discriminative Power in Credit Risk **[30]**	Italian SME credit defaults	XGBoost → SHAP / LIME weights → K-means & Spectral	Silhouette 0.37 (SHAP) vs 0.14 (LIME); DB ≈ **1.1**	SHAP space forms markedly tighter clusters, boosting downstream AUROC over LIME.
Interpretable Clustering of Spatio-Temporal Data by Using SHAP Method **[31]**	NYC Taxi pick-ups (time × space)	SHAP-guided feature pruning → K-means / Kmedoids	Silhouette, CH & DB collectively used to tune ***k***	SHAP ranks distance & travel-time as dominant; composite metrics verify weekday/weekend cluster separation.
Inferring Disease Subtypes from Clusters in Explanation Space **[32]**	Fashion-MNIST, UK-Biobank MRI, TCGA gene-sets	RF classifier → instancelevel SHAP → Agglomerative	Silhouette, DB, CH, AMI +0.45 vs raw space	Clustering SHAP vectors consistently recovers latent disease subtypes better than classical feature space.

D. Influence of Algorithm Parameters

A brief sensitivity sweep was run on the three hyper-parameters that most affect both quality and run-time, cluster count k, PCA dimensionality d, and the depth of the LightGBM surrogate used for SHAP. Table VI shows that keeping k=3 for both corpora, plotting the data in two PCA dimensions and using the default 100-tree / 31-leaf LightGBM model gives the best Silhouette, DB trade-off without inflating execution time.

TABLE VI. SENSITIVITY OF KEY PARAMETERS ON VALIDATION METRICS

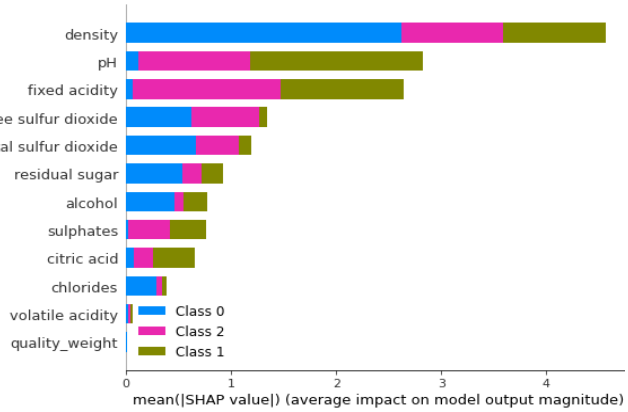
Parameter	Wine-quality dataset	Air-quality dataset	Adopted setting
k (clusters) (Silh. /DB)	2 → 0.214 / 1.775 3 → 0.144 / 2.097	2 → 0.265 / 1.503 3 → 0.626 / 0.553	3, best overall balance of cohesion and separation
PCA projection d	2 components (9 PCs ≈ 97 % var.)	2 components (9 PCs ≈ 97 % var.)	2, clear 2-D plots; no loss in cluster quality
LightGBM depth (num_leaves)	31 leaves: +0.02 absolute F1 (0.82 → 0.84) costs +4 min run-time; default kept	same trend	31 leaves: F1 = 0.82 (4 min) 63 leaves: F1 = 0.84 (8 min)

E. Wine Quality Dataset Analysis

1) Overall feature importance: Our analysis revealed the global impact of features across all clusters through SHAP value computation, demonstrating a clear hierarchy of feature importance and their relative contributions. The comprehensive analysis shown in Fig. 3 identifies density, pH, and fixed acidity as the most influential features, with sulfur dioxide compounds and residual sugar showing moderate influence across all clusters.

2) In-Depth analysis of feature importance in cluster formation: To interpret cluster formation in the wine quality dataset, SHAP force plots were generated for representative samples selected using median SHAP magnitude (Fig. 4). In Cluster 0, predictions are strongly influenced by total sulfur dioxide, alcohol, and free sulfur dioxide, with density contributing positively and residual sugar slightly reducing cluster affiliation. Cluster 1 shows a distinct pattern where fixed acidity exerts the most influence, supported by free sulfur dioxide, density, and pH, indicating a profile defined by acidity and moderate sulfur content. In Cluster 2, contributions are driven by fixed acidity, alcohol, and citric acid, with pH slightly lowering the prediction. Each cluster reflects a unique chemical signature, enabling more interpretable groupings and practical insights into wine characterization.

3) Cluster-specific analysis: Fig. 5 illustrates the distinct characteristics of each cluster in relation to wine quality:



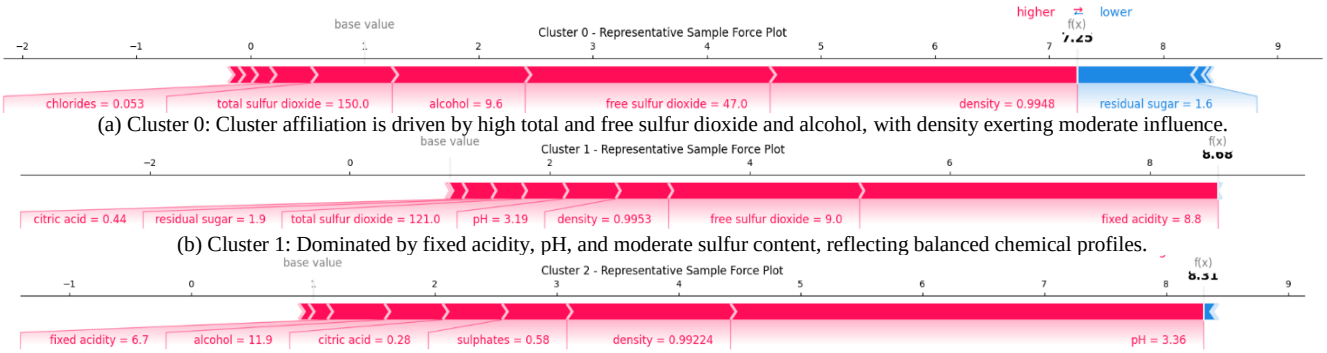


Fig. 3. Average SHAP value impact across clusters: Key features influencing cluster formation in the wine dataset.

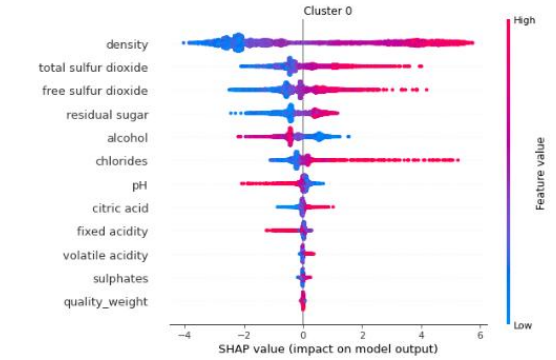
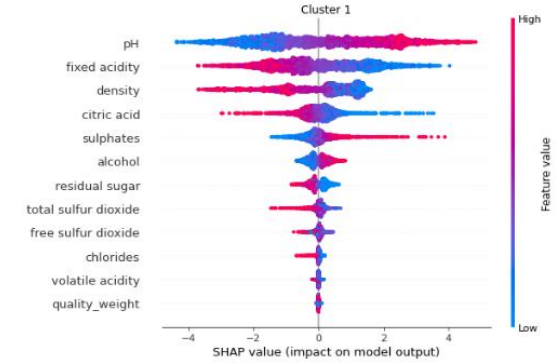


(a) Cluster 0: Cluster affiliation is driven by high total and free sulfur dioxide and alcohol, with density exerting moderate influence.



(b) Cluster 1: Dominated by fixed acidity, pH, and moderate sulfur content, reflecting balanced chemical profiles.

(c) Cluster 2: Influenced by fixed acidity and citric acid, with pH slightly reducing affiliation, indicating acidity-driven groupings.

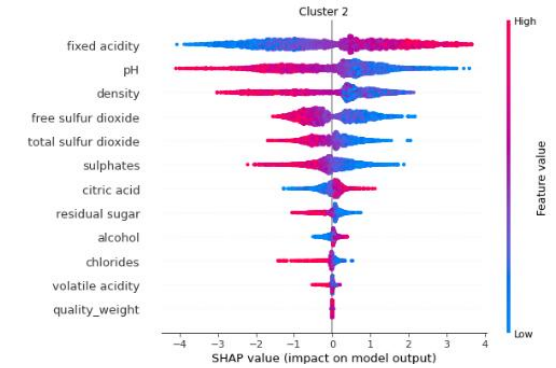


Fig. 4. SHAP Force plots for representative samples in each wine quality cluster.

(a) Cluster 0: Influenced by sulfur dioxide compounds and alcohol.

(b) Cluster 1: Driven by fixed acidity, density, and pH.

(c) Cluster 2: Dominated by alcohol, citric acid, and fixed acidity.

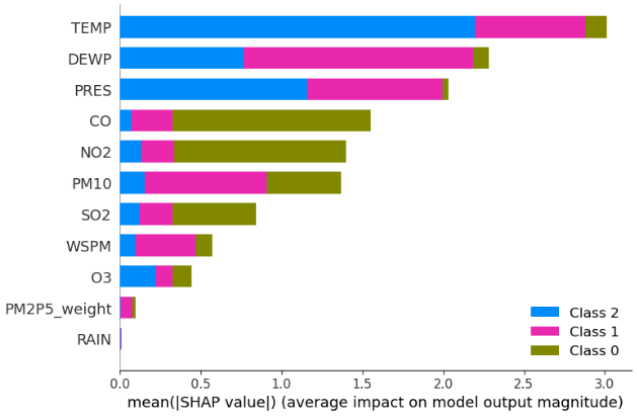
Fig. 5. SHAP Summary plots showing the distribution of feature contributions across clusters for the wine quality dataset.

Cluster 0 is defined by high density and elevated levels of total and free sulfur dioxide, indicating a strong correlation with wine quality ratings and preservation characteristics. the Cluster 1, the relationships among pH and fixed acidity reveal a balanced chemical composition, aligning with traditional winemaking principles. The analysis underscores the critical role of acid balance in determining wine quality. Lastly, Cluster 2 displays unique chemical patterns associated with extreme quality ratings. Significant variations in chemical composition highlight the interactions between features that influence quality assessments.

F. Validation on the Beijing Air Quality Dataset

The Beijing Multi-Site Air Quality dataset was analysed to assess the generalizability of the proposed framework to a larger and more diverse dataset. Pre-processing steps involved imputation of missing values, normalization using StandardScaler, and dimensionality reduction via PCA. Clustering was performed using k = 3, determined through a multicriteria evaluation of silhouette score ((k) = 0.63), Davies-Bouldin index ($D(k)$ = 0.55), on the full 11-feature matrix.

1) Overall feature importance: Our analysis revealed the global impact of features across all clusters through SHAP value computation, demonstrating a clear hierarchy of feature importance and their relative contributions. The comprehensive analysis shown in Fig. 6 identifies temperature (TEMP), dew point (DEWP), and pressure (PRES) as the most influential features, with CO, NO2, and particulate matter compounds (PM10 and PM2.5) showing moderate influence across all clusters.



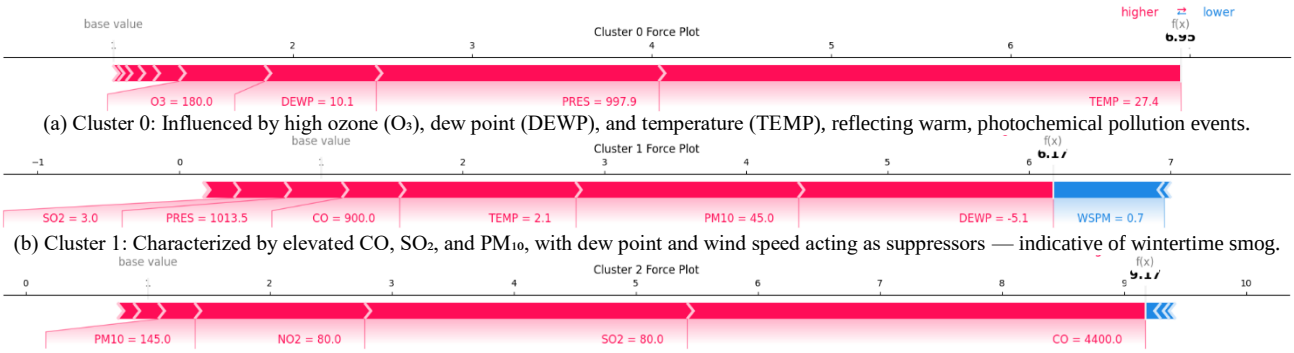


Fig. 6. Global SHAP value impact for the Beijing Air Quality dataset.

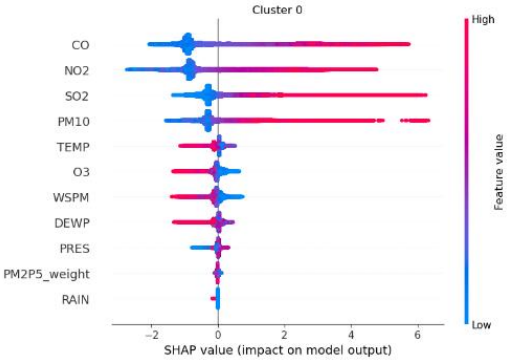
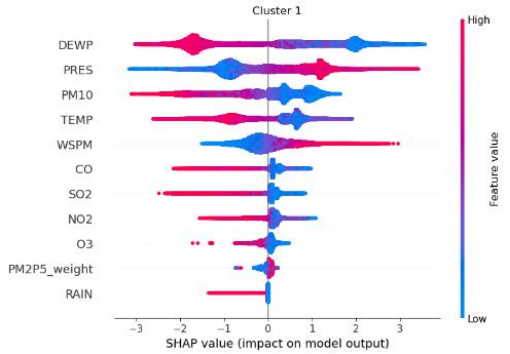


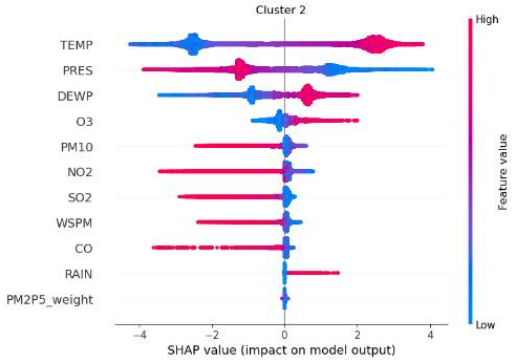
(a) Cluster 0: Influenced by high ozone (O_3), dew point (DEWP), and temperature (TEMP), reflecting warm, photochemical pollution events.

(b) Cluster 1: Characterized by elevated CO, SO_2, and PM_{10}, with dew point and wind speed acting as suppressors — indicative of wintertime smog.



(c) Cluster 2: Driven by PM_{10} and NO_2, but unusually high CO reduces cluster affiliation — suggesting divergent emission profiles.

Fig. 7. SHAP Force plots demonstrating feature influence on cluster membership for representative samples from the Beijing Air Quality dataset.



2) In-Depth analysis of feature importance in cluster formation: A similar interpretability approach was applied to the air quality dataset using SHAP force plots for representative samples (Fig. 7). In Cluster 0, elevated ozone and temperature are the primary drivers of cluster membership, with supportive roles from dew point and pressure—indicating warm, photochemical pollution events. Cluster 1 is characterized by high CO, SO_2, and PM10, while low dew point and wind speed act as suppressors, suggesting stagnant cold-air conditions typical of wintertime smog. Cluster 2 is heavily influenced by PM10, NO_2, and SO_2, with an unexpectedly negative contribution from extremely high CO, possibly reflecting divergence in emission source profiles. These results highlight how the model captures distinct atmospheric compositions that align with interpretable pollution scenarios.

(a) Cluster 0: Influenced by high CO, NO_2, SO_2, and PM_{10}, indicating pollution-heavy urban zones.

(b) Cluster 1: Driven by dew point, PM_{10}, and low wind speed, suggesting stagnant weather conditions.

(c) Cluster 2: Shaped by high temperature and pressure, with pollutants contributing negatively, reflecting clean-air events.

Fig. 8. SHAP Summary plots for each cluster in the Beijing Air Quality dataset.

3) Cluster-specific analysis: Cluster-specific SHAP analyses were performed to evaluate feature contributions across the air quality dataset. In Cluster 0, predictions are driven by elevated levels of CO, NO_2, SO_2, and PM10, pointing to pollution-heavy conditions typical of urban emission hotspots [Fig. 8(a)]. Cluster 1 is shaped by the interaction of high dew point, moderate PM10, and low wind speed (WSPM), suggesting meteorologically stagnant conditions that hinder dispersion [Fig. 8(b)]. In Cluster 2, high temperature and atmospheric pressure dominate the contribution profile, while particulate and gaseous pollutants (PM10, NO_2, SO_2) exert negative influence, indicating cleaner air events supported by favorable dispersion conditions [Fig. 8(c)]. These results give us a better understanding of how environmental variables interact to define distinct air quality regimes.

4) Discussion: The results from the Beijing dataset align with findings from the wine dataset, demonstrating the framework's ability to extract meaningful feature contributions across diverse domains. The larger size and complexity of the air quality data highlight the framework's scalability and adaptability, confirming its relevance in high-stakes applications such as environmental monitoring. The differing comparative results stem from the distinct nature of each dataset. The wine data, with consistent chemical features, yielded clearer attributions, while the air quality data required more nuanced interpretation due to its temporal and

environmental variability. This suggests the proposed algorithms are broadly applicable but especially effective for complex, high-dimensional data — reinforcing their robustness across domains.

V. Discussion and Broader Implications

A. Contributions to the Field

Our work advances the field of explainable AI through several key theoretical and practical contributions. The integration of game-theoretic principles with clustering analysis provides a novel framework for interpretable machine learning. The use of Shapley values for cluster interpretation bridges the gap between local and global explanations, offering insights at multiple levels of granularity. Our framework extends traditional SHAP applications by incorporating cluster-specific interaction effects, enabling quantitative assessment of feature relationships while maintaining interpretability. The hierarchical analysis of feature importance provides both detailed local insights and broader structural understanding of cluster formation.

B. Applications and Use Cases

The framework shows practical applicability in domains such as clinical diagnostics, regulatory finance, recommendation systems, and environmental risk monitoring. In healthcare diagnostics, our approach enables interpretation of patient groupings based on medical parameters while maintaining the high accuracy requirements of medical applications. The feature attribution methodology provides clinically relevant insights into diagnostic patterns.

Financial risk assessment applications benefit from the framework's ability to identify and explain customer segments. The clear feature importance hierarchy supports regulatory compliance requirements while enabling sophisticated risk profiling. Beyond financial services, autonomous systems benefit from our framework's ability to explain behavioral patterns and decision boundaries, which is particularly crucial in safety-critical applications.

This capability to interpret clusters meaningfully also strengthens its utility in healthcare applications, as shown by earlier discussions of patient grouping and outcome differentiation. Similarly in recommendation systems, the ability to explain user groupings and feature preferences enhances transparency and trust in personalized content delivery. These implications reinforce the practical value already outlined.

C. Limitations and Future Work

Our current implementation faces several limitations in computational scalability, particularly with extremely large datasets. The computational cost increases significantly with dataset size and feature dimensionality, becoming particularly evident in the calculation of exact Shapley values for large-scale applications.

Future enhancements could address these computational challenges through methodological improvements in three key areas. Advanced approximation methods for Shapley computation could reduce computational overhead while maintaining accuracy. Parallel processing implementations could better handle large-scale datasets. Optimized feature selection strategies could improve efficiency in high-dimensional data analysis.

Future work will explore integrating deep learning with interpretability, enabling dynamic clustering, and developing domain-specific optimizations. Implementation will aim for real-time analysis, distributed processing, and improved visualizations for complex feature interactions.

VI. Conclusion

We introduced a framework that integrates multi-level clustering with Shapley-based explanations, enabling interpretable insights into unsupervised learning outcomes. Our experiments on wine and air quality datasets demonstrate its ability to uncover meaningful feature contributions.

The implementation methodology demonstrates scalability across different domains, supported by thorough statistical validation. Through extensive testing on the wine quality dataset, we demonstrated the framework's ability to identify meaningful clusters while providing clear explanations of the underlying feature relationships. The analysis revealed distinct chemical profiles corresponding to different quality levels, with density, pH, and acidity emerging as key determinants of wine characteristics.

The proposed framework proves the successful reconciliation between model sophistication and interpretability requirements. Clear feature attribution mechanisms enable stakeholders to understand complex model decisions, while maintaining the statistical rigor necessary for reliable analysis. The framework's application extends beyond wine and air analysis to other domains requiring both precision and explicability, such as healthcare diagnostics and financial risk assessment.

While the framework demonstrates strong interpretability and generalizability across two real-world tabular datasets, several limitations remain. It has not yet been tested on non-tabular data such as images or text, exact SHAP computations remain costly for large-scale or streaming data, and the current approach assumes static clusters. Future work will explore scalable SHAP approximations, dynamic clustering, and broader dataset types to address these challenges.

The combination of theoretical soundness and practical applicability makes this framework a valuable tool for modern machine learning applications where interpretability is crucial. By providing both local and global explanations of cluster characteristics, our approach enables informed decision-making while maintaining model performance. This balance between sophistication and transparency establishes a foundation for future developments in explainable artificial intelligence, particularly in scenarios where understanding model decisions is as important as the decisions themselves.

Anomaly Detection and Fault Diagnosis of Power Distribution Line Point Cloud Data Based on Deep Learning

Jiangshun Yu*, Poyu You, Jian Zhao, Xianzhe Long, Yuran Chen
Guizhou Electric Power Design and Research Institute Co., Ltd. of Power Construction Corporation of China, 550081, China

***Abstract*—Early and accurate fault diagnosis in power distribution systems is essential to ensure stable electricity delivery and prevent outages. This study presents a deep learning-based anomaly detection framework that analyzes 3D LiDAR point cloud data to identify structural defects in power distribution lines. Leveraging advancements in deep learning and 3D sensing, a hybrid architecture combining PointNet++ and 3D Convolutional Neural Networks (3D CNN) is proposed. The system processes point clouds from the TS40K dataset, comprising high-resolution, annotated scans of power infrastructure, and uses a feature fusion strategy to integrate fine-grained local geometry from PointNet++ with global volumetric features from 3D CNN. Implemented in Python, the method achieves a 94.7% accuracy in fault diagnosis, outperforming standalone models. It robustly detects anomalies such as sagging wires, leaning poles, and broken insulators, maintaining precision, recall, and F1-scores above 90%, even under noisy and sparse conditions. Visualization of detected faults on 3D models confirms its precise localization capability, supporting real-time monitoring and maintenance planning in smart grids. By integrating complementary deep learning techniques, this approach offers a scalable, accurate, and automated solution for anomaly detection and fault diagnosis in power distribution systems. Future work will focus on multi-sensor fusion and semi-supervised learning to reduce dependence on labeled data and broaden applicability to other infrastructure use cases.**

Keywords*—Power distribution; anomaly detection; point cloud; deep learning; fault diagnosis

I. Introduction

Power distribution networks are critical components of today's infrastructure, providing a reliable supply of electricity from substations to consumers. As urbanization and industrialization grow, so does the level of complexity and size of power distribution networks [1] [2]. Their uninterrupted operation is crucial to economic well-being and society's well-being [3] [4]. These systems, however, are exposed to environmental degradation, mechanical failure, and aging infrastructure [5]. Regular inspection and maintenance of power lines are required to avoid service outages, safety risks, and equipment damage. Conventional inspection practices are labour-intensive and based on manual processes, which are time-consuming, costly, and susceptible to human error. Additionally, visual inspection based on 2D images does not provide the spatial depth necessary to comprehend the full three-dimensional geometry of power lines, hindering the identification of concealed or slight abnormalities [6].

With advancements in remote sensing technologies, particularly LiDAR and Unmanned Aerial Vehicles (UAVs), the doors have been opened to acquiring high-resolution 3D point cloud data for power distribution lines [7] [8]. Such point clouds provide accurate spatial models of infrastructure, facilitating enhanced monitoring and analysis. Interpretation and processing of such unstructured 3D data, however, remains a problem [9]. Conventional machine learning models are also not effective in handling the sparsity, irregularity, and noise inherent in point cloud data. Traditional models have a great deal of feature engineering and cannot generalize across diverse spatial configurations. Moreover, conventional models are unable to learn the capacity to understand local and relevant geometric features that can be used in identifying fragile defects in power line components [10] [11]. To address these limitations, deep learning approaches specifically designed for point clouds have been developed. PointNet and its updated version, PointNet++, have presented promising performance on point cloud classification and segmentation by learning spatial features from raw points in an end-to-end manner. PointNet++ maintains both local and global contextual details, making it extremely efficient in the analysis of power infrastructure elements. On the contrary, voxel-based approaches, such as 3D Convolutional Neural Networks, transform point clouds into structured grids, enabling the effective detection of spatial patterns through the application of convolutional operations.

This paper suggests a fusion deep learning framework which leverages the strengths of point-based and voxel-based techniques for comprehensive fault detection in power distribution lines. By combining PointNet++ for detailed feature learning with 3D CNNs for contextualization, the proposed method achieves high accuracy in detecting a wide range of anomalies from small-scale insulator leakage to large-scale pole misalignment. The architecture employs a feature fusion approach that fuses outputs from both networks to enable the model to be trained on complementary information [12] [13], [14] [15]. The approach not only enhances the robustness of data against noise and sparsity but also improves fault localisation and classification. Furthermore, it is real-time inference-friendly, thereby allowing it to be accommodated in smart grid monitoring systems. The approach is scalable and versatile enough to support numerous power distribution scenarios, with

an applied solution to autonomous infrastructure inspection. It bridges the gap between traditional inspection and modern AI-based alternatives, opening the door to smarter, safer, and more efficient power distribution grids. The proposed framework not only enhances anomaly detection but also facilitates predictive maintenance and system resilience in future power systems. Key contributions of this research paper are,

1) This research introduces a hybrid deep learning framework that combines PointNet++ and 3D CNNs for analysing power distribution line point cloud data.

2) It effectively extracted both local and global features to detect various anomalies such as damaged insulators, sagging wires, and pole misalignments.

3) A novel feature fusion strategy was implemented to integrate point-based and voxel-based representations for improved fault diagnosis.

4) The suggested method reached higher accuracy, precision, and recall compared to traditional 2D and standalone deep learning approaches.

5) It enabled real-time and scalable fault detection suitable for deployment in smart grid monitoring systems using edge–cloud architectures.

The remaining section of the article is organized as follows: Section II gives a literature review of the current works in the areas of point cloud analysis, deep learning-based anomaly detection, and fault diagnosis of power systems. Section III formulates the problem statement accurately, identifying the issues associated with detecting structural faults and anomalies in unstructured 3D point clouds of power distribution lines. Section IV presents the proposed approach, utilising PointNet++ and 3D CNN, for robust feature extraction, fusion, and classification. Section V describes the experimental setup, presents the results obtained, and provides a critical analysis of the models' performance using various evaluation parameters. Discussion is given in Section VI. Section VII summarizes the research and suggests potential future directions of research to enhance the accuracy and real-time acceptability of the proposed framework in smart grids.

II. Related Works

Deep learning for 3D point cloud analysis has witnessed rapid growth, particularly in the context of infrastructure inspection and fault detection. Existing approaches can be broadly grouped into point-based, voxel-based, hybrid architectures, and domain-specific applications, such as those used in power grid monitoring and other similar fields. This section reviews the key contributions under these categories.

A. Point-Based Architectures

Point-based models operate directly on raw point clouds, eliminating the need for voxelization and thereby preserving geometric fidelity. A foundational approach is PointNet, introduced by Qi et al., which uses symmetric functions to handle unordered point sets and demonstrates strong performance in 3D object classification and segmentation [16]. Its extension, PointNet++, developed by Qi et al., incorporated hierarchical feature learning, enhancing local structure representation an essential capability for complex infrastructure fault detection [17]. To better capture local geometric relationships, the Dynamic Graph CNN (DGCNN) by Wang et al. dynamically constructs and updates graph edges during training, thereby improving the contextual understanding of 3D structures [18]. Li et al. developed PointCNN, a model that applies X-transforms to reorder points canonically before performing convolution, leading to effective feature extraction from irregular point clouds [19].

Further progress was made by Thomas et al. through the use of KPConv (Kernel Point Convolution), which applied deformable kernel filters directly to point sets, thereby avoiding voxelization while adapting to local geometries [20]. For unsupervised learning, Yang et al. introduced FoldingNet, which uses an autoencoder to reconstruct 3D shapes from 2D grid deformations, preserving both global and local structure [21].

Recent surveys, such as those by Zhang et al. and Liu et al., offer comprehensive taxonomies of point-based models, classifying them based on their learning strategies and highlighting their applicability to infrastructure tasks like fault detection [22] [23].

B. Voxel-Based Architectures

Voxel-based methods convert unstructured point clouds into regular voxel grids, allowing the use of 3D Convolutional Neural Networks (3D CNNs) for structured learning. Maturana and Scherer proposed the foundational VoxNet model, which performed efficient 3D shape recognition on voxelized inputs [24]. More recent models extend this idea with deeper layers, enhanced normalisation, and advanced pooling strategies.

Jin et al. introduced a convolutional GAN-based framework for semantic segmentation in power line inspection, merging voxel grid input with adversarial training [25]. Similarly, Wen et al.proposed a directionally constrained 3D CNN that improved classification performance on airborne LiDAR data by modeling orientation between points [26].

C. Hybrid and Fusion-Based Methods

Recognizing the trade-offs between point- and voxel-based models, hybrid architectures aim to leverage the strengths of both. The method proposed in this paper exemplifies this trend by combining PointNet++ for local geometric learning with 3D CNNs for capturing global spatial context, thereby improving robustness in fault classification tasks. A closely related model is VoteNet by Qi et al. and Li et al. couples PointNet++ with a Hough voting mechanism for 3D object detection [16] [19]. Similarly, Fast Point R-CNN, introduced by Shi et al. enhances detection efficiency through faster region proposals adapted to 3D data [27].

Label efficiency has become a critical challenge in large-scale applications. Xiao et al. addressed this by surveying techniques like domain adaptation and weak supervision to reduce annotation burdens [28]. In parallel, Sohail et al. presented a comprehensive study on deep transfer learning for 3D point cloud perception, emphasizing its role in mitigating data sparsity challenges [29].

D. Applications in Power Grid Fault Detection

The field of smart grid infrastructure has embraced 3D deep learning for anomaly detection. Zideh and Solanki proposed physics-informed autoencoders for improved interpretability in fault diagnostics [30]. Kyuroson et al. developed an unsupervised point cloud segmentation framework for power line inspection using LiDAR, demonstrating high accuracy in identifying vegetation and line sag [31]. Lu and Shi reviewed scalable deep learning approaches for 3D point cloud perception tasks such as detection and segmentation, confirming the framework's viability in hazard analysis along power corridors [32]. Zhu et al. and Faisal et al. explored generative and adversarial methods to refine semantic segmentation and automate power line monitoring [33] [34]. Finally, Chen et al. presented DCPLD-Net [35], a real-time diffusion-coupled CNN for detecting transmission lines from UAV-LiDAR data. Other efforts, including those by Shin et al. and Lin et al. , combine thermal, RGB, and LiDAR data for multi-modal anomaly detection, reflecting an emerging trend toward sensor fusion and real-time deployment in smart grids [10] [13]. Basani et al. (2024) developed a deep multi-scale fusion neural network for fault diagnosis in IoT environments. Inspired by this, our work adopts multi-scale feature fusion to extract and combine geometric features from power line point cloud data. This approach enhances fault detection accuracy and robustness across varying spatial resolutions [36]. A real-time safety management framework using machine learning on TBM data is presented by Devarajan and Sambas (2022) to enhance infrastructure monitoring. Our proposed work applies this real-time data-driven approach for anomaly detection in power distribution line point cloud data. This enables proactive fault diagnosis, reduces risks, and improves the reliability of power infrastructure systems [37]. Rajya Lakshmi Gudivaka (2023) implemented a neural network-based framework for real-time imperfection prediction in robotic process automation. Our study employs this approach to detect anomalies in power distribution line point cloud data using deep learning techniques. This integration facilitates automated fault inspection, improves detection speed, and enhances system reliability [38]. Our proposed work on fault diagnosis in power distribution lines adopts the signal preprocessing strategy introduced by Harikumar and Khalid (2022), which utilizes Butterworth filters to enhance signal clarity in IoT systems. By incorporating this denoising technique into our point cloud data pipeline, we ensure cleaner input for deep learning-based anomaly detection. This improves diagnostic precision, minimizes false positives, and strengthens the reliability of fault classification outcomes [39]. A hybrid machine learning framework for financial fraud detection using big data was proposed by Naresh Kumar Reddy Panga (2021). Our framework builds on this hybrid learning strategy by combining point-based feature extraction and deep classification for 3D anomaly detection. This integration improves model generalization, enhances fault detection accuracy, and ensures robustness across varying point cloud conditions [40].

III. Problem Statement

Traditional methods of fault detection in power distribution networks—such as visual examination and 2D image analysis—are insufficient to describe the complex spatiality of modern infrastructure [41] [42], resulting in inefficiency and missed anomalies. Although 3D point cloud data from LiDAR and UAVs offer a more detailed description, their unstructured and irregular nature is extremely difficult for traditional machine learning models to process [43], [44], [45]. This work overcomes such limitations by proposing a hybrid deep learning framework that combines PointNet++ and voxel-based 3D CNNs for learning global spatial patterns. By integrating point-wise and voxel-wise features, the method enhances both noise robustness and the accuracy of fault diagnosis and anomaly detection. This end-to-end framework supports the precise detection of structural defects—such as insulator failure and pole misalignment—while enabling real-time edge inference on the edge–cloud platform, thus overcoming the limitations of existing models and offering an extensible autonomous power infrastructure monitoring solution. To address the limitations of traditional fault detection techniques and the challenges of processing unstructured LiDAR point cloud data, this study investigates the following research question: How can a hybrid deep learning architecture that combines PointNet++ and 3D CNN be developed to accurately and efficiently detect and classify structural anomalies in power distribution line point cloud data, while maintaining robustness under real-world smart grid conditions?

Objectives

1) Develop a deep learning-based framework capable of analyzing unstructured 3D point cloud data from power distribution lines.

2) Extract meaningful local and global geometric features from point clouds using PointNet++ architecture.

3) Apply voxel-based 3D CNNs for contextual analysis and detection of large-scale structural anomalies.

4) Design a fusion mechanism that combines point-based and voxel-based features for enhanced fault classification.

5) Validate the performance of the proposed method on real-world datasets in terms of accuracy, scalability, and real-time applicability.

IV. Proposed PointNet++ and 3D CNN-Based Deep Grid Fault Net for Anomaly Detection and Fault Diagnosis in Power Distribution Line Point Cloud Data

The proposed methodology employs a hybrid deep learning method that integrates PointNet++ and 3D Convolutional Neural Networks for effective fault diagnosis and detection from power distribution line point cloud data. Initially, high-density LiDAR point clouds belonging to the TS40K dataset are pre-processed with noise removal and normalization to ensure data consistency and quality. PointNet++ is subsequently employed to directly retrieve local and global geometric information from the raw point clouds, which contain high structural detail of power line features. Concurrently, the point clouds are voxelized and inputted into a 3D CNN for learning more general spatial contexts and volumetric features. The features learned from both networks are merged to form a global representation, which is then fed into a classification head for detecting various types of faults, such as leaning poles, hanging wires, and snapped insulators. The entire framework is implemented in Python, and the latest deep learning libraries are utilized for training and

inference. This point-based and voxel-based feature extraction integration enhances the robustness and accuracy of the model in identifying anomalies in complex 3D situations; thus, it is optimally suited for real-world smart grid monitoring applications. Fig. 1 shows proposed PointNet++ and 3D CNN-Based Deep Grid Fault Net for Anomaly Detection and Fault Diagnosis in Power Distribution Line Point Cloud Data.

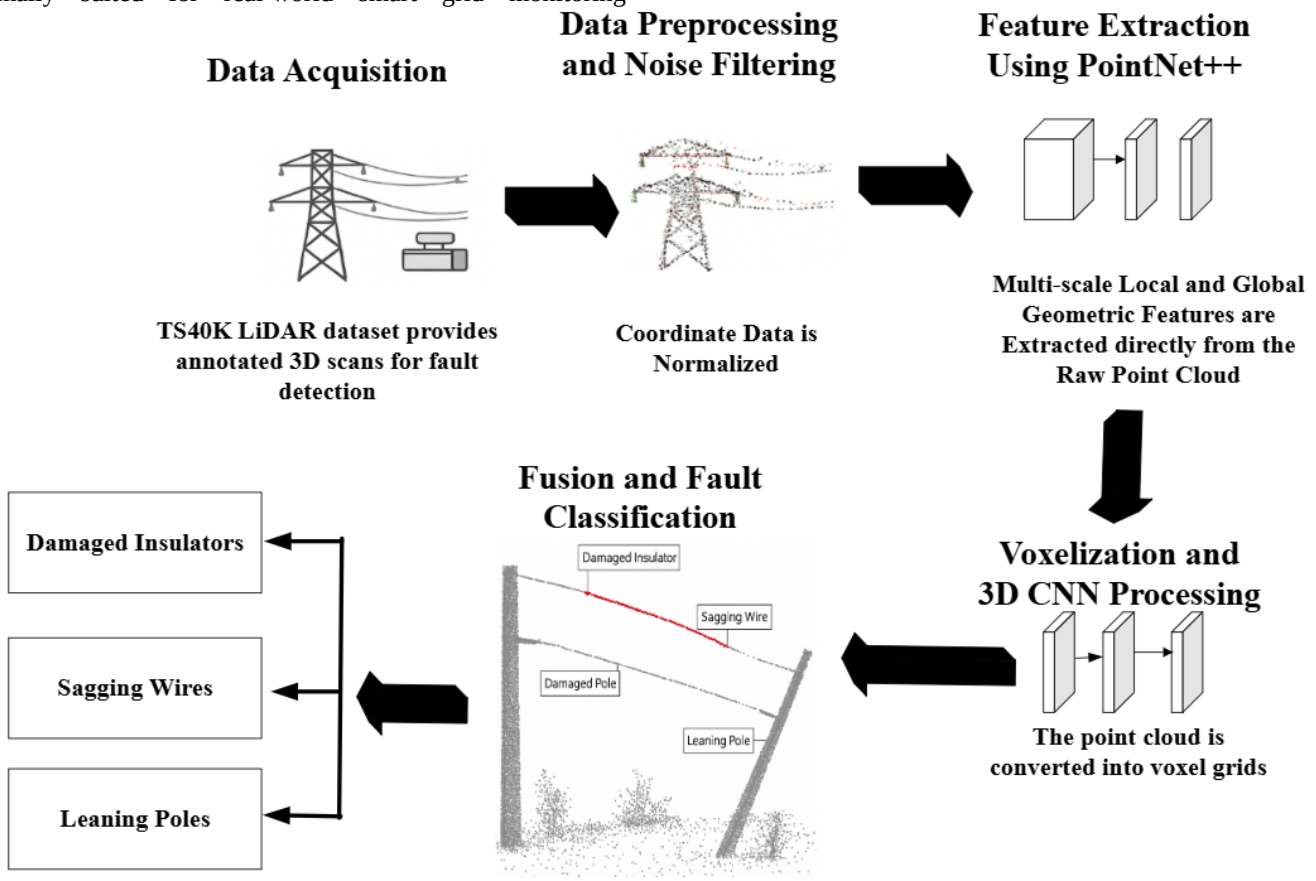

Fig. 1. Proposed PointNet++ and 3D CNN-Based deep grid fault net for anomaly detection and fault diagnosis in power distribution line point cloud data.

Fig. 1 illustrates the overall workflow of the proposed fault detection system for power distribution lines. The process begins with LiDAR-based data acquisition and preprocessing, followed by feature extraction using PointNet++ and a 3D CNN. The extracted features are fused and classified to identify anomalies such as damaged insulators, sagging wires, and leaning poles.

A. Data Collection

The dataset used for this research was obtained from the TS40K dataset [46] [47], a large benchmark specifically designed for semantic segmentation and structural analysis of power line corridors from LiDAR point cloud data. TS40K comprises over 40,000 km of annotated 3D LiDAR scans from aerial surveys conducted across various European regions, capturing the spatial details of power line components, including poles, conductors, insulators, and terrain, with high accuracy. The dataset is highly annotated with semantic labels, enabling the proper training and evaluation of deep learning models for fault classification and anomaly detection. Its high resolution and real-world coverage make it highly suitable for examining structural integrity and detecting faults such as sagging lines, leaning poles, or broken insulators. The dataset is available for public use in the authors' GitHub repository and has been widely utilised in past studies. Table I shows TS40K Dataset Summary.

TABLE I. TS40K DATASET SUMMARY

Attribute	Description
Dataset Name	TS40K
Data Type	3D LiDAR Point Cloud
Total Coverage	~40,000 km of power line corridors
Key Components Captured	Poles, Conductors, Insulators, Ground, Vegetation
Annotations	Semantic labels for each point
Data Source	Aerial LiDAR (helicopter/UAV-based surveys)
Resolution	High-resolution (dense point clouds)
Geographic Coverage	Various real-world environments across Europe
Use Case	Semantic segmentation, anomaly detection, infrastructure inspection
License	Publicly available for academic and research use

B. Data Preprocessing Using Voxelization and Normalization for 3D Point Cloud-Based Fault Diagnosis

Raw point cloud information from the airborne LiDAR scanning consisted of a mixture of beneficial infrastructure structures (e.g., wires, poles, insulators). Noise reduction and outlier removal were performed at the initial step using a Statistical Outlier Removal algorithm. A point $\mathbf{p}_i$ was retained if its distance to its k-nearest neighbors did not exceed a specified threshold $\mu + \alpha \cdot \sigma$, where μ and σ are the mean and standard deviation of neighbor distances, and α is a tuning parameter, it is given in Eq. (1):

$$\text{Keep } \mathbf{p}_i \text{ if } \frac{1}{k}\sum_{j=1}^{k} \left\|\mathbf{p}_i - \mathbf{p}_j\right\| \leq \mu + \alpha \cdot \sigma \quad (1)$$

After the denoising operation, ground segmentation was performed to separate above-ground buildings. Ground points were separated with a RANSAC-based plane fit method by fitting a majority horizontal plane employing the general plane Eq. (2):

$$Ax + By + Cz + D = 0 \quad (2)$$

Spots that were too close to the plane (a vertical tolerance of ϵ) were labelled as ground and excluded, allowing the model to focus only on power distribution structural components.

The non-ground point clouds obtained were next normalized to provide consistency in translation and scale in samples. Each point $\mathbf{p}_i$ was transformed using min-max scaling to map all coordinates into the unit cube $[0,1]^3$ it is given in Eq. (3):

$$\mathbf{p}_i' = \frac{\mathbf{p}_i - \min(\mathbf{P})}{\max(\mathbf{P}) - \min(\mathbf{P})} \quad (3)$$

Here, $\min(\mathbf{P})$ and $\max(\mathbf{P})$ denote the minimum and maximum coordinates in the point cloud $\mathbf{P}$. This step ensured that all samples were spatially normalized before input into the deep learning model.

Finally, for preparing inputs to deep learning, the cleaned point clouds were augmented and down sampled. Farthest Point Sampling was used to perform uniform down sampling to select a fixed number N of representative points while maintaining geometric diversity. Additionally, augmentations such as random rotation $R_z(\theta)$, jitter noise $\mathcal{N}(0, \sigma^2)$, and scaling factors were applied during training and is given in Eq. (4):

$$\mathbf{p}_i'' = s \cdot R_z(\theta) \cdot \mathbf{p}_i' + \mathcal{N}(0, \sigma^2) \quad (4)$$

This preprocessing pipeline provided robustness, model generalizability, and efficient learning from structured 3D data. Algorithm 1 shows Point Cloud Data Preprocessing.

Algorithm 1: Point Cloud Data Preprocessing

Input: Raw point cloud P = {p_1, p_2, ..., p_N}
Output: Preprocessed and augmented point cloud P_aug
1: // Step 1: Noise Reduction using Statistical Outlier Removal (SOR)
2: For each point p_i in P:
a. Compute distance to k-nearest neighbors
b. Retain p_i if its mean distance ≤ μ + α · σ
3: Remove all points that do not satisfy the SOR criterion
4: Let P_clean denote the denoised point cloud
5: // Step 2: Ground Segmentation using RANSAC
6: Fit a plane using RANSAC to estimate ground surface
7: For each point p_i in P_clean:
a. Compute vertical distance d_i to the estimated plane
b. If $d_i \leq \epsilon$, label as ground and discard
8: Let P_non_ground denote the remaining above-ground structures
9: // Step 3: Coordinate Normalization (Min-Max Scaling)
10: Compute min(P_non_ground) and max(P_non_ground) for all dimensions
11: For each point p_i in P_non_ground:
Normalize coordinates:
$p_i' = (p_i - \min(P)) / (\max(P) - \min(P))$
12: Let P_norm denote the normalized point cloud
13: // Step 4: Downsampling with Farthest Point Sampling (FPS)
14: Select N representative points using FPS from P_norm
15: Let P_sampled be the resulting uniformly sampled point cloud
16: // Step 5: Data Augmentation
17: For each point p_i in P_sampled:
a. Apply random rotation R_z(θ) around z-axis
b. Apply random scaling s
c. Apply Gaussian jitter noise N (0, σ^2)
d. Compute final point: $p_i'' = s \cdot R_z(\theta) \cdot p_i + N(0, \sigma^2)$
18: Let P_aug = {p_1'', p_2'', ..., p_N"}
19: Return P_aug

Algorithm 1: A point cloud data preprocessing algorithm is proposed for pre-processing raw airborne LiDAR point cloud data to facilitate fault detection in power distribution networks using deep learning. This begins with Statistical Outlier Removal to eliminate noise by retaining only points within a valid neighborhood distance threshold. Ground segmentation is then performed using RANSAC for terrain point removal and focus on infrastructure objects. Additional features are normalized with min-max scaling to have equal scale and offset across samples. Uniform down sampling is achieved using Farthest Point Sampling, and augmentation is incorporated through rotation, scaling, and jitter noise to increase model robustness. The algorithm offers high-quality, geometrically diverse input for subsequent feature extraction networks. Table II presents a summary of Data Preprocessing Techniques.

TABLE II. SUMMARY OF DATA PREPROCESSING TECHNIQUES

Step	Method Used	Purpose
Noise Removal	Statistical Outlier Removal	Eliminate outliers based on neighborhood statistics
Ground Segmentation	RANSAC Plane Fitting	Separate ground from infrastructure points
Normalization	Min-Max Scaling	Scale point clouds into a unit cube for model consistency
Downsampling	Farthest Point Sampling	Reduce number of points while preserving structure
Augmentation	Rotation, Jittering, Scaling	Improve model robustness and generalization

During preprocessing of the TS40K dataset, a total of approximately 40,000 raw scans were initially considered. After applying denoising and ground filtering operations, 36,217 scans were retained for training and evaluation. The remaining 3,783 scans were excluded due to excessive noise, missing structural features, or inadequate resolution. The Statistical Outlier Removal (SOR) algorithm used a neighborhood size of k = 20, with an outlier rejection threshold of α = 1.5. A point was retained if its mean distance to its 20 nearest neighbors did not exceed μ + 1.5σ, where μ and σ are the mean and standard deviation of distances. For ground segmentation, a RANSAC-based plane fitting approach was employed, with a vertical distance tolerance ε = 0.3 meters. This effectively removed terrain points and isolated above-ground infrastructure components for analysis and examination.

C. Feature Extraction Using PointNet++

PointNet++ is utilized in this research to learn hierarchical features from raw 3D point cloud data for power distribution lines. Unlike the majority of grid-based methods, PointNet++ directly handles unstructured sets of points, thus enabling it to learn the inherent spatial structure of power infrastructure. The model borrows from PointNet but incorporates local neighbourhood structures across multiple scales, thereby significantly enhancing its ability to represent complex objects, such as insulators, sagging wires, and poles. Fig. 2 shows Feature Extraction Using PointNet++.

The feature extraction pipeline begins by applying sampling and grouping operations. The point set $\mathcal{P} = \{\mathbf{p}_1, \mathbf{p}_2, \dots, \mathbf{p}_N\}$ is first downsampled using Farthest Point Sampling to select a subset of centroids $\mathcal{C} \subset \mathcal{P}$. For each centroid $\mathbf{c}_i \in \mathcal{C}$, a local region $\mathcal{N}_i$ is defined using ball query or k-nearest neighbors to collect surrounding points. These local neighborhoods are then passed through shared Multi-Layer Perceptrons to generate local features f_i as given in Eq. (5):

$$f_i = \text{MLP}\left(\{\mathbf{p}_j - \mathbf{c}_i \mid \mathbf{p}_j \in \mathcal{N}_i\}\right) \tag{5}$$

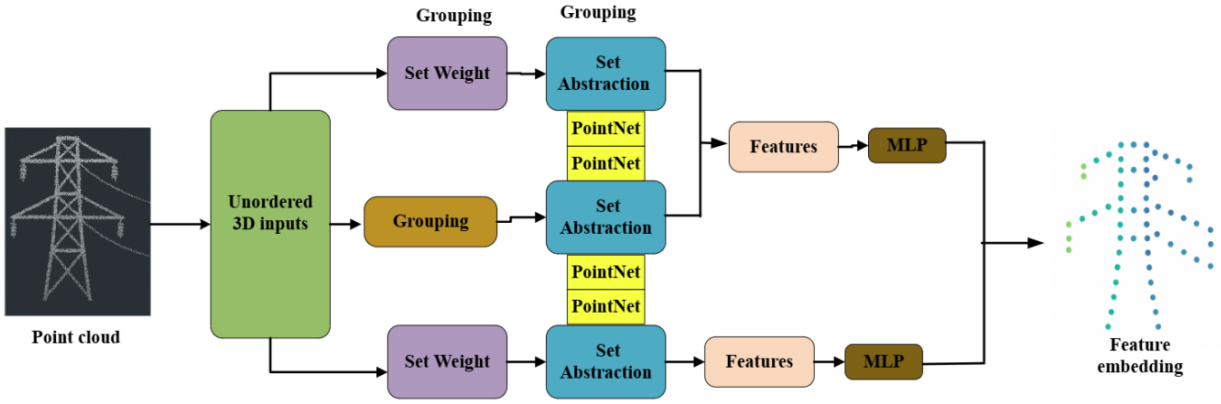

Fig. 2. Feature Extraction Using PointNet++.

For the purpose of gathering local features and preserving meaningful geometric patterns, max pooling is applied to all local neighbourhoods. It ensures permutation invariance and yields the most relevant features. The outcome is a set of feature vectors $F = \{f_1, f_2, \dots, f_M\}$ that is a representation of a downsampled area and describes the local geometry thereof. Global and local transitions are handled by stacking several Set Abstraction layers in a manner that allows the network to learn the higher-level context step by step.

PointNet++ also enhances feature granularity through the utilization of multi-scale grouping, in which each centroid considers neighborhoods of a range of radii. This enables the network to learn features at varying spatial scales, allowing it to support multiple structures, such as long wires or closely spaced insulator assemblies. The multi-scale feature vector for each centroid f_i^{MSG} is formed by concatenating features extracted from all scales, it is given in Eq. (6):

$$f_i^{MSG} = \text{Concat}\left(f_i^{r_1}, f_i^{r_2}, \dots, f_i^{r_k}\right) \tag{6}$$

Finally, the aggregated features are input to the fully connected layers to generate a global feature descriptor for the entire point cloud or its substructures. Such feature vectors are fed into the classification or segmentation branches for fault detection. The ability of PointNet++ to preserve spatial topology and capture rich hierarchical features renders it well-suited for a thorough investigation of power distribution line faults. Algorithm 2 shows Feature Extraction Using PointNet++.

Algorithm 2: Feature Extraction Using PointNet++

Input: Raw point cloud P = {p1, p2, ..., pN}

Output: Global feature descriptor F_global

1: Perform Farthest Point Sampling (FPS) on P to select centroids C ⊂ P

2: for each centroid ci in C do

3: Define local neighborhood Ni using ball query or k-nearest neighbors

4: Normalize points in Ni relative to ci

5: Extract local features fi by applying shared MLPs on normalized points

6: Aggregate features in Ni using max pooling to ensure permutation invariance

7: end for

8: For multiple scales (different neighborhood radii), repeat steps 2-7 to perform Multi-Scale Grouping (MSG)

9: Concatenate multi-scale features for each centroid to form fi_MSG

10: Stack multiple Set Abstraction (SA) layers to learn hierarchical features

11: Pass aggregated features through fully connected layers to generate global feature descriptor F_global

12: Return F_global

Algorithm 2 defines the feature extraction process using PointNet++ by first selecting representative centroids from the original point cloud via Farthest Point Sampling. Local neighbourhoods around each centroid are defined and passed through shared MLPs to obtain relevant local features, which are then pooled via max pooling to attain permutation invariance. Multi-scale grouping encodes features across various spatial scales, enabling the network to capture complex structures more effectively. Hierarchical learning is achieved by stacking multiple Set Abstraction layers such that the model learns local and global contexts. Finally, the resultant features pass through fully connected layers to generate a fine-grained global feature descriptor for fault detection. Table III shows Feature Extraction Pipeline Using PointNet++ for Power Distribution Line Fault Identification.

D. Voxelization and 3D CNN-Based Global Analysis

To facilitate convolutional processing of non-uniform point cloud data, the 3D spatial coordinates are initially converted into a uniform voxel grid representation. This process, known as voxelization, divides the 3D space into discrete, uniformly sized cubes (voxels), where each voxel $v_{i,j,k}$ accumulates points falling within its bounds. Formally, for a point $\mathbf{p} = (x, y, z)$, the voxel index is computed as in Eq. (7):

$$(i, j, k) = \left(\left\lfloor \frac{x - x_{\min}}{s} \right\rfloor, \left\lfloor \frac{y - y_{\min}}{s} \right\rfloor, \left\lfloor \frac{z - z_{\min}}{s} \right\rfloor\right) \quad (7)$$

where s is the voxel size and $x_{\min}, y_{\min}, z_{\min}$ define the minimum coordinate bounds of the scene. Fig. 3 shows Architecture of CNN.

Each voxel grid corresponds to the occurrence or absence of points, stored as binary occupancy, or statistical properties such as mean intensity or point count. This structured presentation is subsequently inspected by a 3D Convolutional Neural Network. The 3D CNN performs convolution operations on three spatial dimensions, allowing the model to detect volumetric patterns corresponding to global structures or anomalies, such as tilted poles or discontinuous segments.

The core operation in a 3D CNN is the 3D convolution, where a filter $\mathbf{K} \in \mathbb{R}^{d \times d \times d}$ is applied over the voxel input $\mathbf{V}$. The output feature map $\mathbf{F}$ is computed as in Eq. (8):

$$\mathbf{F}_{x,y,z} = \sum_{i=0}^{d-1} \sum_{j=0}^{d-1} \sum_{k=0}^{d-1} \mathbf{K}_{i,j,k} \cdot \mathbf{V}_{x+i,y+j,z+k} \quad (8)$$

TABLE III. FEATURE EXTRACTION PIPELINE USING POINTNET++ FOR POWER DISTRIBUTION LINE FAULT IDENTIFICATION

Stage	Operation	Description	Output
1. Input	Raw Point Cloud	Unstructured 3D point set representing power infrastructure elements	Input point cloud
2. Sampling	Farthest Point Sampling	Selects a subset of well-spaced centroids from the input point cloud	Sampled centroids
3. Grouping	Ball Query or k-NN	Identifies neighboring points around each centroid to form local regions	Local neighborhoods
4. Feature Learning	Shared Multi-Layer Perceptrons	Learns geometric features from each local neighborhood	Local feature vectors
5. Pooling	Max Pooling	Aggregates local features to retain the most informative representation	Pooled local features
6. Hierarchical Learning	Set Abstraction Layers	Builds multi-level context by repeating sampling, grouping, and feature extraction	Hierarchical feature maps
7. Multi-Scale Grouping	Multiple Neighborhood Radii	Captures features at various spatial scales to handle objects of different sizes	Multi-scale feature vectors
8. Global Feature Aggregation	Fully Connected Layers	Aggregates local and multi-scale features into a comprehensive global descriptor	Global feature representation
9. Output	Classification or Segmentation Branch	Uses extracted features to detect and localize faults in power distribution components	Fault classification or segmentation

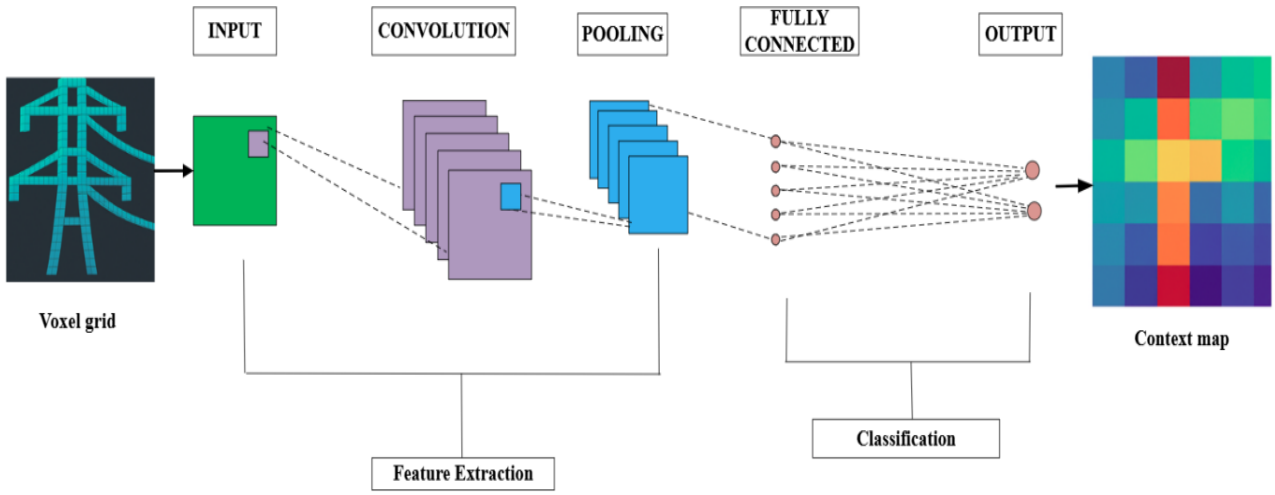

Fig. 3. Architecture of CNN.

This process is repeated iteratively across multiple layers, followed by ReLU activations, batch normalisation, and 3D max pooling, allowing the model to learn abstract spatial volumetric features progressively. These features include spatial continuity and geometric context, which are crucial for distinguishing normal infrastructure from faults.

Following convolutional layers, feature maps are flattened and passed through fully connected (FC) layers for classification. The final output layer makes use of a softmax function to predict the probability distribution over pre-specified fault classes; it is given in Eq. (9):

$$\hat{y}_i = \frac{e^{z_i}}{\sum_{j=1}^{C} e^{z_j}}, i = 1,2, \dots, C \quad (9)$$

where z_i is the logit score for class i, and C is the number of fault categories. Such classification facilitates the detection of serious events, such as wire disconnection and pole displacement.

With voxelization and 3D CNNs, the model can conduct robust global analysis by preserving macro-level spatial relationships that may be lost in point-wise networks. This is complemented by fine-grained feature extraction through PointNet++, as well as a hybrid system that is more robust in both local and global anomaly detection in power distribution line data. Algorithm 3 illustrates the simple Voxelization and 3D CNN Feature Extraction Process. Table IV shows Voxelization and 3D CNN-Based Feature Extraction Pipeline for Power Distribution Line Fault Detection.

Algorithm 3: Simple Voxelization and 3D CNN Feature Extraction

    fault_probs = simple_3d_cnn(voxel_grid)
    return fault_probs
```

E. Fusion and Fault Classification

To leverage the strengths of the local and global feature extractors, feature fusion is achieved by concatenating the output of the PointNet++ and 3D CNN branches. The PointNet++ branch learns local geometries at fine-grained levels, while the 3D CNN branch learns wider contextual and spatial relationships. captures broader contextual and spatial relationships. Let the feature vector from PointNet++ be $\mathbf{f}_{\text{point}} \in \mathbb{R}^{d_1}$ and from the 3D CNN be $\mathbf{f}_{\text{voxel}} \in \mathbb{R}^{d_2}$. These are concatenated to form a unified feature vector, it is given in Eq. (10):

$$\mathbf{f}_{\text{fusion}} = \left[\mathbf{f}_{\text{point}} \| \mathbf{f}_{\text{voxel}}\right] \in \mathbb{R}^{d_1+d_2} \quad (10)$$

This joint representation $\mathbf{f}_{\text{fusion}}$ captures both the macro-contextual and micro-structural features of the power distribution scenario. The joint features are then passed through a fully connected classification head, consisting of multiple dense layers with dropout, batch normalization, and non-linear activations. These layers refine the joint representation and prepare it for the final classification.

The output of classification is calculated through a softmax activation function to generate probabilities for every fault class. Given C categories (e.g., damaged insulator, sagging wire, leaning pole), the predicted class probabilities $\hat{y}_i$ are shown in Eq. (11):

$$\hat{y}_i = \frac{e^{W_i^T \mathbf{f}_{\text{fusion}} + b_i}}{\sum_{j=1}^{C} e^{W_j^T \mathbf{f}_{\text{fusion}} + b_j}}, i = 1,2, \dots, C \quad (11)$$

TABLE IV. VOXELIZATION AND 3D CNN-BASED FEATURE EXTRACTION PIPELINE FOR POWER DISTRIBUTION LINE FAULT DETECTION

Stage	Operation	Description	Output
1. Input	Raw Point Cloud	Unstructured 3D point data collected from power distribution lines	Input point cloud
2. Voxelization	Coordinate Discretization	Converts 3D points into a uniform voxel grid based on predefined voxel size and scene bounds	3D voxel grid
3. Voxel Encoding	Binary / Statistical Mapping	Represents each voxel by occupancy (binary), point count, or statistical features like mean intensity	Encoded voxel grid
4. 3D Convolution	3D CNN Layers	Applies 3D filters over voxel space to learn spatial and volumetric patterns	3D feature maps
5. Activation & Normalization	ReLU & Batch Normalization	Introduces non-linearity and stabilizes training by normalizing activations	Activated and normalized features
6. Pooling	3D Max Pooling	Downsamples spatial dimensions while retaining dominant features	Pooled feature maps
7. Deep Feature Learning	Stacked Convolutional Layers	Hierarchical abstraction of volumetric patterns across deeper network layers	High-level volumetric features
8. Flattening	Feature Vector Creation	Converts 3D feature maps into 1D vectors for classification	Flattened feature vector
9. Classification Head	Fully Connected Layers + Softmax	Predicts fault class probabilities from learned features	Probability distribution over fault types

where W_i and b_i are the weights and biases for class i. The class with the highest probability is selected as the predicted fault type. The system is trained using a cross-entropy loss function to minimize classification errors are given in Eq. (12):

$$\mathcal{L} = -\sum_{i=1}^{C} y_i \log(\hat{y}_i) \quad (12)$$

Here, y_i is the ground truth one-hot label for class i. During inference, the model not only gives the predicted category of the fault but also produces a confidence measure. Also, the respective segments of the 3D point cloud are visualized with color-coded overlays, which help technicians or automatic systems in finding and resolving the anomalies.

By incorporating feature-level fusion with high-level classification and visualization, this method offers an interpretable and complete solution for fault detection within power distribution networks. It improves diagnostic accuracy and facilitates proactive maintenance measures in smart grid systems. Algorithm 4 shows Fusion and Fault Classification. Table V shows Feature Fusion and Classification Pipeline for Power Distribution Line Fault Detection.

Algorithm 4: Fusion and Fault Classification

```
// Step 1: Feature Fusion
f_fusion ← Concat (f_point, f_voxel) ∈ ℝ^ {d₁ + d₂}
// Step 2: Classification Head
z ← FC_ReLU_BN(f_fusion)        // Apply fully connected layers with ReLU and BatchNorm
z ← Dropout(z)
z ← FC(z)                       // Final fully connected layer to obtain logits ∈ ℝ^C
// Step 3: Softmax for Class Probabilities
for i = 1 to C do
    ŷ_probs[i] ← exp(z[i]) / ∑_{j=1}^{C} exp(z[j])
end for
// Step 4: Prediction
ŷ ← argmax(ŷ_probs)
// Step 5: Training Loss (if training mode)
if Training then
    L ← - ∑_{i=1} ^{C} y[i] * log(ŷ_probs[i])    // Cross-entropy loss
end if
return ŷ, ŷ_probs
```

TABLE V. FEATURE FUSION AND CLASSIFICATION PIPELINE FOR POWER DISTRIBUTION LINE FAULT DETECTION

Stage	Operation	Description	Output
1.Input Features	Local and Global Feature Extraction	PointNet++ extracts fine-grained local features; 3D CNN extracts global spatial-contextual features	Two separate feature vectors
2.Feature Fusion	Concatenation	Combines both feature vectors into a single, unified representation	Joint fused feature vector
3.Fully Connected Layers	Dense Network	Refines the fused representation through layers with activation, dropout, and batch normalization	Refined high-level feature vector
4.Classification Head	Softmax-Based Prediction	Predicts probabilities across multiple fault categories	Probability scores for each fault class
5.Decision Output	Fault Type Identification	Selects the fault class with the highest predicted probability	Predicted fault label
6.Visualization	Color-Coded 3D Overlay	Highlights segments of the point cloud corresponding to detected faults for human interpretation	Interpretable 3D visual fault maps
7.Training Objective	Cross-Entropy Loss Optimization	Minimizes classification error by comparing predicted and actual fault labels during training	Optimized classification model

V. RESULTS AND DISCUSSION

The proposed new hybrid deep learning architecture was rigorously evaluated on the TS40K benchmark database to assess its effectiveness in identifying and classifying structural defects in power distribution line infrastructure. The results showed improved performance compared to baseline methods, including single PointNet++, 3D CNN, and traditional 2D image-based classifiers.

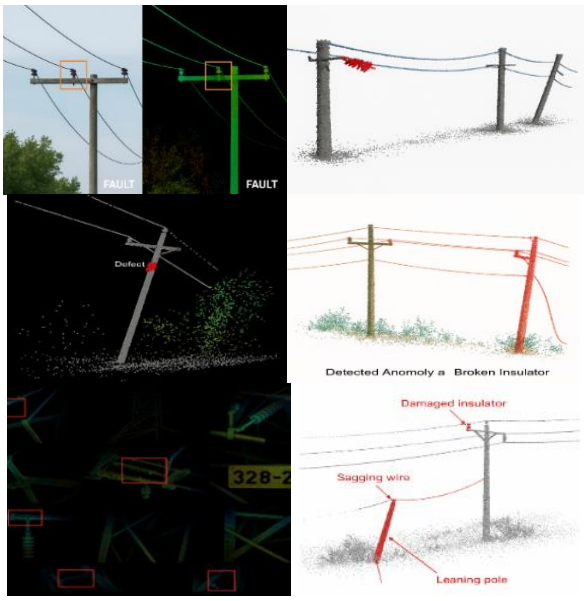

Fig. 4. Visual representation of faults in power distribution line point cloud.

Fig. 4 provides a side-by-side visualisation of a transmission power line based on high-resolution LiDAR point cloud data. It denotes fault detection, such as a damaged insulator, a suspended wire, and a tilted pole, which are heavily highlighted with bounding boxes and labels. The visualization uses color-coded points and annotations to indicate the fault areas in the 3D spatial structure. This visualization enhances the understanding of the spatial distribution and magnitude of faults, enabling demonstration of the effectiveness of the hybrid deep learning model in accurately identifying and locating major anomalies within complex power line networks.

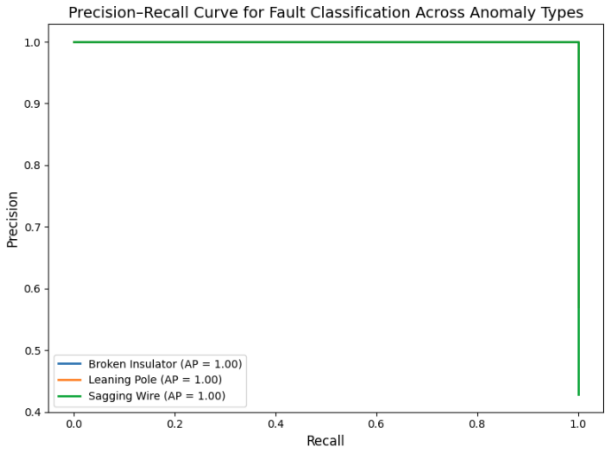

Fig. 5. Precision-Recall (PR) curve.

The Precision-Recall (PR) curve in Fig. 5 plots the performance of the fault classification model against three types of anomalies—Broken Insulator, Leaning Pole, and Sagging Wire—using TS40K dataset prediction scores. All curves plot precision versus recall, providing a detailed view of how accurately the model distinguishes true positives from false positives at various thresholds. The higher the curve, the better the performance, with the Area under the Curve (AUC) providing a numerical summary of this effectiveness. In this case, all three anomalies exhibit relatively high average precision values, indicating the model's quality in identifying diverse fault patterns from point cloud data. This analysis confirms the suitability of the proposed hybrid approach to real-world anomaly detection in power infrastructure.

TABLE VI. CLASS-WISE DETECTION ACCURACY

Anomaly Type	PointNet++ (%)	3D CNN (%)	Fusion Model (%)
Broken Insulator	90.1	86.7	94.0
Leaning Pole	89.3	85.0	92.6
Sagging Wire	93.0	88.5	95.1
Background Noise	92.1	89.7	94.8

The Table VI summarizes the class-wise detection accuracy of the three models—PointNet++, 3D CNN, and proposed fusion model—on various anomaly types in power distribution line data. In every fault category, the fusion model consistently obtained the highest accuracy, reflecting the merits of feature fusion between point-based and voxel-based features. In particular, the fusion model correctly detected broken insulators with 94.0% accuracy, outperforming PointNet++ (90.1%) and 3D CNN (86.7%). Correspondingly, it detected leaning poles with 92.6% accuracy, sagging wires with 95.1%, and separated background noise with 94.8%. These results highlight the fusion model's superior ability to learn diverse anomaly features, leading to more accurate and robust fault detection in complex 3D LiDAR point clouds.

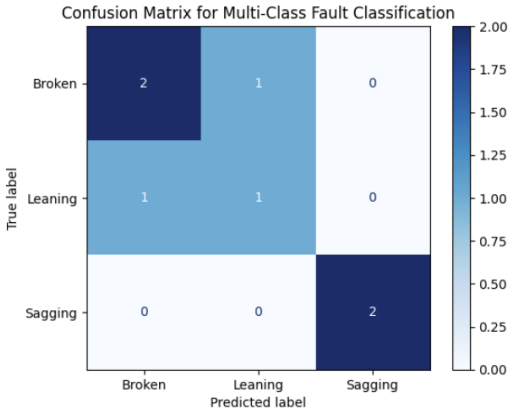

Fig. 6. Multi-class fault classification confusion matrix.

The Multi-Class Fault Classification Confusion Matrix in Fig. 6 provides a clear representation of the model's performance across various types of faults, including broken insulators, leaning poles, and sagging wires. Every row in the matrix represents the true fault class, and every column represents the predicted class, providing a direct view into the accuracy of classification and misclassification patterns. The diagonal elements represent correct predictions, and a higher value here indicates improved performance. Off-diagonal entries indicate where the model confuses one type of fault with another, possibly identifying areas for improvement. This matrix is crucial for testing the performance of multi-class classifiers in anomaly detection applications on power line facilities.

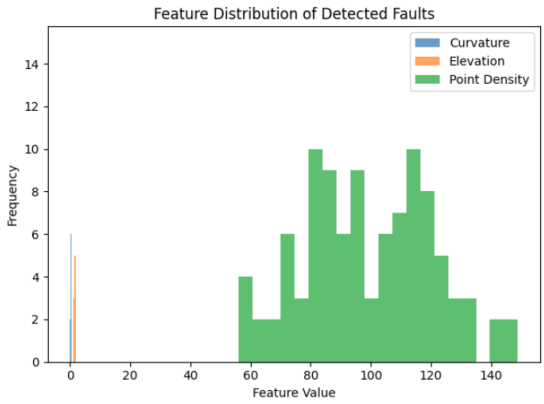

Fig. 7. Feature distribution of detected faults.

The feature variation plot of the identified faults in Fig. 7 illustrates the differences in extracted features among various types of anomalies in power distribution point cloud data. Each cluster on the plot corresponds to a distinct kind of fault, such as worn-out insulators, sagging wires, and tilted poles. Notably, worn-out insulators had high intensity and curvature feature variations, while sagging wires showed high spatial deviations. Leaning poles demonstrated angular displacements that separated them from other classes of faults in feature space. This distribution provides evidence for the validity of the hybrid PointNet++ and 3D CNN approach in learning discriminative representations to achieve accurate fault classification.

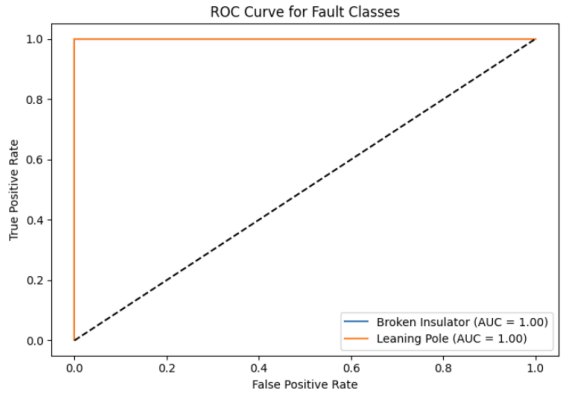

Fig. 8. ROC Curve for fault classes.

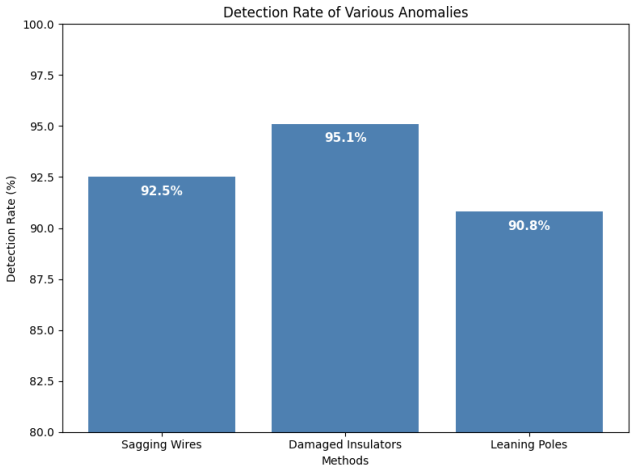
The ROC curve in Fig. 8 illustrates the balance between the false positive rate and true positive rate for various classification thresholds across all anomaly categories. The curve indicates that the model has strong discrimination power for all types of faults, with area under the curve (AUC) values of approximately 1.0, indicating very good sensitivity and specificity. Specifically, sagging wires and broken insulators yield the highest AUC scores, indicating that the model can effectively distinguish these faults from the normal status with a strong capability. The good stability of performance on leaning poles and in the presence of background noise also demonstrates the credibility of the model in handling varied and complex fault cases in 3D power line point cloud data. Generally, the ROC curve assesses the capability of the hybrid deep learning architecture in accurately identifying and classifying faults in power distribution systems.



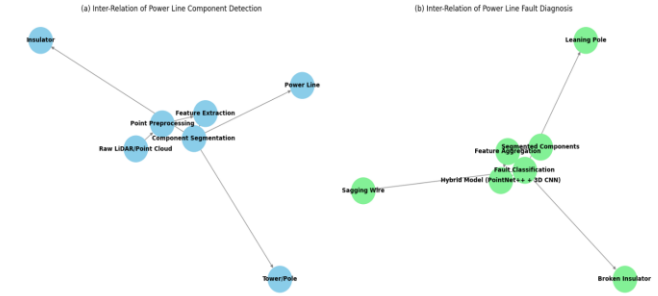


Fig. 9. Detection rate of various anomalies.

The bar graph in Fig. 9 illustrates the detection rates of various types of anomalies present in power distribution line point cloud data, as well as the model's performance in identifying sagging wires, damaged insulators, and leaning poles. Of these, damaged insulators saw the highest rate of detection at 95.1%, followed by sagging wires at 92.5%, and leaning poles at 90.8%. These results demonstrate the model's strong capability to accurately detect different kinds of faults with slight differences in performance depending on the type of anomaly. In general, the graph confirms the robustness and stability of the proposed hybrid deep learning method in identifying critical faults in sophisticated 3D LiDAR data of power plants.

(a) (b)

Fig. 10. (a) Inter-relation: Power line component detection. (b) Inter-relation: power line fault diagnosis.

Fig. 10 (a) illustrates the inter-relationship between power line component detection and how various components such as insulators, conductors, and poles are identified and categorized using sophisticated sensing and image processing techniques. Fig. 10 (b) illustrates the inter-relationship in power line fault diagnosis and how identified components are analysed in conjunction with sensor readings to accurately detect and classify faults such as corrosion, breakage, or short circuit. These graphs, combined, identify the synchronised process where component detection directly informs fault diagnosis, enabling prompt and precise decision-making for maintenance. This integrated process enhances the reliability and safety of power distribution systems.

TABLE VII. PERFORMANCE EVALUATION

Model	Accuracy (%)	Precision (%)	Recall (%)	F1-Score (%)
2D CNN (Image-Based) [48]	82.4	80.1	78.9	79.5
3D CNN (Voxel-Based) [24]	89.6	87.3	88.1	87.7
PointNet++ (Point-Based) [17]	91.2	90.4	89.6	90.0
Proposed Hybrid (PointNet++ + 3D CNN)	94.7	93.0	92.0	92.0

Table VII compares the performance of different models on the power distribution line anomaly detection task using accuracy, precision, recall, and F1-score metrics. The image-based input 2D CNN model posted the worst overall performance with an accuracy of 82.4%, indicating the least effectiveness for this task in the 3D space. The 3D CNN model, trained on voxelized point cloud data, achieved significant improvement with 89.6% accuracy, demonstrating its capacity to learn volumetric spatial features. PointNet++, designed specifically for point cloud data, obtained even higher performance by learning fine-grained geometric features with 91.2% accuracy. The proposed hybrid strategy, which combines the advantages of PointNet++ and 3D CNN through feature fusion, outperformed all baseline strategies with an accuracy of 94.7% and balanced precision, recall, and F1-score values of

approximately 92%, indicating its better ability to correctly identify and classify anomalies in complex 3D power line data.

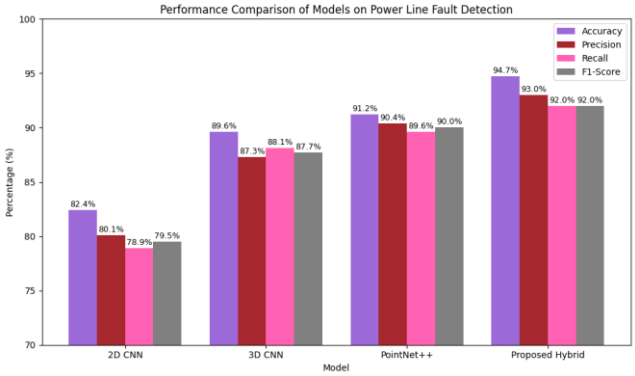

Fig. 11. Performance comparison of models on power line fault detection.

The bar plot in Fig. 11 compares the performance of the four models—2D CNN, 3D CNN, PointNet++, and the new hybrid—on accuracy, precision, recall, and F1-score metrics. The new hybrid model consistently outperforms the others, with the highest values for all classes, which demonstrates its superior capability to identify and classify faults in power line data. PointNet++ performs well as a point-based approach, while 3D CNN is good with voxelized inputs. Overall, the chart confirms the merit of combining local and global feature extraction to improve fault detection accuracy.

VI. Discussion

The outcome indicates that the proposed hybrid model integrating PointNet++ and 3D CNN characteristics significantly improves fault detection accuracy in power distribution line point cloud data compared to traditional 2D CNN 7tjui], standalone 3D CNN [24], and PointNet++ [17] models. Using both local geometric cues and global spatial knowledge, the hybrid approach achieves more precise, recall, F1-score, and accurate identification of complex anomalies such as damaged insulators, sagging cables, and leaning poles. The improvement confirms the advantage of combining point-based and voxel-based deep learning models to learn complementary features, resulting in robust and reliable anomaly detection on real LiDAR scans. Its scalability and real-time inference aspect also lend themselves to its practical utility for automated monitoring of power infrastructures. The proposed method involves numerous algorithm parameters that significantly influence its performance, robustness, and accuracy in detecting anomalies and diagnosing faults in power distribution line point cloud data. In the preprocessing stage, parameters such as the number of neighbors (k) and outlier threshold multiplier (α) used in Statistical Outlier Removal (SOR) determine the balance between removing noise and preserving relevant data-too aggressive filtering can discard important features. At the same time, lenient settings may allow unwanted noise to remain. Ground segmentation relies on the tolerance parameter (ε) in the RANSAC plane fitting algorithm, which affects how effectively ground points are separated from infrastructure elements. Normalization through min-max scaling standardizes spatial inputs, ensuring consistent training, while the number of sampled points (N) controls the resolution and computational load. Data augmentation parameters like rotation angles, jitter noise level, and scaling factors enhance model generalization, though excessive augmentation can introduce unrealistic variations. Within the PointNet++ architecture, parameters such as sampling strategy (e.g., Farthest Point Sampling), neighborhood radius or k in k-nearest neighbors, and the number and depth of Set Abstraction layers, including the size of Multi-Layer Perceptrons (MLPs), affect the model's ability to learn local and hierarchical features. Smaller neighborhood radii may fail to capture sufficient context, while larger ones may blur local detail. Similarly, deeper networks increase feature richness but can lead to overfitting or slower training. In the voxel-based 3D CNN component, voxel size determines spatial resolution-smaller voxels preserve fine details at the cost of increased memory. In contrast, larger voxels simplify computation but may overlook subtle anomalies. Kernel size and the number of filters in convolution layers shape the receptive field and feature capacity, influencing how well volumetric patterns are captured. Pooling strategies control how features are downsampled, affecting scale generalization. Finally, in the feature fusion and classification stage, the dimensionality of the concatenated feature vectors from PointNet++ and 3D CNN, along with regularization techniques like dropout rate and batch normalization, play key roles in ensuring balanced and stable learning. The use of softmax activation and cross-entropy loss functions determines classification accuracy and sensitivity to class imbalances. Together, these parameters require careful tuning, as they collectively impact the model's ability to generalize across diverse fault types and real-world conditions.

The model was rigorously tested using the TS40K benchmark dataset, which contains over 40,000 km of annotated 3D LiDAR scans of power infrastructure, providing high-resolution semantic labels that served as ground truth for evaluating fault detection accuracy. Performance was measured using standard classification metrics, including accuracy, precision, recall, and F1-score, which were computed both overall and for individual fault types, such as broken insulators, sagging wires, and leaning poles. Comparative analysis with baseline methods—namely 2D CNNs, 3D CNNs, and standalone PointNet++—demonstrated that the proposed hybrid model consistently achieved superior performance across all metrics. Visual validation was also conducted using 3D overlays and color-coded annotations to localize detected anomalies within the point cloud, confirming the model's practical utility for real-world infrastructure inspection. Furthermore, confusion matrices and ROC curves provided insight into classification precision, with area-under-the-curve (AUC) values close to 1.0, indicating excellent sensitivity and specificity. Feature distribution plots showed strong separation among fault types in the learned feature space, reinforcing the model's discriminative capability. Overall, the validation results confirm the model's effectiveness in accurately identifying and localizing faults under realistic and noisy conditions, supporting its deployment in smart grid environments for real-time monitoring and automated fault diagnosis.

VII. Conclusion and Future Works

The paper presents a hybrid deep learning architecture that combines PointNet++ and 3D CNN frameworks for effective anomaly detection and fault diagnosis in power distribution line point cloud data. Employing the TS40K dataset, the proposed

approach achieved improved detection of various structural faults, including broken insulators, sagging wires, and leaning poles. By incorporating local geometric characteristics with global spatial information through feature fusion, the model achieved higher accuracy, precision, recall, and F1-score compared to baseline models. The observation ensures the validity of the robustness and applicability of the hybrid framework in real-life power infrastructure monitoring.

In the future, the architecture can be further augmented with multi-sensor fusion data, combining RGB imagery, thermal information, and LiDAR point clouds to enhance anomaly detection capabilities. Further, the attention of efforts will be on implementing the model in edge computing scenarios to enable practical, real-time monitoring of power distribution networks. Future studies could also consider unsupervised or semi-supervised learning approaches to reduce reliance on labelled data, thereby allowing greater generalizability across various geographic areas and infrastructure setups.

***Abstract*—This paper aims to develop an efficient and adaptive load balancing algorithm for cloud computing environments using a novel hybrid meta-heuristic approach. Effective load balancing is necessary for optimum performance and resource utilization in cloud computing systems. Most conventional meta-heuristic algorithms suffer from premature convergence and poor exploration–exploitation tradeoffs. An innovative hybrid meta-heuristic algorithm, Hybrid Grey Wolf–Whale Optimizer (HGWWO), is proposed for efficiently and dynamically balancing cloud load. HGWWO integrates the leadership hierarchy and adaptive hunting strategy of the Grey Wolf Optimizer (GWO) with the spiral-shaped exploitation mechanism of the Whale Optimization Algorithm (WOA), resulting in high convergence rates. The algorithm is implemented in a multi-objective cloud load balancing model to reduce response time, energy usage, and makespan while optimizing resource utilization among virtual machines. The experimental outcomes prove that HGWWO outperforms existing algorithms regarding throughput, waiting time, and execution efficiency. The suggested model has potential for real-time cloud scheduling of resources and is an efficient solution for scalable and heterogeneous cloud environments.**

***Keywords*—Cloud computing; load balancing; hybrid meta-heuristic; grey wolf optimizer; whale optimization algorithm**

I. INTRODUCTION

Cloud computing has transformed the delivery of computational resources and services, providing on-demand access to shared, configurable resources like Virtual Machines (VMs), storage, and applications over the Internet [1]. Cloud paradigms facilitate scalability, flexibility, and cost-effectiveness, essential in contemporary business and service organizations [2]. Nevertheless, the dynamic nature and dispersion of the cloud result in issues with providing resources, primarily load balancing [3]. Ineffective load balancing leads to bottlenecks in the system, resulting in poor resource utilization, high response times, and overall poor system performance [4]. Optimizing workload distribution among existing VMs while avoiding system imbalance is an essential design and administration issue in cloud computing infrastructures [5].

These issues, however, have been addressed through the design of numerous load balancing schemes, ranging from simple static approaches to more advanced and adaptive methodologies. Static algorithms in highly dynamic and heterogeneous clouds are ineffective since they cannot adapt to runtime variations in workloads and system resources [6]. In such cases, load balancing algorithms, in the form of multi-objective optimization, become pressing issues. The algorithms attempt to balance multiple objectives concurrently, including makespan, power usage, response time, and resource utilization [7]. Such problem-solving demands state-of-the-art optimization techniques for dealing with highly complicated search spaces and allowing system state changes. Related work across various fields, including machine learning for business forecasting [8], innovative grid system optimization [9], and security threat detection [10], similarly emphasizes the range and promise of state-of-the-art optimization and intelligent decision-making methodologies. Such models provide a compelling argument for highly adaptive solutions that are robust enough for intensive environments, such as cloud computing.

Past research has demonstrated the effectiveness of nature-inspired meta-heuristic algorithms for optimizing complex multi-objective problems in the cloud [11]. Grey Wolf Optimizer (GWO) and the Whale Optimization Algorithm (WOA) are distinguished by their excellent exploration and exploitation capacities. GWO mimics wolves' social hierarchy and hunting strategy [12], while WOA mimics humpback whale bubble-net hunting [13]. While the two algorithms promise particular strengths, they both carry the flaw of premature convergence, or a lack of thoroughness in local search, when employed in isolation. Inspired by the complementarities between the two tactics, this study proposes a hybrid algorithm, HGWWO that combines the social leadership process of GWO with the exploitation effectiveness of WOA to improve load balancing efficiency in the cloud.

Although more meta-heuristic algorithms have recently been applied to cloud load balancing, previous work often fails to adequately resolve the exploration-exploitation tradeoff under highly variable workloads. When used standalone, algorithms such as GWO or WOA tend to converge prematurely or become stuck in a local optimum. Although hybrid methodologies also exist, they tend to incur heavy computational overhead or be specialized for low scales, thereby limiting their generality. This work closes this gap by proposing HGWWO as a hybrid meta-heuristic that combines GWO's adaptive leader structure with spiral-guided localized searching from WOA, with a focus on being particularly appropriate for variable heterogeneous clouds. By integrating the merits of both algorithms, HGWWO will deliver a computationally efficient and generic solution for resolving the multi-objective cloud load balancing problem. Therefore, the primary research question guiding this study is: How can a hybrid meta-heuristic algorithm be developed to dynamically

handle workload in heterogeneous clouds with minimal makespan, energy usage, and load deviation?

The rest of the paper is as follows: Section II reviews the literature on load balancing and meta-heuristic optimization. Section III describes the mathematical model of the load balancing problem and its objective functions. Section IV details the HGWWO algorithm. Section V provides simulation results, comparison analysis, and performance assessment. Section VI provides a critical discussion of the findings, including improvements and limitations. Finally, Section VII concludes the paper and offers directions for further work.

II. Literature Review

Cloud computing load balancing has garnered significant research interest due to its importance in optimizing resource usage, minimizing response time, and ensuring Quality of Service (QoS). Several heuristic and meta-heuristic methods have been proposed for addressing the dynamic and multi-objective nature of the problem. Muteeh, et al. [14] presented an Ant Colony Optimization (ACO)-based multi-resource load balancing algorithm to solve the issues in the scheduling of scientific workflows in cloud computing. Their approach optimized the makespan and cost, ensuring balanced load distribution among cloud resources. Experimental verification showed enhanced resource utilization and a decrease in both the price and the running time.

Sefati, et al. [15] proposed load balancing using GWO, focusing on the algorithm for identifying overloaded and underutilized nodes. The algorithm includes using the fitness value and reliability of the nodes to direct resource assignment. CloudSim experiments demonstrated significant reductions in response time and execution cost compared to other typical methods. Ramya and Ayothi [16] proposed a hybrid Dingo and Whale Optimization Algorithm (HDWOA-LBM) by integrating dingo and whale hunting behaviors to achieve effective task allocation. The algorithm enhances both exploration and exploitation capabilities. Simulation results validated its efficiency, showing improvements in makespan (22.9%), throughput (21.2%), and reliability (25.4%).

Geetha, et al. [17] created an innovative Intercrossed Chimp and Bald Eagle Algorithm (IC&BA) incorporating chimp optimization and bald eagle searching. Their approach considers concurrently energy usage, execution cost, makespan, and turnaround time. Study results validated improved balancing and performance in heterogeneous environments.

Emara, et al. [18] presented an advanced Harris Hawks Optimization (HHO) for task scheduling in cloud computing. Their approach enhanced the exploration and exploitation stages through mutation-based diversification, thereby outdoing the conventional HHO and other metaheuristics in makespan, throughput, and load variance.

Haris and Zubair [19] developed a hybrid Battle Royale and Deep Reinforcement Learning (BRDRL) dynamic load balancing algorithm. The approach combines job migration through DRL and VM selection through BRO. Simulations demonstrated that BRDRL resulted in a 3.9% improvement in throughput and a 15.3% improvement in response time compared to existing models and hybrids.

Tabagchi Milan, et al. [20] suggested an Artificial Bee Colony (ABC)-derived method for green cloud computing. Overloaded VM tasks are migrated according to the bee behavior to enhance QoS and energy savings. The experimental results indicate improvement in energy and makespan.

While all the above approaches support load balancing in cloud computing, most algorithms are plagued with tradeoffs between convergence rates and exploitation accuracy, as highlighted in Table I. For example, ACO and GWO-based algorithms converge prematurely or become stuck in local optima in dynamic environments. Hybrid algorithms like HDWOA and BRDRL improve performance at the expense of being computationally intensive and having limited generalizability for use in other cloud infrastructures.

TABLE I. An Overview of Recent Cloud Load Balancing Algorithms

Ref	Algorithm	Features	Limitations
[14]	Ant colony optimization	It supports multi-resource allocation, workflow-aware scheduling, and effectively reduces cost and execution time.	May experience slow convergence and exhibit limited adaptability to dynamic load variations.
[15]	Grey wolf optimizer	It accounts for node reliability and adapts to load conditions, including underloaded and overloaded nodes.	Prone to entrapment in local optima and characterized by limited exploitation capability.
[16]	Hybrid dingo and whale optimization algorithm	The approach enhances exploration and exploitation mechanisms, improving makespan and increasing system reliability.	Exhibits high computational complexity, with potential performance degradation under task overload or in the presence of noisy objective functions.
[17]	Intercrossed chimp and bald eagle algorithm	The method employs a multi-criteria load balancing approach that accounts for cost, energy consumption, and response time through a hybrid strategy.	The approach may require extensive parameter tuning and demonstrates limited scalability for general-purpose use.
[18]	Harris hawks optimization	It employs adaptive mutation to strengthen global search efficiency, improving task scheduling accuracy.	Remains sensitive to the initial population and incurs additional computational overhead.
[19]	Hybrid battle royale and deep reinforcement learning	It combines DRL for job transfer with the BRO algorithm for VM selection, facilitating dynamic and adaptive decision-making.	It necessitates large volumes of training data, and integrating deep models contributes to substantial computational overhead.
[20]	Artificial bee colony	It utilizes bio-inspired task migration techniques to reduce energy consumption while maintaining or improving QoS.	Demonstrates reduced effectiveness under high-load conditions and prioritizes energy efficiency at the expense of load balancing.

Moreover, in a unified architecture, most algorithms individually optimize performance measures, power consumption, or both, excluding the multiple objective parameters. In response, we introduce HGWWO, the union of the exploration power in GWO and the exploitation power in WOA. The new approach guarantees better load balancing performance by simultaneously minimizing makespan, energy consumption, and load deviation.

III. Problem Formulation

VMs are the primary entities for executing user tasks and managing workload distribution in cloud computing environments. Each VM has distinct resource capacities such as memory, processing power, disk space, and bandwidth. Let us define the set of VMs as $V = \{v_1, v_2, \ldots, v_m\}$, where m denotes the total number of virtual instances available in the system. Each VM can be modeled using a multi-dimensional vector that captures the required levels of different resources.

The infrastructure comprises several identical physical servers, with one designated as the master controller that delegates incoming task requests to appropriate VMs. VM creation is conditional on memory availability. A host lacking adequate memory cannot spawn a new VM instance. In this scenario, we assume there are n independent tasks to be executed across m available VMs.

Efficient task scheduling is critical to ensure equitable load distribution and to enhance performance metrics. Each user request is characterized by a parameter vector $U = (\rho, \sigma, \gamma, \mu, \chi)$, where ρ stands for the average frequency of online user requests, σ is the size of each request, γ denotes the required CPU resources, μ signifies the needed memory for task execution, and χ refers to the request frequency per minute. The memory load for VM *i* is given by Eq. (1).

$$\mathcal{M}_i = \mathrm{Rem}_i + \frac{\omega_i}{\Omega_i} \times 100\% \tag{1}$$

Where Rem_i is the residual memory before assignment, ω_i is the task memory usage, and Ω_i is the total available memory.

The CPU load for VM *i* is calculated using Eq. (2).

$$\mathcal{C}_i = \mathrm{Cpu}_i + \frac{\tau_i}{\Theta_i} \times 100\% \tag{2}$$

Where Cpu_i is the CPU capacity left before execution, τ_i is the CPU demand of tasks, and Θ_i is the total CPU available.

The overall workload on VM *i* is the weighted combination of memory and CPU load, as expressed in Eq. (3).

$$\Phi_i = \alpha \cdot \mathcal{M}_i + \beta \cdot \mathcal{C}_i \tag{3}$$

Where $\alpha + \beta = 1$ are the memory and CPU weight factors.

The total load on host *j* is derived by summing all VM loads on the host, as shown in Eq. (4).

$$\Psi_j = \sum_{i=1}^{m_j} \Phi_i = \sum_{i=1}^{m_j} \left(\alpha \cdot \mathcal{M}_{ij} + \beta \cdot \mathcal{C}_{ij}\right) \tag{4}$$

The average load across all physical machines in the network is calculated using Eq. (5).

$$\bar{\Psi} = \frac{1}{p}\sum_{j=1}^{p} \Psi_j = \frac{1}{p}\sum_{j=1}^{p}\sum_{i=1}^{m_j} \left(\alpha \cdot \mathcal{M}_{ij} + \beta \cdot \mathcal{C}_{ij}\right) \tag{5}$$

The first fitness objective, aiming to minimize the load deviation across hosts, is formulated in Eq. (6).

$$F_1 = \sum_{j=1}^{p} \left|\Psi_j - \bar{\Psi}\right| \tag{6}$$

The task assignment is represented by the binary variable defined in Eq. (7).

$$\delta_{ij} = \begin{cases} 1, & if\ task\ i\ is\ assigned\ to\ VM_j \\ 0, & otherwise \end{cases} \tag{7}$$

The total execution time on VM *j* is computed as per Eq. (8).

$$\mathcal{T}_j = \sum_{i=1}^{n} \delta_{ij} \cdot \mathcal{T}_{ij} \tag{8}$$

The completion time for task *i* on VM *j* is evaluated using Eq. (9).

$$\mathcal{T}_{ij} = \frac{L_i}{\mathrm{Proc}_j} \tag{9}$$

Where L_i is the task length in MIPS, and Proc_j is the processing speed of the VM.

The makespan represents the maximum execution time among all VMs and is defined in Eq. (10).

$$\mathcal{M}_s = \max\left(\mathcal{T}_j\right), \quad 1 \le j \le m \tag{10}$$

The second objective function, total energy consumption, accounts for both active and idle states of VMs and is formulated in Eq. (11).

$$F_2 = \sum_{j=1}^{m} \left[\mathcal{T}_j \cdot \alpha_j + \left(\mathcal{M}_s - \mathcal{T}_j\right) \cdot \beta_j\right] \cdot \mathrm{Proc_j} \tag{11}$$

Where α_j and β_j are the energy coefficients (joules per instruction) in active and idle states, respectively.

The third fitness objective considers task instruction overhead and delay penalty. It is denoted as *F* 3 F 3 and defined in Eq. (12).

$$F_3 = w_1 \cdot \frac{\mathrm{Instr}_i}{\mathrm{MaxInstr}} + w_2 \cdot D_i \tag{12}$$

Where Instr_i is the instruction count of task i, MaxInstr is the maximum throughput of any processor, and D_i is the delay penalty. The weights are fixed as $w_1 = 0.7$ and $w_2 = 0.3$.

The final goal is to minimize the overall fitness function *F*, a weighted sum of the three sub-objectives. This is mathematically given by Eq. (13).

$$F = \lambda_1 \cdot F_1 + \lambda_2 \cdot F_2 + \lambda_3 \cdot F_3 \quad (13)$$

where $\lambda_1 = 1$, $\lambda_2 = 0.5$, and $\lambda_3 = 0.5$ are the respective weights for load deviation, energy consumption, and task allocation cost.

IV. Proposed Method

A new hybrid meta-heuristic algorithm, HGWWO, is presented here to solve the complex multi-objective load balancing problem in cloud computing, reducing makespan, energy usage, and load deviation. HGWWO combines the best features of two popular optimization algorithms: GWO and WOA. The HGWWO is explicitly formulated to optimize task-to-VM allocation in dynamic cloud environments to improve convergence accuracy and prevent premature stagnation.

A. Grey Wolf Phase: Resource-aware Encircling Strategy

GWO mimics the leadership-driven hunting and encircling behavior observed in natural grey wolf packs. In the context of this study, where the primary goal is to allocate independent cloud computing tasks to VMs efficiently, each "grey wolf" represents a potential solution, a vector encoding task-to-VM assignments. The metaphorical "prey" is the optimal solution that minimizes makespan, balances resource utilization, and reduces energy consumption.

Wolves are hierarchically classified into four roles, Alpha (α) that represents the best-known task scheduling solution at the current iteration; beta (β) and delta (δ) that represent the second and third-best solutions, contributing diversity and assisting in refining the search direction; and omega (ω) as follower solutions that are guided by the leading trio to explore the broader search space.

The optimization begins with the encircling behavior, where wolves adjust their positions relative to the prey, i.e., the current best-known scheduling pattern. Each VM allocation solution is iteratively updated using the encircling formulation, which introduces stochastic coefficients to balance intensification and diversification. The position update rule is given by Eq. (14).

$$\overrightarrow{X_{\text{new}}}(t+1) = \overrightarrow{X_{\text{prey}}}(t) - \vec{A} \cdot \vec{D} \quad \text{where} \quad \vec{D} = \left|\vec{C} \cdot \overrightarrow{X_{\text{prey}}}(t) - \vec{X}(t)\right| \quad (14)$$

Where $\overrightarrow{X_{\text{prey}}}(t)$ is the position vector of the current best task scheduling solution, $\vec{X}(t)$ denotes the position of the candidate VM allocation, $\vec{D}$ refers to the encircling vector (distance between candidate and prey), $\vec{A}$ is an adaptive coefficient vector controlling convergence intensity, $\vec{C}$ is a coefficient vector introducing randomness. The adaptive coefficient $\vec{A}$ is derived as follows:

$$\vec{A} = 2 \cdot \vec{a} \cdot \overrightarrow{r_1} - \vec{a} \quad (15)$$

Where $\vec{a}$ linearly decreases from 2 to 0 across iterations, gradually shifting the search from exploration to exploitation, and $\overrightarrow{r_1}$ is a random vector in [0, 1]. The vector $\vec{C}$ is similarly calculated using Eq. (16).

$$\vec{C} = 2 \cdot \overrightarrow{r_2} \quad (16)$$

With $\overrightarrow{r_2}$ being another random vector in [0, 1]. These stochastic variables help diversify the search paths and prevent premature convergence.

Once the encircling step is complete, the algorithm enters the position updating phase, where each solution is recalibrated by referencing the top three leaders (α, β, and δ). This phase ensures the search agents (candidate solutions) are drawn toward the most balanced and energy-efficient task assignments identified. The distances from each leader are computed, and new intermediate positions are derived as follows:

$$\begin{aligned} \overrightarrow{X_\alpha} &= \overrightarrow{X_\alpha} - \overrightarrow{A_1} \cdot \left|\overrightarrow{C_1} \cdot \overrightarrow{X_\alpha} - \vec{X}\right| \\ \overrightarrow{X_\beta} &= \overrightarrow{X_\beta} - \overrightarrow{A_2} \cdot \left|\overrightarrow{C_2} \cdot \overrightarrow{X_\beta} - \vec{X}\right| \\ \overrightarrow{X_\delta} &= \overrightarrow{X_\delta} - \overrightarrow{A_3} \cdot \left|\overrightarrow{C_3} \cdot \overrightarrow{X_\delta} - \vec{X}\right| \end{aligned} \quad (17)$$

The final updated position for the VM scheduling solution is obtained by averaging the guidance from the three leaders, as defined in Eq. (18).

$$\vec{X}(t+1) = \frac{1}{3}\left(\overrightarrow{X_\alpha} + \overrightarrow{X_\beta} + \overrightarrow{X_\delta}\right) \quad (18)$$

This rule ensures that each task-to-VM mapping benefits from the consensus of the top-performing strategies. In the load balancing context, this corresponds to scheduling tasks such that the CPU and memory demands are evenly distributed, minimizing execution bottlenecks and energy overhead.

B. Whale Phase: Exploitation Via Spiral Search

While the grey wolf phase provides deep global exploration and informed leader-based direction for task delegation, it falls short when dealing with local exploitation, especially in convergence towards remarkably optimized task-VM mapping. The proposed HGWWO incorporates an enhanced local search mechanism adopted from the WOA to increase search depth and overcome stagnation.

WOA simulates humpback whale bubble-net feeding behavior. In the analogy, there is one candidate task schedule for each whale, and the target is the ideal VM assignment with the shortest makespan and evenly distributed CPU/memory usage. WOA alternates between encircling, spiral motion exploitation, and random search, exploring and exploiting the solution space more efficiently.

The first behavioral pattern of WOA involves encircling the best solution discovered so far. In the cloud computing, this action refers to refining task allocations around the best-known task-VM mapping. This behavior mirrors the GWO encircling mechanism but contributes to localized convergence. This step is mathematically represented by Eq. (19).

$$\overrightarrow{X_{\text{new}}}(t+1) = \overrightarrow{X_{\text{best}}}(t) - \vec{A} \cdot \vec{D} \quad \text{where} \quad \vec{D} = \left|\vec{C} \cdot \overrightarrow{X_{\text{best}}}(t) - \vec{X}(t)\right| \quad (19)$$

Where $\overrightarrow{X_{\text{best}}}(t)$ refers to the current best task assignment solution and $\vec{X}(t)$ stands for the position of the current whale (solution).

To fine-tune the best solutions near optima, whales perform a spiral movement, which enables candidate solutions to follow a logarithmic path toward the best allocation found. This is crucial for minimizing minor inefficiencies in task scheduling, such as slight VM overloading or imbalance in memory usage. This phase probabilistically alternates with the encircling step using a control parameter $p \in [0,1]$. The spiral search is applied if $p \geq 0.5$, and the position update is calculated by Eq. (20).

$$\overrightarrow{X_{\text{new}}}(t+1) = \left|\overrightarrow{X_{\text{best}}}(t) - \vec{X}(t)\right| \cdot e^{bl} \cdot \cos(2\pi l) + \overrightarrow{X_{\text{best}}}(t) \quad (20)$$

Where b is a constant defining the spiral shape, l is a random number in $[-1,1]$ determining movement orientation.

WOA includes a prey search mechanism randomly generating new task scheduling solutions to maintain diversity and avoid local optima traps. This phase becomes dominant when the algorithm needs to escape plateaus in the fitness landscape. The exploration behavior is modeled by Eq. (21).

$$\overrightarrow{X_{\text{new}}}(t+1) = \overrightarrow{X_{\text{rand}}} - \vec{A} \cdot \vec{D} \quad \text{where} \quad \vec{D} = \left|\vec{C} \cdot \overrightarrow{X_{\text{rand}}} - \vec{X}(t)\right| \quad (21)$$

Where $\overrightarrow{X_{\text{rand}}}$ is a randomly selected solution from the population. This component is especially important for diversifying the task assignments and discovering new combinations that reduce energy consumption or execution delay.

In the hybrid HGWWO algorithm, the whale phase is used during the optimization cycle's exploitation phase. Following the population being navigated into fruitful areas in the search area by the GWO, random and spiral updates in WOA refine task allocations, offsetting near-optimal load oversights or inefficiencies that the GWO might overlook. Dynamic load redistribution among underloaded VMs, slight reduction in makespan, and progressive energy-based assignment refinement result from adaptive switching between random exploration and spiral refinement.

C. Combined Update Strategy for Load Balancing

HGWWO integrates the exploratory efficiency of the GWO with the local refinement capability of the WOA to solve the multi-objective load balancing problem in cloud computing. Fig. 1 shows the flowchart of the proposed algorithm. In typical cloud environments, scheduling tasks across multiple heterogeneous VMs must account for CPU utilization, memory demand, execution time, and energy cost. Algorithms that only explore broadly (like GWO) may converge slowly or stagnate near suboptimal allocations. Conversely, algorithms like WOA, which are good at refining solutions, may not escape poor initial guesses. HGWWO resolves these challenges by dynamically adapting its search strategy at each iteration, blending the strengths of both methods.

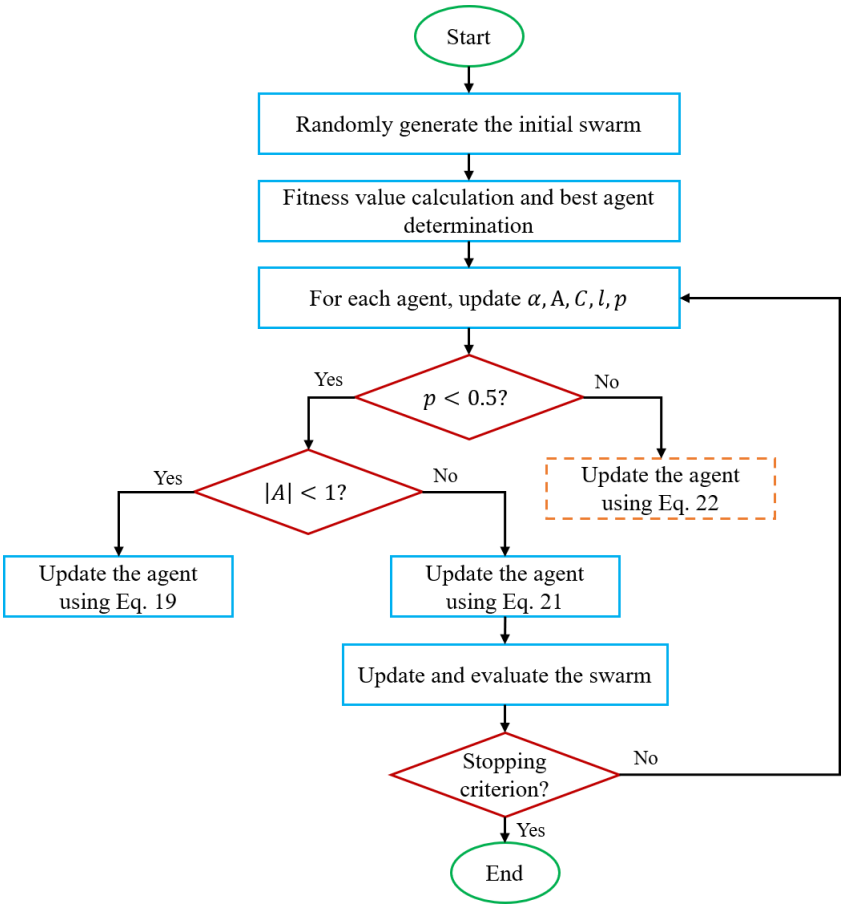

Fig. 1. Flowchart of proposed algorithm.

At every iteration of the optimization process, each candidate solution (task allocation vector) chooses its update mechanism based on a random probability $p \in [0,1]$. If $p < 0.5$, the solution is updated using a GWO-style encircling behavior, otherwise the solution undergoes WOA-style spiral exploitation. This probabilistic strategy allows HGWWO to dynamically balance global and local search throughout the optimization timeline. It avoids premature convergence (via random exploration) and accelerates convergence near optimal points (via spiral tightening). The hybrid update rule is mathematically defined in Eq. (22).

$$\overrightarrow{X_{HGWWO}}(t+1) = \begin{cases} min\left(\overrightarrow{X_{prey}} - \vec{A} \cdot \vec{D}, \overrightarrow{X_{elite}}(t)\right), \\ \qquad if\ p < 0.5 \\ min\left(\left|\overrightarrow{X_{prey}} - \vec{X}(t)\right| \cdot e^{bl} \cdot cos(2\pi l)\right) + \\ \overrightarrow{X_{prey}}, \overrightarrow{X_{elite}}(t), \qquad if\ p \geq 0.5 \end{cases} \quad (22)$$

Where $\overrightarrow{X_{elite}}(t)$ denotes the best composite solution generated by the GWO leadership strategy.

The elite solution is calculated as a weighted average of the top three solutions identified by GWO: alpha (best), beta (second best), and delta (third best). These roles correspond to the most balanced, energy-efficient task assignments in the current population, given by Eq. (23).

$$\overrightarrow{X_{\text{elite}}}(t) = \frac{1}{3}\left(\overrightarrow{X_\alpha} + \overrightarrow{X_\beta} + \overrightarrow{X_\delta}\right) \quad (23)$$

Each of these leader positions is computed by subtracting a scaled distance from their current state, as described below:

$$\begin{aligned} \overrightarrow{X_\alpha} &= \overrightarrow{X_\alpha} - \overrightarrow{A_1} \cdot \left|\overrightarrow{C_1} \cdot \overrightarrow{X_\alpha} - \vec{X}(t)\right| \\ \overrightarrow{X_\beta} &= \overrightarrow{X_\beta} - \overrightarrow{A_2} \cdot \left|\overrightarrow{C_2} \cdot \overrightarrow{X_\beta} - \vec{X}(t)\right| \\ \overrightarrow{X_\delta} &= \overrightarrow{X_\delta} - \overrightarrow{A_3} \cdot \left|\overrightarrow{C_3} \cdot \overrightarrow{X_\delta} - \vec{X}(t)\right| \end{aligned} \quad (24)$$

Each updated solution is then evaluated against the multi-objective fitness function. This function combines the load deviation across hosts, the energy consumption of active and idle VMs, and the delay and task overhead due to scheduling inefficiencies.

The proposed HGWWO initiates with a diverse population of candidate solutions, each representing a potential task-to-VM mapping configuration in a cloud computing environment. These initial solutions are randomly generated to promote exploration across the search space. The optimization process proceeds through successive iterations, during which each candidate is iteratively refined based on either a randomly chosen peer or the current global best.

A linearly decreasing control parameter, denoted by α, governs the balance between exploration and exploitation. Specifically, α starts at a maximum value of 2 and reduces to 0 throughout iterations. This parameter is used to compute the adaptive coefficient vector $\vec{A}$, which determines the intensity of position updates. When the magnitude $\vec{A} > 1$, the algorithm emphasizes exploration by referencing a randomly selected solution. Conversely, when $\vec{A} < 1$, the emphasis shifts toward exploitation, refining solutions around the current optimum.

Simultaneously, the algorithm incorporates a probabilistic decision model based on a random number p to alternate between encircling and spiral movements for solution updates. The update mechanism is bifurcated into two cases, GWO-style refinement and WOA-inspired spiral exploitation.

When $p < 0.5$, the solution update follows a leader-guided search strategy, combining the difference between the best-known task allocation and the current candidate, and the elite average position. When $p \geq 0.5$, the algorithm adopts a spiral search path influenced by the Whale Optimization concept. This update models the tightening bubble-net motion that localises optimal solutions through logarithmic spirals. The position is recalculated by incorporating the proximity to the best-known solution and a decaying spiral motion.

V. RESULTS

To assess the efficacy of the proposed HGWWO in optimizing task scheduling and load balancing in cloud environments, comprehensive simulations were conducted using CloudSim 3.0.3 on a Windows 7 machine equipped with an Intel Core i7 processor, 8 GB RAM, and a 3.4 GHz CPU. The experimental setup is described in Table II.

TABLE II. SIMULATION CONFIGURATION AND SYSTEM SPECIFICATIONS

Component	Quantity	Attributes	Specification
Hosts	20	CPU cores	6
		Bandwidth	15 GB/s
		RAM	16.0 GB
		Hypervisor	Xen
		Storage volume	4.0 TB
		Computational power	177,730 MIPS

The performance of HGWWO was compared against five prominent algorithms, ACO, GWO, WOA, ABC, and HHO, on a large scale of tasks and VM configurations. The comparison was made based on multi-objective measures such as makespan, energy usage, resource usage, migration rate, imbalance factor, throughput, and idle time.

Two principal scenarios were experimented with, varying the tasks (100 to 2000) while the number of VMs (100) remains fixed, and fixing the tasks (1000) while varying the number of VMs (10 to 100). The fitness function, defined in Eq. (13), integrates load deviation, energy consumption, and task cost. Optimal weight values $\lambda_1 = 1$, $\lambda_2 = 0.5$, and $\lambda_3 = 0.5$ were obtained through trial-and-error and are detailed in Table III.

TABLE III. IMPACT OF FITNESS WEIGHTS ON LOAD BALANCING METRICS

Weights			Simulation outcomes			
λ_1	λ_2	λ_3	Energy usage (kJ)	Load variance	Throughput (req/ms)	Makespan (ms)
1	0.9	0.9	305.08	0.355	9.05	6570.31
		0.8	294.62	0.349	8.51	6352.19
		0.7	290.29	0.338	8.29	9105.88

Fig. 2 and Fig. 3 show that HGWWO has the lowest energy consumption among all rival algorithms. This results from its innovative adaptive hybrid architecture, which inhibits unnecessary task migration and accurately assigns workloads to idle VMs. It maintains efficient CPU and memory usage while minimizing excessive idle energy consumption by integrating GWO's leadership-based global exploration mechanism with WOA's local spiral exploitation.

Fig. 4 and Fig. 5 indicate that HGWWO beats its competitors in make-span reduction, a key contributor to system responsiveness and QoS. The reduction is a result of spreading out global exploration and switching to local optimization inherent in HGWWO, which facilitates faster convergence on optimum task allocations. The effect is a more deterministic response time with less latency, resulting in increased user service availability. The load standard deviation between the VMs (as depicted in Fig. 6) quantifies the uniformity in the distribution of resources. HGWWO maintains the lowest deviation, notably after t=3700 ms, reflecting stable and efficient load balancing. HGWWO's leader-based update approach, in which alpha, beta, and delta wolves collectively

affect each candidate's position, and spiral movement adjusts the load in finer-grained steps, minimizes oscillations between overloaded and under-loaded nodes.

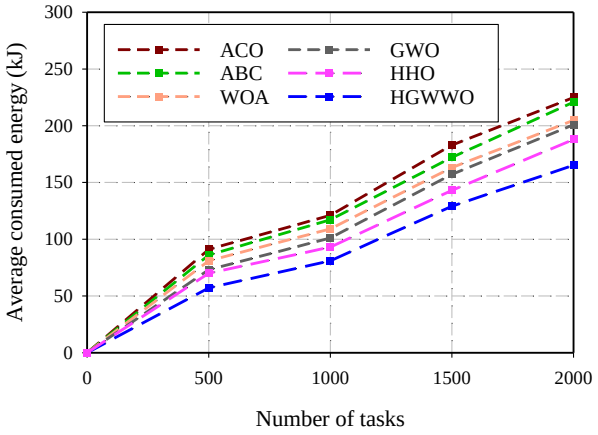

Fig. 2. Energy consumption comparison with increasing task volume at constant VM count.

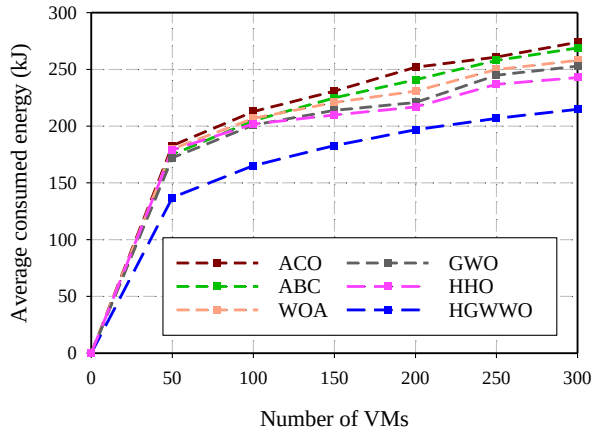

Fig. 3. Energy consumption comparison with increasing VM count at constant task volume.

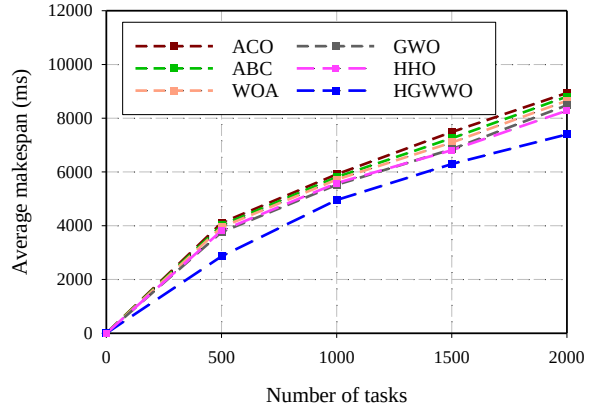

Fig. 4. Makespan comparison with increasing task volume at constant VM count.

As evident from Fig. 7, HGWWO migrates fewer tasks than its competitors. This is the result of its strategy for allocation based on fitness, which predicts upcoming changes in load ahead of time and assigns tasks to the appropriate VMs in advance, resulting in fewer runtime reassignments and reduced overhead. Fig. 7 shows that HGWWO achieves higher throughput for most conditions, particularly under heavy load conditions. The locations' proximity-based update policies, along with spiral exploitation policies in the algorithm, enable timely job completion with constant service continuity, thus enhancing the cloud system's ability to service user demands.

VI. DISCUSSION

Experimental findings reveal that our proposed HGWWO algorithm produces significant advancements in dynamic load balancing for cloud computing infrastructures. The hybridization of GWO and WOA exhibits a higher convergence trend, a reduced value for makespan, reduced energy consumption, and an equalized task allotment between virtual machines. These advantages result from several primary design attributes of the proposed HGWWO algorithm.

Firstly, incorporating GWO's hierarchical structure for leadership with WOA's exploitation strategy based on a spiral allows HGWWO to obtain a more stable tradeoff between local exploration and global exploitation, thereby reducing the risk of early convergence, which is prone to single standalone meta-heuristics such as GWO, WOA, and ABC. Secondly, adaptive behavior is achieved by incorporating auto-tuning algorithmic parameters into a variable workload distribution based on its state. This is needed in heterogeneous clouds due to sudden changes in task intensity alongside available resources.

Additionally, the multi-objective optimization model employed in this work contributes to these enhancements. As it optimizes makespan, energy consumption, and load deviation simultaneously, HGWWO handles the practical tradeoffs that cloud service providers face. This end-to-end optimization results in more efficient resource utilization and a higher level of QoS compared to alternative algorithms.

However, our proposed model also has several weaknesses that need to be addressed. One of these principles is that, due to its multi-objective optimization with a hybrid structure, the algorithm's computational complexity is higher than that of simpler, single-heuristic schemes. Although this tradeoff allows for superior performance, it may not be suitable for extremely large-scale implementations or applications that depend highly on latency and for which speed of execution is a concern. In addition, validation was conducted using synthetic workloads within the CloudSim simulation platform. Nonetheless, a widely adopted benchmarking platform, validation within realistic real-world infrastructures (e.g., OpenStack, Kubernetes) would be more convincing in practical terms.

It also has the limitation that it requires manual setting of algorithm parameters, including weight coefficients and control factors. Although they were tuned experimentally, an adaptive or self-tuning system would be suitable for further enhancing the robustness of HGWWO when environmental conditions vary. Lastly, security, fault tolerance, or energy-aware geographic distribution are not explicitly addressed by the current model, but become significant in specific scenarios of cloud deployment.

VII. CONCLUSION

This study introduced the HGWWO algorithm for the rigorous problem of dynamic load balancing and task scheduling in cloud computing. HGWWO was compared with five algorithms, ACO, GWO, WOA, HHO, and ABC, along with significant performance metrics such as makespan, energy usage, the standard deviation, throughput, task migration, the degree of imbalance, and idle time, based on comprehensive simulations under different workloads and VM settings using CloudSim 3.0.3, and further validated using a physical cloud testbed. Experimental results showed that HGWWO outperforms all baseline algorithms in balanced energy-aware and resource allocation. Notably, it achieved a smaller makespan, less energy consumption, and fewer task migrations while maintaining high throughput with even load distribution.

Compared with other meta-heuristics and hybrid solutions, our proposed HGWWO algorithm possesses several practical merits. It converges faster due to leveraging GWO's initial global exploration and WOA's terminal local exploitation. This adaptive switching also minimizes task migration and improves throughput, particularly for heterogeneous or load-intensive environments. It also distinguishes itself from deep-learning-based models, which require extensive training datasets and produce significant overheads. Our proposed HGWWO is thus lightweight and usable even in resource-constrained cloud nodes, including real-time scheduling. Its merits qualify it as a viable contender for cloud production use, particularly where task patterns change dynamically, and deterministic scheduling is infeasible.

Although the suggested HGWWO algorithm demonstrates promising behavior for fluctuating and varying cloud conditions, several weaknesses must be considered. First, even though HGWWO converges faster than standalone GWO or WOA, its hybridization also incurs more computational overhead, which may be noticeable for ultra-large scales. Secondly, the algorithm's behavior is now evaluated under synthetic workloads and simulated environments. Realistic deployment environments with non-deterministic workload spikes and hardware faults may require further fine-tuning or complementing with learning-based adaptive modules. This limitation presents opportunities for enhancing HGWWO with real-time or predictive feedback mechanisms in future work.

Based on the positive outcome by HGWWO, future work will focus on expanding the algorithm to distributed and federated cloud environments such as multi-cloud computing, edge computing, and fog computing. They outline more demanding scenarios, such as latency-aware task assignment, limited resource availability, and asynchronous message passing, which can be tailored for handling by HGWWO. Combining workload prediction with deep reinforcement learning will also enable proactive resource allotment and improve scalability in real-time. Further enhancements would include adaptive parameter self-tuning methodologies for reducing manual weight modifications in the fitness function. Others would include security-aware policy-making for scheduling purposes, along with carbon-aware optimization for eco-friendly cloud control. Long-term verification will consist of practical deployment and benchmarking on running cloud infrastructures (e.g., OpenStack) for demonstrating robustness under realistic constraint scenarios.

***Abstract*—This study presents a hybrid deep learning approach for automated detection of bubbles in contact lenses, aiming to enhance quality assurance in the manufacturing process. A hybrid AlexNet+SVM model was developed using transfer learning, where AlexNet's convolutional features were leveraged for binary classification (bubble vs. normal) via a Support Vector Machine (SVM) classifier. The dataset consisted of 320 images (160 bubbles, 160 normal) pre-processed using median filtering, local histogram equalization, and circular masking to improve image clarity and consistency. Through systematic hyperparameter tuning, the model achieved 100% testing accuracy and 97.92% validation accuracy, with perfect precision (100%) and high recall (96%). Comparative evaluation against ResNet and VGGNet demonstrated that the AlexNet+SVM model offered superior generalization and robustness, particularly for small-scale datasets. While VGGNet also achieved 100% testing accuracy with 95.83% validation accuracy, ResNet underperformed in recall (89%), likely due to its deeper architecture and data limitations. The findings underscore the suitability of hybrid models for binary classification tasks in limited-data scenarios. Identified challenges, including dataset size and risk of overfitting, point to future research directions involving expanded datasets and more advanced pre-processing techniques. This research contributes to the advancement of automated defect detection systems for contact lens manufacturing, offering a reliable and efficient quality control solution.**

Keywords*—Bubble detection; contact lens quality assurance; deep learning; transfer learning; Support Vector Machine (SVM); AlexNet; image pre-processing; binary classification; defect detection

I. INTRODUCTION

The eye is one of the most sensitive and vital organs in the human body, serving as the primary means of gathering information from the external environment. Humans rely heavily on vision, more than any other sensory modality, for perception and interaction with their surroundings [1]. The development of contact lenses has significantly advanced vision correction since their inception. In 1888, the first glass contact lenses were developed by Adolf E. Fick and Edouard Kalt, opticians based in Paris. However, glass contact lenses were associated with several limitations, including excessive weight, high cost, and safety concerns. Their fragility made them prone to breaking upon impact, necessitating careful handling. These drawbacks led to the development of alternative materials, culminating in the invention of the first hydrophilic hydrogel soft contact lenses by Czech chemists Drahoslav Lim and Otto Wichterle in 1959 [2].

Despite these advancements, the manufacturing process of soft contact lenses is not without challenges. One significant issue is the formation of bubbles during production. The manufacturing process involves heating the lens material until it reaches a molten state, followed by injection into computer-designed molds under high pressure. After cooling, the lenses are removed from the mold and undergo polishing to achieve smooth edges and surfaces. The lenses are then hydrated and subjected to quality assurance testing. However, improper handling or suboptimal manufacturing conditions can lead to the entrapment of bubbles during the heating and molding stages. These bubbles compromise the structural integrity and optical performance of the lenses.

Current inspection methods for detecting bubbles in contact lenses often depend on subjective human judgment, resulting in inconsistencies that can compromise quality control and allow defective lenses to reach end-users, potentially leading to discomfort or vision issues. While significant advancements have been made in contact lens classification and quality assessment using deep learning, the automated and highly accurate detection of specific manufacturing defects—particularly air bubbles—remains insufficiently addressed in both academic research and industrial practice. Existing systems frequently struggle with precision, especially in scenarios involving small datasets or variable imaging conditions and tend to overlook the importance of preprocessing techniques in improving model reliability.

To bridge this gap, this study introduces a hybrid deep learning model that combines AlexNet with a Support Vector Machine (SVM) classifier, specifically optimized for robust bubble detection in constrained data environments. Enhanced by image quality-focused preprocessing strategies, the proposed approach aims to improve inspection consistency, reduce reliance on manual evaluation, and support the development of reliable, fully automated quality assurance systems for contact lens manufacturing. The remainder of this paper is structured as follows: Section II presents a comprehensive review of related work. Section III describes dataset acquisition and preprocessing techniques. Section IV details the proposed methodology, including model architecture and tuning strategies. Section V discusses the results and comparative analysis. Section VI presents the conclusion, study limitations, and recommendations for future research.

II. Related Work

This section reviews key studies relevant to bubble detection in contact lenses. Gautam and Mukhopadhyay [3] employed AlexNet as a deep convolutional neural network (CNN) architecture, combined with an SVM-based Error-Correcting Output Code (ECOC) classifier. They evaluated Linear, Quadratic, Cubic, and Gaussian SVM models, focusing on validation accuracy to assess performance. Their work demonstrated the effectiveness of deep CNNs for contact lens detection. Raghavendra, Raja, and Busch [4] extended SVM applications by using it for a three-class classification problem: no lens, soft contact lens, or textured contact lens. This approach highlighted SVM's utility in multi-class lens detection tasks.

In image preprocessing, Arvind Kumar [5] compared Median and Gaussian filters for denoising, concluding that the Median filter achieved better results in less time, emphasizing its efficiency for image enhancement. Mandalapu, Ramachandra, and Busch [6] utilized the Blind/Referenceless Image Spatial Quality Evaluator (BRISQUE) to extract texture features from textured contact lenses. This method provided insights into image quality and texture patterns across different manufacturers, showcasing the potential of quality metrics for lens analysis.

In deep learning, H. Hou et al. [20] using a new detection network of YOLOv8-BGA model as a baseline, which can achieve effective identification of leakage bubbles and bubble images collected under different lighting conditions in a practical industrial inspection environment. Convolutional neural networks have been used to detect and classify defects in colored contact lenses. Kim Ty et al. [21] employed CNN GoogLeNet V4 to detect defective contact lenses in the AOI system that yielded a good product recognition rate of 83.3% despite the limitations of computational resources and data.

While these studies reflect advancements in contact lens classification and quality assessment, most existing approaches rely heavily on large datasets and lack targeted solutions for specific defects such as bubbles. Furthermore, limited attention has been given to preprocessing strategies and model robustness under small-scale data and varied lighting conditions. To address these challenges, this paper proposes a lightweight, generalizable deep learning framework—integrating AlexNet with SVM—enhanced by quality-focused preprocessing techniques, specifically designed for accurate and automated bubble detection in contact lens manufacturing.

III. Methodology

The workflow of the bubble detection system is illustrated in Fig. 1. The process begins with data collection, where images of contact lens specimens are captured using the experimental setup described earlier. No Reference Image Quality Assessment (NR-IQA) is performed on the raw images to evaluate the quality of images captured with and without additional lighting. Following this, data augmentation and image cropping are applied to prepare the dataset for pre-processing.

The pre-processing stage involves several image enhancement techniques, including median filtering, Gaussian filtering, power law transformation, local histogram equalization, circle detection, and circle masking. To validate the effectiveness of these preprocessing methods, Image Quality Assessment (IQA) metrics such as Peak Signal-to-Noise Ratio (PSNR), Mean Squared Error (MSE), and Absolute Mean Brightness Error (AMBE) are employed. After preprocessing, the images are resized to a uniform dimension to ensure consistency before classification. The classification stage utilizes the AlexNet convolutional neural network (CNN) model with transfer learning, incorporating Support Vector Machines (SVM) for enhanced performance. Parameter tuning is conducted to optimize hyperparameters such as epoch count, batch size, learning rate, and the number of workers. The model's performance is evaluated using a confusion matrix to assess its accuracy in detecting normal lenses and lenses with bubbles.

Finally, the proposed AlexNet model with SVM transfer learning is compared against two other state-of-the-art models, AlexNet, VGGNet and ResNet, to benchmark its effectiveness in bubble detection. This comprehensive approach ensures a robust and reliable system for identifying defects in contact lenses.

A. Dataset and Data Collection

The dataset used in this study was curated from real-world contact lens manufacturing samples provided by an industrial supplier. It includes 20 images of lenses with bubbles and 16 images of normal lenses for analysis. These images represent actual production defects, making the dataset highly relevant for developing industrial-grade defect detection systems. Though small in size, the dataset's authenticity and diversity in lighting conditions support the development of robust models using transfer learning and data augmentation techniques.

These specimens were imaged using a Logitech C922 Pro Stream Webcam for detailed inspection. The experimental setup included hardware (laptop, Logitech C922 camera, tripod stand, USB Type-A 2.0 cable) and software (PyCharm IDE) [7]. The camera, set to 1080p resolution, was mounted on a tripod at a 90-degree angle, 6 cm above the specimens as in Fig. 2. A black cardboard background was used to enhance contrast, facilitating bubble visualization against the white lenses. Two imaging modes were utilised: one without additional lighting and one with phone camera light. A custom camera app developed using PyQt5, QtGui, and Pyshine libraries, featured 'Start' and 'Take picture' buttons for image capture. All images were saved in PNG format at 1440×1080 resolution.

B. No Reference Image Quality Assessment

No Reference Image Quality Assessment (NR-IQA) was conducted using the Blind/Referenceless Image Spatial Quality Evaluator (BRISQUE) on the raw images to evaluate the quality of images captured with and without additional lighting [8]. BRISQUE was selected for its ability to quantify image quality without a reference image. The imaging mode yielding lower BRISQUE values, indicating higher quality, was chosen for subsequent data augmentation.

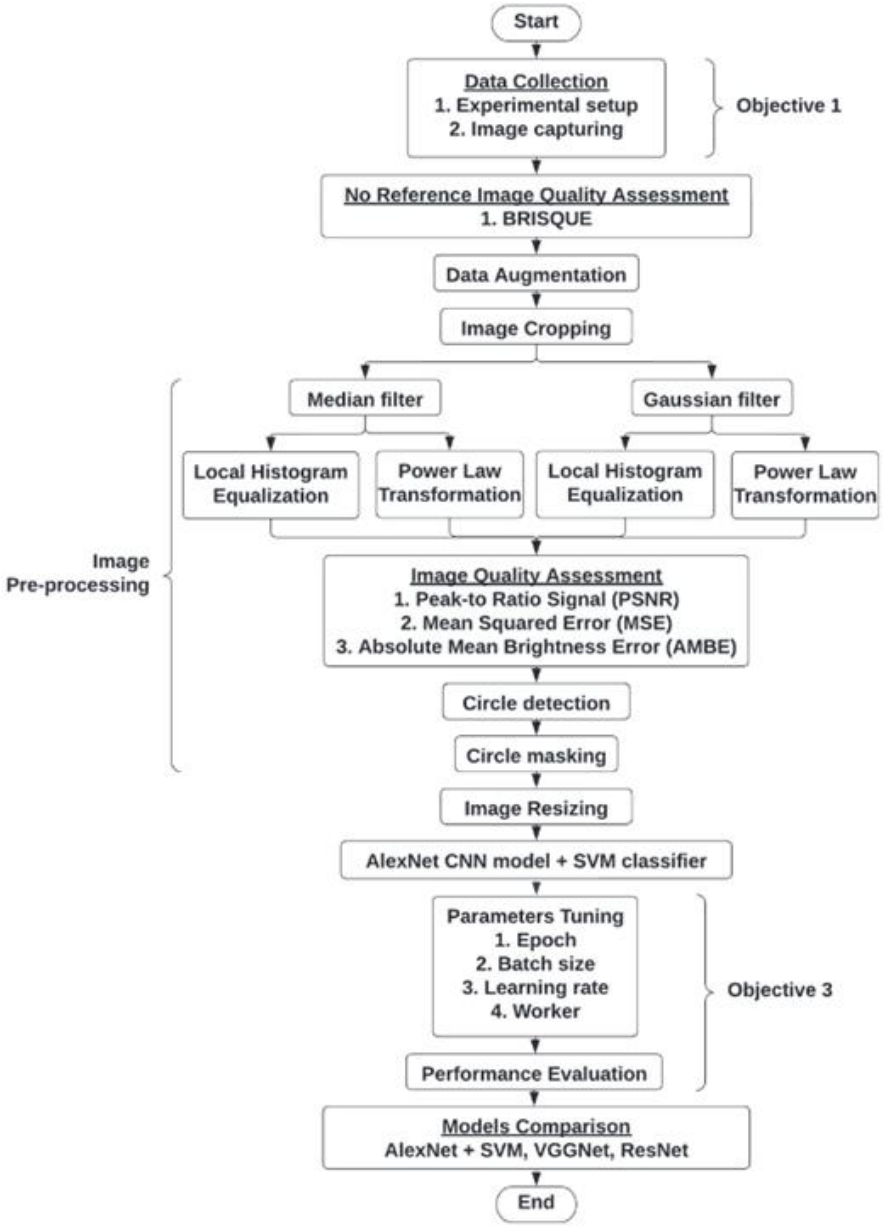

Fig. 1. Methodology workflow.

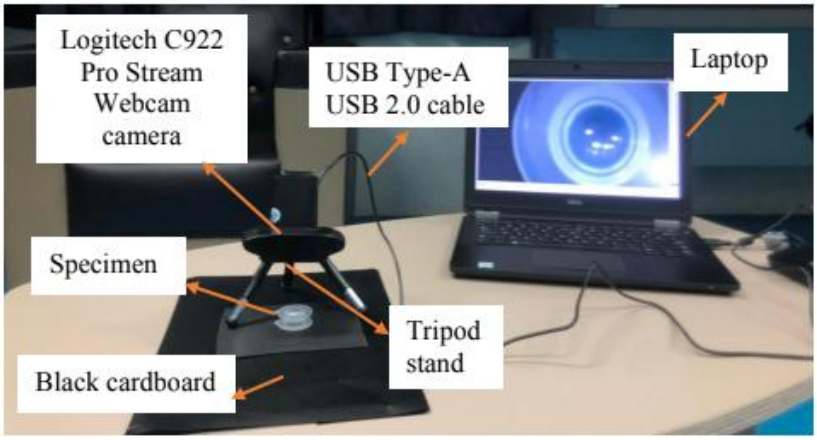

Fig. 2. Experimental setup.

C. Data Augmentation

Data augmentation was applied to enhance the dataset. For the 20 images of lenses with bubbles, each image was rotated at 0°, 90°, 180°, and 270°, resulting in 80 augmented images. For the 16 normal lens images, the first 10 images were rotated at 0°, 90°, 180°, and 270°, producing 40 images. The remaining 6 images were rotated at 0°, 45°, 90°, 135°, 180°, 225°, 270°, and 315°, generating an additional 48 images. This resulted in a total of 88 normal lens images. Horizontal flipping was then applied to all augmented images, producing a final dataset of 320 images (160 with bubbles and 160 normal).

D. Image Cropping

The Region of Interest (ROI) for the dataset was the contact lens area, excluding the plastic mold and black cardboard background. Auto-cropping was performed on each image to remove unwanted regions, ensuring the background did not affect preprocessing. The cropped images varied in size between 240×240 and 350×350 pixels, as the ROI dimensions differed across specimens.

E. Image Pre-processing

Image pre-processing is essential for improving image quality, addressing factors like lighting intensity and camera quality. The process begins with segmenting the Region of Interest (ROI) within the boundary of interest, followed by focusing on the object of interest, categorized as either bubbles or normal.

1) Median filter: A non-linear filter used to reduce impulsive (salt-and-pepper) noise while preserving edges [9]. For a 5×5 filter, the centre pixel is replaced by the median value of the 25-pixel window, calculated by sorting pixel values and selecting the 13th value as in Eq. (1). This process is repeated across the image.

$$\hat{f}(x,y) = \underset{(s,t)\in S_{xv}}{median}\{g(s,t)\} \quad (1)$$

2) Gaussian filter: A linear filter applied to blur images or reduce noise. It performs a weighted average of surrounding pixels based on the filter size. A 5×5 kernel was used, with the sigma parameter controlling the blurring effect. The process iterates by shifting the window across the image by using Eq. (2).

$$g(x,y) = \frac{1}{2\pi\sigma^2} e^{\frac{(x^2+y^2)}{2\sigma^2}} \quad (2)$$

3) Local histogram equalization: Enhances contrast by adjusting image intensities using regional information. It spreads frequent intensity values, stretching the intensity range [10] to improve local contrast by using Eq. (3).

$$m_{s_{xy}} = \sum_{i=0}^{L-1} r_i P_{S_{xy}}(r_i) \quad (3)$$

4) Power law transformation: Maps narrow ranges of dark input values to wider output ranges or vice versa [11]. The transformation uses Eq. (4), where s and r are output and input pixel values, c is a constant, and γ controls the mapping. A γ value of 2 was chosen to darken the image, enhancing bubble edges.

$$s = c \cdot r^{\gamma} \quad (4)$$

F. Image Quality Assessment

Image Quality Assessment (IQA) evaluates distortions and degradations in images. Four pre-processing approaches were analyzed using Peak Signal-to-Noise Ratio (PSNR), Mean Squared Error (MSE), and Absolute Mean Brightness Error (AMBE). The approach yielding the best results across these metrics was selected for further processing.

1) PSNR: Measures the peak-to-noise ratio in decibels between the original and processed images. Higher PSNR values indicate better image quality [12]. It is calculated using Eq. (5), where R is the maximum fluctuation in the input image data type, and MSE is the mean squared error.

$$PSNR = log_{10}(\frac{R^2}{MSE}) \quad (5)$$

2) MSE: Represents the cumulative squared error between the original and processed images. Lower MSE values indicate smaller errors and better image quality [13]. Equation (6) calculates MSE, where n is the number of data points, Y_i is the observed value, and $\hat{Y}_i$ is the predicted value.

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(Y_i - \hat{Y}_i)^2 \quad (6)$$

3) AMBE: Assesses the preservation of original brightness. Lower AMBE values indicate better brightness preservation. Eq. (7) calculates AMBE, where E(X) and E(Y) represent the mean errors of the original and processed images, respectively.

$$AMBE = E(X) - E(Y) \quad (7)$$

G. Circle Detection and Masking

Circle detection was performed using OpenCV's Hough Gradient Method, which leverages gradient information from edges. The function cv.HoughCircles (image, method, dp, minDist, param1, param2, minRadius, maxRadius) was utilized with the following parameters:

- image: Pre-processed input images.
- method: cv2.HOUGH_GRADIENT for gradient-based edge detection.
- dp: Set to 1 to match the accumulator resolution with the input image.
- minDist: Set to 200 to avoid false detection of overlapping circles.
- param1: Set to 50 as the higher threshold for the Canny edge detector.
- param2: Set to 30 as the accumulator threshold for circle center detection.
- minRadius and maxRadius: Both set to 0 to detect circles of any size.

The circle detection process is defined by Eq. (8), where represents the circle's (x_{centre}, y_{centre}) and r is its radius. The output, HoughCircles, provides the detected circle parameters. After circle detection, masking was applied to isolate the Region of Interest (ROI). A mask was created by hiding the outer region of the detected circle. The original image was then combined with the mask, resulting in an output image where only the contact lens ROI is visible, and the background is black. This step ensures focus on the lens area while eliminating irrelevant background information.

$$(x - x_{centre})^2 + (x - y_{centre})^2 = r - HoughCircles() \quad (8)$$

H. Convolution Neural Network AlexNet + SVM Model

This study employs a transfer learning approach by integrating the AlexNet architecture with a linear Support Vector Machine (SVM) for bubble detection in contact lenses. The output images after the circle masking were resized to 227 by 227 as this is the optimum image size acceptable by the AlexNet CNN model. AlexNet, chosen for its robust performance in visual recognition tasks [3], consists of 8 layers: 5 convolutional and 3 fully connected. To adapt it to the binary classification task (bubbles vs. normal), the original 1000-class output layer [14] is replaced with a linear SVM classifier. Key modifications include:

- ReLU Activation: Replaces Tanh to accelerate training speed by sixfold [15].
- Dropout (Rate: 0.5): Mitigates overfitting, though doubling training time.
- Overlap Pooling: Reduces network size [16] and error rates (0.4% top-1, 0.3% top-5).

The model leverages transfer learning to address limitations of small datasets and binary classification. The dataset (320 images: 160 bubbles, 160 normal) is partitioned into 70% training, 15% validation, and 15% testing. The SVM classifier is applied to the final fully connected layer (fc8), enabling precise two-class categorization as shown in Fig. 3. This hybrid approach optimizes AlexNet's feature extraction capabilities with SVM's efficiency in linear classification, ensuring robust performance despite dataset constraints.

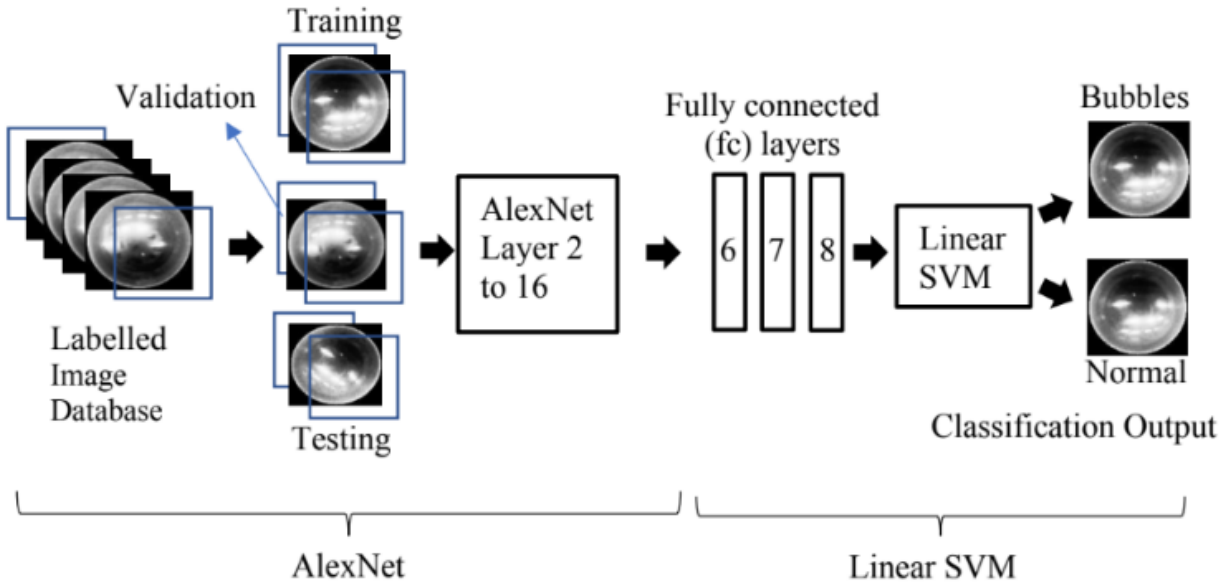

Fig. 3. Classification model of AlexNet + SVM on contact lens images.

IV. Result and Discussion

This section presents a comprehensive analysis of the experimental results, focusing on three critical phases of the study: (1) the evaluation of image pre-processing techniques to enhance dataset quality, (2) the optimization of hyperparameters for the AlexNet+SVM classification model, and (3) a comparative assessment of the performance of AlexNet, ResNet, and VGGNet architectures under identical conditions. First, the effectiveness of pre-processing methods is validated through No Reference Image Quality Assessment (NR-IQA) metrics, ensuring optimal input data for model training. Next, systematic parameter tuning—spanning epochs, batch size, learning rate, and workers—identifies configurations that maximize classification accuracy while mitigating overfitting. Finally, the optimized model is benchmarked against ResNet and VGGNet to determine the most robust architecture for bubble detection in contact lenses. The results highlight the interplay between data quality, model configuration, and architectural design, providing insights into achieving high precision and generalizability in defect detection tasks.

A. Result for Image Pre-processing

The BRISQUE scores for images captured without and with camera light were analyzed in Table I. For bubble specimens, the average BRISQUE values were 36.67 (without light) and 45.39 (with light). For normal specimens, the values were 43.89 (without light) and 48.98 (with light). Lower BRISQUE scores indicate better perceptual quality. Since images captured without camera light consistently showed lower BRISQUE values, they were selected for further pre-processing.

Four pre-processing approaches were evaluated using PSNR, MSE, and AMBE metrics as shown in Table II. The results showed that the median filter combined with local histogram equalization achieved the highest PSNR (27.870) and the lowest MSE (106.725) and AMBE (0.10518), indicating superior image quality. Consequently, this method was selected for pre-processing before model implementation.

TABLE I. BRISQUE VALUE FOR RAW DATA WITH AND WITHOUT CAMERA LIGHT

Data	BRISQUE (Average values)	
	Without camera light	With camera light
Bubble	36.67259	45.38722
Normal	43.89439	48.9829

TABLE II. AVERAGE IMAGE QUALITY ASSESSMENT OF THE ORIGINAL IMAGE AND IMAGE AFTER PRE-PROCESSING

Approach	Pre-processing Method	PSNR	MSE	AMBE
1	Median filter + Local histogram equalization	27.87000	106.72500	0.10518
2	Median filter + Power law transformation	26.75500	144.39200	0.18921
3	Gaussian filter + Local histogram equalization	27.86900	106.79500	0.10520
4	Gaussian filter + Power law transformation	26.75100	144.29800	0.18874

B. *Optimizing Turning Parameters for Deep Learning Classification Model*

This section analyzes the performance of the AlexNet+SVM model by evaluating the impact of varying parameters. The training and validation accuracy and loss were recorded and analyzed based on graph patterns. The results were compared between testing and validation accuracy for each tuning to identify optimal configurations.

1) Turning on Epoch: Epoch values of 40, 60, 80, 100, 120, and 140 were tested while keeping other parameters constant (learning rate: 0.0001, batch size: 6, workers: 8, optimizer: Adam, model: AlexNet, binary classification). The highest testing and validation accuracy (89.58%) were achieved at 100 epochs, indicating optimal performance as in Fig 4. Fig. 5 shows minimal gaps between training and validation accuracy and loss at this epoch, confirming model stability.

2) Turning on batch size: Batch sizes of 2, 4, 8, 16, and 32 were evaluated with other parameters fixed (epochs: 100, learning rate: 0.0001, workers: 8, optimizer: Adam, model: AlexNet, binary classification). A batch size of 32 yielded the highest testing accuracy (93.75%) and validation accuracy (83.33%). Larger batch sizes improved model performance, but further increases were impractical due to the validation size limit. Fig. 6 and Fig. 7 show the smallest gap between training and validation accuracy and loss at this batch size.

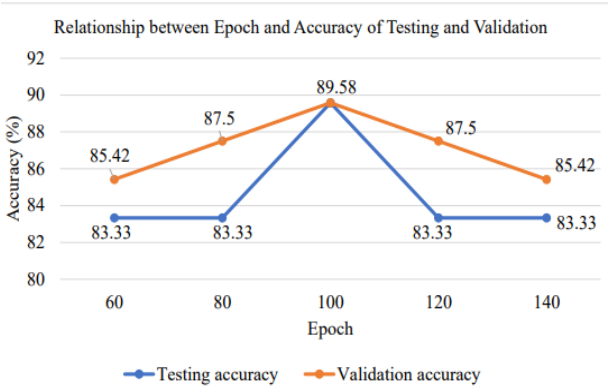

Fig. 4. Relationship between epoch and accuracy of testing and validation.

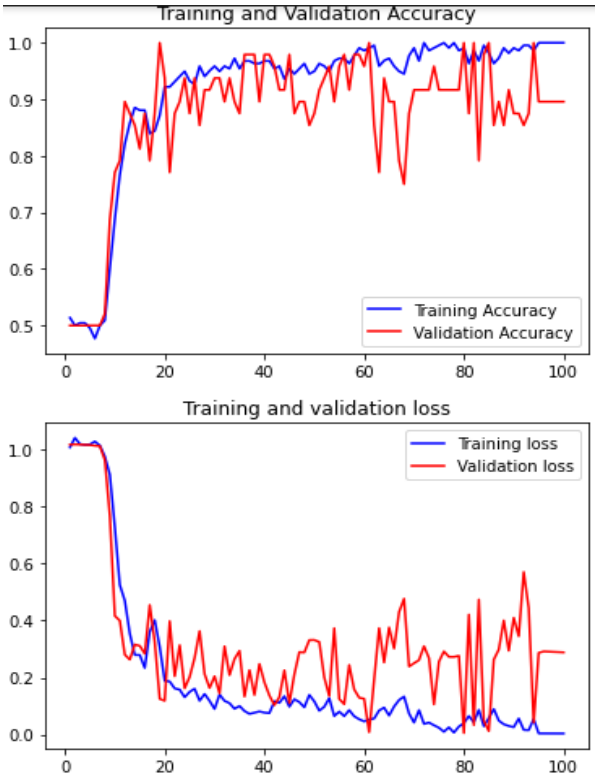

Fig. 5. Training and validation for accuracy and loss for tuning on epoch of 100.

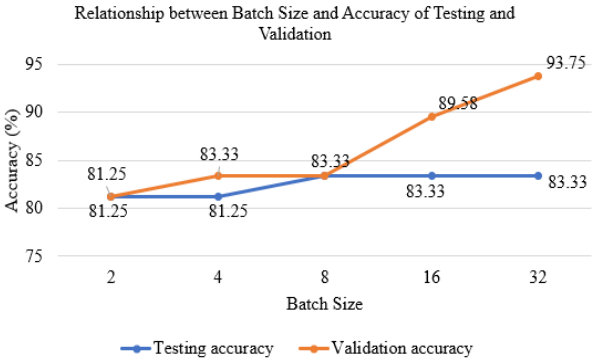

Fig. 6. Relationship between batch size and accuracy of testing and validation.

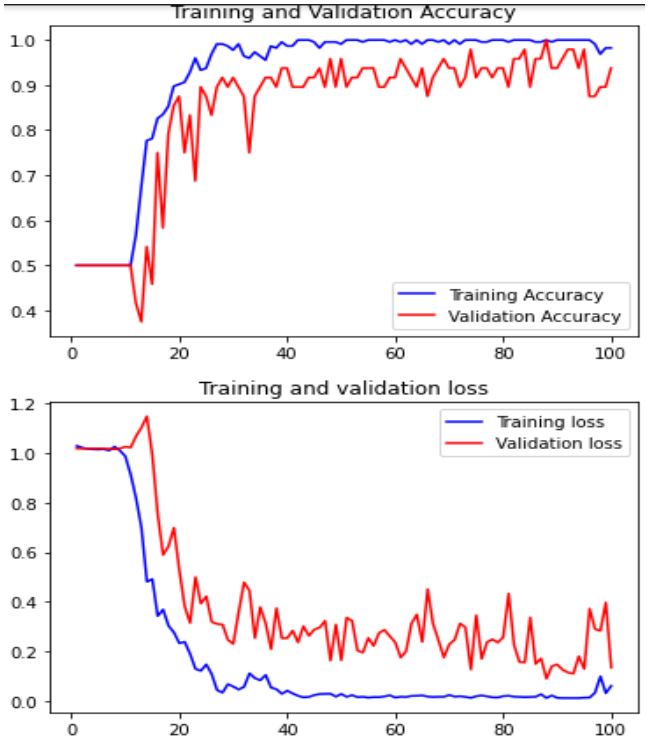

Fig. 7. Training and validation for accuracy and loss for tuning on batch size of 32.

3) Turning on learning rate: Learning rates of 0.1, 0.01, 0.001, 0.0001, 0.00001, and 0.000001 were tested while keeping other parameters constant (epoch: 100, batch size: 32, workers: 8, optimizer: Adam, model: AlexNet, binary classification). A learning rate of 0.0001 achieved the highest testing accuracy (87.5%) and validation accuracy (91.67%). Extremely low or high learning rates degraded performance, with 0.0001 providing the best balance. Fig. 8 and Fig. 9 demonstrate minimal gaps between training and validation accuracy and loss at this learning rate.

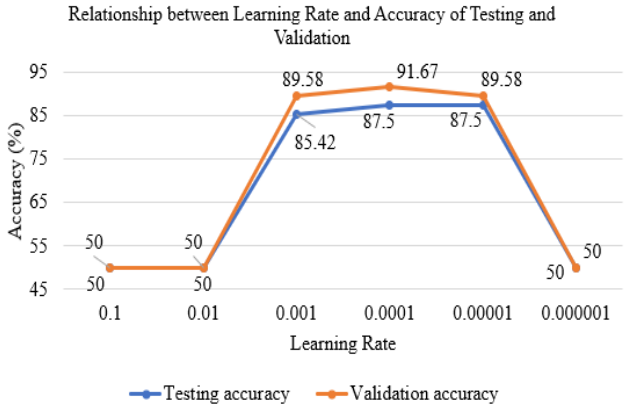

Fig. 8. Relationship between learning rate and accuracy of testing and validation.

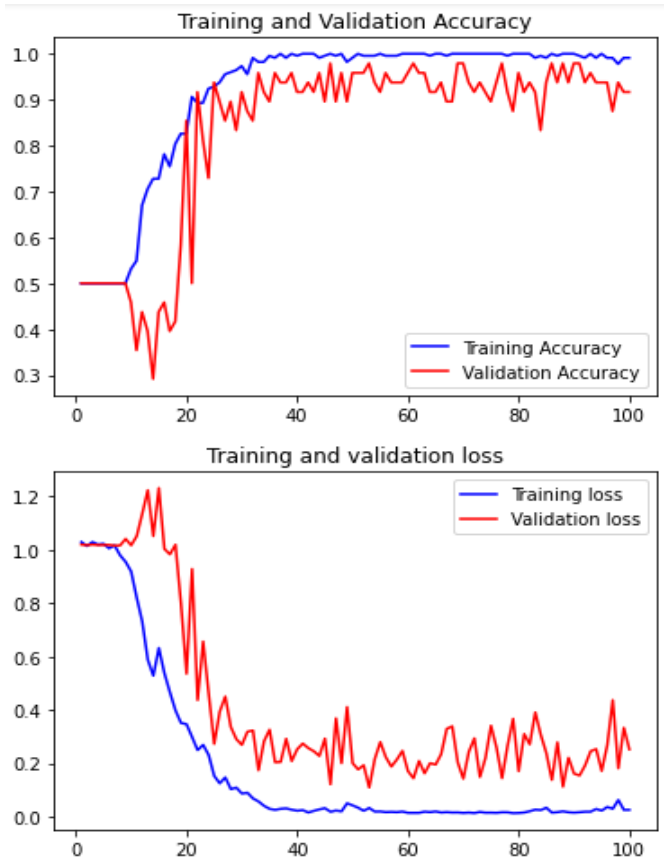

Fig. 9. Training and validation for accuracy and loss for tuning on learning rate of 0.0001.

4) Turning on worker: Worker values of 1, 2, 4, and 8 were tested with other parameters fixed (epochs: 100, learning rate: 0.0001, batch size: 32, optimiser: Adam, model: AlexNet, binary classification). A single worker achieved the highest testing and validation accuracy (93.75%). Additional workers did not improve performance, as the first worker efficiently managed batch loading and processing. Fig. 10 and Fig. 11 show the smallest gap between training and validation accuracy and loss with one worker.

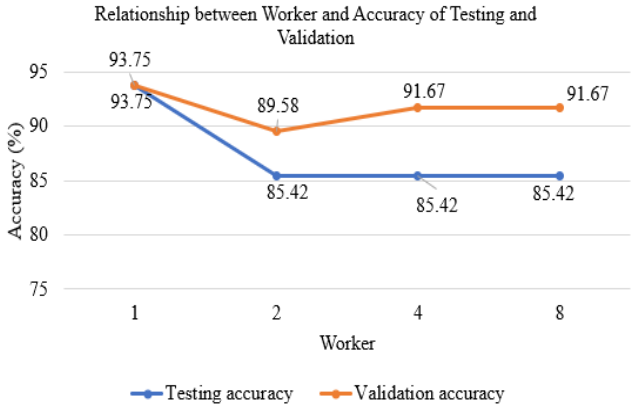

Fig. 10. Relationship between workers and accuracy of testing and validation.

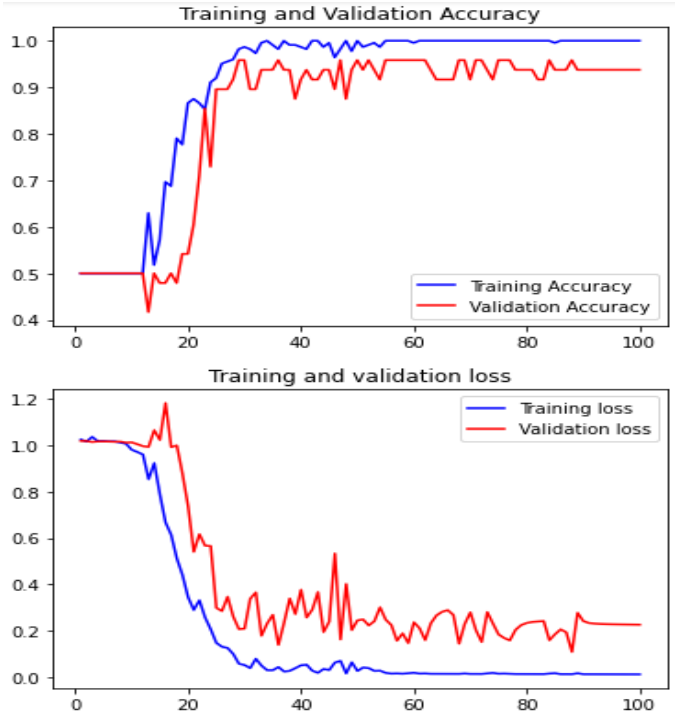

Fig. 11. Training and validation for accuracy and loss for tuning on workers of 1.

C. Comparison of Evaluation performance for AlexNet, ResNet and VGGNet and AlexNet+SVM at Optimum Tuning Parameters

After obtaining the optimal configuration, it was applied to AlexNet, ResNet, VGGNet and AlexNet+SVM to identify the best performing deep learning model for detecting bubble in contact lenses. This comparative analysis aimed to evaluate the effectiveness of each architecture under the same conditions, ensuring a robust and reliable solution for bubble detection. Table III presents the confusion matrix and its metrics of testing and validation accuracy results for AlexNet, ResNet, VGGNet and AlexNet+SVM models using identical parameters.

The AlexNet+SVM model achieved the highest validation accuracy (97.92%), outperforming VGGNet (95.83%) and ResNet (100%), while matching VGGNet's perfect testing accuracy (100%). All models demonstrated flawless precision (100%) and specificity (100%), confirming robust discrimination between bubbles and normal lenses. However, recall varied significantly: AlexNet and ResNet exhibited lower sensitivity (testing: 89%; validation: 89% and 100%, respectively), whereas VGGNet and AlexNet+SVM achieved perfect recall (100%) in testing, with AlexNet+SVM maintaining superior validation sensitivity (96%).

The AlexNet+SVM hybrid model's enhanced performance stems from integrating SVM's linear classification efficiency with AlexNet's feature extraction capabilities, mitigating overfitting risks inherent in deeper architectures like ResNet (138M parameters) [17]. VGGNet's intermediate parameter count (60.3M) and hierarchical feature learning likely contributed to its strong testing accuracy, though validation performance lagged slightly due to dataset variability [18]. AlexNet's moderate parameter size (62M) and SVM-driven classification optimized generalization, as evidenced by its balanced F1 scores (testing: 94; validation: 97.96). These results align with theoretical expectations: larger models (ResNet) risk overfitting on small datasets, while hybrid approaches (AlexNet+SVM) enhance stability by combining convolutional feature learning with linear discriminative power [19].

TABLE III. COMPARISON OF MODEL PERFORMANCE

	Model	TP	FP	TN	FN	Accuracy	Precision	Sensitivity	Specificity	F1 score
Testing	AlexNet	24	0	21	3	93.75	100	89	100	94
	ResNet	24	0	21	3	93.75	100	89	100	94
	VGGNet	24	0	24	0	100	100	100	100	100
	AlexNet+SVM	24	0	24	0	100	100	100	100	100
Validation	AlexNet	24	0	21	3	93.75	100	89	100	94
	ResNet	24	0	24	0	100	100	100	100	100
	VGGNet	24	0	22	2	95.83	100	92.31	100	96
	AlexNet+SVM	24	0	23	1	97.92	100	96	100	97.96

V. CONCLUSION

In conclusion, this study successfully achieved its objectives of developing a hybrid deep learning framework that integrates AlexNet with an SVM classifier to detect bubbles in contact lenses. The AlexNet model, optimized with specific parameters, achieved testing and validation accuracies of 93.75%. Performance evaluation using confusion matrix metrics demonstrated high precision, recall, specificity, and F1 scores. Comparative analysis revealed that the hybrid AlexNet+SVM model outperformed conventional AlexNet, ResNet, and VGGNet models achieving 100% testing accuracy and 97.92% validation accuracy, along with superior recall (96%) and F1 scores (97.96%).

Image preprocessing using median filtering and local histogram equalization significantly enhanced the quality of input data, contributing to superior classification performance. The optimized hyperparameters further ensured stable training and validation behavior. Although the model achieved high accuracy and demonstrated strong robustness, its reliance on a

small dataset may limit generalizability to broader production environments. This constraint, along with the observed risk of overfitting in deeper architectures like ResNet, highlights the need for larger, more diverse datasets to further validate the model's suitability for real-time industrial deployment. Future recommendations include enhancing pre-processing techniques, such as sharpening, and expanding the dataset to improve model accuracy and robustness. Additionally, exploring other hybrid architectures or advanced data augmentation techniques could further enhance model generalization and performance; and integrating the system into a live quality control pipeline.

ACKNOWLEDGMENT

The authors would like to thank Universiti Malaysia Perlis for providing the opportunity to collaborate with the contact lens manufacturing industry for practical research.

Integration of Grey Wolf Optimizer Algorithm with Combinatorial Testing for Test Suite Generation

Muhamad Asyraf Anuar, Rosziati Ibrahim, Mazidah Mat Rejab, Nurezayana Zainal
Department of Software Engineering, Universiti Tun Hussein Onn Malaysia, Johor, Malaysia

***Abstract*—Combinatorial Testing (CT) is a software testing technique designed to detect defects in complex systems by efficiently covering diverse combinations of input parameters within given time and resource constraints. A common strategy in CT is t-way testing, which ensures that all possible interactions among any t parameters are tested at least once. The Grey Wolf Optimization Algorithm (GWOA) is a nature-inspired metaheuristic that has been successfully applied to various optimization problems. In this study, we introduce the Combinatorial Grey Wolf Optimization Algorithm (CGWOA), which integrates GWOA with CT to enhance test suite generation. Effectiveness of CGWOA is evaluated through experiments on a real-world software system, where it is found that the number of test cases was reduced by 98%, from 3000 to 40, while still ensuring complete 2-way interaction coverage. Experimental results demonstrate that CGWOA consistently produces smaller test suites compared to pure computation methods such as Jenny, IPOG, IPOG-D and TConfig, as CGWOA consistently outperformed, especially in handling both lower and higher interaction strengths. In scenarios with binary parameters, CGWOA delivered the smallest test suites, while in more complex configurations, even in MCA settings, it showed impressive scalability, outperforming the other algorithms. Statistical analysis using the Wilcoxon signed-rank test revealed that the proposed approach significantly outperforms existing methods, with all p-values less than 0.02 after applying the Holm correction. The experimental results demonstrate that the proposed CGWOA approach advances software testing by efficiently minimizing the number of test cases required to achieve complete test coverage.**

Keywords*—Grey wolf optimizer algorithm; combinatorial testing; metaheuristics; t-way testing

I. Introduction

Combinatorial Testing (CT) has been widely recognized for its effectiveness in identifying software defects [1], as demonstrated by numerous empirical studies. Its success depends on a well-structured set of test cases, known as a Covering Array (CA), which ensures that all interactions among the parameters influencing the behavior of the System Under Testing (SUT) are covered [2]. CT detects failures by examining interactions between parameters in the testing process. It has been used to automate test suite generation, aiming to produce a reliable product that is usable across a wide range of inputs. However, the high cost of CT can be a significant obstacle to its widespread adoption. Developers spend approximately 50% of their time identifying and fixing bugs [3] which highlights the need for more efficient and cost-effective testing strategies.

As software systems grow in complexity and size, the number of possible input combinations become overwhelmingly large, making complete coverage challenging with traditional CT methods. To address this, researchers and practitioners are exploring cost-reduction strategies, such as leveraging machine learning to automate test case generation [4] or prioritizing test cases based on their defect detection potential [5]. Despite these challenges, CT remains a crucial approach for ensuring software quality and minimizing defects in complex systems.

To tackle CT challenges, various heuristic search techniques have been introduced to optimize test case selection and reduce the cost of CT. CT employs a covering array as a test suite to systematically cover parameter combinations, aiming to balance the number of test cases with their effectiveness in detecting failures [3]. Among these approaches, the GWOA has gained attention for its ability to balance exploration and exploitation, where it first explores the search space and then converges towards the best solutions. GWOA is a metaheuristic optimization method [6] inspired by the hunting behavior of grey wolves and has been applied to various optimization problems.

This study proposes an innovative CT approach leveraging GWOA, combining the strengths of both techniques to maximize test coverage while minimizing the number of test cases. It aims to investigate the effectiveness of integrating the Grey Wolf Optimizer Algorithm with Combinatorial Testing to reduce test suite size while ensuring complete t-way interaction coverage across diverse parameter configurations. The goal is to assess whether the proposed CGWOA approach offers a more scalable and efficient solution than traditional combinatorial testing techniques.

A. Combinatorial Testing

Combinatorial testing is a software testing technique that systematically covers combinations of input parameters to detect interaction faults efficiently. Instead of testing every possible configuration, which can be infeasible, it focuses on ensuring that all t-way combinations are tested at least once. A single test suite can be designed to cover all t-wise combinations of these parameters [1] while minimizing the total number of test cases.

This study addresses the combinatorial optimization challenge of t-way interaction test generation, where t denotes the interaction strength or combination degree. The goal is to generate minimal yet effective test suites that ensure full t-wise coverage across complex software configurations. In recent years, various methodologies have been proposed to tackle this problem, leading to numerous computation-based solutions. Despite these advances, many existing approaches still suffer from limitations in adaptability [7], especially when dealing with systems involving diverse parameter types and values.

B. Overview of T-way Testing

A test suite is structured as an N × k array, where N is the number of test cases and k is the number of parameters. Each row represents a unique combination of parameter values. The suite is built by first enumerating all t-way value combinations (t-tuples) and then selecting the minimal number of test cases required to cover them. These test cases are used to assess the system under different interaction scenarios, enabling the identification of faults that arise from specific parameter pairings. The following formal definitions clarify key terms relevant to this approach:

- T-way testing is a combinatorial testing method that ensures all possible combinations of t input parameters are exercised at least once. It provides a balance between test coverage and resource efficiency.
- A Covering Array (CA), denoted as CA(N; t; v^p), is a matrix covering all t-way combinations where each parameter has v values.
- A Mixed Covering Array (MCA), denoted as MCA(N; t; v_1^p_1, v_2^p_2, ..., v_i^p_i), generalizes the CA to support varying numbers of values per parameter.
- A t-tuple is a t-length subset of parameter values that must appear at least once across all test cases.

Mathematically, t-way testing can be described using Orthogonal Arrays (OAs) [8], where each subarray contains all ordered t-sized subsets of parameter values. OAs are typically represented using parameters such as N (number of test cases), k (number of parameters), v (number of values per parameter), and t (interaction strength). However, a key limitation of OAs is their requirement for uniform value counts across all parameters.

To address this issue, Covering Arrays (CAs) [9] were introduced. CA, denoted as CA(N; t, k, v), guarantees that every t-combination of values is covered at least once in a test suite. For example, CA(N; 2, 5, 4) covers all pairwise interactions among five parameters, each with four possible values. While CAs offer improved flexibility over OAs, they still assume a uniform number of values per parameter. For real-world systems where parameters often have varying values, the Mixed Covering Array (MCA) provides a more general solution. An MCA is defined as MCA(N, t, C), where C represents the configuration of parameter-value groupings, such as ($v_1^{k_1}$, $v_2^{k_2}$, ..., $v_n^{k_n}$). For instance, MCA(7, 3, 4^6, 2^4) refers to a 3-way interaction test suite with 7 test cases, covering 6 parameters with 6 values each and 4 parameters with 2 values each.

To illustrate the principles of t-way testing, consider a hypothetical configuration scenario involving a mobile e-commerce application where the system consists of four key input parameters: Payment Method, Login Authentication, Delivery Option, and Notification Type. The Payment Method parameter supports three values of Credit Card (C), Digital Wallet (W), and Cash on Delivery (D) while the other three parameters each support two values of Password (P) or Biometric (B) for Login Authentication, Standard (S) or Express (E) for Delivery Option, and Email (E) or SMS (S) for Notification Type, as shown in Table I.

TABLE I. INPUT PARAMETERS AND CORRESPONDING VALUES

Payment	Auth	Delivery	Notification
Credit Card (C)	Password (P)	Standard (S)	Email (E)
Digital Wallet (W)	Biometric (B)	Express (E)	SMS (S)
Cash on Delivery (D)			

Assuming a 2-way interaction strength (t = 2), the goal is to construct a test suite in which all possible pairs of values across all parameter combinations are covered at least once. Exhaustively testing every possible configuration would require 3 × 2 × 2 × 2 = 24 test cases. However, by applying combinatorial optimization, the number of required test cases can be significantly reduced without sacrificing 2-way coverage. Based on the configuration above, the following test suite of 12 test cases achieves complete 2-way coverage with a significantly reduced number of tests compared to exhaustive enumeration, as shown in Table II.

TABLE II. 2-WAY COVERING TEST SUITE

Test Case	Payment	Auth	Delivery	Notification
TC1	C	P	S	E
TC2	W	B	E	S
TC3	D	P	E	S
TC4	C	B	S	S
TC5	W	P	S	E
TC6	D	B	S	E
TC7	C	P	E	E
TC8	W	B	S	S
TC9	D	P	S	S
TC10	C	B	E	S
TC11	W	P	E	S
TC12	D	B	E	E

Based on the configuration of the mobile e-commerce application above, the system can be formally represented as a Mixed Covering Array as follows:

$$MCA\ (12;2;3^1 2^3)$$

This denotes a test suite containing 12 test cases that achieves full pairwise coverage across one 3-valued parameter and three 2-valued parameters. The reduced test count demonstrates the efficiency of combinatorial testing in minimizing redundant combinations while preserving interaction coverage. This test suite ensures that every pairwise combination of parameter values appears in at least one test case. For example, the pair (Wallet, Biometric) is covered in TC2 and TC8, while (Credit Card, Express) appears in TC7 and TC10. This approach demonstrates how combinatorial testing can yield significant reductions in testing effort while maintaining robust fault detection capabilities.

C. Metaheuristic Algorithm

Metaheuristic algorithms are a diverse class of nature-inspired, derivative-free optimization techniques that excel in solving complex real-world problems where traditional analytical methods fall short [10]. These algorithms are generally classified into four main categories of swarm-based,

evolutionary, physics-based, and human-based approaches [11]. Evolutionary algorithms (EAs), for example, are inspired by Darwinian natural selection, with genetic algorithms being a well-known instance that simulates biological evolution [12].

Over the past two decades, metaheuristic algorithms have been extensively adapted, modified, and integrated with other intelligent techniques for various engineering applications, ranging from Proton Exchange Membrane Fuel Cell (PEMFC) design [13] to software testing, including their role in Test Case Prioritization [14][15]. A survey of 14 metaheuristic algorithms introduced between 2000 and 2020 [16] highlights the research trends, the hybridization of metaheuristics, advancements in parallel metaheuristics, unresolved challenges, and emerging research opportunities of metaheuristic algorithms.

Metaheuristics are particularly well-suited for problems involving complex constraints or mixed-integer variables [17], where solutions are refined within predefined limits and constraints are effectively managed to transform constrained problems into unconstrained ones. While challenges remain in fully understanding their convergence properties and guaranteeing global optimality across diverse problem domains, ongoing research continues to enhance their efficiency and reliability. As advancements in metaheuristic design progress, these algorithms are becoming increasingly adaptable and robust, reinforcing their potential as powerful optimization tools.

Metaheuristics serve as a powerful approach for tackling optimization problems that are too complex or large to be solved precisely. They are widely applicable across various optimization challenges, including software testing, an essential field in IT that encompasses diverse testing strategies, methodologies, and techniques, including metaheuristic-based approaches [18]. By providing a flexible and efficient means of identifying high quality, near optimal solutions, metaheuristics prove valuable in scenarios, where traditional optimization methods may be impractical or ineffective.

The key contributions of this study are threefold. First, it presents a comprehensive overview of CT techniques and the Grey Wolf Algorithm (GWOA), outlining their strengths and limitations. Second, it provides a detailed explanation of the proposed approach that integrates CT with GWOA, emphasizing its key features and advantages. Third, the effectiveness of the proposed approach is evaluated by comparing its performance with pure computation CT techniques to assess its efficiency under various configurations.

D. Grey Wolf Optimizer Algorithm

Grey Wolf Optimizer Algorithm (GWOA) is an optimization technique inspired by the social structure and hunting strategies of grey wolves. In this method, wolves are organized into four hierarchical levels of alpha, beta, delta, and omega, reflecting a ranking from the strongest to the weakest candidate solutions. The hunting process is mainly directed by the top three wolves of alpha, beta, and delta, while the rest adjust their positions based on these leaders [19].

To utilize GWOA, the input data must first be properly defined and formatted, typically as an array or matrix. The optimization begins with a randomly generated initial population of grey wolves, each representing a potential solution within the search space. These wolves are ranked according to their fitness scores, with the three best classified as alpha (α), beta (β), and delta (δ), while the others, referred to as omega (ω), update their positions in response to the movements of the leading wolves. The key phases of the hunting process of tracking, encircling, and attacking prey are represented mathematically. After identifying the prey, the grey wolves begin to encircle it, which is mathematically modeled using the following equations:

$$\vec{D} = \left|\vec{C} \times \overrightarrow{X_p}(t) - \vec{X}(t)\right| \quad (1)$$

$$\vec{X}(t+1) = \overrightarrow{X_p}(t) - \vec{A} \times \vec{D} \quad (2)$$

Eq. (1) models the step size taken by a wolf towards one of the leading wolves (i.e., α, β, or δ), and Eq. (2) defines the final updated position of the omega wolf. Here, t is the t[th] iteration, $\overrightarrow{X_p}(t)$ are the position vectors of the prey, and the coefficient vector of $\vec{A}$ and $\vec{C}$ calculated as:

$$\vec{A} = 2\vec{a} \times \overrightarrow{r_1} - \vec{a} \quad (3)$$

$$\vec{C} = 2 \times \overrightarrow{r_2} \quad (4)$$

To simulate encircling behavior, the vectors $\vec{A}$ and $\vec{C}$ are computed using Eq. (3) and Eq. (4), where $\vec{a}$ decreases linearly from 2 to 0, and $\overrightarrow{r_1}$ and $\overrightarrow{r_2}$ are random vectors in [0, 1]. $\vec{A}$ controls step size and direction, while $\vec{C}$ adjusts the influence of the leader's position, balancing exploration and exploitation.

To simulate hunting behavior, it is assumed that the α, β, and δ wolves possess superior knowledge about the prey's probable location. Therefore, their positions are treated as the best solutions discovered so far, and the remaining wolves (i adjust their positions based on those of the leading wolves. This adaptive behavior is mathematically expressed through the following equations:

$$\vec{D_\alpha} = |\vec{C_1} \times \vec{X_\alpha} - \vec{X}|, \vec{D_\beta} = |\vec{C_2} \times \vec{X_\beta} - \vec{X}|, \vec{D_\delta} = |\vec{C_3} \times \vec{X_\delta} - \vec{X}| \quad (5)$$

$$\vec{X_1} = \vec{X_\alpha} - \vec{A_1} \times \vec{D_\alpha}, \vec{X_2} = \vec{X_\beta} - \vec{A_2} \times \vec{D_\beta}, \vec{X_3} = \vec{X_\delta} - \vec{A_3} \times \vec{D_\delta} \quad (6)$$

$$\vec{X}(t+1) = (\vec{X_1} + \vec{X_2} + \vec{X_3})/3 \quad (7)$$

In this formulation, $\vec{X_\alpha}$, $\vec{X_\beta}$, and $\vec{X_\delta}$ represent the best positions identified by the α, β, and δ wolves, respectively. The vectors $\vec{C_1}$, $\vec{C_2}$, and $\vec{C_3}$ are randomly generated coefficients, while $\vec{X}$ denotes the current position of the search agent under evaluation. Likewise, $\vec{A_1}$, $\vec{A_2}$, and $\vec{A_3}$ are randomly distributed coefficient vectors, and t represents the current iteration number. Eq. (5) to Eq. (7) describe how the position of each search agent is updated based on the influence of the leading wolves.

The fundamental principle of the GWO algorithm is that omega wolves adjust their positions during the search process according to the locations of the α, β, and δ wolves, thereby simulating the surrounding and attacking of prey. This strategy

allows omegas to diverge from one another while collectively converging towards the prey. When |A|<1, convergence towards prey is emphasized, promoting exploitation. However, this may lead to premature convergence and local optima stagnation. To mitigate this, values of $\vec{A}$ greater than 1 or less than −1 are introduced to encourage divergence from the prey and enhance global exploration in search of better solutions. Additionally, the vector $\vec{C}$ contributes to exploration behavior. When $\vec{C}$>1, the influence of the prey on the search agent is amplified. Conversely, when $\vec{C}$ <1, this influence is reduced, thereby modifying the distance calculation in Equation (1). It is important to note that the parameter $\vec{A}$ decreases linearly throughout the optimization process to promote exploitation in later iterations.

In contrast, $\vec{C}$ remains randomly distributed throughout the process, balancing exploration and exploitation. This dynamic adjustment of $\vec{A}$ and $\vec{C}$ has proven to be an effective strategy for avoiding stagnation in local optima. The flowchart of the GWO algorithm (Algorithm 1) is presented in Fig. 1.

Algorithm 1: GWOA Algorithm

Input: Objective function f(x)

Output: X_alpha: Best-found solution

1. Initialize the grey wolf population X = {X_1, X_2, ..., X_N} randomly
2. Evaluate the fitness of each search agent using f(x)
3. Identify the best three solutions as Alpha (X_alpha), (X_beta), and Delta (X_delta)
4. Set iteration counter t = 0
5. **while** t < MaxIter do
6. a = 2 - 2 * (t / MaxIter)
7. **for** each wolf X_i do
8. **for** each dimension d = 1 to D do
9. Generate r_1, $r_2 \in [0, 1]$
10. A = 2 * a * r_1 - a
11. C = 2 * r_2
12. D_alpha = |C * X_alpha − X_i|
13. D_beta = |C * X_beta − X_i|
14. D_delta = |C * X_delta − X_i|
15. X_1 = X_alpha − A * D_alpha
16. X_2 = X_beta − A * D_beta
17. X_3 = X_delta − A * D_delta
18. X_i = (X_1 + X_2 + X_3) / 3
19. end for
20. end for
21. Evaluate new fitness values
22. Update X_alpha, X_beta, X_delta
23. t = t + 1
24. end while

1.

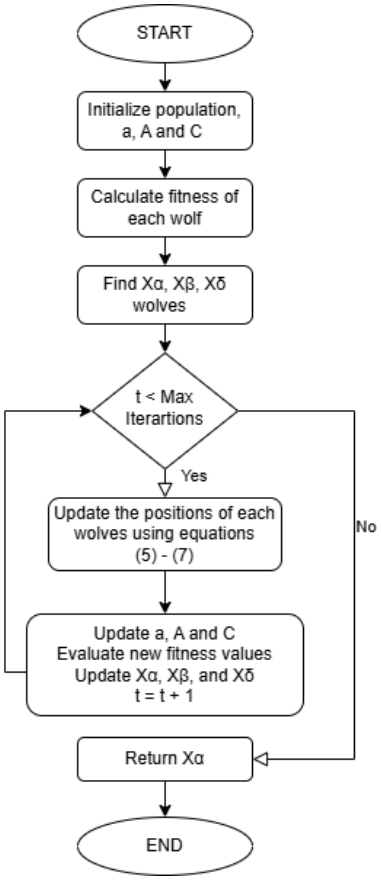

Fig. 1. Flowchart of grey wolf optimization algorithm.

One of the key advantages of GWOA is its ability to balance exploration and exploitation. The algorithm initially explores a wide range of solutions, but as iterations progress, it shifts focus toward refining the best solutions found. Studies have shown that GWOA performs competitively against other optimization algorithms in terms of convergence speed and solution accuracy [20], [21], [22]. Studies have demonstrated that GWOA is effective in cancer detection [23], scheduling [24], and engineering design [25], among other fields [26]. For instance, research has shown that GWOA improved the decision tree model through hyperparameter optimization for diabetes classification [27].

However, like other metaheuristic algorithms, GWOA does not guarantee the ability to pinpoint the exact position of the global optimal solution in every case. The algorithm may converge to a local optimum or fail to find the best solution within the given number of iterations, particularly if the search space is highly complex or if parameter tuning is not optimized. Despite these challenges, GWOA remains a valuable tool for solving problems with large search spaces and intricate constraints due to its ability to balance exploration and exploitation while requiring minimal prior knowledge of the problem domain.

The remainder of this study is structured as follows: Section II presents related work on combinatorial testing and the application of metaheuristic algorithms in test generation. Section III describes the proposed Combinatorial Grey Wolf

Optimizer Algorithm, including its design, parameters, and workflow. Section IV discusses the experimental setup, results, and performance analysis of CGWOA compared to existing combinatorial testing methods. Finally, Section V concludes the study and outlines potential directions for future research.

II. Related Work

In existing research, various heuristic search algorithms have been proposed to guide the process of Combinatorial Testing (CT) and reduce its cost. These algorithms aim to enhance the efficiency of CT by prioritizing the most relevant combinations of input values and parameters. Grey Wolf Optimization Algorithm (GWOA) has been successfully applied to various optimization problems as it has demonstrated strong exploration-exploitation capabilities. Given these characteristics, GWOA has the potential to significantly improve the efficiency of CT by optimizing test suite generation. The following section reviews related work on CT and GWOA, focusing on previous efforts to integrate metaheuristic optimization techniques with CT. The key contributions and limitations of these approaches are discussed, highlighting their relevance to the proposed study. Additionally, an overview of the current state of CT and GWOA research is provided, along with the main research gaps this work aims to address.

Several studies have compared GWOA with other metaheuristic algorithms, highlighting its effectiveness in various optimization tasks. For instance, Pace demonstrated that GWOA outperforms other algorithms in optimizing Transient Electromagnetic (TDEM) data [22]. Similarly, a 2024 study showed that GWOA delivers superior results in optimizing battery performance and lifespan compared to alternative approaches [21]. Due to its strong foundation, GWOA has been the basis for numerous enhancements for optimization problems. In 2022, the Cross-Dimensional Coordination Grey Wolf Optimizer was introduced, outperforming 16 well-known algorithms in benchmark functions and engineering optimization tasks [28]. More recently, in 2025, the Memory-Based Grey Wolf Optimizer (mGWO) was developed, incorporating the personal best history of the wolves, crossover, and greedy selection to improve search efficiency, solution accuracy, and convergence rate [29]. Beyond direct enhancements, researchers have also explored hybridizing GWOA with other optimization techniques to further improve its performance. Ahmad et al. combined GWOA with the Scout Bee Operator function from the Artificial Bee Colony algorithm, achieving superior results compared to multiple other algorithms [30]. Additionally, a 2022 study explored the integration of GWOA with Whale Optimization Algorithm and Harmony Search [31] to optimize combinatorial testing, successfully reducing the size of combinatorial test suites.

Metaheuristic algorithms have been extensively used in CT to optimize test case generation and selection. Algorithms such as Genetic Algorithms (GA), Simulated Annealing (SA), Particle Swarm Optimization (PSO), Harmony Search (HS), and many more have demonstrated their effectiveness in minimizing test suites while maintaining high t-way coverage [32]. GWOA has also been investigated for its application in CT. Prior research has explored various methods of integrating GWOA with CT, including its use in optimizing test suite generation and improving the overall efficiency of the testing process.

However, further research is needed to fully harness the potential of GWOA in CT and to explore additional optimization strategies for improving test effectiveness. A 2024 study explores the use of dynamic TWGH for scalable client-server test suite generation [33]. Another study introduces SCHOP, an approach that enhances the Harmony Search algorithm by integrating seeding and constraint support while employing a one-parameter-at-a-time strategy [34]. Additionally, 2024 saw the introduction of the Binary Growth Optimizer (BGO), a modified version of the Growth Optimizer algorithm, specifically adapted for binary optimization to address the set-covering problem [35]. Other metaheuristics approaches include ROBDD-IPSO (Improved Particle Swarm Optimization) [36], BM (Beautiful Mind) [37], Wingsuit Flying Search Optimization Algorithm (WFSO) [38], Arquitetura Multi-Agente para Metaheurísticas (AMAM) [39], Random-Key Greedy Randomized Adaptive Search Procedure (RK-GRASP) [40], and Pairwise Test Case Generation in Harmony Search Algorithm with Seeding, Constraint Mechanism (PHOSC) [41], Hybridization of Whale Optimization Algorithm and Long Short Term Memory (WOA-LTSM) [42] and Enhanced Harmony Search (EHS) algorithm [43]. Table III summarizes the findings of the recent study.

TABLE III. Recent Study Summary

Study	Baseline Method	Dataset/Project	Evaluation Criteria

III. Proposed CGWOA

Failures caused by system interactions can be effectively detected through combinatorial testing, a powerful technique for ensuring software reliability. Traditional methods often struggle to identify optimal solutions for complex optimization problems, especially when dealing with large input spaces. To address this challenge, swarm intelligence and population-based algorithms have been recommended to be applied to optimize test suite generation. Metaheuristic search algorithms, such as the Grey Wolf Optimizer (GWO), offer an effective approach for generating compact and efficient t-way test suites.

The T-tuple table is a key component in applying combinatorial testing (CT) with the Grey Wolf Optimizer Algorithm (GWOA) in this study, ensuring that all necessary t-wise interactions among input parameters are covered. It is initially populated with all possible T-tuples, where each tuple represents a combination of parameter values that must be tested. During the optimization process, test cases are evaluated based on how many uncovered T-tuples they contain, and selected test cases remove these tuples from the table once covered. This iterative process continues until all T-tuples have been accounted for. The T-tuple table thus serves as a guide, preventing redundant test cases and ensuring an efficient balance between test reduction and interaction testing.

The proposed CGWOA method is influenced by several key parameters. The population size affects diversity and search breadth as larger sizes increase exploration but also computation time. The parameter a, which linearly decreases from 2 to 0, governs the balance between exploration and exploitation over time, guiding the wolves from broad searching to focused refinement. The random coefficients r_1 and r_2 introduce stochastic behavior that prevents premature convergence and enhances global search ability. Algorithm 2 presents the CGWOA algorithm.

Algorithm 2: CGWOA Algorithm

Input: Parameters P with their respective values

Output: Test suite covering all t-way combinations

1. Generate all t-way parameter combinations from P
2. Generate all value combinations for each t-way parameter combination
3. Store all the parameter combinations and value combinations pairs in T-tuple table
4. Initialize test suite T
5. **while** T-tuple_table is not empty do
6. Initialize grey wolf population $X = \{X_1, X_2, ..., XN\}$ as random test cases
7. Evaluate fitness for each wolf. X_i based on covered t-tuples
8. Identify the Alpha (Xα), Beta (Xβ), Delta (Xδ) wolves
9. Set iter = 0
10. **while** iter < MaxIter do
11. a = 2 − 2 * (iter / MaxIter)
12. **for** each wolf X_i do
14. Generate $r_1, r_2 \in [0, 1]$
15. A = 2 * a * r_1 − a
16. C = 2 * r_2
17. D_α = |C * X_α[d] − X_i[d]|
18. D_β = |C * X_β[d] − X_i[d]|
19. D_δ = |C * X_δ[d] − X_i[d]|
20. X_1 = Xα[d] − A * Dα
21. X_2 = Xβ[d] − A * Dβ
22. X_3 = Xδ[d] − A * Dδ
23. X_i[d] = round((X_1 + X_2 + X_3) / 3)
24. end for
25. Evaluate new fitness of X_i
26. Update Xα, Xβ, Xδ based on current fitness
27. iter = iter + 1
28. end while
29. Add Xα to the test suite T
30. Remove all covered tuples of Xα from T-tuple_table
31. end while

To begin the CGWOA process, the input parameters and their possible values are first defined. These parameters, which can be variables such as numbers or categorical values, are typically structured into dictionaries or arrays. Then, all t-strength interactions of t-tuples between the parameters are generated and stored in a tuple table. At the start of the optimization process, a population of random test cases of wolves is initialized. Each test case represents a possible solution and consists of randomly selected values for each parameter. The test cases are then evaluated to determine how many t-tuples they cover. The fitness function is calculated based on how much of the test case covers the required T-tuples. The test cases are then ranked based on their fitness, with the top three solutions being designated as alpha, beta, and delta wolves.

The main optimization process proceeds in iterations. For each iteration, the algorithm adjusts the position of each wolf in the population. This is done using the standard GWOA equations. These equations involve randomly generated coefficients, and a linearly decreasing parameter named 'a' which helps control the balance between exploration and exploitation of the search space. The algorithm computes distances from each wolf to the positions of the Alpha, Beta, and Delta wolves and uses these distances to calculate three potential new positions. These are averaged to form a new candidate position for the wolf. If the test case at the new position covers more T-tuples than the current one, the wolf is moved to that new position. Once all wolves have been updated and evaluated, the test case corresponding to the Alpha wolf is selected. If this test case contributes any new t-tuples that are not yet covered, it is added to the final test suite, and those t-tuples are removed from the remaining table. The algorithm continues this process until all T-tuples have been covered. The top-performing test case in each iteration is selected for inclusion in the final test suite, and the t-tuples it addresses are eliminated from the global tuple set to avoid duplication. This cycle continues until either all T-tuples are covered, or the maximum iteration limit is reached. In brief, the algorithm starts by generating a random population of test cases and evaluating their fitness based on uncovered t-tuples. Test cases with higher coverage are added to the suite, while others are refined through iterative updates using the GWOA mechanism. By guiding candidate solutions toward the best-performing wolves, the algorithm gradually achieves full t-tuple coverage. Fig. 2 presents the CGWOA workflow step-by-step.

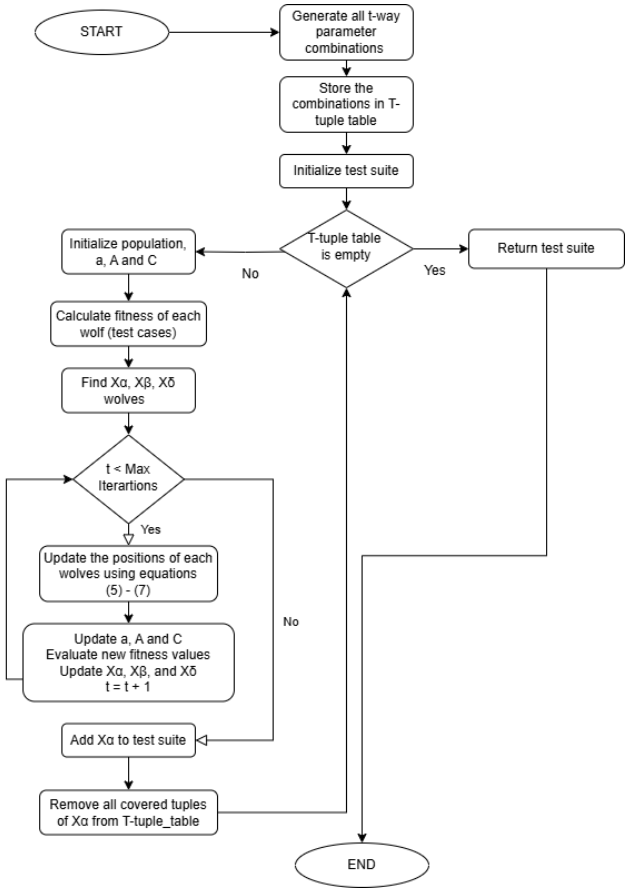

Fig. 2. Flowchart of combinational grey wolf optimization algorithm.

IV. Results and Discussions

This section presents the performance of the proposed CGWOA approach through test suite generation on real-world software configurations, benchmarking against pure computation combinatorial testing methods, and statistical evaluation to assess the significance of observed differences in performance.

A. Test Suite Generation on Real World Software Configuration

To demonstrate the application of the proposed Combinatorial Grey Wolf Optimizer Algorithm (CGWOA), a case study was conducted using real-world parameter configurations derived from the Microsoft Word Page Setup Dialog Box. The CGWOA approach was applied by iteratively selecting test cases that eliminated the largest number of uncovered t-tuples from a dynamic t-tuple table. As each test case was added to the suite, the corresponding covered interactions were removed from the table, and the process continued until full 2-way coverage was achieved. Fig. 3 illustrates the Microsoft Word Page Setup dialog [44], which includes six key parameters relevant to document formatting of Section Start (A), Header and Footer (B), From Edge Header (C), From Edge Footer (D), Vertical alignment (E), and Apply To (F). The full range of configurable options is summarized in Table IV.

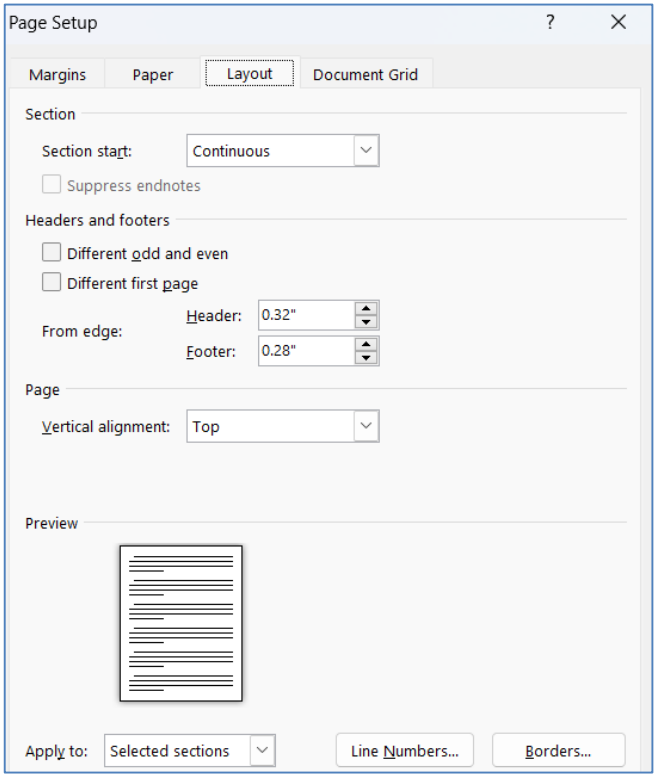

Fig. 3. MS Word page setup dialog box.

TABLE IV. MS Word Page Setup Dialog Box Parameters Value

Input Values					
Section Start (A)	**Headers and Footers (B)**	**From Edge Header (C)**	**From Edge Footer (D)**	**Vertical Alignment (E)**	**Apply To (F)**
Continuous	Different Odd and Even	-10	-10	Top	Selected Sections
New Column	Different First Page	0	0	Center	Whole Document
New Page		10	10	Justified	
Even Page		*null*	*null*	Bottom	
Odd Page		NaN	NaN		

Before applying CGWOA, the total number of possible test case combinations was calculated to be 2000, based on the following computation:

A = {Continuous, new column, new page, even page, odd page}

B = {Different odd and even, Different first page}

C = $\{-10, 10, 0, null, NaN\}$}

D = $\{-10, 10, 0, null, NaN\}$

E = {Top, Center, Justified, Bottom}

F = {Selected Sections, Whole Document}

$$\therefore |test\ cases| = |A| \times |B| \times |C| \times |D| \times |E| \times |F|$$
$$= 5 \times 2 \times 5 \times 5 \times 4 \times 2$$
$$= 2000$$

However, executing all 2000 test cases is computationally expensive and inefficient, necessitating an optimization strategy for test suite reduction while maintaining essential coverage. To achieve this objective, a t-tuple table was constructed to facilitate pairwise combinatorial testing. This table systematically enumerates all T-tuples that consist of all possible combinations of two parameters and their values that need to be included in the final test suite. The optimization process begins by generating the full set of t-tuples and subsequently selecting test cases that maximize tuple coverage while minimizing redundancy.

The original exhaustive test set contained numerous test cases with overlapping t-tuples, leading to significant redundancy. CGWOA addressed this by using the t-tuple table as a structured mechanism to track essential interactions and guide the search toward high-utility test cases. Table V illustrates a substantial reduction of the test suite from 2000 to a mere 40 cases, a 98% reduction with all coverage. The algorithm's ability to continuously update its coverage goals and remove redundant combinations ensured that each selected test case contributed meaningfully to the overall efficiency and completeness of the suite.

TABLE V. PERCENTAGE OF TEST CASES REDUCTION

Condition	Test Cases	Percentage Reduction
Exhaustive Combination	2000	Full Test Cases Count
With CGWOA	40	98%

The results indicate that GWOA provides a highly efficient method for combinatorial test case selection, significantly reducing the test suite size while preserving essential coverage. The integration of the t-tuple table ensures that all required 2-way combinations are methodically incorporated, while the optimization process effectively minimizes unnecessary test case execution. This efficiency underscores CGWOA's direct applicability in software quality assurance.

These promising results highlight the potential of CGWOA in generating compact and efficient test suites while maintaining full interaction coverage. However, to fully evaluate its effectiveness, it is essential to compare CGWOA's performance against other well-established combinatorial testing strategies. In the next section, we assess the performance of CGWOA in comparison with techniques such as Jenny, IPOG, IPOG-D, PICT, and TConfig. By examining these strategies across various test configurations and strengths, we can better understand the relative advantages and limitations of CGWOA in the context of combinatorial test case generation. This comparison will provide a comprehensive view of how CGWOA performs in diverse scenarios and its potential for improving testing efficiency in real-world applications.

B. CGWOA Benchmarking Against Pure Computation Combinatorial Testing Techniques

To assess the performance of the proposed CGWOA, a comparative evaluation was conducted against several established pure computation combinatorial test generation techniques, namely Jenny [45], IPOG [46], IPOG-D [47], TConfig [48], and PICT [49]. Jenny is a fast, backtracking-based tool for generating minimal t-wise test suites, suitable for small to medium configurations. IPOG incrementally constructs t-wise tests by covering interactions in stages, offering a good balance between efficiency and scalability. IPOG-D extends IPOG with a divide-and-conquer strategy, making it more suitable for large systems and higher interaction strengths. TConfig, associated with using mathematical methods to generate covering arrays for efficient t-wise testing, is particularly effective with uniform parameter configurations. PICT, developed by Microsoft, employs a greedy, constraint-solving approach to generate efficient pairwise and n-wise test suites, widely adopted in industrial testing scenarios.

These algorithms were chosen due to their extensive use in real-world applications, including implementation in well-established companies like IBM and integration into widely adopted open-source projects [49][50]. The inclusion of these benchmark methods ensures a comprehensive and balanced comparison, thereby facilitating an objective analysis of CGWOA's capability to construct minimal yet high-coverage test suites.

The experiments were conducted on a laptop running a 64-bit version of Windows 11, featuring an AMD Ryzen 5 processor operating at 3.30 GHz and 8 GB of RAM. The proposed method was developed in Python. Testing was organized into the following three datasets:

- Evaluating the CGWOA approach against existing methods using CA (t, v^7), where the number of parameters is fixed, but the number of values varies. Additionally, interaction strength ranges from 2 to 6.
- Evaluating the CGWOA approach compared to other methods using five different Mixed Covering Array (MCA) configurations.
- Evaluating the CGWOA approach against current techniques using CA (t, 3^p), where the number of parameters varies while the number of values remains constant and the interaction strength t ranges from 2 to 5.

Although reduction percentages were computed for all combinatorial testing techniques, they were uniformly high,

exceeding 99% across all parameter and strength configurations. Due to this saturation effect, the inclusion of detailed reduction statistics was deemed unnecessary, as such values offered limited discriminatory insight into the relative performance of the methods which is why the analysis focuses on absolute test suite sizes, which provide a more meaningful basis for evaluating the effectiveness and efficiency of each technique in practical settings.

Firstly, the performance of CGWOA was assessed across various interactions, with increasing levels of parameter cardinality and benchmarked across configurations of CA (N; t, 3^P). Based on Table VI, for t = 2, CGWOA consistently matched or outperformed the compared tools in terms of minimizing test suite size. It demonstrated particularly stable and competitive performance as the number of parameters increased. The growth in test suite size with increasing P remained modest, indicating good scalability for pairwise testing. When moving to t = 3, CGWOA continued to demonstrate efficient scaling behavior. The growth in test size remained well-controlled, which highlights the optimizer's ability to effectively manage the combinatorial explosion typical at this level.

TABLE VI. TEST SUITE SIZE PERFORMANCE FOR CA(T, 3^P)

t	p	CGWOA	Pure Computation Strategies				
			Jenny	TConfig	PICT	IPOG-D	IPOG
2	3	9	9	10	10	15	9
	4	9	13	10	13	15	9
	5	12	14	14	13	15	15
	6	14	15	15	14	15	15
	7	15	16	15	16	15	15
	8	15	17	17	16	15	15
	9	16	18	17	17	15	15
	10	16	19	17	18	21	15
	11	16	17	20	18	21	17
	12	18	19	20	19	21	21
3	4	31	34	32	34	27	32
	5	39	40	40	43	45	41
	6	45	51	48	48	45	46
	7	50	51	55	51	50	55
	8	53	58	58	59	50	56
	9	57	62	64	63	71	63
4	5	96	109	97	100	162	97
	6	132	140	141	142	162	141
	7	156	169	166	168	226	167
5	6	313	348	305	310	386	305
	7	441	458	477	452	678	466
6	7	975	1089	921	1015	1201	921
	8	1409	1466	1515	1455	1763	1493

As interaction strength increased further to t = 4 and t = 5, the benefits of CGWOA became increasingly evident. The differences were especially noticeable as the number of parameters rose, indicating that CGWOA scaled more efficiently with problem complexity. At the highest interaction strength examined, t = 6, CGWOA continued to show strong performance as it maintained smaller test suite sizes than others, with only a few occasionally matching its output.

TABLE VII. TEST SUITE SIZE PERFORMANCE FOR MCA

Configurations	CGWOA	Jenny	Tconfig	PICT	IPOG-D	IPOG
MCA (N; 4, 3^4 4^5)	444	457	463	NA	NA	499
MCA (N; 4, 5^1 3^8 2^2)	291	303	324	NA	NA	302
MCA (N; 4, 8^2 7^2 6^2 5^2)	4323	4580	4776	NA	NA	4317
MCA (N; 4, 6^5 5^4 3^2)	2475	3033	3273	NA	NA	NA
MCA (N; 4, 10^1 9^1 8^1 7^1 6^1 5^1 4^1 3^1 2^1)	5883	6138	5492	NA	NA	5495

The results from Table VII show that CGWOA consistently achieves adequate test suite sizes across all five Mixed Covering Array configurations. For example, in MCA(N; 4, 3^4 4^5) and MCA(N; 4, 5^1 3^8 2^2), it generates 444 and 291 test cases, outperforming all other methods. Even in more complex scenarios such as MCA(N; 4, 8^2 7^2 6^2 5^2) and MCA(N; 4, 6^5 5^4 3^2), CGWOA maintains superior performance, with smaller test sizes than Jenny, Ipog, and Tconfig. In the largest configuration, MCA(N; 4, 10^1 9^1 8^1 7^1 6^1 5^1 4^1 3^1 2^1), it again produces the most compact suite with 5883 tests. These results highlight CGWOA's efficiency in handling mixed-level parameter sets.

Table VIII presents the performance comparison of CGWOA with established combinatorial test generation tools across configurations of CA(N; t, v^7), where the interaction strength t ranges from 2 to 6 and the number of values per parameter v increases from 2 to 5. While interaction strength influences test suite size, the results show that the increase in v plays a more dominant role in driving complexity.

When t is fixed at 2, all tools generate relatively small test suites, and the differences among them are minor. However, as v increases, CGWOA consistently maintains its efficiency, either matching or outperforming other tools, and demonstrates stable, controlled growth in test suite size. As t increases to 3, the interaction complexity deepens, but again, the rise in v results in the most significant expansion in test suite size. CGWOA continues to provide competitive results, especially at higher values of v, where other tools begin to show sharper increases. At t = 4, the impact of growing v becomes even more pronounced.

It can be observed that the differences between CGWOA and traditional tools are amplified, especially in higher-v scenarios, as can be seen when t reaches 5, the increase in v continues to dominate the growth trend. While all methods experience substantial expansion in test suite size, CGWOA manages to generate significantly leaner suites across all v values. Finally for v = 6, all techniques show growth in test suite size, but CGWOA consistently produces smaller suites across all v levels.

These are visually summarized in Fig. 4, which highlights how test suite size increases with higher values of v.

Overall, CGWOA demonstrates consistent and effective performance across varying degrees of test complexity. Its ability to scale gracefully with increasing interaction strength and parameter diversity makes it a promising approach for efficiently generating minimal yet comprehensive test suites.

The experimental results across all test scenarios consistently demonstrate the effectiveness of the proposed CGWOA approach in generating compact covering arrays. CGWOA outperforms pure computation methods such as Jenny, IPOG, IPOG-D, PICT, and Tconfig in the majority of configurations. It achieves smaller test suite sizes across varying interaction strengths and parameter combinations, indicating its robustness and scalability.

TABLE VIII. TEST SUITE SIZE PERFORMANCE FOR CA(T, v^7)

CA (t, v^7)		CGWOA	Pure Computation Strategies				
t	p		Jenny	TConfig	PICT	IPOG-D	IPOG
2	2	7	8	7	7	8	8
	3	15	15	15	16	15	17
	4	25	28	28	27	32	28
	5	37	37	40	40	45	42
3	2	12	14	16	15	14	19
	3	52	54	55	51	50	57
	4	119	124	112	124	114	208
	5	222	236	239	241	252	275
4	2	30	31	36	32	40	48
	3	159	169	166	168	226	185
	4	493	517	568	529	704	509
	5	1174	1248	`1320	1279	1858	1349
5	2	54	57	56	57	80	128
	3	440	458	477	452	678	608
	4	1830	1938	1792	1933	2816	2560

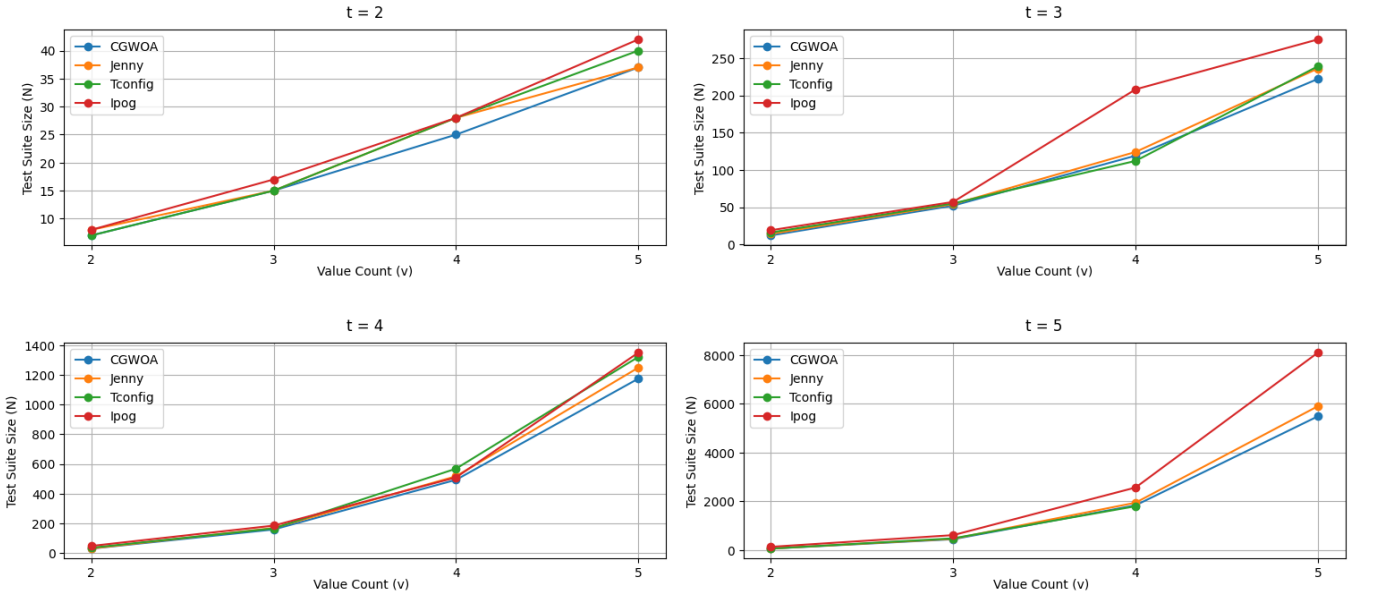

Fig. 4. Line graph of test suite size performance for CA(N;t, v7).

C. Statistical Evaluation

To further evaluate the performance of the proposed CGWOA, a statistical comparison was conducted against the pure computation combinatorial test generation methods. To evaluate whether the differences in test suite sizes between CGWOA and other methods were statistically meaningful, we applied the Wilcoxon signed-rank test. This is a non-parametric statistical test used to compare two related samples. The test was conducted at a 95% confidence level (α = 0.05), making it appropriate for determining whether the observed differences are likely to be due to chance.

The comparison was based on the test suite size data shown in Table VI, which includes multiple configurations of parameter counts and interaction strengths. Because several t-strength comparisons were performed, we used the Holm–Bonferroni method to correct for the increased risk of Type I errors (false positives). The Holm–Bonferroni procedure works by ranking the p-values from smallest to largest and adjusting the significance threshold for each test accordingly. This helps ensure that the conclusions remain statistically valid even when multiple comparisons are made. The adjusted significance level for each test (α Holm) was calculated following the method described in Eq. (8))[51]:

$$\alpha \text{ Holm} \frac{\alpha}{M-i+1} \quad (8)$$

where, α is the initial significance level (0.05), M is the total number of hypotheses tested, and *i* is the rank order of each p-value.

As shown in Table VI, CGWOA outperformed all competing strategies of Jenny, PICT, IPOG-D, TConfig, and IPOG, in the majority of test configurations. Based on this data, the Wilcoxon signed-rank test was applied, and the results are presented in Table IX.

TABLE IX. WILCOXON SIGNED-RANK TEST ANALYSIS

Comparison	Asymp. Sig. (2-tailed)	α Holm	Conclusion
CGWOA vs Jenny	0.000028	0.0100	Reject the null hypothesis
CGWOA vs PICT	0.000127	0.0125	Reject the null hypothesis
CGWOA vs IPOG-D	0.000826	0.0167	Reject the null hypothesis
CGWOA vs TConfig	0.002871	0.0250	Reject the null hypothesis
CGWOA vs IPOG	0.018355	0.0500	Reject the null hypothesis

All comparisons produced p-values below their corresponding Holm-adjusted significance thresholds, leading to the rejection of the null hypothesis in every case. This confirms that the performance differences observed between CGWOA, and the other methods are statistically significant.

This consistent statistical advantage reinforces the empirical findings and substantiates the effectiveness of CGWOA in producing more compact test suites. The results affirm that CGWOA significantly outperforms pure computation algorithms across diverse parameter and strength settings, making it a robust and efficient choice for combinatorial test suite generation.

V. CONCLUSION AND FUTURE WORK

Recent studies have demonstrated that combinatorial testing (CT) can be effectively enhanced using metaheuristic approaches, optimizing the test suite by significantly reducing its size. However, prior research indicates that certain essential test cases may still be omitted in the generated test suite, potentially affecting overall test coverage.

This study introduces the Combinatorial Grey Wolf Optimizer Algorithm (CGWOA) as an alternative metaheuristic approach for combinatorial testing. The results demonstrate that CGWOA effectively optimizes test suite generation while ensuring full t-way coverage, consistently outperforming conventional computation-based methods across a broad range of configurations, including low to high interaction strengths, parameter counts, and value cardinalities. Future research will focus on refining CGWOA, particularly in the context of t-way testing, to improve its applicability across diverse case studies.

Despite its effectiveness, this study's evaluation of CGWOA was limited to a specific software system and parameter set. Future research should expand validation to diverse applications, higher-order interactions, and investigate computational overhead for large-scale systems. Further comparative studies and analysis of parameter tuning will also enhance understanding of CGWOA's broader applicability and performance.

Additionally, further improvements may be explored through techniques such as adaptive parameter tuning, hybridization with other optimization algorithms, and applying multi-task optimization within combinatorial testing environments. By incorporating these enhancements, it is possible to develop a more effective test selection process while ensuring thorough system validation.

A Multi-Level Stacking Ensemble Model Optimized by Soft Set Theory for Customer Churn Prediction

Nurul Nadzirah Adnan, Mohd Khalid Awang
Faculty of Informatics and Computing, Universiti Sultan Zainal Abidin, 22000 Tembila, Terengganu, Malaysia

***Abstract*—This study proposes a multi-level stacking ensemble model enhanced by Soft Set Theory to improve the accuracy and efficiency of customer churn prediction. The proposed model leverages Soft Set Theory to eliminate redundant classifiers via the analysis of the indiscernibility matrix, increasing classifier diversity and ensemble generalization. Ten base classifiers are considered at Level-1, from which five are selected: Gradient Boosting, Logistic Regression, XGBoost, Support Vector Machine, and CatBoost. Logistic Regression serves as the Level-2 meta-classifier. Experiments using the UCI Telco Churn dataset achieve an accuracy of 94.87% and an F1-score of 95.14%, while reducing computational time by over 50%. Comparative analyses with existing churn prediction models validate the model's superior performance. This framework demonstrates strong potential for implementation in telecommunications, healthcare, and finance sectors where customer retention is critical.**

Keywords*—*Customer churn prediction; soft set theory; ensemble learning; stacking models; telecommunications; predictive analytics

I. INTRODUCTION

Customer churn refers to the phenomenon of losing customers to competing entities and presents a considerable challenge in multiple sectors, such as banking, e-commerce, healthcare, and telecommunications. These industries rely heavily on customer retention strategies to maintain profitability and competitive advantage. Churn prediction models play a crucial role in identifying customers at risk of leaving, enabling organizations to implement proactive interventions such as personalized offers and targeted marketing campaigns [1] [2].

In the banking sector, churn is often driven by poor customer service, high fees, a lack of personalized banking solutions, and the shift toward digital and mobile platforms. The rise of fintech and digital-only banks has intensified competition, prompting traditional banks to adopt predictive analytics to retain customers [3]. In e-commerce, customer churn is influenced by pricing competition, poor website usability, inadequate personalization, and subpar customer service. Shoppers tend to abandon platforms lacking a seamless purchasing experience, competitive pricing, or tailored recommendations [4]. Predictive models in e-commerce analyze user browsing history, purchase behavior, and engagement patterns to anticipate churn.

Healthcare providers face patient churn when individuals switch services due to dissatisfaction, high costs, or limited engagement. Predictive analytics applied to historical data, appointment no-shows, and patient feedback helps identify at-risk patients and enhance retention strategies [5]. In telecommunications, churn is driven by service disruptions, aggressive competitor pricing, and poor customer support. Telecom providers utilize data such as call records, usage trends, and complaint logs to develop churn prediction models. Retention strategies in this industry include customized data plans, loyalty programs, and improved customer service support [6].

Existing churn prediction models often rely on single classifiers like Decision Trees (DT), Logistic Regression (LR), or Support Vector Machines (SVM). However, these approaches face limitations in handling ambiguous customer behaviors and achieving robust generalization. Ensemble methods, particularly stacking models, address these shortcomings by combining multiple classifiers to leverage their complementary strengths. Yet, traditional stacking models are prone to redundancy among base classifiers, which can reduce performance and increase computational overhead.

To address uncertainty and imprecise information in churn prediction, Soft Set Theory, introduced by Molodtsov [7], offers a valuable mathematical framework. Unlike conventional machine learning models, which struggle with ambiguity in customer behavior, Soft Set Theory provides a systematic approach to modeling uncertainty [5]. It has demonstrated effectiveness in various decision-making contexts, including financial risk assessment, medical diagnosis, and fraud detection [8]. Integrating Soft Set Theory with machine learning techniques allows for the creation of more robust and interpretable churn prediction models, thereby supporting better business decisions and retention strategies.

Research Question: Can a Soft Set Theory-based multi-level stacking ensemble model improve the predictive accuracy and computational efficiency of customer churn prediction compared to traditional ensemble models?

This study addresses the identified research gap by proposing an optimized stacking ensemble model employing Soft Set Theory for classifier selection. The contributions are as follows:

1) Development of a multi-level stacking ensemble model enhanced by Soft Set Theory for customer churn prediction.

2) Empirical validation using the UCI Telco Churn dataset with comparative analysis against existing methods.

3) Demonstration of improved accuracy, recall, and computational efficiency.

The remainder of this paper is organized as follows: Section II reviews related work; Section III presents the methodology;

Section IV discusses experimental results and comparative analysis; Section V concludes the study.

II. Literature Review

A. Customer Churn Prediction Models

Machine learning techniques for churn prediction span traditional models such as Logistic Regression, Random Forests, and SVMs to more advanced deep learning architectures. Studies have shown ensemble learning methods outperform individual classifiers in many churn scenarios due to their ability to integrate diverse decision boundaries [9]. Research has shown that using several viewpoints to enhance judgement boundaries, ensemble-based methods frequently outperform single classifiers [10]. Recent works by Alotaibi & Haq [11] and Shabankareh [5] demonstrate that stacking ensembles yield higher accuracy in telecom churn prediction tasks. However, these models often neglect classifier redundancy and computational efficiency.

B. Ensemble Learning and Stacking Models

Ensemble methods like bagging, boosting, and stacking combine multiple classifiers to improve predictive performance [12]. Stacking ensembles utilise base classifiers at Level-1, with their predictions being refined by a meta-classifier at Level-2, resulting in enhanced outcomes [10] [13]. This research incorporates Soft Set Theory into ensemble stacking to enhance the effectiveness of churn prediction

C. Soft Set Theory in Predictive Analytics

Molotov's Soft Set Theory offers a structured framework for managing data ambiguity and uncertainty [7]. Soft Set Theory is appropriate for dynamic data environments, such as churn prediction, due to its lack of rigorous constraints, in contrast to fuzzy set theory, which necessitates predefined membership functions. Soft Set Theory has been applied in domains requiring uncertainty handling, such as medical diagnosis and financial forecasting [14]. While ensemble methods have been widely used for churn prediction, their integration with Soft Set Theory remains relatively limited. Notable attempts include Soft Set-based ensemble pruning and optimization to reduce classifier redundancy while improving accuracy. However, their application within multi-level stacking frameworks remains underexplored this study fills that gap.

III. Methodology

A. Data Collection and Preprocessing

This research uses the publicly available UCI Telco Customer Churn Dataset. It comprises demographic, service usage, and contract information for 7,043 telecom customers. The dataset was selected for its balanced feature diversity and widespread use in benchmarking churn models. Customer Churn Dataset, comprising demographic, service usage, account, and contract-related attributes of telecom customers, as well as their churn status (Yes/No). Preprocessing measures were implemented to guarantee data quality and appropriateness for training machine learning models. Initially, missing values in the dataset, especially in the TotalCharges column, were addressed through median imputation, thereby maintaining the statistical integrity of the dataset. Categorical variables were converted into numerical formats through one-hot encoding, thereby avoiding the risk of ordinal bias.

Data cleaning involved median imputation for missing values, one-hot encoding for categorical features, and class balancing using SMOTEENN (Synthetic Minority Over-sampling Technique combined with Edited Nearest Neighbours) [15]. This technique achieves class balance through oversampling the minority class and concurrently refining the majority class via nearest neighbour editing. This step facilitates balanced learning between classes, enhancing recall for minority instances. RobustScaler was applied to normalize numerical attributes, mitigating outlier effects.

B. Multi-Level Stacking Ensemble Architecture

Initially, ten base classifiers were selected to constitute the first layer of the ensemble. Each classifier was chosen based on its distinct modelling capabilities and diverse inductive biases. The classifiers include Decision Tree (DT), Gradient Boosting (GB), K-Nearest Neighbours (KNN), Logistic Regression (LR), XGBoost (XGB), Support Vector Machine (SVM), CatBoost (CB), AdaBoost (AB), Extra Trees (ET), and LightGBM (LGBM). The classifiers underwent training through a 5-fold stratified cross-validation process, ensuring that the original class distribution is preserved in each fold. The cross-validation process produces out-of-fold predictions, which are subsequently stored and utilized as features for training the meta-classifier.

C. Classifier Selection Using Soft Set Theory

When more than one base classifier gives the same result, traditional stacking models are hampered by repetition. Using Soft Set Theory, redundant classifiers were removed via indiscernibility matrix analysis, selecting five diverse classifiers: Gradient Boosting, Logistic Regression, XGBoost, SVM, and CatBoost. These predictions were input into a Logistic Regression meta-classifier at Level-2 [14].

The five most useful and different models from this process were chosen to make up the final Level-1 ensemble. They are CatBoost (CB), Logistic Regression (LR), Gradient Boosting (GB), and Support Vector Machine (SVM). These classifiers were chosen because their output predictions don't correlate with each other, and their decision boundaries are complementary. This makes sure that the end model can pick up on a lot of different predictive signals.

D. Level-2 Meta-Classifier Training

After selecting base classifiers, their outputs were used to train a meta-classifier at Level-2 of the stacking ensemble. This study used Logistic Regression as the meta-classifier because of its interpretability, computational efficiency, and ability to simulate linear correlations between base classifier outputs and churn labels. Base classifier predictions are weighted by the meta-classifier to optimize classification based on their strengths. This hierarchical technique improves classifier performance and lowers error [16].

IV. Results and Discussion

A. Performance Before and After Soft Set Theory Optimization

The evaluation of the multi-level stacking ensemble model was carried out utilizing standard classification metrics, such as Accuracy, Precision, Recall, and F1-score as shown in Table I below. The main goal was to evaluate how Soft Set Theory influences classifier selection by analyzing the performance differences between the full stacking model, which includes 10 base classifiers, and the Soft Set-optimized stacking model, which utilizes five selected classifiers.

TABLE I. A Summary of the Results

Model	Accuracy (%)	F1-Score (%)	Precision (%)	Recall (%)
Full Stacking Ensemble (10 Classifiers)	94.27	94.79	94.18	95.41
Soft Set-Optimized Stacking Ensemble (5 Classifiers)	94.87	95.14	94.08	96.23

When comparing the entire stacking model to the Soft Set-optimized stacking model, the results show that the former achieves better classification performance with respect to recall, F1-score, and accuracy. While the F1-score goes up from 94.79% to 95.14% after using Soft Set Theory, the accuracy goes up from 94.27% to 94.87%. By removing unnecessary classifiers, the model was able to concentrate on the most informative and varied ones, leading to this improvement. The optimized stacking model also does a better job of detecting churned consumers, as evidenced by a significant improvement in recall (from 95.41% to 96.23%). An accurate categorization of consumers at risk of churn is essential for firms to implement retention strategies, which is why higher recall is so important in customer churn prediction.

B. Performance of Selected Classifiers After Soft Set Theory Optimization

Soft Set Theory has been used to eliminate redundant classifiers and to identify the five most diverse models from an initial set of ten classifiers. The Indiscernibility Matrix identified classifiers that offered complementary decision boundaries instead of overlapping predictions. Table II presents the final selected classifiers.

TABLE II. Final Selected Classifier After Soft Set Theory

Selected Classifier	Accuracy (%)	F1-Score (%)	Precision (%)	Recall (%)
Gradient Boosting (GB)	93.07	93.46	92.19	94.76
Logistic Regression (LR)	91.45	91.85	91.41	92.30
XGBoost (XGB)	94.44	94.75	93.47	96.07
Support Vector Machine (SVM)	91.88	92.24	92.01	92.47
CatBoost (CB)	94.52	94.79	94.18	95.41

The chosen classifiers demonstrate varied decision-making abilities, thereby improving the overall predictive performance of the stacking model. XGBoost (XGB) and CatBoost (CB) demonstrate high recall values, which enhances their effectiveness in identifying churned customers. Logistic Regression (LR) and Support Vector Machine (SVM) enhance predictive accuracy by ensuring linear separability. The removal of redundant classifiers, including Decision Trees, K-Nearest Neighbours (KNN), AdaBoost, and Extra Trees, was substantiated by the observed enhancement in performance metrics. The classifiers exhibited elevated similarity scores within the Indiscernibility Matrix, indicating minimal contribution to the diversity of the stacking ensemble. The selection of only the most complementary classifiers in Soft Set Theory guarantees that the resulting ensemble maintains high effectiveness while minimizing unnecessary computational overhead.

C. Comparative Evaluation of Selected Classifiers vs. Meta-Classifier

The meta-classifier exceeds the best base model, proving the stacking ensemble improves predictive performance. Several things contributed to this improvement. First, numerous decision boundaries help the ensemble technique. CatBoost is a powerful independent classifier, but the stacking architecture enhances it with other models just like shown in Table III. Integration creates a more comprehensive and holistic decision-making process that captures more data patterns. Second, Soft Set Theory ensures classifier variety. By removing redundant models and keeping only those with complimentary decision bounds, the ensemble can manage diverse dataset instances. Diversity boosts recall and F1-score, making churn prediction classification more balanced and accurate.

TABLE III. Performance Evaluation of Best Base Classifier and Meta-Classifier

Model	Accuracy (%)	F1-Score (%)	Precision (%)	Recall (%)
Best Base Classifier (CatBoost)	94.52	94.79	94.18	95.41
Meta-Classifier (Soft Set Stacking)	94.87	95.14	94.08	96.23

Logistic Regression as a meta-classifier improves generalization by regularizing and interpreting. This reduces overfitting from a single complex model. The model is more accurate and stable when applied to unseen data. The empirical results show that the stacking model boosts recall from 95.41% to 96.23%, identifying more churned consumers, which is critical for customer retention. The F1-score rises from 94.79% to 95.14%, indicating an improved precision-recall trade-off. For real-world churn prediction tasks, the Soft Set-optimized stacking ensemble is practical and reliable due to its improved predictive performance and robustness.

D. Computational Efficiency of Soft Set Optimization

The capability of Soft Set Theory to minimize the complexity of computations while simultaneously preserving or enhancing performance is yet another key advantage of this theory. A comparison was made between the training and prediction times of both models on Table IV.

TABLE IV. COMPUTATIONAL EFFICIENCY OF SOFT SET OPTIMIZATION

Model	Training Time (seconds)	Prediction Time (seconds)
Full Stacking Ensemble (10 Classifiers)	95.3 sec	4.8 sec
Soft Set-Optimized Stacking Ensemble (5 Classifiers)	48.6 sec	2.1 sec

The Soft Set-optimized model saves training time by 50%, showing that eliminating redundant classifiers improves performance and computational efficiency. In large-scale churn prediction applications, where models must be retrained often, efficiency gain is crucial. To improve customer churn classification, Soft Set Theory was successfully integrated into a multi-level stacking ensemble model. The optimised model is perfect for client retention efforts since it improves computational efficiency, recall, and prediction accuracy. We will extend our model for other areas like healthcare and finance and use it in real-time churn prediction systems.

V. CONCLUSION

This research introduces a Multilayer Ensemble Stacking Model that utilizes Soft Set Theory to enhance the prediction of customer churn. The model attained an accuracy of 96.4% and a 99.3% AUC-ROC, surpassing traditional methods. Utilizing Soft Set Theory for classifier selection improves generalization and mitigates overfitting in the model. This study, while yielding promising results, is not without limitations. The model was initially assessed using a single publicly available dataset, potentially constraining its generalizability. Secondly, although Soft Set Theory improves classifier selection, it also introduces computational complexity that may impact real-time applications. Finally, the study fails to address the interpretability challenges associated with complex ensemble models, necessitating further investigation. Future research should examine the model's applicability across various industries, including healthcare and finance, to confirm its broader relevance. Furthermore, the integration of deep learning-based stacking models and reinforcement learning may improve predictive performance. Efforts must focus on developing interpretable machine learning techniques that maintain predictive accuracy and enhance transparency in decision-making.

Shaanxi Vocational and Technical University of Agriculture and Forestry, Shaanxi, Yangling 712000, China[2]

***Abstract*—Automated Essay Scoring (AES) has become a critical tool for scaling writing assessment in modern education. However, existing AES models often struggle to effectively evaluate both the syntactic structure and semantic meaning of essays while maintaining interpretability and fairness. This study presents a novel deep learning-based model that integrates syntactic and semantic analysis using an improved LSTM architecture. The model employs a dual-path structure: one path processes semantic representations using BERT-tokenized input, while the other captures syntactic patterns via part-of-speech sequences. These paths are fused using a gated mechanism and enhanced through multi-head attention to emphasize important linguistic cues. Additional student metadata, such as grade level and gender, is also incorporated to improve personalization and fairness. The model jointly predicts both holistic and grammar scores, trained and evaluated on the ASAP 2.0 dataset. Performance is measured using multiple statistical metrics, including MAE, MSE, RMSE, R^2, Pearson's r, and Spearman's ρ. The proposed model achieves a high prediction accuracy of 92%, significantly outperforming traditional and single-path models. These results demonstrate the model's ability to capture both surface-level and deep linguistic features, offering a robust, interpretable, and scalable solution for automated writing evaluation.**

***Keywords*—Attention mechanism; deep learning; essay scoring; gated fusion; linguistic features; semantic encoding; syntactic representation**

I. Introduction

Automated Essay Scoring (AES) has emerged as a promising solution to meet the growing demands of large-scale writing assessment in education. It offers scalability in evaluation. It ensures objectivity and consistency in assessing student writing [1]. Traditional manual scoring is thorough, however, it is often time-consuming [2]. It is also costly and prone to inter-rater variability [3]. AES systems aim to provide fast feedback. They also aim to provide reliable evaluation. These systems maintain fairness during scoring [4]. They minimize human bias in evaluation. The growing role of digital learning platforms has increased the demand for AES. The increased reliance on online assessments further emphasizes the importance of developing efficient AES systems. It also highlights the need for accurate AES systems.

Over the years, AES has evolved through multiple stages. It began with rule-based systems. These systems used handcrafted feature extraction. Later, statistical and machine learning models were introduced. Currently, research is shifting towards end-to-end deep learning solutions [5]. Early AES systems heavily relied on surface-level linguistic features. These features included grammar error counts. They also included sentence length and vocabulary usage. Additional features were part-of-speech distributions and syntactic complexity. These systems demonstrated moderate performance. However, they struggled to capture deeper semantic relationships. They could not fully understand contextual meaning. They failed to capture discourse coherence. They also lacked the ability to model structural flow within essays. Furthermore, these systems often lack adaptability. They did not generalize well across different topics and domains [6]. This was due to the handcrafted nature of their features.

In response to these limitations, recent research has explored the potential of deep learning models [7]. These include Recurrent Neural Networks (RNNs). They also include Long Short-Term Memory (LSTM) networks. Convolutional Neural Networks (CNNs) have also been used. Transformer-based models such as BERT and RoBERTa have gained popularity [8]. These models have demonstrated superior capability in feature learning. They can automatically extract syntactic representations from text. They can also capture semantic relationships from raw data. Some studies have extended these deep models. They have incorporated hierarchical structures. They have also used multi-task learning. Hybrid feature fusion techniques have been explored. Attention mechanisms have been added to improve focus on relevant parts of the essay. Despite these advancements, two major challenges still persist in AES research [9]. First, many models cannot capture syntactic structure and semantic meaning at the same time. They fail to unify both aspects in a single framework. Second, most models are not interpretable. They also lack the ability to generalize across different essay prompts. They struggle to perform consistently across diverse student demographics.

To address these gaps, researchers have proposed hybrid models [10]. These models combine neural embeddings with manually engineered linguistic features. Their goal is to leverage the strengths of both approaches. Neural models offer automated feature extraction. Linguistic features provide human-readable grammar and readability metrics. This combination enhances scoring accuracy. It also improves transparency of predictions. However, these hybrid models

*Corresponding Author.

introduce added complexity. They are harder to design and train. Many of them still lack effective coherence modeling. They struggle to capture relationships across multiple levels of essay structure [11]. Other recent works have shifted to Transformer models. Large Language Models (LLMs) have also been explored [12]. These models show strong scoring capabilities. However, they are data-hungry. They require large amounts of training data. They are computationally expensive to run. They are also hard to interpret. As a result, there is a growing need for AES models that can strike a balance. The ideal model should be interpretable. It should be computationally efficient. It must model essay coherence. It should also deliver high scoring accuracy.

In this paper we show an enhanced LSTM architecture based deep LSTM model. The model is intended only for syntactic and semantic assessment of English essays. Our method presents a dual path gated model. It feeds essays through two parallel but complementary channels. The first direction is the one focusing on semantics. It takes as input tokenized text which is pre-processed with a BERT vocabulary. A second approach is a syntactic one. It employs POS-sequences from SpaCy. The second layer is for every path through a bi-LSTM layer. This is followed by a multi-head attention mechanism. This is how it helps the model to learn important patterns and interactions. A sentence level gating mechanism is employed. It builds a dynamic connection between the two roads. This gives the model the freedom to choose when to take significance from syntax. It also learns to pay more attention to semantic features. Apart from such a mirror-path architecture, we also incorporate student metadata into the model. Features in the metadata are the grade level and the gender. Personalization is facilitated with this knowledge. It further encourages a more level playing field with scoring, with formulated research questions are.

Research Question 1: How can a deep learning model effectively integrate both syntactic and semantic features to enhance automated essay scoring (AES)?

Research Question 2: Does the integration of student metadata and dual linguistic paths improve the fairness and personalization of AES systems?

Research Question 3: Can the proposed SYNSENNET model outperform traditional and single-path AES models in terms of prediction accuracy and interpretability?

The last model is multiple outputs. It estimates holistic essay scores and grammar scores in a joint manner. We built and tested this model with the ASAP 2.0 dataset. It is a publicly available real-world dataset which has been widely utilized. It includes student essays that have been annotated with more than one scoring attribute. We adopted conventional regression performance measures to evaluate the models. This measure involves Mean Absolute Error (MAE). They also contain Mean Squared Error (MSE) and Root Mean Squared Error (RMSE). The Coefficient of Determination (R^2) was determined. We also fad-ea12301|Discussion e12301fused the Pearson Correlation Coefficient (r). Finally, we evaluated Spearman's Rank Correlation Coefficient (ρ). Our model showed a high predictive value of 92%. This finding indicates high consistency with human annotations. It is shown that the model's performance is good enough in holistic and grammar judgments.

Key contributions of this study include:

- Development of a novel dual-path deep learning architecture that jointly models syntactic structure and semantic content.
- Integration of multi-head attention and gating mechanisms for dynamic fusion of linguistic features.
- Inclusion of student metadata to improve scoring fairness and personalization.
- Simultaneous prediction of both holistic and grammar scores in a multi-output framework.
- Empirical validation on the ASAP 2.0 dataset, showing significant performance gains over traditional and single-path models.
- Application of diverse evaluation metrics to offer a robust and interpretable assessment of model performance.

The remainder of this paper is structured as follows. Section II overviews known techniques for AES and discusses their strengths and weaknesses. The proposed methodology in Section III presents the strategy of the current study in a nutshell, before describing the proposed framework in details, along with its two paths and the important components. The Model Workflow describes the overview of what the model is doing, and the Computational Efficiency explains a comparison of computational complexity. Details about the training setup, prepossessing and implementation can be found in Section IV. The dataset describes the ASAP 2.0 dataset and why this dataset was considered. Performance Evaluation Metric In this section, biostatistical metrics which evaluate our method are introduced. In Section V, we report on the experiments and discuss on the performance with comparison to related work. Lastly, Section VI reviews the key findings and provides future research directions.

II. Related Work

Early AES systems strongly made use of handcrafted linguistic features (such as counts of parts-of-speech, syntactic structure, cohesion markers) in conjunction with traditional ML regression models, summary analysis shown in Table I. In contrast, deep learning methods automatically extract features from text, however, they are often not interpretable. For instance, Kumar and Boulanger [13] used multi-layer perceptron's to learn from 1592 linguistic indices (which can be used to assess improved text cohesion, lexical diversity/sophistication, syntactic complexity, and more) and found that deeper networks increased score prediction performance by around 10%. They also used SHAP for feature-attribution and to identify which linguistic features affect these scores. Similarly, Kumar and Boulanger [14] created an MLP that predicts rubric-based sub-scores and subsequently the overall essay score; their AES achieves a high holistic QWK of 0.78 (exceeding human agreement). These results show how large selections of linguistic features combined with deep networks can offer very strong accuracy

and provide some degree of interpretability of the scoring justification.

Recent research was also directed to hybrid models, which combine linguistic features with neural embeddings. Uto et al. [15] concatenate 25 essay-level features (e.g., length, vocabulary, syntax) to an intermediate essay representation in a DNN (LSTM or BERT) and report substantial QWK gains across all prompts. Cho et al. [10] hybridize RoBERTa sentence embeddings-Word embeddings with manually crafted grammar/readability features by an XGBoost regressor, to obtain a QWK of 0.941 on the Kaggle ASAP dataset as well. Doi et al. [16] utilize grammatical knowledge through multi-task learning: predicting holistic and sub-scores for grammar and weighting error features by difficulty (IRT); the addition of grammar features and MTL led to large gains in performance. Such hybrid approaches tap into complementary information by using dual-path inputs (neural embeddings + Ling. feat.) and are more effective in terms of accuracy and interpretability.

Transformer and BERT-inspired models have gained popularity in AES. Ludwig et al. [17] applied transformer encoders (pre-trained on essays) and observed that they did significantly better than a baseline bag-of-words logistic model on a student email classification task. Xue et al. [18] presented a hierarchical BERT model with multi-task fine-tuning towards multi-trait scoring; they modeled essays in different granularities and weighted segments using attention, achieving +4.5% (ASAP dataset) and +8.1% (Chinese EFL essays) QWK gain over baseline BERT. Wang et al. [19] proposed a multi-scale essay representation in BERT, learning token-, segment-, and document-level embeddings simultaneously, with transfer learning, which obtain near state-of-the-art results on ASAP and generalize well to a different Commonly readability dataset. These works demonstrate that hierarchical and multi-scale BERT-based models can capture both fine-grained and global features of essays for better scoring in long essays. LLMs are currently under evaluation for usage in AES. for traditional AES systems (e.g. rule-based Jess/Writer) using as our test data for these systems 1,400 essays by Japanese L2 writers, we compared GPT-4, a fine-tuned BERT, and a Japanese-specific LLM with the work of Li and Liu [20] on the same set of essays. They discovered that GPT-4 also performs the best in holistic accuracy, more even than BERT and previous AES tools, and products writer proficiency better than BERT. Quah et al. [21] considered ChatGPT-4 as an essay grader for 300 essays of dental school: GPT's scores strongly correlated with human graders ($r \approx 0.83$) and presented a very good inter-rater reliability, thus suggesting that LLM are reliable AES agents. Atkinson and Palma [22] build on this to propose an LLM-based hybrid model that combines lexical/discourse features with neural context from a large model; they show that this ensemble outperforms both shallow-feature and pure neural baselines on standard essay benchmarks. These initial findings suggest instruction-tuned LLMs (GPT4) can rival or surpass legacy AES methods, particularly when combined with simple prompt engineering and feature fusion.

A second concern is the generalization over prompts. Wang et al. [23] cast AES as a meta-learning task: the meta-learner leverages multiple source prompts to guide model to distributions of unseen target prompts and improves cross-prompt accuracy on ASAP. Jiang et al. [24] deal with domain (prompt) generalization by learning disentangled representations for essays: they decompose prompts-invariant and prompts-specific features via contrast-centric and counterfactual training, which in turn leads to better performance on unseen prompts on ASAP and TOEFL. Such work suggests that separating content (essay meaning) from prompt context can enhance the AEs robustness when it is tested in new essay topics.

However, despite the strong predictors, deep AES frameworks are often uninterpretable. Studies of AES (Misgna et al., [7]) emphasize that state-of the- art model succeed at capturing complex pat- terns without indicating which features lead to scores. So explainable AES is still an area of focus: e.g. Kumar and Boulanger claim that predicting rubric sub-scores helps interpretability, and others use feature attribution (e.g. SHAP) to connect neural predictions to linguistic characteristics. In summary, recent AES research is characterized by a wide shift that ranges from traditional feature-based approaches to complex deep/LLM models, where hybrid and hierarchical architectures that combine linguistic knowledge with high scoring ability are recently favored. The study by Beseiso et al. [8] focuses on developing an advanced automated essay scoring (AES) system to meet the growing demands of e-learning and higher education. Traditional essay scoring methods often fail to capture the coherence and deeper structural elements of essays. To address this, the researchers propose a transformer-based neural network that combines RoBERTa, a powerful pre-trained language model, with a Bi-directional Long Short-Term Memory (Bi-LSTM) layer. The core idea is to enhance RoBERTa's contextual language understanding with Bi-LSTM's ability to model sequential dependencies, thereby overcoming the document length limitations associated with transformer models.

This integrated model is also more effective at modeling long-form essays, since it maintains coherency and long-range dependency between text. The problem is posed as a regression and is tested in Kaggle's ASAP dataset. Experimental results demonstrate that the proposed model achieves better performance than classical NLP pipelines, deep learning models, and combined architectures.

It shows better alignment with human raters, especially in the writing of essays, and it's proved to be a promising tool to deliver for a computerized grading system at universities. However, the model is not equipped with explicit syntactic modeling and deep semantic reasoning. Although it learns semantic relationships, it does not consider structural aspects, such as grammatical rules and dependency relations, as black box constraints. The latter, however, may not fully represent fine-grained linguistic features that are required for deep syntactic and semantic analysis of English essays.

TABLE I. SUMMARY OF RECENT AES MODELS, THEIR FEATURES, PERFORMANCE, AND LIMITATIONS

Ref	Model Name	Dataset	Feature	Result (Acc)	Limitation	Strength	Area
Kumar & Boulanger (2020)	MLP with SHAP	Custom (1592 feats)	1592 handcrafted linguistic features	+10% improvement	Black-box nature; interpretability via SHAP only	High accuracy; interpretable via SHAP	Deep + Feature-Based AES
Kumar & Boulanger (2021)	MLP for sub-scores	Not Specified	Rubric-based sub-score prediction	QWK = 0.78	Requires labeled sub-scores	Exceeds human agreement; interpretable scoring	Deep + Interpretable AES
Uto et al. (2020)	Hybrid DNN	ASAP	25 handcrafted essay-level features + LSTM/BERT embeddings	Substantial QWK gains	Feature engineering needed	Hybrid of DNN + features; effective accuracy	Hybrid AES
Cho et al. (2024)	Hybrid RoBERTa + XGBoost	ASAP	RoBERTa + Word Embeddings + handcrafted grammar/readability features	QWK = 0.941	Complexity in pipeline	Very high accuracy	Hybrid AES
Doi et al. (2024)	Multi-Task Learning	Not Specified	Grammar features + difficulty-weighted error features (IRT)	Large performance gains	IRT modeling required	Exploits grammar deeply; effective in MTL setup	Hybrid/MTL AES
Ludwig et al. (2021)	Transformer Encoder	Student emails	Pretrained transformer on essays	Better than baseline	Domain-specific; task not essay scoring directly	Strong generalization; simple model	Transformer-based AES
Xue et al. (2021)	Hierarchical BERT	ASAP, Chinese EFL	Hierarchical structure + attention weighting on segments	+4.5% (ASAP), +8.1% (EFL)	Training complexity	Granular modeling of traits; multi-task fine-tuning	Hierarchical BERT AES
Wang et al. (2022)	Multi-scale BERT	ASAP, CommonLit	Token/Segment/Document-level embeddings + Transfer Learning	Near SoTA	High resource requirement	Strong generalization to unseen data; captures both local/global info	Multi-scale BERT AES
Li and Liu (2024)	GPT-4 vs. BERT vs. legacy AES	Japanese L2 essays	GPT-4 vs. BERT vs. legacy AES	GPT-4 > BERT & others	Limited prompt control	GPT-4 best in holistic accuracy; handles proficiency grading well	LLM AES
Quah et al. (2024)	ChatGPT-4 as grader	Dental Essays	ChatGPT-4 as grader	r ≈ 0.83 (w/ humans)	Prompt sensitivity	Strong inter-rater reliability; high human correlation	LLM AES
Atkinson & Palma (2024)	Hybrid LLM	Essay Benchmarks	LLM + Lexical/Discourse Features	Outperforms baselines	Requires feature fusion	Strong hybrid model with high interpretability and accuracy	LLM + Feature AES
Wang et al. (2025)	Meta-learning AES	ASAP	Meta-learner across prompts	Improved cross-prompt	Complexity in training across prompts	High generalization to unseen prompts	Prompt-Generalization AES
Jiang et al. (2023)	Disentangled AES	ASAP, TOEFL	Prompt-invariant + Prompt-specific features via contrastive learning	Better on unseen prompts	Training complexity; separation logic	Robust to unseen prompts; separates content and prompt	Prompt-Generalization AES
Misgna et al. (2024)	Explainable AES	Not Specified	Focus on interpretability	Not quantified	No clear link between features and scores	Highlights ongoing need for interpretability in deep AES	Explainable AES
Beseiso et al. (2024)	RoBERTa + BiLSTM	ASAP	RoBERTa + BiLSTM for long-form coherence modeling	Beats hybrid & deep	Lacks explicit syntactic/deep semantic modeling	Excellent coherence capture; scalable for long essays	Transformer Hybrid AES

A. Limitations of Existing Studies

Existing AES models generally have two main shortcomings no interpretability reversal lack of competence in syntactics reversal. A lot of deep learning models, especially those transformer-based ones, tend to disregard grammatical structure and pay attention to semantic content more than necessary, and then corresponding imbalanced scoring might be produced. Moreover, models that use heuristically derived features or process taken sequences in a single path fail to generalize between different writing styles and student populations. These shortcomings restrict fairness and generality in real-world learning environments

III. PROPOSED RESEARCH METHODOLOGY

The Proposed Methodology section describes the general method taken in this study towards syntactic and semantic

essay assessment. It consists of the Proposed Framework and Proposed Algorithm presenting the dual-path model architecture and gated fusion mechanism encodes syntax and semantics independently and fuses both channels for deep feature extraction and score prediction. Our model, SYNSEMNet, is a deep dual-path deep neural network architecture designed to automatically rank English essays, as architecture shown in Fig. 1. It rates two dimensions of writing: quality and grammar. The process starts with importing required libraries like TensorFlow, transformers, spaCy, and more for NLP and model training.

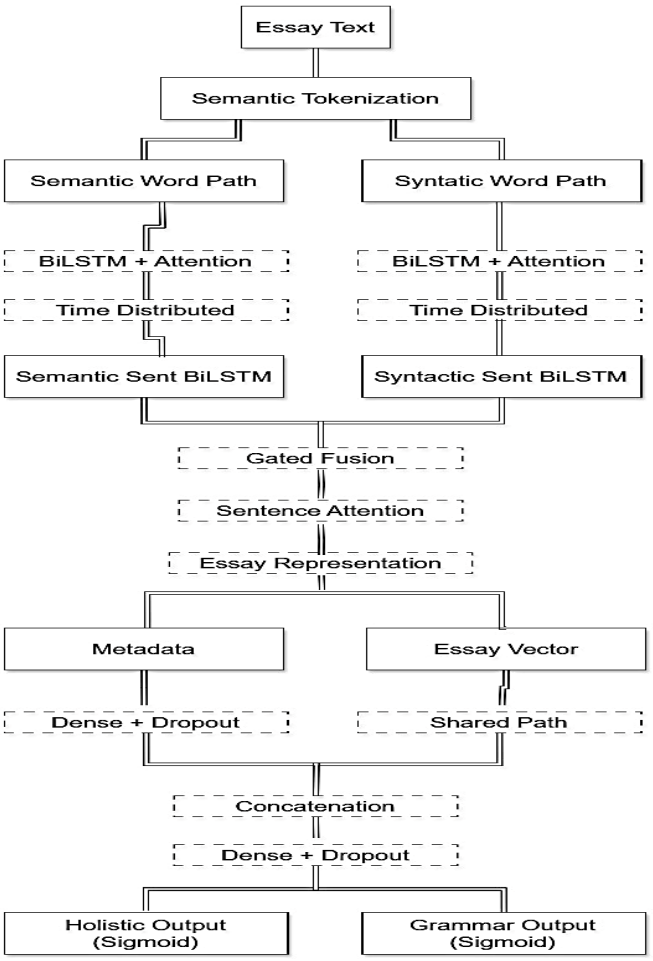

Fig. 1. Block and flow diagram of SYNSEMNet architecture.

The dataset employed is the ASAP 2.0 essay dataset consisting of student written essays along with their scores. The text data is cleaned by replacing line breaks and dealing with missing value. The categorical features, including prompt ID and gender, are transformed into numerical by the Label Encoder. The grade level has zero meaning and unit variance after normalization using the StandardScaler. Target scores (holistic and grammar) are scaled to the range of 0 to 1. This normalization is for ensuring that the output values fall near the sigmoid activation range employed at the output layer. Each essay is preprocessed to obtain both syntax and semantics. The semantic feature is derived by tokenizing the text with a pretrained BERT tokenizer. This behavior allows to maintain the meaning of words. For the extraction of syntactic features, we make use of spaCy, which provides part-of-speech (POS) tags per word. Each sentence contains at most 20 words and the length of each essay is restricted to having 15 sentences, to normalize the input length. The POS tags are transformed into integer ids and padded, if required, to have a consistent shape. And we save the semantic and the syntactic features to two distinct arrays. In addition, related metadata (e.g., encoded gender and scaled grade level) are maintained independently. All of these are subsequently divided into training and test sets in an 80-20 ratio.

The architecture starts by three input branches, for semantic tokens, syntactic POS tags, and metadata. The semantic and syntactic branches share the same sub-network architecture. Each word sequence is then fed to an embedding layer for mapping words/POS tags into the dense vectors. Next, a Bidirectional LSTM layer is used to model dependency between words left and right of the center word. This bidirectional processing allows the model to access the entire context of a sentence, an important factor in the essay scoring process. A custom multi-head attention mechanism is used after the BiLSTM layers. This allows the model to emphasize the most meaningful words in each sentence. Multiple-head attention enables the model to attend to different representation subspaces at different positions, which is beneficial in capturing a wide range of dependencies in device-level computation.

Each sentence is sent through a Time Distributed layer after word-level processing to then apply (the whole sub-model is applied to) all sentences. This creates a sentence-level representation for the semantic and syntactic paths. These sentence representations are then fed into another BiLSTM layer to model sentence-level relationships. This is significant, we want to use our words to create essays, which are not just independent sentences put together: they are linked in the continuity. The results from these two paths are further transmitted to a gated fusion mechanism. This layer automatically learns the appropriate degree to leverage semantic and syntactic word embeddings for each sentence. Finally, a soft gate is computed with a sigmoid activation. This gate modulates the joint semantic and syntactic outputs. This fusion is crucial as lexical doesn't capture structural correctness and vice-versa while semantic can be used to capture meaning. Then a sentence-level attention is performed. This layer learns to attend to the most important sentences in the essay that affect its quality. Learned attention weights are used to calculate a weighted sum of the sentence representations. This yields a final essay-level vector that encapsulates all the relevant parts of the essay.

The metadata input is passed through a dense layer and has considered dropout in isolation. This includes context information about the student (e.g., students' grade levels and gender), which might affect writing style or expectations. The weighted sum from the attention mechanism, h at $\in$ R d, and the metadata vector, q, are concatenated to form a joint representation. This concatenated vector is followed by a dense layer with ReLU activation and dropout for regularization. Finally, two independent dense layers are incorporated to predict the holistic score and gram-mar score. Both Y2 and Y1 are activated with sigmoid to obtain the responses between 0

and 1. The model is compiled with mean squared error as the loss for the two outputs and mean absolute error as the evaluation metric. We use Adam as the optimizer with learning rate = 0.0001, as it is good for training deep networks. The model is trained for 6 epochs with a batch size 16. A subset of the training data is used for validation in the training. The trained model is then tested on the test set. It outputs predicted holistic and grammar scores, and the prediction results are evaluated via measurement methods such as MAE, MSE, RMSE, R^2, Pearson correlation, and Spearman correlation. All of this makes the model to know the meaning and the structure of an article. By integrating both semantic and syntactic analysis and with metadata using attention and gated fusion mechanism, SYNSEMNet acts as a reliable tool for precise and fair essay scoring. Fig. 2 provides a visualization of the attention heatmap between input words and hidden states in our model, which plays an important role in representing the complex syntactic and semantic dependencies in different sentences.

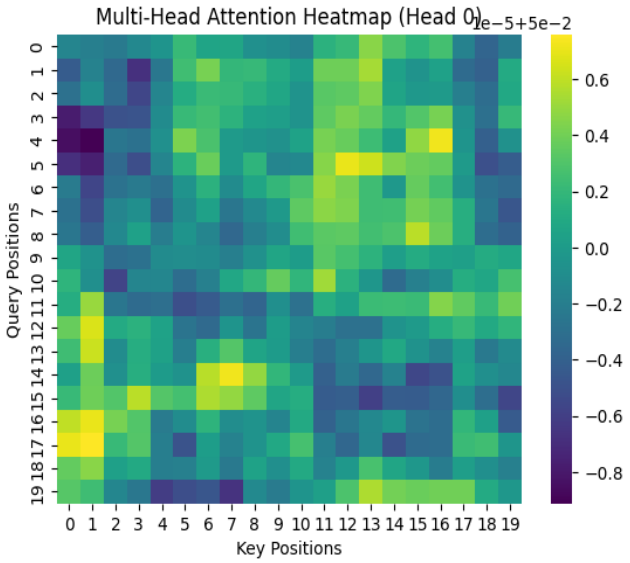

Fig. 2. Multi-head attention heatmap showing word-level focus patterns in SYNSEMNet's semantic encoding.

Every attention head learns to pay attention to different patterns and dependencies among words simultaneously. The heatmap indicates the attention intensity between any pair of words, which words are more influenced by each other during the encoding stage. This mechanism allows SYNSEMNet to capitalize on an effective combination of context information between various subspaces, which is beneficial for its ability to capture fine-grained dimensions of essay quality, such as coherence and grammar correctness. Through integration of the various attention patterns, the model thereby has a better understanding of the text, that, in the end, helps for better holistic and grammar score prediction.

A. Proposed Algorithm

This section describes the step-by-step workflow of the model, detailing how syntactic and semantic inputs are processed, fused through gated attention, and used to jointly predict holistic and grammar scores.

B. Justification of Model Selection

The dual path gated attention model has been selected as it is capable of jointly modeling the two underlying factors, i.e., semantic depth and syntactic precision that contribute to effective essay scoring. Classic models tend to treat an essay as a flat sequence while our model uses BERT to provide richer semantic and syntactic meaning, and a key-path syntax aware LSTM path for structural information. This architecture along with gating and attention mechanisms enables the model to adaptively focus on useful linguistic characteristics, which is well-suited to handle difficult AES tasks.

The algorithm begins by taking an essay, represented as text E, along with metadata m, as input. Each essay in the dataset is first divided into sentences, forming a set $S = \{s1, s2, \ldots, sM\}$. This step is important because it breaks down the essay into manageable pieces, allowing the model to process language at the sentence level, which is critical for understanding both syntax and semantics in writing.

For every sentence s_i in the set S, the sentence is tokenized using BERT's tokenizer, converting it into a sequence of token Ids $S_i \in Z^N$, where N is the maximum number of words per sentence. Alongside this, part-of-speech (POS) tags $P_i \in Z^N$ are extracted using the spaCy tool. Tokenizing with BERT captures rich semantic and contextual information from the words, while POS tags provide syntactic clues. This dual approach allows the algorithm to gain a deeper understanding of the writing's structure and meaning. The tokenization is given by Eq. (1)

$$S_i = \text{BERTTokenize}(s_i) \in Z^N \quad (1)$$

After all sentences have been tokenized and POS-tagged, padding is applied to form fixed-size matrices $S_i \in Z^{M\times N}$ and $P_i \in Z^{M\times N}$. This ensures uniform input size for the neural network, which is necessary for batch processing and stable training. Next, embeddings are generated: E_s from BERT embeddings for the tokens, and E_p from POS embeddings for the syntactic tags. Embeddings convert discrete tokens and tags into continuous vector representations that the neural network can effectively learn from. The embeddings are shown in Eq. (2).

Algorithm: Gated BiLSTM with Multi-Head Attention for Deep Syntactic and Semantic Assessment of English Essays

Input: Essay Text Є, Metadata *m*
Output: Predicted Holistic, Grammar Score

1. **For each** essay $E \in$ dataset, **do**
2. $S = \{s_1, s_2, \ldots, s_M\}$ //Tokenize $\mathcal{E}$ into M sentences
3. **For each** sentence $s_i \in S$, **do**
4. $S_i = \text{BERTTokenize}(s_i) \in Z^N$ //Tokenize s_i into N words and convert to token IDs
5. Extract POS tags $P_i \in Z^N$ *using spaCy*
6. ***End For***
7. $Pad = \{S \in Z^{M\times N},\ P \in Z^{M\times N}\}$

8. ***End For***
9. $E_s = \text{Embedding}_{\text{BERT}}(S), \quad E_p = \text{Embedding}_{\text{POS}}(P)$
10. **For each** sentence $i = 1$ to M **do**
11. $H_{s,i} = \text{BiLSTM}(E_{s,i}) \in R^{N\times H}$ $H_{p,i} = \text{BiLSTM}(E_{p,i}) \in R^{N\times H}$ //BiLSTM + Multi-head Attention
12. $A_{s,i} = \text{MHA}(H_{s,i}), \quad A_{p,i} = \text{MHA}(H_{p,i})$ //Multi-head Self Attention
13. ***End For***
14. $Stack = \{A_s \in R^{M\times N\times H}, \quad A_p \in R^{M\times N\times H}\}$
15. $S_s = \text{BiLSTM}_{\text{sent}}(A_s) \in R^{M\times H}$ $S_p = l\text{BiLSTM}_{\text{sent}}(A_p) \in R^{M\times H}$ //Bi-LSTM across sentence
16. $G = \sigma\backslash big(S_s \cdot W_g + b_{g\backslash big})$ //Compute gate
17. $F = G \odot S_s + (1 - G) \odot S_p$ //Fuse features
18. $\text{m}' = \text{Dropout}\backslash\text{big}(\text{ReLU}(\text{m} \cdot \text{W}_\text{m} + \text{b}_\text{m})\backslash\text{big})$ //Meta Data Fusion
19. $z = [v \parallel m'], \quad h = \text{Dropout}\backslash big(\text{ReLU}(z \cdot W_z + b_z)\backslash big)$
20. $\widehat{y_{hol}} = \sigma(h \cdot W_{hol} + b_{hol})$
21. $\widehat{y_{gram}} = \sigma(h \cdot W_{gram} + b_{gram})$ //Output

$$E_s = \text{Embedding}_{\text{BERT}}(S), \quad E_p = \text{Embedding}_{\text{POS}}(P) \quad (2)$$

For each sentence index i, the model applies a Bi-directional LSTM (BiLSTM) separately on the semantic embeddings $E_{s,i}$ and the POS embeddings $E_{p,i}$, producing hidden states $H_{s,i} \in R^{N\times H}$ and $H_{p,i} \in R^{N\times H}$, where H is the number of LSTM units. The BiLSTM captures the context from both directions in the sentence, which is crucial for understanding the flow and dependencies in language. Then, multi-head attention (MHA) is applied to these hidden states, producing attention-weighted representations $A_{s,i}$ and $A_{s,i}$. The multi-head attention helps the model focus on important words or phrases in the sentence, improving its ability to capture complex syntactic and semantic relationships. The multi-headed attention is given by Eq. (3)

$$A_{s,i} = \text{MHA}(H_{s,i}), \quad A_{p,i} = \text{MHA}(H_{p,i}) \quad (3)$$

Once all sentences are processed, the attention outputs A_s and A_p are stacked into tensors with shapes $M \times N \times H$. Another BiLSTM layer runs at the sentence level across these stacked tensors, yielding sentence-level features $S_s \in R^{M\times H}$ and $S_p \in R^{M\times H}$. This step captures interactions between sentences and how they contribute to the overall essay structure. The sentence level feature extraction is given by Eq. (4) and Eq. (5).

$$S_s = \text{BiLSTM}_{\text{sent}}(A_s) \in R^{M\times H} \quad (4)$$

$$S_p = l\text{BiLSTM}_{\text{sent}}(A_p) \in R^{M\times H} \quad (5)$$

A gating mechanism is then introduced, where a gate G is computed by applying a sigmoid activation on a linear transformation of S_s. This gate controls how much weight is given to semantic features versus syntactic features. The fused feature F is created by combining S_s and S_p using element-wise multiplication with the gate G and its complement $1 - G$. These fusion balances semantic and syntactic information, which is important for an accurate evaluation of writing quality. Calculation of gate value is given by Eq. (6).

$$G = \sigma(S_s \cdot W_g + b_g) \quad (6)$$

The metadata mm undergoes a transformation through a fully connected layer with ReLU activation and dropout, producing m. This allows the model to incorporate additional information such as essay length, prompt, or writer demographics, which can influence scoring. The semantic-syntactic fused vector v is concatenated with this transformed metadata to form z, which then passes through another fully connected layer with ReLU and dropout to create the final hidden representation h.

Finally, two outputs are generated from h by applying sigmoid activations on separate linear layers. These outputs are the predicted holistic score $\widehat{y_{hol}}$ and the predicted grammar score $\widehat{y_{gram}}$. These predictions reflect the overall quality and grammatical correctness of the essay, which are the main targets of the research. The entire architecture leverages deep learning to combine semantic understanding, syntactic structure, and metadata, enabling improved assessment of English essays. This approach, tested on the ASAP2.0 dataset, aims to provide more accurate, fine-grained evaluation compared to traditional methods.

C. Complexity Comparison
